HEMATOLOGY-ONCOLOGY THERAPY

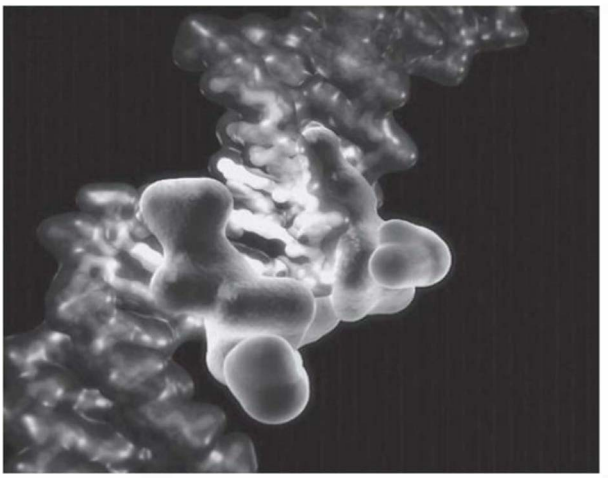
SECOND EDITION



MICHAEL M. BOYIADZIS, MD, MHSc
Associate Professor of Medicine
Division of Hematology-Oncology
Department of Medicine
University of Pittsburgh School of Medicine
University of Pittsburgh Cancer Institute
Pittsburgh, Pennsylvania

JAMES N. FRAME, MD, FACP
Clinical Professor of Medicine
Robert C. Byrd Health Sciences Center
West Virginia University School of Medicine
Medical Director, David Lee Cancer Center
Charleston Area Medical Center Health Systems
Charleston, West Virginia

DAVID R. KOHLER, PharmD
Oncology Clinical Pharmacy Specialist
Bethesda, Maryland

TITO FOJO, MD, PhD
Senior Investigator
Medical Oncology
Center for Cancer Research
National Cancer Institute
National Institutes of Health
Bethesda, Maryland

Notice

Medicine is an ever-changing science. As new research and clinical experience broaden our knowledge, changes in treatment and drug therapy are required. The authors and the publisher of this work have checked with sources believed to be reliable in their efforts to provide information that is complete and generally in accord with the standards accepted at the time of publication. However, in view of the possibility of human error or changes in medical sciences, neither the authors nor the publisher nor any other party who has been involved in the preparation or publication of this work warrants that the information contained herein is in every respect accurate or complete, and they disclaim all responsibility for any errors or omissions or for the results obtained from use of the information contained in this work. Readers are encourage to confi rm the information contained herein with other sources. For example and in particular, readers are advised to check product information sheet included in the package of each drug they plan to administer to be certain that the information contained in this work is accurate and that changes have not been made in the recommended dose or in the contraindications for administration. This recommendation is of particular importance in connection with new or infrequently used drugs.

TERMS OF USE

This is a copyrighted work and McGraw-Hill Education and its licensors reserve all rights in and to the work. Use of this work is subject to these terms. Except as permitted under the Copyright Act of 1976 and the right to store and retrieve one copy of the work, you may not decompile, disassemble, reverse engineer, reproduce, modify, create derivative works based upon, transmit, distribute, disseminate, sell, publish or sublicense the work or any part of it without McGraw-Hill Education's prior consent. You may use the work for your own noncommercial and personal use; any other use of the work is strictly prohibited. Your right to use the work may be terminated if you fail to comply with these terms.

THE WORK IS PROVIDED "AS IS." McGRAW-HILL EDUCATION AND ITS LICENSORS MAKE NO GUARANTEES OR WARRANTIES AS TO THE ACCURACY, ADEQUACY OR COMPLETENESS OF OR RESULTS TO BE OBTAINED FROM USING THE WORK, INCLUDING ANY INFORMATION THAT CAN BE ACCESSED THROUGH THE WORK VIA HYPERLINK OR OTHERWISE, AND EXPRESSLY DISCLAIM ANY WARRANTY, EXPRESS OR IMPLIED, INCLUDING BUT NOT IMITED TO IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. McGraw-Hill Education and its licensors do not warrant or guarantee that the functions contained in the work will meet your requirements or that its operation will be uninterrupted or error free. Neither McGraw-Hill Education nor its licensors shall be liable to you or anyone else for any inaccuracy, error or omission, regardless of cause, in the work or for any damages resulting therefrom. McGraw-Hill Education has no responsibility for the content of any information accessed through the work. Under no circumstances shall McGraw-Hill Education and/or its licensors be liable for any indirect, incidental, special, punitive, consequential or similar damages that result from the use of or inability to use the work, even if any of them has been advised of the possibility of such damages. This limitation of liability shall apply to any claim or cause whatsoever whether such claim or cause arises in contract, tort or otherwise.

To the patients our profession has the privilege to serve, and to our colleagues whose compassionate care and research efforts continue to extend the spectrum of hope.

Contents

Authors ix
Preface xvii

SECTION I: ONCOLOGY 1

1. Adrenocortical Cancer 5
Peter F. Lebowitz, MD, PhD and Tito Fojo, MD, PhD

2. Anal Cancer 15
Irfan Jawed, MD and John Marshall, MD

3. Biliary: Gallbladder Cancer and Cholangiocarcinoma 24
Tim Greten, MD, PhD, Susanna Ulahannan, MD, and Werner Scheithauer, MD

4. Bladder Cancer 36
Andrea Apolo, MD and Dean Bajorin, MD

5. Brain Cancer 48
Lyndon Kim, MD and Howard Fine, MD

6. Breast Cancer 88
Rachel C. Jankowitz, MD and Nancy E. Davidson, MD

7. Carcinoma of Unknown Primary 191
David R. Spigel, MD and F. Anthony Greco, MD

8. Cervical Cancer 203
Peter G. Rose, MD

9. Colorectal Cancer 229
Julia Lee Close, MD and Carmen Joseph Allegra, MD

10. Endometrial Cancer 303
Maurie Markman, MD

11. Esophageal Cancer 312
Jimmy Hwang, MD and John Marshall, MD

12. Gastric Cancer 345
Jonas W. Feilchenfeldt, MD and Manish A. Shah, MD

13. Gestational Trophoblastic Neoplasia 382
John R. Lurain, MD

14. Head and Neck Cancers 394
Pol Specenier, MD, PhD and JB Vermorken, MD, PhD

15. Hepatocellular Carcinoma 468
Tim Greten, MD, PhD and Nadine Abi-Jaoudeh, MD

16. HIV-Related Malignancies 494
Bruce J. Dezube, MD

17. Leukemia, Acute Lymphoblastic (ADULT) 511
Michael M. Boyiadzis, MD, MHSc, Ivan Aksentijevich, MD, and Judith Karp, MD

18. Leukemia, Acute Myeloid 544
Michael M. Boyiadzis, MD, MHSc, Ivan Aksentijevich, MD, and Judith Karp, MD

19. Leukemia, Chronic Lymphocytic 559
Patricia Kropf, MD and Kenneth Foon, MD

20. Leukemia, Chronic Myelogenous 581
Michael W.N. Deininger, MD, PhD and Brian J. Druker, MD

21. Leukemia, Hairy Cell 607
Martin S. Tallman, MD

22. Lung Cancer 614
Enriqueta Felip, MD, PhD and Rafael Rosell, MD

23. Lymphoma, Hodgkin 656
Michael Fuchs, MD, Dennis A. Eichenauer, MD, and Volker Diehl, MD

24. Lymphoma, Non-Hodgkin 684
Carla Casulo, MD, Julia Schaefer-Cutillo, MD, Jonathan W. Friedberg, MD, MMSc, and Richard Fisher, MD

25. Melanoma 804
Ahmad A. Tarhini, MD, PhD, Amanda L. Gillespie-Twardy, MD, and John M. Kirkwood, MD

26. Mesothelioma 826
Verna Vanderpuye, MD, Anish Thomas, MD, and Nicholas J. Vogelzang, MD

27. Multiple Myeloma 836
Aldo Roccaro, MD, PhD, Giada Bianchi, MD, Irene M. Ghobrial, MD, and Kenneth C. Anderson, MD

28. Ovarian Cancer 928
Eddie Reed, MD

29. Pancreatic Cancer 975
Ramesh K. Ramanathan, MD, PhD, Sc and Daniel D. Von Hoff, MD, FACP

30. Pancreatic Endocrine Tumors 997
Sara Ekeblad, MD, PhD and Britt Skogseid, MD, PhD

31. Pheochromocytoma 1021
Karel Pacak, MD, PhD, DSc and Tito Fojo, MD, PhD

32. Prostate Cancer 1026
Avni Shah, MD, Wenhui Zhu, MD, PhD, and William L. Dahut, MD

33. Renal Cell Cancer 1055
Susan Bates, MD and Olivier Rixe, MD, PhD

34. Sarcomas 1097
Brigitte Widemann, MD, Tito Fojo, MD, PhD, and Jean-Yves Blay, MD

35. Testicular Cancer 1180
Darren R. Feldman, MD and George J. Bosl, MD

36. Thymic Malignancies 1194
Arun Rajan, MD and Giuseppe Giaccone, MD, PhD

37. Thyroid Cancer 1205
Ann Gramza, MD and Sam Wells, MD

38. Vaginal Cancer 1223
Leslie Boyd, MD and Franco Muggia, MD

SECTION II: SUPPORTIVE CARE, DRUG PREPARATION, COMPLICATIONS, AND SCREENING 1231

39. Prophylaxis and Treatment of Chemotherapy-Induced Nausea and Vomiting 1233
Thomas E. Hughes, PharmD, BCOP

40. Drug Preparation and Administration 1241
David R. Kohler, PharmD

41. Guidelines for Chemotherapy Dosage Adjustment 1385
Pamela W. McDevitt, PharmD, BCOP and Tito Fojo, MD, PhD

42. Antineoplastic Drugs: Preventing and Managing Extravasation 1421
David R. Kohler, PharmD

43. Indications for Growth Factors in Hematology-Oncology 1437
Pamela W. McDevitt, PharmD, BCOP, James N. Frame, MD, FACP, and Lee S. Schwartzberg, MD, FACP

44. Indications for Bone-Modifying Agents in Hematology-Oncology 1454
Reem Abozena Shalabi, PharmD, BCOP and James N. Frame, MD, FACP

45. Transfusion Therapy 1475
Ashok Nambiar, MD and Joseph E. Kiss, MD

46. Oncologic Emergencies 1491
Mauricio Burotto Pichun, MD and Tito Fojo, MD, PhD

47. Fever and Neutropenia 1516
Jennifer Cuellar-Rodriguez, MD and Juan C. Gea-Banacloche, MD

48. Catheter-Related Bloodstream Infections: Management and Prevention 1525
Naomi P. O'Grady, MD

49. Venous Catheter-Related Thrombosis 1530
Roy E. Smith, MD, MS

50. Complications and Follow-Up After Hematopoietic Cell Transplantation 1534
Michael M. Boyiadzis, MD, MHSc, Juan C. Gea-Banacloche, MD, and Michael R. Bishop, MD

51. Radiation Complications 1552
Ramesh Rengan, MD, PhD, Diana C. Stripp, MD, and Eli Glatstein, MD

52. Cancer Pain: Assessment and Management 1576
Ann Berger, MSN, MD

53. Hospice Care and End-of-Life Issues 1590
Charles F. von Gunten, MD, PhD and David E. Weissman, MD

54. Cancer Screening 1595
Kathleen A. Calzone, PhD, RN, APNG, FAAN, Jennifer Eng-Wong, MD, MPH, and Sheila Prindiville, MD, MPH

55. Genetics of Common Inherited Cancer Syndromes 1599
Kathleen A. Calzone, PhD, RN, APNG, FAAN and Sheila Prindiville, MD, MPH

SECTION III: SELECTED HEMATOLOGIC DISEASES 1607

56. von Willebrand Disease 1609
Pier M. Mannucci, MD

57. Hemophilia 1633
Steven J. Jubelirer, MD and Margaret Ragni, MD, MPH

58. The Hypercoagulable State 1657
Jeffrey I. Zwicker, MD and Kenneth A. Bauer, MD

59. Heparin-Induced Thrombocytopenia 1669
James N. Frame, MD, FACP and John R. Bartholomew, MD, FACC, MSVM

60. Autoimmune Hemolytic Anemia 1689
James N. Frame, MD, FACP

61. Sickle Cell Disease: Acute Complications 1723
James N. Frame, MD, FACP and Griffin P. Rodgers, MD, MACP

62. Aplastic Anemia 1749
Michael M. Boyiadzis, MD, MHSc and Neal S. Young, MD

63. Thrombotic Thrombocytopenic Purpura/ Hemolytic Uremic Syndrome 1757
Arafat Tfayli, MD, Kiarash Kojouri, MD, MPH, and James N. George, MD

64. Idiopathic Thrombocytopenic Purpura 1765
Kiarash Kojouri, MD, MPH, Arafat Tfayli, MD, and James N. George, MD

65. Hemochromatosis 1779
James C. Barton, MD

66. Myeloproliferative Neoplasms 1786
Naxeema Gangat, MD and Ayalew Tefferi, MD

67. Myelodysplastic Syndromes 1826
Michael M. Boyiadzis, MD, MHSc and Neal S. Young, MD

Index 1845

Authors

Nadine Abi-Jaoudeh, MD
Physician, Assistant Professor
Radiology & Imaging Sciences
National Institutes of Health
Bethesda, Maryland
Hepatocellular Carcinoma

Ivan Aksentijevich, MD
Virginia Cancer Specialists
Specialist in Medical Oncology and Hematology
Alexandria, Virginia
Leukemia, Acute Lymphoblastic (ADULT); Leukemia, Acute Myeloid

Carmen Joseph Allegra, MD
Professor and Chief Hematology and Oncology
Department of Medicine
University of Florida Health
Gainesville, Florida
Colorectal Cancer

Kenneth C. Anderson, MD
Professor of Medicine, Department of Medicine,
Harvard Medical School
Physician, Oncology, Brigham and Women's Hospital
Medical Director, Kraft Family Blood Center,
Dana-Farber Cancer Institute
Boston, Massachusetts
Multiple Myeloma

Andrea Apolo, MD
Head, Bladder Cancer Section
Genitourinary Malignancies Branch
Center for Cancer Research, National Cancer Institute
National Institutes of Health
Bethesda, Maryland
Bladder Cancer

Dean Bajorin, MD
Member and Professor of Medicine
Genitourinary Oncology Service
Memorial Sloan-Kettering Cancer Center
New York, New York
Bladder Cancer

John R. Bartholomew, MD, FACC, MSVM
Professor of Medicine and
Section Head of Vascular Medicine
Cardiovascular Medicine and Hematology
Cleveland Clinic
Cleveland, Ohio
Heparin-Induced Thrombocytopenia

James C. Barton, MD
Medical Director, Southern Iron Disorders Center
Clinical Professor of Medicine
University of Alabama at Birmingham
Birmingham, Alabama
Hemochromatosis

Susan Bates, MD
Senior Investigator
Head, Molecular Therapeutics Section
Medical Oncology
National Cancer Institute, National Institutes of Health
Bethesda, Maryland
Renal Cell Cancer

Kenneth A. Bauer, MD
Professor of Medicine, Harvard Medical School
Director, Thrombosis Clinical Research,
Beth Israel Deaconess Medical Center
Boston, Massachusetts
The Hypercoagulable State

Ann Berger, MSN, MD
Chief, Pain and Palliative Care Service
National Institutes of Health Clinical Center
Bethesda, Maryland
Cancer Pain: Assessment and Management

Giada Bianchi, MD
Department of Medical Oncology
Dana Farber Cancer Institute
Harvard Medical School
Boston, Massachusetts
Multiple Myeloma

Michael R. Bishop, MD
Professor of Medicine
Director, Hematopoietic Stem Cell Transplantation Program
The University of Chicago Medicine
Chicago, Illinois
Complications and Follow-Up After Hematopoietic Cell Transplantation

Jean-Yves Blay, MD
Professor of Medicine in Medical Oncology
Head of the Medical Oncology Department
Centre Leon Berard of the Université Claude Bernard
Scientific Director, Canceropole Lyon Rhône Alpes
Lyon, France
Sarcomas

George J. Bosl, MD
Chair, Department of Medicine, and
Member, Memorial Sloan Kettering Cancer Center
Professor of Medicine, Weill Cornell Medical College
Testicular Cancer

Leslie Boyd, MD
Assistant Professor of Gynecology
Perlmutter Cancer Center
NYU Langone Medical Center
New York, New York
Vaginal Cancer

Michael M. Boyiadzis, MD, MHSc
Associate Professor of Medicine
Division of Hematology-Oncology
Department of Medicine
University of Pittsburgh School of Medicine
University of Pittsburgh Cancer Institute
Pittsburgh, Pennsylvania
Leukemia, Acute Lymphoblastic (ADULT); Leukemia, Acute Myeloid; Complications and Follow-Up After Hematopoietic Cell Transplantation; Aplastic Anemia; Myelodysplastic Syndromes

Kathleen A. Calzone, PhD, RN, APNG, FAAN
Senior Nurse Specialist, Research
National Cancer Institute
Center for Cancer Research, Genetics Branch
Bethesda, Maryland
Cancer Screening; Genetics of Common Inherited Cancer Syndromes

Carla Casulo, MD
Assistant Professor of Medicine
University of Rochester Medical Center at Strong Memorial Hospital
Rochester, New York
Lymphoma, Non-Hodgkin

Julia Lee Close, MD
Assistant Professor, University of Florida
Section Chief, Hematology/Oncology,
Gainesville VA Medical Center
Gainesville, Florida
Colorectal Cancer

Jennifer Cuellar-Rodriguez, MD
Staff Clinician
Laboratory of Clinical Infectious Diseases
National Institute of Allergy and Infectious Diseases
Bethesda, Maryland
Fever and Neutropenia

William L. Dahut, MD
Principal Investigator
Medical Oncology
Genitourinary Malignancies Branch
Center for Cancer Research
National Cancer Institute, National Institutes of Health
Bethesda, Maryland
Prostate Cancer

Nancy E. Davidson, MD
Director, University of Pittsburgh Cancer Institute
UPMC Cancer Center
Associate Vice Chancellor for Cancer Research
Professor of Medicine, University of Pittsburgh
Pittsburgh, Pennsylvania
Breast Cancer

Michael W.N. Deininger, MD, PhD
Chief, Division of Hematology and Hematologic Malignancies
M.M. Wintrobe Professor of Medicine
University of Utah
Huntsman Cancer Institute
Salt Lake City, Utah
Leukemia, Chronic Myelogenous

Bruce J. Dezube, MD
Associate Professor of Medicine
Beth Israel Deaconess Medical Center
Harvard Medical School
Boston, Massachusetts
HIV-Related Malignancies

Volker Diehl, MD
Emeritus Professor of Medicine, Hematology, Oncology
University of Cologne
Germany
Lymphoma, Hodgkin

Brian J. Druker, MD
Director, Oregon Health & Science University Knight Cancer Institute
JELD-WEN Chair of Leukemia Research
Investigator, Howard Hughes Medical Institute
Portland, Oregon
Leukemia, Chronic Myelogenous

Dennis A. Eichenauer, MD
First Department of Internal Medicine and German
Hodgkin Study Group
University Hospital Cologne
Cologne, Germany
Lymphoma, Hodgkin

Sara Ekeblad, MD, PhD
Uppsala University Hospital
Stockholm, Sweden
Pancreatic Endocrine Tumors

Jennifer Eng-Wong, MD, MPH
Assistant Medical Director
Genentech
South San Francisco, California
Cancer Screening

Jonas W. Feilchenfeldt, MD
Attending Physician
FMH Internal Medicine and Medical Oncology
Department of Medical Oncology
Hôpital du Valais
Sion, Switzerland
Gastric Cancer

Darren R. Feldman, MD
Assistant Member, Department of Medicine
Memorial Sloan Kettering Cancer Center, and
Assistant Professor in Medicine, Weill Cornell Medical College
New York, New York
Testicular Cancer

Enriqueta Felip, MD, PhD
Department of Medical Oncology
Vall d'Hebron University Hospital
Barcelona, Spain
Lung Cancer

Howard Fine, MD
Director, Division of Hematology and Oncology
Director, NYU Brain Tumor Center
Deputy Director, NYU Cancer Institute
Director, Bellevue Hospital Cancer Center
The New York University (NYU) Langone Medical Center
NYU Cancer Institute
New York, New York
Brain Cancer

Richard Fisher, MD
President and CEO
Fox Chase Cancer Center - Temple Health
Senior Associate Dean
Temple University School of Medicine
Philadelphia, Pennsylvania
Lymphoma, Non-Hodgkin

Tito Fojo, MD, PhD
Senior Investigator
Medical Oncology
Center for Cancer Research
National Cancer Institute
National Institutes of Health
Bethesda, Maryland
Adrenocortical Cancer; Pheochromocytoma; Sarcomas; Guidelines for Chemotherapy Dosage Adjustment; Oncologic Emergencies

Kenneth Foon, MD
Vice President, Global Medical Affairs, Lymphoma and CLL
Medical Affairs
Celgene Corporation
Summit, New Jersey
Leukemia, Chronic Lymphocytic

James N. Frame, MD, FACP
Clinical Professor of Medicine

Department of Neurological Surgery
Department of Medical Oncology
Thomas Jefferson University Hospital
Philadelphia, Pennsylvania
Brain Cancer

John M. Kirkwood, MD
Usher Professor of Medicine, Dermatology and Translational Science
Co-Director, Melanoma and Skin Cancer Program
University of Pittsburgh Cancer Institute
Pittsburgh, Pennsylvania
Melanoma

Joseph E. Kiss, MD
Associate Professor of Medicine
Department of Medicine
Division of Hematology/Oncology
Medical Director, Hemapheresis and Blood Services
University of Pittsburgh
Pittsburgh, Pennsylvania
Transfusion Therapy

David R. Kohler, PharmD
Oncology Clinical Pharmacy Specialist
Bethesda, Maryland
Drug Preparation and Administration;
Antineoplastic Drugs: Preventing and Managing Extravasation

Kiarash Kojouri, MD, MPH
Skagit Valley Hospital Regional Cancer Care Center
Seattle Cancer Care Alliance
Hematologist-Oncologist
Skagit Valley Hospital Regional Cancer Care Clinic
Mount Vernon, Washington
Thrombotic Thrombocytopenic Purpura/Hemolytic Uremic Syndrome;
Idiopathic Thrombocytopenic Purpura

Patricia Kropf, MD
Assistant Professor of Medicine
Fox Chase Cancer Center
Temple Health
Philadelphia, Pennsylvania
Leukemia, Chronic Lymphocytic

Peter F. Lebowitz, MD, PhD
Global Head of Oncology Research and Development
Janssen, Pharmaceutical Companies of Johnson & Johnson
Spring House, Pennsylvania
Adrenocortical Cancer

John R. Lurain, MD
Marcia Stenn Professor of Gynecologic Oncology
Gynecologic Oncology Fellowship Program Director
Northwestern University, Feinberg School of Medicine
Chicago, Illinois
Gestational Trophoblastic Neoplasia

Pier M. Mannucci, MD
Professor
Scientific Direction
IRCCS Ca' Granda Maggiore Policlinico Hospital Foundation
Milano, Italy
von Willebrand Disease

Maurie Markman, MD
Senior Vice President for Clinical Affairs
Cancer Treatment Centers of America
Clinical Professor of Medicine
Drexel University of College of Medicine
Philadelphia, Pennsylvania
Endometrial Cancer

John Marshall, MD
Director, The Ruesch Center for the Cure of GI Cancers
Chief, Hematology and Oncology
Lombardi Comprehensive Cancer Center
Georgetown University Medical Center
Washington, DC
Anal Cancer; Esophageal Cancer

Pamela W. McDevitt, PharmD, BCOP
Oncology Clinical Pharmacy Specialist
David Lee Cancer Center
Charleston, West Virginia

Preface

The practical need for a readily accessible, up-to-date, comprehensive therapy resource, supported by referenced literature, was the original inspiration of the first edition of *Hematology-Oncology Therapy*. The book received considerable acclaim and filled a void in the medical literature as a practical guide and reference for practicing oncologists and hematologists. The rapid and numerous advances in the field of hematology-oncology are reflected in the updated information of this second edition. Over 500 treatment regimens are presented in a concise and uniform format that includes oncologic disorders, non-neoplastic hematologic disorders, and supportive care.

The three sections of *Hematology-Oncology Therapy* are:

I. Oncology
II. Supportive Care, Drug Preparation, Complications, and Screening
III. Selected Hematologic Diseases.

Section I provides detailed information about the administration, supportive care, toxicity, dose modification, monitoring, and efficacy of commonly used and recently approved chemotherapeutic regimens, drugs, and biological agents. Each chapter is focused on a specific cancer, and contains information about epidemiology, pathology, work-up, and staging, as well as survival data. In addition, each chapter has a new feature, Expert Opinion, in which experts in the field provide treatment recommendations and guidance on the use of the included regimens.

Section II consists of topics commonly encountered in clinical hematology-oncology practice. Section III provides an authoritative guide to therapy for principal diseases in consultative hematology.

Hematology-Oncology Therapy integrates extensive information that is critical to both office- and hospital-based clinical practice of hematology and oncology. This comprehensive approach makes the book invaluable to all practitioners involved in the care of patients with cancer or hematologic diseases and complements other excellent book references in hematology-oncology.

We wish to express our appreciation to the many contributors to this book, whose expert knowledge in their fields makes *Hematology-Oncology Therapy* a unique addition to the medical literature. They helped us compile the extensive and detailed therapy information contained in this book, which is a testament to the efforts of so many to improve the treatment of patients with oncologic and hematologic diseases. We also wish to thank our editors at McGraw-Hill for their continued support, patience, and faith in our vision and concept for this book. Their professional support has earned our praise and debt of gratitude. Finally, we would like to thank those with whom we work and those we love for their support during the writing and editing of the second edition.

SECTION I. Oncology

1. Adrenocortical Cancer 5

Mitotane 7 *Cisplatin + Mitotane* 9 *Etoposide + Doxorubicin + Cisplatin + Mitotane (EDP-M)* 10 *Doxorubicin* 12 *Streptozocin + Mitotane (Sz-M)* 13

2. Anal Cancer 15

Mitomycin + Fluorouracil + Radiation Therapy 18 *Fluorouracil + Cisplatin + External Beam Radiation Therapy* 20 *Cisplatin + Fluorouracil by Continuous Intravenous Infusion* 22

3. Biliary: Gallbladder Cancer and Cholangiocarcinoma 24

Cisplatin + Gemcitabine 29 *Gemcitabine + Oxaliplatin (GEMOX)* 31 *Gemcitabine + Capecitabine* 32 *Capecitabine + Oxaliplatin* 33 *Gemcitabine* 34 *Mitomycin + Capecitabine* 35

4. Bladder Cancer 36

Methotrexate + Vinblastine + Doxorubicin + Cisplatin (MVAC) 38 *Gemcitabine + Cisplatin (GC)* 39 *Gemcitabine + Carboplatin* 40 *Neoadjuvant Methotrexate + Vinblastine + Doxorubicin + Cisplatin (MVAC) before Radical Cystectomy* 41 *Neoadjuvant Gemcitabine + Cisplatin (GC)* 42 *High-Dose or Dose-Dense Methotrexate, Vinblastine, Doxorubicin, and Cisplatin (HD-MVAC or DD-MVAC)* 43 *Neoadjuvant Cisplatin, Methotrexate, and Vinblastine* 46

5. Brain Cancer 48

Temozolomide 55 *Temozolomide with Radiation Therapy* 58 *Carmustine* 59 *Lomustine* 60 *Carboplatin* 62 *Procarbazine, Lomustine, Vincristine (PCV)* 63 *Adjuvant Procarbazine, Lomustine, Vincristine (PCV)* 65 *High-Dose Tamoxifen* 68 *Erlotinib* 69 *Bevacizumab ± Irinotecan* 71 *High-Dose Methotrexate for Primary CNS Lymphoma* 73 *Rituximab, Methotrexate, Procarbazine, and Vincristine followed by Consolidation, Reduced-Dose Whole-Brain Radiotherapy, and Cytarabine (R-MPV → RT + C) Newly Diagnosed Primary CNS Lymphoma* 75 *High-Dose Methotrexate and Rituximab with Deferred Radiotherapy Newly Diagnosed CNS Lymphoma* 79 *Long-Acting Octreotide Acetate* 82 *Interferon Alfa* 84 *Hydroxyurea* 86

6. Breast Cancer 88

Docetaxel + Doxorubicin + Cyclophosphamide (TAC) 94 *Dose-Dense Doxorubicin + Cyclophosphamide, then Paclitaxel Every 2 Weeks (ddAC → P)* 95 *Doxorubicin + Cyclophosphamide, then Weekly Paclitaxel (AC → P)* 97 *Docetaxel + Cyclophosphamide (TC) Every 3 Weeks × 4 Cycles* 100 *Doxorubicin + Cyclophosphamide (AC)* 102 *Cyclophosphamide + Epirubicin + Fluorouracil (FEC 100)* 104 *Cyclophosphamide + Methotrexate + Fluorouracil (CMF; Oral)* 106 *Doxorubicin + Cyclophosphamide then Docetaxel Every 3 Weeks (AC → T)* 108 *Cyclophosphamide + Epirubicin + Fluorouracil (FEC) × 3 Cycles → Docetaxel × 3 Cycles* 110 *Cyclophosphamide + Epirubicin + Fluorouracil (FEC) × 4 Cycles → Weekly Paclitaxel × 8 Cycles* 113 *Docetaxel + Carboplatin + Trastuzumab (TCH)* 116 *Doxorubicin + Cyclophosphamide, then Paclitaxel + Trastuzumab, then Trastuzumab Alone (AC × 4 → TH × 12 Weeks → H × 40 Weeks)* 120 *Docetaxel + Trastuzumab followed by Cyclophosphamide + Epirubicin + Fluorouracil (FEC)* 124 *Doxorubicin + Cyclophosphamide (AC) followed by Docetaxel with Trastuzumab (TH) (AC → TH)* 128 *Everolimus + Exemestane* 132 *Doxorubicin, Every 3 Weeks* 135 *Weekly Doxorubicin or Epirubicin* 136 *Doxorubicin HCl Liposome Injection (Liposomal Doxorubicin)* 138 *Weekly Paclitaxel* 140 *Paclitaxel Every 3 Weeks* 141 *Weekly Docetaxel* 143 *Docetaxel Every 3 Weeks* 144 *Albumin-Bound Paclitaxel* 145 *Capecitabine* 147 *Gemcitabine* 150 *Weekly Vinorelbine* 151 *Eribulin Mesylate* 152 *Ixabepilone* 154 *Paclitaxel Plus Bevacizumab* 157 *Docetaxel + Capecitabine* 159 *Paclitaxel and Gemcitabine* 161 *Ixabepilone + Capecitabine* 163 *Trastuzumab* 167 *Pertuzumab + Trastuzumab + Docetaxel* 168 *Docetaxel Every 3 Weeks + Weekly Trastuzumab* 171 *Weekly Docetaxel + Trastuzumab* 173 *Trastuzumab + Paclitaxel, Every 3 Weeks* 175 *Weekly Paclitaxel + Trastuzumab* 177 *ado-Trastuzumab Emtansine (T-DM1) or Lapatinib + Capecitabine* 180 *Weekly Vinorelbine + Trastuzumab* 185 *Capecitabine + Trastuzumab* 187 *Hormonal Therapy Agents* 189

7. Carcinoma of Unknown Primary 191

Paclitaxel + Carboplatin +/– Etoposide 194 *Gemcitabine + Irinotecan* 196 *Bevacizumab + Erlotinib* 198 *Oxaliplatin + Capecitabine* 200

8. Cervical Cancer 203

Concurrent Radiation Therapy + Chemotherapy/Weekly Cisplatin 207 *Concurrent Radiation Therapy + Chemotherapy/Cisplatin + Fluorouracil* 209 *Concurrent Radiation Therapy + Chemotherapy/Weekly Carboplatin* 211 *Cisplatin + Vinorelbine* 213 *Cisplatin + Topotecan* 215 *Cisplatin + Paclitaxel* 217 *Cisplatin + Gemcitabine* 219 *Cisplatin + Irinotecan* 221 *Paclitaxel Protein-Bound Particles for Injectable Suspension (Albumin-Bound) (nab-Paclitaxel)* 223 *Paclitaxel + Topotecan* 225 *Paclitaxel + Cisplatin + Bevacizumab* 227

9. Colorectal Cancer 229

Bolus Fluorouracil + Leucovorin (Roswell Park Regimen) 231 *Bolus Fluorouracil* 233 *Capecitabine* 235 *Infusional Fluorouracil* 237 *Single-Agent Irinotecan* 239 *Irinotecan + Bolus Fluorouracil + Leucovorin (IFL)* 243 *Leucovorin + Infusional Fluorouracil + Irinotecan (FOLFIRI)* 246 *Leucovorin + Infusional Fluorouracil + Oxaliplatin (FOLFOX)* 250

(Continued on following page)

Leucovorin + Bolus Fluorouracil + Irinotecan (IFL) + Bevacizumab 253
Cetuximab 257 *Cetuximab + FOLFOX-4* 259 *Cetuximab + FOLFIRI* 263
Panitumumab + Best Supportive Care 267
Panitumumab + FOLFOX-4 269
Panitumumab + FOLFIRI 272
ziv-Aflibercept + FOLFIRI 276
Bevacizumab after First Progression
Bevacizumab + FOLFIRI 282
Regorafenib 288 *Adjuvant or Neoadjuvant Chemotherapy + Radiation* 292 *Chemoradiotherapy with Capecitabine* 294
Capecitabine + Oxaliplatin 297

10. Endometrial Cancer 303

Doxorubicin + Cisplatin (AC) 307
Paclitaxel + Carboplatin (TC) 309
Paclitaxel, Doxorubicin, Cisplatin (TAP) 311

11. Esophageal Cancer 312

Fluorouracil + Cisplatin + Radiation 315
Weekly Irinotecan + Cisplatin + Concurrent Radiotherapy 316 *Oxaliplatin + Protracted Infusion Fluorouracil and External Beam Radiation Therapy Prior to Surgery* 319 *Carboplatin + Paclitaxel + Concurrent Radiotherapy* 320
Cisplatin + Capecitabine 324
Irinotecan + Cisplatin 327 *Epirubicin + Cisplatin + Fluorouracil (ECF)* 329
Fluorouracil + Cisplatin 331
Docetaxel + Cisplatin + Fluorouracil (DCF) 332 *Oxaliplatin + Fluorouracil + Leucovorin (FOLFOX)* 334 *Epirubicin + Oxaliplatin + Capecitabine (EOC, EOX)* 336
Irinotecan + Fluorouracil + Leucovorin (FOLFIRI) 338 *Cisplatin + Capecitabine ± Trastuzumab* 341

12. Gastric Cancer 345

Fluorouracil + Leucovorin + Radiation 348
Epirubicin + Cisplatin + Fluorouracil 350
Adjuvant Capecitabine and Oxaliplatin 353
Epirubicin + Cisplatin + Fluorouracil (ECF) 356 *Docetaxel + Cisplatin + Fluorouracil (DCF)* 358 *Epirubicin (E), Cisplatin (C), Fluorouracil (F), Oxaliplatin (O), Capecitabine (X) ECF, ECX, EOF, and EOX* 360 *Irinotecan + Cisplatin* 363
Cisplatin + Fluorouracil (FUP) 365
Cisplatin + Fluorouracil (CF) Irinotecan + Fluorouracil (IF) 367 *Cisplatin + Trastuzumab with Capecitabine or Fluorouracil* 373 *Single-Agent Docetaxel or Single-Agent Irinotecan* 378

13. Gestational Trophoblastic Neoplasia 382

Methotrexate 385 *Methotrexate with Leucovorin* 386 *Dactinomycin* 387
Etoposide + Methotrexate + Dactinomycin + Cyclophosphamide + Vincristine (EMA/CO) 388 *Etoposide + Methotrexate + Dactinomycin/Etoposide + Cisplatin (EP/EMA)* 390 *Paclitaxel + Cisplatin/ Paclitaxel + Etoposide (TP/TE)* 392

14. Head and Neck Cancers 394

Cisplatin with Radiation Therapy 398
Cisplatin + Paclitaxel with Radiation Therapy 400 *Carboplatin + Fluorouracil with Radiation Therapy* 402 *Cisplatin with Radiation Therapy followed by Cisplatin + Fluorouracil* 404 *Docetaxel + Cisplatin + Fluorouracil (TPF) or Cisplatin + Fluorouracil (PF)* 407 *Docetaxel + Cisplatin + Fluorouracil (TPF) or Cisplatin + Fluorouracil (PF)* 413 *Cisplatin Alone or Cisplatin + Fluorouracil* 416
Chemoradiation for Larynx Preservation: Cisplatin with Radiation Therapy 419
Postoperative Chemoradiation with Cisplatin 423 *Postoperative Chemoradiation with Cisplatin + Fluorouracil* 427 *Cetuximab ± Radiation* 429 *Methotrexate* 432
Cisplatin + Fluorouracil 434
Carboplatin + Fluorouracil 437
Cisplatin 440 *Docetaxel* 441
Gefitinib or Erlotinib 443 *Docetaxel + Cisplatin* 445 *Paclitaxel + Carboplatin* 447 *Platinum-Refractory Tumors Single-Agent Cetuximab* 449
Cisplatin- or Carboplatin-Based Chemotherapy + Cetuximab 450
Cisplatin + Paclitaxel; Cisplatin + Fluorouracil 454 *Cisplatin or Carboplatin with Fluorouracil + Cetuximab* 458 *Weekly Docetaxel* 462
Methotrexate or Cisplatin + Fluorouracil or Carboplatin + Fluorouracil 464

15. Hepatocellular Carcinoma 468

Chemoembolization with Doxorubicin 475
Chemoembolization with Cisplatin 479
DEB-TACE: Transarterial Chemoembolization (TACE) Using Drug-Eluting Beads (DEB) 485 *Sorafenib* 488

16. HIV-Related Malignancies 494

Daunorubicin Citrate Liposome Injection 498 *Doxorubicin HCl Liposome Injection (Liposomal Doxorubicin)* 499
Paclitaxel 501 *Interferon alfa-2B* 503
Etoposide + Prednisone + Vincristine + Cyclophosphamide + Doxorubicin ± Rituximab (Dose-Adjusted EPOCH ± R: DA-EPOCH ± R) 506
Cyclophosphamide + Doxorubicin + Vincristine + Prednisone (CHOP) ± Rituximab (CHOP ± Rituximab) 509

17. Leukemia, Acute Lymphoblastic (ADULT) 511

Larson Regimen 517 *Hyper-CVAD* 522
Linker Regimen 527 *ALL Trial: MRC Ukall XII/ECOG E2993* 534 *Liposomal Vincristine Sulfate* 540 *Nelarabine* 542

18. Leukemia, Acute Myeloid 544

Cytarabine + Daunorubicin 549
Cytarabine + Idarubicin 551
High-Dose Cytarabine 552 *Tretinoin (All trans-Retinoic Acid) + Idarubicin* 554
Tretinoin + Arsenic Trioxide 556
Arsenic Trioxide 558

19. Leukemia, Chronic Lymphocytic 559

Fludarabine + Cyclophosphamide + Rituximab (FCR) 562 *Fludarabine + Cyclophosphamide with High-Dose Rituximab* 564 *Chlorambucil* 566
Bendamustine + Rituximab 567
Ofatumumab 569 *Fludarabine + Rituximab* 571 *Pentostatin + Cyclophosphamide + Rituximab* 573
Ibrutinib 575 *Obinutuzumab + Chlorambucil* 578

20. Leukemia, Chronic Myelogenous 581

Imatinib 588 *Dasatinib* 589
Nilotinib 591 *Ponatinib* 592
Bosutinib 598 *Omacetaxine Mepesuccinate* 603 *Hydroxyurea* 605
Interferon alfa 606

21. Leukemia, Hairy Cell 607

Cladribine 610 *Pentostatin* 611
Rituximab 612

22. Lung Cancer 614

Paclitaxel + Carboplatin 617 *Paclitaxel + Cisplatin* 619 *Gemcitabine + Cisplatin* 621 *Docetaxel + Cisplatin* 622
Vinorelbine + Cisplatin 623 *Cisplatin + Pemetrexed* 624 *Crizotinib* 625
Weekly nab*-Paclitaxel + Carboplatin* 629
Cisplatin + Pemetrexed 632
Docetaxel 635 *Vinorelbine* 636
Maintenance Pemetrexed 637
Gefitinib 640 *Erlotinib* 643
Afatinib 647 *Pemetrexed* 649
Paclitaxel + Carboplatin + Bevacizumab 651 *Etoposide + Cisplatin with Concurrent Thoracic Radiation Therapy* 654 *Topotecan* 655

23. Lymphoma, Hodgkin 656

Doxorubicin, Bleomycin, Vinblastine, Dacarbazine (ABVD) 659
Stanford V 661 *Bleomycin, Etoposide, Doxorubicin, Cyclophosphamide, Vincristine, Procarbazine, Prednisone (BEACOPP)* 663 *Dexamethasone + Cytarabine + Cisplatin (DHAP)* 665

(Continued on following page)

Ifosfamide + Carboplatin + Etoposide (ICE) 667 *Ifosfamide + Gemcitabine + Vinorelbine (IGEV)* 669 *Gemcitabine + Vinorelbine + Doxorubicin, Liposomal (GVD)* 671 *Dexamethasone, Carmustine, Etoposide, Cytarabine, Melphalan (Dexa-Beam)* 673 *High-Dose Ifosfamide, Etoposide and Epirubicin (IVE)* 674 *Carmustine + Etoposide + Cytarabine + Melphalan (BEAM)* 675 *Cyclophosphamide, Carmustine (BCNU), Etoposide (CBV)* 676 *Brentuximab Vedotin* 677 *Gemcitabine* 680 *Vinorelbine* 681 *Bendamustine HCl* 682

24. Lymphoma, Non-Hodgkin 684

Cyclophosphamide, Doxorubicin, Vincristine, Prednisone (CHOP) + Rituximab 688 *Dose-Adjusted Etoposide, Prednisone, Vincristine, Cyclophosphamide, and Doxorubicin with Rituximab (DA-EPOCH with Rituximab)* 690 *Cyclophosphamide, Doxorubicin, Vincristine, Prednisone (CHOP) + Rituximab Every 14 Days (R-CHOP-14)* 692 *R-miniCHOP (Rituximab + Cyclophosphamide + Doxorubicin + Vincristine + Prednisone)* 694 *Mini-CEOP (Cyclophosphamide + Epirubicin + Vinblastine + Prednisone)* 698 *Rituximab, Ifosfamide, Carboplatin, and Etoposide (RICE)* 700 *Etoposide, Methylprednisolone, Cytarabine (Ara-C), Cisplatin (ESHAP)* 702 *Dexamethasone, Cytarabine (High-Dose Ara-C), and Cisplatin (DHAP)* 703 *Gemcitabine + Dexamethasone + Cisplatin (GDP)* 705 *Cyclophosphamide, Vincristine, and Prednisone (CVP)* 708 *Rituximab + Cydophosphamide, Vincristine, and Prednisone (R-CVP)* 709 *Fludarabine* 711 *Fludarabine + Rituximab* 712 *Bendamustine + Rituximab* 716 *Fludarabine, Mitoxantrone, and Dexamethasone (FN-D)* 720 *Rituximab* 721 *Extended-Schedule Rituximab* 722 *Maintenance Rituximab* 724 *Fludarabine + Cyclophosphamide + Rituximab (FCR)* 725 *^{131}I Tositumomab* 727 *Yttrium ^{90}Y Ibritumomab Tiuxetan + Rituximab* 729 *Fludarabine + Rituximab* 732 *Fludarabine + Cyclophosphamide + Rituximab* 737 *Cyclophosphamide + Pentostatin + Rituximab* 742 *Ibrutinib* 745 *Rituximab with Hyperfractionated Cyclophosphamide + Vincristine + Doxorubicin + Dexamethasone (R-Hyper-CVAD) Alternating with Rituximab with Methotrexate + Cytarabine (R-MC)* 750 *Bortezomib* 756 *Lenalidomide* 759 *Rituximab + Fludarabine + Cyclophosphamide (R-FC) or Rituximab + Cyclophosphamide + Doxorubicin + Vincristine + Prednisone (R-CHOP)* 764 *Cyclophosphamide + Doxorubicin + Vincristine + Etoposide + Prednisolone (CHOEP)* 768 *Romidepsin* 770 *Pralatrexate* 774 *Dose-Adjusted Etoposide + Prednisone + Vincristine + Cyclophosphamide + Doxorubicin + Rituximab (DA-EPOCH-R)* 778 *Cyclophosphamide, Vincristine, Doxorubicin, Methotrexate + Ifosfamide, Etoposide, and Cytarabine (CODOX-M/IVAC)* 784 *NHL-BFM 86 (Berlin-Frankfurt-Münster 86)* 789 *Rituximab + Hyperfractionated Cyclophosphamide, Vincristine, Doxorubicin, and Dexamethasone (R-Hyper-CVAD)* 792 *Methotrexate, Cytarabine (Ara-C), Cyclophosphamide, Vincristine, Prednisone, and Bleomycin (MACOP-B)* 795 *The Bonn Protocol* 797 *New Approaches to Brain Tumor Therapy (NABTT) CNS Consortium 96-07* 800 *Memorial Sloan-Kettering Regimen* 801

25. Melanoma 804

Interferon alfa-2b 809 *Pegylated Interferon alfa-2b* 811 *Dacarbazine* 813 *Temozolomide* 814 *Carboplatin + Paclitaxel* 815 *Ipilimumab* 817 *Vemurafenib* 821 *Dabrafenib + Trametinib* 822

26. Mesothelioma 826

Pemetrexed + Cisplatin 828 *Pemetrexed + Carboplatin* 829 *Gemcitabine + Cisplatin* 833 *Intraperitoneal Cisplatin + Paclitaxel* 835

27. Multiple Myeloma 836

Lenalidomide + Low-Dose Dexamethasone 845 *Bortezomib + Dexamethasone* 848 *Bortezomib + Lenalidomide + Dexamethasone* 851 *Bortezomib + Thalidomide + Dexamethasone* 855 *Bortezomib + Doxorubicin + Dexamethasone* 858 *Cyclophosphamide + Bortezomib + Dexamethasone (CyBorD)* 862 *Carfilzomib + Lenalidomide + Dexamethasone (CRd)* 865 *Thalidomide + Dexamethasone* 870 *Melphalan + Prednisone + Thalidomide (MPT)* 872 *Bortezomib + Melphalan + Prednisone* 875 *Melphalan + Prednisone + Lenalidomide* 878 *Bortezomib ± Dexamethasone* 881 *Lenalidomide + Dexamethasone* 883 *Carfilzomib* 887 *Pomalidomide + Dexamethasone* 894 *Pomalidomide + Cyclophosphamide + Prednisone* 900 *Liposomal Doxorubicin + Bortezomib* 905 *Conditioning Regimen before Autologous Peripheral Blood Stem Cell Transplantation; High-Dose Melphalan* 910 *Bortezomib* 913 *Lenalidomide* 917 *Thalidomide* 925

28. Ovarian Cancer 928

Carboplatin + Paclitaxel 936 *Cisplatin + Paclitaxel* 938 *Intraperitoneal Cisplatin and Paclitaxel* 939 *Cisplatin and Cyclophosphamide* 942 *Platinum Retreatment (Cisplatin or Carboplatin)* 943 *Gemcitabine + Carboplatin* 946 *Liposomal Doxorubicin + Carboplatin* 948 *Carboplatin + Docetaxel* 951, 953 *Cisplatin + Gemcitabine* 955 *Carboplatin + Weekly (Dose-Dense) Paclitaxel* 958 *Pemetrexed* 960 *Docetaxel* 962 *Fluorouracil + Leucovorin* 964 *Gemcitabine* 965 *Oral Altretamine (Hexamethylmelamine)* 966 *Doxorubicin HCl Liposome Injection (Liposomal Doxorubicin)* 967 *Vinorelbine* 969 *Paclitaxel (24-Hour Paclitaxel Infusion Every 3 Weeks; Weekly Paclitaxel)* 970 *Topotecan HCl* 972 *Oral Etoposide* 973 *Tamoxifen* 974

29. Pancreatic Cancer 975

Gemcitabine + Radiation Therapy 980 *Gemcitabine* 981 *Gemcitabine + Erlotinib* 982 *Gemcitabine + nab-Paclitaxel* 983 *Oxaliplatin + Irinotecan + Fluorouracil + Leucovorin (FOLFIRINOX)* 990 *Oxaliplatin + Leucovorin (Folinic Acid) + Fluorouracil (OFF) + Best Supportive Care* 995

30. Pancreatic Endocrine Tumors 997

Somatostatin Analogs Octreotide Acetate 1001 *Long-Acting Somatostatin Analogs* 1003 *Streptozocin + Fluorouracil* 1005 *Streptozocin + Doxorubicin* 1007 *Sunitinib Malate* 1008 *Everolimus* 1013 *Cisplatin + Etoposide* 1017 *Temozolomide* 1018 *^{177}Lu-Octreotate ([^{177}Lu-DOTA^{0}, Tyr^{3}] Octreotate)* 1019

31. Pheochromocytoma 1021

Cyclophosphamide, Vincristine, and Dacarbazine (CVD) 1025

32. Prostate Cancer 1026

Abiraterone Acetate Metastatic Castration-Resistant Prostate Cancer—No Prior Chemotherapy 1031 *Docetaxel + Prednisone* 1034

(Continued on following page)

1. Adrenocortical Cancer

Peter F. Lebowitz, MD, PhD and Tito Fojo, MD, PhD

Epidemiology

Incidence: 0.5 to 2.0 cases per one million population
Deaths: 0.2% of cancer deaths
Median age: Bimodal median, at age 4 years and ages 40–50 years
Male to female ratio: 1:1.3

Cohn K et al. Surgery 1986;100:1170–1177
Wooten MD, King DK. Cancer 1993;72:3145–3155

Stage at Presentation
Stage I: 3%
Stage II: 29%
Stage III: 19%
Stage IV: 49%

Pathology

1. Unlike renal cell carcinoma, adrenocortical cancer stains positive for vimentin
2. >20 mitoses per HPF—median survival 14 months
   ≤20 mitoses per HPF—median survival 58 months
3. Tumor necrosis—poor prognosis
4. Vascular invasion—poor prognosis
5. Capsular invasion—poor prognosis

Weiss LM et al. Am J Surg Pathol 1989;13:202–206

Survival After Complete Resection

5-Year Actuarial Survival	
Stages I–II	54%
Stage III	24%
1-Year survival	
Stage IV	9%

Icard P et al. Surgery 1992;112:972–980; discussion 979–980
Icard P et al. World J Surg 1992;16:753–758

Work-up

1. CT scan of chest, abdomen, and pelvis to determine extent of disease
2. MRI of abdomen may help to identify and follow liver metastases
3. If IVC is compressed, consider IVC contrast study, ultrasound, or MRI to assess disease involvement before surgical exploration, although apparent extent of involvement should not deter exploration
4. Serum and 24-hour urinary cortisol; 24-hour urinary 17-ketosteroid
5. Additional studies can be performed to determine the functional status of the tumor including: serum estradiol, estrone, testosterone, dehydroepiandrosterone sulfate (S-DHAS), 17-OH-progesterone, and androstenedione

Staging

Stage I	<5-cm tumor confined to adrenal
Stage II	>5-cm tumor confined to adrenal
Stage III	Positive lymph nodes or local invasion with tumor outside adrenal in fat or adjacent organs
Stage IV	Distant metastasis

Macfarlane DA. Ann R Coll Surg Engl 1958;23:155–186
Sullivan M et al. J Urol 1978;120:660–665

Expert Opinion

1. *Primary therapy:* Primary therapy is complete surgical resection
2. *Surgery and Radio Frequency Ablation (RFA) as therapies for recurrences:* When possible, local recurrences should be addressed surgically. Some advocate surgical resection of metastatic disease, and although it may improve survival, firm evidence is lacking. Radio frequency ablation may be used as an alternative if the recurrence is deemed amenable to ablation and has an expendable margin. Just as incomplete resections should not be embarked on, neither should incomplete ablations be performed
3. *Management of excess hormone production:* Excess hormone production should not be ignored. Manage severe hypercortisolism aggressively. Because chemotherapy is usually ineffective, treatment of hormonal excess should not be delayed in expectation that chemotherapy will reduce the tumor burden and improve symptoms. Instead, use steroidogenesis inhibitors either singly or in combination. **Mitotane** is the cornerstone of any strategy and should be started as soon as a diagnosis has been made. Use mitotane at the highest tolerable dose. However, because a therapeutic mitotane level and steady state will not be reached for several months, other agents must be initiated concurrently. In patients with LFT results not more than 3 times normal range, begin therapy with **ketoconazole**, mindful of the potential for a pharmacokinetic interaction with other drugs. If LFTs are elevated, if an aggressive ketoconazole dose escalation is unsuccessful in controlling symptoms, or if toxicity develops, use **metyrapone***, either alone or in combination with ketoconazole. Cortisol levels must be monitored frequently to adjust steroidogenesis inhibitor drug doses and to avoid adrenal insufficiency, which occurs infrequently in patients with cortisol-producing tumors. Should adrenal insufficiency occur, hydrocortisone and mineralocorticoid replacement should be instituted as indicated below
   - *Mitotane:* Refer to section describing mitotane as a regimen for ACC
   - *Ketoconazole:* In patients with ACC and frank Cushing syndrome, treatment can start with 200 mg/dose given 3 or 4 times per day. The dose can then be increased by 400 mg/day every few days to a maximum single doses of 1200–1600 mg administered 3 or 4 doses per day (ie, total daily doses = 3600–6400 mg) while monitoring liver function. Because ketoconazole requires stomach acidity for absorption, proton pump inhibitors should be avoided, and achlorhydria should be suspected in elderly individuals who do not respond to therapy
   - *Metyrapone**: Metyrapone is begun at a low dose of 500–1000 mg (250–500 mg 2–4 times daily) and is escalated every few days to the maximum daily dose. The dose needed to inhibit cortisol production ranges from 500–6000 mg/day, although little is gained with total daily doses greater than 2000 mg
4. *Chemotherapy for unresectable, advanced, and recurrent disease:* Chemotherapy is recommended for patients with metastatic disease, although evidence of survival benefit is not and will never be available. EDP (etoposide + doxorubicin + cisplatin) plus mitotane or streptozocin plus mitotane should be used as first-line therapy. "Novel targeted therapies" that may seem attractive have not been proved and should not be substituted for these chemotherapies that have known activity in ACC
5. *Adjuvant mitotane:* A recent analysis of 177 patients with ACC compared the outcome in 47 patients treated with adjuvant mitotane therapy with 130 patients who received no additional therapy (Terzolo et al., 2007). Surprisingly, when used at "more tolerable" daily doses of 2000–3000 mg, the authors reported that mitotane demonstrated significant benefit in the adjuvant setting. However, the results of this retrospective nonrandomized study must be viewed cautiously. Because the advantage was confined to time to recurrence and not to overall survival, the value of adjuvant mitotane is diminished. Furthermore, the short follow-up period of patients treated with mitotane leaves the conclusions in doubt. The lack of convincing evidence and the difficulty of administering mitotane has often guided a recommendation that "adjuvant" mitotane therapy should be used only in cases where a tumor cannot be fully removed surgically or in patients with a high likelihood of recurrence; that is, large tumors with extensive necrosis, capsular, lymphatic, or venous invasion, a high mitotic or Ki67 labeling index, and small or questionable surgical margins. Until further data are available, this continues to be the most reasonable approach
6. *Long-term mitotane monotherapy:* Administer mitotane long-term only to patients who tolerate it well and experience a therapeutic response or those who are at high-risk for recurrence. The optimal duration of therapy is not known: a recommendation of "indefinite" is most conservative. *Prolonged therapy is often made possible by the fact that after months of therapy body stores are finally saturated, and the dose needed to maintain serum levels is then markedly reduced.* In this case the tolerability improves markedly. However, suboptimal therapy (judged by serum mitotane levels) that is limited by side effects should not be continued; in this setting there is little chance of benefit in the face of continued toxicity. Although suboptimal therapy cannot be accurately defined, blood levels of 10–14 mg/L are often cited as optimal based on two small studies, but lower levels are likely of some value; a clinical observation also noted in the recent retrospective analysis of adjuvant mitotane (Terzolo et al., 2007)

*At present, metyrapone is not available in pharmacies. To obtain metyrapone (Metopirone), a pharmacist or physician must call Novartis Pharmaceuticals Corporation at 1-800-988-7768

REGIMEN

MITOTANE (*o,p'*-DDD)

Luton J-P et al. N Engl J Med 1990;322:1195–1201

Mitotane 2000–20,000 mg/day; administer orally as a single dose or in 2–4 divided doses

Glucocorticoid replacement is necessary in all patients:
Hydrocortisone 15–20 mg; administer orally every morning, *plus:*
Hydrocortisone 7.5–10 mg; administer orally every afternoon around 4 PM
Mineralocorticoid replacement is also recommended:
Fludrocortisone acetate 100–200 mcg/day; administer orally every morning, *or:*
Fludrocortisone acetate 100 mcg/day; administer orally every morning and every evening

Supportive Care
Antiemetic prophylaxis
Emetogenic potential: ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Mitotane is available in the United States for oral administration in tablets that contain 500 mg mitotane. Lysodren (mitotane tablets). Bristol-Myers Squibb Company, Princeton, NJ

Patient Population Studied

A study of 59 patients with adrenocortical carcinoma treated with mitotane at different times in relation to surgery

Efficacy (N = 37)

Overall response rate	22%
Stable disease >12 months	5%
Clinical benefit rate	27%

Complete responses have been reported in other studies but are rare

Toxicity

Adverse Event	% Patients	No. of Patients
Anorexia/nausea	93	28
Vomiting	82	
Diarrhea	68	
Skin rash	32	
Confusion/ sleepiness	100	18
Ataxia	39	
Depression	33	
Dysarthria	28	
Tremor	22	
Visual disturbance	17	
Leukopenia	17	

Van Slooten H et al. Eur J Cancer Clin Oncol 1984;20:47–53

Treatment Modifications

Adverse Event	Dose Modification
General Guidelines:	First step with most side effects, especially if they occur as mitotane dose is advanced: (1) stop mitotane; (2) wait up to 7 days for symptoms to resolve; (3) restart mitotane at lower dose (500–1000 mg/day less than previous dose) or at previously tolerated dose; (4) increase dose in 500-mg/day increments at 1-week intervals
Anorexia Nausea/vomiting	Administer mitotane in divided doses, and/or most of dose before bedtime. Crush tablets and dissolve in vehicle. Use antiemetics as needed. Reassess adrenal replacement
Diarrhea	Administer as divided doses. Use loperamide or diphenoxylate/ atropine
Altered mental status	Stop therapy. Follow general guidelines. Obtain imaging study only if symptoms persist after 1 week off therapy
Skin rash	If not severe, continue mitotane and treat rash with local measures and antipruritics

Therapy Monitoring

1. Check mitotane level at least every 4 weeks initially. Patients receiving long-term mitotane therapy can have monitoring reduced to every 2–3 months
2. Adrenal function can be monitored by measuring ACTH, but this alone is not reliable and should be interpreted together with clinical assessment
3. *Response assessment:* Initially every 6–8 weeks. Patients receiving long-term mitotane therapy can have monitoring reduced to every 3–6 months

Notes

1. Begin mitotane administration at a low dosage, usually no more than 2000 mg/day
2. Increase dose in increments of 500 mg to a maximum of 1000 mg/day, usually at intervals of not less than 1 week
3. Do not increase mitotane if a patient is experiencing side effects; follow General Guidelines in the Treatment Modifications section. Although mitotane is considered to have low to no emetogenic potential, it often produces low-grade nausea that is difficult to tolerate because it occurs every day. In some patients, chronic administration of antiemetics is required. See Chapter 39
4. The optimal dosage is not known; however, mitotane levels should be monitored with a goal of attaining a level of 14–20 mcg/mL. Levels greater than 20 mcg/mL are usually associated with intolerable side effects
5. A dosage of 4000–6000 mg/day usually results in a therapeutic level of mitotane in most patients after 6–10 weeks; however, some patients tolerate or require doses as high as 10,000–12,000 mg/day
6. Therapeutic levels can be achieved more quickly by administering higher doses and by increasing doses more aggressively, but this strategy usually fails because of side effects that result
7. With long-term administration of mitotane, the dosage required to maintain a therapeutic level may be substantially less, even as low as 500–1000 mg/day
8. Chronic administration results in adrenal insufficiency requiring steroid replacement therapy, as recommended in Regimen. Some physicians prefer to begin replacement therapy at the time mitotane therapy is started; others wait until there is evidence of incipient adrenal insufficiency, usually 6–8 weeks after the start of therapy. Replacement therapy is recommended with twice-daily hydrocortisone and with once- or twice-daily fludrocortisone replacement. Measuring ACTH levels to monitor the adequacy of replacement therapy is of limited value, because normal ACTH levels are difficult if not impossible to achieve. Patients should be instructed to obtain and wear identification that warns health care providers about possible adrenal insufficiency
9. Even without effecting a reduction in tumor size, mitotane may reduce circulating hormone levels, so that mitotane therapy can be continued solely to control the signs and symptoms of hormonal excess. Furthermore, if, after a period of mitotane administration, there is evidence of disease progression, discontinuing mitotane will result in a recurrence of the signs and symptoms of hormonal excess. The latter may appear gradually as mitotane is slowly cleared, but may eventually be worse than before mitotane therapy because of interval growth of the tumor. In these patients, consider continuing mitotane or begin an alternate drug to control hormonal excess

Hoffman DL, Mattox VR. Med Clin North Am 1972;56:999–1012
Van Slooten H et al. Eur J Cancer Clin Oncol 1984;20:47–53

REGIMEN

CISPLATIN + MITOTANE

Bukowski RM et al. J Clin Oncol 1993;11:161–165

Hydration: ≥2000 mL 0.9% Sodium Chloride injection (0.9% NS), at ≥100 mL/hour before and after cisplatin administration. Also encourage increased oral fluid intake. Monitor and replace magnesium/electrolytes as needed

Cisplatin 75–100 mg/m²; administer intravenously in 50–250 mL of 0.9% NS over 30 minutes on day 1 every 3 weeks (total dosage per cycle = 75–100 mg/m²)
Mitotane* 4000 mg/day; administer orally, continually

Glucocorticoid replacement is necessary in all patients:
Hydrocortisone 15–20 mg; administer orally every morning, *plus*
Hydrocortisone 7.5–10 mg; administer orally every evening, continually
Mineralocorticoid replacement is also recommended
Fludrocortisone acetate 100–200 mcg/day; administer orally every morning, *or*
Fludrocortisone acetate 100 mcg/day; administer orally every morning and every evening, continually

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1: ***HIGH****. Potential for delayed symptoms*
Emetogenic potential on days with mitotane alone: ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

*Mitotane therapy may be better tolerated if started at a dose of 2000 mg/day, increasing by 500–1000 mg/day at 1-week intervals. The total daily mitotane dosage can be taken in 2–4 divided doses or as a single daily dose, which often is best tolerated at bedtime

Mitotane is available in the United States for oral administration in tablets that contain 500 mg mitotane Lysodren (mitotane tablets). Bristol-Myers Squibb Company, Princeton, NJ

Treatment Modifications

Adverse Event	Dose Modification
CrCl 30–50 mL/min (0.5–0.83 mL/s)	Hold cisplatin until CrCl ≥50 mL/min (≥0.83 mL/s), then reduce dose to 75 mg/m² if previous dose was 100 mg/m² or 60 mg/m² if previous dose was 75 mg/m²
CrCl <30 mL/min (<0.5 mL/s)	Discontinue cisplatin
Unacceptable GI or neuromuscular side effects from mitotane	Reduce mitotane to 2000 mg/day
Unacceptable side effects from mitotane at 2000 mg/day	Reduce mitotane to 1000 mg/day
Unacceptable side effects from mitotane at 1000 mg/day	Discontinue mitotane

CrCl, creatinine clearance

Patient Population Studied

A trial of 42 patients with metastatic or residual adrenocortical carcinoma because complete resection was not possible. Prior therapy with mitotane was allowed

Efficacy (N = 37)

Complete response	2.7%
Partial response	27%
Median response duration	7.9 months
Median time to response	76 days

Toxicity (N = 36)

Adverse Event	% G1/2	% G3/4
Hematologic		
Anemia	8	8
Leukopenia	36	6
Thrombocytopenia	—	3
Nonhematologic		
Nausea/vomiting	75	22
Diarrhea	11	—
Mucositis	6	—
Increased bilirubin	6	—
Renal	17	8
Peripheral neuropathy	3	6
Myalgias	17	6

N = 36, but reported as percent of 37 eligible patients

Therapy Monitoring

1. CBC with leukocyte differential count, serum creatinine and electrolytes, serum magnesium, and LFTs on day 1
2. *Response assessment:* Repeat imaging studies every 2 cycles; 24-hour urine cortisol and 17-ketosteroids with each cycle, if abnormal at baseline
3. Mitotane level at least every 4 weeks initially. A level of 14–20 mcg/mL is desirable
4. Adrenal function can be monitored by measuring ACTH, but this alone is not reliable and should be interpreted together with clinical assessment

ADVANCED OR METASTATIC ADRENAL CANCER REGIMEN

ETOPOSIDE + DOXORUBICIN + CISPLATIN + MITOTANE (EDP-M)

Fassnacht M et al. N Engl J Med 2012;366:2189–2197

Mitotane 500–5000 mg/day; administer orally, continually

- If possible, mitotane is started a minimum of 1 week before cytotoxic treatment is initiated. The ultimate goal is to attain mitotane concentrations in blood of 14–20 mcg/mL over time, as tolerated, trying not to exceed these values as side effects worsen with higher values. Note that side effects may preclude this range from being attained
- Initiate treatment with doses of 1000–1500 mg per day at bedtime to minimize sedative effects during waking hours, and escalate doses as tolerated
- Large daily doses may be divided in ≥2 doses

Doxorubicin 40 mg/m^2; administer by intravenous injection over 3–5 minutes on day 1, every 4 weeks (total dosage/cycle = 40 mg/m^2)

Prehydration for cisplatin: ≥500 mL 0.9% sodium chloride injection (0.9% NS) per day; administer intravenously at ≥100 mL/hour for 2 consecutive days, starting before cisplatin on days 3 and 4

Cisplatin 40 mg/m^2 per day; administer intravenously in 50–500 mL of 0.9% NS over 30–60 minutes for 2 doses on 2 consecutive days, days 3 and 4, every 4 weeks (total dosage/cycle = 80 mg/m^2)

Posthydration for cisplatin: ≥500 mL 0.9% NS per day; administer intravenously at ≥100 mL/hour for 2 consecutive days, after cisplatin on days 3 and 4. Encourage increased oral fluid intake. Monitor and replace magnesium and electrolytes as needed

± *Mannitol diuresis:* May be given to patients who have received adequate hydration

Mannitol 12.5–25 g may be administered by intravenous injection before or during cisplatin administration, *or*

Mannitol 10–40 g; administer intravenously over 1–4 hours before or during cisplatin administration, or may be prepared as an admixture with cisplatin

Note: Diuresis with mannitol requires maintaining hydration with intravenously administered fluid during and for hours after mannitol administration

Etoposide 100 mg/m^2 per dose; administer intravenously diluted to a concentration within the range 0.2–0.4 mg/mL in 5% dextrose injection or 0.9% NS over at least 60 minutes for 3 consecutive days, on days 2, 3, and 4, every 4 weeks (total dosage/cycle = 300 mg/m^2)

Glucocorticoid replacement is necessary in all patients taking mitotane
Hydrocortisone 15–20 mg orally every morning, *plus*:
Hydrocortisone 7.5–10 mg orally every evening
Mineralocorticoid replacement is also recommended:
Fludrocortisone acetate 100–200 mcg/day orally every morning, *or*:
Fludrocortisone acetate 100 mcg/day orally every morning and every evening

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1: ***MODERATE***
Emetogenic potential on day 2: ***LOW***
Emetogenic potential on days 3 and 4: ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Patients with histologically confirmed adrenocortical carcinoma not amenable to radical surgical resection who had not received any previous treatment with cytotoxic drugs, except mitotane, and had an Eastern Cooperative Oncology Group (ECOG) performance status of 0, 1, or 2. One hundred fifty-one patients received etoposide + doxorubicin + cisplatin + mitotane

Age (y)	
Median	51.9
Range	19.0–76.2
Sex—Number (%)	
Male	60 (39.7)
Female	91 (60.3)
Tumor stage—Number (%)	
III	0
IV	151 (100.0)
Endocrine symptoms—Number (%)	
Cushing syndrome ± other symptoms	60 (39.7)
Conn syndrome only	2 (1.3)
Virilization only	6 (4.0)
Feminization only	3 (2.0)
No symptoms	70 (46.4)
Missing data	10 (6.6)
ECOG performance status score—Number (%)	
0	73 (48.3)
1	64 (42.4)
2	13 (8.6)
4	1 (0.7)
Time since primary diagnosis—Months	
Median	7.3
Range	0–183.7
Number of affected sites*	
Median	3
Range	1–7

*The following sites were calculated as separate sites of adrenocortical carcinoma: adrenal gland (including local recurrence), liver, lung, bone, peritoneum, retroperitoneum, pleura, mediastinum, central nervous system, soft tissue, spleen, and ovary

Treatment Modifications

Adverse Event	Dose Modification
Day 1 WBC <1000/mm³ *or* platelet count <100,000/mm³ *or* G >2 nonhematologic toxicity	Delay chemotherapy until WBC ≥1000/mm³ and platelet count ≥100,000/mm³, or nonhematologic toxicity G ≤1 for a maximum delay of 2 weeks
>2-week delay in reaching WBC >1000/mm³ *or* platelet count >100,000/mm³ *or* for resolution of non-hematologic toxicity to G ≤1	Discontinue therapy
G4 ANC or G ≥3 platelet counts	Reduce dosages of all drugs by 25% except mitotane
Creatinine clearance <50 to 60 mL/min	Hold cisplatin until creatinine clearance >50–60 mL/min

*Responses according to Response Evaluation Criteria in Solid Tumors (RECIST)
†EDP + M = etoposide + doxorubicin + cisplatin + mitotane; Sz + M = streptozocin + mitotane
‡Surgery performed >PR to study treatment; not included in PR category
§Stable disease was defined as no disease progression for at least ≥8 weeks and no objective response to treatment. Confirmatory scans were not required for this determination, according to the study protocol
¶Objective response = CR + PR
**Disease control + CR + PR + SD
††Patients classified according to first-line therapy, but they were allowed to receive the alternate therapy in second line

Toxicity

Event	Number of Patients (%)
Any serious adverse event	86 (58.1)
Adrenal insufficiency	5 (3.4)
Bone marrow toxicity	17 (11.5)
Cardiovascular or thromboembolic event	10 (6.8)
Fatigue or general health deterioration	8 (5.4)
Gastrointestinal disorder	6 (4.1)
Impaired liver function	0
Impaired renal function	1 (0.7)
Infection	10 (6.8)
Neurologic toxicity	5 (3.4)
Respiratory disorder	9 (6.1)
Other	15 (10.1)

Therapy Monitoring

1. CBC with leukocyte differential count, serum creatinine and electrolytes, serum magnesium, and LFTs on day 1 of each cycle
2. *Response assessment:* Repeat imaging studies every 2 cycles; 24-hour urine 17-ketosteroids and cortisol with each cycle if abnormal at baseline
3. Mitotane level at least every 4 weeks initially. A level of 14–20 mcg/mL is desirable but may not be attained
4. Adrenal function can be monitored by measuring ACTH, but this alone is not reliable and should be interpreted together with clinical assessment

REGIMEN

DOXORUBICIN

Decker RA et al. Surgery 1991;110:1006–1013

Doxorubicin 60 mg/m^2; administer by intravenous injection over 3–5 minutes on day 1, every 3 weeks to a maximum cumulative lifetime dosage of 500 mg/m^2 (total dosage per cycle = 60 mg/m^2)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential: ***HIGH***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 31 patients with unresectable adrenocortical carcinoma with ECOG PS 0–3. Fifteen of the 31 patients had been treated with mitotane immediately before doxorubicin

Efficacy (N = 31)

	Response Rate	No. of Patients
Initial treatment with chemotherapy (doxorubicin); no prior mitotane	19%	16
Tumor did not respond, or progressed when treated with mitotane	0%	15

Toxicity (N = 31)

	% Mild/ Moderate	% Severe
Hematologic		
Any hematologic	48	19
Nonhematologic		
Nausea/vomiting	45	3
Diarrhea	19	3
Skin/mucosa	16	0
Neurologic	13	0
Hepatic	6	0

Bear HD et al. J Clin Oncol 2003;21:4165–4174

Therapy Monitoring

1. CBC with leukocyte differential count, serum creatinine, electrolytes, and LFTs on day 1
2. *Response assessment:* Repeat imaging studies every 2 cycles; 24-hour urine cortisol and 17-hydroxycorticosteroids with each cycle if abnormal at baseline

Treatment Modifications

Adverse Event	Dose Modification
Day 1 ANC <1500/mm^3, platelet count <75,000/mm^3	Delay chemotherapy until ANC >1500/mm^3 and platelet counts >75,000/mm^3 for a maximum delay of 2 weeks. Use filgrastim or pegfilgrastim in subsequent cycles if delay for low ANC
Febrile neutropenia	Filgrastim or pegfilgrastim in subsequent cycles
Febrile neutropenia on filgrastim or pegfilgrastim	Reduce doxorubicin dosage by 25%
G ≥3 Nonhematologic toxicity	Hold therapy until resolution to G1. Reduce doxorubicin dosage by 25% if recovery occurs in <2 weeks

Bear HD et al. J Clin Oncol 2003;21:4165–4174

Notes

The recommended limit for total cumulative lifetime doxorubicin dosage of 450–500 mg/m^2 may be exceeded, provided that adequate cardiac monitoring is conducted before every or every other chemotherapy cycle

ADVANCED OR METASTATIC ADRENAL CANCER REGIMEN

STREPTOZOCIN + MITOTANE (Sz-M)

Fassnacht M et al. N Engl J Med 2012;366:2189–2197

Mitotane 500–5000 mg/day; administer orally, continually

- If possible, mitotane is started a minimum of 1 week before cytotoxic treatment is initiated. The ultimate goal is to attain mitotane concentrations in blood of 14–20 mcg/mL over time, as tolerated, trying not to exceed these values as side effects worsen with higher values. Note that side effects may preclude this range from being attained
- Initiate treatment with doses of 1000–1500 mg/day at bedtime to minimize sedative effects during waking hours, and escalate doses as tolerated
- Large daily doses may be divided in ≥2 doses

Hydration for streptozocin (all cycles): 1000 mL 0.9% sodium chloride injection (0.9% NS) per day; administer intravenously with 500 mL given before streptozocin and 500 mL given after streptozocin

First cycle: **Streptozocin** 1000 mg/day; administer intravenously in 50–500 mL of 0.9% NS or 5% dextrose injection (D5W) over 30–60 minutes for 5 doses on 5 consecutive days, days 1–5, every 3 weeks (total dose/cycle = 5000 mg)

Second and subsequent cycles: **Streptozocin** 2000 mg; administer intravenously in 50–500 mL of 0.9% NS or D5W over 30–60 minutes on day 1, every 3 weeks (total dose/cycle = 2000 mg)

Glucocorticoid replacement is necessary in all patients taking mitotane
Hydrocortisone 15–20 mg orally every morning, *plus*:
Hydrocortisone 7.5–10 mg orally every evening
Mineralocorticoid replacement is also recommended:
Fludrocortisone acetate 100–200 mcg/day orally every morning, *or*:
Fludrocortisone acetate 100 mcg/day orally every morning and every evening

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **HIGH** each day streptozocin is administered. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
Day 1 WBC <1000/mm³ *or* platelet count <100,000/mm³ *or* G >2 nonhematologic toxicity	Delay chemotherapy until WBC ≥1000/mm³ and platelet count ≥100,000/mm³, or nonhematologic toxicity G ≤1 for a maximum delay of 2 weeks
>2-week delay in reaching WBC, >1000/mm³ *or* platelet count >100,000/mm³, *or* for resolution of nonhematologic toxicity to G ≤1	Discontinue therapy
G4 ANC or G ≥3 platelet counts	Reduce streptozocin dose by 25%
Creatinine clearance <50–60 mL/min	Hold streptozocin until creatinine clearance >50–60 mL/min

Patient Population Studied

Patients with histologically confirmed adrenocortical carcinoma not amenable to radical surgical resection who had not received any previous treatment with cytotoxic drugs, except mitotane, and had an Eastern Cooperative Oncology Group (ECOG) performance status of 0, 1, or 2. One-hundred fifty-three patients received streptozocin + mitotane

Age (y)	
Median	50.0
Range	18.8–72.8

Respiratory disorder	5 (3.4)
Other	13 (8.7)

Therapy Monitoring

1. CBC with leukocyte differential count, serum creatinine, electrolytes, and LFTs on day 1; obtain creatinine clearance on day 1 if an elevation in serum creatinine is observed
2. Twenty-four–hour urine for protein on day 1
3. *Response assessment:* Repeat imaging studies every 2 cycles; 24-hour urine 17-ketosteroids and cortisol with each cycle if abnormal at baseline
4. Mitotane level at least every 4 weeks initially. A level of 14–20 mcg/mL is desirable, but may not be attained
5. Adrenal function can be monitored by measuring ACTH, but this alone is not reliable and should be interpreted together with clinical assessment

2. Anal Cancer

Irfan Jawed, MD and John Marshall, MD

Epidemiology

Incidence: 7,210 (male: 2,660; female: 4,550. Estimated new cases for 2014 in the United States)
1.5 per 100,000 male per year, 1.9 per 100,000 female
Deaths: Estimated 950 in 2014 (male: 370; female: 580)
Median age at diagnosis: 60 years
Male to female ratio: Slight female predominance

Stage at Presentation
Stages I/II: 50%
Stage III: 29–40%
Stage IV: 10–13%

Work-up

All stages

1. Sigmoidoscopy with biopsy
2. CT scan of abdomen and pelvis, or MRI
3. Chest x-ray or chest CT
4. Consider HIV testing
5. Consider PET-CT scan
6. Gynecologic exam for women, including screening for cervical cancer

Positive inguinal lymph node on imaging

1. Fine-needle aspiration or biopsy of node

Pathology

By convention, anal cancer should now refer only to *squamous cell cancers* arising in the anus. Earlier surgical series often did not make this distinction. *Adenocarcinomas* occurring in the anal canal should be treated according to the same principles applied to rectal adenocarcinoma. Similarly, melanomas and sarcomas should be treated according to the same principles applied to those tumor types at other sites

The distal anal canal is lined by squamous epithelium, and tumors arising in this portion are often keratinizing. Around the dentate line, the mucosa transitions from squamous mucosa to the nonsquamous rectal mucosa. Tumors arising in this transitional zone are often nonkeratinizing and previously were referred to as basaloid or cloacogenic

Clark MA et al. Lancet Oncol 2004;5:149–157
Ryan DP et al. N Engl J Med 2000;342:792–800

Five-Year Survival (After Chemoradiation)

Stages I/II: 80%
Stage III: 60%
Stage IV: 30.5%

Howlader N et al., eds. SEER Cancer Statistics Review, 1975–2008. Bethesda, MD: National Cancer Institute, http://seer.cancer.gov/csr/1975_2008/, based on November 2010 SEER data submission, posted to the SEER website, 2011

Poor Prognostic Factors

1. Nodal involvement
2. Skin ulceration
3. Male gender
4. Tumor >5 cm

Staging

Primary Tumor (T)

TX	Primary tumor cannot be assessed
T0	No evidence of primary tumor
Tis	Carcinoma *in situ* (Bowen disease, High-grade Squamous Intraepithelial Lesion (HSIL), Anal Intraepithelial Neoplasia II–III (AIN II–III)
T1	Tumor 2 cm or less in greatest dimension
T2	Tumor more than 2 cm but not more than 5 cm in greatest dimension
T3	Tumor more than 5 cm in greatest dimension
T4	Tumor of any size invades adjacent organ(s), eg, vagina, urethra, bladder*

*Direct invasion of the rectal wall, perirectal skin, subcutaneous tissue, or the sphincter muscle(s) is not classified as T4

Regional Lymph Nodes (N)

NX	Regional lymph nodes cannot be assessed
N0	No regional lymph node metastasis
N1	Metastasis in perirectal lymph node(s)
N2	Metastasis in unilateral internal iliac and/or inguinal lymph node(s)
N3	Metastasis in perirectal and inguinal lymph nodes and/or bilateral internal iliac and/or inguinal lymph nodes

Distant Metastasis (M)

M0	No distant metastasis (no pathologic M0; use clinical M to complete stage group)
M1	Distant metastasis

Group	T	N	M
0	Tis	N0	M0
I	T1	N0	M0
II	T2	N0	M0
	T3	N0	M0
IIIA	T1	N1	M0
	T2	N1	M0
	T3	N1	M0
	T4	N0	M0
IIIB	T4	N1	M0
	Any T	N2	M0
	Any T	N3	M0
IV	Any T	Any N	M1

Expert Opinion

Locoregional disease ***(squamous cell cancers)***

Anal canal cancer

- Concurrent chemoradiation is the recommended primary treatment for patients with anal canal cancer that has not metastasized, with fluorouracil 1000 mg/m² per day by continuous intravenous infusion over 24 hours for 4 consecutive days on days 1–4, *plus* mitomycin 10 mg/m² by slow intravenous injection on day 1, every 28 days for 2 cycles (see Regimens below)
- Long-term update of U.S. GI intergroup RTOG 98-11 phase III trial for anal carcinoma: disease-free and overall survival with RT + fluorouracil + mitomycin versus RT + fluorouracil + cisplatin

Long-term Update of U.S. GI Intergroup RTOG 98-11

Gunderson LL et al. Proc Am Soc Clin Oncol 2011;29:257s [abstract 4005]

		DFS		OS		CFS		LRF		DM		CF	
	# Patients	TF	%, 5-Years	TF	%, 5-Years	TF	%, 5-Years	TF	%, 5-Years	TF	%, 5-Years	TF	%, 5-Years
RT + fluorouracil + mitomycin	325	117	67.7	80	78.2	101	71.8	67	20.0	45	13.1	38	11.9
RT + fluorouracil + cisplatin	324	156	57.6	108	70.5	126	64.9	86	26.5	60	17.8	55	17
p Value		0.0044		0.021		0.053		0.089		0.12		0.075	

CF, colostomy failure; CFS, colostomy-free survival; DFS, Disease-free survival; DM, distant metastases; LRF, locoregional failure; OS, overall survival; RT, radiation therapy; TF, total failures

- Locoregional failure rate is 10–30%. If locally persistent or progressive disease is present, consider abdominoperineal resection (APR). If positive lymph nodes are found, perform groin dissection with RT (if RT was not previously administered) or without RT

Anal margin cancer

- A well-differentiated anal margin lesion characterized as T1, N0, can be treated with margin negative excision alone with close follow-up
- For T2–T4 or any N, the recommended treatment is chemoradiation: fluorouracil 1000 mg/m² per day by continuous intravenous infusion over 24 hours for 4 consecutive days on days 1–4, *plus* mitomycin 10 mg/m² intravenously on day 1, every 28 days for 2 cycles (see Regimens below)

Metastatic anal cancer ***(squamous cell cancers)***

Metastatic disease should be treated with cisplatin-based chemotherapy or enrollment in a clinical trial

Faivre C et al. Bull Cancer 1999;86:861–865

(continued)

Expert Opinion (*continued*)

Fluorouracil 1000 mg/m^2 per day administer by continuous intravenous infusion over 24 hours for 5 consecutive days on days 1–5, every 4 weeks, *plus*
Cisplatin 100 mg/m^2 administer intravenously over 30–60 minutes on day 2, every 4 weeks

- The regimen of choice
- Should be repeated until there is evidence of disease progression or toxicity requires cessation of treatment

Note: If the above regimen fails, no other regimen has been shown to be effective

Supportive Care/Alternate Treatments

- Radiotherapy might be delivered with less toxicity by means of 3D conformal radiotherapy or IMRT followed by conventional radiotherapy as shown in RTOG 0529 trial (2-year outcomes of RTOG 0529: a phase II evaluation of dose-painted IMRT in combination with fluorouracil and mitomycin for the reduction of acute morbidity in carcinoma of the anal canal). However, IMRT is not recommended in obese patients with nonreproducible external skin contours or patients with a major component of tumor outside the anal canal

Two-Year Outcomes of RTOG 0529

Kachnic LA et al. J Clin Oncol 2011;29(Suppl 4) [abstract 368]

	0529 (N = 52)		9811 (N = 325)	
End Point	Events	2-Year % (95% CI)	Events	2-Year % (95% CI)
LRF	10	20 (9, 31)	67	19 (14, 23)
CF	4	8 (0.4, 15)	38	11 (8, 14)
OS	7	88 (75, 94)	80	91 (87, 94)
DFS	12	77 (62, 86)	117	76 (70, 80)
CFS	7	86 (73, 93)	101	83 (79, 87)

CF, colostomy failures; CFS, colostomy-free survival; DFS, disease-free survival; LRF, Locoregional failure; OS, overall survival

- Capecitabine has been assessed in a phase II trial as a replacement for fluorouracil, but, to date, there is insufficient evidence to recommend substitution (Glynne-Jones R et al. Int J Radiat Oncol Biol Phys 2008;72:119–126)
- Tolerance to treatment can be maximized with antibiotics, antifungals, antiemetics, analgesia, skin care, advice regarding nutrition, and psychological support

Prevention of Anal Cancer

The U.S. Food and Drug Administration in 2010 approved recombinant human papillomavirus quadrivalent vaccine (Gardasil) for use in females and males ages 9 through 26 years for indications, including the prevention of anal intraepithelial neoplasia and associated precancerous lesions caused by human papillomavirus (HPV) types 6, 11, 16, and 18

Management of HIV Positive Patients

HIV-positive patients are generally treated similarly to those without HIV infection, however dosage may need to be adjusted (or treat without mitomycin) specifically if CD4 count is <200 cells/mm^3 or patients with a history of HIV-related complications as outcomes appear to be comparable but treatment-related toxicity may be worse

Post-treatment surveillance

There are no prospective trials to guide the post-treatment surveillance strategy for patients treated for anal cancer

- For patients who have a complete remission at 8–12 weeks from initial chemoradiotherapy, guidelines from the NCCN suggest the following every three to six months for five years:
  - Digital rectal examination
  - Anoscopy
  - Inguinal node palpation
  - If initially T3-4 disease or inguinal node-positive, or for those with persistent disease at the initial post-treatment biopsy who regress on serial examinations, consider imaging of the chest/abdomen and pelvis annually for three years
- For patients who have persistent disease at 8–12 weeks on DRE, it is recommended to re-evaluate in four weeks, and, if regression is observed on serial exams, continue to observe and re-evaluate in 3 months. If progressive disease is documented, perform a biopsy and restage
- For patients who undergo APR for biopsy-proven progressive or recurrent disease, perform inguinal node palpation every three to six months for five years, and annual radiographic imaging of the chest/abdomen/pelvis for three years

REGIMEN

MITOMYCIN + FLUOROURACIL + RADIATION THERAPY (RTOG 8704/ECOG 1289 AND RTOG-0529)

Flam M et al. J Clin Oncol 1996;14:2527–2539
Kachnic LA et al. J Clin Oncol 2011;29(Suppl 4) (American Society of Clinical Oncology 2011 Gastrointestinal Cancers Symposium, abstract 368)

Mitomycin 10 mg/m² single dose (maximum dose = 20 mg); administer by intravenous injection over 3–5 minutes on day 1 every 4 weeks for 2 cycles (days 1 and 29 of radiation) (total dosage/cycle = 10 mg/m², but *not* greater than 20 mg)
Fluorouracil 1000 mg/m² per day (maximum daily dose = 2000 mg); administer by continuous intravenous infusion over 24 hours for 4 consecutive days, on days 1–4 every 4 weeks for 2 cycles (days 1–4 and 29–32 of radiation therapy) (total dosage/cycle = 4000 mg/m², but *not* greater than 8000 mg)
External beam radiation therapy 1.8 Gy/fraction; administer daily 5 days/week for 5 weeks (total dose to pelvis/complete course = 45 Gy in 5 weeks)
For patients with T3, T4, or N+ lesions or T2 lesions with residual disease after 45 Gy, current RTOG protocol recommends an additional 10–14 Gy to a reduced field

Alternate RT regimen: dose-painted (DP) IMRT
DP-IMRT prescribed as follows:
- T2N0: 42-Gy elective nodal and 50.4-Gy anal tumor planning target volumes (PTVs), 28 fractions
- T3-4N0-3: 45-Gy elective nodal, 50.4-Gy ≤3 cm, and 54-Gy >3 cm metastatic nodal and 54-Gy anal tumor PTVs, 30 fractions

Note: IMRT is not recommended in obese patients with nonreproducible external skin contours, or patients with a major component of tumor outside the anal canal

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
***Latent or delayed onset diarrhea**:**
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)
- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily

(continued)

Treatment Modifications

Adverse Event	Dose Modification
G3/4 Diarrhea or stomatitis	Reduce fluorouracil dosage 50% during second cycle
G3 Radiation dermatitis	
G4 Radiation dermatitis	Do not give second cycle of chemotherapy
ANC <500/mm³ or platelets <50,000/mm³	Reduce fluorouracil and mitomycin dosages 50%
G3/4 Hematologic or nonhematologic events	Suspend chemoradiation until recovers to G ≤2

Based on RTOG protocol 98-11

Toxicity (N = 146)

	% G4/5
Acute (≤90 days after starting treatment)	25
Hematologic	18
Nonhematologic (diarrhea, skin, mucositis)	7
Late (>90 days after starting treatment)	5
Any grade 4 adverse event	23
Toxic death rate*	2.8

*All treatment-related deaths occurred in a setting of neutropenia and sepsis
NCI Common Toxicity Criteria, version 2.0

Efficacy (N = 129–146)

Positive biopsy after induction	8%
5-Year locoregional failure	36%
5-Year colostomy rate	22%
5-Year colostomy-free survival	64%
5-Year disease-free survival	67%
5-Year overall survival	67%

Flam M et al. Classic Papers and Current Comments: Highlights of Gastrointestinal Cancer Research 1999;3:539–552

(continued)

- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count $<500/mm^3$ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178
Abigerges D et al. J Natl Cancer Inst 1994;86:446–449

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population Studied

A study of 146 patients with localized (nonmetastatic) squamous cell cancer of the anal canal

Therapy Monitoring

1. *Every week:* CBC with differential
2. *Response assessment:* PE 6 weeks after completion of chemoradiotherapy. If there is regression of tumor on exam, then 12 weeks after completion of therapy repeat PE, perform sigmoidoscopy and obtain CT scan. If there is a residual mass or thickening, a biopsy should be performed. If there is residual disease at 12 weeks or if there is progression of disease on exam, consider salvage abdominoperineal resection

Notes

Severely immunocompromised patients or HIV-positive patients with low CD4 counts should be treated with caution. Consider omitting and/or reducing the dose of chemotherapy

REGIMEN

FLUOROURACIL + CISPLATIN + EXTERNAL BEAM RADIATION THERAPY

Doci R et al. J Clin Oncol 1996;14:3121–3125

Fluorouracil 750 mg/m² per day; administer by continuous intravenous infusion in 500–1000 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 24 hours for 4 consecutive days, on days 1–4, every 21 days for 2 cycles (total dosage/cycle = 3000 mg/m²)
(Days 1–4 and 21–24 of radiation therapy)
Hydration before cisplatin ≥1000 mL 0.9% NS; administer intravenously over a minimum of 2–4 hours
Cisplatin 100 mg/m²; administer intravenously in 50–250 mL 0.9% NS over 60 minutes, on day 1 every 21 days for 2 cycles (total dosage/cycle = 100 mg/m²)
(Days 1 and 21 of radiation therapy)
Hydration after cisplatin ≥1000 mL 0.9% NS; administer intravenously over a minimum of 2–4 hours. Encourage patients to supplement their usual oral hydration with extra non–alcohol-containing fluids for at least 24 hours after receiving cisplatin
External beam radiation therapy 1.8 Gy/fraction; administer daily 5 days/week up to 54–58 Gy

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential on days with cisplatin, fluorouracil, and RT is **HIGH**. Potential for delayed symptoms*
*Emetogenic potential on days with fluorouracil and RT is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)
- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

(*continued*)

Patient Population Studied

A study of 35 patients with previously untreated basaloid (n = 5) or squamous cell carcinoma (n = 30) of the anus. In all patients, the cancer was located in the anal canal; in 28, the tumor extended to adjacent sites. Nine patients had nodal metastases; no patient had distant metastases

Efficacy (N = 35)

Complete response	94%
Partial response*	6%
Local recurrence	6%
At median follow-up of 37 months	
No evidence of disease	94%
Colostomy free	86%

Normal anal function preserved in 30 of 35 patients
*Two partial responses in 2 of 5 (40%) patients with T3 tumors

Toxicity* (N = 35)

	% G1	% G2	% G3
Hematologic (leukopenia)	40	31	—
Vomiting	40	33	10
Dermatitis, proctitis, diarrhea	8.5	88.5	3
Cardiac	—	3†	—

*Acute toxicities. Chronic toxicities not reported.
No grade 4 toxicities reported
†Transient at end of first cycle; resolved
WHO criteria

(continued)

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Note: The RTOG has amended the above regimen as follows:
Two cycles of chemotherapy are given before external beam radiation therapy commences; that is, radiation therapy begins coincident with the start of chemotherapy cycle 3
The chemotherapy regimen used has been modified as follows:
Fluorouracil 1000 mg/m^2 per day; administer by continuous intravenous infusion in 500–1000 mL 0.9% NS or D5W over 24 hours for 4 consecutive days on days 1–4, every 28 days for 4 cycles (total dosage/cycle = 4000 mg/m^2)
Cisplatin 75 mg/m^2; administer intravenously in 250 mL 0.9% NS over 60 minutes on day 1 every 28 days for 4 cycles on days 1, 29, 57, and 85 (total dosage/cycle = 75 mg/m^2)

Treatment Modifications

Adverse Event	Dose Modification
ANC <500/mm^3 or platelets <50,000/mm^3	Decrease fluorouracil and cisplatin dosages by 50%
G3/4 diarrhea or stomatitis	Decrease fluorouracil dosage by 50%
G3 radiation dermatitis	
G4 radiation dermatitis	Hold radiation until dermatitis resolves to G ≤2, and do not administer additional fluorouracil
Creatinine 1.5–2.0 mg/dL (133–177 µmol/L)	Decrease cisplatin dosage by 50%
Creatinine >2.0 mg/dL (>177 µmol/L)	Hold cisplatin

Recommended by RTOG 98-11

Therapy Monitoring

1. *Before each cycle:* CBC with differential, BUN, creatinine, magnesium, and electrolytes
2. *Response assessment:* PE 4–6 weeks after completion of chemoradiotherapy. Perform a biopsy only in the absence of a response to therapy. If there has been a response to therapy, reevaluate at 12 weeks with PE, sigmoidoscopy, and CT scan. If residual tumor is suspected, biopsy the affected area. If residual disease is documented at 12 weeks or if there is progression of disease on exam, consider salvage abdominoperineal resection

ADVANCED DISEASE REGIMEN

CISPLATIN + FLUOROURACIL BY CONTINUOUS INTRAVENOUS INFUSION

Faivre C et al. Bull Cancer 1999;86:861–865

Hydration before, during, and after cisplatin administration ± mannitol:

- *Pre-cisplatin hydration* with ≥1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously with potassium and magnesium supplementation as needed based on pretreatment values
- *Mannitol diuresis:* May be given to patients who have received adequate hydration. A dose of **mannitol** 12.5–25 g may be administered by intravenous injection or a short infusion before or during cisplatin administration, or prepared as an admixture with cisplatin. Continued intravenous hydration is essential
- *Continued mannitol diuresis:* In an inpatient or day-hospital setting, one may administer additional mannitol in the form of an intravenous infusion: **mannitol** 10–40 g administer intravenously over 1–4 hours. This can be done either during or immediately after cisplatin, but requires maintenance of adequate intravenously administered fluids during and for hours after mannitol administration
- Post-cisplatin hydration with ≥1000 mL 0.9% NS; administer intravenously with potassium and magnesium supplementation as needed based on measured values. Encourage patients to supplement their usual oral hydration with extra non–alcohol-containing fluids for at least 24 hours after receiving cisplatin

Cisplatin 100 mg/m^2; administer intravenously in 100–500 mL 0.9% NS over 30–60 minutes on day 2, every 4 weeks (total dosage/cycle = 100 mg/m^2)
Fluorouracil 1000 mg/m^2 per day; administer by continuous intravenous infusion in 50–1000 mL 0.9% NS or 5% dextrose injection over 24 hours for 5 consecutive days, on days 1–5, every 4 weeks (total dosage/cycle = 5000 mg/m^2)

Notes:

- Ten patients received further local treatment
- Carboplatin used instead of cisplatin in the event of renal toxicity

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on days with cisplatin is **HIGH** Potential for delayed symptoms*
*Emetogenic potential on days with fluorouracil alone is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
G3/4 hematologic	Reduce fluorouracil and cisplatin dosages by 20%
Hand-foot syndrome (palmar-plantar erythrodysesthesia)	Interrupt fluorouracil therapy until symptoms resolve. Then, reduce fluorouracil dosage by 20%, or discontinue fluorouracil
Mucositis	Interrupt fluorouracil therapy until symptoms resolve. Then, reduce fluorouracil dosage by 20%
Diarrhea	
Reduction in creatinine clearance* to ≤60% of on study value	Delay therapy for 1 week. If creatinine clearance does not recover to pretreatment values, consider reducing cisplatin dose or replace cisplatin with carboplatin
Creatinine clearance* 40–60 mL/min (0.66–1 mL/s)	Consider reducing cisplatin dose, so that dose in milligrams equals the creatinine clearance* value expressed in mL/min†. Alternatively, replace cisplatin with carboplatin
Creatinine clearance* <40 mL/min (<0.66 mL/s)	Hold cisplatin
Clinically significant ototoxicity	Discontinue cisplatin
Clinically significant sensory loss	Discontinue cisplatin

*Creatinine clearance is used as a measure of glomerular filtration rate
†This also applies to patients with creatinine clearance of 40–60 mL/min before commencing treatment

Patient Population Studied

Study of 19 patients (3 males, 16 females), median age 58 years, WHO performance status: G0-1 in 68% and G2 in 32%. Metastasis were synchronous in 6 patients and metachronous in 13 patients. Metastatic sites included liver (10/19 patients), lymph nodes (11/19 patients: paraaortic 5, iliac 4, and inguinal 2) and pulmonary (3/11 patients). In 9 of 19 patients lymph node metastases were isolated; in 7 of 19 patients liver metastases were isolated

(*continued*)

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)

- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count $<500/mm^3$ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

G3/4 diarrhea	0
G3/4 mucositis	0
Neurotoxicity	0
Ototoxicity	0
G1–2 nephrotoxicity	11.1%

Mean fluorouracil dose intensity during cycles 1 and 2	92.5%
Mean cisplatin dose intensity during cycles 1 and 2	95%

*WHO criteria

Efficacy (N = 18)*

Overall response rate	66%
Complete response	5.5%
Partial response	61.1%
Stable disease	22.2%
Progressive disease	11.1%
Median number of cycles (range)	4 (2–7)

1-Year survival	62.2%
5-Year survival	32.2%
Overall survival	34.5 months

*WHO criteria
Note: Three patients who were alive at 4, 5, and 7 years, respectively, had received additional local treatment (1 patient received chemotherapy after hepatic resection and 2 patients were treated after response to the FUP regimen with surgery or radiotherapy)

Treatment Monitoring

1. CBC with diff, electrolytes (including sodium, potassium, magnesium), and serum creatinine and LFTs before each cycle
2. Assessment evaluation: every 8 weeks

3. Biliary: Gallbladder Cancer and Cholangiocarcinoma

Tim Greten, MD, PhD, Susanna Ulahannan, MD, and Werner Scheithauer, MD

Epidemiology

Gallbladder Cancer & Other Biliary

Incidence: 10,650 (male: 4,960; female: 5,690. Estimated new cases for 2014 in the United States)

Deaths: Estimated 3,630 in 2014 (male: 1,610; female: 2,020)

Median age, cholangiocarcinoma: 65 years

Gallbladder: 7th decade

Gallbladder cancer: Women are two to six times more likely to develop gallbladder cancer than men

Cholangiocarcinoma: Slighlty more common in men

Siegel R et al. CA Cancer J Clin 2014;64:9–29

Work-up

1. Early diagnosis of gallbladder or cholangiocellular carcinoma is nearly impossible or can only be realized in exceptional cases
2. In a patient with specific clinical symptoms or ultrasound suspicion of biliary tract cancer, a spiral CT and chest x-ray should be performed
3. Medically fit, nonjaundiced patients whose disease appears *potentially resectable* may proceed directly to surgical exploration without needle biopsy to avoid tumor spread. Consider a laparoscopic evaluation before open surgery owing to the common occurrence of otherwise nonvisible metastatic spread to the peritoneum
4. If the potential to perform a resection remains *uncertain* and for those with jaundice, a more precise assessment of tumor extent and lymph node involvement should be obtained with MRCP ± MRA, which may help to rule out vascular invasion and anomalous anatomic findings for surgical planning
5. If it is obvious that a resection will *not* be possible or if distant metastases are present, fine-needle biopsy for tissue confirmation should be obtained
6. In *nonresectable jaundiced* patients, depending on the location of the biliary obstruction, a percutaneous transhepatic cholangiography (PTC) or an endoscopic retrograde cholangiography (ERC) should be considered to guide placement of a stent

Fong Y et al. Cancer of the liver and biliary tree. In: Principles and Practice of Oncology, 6th ed. Baltimore, MD: Lippincott Williams & Wilkins 2001:1162–1203

Pathology

1. Gallbladder cancer	(60%)
2. Cholangiocarcinoma	(40%)
Intrahepatic	10%
Perihilar (Klatskin tumor)	40–60%
Distal	20–30%
Multifocal	<10%

Histopathology

1. Adenocarcinoma Papillary, nodular, tubular, medullary	80–90%
2. Pleomorphic giant cell carcinoma	>10%
3. Squamous cell carcinoma	5%
4. Mucoid carcinoma	<1%
5. Anaplastic carcinoma	<1%
6. Cystadenocarcinoma	<1%
7. Clear cell carcinoma	<1%
8. Other rare forms	<1%

Five-Year Survival (Cholangiocarcinoma and Gallbladder Cancer)*

Stage IA	85–100%
Stage IB	30–40% to 70–90%
Stage II	10–60%
Stage III	10–40%
Stage IV	0%

*Statistics for gallbladder cancer not certain because few cases reported in the literature

Staging

Gallbladder Cancer

Primary Tumor (T)	
TX	Primary tumor cannot be assessed
T0	No evidence of primary tumor
Tis	Carcinoma *in situ*
T1	Tumor invades lamina propria or muscular layer
T1a	Tumor invades lamina propria
T1b	Tumor invades muscular layer
T2	Tumor invades perimuscular connective tissue; no extension beyond serosa or into liver
T3	Tumor perforates the serosa (visceral peritoneum) and/or directly invades the liver and/or one other adjacent organ or structure, such as the stomach, duodenum, colon, pancreas, omentum, or extrahepatic bile ducts
T4	Tumor invades main portal vein or hepatic artery or invades 2 or more extrahepatic organs or structures

Regional Lymph Nodes (N)	
NX	Regional lymph nodes cannot be assessed
N0	No regional lymph node metastasis
N1	Metastases to nodes along the cystic duct, common bile duct, hepatic artery, and/or portal vein
N2	Metastases to periaortic, pericaval, superior mesentery artery, and/or celiac artery lymph nodes

Distant Metastasis (M)			
M0	No distant metastasis		
M1	Distant metastasis		
Group	**T**	**N**	**M**
0	Tis	N0	M0
I	T1	N0	M0
II	T2	N0	M0
IIIA	T3	N0	M0
IIIB	T1-3	N1	M0
IVA	T4	N0-1	M0
IVB	Any T	N 2	M0
	Any T	Any N	M1

Intrahepatic Bile Duct Staging

Primary Tumor (T)	
TX	Primary tumor cannot be assessed
T0	No evidence of primary tumor
Tis	Carcinoma *in situ* (intraductal tumor)
T1	Solitary tumor without vascular invasion
T2a	Solitary tumor with vascular invasion
T2b	Multiple tumors, with or without vascular invasion
T3	Tumor perforating the visceral peritoneum or involving the local extra hepatic structures by direct invasion
T4	Tumor with periductal invasion

Regional Lymph Nodes (N)	
NX	Regional lymph nodes cannot be assessed
N0	No regional lymph node metastasis
N1	Regional lymph node metastasis present

Distant Metastasis (M)			
M0	No distant metastasis		
M1	Distant metastasis

	Any T	Any N	M1

(*continued*)

Staging (*continued*)

Perihilar Bile Ducts Staging

Primary Tumor (T)

TX	Primary tumor cannot be assessed
T0	No evidence of primary tumor
Tis	Carcinoma *in situ*
T1	Tumor confined to the bile duct, with extension up to the muscle layer or fibrous tissue
T2a	Tumor invades beyond the wall of the bile duct to surrounding adipose tissue
T2b	Tumor invades adjacent hepatic parenchyma
T3	Tumor invades unilateral branches of the portal vein or hepatic artery
T4	Tumor invades main portal vein or its branches bilaterally; or the common hepatic artery; or the second-order biliary radicals bilaterally; or unilateral second-order biliary radicals with contralateral portal vein or hepatic artery involvement

Regional Lymph Nodes (N)

NX	Regional lymph nodes cannot be assessed
N0	No regional lymph node metastasis

Expert Opinion

Biliary tract malignancies include carcinoma of the gallbladder as well as of the intrahepatic, perihilar, and distal bile ducts. Complete surgical resection remains the only curative modality for gallbladder cancer (cholecystectomy, en bloc hepatic resection, and lymphadenectomy with or without bile duct excision). Postoperative therapy for patients who undergo an operative resection might be considered with adjuvant chemotherapy and/or fluoropyrimidine-based radiochemotherapy, in selected cases. Patients with unresectable tumor without obvious metastatic disease and without jaundice may benefit from a regimen of fluorouracil- or capecitabine-based chemotherapy ± radiation. Metastatic disease is typically treated with systemic chemotherapy. Interventional procedures including brachytherapy and photodynamic therapy represent a therapeutic option for selected patients. However, overall survival of such patients remains poor (Razumilava and Gores, 2013)

Less than 20% of all patients have disease that is deemed resectable, and even after having undergone potential curative resection, recurrence rates are high. Thus for the majority of patients, systemic chemotherapy is the mainstay of treatment. The problem concerning chemotherapy is the fact that most studies conducted in the past have been single-center, nonrandomized, phase II studies with relatively small patient numbers (Hezel and Zhu, 2008). Heterogeneous inclusion criteria, inherent difficulties in measuring tumor response, and the lack of studies having applied RECIST (Response Evaluation Criteria in Solid Tumors) methodology for confirmation of treatment effects further contribute to our limited knowledge how to best treat patients with advanced tumors (Eckel and Schmid, 2007)

In the absence of validated data from prospective randomized studies, patients with biliary cancer were usually treated with gemcitabine or fluoropyrimidines ± platinum compounds. This, however, changed with the publication of the results from the ABC-01 trial that evaluated patients with locally advanced or metastatic cholangiocarcinoma, gallbladder cancer, or ampullary cancer (Valle et al, 2010). After a median follow-up of 8.2 months, the median overall survival was 11.7 months in the cisplatin plus gemcitabine group and 8.1 months in the gemcitabine group (HR, 0.64; 95% CI, 0.52 to 0.80; $P < 0.001$). The median progression-free survival was 8 months in the cisplatin plus gemcitabine group and 5 months in the gemcitabine-only group ($P < 0.001$). Adverse events were similar in both groups, with the exception of neutropenia—higher in the cisplatin plus gemcitabine group—although the number of neutropenia-associated infections was similar in the 2 groups. Consequently, a cisplatin + gemcitabine regimen has become the standard of care on this indication

Novel agents, such as epidermal growth factor receptor blockers, MEK inhibitors and angiogenesis inhibitors, may hold promise for improving the therapeutic results obtained with conventional chemotherapy alone, but clinical study results are pending (Sasaki et al, 2013)

Intrahepatic cholangiocarcinoma

Patients who have undergone a tumor resection with or without ablation with negative margins may be followed up with observation, because there is no definitive adjuvant regimen to improve their overall survival. For individuals whose disease is resectable but who are left with positive margins after resection: (a) consider additional resection, (b) ablative therapy, or (c) combined radiation with or without chemotherapy using either fluorouracil- or capecitabine-based regimens or gemcitabine (Horgan et al, 2012). For patients with unresectable disease, therapeutic options include, depending on tumor location, extent of disease, and performance status: (a) chemotherapy with cisplatin plus gemcitabine or a fluorouracil- or capecitabine-based regimen, (b) combined radiochemotherapy, or (c) best supportive care

Extrahepatic cholangiocarcinoma

Patients with positive margins after resection should be considered candidates for either cisplatin plus gemcitabine or fluorouracil- or capecitabine-based chemotherapy with radiation (external beam therapy or brachytherapy) (Valero et al, 2012). The addition of adjuvant therapy in patients after potential curative surgical resection remains a subject of clinical investigation. Patients whose disease is deemed unresectable at the time of surgery should undergo biliary drainage if required, ideally nonsurgically; that is, by using a stent. Photodynamic therapy has demonstrated to be even more effective than stenting alone (Ortner et al, 2003). Given their overall poor prognosis, further options for patients with unresectable disease, include: (a) chemotherapy with cisplatin plus gemcitabine, (b) a clinical trial, (c) chemoradiation (fluorouracil- or capecitabine-based chemotherapy/RT), and (d) best supportive care

ADVANCED DISEASE REGIMEN

CISPLATIN + GEMCITABINE

Valle J et al. N Engl J Med 2010;362:1273–1281

Note: Biliary obstruction per se is not considered to be disease progression in the absence of radiologically confirmed disease progression, and treatment can be recommenced after initial or further biliary stenting and normalization of liver function

Hydration before cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS); administer by intravenous infusion over ≥1 hour

Cisplatin 25 mg/m² per dose; administer intravenously in 50–1000 mL 0.9% NS over 1 hour for 2 doses on days 1 and 8, every 3 weeks for 4 cycles (total dosage/cycle = 50 mg/m²), *followed by:*

Hydration after cisplatin: ≥1000 mL 0.9% NS; administer by intravenous infusion over ≥1 hour

Gemcitabine 1000 mg/m² per dose; administer intravenously in 50–250 mL 0.9% NS over 30 minutes for 2 doses on days 1 and 8, every 3 weeks, for 4 cycles (total dosage/cycle = 2000 mg/m²)

- Gemcitabine may be administered concurrently with hydration after cisplatin administration is completed

Note: In the absence of disease progression at 12 weeks, treatment with the same regimen may continue for an additional 12 weeks

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***HIGH***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
Cisplatin	
Any G ≥3 adverse event Hematologic toxicity, abnormal renal function, nausea, vomiting, edema, or tinnitus	Decrease cisplatin dosage by 25%
Reduction in creatinine clearance* to ≤60% of onstudy value	Delay therapy 1 week. If creatinine clearance does not recover to pretreatment values, then consider reducing cisplatin dose
Creatinine clearance* 40–60 mL/min (0.66–1 mL/s)	Consider reducing cisplatin so that dose in milligrams equals the creatinine clearance* value in mL/min (mL/s × 1/0.0166)†
Creatinine clearance* <40 mL/min (<0.66 mL/s)	Hold cisplatin
Clinically significant ototoxicity	Discontinue cisplatin
Persistent (>14 days) peripheral neuropathy without functional impairment	Decrease cisplatin dosage by 50%
Clinically significant sensory loss—persistent (>14 days) peripheral neuropathy with functional impairment	Discontinue cisplatin
Day 1 WBC count <2000/mm³ or platelet count <100,000/mm³	Delay cisplatin and gemcitabine for 1 week or until myelosuppression resolves
Recurrent treatment delay because of myelosuppression	Delay cisplatin for 1 week, or until myelosuppression resolves, then decrease cisplatin and gemcitabine dosages by 25% during subsequent treatments
Sepsis during an episode of neutropenia	

*Creatinine clearance is used as a measure of glomerular filtration rate

†This also applies to patients with creatinine clearance (GFR) of 40–60 mL/min at the outset of treatment

Patient Population Studied

Patients with a diagnosis of nonresectable, recurrent, or metastatic biliary tract carcinoma (intrahepatic or extrahepatic cholangiocarcinoma, gallbladder cancer, or ampullary carcinoma); an Eastern Cooperative Oncology Group performance status of 0, 1, or 2; and an estimated life expectancy of more than 3 months. Other eligibility criteria included a total bilirubin level ≤1.5 times the upper limit of the normal range; liver-enzyme levels that were ≤5 times the upper limit of the normal range; renal function with levels of serum urea and serum creatinine that were <1.5 times the upper limit of the normal range; and an estimated glomerular filtration rate ≥45 mL/minute (≥0.75 mL/s)

Efficacy (N = 161)*

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
Nadir WBC <1000/mm³, ANC <500/mm³, or platelets <50,000/mm³	Delay chemotherapy for up to 2 weeks until adverse events are G ≤1, then decrease subsequent mitomycin and capecitabine dosages by 25%
Any G ≥3 nonhematologic adverse events during the previous treatment cycle	
Duration of treatment delay >2 weeks for recovery from adverse events	Discontinue treatment

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Before each cycle:* Biochemical profile
3. *Response assessment:* Every 2 cycles

Patient Population Studied

A study of 26 chemotherapy-naïve patients with advanced biliary tract cancer

Efficacy (N = 26)

Partial responses	30.8%
Stable disease	34.6%
Progressive disease	34.6%
Median progression-free survival	5.35 months
Median overall survival	9.25 months

WHO Criteria

Toxicity (N = 24)

	% G1/2	% G3
Hematologic		
Neutropenia	N/A	17
Thrombocytopenia	48	17
Nonhematologic		
Nausea/vomiting	42	—
Fatigue	42	—
Diarrhea	28	—
Hand-foot syndrome	17	—
Alopecia	12	—
Increased liver function results*	54	—

Fever without documented infection: 8%

*Possibly a result of progressive disease because >80% of patients had liver involvement
WHO criteria

4. Bladder Cancer

Andrea Apolo, MD and Dean Bajorin, MD

Epidemiology

Incidence: 74,690 (male: 56,390; female: 18,300 Estimated new cases for 2014 in the United States)
20.7 per 100,000 male and female per year (36.6 per 100,000 men, 8.9 per 100,000 women)

Deaths: Estimated 15,580 in 2014 (male: 11,170; female: 4,410)

Median age: Seventh decade

Male to female ratio: 3:1

Stage at Presentation:

Stage I:	70%
Stages II/III:	25%
Stage IV:	5%

Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Work-up

Stage I	H&P, cystoscopy, exam under anesthesia, transurethral resection of the bladder tumor (TURBT), and cytology. Consider CT or MRI of the abdomen and pelvis prior to TURBT if sessile or high grade. Consider upper tract imaging with either CT urogram, retrograde pyelogram, or intravenous pyelogram (IVP). Transurethral biopsy of prostate if clinically indicated
Stages II/III	H&P, cystoscopy, exam under anesthesia, TURBT, and cytology. CT or MRI of the abdomen and pelvis prior to TURBT. CT of chest. Consider upper tract imaging with either CT urogram, retrograde pyelogram, or IVP. Bone scan if alkaline phosphatase is elevated or symptoms. Transurethral biopsy of prostate if clinically indicated
Stage IV	H&P, cystoscopy, exam under anesthesia, TURBT, and cytology. CT or MRI of the abdomen and pelvis prior to TURBT. CT of chest. Upper tract imaging with either CT urogram, retrograde pyelogram, or IVP. Bone scan if alkaline phosphatase is elevated or symptoms

Pathology

Transitional cell carcinoma	90–95%
Squamous cell carcinoma	5%
Adenocarcinoma	2%
Small cell carcinoma	1%

Histopathologic evaluation should include a description of cell type(s), whether or not there are areas of differing differentiation and the extent of differentiation, whether the tumor is a micropapillary or nested variant, grade (low [G1] vs. high [G2, G3]), presence or absence of lymphatic invasion, the depth of invasion, and whether or not there is muscle in the specimen. Pathologic grade is important in the management of noninvasive tumors

McDougal WS et al. Cancer of the bladder, ureter, and renal pelvis. In: Devita VT, Lawrence TS, Rosenberg SA, eds. Cancer: Principles and Practice of Oncology. Philadelphia: Lippincott Williams and Wilkins, 2008

Expert Opinion

1. MVAC is the historic standard of care for systemic therapy of patients with metastatic bladder cancer based on high response rates and cure in a subset of patients. A phase III trial demonstrated that the 2-drug doublet of gemcitabine and cisplatin (GC) and MVAC are similar in response and survival but that GC has a better toxicity profile. A phase III trial compared dose dense or high dose (DD) MVAC (plus granulocyte-colony stimulating factor (G-CSF) on 2 week cycles) to standard MVAC (on a 4-week cycle) [1–2]. Although there was no significant difference in median survival, DD MVAC was superior in response rate, 5-year survival rates and progression fee survival. DD- M-VAC is another first-line chemotherapy option for metastatic bladder cancer

   After completion of therapy, imaging with CT or MRI of the abdomen and pelvis, chest x-ray or CT of the chest, urine cytology (if applicable), creatinine and electrolytes recommended at 3–6 month intervals for 2 years and then as clinically indicated

(continued)

Staging

Primary Tumors of the Bladder (T)

TX	Primary tumor cannot be assessed
T0	No evidence of primary tumor
Ta	Noninvasive papillary carcinoma
Tis	Carcinoma in situ (ie, flat tumor)
T1	Tumor invades subepithelial connective tissue
T2	Tumor invades muscularis propria
pT2a	Tumor invades superficial muscularis propria (inner half)
pT2b	Tumor invades deep muscularis propria (outer half)
T3	Tumor invades perivesical tissue
pT3a	Microscopically
pT3b	Macroscopically (extravesical mass)
T4	Tumor invades any of the following: prostatic stroma, seminal vesicles, uterus, vagina, pelvic wall, abdominal wall
T4a	Tumor invades the prostatic stroma, uterus, vagina
T4b	Tumor invades the pelvic wall, abdominal wall

Regional Lymph Nodes for Urothelial Tumors (N)

NX	Regional lymph nodes cannot be assessed
N0	No lymph node metastasis
N1	Single regional lymph node metastasis in the true pelvis (hypogastric, obturator, external iliac, or presacral node)
N2	Multiple regional lymph node metastases in the true pelvis (hypogastric, obturator, external iliac, or presacral node)
N3	Lymph node metastasis to the common iliac lymph nodes

Distant Metastasis for Urothelial Tumors (M)

M0	No distant metastasis
M1	Distant metastasis

Anatomic Stage

Stage 0a	Ta	N0	M0
Stage 0is	Tis	N0	M0
Stage I	T1	N0	M0
Stage II	T2a	N0	M0
	T2b	N0	M0
Stage III	T3a	N0	M0
	T3b	N0	M0
	T4a	N0	M0
Stage IV	T4b	N0	M0
	Any T	N1–3	M0
	Any T	any	M1

Edge SB, Byrd DR, Compton CC, Fritz AG, Greene FL, Trotti A, editors. AJCC Cancer Staging Manual. 7th ed. New York: Springer; 2010

Five-Year Survival*

Stage 0	98.4%
Stage I	87.7%
Stage II	62.6%
Stage III	45.5%
Stage IV	14.8%

*Lynch CF et al. Chapter 23. Cancer of the urinary bladder. In: Ries LAG, Young JL, Keel GE, Eisner MP, Lin YD, Horner M-J, eds. SEER Survival Monograph: Cancer Survival Among Adults: U.S. SEER Program, 1988–2001, Patient and Tumor Characteristics. Bethesda, MD, National Cancer Institute, SEER Program, NIH Pub. No. 07-6215, 2007

Expert Opinion (*continued*)

2. Because MVAC includes doxorubicin, the regimen should be avoided in patients with preexisting cardiac disease unless cleared by a cardiologist familiar with doxorubicin-induced cardiac toxicity
3. Patients with marginal renal function (60–70 mL/min) may benefit from administering cisplatin divided over 2 days rather than over 1 day
4. Patients with inadequate renal function for cisplatin (creatinine clearance <60 mL/min [<1 mL/s]) and stage IV disease should be treated with carboplatin-based therapy. Gemcitabine and carboplatin is a regimen well-studied in randomized studies and is considered a standard of care based on a higher response rate and less toxicity than carboplatin, vinblastine, and methotrexate
5. Encourage neoadjuvant cisplatin-based chemotherapy (either DD MVAC or GC) in patients with muscle-invasive bladder cancer who have a good performance status and adequate renal function. Adjuvant chemotherapy is a consideration for patients at high risk of relapse after cystectomy if neoadjuvant chemotherapy was not administered

   After cystectomy, imaging with CT or MRI of the abdomen and pelvis, urine cytology, creatinine, and electrolytes recommended at 3–6 month intervals for 2 years and then as clinically indicated
6. Patients with metastatic bladder cancer, as well as those with organ-confined, muscle-invasive bladder cancer, should be considered for clinical trials

REGIMEN

METHOTREXATE + VINBLASTINE + DOXORUBICIN + CISPLATIN (MVAC)

von der Maase H et al. J Clin Oncol 2000;17:3068–3077
von der Maase H et al. J Clin Oncol 2005;21:4602–4608

Methotrexate 30 mg/m² per dose; administer by intravenous injection over 15–60 seconds for 3 doses on days 1, 15, and 22, every 28 days for a maximum of 6 cycles (total dosage/cycle = 90 mg/m²)
Vinblastine 3 mg/m² per dose; administer by intravenous injection over 1–2 minutes for 3 doses on days 2, 15, and 22, every 28 days for a maximum of 6 cycles (total dosage/cycle = 9 mg/m²)
Doxorubicin 30 mg/m²; administer by intravenous injection over 3–5 minutes on day 2, every 28 days for a maximum of 6 cycles (total dosage/cycle = 30 mg/m²)

Hydration before and after cisplatin administration: Administer intravenously ≥1000 mL 0.9% sodium chloride injection (0.9% NS) over at least 2 hours, both before and after cisplatin administration. Also encourage patients to increase oral intake of non-alcoholic fluids. Monitor serum electrolytes and replace as needed (potassium, magnesium, sodium)
Cisplatin 70 mg/m²; administer intravenously in 100–1000 mL 0.9% NS over 1 to 8 hours on day 2, every 28 days for a maximum of 6 cycles (total dosage/cycle = 70 mg/m²)

Supportive Care: Antiemetic prophylaxis
Emetogenic potential on days 1, 15, and 22: ***LOW***
Emetogenic potential on day 2: ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated between doses of myelosuppressive chemotherapy
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care: Encourage patients to maintain intake of non-alcoholic fluids
If mucositis or stomatitis is present:
- Rinse mouth several times a day with ¼ teaspoon (1.25 g) each of baking soda and table salt in one quart of warm water. Follow with a plain water rinse
- Do not use mouthwashes that contain alcohols

Patient Population Studied

Study of 202 patients with locally advanced or metastatic transitional cell urothelial cancer without prior systemic chemotherapy or immunotherapy. Prior local intravesical therapy, immunotherapy, or RT were allowed. Karnofsky Performance Status ≥70; and measured creatinine clearance ≥60 mL/min (≥1 mL/s)

Efficacy (N = 196)

Complete response	11.9%
Partial response	33.8%
Median overall survival	14.8 months
Median time to treatment failure	4.6 months
Median time to disease progression	7.4 months
Median duration of response	9.6 months

Therapy Monitoring

1. *Prior to each cycle:* CBC with differential count, serum electrolytes, BUN, creatinine, and LFTs
2. *Days 15 and 22:* CBC with differential count
3. *Response evaluation every 2–3 cycles:* CT or MRI of chest, abdomen or pelvis, or chest x-ray for lung lesions every 2–3 cycles. (von der Maase H et al. J Clin Oncol 2000;17:3068–3077)
4. *Follow-up after completion of therapy:* Imaging with CT or MRI of the abdomen and pelvis, chest x-ray or CT of the chest, urine cytology (if applicable), creatinine and electrolytes recommended at 3–6 months intervals for 2 years, and then as clinically indicated

Toxicity (N = 202)

(WHO Criteria)

Toxicity	% G3	% G4
Hematologic Toxicities		
Anemia	15.5	2.1
Thrombocytopenia	7.7	12.9
Neutropenia	17.1	65.2
Nonhematologic Toxicities		
Mucositis	17.7	4.2
Nausea	19.2	1.6
Alopecia	54.2	1.0
Infection	9.9	5.2
Diarrhea	7.8	0.5
Pulmonary	2.6	3.1
Hematuria	2.3	0
Constipation	2.6	0.5
Hemorrhage	2.1	0
State of consciousness	3.1	0.5
Fever	3.1	0

Treatment Modifications

Adverse Events	Treatment Modifications
Day 1 if WBC <3000/mm³, or platelet counts <100,000/mm³	Delay chemotherapy for 1 week
Day 15 or 22 if WBC ≤2900/mm³ or platelet count ≤74,000/mm³	Hold dose of methotrexate and vinblastine
G3/4 mucositis*	Reduce methotrexate dosage by 33% (all remaining doses and into next cycle)
Severe neurotoxicity	Reduce vinblastine dosage by 33%
Clinical evidence of CHF	Discontinue doxorubicin

*Leucovorin may be given 24 hours after methotrexate for patients who experienced G3/4 mucositis after previously administered doses

Notes

1. Give 6 cycles unless document disease progression
2. Avoid this regimen in patients with preexisting cardiac disease without guidance from a cardiologist familiar with effects of doxorubicin

BLADDER CANCER REGIMEN

GEMCITABINE + CISPLATIN (GC)

von der Maase H et al. J Clin Oncol 2000;17:3068–3077

Gemcitabine 1000 mg/m² per dose; administer intravenously in 50–250 mL 0.9% sodium chloride injection (0.9% NS) over 30–60 minutes for 3 doses on days 1, 8, and 15, every 28 days for a maximum of 6 cycles, (total dosage/cycle = 3000 mg/m²)
Hydration before and after cisplatin administration: ≥500 mL 0.9% NS intravenously over a minimum of 1 hour both before and after cisplatin. Encourage increased oral fluid intake
Cisplatin 70 mg/m²; administer intravenously in 100–250 mL 0.9% NS over 1 hour on day 2, every 28 days for a maximum of 6 cycles (total dosage/cycle = 70 mg/m²)

Supportive Care

Antiemetic prophylaxis
*Emetogenic potential on days 1, 8, and 15: **LOW***
*Emetogenic potential on day 2 is: **HIGH**. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated between doses of myelosuppressive chemotherapy
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Study of 203 patients with locally advanced or metastatic transitional cell urothelial cancer without prior systemic chemotherapy or immunotherapy. Prior local intravesical therapy, immunotherapy, or RT were allowed. Karnofsky performance status ≥70; and measured creatinine clearance ≥60 mL/minute (≥1 mL/s)

Efficacy (N = 200)

Complete response	12.2%
Partial response	37.2%
Median overall survival	13.8 months
Median time to disease progression	5.4 months
Median time to treatment failure	7.8 months
Median duration of response	9.6 months

Toxicity (N = 203)

(WHO Criteria)

Toxicity	% G3	% G4
Hematologic Toxicities		
Anemia	23.5	3.5
Thrombocytopenia	28.5	28.5
Neutropenia	41.2	29.9
Nonhematologic Toxicities		
Mucositis	1.0	0
Nausea	22	0
Alopecia	10.5	0
Infection	2.0	0.5
Diarrhea	3.0	0
Pulmonary	2.5	0.5
Hematuria	4.5	0
Constipation	1.5	0
Hemorrhage	2.0	0
State of consciousness	0.5	0
Fever	0	0

Treatment Modifications

Adverse Events	Treatment Modifications
Day 1 WBC count <3000/mm³ or platelet count <100,000/mm³	Hold chemotherapy until WBC count is >3000/mm³ and platelet count >100,000/mm³
Days 8 or 15 WBC count ≤1990/mm³ or platelet count ≤49,000/mm³	Omit gemcitabine on that day*
Treatment delay >4 weeks	Discontinue treatment

*Missed chemotherapy doses are not given. If gemcitabine is omitted on day 15, the cycle duration may be shortened to 21 days

Therapy Monitoring

1. *Prior to each cycle for 6 cycles:* CBC with differential count, serum electrolytes, BUN, and creatinine
2. *On all treatment days:* CBC with differential count
3. *Response evaluation every 2–3 cycles:* CT or MRI of chest, abdomen or pelvis, or chest x-ray for lung lesions every 2–3 cycles. (von der Maase H et al. J Clin Oncol 2000;17:3068–3077)
4. *Follow-up after completion of therapy:* Imaging with CT or MRI of the abdomen and pelvis, chest x-ray or CT of the chest, urine cytology (if applicable), creatinine and electrolytes recommended at 3–6 month intervals for 2 years, and then as clinically indicated

Notes

1. Give 6 cycles unless disease progression can be documented

REGIMEN

GEMCITABINE + CARBOPLATIN

De Santis M et al. J Clin Oncol 2009;27:5634–5639
De Santis M et al. J Clin Oncol 2012;30(2):191–199

Gemcitabine 1000 mg/m^2 per dose; administer intravenously 50–250 mL 0.9% sodium chloride injection over 30 minutes for 2 doses on days 1 and 8, every 21 days × 6 cycles (total dosage/cycle = 2000 mg/m^2)
Carboplatin* (calculated dose) AUC = 4.5 mg/mL · min administer intravenously in 50–150 mL 5% dextrose injection over 60 minutes after gemcitabine on day 1, every 21 days × 6 cycles (total dose/cycle calculated to produce an AUC = 4.5 mg/mL · min)

*Carboplatin dose is based on Calvert et al.'s formula to achieve a target area under the plasma concentration versus time curve (AUC) (AUC units = mg/mL · min)

$$\text{Total carboplatin Dose (mg)} = (\text{target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be calculated from the equation of Cockcroft and Gault:

$$\text{For males, Clcr} = \frac{(140 \pm \text{age [years]}) \times \text{body weight [kg]}}{72 \times (\text{Serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times \text{body weight [kg]}}{72 \times (\text{Serum creatinine [mg/dL]})} \times 0.85$$

Note: A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula could exceed an expected exposure (AUC) and result in increased drug-related toxicity. The FDA recommends capping an estimated GFR at 125 mL/min for any targeted AUC value. [online] May 23, 2013. Available from: http://www.fda.gov/AboutFDA/CentersOffices/OfficeofMedicalProductsandTobacco/CDER/ucm228974.htm [accessed February 26, 2014]

Jodrell DI et al. J Clin Oncol 1992;10:520–528
Sorensen BT et al. Cancer Chemother Pharmacol 1991;28:397–401

Supportive Care

Antiemetic prophylaxis—first regimen
Emetogenic potential on day 1: ***HIGH****. Potential for delayed symptoms*
Emetogenic potential on days 8: ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Study of 88 patients with either transitional cell tumors of the urothelial tract that are unresectable and measurable, or those with metastatic (N+ or M+) tumors. Patients "unfit" for cisplatin met any of the following criteria: (a) ECOG performance status of 2; (b) GFR <60 mL/min but >30 mL/min and normal cardiovascular and hepatic function

Efficacy (N = 88)

Complete response	3.4%
Partial response	34%
Median overall survival	Too early

Serious Adverse Toxicity (N = 119)

Death	2.3%
G3 Mucositis	1.1%
G4 Thrombocytopenia plus bleeding	3.4%
Neutropenia and fever	5.7%
Grades 3/4 renal toxicity	3.4%

Data above are from the phase II portion of a randomized phases II/III study. More definitive data will be available with completion of accrual and maturation of the phase III part of the trial

Treatment Modifications

Adverse Events	Treatment Modifications
Day 1 ANC <1500/mm^3, platelets <100,000/mm^3, or mucositis present	Hold treatment until ANC >1500/mm^3, platelets >100,000/mm^3, and mucositis resolves
Day 8 ANC 500–1000/mm^3 or platelets 50,000–99,000/mm^3	Reduce gemcitabine dosage by 50% on day of treatment
G4 neutropenia and fever, G4 thrombocytopenia >3 days, or thrombocytopenia and active bleeding	Reduce doses of both drugs by 25%

Therapy Monitoring

1. *Day 1:* CBC with differential count, serum electrolytes, BUN, and creatinine
2. *Day 8:* CBC with differential count
3. *Treatment evaluation after C3 and C6:* CT (or MRI) scan of the initial evaluable/measurable sites
4. *Duration of treatment:* Treat for 6 cycles unless progression documented
5. *Follow-up after completion of therapy:* Imaging with CT or MRI of the abdomen and pelvis, chest x-ray or CT of the chest, urine cytology (if applicable), creatinine, and electrolytes recommended at 3–6 month intervals for 2 years, and then as clinically indicated

Notes

1. Give platelet transfusions if platelet <20,000/mm^3
2. Treat for 6 cycles unless progression documented

REGIMEN

NEOADJUVANT METHOTREXATE + VINBLASTINE + DOXORUBICIN + CISPLATIN (MVAC) BEFORE RADICAL CYSTECTOMY

Grossman HB et al. N Engl J Med 2003;349:859–866. Erratum in: N Engl J Med 2003;349:1880

Methotrexate 30 mg/m² per dose; administer by intravenous injection over 15–60 seconds on days 1, 15, and 22, every 28 days for 3 cycles (total dosage/cycle = 90 mg/m²)
Vinblastine 3 mg/m² per dose; administer by intravenous injection over 1–2 minutes on days 2, 15, and 22, every 28 days for 3 cycles (total dosage/cycle = 9 mg/m²)
Doxorubicin 30 mg/m²; administer by intravenous injection over 3–5 minutes on day 2, every 28 days for 3 cycles (total dosage/cycle = 30 mg/m²)
Hydration before and after cisplatin administration: Administer intravenously ≥1000 mL 0.9% sodium chloride injection (0.9% NS), at ≥100 mL/hour before and after cisplatin administration. Also encourage patients to increase oral intake of non-alcoholic fluids. Monitor serum electrolytes and replace as needed (potassium, magnesium, sodium)
Cisplatin 70 mg/m²; administer intravenously in 100–250 mL 0.9% NS over 70 minutes on day 2 every 28 days for 3 cycles (total dosage/cycle = 70 mg/m²)

Supportive Care

Antiemetic prophylaxis
Emetogenic potential on days 1, 15, and 22: ***LOW***
Emetogenic potential on day 2: ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated between doses of myelosuppressive chemotherapy
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care
Encourage patients to maintain intake of non-alcoholic fluids
If mucositis or stomatitis is present:
- Rinse mouth several times a day with ¼ teaspoon (1.25 g) each of baking soda and table salt in one quart of warm water. Follow with a plain water rinse
- Do not use mouthwashes that contain alcohols

Therapy Monitoring

1. *Prior to each cycle:* CBC with differential count, serum electrolytes, BUN, creatinine, and LFTs
2. *Weekly:* CBC with differential
3. *Response evaluation:* None needed during neoadjuvant therapy
4. *Follow-up after cystectomy:* Imaging with CT or MRI of the abdomen and pelvis, chest x-ray, urine cytology, creatinine, and electrolytes recommended at 3–6 month intervals for 2 years, and then as clinically indicated

Efficacy (N = 153)

(Intention-to-Treat Analysis)

Median survival	77 months
5-Year survival	57%

Patient Population Studied

Study of 153 patients with muscle-invasive bladder tumors without nodal or metastatic disease eligible for radical cystectomy. No previous pelvic radiation; adequate renal, hepatic, hematologic function; ECOGG performance status ≤1

Treatment Modifications

Adverse Events	Treatment Modifications
On day 1 if WBC count <3000/mm³ or platelet count <100,000/mm³	Delay chemotherapy for 1 week
On day 15 or 22: WBC count ≤2900/mm³ or platelet count ≤74,000/mm³	Hold dose of methotrexate and vinblastine
Severe mucositis (G3 or G4)*	Reduce methotrexate dosage by 33% (for all doses and into next cycle)
Severe neurotoxicity	Reduce vinblastine dosage by 33%
Clinical evidence of congestive heart failure	Discontinue doxorubicin

*Leucovorin may be started 24 hours after methotrexate infusion

Toxicity (N = 150*)

Adverse Event	% G3†	% G4‡
Hematologic Toxicities		
Granulocytopenia	23	33
Thrombocytopenia	5	0
Anemia	6	1
Nonhematologic Toxicities		
Nausea or vomiting	6	0
Stomatitis	10	0
Diarrhea or constipation	4	0
Renal effects	1	0
Neuropathy	2	0
Fatigue, lethargy, and malaise	3	0
All Toxicities		
Maximal grade of any adverse effect	35	37

*Patients who received any methotrexate, vinblastine, doxorubicin, and cisplatin
†Grade 3 described as adverse events of moderate severity
‡Grade 4 described as severe adverse events

REGIMEN

NEOADJUVANT GEMCITABINE + CISPLATIN (GC)

Dash A et al. Cancer 2008;113:2471–2477

Gemcitabine 1000 mg/m² per dose; administer intravenously in 50–250 mL 0.9% sodium chloride injection (0.9% NS) over 30–60 minutes for 2 doses on days 1 and 8, every 21 days for 4 cycles (total dosage/cycle = 2000 mg/m²)
Hydration before and after cisplatin administration: Administer ≥500 mL 0.9% NS intravenously over a minimum of 1 hour both before and after cisplatin. Encourage patients to increase oral intake of non-alcoholic fluids. Monitor serum electrolytes and replace as needed (potassium, magnesium, sodium)
Cisplatin 70 mg/m² single dose; administer intravenously in 100–250 mL 0.9% NS over 60 minutes on day 1, every 21 days for 4 cycles (total dosage/cycle = 70 mg/m²)*

or

Cisplatin 35 mg/m² per dose; administer intravenously in 100–250 mL 0.9% NS over 60 minutes for 2 doses, after gemcitabine on days 1 and 8, every 21 days for 4 cycles (total dosage/cycle = 70 mg/m²)†

*Soto Parra H et al. Ann Oncol 2002;13:1080–1086
†Hussain SA et al. Br J Cancer 2004;91:844–849

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days with cisplatin and gemcitabine: ***HIGH*** *Potential for delayed symptoms*
Emetogenic potential on days with gemcitabine alone: ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Efficacy (Response at Cystectomy, N = 52)

Cisplatin dose intensity achieved	90%
Gemcitabine dose intensity achieved	90%
Pathologic complete response	26%
<pT2 disease	36%
Median overall survival	Not reached
Median duration of response	9.6 months

Patient Population Studied

Study of 52 patients with locally advanced transitional cell urothelial cancer defined as muscle invasive (T2-T4a) without evidence of adenopathy (N0) and without prior systemic chemotherapy. Prior local intravesical therapy and/or immunotherapy were allowed. Karnofsky performance status ≥70; and measured creatinine clearance ≥60 mL/min (≥1 mL/s)

Notes

1. Administer 4 cycles followed by CT scan and cystectomy
2. This study randomized patients with multiple malignancies and not just urothelial cancer to 3-week (days 1 and 8) or 4-week (days 1, 8, 15) GC

Treatment Modifications

Adverse Events	Treatment Modifications
Day 1 WBC count <3000/mm³, or platelet count <100,000/mm³	Hold chemotherapy until WBC count >3000/mm³ and platelet count >100,000/mm³
Day 8 WBC count ≤1000/mm³, or platelet count ≤100,000/mm³	Hold chemotherapy and reduce following doses of gemcitabine by 10%
Febrile neutropenia or G4 thrombocytopenia	Reduce following gemcitabine doses by 10%

Missed chemotherapy doses are not given

Toxicity with 21-Day GC (N = 53)

Toxicity	% G3	% G4
Hematologic Toxicities		
Anemia	9.4	0
Thrombocytopenia	3.7	1.8
Neutropenia	16.9	5.6
Nonhematologic Toxicities		
Mucositis	1.8	1.8
Nausea	5.6	0
Alopecia	0	0
Infection	1.8	0
Fatigue	3.0	0
Cardiac	1.8	0
Fever	0	0

Soto Parra H et al. Ann Oncol 2002;13:1080–1086

Therapy Monitoring

1. *Prior to each dose of cisplatin:* CBC with differential count, serum electrolytes, BUN, and creatinine
2. *On all treatment days:* CBC with differential count
3. *Response evaluation after 4 cycles:* CT scan
4. *Follow-up after cystectomy:* Imaging with CT or MRI of the abdomen and pelvis, chest x-ray, urine cytology, creatinine, and electrolytes recommended at 3–6 month intervals for 2 years, and then as clinically indicated

ADVANCED TRANSITIONAL CELL CARCINOMA (TCC) REGIMEN

HIGH-DOSE (INTENSITY) OR DOSE-DENSE METHOTREXATE, VINBLASTINE, ADRIAMYCIN, AND CISPLATIN (HD-MVAC OR DD-MVAC)

Plimack et al. J Clin Oncol 2012;30, suppl; abstr 4526
Sternberg CN et al. J Clin Oncol 2001;19:2638–2646
Sternberg CN et al. Eur J Cancer 2006;42:50–54

Methotrexate 30 mg/m²; administer by intravenous injection over ≤1 minute *or* intravenously in 10–100 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 10–30 minutes on day 1, every 14 days (total dosage/14-day cycle = 30 mg/m²)
Hydration before cisplatin: 1000 mL 0.9% NS; administer intravenously over a minimum of 1 hour before commencing cisplatin administration
Vinblastine 3 mg/m²; administer by intravenous injection over 1–2 minutes on day 2, every 14 days (total dosage/14-day cycle = 3 mg/m²)
Doxorubicin 30 mg/m²; administer by intravenous injection over 3–5 minutes on day 2, every 14 days (total dosage/14-day cycle = 30 mg/m²)
Cisplatin 70 mg/m²; administer intravenously in 50–500 mL 0.9 NS over 30–60 minutes on day 2, every 14 days (total dosage/14-day cycle = 70 mg/m²)
Hydration after cisplatin: 1000 mL 0.9% NS; administer intravenously over a minimum of 2 hours. Monitor and replace magnesium and other electrolytes as needed. Encourage patients to increase their intake of non-alcoholic fluids
OR
2000 mL 0.45% NS; administer intravenously over a minimum of 2 hours
± *Mannitol diuresis:* May be given to patients who have received adequate hydration
Mannitol 37.5 grams; administer intravenously over 1–4 hours before or during cisplatin administration, or may be prepared as an admixture with cisplatin
Note: Diuresis with mannitol requires maintaining hydration with intravenously administered fluid during and for hours after mannitol administration

Filgrastim 240 mcg/m² per dose; administer subcutaneously, daily for 7 consecutive days, on days 4–10, every 14 days

- Calculated doses may be rounded by ±10% to use the most economical combination of commercially available products
- Filgrastim is discontinued when patients achieve a post-nadir ANC = 30,000/mm³
- The duration of filgrastim use may be extended to a total of 14 consecutive days if neutrophil recovery is inadequate after a 7-day course

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on Day 1 is ***MINIMAL***
Emetogenic potential on Day 2 is ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis with granulocyte-colony stimulating factor is an integral part of the treatment regimen

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care
Encourage patients to maintain intake of non-alcoholic fluids
If mucositis or stomatitis is present:

- Rinse mouth several times a day with ¼ teaspoon (1.25 g) each of baking soda and table salt in one quart of warm water. Follow with a plain water rinse
- Do not use mouthwashes that contain alcohols

Dose Modifications

Adverse Event	Treatment Modification
G3/4 hematologic toxicity	Extend the duration of filgrastim treatment as needed, up to a total of 14 consecutive days
ANC >30,000/mm³	Discontinue filgrastim
G3/4 mucositis	Reduce methotrexate dosage by 33%
G3/4 neurotoxicity	Reduce vinblastine dosage by 33%
Clinical evidence of congestive heart failure	Discontinue doxorubicin

Patient Population Studied

263 patients with metastatic or advanced transitional-cell carcinoma (TCC) were randomly assigned to HD-MVAC (2-week cycles) or MVAC (4-week cycles). Eligibility criteria included the presence of TCC of the urinary tract (bladder, ureter, urethra, or renal pelvis) and bi-dimensionally measurable metastatic or locally advanced disease, no prior systemic cytotoxic or biologic treatment, and a World Health Organization (WHO) performance status of 0, 1, or 2; the median WHO performance status was 1. Sixty to 65% of patients were considered at low risk, 30–35% intermediate risk, and 5% high risk; 15–20% had had prior radiotherapy, and 73–75% had prior surgery. Sites of origin included bladder (82–88%), the renal pelvis (8–12%), and other sites (ureter, urethra, or prostatic ducts). Visceral metastases were present in 28–36%. The majority of patients had abdominal masses (pelvic, extranodal, or retroperitoneal masses) and more than one disease site

MUSCLE-INVASIVE BLADDER CANCER REGIMEN

NEOADJUVANT CISPLATIN, METHOTREXATE, AND VINBLASTINE

International Collaboration of Trialists. Lancet 1999;354:533–540
International Collaboration of Trialists. J Clin Oncol 2011;29:2171–2177

Methotrexate 30 mg/m² per dose; administer by intravenous injection over ≤1 minute *or* intravenously in 10–100 mL 0.9% sodium chloride Injection (0.9% NS) or 5% dextrose injection (D5W) over 5–30 minutes for 2 doses on days 1 and 8, every 21 days for 3 cycles (total dosage/cycle = 60 mg/m²)
Vinblastine 4 mg/m² per dose; administer by intravenous injection over 1–2 minutes for 2 doses on days 1 and 8, every 21 days for 3 cycles (total dosage/cycle = 8 mg/m²)
Hydration before cisplatin: 1000 mL 0.9% NS; administer intravenously over a minimum of 1 hour on day 2 before commencing cisplatin administration
Cisplatin 100 mg/m²; administer intravenously in 50–500 mL 0.9 NS over 30–60 minutes on day 2, every 21 days for 3 cycles (total dosage/cycle = 100 mg/m²)
Hydration after cisplatin: 1000 mL 0.9% NS; administer intravenously over a minimum of 2 hours. Monitor and replace magnesium and other electrolytes as needed. Encourage patients to increase their intake of non-alcoholic fluids
Leucovorin calcium 15 mg; administer orally or intravenously every 6 hours commencing 24 hours after methotrexate was administered for 4 doses on day 2 and 4 doses on day 9 (total dose/cycle = 120 mg)
- *Alternatively,* **Levoleucovorin calcium** 7.5 mg may be given orally or intravenously every 6 hours commencing 24 hours after methotrexate was administered for 4 doses starting on day 2 and 4 doses starting on day 9 (total dose/cycle = 60 mg)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on Days 1, 8, and 9 is ***MINIMAL***
Emetogenic potential on Day 2 is ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
***Latent or delayed-onset diarrhea**:**
Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then* **Loperamide** 2 mg every 2 hours while awake; every 4 hours during sleep
Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®) two tablets four times daily until control is achieved.
Persistent diarrhea:
Octreotide acetate (solution) 100–150 mcg; administer subcutaneously 3 times daily.
Antibiotic therapy during latent or delayed-onset diarrhea:
A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm³

Dose Modifications

Adverse Event	Treatment Modification
G3/4 mucositis	Reduce methotrexate dosage by 33%
G3/4 neurotoxicity	Reduce vinblastine dosage by 33%
Creatinine clearance <50 mL/min (<0.83 mL/s)	Hold cisplatin until creatinine clearance >50 mL/min (>0.83 mL/s)

Patient Population Studied

Patients with T2 G3, T3, T4a, N0-NX, or MO transitional-cell carcinoma of the bladder undergoing curative cystectomy or full-dose external-beam radiotherapy were randomly assigned three cycles of neoadjuvant chemotherapy (cisplatin, methotrexate, and vinblastine, with folinic acid rescue (n = 491) or no chemotherapy (n = 485). Thirty-four, 58, and 8% of patients had T2, T3, and T4a disease, respectively. Eighty-eight percent of patients had grade 3 disease, and 65% had N0. The median age was 64 years; 88% of patients were male; and 43%, 50%, and 7% of patients chose as local radical treatment radiotherapy, cystectomy, and a combination of radiotherapy and cystectomy, respectively

Toxicity

Chemotherapy-related mortality	1%
Nausea and vomiting	Common despite antiemetics
WHO G3/4 leucopenia	16%
WHO G3/4 thrombocytopenia	6.5%
Fever and neutropenia	10%
G1/2 nephrotoxicity requiring dose reduction/delay	26%

5. Brain Cancer

Lyndon Kim, MD and Howard Fine, MD

Epidemiology

Incidence: 23,380 (male: 12,820; female: 10,560. Estimated new cases for 2014 in the United States)
7.7 per 100,000 men 5.4 per 100,000 women
Deaths: Estimated 14,320 in 2014 (male: 8,090; female: 6,230)
Median age at diagnosis: 57 years
Male to female ratio: Slight male predominance in the incidence of malignant brain tumors

Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Work-up

1. Neuroimaging study (MRI of the brain preferred over CT)

No other staging work-up is required except:

2. *Primary CNS lymphoma:* MRI of spine, lumbar puncture, and ophthalmologic examination
3. *PNET/medulloblastoma:* MRI of spine and lumbar puncture when safe to do so

Pathology

I. Neuroepithelial Tumors

A. Glial tumors

1. Astrocytic tumors (45–50%)
   - Glioblastoma multiforme (GBM grade IV): 50%
   - Anaplastic astrocytoma (AA grade III): 30%
   - Diffuse astrocytoma (grade II): 20%
   - Gliosarcoma (grade IV): <5% of GBM
   - Pilocytic astrocytoma (grade I): <1%
2. Oligodendrogliomas/ oligoastrocytomas (5–10%)
   - Oligodendroglioma (O grade II)
   - Anaplastic oligodendroglioma (AO grade III)
   - Oligoastrocytoma (OA grade II)
   - Anaplastic oligoastrocytoma (AOA grade III)
3. Ependymal tumors (5%)
   - Myxopapillary ependymoma (grade I)
   - Ependymoma (grade II)
   - Anaplastic ependymoma (grade III)
   - Subependymoma

B. Neuronal and mixed glial-neuronal tumors (<1%)
   - Central neurocytoma
   - Dysembryoplastic neuroepithelial tumor
   - Desmoplastic infantile astrocytoma/ganglioma
   - Ganglioma
   - Paraganglioma

C. Nonglial tumors

1. Embryonal tumors (<5%)
   - Primitive neuroectodermal tumors (PNET)
   - Medulloblastoma
   - Ependymoblastoma
2. Choroid plexus tumors (<1%)
   - Choroid plexus papilloma
3. Pineal tumors (<1%)
   - Pineoblastoma
   - Pineocytoma

II. Meningeal Tumors (15–28%)
- Benign meningioma (grade I): >90%
- Atypical meningioma (grade II): 6%
- Anaplastic meningioma (grade III): 2%
- Hemangiopericytoma

III. Germ Cell Tumors (<1%)

IV. Nerve Sheet Tumors (4–8%)
- Schwannoma

V. Primary CNS Lymphoma (PCNSL) (1–5%)

VI. Metastatic Tumors

Adesina AM et al. Histopathology of primary tumors of the central nervous system. In: Prados M, ed. Brain Cancer: American Cancer Society Atlas of Clinical Oncology. Hamilton, Ontario, Canada: BC Decker Inc.; 2002:16–47
Greenberg H et al. Brain Tumors. Oxford University Press, 1999:1–26
WHO Classification of Tumors. IARC Press, 2000:6–7

Staging

(TNM staging does not apply to most brain tumors because they rarely metastasize. Ependymal tumors such as medulloblastoma are exceptions to this rule)

WHO Designation*	WHO Grade*					St. Anne–Mayo Grade†
	Grade	Nuclear Atypia	Mitosis	Endothelial Proliferation	Necrosis	
Pilocytic astrocytoma	I	—	—	—	—	Astrocytoma grade 1 (no criteria present)
Diffuse astrocytoma	II	+	Usually −	—	—	Astrocytoma grade 2 (1 criterion present)
Anaplastic astrocytoma	III	+	+	±	—	Astrocytoma grade 3 (2 criteria present)
Glioblastoma	IV	+	+, Active	Usually +	Usually +	Astrocytoma grade 4 (3 or 4 criteria present)

*The current 2000 WHO grading system stratifies previous low-grade astrocytomas (WHO grades I and II) into different subtypes. WHO grade I pilocytic astrocytoma is characteristically well circumscribed, cystic, and localized. WHO grade II diffuse astrocytoma, like WHO grades III and IV, is characteristically infiltrative and progressive
†In the St. Anne–Mayo grading system, the grades are based on the total number of criteria present. The criteria are similar to those in the WHO system: nuclear atypia, mitosis, endothelial proliferation, and necrosis

Daumas-Duport et al. Cancer 1988;62:2152–2165
Kleihues P et al. Histological Typing Tumours of the Central Nervous System. 2nd ed. WHO. Berlin: Springer-Verlag, 1993
WHO Classification of Tumors. Lyons, France: IARC Press, 2000:6–7

Prognosis

	Median Survival*
Grade I	>10 years
Grade II	5–8 years
Grade III	3–5 years
Grade IV	0.9–1 year

*Because oligodendrogliomas and oligoastrocytomas are uniquely sensitive to both chemotherapy and radiation therapy with better overall survival and prognosis, every effort should be made to look for oligodendroglial cell components and provide proper treatment options based on the pathology

Burger PC et al. Cancer 1985;56:1106–1111
Piepmeier J et al. Neurosurgery 1987;67:177–181

Expert Opinion

Grade I Astrocytoma (Pilocytic Astrocytoma)

Pilocytic astrocytoma is a rare tumor commonly seen in the pediatric or young adult population. The tumor is well circumscribed and MRI findings reveal a homogenously enhancing lesion with an associated macrocyst commonly seen in the cerebellum, brainstem, and optic pathways

1. **Observation following surgery:** Most patients can be cured with surgery alone. Following surgery, patients can be simply observed. The role of radiation therapy for incomplete resection remains undetermined

Grade II Astrocytomas (Diffuse Astrocytoma)

Diffuse astrocytoma patients can be seen in the young adult population. Although considered as a low grade, the prognosis is still not optimal with overall survival of 5–8 years. MRI usually reveals nonenhancing lesion that could be best seen on T2 or FLAIR images

1. **Observation:** Patients with the following good prognostic factors can be closely monitored with serial scans:
   - Young age (<40 years)
   - Asymptomatic
   - Good performance score (KPS >70)
   - Near or complete resection
   - Small nonenhancing lesion
   - Low Ki-67 or MIB-1 proliferative index
   - Presence of IDH1 or IDH2 mutation

   Note: About a third of patients who have nonenhancing lesions may ultimately prove on biopsy to have anaplastic tumors. Thus, close surveillance (particularly early on until the natural course of the diseases becomes apparent) is recommended for all patients with diffuse astrocytomas for whom a watch-and-wait strategy is employed

(*continued*)

Expert Opinion (*continued*)

2. **Treatment:** General indications for treatment include:
   - Older patient (>40 years)
   - Symptomatic
   - Large or inoperable lesion
   - Enhancement on imaging studies
   - High Ki-67 or MIB-1 proliferative index
   - Lack of IDH1 or IDH2 mutation

   a. **Radiation therapy:** Radiation therapy was considered as the standard treatment until the randomized phase III RTOG 9802 trial revealed a significantly longer survival for radiation therapy plus PCV chemotherapy over radiation therapy alone for high-risk low-grade gliomas. Radiation therapy can be still considered for those who could not tolerate chemoradiation therapy or chemotherapy. Delayed radiation-mediated neurotoxicity remains a concern, although prospective studies suggest it occurs less commonly than was once feared. Factors that increase the chance of clinically significant delayed radiation-induced neurotoxicity include:
      - Large radiation fields
      - Large fraction dose and total dose
      - Older age
      - Underlying neurodegenerative disease
      - Radiation of temporal and frontal lobes

      For patients considered at significant risk of radiation-induced neurotoxicity, treatment with temozolomide alone is a consideration, although the data suggest that the period of tumor control is generally relatively short

   b. **Chemotherapy:** Chemotherapy with deferred radiation therapy can be considered especially for those patients with large inoperable tumors or whose tumor has mutated IDH1 and IDH2 unable to tolerate radiation therapy or chemoradiation therapy. Recently, temozolomide, an oral agent, has shown efficacy in unirradiated low-grade gliomas. It causes no delayed neurotoxicity and can be considered as a treatment option for low-grade gliomas requiring treatment to defer radiation therapy. At a median follow-up of 45.5 months and after the tumors of 246/477 patients had progressed, there was no statistical difference in the primary end point, progression-free survival (PFS). Overall toxicity was mild. Grade 3 hematologic toxicity was observed in 9% of the temozolomide-treated patients [temozolomide chemotherapy versus radiotherapy in molecularly characterized (1p loss) low-grade glioma: a randomized phase III intergroup study by the EORTC/NCIC-CTG/TROG/MRC-CTU (EORTC 22033-26033), Baumert et al. Abstract 2007, ASCO 2013 Annual Meeting]

   c. **Chemoradiation therapy:** Radiation followed by PCV chemotherapy is now considered as the standard of care for patients with high-risk low grade gliomas (astrocytomas, oligoastrocytomas, oligodendrogliomas, and neurofibromatosis). Recent long-term follow-up result of the phase III RTOG 9802* clinical trial revealed a significant survival benefit for patients who were randomized to radiation followed by PCV chemotherapy over radiation therapy alone. Median survival time was 13.3 years and 7.8 years, respectively. Additional molecular and genetic studies are ongoing to further identify patients who would most likely benefit from chemotherapy. Patients who are felt to be appropriate candidates for radiation therapy or chemotherapy should be considered for chemoradiation therapy

*A Phase II Study of Observation in Favorable Low-Grade Glioma and A Phase III Study of Radiation with or without PCV Chemotherapy in Unfavorable Low-Grade Glioma. NCI Press Release February 03, 2014

Grade III Astrocytoma (Anaplastic Astrocytoma)

Anaplastic astrocytoma is an aggressive tumor that has overall survival of 3–5 years. MRI often reveals heterogeneous enhancement that is usually intermixed with nonenhancing tumor, although as many as half of all anaplastic astrocytomas may be largely nonenhancing. Mitosis, endothelial proliferation, and atypia can be seen

1. **Treatment:**

   a. **Radiation therapy:** Radiation therapy remains as standard of care

   b. **Chemotherapy:** The standard of care for anaplastic gliomas had been surgery followed by radiotherapy. The role of chemotherapy for anaplastic astrocytomas remains unclear. In patients with newly diagnosed anaplastic gliomas (anaplastic oligodendroglioma, oligoastrocytoma, and astrocytoma), the NOA-04 phase III trial compared the efficacy and safety of radiotherapy followed by chemotherapy at progression with the reverse sequence. The results showed comparable results with either initial radiotherapy or initial chemotherapy (Wick et al, 2009). [Median TTF hazard ratio HR = 1.2; 95% CI, 0.8–1.8, PFS HR = 1.0; 95% CI, 0.7–1.3, and overall survival HR = 1.2; 95% CI, 0.8–1.9] were similar for radiotherapy and procarbazine, lomustine, and vincristine (PCV)/temozolomide. A more recent phase III study of anaplastic gliomas (NOA-08) randomly assigned patients to receive either chemotherapy (PCV or temozolomide) versus radiation therapy as initial treatment. This study showed no difference in time to treatment failure, progression free survival, or overall survival [median overall survival 8.6 months (95% CI 7.3–10.2) in the temozolomide group and 9.6 months (8.2–10.8) in the radiotherapy group HR 1.09, 95% CI 0.84–1.42, noninferiority = 0.033], leading the authors to concluded temozolomide alone is noninferior to radiotherapy alone in the treatment of elderly patients with malignant astrocytoma (Wick et al, 2012)

   c. **Chemoradiation Therapy:** The use of concurrent and postirradiation temozolomide therapy, an approach employed in newly diagnosed glioblastoma (grade IV astrocytoma) also has become widely accepted for the treatment of other types of malignant gliomas

Wick W et al. J Clin Oncol 2009;27:5874–5880

(*continued*)

Expert Opinion (*continued*)

Grade IV Astrocytomas (Glioblastomas)

Glioblastomas are the most common malignant tumors of the elderly population. The tumor grows rapidly and causes significant morbidity and mortality with overall survival of 14–18 months. Imaging studies usually reveal a heterogeneously enhancing lesion or lesions with a significant amount of surrounding edema. Increased number of mitosis, endothelial proliferation, atypia, and necrosis are commonly seen

1. **Treatment:**

Chemoradiation therapy:

Initial therapy:

- For patients age 18–70 years, combined radiation therapy with low-dose daily temozolomide followed by monthly temozolomide is the standard of care (Stupp et al, 2005)
- Combined radiation therapy with low-dose daily temozolomide followed by monthly temozolomide can be also considered for patients who are older than 70 years with a good performance status
- Alternatively, for patients 70 years or older with a poor performance status, temozolomide or radiation therapy alone can be an option. A 2- or 3-week course of hypofractionated radiation therapy could be an option for patients with poor performance status
- Radiation therapy followed by one of the nitrosoureas (carmustine [BCNU] or lomustine [CCNU]) is an option for those who could not receive temozolomide

Recurrent disease:

- Bevacizumab is the treatment of choice for patients for whom it is not medically or neurologically contraindicated (Kreisl et al, 2009)
- *Retreatment with a continuous low-dose (metronomic) temozolomide dosing schedule is an option especially for patients who have never been treated with bevacizumab and responded well to their original temozolomide with the last treatment greater than 6 months and whose tumor has a methylated MGMT status (see Table below)*
- Other molecular targeted drugs such as erlotinib can be considered for malignant gliomas expressing EGFR or EGFRviii
- Second-line chemotherapeutic agents such as BCNU, CCNU, or carboplatin are also options
- Participation in a well-designed clinical trial is highly recommended

Oligodendroglioma (WHO grade II)

Oligodendrogliomas are rare tumors that can respond extremely well to radiation and chemotherapy. They appear as fried egg, round cells under the microscope and imaging studies that show calcifications can help establish the diagnosis. Co-deletion of 1p and 19q usually confers a good prognosis

1. **Observation:** Patients with the following good prognostic factors can be closely monitored with serial scans:
   - Young age (<40 years)
   - Asymptomatic
   - Good performance score (KPS >70)
   - Small non-enhancing lesion
   - Nearly or completely resected tumor
   - Low Ki-67 or MIB-1 proliferative index
   - Co-deletion of 1p and 19q
   - Presence of IDH1 or IDH2 mutation
2. **Treatment:**

   General indications for treatment include: Older patient (>40 years)
   - Symptomatic
   - Poor performance score (<70)
   - Large or inoperable, enhancing tumor
   - High Ki-67 or MIB-1 proliferative index
   - Lack of IDH1 or IDH2 mutation
   - Intact 1p and 19q status

   a. **Chemotherapy:** If the tumor cannot be completely resected, radiation therapy or chemotherapy can be considered as oligodendrogliomas can respond to either treatment extremely well. However, because oligodendrogliomas with 1p, 19q co-deletion can be exquisitely sensitive to chemotherapy, temozolomide or PCV can be offered as alternative treatments, especially for young patients with good prognostic features, in order to avoid the potential for delayed neurotoxicity

   b. **Radiation therapy:** Radiation therapy is usually reserved for patients with poor prognostic features, who are unable to tolerate chemotherapy or for chemotherapy resistant and progressive disease

   c. **Combined chemotherapy and radiation therapy:** Recent RTOG 9802* phase III trial for high-risk low-grade gliomas (astrocytomas, oligodendrogliomas, oligoastrocytomas, and neurofibromatosis) reveled a significant long-term survival benefit for patients who were randomized to radiation followed by PCV chemotherapy over radiation therapy alone. Median survival time was 13.3 years for radiation plus PCV arm and 7.8 years for radiation alone arm. Based on these findings, this combination therapy is now considered as the standard treatment for high-risk low-grade gliomas especially when oligodendrogliomas are well known to be extremely sensitive to radiation therapy and chemotherapy. Additional molecular and genetic studies are ongoing to further identify patients who would most likely benefit from chemotherapy. Patients who are felt to be appropriate candidates for radiation therapy or chemotherapy should be considered for chemoradiation therapy

*A Phase II Study of Observation in Favorable Low-Grade Glioma and A Phase III Study of Radiation with or without PCV Chemotherapy in Unfavorable Low-Grade Glioma. NCI Press Release. February 03, 2014

Anaplastic Oligodendroglioma (WHO grade III)

Anaplastic oligodendrogliomas, like grade II oligodendrogliomas, can be extremely sensitive to radiation and chemotherapy. Co-deletion of 1p and 19q confers a good prognosis

1. **Treatment:** Combined chemotherapy with PCV and pre- or postradiation therapy is standard of treatment. Radiation therapy alone and chemotherapy alone are no longer considered as standard of care and they are reserved for patients who could not tolerate combination therapy

   a. **Combined chemotherapy and radiation therapy:** Two recent long-term follow-up results from the phase III randomized trials for newly diagnosed anaplastic oligodendrogliomas revealed a significant survival benefit for combination PCV chemotherapy and radiation therapy over radiation therapy alone (van den Bent et al, 2012; Cairncross et al, 2012). These trials also validated the role of 1p, 19q as a predictive biomarker for survival. Therefore, PCV chemotherapy given either pre- or postradiation therapy is now considered as the standard of treatment. However, because PCV chemotherapy compared to temozolomide carries a greater toxicity with a less-favorable dosing schedule and administration, many still debate accepting PCV chemotherapy as standard of care. The role of concurrent radiation and postradiation chemotherapy with temozolomide, the treatment standard for glioblastomas, is now commonly adopted for the treatment of other malignant gliomas like anaplastic oligodendrogliomas

Expert Opinion (*continued*)

Medulloblastoma and Primitive Neuroectodermal Tumors

These tumors usually occur in children and young adults. They are aggressive in nature and have a high propensity to spread through the cerebrospinal fluid resulting in distant metastasis within the central nervous system. A thorough staging work up, including a careful examination of the cerebrospinal fluid and spine, are required. Medulloblastoma usually arises in the posterior fossa causing hydrocephalus and associated obstructive symptoms, including headaches, nausea, vomiting, and gait difficulties requiring urgent ventriculoperitoneal shunt placement to relieve the intracranial pressure

1. **Treatment:**
   a. **Radiation Therapy:** Craniospinal radiation therapy is the standard of care
   b. **Chemotherapy:** Chemotherapy is usually provided after the completion of radiation therapy. When chemotherapy is considered, craniospinal radiation dose can be reduced to minimize the toxicity (Packer et al, 2006). For recurrent disease, stereotactic radiation therapy, chemotherapy or high dose chemotherapy with stem cell rescue can be considered

Packer et al. J Clin Oncol 2006;24:4202–4208

Primary Central Nervous System Lymphomas

Primary central nervous system lymphomas are rare non-Hodgkin lymphomas arising within the central nervous system without systemic involvement. They occur mostly in the elderly population and in patients who are immunocompromised. The most common type is diffuse large B-cell lymphoma and they invariably express CD20. MRI findings usually reveal homogenously enhancing lesion(s) involving periventricle or splenium (butterfly lesion). If a primary central system lymphoma is suspected, a stereotactic biopsy is sufficient to establish the diagnosis as this tumor can be successfully treated with radiation and methotrexate containing chemotherapy with high cure rates. However, in the presence of significant mass effect, partial or total resection can be considered. As an initial work up, a thorough examination of eyes and cerebrospinal fluid are required because of the propensity to involve these sites. If a primary central nervous system lymphoma is suspected, the administration of steroids is discouraged as steroids can be oncolytic and could cause a decrease in the size of the tumor making the diagnosis difficult. Steroids are usually administered after a biopsy or surgery

1. **Treatment:**
   a. **Chemotherapy:** High-dose methotrexate (3.5–8 g/m^2) given alone or as part of multiagent regimen remains as the standard therapy (Batchelor et al, 2003). Even at high dose as a single agent the treatment is well tolerated and causes minimal side effects. The complete response and survival rates are found to be comparable or better than radiation therapy. Delayed neurotoxicity commonly seen in long-term survivors of whole-brain radiation therapy is less frequent. Because of high central nervous system penetration of the drug, patients with ocular, cerebrospinal fluid or leptomeningeal involvement can be safely treated with high-dose methotrexate alone without concurrent radiation or intraocular or intrathecal chemotherapy. CD20-directed rituximab in combination with high-dose methotrexate is also commonly used (Chamberlain and Johnston, 2010). Patients who receive high-dose methotrexate alone can be treated with rituximab as maintenance therapy following high-dose methotrexate. For recurrence, retreatment with high-dose methotrexate with and without rituximab, (Chamberlain and Johnston, 2010) topotecan, (Voloschin et al, 2008) high-dose cytarabine or temozolomide can be considered. If chemotherapy is not considered as a good option because of the patient's high comorbidities, renal failure, or inability to tolerate chemotherapy, radiation therapy could be an alternative option

      Recent long-term follow-up results of a phase II high-dose methotrexate-based multiagent chemotherapy followed by consolidation, reduced-dose radiation therapy, and high-dose cytarabine for newly diagnosed primary central nervous system lymphoma patients revealed a high rate of response and overall survival with favorable cognitive outcomes compared to historical controls treated with whole-brain radiation therapy alone (Morris et al, 2013). A randomized phase III Radiation Therapy Oncology Group trial based on an earlier phase II regimen with or without reduced-dose whole-brain radiation therapy is currently underway

      In newly diagnosed primary central nervous system lymphoma patients who responded to a chemotherapy trial, a phase II study of a methotrexate-based chemotherapy regimen followed by high-dose chemotherapy with autologous stem cell transplantation and reduced-dose whole-brain radiation therapy revealed an encouraging high response rate and survival results that warrants further investigation in a larger phase III trial (Colombat et al, 2006)

   b. **Radiation therapy:** Radiation therapy was a standard of care in the past, but because of high treatment failure and high incidence of delayed neurotoxicity commonly seen in long-term survivors, this approach is no longer considered as first-line therapy. However, radiation therapy is still considered for patients who have poor performance status and/or are unable to tolerate chemotherapy or for recurrent disease

Expert Opinion (*continued*)

Meningiomas

Meningiomas are rare brain tumors arising from the meninges. They usually affect the elderly population and have a slight female preponderance. Calcifications and bone involvement can be seen on CT scan. MRI scan usually reveals a dural-based homogenously enhancing lesion that has a typical tail sign

Treatment options include observation of asymptomatic patients and surgery for those who have symptoms

Benign Meningiomas (Grade I):

1. **Observation:** Grade I meningiomas are slow growing benign tumors that have an excellent prognosis with overall survival greater than 10 years. They can be simply followed without any therapeutic intervention
2. **Treatment:**
   a. **Surgery:** If the tumor grows and or a patient becomes symptomatic, surgery may be indicated

Atypical Meningiomas (Grade II):

1. **Observation:** For most atypical meningioma (grade II) patients, close observation following surgery is usually sufficient if the patient is asymptomatic and the pathology showed a low Ki-67 or MIB-1 proliferation index
2. **Treatment:**
   a. **Radiation therapy:** Radiation can be considered if the patient is symptomatic and or the pathology showed a high Ki-67 or MIB-1 proliferation index

Malignant meningiomas (Grade III):

Malignant meningiomas (grade III) are a rapidly growing tumor that carries a poor prognosis with overall survival less than 2–3 years. MRI scan typically reveals a significant vasogenic edema

1. **Treatment:**
   a. **Surgery followed by radiation therapy:** For recurrent tumors, surgery, additional radiation therapy, or stereotactic radiation therapy can be considered. Immunomodulating agents, such as α-interferon (Chamberlain and Glantz, 2008) and somatostatin analogs for somatostatin receptor-positive tumors (positive octreotide scan) (Chamberlain et al, 2007) have shown some modest responses that can be durable. Chemotherapeutic agents, such as hydroxyurea (Chamberlain, 2012) and platinum compounds, also have shown some modest benefits. Bevacizumab, as a single agent or in combination with chemotherapy (Lou et al, 2012), can be safely administered and it appears to have encouraging antitumor effects. Further trials to investigate the efficacy and side effects are warranted

REGIMEN

TEMOZOLOMIDE

Bower M et al. Cancer Chemother Pharmacol 1997;40:484–488

Cycle 1:
Temozolomide 150 mg/m^2 per day; administer orally for 5 consecutive days, on days 1–5 of a 4-week cycle (total dosage/cycle = 750 mg/m^2)
Cycle 2 and subsequent cycles:
Temozolomide 200 mg/m^2 per day; administer orally for 5 consecutive days, on days 1–5, every 4 weeks (total dosage/cycle = 1000 mg/m^2)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential: MODERATE
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
G ≤1 myelosuppression in cycle 1	Escalate temozolomide dosage to 200 mg/m^2 per day, days 1–5
WBC <3000/mm^3 or platelets <100,000/mm^3 on day 1 of any cycle	Delay retreatment for 1 week
After a 1-week delay, if WBC <2000/mm^3 or platelets <75,000/mm^3	Reduce temozolomide dosage by 25%
After a 1-week delay, if WBC <1000/mm^3 or platelets <25,000/mm^3	Reduce temozolomide dosage by 50%

Efficacy (N = 103)

Objective response	11%
Stable disease	47%
Median survival	5.8 months
Progression-free survival at 6 months	22%

The study included 18 patients not evaluable for response

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Every 4 weeks:* Serum electrolytes, mineral panel, and LFTs

REGIMEN

TEMOZOLOMIDE WITH RADIATION THERAPY

Stupp R et al. J Clin Oncol 2002;20:1375–1382
Stupp R et al. N Engl J Med 2005;352:987–996

Temozolomide with radiation therapy:
Temozolomide 75 mg/m² per day; administer orally, continually, 7 days/week for 6–7 weeks in a fasting state 1 hour before radiation therapy (RT), and in the morning in a fasting state on days without RT (total dosage/6- to 7-week cycle = 3150–3675 mg/m²)
Radiation therapy once daily at 2 Gy/fraction for 5 days/week for a total of 60 Gy

Adjuvant temozolomide starting 4 weeks after completing RT:
Temozolomide 200 mg/m² per day; administer orally for 5 consecutive days, on days 1–5 every 28 days for up to 6 cycles (total dosage/cycle = 1000 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential: MODERATE
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
WBC <3000/mm³ or platelets <100,000/mm³ on day 1 of any cycle	Delay retreatment for 1 week
After a 1-week delay, if WBC <2000/mm³ or platelets <75,000/mm³	Reduce temozolomide dosage by 25%
After a 1-week delay, if WBC <1000/mm³ or platelets <25,000/mm³	Reduce temozolomide dosage by 50%

Adapted from Stupp R et al. J Clin Oncol 2002;20:1375–1382, in which dose modifications were not specified

Patient Population Studied

A multicenter phase III trial of 573 patients with newly diagnosed GBM in which 287 patients received temozolomide with RT

Efficacy (N = 287)

Median Survival	14.6 months
1-Year survival	61.1%
2-Year survival	26.5%

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Every 4 weeks:* Serum electrolytes, chemistry panel, and LFTs

REGIMEN

CARMUSTINE (BCNU)

Levin VA et al. Cancer Treat Rep 1976;60:719–724
Walker MD et al. J Neurosurg 1978;49:333–343

Carmustine 80 mg/m² per dose; administer intravenously in 100–250 mL 5% dextrose injection (D5W) over at least 60 minutes for 3 consecutive days, on days 1–3, every 6–8 weeks (total dosage/cycle = 240 mg/m²)

or

Carmustine 200 mg/m²; administer intravenously in 100–500 mL D5W over at least 60 minutes, given on day 1, every 6–8 weeks (total dosage/cycle = 200 mg/m²)
Note: Both schedules are comparable. However, there is no good rationale for the 3-day treatment schedule

Supportive Care
Antiemetic prophylaxis
Emetogenic potential: ***MODERATE*** *(3-day regimen)* ***to HIGH*** *(1-day regimen)*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A phase III randomized study of supportive care alone in 303 patients with newly diagnosed malignant gliomas versus BCNU and/or radiation therapy

Walker MD et al. J Neurosurg 1978;49:333–343

Efficacy (N = 222)

Therapy	Median Survival
Best conventional care only	14 weeks
Carmustine only	18.5 weeks
Radiation therapy only	36 weeks
Radiation therapy + carmustine	34.5 weeks

Note: The addition of carmustine to radiation therapy failed to alter median survival significantly. However, there was a significantly greater surviving percentage of patients at the end of 18 months among those who received combination therapy

Walker MD et al. J Neurosurg 1978;49:333–343

Toxicity (N = 51 for BCNU Group)

	% Patients
Thrombocytopenia: Platelets <100,000/mm³	54
Platelets <50,000/mm³	30
Leukopenia: WBC <4000/mm³	61
WBC <2000/mm³	18
Anemia	Occasional; no profound anemia encountered
Nausea	Occasional
Vomiting	Occasional
Elevated LFTs	Occasional

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *A minimum of every 6 weeks:* LFTs, BUN, creatinine
3. *Every 2–3 cycles:* Pulmonary function test

Treatment Modifications

Adverse Event	Dose Modification
Nadir prior cycle: WBC 2000–3000/mm³ or platelets 25,000–75,000/mm³	Delay treatment until WBC ≥3000/mm³ and platelets ≥100,000/mm³, then resume treatment with carmustine dosage reduced by 10–25%
Nadir prior cycle: WBC <2000/mm³ or platelets <25,000/mm³	Delay treatment until WBC ≥3000/mm³ and platelets ≥100,000/mm³, then resume treatment with carmustine dosage reduced by 25–50%
Cumulative carmustine dosage >1400 mg/m² or worsening forced vital capacity (FVC) or carbon monoxide diffusing capacity (DL_{co})	Discontinue carmustine

Note: Usually no more than 5–6 cycles (total cumulative dose of 1000–1200 mg/m²) of carmustine is recommended. Patients receiving >1400 mg/m² cumulative carmustine dosage have a higher risk of developing pulmonary toxicity. Patients with a baseline FVC or DL_{co} <70% are particularly at risk. BiCNU® (carmustine for injection); product label, May 2011. Ben Venue Laboratories, Inc., Bedford, OH

Notes

Two meta-analyses showed a survival benefit for patients treated with nitrosoureas after radiation

Fine HA et al. Cancer 1993;71:2585–2597
Stewart LA et al. Lancet 2002;359:1011–1018

REGIMEN

LOMUSTINE (CCNU)

Batchelor TT, J Clin Oncol 31:3212–3218

Lomustine 110 mg/m²; administer orally as a single dose on day 1, every 6–8 weeks for a total of 6 cycles (total dosage/cycle = 110 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***MODERATE–HIGH***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
WBC nadir during the prior cycle 2000–3000/mm³, or platelets 25,000–75,000/mm³	Reduce lomustine dosage by 10–25%
WBC nadir during the prior cycle <2000/mm³, or platelets <25,000/mm³	Reduce lomustine and dosage by 25–50%
Cumulative lomustine dosage >1100 mg/m², or worsening forced vital capacity (FVC) or carbon monoxide diffusing capacity (DLco)*	Discontinue lomustine

**Note:* Usually no more than a total of 6–7 cycles of lomustine (660–770 mg/m²) is recommended. Patients receiving cumulative lomustine dosages >1100 mg/m² are at increased risk for developing pulmonary toxicity. Patients with baseline FVC or DLco<70% are particularly at risk
(CCNSB™ (lomustine) Capsules; May 2013 product label. Next Source Biotechnolgy, LLC, Miami, FL)

Patient Population Studied

Patients with recurrent glioblastoma, prior treatment with a temozolomide-containing chemotherapy regimen, prior treatment with radiation, Karnofsky performance status (KPS) ≥70, Mini-Mental Status Examination score ≥15, and who had not received any prior anti-VEGF therapy or cranial radiation within 3 months before study entry

Toxicity

Grades 3/4 Adverse Events	Placebo + Lomustine (n = 64)	
	Number	%
Any AE, ≥ grade 3	39	60.9
Thrombocytopenia	14	22
Neutropenia	2	3.1
Fatigue	6	9.4
Leukopenia	3	4.7

Diarrhea	1	1.6
Pulmonary embolism	4	6.3
Lymphopenia	5	7.8
Convulsion	3	4.7
Intracranial hemorrhage	2	3.1

AE, adverse event; GGT, γ-glutamyltransferase

Efficacy

Best Overall Response	Lomustine + Placebo (n = 56)	
	Number	%
Overall response rate	5	8.9
Complete response (CR)	0	—
Partial response (PR)	5	8.9
Stable disease	23	41.1
Unconfirmed CR	0	—
Unconfirmed PR	2	3.6
PD	16	28.6
Nonevaluable	5	8.9

Median reduction in contrast-enhanced tumor area	+14% increase
APF6 proportions	25%
Corticosteroid usage	+5%

Median progression-free survival	82 days (first quartile = 42 days, third quartile = 168 days)
Median overall survival	9.8 months

REGIMEN

CARBOPLATIN

Yung WK et al. J Clin Oncol 1991;9:860–864

Carboplatin 400 mg/m²; administer intravenously over 30 minutes to 2 hours in 250 mL 5% dextrose injection (D5W) or 0.9% sodium chloride injection (0.9% NS) on day 1, every 4 weeks (total dosage/cycle = 400 mg/m²)

or

Carboplatin (calculated dose) AUC = 5–7 mg/mL • min; administer intravenously over 30 minutes to 2 hours in a volume of D5W or 0.9% NS sufficient to produce a concentration ≥0.5 mg/mL, on day 1, every 4 weeks (total dosage/cycle calculated to produce an AUC = 5–7 mg/mL • min)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MODERATE–HIGH**. Potential for delayed symptoms*

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Carboplatin dose is based on a formula described by Calvert et al. to achieve a target area under the plasma concentration versus time curve (AUC)

$$\text{Total carboplatin dose (mg)} = (\text{Target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be calculated from the equation of Cockcroft and Gault, thus:

$$\text{For males, Clcr} = \frac{(140 - \text{age [years]}) \times \text{body weight [kg]}}{72 \times (\text{serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times \text{body weight [kg]}}{72 \times (\text{serum creatinine [mg/dL]})} \times 0.85$$

Calvert AH et al. J Clin Oncol 1989;7:1748–1756
Cockcroft DW, Gault MH. Nephron 1976;16:31–41
Jodrell DI et al. J Clin Oncol 1992;10:520–528
Sorensen BT et al. Cancer Chemother Pharmacol 1991;28:397–401

Note: On October 8, 2010, the FDA identified a potential safety issue with carboplatin dosing based on recent changes in the measurement of serum creatinine. By the end of 2010, all clinical laboratories in the United States will use the standardized Isotope Dilution Mass Spectrometry (IDMS) method to measure serum creatinine, which could result in an overestimation of the GFR in some patients with normal renal function. A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula could exceed an expected exposure (AUC) and result in increased drug-related toxicity
Provided actual GFR measurements are made to assess renal function, carboplatin can be safely dosed according to the Calvert formula described in product labeling
If GFR (or creatinine clearance) is estimated based on serum creatinine measurements by the IDMS method, the FDA recommended for patients with normal renal function capping an estimated GFR at 125 mL/min for any targeted AUC value. No greater estimated GFR values should be used
U.S. FDA. Carboplatin dosing. [online] October 8, 2010. Available from: http://www.fda.gov/AboutFDA/CentersOffices/OfficeofMedicalProductsandTobacco/CDER/ucm228974.htm [accessed February 26, 2014]

Patient Population Studied

A study of 30 patients with recurrent malignant gliomas

Treatment Modifications

Adverse Event	Dose Modification
Day 1 WBC <3000/mm³ or platelets <50,000/mm³	Delay treatment until WBC ≥3000/mm³ and platelets ≥100,000/mm³
ANC nadir <500/mm³ or platelets <50,000/mm³	Reduce carboplatin dosage by 25%
Cycle 1 ANC nadir ≥1500/mm³ and platelet nadir ≥100,000/mm³	Increase carboplatin dosage by 12.5%

Toxicity (N = 29)

Nonhematologic Toxicity

	Percent Cycles with Toxicity		
Toxicity	Mild	Moderate	Severe
Nausea/vomiting	8	24	2.4
Malaise	18		—

Hematologic Toxicity at 400 mg/m²

Toxicity	Percent of Patients
Neutropenia (ANC <500/mm³)	7
Thrombocytopenia* <50,000/mm³	7

*Although the incidence of thrombocytopenia in this study was low, significant thrombocytopenia often follows carboplatin treatment

Efficacy (N = 29)

Partial response (PR)	7%
Minor response (MR)	7%
Stable disease (S)	34%
Median time to progression (PR/MR/S)	26 weeks
Median survival time (PR/MR/S)	50 weeks

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Every 28 days:* LFTs. BUN, serum creatinine, serum calcium, magnesium, and uric acid
3. *Every other cycle:* Urine for creatinine clearance
4. *When clinically indicated:* Audiogram

Notes

Adjust the dose based on hematologic toxicity and/or urine creatinine clearance

REGIMEN

PROCARBAZINE, LOMUSTINE (CCNU), VINCRISTINE (PCV)

Levin VA et al. Cancer Treat Rep 1980;64:237–241

Special instructions:
Because procarbazine is a weak monoamine oxidase inhibitor, one should restrict tyramine-containing foods in patients receiving procarbazine

Anon. Med Lett Drugs Ther 1989;31:11–12
DaPrada M et al. J Neural Transm 1988;26:31–56
McCabe BJ. J Am Diet Assoc 1986 86:1059–1064

Lomustine (CCNU) 110 mg/m^2; administer orally as a single dose on day 1, every 6–8 weeks (total dosage/cycle = 110 mg/m^2)
Procarbazine 60 mg/m^2 per day; administer orally for 14 consecutive days on days 8–21, every 6–8 weeks (total dosage/cycle = 840 mg/m^2)
Vincristine 1.4 mg/m^2 per dose (maximum single dose = 2 mg); administer by intravenous injection over 1–2 minutes for 2 doses, on days 8 and 29, every 6–8 weeks (total dosage/cycle = 2.8 mg/m^2, but *not* >4 mg/cycle)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 and days 8–21 is ***MODERATE–HIGH***
Emetogenic potential on day 29 is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
Nadir prior cycle: WBC 2000–3000/mm^3 or platelets 25,000–75,000/mm^3	Reduce lomustine and procarbazine dosages by 10–25%
Nadir prior cycle: WBC <2000/mm^3 or platelets <25,000/mm^3	Reduce lomustine and procarbazine dosages by 25–50%
Severe neurotoxicity, eg, painful paresthesia or peripheral weakness	Discontinue vincristine
Cumulative lomustine dosage >1100 mg/m^2 or worsening forced vital capacity (FVC) or carbon monoxide diffusing capacity (DL_{co})*	Discontinue lomustine

**Note:* Usually no more than a total of 6–7 cycles (660–770 mg/m^2) of lomustine is recommended. Patients receiving >1100 mg/m^2 cumulative lomustine dosage have a higher risk of developing pulmonary toxicity. Patients with a baseline FVC or DLco <70% are particularly at risk

(CCNSB™ (lomustine) Capsules; May 2013 product label. NextSource Biotechnolgy, LLC, Miami, FL)

Efficacy (N = 46)

Objective response (OR)	26%
Stable disease (SD)	35%
Median time to progression (OR + SD)	26 weeks
Progression-free survival at 12 months	30%

NOA-04 Randomized Phase III Trial of Sequential Radiochemotherapy of Anaplastic Glioma with Procarbazine, Lomustine, and Vincristine (PCV) or Temozolomide (TMZ)

Wick W et al. J Clin Oncol 2009;27:5874–5880

CTCAE, National Cancer Institute (USA) Common Terminology Criteria for Adverse Events, all versions. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]

Patient Population Studied

A phase II study of 46 patients with recurrent malignant brain tumor

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Before each treatment:* LFTs
3. *Every 3–4 cycles:* Pulmonary function test

Notes

This regimen has been particularly effective for the treatment of high risk low grade gliomas following radiation therapy, anaplastic oligodendrogliomas and oligoastrocytomas

Cairncross JG et al. Ann Neurol 1988;23:360–364
Kim L et al. J Neurosurg 1996;85:602–607

REGIMEN

ADJUVANT PROCARBAZINE, LOMUSTINE (CCNU), AND VINCRISTINE (PCV) NEWLY DIAGNOSED ANAPLASTIC OLIGODENDROGLIOMA

van den Bent MJ et al. J Clin Oncol 2013;31:344–350
van den Bent MJ et al. J Clin Oncol 2006;24:2715–2722

Special instructions:
Because procarbazine is a weak monoamine oxidase inhibitor, clinicians should guide patients who receive the drug in limiting their dietary intake of tyramine-containing foods and beverages

Anon. Med Lett Drugs Ther 1989;31:11–12
DaPrada M et al. J Neural Transm Suppl 1988;26:31–56
McCabe BJ. J Am Diet Assoc 1986;86:1059–1064

PCV chemotherapy started within 4 weeks after the end of RT
Lomustine 110 mg/m^2; administer orally as a single dose on day 1, every 6 weeks for a total of 6 cycles (total dosage/cycle = 110 mg/m^2)
Procarbazine 60 mg/m^2 per day; administer orally for 14 consecutive days on days 8–21, every 6 weeks for a total of 6 cycles (total dosage/cycle = 840 mg/m^2)
Vincristine 1.4 mg/m^2; administer per dose (maximum single dose = 2 mg); administer by intravenous injection over 1–2 minutes for 2 doses, on days 8 and 29, every 6 weeks for a total of 6 cycles (total dosage/cycle = 2.8 mg/m^2; maximum dose/cycle = 4 mg)
Radiotherapy within 6 weeks after surgery. 45 Gy is administered to the planning target volume-1 (PTV-1) in twenty-five 1.8-Gy fractions, 5 days/week over 5 weeks. Thereafter, a boost of 14.4 Gy (up to a cumulative dose of 59.4 Gy) is delivered to the PTV-2 in 8 fractions of 1.8 Gy, 1 fraction per day, 5 fractions per week. PTV-2 is to include the nonenhancing tumor area and/or the enhancing area as visible on the postoperative CT scan with contrast with a 1.5-cm margin; in case of a nonenhancing tumor on CT scan, a postoperative MRI scan with and without gadolinium is recommended to further define the tumor volume

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 and days 8–21 is ***MODERATE–HIGH***
Emetogenic potential on day 29 is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Note: Treatment at the time of progression was left to the discretion of local investigators, but the study protocol strongly advised treating physicians to consider (PCV) chemotherapy, especially for patients in the RT-only arm

Treatment Modifications

Adverse Event	Dose Modification
WBC nadir during the prior cycle 2000–3000/mm^3, or platelets 25,000–75,000/mm^3	Reduce lomustine and procarbazine dosages by 10–25%
WBC nadir during the prior cycle <2000/mm^3, or platelets <25,000/mm^3	Reduce lomustine and procarbazine dosages by 25–50%
Severe neurotoxicity; eg, painful paresthesia or peripheral weakness	Discontinue vincristine
Cumulative lomustine dosage >1100 mg/m^2, or worsening forced vital capacity (FVC) or carbon monoxide diffusing capacity (DL_{co})*	Discontinue lomustine

**Note:* Usually no more than a total of 6–7 cycles of lomustine (660–770 mg/m^2) is recommended. Patients receiving cumulative lomustine dosages >1100 mg/m^2 are at increased risk for developing pulmonary toxicity. Patients with baseline FVC or DL_{co} <70% are particularly at risk

Patient Population Studied

Patient Characteristic	Radiotherapy Plus PCV (N = 185)	Radiotherapy Only (N = 183)
	Number of Patients (Percent)

MMSE, Mini-Mental State Examination; PCV, procarbazine, lomustine, and vincristine
*The extent of resection as assessed by the neurosurgeon

Toxicity

- Most patients who discontinued PCV prematurely did so for (usually asymptomatic) hematologic toxicity or for tumor progression
- A quality-of-life analysis that was part of this study has shown that patients in the RT/PCV arm complained more frequently of nausea/vomiting, loss of appetite, and drowsiness during and shortly after PCV chemotherapy
- However, no long-term effects of PCV chemotherapy on quality of life were identified

G3/4 Toxicity in the Patients Who Started PCV Chemotherapy (N = 161)

Toxicity	Grade 3	Grade 4
	Number of Patients (Percent)	
WBC count	43 (27)	5 (3)
Neutrophils	39 (24)	13 (8)
Platelets	23 (14)	11 (7)
Hemoglobin	10 (6)	1 (1)
Any hematologic toxicity	51 (32)	23 (14)
Nausea	9 (6)	—
Vomiting	10 (6)	—
Polyneuropathy	3 (2)	—
Allergic skin reactions	2 (1)	—

PCV, procarbazine, lomustine, and vincristine

Efficacy*

Median and 5-Year Overall Survival and Progression-Free Survival According to Assigned Treatment in the Various Subgroups

	HR, 0.73 (95% CI, 0.55–0.96)							

CI, confidence interval; IDH, isocitrate dehydrogenase; MGMT, O_6-methylguanine-DNA methyltransferase; NR, not reached; PCV, procarbazine, lomustine, and vincristine; RT, radiotherapy

*The increase in OS was achieved despite the fact that the median number of PCV cycles was 3, with only 30% of patients completing the intended 6 cycles; most patients that discontinued PCV prematurely did so for (usually asymptomatic) hematologic toxicity or for tumor progression

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Before each treatment:* LFTs
3. *Every 3–4 cycles:* Pulmonary function tests

REGIMEN

HIGH-DOSE TAMOXIFEN

Couldwell WT et al. Clin Cancer Res 1996;2:619–622

Initial dose and schedule:
Tamoxifen 20 mg/dose; administer orally, twice daily for 4 days (total dose/4 days = 160 mg)

If tolerated advance dose as follows:
Increase the tamoxifen dose every week in increments of 20 mg/dose (40 mg/day) to achieve after 1 month the target doses indicated below

Target dose for females:
Tamoxifen 80 mg/dose; administer orally, twice daily, continually
(total dose/30 days = 4800 mg)

Target dose for males:
Tamoxifen 100 mg/dose; administer orally, twice daily, continually
(total dose/30 days = 6000 mg)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential: MINIMAL
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A phase II study of 32 patients with recurrent malignant gliomas

Efficacy (N = 32)

Clinical and radiographic responses	25%
Stable disease	19%
Median survival	10.1 months

Toxicity (N = 32)

	% Patients
Deep vein thrombosis	6
Nausea	3
Hot flashes	3
Fatigue	6

Treatment Modifications

Adverse Event	Dose Modification
Deep venous thrombosis	Discontinue tamoxifen
Nausea/vomiting	Hold tamoxifen. Restart previously tolerated dose when symptoms resolve to G ≤1
G3 fatigue	Hold tamoxifen. Restart previously tolerated dose when symptoms resolve to G ≤1

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Weekly while escalating dose:* LFTs, BUN, and serum creatinine
3. *Every 2 months when not escalating dose:* LFTs, BUN, and serum creatinine

REGIMEN

ERLOTINIB (TARCEVA)

Prados MD et al. Neuro Oncol 2006;8:67–78
Raizer JJ et al. Proc Am Soc Clin Oncol 2004;22:107s (abstract #1502)
Yung A et al. Proc Am Soc Clin Oncol 2004;22:120s (abstract #1555)

Patients receiving non–enzyme-inducing antiepileptic drugs (NEIAED)
Erlotinib 200 mg per day; administer orally, continually, every day of a 4-week cycle (total dosage/cycle = 5600 mg)

Patients receiving enzyme-inducing antiepileptic drugs (EIAED)
Erlotinib 500 mg per day; administer orally, continually, every day of a 4-week cycle (total dosage/cycle = 14,000 mg)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential: ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of Diphenoxylate hydrochloride 2.5 mg with Atropine sulfate 0.025 mg (eg, Lomotil®)
- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:
Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:
A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea
- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Treatment Modifications

Adverse Event	Dose Modification
Pulmonary symptoms (dyspnea, cough, fever)	Hold erlotinib
Interstitial lung disease	Discontinue erlotinib
G1/2 diarrhea	Administer loperamide, 2 mg orally several times a day; if symptoms do not improve, hold erlotinib until symptoms resolve and then reduce dose
G2+/3/4 diarrhea	Reduce dose, *or* hold erlotinib until symptoms resolve and then reduce dose
G1/2 rash, skin reaction	Hold erlotinib. Administer supportive care. If symptoms resolve, restart the same dose
G2+/3/4 rash, skin reaction	Hold erlotinib. Administer supportive care. If symptoms resolve, restart at a reduced dose

Patient Population Studied

- A phase I study of 83 patients with stable or progressive malignant primary glioma (Prados et al.)
- A phase II study of 48 patients with glioblastoma in first relapse
- A phase II study of 45 patients with recurrent malignant gliomas not on EIAED

Yung A et al. Proc Am Soc Clin Oncol 2004;22:120s (abstract #1555)

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Every 4 weeks:* Serum electrolytes, mineral panel, and LFTs

Notes

This regimen might be useful particularly for patients whose tumor expresses EGFR or EGFRviii, which are commonly found in GBM

REGIMEN

BEVACIZUMAB (AVASTIN) ± IRINOTECAN

Kreisl T et al. J Clin Oncol 2009;27:740–745

Initial therapy:
Bevacizumab 10 mg/kg per dose; administer intravenously in 100 mL 0.9% sodium chloride injection, USP (0.9% NS) every 14 days on a 28-day cycle (total dosage/cycle = 20 mg/kg)
- First dose is administered over 90 minutes
- Second dose may be administered over 60 minutes, if the first dose was well tolerated
- Third and subsequent doses may be administered over 30 minutes, if doses administered over 60 minutes were well tolerated

Therapy after documented tumor progression:
Bevacizumab 10 mg/kg per dose; administer intravenously in 100 mL 0.9% NS every 14 days on a 28-day cycle (total dosage/cycle = 20 mg/kg), *plus*
Irinotecan
Patients receiving non–enzyme-inducing antiepileptic drugs (NEIAED)
125 mg/m^2; administer intravenously over 90 minutes in 250 mL 0.9% NS or 5% dextrose injection, USP (D5W), every 14 days on a 28-day cycle (total dosage per cycle = 250 mg/m^2)
Patients receiving enzyme-inducing antiepileptic drugs (EIAED)
340 mg/m^2; administer intravenously over 90 minutes in 250 mL 0.9% NS or D5W every 14 days on a 28-day cycle (total dosage per cycle = 680 mg/m^2)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential with bevacizumab alone is **MINIMAL***
*Emetogenic potential with bevacizumab + irinotecan is **MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome
Atropine sulfate 0.25–1 mg administer subcutaneously or intravenously if abdominal cramping or diarrhea develop during or within 1 hour after irinotecan administration
- If symptoms are severe, add as primary prophylaxis at least 30 min before irinotecan during subsequent cycles
- For irinotecan, acute cholinergic syndrome may be characterized by: abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

Diarrhea management
Latent or delayed onset diarrhea:*
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

(*continued*)

Toxicity (N = 48)

Toxicity	% G1	% G2	% G3	% G4
Thrombo-embolic events			4.2	8.4
Hypertension		8.4	4.2	
Hypophos-phatemia		4.2	6.3	
Thrombo-cytopenia		4.2	2.1	
Hepatic dysfunction			2.1	
Proteinuria	2.1			
Bowel perforation			2.1	

Patient Population Studied

A phase II study of 48 patients with recurrent glioblastoma

Efficacy (N = 48)

Partial response	71%
6-Month survival rate	57%
6-Month progression-free survival	29%
Median overall survival	31 weeks
Median progression-free survival	16 weeks

Note: Of 19 patients treated with bevacizumab plus irinotecan at progression, there were no objective radiographic responses

Therapy Monitoring

1. *Every 2 weeks:* CBC with differential, urinalysis for urine protein: creatinine ratio, BP check
2. *Every 4 weeks:* CBC with differential, serum electrolytes, mineral panel, and LFTs

(*continued*)

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)

- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count $<500/mm^3$ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807; Abigerges D et al. J Natl Cancer Inst 1994;86:446–449; Wadler S et al. J Clin Oncol 1998;16:3169–3178

Treatment Modifications: Bevacizumab-Related Adverse Events

Note: There are no recommended dose reductions for the use of bevacizumab. Consequently, bevacizumab use is either temporarily interrupted or discontinued

Adverse Event	Toxicity Grade	Dose Modification/Action to Be Taken
Allergic reactions or Acute infusional reactions/ cytokine release syndrome	G1–3	Premedications should be given before the next dose, and infusion time may not be shortened for subsequent infusions For patients with G3 reactions, bevacizumab infusion should be stopped and not restarted on the same day. At a physician's discretion, bevacizumab may be permanently discontinued or reinstituted with premedications and at a rate designed to complete administration over 90 ± 15 minutes. If bevacizumab is reinstituted, the patient should be closely monitored for a duration comparable to or longer than the duration of the previous reactions
	G4	Discontinue bevacizumab
Arterial thrombosis • Cardiac ischemia/infarction • CNS ischemia (TIA, CVA) • Any peripheral or visceral arterial ischemia/thrombosis	G2 (if new or worsened after starting bevacizumab therapy)	Discontinue bevacizumab
	G3/4	Discontinue bevacizumab
Venous thrombosis	G3 or asymptomatic G4	• Hold bevacizumab treatment. If the planned duration of full-dose anticoagulation is <2 weeks, bevacizumab should be withheld until the full-dose anticoagulation period is over. Prophylaxis against pulmonary emboli can be accomplished through placement of an IVC filter • If the planned duration of full-dose anticoagulation is >2 weeks, permanently discontinue bevacizumab • If thromboemboli worsen/recur upon resumption of therapy, discontinue bevacizumab
	G4 (symptomatic)	Discontinue bevacizumab
Hypertension (Treat with antihypertensive medications as needed. The goal of BP control should be consistent with general medical practice)	If BP is controlled medically	Continue bevacizumab
	Persistent or symptomatic HTN	Hold bevacizumab. If treatment is delayed for >4 weeks because of uncontrolled hypertension, discontinue bevacizumab
	G4	Discontinue bevacizumab
Proteinuria (Proteinuria should be monitored by urine analysis for urine protein:creatinine [UPC] ratio prior to every dose of bevacizumab)	UPC ratio <3.5	Continue bevacizumab
	UPC ratio ≥3.5	Hold bevacizumab until UPC recovers to <3.5. If therapy is held for >2 months because of proteinuria, discontinue bevacizumab
	G4 or nephrotic syndrome	Discontinue bevacizumab
Wound dehiscence requiring medical or surgical intervention		Discontinue bevacizumab
GI perforation, GI leak or fistula		Discontinue bevacizumab

REGIMEN

HIGH-DOSE METHOTREXATE FOR PRIMARY CNS LYMPHOMA

Batchelor T et al. J Clin Oncol 2003;21:1044–1049

Induction phase:
Methotrexate every 14 days until complete response (CR) or a maximum of 8 cycles are delivered
Consolidation phase:
For patients achieving a CR during induction, give 2 cycles of methotrexate every 14 days, then give:
Maintenance phase:
Eleven cycles of methotrexate every 28 days

Hydration before, during, and after methotrexate:
Before methotrexate administration:
5% Dextrose injection (D5W) or 5% dextrose/0.45% sodium chloride injection (D5W/0.45% NS) with 50–100 mEq sodium bicarbonate injection/L; administer intravenously at 100–150 mL/hour
- Adjust infusion rate to achieve and maintain a urine output ≥100 mL/hour for ≥4 hours before starting methotrexate
- Adjust sodium bicarbonate to produce a urine pH within the range ≥7.0 to ≤8.0 before starting methotrexate

During methotrexate administration:
No additional hydration (see below)

After methotrexate administration:
D5W or D5W/0.45% NS with 50–100 mEq sodium bicarbonate injection/L; administer intravenously at 100–150 mL/hour until serum methotrexate concentration <0.1 μmol/L
- Adjust infusion rate to maintain urine output ≥100 mL/hour
- Adjust sodium bicarbonate to maintain urine pH ≥7.0 to ≤8.0

Methotrexate 8000 mg/m² in 500–1000 mL D5W with 50–100 mEq sodium bicarbonate per dose; administer intravenously over 4 hours (total dosage every 14 days [induction and consolidation cycles] and every 28 days [maintenance cycles] = 8000 mg/m²)
(Add sodium bicarbonate in amounts sufficient to produce a bicarbonate concentration equivalent to fluid used for the same volume of hydration fluid given over a 4-hour period)
Leucovorin calcium 25 mg per dose; administer intravenously every 6 hours for 4 doses, starting 24 hours after methotrexate administration began
Six hour after the last dose of intravenously administered leucovorin, start oral leucovorin or continue with intravenous leucovorin calcium every 6 hours if patient is nauseated or vomiting otherwise:
Leucovorin calcium 25 mg per dose; administer orally or intravenously every 6 hours until serum methotrexate concentration <0.1 μmol/L

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is MODERATE
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A multicenter phase II trial of 25 patients with newly diagnosed non–AIDS-related primary CNS lymphoma (PCNSL). Previous radiation therapy was not allowed

Efficacy (N = 24)

Complete response*	50%
Partial response	21%
Stable disease	4.2%
Median progression-free survival	12.8 months
Median overall survival	>22.8 months

*Median number of cycles to CR = 6

Treatment Modifications

Methotrexate dosage is based on a measured creatinine clearance before treatment commences. For any creatinine clearance <100 mL/min, methotrexate dosage is calculated by multiplying the planned dosage (8000 mg/m²) by the ratio between the measured creatinine clearance (Clcr) and 100

Example:
For a measured Clcr = 75 mL/min:

$$\frac{75}{100} = 0.75 \text{ (ie, 75\%)}$$

Thus, the adjusted methotrexate dosage is:

$$8000 \text{ mg/m}^2 \times 0.75 = 6000 \text{ mg/m}^2$$

Toxicity

(N = 25 Patients; N = 287 Cycles)

Toxicity	% Patients
G ≥3/4 toxicity	48
No G3/4 toxicity	52
Leukoencephalopathy	—

Batchelor T et al. J Clin Oncol 2003;21:1044–1049

(N = 31 Patients; N = 375 Cycles)*

Toxicity	% Cycles
Leukopenia (<2000 WBC/mm^3)	1
Nonoliguric acute renal failure	1
G3 mucositis	2
Leukoencephalopathy	—
Acute cerebral dysfunction	—
Delayed methotrexate clearance†	13

Guha-Thakurta N et al. J Neurooncol 1999;43:259–268

*Treatment:
1. Methotrexate 8000 mg/m^2 for ≥3 induction cycles
2. Methotrexate 3500–8000 mg/m^2/cycle until CR
3. Methotrexate 3500 mg/m^2/month for 3 months
4. Methotrexate 3500 mg/m^2/3 months indefinitely

Median: 10 cycles/patient (range: 3–30 cycles)

†Risk factors for delayed methotrexate clearance:
1. Cycle intervals <10 days
2. Concurrent SIADH or diabetes insipidus
3. Acute renal failure
4. "Third-space" fluid compartments (eg, effusions)

Therapy Monitoring

Before each treatment cycle:
1. CBC with differential
2. Serum electrolytes
3. LFTs
4. 24-hour urine collection for creatinine clearance

During hospitalization:
1. Check urine output and pH frequently
2. Daily CBC with differential and serum electrolytes
3. Monitor daily methotrexate levels starting the day after methotrexate administration begins and continue until serum methotrexate concentrations are <0.1 μmol/L. In patients with renal impairment or pleural effusion, continue leucovorin and check serum methotrexate concentrations daily until methotrexate is undetectable

Notes

1. The regimen is for the treatment of primary central nervous system lymphoma for which radiation therapy has been deferred
2. In patients with renal impairment or an effusion, consider empirically continuing leucovorin calcium administration until serum methotrexate concentrations become undetectable

CNS LYMPHOMA REGIMEN

RITUXIMAB, METHOTREXATE, PROCARBAZINE, AND VINCRISTINE FOLLOWED BY CONSOLIDATION, REDUCED-DOSE WHOLE-BRAIN RADIOTHERAPY, AND CYTARABINE (R-MPV → RT + C) NEWLY DIAGNOSED PRIMARY CNS LYMPHOMA

Morris PG et al. J Clin Oncol 2013;31:3971–3979
Shah GD et al. J Clin Oncol 2007;25:4730–4735

Induction Chemotherapy: Five 14-Day Cycles

Premedication for rituximab:
Acetaminophen 650–1000 mg orally, *plus*
Diphenhydramine 25–50 mg orally or intravenously, 30–60 minutes before starting rituximab
Rituximab 500 mg/m^2; administer intravenously in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W), USP, diluted to a concentration within the range 1–4 mg/mL on day 1, every 2 weeks, for 5–7 cycles (total dosage/cycle = 500 mg/m^2)

Notes on rituximab administration:
- Administer initially at a rate of 50 mg/h. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/h every 30 minutes as tolerated to a maximum rate of 400 mg/h
- During subsequent treatments, if previous rituximab administration was well tolerated, start at 100 mg/hour and increase by 100 mg/hour every 30 minutes as tolerated to a maximum rate of 400 mg/hour
- Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate

Methotrexate 3500 mg/m^2; administer intravenously over 2 hours on day 2, every 2 weeks, for 5–7 cycles (total dosage/cycle *not* including intrathecal therapy = 3500 mg/m^2)
Note: For logistical practicality and efficiency, parenteral admixtures containing methotrexate may include a portion or all of the fluid and sodium bicarbonate needed to meet hydration and urinary alkalinization requirements during methotrexate administration

Hydration before, during, and after methotrexate:
Administer 1500–3000 mL/m^2 per day. Use a solution containing a total amount of sodium not greater than 0.9% sodium chloride injection (ie, ≤154 mEq/1000 mL), by intravenous infusion during methotrexate administration and for at least 24 hours afterward
- Commence fluid administration 2–12 hours before starting methotrexate, depending upon a patient's fluid status
- Urine output should be at least 100 mL/h before starting methotrexate infusion
- Maintain hydration at a rate that maintains urine output of at least 100 mL/h until the serum methotrexate concentration is <0.05 µmol/L
- Adverse effects attributable to methotrexate are related to systemic methotrexate concentrations *and* the duration for which concentrations are maintained

Sodium bicarbonate 50–150 mEq/1000 mL is added to parenteral hydration solutions to maintain urine pH ≥7.0 to ≤8.0

Base Solution Sodium Content	Sodium Bicarbonate Additive	Total Sodium Content
0.45% Sodium Chloride Injection (0.45% NS)		
77 mEq/L	50–75 mEq	125–152 mEq/L
0.2% Sodium Chloride Injection (0.2% NS)		
34 mEq/L	100–125 mEq	134–159 mEq/L
5% Dextrose Injection (D5W)		
0	125–150 mEq	125–150 mEq/L
D5W/0.45% NS		
77 mEq/L	50–75 mEq	125–152 mEq/L
D5W/0.2% NS		
34 mEq/L	100–125 mEq	134–159 mEq/L

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
WBC nadir during the previous cycle 2000–3000/mm^3, or platelets 25,000–75,000/mm^3	Reduce procarbazine dosage by 10–25%
WBC nadir during the previous cycle <2000/mm^3, or platelets <25,000/mm^3	Reduce procarbazine dosage by 25–50%
Severe neurotoxicity; eg, painful paresthesia or peripheral weakness	Discontinue vincristine
Leucovorin doses	See leucovorin guidelines

Patient Population Studied

Clinical Characteristics (N = 30)

Characteristic	
Age (years), median/range	57 (30–76)
Sex, Male/Female	17/13
Karnofsky performance score, median/range	70 (50–90)
Positive CSF	6
Ocular involvement	3

(continued)

Leucovorin calcium 25 mg/m²; administer intravenously in 25–250 mL 0.9% NS or D5W over 15–30 minutes every 6 hours starting 24 hours after methotrexate administration began, for at least 72 hours (≥12 doses) or until serum methotrexate concentrations are ≤0.05 μmol/L or undetectable, every 2 weeks, for 5–7 cycles

Leucovorin Rescue Guidelines

Clinical Situation	Serum Methotrexate Concentration*	Leucovorin Dosage, Schedule, and Duration
Normal Methotrexate Elimination	• ≤10 μmol/L at 24 hours, *or* • ≤1 μmol/L at 48 hours, *or* • ≤0.2 μmol/L at 72 hours	• Give leucovorin calcium 25 mg/m² intravenously every 6 hours until serum methotrexate concentrations are <0.1 μmol/L (<1 × 10^{-7} mol/L or <100 nmol/L), then give leucovorin calcium 25 mg orally every 6 hours for 8 doses
Delayed/Late Methotrexate Elimination	• ≥10 μmol/L at 24 hours, *or* • ≥1 μmol/L at 48 hours, *or* • ≥0.1 μmol/L at 72 hours, *or* • ≥0.05 μmol/L at 96 hours *or* • ≥100% increase in serum creatinine concentration at 24 hours after methotrexate administration	• Give leucovorin calcium 100 mg/m² intravenously every 3 hours • When serum methotrexate concentration results are <0.1 μmol/L the leucovorin dosage may be decreased to 10 mg/m² intravenously given every 3 hours until the serum methotrexate concentration is <0.05 μmol/L or undetectable

*After methotrexate administration began
Methotrexate concentration conversions: 1 μmol/L = 10^{-6} mol/L = 1000 nmol/L)

Vincristine 1.4 mg/m² (maximum dose = 2.8 mg); administer by intravenous injection over 1–2 minutes on day 2, every 2 weeks, for 5–7 cycles (total dosage/cycle = 1.4 mg/m²; maximum dose/cycle = 2.8 mg)
Procarbazine 100 mg/m² per day; administer orally for 7 consecutive days on days 1 through 7, *only* during odd-numbered cycles (cycles 1, 3, 5 ± 7; ie, every 4 weeks) for 3 or 4 cycles (total dosage/cycle = 700 mg/m²)

For patients with cerebrospinal fluid cytologically positive for lymphoma:
Preservative-free methotrexate 12 mg; administer intrathecally via intraventricular catheter or reservoir (eg, Ommaya) once per cycle between days 5 and 8, every 2 weeks, for 5–7 cycles

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***MINIMAL***
Emetogenic potential on day 2 during odd-numbered cycles (with procarbazine) is ***MODERATE–HIGH***
Emetogenic potential on day 2 during even-numbered cycles (without procarbazine) is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with:
Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection
- Begin use during odd-numbered cycles on day 8 (24 hours after the last dose of procarbazine)
- Begin use during even-numbered cycles 24 hours after serum methotrexate concentrations are <0.01 μmol/L(<1 × 10^{-8} mol/L, <10 nmol/L, or undetectable)
- Discontinue daily filgrastim use at least 24 hours before resuming myelosuppressive treatment

See Chapter 43 for more information

(continued)

Efficacy

Response Rate to R-MPV (n = 27)

Time Point	Complete Response Number (Percent)	Partial Response Number (Percent)	Overall Response Number (Percent)
After ≥5 cycles	12 (44%)	13 (59%)	25 (93%)
After all cycles	21 (78%)	4 (15%)	25 (93%)

R-MPV, rituximab, methotrexate, procarbazine, and vincristine

(*continued*)

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Infusion reactions associated with rituximab

Fevers, chills, and rigors

1. Interrupt rituximab administration for severe symptoms, and give:
   - **Acetaminophen** 650 mg; administer orally for fever. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Diphenhydramine** 25–50 mg; administer orally or by intravenous injection for pruritus, hypotension, or angioedema. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Meperidine** 12.5–25 mg; administer by intravenous injection every 10–20 minutes as needed for shaking chills (generally, cumulative doses >100 mg are not needed; use repeated doses with caution in persons with moderate or more severely impaired renal function)
2. If rituximab administration was interrupted, resume infusion at a slower rate than the maximum rate previously attempted. Rate escalation may be reattempted at smaller incremental steps with close monitoring. Do not exceed the maximum recommended rate of 400 mg/hour

Dyspnea or wheezing without allergic findings (urticaria, or tongue or laryngeal edema)

1. Interrupt rituximab administration immediately
2. Give **hydrocortisone** 100 mg; administer by intravenous injection (or an alternative steroid with equivalent glucocorticoid potency)
3. Give a **histamine (H_2) receptor antagonist** (ranitidine 50 mg, cimetidine 300 mg, or famotidine 20 mg); administer intravenously over 15–30 minutes
4. After symptoms resolve, resume rituximab administration at 25 mg/hour with close monitoring. Do not increase the administration rate

CONSOLIDATION AFTER RADIOTHERAPY: TWO 28-DAY CYCLES

Cytarabine 3000 mg/m^2 per day (maximum daily dose = 6000 mg); administer intravenously in 25–500 mL 0.9% NS or D5W over 3 hours for 2 days (2 doses), on days 1 and 2, every 28 days (total dosage/cycle = 6000 mg/m^2; maximum dose/cycle = 12,000 mg)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with one of the following:

Filgrastim (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL; administer by subcutaneous injection for 1 dose

- Begin use from 24–72 hours after cytarabine is completed
- Continue daily filgrastim use until ANC ≥10,000/mm^3 on two measurements separated temporally by ≥12 hours
- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment. Do not administer pegfilgrastim within 14 days before resuming myelosuppressive treatment

See Chapter 43 for more information

3-year PFS patients ≥60 years	38% (95% CI, 19–57%)	

*The favorable regimen performance in patients expected to have a poor prognosis (elderly and low KPS) abrogated the predictive value of the Memorial Sloan Kettering Cancer Center RPA class, and no differences were seen in PFS or OS according to methotrexate pharmacokinetic parameters

†Median follow-up of 5.9 years for survivors

‡Median follow-up of 5.6 years for survivors

(*continued*)

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended; consider use during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Keratitis prophylaxis

Steroid ophthalmic drops (prednisolone 1% or dexamethasone 0.1%) by intraocular instillation daily until 24 hours after high-dose cytarabine is completed

Patients with CSF evidence of malignancy received 12 mg of intra-Ommaya methotrexate between cycles

Response Assessment After Five Induction Chemotherapy Cycles*

Assessment	Plan
Complete Response (CR)	Reduced-dose whole-brain radiotherapy (rdWBRT) (23.40 Gy in 1.8-Gy fractions × 13 fractions) 3–5 weeks after chemotherapy completion. Opposed lateral radiation fields were used to include the whole brain down to the level of C2 (so-called German helmet shape) and excluded the anterior two-thirds of the orbit
Partial Response (PR)	Two additional cycles of R-MPV, and, if a CR was achieved, rdWBRT was given as previously described. Otherwise, a standard dose of WBRT (45 Gy in 25 fractions) was offered
Stable or progressive disease	Standard WBRT. Patients with ocular involvement were irradiated without orbital shielding to the full dose of 23.40 Gy (patients in CR) or to a dose of 36 Gy (patients with less than a CR)

*Response was assessed using International PCNSL Collaborative Group criteria, based on imaging, corticosteroid use, and CSF cytology and slit-lamp examination in case of CSF or ocular involvement

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Before each treatment:* serum creatinine and liver function tests
3. *Every 3–4 cycles:* pulmonary function test

Toxicity (N = 52)*

Acute renal failure	3%
Septic shock	2%
Fatal febrile neutropenia >2 cycles	2%
G4/5 neutropenia†	13%
G3 anemia	10%
G3 thrombocytopenia	27%
G3 lymphopenia	40%
G3 neutropenia	20%

*Median number of R-MPV (rituximab, methotrexate, procarbazine, and vincristine) cycles received was 5 (range: 0–7)
†Includes 2 of the first 5 treated patients; the protocol was the amended to require prophylactic filgrastim

Toxicity

Exploratory Neuropsychological and Imaging Correlates (N = 12 treated with rdWBRT)

- At baseline: Cognitive impairment present in several domains
- After induction chemotherapy: significant improvement in executive ($P < 0.01$) and verbal memory ($P < 0.05$)
- During follow-up: no evidence of significant cognitive decline except for motor speed ($P < 0.05$)
- During follow-up: no evidence of depressed mood, and self-reported quality of life remained stable during the follow-up period
- *At baseline:* 5/12 patients had G ≥2 white matter disease
- *After induction chemotherapy:* 1/12 patients had G ≥2 white matter disease
- *At 4-year evaluation:* 5/12 patients had G2 and 2/12 patients had G3 white matter disease
- *During follow-up:* no patient developed Fazekas scores of 4 or 5

REGIMEN

HIGH-DOSE METHOTREXATE AND RITUXIMAB WITH DEFERRED RADIOTHERAPY NEWLY DIAGNOSED PRIMARY B-CELL CNS LYMPHOMA

Chamberlain MC, Johnson SK. Neuro Oncol 2010;12:736–744

INDUCTION (≥4 BI-WEEKLY CYCLES)

Methotrexate; administer intravenously over 6 hours on day 1, every 2 weeks

Methotrexate Dosage

Estimated or measured creatinine clearance	≥60 mL/minute (≥1 mL/s)	<60 mL/minute (<1 mL/s)
Methotrexate	8000 mg/m² (total dosage/2-week cycle = 8000 mg/m²)	4000 mg/m² (total dosage/2-week cycle = 4000 mg/m²)

Notes: For logistical practicality and efficiency, parenteral admixtures containing methotrexate may include a portion or all of the fluid and sodium bicarbonate needed to meet hydration and urinary alkalinization requirements during methotrexate administration

Hydration before, during, and after methotrexate:

Administer intravenously 1500–3000 mL/m² per day. Administer a solution containing a total amount of sodium not greater than 0.9% sodium chloride injection (ie, 154 mEq/1000 mL) by intravenous infusion during methotrexate administration and for at least 24 hours afterward

- Commence fluid administration 2–12 hours before starting methotrexate, depending upon a patient's fluid status
- Urine output should be at least 100 mL/hour before starting methotrexate infusion
- Urine pH should be ≥7.0 but ≤8.0 before, during, and after methotrexate administration
- Maintain hydration at a rate that maintains urine output of at least 100 mL/hours until the serum methotrexate concentration is <0.1 μmol/L
- Adverse effects attributable to methotrexate are related to systemic methotrexate concentrations *and* the duration for which concentrations are maintained

Sodium bicarbonate 50–150 mEq/1000 mL is added to parenteral hydration solutions to maintain urine pH ≥7.0 to ≤8.0

Base Solution Sodium Content	Sodium Bicarbonate Additive	Total Sodium Content
0.45% Sodium chloride injection (0.45% NS)		
77 mEq/L	50–75 mEq	125–152 mEq/L
0.2% Sodium chloride injection (0.2% NS)		
34 mEq/L	100–125 mEq	134–159 mEq/L
5% Dextrose injection (D5W)		
0	125–150 mEq	125–150 mEq/L
D5W/0.45% NS		
77 mEq/L	50–75 mEq	125–152 mEq/L
D5W/0.2% NS		
34 mEq/L	100–125 mEq	134–159 mEq/L

Leucovorin calcium 10 mg/m²; administer intravenously in 25–250 mL 0.9% NS or D5W over 15–30 minutes every 6 hours starting 24 hours after methotrexate administration begins, and continue until serum methotrexate concentrations are ≤0.1 μmol/L, every 2 weeks for a minimum of 4 cycles. When serum methotrexate concentrations are ≤0.1 μmol/L, discontinue intravenous hydration and leucovorin, *then:*

- Give **leucovorin** calcium 25 mg; administer orally every 6 hours for 2 days (8 doses), *and*
- Continue hydration orally with >1500 mL/m² (>50 fluid ounces/m²) for 3 days after intravenous hydration is discontinued

(*continued*)

Treatment Modifications

Adverse Event	Treatment Modification
G ≥3 hematologic toxicity on day 1 of a cycle or G >1 nonhematologic toxicity on day 1 of a cycle	Withhold treatment until all hematologic toxicity has resolved to G ≤2 and all nonhematologic toxicity has resolved to G ≤1
G ≥4 toxicity ascribed to methotrexate	Reduce the methotrexate dosage by 50%
G ≥3 toxicity ascribed to methotrexate after the dosage has been reduced by 50%	Discontinue methotrexate

Patient Population Studied

Patient Characteristics

N = 40

Forty patients (25 men; 15 women), ages 18–93 years (median: 61.5 years), with newly diagnosed B-cell primary central nervous system lymphoma (PCNSL). Histopathology was determined by stereotactic biopsy in 29 patients, resective surgery in 9 patients, cerebrospinal fluid (CSF) flow cytometry in 1, and vitrectomy in 1 patient

Variables	Number of Patients (Percent)
Age, Median (range)	61.5 y (18–93 y)
≥50 y/≥70 y	33 (82.5)/17(42.5)
Sex, Male/Female	25 (62.5)/15 (37.5)
Location of tumor	
Frontal	18 (45)
Temporal	3 (7.5)

(*continued*)

Rituximab 375 mg/m²; administer intravenously in 0.9% NS or D5W diluted to a concentration within the range 1–4 mg/mL between days 7 and 10 every 2 weeks for a minimum of 4 cycles; ie, within a 2-week cycle, during the week when methotrexate is not given (total dosage/2-week cycle = 375 mg/m²)

Notes on rituximab administration:

- Administer initially at a rate of 50 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/hour every 30 minutes as tolerated to a maximum rate of 400 mg/hour
- During subsequent treatments, if previous rituximab administration was well tolerated, start at 100 mg/hour and increase the rate by 100 mg/hour every 30 minutes as tolerated to a maximum rate of 400 mg/hour
- Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate

MAINTENANCE (4-WEEK CYCLES)

Methotrexate; administer intravenously over 6 hours on day 1, every 4 weeks

Methotrexate Dosage

Estimated or measured creatinine clearance	≥60 mL/minute (≥1 mL/s)	<60 mL/minute (<1 mL/s)
Methotrexate	8000 mg/m² (Total dosage/4-week cycle = 8000 mg/m²)	4000 mg/m² (Total dosage/4-week cycle = 4000 mg/m²)

Notes: For logistical practicality and efficiency, parenteral admixtures containing methotrexate may include a portion or all of the fluid and sodium bicarbonate needed to meet hydration and urinary alkalinization requirements during methotrexate administration

Hydration before, during, and after methotrexate:

Administer intravenously 1500–3000 mL/m² per day. Administer a solution containing a total amount of sodium not greater than 0.9% sodium chloride injection (ie, 154 mEq/1000 mL) by intravenous infusion during methotrexate administration and for at least 24 hours afterward

- Commence fluid administration 2–12 hours before starting methotrexate, depending upon a patient's fluid status
- Urine output should be at least 100 mL/hour before starting methotrexate infusion
- Urine pH should be ≥7.0 but ≤8.0 before, during, and after methotrexate administration
- Maintain hydration at a rate that maintains urine output of at least 100 mL/hour until the serum methotrexate concentration is <0.1 μmol/L
- Adverse effects attributable to methotrexate are related to systemic methotrexate concentrations *and* the duration for which concentrations are maintained

Sodium bicarbonate 50–150 mEq/1000 mL is added to parenteral hydration solutions to maintain urine pH ≥7.0 to ≤8.0

Base Solution Sodium Content	Sodium Bicarbonate Additive	Total Sodium Content

Leucovorin Rescue Guidelines

Clinical Situation	Serum Methotrexate Concentration*	Leucovorin Dosage, Schedule, and Duration
Normal methotrexate elimination	• ≤10 µmol/L at 24 hours, *or* • ≤1 µmol/L at 48 hours, *or* • ≤0.2 µmol/L at 72 hours	• Give leucovorin calcium 10 mg/m² intravenously every 6 hours until serum methotrexate concentrations are <0.1 µmol/L (<1 × 10^{-7} mol/L, or <100 nmol/L), then give leucovorin calcium 25 mg orally every 6 hours for 8 doses
Delayed/late methotrexate elimination	• ≥10 µmol/L at 24 hours, *or* • ≥1 µmol/L at 48 hours, *or* • ≥0.1 µmol/L at 72 hours, *or* • ≥0.05 µmol/L at 96 hours, *or* • ≥100% increase in serum creatinine concentration at 24 hours after methotrexate administration	• Give leucovorin calcium 100 mg/m² intravenously every 3 hours • When serum methotrexate concentration results are <0.1 µmol/L the leucovorin dosage may be decreased to 10 mg/m² intravenously given every 3 hours until the serum methotrexate concentration is <0.05 µmol/L or undetectable

*After methotrexate administration is begun
Methotrexate concentration conversions: 1 µmol/L = 10^{-6} mol/L = 1000 nmol/L

Toxicity

Toxicity	G2	G3	G4	G5	Total
Anemia	1	2	0	0	3
Fatigue	6	1	0	0	7
Hepatic	2	1	0	0	3
Hyperglycemia	6	2	0	0	8
Neutropenia without fever	1	4	0	0	5
Nausea	2	0	0	0	2
Renal	13	4	2	0	19
Thrombophlebitis	0	2	0	0	2
Totals	31	16	2	0	49

Treatment Monitoring

1. CBC with differential every week
2. Serum creatinine and liver function tests at the beginning of each cycle
3. Serum creatinine levels and serum methotrexate concentrations at 24 hours, 48 hours, and 72 hours after administration of methotrexate began, continuing at least until a serum methotrexate concentration ≤0.1 µmol/L is achieved

Efficacy (N = 40)

Following induction with 4–6 cycles of methotrexate/rituximab (N = 40)	
Complete radiographic response	24 (60%)
Partial radiographic response	8 (20%)*
Progressive disease	8 (20%)
Following maintenance methotrexate (N = 40)	
Progression during maintenance	4 (10%)
At conclusion of induction and maintenance methotrexate (N = 28)†	
Complete radiographic response	27/28
Partial radiographic response	1/28
Median OS	33.5 months (11–80 months)
Median PFS	21.0 months (95% CI, 13.8–28.2)
Entire cohort (N = 40)	
Median overall survival, entire cohort	29.0 months (95% CI, 19.7–38.3)
Probability of disease-free survival, <50 years	86% (6/7)
Probability of disease-free survival, 50–59 years	33% (4/12)
Probability of disease-free survival, 60–69 years	25% (1/4)
Probability of disease-free survival, >70 years	0 (0/17)

*Six of the 8 patients (75%) with a PR to induction methotrexate/rituximab converted to a complete response with maintenance methotrexate
†6–8 months of total therapy

RECURRENT MENINGIOMA

LONG-ACTING OCTREOTIDE ACETATE

Chamberlain MC et al. Neurology 2007;69:969–973

Long-acting octreotide acetate 30 mg; administer by intramuscular injection (intragluteally) every 4 weeks (total dose/cycle = 30 mg)

Note: If after 2 cycles of therapy a patient has achieved stable disease or a better response and has tolerated a 30-mg dose, the dose of long-acting octreotide acetate may be increased to 40 mg every 4 weeks for the third and subsequent cycles of therapy (total dose/cycle = 40 mg)
Note: For patients not previously treated with subcutaneously-administered octreotide acetate, it is recommended to start with the administration of subcutaneous octreotide at a dosage of 0.1 mg 3 times daily for a short period (approximately 2 weeks) to assess the response and systemic tolerability of octreotide before initiating the treatment with long-acting octreotide acetate
Note: Limited published data indicate somatostatin analogs might decrease the metabolic clearance of compounds known to be metabolized by cytochrome P450. Use with caution drugs mainly metabolized by CYP3A4 and which have a low therapeutic index (eg, quinidine, terfenadine)

Supportive Care

Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—*Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Treatment Modification
Asymptomatic gallstones	Continue long-acting octreotide acetate depending on reassessment of the benefit-to-risk ratio. Either way, no action is required except to continue monitoring with increased frequency if treatment with long-acting octreotide acetate is continued
Symptomatic gallstones	Long-acting octreotide acetate may be either stopped or continued, depending on reassessment of the benefit-to-risk ratio. Either way, the gallstones should be treated like any other symptomatic gallstones

Efficacy

Partial response	4/16
Stable disease	5/16
Progressive disease	7/16
6-Month progression-free survival	44% (7/16)
Median duration of response	5.0 months (range: 2–20+ months)
Median overall survival	7.5 months (range: 3–20+ months)

Treatment/Therapy Monitoring

1. Ultrasound examination of the gallbladder prior to commencing octreotide treatment and at approximately 6-month intervals throughout treatment
2. Monitor vitamin B_{12} levels in patients who have a history of vitamin B_{12} deprivation

Toxicity

Adverse Drug Reactions Reported in Clinical Studies

Gastrointestinal Disorders	
Very common	Diarrhea, abdominal pain, nausea, constipation, flatulence
Common	Dyspepsia, vomiting, abdominal bloating, steatorrhea, loose stools, discoloration of feces
Nervous System Disorders	
Very common	Headache
Common	Dizziness
Endocrine Disorders	
Common	Hypothyroidism, thyroid dysfunction (eg, decreased TSH, decreased total T_4, and decreased free T_4)
Hepatobiliary Disorders	
Very common	Cholelithiasis
Common	Cholecystitis, biliary sludge, hyperbilirubinemia
Metabolism and Nutrition Disorders*	
Very common	Hyperglycemia
Common	Hypoglycemia, impaired glucose tolerance, anorexia
Uncommon	Dehydration
General Disorders and Administration Site Reactions	
Very common	Localized pain at injection site
Laboratory Investigations	
Common	Elevated transaminase levels
Uncommon	Depressed vitamin B_{12} levels and abnormal Schilling tests
Skin and Subcutaneous Tissue Disorders	
Common	Pruritus, rash, alopecia
Respiratory Disorders	
Common	Dyspnea
Cardiac Disorders	
Common	Bradycardia
Uncommon	Tachycardia

Very common: ≥1/10; Common: ≥1/100, <1/10; Uncommon: ≥1/1000, <1/100
**Note:* Because of its inhibitory action on growth hormone, glucagon, and insulin release, long-acting somatostatin may affect glucose regulation. Postprandial glucose tolerance may be impaired. In some instances, a state of persistent hyperglycemia may be induced as a result of chronic administration

RECURRENT MENINGIOMA

INTERFERON ALFA

Chamberlain MC, Glantz MJ. Cancer 2008;113:2146–2151

Interferon alfa-2b 10 million Units/m²; administer subcutaneously every-other-day for 4 weeks (total dose/week [4 doses] = 40 million Units/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—*Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Toxicity

Toxicity	G2	G3	G4	G5	All Grades
Alopecia	1				1
Anemia	8	3			11
Constipation	3	1			4
Diarrhea	3				3
Fatigue	17	4	2		23
Granulocytopenia	2	1			3
Infection, neutropenia	1				1
Leukopenia	6	3			9
Nausea	4				4
Thrombocytopenia	2				2
Thrombophlebitis	2				2
Vomiting	2				2
Totals	51	12	2	0	65

Treatment Modifications

Adverse Event	Treatment Modification
G3/4 hematologic toxicity on day 1 of a cycle	Withhold interferon alfa-2b until all hematologic toxicity is G ≤2, then resume at 50% of the previous dose
G2/3/4 nonhematologic toxicity on day 1 of a cycle	Withhold interferon alfa-2b until all nonhematologic toxicity is G ≤1, then resume at 50% of the previous dose if toxicity was G3/4
G3/4 hematologic or nonhematologic toxicity after dosage reduced to 50%	Discontinue therapy
ALT/AST >5× to 10× the upper limit of normal range	Withhold interferon alfa-2b until adverse reactions abate, then resume at 50% of the previous dose

Efficacy

Intention to Treat (N = 35)

Median OS	8 months (range: 3–28 months; 95% confidence interval, 5.6–10.4 months)
PFS at 6 months	54%
PFS at 12 months	31%
Median time to tumor progression	7 months (range: 2–24 months; 95% confidence interval, 4.9–9.1 months)

Treatment Monitoring

1. CBC with differential, serum electrolytes, BUN, creatinine, and liver function tests initially 3 times per week, then every week, and, eventually, monthly
2. Serum TSH level at start of treatment and at 3 and 6 months

RECURRENT MENINGIOMA

HIGH-GRADE MENINGIOMA REFRACTORY TO RECURRENT SURGERY AND RADIATION HYDROXYUREA

Chamberlain MC. J Neurooncol 2012;107:315–321

Hydroxyurea 1000 mg/m^2 per day; administer orally, continually for 28 consecutive days, every 4 weeks (total dosage/cycle = 28,000 mg/m^2)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—*Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

6. Breast Cancer

Rachel C. Jankowitz, MD and Nancy E. Davidson, MD

Epidemiology

Incidence: 235,030 (male: 2,360; female: 232,670. Estimated new cases for 2014 in the United States)
123.8 per 100,000 females per year
Deaths: Estimated 40,430 in 2014 (male: 430; female: 40,000)
Median age: 61 years
Male to female ratio: 1:160

Stage at Presentation
Stage I: 49%
Stage II: 39%
Stage III: 7%
Stage IV: 5%

Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Pathology

Invasive Carcinoma

1. Ductal: 49–75%
2. Lobular: 5–16%
3. Medullary: 3–9%
4. Mucinous: 1–2%
5. Tubular: 1–3%

Ductal Carcinoma In Situ

1. Comedo
2. Cribriform
3. Micropapillary
4. Papillary
5. Solid

Harris JR et al. Disease of the Breast, 4th ed. Philadelphia: Lippincott Williams & Wilkins, 2010

Work-up

In situ:

1. History and physical
2. Bilateral diagnostic mammogram
3. Pathology review with ER status
4. Genetic counseling if patient is high risk for hereditary breast cancer

Stages I & II:

1. History and physical
2. CBC with platelets
3. LFTs and alkaline phosphatase
4. Diagnostic bilateral mammogram
5. Pathology review with ER/PR/HER-2 status
6. Genetic counseling if the patient is at high risk for hereditary breast cancer

Stage III:

1. History and physical
2. CBC with platelets
3. LFTs and alkaline phosphatase
4. Diagnostic bilateral mammogram
5. Pathology review with ER/PR/HER-2 status
6. Consider bone scan, abdominal ± pelvis CT or US or MRI, and chest imaging
7. Genetic counseling if the patient is at high risk for hereditary breast cancer

Stage IV:

1. History and physical
2. CBC with platelets
3. LFTs and alkaline phosphatase
4. Diagnostic bilateral mammogram
5. Pathology review with ER/PR/HER-2 status
6. Chest imaging
7. Bone scan, X-rays of symptomatic bones and long or weight-bearing bones and bones abnormal on bone scan
8. Consider abdominal ± pelvis CT or MRI
9. Biopsy at first recurrence with pathology review
10. Genetic counseling if the patient is at high risk for hereditary breast cancer

Staging

Primary Tumor (T)

TX	Primary tumor cannot be assessed
T0	No evidence of primary tumor
Tis	Carcinoma in situ
Tis (DCIS)	Ductal carcinoma in situ
Tis (LCIS)	Lobular carcinoma in situ
Tis (Paget)	Paget disease of the nipple is NOT associated with invasive carcinoma and/or carcinoma in situ (DCIS and/or LCIS) in the underlying breast parenchyma. Carcinomas in the breast parenchyma associated with Paget's disease are categorized based on the size and characteristics of the parenchymal disease, although the presence of Paget disease should still be noted
T1	Tumor ≤20 mm in greatest dimension
T1mi	Tumor ≤1 mm in greatest dimension
T1a	Tumor >1 mm but ≤5 mm in greatest dimension
T1b	Tumor >5 mm but ≤10 mm in greatest dimension
T1c	Tumor >10 mm but ≤20 mm in greatest dimension
T2	Tumor >20 mm but ≤50 mm in greatest dimension
T3	Tumor >50 mm in greatest dimension
T4	Tumor of any size with direct extension to the chest wall and/or to the skin (ulceration or skin nodules)*
T4a	Extension to the chest wall, not including only pectoralis muscle adherence/invasion
T4b	Ulceration and/or ipsilateral satellite nodules and/or edema (including peau d'orange) of the skin which do not meet the criteria for inflammatory carcinoma
T4c	Both T4a and T4b
T4d	Inflammatory carcinoma†

*Invasion of the dermis alone does not qualify as T4
†Inflammatory carcinoma is restricted to cases with typical skin changes involving a third or more of the skin of the breast. Although the histologic presence of invasive carcinoma invading dermal lymphatics is supportive of the diagnosis, it is not required, nor is dermal lymphatic invasion without typical clinical findings sufficient for a diagnosis of inflammatory breast cancer

Distant Metastasis (M)

M0	No clinical or radiographic evidence of distant metastases (no pathologic M0; use clinical M to complete stage group)
cM0(i+)	No clinical or radiographic evidence of distant metastases, but deposits of molecularly or microscopically detected tumor cells in circulating blood, bone marrow or other nonregional nodal tissue that are no larger than 0.2 mm in a patient without symptoms or signs of metastases
M1	Distant detectable metastases as determined by classic clinical and radiographic means and/or histologically proven larger than 0.2 mm

Regional Lymph Nodes (N)

NX	Regional lymph nodes cannot be assessed (eg, previously removed)
pNX*	Regional lymph nodes cannot be assessed (eg, previously removed, or not removed for pathologic study)
N0	No regional lymph node metastases
pN0	No regional lymph node metastasis identified histologically
pN0(i-)	No regional lymph node metastases histologically, negative IHC
pN0(i+)	Malignant cells in regional lymph node(s) no greater than 0.2 mm (detected by H&E or IHC including ITC)
pN0(mol-)	No regional lymph node metastases histologically, negative molecular findings (RT-PCR)
pN0(mol+)	Positive molecular findings (RT-PCR), but no regional lymph node metastases detected by histology or IHC
N1	Metastases to movable ipsilateral level I, level II axillary lymph node(s)
pN1	Micrometastases; or metastases in 1–3 axillary lymph nodes; and/or in internal mammary nodes with metastases detected by sentinel lymph node biopsy but not clinically detected‡
pN1mi	Micrometastases (greater than 0.2 mm and/or more than 200 cells, but none greater than 2.0 mm)
pN1a	Metastases in 1–3 axillary lymph nodes, at least 1 metastasis greater than 2.0 mm
pN1b	Metastases in internal mammary nodes with micrometastases or macrometastases detected by sentinel lymph node biopsy but not clinically detected‡
pN1c	Metastases in 1–3 axillary lymph nodes and in internal mammary lymph nodes with micrometastases or macrometastases detected by sentinel lymph node biopsy but not clinically detected‡
N2	Metastases in ipsilateral level I, level II axillary lymph nodes that are clinically fixed or matted; or in clinically detected* ipsilateral internal mammary nodes in the *absence* of clinically evident axillary lymph node metastases
pN2	Metastases in 4–9 axillary lymph nodes; or in clinically detected§ internal mammary lymph nodes in the *absence* of axillary lymph node metastases
N2a	Metastases in ipsilateral axillary lymph nodes fixed to one another (matted) or to other structures
pN2a	Metastases in 4–9 axillary lymph nodes (at least 1 tumor deposit greater than 2.0 mm)
N2b	Metastases only in clinically detected§ ipsilateral internal mammary nodes and in the *absence* of clinically evident axillary lymph node metastases

(*continued*)

Staging (*continued*)

Staging

0	Tis	N0	M0
IA	T1*	N0	M0
IB	T0	N1mi	M0
	T1*	N1mi	M0
IIA	T0	N1†	M0
	T1*	N1†	M0
	T2	N0	M0
IIB	T2	N1	M0
	T3	N0	M0
IIIA	T0	N2	M0
	T1*	N2	M0
	T2	N2	M0
	T3	N1	M0
	T3	N2	M0
IIIB	T4	N0	M0
	T4	N1	M0
	T4	N2	M0
Stage IIIC	Any T	N3	M0
Stage IV	Any T	Any N	M1

*T1 includes T1mi
†T0 and T1 tumors with nodal micrometastases only are excluded from Stage IIA and are classified Stage IB

Edge SB, Byrd DR, Compton CC, Fritz AG, Greene FL, Trotti A, editors. AJCC Cancer Staging Manual. 7th ed. New York: Springer; 2010

Adjusted Survival

	5-Year	8-Year
In situ	98%	97%
Stage I	96%	92%
Stage II	82%	72%
Stage III	53%	41%
Stage IV	17%	9%

SEER data (1977–1983) from Seidman et al. CA Cancer J Clin 1987;37(5):258–290

Regional Lymph Nodes (N) (*continued*)

pN2b	Metastases in clinically detected‡ internal mammary lymph nodes in the absence of axillary lymph node metastases
N3	Metastases in ipsilateral infraclavicular (level III axillary) lymph node(s) with or without level I, level II axillary lymph node involvement; or in clinically detected* ipsilateral internal mammary lymph node(s) with clinically evident level I, level II axillary lymph node metastases; or metastases in ipsilateral supraclavicular lymph node(s) with or without axillary or internal mammary lymph node involvement
pN3	Metastases in 10 or more axillary lymph nodes; or in infraclavicular (level III axillary) lymph nodes; or in clinically detected‡ ipsilateral internal mammary lymph nodes in the *presence* of 1 or more positive level I, level II axillary lymph nodes; or in more than 3 axillary lymph nodes and in internal mammary lymph nodes with micrometastases or macrometastases detected by sentinel lymph node biopsy but not clinically detected†; or in ipsilateral supraclavicular lymph nodes
N3a	Metastases in ipsilateral infraclavicular lymph node(s)
pN3a	Metastases in 10 or more axillary lymph nodes (at least 1 tumor deposit greater than 2.0 mm); or metastases to the infraclavicular (level III axillary lymph) nodes
N3b	Metastases in ipsilateral internal mammary lymph node(s) and axillary lymph node(s)
pN3b	Metastases in clinically detected‡ ipsilateral internal mammary lymph nodes in the *presence* of 1 or more positive axillary lymph nodes; or in more than 3 axillary lymph nodes and in internal mammary lymph nodes with micrometastases or macrometastases detected by sentinel lymph node biopsy but not clinically detected†
N3c	Metastases in ipsilateral supraclavicular lymph node(s)
pN3c	Metastases in ipsilateral supraclavicular lymph nodes

*Classification is based on axillary lymph node dissection with or without sentinel lymph node biopsy. Classification based solely on sentinel lymph node biopsy without subsequent axillary lymph node dissection is designated (sn) for "sentinel node," for example, pN0(sn)
†*Not clinically detected* is defined as not detected by imaging studies (excluding lymphoscintigraphy) or not detected by clinical examination
‡*Clinically detected* is defined as detected by imaging studies (excluding lymphoscintigraphy) or by clinical examination and having characteristics highly suspicious for malignancy or a presumed pathologic macrometastasis based on fine-needle aspiration biopsy with cytologic examination. Confirmation of clinically detected metastatic disease by fine-needle aspiration without excision biopsy is designated with an (f) suffix, for example, cN3a(f). Excisional biopsy of a lymph node or biopsy of a sentinel node, in the absence of assignment of a pT, is classified as a clinical N, for example, cN1. Information regarding the confirmation of the nodal status will be designated in site-specific factors as clinical, fine-needle aspiration, core biopsy, or sentinel lymph node biopsy. Pathologic classification (pN) is used for excision or sentinel lymph node biopsy only in conjunction with a pathologic T assignment
Note: Isolated tumor cell clusters (ITC) are defined as small clusters of cells not greater than 0.2 mm, or single tumor cells, or a cluster of fewer than 200 cells in a single histologic cross-section. ITCs may be detected by routine histology or by immunohistochemical (IHC) methods. Nodes containing only ITCs are excluded from the total positive node count for purposes of N classification but should be included in the total number of nodes evaluated

Expert Opinion

DCIS

- Local treatment consists of lumpectomy plus radiation versus mastectomy
- Tamoxifen is used to lower the likelihood of in-breast recurrence and/or contralateral DCIS and invasive breast cancer

Early Stage Breast Cancer

- Local treatment is lumpectomy plus radiation versus mastectomy
- Decisions regarding adjuvant therapy must be individualized, but general guidelines are outlined below
- Molecular assays such as the 21-gene recurrence score can be incorporated into decision making regarding chemotherapy treatment for patients with node-negative ER-positive disease
- In patients with ER-positive and/or PR-positive disease, adjuvant hormonal therapy should be used
- If ovarian suppression is given, it should be given with tamoxifen, not an aromatase inhibitor (AI)
- In women who are pre-/perimenopausal at diagnosis, tamoxifen with or without ovarian suppression/ablation should be used for 5 years. After 5 years, if a patient still is premenopausal, an additional 5 years of tamoxifen should be considered. If after 5 years, the patient is postmenopausal, consider an additional 5 years of tamoxifen or 5 years of an AI
- In women who are postmenopausal at diagnosis, an AI should be used in one of the following adjuvant dosing strategies based on assessment of risk and patient preference:
  - **Upfront** (AI for 5 years),
  - **Sequential** (tamoxifen for 2–3 years followed by an AI to complete 5 years of therapy *or* an AI for 2–3 years followed by tamoxifen to complete 5 years of therapy),
  - **Extended** (tamoxifen for 5 years followed by an AI for 5 years)
- At this time, there is no evidence to support continuing AI therapy beyond 5 years until trials in progress mature

Locally Advanced Breast Cancer

- Neoadjuvant chemotherapy incorporating an anthracycline and a taxane allows for higher rates of breast conservation than adjuvant chemotherapy
- Neoadjuvant endocrine therapy may be considered for hormone receptor-positive postmenopausal patients

Metastatic Disease

Chemotherapy: In general, single chemotherapy agents (monotherapy) may be used sequentially. If a rapid clinical response is needed, combination chemotherapy regimens may be used

Hormonal therapy: For patients with ER-positive and/or PR-positive disease without visceral involvement or with low-volume disease, hormonal therapy is preferred. For postmenopausal women there is a survival benefit with aromatase inhibitor vs. other endocrine therapies. For premenopausal women, ovarian suppression/ablation should be used with an AI if a patient has previously received tamoxifen

HER2-positive disease (IHC 3+ or FISH+): Trastuzumab and pertuzumab should be used in combination with a taxane for patients with ER- and PR-negative disease, and for patients with ER-positive and/or PR-positive disease whose tumors are refractory to endocrine therapies

Bone Disease Present: Add denosumab, zoledronic acid, or pamidronate disodium

SYSTEMIC ADJUVANT TREATMENT GUIDELINES

Less-Favorable Histologies: Ductal, Lobular, Mixed, and Metaplastic

1. **Hormone receptor-positive–HER2-negative**
   pT1, pT2, or pT3 and pN0 or pN1mi:
   Tumor ≤0.5 cm or microinvasive:
   - N0: consider adjuvant endocrine therapy
   - N1mi: Adjuvant endocrine therapy ± adjuvant chemotherapy

   Tumor >0.5 cm (consider 21-gene RT-PCR assay):
   - Assay not done: adjuvant endocrine therapy ± adjuvant chemotherapy
   - Low recurrence score (<18): adjuvant endocrine therapy
   - Intermediate recurrence score (18–30): adjuvant endocrine therapy ± adjuvant chemotherapy
   - High recurrence score (≥31): adjuvant endocrine therapy + adjuvant chemotherapy

   Node positive:
   - Adjuvant endocrine therapy + adjuvant chemotherapy

2. **Hormone receptor-positive–HER2-positive**
   pT1, pT2, or pT3 and pN0 or pN1mi:
   Tumor ≤0.5 cm or micro-invasive:
   - N0: consider adjuvant endocrine therapy
   - N1mi: adjuvant endocrine therapy ± adjuvant chemotherapy + trastuzumab

   Tumor 0.6–1.0 cm:
   - Adjuvant endocrine therapy ± adjuvant chemotherapy and trastuzumab

   Tumor >1.0 cm:
   - Adjuvant endocrine therapy + adjuvant chemotherapy + trastuzumab

   Node positive:
   - Adjuvant endocrine therapy + adjuvant chemotherapy + trastuzumab

3. **Hormone receptor-negative–HER2-positive**
   pT1, pT2, or pT3 and pN0 or pN1mi:
   Tumor ≤0.5 cm or micro-invasive:
   - N0: no adjuvant therapy
   - N1mi: consider adjuvant chemotherapy + trastuzumab

   Tumor 0.6–1.0 cm:
   - Consider adjuvant chemotherapy + trastuzumab

   Tumor >1.0 cm:
   - Adjuvant chemotherapy + trastuzumab

   Node positive:
   - Adjuvant chemotherapy + trastuzumab

4. **Hormone receptor-negative–HER2-negative:**
   pT1, pT2, or pT3 and pN0 or pN1mi:
   Tumor ≤0.5 cm or microinvasive:
   - N0: no adjuvant therapy
   - N1mi: Consider adjuvant chemotherapy

   Tumor 0.6–1.0 cm:
   - Consider adjuvant chemotherapy

   Tumor >1.0 cm:
   - Adjuvant chemotherapy

   Node positive:
   - Adjuvant chemotherapy

Favorable Histologies: Tubular, Colloid

1. **ER-positive and/or PR-positive**
   pT1, pT2, or pT3 and pN0 or pN1mi:
   Tumor <1.0 cm:
   - No adjuvant therapy

   Tumor 1.0–2.9 cm:
   - Consider adjuvant endocrine therapy

   Tumor ≥3.0 cm:
   - Adjuvant endocrine therapy

   Node positive:
   - Adjuvant endocrine therapy ± adjuvant chemotherapy

2. **ER-negative and PR-negative:**
   Repeat ER and PR status; if truly negative, treat as usual breast cancer histology

PREFERRED *ADJUVANT CHEMOTHERAPY REGIMENS*

Non-Trastuzumab Regimens

1. TAC (docetaxel/doxorubicin/cyclophosphamide)
2. Dose-dense AC (doxorubicin and cyclophosphamide) followed by paclitaxel every 2 weeks
3. AC (doxorubicin/cyclophosphamide) followed by weekly paclitaxel
4. TC (docetaxel and cyclophosphamide)
5. AC (doxorubicin/cyclophosphamide)

Other Adjuvant Regimens

1. FEC (fluorouracil/epirubicin/cyclophosphamide)
2. CMF (cyclophosphamide/methotrexate/fluorouracil)
3. AC (doxorubicin/cyclophosphamide) followed by docetaxel every 3 weeks
4. FEC followed by docetaxel
5. FEC followed by weekly paclitaxel

Trastuzumab-Containing Regimens

Preferred adjuvant trastuzumab-containing regimens:

Pertuzumab should be administered to patients receiving neoadjuvant therapy with ≥T2 or ≥N1, HER2-positive, early-stage breast cancer

1. TCH (docetaxel/carboplatin/trastuzumab)
2. AC (doxorubicin/cyclophosphamide) followed by a taxane + concurrent trastuzumab

Other adjuvant trastuzumab-containing regimens:

1. Docetaxel + trastuzumab followed by FEC (fluorouracil/epirubicin/cyclophosphamide)
2. AC (doxorubicin/cyclophosphamide) followed by docetaxel with trastuzumab

PREFERRED CHEMOTHERAPY FOR *METASTATIC BREAST CANCER (MBC)*

Single Agents

Anthracyclines:

1. Doxorubicin
2. Epirubicin
3. Doxorubicin HCl liposomal injection

Taxanes:

1. Paclitaxel (preferred agent with bevacizumab)
2. Docetaxel
3. Paclitaxel protein bound particles for injectable suspension (albumin-bound)

Antimetabolites:

1. Capecitabine
2. Gemcitabine

Other microtubule inhibitors:

1. Vinorelbine
2. Eribulin

Other Single Agents

1. Cyclophosphamide
2. Mitoxantrone
3. Cisplatin
4. Etoposide (oral)
5. Ixabepilone

Preferred Chemotherapy Combinations

1. FEC (fluorouracil/epirubicin/cyclophosphamide)
2. AC (doxorubicin/cyclophosphamide)
3. CMF (cyclophosphamide /methotrexate/fluorouracil)
4. Docetaxel/capecitabine
5. GT (gemcitabine/paclitaxel)

Other Combinations

1. Ixabepilone + capecitabine

Preferred First-line Agents for HER2-Positive Disease

1. Pertuzumab + trastuzumab + docetaxel
2. Pertuzumab + trastuzumab + paclitaxel

Other First-line Agents for HER2-Positive Disease

Trastuzumab alone or in combination with:

1. Paclitaxel + carboplatin
2. Paclitaxel
3. Docetaxel
4. Vinorelbine
5. Capecitabine

Preferred Agents for Trastuzumab-Exposed HER2-Positive Disease

1. ado-Trastuzumab emtansine (TDM-1)

Other Agents for Trastuzumab-exposed HER2-Positive Disease

1. Lapatinib + capecitabine
2. Trastuzumab + capecitabine
3. Trastuzumab + lapatinib

ADJUVANT, METASTATIC REGIMEN

DOCETAXEL + DOXORUBICIN + CYCLOPHOSPHAMIDE (TAC)

Nabholtz JM et al. J Clin Oncol 2001;19:314–321 [Treatment for metastatic disease]
Nabholtz J-M et al. Proc Am Soc Clin Oncol 2002;21:36a [Abstract 141; adjuvant treatment]

Premedication:
Dexamethasone 8 mg/dose; administer orally twice daily for 3 days, starting on the day before docetaxel administration (total dose/cycle = 48 mg)
Hydration with 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously 500 mL before starting cyclophosphamide and 500 mL after completing cyclophosphamide

Doxorubicin HCl 50 mg/m²; administer by intravenous injection over 3–5 minutes on day 1, every 3 weeks for 6 cycles (total dosage/cycle = 50 mg/m²), *followed by:*
Cyclophosphamide 500 mg/m²; administer intravenously in 100–500 mL 0.9% NS or 5% dextrose injection (D5W), over 15–60 minutes on day 1, every 3 weeks for 6 cycles (total dosage/cycle = 500 mg/m²), *followed by:*
Docetaxel 75 mg/m²; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a docetaxel concentration within the range 0.3–0.74 mg/mL over 60 minutes on day 1, every 3 weeks for 6 cycles (total dosage/cycle = 75 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL, by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Continue daily filgrastim until ANC ≥5000/mm³

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Steroid-associated gastritis
Add a **proton pump inhibitor** during steroid use to prevent gastritis and duodenitis

Treatment Modifications

Adverse Events	Treatment Modifications
Febrile neutropenia or documented infection after treatment	Reduce docetaxel dosage to 60 mg/m² during subsequent cycles
G3 or G4 nausea, vomiting, or diarrhea despite appropriate prophylaxis	Reduce doxorubicin dosage to 40 mg/m² during subsequent cycles
First episode of G3 or G4 stomatitis	Reduce doxorubicin dosage to 40 mg/m² during subsequent cycles
Second episode of G3 or G4 stomatitis	Reduce docetaxel dosage to 60 mg/m² during subsequent cycles
G3 or G4 neuropathy	Discontinue treatment
Other severe adverse events	Hold treatment until toxicity resolves to G ≤1, then resume at decreased dosages appropriate for the toxicity

Note: Dosages reduced for adverse events are not re-escalated

Patient Population Studied

Nabholtz JM et al. J Clin Oncol 2001;19:314–321 [Treatment for metastatic disease]
Nabholtz J-M et al. Proc Am Soc Clin Oncol 2002;21:36a [Abstract 141]

Study of 745 patients with node-positive primary breast cancer treated with adjuvant TAC and 54 patients with metastatic breast cancer and no prior chemotherapy for metastatic disease. All patients were anthracycline-naïve

Efficacy

Nabholtz J-M et al. 2002

	TAC (N = 745)	FAC (N = 746)
Disease-free survival*	82%	74%
Overall survival	TAC demonstrated a reduction in risk of 25% compared with FAC	

*Median follow-up was 33 months

Toxicity (N = 745)

Nabholtz J-M et al. 2002

Toxicity	Percent
Febrile neutropenia	24%
G3/4 infection	2.8%
G3/4 asthenia	11%
G3/4 stomatitis	7%
CHF	1.2%

Therapy Monitoring

Before each cycle: CBC with differential and platelet count, LFTs, and serum electrolytes

ADJUVANT REGIMEN

DOSE-DENSE DOXORUBICIN + CYCLOPHOSPHAMIDE, THEN PACLITAXEL EVERY 2 WEEKS (ddAC → P)

Citron ML et al. J Clin Oncol 2003;21:1431–1439

Note: Doxorubicin and cyclophosphamide (ddAC) are given in combination, followed sequentially by paclitaxel (P). Both ddAC and P are given for 4 complete cycles

Hydration with 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously 500 mL before starting cyclophosphamide and 500 mL after completing cyclophosphamide

Doxorubicin HCl 60 mg/m²; administer by intravenous injection over 3–5 minutes on day 1, every 14 days for 4 cycles (total dosage/cycle = 60 mg/m²)

Cyclophosphamide 600 mg/m²; administer intravenously in 100–500 mL 0.9% NS or 5% dextrose injection (D5W) over 15–60 minutes on day 1, every 14 days for 4 cycles (total dosage/cycle = 600 mg/m²)

Filgrastim 5 mcg/kg per day; administer subcutaneously for 7 consecutive days on days 3–9, every 14 days for 4 cycles

• Calculated doses may be rounded by ±10% to use the most economical combination of commercially available products (containing 300 mcg or 480 mcg)

After 4 cycles, doxorubicin + cyclophosphamide are followed by:

Premedication:

Dexamethasone 10 mg/dose; administer orally for 2 doses 12 hours and 6 hours before paclitaxel (total dose/cycle = 20 mg), *or*

Dexamethasone 20 mg; administer intravenously over 10–15 minutes, 30–60 minutes before paclitaxel (total dose/cycle = 20 mg)

Note: Dexamethasone doses may be gradually decreased in the absence of hypersensitivity reactions during repeated paclitaxel treatments

Diphenhydramine 50 mg; administer by intravenous injection 30–60 minutes before paclitaxel

Cimetidine 300 mg (or Ranitidine 50 mg, Famotidine 20 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer intravenously over 15–30 minutes, 30–60 minutes before paclitaxel

Paclitaxel 175 mg/m²; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 3 hours, on day 1, every 14 days for 4 cycles (total dosage/cycle = 175 mg/m²)

Filgrastim 5 mcg/kg per day; administer subcutaneously for 7 consecutive days on days 3–9, every 14 days for 4 cycles

• Calculated doses may be rounded by ±10% to use the most economical combination of commercially available products (containing 300 mcg or 480 mcg)

Supportive Care with Doxorubicin + Cyclophosphamide (AC) Chemotherapy

Antiemetic prophylaxis

*Emetogenic potential is **HIGH**. Potential for delayed symptoms*

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis, is indicated as described in the regimens

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Supportive Care with Paclitaxel (P) Chemotherapy

Antiemetic prophylaxis

Emetogenic potential is LOW

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis, is indicated as described in the regimens

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Events	Treatment Modifications
ANC <1000/mm³, or platelets <100,000/mm³ at start of cycle	Delay treatment until ANC ≥1000/mm³ and platelets ≥100,000/mm³. If a treatment delay is >3 weeks, consider decreasing implicated drug dosage by 25%
G3/4 nonhematologic toxicity	If adjustment indicated, decrease implicated drug dosage by 25%
G3/4 neuropathy	Discontinue paclitaxel

Patient Population Studied

Women with node-positive operable breast cancer. Chemotherapy was given adjuvantly after recovery from surgery. A total of 2005 females were randomly assigned to receive one of the following regimens: (1) Sequential A × 4 → P × 4 → C × 4 with doses every 3 weeks; (2) sequential A × 4 → P × 4 → C × 4 every 2 weeks with filgrastim; (3) concurrent AC × 4 → P × 4 every 3 weeks, or (4) concurrent AC × 4 → P × 4 every 2 weeks with filgrastim

Toxicity

	AC → P (N = 495)	A → P → C (N = 493)
Toxicity	G3/4	G3/4
Hematologic Toxicity		
Leukopenia	6%	<1%
Neutropenia	9%	3%
Thrombocytopenia	<1%	0
Anemia	<1%	<1%
RBC transfusions	13% of cycles	1% of cycles
Nonhematologic Toxicity		
Nausea	8%	7%
Vomiting	6%	4%
Diarrhea	1%	3%
Stomatitis	3%	1%
Cardiac function	<1%	1%
Phlebitis/thrombosis	1%	1%
Sensory	4%	4%
Myalgias/arthralgias	5%	5%
Infection	3%	4%

Efficacy

		Survival*	
		Disease-Free	Overall
Dose-dense regimens (every 2 weeks)	N = 988	82%	92%
Standard 3-week-interval regimens	N = 985	75%	90%

*Median follow-up of 36 months; no difference between sequential and concurrent arms in efficacy

Therapy Monitoring

Before each cycle: CBC with differential and platelet count, LFTs, and serum electrolytes

ADJUVANT REGIMEN

DOXORUBICIN + CYCLOPHOSPHAMIDE, THEN WEEKLY PACLITAXEL (AC → P)

Perez EA et al. J Clin Oncol 2001;19:4216–4223
Seidman AD et al. J Clin Oncol 1998;16:3353–3361
Sparano JA. N Engl J Med 2008;258:1663–1671

Hydration with 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously 500 mL before starting cyclophosphamide and 500 mL after completing cyclophosphamide

Doxorubicin HCl 60 mg/m^2; administer by intravenous injection over 3–5 minutes on day 1 every 21 days for 4 cycles (total dosage/cycle = 60 mg/m^2)
Cyclophosphamide 600 mg/m^2; administer intravenously in 100–500 mL 0.9% NS or 5% dextrose injection (D5W) over 30–60 minutes on day 1, every 21 days for 4 cycles (total dosage/cycle = 600 mg/m^2), *followed after 4 cycles by:*

Premedication:
Dexamethasone 10 mg/dose; administer orally for 2 doses at 12 hours and 6 hours before paclitaxel (total dose/cycle = 20 mg), *or*
Dexamethasone 20 mg; administer intravenously over 10–15 minutes, 30–60 minutes before starting paclitaxel (total dose/cycle = 20 mg)
Diphenhydramine 50 mg; administer intravenously 30 minutes prior to starting paclitaxel
Cimetidine 300 mg (or ranitidine 50 mg, or famotidine 20 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer intravenously over 15–30 minutes, 30–60 minutes before starting paclitaxel

Paclitaxel 80 mg/m^2 per dose; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 60 minutes, weekly for 12 consecutive weeks (total dosage/21-day cycle = 240 mg/m^2)

Supportive Care with Doxorubicin + Cyclophosphamide (AC) Chemotherapy
Antiemetic prophylaxis
*Emetogenic potential is **HIGH**. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Supportive Care with Paclitaxel (P) Chemotherapy
Antiemetic prophylaxis
*Emetogenic potential is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications: AC

Bear HD et al. J Clin Oncol 2003;21:4165–4174
Citron ML et al. J Clin Oncol 2003;21:1431–1439

Adverse Events	Treatment Modifications
Absolute neutrophil count (ANC) $<1500/mm^3$ or platelets $<100,000/mm^3$ at start of cycle*	Delay treatment until ANC $\geq 1500/mm^3$ and platelets $\geq 100,000/mm^3$. Give filgrastim after chemotherapy during subsequent cycles
First episode of febrile neutropenia	Give filgrastim after chemotherapy during subsequent cycles†
Second episode of febrile neutropenia	During subsequent cycles, consider prophylaxis with ciprofloxacin‡
Third episode of febrile neutropenia	Decrease both doxorubicin and cyclophosphamide dosages by 25%

*Although an ANC of $1500/mm^3$ is often identified as a minimum acceptable ANC to safely proceed with treatment, recent data shows that an ANC $\geq 1000/mm^3$ is acceptable if filgrastim is given after chemotherapy
†Filgrastim 5 mcg/kg per day; administer subcutaneously starting at least 24 hours after completing chemotherapy until ANC $>5000/mm^3$
‡Ciprofloxacin 500 mg orally twice daily for 7 consecutive days starting on day 5

Treatment Modifications: Paclitaxel

Adverse Events	Treatment Modifications
ANC $\leq 800/mm^3$ or platelets $\leq 50,000/mm^3$	Hold treatment until ANC $>800/mm^3$ and platelets $>50,000/mm^3$, then resume with weekly paclitaxel dosage reduced by 10 mg/m^2
G2 motor or sensory neuropathies	Reduce weekly paclitaxel dosage by 10 mg/m^2 without interrupting planned treatment
Other nonhematologic adverse events G2 or G3	Hold treatment until adverse events resolve to G ≤ 1, then resume with weekly paclitaxel dosage reduced by 10 mg/m^2
Patients who cannot tolerate paclitaxel at 60 mg/m^2 per week	Discontinue treatment
Treatment delay >2 weeks	Decrease weekly paclitaxel dosage by 10 mg/m^2 or consider discontinuing treatment

Patient Population Studied

Sparano JA. N Engl J Med 2008;258:1663–1671

Study of 4950 patients with operable, hormone receptor positive adenocarcinoma of the breast with either (a) histologically involved lymph nodes (tumor stage T1, T2, or T3 and nodal stage N1 or N2) or (b) "high-risk, axillary node-negative disease" (T2 or T3, N0) without distant metastases. Of the study patients, 88% were node-positive and 19% HER2neu+. All patients received 4 cycles of intravenous doxorubicin and cyclophosphamide at 3-week intervals and were assigned to intravenous paclitaxel or docetaxel given at 3-week intervals for 4 cycles or at 1-week intervals for 12 cycles. The primary end point was disease-free survival

Efficacy (N = 4950)

Sparano JA. N Engl J Med 2008;258:1663–1671

	Number of Patients	5-Year DFS (%)	Hazard Ratio for DFS*	5-Year OS (%)	Hazard Ratio for OS*
Paclitaxel every 3 weeks	1253	76.9	1	86.5	1
Weekly Paclitaxel	1231	81.5	1.27, p = 0.006	89.7	1.32, p = 0.01
Docetaxel every 3 weeks	1236	81.2	1.23, p = 0.020	87.3	1.13, p = 0.25
Weekly docetaxel	1230	77.6	1.09, p = 0.290	86.2	1.02, p = 0.80

DFS, Disease-free survival; OS, overall survival
*Hazard ratio >1 favors the group receiving that therapy

Toxicity of Paclitaxel and Docetaxel

Sparano JA. N Engl J Med 2008;258:1663–1671

	Paclitaxel Every 3 Weeks	Weekly Paclitaxel	Docetaxel Every 3 Weeks	Weekly Docetaxel
Toxicity*	Percent			
Neutropenia†	4	2	46	3
Febrile neutropenia†	<1	1	16	1
Infection	3	3	13	4
Stomatitis	<1	0	5	2
Fatigue	2	3	9	11
Myalgia	7	2	6	1
Arthralgia	6	2	6	1
Lacrimation	<1	0	<1	5
G3/4 neuropathy	5	8	4	6
G2/3/4 neuropathy	20	27	16	16

*Tabulation of G3/4 toxic effects and G2/3/4 neuropathies resulting from the taxane component of therapy that occurred in at least 5% of all treated patients
†Information on only G4 neutropenia (ANC $<500/mm^3$) was collected

Therapy Monitoring

1. *Weekly:* CBC with differential and platelet count
2. *Monthly:* LFTs and serum electrolytes

ADJUVANT REGIMEN

DOCETAXEL + CYCLOPHOSPHAMIDE (TC) EVERY 3 WEEKS × 4 CYCLES

Jones S et al. J Clin Oncol 2006;24:5381–5387
Jones S et al. J Clin Oncol 2009;27:1177–1183

Hydration with 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously 500 mL before starting cyclophosphamide and 500 mL after completing cyclophosphamide

Premedication:
Dexamethasone 8 mg/dose; administer orally every 12 hours for 3 days starting on the day before docetaxel administration (total dose/cycle = 48 mg)
Docetaxel 75 mg/m²; administer intravenously in a volume of 0.9% NS or 5% dextrose injection (D5W) sufficient to produce a docetaxel concentration within the range 0.3–0.74 mg/mL over 30–60 minutes on day 1 every 21 days for 4 cycles (total dosage/cycle = 75 mg/m²)
Cyclophosphamide 600 mg/m²; administer intravenously in 100–500 mL 0.9% NS or D5W over 30–60 minutes on day 1 every 21 days for 4 cycles (total dosage/cycle = 600 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Steroid-associated gastritis
Add a **proton pump inhibitor** during steroid use to prevent gastritis and duodenitis

Efficacy

	7-Year DFS		7-Year OS	
TC × 4 (N = 506)	81%	HR = 0.74 [95% CI, 0.56–0.98] $P = 0.033$	87%	HR = 0.69 [95% CI, 0.50–0.97] $P = 0.032$
AC × 4 (N = 510)	75%		82%	

Unplanned, exploratory analyses of disease-free survival hazard ratios (HR) and CI

	Hazard Ratio	95% Confidence Interval (CI)
HER2− (TC = 55; AC = 69)	0.56	0.30–1.05
HER2+ (TC = 28; AC = 18)	0.73	0.32–1.70
ER− and PR− (TC = 136; AC = 158)	0.70	0.44–1.10
ER+ or PR+ (TC = 368; AC = 351)	0.79	0.56–1.13
Age ≥65 (TC = 78; AC = 82)	0.70	0.40–1.24
Age <65 (TC = 428; AC = 428)	0.76	0.55–1.04

AC, doxorubicin + cyclophosphamide; DFS, Disease-free survival; ER, estrogen receptor; OS, overall survival; PR, progesterone receptor; TC, docetaxel + cyclophosphamide

Treatment Modifications

Patients were taken off treatment if administration of any study drug was delayed more than 2 weeks as a result of drug-related toxicities. *No dose reductions were permitted.* No prophylactic growth factors were used and the use of oral prophylactic antibiotics was at the discretion of the treating physician

Patient Population Studied

Phase III randomized prospective clinical trial comparing 4 cycles of doxorubicin + cyclophosphamide (AC) with 4 cycles of docetaxel + cyclophosphamide (TC) as adjuvant chemotherapy in 1016 women with operable stages I to III invasive breast cancer. Eligible patients had a Karnofsky performance status of ≥80% and no evidence of metastatic disease. Before treatment, a complete surgical excision of the primary tumor (lumpectomy and axillary dissection or modified radical mastectomy) was performed. Neoadjuvant chemotherapy was *not* permitted. Eligible primary tumor size was ≥1.0 cm and <7.0 cm. Patients were randomly assigned to 4 cycles of either standard-dose AC (60 and 600 mg/m², respectively) or TC (75 and 600 mg/m², respectively) administered on day 1 of each 21-day cycle for 4 cycles as adjuvant treatment after complete surgical excision of the primary tumor. Chemotherapy was administered before radiation therapy (XRT) when XRT was indicated (breast conservation or postoperative XRT for patient with 4 or more involved axillary lymph nodes). On completion of 4 cycles of chemotherapy (±XRT), tamoxifen was administered to all patients with hormone receptor-positive breast cancer for 5 years. The majority (71%) of patients had breast cancer that was estrogen receptor (ER)-positive and/or progesterone receptor (PR)-positive. The number of patients with node-negative disease was balanced between groups (47% TC and 49% AC); 12% of TC and 9% of AC patients had ≥4 positive nodes

Toxicity*

Frequency of Most Common Adverse Events (All Grades)*

	TC Patients (N = 506)				AC Patients (N = 510)

Age <65 (TC = 428; AC = 428)	0.76	0.55–1.04

AC, doxorubicin + cyclophosphamide; DFS, Disease-free survival; ER, estrogen receptor; OS, overall survival; PR, progesterone receptor; TC, docetaxel + cyclophosphamide

ADJUVANT, METASTATIC REGIMEN

CYCLOPHOSPHAMIDE + EPIRUBICIN + FLUOROURACIL (FEC 100)

Bonneterre et al. J Clin Oncol 2004;22:3070–3079
French Adjuvant Study Group. J Clin Oncol 2001;19:602–611

Fluorouracil 500 mg/m²; administer by intravenous injection over 1–3 minutes on day 1, every 21 days for 6 cycles (total dosage/cycle = 500 mg/m²)
Epirubicin HCl 100 mg/m²; administer by intravenous injection over 3–5 minutes on day 1, every 21 days for 6 cycles (total dosage/cycle = 100 mg/m²)

Hydration with 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously 500 mL before starting cyclophosphamide and 500 mL after completing cyclophosphamide
Cyclophosphamide 500 mg/m²; administer intravenously in 100–500 mL 0.9% NS or 5% dextrose injection over 15–60 minutes on day 1, every 21 days for 6 cycles (total dosage/cycle = 500 mg/m²)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **HIGH**. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Continue daily filgrastim until ANC ≥5000/mm³

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Premenopausal and postmenopausal women with histologically proven axillary lymph node involvement (at least 5 axillary nodes resected) with more than 3 positive nodes or between 1 and 3 positive nodes with Scarff-Bloom-Richardson (SBR) grade ≥2 and hormone receptor negativity (both estrogen and progesterone) were enrolled. Postmenopausal status was defined as an amenorrhea for at least 1 year. Main eligibility criteria included a World Health Organization (WHO) performance status ≤2, no cardiac dysfunction (baseline left ventricular ejection fraction [LVEF] ≥50%). Patients were randomized after surgery to receive either fluorouracil 500 mg/m², epirubicin 50 mg/m², and cyclophosphamide 500 mg/m² every 21 days for 6 cycles (FEC 50), or the same regimen except with epirubicin dose of 100 mg/m² (FEC 100). Treatment was begun within 42 days of surgery

Treatment Modifications

Adverse Events	Treatment Modifications
ANC <1500/mm³, or platelets <100,000/mm³ at start of cycle	Delay treatment until ANC ≥1500/mm³ and platelets ≥100,000/mm³
Hematologic recovery >3 weeks	Discontinue treatment
First episode of febrile neutropenia	During subsequent cycles, consider prophylaxis with ciprofloxacin*
Second episode of febrile neutropenia	Decrease chemotherapy doses by 20% (epirubicin by 20 mg/m², fluorouracil and cyclophosphamide by 100 mg/m²) and administer ciprofloxacin*
First episode of G4 documented infection	Add ciprofloxacin prophylaxis during subsequent cycles*
Second episode of G4 documented infection	Decrease chemotherapy doses by 20% (epirubicin by 20 mg/m², fluorouracil and cyclophosphamide by 100 mg/m²) and administer ciprofloxacin*
Third episode of G4 documented infection	Discontinue chemotherapy
Serum total bilirubin levels 2 to 3 mg/dL (34.2 to 51.3 mmol/L)	Reduce epirubicin dose by 50%
Serum bilirubin levels ≥3 mg/dL (≥51.3 mmol/L)	Discontinue treatment

*Ciprofloxacin 500 mg orally twice daily for 7 consecutive days starting on day 5

Efficacy

5-Year DFS and OS Rates

	5-Year DFS			5-Year OS		
Group	FEC 50	FEC 100		FEC 50	FEC 100	
All patients	54.8%	66.3%	P = 0.03	65.3%	77.4%	P = 0.007
1–3 Nodes	77.6%	71.0%	P = 0.42	83.8%	78.2%	P = 0.63
>3 Nodes	49.6%	65.3%	P = 0.005	60.9%	77.2%	P = 0.001

DFS, Disease-free survival; FEC 50, fluorouracil + cyclophosphamide + epirubicin 50 mg/m²; FEC 100, fluorouracil + cyclophosphamide + epirubicin 100 mg/m²; OS, overall survival

Toxicity

	FEC 50 (N = 278)		FEC 100 (N = 268)		
Toxicity	G1/2	G3/4	G1/2	G3/4	P Value
Hematologic Toxicity					
Neutropenia	43.5%	11.1%	30.1%	25.2%	0.001
Anemia	11.1%	0	41.6%	0.8%	0.001
Nonhematologic Toxicity					
Nausea/vomiting	61.6%	23.3%	58%	34.7%	0.008
Stomatitis	7.8%	0	24.1%	3.8%	0.001
Infection	15.9%	0	17.2%	3.4%	0.003
Cardiac, all	6/278		4/268		
Cardiac, acute	1/278 (MI)		1/268 (↓LVEF)		
Cardiac, delayed	5/278		3/268		

After more than 8 years of follow-up, the cardiac toxicity observed after adjuvant treatment with FEC 100 consists of 2 cases of well-controlled congestive heart failure and 18 cases of asymptomatic left ventricular dysfunction. In the majority of women with primary breast cancer, the benefits of treatment with FEC 100 in terms of disease-free and overall survival outweigh the risks, and cardiac risk factors should be carefully evaluated in patient selection

Therapy Monitoring

1. *Weekly:* CBC with differential and platelet count
2. *Before each cycle:* CBC with differential and platelet count, LFTs, and serum electrolytes

ADJUVANT, METASTATIC REGIMEN

CYCLOPHOSPHAMIDE + METHOTREXATE + FLUOROURACIL (CMF; ORAL)

Amadori D et al. J Clin Oncol 2000;18:3125–3134

Cyclophosphamide 100 mg/m² per day; administer orally for 14 consecutive days on days 1–14, every 4 weeks for 6 cycles, (total dosage/cycle = 1400 mg/m²)
Note: Encourage patients to supplement their usual oral hydration with (extra) non–alcohol-containing fluids, 1000–2000 mL/day, to take cyclophosphamide doses at the beginning of a waking cycle, and to void urine frequently while taking cyclophosphamide
Methotrexate 40 mg/m² per dose; administer by intravenous injection over ≤1 minute for 2 doses on days 1 and 8, every 4 weeks for 6 cycles (total dosage/cycle = 80 mg/m²)
Fluorouracil 600 mg/m² per dose; administer by intravenous injection over 1–3 minutes for 2 doses on days 1 and 8, every 4 weeks for 6 cycles (total dosage/cycle = 1200 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on Days 1–14 is LOW–MODERATE
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Events	Treatment Modifications
WBC <3500/mm³ or platelets <100,000/mm³ on first day of a cycle	Delay treatment for a maximum of 2 weeks until WBC >3500/mm³ and platelets >100,000/mm³. Continue at full dosages if counts recover within 2 weeks
If after 2 weeks WBC <3500/mm³ or platelets <100,000/mm³ reduce all drugs' dosages as follows:	
WBC 3000–3499/mm³, or platelets 75,000–99,999/mm³	Reduce dosages by 25%
WBC 2500–2999/mm³ and platelets ≥75,000/mm³	Reduce dosages by 50%
WBC <2500/mm³, or platelets <75,000/mm³	Hold treatment
ANC <1500/mm³, or platelets <100,000/mm³ at start of cycle	Delay treatment until ANC ≥1500/mm³ and platelets ≥100,000/mm³. Give filgrastim* in subsequent cycles
Hematologic recovery >3 weeks	Discontinue treatment
First episode of febrile neutropenia	Give filgrastim* during subsequent cycles
Second episode of febrile neutropenia	During subsequent cycles, consider prophylaxis with ciprofloxacin†
Third episode of febrile neutropenia	Decrease chemotherapy doses by 20% and administer filgrastim* + ciprofloxacin†
First episode of G4 documented infection	Add filgrastim* and ciprofloxacin† prophylaxis during subsequent cycles
Second episode of G4 documented infection	Decrease chemotherapy doses by 20% and administer filgrastim* + ciprofloxacin†
Third episode of G4 documented infection	Discontinue chemotherapy
G3 stomatitis	Reduce methotrexate and fluorouracil dosage by 50% during subsequent cycles
G4 non-hematologic toxicity	Discontinue chemotherapy

*Filgrastim 5 mcg/kg per day; administer subcutaneously for 8 consecutive days (days 3–10)
†Ciprofloxacin 500 mg orally twice daily for 7 consecutive days starting on day 5

Patient Population Studied

Amadori D et al. J Clin Oncol 2000;18:3125–3134

Study of 281 women with node-negative resectable breast cancer. CMF was given as adjuvant therapy within 6 weeks of surgery. All patients had rapidly proliferating tumors as determined by thymidine-labeling index

Toxicity

Boccardo F et al. J Clin Oncol 2000;18:2718–2727
Bonnadonna G et al. N Engl J Med 1976;294:405–410

Toxicity (N = 207)	% of Patients
Leukocytes = 2500–3900/mm^3	67%
Leukocytes <2500/mm^3	4%
Platelets = 75,000–129,000/mm^3	57%
Platelets <75,000/mm^3	14%
Oral mucositis	18%
Conjunctivitis	25%
Hair loss	55%
Cystitis	28%
Amenorrhea	54%
Febrile neutropenia	3%

Efficacy

Early Breast Cancer Trialists' Collaborative Group. Lancet 1998;352:930–942

Absolute Risk Reduction with Adjuvant Chemotherapy (Primarily CMF)

	5-year	
	Recurrence	Mortality
Node+, Age <50 years	15.4%	12.4%
Node+, Age >50 years	5.4%	2.3%
Node−, Age <50 years	10.4%	5.7%
Node−, Age >50 years	5.7%	6.4%

Note: Anthracycline-containing regimens may be superior to CMF with additional absolute risk reductions of 3.2% for recurrence and 2.7% for mortality

Therapy Monitoring

Before each cycle: CBC with differential and platelet counts

ADJUVANT, NEOADJUVANT REGIMEN

DOXORUBICIN + CYCLOPHOSPHAMIDE THEN DOCETAXEL EVERY 3 WEEKS (AC → T)

Bear HD et al. J Clin Oncol 2003;21:4165–4174

AC (Doxorubicin + Cyclophosphamide) × 4 cycles
Hydration with 0.9% sodium chloride injection (0.9% NS); administer intravenously 500 mL before and 500 mL after cyclophosphamide

Doxorubicin HCl 60 mg/m²; administer by intravenous injection over 3–5 minutes on day 1, every 21 days for 4 cycles (total dosage/cycle = 60 mg/m²)
Cyclophosphamide 600 mg/m²; administer intravenously in 100–500 mL 0.9% NS or 5% dextrose injection (D5W), over 15–60 minutes on day 1, every 21 days for 4 cycles (total dosage/cycle = 600 mg/m²), *followed after 4 cycles by:*

T (Docetaxel) × 4 cycles
Premedication:
Dexamethasone 8 mg/dose; administer orally twice daily for 3 days, starting on the day before docetaxel administration (total dose/cycle = 48 mg)

Docetaxel 100 mg/m²; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a docetaxel concentration within the range 0.3–0.74 mg/mL over 60 minutes on day 1, every 21 days for 4 cycles (total dosage/cycle = 100 mg/m²)

Supportive Care for Doxorubicin + Cyclophosphamide (AC) Chemotherapy
Antiemetic prophylaxis
*Emetogenic potential is **HIGH**. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Supportive Care for Docetaxel (T) Chemotherapy
Antiemetic prophylaxis
*Emetogenic potential is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL, by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Steroid-associated gastritis
Add a **proton pump inhibitor** during steroid use to prevent gastritis and duodenitis

Patient Population Studied

Study of 1584 women with primary breast cancer with tumor size >1 cm *or* lymph nodes with clinical evidence of malignant disease. Regimen was given as neoadjuvant therapy in this study, but is also often given as adjuvant therapy in node-positive disease. The regimen is 1 of 3 arms in NSABP B-30

Efficacy (N = 752/1534)

Neoadjuvant Therapy	AC → T (N = 752)	AC (N = 1534)
Overall response	91%	85%
CR (pathologic)	26%	13%

Toxicity (for Docetaxel) (N = 1584)

NCI Common Toxicity Criteria (CTC)

Toxicity	G3	G4
Neutropenia	2%	<0.5%
Febrile neutropenia	NA	21%
Infection	0.7%	6%
Nausea/vomiting	0.5%	0.4%
Stomatitis	2.2%	0.4%
Diarrhea	NR	0.6%
Thrombosis	NR	0.7%
Allergy	NR	0.3%
Neuropathy	2.3%	0.1%

Therapy Monitoring

Before each cycle: CBC with differential and platelet count, LFTs, and serum electrolyte

Treatment Modifications

Doxorubicin and Cyclophosphamide

Adverse Events	Treatment Modifications
ANC <1500/mm³, or platelets <100,000/mm³ at start of cycle*	Delay treatment until ANC ≥1500/mm³ and platelets ≥100,000/mm³. Administer filgrastim† during subsequent cycles*
First episode of febrile neutropenia	Give filgrastim during subsequent cycles
Second episode of febrile neutropenia	Consider ciprofloxacin‡ prophylaxis in subsequent cycles
Third episode of febrile neutropenia	Decrease both doxorubicin and cyclophosphamide dosages by 25% and administer ciprofloxacin‡
First episode of G4 documented infection	Add filgrastim† and ciprofloxacin‡ prophylaxis during subsequent cycles
Second episode of G4 documented infection	Decrease both doxorubicin and cyclophosphamide dosages by 25%. Administer filgrastim† and ciprofloxacin‡ during subsequent cycles
Third episode of G4 documented infection	Discontinue chemotherapy

Docetaxel

Adverse Events	Treatment Modifications
ANC <1500/mm³ on day of planned treatment*	Delay treatment until ANC ≥1500/mm³; administer filgrastim† during subsequent cycles*
First episode of febrile neutropenia	Reduce docetaxel dosage to 75 mg/m² during subsequent cycles
Second episode of febrile neutropenia	Continue docetaxel 75 mg/m² and give filgrastim† during subsequent cycles
Third episode of febrile neutropenia	Add ciprofloxacin‡
First episode of G4 documented infection	Reduce docetaxel dosage to 75 mg/m² during subsequent cycles
Second episode of G4 documented infection	Continue docetaxel at 75 mg/m² per dose and give filgrastim† and ciprofloxacin‡ during subsequent cycles
Third episode of G4 documented infection	Discontinue docetaxel

*Although an ANC of 1500/mm³ is often identified as a minimum acceptable ANC to safely proceed with treatment, recent data shows that an ANC ≥1000/mm³ is acceptable if filgrastim is given after chemotherapy
†Filgrastim 5 mcg/kg per day; administer subcutaneously starting at least 24 hours after completing chemotherapy until ANC ≥5000/mm³
‡Ciprofloxacin 500 mg orally twice/day for 7 days starting on day 5

ADJUVANT REGIMEN

CYCLOPHOSPHAMIDE + EPIRUBICIN + FLUOROURACIL (FEC) × 3 CYCLES → DOCETAXEL × 3 CYCLES

Roché HJ. Clin Oncol 2006;24:5664–5671

FEC (Cyclophosphamide + Epirubicin + Fluorouracil) × 3 cycles
Hydration before and after cyclophosphamide with 0.9% sodium chloride injection (0.9% NS); administer intravenously 500 mL before starting cyclophosphamide and 500 mL after completing cyclophosphamide

Fluorouracil 500 mg/m²; administer by intravenous injection over 1–3 minutes on day 1, every 21 days for 3 cycles (total dosage/cycle = 500 mg/m²)
Epirubicin HCl 100 mg/m²; administer by intravenous injection over 3–5 minutes on day 1, every 21 days for 3 cycles (total dosage/cycle = 100 mg/m²)
Cyclophosphamide 500 mg/m²; administer intravenously in 100–500 mL 0.9% NS or 5% dextrose injection (D5W) over 30–60 minutes on day 1, every 21 days for 3 cycles (total dosage/cycle = 500 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Docetaxel × 3 cycles
Premedication:
Dexamethasone 8 mg/dose; administer orally twice daily for 3 days, starting on the day before docetaxel administration (total dose/cycle = 48 mg)
Docetaxel 100 mg/m²; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a final docetaxel concentration of 0.3–0.74 mg/mL over 30–60 minutes on day 1, every 21 days for 3 cycles (total dosage/cycle = 100 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection, *or*
Sargramostim (GM-CSF) 250 mcg/m² per day, by subcutaneous injection
- Begin use from 24–72 h after myelosuppressive chemotherapy is completed

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Events	Treatment Modifications
WBC <3500/mm^3 or platelets <100,000/mm^3 on first day of a cycle	Delay treatment for a maximum of 2 weeks until WBC >3500/mm^3 and platelets >100,000/mm^3. Continue at full dosages if counts recover within 2 weeks
If after 2 weeks WBC <3500/mm^3 or platelets <100,000/mm^3, reduce all drugs' dosages as follows:	
WBC 3000–3499/mm^3, or platelets 75,000–99,999/mm^3	Reduce dosages by 25%
WBC 2500–2999/mm^3 and platelets ≥75,000/mm^3	Reduce dosages by 50%
WBC <2500/mm^3, or platelets <75,000/mm^3	Hold treatment
ANC <1500/mm^3, or platelets <100,000/mm^3 at start of cycle	Delay treatment until ANC ≥1500/mm^3 and platelets ≥100,000/mm^3. Give filgrastim* in subsequent cycles
Hematologic recovery >3 weeks	Discontinue treatment
Second episode of febrile neutropenia	During subsequent cycles, consider prophylaxis with ciprofloxacin†
Third episode of febrile neutropenia	Decrease chemotherapy doses by 20% (epirubicin by 20 mg/m^2, fluorouracil and cyclophosphamide by 100 mg/m^2, and docetaxel by 20 mg/m^2) and administer filgrastim* + ciprofloxacin†
First episode of G4 documented infection	During subsequent cycles, consider prophylaxis with ciprofl oxacin†
Second episode of G4 documented infection	Decrease chemotherapy doses by 20% (epirubicin by 20 mg/m^2, fluorouracil and cyclophosphamide by 100 mg/m^2, and docetaxel by 20 mg/m^2) and administer filgrastim* + ciprofloxacin†
Third episode of G4 documented infection	Discontinue chemotherapy
Serum bilirubin levels 2–3 mg/dL (34.1–51.3 mmol/L)	Reduce epirubicin dose by 50%
Bilirubin levels ≥3 mg/dL (≥51.3 mmol/L)	Discontinue treatment
G3 stomatitis	Reduce epirubicin and fluorouracil dosage by 50% during subsequent cycles
G4 nonhematologic toxicity	Discontinue chemotherapy
G2 motor or sensory neuropathies	Reduce docetaxel dosage by 20–50 mg/m^2
G3/4 motor or sensory neuropathies	Discontinue docetaxel

*Filgrastim 5 mcg/kg per day; administer subcutaneously starting at least 24 hours after completing chemotherapy until ANC ≥5000/mm^3
†Ciprofloxacin 500 mg; administer orally twice daily for 7 days starting on day 5

Patient Population Studied

Study of 1999 patients with operable node-positive breast cancer who were randomly assigned to receive fluorouracil 500 mg/m^2, epirubicin 100 mg/m^2, and cyclophosphamide 500 mg/m^2 (FEC) intravenously on day 1 every 21 days for 6 cycles or the same regimen of FEC for 3 cycles followed by docetaxel 100 mg/m^2 intravenously on day 1 every 21 days for 3 cycles

Efficacy

Analysis of Events in the ITT Population

	FEC (N = 996)		FEC-D (N = 1003)				
	No of Pts	%	No of Pts	%	HR	95%CI	p*

G3/4 Nausea-vomiting, cycles 4–6	11	1.6	<0.001
G3/4 Stomatitis	4.0	5.9	0.054
G3/4 Stomatitis, cycles 4–6	2.3	4.0	0.030
Alopecia grade 3	83.9	82.6	0.40
Edema moderate or severe, cycles 4–6	0.3	4.8	<0.001
Nail disorder moderate or severe, cycles 4–6	1.0	10.3	<0.001
Any cardiac event reported as SAE†	1.3	0.4	0.030

*Toxicity graded according to WHO criteria and serious adverse events (SAEs) defined according to International Conference on Harmonization (ICH) guidelines
†Although rare overall, there were fewer cardiac events after FEC-D (P = 0.03), attributable mainly to the lower anthracycline cumulative dose

Therapy Monitoring

1. *Before each cycle:* CBC with differential and platelet count, serum total bilirubin
2. *Before each cycle with docetaxel:* Neurologic examination

ADJUVANT REGIMEN

CYCLOPHOSPHAMIDE + EPIRUBICIN + FLUOROURACIL (FEC) × 4 CYCLES → WEEKLY PACLITAXEL × 8 CYCLES

Martin et al. J Natl Cancer Inst 2008;100:805–814

FEC × 4 cycles
Hydration with 0.9% sodium chloride injection (0.9% NS); administer intravenously 500 mL before starting cyclophosphamide and 500 mL after completing cyclophosphamide

Fluorouracil 600 mg/m²; administer by intravenous injection over 1–3 minutes on day 1, every 21 days for 4 cycles (total dosage/cycle = 600 mg/m²)
Epirubicin HCl 90 mg/m²; administer by intravenous injection over 3–5 minutes on day 1, every 21 days for 4 cycles (total dosage/cycle = 90 mg/m²)
Cyclophosphamide 600 mg/m²; administer intravenously in 100–500 mL 0.9% NS or 5% dextrose injection (D5W) over 30–60 minutes on day 1, every 21 days for 4 cycles (total dosage/cycle = 600 mg/m²)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **HIGH**. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Paclitaxel, weekly × 8 weeks
Follows 3 weeks after completing 4 cycles of FEC

Premedication:
Dexamethasone 10 mg/dose; administer orally or intravenously for 2 doses at 12 hours and 6 hours before paclitaxel, *or*
Dexamethasone 20 mg; administer intravenously 30–60 minutes before paclitaxel (total dose/cycle = 20 mg)
Note: Dexamethasone doses may be gradually decreased in the absence of hypersensitivity reactions during repeated paclitaxel treatments
Diphenhydramine 50 mg; administer by intravenous injection 30–60 minutes before paclitaxel
Cimetidine 300 mg (or ranitidine 50 mg, or famotidine 20 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer intravenously over 15–30 minutes, 30–60 minutes before starting paclitaxel administration

Paclitaxel 100 mg/m²; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 60 minutes, once weekly for 8 weeks (total dosage/week = 100 mg/m²)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

(continued)

(continued)

Notes:

On completion of chemotherapy, tamoxifen (20 mg daily; administer orally for 5 years) was mandatory for all patients whose tumors were positive for estrogen receptor, progesterone receptor, or both (according to institutional guidelines). Subsequently an amendment to the study protocol allowed the use of aromatase inhibitors in postmenopausal women

1. Radiotherapy was mandatory after breast-conserving surgery, and was administered after mastectomy according to the guidelines of each participating institution, mostly to women with tumors >5 cm or with ≥4 affected lymph nodes
2. Prophylaxis with filgrastim (granulocyte colony-stimulating factor) was not routine. However, secondary prophylaxis with filgrastim was mandatory among patients who had at least 1 episode of febrile neutropenia or an infection

Treatment Modifications–FEC

Adverse Events	Treatment Modifications
WBC <3500/mm³ or platelets <100,000/mm³ on first day of a cycle	Delay treatment for a maximum of 2 weeks until WBC >3500/mm³ and platelets >100,000/mm³. Continue at full dosages if counts recover within 2 weeks
If after 2 weeks WBC <3500/mm³ or platelets <100,000/mm³ reduce all drugs' dosages as follows:	
WBC 3000–3499/mm³, or platelets 75,000–99,999/mm³	Reduce dosages by 25%
WBC 2500–2999/mm³ and platelets ≥75,000/mm³	Reduce dosages by 50%
WBC <2500/mm³, or platelets <75,000/mm³	Hold treatment
ANC <1500/mm³, or platelets <100,000/mm³ at start of cycle	Delay treatment until ANC ≥1500/mm³ and platelets ≥100,000/mm³. Give filgrastim* in subsequent cycles
Hematologic recovery >3 weeks	Discontinue treatment
First episode of febrile neutropenia	Give filgrastim* during subsequent cycles
Second episode of febrile neutropenia	During subsequent cycles, consider prophylaxis with ciprofloxacin†
Third episode of febrile neutropenia	Decrease chemotherapy doses by 20% (epirubicin by 20 mg/m², fluorouracil and cyclophosphamide by 100 mg/m²) and administer filgrastim* + ciprofloxacin†
First episode of G4 documented infection	Add filgrastim* and ciprofloxacin† prophylaxis during subsequent cycles
Second episode of G4 documented infection	Decrease chemotherapy doses by 20% (epirubicin by 20 mg/m², fluorouracil and cyclophosphamide by 100 mg/m²) and administer filgrastim* + ciprofloxacin†
Third episode of G4 documented infection	Discontinue chemotherapy
Serum bilirubin levels 2 to 3 mg/dL (34.1 to 51.3 mmol/L)	Reduce epirubicin dose by 50%
Bilirubin levels ≥3 mg/dL (≥51.3 mmol/L)	Discontinue treatment
G3 stomatitis	Reduce epirubicin and fluorouracil dosage by 50% during subsequent cycles
Any other G3 nonhematologic toxicity	Reduce the dosage of all drugs 25%
G4 nonhematologic toxicity	Discontinue chemotherapy

Treatment Modifications–Paclitaxel

Adverse Events	Treatment Modifications
ANC ≤800/mm³ or platelets ≤50,000/mm³	Hold treatment until ANC >800/mm³ and platelets >50,000/mm³, then resume with weekly paclitaxel dosage reduced by 10 mg/m²
G2 motor or sensory neuropathies	Reduce weekly paclitaxel dosage by 10 mg/m² without interrupting planned treatment
Other nonhematologic adverse events G2 or G3	Hold treatment until adverse events resolve to G ≤1, then resume with weekly paclitaxel dosage reduced by 10 mg/m²
Patients who cannot tolerate paclitaxel at 60 mg/m² per week	Discontinue treatment
Treatment delay >2 weeks	Decrease weekly paclitaxel dosage by 10 mg/m² or consider discontinuing treatment

*Filgrastim 5 mcg/kg per day; administer subcutaneously starting at least 24 hours after completing chemotherapy until ANC ≥5000/mm³

†Ciprofloxacin 500 mg administer orally twice daily for 7 days starting on day 5

Patient Population Studied

Study of 1246 women who had undergone primary curative surgery (ie, mastectomy, tumorectomy, or lumpectomy) with axillary lymph node dissection (in which at least 6 lymph nodes were isolated) for operable unilateral carcinoma of the breast (stage T1–T3) and were found to have node-positive breast cancer. All patients had at least 1 axillary lymph node that was positive for cancer on histologic examination. The margins of resected specimens had to be histologically free of invasive carcinoma and ductal carcinoma in situ. A complete staging work-up was carried out within 16 weeks before registration in the study. Criteria for exclusion included advanced disease (ie, stage T4, N2 or N3, or M1) and motor or sensory neuropathy of NCI Common Toxicity Criteria G2 or more

Efficacy

Analysis of Events in the ITT Population

	FEC (N = 632)		FEC-P (N = 614)	
	No of Pts	%	No of Pts	%

Local and second primary	1	0.2	0	0
Second primary cancer	16	2.5	23	3.7
Contralateral breast cancer	4	0.6	7	1.1

FEC, Fluorouracil, epirubicin, and cyclophosphamide; FEC-P, FEC + paclitaxel

DFS, RFS, and OS by Kaplan-Meier Method

	FEC	FEC-P	p-Value	HR	CI
Unadjusted 5-year DFS	72.1%	78.5%	0.006	0.74	0.60–0.92
Adjusted 5-year DFS*			0.006	0/77	0.62–0.95
5-Year distant RFS	78.1%	83.8%	0.006	0.70	0.54–0.90
5-Year OS	87.1%	89.9%	0.109	0.78	0.57–1.06

CI, confidence interval; DFS, Disease-free survival; FEC, fluorouracil, epirubicin, and cyclophosphamide; FEC-P, FEC + paclitaxel; HR, hazard ratio; RFS, relapse-free survival; OS, overall survival
*Adjusted for lymph node status, age, tumor size, histology, hormone receptor status, and hormonal therapy

Toxicity*

Toxicity	FEC	FEC-P
G3/4 neutropenia	25.5%	19.1%
G3/4 febrile neutropenia	9.5%	5.1%
G3/4 fatigue	2.4%	4.2%
G3/4 nausea	5.9%	5.4%
G3/4 vomiting	9.9%	7.3%
G3/4 stomatitis	4.9%	3.1%
Amenorrhea	58%	65%
G2 alopecia	>90%	>90%
G2 neuropathy	N/A	22.2%
G3 neuropathy	N/A	3.7%
G2 arthralgia/myalgia	N/A	20.6%
G3 arthralgia/myalgia	N/A	2.8%
G2 LV dysfunction	7.2%	7.8%

*Comparison of treatment arms as follows:
FEC, Six 21-day cycles of fluorouracil 600 mg/m², epirubicin 90 mg/m², and cyclophosphamide 600 mg/m²
FEC-P, Four 21-day cycles of the same FEC schedule and, after 3 weeks of no treatment, eight 1-week courses of paclitaxel 100 mg/m²

Therapy Monitoring

1. *Before each cycle:* CBC with differential and platelet count, serum total bilirubin
2. *Before each treatment with paclitaxel:* Neurologic examination

ADJUVANT, NEOADJUVANT REGIMEN

DOCETAXEL + CARBOPLATIN + TRASTUZUMAB (TCH)

Slamon S et al. N Engl J Med 2011;365:1273–1283
(Third Interim Analysis Phase III Randomized Trial Comparing Doxorubicin and Cyclophosphamide Followed by Docetaxel [AC →T] with Doxorubicin and Cyclophosphamide Followed by Docetaxel and Trastuzumab [AC →TH] with Docetaxel, Carboplatin and Trastuzumab [TCH] in Her2neu Positive Early Breast Cancer Patients: BCIRG 006 Study)

TCH regimen

Premedication:

Dexamethasone 8 mg/dose; administer orally twice daily for 3 days, starting on the day before docetaxel administration (total dose/cycle = 48 mg)

Docetaxel 75 mg/m^2; administer intravenously in a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) sufficient to produce a final docetaxel concentration of 0.3–0.74 mg/mL over 30–60 minutes on day 1, every 3 weeks for 6 cycles (total dosage/cycle = 75 mg/m^2)

Carboplatin target AUC = 6 mg/mL · min; administer intravenously in 250 mL D5W or 0.9% NS over 30–60 minutes on day 1, every 3 weeks for 6 cycles (total dose/cycle calculated to achieve a target AUC = 6 mg/mL · min), *concurrently with:*

Trastuzumab every 21 days for 6 cycles:

Loading Dose: **Trastuzumab** 8 mg/kg; administer intravenously in 250 mL 0.9% NS over 90 minutes as a loading dose on day 1, cycle 1 only (total dosage during the first cycle = 8 mg/kg), *followed 3 weeks later by:*

Maintenance Doses: **Trastuzumab** 6 mg/kg; administer intravenously in 250 mL 0.9% NS over 30 minutes on day 1, every 3 weeks for 5 cycles (total dosage/cycle = 6 mg/kg)

Three weeks after completing combination (TCH) chemotherapy:

Trastuzumab 6 mg/kg; administer intravenously in 250 mL 0.9% NS over 30 minutes every 3 weeks for 11 doses (total dosage/3-week cycle = 6 mg/kg)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on days with TCH combination chemotherapy is **HIGH**. Potential for delayed symptoms*
*Emetogenic potential on days with trastuzumab alone is **LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

(*continued*)

Treatment Modifications

Adverse Events	Treatment Modifications
WBC <3500/mm^3, or absolute neutrophil count (ANC) <1500/mm^3, or platelets <100,000/mm^3 on first day of a cycle	Delay treatment for a maximum of 2 weeks until WBC >3500/mm^3, ANC >1500/mm^3, and platelets >100,000/mm^3. Continue at full dosages if counts recover within 2 weeks. Give filgrastim* in subsequent cycles
If after 2 weeks WBC <3500/mm^3, ANC <1500/mm^3, or platelets <100,000/mm^3, reduce all drugs' dosages as follows:	
WBC 3000–3499/mm^3, ANC 1000–1500/mm^3, or platelets 75,000–99,999/mm^3	Reduce dosages by 20%
WBC 2500–2999/mm^3, ANC 500–1000/mm^3, or platelets ≥ 75,000/mm^3	Reduce dosages by 50%
WBC <2500/mm^3, ANC <500/mm^3, or platelets <75,000/mm^3	Hold treatment
Hematologic recovery >3 weeks	Discontinue treatment
First episode of febrile neutropenia or documented infection after treatment	Filgrastim* prophylaxis administered during subsequent cycles
Second episode of febrile neutropenia or documented infection after treatment	Reduce docetaxel dosage to 60 mg/m^2 during subsequent cycles, administer filgrastim* and consider prophylaxis with ciprofloxacin†
Third episode of febrile neutropenia or documented infection after treatment	Discontinue chemotherapy
G3/4 stomatitis	Reduce docetaxel dosage to 60 mg/m^2 during subsequent cycles
G3/4 neuropathy	Discontinue treatment

(*continued*)

(continued)

Trastuzumab infusion reactions:

- A symptom complex most commonly consisting of chills and/or fever may occur in as many as 40% of patients during the first infusion of trastuzumab. These symptoms occur infrequently with subsequent trastuzumab infusions. Other signs and/or symptoms may include nausea, vomiting, pain (in some cases at tumor sites), rigors, headache, dizziness, dyspnea, hypotension, rash, and asthenia. Although the symptoms are usually mild to moderate in severity, infrequently, trastuzumab may need to be discontinued
- When such a symptom complex is observed it can be treated with or without reduction in the rate of trastuzumab infusion, and:
  - **Acetaminophen** 650 mg; administer orally
  - **Diphenhydramine** 25–50 mg; administer orally or by intravenous injection, and
  - **Meperidine** 12.5–25 mg; administer by intravenous injection every 10 minutes if needed for shaking chills (generally, cumulative doses >50 mg are not needed; use with caution in persons with moderate or more severely impaired renal function)
  - With or without reduction in the rate of trastuzumab infusion

Treatment plan notes:

- LVEF assessment (MUGA or echocardiography) every 3 months in patients receiving trastuzumab
- One year of trastuzumab therapy = 51 weeks or 17 total doses (6 doses [cycles] with docetaxel and carboplatin and 11 doses [cycles] of single agent trastuzumab)

Carboplatin dose

Carboplatin dose is based on a formula described by Calvert et al. to achieve a target area under the plasma concentration versus time curve (AUC)

$$\text{Total Carboplatin Dose (mg)} = (\text{target AUC})\,(\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be estimated from the equation of Cockcroft and Gault, thus:

$$\text{For males, Clcr} = \frac{(140 - \text{age[years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age[years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})} \times 0.85$$

Calvert AH et al. J Clin Oncol 1989;7:1748–1756
Cockcroft DW, Gault MH. Nephron 1976;16:31–41
Jodrell DI et al. J Clin Oncol 1992;10:520–528
Sorensen BT et al. Cancer Chemother Pharmacol 1991;28:397–401

Note: On October 8, 2010, the U.S. Food and Drug Administration (FDA) identified a potential safety issue with carboplatin dosing based on recent changes in the measurement of serum creatinine. By the end of 2010, all clinical laboratories in the United States will use the standardized isotope dilution mass spectrometry (IDMS) method to measure serum creatinine, which could result in an overestimation of the GFR in some patients with normal renal function. A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula could exceed an expected exposure (AUC) and result in increased drug-related toxicity. Provided actual GFR measurements are made to assess renal function, carboplatin can be safely dosed according to the Calvert formula described in product labeling. If GFR (or creatinine clearance) is estimated based on serum creatinine measurements by the IDMS method, the FDA recommended for patients with normal renal function capping an estimated GFR at 125 mL/min for any targeted AUC value. No greater estimated GFR values should be used U.S. Food and Drug Administration. Carboplatin dosing. May 23, 2013. Treatment Modifications *(continued)*

Adverse Events	Treatment Modifications
Other severe adverse events	Hold treatment until toxicity resolves to G ≤1, then resume at decreased dosages appropriate for the toxicity
Asymptomatic decreases in ejection fraction	Monitor patient closely for evidence of clinical deterioration
Clinically significant congestive heart failure	Discontinue trastuzumab

*Filgrastim 5 mcg/kg per day; administer subcutaneously starting at least 24 hours after completing chemotherapy until ANC ≥5000/mm³
†Ciprofloxacin 500 mg; administer orally twice daily for 7 days starting on day 5
Note: Dosages reduced for adverse events are not re-escalated

Patient Population Studied

Study of 3222 women with HER2+ by FISH, T1–3, N0/N1, M0 breast cancer (AC → T: 1073; AC→TH: 1074; TCH: 1075). Stratified by nodes and hormonal receptor status

Therapy Monitoring

1. *Before each cycle:* CBC with differential and platelet count, LFTs, serum electrolytes, BUN, and creatinine
2. *Assessment of ejection fraction:* Every 3 months or as clinically indicated
3. *Hearing test:* At baseline and as needed

Note

In the neoadjuvant setting, consider adding Pertuzumab to TCH chemotherapy
Give pertuzumab every 21 days for 6 cycles:
Loading dose: **Pertuzumab** 840 mg; administer intravenously in 250 mL of 0.9% NS over 90 minutes on day 1 after trastuzumab, cycle 1 only (total dose during the first cycle = 840 mg), *followed 3 weeks later by:*
Maintenance doses: **Pertuzumab** 420 mg; administer intravenously in 250 mL of 0.9% NS over 30–60 minutes on day 1 after trastuzumab, every 3 weeks for 5 cycles (total dose/cycle = 420 mg)

Schneeweiss A et al. Ann Oncol 2013;24:2278–2284

ADJUVANT, NEOADJUVANT REGIMEN

DOXORUBICIN + CYCLOPHOSPHAMIDE, THEN PACLITAXEL + TRASTUZUMAB, THEN TRASTUZUMAB ALONE (AC × 4 → TH × 12 WEEKS → H × 40 WEEKS)

Romond EH et al. N Engl J Med 2005;353:1673–1684
Seidman AD et al. J Clin Oncol 2001;19:2587–2595

AC (doxorubicin + cyclophosphamide) regimen
Hydration with 0.9% sodium chloride injection (0.9% NS); administer intravenously 500 mL before starting cyclophosphamide and 500 mL after completing cyclophosphamide administration

Doxorubicin HCl 60 mg/m^2; administer by intravenous injection over 3–5 minutes on day 1, every 21 days for 4 cycles (total dosage/cycle = 60 mg/m^2)
Cyclophosphamide 600 mg/m^2; administer intravenously in 100–500 mL 0.9% NS or 5% dextrose injection (D5W) over 15–60 minutes on day 1, every 21 days for 4 cycles (total dosage/cycle = 600 mg/m^2)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Weekly TH (paclitaxel + trastuzumab) regimen

Schedule for first week of paclitaxel + trastuzumab
Trastuzumab 4 mg/kg (loading dose); administer intravenously in 250 mL 0.9% NS over at least 90 minutes, 1 day before the first dose of paclitaxel is administered (total trastuzumab dosage during the first treatment week = 4 mg/kg), *followed 1 day later by:*

Premedication for paclitaxel:
Dexamethasone 10 mg; administer intravenously 30–60 minutes before paclitaxel (total dose/cycle = 10 mg)
Note: Dexamethasone doses may be gradually reduced in 2- to 4-mg increments if a patient has no hypersensitivity reactions during repeated paclitaxel treatments
Diphenhydramine 50 mg; administer intravenously 30–60 minutes before paclitaxel
Cimetidine 300 mg (or ranitidine 50 mg, or famotidine 20 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer intravenously over 15 to 30 minutes, 30 to 60 minutes before starting paclitaxel administration

Paclitaxel 80 mg/m^2; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 60 minutes (total dosage = 80 mg/m^2)

Paclitaxel + trastuzumab during the second and subsequent weeks
Premedication for paclitaxel:
Dexamethasone 10 mg; administer intravenously 30–60 minutes before paclitaxel
Note: If a patient does not experience any manifestations of hypersensitivity or an allergic reaction after 8 paclitaxel infusions, the **dexamethasone** dose may be reduced as follows:
- Weeks 9 and 10: **Dexamethasone** 8 mg IV
- Weeks 11 and 12: **Dexamethasone** 6 mg IV
- Weeks 13 and beyond: **Dexamethasone** 4 mg IV

Diphenhydramine 50 mg; administer by intravenous injection 30–60 minutes before paclitaxel
Cimetidine 300 mg (or ranitidine 50 mg, or famotidine 20 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer intravenously over 15–30 minutes, 30–60 minutes before starting paclitaxel administration

(*continued*)

(*continued*)

Paclitaxel 80 mg/m² per week; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 60 minutes, weekly, for 11 weeks (total dosage/week = 80 mg/m²), *followed immediately afterward by:*
Trastuzumab 2 mg/kg per week; administer intravenously in 250 mL 0.9% NS over 30 minutes, weekly, for 11 weeks
(total trastuzumab dosage/week during the second and later weeks = 2 mg/kg)
Note: The duration of trastuzumab administration may be decreased from an initial infusion duration of 90 to 30 minutes if administration over longer durations is well tolerated

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Weekly H (*trastuzumab*) regimen
Trastuzumab 2 mg/kg per week; administer intravenously in 250 mL 0.9% NS over 30 minutes, weekly, for 40 weeks
(total trastuzumab dosage/week = 2 mg/kg)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Trastuzumab infusion reactions
- A symptom complex most commonly consisting of chills and/or fever may occur in as many as 40% of patients during the first infusion of trastuzumab. These symptoms occur infrequently with subsequent trastuzumab infusions. Other signs and/or symptoms may include nausea, vomiting, pain (in some cases at tumor sites), rigors, headache, dizziness, dyspnea, hypotension, rash, and asthenia. Although the symptoms are usually mild to moderate in severity, infrequently, trastuzumab may need to be discontinued
- When such a symptom complex is observed it can be treated with or without reduction in the rate of trastuzumab infusion, and:
  - **Acetaminophen** 650 mg; administer orally
  - **Diphenhydramine** 25–50 mg; administer orally or by intravenous injection, and
  - **Meperidine** 12.5–25 mg; administer by intravenous injection every 10 minutes if needed for shaking chills (generally, cumulative doses >50 mg are not needed; use with caution in persons with moderate or more severely impaired renal function)
  - With or without reduction in the rate of trastuzumab infusion

Treatment Plan Notes:
- LVEF assessment (MUGA or echocardiography) every 3 months in patients receiving trastuzumab

Treatment Modifications: Cyclophosphamide + Doxorubicin

Adverse Events	Treatment Modifications
Absolute neutrophil count (ANC) <1500/mm³, or WBC <3500/mm³, or platelets <100,000/mm³ at start of cycle*	Delay treatment for a maximum of 2 weeks until ANC ≥1500/mm³, WBC ≥3500/mm³, and platelets ≥100,000/mm³. Continue at full dosages if counts recover within 2 weeks. Give filgrastim† after chemotherapy during subsequent cycles
If after 2 weeks ANC <1500/mm³, or WBC <3500/mm³, or platelets <100,000/mm³, reduce all drug dosages as follows:	
ANC 1000–1500/mm³, WBC 3000–3499/mm³, or platelets 75,000–99,999/mm³	Reduce cyclophosphamide and doxorubicin dosages by 20%
ANC 500–1000/mm³, WBC 2500–2999/mm³, and platelets ≥75,000/mm³	Reduce cyclophosphamide and doxorubicin dosages by 50%
ANC <500/mm³, WBC <2500/mm³, or platelets <75,000/mm³	Hold treatment
First episode of febrile neutropenia	Give filgrastim† after chemotherapy during subsequent cycles
Second episode of febrile neutropenia	During subsequent cycles, consider prophylaxis with ciprofloxacin‡
Third episode of febrile neutropenia	Decrease both doxorubicin and cyclophosphamide dosages by 25%

*Although an ANC of 1500/mm³ is often identified as a minimum acceptable ANC to safely proceed with treatment, recent data shows that an ANC ≥1000/mm³ is acceptable if filgrastim is given after chemotherapy
†Filgrastim 5 mcg/kg per day; administer subcutaneously starting at least 24 hours after completing chemotherapy until ANC ≥5000/mm³
‡Ciprofloxacin 500 mg; administer orally twice daily for 7 days starting on day 5

Treatment Modifications: Paclitaxel

Adverse Events	Adverse Events
ANC ≤800/mm³, platelets ≤50,000/mm³, or documented infection	Hold treatment until ANC >1000/mm³, platelets >100,000/mm³, and/or infection resolved, then resume with weekly paclitaxel dosage reduced by 10 mg/m²
G2 motor or sensory neuropathies	Reduce weekly paclitaxel dosage by 10 mg/m² without interrupting planned treatment
G2 nonhematologic adverse events (other than sensory or motor neuropathies)	Hold treatment until adverse events resolve to G ≤1, then resume with weekly paclitaxel dosage reduced by 10 mg/m²
G3 nonhematologic adverse events (other than sensory or motor neuropathies)	Hold treatment until adverse events resolve to G ≤1, then resume with weekly paclitaxel dosage reduced by 20 mg/m²
Patients who cannot tolerate paclitaxel at 60 mg/m² per week	Discontinue treatment
Treatment delay >2 weeks	Decrease weekly paclitaxel dosage by 10 mg/m² or consider discontinuing treatment

Patient Population Studied

Romond EH et al. J Clin Oncol 2005;16:1673–1684: Report of two trials that treated 1672 women with a regimen of AC followed by paclitaxel with trastuzumab, followed by trastuzumab alone [**AC → P + H → H**]. Two studies were combined in one analysis: (a) National Surgical Adjuvant Breast and Bowel Project trial B-31 and (b) North Central Cancer Treatment Group trial N9831. Both trials enrolled women with a pathologic diagnosis of adenocarcinoma of the breast with immunohistochemical staining for HER2 protein of 3+ intensity or amplification of the *HER2* gene on fluorescence in situ hybridization. Initially, required patients to have histologically proven, node-positive disease; subsequently, N9831 was amended to include patients with high-risk node-negative disease (defined as a tumor that was more than 2 cm in diameter and positive for estrogen receptors or progesterone receptors or as a tumor that was more than 1 cm in diameter and negative for both estrogen receptors and progesterone receptors). Other requirements included a left ventricular ejection fraction (LVEF) that met or exceeded the lower limit of normal. Complete resection of the primary tumor and axillary-node dissection were required (negative sentinel-node biopsy was allowed in trial N9831). Patients were ineligible if they had one of several cardiac risk factors

Note

In the neoadjuvant setting, consider adding pertuzumab to paclitaxel and trastuzumab
Give pertuzumab every 21 days for 4 cycles:

Loading dose: **Pertuzumab** 840 mg; administer intravenously in 250 mL of 0.9% NS over 90 minutes on the same day as trastuzumab, but after completing trastuzumab administration (total dose during the first cycle = 840 mg), *followed 3 weeks later by:*

Maintenance doses: **Pertuzumab** 420 mg; administer intravenously in 250 mL of 0.9% NS over 30–60 minutes after trastuzumab, every 3 weeks for 3 cycles (total dose/3-week cycle = 420 mg)

Schneeweiss A et al. Ann Oncol 2013;24:2278–2284

Efficacy (Combined Analysis of NSABP B-31 and NCCTG N9831)

Romond EH et al. N Eng J Med 2005;353:1673–1684

3-Year OS	91.7%	94.3%	0.67
4-Year OS	86.6%	91.4%	
Isolated brain metastases as first event, B-31*	11/872	21/864	
Isolated brain metastases as first event, N9831*	4/807	12/808	
Brain metastases as first/subsequent event, B-31*	35/872	28/864	0.79

AC → PTX, doxorubicin (Adriamycin) + cyclophosphamide followed by paclitaxel; AC → P + H → H, doxorubicin + cyclophosphamide followed by paclitaxel plus trastuzumab (Herceptin) then trastuzumab alone; DFS, disease-free survival; OS, overall survival

*The imbalance in brain metastases as first events can be attributed to earlier failures at other distant sites among patients in the control group

Toxicity

(Romond EH et al. N Eng J Med 2005;353:1673–1684)

	AC → PTX N = 1679	AC → P + H → H N = 1672
NYHA III/IV CHF* or cardiac death at 3 yrs, B-31†	0.8%‡	4.1%§
NYHA III/IV CHF* or cardiac death at 3 yrs, N9831†	0	2.9%¶
Interstitial pneumonitis, B-31		4/864**
Interstitial pneumonitis, N9831		5/808††
Other toxicities	Similar CTC v2 toxicities‡‡	

AC → PTX, doxorubicin (Adriamycin) + cyclophosphamide followed by paclitaxel; AC → P + H → H, doxorubicin + cyclophosphamide followed by paclitaxel plus trastuzumab (Herceptin) then trastuzumab alone

*New York Heart Association classes III or IV congestive heart failure

†Cumulative incidence in patients who remained free of cardiac symptoms during doxorubicin and cyclophosphamide therapy and who had LVEF values that met requirements for the initiation of trastuzumab therapy

‡Four patients had congestive heart failure, and 1 died from cardiac causes

§Thirty-one patients had congestive heart failure. (Amongst 27 patients followed ≥6 months after onset of CHF, only 1 reported persistent symptoms of CHF)

¶Twenty patients had congestive heart failure; 1 died of cardiomyopathy

**One died

††G3+ pneumonitis or pulmonary infiltrates; 1 died

‡‡During treatment with paclitaxel alone or with trastuzumab, there was little imbalance between treatment groups in the incidence of any Common Toxicity Criteria version 2.0

Therapy Monitoring

General:

1. *At intervals:* CBC with differential and platelet count, LFTs, serum electrolytes, BUN, and creatinine
2. *Assessment of ejection fraction:* Every 3 months or as clinically indicated

For doxorubicin + cyclophosphamide:

1. *Each cycle:* CBC with differential and platelet count, serum electrolytes, LFTs

For weekly paclitaxel

1. *Every week:* CBC with differential and platelet count
2. *Every 3 to 4 weeks:* LFTs, serum electrolytes, calcium, and magnesium

For trastuzumab cycles:

Assessment of ejection fraction: Every 3 months or as clinically indicated

Notes:

- In NSABP B31 and NCCTG N9831, cardiac ejection fraction assessed before entry, after completion of doxorubicin/cyclophosphamide, and 6, 9, and 18 months after initiation of trastuzumab
- Initiation of trastuzumab required cardiac ejection fraction to be in the normal range with no more than a 16-percentage point decrease from baseline
- At 6 and 9 months assessment, if the cardiac ejection fraction had declined by ≥16% from initial or was 10–15% below the normal range, trastuzumab was held for 4 weeks and reassessed. Trastuzumab could be restarted if the cardiac ejection fraction recovered

ADJUVANT REGIMEN

DOCETAXEL + TRASTUZUMAB FOLLOWED BY CYCLOPHOSPHAMIDE + EPIRUBICIN + FLUOROURACIL (FEC)

Joensuu H et al. N Engl J Med 2006;354:809–820
Joensuu H et al. J Clin Oncol 2009;27:5685–5692

Docetaxel + Trastuzumab: weeks 1 through 9
Trastuzumab 4 mg/kg (loading dose); administer intravenously in 250 mL 0.9% sodium chloride injection (0.9% NS) over at least 90 minutes, 1 day before the first dose of docetaxel is administered (total trastuzumab dosage during the first treatment week = 4 mg/kg), *followed during subsequent weeks by:*
Trastuzumab 2 mg/kg per week; administer intravenously in 250 mL 0.9% NS over 30 minutes, weekly, continually for 8 weeks (total trastuzumab dosage/week during the second to ninth weeks = 2 mg/kg)
Notes:
Trastuzumab administration preceded docetaxel administration on days when both drugs were administered
Trastuzumab administration duration may be decreased from 90 to 30 minutes if administration over longer durations is well tolerated

Premedication:
Dexamethasone 8 mg/dose; administer orally twice daily for 3 days, starting on the day before docetaxel administration (total dose/cycle = 48 mg)

Docetaxel 80 mg/m² or 100 mg/m²; administer by intravenous infusion in a volume of 0.9% NS or 5% dextrose injection (D5W) sufficient to produce a final docetaxel concentration of 0.3–0.74 mg/mL over 60 minutes on day 1, every 21 days for 3 cycles (total dosage/cycle = 80 mg/m² or 100 mg/m²)
Note:
An independent study monitoring committee recommended the docetaxel dosage be reduced because of a high incidence of febrile neutropenia following treatment. Therefore, 41% of patients received docetaxel 100 mg/m² and 59% received docetaxel 80 mg/m² as the starting dose

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW–INTERMEDIATE
(risk varies directly with docetaxel dosage)
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Trastuzumab infusion reactions
- A symptom complex most commonly consisting of chills and/or fever may occur in as many as 40% of patients during the first infusion of trastuzumab. These symptoms occur infrequently with subsequent trastuzumab infusions. Other signs and/or symptoms may include nausea, vomiting, pain (in some cases at tumor sites), rigors, headache, dizziness, dyspnea, hypotension, rash, and asthenia. Although the symptoms are usually mild to moderate in severity, infrequently, trastuzumab may need to be discontinued
- When such a symptom complex is observed it can be treated with or without reduction in the rate of trastuzumab infusion, and:
  - **Acetaminophen** 650 mg; administer orally
  - **Diphenhydramine** 25–50 mg; administer orally or by intravenous injection, and

(*continued*)

Treatment Modifications

Adverse Events	Treatment Modifications
WBC <3500/mm³ or platelets <100,000/mm³ on the first day of a cycle	Delay treatment for a maximum of 2 weeks until WBC >3500/mm³ and platelets >100,000/mm³. Continue at full dosages if counts recover within 2 weeks
If after 2 weeks WBC <3500/mm³ or platelets <100,000/mm³, reduce all drug dosages as follows:	
WBC 3000–3499/mm³, or platelets 75,000–99,999/mm³	Reduce dosages by 20%
WBC 2500–2999/mm³ and platelets ≥75,000/mm³	Reduce dosages by 50%
WBC <2500/mm³, or platelets <75,000/mm³	Hold treatment
ANC <1500/mm³, or platelets <100,000/mm³ at start of cycle	Delay treatment until ANC ≥1500/mm³ and platelets ≥100,000/mm³. Give filgrastim* in subsequent cycles
Hematologic recovery >3 weeks	Discontinue treatment
First episode of febrile neutropenia or documented infection after treatment	Filgrastim* prophylaxis administered during subsequent cycles
Second episode of febrile neutropenia or documented infection after treatment	Reduce docetaxel dosage to 60 mg/m² during subsequent cycles; administer filgrastim* and consider prophylaxis with ciprofloxacin†
Third episode of febrile neutropenia or documented infection after treatment	Discontinue chemotherapy

(*continued*)

(continued)

- **Meperidine** 12.5–25 mg; administer by intravenous injection every 10 minutes if needed for shaking chills (generally, cumulative doses >50 mg are not needed; use with caution in persons with moderate or more severely impaired renal function)
- With or without reduction in the rate of trastuzumab infusion

Treatment Plan Notes:
- LVEF assessment (MUGA or echocardiography) every 3 months in patients receiving trastuzumab

FEC (Cyclophosphamide + Epirubicin + Fluorouracil): weeks 10 through 18
Hydration with 0.9% sodium chloride injection (0.9% NS); administer intravenously 500 mL before starting cyclophosphamide and 500 mL after completing cyclophosphamide administration

Fluorouracil 600 mg/m²; administer by intravenous injection over 1–3 minutes on day 1, every 21 days for 3 cycles (total dosage/cycle = 600 mg/m²)
Epirubicin HCl 60 mg/m²; administer by intravenous injection over 3–5 minutes on day 1, every 21 days for 3 cycles (total dosage/cycle = 60 mg/m²)
Cyclophosphamide 600 mg/m²; administer intravenously in 100–500 mL 0.9% NS or D5W over 30–60 minutes on day 1, every 21 days for 3 cycles (total dosage/cycle = 600 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Efficacy

Treatment Modifications *(continued)*

Adverse Events	Treatment Modifications
G3/4 stomatitis	Reduce docetaxel dosage to 60 mg/m² during subsequent cycles. Reduce epirubicin and fluorouracil dosage by 50% during subsequent cycles
G3/4 neuropathy	Discontinue treatment
Serum bilirubin levels 2 to 3 mg/dL (34.2 to 51.3 mmol/L)	Reduce epirubicin dosage by 50%
Bilirubin levels ≥3 mg/dL (≥51.3 mmol/L)	Discontinue treatment
Any other G3 nonhematologic toxicity	Hold treatment until toxicity resolves to G ≤1, then resume treatment with dosages of all drugs reduced by 25%
G4 nonhematologic toxicity	Discontinue chemotherapy
Asymptomatic decreases in ejection fraction	Monitor patient closely for evidence of clinical deterioration
Clinically significant congestive heart failure	Discontinue trastuzumab

*Filgrastim 5 mcg/kg per day; administer subcutaneously starting at least 24 hours after completing chemotherapy until ANC ≥5000/mm³
†Ciprofloxacin 500 mg; administer orally twice daily for 7 days starting on day 5
Note: Dosages reduced for adverse events are not re-escalated

Patient Population Studied

Joensuu H et al. N Engl J Med 2006;354:809–820

Study of 1010 women with axillary node-positive or high-risk node-negative breast cancer were randomly assigned to receive 3 cycles of docetaxel or vinorelbine, followed in both groups by 3 cycles of fluorouracil, epirubicin, and cyclophosphamide (FEC). Women with HER2-positive cancer (n = 232) were further assigned to either receive or not receive trastuzumab for 9 weeks with docetaxel or vinorelbine. The median follow-up time was 62 months after random assignment

ADJUVANT, NEOADJUVANT REGIMEN

DOXORUBICIN + CYCLOPHOSPHAMIDE (AC) FOLLOWED BY DOCETAXEL WITH TRASTUZUMAB (TH) (AC → TH)

Slamon D et al. N Engl J Med 2011;365:1273–1283
Slamon D. Abstract 62. SABCS 2009
(Third Interim Analysis Phase III Randomized Trial Comparing Doxorubicin and Cyclophosphamide Followed by Docetaxel [AC → T] with Doxorubicin and Cyclophosphamide Followed by Docetaxel and Trastuzumab [AC → TH] with Docetaxel, Carboplatin and Trastuzumab [TCH] in Her2neu Positive Early Breast Cancer Patients: BCIRG 006 Study)

Hydration with 0.9% sodium chloride injection (0.9% NS); administer 500 mL before starting cyclophosphamide and 500 mL after completing cyclophosphamide administration

Doxorubicin HCl 60 mg/m²; administer by intravenous injection over 3–5 minutes on day 1, every 21 days for 4 cycles (total dosage/cycle = 60 mg/m²)
Cyclophosphamide 600 mg/m²; administer intravenously in 100–500 mL 0.9% NS or 5% dextrose injection (D5W) over 15–60 minutes on day 1, every 21 days for 4 cycles (total dosage/cycle = 600 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Followed by:
Trastuzumab every 21 days for 4 cycles,
Loading Dose: **Trastuzumab** 4 mg/kg; administer intravenously in 250 mL 0.9% NS over 90 minutes on day 1 only during the first cycle, *then*
Maintenance Dose: **Trastuzumab** 2 mg/kg per dose; administer intravenously in 250 mL 0.9% NS over 30 minutes, once weekly on days 8 and 15 during cycle 1, and days 1, 8, and 15 during cycles 2–4 (total dosage during the first cycle = 8 mg/kg; total dosage during cycles 2–4 = 6 mg/kg)

Premedication:
Dexamethasone 8 mg/dose; administer orally twice daily for 3 days, starting on the day before docetaxel administration (total dose/cycle = 48 mg)

Docetaxel 100 mg/m²; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a final docetaxel concentration within the range of 0.3–0.74 mg/mL over 60 minutes on day 1 after trastuzumab, every 21 days for 4 cycles (total dosage/cycle = 100 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

(*continued*)

Treatment Modifications

Adverse Events	Treatment Modifications
WBC <3500/mm³, or absolute neutrophil count (ANC) <1500/mm³, or platelets <100,000/mm³ on first day of a cycle	Delay treatment for a maximum of 2 weeks until WBC >3500/mm³, ANC >1500/mm³, and platelets >100,000/mm³. Continue at full dosages if counts recover within 2 weeks. Give filgrastim* in subsequent cycles
If after 2 weeks, WBC <3500/mm³, ANC <500/mm³, or platelets <100,000/mm³, reduce all drug dosages as follows:	
WBC 3000–3499/mm³, ANC 1000–1500/mm³, or platelets 75,000–99,999/mm³	Reduce dosages by 20%
WBC 2500–2999/mm³, ANC 500–1000/mm³, or platelets ≥75,000/mm³	Reduce dosages by 50%
WBC <2500/mm³, ANC <500/mm³, or platelets <75,000/mm³	Hold treatment
Hematologic recovery >3 weeks	Discontinue treatment
First episode of febrile neutropenia or documented infection after treatment	Filgrastim* prophylaxis administered during subsequent cycles
Second episode of febrile neutropenia or documented infection after treatment	Reduce docetaxel dosage to 60 mg/m² *or* doxorubicin and cyclophosphamide dosages by 25% during subsequent cycles; administer filgrastim* and consider prophylaxis with ciprofloxacin†
Third episode of febrile neutropenia or documented infection after treatment	Discontinue chemotherapy

(*continued*)

(continued)

Four cycles of trastuzumab and docetaxel are followed by:
Trastuzumab 6 mg/kg; administer intravenously in 250 mL 0.9% NS over 30 minutes on day 1, every 21 days for 9 months to complete 1 year of trastuzumab

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Trastuzumab infusion reactions
- A symptom complex most commonly consisting of chills and/or fever may occur in as many as 40% of patients during the first infusion of trastuzumab. These symptoms occur infrequently with subsequent trastuzumab infusions. Other signs and/or symptoms may include nausea, vomiting, pain (in some cases at tumor sites), rigors, headache, dizziness, dyspnea, hypotension, rash, and asthenia. Although the symptoms are usually mild to moderate in severity, infrequently, trastuzumab may need to be discontinued
- When such a symptom complex is observed it can be treated with or without reduction in the rate of trastuzumab infusion, and:
  - **Acetaminophen** 650 mg; administer orally
  - **Diphenhydramine** 25–50 mg; administer orally or by intravenous injection, and
  - **Meperidine** 12.5–25 mg; administer by intravenous injection every 10 minutes if needed for shaking chills (generally, cumulative doses >50 mg are not needed; use with caution in persons with moderate or more severely impaired renal function)
  - With or without reduction in the rate of trastuzumab infusion

Treatment Plan Notes:
- LVEF assessment (MUGA or echocardiography) every 3 months in patients receiving trastuzumab

Note

In the neoadjuvant setting, consider adding pertuzumab with docetaxel and trastuzumab chemotherapy
Give Pertuzumab every 21 days for 4 cycles:
Loading dose: **Pertuzumab** 840 mg; administer intravenously in 250 mL of 0.9% NS over 90 minutes on day 1 after trastuzumab, cycle 1 only (total dose during the first cycle = 840 mg), *followed 3 weeks later by:*
Maintenance doses: **Pertuzumab** 420 mg; administer intravenously in 250 mL of 0.9% NS over 30–60 minutes on day 1 after trastuzumab, every 3 weeks for 3 cycles (total dose/cycle = 420 mg)

Schneeweiss A et al. Ann Oncol 2013;24:2278–2284

Treatment Modifications (*continued*)

Adverse Events	Treatment Modifications
G3/4 stomatitis	Reduce docetaxel dosage to 60 mg/m² *or* doxorubicin dosage by 25% during subsequent cycles
G3/4 neuropathy	Discontinue treatment
Other severe adverse events	Hold treatment until toxicity resolves to G ≤1, then resume at decreased dosages appropriate for the toxicity
Asymptomatic decreases in ejection fraction	Monitor patient closely for evidence of clinical deterioration
Clinically significant congestive heart failure	Discontinue trastuzumab

*Filgrastim 5 mcg/kg per day; administer subcutaneously starting at least 24 hours after completing chemotherapy until ANC ≥5000/mm³
†Ciprofloxacin 500 mg; administer orally twice daily for 7 days starting on day 5
Note: Dosages reduced for adverse events are not re-escalated

Patient Population Studied

Study of 3222 women with HER2+ by FISH, T1–3, N0/N1, M0 breast cancer (AC → T: 1073; AC → TH: 1074; TCH: 1075). Stratified by nodes and hormonal receptor status

Therapy Monitoring

1. *Before each cycle:* CBC with differential and platelet count, LFTs, serum electrolytes, BUN, and creatinine
2. *Assessment of ejection fraction:* Every 3 months or as clinically indicated
3. *Hearing test:* At baseline and as needed

POSTMENOPAUSAL HORMONE RECEPTOR-POSITIVE ADVANCED BREAST CANCER REGIMEN

EVEROLIMUS + EXEMESTANE

Baselga J et al. N Engl J Med 2012;366:520–529

Everolimus 10 mg/day; administer orally, continually (total dose/week = 70 mg)
Exemestane 25 mg/day; administer orally, continually (total dose/week = 175 mg)
or
Placebo (formulated to match everolimus); administer orally, continually
Exemestane 25 mg/day; administer orally, continually (total dose/week = 175 mg)

Efficacy

Patient Population Studied

The Breast Cancer Trials of Oral Everolimus-2 (BOLERO-2) was an international, double-blind, phase 3 study in which 724 women with hormone receptor-positive breast cancer refractory to nonsteroidal aromatase inhibitors were randomly assigned to either everolimus + exemestane (485 patients) or exemestane + placebo (239 patients) (2:1 assignment ratio favoring everolimus + exemestane; patients were stratified according to the presence of visceral metastasis and previous sensitivity to endocrine therapy). Median age was 62 y; 56% of patients had visceral involvement, 76% had bone metastases, and 69% had measurable disease. All patients had ER-positive and Her2-negative disease, and had previously received aromatase inhibitor therapy; 68% had prior chemotherapy and 84% had previous sensitivity to endocrine therapy

Toxicity

Treatment Modifications for Everolimus

Adverse Event	Dose Modification
Noninfectious pneumonitis	
Grade 1 (asymptomatic radiologic changes suggestive of pneumonitis)	No dosage adjustment necessary; monitor appropriately
Grade 2 (symptomatic but not interfering with ADL	Consider interrupting treatment, rule out infection, and consider corticosteroids until symptoms improve to G ≤1; reinitiate at a lower dose. Discontinue if recovery does not occur within 4 weeks
Grade 3 (symptomatic, interferes with ADL; oxygen indicated)	Interrupt treatment until symptoms improve to G ≤1; rule out infection and consider corticosteroid treatment; may reinitiate at a lower dose. If G3 toxicity recurs, consider discontinuing
Grade 4 (life-threatening; ventilatory support indicated)	Discontinue treatment; rule out infection; consider corticosteroid treatment

(*continued*)

Treatment Modifications for Everolimus (*continued*)

Adverse Event	Dose Modification
Stomatitis (avoid the use of products containing alcohol, hydrogen peroxide, iodine, or thyme derivatives)	
Grade 1 (minimal symptoms, normal diet)	No dosage adjustment necessary; manage with mouth washes several times a day (see Supportive Care recommendations)
Grade 2 (symptomatic but can eat and swallow modified diet)	Interrupt treatment until symptoms improve to G ≤1; reinitiate at same dose; if stomatitis recurs with G2 severity, interrupt treatment until symptoms improve to G ≤1 and then reinitiate at a lower dose. Also manage with topical (oral) analgesics (eg, benzocaine, butyl aminobenzoate, tetracaine, menthol, or phenol) ± topical (oral) corticosteroids (eg, triamcinolone)
Grade 3 (symptomatic and unable to orally aliment or hydrate adequately)	Interrupt treatment until symptoms improve to G ≤1; then reinitiate at a lower dose. Also manage with topical (oral) analgesics (eg, benzocaine, butyl aminobenzoate, tetracaine, menthol, or phenol) ± topical (oral) corticosteroids (eg, triamcinolone)
Grade 4 (life-threatening symptoms)	Discontinue treatment; initiate appropriate medical intervention
Metabolic toxicity (eg, hyperglycemia, dyslipidemia)	
Grade 1	No dosage adjustment necessary; initiate appropriate medical intervention and monitor
Grade 2	No dosage adjustment necessary; manage with appropriate medical intervention and monitor
Grade 3	Temporarily interrupt treatment; reinitiate at a lower dose; manage with appropriate medical intervention and monitor
Grade 4	Discontinue treatment; manage with appropriate medical intervention
Nonhematologic toxicities (excluding pneumonitis, stomatitis, or metabolic toxicity)	
Grade 1	If toxicity is tolerable, no dosage adjustment necessary; initiate appropriate medical intervention and monitor
Grade 2	If toxicity is tolerable, no dosage adjustment necessary; initiate appropriate medical intervention and monitor. If toxicity becomes intolerable, temporarily interrupt treatment until improvement to G ≤1 and reinitiate at the same dose; if toxicity recurs at G2, temporarily interrupt treatment until improvement to G ≤1 and then reinitiate at a lower dose
Grade 3	Temporarily interrupt treatment until improvement to G ≤1; initiate appropriate medical intervention and monitor. May reinitiate at a lower dose; if toxicity recurs at G3, consider discontinuing
Grade 4	Discontinue treatment; initiate appropriate medical intervention
Everolimus dose modifications for organ dysfunction	
Mild hepatic impairment	Everolimus 7.5 mg daily
Moderate hepatic impairment	Everolimus 5 mg daily
Severe hepatic impairment	Maximum dose, Everolimus 2.5 mg daily
Renal Impairment	No adjustment needed

ADL, activities of daily life

Therapy Monitoring

1. *Baseline and Monthly:* CBC with differential and platelet count, and serum electrolytes and LFTs
2. Lipid profile every 6 weeks

METASTATIC REGIMEN

DOXORUBICIN, EVERY 3 WEEKS

Chan S et al. J Clin Oncol 1999;17:2341–2354

Doxorubicin 75 mg/m²; administer intravenously over 15–20 min on day 1, every 3 weeks for 7 cycles (total dosage/cycle = 75 mg/m²)

Notes:

- A maximum of 7 cycles was established because of the unacceptable incidence of CHF associated with cumulative doxorubicin dosages >550 mg/m². Continuation of treatment is given on a case-by-case basis
- Doxorubicin use is discontinued for either a decrease in LVEF (cardiac ejection fraction) ≥10% (absolute units) or a LVEF decline to <50%

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **HIGH**. Potential for delayed emetic symptoms*

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
G4 neutropenia	Administer 75% dosage
ANC <1000/mm³	Delay next cycle until ANC ≥1000/mm³
Platelet count <100,000/mm³	Delay next cycle until platelet count ≥100,000/mm³
G3/4 nonhematologic toxicity	Delay next cycle until nonhematologic toxicities decrease to G ≤1
Bilirubin 1.2–3.0 mg/dL (21–51 µmol/L)	Administer 50% dosage
Bilirubin 3.1–5 mg/dL (53–86 µmol/L)	Administer 25% dosage

Patient Population Studied

Study of 326 patients with MBC randomized to either doxorubicin 75 mg/m² or docetaxel 100 mg/m² every 3 weeks. All patients had previously received alkylating agent chemotherapy (eg, cyclophosphamide, methotrexate, and fluorouracil [CMF], or its variants) either in the adjuvant setting or for advanced disease. Criteria for exclusion included: more than 1 line of chemotherapy for advanced or metastatic disease; previous treatment with anthracyclines, anthracenes, or a taxane; no alkylating agent in last chemotherapeutic regimen

Efficacy* (N = 147)

WHO Criteria

% Complete response	4.8
% Partial response	28.5

Median time to progression	21 weeks
Median time to treatment failure	18 weeks
Median overall survival	14 months†

*All randomized patients. Evaluated by WHO Criteria
†26% of patients received taxane-containing therapy

Toxicity (N = 193)

NCI CTCAE

Toxicity	Percent of Patients
Neutropenia, all grades	96.7
G3 neutropenia	11.1
G4 neutropenia	77.8
Febrile neutropenia	12.3
G3/4 infection	4.3
G3/4 anemia	16.1
RBC transfusion	20.9
G4 thrombocytopenia	7.5
>20% LVEF decrease*	31.7
>40% LVEF decrease*	16

*Number of patients assessable for LVEF: 101

Therapy Monitoring

1. CBC with differential and platelet count, and serum LFTs and bilirubin before each treatment. Consider intracycle assessment in early cycles
2. LVEF assessment (MUGA or echocardiography) before starting doxorubicin, after completing 300 mg/m², then before every subsequent treatment

METASTATIC REGIMEN

WEEKLY DOXORUBICIN OR EPIRUBICIN

Gasparini G et al. Am J Clin Oncol 1991;14:38–44

Doxorubicin HCl 20 mg/m²; administer by intravenous injection over 3–5 minutes every week, continually (total dosage/week = 20 mg/m²)

or

Epirubicin HCl 20 mg/m²; administer by intravenous injection over 3–5 minutes every week, continually (total dosage/week = 20 mg/m²)

Notes:

Cumulative doxorubicin and epirubicin dosages >550 mg/m² are associated with an unacceptable incidence of CHF. Continuation of treatment is given on a case-by-case basis Doxorubicin or Epirubicin use is discontinued for either a decrease in LVEF ≥10% (absolute units) or a LVEF (cardiac ejection fraction) decline to <50%

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Efficacy WHO Criteria

Treatment delays	1 patient (9%)	7 patients (38%); p = 0.05

*No significant differences were evident; however, the only case that developed symptomatic congestive heart failure was in the doxorubicin arm, after a cumulative dose of 820 mg/m² at 11.5 months

Therapy Monitoring

1. *Before each doxorubicin or epirubicin treatment:* CBC with leukocyte differential count and platelet counts, and serum LFTs including total bilirubin
2. *Before starting doxorubicin or epirubicin, after receiving a total cumulative lifetime dosage of 300 mg/m², then before every third subsequent treatment:* LVEF assessment (MUGA or echocardiography). Consider more frequent assessment in patients with cardiac disease or previous radiation therapy to fields involving the mediastinum

METASTATIC REGIMEN

DOXORUBICIN HCl LIPOSOME INJECTION (LIPOSOMAL DOXORUBICIN)

O'Brien MER et al. Ann Oncol 2004;15:440–449

Doxorubicin HCl liposome injection 40–50 mg/m²; administer intravenously in 250 mL (doses ≤90 mg) or 500 mL (doses >90 mg) 5% dextrose injection over 60 minutes on day 1, every 3 weeks (total dosage/cycle = 40–50 mg/m²)
Note: Liposomal doxorubicin is administered at an initial rate of 1 mg/min to minimize the risk of infusion reactions. If no infusion-related adverse reactions are observed within 15 min after starting administration, the infusion rate may be increased to complete administration over 1 hour

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

DOXIL (Doxorubicin HCl Liposome Injection) Product Label, November 2010. Centocor Ortho Biotech Products, L.P.

Adverse Events	Treatment Modifications
Hematologic Adverse Events	
ANC 500–1500/mm³ or platelets 25,000–75,000/mm³	Delay treatment until ANC >1500/mm³ and platelets >75,000/mm³, then resume treatment at the same dosage and schedule
ANC <500/mm³ or platelets <25,000/mm³	Delay treatment until ANC >1500/mm³ and platelets >75,000/mm³, then resume treatment with dosage reduced by 25% from the last dose administered, *or* add hematopoietic growth factor
Stomatitis	
G2	Delay treatment until stomatitis resolves to G ≤1
G3/4	Delay treatment until stomatitis resolves to G ≤1, then resume treatment with liposomal doxorubicin dosage decreased by 25%
For delays >2 weeks because of stomatitis	Discontinue treatment
Other G3 adverse events (except nausea, vomiting, or alopecia)	Delay treatment until stomatitis resolves to G1, then resume treatment with liposomal doxorubicin dosage decreased by 25%
Guidelines for Cardiac Toxicity	
LVEF decreases by ≥15% from baseline, or to <45%	Discontinue pegylated liposomal doxorubicin

(*continued*)

Patient Population Studied

Study of 509 women with stages IIIB, IV MBC and normal cardiac function were randomly assigned to receive either liposomal doxorubicin 50 mg/m² every 4 weeks, or doxorubicin 60 mg/m² every 3 weeks

Efficacy WHO Criteria

	Liposomal Doxorubicin*	Doxorubicin*
Overall response rate (CR + PR)	33%	38%
Stable disease	25%	25%
Progressive disease	18%	11%
Median duration of response	7.3 months	7.1 months
Median overall survival	21 months	22 months

*The HR for PFS was 1.00 (95% CI for HR 0.82–1.22); consistent with noninferiority of liposomal doxorubicin compared with doxorubicin

Treatment Modifications (*continued*)

Adverse Events	Treatment Modifications		
Guidelines for Palmar-Plantar Erythrodysesthesia			
Grade of Toxicity	4 Weeks > Dose	5 Weeks > Dose	6 Weeks > Dose
G1: Mild erythema, swelling, or desquamation not interfering with daily activities	Redose unless patient has previous G3/4 skin toxicity. If so, delay an additional week	Redose unless patient has previous G3/4 skin toxicity. If so, delay an additional week	Redose at 25% dosage reduction; return to 4-week interval or discontinue therapy
G2: Erythema, desquamation, or swelling interfering with, but not precluding, normal physical activities; small blisters or ulcerations <2 cm in diameter	Delay treatment 1 week	Delay treatment 1 week	Redose at 25% dosage reduction; return to 4-week interval or discontinue therapy
G3: Blistering, ulceration, or swelling interfering with walking or normal daily activities; cannot wear regular clothing	Delay treatment 1 week	Delay treatment 1 week	Discontinue therapy
G4: Diffuse or local process causing infectious complications, or a bedridden state, or hospitalization	Delay treatment 1 week	Delay treatment 1 week	Discontinue therapy

Richardson et al. J Clin Oncol 2006;24:3113–3120

Therapy Monitoring

1. *Before each dose:* CBC with differential and platelet count. Consider intracycle assessment during first few cycles
2. *Every other cycle or every third cycle during therapy:* LFTs, serum electrolytes, cardiac function by ECHO

METASTATIC REGIMEN

WEEKLY PACLITAXEL

Perez EA et al. J Clin Oncol 2001;19:4216–4223

Premedication:
Dexamethasone 10 mg/dose; administer orally for 2 doses 12 hours and 6 hours before paclitaxel (total dose/cycle = 20 mg), *or*
Dexamethasone 20 mg; administer intravenously over 10–15 minutes, 30–60 minutes before paclitaxel (total dose/cycle = 20 mg)

Note: Dexamethasone doses may be gradually decreased in the absence of hypersensitivity reactions during repeated paclitaxel treatments
Diphenhydramine 25–50 mg; administer orally 60 minutes before paclitaxel, *or* administer by intravenous injection 30–60 minutes before paclitaxel
Cimetidine 300 mg (or ranitidine 150 mg, famotidine 20–40 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer orally 60 minutes before paclitaxel, *or* cimetidine 300 mg (or ranitidine 50 mg, famotidine 20 mg); administer intravenously over 15–30 minutes, 30–60 minutes before paclitaxel
Paclitaxel 80 mg/m² per dose; administer intravenously in a volume of 0.9% sodium chloride injection or 5% dextrose injection sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 60 minutes, weekly for 4 consecutive weeks, every 4 weeks (total dosage/4-week cycle = 320 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Events	Treatment Modifications
ANC ≤800/mm³ or platelets ≤50,000/mm³	Hold treatment until ANC >800/mm³ and platelets >50,000/mm³, then resume with weekly paclitaxel dosage reduced by 10 mg/m²
G2 motor or sensory neuropathies	Reduce weekly paclitaxel dosage by 10 mg/m² without interrupting planned treatment
Other nonhematologic adverse events G2 or G3	Hold treatment until adverse events resolve to G ≤1, then resume with weekly paclitaxel dosage reduced by 10 mg/m²
Patients who cannot tolerate paclitaxel at 60 mg/m² per week	Discontinue treatment
Treatment delay >2 weeks	Decrease weekly paclitaxel dosage by 10 mg/m² or consider discontinuing treatment

Patient Population Studied

Study of 212 women with metastatic breast cancer who had previously received up to 2 chemotherapy regimens for metastatic disease. Prior taxane treatment was allowed if the administration interval was every 3 weeks or less frequently

Efficacy (N = 177 Evaluable) as Defined

PACLITAXEL EVERY 3 WEEKS

Nabholtz J-M et al. J Clin Oncol 1996;14:1858–1867

Premedication:
Dexamethasone 10 mg/dose; administer orally for 2 doses 12 hours and 6 hours before paclitaxel (total dose/cycle = 20 mg), *or*
Dexamethasone 20 mg; administer intravenously over 10–15 minutes, 30–60 minutes before paclitaxel (total dose/cycle = 20 mg)
Note: Dexamethasone doses may be gradually decreased in the absence of hypersensitivity reactions during repeated paclitaxel treatments
Diphenhydramine 25–50 mg; administer orally 60 minutes before paclitaxel, *or* administer by intravenous injection 30–60 minutes before paclitaxel
Cimetidine 300 mg (or ranitidine 150 mg, famotidine 20–40 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer orally 60 minutes before paclitaxel, *or* cimetidine 300 mg (or ranitidine 50 mg or famotidine 20 mg); administer intravenously over 15–30 minutes, 30–60 minutes before paclitaxel
Paclitaxel 175 mg/m²; administer intravenously in a volume of 0.9% sodium chloride injection or 5% dextrose injection sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 3 hours on day 1, every 3 weeks (total dosage/cycle = 175 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is LOW
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Events	Treatment Modifications
WHO G3/4 neutropenia for ≥7 days	Decrease paclitaxel dosage by 25%
Platelet counts ≤100,000/mm³ for ≥7 days	
Febrile neutropenia, documented infection, or hemorrhage	
WHO G3 mucositis	
WHO G >2 paresthesias	Discontinue therapy
Symptomatic arrhythmia or heart block >1°	
Other major organ toxicities WHO G >2	
Severe hypersensitivity reaction	

Patient Population Studied

Study of 471 women with measurable metastatic breast cancer who had received 1 prior chemotherapy regimen (as adjuvant therapy or for metastatic disease), or 2 prior regimens (1 adjuvant and 1 for metastatic disease)

Efficacy (N = 471)

WHO Criteria

	Paclitaxel Dosage (mg/m²)	
	175	135
Complete response	5%	2%
Partial response	24%	20%

G3 mucositis	3%	<1%

*Includes any of the following: hypotension requiring vasopressors, angioedema, respiratory distress requiring bronchodilators, or generalized urticaria

Therapy Monitoring

Before each cycle: CBC with differential and platelet count. Consider intracycle monitoring during first few cycles

METASTATIC REGIMEN

WEEKLY DOCETAXEL

Burstein HJ et al. J Clin Oncol 2000;18:1212–1219

Premedication:
Dexamethasone 8 mg/dose; administer orally for 3 doses at approximately 12 hours and 1 hour before docetaxel, and 12 hours after docetaxel administration (total dose/week = 24 mg)
Diphenhydramine 50 mg; administer by intravenous injection 30 minutes before docetaxel
Docetaxel 40 mg/m^2; administer intravenously in a volume of 0.9% sodium chloride injection or 5% dextrose injection sufficient to produce a final docetaxel concentration within the range 0.3–0.74 mg/mL over 60 minutes, every week for 6 consecutive weeks, every 8 weeks (total dosage/8-week cycle = 240 mg/m^2)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Events	Treatment Modifications
G2 neurotoxicity	Decrease docetaxel dosage by 25%*
Febrile neutropenia	
G4 thrombocytopenia	
Any G3 nonhematologic adverse event	
G4 nonhematologic toxicity	Consider discontinuing treatment
ANC <1000/mm^3	Hold treatment until ANC >1000/mm^3, platelets >100,000/mm^3, bilirubin normalizes, and AST <1.5 × ULN. If delay is >3 weeks, consider discontinuing therapy
Platelets <100,000/mm^3	
Bilirubin greater than upper limit of normal (ULN) range	
AST >1.5 ULN	
ANC <1000/mm^3 for >2 weeks	Consider adding filgrastim during subsequent cycles
Patients who miss 1–2 weekly treatments in a cycle, but remain eligible for retreatment	Consider retreatment during week 7 of the affected cycle

*Do not re-escalate dose after a dosage decrease

Patient Population Studied

Study of 29 women with metastatic breast cancer with prior treatment of metastatic disease limited to 1 prior chemotherapy regimen. No limitation on prior hormonal therapy

Efficacy (N = 29)

Partial response	41%
Stable disease ≥6 months	17%

Toxicity (N = 29)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Study of 302 patients with stage IV metastatic breast cancer who had not previously received treatment for metastatic disease who were randomly assigned to 1 of 3 treatment regimens with *nab*-paclitaxel or docetaxel. Prior neoadjuvant or adjuvant chemotherapy was allowed if at least 1 year had elapsed since administration. Forty-three percent of patients had previously received chemotherapy in the adjuvant or neoadjuvant settings, and 10% of patients had grade 1 neuropathy before receiving study therapy

Treatment Modifications

Adverse Event	Treatment Modification
ANC <500/mm^3 for ≥1 week	Withhold *nab*-paclitaxel until symptoms resolve to G ≤1, then resume at a dosage decreased by 25%
Sensory neuropathy G2	Delay *nab*-paclitaxel until symptoms resolve to G ≤1, then resume treatment at the same dosage and schedule
Sensory neuropathy G ≥3	Withhold *nab*-paclitaxel until symptoms resolve to G ≤1, then resume on the same administration schedule with a dosage decreased by 25%. Do not re-escalate *nab*-paclitaxel dosage during subsequent use
Second recurrence of sensory neuropathy G ≥3 after dosage reduction	Withhold *nab*-paclitaxel until symptoms resolve to G ≤1, then resume on the same administration schedule with a dosage decreased by an additional 25% (total 50% dosage reduction). Do not re-escalate *nab*-paclitaxel dosage during subsequent use
Third recurrence of sensory neuropathy G ≥3 after 2 dosage reductions	Discontinue *nab*-paclitaxel
Severe hypersensitivity reaction	Discontinue *nab*-paclitaxel
Hypotension, during the 30-minute infusion (may occur in 5% of patients)	Most often occurs without symptoms and requires neither specific therapy nor treatment discontinuation
Bradycardia, during the 30-minute infusion (may occur in <1% of patients)	Most often occurs without symptoms and require neither specific therapy nor treatment discontinuation

Efficacy

RECIST*

	nab-Paclitaxel		
	300 mg/m² every 3 wks	100 mg/m² weekly*	150 mg/m² weekly†

Partial response	36%	45%	49%
Complete response	1%	0	0
Stable disease ≥16 weeks	32%	30%	31%
Median progression-free survival	11 months	12.9 months	12.9 months

*RECIST, Response Evaluation Criteria in Solid Tumors (Therasse P et al. J Natl Cancer Inst 2000;92:205–216)
†Weekly regimens are given for 3 consecutive weeks followed by 1 week without retreatment during a 4-week cycle

Toxicity

NCI Common Terminology Criteria for Adverse Events

Toxicity	300 mg/m² every 3 wks	100 mg/m² weekly*	150 mg/m² weekly*
	Percent of Patients Experiencing Toxicity		
G1/2 neutropenia	49	55	47
G1/2 sensory neuropathy	56	50	54
G1/2 fatigue	31	34	42
G1/2 arthralgia	31	19	35
Alopecia	47	57	53
G3/4 neutropenia	44	25	44
G3/4 sensory neuropathy	17	8	14
G3/4 fatigue	5	0	3
G3/4 arthralgia	1	0	0

*Weekly regimens are given for 3 consecutive weeks followed by 1 week without retreatment during a 4-week cycle

Therapy Monitoring

1. *Before each dose:* CBC with differential count and platelet count, LFTs, and neurologic exam
2. *Weekly:* CBC with differential and platelet count through cell count nadirs, particularly for a 150-mg/m² for 3-weeks-out-of-4-weeks regimen

METASTATIC REGIMEN

CAPECITABINE

Bajetta E et al. J Clin Oncol 2005;23:2155–2161
Blum JL et al. J Clin Oncol 1999;17:485–493
Blum JL et al. Cancer 2001;92:1759–1768
Reichardt P et al. Ann Oncol 2003;14:1227–1233
Xeloda (capecitabine) Tablets, Film Coated for Oral Use Product Label, December 2013. Genentech USA, Inc., South San Francisco, CA

Capecitabine 1250 mg/m² per dose; administer orally twice daily within 30 minutes after a meal for 14 consecutive days (28 doses) on days 1–14, every 3 weeks (total dosage/cycle = 35,000 mg/m²)

Notes:

- Capecitabine is given for 2 consecutive weeks followed by 1 week without treatment
- Doses are rounded to use combinations of 500-mg and 150-mg tablets that most closely approximate calculated values
- In practice, treatment often is begun with capecitabine 1000 mg/m² per dose twice daily for 14 consecutive days on days 1–14, every 3 weeks, because of a high rate of dose reduction with higher dosages (total dosage/cycle = 28,000 mg/m²)
- Initial capecitabine dosage should be decreased by 25% in patients with moderate renal impairment (baseline creatinine clearance = 30–50 mL/min [0.5–0.83 mL/s]); ie, a dosage reduction from 1250 mg/m² per dose, to 950 mg/m² per dose, twice daily. Capecitabine use is contraindicated in persons with severe renal impairment (creatinine clearance <30 mL/min [<0.5 mL/s])
- Although food decreases the rate and extent of drug absorption and the time to peak plasma concentration and systemic exposure (AUC) for both capecitabine and fluorouracil, product labeling recommends giving capecitabine within 30 minutes after the end of a meal because established safety and efficacy data are based on administration with food

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed onset diarrhea:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Hand-foot reaction

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine 50–150 mg/day administer orally

Treatment Modifications

Adapted from NCI of Canada CTC

Adverse Event	Dose Modification
First G2 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. No change in dosage required
Second G2 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 25%
Third G2 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 50%
Fourth G2 toxicity	Discontinue capecitabine
First G3 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 25%
Second G3 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 50%
Third G3 toxicity	Discontinue capecitabine
First G4 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 50%
Second G4 toxicity	Discontinue capecitabine
Diarrhea, nausea, and vomiting	Treat symptomatically. Resume previous dosage if toxicity is adequately controlled within 2 days after initiation of treatment. If control takes longer, reduce the capecitabine dosage, or if it occurs despite prophylaxis, reduce the capecitabine dosage 25–50%

Toxicity

Xeloda (capecitabine) Tablets, Film Coated for Oral Use Product Label, December 2013. Genentech USA, Inc., South San Francisco, CA

Incidence of selected adverse reactions possibly or probably related to treatment in ≥5% of patients participating in a single arm trial in stage IV breast cancer (n = 162)

*Twice-daily oral capecitabine at 1255 mg/m² per dose given for 2 treatment weeks, followed by a 1-week rest period and repeated in 3-week cycles (total daily dose = 2510 mg/m²)

Therapy Monitoring

1. *Before starting each cycle:* CBC with differential and platelet counts. Consider intracycle monitoring in first few cycles
2. *Every other cycle:* Serum electrolytes, serum creatinine and BUN, and LFTs
3. Frequently monitor anticoagulant response (INR or PT) in patients who use coumarin anticoagulants (eg, warfarin) and capecitabine concomitantly, and adjust anticoagulant dose accordingly, or consider alternative anticoagulant agents

METASTATIC REGIMEN

GEMCITABINE

Blackstein M et al. Oncology 2002;62:2–8
Carmichael J et al. J Clin Oncol 1995;13:2731–2736

Gemcitabine 800–1200 mg/m² per dose; administer by intravenous infusion in 50–250 mL 0.9% sodium chloride injection (0.9% NS) over 30 minutes on days 1, 8, and 15, every 28 days for up to 8 cycles (total dosage/cycle = 2400–3600 mg/m²)

Note: Gemcitabine use in patients with concurrent liver metastases or a preexisting history of hepatitis, alcoholism, or liver cirrhosis, may lead to exacerbation of the underlying hepatic insufficiency

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Events	Treatment Modifications
ANC 1000–1499/mm³, WBC 1000–1999/mm³, or platelets 50,000–99,999/mm³ on day of treatment	Reduce dosage by 25%
ANC and WBC <1000/mm³ or platelets <50,000/mm³ on day of treatment	Hold treatment until ANC and WBC >1000/mm³, and platelets >50,000/mm³. Resume treatment with gemcitabine dosage reduced by 50%
ANC and WBC <500/mm³, or platelets <25,000/mm³ on day of treatment	Consider discontinuing therapy
WHO G3 nonhematologic adverse events (excluding nausea, vomiting, and alopecia)	Decrease dosage by 50%, or withhold treatment until recovery to G ≤1
WHO G4 nonhematologic adverse events	Hold treatment until resolution to G ≤1 then resume with a 50% dose reduction

Patient Population Studied

Blackstein M et al. Oncology 2002;62:2–8

Study of 39 patients with metastatic breast cancer who had not previously received chemotherapy for metastatic disease

Efficacy (N = 35)

Blackstein M et al. Oncology 2002;62:2–8

WHO Criteria	
Overall response rate	37.1% (95% CI, 21.5–55.1)
Complete response rate	5.7%
Partial response rate	31.4%
Median time to progression	5.1 months (95% CI, 3.5–5.8)
Median response duration in 13 responders	8.8 months (95% CI, 5.2–12.7)
Median overall survival	21.1 months (95% CI, 11–26.9)
Estimated 1-year survival	65%

Toxicity (N = 39)

Blackstein M et al. Oncology 2002;62:2–8

WHO Criteria		
Toxicity	% G1/2	% G3/4
Hematologic Toxicity

Nisticò C et al. Breast Cancer Res Treat 2000;59:223–229
Zelek L et al. Cancer 2001;92:2267–2272

Vinorelbine 25–30 mg/m² per dose; administer by intravenous infusion in a volume of 0.9% sodium chloride injection or 5% dextrose injection sufficient to produce a vinorelbine concentration within the range 0.5–2 mg/mL over 20 minutes, every week, continually (total dosage/week = 25–30 mg/m²)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Burstein HJ et al. J Clin Oncol 2001;19:2722–2730
Nisticò C et al. Breast Cancer Res Treat 2000;59:223–229

Adverse Event	Treatment Modifications
ANC >1250/mm³ and platelets >100,000/mm³ on treatment day	Give starting dose
ANC 750–1250/mm³ or platelets 50,000–99,000/mm³ on treatment day	Reduce vinorelbine dosage to 75% of starting dose
ANC <750/mm³ or platelets <50,000/mm³	Hold vinorelbine dose until ANC >750/mm³ and platelets >50,000/mm³ then resume at dose as determined by ANC and platelets
Treatment delays for neutropenia ≥2 weeks	Add filgrastim
For treatment delays >3 weeks	Consider discontinuing treatment
Total bilirubin 2–3 mg/dL (34.2–51.3 µmol/L)	Give vinorelbine at 12.5 mg/m²
Total bilirubin >3 mg/dL (>51.3 µmol/L)	Hold vinorelbine
G2 neurologic adverse events	Hold vinorelbine until adverse events resolve to G ≤1, then resume treatment with dosage decreased by 25%
G3 nonhematologic adverse events	Hold vinorelbine dose until adverse events resolve to G ≤1, then resume treatment with dosage decreased by 25%
G4 nonhematologic adverse events	Consider discontinuing treatment

Patient Population Studied

Nisticò C et al. Breast Cancer Res Treat 2000;59:223–229

Study of 40 women with metastatic breast cancer, prior treatment with at least 1 anthracycline-containing regimen in the adjuvant or metastatic setting

Efficacy (N = 40)

Nisticò C et al. Breast Cancer Res Treat 2000;59:223–229

WHO Criteria	
Overall response	52.5% (95% CI, 37–68)
Complete response	12.5%
Partial response	40%
Median duration of response	10 months (Range: 5–21)
Median time to progression	9 months (Range: 1–27)
Estimated overall survival	19 months (Range: 2–54+)

Toxicity (N = 40)

Nisticò C et al. Breast Cancer Res Treat 2000;59:223–229

WHO Criteria		
Toxicity	% G1/2	% G3/4
Hematologic Toxicity		
Neutropenia	57.5	25
Anemia	65	10
Thrombocytopenia	7.5	0
Nonhematologic Toxicity

Therapy Monitoring

1. *Before each dose:* CBC with differential count and platelet count
2. *Every other week:* LFTs

METASTATIC REGIMEN

ERIBULIN MESYLATE

Cortes J et al. J Clin Oncol 2010;28:3922–3928
Cortes J et al. Lancet 2011;377:914–923

Eribulin mesylate 1.4 mg/m² per dose*; administer (undiluted) by slow intravenous injection over 2–5 minutes for 2 doses on days 1 and 8, every 21 days (total dosage/cycle = 2.8 mg/m²)

*Dosage Recommendations for Impaired Liver and Renal Function

Condition	Dosage (days 1 and 8; 21-day cycle)
Mild hepatic impairment (Child-Pugh A)	1.1 mg/m² per dose (total dosage/cycle = 2.2 mg/m²)
Moderate hepatic impairment (Child-Pugh B)	0.7 mg/m² per dose (total dosage/cycle = 1.4 mg/m²)
Moderate renal impairment (creatinine clearance: 30–50 mL/min [0.5–0.83 mL/s])	1.1 mg/m² per dose (total dosage/cycle = 2.2 mg/m²)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

Treatment Modifications

Eribulin Mesylate Dosage Levels	
Dosage Level 1	1.4 mg/m²
Dosage Level −1	1.1 mg/m²
Dosage Level −2	0.7 mg/m²
Adverse Events	**Treatment Modifications**
ANC <1000/mm³ on cycle days 1 or 8	Hold eribulin mesylate. Administer when ANC >1000/mm³
Platelet count <75,000/mm³ on cycle days 1 or 8	Hold eribulin mesylate. Administer when platelet count >75,000/mm³
Nonhematologic toxicities G ≥3 on cycle days 1 or 8	Hold eribulin mesylate. Administer when toxicities < G2
ANC <1000/mm³ on cycle day 8 resolved by day 15	Give eribulin mesylate at a dosage decreased by 1 dose level but do not administer less than 0.7 mg/m². Initiate a subsequent cycle no sooner than 2 weeks later
Platelet count <75,000/mm³ on cycle day 8 resolved by day 15	
Nonhematologic toxicities G ≥3 on cycle day 8 resolved by day 15	
ANC <1000/mm³ on cycle day 8 and still <1000/mm³ on day 15	Omit day 8 eribulin mesylate dose
Platelet count <75,000/mm³ on cycle day 8 and still <75,000/mm³ on day 15	
Nonhematologic toxicities G ≥3 on cycle day 8 and still G ≥3 on day 15	
ANC <500/mm³ for >7 days	Permanently decrease eribulin mesylate dosage by one dosage level but do not administer less than 0.7 mg/m²
ANC <1000/mm³ with fever or infection	
Platelet count <25,000/mm³	
Platelet count <50,000/mm³ requiring transfusion	
Nonhematologic toxicities G ≥3 lasting >7 days	
Omission or delay of a day 8 dose during the previous cycle for toxicity	

Note: After any dosage decrease, do not re-escalate eribulin mesylate dosages during subsequent treatments

Patient Population Studied

Cortes J et al. Lancet 2011;377:914–923

EMBRACE trial (study E7389-G000-305). A phase 3 open-label, multicenter study that enrolled women with locally recurrent or metastatic breast cancer and randomly allocated them (2:1) to eribulin mesylate or treatment of physician's choice (TPC). Patients were previously treated for locally recurrent or metastatic breast cancer (508 eribulin mesylate vs. 254 TPC). Patients were heavily pretreated (median of 4 previous chemotherapy regimens); 559 (73%) of 762 patients had received capecitabine previously. No TPC patient received supportive care alone; most (238 [96%] of 247) received chemotherapy, which was most often vinorelbine, gemcitabine, or capecitabine. Overall, 16% (123 of 762 patients) had HER2- positive disease, and 19% (144 patients) had triple-negative disease. The most common metastatic sites were bone and liver; 386 (51%) of 762 patients had metastatic disease involving 3 or more organs. Randomization was stratified by geographical region, previous capecitabine treatment, and human epidermal growth factor receptor 2 status. The primary end point was overall survival in the intention-to-treat population

Efficacy (N = 508)

RECIST		
	Independent Review	Investigator Review
Median overall survival	13.1 months	
1-Year survival rates	53.9%	
Median duration of treatment	3.9 months (Range: 0.7–16.3)	
Median progression-free survival	3.7 months (95% CI, 3.3–3.9)	3.6 months (95% CI, 3.3–3.7)

Best Overall Tumor Response		
Complete response	3 (1%)	1 (<1%)
Partial response	54 (12%)	61 (13%)
Stable disease	208 (44%)	219 (47%)
Progressive disease	190 (41%)	176 (38%)
Not evaluable	12 (3%)	11 (2%)
Unknown	1 (<1%)	0
Objective response rate	57 (12%) (95% CI, 9.4–15.5)	62 (13%) (95% CI, 10.3–16.7)

RECIST, Response Evaluation Criteria in Solid Tumors (Therasse P et al. J Natl Cancer Inst 2000;92:205–216)

Therapy Monitoring

1. ECG at baseline (pretreatment on cycle 1, day 1), prior to treatment on day 8, and prior to all eribulin mesylate treatments in patients with CHF or bradyarrhythmias, and in patients concomitantly using drugs known to prolong the QT/QTc interval. Avoid use in patients with congenital long QT syndrome
2. *Before each dose:* CBC with differential and platelet count, serum sodium, potassium, magnesium, creatinine and BUN, and LFTs. Correct electrolyte abnormalities before commencing treatment
3. *Before each cycle:* Neurologic examination

Toxicity (N = 503)*

*Dose interruptions, delays, and reductions were undertaken in 28 (6%), 248 (49%), and 145 (29%) of 503 patients, respectively

†Peripheral neuropathy includes neuropathy peripheral, neuropathy, peripheral motor neuropathy, polyneuropathy, peripheral sensory neuropathy, peripheral sensorimotor neuropathy, demyelinating polyneuropathy, and paraesthesia

METASTATIC REGIMEN

IXABEPILONE

Perez EA et al. J Clin Oncol 2007;25:3407–3414

Premedication:
Diphenhydramine 50 mg or an equivalent histamine receptor [H_1-subtype] antagonist); administer orally 60 minutes before ixabepilone
Ranitidine 150–300 mg (or cimetidine 300 mg, famotidine 20 mg, or an equivalent histamine receptor [H_2-subtype] antagonist); administer orally 60 minutes before ixabepilone

Ixabepilone 40 mg/m²; administer by intravenous infusion in a volume of lactated Ringer injection, or, alternatively, 0.9% sodium chloride injection with sodium bicarbonate (2 mEq/250–500 mL) sufficient to produce an ixabepilone concentration within the range 0.2–0.6 mg/mL over 3 hours on day 1, every 21 days (total dosage/cycle = 40 mg/m²)

Notes:
- Ixabepilone is a substrate for catabolism by cytochrome P450 (CYP) CYP3A subfamily enzymes
- Concomitant use of ixabepilone with strong CYP3A4 inhibitors or inducers should be avoided
- Grapefruit juice may also increase plasma ixabepilone concentrations and should be avoided
- If a strong CYP3A4 INHIBITOR and ixabepilone must be coadministered, a decrease in ixabepilone dosage to 20 mg/m² is predicted to adjust the ixabepilone AUC to the range observed without inhibitors
- If a concomitantly administered strong CYP3A4 inhibitor is discontinued, a period of approximately 1 week should elapse before the ixabepilone dosage is increased to the indicated (unmodified) dosage
- If a strong CYP3A4 INDUCER and ixabepilone must be coadministered (ie, no alternatives are feasible), based on extrapolation from a drug interaction study with rifampin, after a patient has been maintained on a strong CYP3A4 inducer, the dose of ixabepilone may be gradually increased from 40 mg/m² to 60 mg/m², depending on tolerance, which is predicted to adjust the AUC to the range observed without inducers
- Proceed cautiously; there are no clinical data with this dose adjustment in patients receiving strong CYP3A4 inducers
- Patients whose dose is increased >40 mg/m² should be monitored carefully for toxicities. If the strong inducer is discontinued, the ixabepilone dosage should be decreased to the (unmodified) dosage indicated without a strong CYP3A4 inducer

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

One-hundred twenty-eight women with metastatic or locally advanced breast cancer resistant to anthracyclines (doxorubicin or epirubicin), taxanes (paclitaxel or docetaxel), and capecitabine were enrolled in a phase II, multicenter, single-arm study designed to evaluate objective response rates to ixabepilone monotherapy administered every 21 days in repeated treatment cycles. Treatment continued for ≤18 cycles or until disease progression or unacceptable toxicity

Treatment Modifications

Ixabepilone Dosage Levels	
Dosage level 1	40 mg/m²
Dosage level −1	32 mg/m²
Dosage level −2	25 mg/m²
Adverse Events	**Treatment Modifications**
On day 1 of repeated cycles, an ANC <1500/mm³	Withhold treatment until ANC >1500/mm³ then administer dosage administered in previous cycle
On day 1 of repeated cycles, a platelet count <100,000/mm³	Withhold treatment until platelet count >100,000/mm³ then administer dosage administered in previous cycle
On day 1 of repeated cycles, nonhematologic toxicities ≥ G2 are present	Withhold treatment until nonhematologic toxicities are G1 or have resolved, then administer dosage administered in previous cycle
Transient G3 arthralgia/myalgia or fatigue	Continue same ixabepilone dosage
ANC <500/mm³ for ≥7 days	Reduce ixabepilone dosage by 1 dosage level
Febrile neutropenia	
Platelet count <25,000/mm³, or platelets <50,000/mm³ with bleeding	
G2 neuropathy lasting ≥7 days	
G3 neuropathy independent of duration	
G3 nonhematologic toxicity other than transient G3 arthralgia/myalgia or fatigue	
ANC still <1500/mm³ 2 weeks after planned start of cycle	Discontinue ixabepilone treatment
Platelet count still <100,000/mm³ 2 weeks after planned start of cycle	
G3 neuropathy lasting ≥7 days or disabling neuropathy	
Any G4 toxicity	
Hypersensitivity reaction to ixabepilone administration despite H_1 and H_2 antagonists	In addition to H_1- and H_2-antihistamines prophylaxis, administer **dexamethasone** 20 mg orally 60 minutes before commencing ixabepilone administration, *or* **Dexamethasone** 20 mg intravenously at least 30 minutes prior to starting ixabepilone administration

Efficacy

RECIST

IRF Best Response (N = 113)*	
Partial response	12%
Stable disease	50%
Progressive disease	32%
Median duration of response	5.7 months (95% CI, 4.4–7.3)
Median time to response	6.1 weeks (range: 5–19)
Stable disease >6 months	13.3%

RECIST, Response Evaluation Criteria in Solid Tumors (Therasse P et al. J Natl Cancer Inst 2000;92:205–216)
*Defined by Response Evaluation Criteria in Solid Tumors and assessed by an Independent Radiology Facility

Toxicity

*Peripheral neuropathy

1. Primarily, sensory neuropathy was the most common nonhematologic adverse event: G1/2 neuropathy in 49% of patients, G3/4 in 13% of patients
2. Severe peripheral neuropathy generally was characterized by paresthesias of the hands and feet, and developed after a median of 4 cycles (range: 1–11 cycles)
3. Peripheral neuropathy G ≥3 resolved to baseline or G1 in 13 of 17 patients, with a median time to resolution of 5.4 weeks
4. Median time to resolution of neuropathy G ≥2 was 4 weeks
5. Patients whose ixabepilone dosage was decreased because of neuropathy received a median of 3 additional treatment cycles, among whom 20 of 23 patients did not experience additional worsening or an improvement in their conditions

NCI-CTC, National Cancer Institute (USA) Common Toxicity Criteria. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]

Therapy Monitoring

1. *Before each cycle:* Neurologic examination, CBC with differential and platelet count, serum creatinine, BUN, and LFTs. Consider intracycle assessments in first few cycles
2. *During concomitant use with CYP3A4 inhibitors or inducers:* Frequently monitor CBC with differential and platelet count as means to guide ixabepilone dosage adjustments based on altered pharmacodynamic responses

METASTATIC REGIMEN

PACLITAXEL PLUS BEVACIZUMAB

Miller K et al. N Engl J Med 2007;357:2666–2676

Premedication:
Dexamethasone 10 mg/dose; administer orally for 2 doses 12 hours and 6 hours before paclitaxel (total dose/cycle = 20 mg), *or*
Dexamethasone 20 mg; administer intravenously over 10–15 minutes, 30–60 minutes before paclitaxel (total dose/cycle = 20 mg)
Note: Dexamethasone doses may be gradually decreased in the absence of hypersensitivity reactions during repeated paclitaxel treatments
Diphenhydramine 25–50 mg; administer orally 60 minutes before paclitaxel, *or* administer by intravenous injection 30–60 minutes before paclitaxel
Cimetidine 300 mg (or **ranitidine** 150 mg, **famotidine** 20–40 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer orally 60 minutes before paclitaxel, *or* **cimetidine** 300 mg (or **ranitidine** 50 mg, **famotidine** 20 mg); administer intravenously over 15–30 minutes, 30–60 minutes before paclitaxel

Paclitaxel 90 mg/m² per dose; administer intravenously in a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 60 minutes, for 3 doses on days 1, 8, and 15, every 28 days (total dosage/cycle = 270 mg/m²)
Bevacizumab 10 mg/kg per dose; administer intravenously in 100 mL 0.9% NS every 2 weeks (days 1 and 15) every 28 days (total dosage/cycle = 20 mg/kg)
Note: The initial bevacizumab dose is administered over 90 minutes. If administration is well tolerated, the administration duration may be decreased stepwise during subsequent administrations to 60 minutes, and, finally, to a minimum duration of 30 minutes

Note:
- Bevacizumab therapy is not withheld or discontinued for paclitaxel-related toxic effects. If paclitaxel use is discontinued, patients whose disease has not progressed may continue to receive bevacizumab at the same dosage and schedule previously administered during combination therapy with paclitaxel
- Treat with antihypertensive medication as needed. The goal of BP control should be consistent with general medical practice

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Treatment Modification
ANC 1000–1499/mm³	Reduce paclitaxel dosage to 65 mg/m² for the next dose given
Platelet count 75,000–99,000/mm³	
AST (SGOT) >5 times, but ≤10 times the upper limit of normal range	
Total bilirubin 1.6–2.5 mg/dL (27.4–42.8 μmol/L)	
Prolonged neutropenia	Permanently reduce paclitaxel dosage to 65 mg/m²
Febrile neutropenia	
Platelet count ≤40,000/mm³ with bleeding	
Any platelet count ≤20,000/mm³	
G3 neuropathy	Withhold paclitaxel until neuropathy improves to G ≤1, then resume paclitaxel at 65 mg/m²
Hypersensitivity reactions G ≥3	Permanently discontinue paclitaxel use*
G ≥3 neuropathy persisting >3 weeks	
Neuropathy recurrent after paclitaxel dosage reduction	
>2+ proteinuria by dipstick	Collect 24-hour urine for protein analysis
24-hour urine protein is <2000 mg	Continue same bevacizumab dosage
24-hour urine protein is ≥2000 mg	Withhold bevacizumab until 24-hour urine protein <2000 mg. Discontinue bevacizumab if 24-hour urine protein does not recover to <2000 mg after 4 weeks of bevacizumab interruption

(*continued*)

Toxicity* (N = 365)

*Toxic effects are graded according to the National Cancer Institute Common Toxicity Criteria, version 2.0. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013] The worst grade considered at least possibly related to treatment is given

Therapy Monitoring

- *Before each dose of paclitaxel:* CBC with leukocyte differential count and platelet count, serum creatinine and BUN, and LFTs, and neurologic examination
- *Before each dose of bevacizumab:* Urinalysis for protein excretion (dipstick screening for proteinuria or quantitative analysis)

Treatment Modifications (*continued*)

Adverse Event	Treatment Modification
G1 HTN (SBP 120–139 mm Hg or DBP 80–89 mm Hg)	Consider increased BP monitoring; start antihypertensive medication if appropriate
G2 HTN, asymptomatic (SBP 140–159 mm Hg or DBP 90–99 mm Hg)	Begin antihypertensive therapy and continue bevacizumab
G2 HTN, symptomatic (SBP 140–159 mm Hg or DBP 90–99 mm Hg)	Start or adjust antihypertensive medication Hold bevacizumab until symptoms resolve *and* BP <160/90 mm Hg. Resume bevacizumab after BP under control (<160/99 mm Hg)
G3 HTN (SBP ≥160 mm Hg or DBP ≥100 mm Hg)	For refractory hypertension requiring delay of bevacizumab for >4 wk, discontinue bevacizumab
G4 HTN (hypertensive crisis or malignant hypertension)	Permanently discontinue bevacizumab

Patient Population Studied

Study of 722 patients who were randomly assigned to receive initial treatment for metastatic breast cancer with either paclitaxel alone or paclitaxel plus bevacizumab in an open-label study

Efficacy (N = 347)

RECIST	
Overall response rate	36.9%
Median progression-free survival	11.8 months
Median overall survival	26.7 months
1-Year survival rate	81.2%

METASTATIC REGIMEN

DOCETAXEL + CAPECITABINE

O'Shaughnessy J et al. J Clin Oncol 2002; 12:2812–2823

Premedication:
Dexamethasone 8 mg/dose; administer orally twice daily for 3 days, starting on the day before docetaxel administration (total dose/cycle = 48 mg)
Docetaxel 75 mg/m^2; administer intravenously in a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) sufficient to produce a final docetaxel concentration within the range 0.3–0.74 mg/mL over 60 minutes on day 1, every 3 weeks for 4 cycles (total dosage/cycle = 75 mg/m^2)
Capecitabine 1250 mg/m^2 per dose; administer orally twice daily with approximately 200 mL water within 30 minutes after a meal for 14 consecutive days on days 1–14 (28 doses), every 3 weeks (total dosage/cycle = 35,000 mg/m^2)

Notes:
- Capecitabine is given for 2 consecutive weeks followed by 1 week without treatment
- Doses are rounded to use combinations of 500-mg and 150-mg tablets that most closely approximate calculated values
- In practice, treatment often is begun with capecitabine 1000 mg/m^2 per dose twice daily for 14 consecutive days on days 1–14, every 3 weeks, because of a high rate of dose reduction with higher dosages (total dosage/cycle = 28,000 mg/m^2)
- Initial capecitabine dosage should be decreased by 25% in patients with moderate renal impairment (baseline creatinine clearance = 30–50 mL/min [0.5–0.83 mL/s]); ie, a dosage reduction from 1250 mg/m^2 per dose to 950 mg/m^2 per dose, twice daily. Capecitabine use is contraindicated in persons with severe renal impairment (creatinine clearance <30 mL/min [<0.5 mL/s])
- Although food decreases the rate and extent of drug absorption and the time to peak plasma concentration and systemic exposure (AUC) for both capecitabine and fluorouracil, product labeling recommends giving capecitabine within 30 minutes after the end of a meal because established safety and efficacy data are based on administration with food

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed onset diarrhea:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)
- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Hand-foot reaction
For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine 50–150 mg/day; administer orally

Treatment Modifications

NCI of Canada CTC

Adverse Event	Treatment Modification
First G2*	Withhold chemotherapy until adverse events resolve to G ≤1, then resume
Recurrent G2 (second episode)* or Any G3	Withhold chemotherapy for up to 2 weeks • If adverse events resolve to G ≤1 within 2 weeks, resume treatment with docetaxel and capecitabine dosage decreased by 25% • If adverse events do not resolve to G ≤1 within 2 weeks, docetaxel is permanently discontinued, but capecitabine treatment may resume after adverse events resolve to G ≤1 at a dosage decreased by 25%
Recurrent G2 (third episode)* or Recurrent G3 (second episode) or Any G4	Permanently discontinue docetaxel. Withhold capecitabine for up to 2 weeks. If adverse events resolve to G ≤1 within 2 weeks, resume capecitabine treatment at 50% of the previous dosage
Recurrent G2 (fourth episode)* or Recurrent G3 (third episode) or Recurrent G4 (second episode)	Permanently discontinue capecitabine
Patients who continue capecitabine alone without evidence of adverse events G ≥2 during a cycle	Capecitabine dosage may be escalated by 25% greater than the previously administered dose during each subsequent cycle
G3/4 neutropenia	Withhold docetaxel. Resume docetaxel only after ANC ≥1500/mm^3; continue capecitabine treatment without interruption
G3/4 neutropenia + any other G2 clinical adverse event	Discontinue capecitabine. Consider hospitalization for management
Neutropenia + fever ≥38°C	
ANC <500/mm^3 for >7 days at 75 mg/m^2 docetaxel	Withhold docetaxel until ANC ≥1500/mm^3 and patient is afebrile for ≥48 hours, then resume docetaxel at 55 mg/m^2
ANC <500/mm^3 for >7 days at 55 mg/m^2 docetaxel	Permanently discontinue docetaxel

*Except isolated neutropenia

Efficacy (N = 256)

WHO Criteria

Response category	Percent	95% Confidence Interval
Overall response	42%	36–48%
Complete response	5%	2–8%
Stable disease >6 weeks	38%	32–44%
Median time to progression	6.1 months	5.4–6.5 months
12-Month survival	57%	51–63%
Median survival	14.5 months	12.3–16.3 months

Patient Population Studied

Study of 255 patients with metastatic breast cancer with prior anthracycline, no prior docetaxel, and less than 3 prior chemotherapy regimens

Toxicity (N = 251)

NCI of Canada CTC

Toxicity	% G3*	% G4*
Hematologic Toxicity		
Neutropenia†,‡	5	11
Febrile neutropenia‡,§	3	13
Nonhematologic Toxicity		
Hand-foot syndrome	24	N/A
Stomatitis	17	0.4
Diarrhea	14	0.4
Nausea	6	—
Fatigue/asthenia	8	0.4
Alopecia	6	—
Laboratory Abnormalities‡		
Hyperglycemia	13	1
Hyperbilirubinemia	6.8	2
Elevated ALT/AST	1.6	2.8

*National Cancer Institute of Canada common toxicity criteria scale, except hand-foot syndrome
†Requiring medical intervention; eg, antibiotics, hematopoietic growth factor support. The overall incidence of G3 or G4 adverse events was greatest during the first treatment cycle (38%)
‡Six patients withdrew from further treatment for adverse events, including neutropenia, thrombocytopenia, and increased liver transaminases, each in 1 patient, respectively, and hyperbilirubinemia in 3 patients
§The most common cause of hospitalization was febrile neutropenia (12%)

Dose reductions, treatment interruptions:
- 65% of patients required dose reduction of capecitabine alone (4%), docetaxel alone (10%), or both drugs (51%) for adverse events
- Capecitabine treatment interruption was required in 34% of cycles
- Adverse events, either alone or in combination, most frequently leading to capecitabine treatment interruption, included:
  - Hand-foot syndrome (11.1%)
  - Diarrhea (8.5%)
  - Stomatitis (4.6%)

Note: Deaths classified as probably, possibly, or remotely related to study treatment, during or within 28 days after completing study, occurred in 3 patients (1.2%) in association with enterocolitis, sepsis, and pulmonary edema, each in 1 patient

Therapy Monitoring

Start of each cycle: CBC with leukocyte differential count and platelet counts, LFTs, and serum electrolytes. Consider intracycle assessment in first few cycles

METASTATIC REGIMEN

PACLITAXEL AND GEMCITABINE

Albain KS et al. J Clin Oncol 2008;26:3950–3957

Premedication:
Dexamethasone 10 mg/dose; administer orally for 2 doses 12 hours and 6 hours before paclitaxel (total dose/cycle = 20 mg), *or*
Dexamethasone 20 mg; administer intravenously over 10–15 minutes, 30–60 minutes before paclitaxel (total dose/cycle = 20 mg)

Note:
Dexamethasone doses may be gradually decreased in the absence of hypersensitivity reactions during repeated paclitaxel treatments
Diphenhydramine 25–50 mg administer orally 60 minutes before paclitaxel, *or* administer by intravenous injection 30–60 minutes before paclitaxel
Cimetidine 300 mg (or ranitidine 150 mg, famotidine 20–40 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer orally 60 minutes before paclitaxel, *or* cimetidine 300 mg (or ranitidine 50 mg, famotidine 20 mg); administer intravenously over 15–30 minutes, 30–60 minutes before paclitaxel
Paclitaxel 175 mg/m^2; administer intravenously in a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 3 hours, on day 1 before gemcitabine, every 21 days (total dosage/cycle = 175 mg/m^2)
Gemcitabine 1250 mg/m^2 per dose; administer intravenously in 50–250 mL 0.9% NS over 30–60 minutes for 2 doses on days 1 and 8, every 21 days (total dosage/cycle = 2500 mg/m^2)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Women with locally recurrent or metastatic breast carcinoma after 1 neoadjuvant/adjuvant regimen participated in a multicenter, open-label, phase III trial, in which 266 patients were randomly assigned to receive gemcitabine + paclitaxel and 263 to receive paclitaxel alone. All patients assigned to a treatment arm were analyzed for efficacy on the basis of intention-to-treat, and all who received at least 1 dose of chemotherapy were evaluated for safety

Efficacy (N = 266)

	% Response or Duration	95% CI
Overall response rate	41.4%	35.4–47.3
Complete responses	7.9%	
Partial response	33.5%	

(*continued*)

Treatment Modifications

Adverse Events	Treatment Modifications
ANC 1000–1499/mm^3 or platelets 50,000–99,999/mm^3 on days 1 or 8	Proceed with treatment, but decrease gemcitabine dosage by 25%
ANC <1000/mm^3 or platelets <50,000/mm^3 on day 1	Withhold treatment until ANC is >1000/mm^3 and platelets >50,000/mm^3, then resume treatment and give filgrastim from day 9 until postnadir ANC >5000/mm^3
ANC <500/mm^3 on day of treatment, febrile neutropenia during cycle, or ANC <500/mm^3 for ≥7 days during cycle	Withhold treatment until ANC is >1000/mm^3, then resume treatment with gemcitabine dosage decreased by 25%, and give filgrastim from day 9 until post-nadir ANC >5000/mm^3
ANC <500/mm^3 on day of treatment (second episode) after decreasing gemcitabine dosage and with filgrastim use	Withhold treatment until ANC is >1000/mm^3, then resume treatment with gemcitabine and paclitaxel dosages decreased by 25%, and give filgrastim from day 9 until postnadir ANC >5000/mm^3
Platelet count <25,000/mm^3 on day of treatment	Withhold treatment until platelet count is >50,000/mm^3, then resume treatment with paclitaxel dosage decreased by 25%
G3 nonhematologic adverse events (excluding nausea, vomiting, and alopecia)	Withhold treatment until adverse events recover to G ≤1, then resume treatment with gemcitabine and paclitaxel dosages decreased by 25%
G4 nonhematologic adverse events	Withhold treatment until adverse events recover to G ≤1, then resume treatment with gemcitabine and paclitaxel dosages decreased by 50%
G >2 paresthesias	Discontinue paclitaxel; consider alternative treatment
Symptomatic arrhythmia or heart block >1°	
Other major organ toxicities G >2	
Severe hypersensitivity reaction	

Efficacy (N = 266) (*continued*)

	% Response or Duration	95% CI
Overall response rate, nonvisceral sites only	56.9%	
Overall response rate, visceral sites	35.6%	
Duration of response	9.89 months	8.31–11.73
Median time to progression	6.14 months	5.32–6.70
Progression-free survival	5.9 months	
Median overall survival	18.6 months	

Toxicity (N = 261)

Increased AST	6.5	1.5	0

*Treatment delays were most often related to hematologic toxicities
†G3/4 fatigue often not associated with anemia
‡Patients who developed G3/4 dyspnea had active disease in the lungs or pleura

Therapy Monitoring

1. *Start of each cycle:* CBC with leukocyte differential count and platelet count, LFTs, neurologic examination
2. *Before gemcitabine:* CBC with leukocyte differential count and platelet count. Consider intracycle monitoring in early cycles

METASTATIC REGIMEN

IXABEPILONE + CAPECITABINE

Sparano JA et al. J Clin Oncol 2010;28:3256–3263

Premedication:

Diphenhydramine 50 mg or an equivalent histamine receptor [H_1]-subtype antagonist); administer orally 60 minutes before ixabepilone

Ranitidine 150–300 mg (or cimetidine 300 mg, famotidine 20 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer orally 60 minutes before ixabepilone

Ixabepilone 40 mg/m²; administer intravenously in a volume of lactated Ringer injection, or, alternatively, 0.9% sodium chloride injection with sodium bicarbonate (2 mEq/250–500 mL) sufficient to produce an ixabepilone concentration within the range 0.2–0.6 mg/mL over 3 hours on day 1, every 21 days (total dosage/cycle = 40 mg/m²)

Capecitabine 1000 mg/m² per dose; administer orally twice daily with approximately 200 mL water within 30 minutes after a meal for 14 consecutive days on days 1–14 (28 doses), every 3 weeks (total dosage/cycle = 28,000 mg/m²)

Notes:

- Ixabepilone is a substrate for catabolism by cytochrome P450 (CYP) CYP3A subfamily enzymes
- Concomitant use of ixabepilone with strong CYP3A4 inhibitors or inducers should be avoided
- Grapefruit juice may also increase plasma ixabepilone concentrations and should be avoided
- If a strong CYP3A4 INHIBITOR and ixabepilone must be coadministered, a decrease in ixabepilone dosage to 20 mg/m² is predicted to adjust the ixabepilone AUC to the range observed without inhibitors
- If a concomitantly administered strong CYP3A4 inhibitor is discontinued, a period of approximately 1 week should elapse before the ixabepilone dosage is increased to the indicated (unmodified) dosage
- If a strong CYP3A4 INDUCER and ixabepilone must be coadministered (ie, no alternatives are feasible), based on extrapolation from a drug interaction study with rifampin, after a patient has been maintained on a strong CYP3A4 inducer, the dose of ixabepilone may be gradually increased from 40 mg/m² to 60 mg/m², depending on tolerance, which is predicted to adjust the AUC to the range observed without inducers
  - Proceed cautiously: there are no clinical data with this dose adjustment in patients receiving strong CYP3A4 inducers
  - Patients whose dose is increased >40 mg/m² should be monitored carefully for toxicities. If the strong inducer is discontinued, the ixabepilone dosage should be decreased to the (unmodified) dosage indicated without a strong CYP3A4 inducer
- Capecitabine is given for 2 consecutive weeks followed by 1 week without treatment
- Doses are rounded to use combinations of 500-mg and 150-mg tablets that most closely approximate calculated values
- Initial capecitabine dosage should be decreased by 25% in patients with moderate renal impairment (baseline creatinine clearance = 30–50 mL/min [0.5–0.83 mL/s]); ie, a dosage reduction from 1000 mg/m² per dose, to 750 mg/m² per dose, twice daily. Capecitabine use is contraindicated in persons with severe renal impairment (creatinine clearance <30 mL/min [<0.5 mL/s])
- Although food decreases the rate and extent of drug absorption and the time to peak plasma concentration and systemic exposure (AUC) for both capecitabine and fluorouracil, product labeling recommends giving capecitabine within 30 minutes after the end of a meal because established safety and efficacy data are based on administration with food

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days with ixabepilone + capecitabine is LOW–MODERATE

Emetogenic potential on days with capecitabine alone is LOW

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed onset diarrhea:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea free interval is treated as a new episode

(*continued*)

(*continued*)

- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Hand-foot reaction

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine 50–150 mg/day administer orally

Treatment Modifications

Adverse Events	Treatment Modifications
General Dose Modifications: Ixabepilone and Capecitabine	
On day 1 of repeated cycles ANC <1500/mm^3	Withhold treatment until ANC >1500/mm^3, then administer dosage administered in previous cycle
On day 1 of repeated cycles platelet count <100,000/mm^3	Withhold treatment until platelet count >100,000/mm^3, then administer dosage administered in previous cycle
On day 1 of repeated cycles nonhematologic toxicities G ≥2 are present	Withhold treatment until nonhematologic toxicities are G1 or have resolved, then administer dosage administered in previous cycle
Ixabepilone Dose Modifications	
Ixabepilone Dosage Levels	
Dosage level 1	40 mg/m^2
Dosage level −1	32 mg/m^2
Dosage level −2	25 mg/m^2
Transient G3 arthralgia/myalgia or fatigue	Continue same ixabepilone dosage
ANC <500/mm^3 for ≥7 days	Reduce ixabepilone dosage by one dosage level
Febrile neutropenia	
Platelet count <25,000/mm^3 (G4), or platelets 25,000 to 50,000/mm^3 (G3) with bleeding	
G2 neuropathy lasting ≥7 days	
G3 neuropathy independent of duration	
G3 nonhematologic toxicity other than transient G3 arthralgia/myalgia or fatigue	

(*continued*)

Patient Population Studied

Study of 1221 patients with metastatic or locally advanced breast cancer who had prior treatment with anthracyclines and taxanes who were randomly assigned to receive either ixabepilone plus capecitabine (n = 609) or capecitabine alone (n = 612) at 199 sites across 29 countries from November 2003 to August 2006. A total of 1198 patients were treated: 595 with the combination and 603 with capecitabine alone

Treatment Modifications (*continued*)

Adverse Events	Treatment Modifications
ANC still $<1500/mm^3$ 2 weeks after planned start of cycle	Discontinue ixabepilone treatment
Platelet count still $<100{,}000/mm^3$ 2 weeks after planned start of cycle	
G3 neuropathy lasting ≥7 days or disabling neuropathy	
Any G4 toxicity	
Hypersensitivity reaction to ixabepilone administration despite H_1 and H_2 antagonists	In addition to H_1- and H_2-antihistamines prophylaxis, administer **dexamethasone** 20 mg orally 60 minutes before commencing ixabepilone administration, *or* **Dexamethasone** 20 mg intravenously at least 30 minutes prior to starting ixabepilone administration

Dose Adjustments for Capecitabine

Adverse Event	Dose Modification
First G2 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. No change in dosage required
Second G2 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 25%
Third G2 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 50%
Fourth G2 toxicity	Discontinue capecitabine
First G3 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 25%
Second G3 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 50%
Third G3 toxicity	Discontinue capecitabine
First G4 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 50%
Second G4 toxicity	Discontinue capecitabine

Diarrhea, nausea, and vomiting	Treat symptomatically. Resume previous dosage if toxicity adequately controlled within 2 days after initiation of treatment. If control takes longer, reduce the capecitabine dosage, or if occurs despite prophylaxis, reduce the capecitabine dosage 25 to 50%

*NCI-CTCAE, National Cancer Institute (USA) Common Terminology Criteria for Adverse Events, version 3.0. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]
†Included the MedDRA version 9.1 terms of burning sensation, dysesthesia, hyperesthesia, hypoesthesia, neuralgia, neuritis, neuropathy, neuropathy peripheral, neurotoxicity, painful response to normal stimuli, paresthesia, pallanesthesia, peripheral sensory neuropathy, polyneuropathy, and polyneuropathy toxicity

Therapy Monitoring

1. *Before each cycle:* Neurologic examination, CBC with leukocyte differential count and platelet count, serum creatinine, BUN, and LFTs. Consider intracycle assessments in first few cycles
2. *During concomitant use with CYP3A4 inhibitors or inducers:* Frequently monitor CBC with differential and platelet count as means to guide ixabepilone dosage adjustments based on altered pharmacodynamic responses

METASTATIC REGIMEN

TRASTUZUMAB

Esteva FJ et al. J Clin Oncol 2002;20:1800–1808
Leyland-Jones B et al. J Clin Oncol 2003;21:3965–3971
Vogel CL et al. J Clin Oncol 2002;20:719–726

Trastuzumab 4 mg/kg initial (loading) dose; administer intravenously in 250 mL 0.9% sodium chloride injection (0.9% NS), over at least 90 minutes (total initial dosage = 4 mg/kg), *followed at weekly intervals by:*
Trastuzumab 2 mg/kg per dose; administer intravenously in 250 mL 0.9% NS over 30–90 minutes, every week, continually (total dosage/week = 2 mg/kg)
Note: Administration duration may be decreased from 90 to 30 minutes if administration over longer durations is well tolerated
or
Trastuzumab 8 mg/kg initial (loading) dose; administer intravenously in 250 mL 0.9% NS over at least 90 minutes (total initial dosage = 8 mg/kg), *followed 3 weeks later by:*
Trastuzumab 6 mg/kg per dose; administer intravenously in 250 mL 0.9% NS over 30–90 minutes, every 3 weeks, continually (total dosage/3-week cycle = 6 mg/kg)
Note: Administration duration may be decreased from 90 to 30 minutes if administration over longer durations is well tolerated

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Trastuzumab infusion reactions
- A symptom complex most commonly consisting of chills and/or fever may occur in as many as 40% of patients during the first infusion of trastuzumab. These symptoms occur infrequently with subsequent trastuzumab infusions. Other signs and/or symptoms may include nausea, vomiting, pain (in some cases at tumor sites), rigors, headache, dizziness, dyspnea, hypotension, rash, and asthenia. Although the symptoms are usually mild to moderate in severity, infrequently, trastuzumab may need to be discontinued
- When such a symptom complex is observed, it can be treated with or without reduction in the rate of trastuzumab infusion, and:
  - **Acetaminophen** 650 mg; administer orally
  - **Diphenhydramine** 25–50 mg; administer orally or by intravenous injection, and
  - **Meperidine** 12.5–25 mg; administer by intravenous injection every 10 minutes if needed for shaking chills (generally, cumulative doses >50 mg are not needed; use with caution in persons with moderate or more severely impaired renal function)
  - **With or without reduction in the rate of trastuzumab infusion**

Treatment Plan Notes:
- LVEF assessment (MUGA or echocardiography) every 3 months in patients receiving trastuzumab

Patient Population Studied

Vogel CL et al. J Clin Oncol 2002;20:719–726

Study of 84 women with HER2-overexpressing (IHC 3+) metastatic breast cancer with no prior cytotoxic chemotherapy for metastatic disease. Also enrolled were 27 women with HER-2 (IHC 2+) metastatic breast cancer

Treatment Modifications

Adverse Events	Treatment Modifications
Left ventricle ejection fraction <45%, or symptomatic congestive heart failure	Discontinue trastuzumab

Efficacy (N = 84*)

METASTATIC BREAST CANCER

PERTUZUMAB + TRASTUZUMAB + DOCETAXEL

Baselga J et al. N Engl J Med 2012;366:109–119

Trastuzumab 8 mg/kg initial (loading) dose; administer intravenously in 250 mL 0.9% sodium chloride injection (0.9% NS) over at least 90 minutes (total initial dosage = 8 mg/kg), *followed 3 weeks later by:*
Trastuzumab 6 mg/kg per dose; administer intravenously in 250 mL 0.9% NS over 30–90 minutes, every 3 weeks, continually (total dosage/3-week cycle = 6 mg/kg)
Note: Administration duration may be decreased from 90 to 30 minutes if administration over longer durations is well tolerated

Premedication for docetaxel:
Dexamethasone 8 mg/dose; administer orally every 12 hours for 3 days starting on the day before docetaxel administration (total dose/cycle = 48 mg)
Docetaxel 75 mg/m^2; administer intravenously in a volume of 0.9% NS or 5% dextrose injection (D5W) sufficient to produce a docetaxel concentration within the range 0.3–0.74 mg/mL over 60 minutes on day 1, every 3 weeks for at least 6 cycles (total dosage/cycle = 75 mg/m^2)

Pertuzumab 840 mg initial (loading) dose; administer intravenously in 250 mL 0.9% NS over 60 minutes (total initial dose = 840 mg), *followed 3 weeks later by:*
Pertuzumab 420 mg per dose; administer intravenously in 250 mL 0.9% NS over 30–60 minutes, every 3 weeks, continually (total dose/3-week cycle = 420 mg)

Note: Treatment continued until disease progression or the development of adverse effects that could not be effectively managed

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Trastuzumab infusion reactions
- A symptom complex most commonly consisting of chills and/or fever may occur in as many as 40% of patients during the first infusion of trastuzumab. These symptoms occur infrequently with subsequent trastuzumab infusions. Other signs and/or symptoms may include nausea, vomiting, pain (in some cases at tumor sites), rigors, headache, dizziness, dyspnea, hypotension, rash, and asthenia. Although the symptoms are usually mild to moderate in severity, infrequently, trastuzumab may need to be discontinued
  - When such a symptom complex is observed it can be treated with or without reduction in the rate of trastuzumab infusion, and:
    - **Acetaminophen** 650 mg orally
    - **Diphenhydramine** 25–50 mg orally or by intravenous injection, and
    - **Meperidine** 12.5–25 mg by intravenous injection every 10 minutes if needed for shaking chills (generally, cumulative doses >50 mg are not needed; use with caution in persons with moderate or more severely impaired renal function)
- Include in treatment plan notes:
  - LVEF assessment (MUGA or echocardiography) every 3 months in patients receiving trastuzumab

Diarrhea management
Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

(*continued*)

(continued)

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)
- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:
- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:
- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultrasoft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, nonalcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:
- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in 1 quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population Studied

The Clinical Evaluation of Pertuzumab and Trastuzumab (CLEOPATRA) study was a randomized, double-blind, placebo-controlled, phase 3 trial involving patients with HER2-positive metastatic breast cancer in which the efficacy and safety of pertuzumab versus placebo were evaluated in combination with trastuzumab plus docetaxel as first-line treatment for patients with HER2-positive metastatic breast cancer. It was a randomized, double-blind, placebo-controlled, phase 3 trial involving patients with HER2-positive metastatic breast cancer. Among 808 patients enrolled in the study, 402 were assigned to receive pertuzumab and 406 to receive placebo (control), both in combination with trastuzumab and docetaxel. Eligible patients had locally recurrent, unresectable, or metastatic HER2-positive breast cancer and may have received 1 hormonal treatment for metastatic breast cancer before randomization. Patients may have received adjuvant or neoadjuvant chemotherapy with or without trastuzumab before randomization, with an interval of at least 12 months between completion of the adjuvant or neoadjuvant therapy and the diagnosis of metastatic breast cancer. Median age was 54 y; 78% of patients had visceral involvement, and about 50% of patients had ER-positive and 50% ER-negative disease. Approximately half of the patients had not previously received adjuvant/neoadjuvant chemotherapy, and among them, approximately 10% had received trastuzumab. Patients were stratified according to geographic region (Asia, Europe, North America, or South America) and prior treatment status (prior adjuvant or neoadjuvant chemotherapy vs. no prior treatment)

Efficacy

Overall Response, Independent Review

	Placebo + Trastuzumab + Docetaxel (N = 336)	Pertuzumab + Trastuzumab + Docetaxel (N = 343)
	no. (%)	no. (%)

Fatigue	13 (3.3)	9 (2.2)
Left ventricular systolic dysfunction	11 (2.8)	5 (1.2)
Dyspnea	8 (2.0)	4 (1.0)

Therapy Monitoring

1. Assess left ventricular ejection fraction at baseline, every 9 weeks during the treatment period, every 6 months in the first year after treatment is discontinued, and annually thereafter for up to 3 years
2. *Day 1 (Every cycle):* CBC with differential and platelet count and serum electrolytes and LFTs

Treatment Modifications

Adverse Event	Dose Modification
Pertuzumab-related infusion reactions	Slow or interrupt pertuzumab infusion. Consider use of supportive medication to treat symptoms (H_1- and H_2-receptor antagonist antihistamines, steroids) if needed. Reinitiate at a slower rate only when symptoms abate
Serious hypersensitivity	Discontinue immediately. Consider permanent discontinuation of pertuzumab
If trastuzumab is withheld	Pertuzumab also should be withheld
Cardiotoxicity: Left ventricular ejection fraction (LVEF) declines to <40% *or* LVEF between 40 and 45% with ≥10% absolute decrease from pretreatment values	Withhold pertuzumab and trastuzumab for at least 3 weeks. Pertuzumab and trastuzumab treatment may resume if LVEF returns to >45% *or* to 40–45% with <10% absolute decrease below pretreatment values. If after a repeat assessment within ~3 weeks LVEF has not improved (or has declined further), consider discontinuing pertuzumab and trastuzumab unless the benefit of continuing treatment outweighs risks
Dose modifications for organ dysfunction	
Hepatic impairment	No adjustment needed
Renal impairment	No adjustment needed

Note: Pertuzumab dose reductions are not recommended

METASTATIC REGIMEN

DOCETAXEL EVERY 3 WEEKS + WEEKLY TRASTUZUMAB

Marty M et al. J Clin Oncol 2005;23:4265–4274

Premedication:
Dexamethasone 8 mg/dose; administer orally twice daily for 3 days, starting on the day before docetaxel administration (total dose/cycle = 48 mg)

Docetaxel 100 mg/m²; administer intravenously in a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection sufficient to produce a docetaxel concentration within the range 0.3–0.74 mg/mL over 60 minutes on day 1, every 3 weeks for 6 cycles (total dosage/cycle = 100 mg/m²)

Trastuzumab 4 mg/kg initial (loading) dose; administer intravenously in 250 mL 0.9% NS, over at least 90 minutes (total initial dosage = 4 mg/kg), *followed at weekly intervals by:*
Trastuzumab 2 mg/kg per dose; administer intravenously in 250 mL 0.9% NS over 30–90 minutes, every week, continually until disease progression (total dosage/week = 2 mg/kg)
Notes: Administration duration may be decreased from 90 to 30 minutes if administration over longer durations is well tolerated
Patients who tolerated combination treatment and did not develop disease progression may receive docetaxel for more than 6 cycles

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW–INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Trastuzumab infusion reactions
- A symptom complex most commonly consisting of chills and/or fever may occur in as many as 40% of patients during the first infusion of trastuzumab. These symptoms occur infrequently with subsequent trastuzumab infusions. Other signs and/or symptoms may include nausea, vomiting, pain (in some cases at tumor sites), rigors, headache, dizziness, dyspnea, hypotension, rash, and asthenia. Although the symptoms are usually mild to moderate in severity, infrequently, trastuzumab may need to be discontinued
- When such a symptom complex is observed, it can be treated with or without reduction in the rate of trastuzumab infusion, and:
  - **Acetaminophen** 650 mg; administer orally
  - **Diphenhydramine** 25–50 mg; administer orally or by intravenous injection, and
  - **Meperidine** 12.5–25 mg; administer by intravenous injection every 10 minutes if needed for shaking chills (generally, cumulative doses >50 mg are not needed; use with caution in persons with moderate or more severely impaired renal function)

Treatment Plan Notes:
- LVEF assessment (MUGA or echocardiography) every 3 months in patients receiving trastuzumab

Treatment Modifications

Adverse Events	Treatment Modifications
Left ventricle ejection fraction <45%, or symptomatic congestive heart failure	Discontinue trastuzumab
First episode of hematologic or nonhematologic adverse events G ≥3 other than alopecia and anemia	Reduce docetaxel dosage from 100 mg/m² to 75 mg/m²
Second episode of hematologic or nonhematologic adverse events G3 other than alopecia and anemia	Reduce docetaxel dosage from 75 mg/m² to 55 mg/m²

Patient Population Studied

Study of 188 patients with HER2-positive MBC included in an open-label, comparative, randomized, multicenter, multinational trial comparing the efficacy and safety of first-line trastuzumab plus docetaxel *vs.* docetaxel alone

Efficacy (N = 92)

NCI-CTC, National Cancer Institute (USA) Common Toxicity Criteria, version 2.0. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]

Therapy Monitoring

1. *Every 3 to 4 months:* Evaluate cardiac ejection fraction
2. *Start of each cycle:* CBC with leukocyte differential count and platelet counts, LFTs, and serum electrolytes. Consider intracycle assessment in first few cycles

METASTATIC REGIMEN

WEEKLY DOCETAXEL + TRASTUZUMAB

Esteva FJ et al. J Clin Oncol 2002;20:1800–1808

Initial treatment (first cycle):
Trastuzumab 4 mg/kg (loading dose); administer intravenously in 250 mL 0.9% sodium chloride injection (0.9% NS), over at least 90 minutes 1 day before the first dose of docetaxel is administered (total initial dosage = 4 mg/kg)

Premedication for docetaxel:
Dexamethasone 8 mg/dose; administer orally for 3 doses at approximately 12 hours and 1 hour before docetaxel, and 12 hours after docetaxel administration (total dose during week 1 = 24 mg)
Docetaxel 35 mg/m^2; administer intravenously in a volume of 0.9% NS or 5% dextrose injection (D5W), sufficient to produce a final docetaxel concentration within the range 0.3–0.74 mg/mL over 30 minutes, the day after the initial (loading) dose of trastuzumab

Second and subsequent treatments:
Premedication for docetaxel:
Dexamethasone 8 mg/dose; administer orally for 3 doses at approximately 12 hours and 1 hour before docetaxel, and 12 hours after docetaxel administration (total dose during week 1 = 24 mg)
- Initially, dexamethasone is given approximately every 12 hours for 3 doses, starting the evening before docetaxel administration
- If no significant fluid retention or hypersensitivity reactions occur during the first 2 cycles, give dexamethasone 8 mg/dose orally every 12 hours for 2 doses on the day of docetaxel administration, with the first dose given at least 1 hour before docetaxel
- If there is no evidence of fluid retention after a fourth cycle, give a single dose of dexamethasone 8 mg orally just before docetaxel administration

Docetaxel 35 mg/m^2 per dose; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a final docetaxel concentration within the range 0.3–0.74 mg/mL over 30 minutes, weekly for 3 consecutive weeks (days 1, 8, and 15), every 4 weeks (total dosage/4-week cycle = 105 mg/m^2), *followed by:*
Trastuzumab 2 mg/kg per dose; administer intravenously in 250 mL 0.9% NS over 30–90 minutes, weekly for 3 consecutive weeks (days 1, 8, and 15), every 4 weeks (after an initial 4-mg/kg dose, the total dosage/4-week cycle for the second and subsequent cycles = 6 mg/kg)

Note: Trastuzumab administration duration may be decreased from 90 to 30 minutes if administration over longer durations is well tolerated

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential on days with trastuzumab alone is **MINIMAL–LOW***
*Emetogenic potential on days with docetaxel is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Trastuzumab infusion reactions
- A symptom complex most commonly consisting of chills and/or fever may occur in as many as 40% of patients during the first infusion of trastuzumab. These symptoms occur infrequently with subsequent trastuzumab infusions. Other signs and/or symptoms may include nausea, vomiting, pain (in some cases at tumor sites), rigors, headache, dizziness, dyspnea, hypotension, rash, and asthenia. Although the symptoms are usually mild to moderate in severity, infrequently, trastuzumab may need to be discontinued
- When such a symptom complex is observed, it can be treated with or without reduction in the rate of trastuzumab infusion, and:
  - **Acetaminophen** 650 mg; administer orally
  - **Diphenhydramine** 25–50 mg; administer orally or by intravenous injection, and
  - **Meperidine** 12.5–25 mg; administer by intravenous injection every 10 minutes if needed for shaking chills (generally, cumulative doses >50 mg are not needed; use with caution in persons with moderate or more severely impaired renal function)

Treatment Plan Notes:
- LVEF assessment (MUGA or echocardiography) every 3 months in patients receiving trastuzumab

Treatment Modifications

Adverse Events	Treatment Modifications*
ANC <500/mm^3	Reduce docetaxel dosage by 5 mg/m^2 per week
Febrile neutropenia	
Platelets <50,000/mm^3	
G2 nonhematologic adverse events	
G3 nonhematologic adverse events (except fatigue)	Reduce docetaxel dosage by 10 mg/m^2 per week
G3 fatigue	Reduce docetaxel dosage by 5 mg/m^2 per week
Left ventricle ejection fraction <45% or congestive heart failure	Discontinue trastuzumab

*Minimum docetaxel dosage to continue treatment = 20 mg/m^2

Patient Population Studied

Study of 30 women with HER2-overexpressing (FISH+ or IHC 3+) metastatic breast cancer who had not received >3 prior chemotherapy regimens. No limitation on prior hormonal therapy

Therapy Monitoring

1. *Before each docetaxel dose:* CBC with differential and platelet count and LFTs
2. *Every second or third cycle:* Serum electrolytes, calcium, magnesium
3. *Every 3–4 months:* Cardiac ejection fraction

METASTATIC REGIMEN

TRASTUZUMAB + PACLITAXEL, EVERY 3 WEEKS

Leyland-Jones B et al. J Clin Oncol 2003;21:3965–3971
Slamon DJ et al. N Engl J Med 2001;344:783–792

Initial treatment (first cycle):
Premedication for paclitaxel:
Dexamethasone 20 mg/dose; administer orally for 2 doses at 12 hours and 6 hours before paclitaxel (total dose/cycle = 40 mg)
Diphenhydramine 50 mg; administer by intravenous injection 30–60 minutes before paclitaxel
Cimetidine 300 mg (or **ranitidine** 50 mg, **famotidine** 20 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer intravenously in 20–50 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 15–30 minutes, 30–60 minutes before paclitaxel
Paclitaxel 175 mg/m^2; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 3 hours, 24 hours before the first dose of trastuzumab (total dosage = 175 mg/m^2)
Trastuzumab 8 mg/kg (loading dose); administer intravenously in 250 mL 0.9% NS over at least 90 minutes, 24 hours after the initial paclitaxel dose (total initial dosage = 8 mg/kg)

Second and subsequent treatments:
Trastuzumab 6 mg/kg per dose; administer intravenously in 250 mL 0.9% NS over 30–90 minutes, on day 1 before paclitaxel, every 3 weeks (total dosage/cycle = 6 mg/kg)
Note: Trastuzumab administration duration may be decreased from 90 to 30 minutes if administration over longer durations is well tolerated
Premedication for paclitaxel:
Dexamethasone 20 mg/dose; administer orally for 2 doses at 12 hours and 6 hours before paclitaxel (total dose/cycle = 40 mg)
Diphenhydramine 50 mg; administer by intravenous injection 30–60 minutes before paclitaxel
Cimetidine 300 mg (or **ranitidine** 50 mg, **famotidine** 20 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer intravenously in 20–50 mL 0.9% NS or D5W over 15–30 minutes, 30–60 minutes before paclitaxel
Paclitaxel 175 mg/m^2; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 3 hours, on day 1 starting 30 minutes after completing trastuzumab administration, every 3 weeks for a total of 6 cycles (total dosage/cycle = 175 mg/m^2)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days with docetaxel is ***LOW***
Emetogenic potential on days with trastuzumab alone is ***MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Trastuzumab infusion reactions
- A symptom complex most commonly consisting of chills and/or fever may occur in as many as 40% of patients during the first infusion of trastuzumab. These symptoms occur infrequently with subsequent trastuzumab infusions. Other signs and/or symptoms may include nausea, vomiting, pain (in some cases at tumor sites), rigors, headache, dizziness, dyspnea, hypotension, rash, and asthenia. Although the symptoms are usually mild to moderate in severity, infrequently, trastuzumab may need to be discontinued
- When such a symptom complex is observed, it can be treated with or without reduction in the rate of trastuzumab infusion, and:
  - **Acetaminophen** 650 mg; administer orally
  - **Diphenhydramine** 25–50 mg; administer orally or by intravenous injection, and
  - **Meperidine** 12.5–25 mg; administer by intravenous injection every 10 minutes if needed for shaking chills (generally, cumulative doses >50 mg are not needed; use with caution in persons with moderate or more severely impaired renal function)

Treatment Plan Notes:
- LVEF assessment (MUGA or echocardiography) every 3 months in patients receiving trastuzumab

Treatment Modifications

Nabholtz J-M et al. J Clin Oncol 1996;14:1858–1867

Adverse Events	Treatment Modifications
G3/4 ANC for ≥7 days	Reduce paclitaxel dosage by 25%
Any thrombocytopenia for >7 days	
Febrile neutropenia, documented infection, or hemorrhage	
G3 mucositis	
G3/4 neuropathy	Discontinue paclitaxel
Symptomatic arrhythmia or heart block other than first degree	Discontinue trastuzumab
Left ventricular ejection fraction <45% or NYHA classes III/IV cardiac dysfunction	
Severe hypersensitivity reaction	

Patient Population Studied

Leyland-Jones B et al. J Clin Oncol 2003;21:3965–3971

Study of 92 women with HER2 (IHC 2+, IHC 3+, or FISH+) progressive metastatic breast cancer that had not previously received chemotherapy for metastatic disease

Efficacy (N = 32)

Leyland-Jones B et al. J Clin Oncol 2003;21:3965–3971

WHO Criteria	
Overall response	59%
Complete response	13%
Partial response	47%
Median duration of response	10.5 months

Therapy Monitoring

1. *Every 3 weeks:* CBC with differential and platelet count, LFTs, and serum electrolytes. Consider intracycle assessment in early cycles
2. *Every 3–4 months:* Cardiac ejection fraction

Note

Consider adding pertuzumab in combination with trastuzumab + paclitaxel chemotherapy
Loading dose: **Pertuzumab** 840 mg; administer intravenously in 250 mL of 0.9% NS over 90 minutes after trastuzumab, cycle 1 only (total dose during the first cycle = 840 mg), *followed 3 weeks later by:*
Maintenance doses: **Pertuzumab** 420 mg; administer intravenously in 250 mL of 0.9% NS over 30–60 minutes on day 1 after trastuzumab, every 3 weeks (total dose/cycle = 420 mg)

METASTATIC REGIMEN

WEEKLY PACLITAXEL + TRASTUZUMAB

Seidman AD et al. J Clin Oncol 2008;26:1642–1649

Initial treatment (first week)
Trastuzumab 4 mg/kg (loading dose); administer intravenously in 250 mL 0.9% sodium chloride injection (0.9% NS) over at least 90 minutes, 1 day before the first dose of paclitaxel is administered (total dosage during the first treatment week = 4 mg/kg)

Premedication for paclitaxel:
Dexamethasone 10 mg; administer intravenously over 10–15 minutes, 30–60 minutes before paclitaxel
Diphenhydramine 50 mg; administer by intravenous injection 30–60 minutes before paclitaxel
Cimetidine 300 mg (or **ranitidine** 50 mg, **famotidine** 20 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer in 20–50 mL 0.9% NS or 5% dextrose injection (D5W) over 15–30 minutes, 30–60 minutes before paclitaxel
Paclitaxel 80–90 mg/m^2; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 60 minutes (total dosage = 80–90 mg/m^2)

Schedule for second and subsequent weeks
Premedication for paclitaxel:
Dexamethasone 10 mg; administer intravenously over 10–15 minutes, 30–60 minutes before paclitaxel
Note: Dexamethasone doses may be gradually reduced in 2- to 4-mg increments if the patient has no hypersensitivity reactions during repeated paclitaxel treatments
Diphenhydramine 50 mg; administer intravenously per push 30–60 minutes before paclitaxel
Cimetidine 300 mg (or **ranitidine** 50 mg, **famotidine** 20 mg, or an equivalent histamine receptor [H_2]-subtype antagonist); administer in 20–50 mL 0.9% NS or D5W over 15–30 minutes, 30–60 minutes before paclitaxel
Paclitaxel 80–90 mg/m^2 per dose; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 60 minutes, every week, continually (total dosage/week = 80–90 mg/m^2), *followed by:*
Trastuzumab 2 mg/kg per dose; administer intravenously in 250 mL 0.9% NS over 30–90 minutes, every week, continually (total dosage/week during the second & subsequent weeks = 2 mg/kg)
Note: The duration of trastuzumab administration may be decreased from 90 to 30 minutes if administration over longer durations is well tolerated

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential on days with trastuzumab alone is **MINIMAL–LOW***
*Emetogenic potential on days with paclitaxel is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Trastuzumab infusion reactions
- A symptom complex most commonly consisting of chills and/or fever may occur in as many as 40% of patients during the first infusion of trastuzumab. These symptoms occur infrequently with subsequent trastuzumab infusions. Other signs and/or symptoms may include nausea, vomiting, pain (in some cases at tumor sites), rigors, headache, dizziness, dyspnea, hypotension, rash, and asthenia. Although the symptoms are usually mild to moderate in severity, infrequently, trastuzumab may need to be discontinued
- When such a symptom complex is observed, it can be treated with or without reduction in the rate of trastuzumab infusion, and:
  - **Acetaminophen** 650 mg; administer orally
  - **Diphenhydramine** 25–50 mg; administer orally or by intravenous injection, and
  - **Meperidine** 12.5–25 mg; administer by intravenous injection every 10 minutes if needed for shaking chills (generally, cumulative doses >50 mg are not needed; use with caution in persons with moderate or more severely impaired renal function)

Treatment Plan Notes:
- LVEF assessment (MUGA or echocardiography) every 3 months in patients receiving trastuzumab

Treatment Modifications

Adverse Events	Treatment Modifications
ANC <1000/mm^3 or platelets <100,000/mm^3 on a day of planned treatment	Hold paclitaxel until ANC ≥1000/mm^3 and platelets ≥100,000/mm^3
If >2 weeks are required for recovery to ANC ≥1000/mm^3 and platelets ≥100,000/mm^3	Reduce paclitaxel dosage by 20 mg/m^2
Platelet nadir count ≤50,000/mm^3	
Documented infection	
G2 nonhematologic adverse events	Reduce paclitaxel dosage by 10 mg/m^2
G3 nonhematologic adverse events	Hold paclitaxel until toxicity resolves to G ≤2 and reduce paclitaxel dosage by 20 mg/m^2 during subsequent treatments
Left ventricular ejection fraction <45% or NYHA classes III or IV cardiac dysfunction	Discontinue trastuzumab

Efficacy

Patients	Paclitaxel Dose Frequency	Response (%)	95% CI	OR	95% CI for OR	P Value
All patients (combined)	3-Weekly Weekly	29 42	25–34 37–47	1.75	1.28–2.37	0.0004
All patients (limited)	3-Weekly Weekly	35 42	28–41 37–47	1.36	0.96–1.23	0.093

Platelets	3-Weekly Weekly	2 1	0 1
Hemoglobin	3-Weekly Weekly	3 5	0 <1
Granulocytes/bands	3-Weekly Weekly	10 5	5 3
Lymphocytes	3-Weekly Weekly	8 15	4 4

(*continued*)

Patient Population Studied

Patients were randomly assigned to paclitaxel 175 mg/m^2 every 3 weeks or 80 mg/m^2 weekly. After the first 171 patients, all HER-2–positive patients received trastuzumab; HER-2 non-overexpressers were randomly assigned to receive or not receive trastuzumab, in addition to paclitaxel. A total of 577 patients were treated on 9840 (limited). An additional 158 patients (158 patients from the 175-mg/m^2 arm of CALGB 9342) were included in analyses, for a total of 735 patients

Therapy Monitoring

1. *Every week:* CBC with differential and platelet count
2. *Every other cycle:* LFTs, serum electrolytes, calcium, and magnesium
3. *Every 3–4 months:* Cardiac ejection fraction

Note

Consider adding pertuzumab in combination with trastuzumab + paclitaxel chemotherapy

Loading dose: **Pertuzumab** 840 mg; administer intravenously in 250 mL of 0.9% NS over 90 minutes after trastuzumab, cycle 1 only (total dose during the first cycle = 840 mg), *followed 3 weeks later by:*

Maintenance Doses: **Pertuzumab** 420 mg; administer intravenously in 250 mL of 0.9% NS over 30–60 minutes on the same day as trastuzumab but after trastuzumab, every 3 weeks (total dose/cycle = 420 mg)

Datko F et al. Cancer Research 2012;72(24 Suppl 3) [Cancer Therapy & Research Center-American Association of Cancer Research. 35th annual San Antonio Breast Cancer Symposium; poster P5-18–20]

HER2-POSITIVE ADVANCED BREAST CANCER REGIMEN

ado-TRASTUZUMAB (TRASTUZUMAB EMTANSINE, T-DM1) *OR* LAPATINIB + CAPECITABINE

Verma S et al. N Engl J Med 2012;367:1783–1791

ado-Trastuzumab 3.6 mg/kg; administer intravenously in 250 mL 0.9% sodium chloride injection on day 1, every 21 days (total dosage/cycle = 3.6 mg/kg)

Exposure	Administration Rate	Monitoring
First infusion	Intravenously over 90 minutes	• Patients should be observed closely for infusion-related reactions, especially during the first infusion • Administration should be slowed or interrupted if a patient develops an infusion-related reaction • Permanently discontinue ado-trastuzumab for life-threatening infusion-related reactions
Second and subsequent infusions	• Intravenously over 30 minutes if prior administration were was tolerated • Subsequent doses may be administered at the rate tolerated during the most recently administered treatment	

or

Lapatinib 1250 mg/dose; administer orally, once daily, continually, for 21 consecutive days either at least one hour before or at least one hour after a meal (total dose/21-day cycle = 26,250 mg) *plus*
Capecitabine 1000 mg/m² per dose (maximum planned daily dose = 2000 mg/m²); administer orally within 30 minutes after eating food every 12 hours for 14 consecutive days (28 doses), on days 1–14, every 21 days (total dosage/21-day cycle = 28,000 mg/m²; maximum planned dosage/21-day cycle = 28,000 mg/m²)

Notes:
- Capecitabine is given for 2 consecutive weeks followed by 1 week without treatment
- Doses are rounded to use combinations of 500-mg and 150-mg tablets that most closely approximate calculated values
- In practice, treatment often is begun with capecitabine 1000 mg/m² per dose twice daily for 14 consecutive days on days 1–14, every 3 weeks, because of a high rate of dose reduction with higher dosages (total dosage/cycle = 28,000 mg/m²)
- Initial capecitabine dosage should be decreased by 25% in patients with moderate renal impairment (baseline creatinine clearance = 30–50 mL/min [0.5–0.83 mL/s]); ie, a dosage reduction from 1250 mg/m² per dose to 950 mg/m² per dose, twice daily. Capecitabine use is contraindicated in persons with severe renal impairment (creatinine clearance <30 mL/min [<0.5 mL/s])
- Although food decreases the rate and extent of drug absorption and the time to peak plasma concentration and systemic exposure (AUC) for capecitabine, product labeling recommends giving capecitabine within 30 minutes after the end of a meal because established safety and efficacy data are based on administration with food

Supportive Care (ado-trastuzumab or lapatinib + capecitabine)
Antiemetic prophylaxis
Emetogenic potential for ado-trastuzumab and for lapatinib + capecitabine is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Supportive Care (lapatinib + capecitabine only)
Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)
For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine
Pyridoxine may provide relief for discomfort/pain associated with PPE although the mechanism through which this occurs remains unclear
- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

(*continued*)

(continued)

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of nonalcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultrasoft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, nonalcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in 1 quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Efficacy

	Independent Review			
	Lapatinib Plus Capecitabine (N = 389)	ado-Trastuzumab (N = 397)	Difference	P Value
	no. (%)	no. (%)		
CR or PR	120 (30.8)	173 (43.6)	12.7 (6.0–19.4)	<0.001
CR	2 (0.5)	4 (1.0%)		
PR	118 (30.3)	169 (42.6)		
Duration of CR or PR (months)				
Median	6.5	12.6		
95% CI	5.5–7.2	8.4–20.8		

Therapy Monitoring

1. *Before each cycle:* CBC with differential and platelet count, serum electrolytes and LFTs
2. *LVEF assessment:* recommended at baseline and repeat serially every 3–4 months for adjuvant treatment, or with the development of cardiac symptoms and/or regimen changes for metastatic treatment

Patient Population Studied

The EMILIA study, a randomized phase 3 trial, assessed the efficacy and safety of lapatinib plus capecitabine (496 patients) versus ado-trastuzumab (495 patients) in patients with HER2-positive advanced breast cancer previously treated with trastuzumab and a taxane. In both treatment arms, 61% of patients had previously received anthracycline therapy, 41% endocrine therapy, 84% had received trastuzumab, and 39% >1 prior chemotherapy regimen for locally advanced or metastatic disease

Toxicity

Treatment Modification for ado-Trastuzumab

ado-Trastuzumab Dose Levels	Dosage
Starting dosage	3.6 mg/kg
First dose reduction	3 mg/kg
Second dose reduction	2.4 mg/kg
Requirement for further dose reduction	Discontinue ado-trastuzumab

Dose delays	If significant related toxicities (other than those described below) have not recovered to G1 or baseline, dose may be delayed for up to 42 days from the last dose. If treatment resumes, it may be at either the same dose level or one dose level lower
Platelet nadir 25,000–50,000/mm^3	Withhold ado-trastuzumab until platelet count recovers to ≥75,000/mm^3, then resume treatment at the same dose level
Platelet nadir <25,000/mm^3	Withhold ado-trastuzumab until platelet count recovers to ≥75,000/mm^3, then resume treatment with ado-trastuzumab 3 mg/kg every 3 weeks
AST or ALT >2× to ≤5× ULN (G2)	Treat at the same ado-trastuzumab dose level
AST or ALT >5× to ≤20× ULN (G3)	Withhold ado-trastuzumab until AST and ALT recover to G ≤2, then resume ado-trastuzumab with dosage decreased by one dose level
AST or ALT >20× ULN (G4)	Permanently discontinue ado-trastuzumab
Total bilirubin >1.5× to ≤3× ULN (G2)	Withhold ado-trastuzumab until total bilirubin recovers to G ≤1, then resume ado-trastuzumab at the same dose level
Total bilirubin >3× to ≤10× ULN (G3)	Withhold ado-trastuzumab until total bilirubin recovers to G ≤1, then resume ado-trastuzumab with dosage decreased by one dose level
Total bilirubin >10× ULN (G4)	Permanently discontinue ado-trastuzumab

(*continued*)

Treatment Modification for ado-Trastuzumab (*continued*)

ado-Trastuzumab Dose Levels	Dosage
AST or ALT >3× ULN and total bilirubin >2× ULN	Permanently discontinue ado-trastuzumab
Patients diagnosed with nodular regenerative hepatic hyperplasia	Permanently discontinue ado-trastuzumab
Symptomatic CHF (G ≥3 left ventricular systolic dysfunction per NCI CTCAE v3.0)	Discontinue ado-trastuzumab
LVEF <40%	Withhold ado-trastuzumab. Repeat LVEF assessment within 3 weeks. If LVEF <40% is confirmed, discontinue ado-trastuzumab
LVEF 40% to ≤45%, and decrease is ≥10% points from baseline measurement	Withhold ado-trastuzumab. Repeat LVEF assessment within 3 weeks. If LVEF has not recovered to within 10% points from baseline, discontinue ado-trastuzumab
LVEF 40% to ≤45%, and decrease is <10% points from baseline	Continue ado-trastuzumab treatment. Repeat LVEF assessment within 3 weeks
LVEF >45%	Continue treatment with ado-trastuzumab
G3/4 peripheral neuropathy	Withhold ado-trastuzumab until symptoms abate to G ≤2 then resume treatment with ado-trastuzumab
Patients diagnosed with interstitial lung disease or pneumonitis	Permanently discontinue ado-trastuzumab
Life-threatening infusion-related reactions	Permanently discontinue ado-trastuzumab

Notes: ado-trastuzumab dosages should not be re-escalated after a dosage reduction is made

If a planned dose is delayed or missed, it should be administered as soon as possible: Do not wait until the next planned cycle. The schedule of administration should be adjusted to maintain a 3-week interval between doses

Treatment Modifications for Lapatinib

Geyer CE et al. N Engl J Med 2006;355:2733–2743
TYKERB® (lapatinib) tablets, for oral use; product label October 2013. GlaxoSmithKline, Research Triangle Park, NC

Adverse Event	Modification
First occurrence ANC 1000–1500/mm^3 or platelet count 50,000–74,999/mm^3 (G2 toxicity)	Withhold lapatinib until ANC >1000/mm^3 and platelet count is >50,000/mm^3, or for up to 14 days. Resume lapatinib at the same dose if toxicity resolves within 14 days, otherwise discontinue lapatinib use
Second occurrence ANC 1000–1500/mm^3 or platelet count 50,000–74,999/mm^3 (G2 toxicity)	Withhold lapatinib until ANC >1000/mm^3 and platelet count is >50,000/mm^3, or for up to 14 days. Resume lapatinib with dose decreased to 1000 mg/day if toxicity resolves within 14 days, otherwise discontinue lapatinib use
Any G3/4 toxicities	Withhold lapatinib until adverse events abate to G ≤1 or for up to 14 days. Resume lapatinib with dose decreased to 1000 mg/day if toxicity resolves within 14 days, otherwise discontinue lapatinib use
Recurrent G3/4 toxicities	Permanently discontinue lapatinib
Decreased LVEF G ≥2 per NCI CTCAE v3.0	Permanently discontinue lapatinib
LVEF decreased to less than institutional LLN	Withhold lapatinib for at least 2 weeks. Repeat LVEF assessment, and if LVEF returns to within normal range, resume lapatinib with dosage decreased to 1000 mg/day
Patients with pre-existing severe hepatic impairment (Child-Pugh class C)	Decrease lapatinib dose to 750 mg/day
G ≥3 increase in ALT or AST	Permanently discontinue lapatinib

(*continued*)

Treatment Modifications for Lapatinib (*continued*)

Adverse Event	Modification
G3 diarrhea, or G1/2 diarrhea with complicating features (moderate to severe abdominal cramping, nausea with significantly decreased oral intake or vomiting [2–5 episodes/24 h], decreased performance status, fever, sepsis, neutropenia, frank bleeding, or dehydration)	Withhold lapatinib until diarrhea decreases to G ≤1. Consider resuming lapatinib treatment at dosage decreased by 20–25% or discontinuing lapatinib
G4 diarrhea	Permanently discontinue lapatinib
Pulmonary symptoms indicative of interstitial lung disease or pneumonitis G ≥3	Permanently discontinue lapatinib
Hypokalemia or hypomagnesemia before starting or during treatment with lapatinib	Correct hypokalemia and hypomagnesemia before starting or continuing lapatinib
Other G2 adverse events	Withhold lapatinib until the adverse condition decreases to G ≤1, then resume lapatinib treatment at dosage decreased by 20–25%
Recurrent G2 and G ≥3 adverse events other than conditions described above	Permanently discontinue lapatinib

ALT, alanine aminotransferase (SGPT); AST, aspartate aminotransferase (SGOT); CHF, congestive heart failure; LLN, lower limit of normal range; LVEF, left ventricular ejection fraction; ULN, upper limit of normal range

NCI, CTCAE, National Cancer Institute (USA) Common Terminology Criteria for Adverse Events, version 3. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]

Treatment Modifications for Capecitabine

Adapted from NCI of Canada CTC

Adverse Event	Dose Modification
First G2 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. No change in dosage required
Second G2 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 25%
Third G2 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 50%
Fourth G2 toxicity	Discontinue capecitabine
First G3 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 25%
Second G3 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 50%
Third G3 toxicity	Discontinue capecitabine
First G4 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 50%
Second G4 toxicity	Discontinue capecitabine

Diarrhea, nausea, and vomiting	Treat symptomatically. Resume previous dosage if toxicity is adequately controlled within 2 days after initiation of treatment. If control takes longer, reduce the capecitabine dosage, or if it occurs despite prophylaxis, reduce the capecitabine dosage 25–50%

METASTATIC REGIMEN

WEEKLY VINORELBINE + TRASTUZUMAB

Burstein HJ et al. J Clin Oncol 2001;19:2722–2730
Burstein HJ et al. Cancer 2007;110:965–972
Jahanzeb M et al. Oncologist 2002;7:410–417

Preferred Regimen

First week:

Trastuzumab 4 mg/kg (loading dose); administer intravenously in 250 mL 0.9% sodium chloride injection (0.9% NS) over at least 90 minutes before vinorelbine (total dosage during the first week = 4 mg/kg)

Second and subsequent weeks:

Trastuzumab 2 mg/kg per dose; administer intravenously in 250 mL 0.9% NS over 30–90 minutes before vinorelbine administration, weekly, continually (total dosage during the second and subsequent weeks = 2 mg/kg)

Note: The duration of trastuzumab administration may be decreased from 90 to 30 minutes if administration over longer durations is well tolerated

Every week:

Vinorelbine 25 mg/m^2 per dose; administer by peripheral or central venous access in a volume of 0.9% NS or 5% dextrose injection (D5W) sufficient to produce a concentration within the range 1.5–3 mg/mL over 6–10 minutes after completing trastuzumab administration, weekly, continually (total dosage/week = 25 mg/m^2)

Alternate Regimen

First cycle:

Trastuzumab 4 mg/kg (loading dose); administer intravenously in 250 mL 0.9% NS over at least 90 minutes, on the day before the first dose of vinorelbine is administered

Vinorelbine 30 mg/m^2 per dose; administer by peripheral or central venous access in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range 1.5–3 mg/mL over 6–10 minutes, for 4 doses on days 1, 8, 15, and 22, every 28 days (total dosage/cycle = 120 mg/m^2)

Trastuzumab 2 mg/kg per dose; administer intravenously in 250 mL 0.9% NS over 30–90 minutes for 3 doses on days 8, 15, and 22, before vinorelbine administration, every 28 days (total dosage during the first cycle = 10 mg/kg)

Note: The duration of trastuzumab administration may be decreased from 90 to 30 minutes if administration over longer durations is well tolerated

Second and subsequent cycles

Trastuzumab 2 mg/kg per dose; administer intravenously in 250 mL 0.9% NS over 30–90 minutes for 4 doses on days 1, 8, 15, and 22, before vinorelbine administration, every 28 days (total dosage/cycle = 8 mg/kg)

Note: The duration of trastuzumab administration may be decreased from 90 to 30 minutes if administration over longer durations is well tolerated

Vinorelbine 30 mg/m^2 per dose; administer by peripheral or central venous access in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range 1.5–3 mg/mL over 6–10 minutes for 4 doses on days 1, 8, 15, and 22, every 28 days (total dosage/cycle = 120 mg/m^2)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on days with trastuzumab alone is **MINIMAL–LOW***

*Emetogenic potential on days with vinorelbine is **LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

(*continued*)

Treatment Modifications

Burstein HJ et al. J Clin Oncol 2001;19:2722–2730
Jahanzeb M et al. Oncologist 2002;7:410–417

Adverse Events	Treatment Modifications
ANC >1250/mm^3 and platelets >100,000/mm^3 on day of treatment	No modification, give 100% doses
G ≥2 neurologic toxicity	Delay vinorelbine dosing 1 week. If neurotoxicity abates to G ≤1, resume vinorelbine with dosage decreased to 15 mg/m^2
ANC 750–1250/mm^3 on day of treatment	Reduce vinorelbine dosage to 15 mg/m^2
Platelets count 50,000–99,000/mm^3 on day of treatment	
ANC <750/mm^3 or platelets <50,000/mm^3 on day of treatment	Delay vinorelbine dose until ANC >750/mm^3 and platelets >50,000/mm^3
Treatment delay of ≥2 weeks because of low ANC	Consider adding filgrastim prophylaxis after subsequent treatments
Treatment delay >3–4 weeks because of low ANC	Consider discontinuing treatment
Total bilirubin 2–3 mg/dL (34.2–51.3 µmol/L)	Reduce vinorelbine dosage to 12.5 mg/m^2
Total bilirubin >3 mg/dL (>51.3 µmol/L)	Hold vinorelbine
G3 nonhematologic adverse events	Hold vinorelbine until toxicity resolves to G ≤1
G4 nonhematologic adverse events	Consider discontinuing treatment
Left ventricular ejection fraction <45% or congestive heart failure	Discontinue trastuzumab

(continued)

Trastuzumab infusion reactions

- A symptom complex most commonly consisting of chills and/or fever may occur in as many as 40% of patients during the first infusion of trastuzumab. These symptoms occur infrequently with subsequent trastuzumab infusions. Other signs and/or symptoms may include nausea, vomiting, pain (in some cases at tumor sites), rigors, headache, dizziness, dyspnea, hypotension, rash, and asthenia. Although the symptoms are usually mild to moderate in severity, infrequently, trastuzumab may need to be discontinued
- When such a symptom complex is observed, it can be treated with or without reduction in the rate of trastuzumab infusion, and:
  - **Acetaminophen** 650 mg; administer orally
  - **Diphenhydramine** 25–50 mg; administer orally or by intravenous injection, and
  - **Meperidine** 12.5–25 mg; administer by intravenous injection every 10 minutes if needed for shaking chills (generally, cumulative doses >50 mg are not needed; use with caution in persons with moderate or more severely impaired renal function)

Treatment Plan Notes:

- LVEF assessment (MUGA or echocardiography) every 3 months in patients receiving trastuzumab

Patient Population Studied

Burstein HJ et al. Cancer 2007;110:965–972

Study of 81 evaluable women with HER2-overexpressing metastatic breast cancer that had not previously received chemotherapy for advanced disease. Patients were randomized 1:1 to receive either trastuzumab with weekly vinorelbine therapy or weekly taxane therapy (paclitaxel or docetaxel at the investigator's choice). Originally planned for 250 patients, the study was closed because of poor accrual with 81 evaluable patients, including 41 patients who received vinorelbine and 40 patients who received taxane for metastatic disease

Efficacy (N = 40)

Burstein HJ et al. Cancer 2007;110:965–972

RECIST	
	Percent or Duration
Overall response rate	51% (95% CI 35–67)
Complete response	12%
Partial response	39%
Stable disease	17%
Progressive disease	0
Unevaluable	31%
Median time to progression	8.5 months
Time to treatment failure	5.8 months

RECIST criteria, v.1.0: Response Evaluation Criteria in Solid Tumors, version 1.0. Therasse P et al. J Natl Cancer Inst 2000;92:205–216

Therapy Monitoring

1. *Weekly:* CBC with differential and platelet count and LFTs
2. *Every 3–4 months:* Cardiac ejection fraction

METASTATIC REGIMEN

CAPECITABINE + TRASTUZUMAB

Bartsch R et al. J Clin Oncol 2007;25:3853–3858

Trastuzumab 8 mg/kg initial (loading) dose; administer intravenously in 250 mL sodium chloride injection (0.9% NS) over at least 90 minutes (total initial dosage = 8 mg/kg), *followed 3 weeks later by:*
Trastuzumab 6 mg/kg per dose; administer intravenously in 250 mL 0.9% NS over 30–90 minutes, every 3 weeks, continually (total dosage/3-week cycle = 6 mg/kg)
Note: Administration duration may be decreased from 90 to 30 minutes if administration over longer durations is well tolerated

Capecitabine 1250 mg/m² per dose; administer orally twice daily within 30 minutes after a meal for 14 consecutive days on days 1–14, every 3 weeks (total dosage/cycle = 35,000 mg/m²)
Notes:
- Capecitabine is given for 2 consecutive weeks followed by 1 week without treatment
- Doses are rounded to use combinations of 500-mg and 150-mg tablets that most closely approximate calculated values
- In practice, treatment often is begun with capecitabine 1000 mg/m² per dose twice daily for 14 consecutive days on days 1–14, every 3 weeks, because of a high rate of dose reduction with higher dosages (total dosage/cycle = 28,000 mg/m²)
- Initial capecitabine dosage should be decreased by 25% in patients with moderate renal impairment (baseline creatinine clearance = 30–50 mL/min [0.5–0.83 mL/s]; ie, a dosage reduction from 1250 mg/m² per dose to 950 mg/m² per dose, twice daily. Capecitabine use is contraindicated in persons with severe renal impairment (creatinine clearance <30 mL/min [<0.5 mL/s])
- Although food decreases the rate and extent of drug absorption and the time to peak plasma concentration and systemic exposure (AUC) for both capecitabine and fluorouracil, product labeling recommends giving capecitabine within 30 minutes after the end of a meal because established safety and efficacy data are based on administration with food

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days with capecitabine is ***LOW***
Emetogenic potential on days with trastuzumab alone is ***MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed onset diarrhea:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

(*continued*)

Treatment Modifications

Dose Adjustments for Capecitabine

Adverse Event	Dose Modification
First G2 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. No change in dosage required
Second G2 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 25%
Third G2 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 50%
Fourth G2 toxicity	Discontinue capecitabine
First G3 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 25%
Second G3 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 50%
Third G3 toxicity	Discontinue capecitabine
First G4 toxicity	Hold capecitabine and resume after adverse events resolve to G ≤1. Reduce dosage by 50%
Second G4 toxicity	Discontinue capecitabine
Left ventricular ejection fraction <45% or congestive heart failure	Discontinue trastuzumab

Patient Population Studied

Study of 40 patients with advanced breast cancer. All had prior adjuvant or palliative anthracycline and taxane or vinorelbine treatment; further, a minimum of 1 earlier line of trastuzumab-containing therapy for metastatic disease was obligatory

(*continued*)

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Hand-foot reaction

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine 50–150 mg/day; administer orally

Trastuzumab infusion reactions

- A symptom complex most commonly consisting of chills and/or fever may occur in as many as 40% of patients during the first infusion of trastuzumab. These symptoms occur infrequently with subsequent trastuzumab infusions. Other signs and/or symptoms may include nausea, vomiting, pain (in some cases at tumor sites), rigors, headache, dizziness, dyspnea, hypotension, rash, and asthenia. Although the symptoms are usually mild to moderate in severity, infrequently, trastuzumab may need to be discontinued
- When such a symptom complex is observed, it can be treated with or without reduction in the rate of trastuzumab infusion, and:
  - **Acetaminophen** 650 mg; administer orally
  - **Diphenhydramine** 25–50 mg; administer orally or by intravenous injection, and
  - **Meperidine** 12.5–25 mg; administer by intravenous injection every 10 minutes if needed for shaking chills (generally, cumulative doses >50 mg are not needed; use with caution in persons with moderate or more severely impaired renal function)

Treatment Plan Notes:

- LVEF assessment (MUGA or echocardiography) every 3 months in patients receiving trastuzumab

Efficacy

1. *Days 1 and 10 of the first cycle:* Complete blood count with differential
2. *Day 1 during consecutive cycles:* Blood count with differential if no G3/G4 hematologic toxicity observed

METASTATIC BREAST CANCER

HORMONAL THERAPY AGENTS

Selective Estrogen Receptor Modulators
Tamoxifen 20 mg daily; administer orally

Selective Estrogen Receptor Downregulator
Fulvestrant 500 mg/treatment; administer by intramuscular injection, 250 mg into each buttock, on days 1, 15, 29, and once monthly thereafter

Aromatase Inhibitors
Anastrozole 1 mg daily; administer orally
Letrozole 2.5 mg daily; administer orally
Exemestane 25 mg daily; administer orally

Progestins
Megestrol Acetate 40 mg 4 times daily; administer orally

LHRH Agonists
Goserelin 3.6 mg implant every 28 days; administer subcutaneously
Goserelin 10.8 mg implant every 3 months; administer subcutaneously

Efficacy

Tamoxifen	
Prevention:	50% reduction in breast cancer (invasive and noninvasive) in women at increased risk (5-year risk of 1.66%)
Adjuvant:	50% reduction in recurrence, 28% reduction in mortality
Metastatic:	Response rate 30–70% depending on ER/PR status: ER+/PR+ > ER+/PR− > ER−/PR+
Fulvestrant	
Metastatic:	At least equivalent to anastrozole
Anastrozole	
Adjuvant:	Superior disease-free survival *vs.* tamoxifen
Metastatic:	Likely superior to tamoxifen
Letrozole	
Neoadjuvant:	Superior to tamoxifen
Adjuvant:	Improved DFS when started after 5 years of tamoxifen
Metastatic:	Superior to tamoxifen
Exemestane	
Metastatic:	Superior to megestrol acetate
Progestins	
Metastatic:	Equivalent to tamoxifen
LHRH Agonists	
Adjuvant:	Evidence of efficacy in combination with tamoxifen for premenopausal women
Metastatic:	Evidence of efficacy in combination with tamoxifen for premenopausal women

Therapy Monitoring

Tamoxifen

1. LFTs >1 month, then every 3–6 months
2. Serum chemistries and LFTs every 6 months

Fulvestrant

1. Clinic visit at 1 month
2. Serum chemistries and LFTs every 6 months

Anastrozole

1. Clinic visit at 1 month
2. Bone density scan at baseline and every 6–12 months when used as adjuvant therapy
3. Serum chemistries and LFTs every 6 months

Letrozole

1. Clinic visit at 1 month
2. Bone density scan at baseline and every 6–12 months when used as adjuvant therapy
3. Serum chemistries and LFTs every 6 months

Exemestane

1. Clinic visit at 1 month
2. Bone density scan at baseline and every 6–12 months when used as adjuvant therapy
3. Serum chemistries and LFTs every 6 months

Megestrol

1. Clinic visit, serum chemistries, and LFTs at 1 month then every 3–6 months
2. Monitor adrenal function every 3 months
3. *Note:* Consider replacement (or stress dose) steroids with withdrawal or physiologic stress

LHRH Agonists (Goserelin)

1. Clinic visit at 1 month
2. Serum chemistries and LFTs every 6 months

7. Carcinoma of Unknown Primary

David R. Spigel, MD and F. Anthony Greco, MD

Epidemiology

Incidence: Unknown* (Estimated at 30,000–45,000 patients/year)
Median age: Varies by histology (usually sixth decade)
Male to female ratio: M ≅ F

Stage at Presentation
Local/regional: <10%
≥2 sites: >90%

*Due to patient heterogeneity and tumor registry misclassification

Cancer Facts and Figures 2013, the America Cancer Society

Work-up

Clinical evaluation
- H&P, including pelvic, breast, and rectal exams
- CBC
- Comprehensive metabolic profile
- Urinalysis
- Occult blood in feces
- Lactate dehydrogenase (LDH)
- Serum human chorionic gonadotropin (HCG)
- Alpha-fetoprotein (AFP)
- Carcinoembryonic antigen (CEA)
- CA 19-9, CA 27–29 (or CA 15-3), CA 125
- Chest/abdominal/pelvic CT

Where appropriate:
- Positron emission tomography (PET)
- Prostate specific antigen (PSA)
- Mammography, bronchoscopy, and panendoscopy (particularly for squamous carcinomas)

Pathologic studies
- Core needle or excisional biopsy preferred over fine-needle aspiration (FNA)/cytology (consider rebiopsy if insufficient material from initial biospy)
- Immunohistochemistry (IHC) analyses for:
  - PSA in men
  - Estrogen receptor (ER) in women
  - Progesterone receptor (PR) in women
  - HER2/neu overexpression in women
  - CD 117
  - Consider gene signature profiling of tissue of origin

Where appropriate:
- Electron microscopy
- Cytogenetic analysis
- Molecular profiling

Focused Work-up

Presentation	Men	Women
Head and neck or supraclavicular adenopathy	• ENT exam • Chest/abdominal CT • PSA, testicular ultrasound	• ENT exam • Chest/abdominal CT • Mammography, ER/PR • Pathologic evaluation
Axillary adenopathy	• Chest/abdominal CT • PSA	• Chest/abdominal CT • Mammography, ER/PR • (Consider ultrasound or MRI)
Mediastinal involvement	• Chest/abdominal CT • HCG/AFP • PSA	• Chest/abdominal CT • HCG/AFP • Mammography, ER/PR
Chest (effusion and/or nodules) involvement	• Chest/abdominal CT • PSA	• Chest/abdominal/pelvic CT • Mammography, ER/PR • CA 125
Peritoneal involvement	• Chest/abdominal/pelvic CT • PSA	• Chest/abdominal/pelvic CT • Mammography, ER/PR • CA 125
Retroperitoneal mass	• Chest/abdominal/pelvic CT • PSA • HCG/AFP • Testicular ultrasound	• Chest/abdominal/pelvic CT • Mammography, ER/PR • CA 125
Inguinal adenopathy	• Abdominal/pelvic CT • PSA	• Abdominal/pelvic CT • Mammography, ER/PR • CA 125
Hepatic involvement	• Chest/abdominal/pelvic CT • Colonoscopy • AFP • PSA	• Chest/abdominal/pelvic CT • Colonoscopy • AFP • Mammography, ER/PR
Skeletal involvement	• Bone scan • PSA	• Bone scan • Mammography, ER/PR
Brain involvement	• Chest/abdominal CT	• Chest/abdominal CT • Mammography, ER/PR

Greco FA, Hainsworth JD. In: DeVita VT, Jr, Hellman S, Rosenberg SA, eds. Cancer: Principles & Practice of Oncology, 8th ed. Lippincott; 2008:2363–2388

Survival

- 1-Year survival: 35-–40%
- 2-Year survival: 15–20%
- 3-Year survival: 10–15%
- 5-Year survival: 10%
- 8-Year survival: < 10%

Survival varies by histology and clinical subsets

Expert Opinion

General: For most patients with CUP who do not fit into a favorable prognostic group and presenting with poor prognostic features and disseminated disease, the prognosis is poor, and resistance to available cytotoxic therapy occurs early. However, survival has improved for a minority of patients with otherwise unfavorable prognostic factors. Empiric regimens were the preferred approach in the past and continue to be acceptable alternatives to offer patients however, emerging data suggest that a more tailored approach to therapy is superior. With the emergence of modern molecular testing to help define CUP subtypes, the focus will shift from empiric combinations to more tailored regimens. Clinical features, immunohistochemical evaluation, and molecular profiling used together are likely to better define CUP subsets. The detailed molecular characterization of these tumors is also likely to suggest appropriate and perhaps more effective targeted therapies. Furthermore, as therapies for known primary cancers improve and become more selective based on biomarkers newer therapeutic approaches should be evaluated in the appropriate CUP subsets as well

Recognizing favorable subsets: Most patients with unknown primary cancer have variable clinical and pathologic presentations making treatment selection somewhat empiric. However, approximately 20% of patients present with recognizable features characteristic of known primary cancers where specific therapies are more established. It is important to recognize these favorable clinical and pathologic subsets when choosing therapy, such as local therapy with curative intent in a patient with isolated neck nodes involved with squamous cell carcinoma or a woman with isolated axillary adenocarcinoma

Empiric therapy: Paclitaxel/carboplatin (± etoposide) and gemcitabine/irinotecan are broad-spectrum regimens that can be used in patients who present without characteristic clinical or pathologic features, particularly in patients with adenocarcinomas. Recently, the combination of oxaliplatin and capecitabine was found to have activity as a salvage treatment for patients with CUP. This regimen should be considered in patients with clinical and pathologic features suggesting a primary site in the gastrointestinal tract

Empiric therapy for unknown primary tumors can also include modern regimens in the appropriate clinical setting. When one's clinical suspicion is NSCLC, despite the absence of a definitive primary site, selecting paclitaxel/carboplatin + bevacizumab or pemetrexed/platinum regimens are appropriate for a patient who is otherwise eligible. Likewise, if the clinical impression is of a primary colorectal malignancy, for example in a patient with hepatic metastases and a negative endoscopic evaluation, choosing infusional fluorouracil and oxaliplatin (FOLFOX) + bevacizumab would be a reasonable option

Tailoring therapy: Advances in imaging (PET/CT) and in our use of immunohistochemistry (TTF-1, CDX2, CK20, CK7, etc.) have helped expand our ability to identify a primary site at diagnosis. However, none of these tests are absolute, and still leave clinicians with some degree of uncertainty when assessing prognosis and selecting treatment. Recently, genomic and proteomic technologies have emerged as additional tools to potentially help identify a tumor's primary origin. These tests analyze which genes are active or inactive in the tumor specimen and compare these genetic signatures with gene profiles from known tumor libraries. Several commercial tests are now available, but still require additional prospective validation. Encouraging preliminary results have been obtained by performing molecular profiling with a reverse transcriptase-polymerase chain reaction (RT-PCR) assay (Cancer Type ID; bioTheranostics, Inc., San Diego, CA). The assay can be performed on formalin-fixed paraffin-embedded biopsy specimens. In a recent blinded study, 15 of the 20 assay predictions (75%) were correct (95% confidence interval, 60–85%), corresponding to the actual latent primary sites identified after the initial diagnosis of CUP. Moreover, in a recent large prospective trial 194 patients with CUP received assay-directed site-specific treatment. The median survival was 12.5 months - and longest in tumor types regarded as clinically more responsive (eg breast, colorectal) when compared with more resistant tumor types (eg biliary, pancreatic). As these diagnostic tests improve, along with our understanding of molecular targets critical to cancer cell growth, we will be better able to select optimal therapies for our patients with unknown primary cancers

REGIMEN

PACLITAXEL + CARBOPLATIN +/− ETOPOSIDE

Hainsworth JD, Greco FA. J Clin Oncol 1997;15:2385–2393

Premedication against hypersensitivity reactions to paclitaxel:
Dexamethasone 20 mg per dose; administer orally for 2 doses at 12 hours and 4 hours before starting paclitaxel
Diphenhydramine 50 mg; administer by intravenous injection, 30–60 minutes before starting paclitaxel
Cimetidine 300 mg (or equivalent histamine H_2 antagonist); administer intravenously in 25–100 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 15–30 minutes, before starting paclitaxel
Dexamethasone 20 mg; administer intravenously over 10–15 minutes, 30 minutes before starting paclitaxel

Paclitaxel 200 mg/m²; administer intravenously diluted in 0.9% NS or D5W to a concentration within the range 0.3 to 1.2 mg/mL, over 1 hour, before starting carboplatin on day 1, every 21 days (total dosage/cycle = 200 mg/m²)

Carboplatin [calculated dose] AUC = 6 mg/mL · min; administer intravenously diluted in 0.9% NS or D5W to a concentration >0.5 mg/mL over 20–30 minutes on day 1, every 21 days (total dosage/cycle calculated to produce an AUC = 6 mg/mL · min)

Etoposide 50 mg per dose; administer orally for 5 doses on days 1, 3, 5, 7, and 9, alternating *with:*
Etoposide 100 mg per dose; administer orally for 5 doses on days 2, 4, 6, 8, and 10
(total dose/cycle = 750 mg)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed symptoms*
Emetogenic potential on days 2 to 10 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Carboplatin dose is based on a formula described by Calvert et al. to achieve a target area under the plasma concentration versus time curve (AUC)

$$\text{Total carboplatin dose (mg)} = (\text{target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be estimated from the equation of Cockcroft and Gault, thus:

$$\text{For males, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})} \times 0.85$$

(continued)

Treatment Modifications

Adverse Event	Dose Modification
Day 21: ANC >1500/mm³ and platelets ≥100,000/mm³	Administer 100% doses
Day 21: ANC <1500/mm³ or platelets <100,000/mm³	Delay treatment 1 week or until ANC >1500/mm³ and platelets >100,000/mm³ Then, retreat at 100% doses
Day 8: ANC ≥1000/mm³ and platelets ≥75,000/mm³	Complete 10 days of etoposide
Day 8: ANC <1000/mm³ *or* platelets <75,000/mm³	Hold days 8, 9, and 10 etoposide doses
Hospitalization for febrile neutropenia	Administer 75% of paclitaxel and carboplatin and give etoposide only on days 1–8 (8 daily doses) during all subsequent cycles
Reversible G3 or G4 nonhematologic toxicity (except for alopecia, nausea, and vomiting)	Decrease the dose of the suspected offending drug(s) by 25% during subsequent cycles

Hematopoietic growth factors may be used as secondary prophylaxis at the discretion of a treating physician, but should not substitute for recommended dose modifications for hematological toxicities

Patient Population Studied

A study of 55 patients with carcinoma of unknown primary site were treated and available for assessment. Responding patients received 4 courses of treatment. The following histologies were included: adenocarcinoma (n = 30); poorly differentiated carcinoma or poorly differentiated adenocarcinoma (n = 21); poorly differentiated neuroendocrine carcinoma (n = 3); and squamous carcinoma (n = 1)

(*continued*)

Note: On October 8, 2010, the U.S. FDA identified a potential safety issue with carboplatin dosing. By the end of 2010, all clinical laboratories in the United States will use the standardized Isotope Dilution Mass Spectrometry (IDMS) method to measure serum creatinine, which could result in an overestimation of the GFR in some patients with normal renal function. A carboplatin dose calculated from an estimated creatinine clearance based on an IDMS-measured serum creatinine could exceed exposure predicted by the Calvert formula and result in increased drug-related toxicity

Provided actual GFR measurements are made to assess renal function, carboplatin can be safely dosed according to the Calvert formula described in product labeling

If GFR (or Clcr) is estimated using serum creatinine measurements by the IDMS method, the FDA recommended for patients with normal renal function limiting estimated GFR (Clcr) to not more than 125 mL/min for any targeted AUC value

Hainsworth JD, Greco FA. J Clin Oncol 1997;15:2385–2393

Therapy Monitoring

1. *Weekly:* CBC with differential platelet count
2. *Response evaluation:* After 2 treatment cycles. If objective response or stable disease with symptomatic improvement recorded, administer 2 more cycles for a total of 4 cycles

Notes

1. Responses are similar in adenocarcinoma and poorly differentiated carcinoma
2. This regimen is easier to administer and less toxic than cisplatin-based regimens
3. Toxicity is primarily myelosuppression

REGIMEN

GEMCITABINE + IRINOTECAN

Doss HH et al. Proc Am Soc Clin Oncol 2004;23:354 [Abstract 4167]
Greco FA et al. Proc Am Soc Clin Oncol 2002;21:161a [Abstract 642]
Hainsworth JD et al. Cancer 2005;104:1992–1997

Gemcitabine 1000 mg/m² per dose; administer intravenously in 0.9% sodium chloride injection diluted to a concentration ≥0.1 mg/mL over 30 minutes, for 2 doses on days 1 and 8, every 21 days (total dosage per cycle = 2000 mg/m²)
Irinotecan 100 mg/m² per dose; administer intravenously in 5% dextrose injection diluted to a concentration within the range of 0.12–2.8 mg/mL over 90 minutes, for 2 doses on days 1 and 8, every 21 days (total dosage per cycle = 200 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)
- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:
Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:
A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count is <500/mm³, with or without accompanying fever in association with diarrhea
- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

(continued)

Treatment Modifications*

Adverse Event	Dose Modification†
ANC >1500/mm³ *and* platelet count >100,000/mm³	Administer 100% dosage
ANC 1000–1500/mm³ *or* platelet count 75,000–100,000/mm³	Reduce gemcitabine and irinotecan dosages by 25%
ANC <1000/mm³ *or* platelet count <75,000/mm³	Delay treatment 1 week, or until ANC >1000/mm³ *and* platelets >100,000/mm³, then administer both drugs at 75% dosages
G3/4 Diarrhea‡	Hold irinotecan until diarrhea G ≤1; reduce irinotecan dosage to 75% for all subsequent doses
Other reversible G3/4 nonhematologic toxicity	Administer 75% dosage of the offending drug in subsequent courses

*Hematopoietic growth factors may be used as secondary prophylaxis at the discretion of a treating physician, but should not substitute for recommended dose modifications for hematological toxicities
†Parameters for both day 1 and day 8
‡G1/2 diarrhea administer 100% irinotecan dosage

Patient Population Studied

A multicenter community-based trial of 31 patients with previously treated (1 prior regimen) CUP (adenocarcinoma, poorly differentiated carcinoma, poorly differentiated adenocarcinoma, or poorly differentiated neuroendocrine carcinoma) who received gemcitabine + irinotecan every 21 days for 6 cycles

Hainsworth JD et al. Cancer 2005;104:1992–1997

(continued)

Acute cholinergic syndrome
Atropine sulfate 0.25–1 mg; administer subcutaneously or intravenously if abdominal cramping or diarrhea develop during or within 1 hour after irinotecan administration

- If symptoms are severe, add as primary prophylaxis at least 30 minutes before irinotecan during subsequent cycles

For irinotecan, acute cholinergic syndrome may be characterized by abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

Efficacy (N = 31)

Complete response	2.5%
Partial response	7.5%
Stable disease	41%
Median survival	4.5 months
1-Year survival	25%
2-Year survival	13%

Hainsworth JD et al. Cancer 2005;104:1992–1997

Toxicity (N = 31)

	% G3/4
Hematologic	
Neutropenia	30
Thrombocytopenia	8
Anemia	9
Febrile neutropenia	3
Nonhematologic	
Diarrhea	8
Nausea/vomiting	8
Fatigue	8

Therapy Monitoring

1. *Before each cycle:* CBC, serum electrolytes, BUN, creatinine, and LFTs
2. *Response evaluation:* Every 2 cycles

REGIMEN

BEVACIZUMAB + ERLOTINIB

Hainsworth JD et al. J Clin Oncol 2007;25:1747–1752

Bevacizumab 10 mg/kg per dose; administer intravenously in 100 mL 0.9% sodium chloride injection for 2 doses on days 1 and 15, every 28 days (total dosage/cycle = 20 mg/kg)

Note: Administration duration for the initial dose is 90 minutes. If administration is well tolerated, the administration duration may be decreased stepwise during subsequent treatments to 60 minutes and, finally, to a minimum duration of 30 minutes

Erlotinib 150 mg/day; administer orally at least 1 hour before or 2 hours after meals, continually (total dose/week = 1050 mg)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed-onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)

- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

Wadler S et al. J Clin Oncol 1998;16:3169–3178
Abigerges D et al. J Natl Cancer Inst 1994;86:446–449

Treatment Modifications

Adverse Event	Dose Modification
Proteinuria ≥2+ by dipstick examination	Hold bevacizumab and obtain a 24-hour urine
Proteinuria ≥2000 mg/24 hours	Hold bevacizumab. Resume after proteinuria decreases to <2000 mg/24 hours
G3/4 bleeding	Hold bevacizumab
Life-threatening hemorrhagic event	Discontinue bevacizumab
G3 hypertension on bevacizumab	Treat using standard antihypertensives
G4 hypertension	Interrupt bevacizumab and begin or advance antihypertensive treatment
G1/2 acneiform skin rash and diarrhea	Treat symptoms. Continue same dose of erlotinib
G3/4 skin toxicity	Stop erlotinib for 1 week or until the toxicity improves to G ≤2 then resume erlotinib at full dose
Recurrent G3/4 skin toxicity	Reduce erlotinib dose to 100 mg daily
G3/4 diarrhea not controlled by using standard schedules of loperamide	Interrupt erlotinib for at least one week or until diarrhea has improved to G ≤2. Erlotinib can then be reinstituted at full dose
Recurrence of G3/4 diarrhea	Interrupt erlotinib for at least one week or until diarrhea has improved to G ≤2. Then, resume erlotinib use with dose decreased to 100 mg daily
Other G3/4 toxicities caused by either of these agents or their combination	The offending agent or agents should be discontinued for 2 weeks or until toxicity has improved to G ≤2. Treatment can be reinstituted at full dose at the discretion of the treating physician

Patient Population Studied

Fifty-one patients with histologically or cytologically confirmed carcinoma of unknown primary site were enrolled in this single cohort, multicenter, phase II trial. Eligible tumor histologies included adenocarcinoma, poorly differentiated adenocarcinoma, and poorly differentiated carcinoma. For study purposes, patients were considered to have carcinoma of unknown primary site if the following diagnostic procedures were unrevealing of a primary site: complete history, physical examination, chemistry profile, CT scans of the chest and abdomen, and directed radiologic work-up of the symptomatic areas. Patients previously treated with either one or two chemotherapy regimens were eligible. In addition, previously untreated patients were eligible if they had advanced liver metastases, predominant bone metastases, or ≥3 visceral sites of metastases (ie, clinical settings in which standard chemotherapy has had relatively little effect). Patients were reevaluated after 8 weeks of treatment; those with objective response or stable disease continued treatment until disease progression

Efficacy*

Complete response	0
Partial response	10%, 95% CI = 3 – 23%
Stable disease	61%
Progressive disease	29%
Median overall survival	7.4 months
1-Year overall survival	33%
Median progression-free survival	3.9 months

*RECIST criteria (Response Evaluation Criteria in Solid Tumors, Therasse P et al. J Natl Cancer Inst 2000;92:205–216)

Therapy Monitoring

1. *Before each dose of bevacizumab:* CBC, serum electrolytes, creatinine, LFTs, and urinalysis
2. *Every month:* History and physical exam
3. After 8 weeks of treatment, evaluate for response by imaging

Toxicity

Toxicity Grade

	1/2		3		4	
Toxicity	No	%	No	%	No	%
Fatigue	21	42	8	16	0	0
Rash	39	78	4	8	1	2
Diarrhea	29	58	4	8	0	0

REFRACTORY OR RECURRENT CARCINOMA OF UNKNOWN PRIMARY REGIMEN

OXALIPLATIN + CAPECITABINE

Hainsworth JD et al. Cancer 2010;116:2448–2454

Oxaliplatin 130 mg/m²; administer intravenously in 250–500 mL 5% dextrose injection over 2 hours on day 1, every 21 days (total dosage/cycle = 130 mg/m²)
Capecitabine 1000 mg/m² per dose; administer orally twice daily (approximately every 12 hours) for 28 doses on days 1–14, every 21 days, (total dose/cycle = 28,000 mg/m²)

Notes:
- Capecitabine is given for 2 consecutive weeks followed by 1 week without treatment
- Doses are rounded to use combinations of 500-mg and 150-mg tablets that most closely approximate calculated values
- Although food decreases the rate and extent of drug absorption and the time to peak plasma concentration and systemic exposure (AUC) for both capecitabine and fluorouracil, product labeling recommends giving capecitabine within 30 minutes after the end of a meal because established safety and efficacy data are based on administration with food

Note: Patients with objective response or stable disease after 2 cycles continued treatment for 6 cycles or until disease progression. Patients who continued to benefit and were tolerating treatment well had the option to receive additional treatment cycles at the discretion of their physician
Note: Leukocyte growth factors are not routinely used during cycle 1, but may be used subsequently as secondary prophylaxis according to standard guidelines
Note: The combination of oxaliplatin and capecitabine has activity as a salvage treatment for patients with CUP. Consider in patients with clinical and pathologic features suggesting a primary site in the gastrointestinal tract

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***MODERATE***
Emetogenic potential on days with capecitabine alone is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)
For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine
Pyridoxine may provide relief for discomfort/pain associated with PPE, although the mechanism through which this occurs remains unclear
- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Oral care
Prophylaxis and treatment for mucositis/stomatitis
General advice:
- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:
- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

(continued)

(continued)

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE, although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day
- Patients who develop G1/2 PPE while receiving doxorubicin HCl liposome injection may receive a fixed daily dose of pyridoxine 200 mg. This may allow for treatment to be completed without dosage reduction, treatment delay, or recurrence of PPE

Treatment Modifications

Adverse Event	Dose Modification
ANC <1500/mm³ *or* platelet count <75,000/mm³ on day 1 of a cycle	Delay treatment for 1 week and remeasure blood counts. If, after a 1-week delay, ANC ≥1500/mm³ *and* platelet count ≥75,000/mm³, decrease dosages of both agents by 25% and resume treatment
ANC <1500/mm³ *or* platelet count <75,000/mm³ after a 1-week delay	Delay treatment for 1 additional week and remeasure blood counts. If, after a second 1-week delay, ANC ≥1500/mm³ *and* platelet count ≥75,000/mm³, decrease dosages of both agents by 25% and resume treatment
ANC <1500/mm³ *or* platelet count <75,000/mm³ after a second 1-week delay	Discontinue therapy
Hospitalization for fever and neutropenia	Continue therapy with dosages of both drugs decreased by 25% in subsequent cycles
Neutropenia and fever during a 14-day course of capecitabine	Discontinue capecitabine for remainder of cycle
G2 peripheral neuropathy	Reduce dose of oxaliplatin by 25% during subsequent cycles
G3/4 peripheral neuropathy	Discontinue oxaliplatin; continue single agent capecitabine if patient is benefiting
Laryngopharyngeal dysesthesia during oxaliplatin administration	Increase duration of subsequent oxaliplatin infusions from 2 to 6 hours
G >1 hand-foot syndrome during or after capecitabine	Discontinue remaining capecitabine doses for ongoing cycle Delay starting a subsequent cycle of therapy until the hand-foot syndrome recovers to G ≤1 Give capecitabine during subsequent cycles at dosages decreased by 25%
Hand-foot syndrome G >1 after 2 dose reductions, or requiring delay of >2 weeks for symptoms to resolve	Discontinue capecitabine; continue oxaliplatin in patients benefiting from treatment
Other nonhematologic toxicity G >2	Reduce offending agents dosages by 25% during subsequent courses
Irreversible nonhematologic toxicity, or toxicity that requires treatment delay >2 weeks	Discontinue therapy

Patient Population Studied

Histologically or cytologically confirmed CUP. Eligible tumor histologies included adenocarcinoma, poorly differentiated adenocarcinoma, poorly differentiated carcinoma, squamous carcinoma, and poorly differentiated neuroendocrine carcinoma. Patients were required to have been treated previously with 1 chemotherapy regimen, but could not have previously received oxaliplatin, capecitabine, or fluorouracil. Patients may also have had treatment with 1 immunotherapy or targeted therapy regimen

Previous chemotherapy: Taxane/platinum-based: 30 (63%); bevacizumab/erlotinib: 5 (10%); taxane ± bevacizumab: 3 (6%); irinotecan/gemcitabine: 5 (10%); platinum/etoposide: 2 (4%); others (1 regimen each): 3 (6%)—22 of 31 patients had previously received carboplatin or cisplatin

Best response to previous treatment: Complete: 1 (2%); partial: 11 (23%); stable disease or progression: 33 (69%); unknown: 3 (6%)

Efficacy* (N = 48)

Complete response	0
Partial response	19%
Stable disease at first evaluation†	46%
Remission duration in 9 patients who achieved PR	Median 10 months (range: 2–48 months)
Median progression-free survival	3.7 months
Median overall survival‡	9.7 months
1 Year PFS	22%

*RECIST criteria (Response Evaluation Criteria in Solid Tumors, Therasse P et al. J Natl Cancer Inst 2000;92:205–216)
†8/22 with SD had SD >3 months, and 4/22 had SD >6 months
‡28 patients (58%) subsequently received further treatment for CUP

Note: Patients received a median of 12 weeks (4 cycles) of treatment (range: 3–66 weeks). Fifteen patients completed ≥6 cycles with oxaliplatin + capecitabine

Toxicity (N = 48 patients; 209 Treatment Courses)*

	% G3	% G4
Hematologic		
Neutropenia	3 (6%)	—
Thrombocytopenia	4 (8%)	2 (4%)
Anemia	—	1(2%)

Therapy Monitoring

At the beginning of each 21-day cycle, patients seen and examined by physician. Complete blood counts and serum electrolytes, creatinine, LFTs performed Response assessment every 2 cycles

8. Cervical Cancer

Peter G. Rose, MD

Epidemiology

Incidence: 12,360 (Estimated new cases for 2014 in the United States)
7.9 per 100,000 women per year
Deaths: Estimated 4020 in 2014
Median age: 49 years

Stage at Presentation

Localized:	55%
Regional:	32%
Distant:	8%
Unstaged:	6%

Siegel R et al. CA Cancer J Clin 2013;63:11–30
Surveillance, Epidemiology and End Results (SEER) Program. Available from: <http://seer.cancer.gov>; Accessed 20 13

Work-up

Stage IA/Stage IB1:	• H&P • CBC with platelet count, LFTs, BUN, creatinine • Cervical biopsy (pathologic review) • Cone biopsy as indicated • Chest x-ray, intravenous pyelogram, for IB1 CT/MRI ± PET ± lymphangiogram
Stage IB2 or greater:	• Chest x-ray, intravenous pyelogram, or CT/MRI ± PET ± lymphangiogram • Consider examination under anesthesia
Stages III/IV:	• Consider cystoscopy/proctoscopy

Pathology

Squamous cell carcinomas • Large cell, keratinizing • Large cell, nonkeratinizing • Small cell (not neuroendocrine) • Verrucous carcinoma	75–80%
Adenocarcinomas • Adenoma malignum • Mucinous • Papillary • Endometrioid • Clear cell • Adenoid cystic	17%
Adenosquamous	6%
Glassy cell carcinoma	Rare
Neuroendocrine small cell carcinoma	Rare

Histologic Grade

Gx	Cannot be assessed
G1	Well differentiated
G2	Moderately differentiated
G3	Poorly differentiated
G4	Undifferentiated

Staging

Primary Tumor (T)

TNM Category	FIGO Stage	
TX		Primary tumor cannot be assessed
T0		No evidence of primary tumor
Tis	*	Carcinoma *in situ* (preinvasive carcinoma)
T1	I	Cervical carcinoma confined to uterus (extension to corpus should be disregarded)
T1a†	IA	Invasive carcinoma diagnosed only by microscopy. Stromal invasion with a maximum depth of 5.0 mm measured from the base of the epithelium and a horizontal spread of 7.0 mm or less. Vascular space involvement, venous or lymphatic, does not affect classification
T1a1	IA1	Measured stromal invasion 3.0 mm or less in depth and 7.0 mm or less in horizontal spread
T1a2	IA2	Measured stromal invasion more than 3.0 mm and not more than 5.0 mm with a horizontal spread 7.0 mm or less
T1b	IB	Clinically visible lesion confined to the cervix or microscopic lesion greater than T1a/IA2
T1b1	IB1	Clinically visible lesion 4.0 cm or less in greatest dimension
T1b2	IB2	Clinically visible lesion more than 4.0 cm in greatest dimension
T2	II	Cervical carcinoma invades beyond uterus but not to pelvic wall or to lower third of vagina
T2a	IIA	Tumor without parametrial invasion
T2a1	IIA1	Clinically visible lesion 4.0 cm or less in greatest dimension
T2a2	IIA2	Clinically visible lesion more than 4.0 cm in greatest dimension
T2b	IIB	Tumor with parametrial invasion
T3	III	Tumor extends to pelvic wall and/or involves lower third of vagina, and/or causes hydronephrosis or non-functioning kidney
T3a	IIIA	Tumor involves lower third of vagina, no extension to pelvic wall
T3b	IIIB	Tumor extends to pelvic wall and/or causes hydronephrosis or non-functioning kidney
T4	IVA	Tumor invades mucosa of bladder or rectum, and/or extends beyond true pelvis (bullous edema is not sufficient to classify a tumor as T4)

*FIGO staging no longer includes Stage 0 (Tis)
†All macroscopically visible lesions—even with superficial invasion—are T1b/IB

(*continued*)

Regional Lymph Nodes (N)

TNM Category	FIGO Stage	
NX		Regional lymph nodes cannot be assessed
N0		No regional lymph node metastasis
N1	IIIB	Regional lymph node metastasis

Distant Metastasis (M)

TNM Category	FIGO Stage	
		No distant metastasis (no pathologic M0; use clinical M to complete stage group)
M1	IVB	Distant metastasis (including peritoneal spread, involvement of supraclavicular or mediastinal lymph nodes, lung, liver, or bone)

Staging (*continued*)

Group	T	N	M
Stage 0*	Tis	N0	M0
Stage I	T1	N0	M0
Stage IA	T1a	N0	M0
Stage IA1	T1a1	N0	M0
Stage IA2	T1a2	N0	M0
Stage IB	T1b	N0	M0

Overall 5-Year Survival Relative to FIGO* Disease Stage

Stage	% Survival
IA1	94.6
IA2	92.6
IB1	90.4
IB2	79.8
IIA	76
IIB	73.3
IIIA	50.5
IIIB	46.4
IVA	29.6
IVB	22

*International Federation of Gynecology and Obstetrics

Expert Opinion

1. The use of concurrent chemotherapy and radiation has reduced the overall mortality rate by nearly 50%
2. Concurrent chemoradiation should be given to women with high-risk local disease or regionally advanced disease
3. In cervical cancer, survival rates and rates of local control appear to correlate with radiation dose and the time of administration. Better results are achieved with higher radiation doses and shorter periods of administration
4. Chemotherapy agents with single-agent activity include:
   - **Cisplatin:** Considered the most active drug with response rates of 20–30%. At a dosage of 50 mg/m², cisplatin remains the platinum compound of choice in chemotherapy naive patients based on a randomized trial performed by the Japanese GOG despite less toxicity with carboplatin
   - **Paclitaxel:** 17% response rate in GOG trial (McGuire WP et al. J Clin Oncol 1996;14:792–795)
   - **Vinorelbine:** 18% response rate in patients with recurrent/metastatic carcinoma of the cervix (Morris M et al. J Clin Oncol 1998;16: 1094–1098; Lacava JA et al. J Clin Oncol 1997;15:604–609); and 45% response rate in patients with previously untreated, locally advanced cervical cancer (Lhommé et al. Eur J Cancer 2000;36:194–199)
   - **Topotecan:** 18.6% response rate in advanced, recurrent, or persistent squamous cell carcinoma of the uterine cervix (Muderspach LI et al. Gynecol Oncol 2001;81:213–215)
   - **Gemcitabine:** 11–18% response rate in patients with advanced disease with symptomatic relief in 69–90% of patients (Goedhals L et al. Proc Am Soc Clin Oncol 1996;15:296 [abstract 819]; Hansen HH. Ann Oncol 1996;7[Suppl 1]:29 [abstract 058])
   - **Irinotecan:** 13.3% response rate in patients with recurrent squamous carcinoma of the cervix (Look KY et al. Gynecol Oncol 1998;70:334–338)
   - **Ifosfamide:** Active in patients who have not received prior chemotherapy with response rates of 16–40% (Coleman RE et al. Cancer Chemother Pharmacol 1986;18:280–283; Meanwell CA et al. Cancer Treat Rep 1986;70:727–730; Sutton GP et al. Am J Obstet 1993;168:805–807)
   - **Nab paclitaxel:** Active in women who have had progressive disease following first-line cytotoxic treatment with a 28.6% response rate (95% CI, 14.6–46.3%). It is also well-tolerated in women who have experienced a paclitaxel-associated hypersensitivity reaction (Fader and Rose, Int J Gynecol Cancer 2009;19:1281–1283; Alberts et al. Gynecol Oncol. 2012;127:451–455)
5. Despite activity, single agents have not had much impact on survival
6. Combination chemotherapy is essential if systemic treatment is to have an impact on survival
7. Platinum combinations yield high response rates, particularly in patients with no prior radiation therapy
8. Two randomized trials have shown improvement in progression-free survival (Long HJ III et al. J Clin Oncol 2005;26:4626–4633; Moore DH et al. J Clin Oncol 2004;22:3113–3119), with 1 trial demonstrating an improvement in survival for combinations (Long HJ III et al. J Clin Oncol 2005;26:4626–4633)
9. The GOG completed a randomized phase III trial of 4 cisplatin (CIS)-containing doublet combinations in stage IVB, recurrent or persistent cervical carcinoma. The study demonstrated that in patients with stage IVB, recurrent or persistent cancer, the combination of paclitaxel 135 mg/m² over 24 hours with cisplatin 50 mg/m² was superior to combinations of vinorelbine 30 mg/m², or gemcitabine 1000 mg/m², or topotecan 0.75 mg/m² with cisplatin 50 mg
10. In view of the fact that most patients currently receive cisplatin-based chemoradiation a subsequent trial GOG 240 compared the combination of paclitaxel with cisplatin versus paclitaxel and topotecan. The study had a secondary randomization to bevacizumab. The trial demonstrated that despite prior platinum exposure during chemoradiation, patients who received the combination of paclitaxel with cisplatin had a higher response rate and a progression-free survival but no improvement in overall survival when compared to patients who received paclitaxel and topotecan. Patients who received bevacizumab had a statistically improved survival by 3.7 months

REGIMEN FOR INITIAL THERAPY

CONCURRENT RADIATION THERAPY + CHEMOTHERAPY/ WEEKLY CISPLATIN

Keys HM et al. N Engl J Med 1999;340:1154–1161
Rose PG et al. N Engl J Med 1999;340:1144–1153

Note: Chemotherapy is given concomitantly with radiation therapy

Cisplatin 40 mg/m² per dose (maximum weekly dose 70 mg); administer intravenously in 50–250 mL 0.9% sodium chloride injection (0.9% NS) over 60 minutes weekly for 6 doses during weeks 1–6 (days 1, 8, 15, 22, 29, and 36) starting 4 hours before radiation therapy (total dosage/week = 40 mg/m²)

Optional hydration with cisplatin: ≥500 mL 0.9% NS; administer intravenously at ≥100 mL/hour before and after cisplatin administration. Also, encourage patients to increase oral intake of non-alcoholic fluids and provide electrolyte replacement as needed (potassium, magnesium, sodium)

Supportive Care

Antiemetic prophylaxis
Emetogenic potential is ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
WBC <2000/mm³	Delay radiation therapy for up to 1 week until WBC >2000/mm³
Radiation-related gastrointestinal or genitourinary toxicity	Delay radiation therapy for up to 1 week until symptoms resolve
WBC <2500/mm³ or platelet count <50,000/mm³	Hold cisplatin until WBC >2500/mm³ and platelet >50,000/mm³
G2 neurotoxicity	Reduce cisplatin dosage to 30 mg/m² per dose or substitute Carboplatin AUC of 2
≥G3 neurotoxicity	Discontinue cisplatin
Serum creatinine ≥2 mg/dL (≥177 µmol/L)	Reduce cisplatin dosage to 30 mg/m² per dose
Serum creatinine ≥2 mg/dL (≥177 µmol/L) despite reduction of cisplatin dosage to 30 mg/m²	Discontinue cisplatin and substitute Carboplatin dosed to achieve a target AUC of 2 mg/mL · min

Patient Population Studied

Women with untreated invasive squamous cell carcinoma, adenosquamous carcinoma, or adenocarcinoma of the cervix of International Federation of Gynecology and Obstetrics stage IIB (localized disease with parametrial involvement), stage III (extension of tumor to the pelvic wall), or stage IVB (involvement of the bladder and rectal mucosa). Patients with disease outside the pelvis and those with metastases to paraaortic lymph nodes or intraperitoneal disease were not eligible

Therapy Monitoring

Every week: CBC with differential, serum magnesium, BUN, and creatinine

Toxicity (N = 176)

	% G1	% G2	% G3	% G4
Hematologic				
Leukopenia	17	26	21	2
Thrombocytopenia	15	4	2	0
Other hematologic	13	27	10	5
Nonhematologic				
Gastrointestinal	32	28	8	4
Genitourinary	11	6	3	2
Cutaneous	7	6	1	1
Neurologic	6	8	1	0
Pulmonary	0	1	0	0
Cardiovascular	0	0	0	0
Fever	2	4	0	0
Fatigue	5	3	0	0
Pain	2	2	0	0
Weight loss	2	2	1	0
Hypomagnesemia	3	2	2	1
Other*	5	2	1	2

NCI Common Toxicity Criteria (version not specified). All versions available at: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]
*Includes G3 renal abnormalities (serum creatinine 3.1–6 times institutional upper limit of normal), G3 electrolyte imbalance, G3 dehydration, G3 hepatic infection, G4 lymphopenia, G4 vaginal necrosis, G4 edema, and G4 renal abnormalities (serum creatinine >6 times institutional upper limit of normal)

G1, minimal; G2, mild; G3, moderate; G4, severe
Rose PG et al. N Engl J Med 1999;340:1144–1153

Notes

1. Number of cycles of chemotherapy:

No. of Cycles	% of Patients
0	0.6
1	1.1
2	1.1
3	4
4	10.2
5	33.5
≥6	49.4

2. Radiation therapy (RT) administered:

Percentage of patients who received ≥85% of prescribed RT to both points A and B	90%
Median delay in patients receiving ≥85% of prescribed RT	8 days
Median duration of treatment	9 weeks

3. The rate of local recurrences was significantly lower than the comparison arm with hydroxyurea, whereas the rate of distant recurrences, especially in the lungs, was only slightly less. These results suggest that the principal effect of cisplatin is radiosensitization

Efficacy (N = 176)

	%	*P* value*
Probability of progression-free survival at 48 months	62	0.001
Probability of survival at 48 months	66.5	0.004
Progression-free survival at 24 months	67[2]	—
Local progression	19†	—
Lung metastases	20†	—

*Compared with control group (RT + hydroxyurea)
†In control group (RT + hydroxyurea), progression-free survival at 24 months = 47%, local progression = 30%, and lung metastases = 10%

Rose PG et al. N Engl J Med 1999;340:1144–1153

REGIMEN FOR INITIAL THERAPY

CONCURRENT RADIATION THERAPY + CHEMOTHERAPY/CISPLATIN + FLUOROURACIL

Morris M et al. N Engl J Med 1999;340:1137–1143
Peters WA III et al. J Clin Oncol 2000;18:1606–1613
Whitney CW et al. J Clin Oncol 1999;17:1339–1348

Notes:
- Chemotherapy is given concomitantly with radiation therapy (begins within 16 hours after the first radiation fraction is administered)
- One cycle is administered at the time of the second intracavitary insertion

Cisplatin 50–75 mg/m² per dose; administer intravenously in 100–500 mL 0.9% sodium chloride injection (0.9% NS) over 4 hours every 3 weeks for 3 cycles. Administration commences within 16 hours after starting radiation therapy (total dosage/3-week cycle = 50–75 mg/m²)

Optional hydration with cisplatin: ≥500 mL 0.9% NS; administer intravenously at ≥100 mL/hour before and after cisplatin administration. Also, encourage patients to increase oral intake of nonalcoholic fluids and provide electrolyte replacement as needed (potassium, magnesium, sodium)

Fluorouracil 1000 mg/m² per day; administer by continuous intravenous infusion in 100–1000 mL 0.9% NS or 5% dextrose injection over 24 hours daily for 4 consecutive days (96-hour infusion) every 3 weeks (starting on days 1, 22, and 43). Administration commences immediately after completing cisplatin infusion (total dosage/cycle = 4000 mg/m²)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on days with cisplatin is **HIGH**. Potential for delayed symptoms*
*Emetogenic potential on days with fluorouracil + RT is **LOW–MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care

Encourage patients to maintain intake of non-alcoholic fluids

If mucositis or stomatitis is present:
- Rinse mouth several times a day with ¼ teaspoon (1.25 g) each of baking soda and table salt in one quart of warm water. Follow with a plain water rinse
- Do not use mouthwashes that contain alcohols

Efficacy (N = 195)

5-Year survival*	73%	$P = 0.004$†
5-Year disease-free survival*	67%	$P = 0.001$†
Rate of distant relapse	14%	$P < 0.001$†
Rate of locoregional recurrence	19%	$P < 0.001$†

*Estimated from Kaplan-Meier curves
†*P* value compared with radiation therapy alone with estimated 5-year survival = 58%; estimated 5-year disease-free survival = 40%; rate of distant relapse = 33%; and rate of locoregional recurrence = 35%

Morris M et al. N Engl J Med 1999;340:1137–1143

Treatment Modifications

Adverse Event	Dose Modification
WBC <2000/mm³	Delay radiation therapy for up to 1 week until WBC >2000/mm³
Radiation-related gastrointestinal or genitourinary toxicity	Delay radiation therapy for up to 1 week until symptoms resolve
WBC <2500/mm³ *or* platelet count <50,000/mm³	Hold cisplatin until WBC >2500/mm³ *and* platelet >50,000/mm³
WBC <3000/mm³ *or* platelet count <100,000/mm³	Hold fluorouracil until WBC >3000/mm³ *and* platelet >100,000/mm³
G3 WBC count	Reduce fluorouracil dosage to 750 mg/m²
G4 WBC count	Reduce fluorouracil dosage to 500 mg/m²
G3 platelet count	Reduce fluorouracil dosage to 750 mg/m²
G4 platelet count	Reduce fluorouracil dosage to 500 mg/m²
G3 stomatitis or diarrhea	Reduce fluorouracil dosage to 750 mg/m²
G4 stomatitis or diarrhea	Reduce fluorouracil dosage to 500 mg/m²
G2 neurotoxicity	Reduce cisplatin dosage to 30 mg/m²
G ≥3 neurotoxicity	Discontinue cisplatin
Serum creatinine ≥2 mg/dL (≥177 µmol/L)	Reduce cisplatin dosage to 30 mg/m²
Serum creatinine ≥2 mg/dL (≥177 µmol/L) despite reduction of cisplatin dosage to 30 mg/m²	Discontinue cisplatin

Patient Population Studied

Women of all ages with squamous cell carcinoma, adenocarcinoma, or adenosquamous carcinoma of the cervix who had stages IIB through IVA according to the staging system of the International Federation of Gynecology and Obstetrics, or stage IB or IIA with a tumor diameter of at least 5 cm, or biopsy-proven metastases to the pelvic lymph nodes. Women who had disease outside the pelvic area or disease that had spread to paraaortic lymph nodes were excluded

Toxicity (N = 193, 195)

Worst Side Effects Reported During Treatment or Within 60 Days After Completion of Treatment (N = 195)

	% G3	% G4	% G5
Skin abnormalities	2	1	0

Acute Radiation Morbidity Scoring Criteria
Cooperative Group Common Toxicity Criteria
Late Radiation Morbidity Scoring Scheme of the Radiation Therapy Oncology Group (RTOG) and the European Organization for Research and Treatment of Cancer (EORTC)

Therapy Monitoring

1. *Weekly during treatment:* Clinical assessment, CBC with differential and platelet count, and pelvic examination
2. *Before each cycle of chemotherapy:* CBC with differential and platelet count, serum magnesium, creatinine, urea nitrogen, alanine aminotransferase, alkaline phosphatase, and bilirubin
3. *At time of each intracavitary treatment:* Pelvic examination under anesthesia

Notes

Chemotherapy with cisplatin and fluorouracil is more effective than pelvic and paraaortic radiation alone. However, when compared to weekly cisplatin, the combination of cisplatin and 5-FU was associated with more adverse affects. There were significant differences in symptom scores for well-being, anorexia, fatigue, diarrhea, and stomatitis favoring the weekly cisplatin regimen (Likhacheva A et al. Int J Gynecol Cancer. 2013;23:1520–1527)

REGIMEN FOR INITIAL THERAPY

CONCURRENT RADIATION THERAPY + CHEMOTHERAPY/WEEKLY CARBOPLATIN

Duenas-Gonzalez A et al. Int J Radiat Oncol Biol Phys 2003;56:1361–1365
Higgins RV et al. Gynecol Oncol 2003;89:499–503

Carboplatin (calculated dose) AUC = 2 mg/mL • min*; administer by intravenous infusion in 50–150 mL 5% dextrose injection over 30 minutes on day 1 every 3 weeks (total dosage/cycle calculated to produce an AUC = 2 mg/mL • minute)
*Carboplatin dose is based on a formula described by Calvert et al. to achieve a target area under the plasma concentration versus time curve (AUC)

$$\text{Total Carboplatin Dose (mg)} = (\text{Target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be estimated from the equation of Cockcroft and Gault, thus:

$$\text{For males, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})} \times 0.85$$

Calvert AH et al. J Clin Oncol 1989;7:1748–1756
Cockcroft DW, Gault MH. Nephron 1976;16:31–41
Jodrell DI et al. J Clin Oncol 1992;10:520–528
Sorensen BT et al. Cancer Chemother Pharmacol 1991;28:397–401

Note: On October 8, 2010, the U.S. FDA identified a potential safety issue with carboplatin dosing based on recent changes in the measurement of serum creatinine. By the end of 2010, all clinical laboratories in the USA will use the standardized Isotope Dilution Mass Spectrometry (IDMS) method to measure serum creatinine, which could result in an overestimation of the GFR in some patients with normal renal function. A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula could exceed an expected exposure (AUC) and result in increased drug-related toxicity
Provided actual GFR measurements are made to assess renal function, carboplatin can be safely dosed according to the Calvert formula described in product labeling
If GFR (or creatinine clearance) is estimated based on serum creatinine measurements by the IDMS method, the FDA recommended for patients with normal renal function capping an estimated GFR at 125 mL/min for any targeted AUC value. No greater estimated GFR values should be used
U.S. FDA. Carboplatin dosing. [online] October 8, 2010. Available from: http://www.fda.gov/AboutFDA/CentersOffices/OfficeofMedicalProductsandTobacco/CDER/ucm228974.htm [accessed February 26, 2014]

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MODERATE–HIGH***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
ANC <500/mm³ *or* platelet count <50,000/mm³	Delay therapy for 1 week until ANC >500/mm³ *and* platelet count >50,000/mm³
ANC 500–999/mm³ *or* platelet count 50,000 to 100,000/mm³	Administer radiation therapy without carboplatin

Note: Do not reduce or escalate the dose of carboplatin

Patient Population Studied

Patients with stages IB-1, IB-2, IIA, IIB, IIIA, IIIB, IVA primary, invasive squamous cell carcinoma or adenocarcinoma, or adenosquamous carcinoma of the uterine cervix, not previously treated, without evidence of paraaortic nodal involvement by radiography or surgical evaluation

Efficacy (N = 31)

Complete response	90%
Disease-free at median follow-up 12 months	74%

Gastrointestinal	48.3	6.9	0	0
Genitourinary	34.5	13.8	0	0
Cutaneous	3.4	3.4	0	0

Higgins RV et al. Gynecol Oncol 2003;89:499–503

Therapy Monitoring

1. *Weekly during treatment:* Clinical assessment, CBC with differential and platelet count, and pelvic examination
2. *Weekly or every other week during treatment:* Serum creatinine, urea nitrogen, alanine aminotransferase, alkaline phosphatase, and bilirubin

Notes

Success rate in administering planned carboplatin treatments was 94%

REGIMEN FOR ADVANCED/ RECURRENT CERVICAL CANCER

CISPLATIN + VINORELBINE

Gebbia V et al. Oncology 2002;63:31–37

Hydration before cisplatin: ≥500 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously at ≥100 mL/hour before and after cisplatin administration. Also, encourage patients to increase oral intake of non-alcoholic fluids and provide electrolyte replacement as needed (potassium, magnesium, sodium)

Mannitol diuresis: May be given to patients who have received adequate hydration. Administer 250 mL of a 15–25% mannitol solution intravenously over 1 hour before starting cisplatin or simultaneously with cisplatin. Continued intravenous hydration is essential with adequate fluid input during and for a minimum of 4 hours after the administration of mannitol

Note: The referenced study recommended 18% mannitol. Although this can be compounded, commercially available (ready-to-use) parenteral products in the United States include 5%, 10%, 15%, and 25% solutions

Cisplatin 80 mg/m^2; administer intravenously in 500 mL 0.9% NS over 60 minutes on day 1, every 21 days (total dosage per cycle = 80 mg/m^2)

Vinorelbine 25 mg/m^2 per dose; administer intravenously in a volume of 0.9% NS or 5% dextrose injection sufficient to produce a solution with a concentration of 1.5–3 mg/mL over 6–10 minutes for 2 doses on days 1 and 8 every 21 days (total dosage/cycle = 50 mg/m^2)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on day 1 is **HIGH**. Potential for delayed symptoms*

*Emetogenic potential on day 8 is **MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Decreased bowel motility

Give a bowel regimen based initially on **stool softeners** to prevent constipation

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

(continued)

Treatment Modifications

Adverse Event	Dose Modification
WBC <4000/mm^3 *or* platelet count <100,000/mm^3	Delay therapy for 1 week until WBC >4000/mm^3 *and* platelet count >100,000/mm^3
G >2 neutropenia on day 8	Omit day 8 vinorelbine, and reduce all subsequent doses by 5 mg/m^2
Day 8 platelet count <50,000/mm^3	Omit vinorelbine dose
G2 neurotoxicity	Reduce cisplatin dosage by 20 mg/m^2 and vinorelbine dosage by 5 mg/m^2
G >2 neurotoxicity	Hold cisplatin and vinorelbine until neurotoxicity G ≤1; then reduce cisplatin dosage by 20 mg/m^2 and vinorelbine dosage by 5 mg/m^2
G1 renal toxicity	Reduce all subsequent cisplatin dosages by 20 mg/m^2
G ≥2 renal toxicity	Hold cisplatin dose until renal toxicity G ≤1; then reduce all subsequent cisplatin dosages by 20 mg/m^2
G4 nonhematologic toxicity	Discontinue therapy

Toxicity (N = 42)

	% G1/2	% G3	% G4
Hematologic			
Neutropenia	26	21	12
Thrombocytopenia	19	—	—
Anemia	12	12	5
Nonhematologic			
Vomiting	52	21	—
Mucositis	14	—	—
Diarrhea	5	—	—
Constipation	38	—	—
Peripheral neuropathy	19	—	—
Alopecia	12	—	—

WHO Toxicity Criteria

(continued)

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy, or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population Studied

A study of women with stage IV de novo or metastatic/recurrent cervical cancer no longer amenable to surgery and/or radiation therapy, with adequate hematopoietic, hepatic, and renal parameters, and a GOG performance status of 0–2

Efficacy (N = 42)

Complete response	12%
Partial response	36%
Median time to progression	5.6 months
Median overall survival	9.1 months

WHO Criteria

Therapy Monitoring

1. *Before each cycle:* PE, CBC with differential, serum electrolytes, magnesium, BUN, and creatinine
2. *Every week:* CBC with differential, serum electrolytes, magnesium, BUN, and creatinine
3. *Response evaluation:* Every 3 cycles

REGIMEN FOR ADVANCED/ RECURRENT CERVICAL CANCER

CISPLATIN + TOPOTECAN

Long HJ III et al. J Clin Oncol 2005;23:4626–4633 (GOG 204)

Topotecan HCl 0.75 mg/m² per day; administer intravenously in 50–250 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 30 minutes for 3 consecutive days on days 1–3, every 21 days (total dosage/cycle = 2.25 mg/m²)

Hydration before and after cisplatin: ≥1000 mL 0.45% sodium chloride injection; administer intravenously over a minimum of 2–4 hours. Encourage patients to increase oral intake of nonalcoholic fluids, and provide electrolyte replacement as needed (potassium, magnesium, sodium)

Cisplatin 50 mg/m²; administer intravenously in 50–250 mL 0.9% NS at 1 mg/min on day 1, every 21 days (total dosage/cycle = 50 mg/m²)

Note: Administer cisplatin within 4 hours after completing topotecan administration

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on day 1 is **HIGH**. Potential for delayed symptoms*

*Emetogenic potential on days 2 and 3 is **LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of women with advanced (stage IVB), recurrent or persistent carcinoma of the uterine cervix, who were unsuitable candidates for curative treatment with surgery and/or radiation therapy. Histologic types included squamous, adenosquamous, and adenocarcinoma. Prior cisplatin therapy was allowed

Treatment Modifications

Cisplatin Dose Levels	
Initial dosage	50 mg/²
Dose level −1	37.5 mg/m²
Dose level −2	25 mg/m²

Topotecan Dose Levels	
Initial dosage	0.75 mg/m² · d × 3 d
Dose level −1	0.6 mg/m² · d × 3 d
Dose level −2	0.45 mg/m² · d × 3 d

Topotecan Dosage Modifications

Total Bilirubin (mg/dL)	% Starting Topotecan Dosage
≤2.0 (≤34.2 µmol/L)	100
2.1–3.0 (35.9–51.3 µmol/L)	50
>3.0 (>51.3 µmol/L)	25

Adverse Event	Dose Modification
Day 1 ANC <1500/mm³ *or* platelet count <100,000/mm³	Hold chemotherapy until ANC ≥1500/mm³ *and* platelet count ≥100,000/mm³
G4 thrombocytopenia	Reduce topotecan dosage 1 level; continue with same cisplatin dosage
G3/4 ANC with fever	
G3/4 ANC with fever despite 1 dose level reduction	Administer filgrastim with all subsequent courses
G2/3/4 nephrotoxicity	Hold cisplatin until serum creatinine ≤1.5 mg/dL (≤133 µmol/L); then resume treatment. If creatinine >1.5 mg/dL >2 weeks beyond scheduled start of next cycle, discontinue cisplatin
G2 peripheral neuropathy or ototoxicity*	Reduce cisplatin dosage by 2 levels
G3/4 peripheral neuropathy or ototoxicity	Hold cisplatin until neuropathy G ≤1; then reduce cisplatin dosage by 2 levels. If G3/4 toxicity persists >2 weeks beyond scheduled start of next cycle, discontinue cisplatin
G4 gastrointestinal toxicity	Continue cisplatin at same dosage
Second event of G4 gastrointestinal toxicity	Reduce cisplatin dosage by 1 level
G2/3 mucositis or diarrhea	Reduce topotecan dosage by 1 level
G4 mucositis or diarrhea	Reduce topotecan dosage by 1–2 levels
Recurrent mucositis or diarrhea despite dosage reduction or persistence of mucositis/diarrhea >2 weeks beyond scheduled start of next cycle	Discontinue topotecan

*G2 ototoxicity consists of tinnitus and symptomatic hearing loss

Toxicity (N = 147)

	% G3	% G4
Hematologic		
Leukopenia	39.4	23.8

NCI, CTC, National Cancer Institute (USA) Common Toxicity Criteria, version 2.0. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]

Efficacy (N = 147)

Complete response	10%
Partial response	16%
Stable disease	45%
Median progression-free survival	4.6 months
Median survival	9.4 months

Gynecologic Oncology Group Criteria

Therapy Monitoring

1. *Once per week:* CBC with differential
2. *Before the start of a cycle:* CBC with differential, serum calcium, magnesium, potassium, bilirubin, and creatinine

REGIMEN FOR ADVANCED/ RECURRENT CERVICAL CANCER

CISPLATIN + PACLITAXEL

Moore DH et al. J Clin Oncol 2004;22:3113–3119
(GOG 204)

Premedication for paclitaxel:
Dexamethasone 20 mg/dose; administer orally or intravenously for 2 doses at 12 hours and 6 hours before paclitaxel
Note: If patient has no acute toxicities to paclitaxel, the dexamethasone doses at 12 hours and 6 hours before paclitaxel may eventually be omitted
Diphenhydramine 50 mg; administer intravenously 30 minutes before paclitaxel
Cimetidine 300 mg, *or* **ranitidine** 50 mg, *or* **Famotidine** 20 mg; administer intravenously over 5–20 minutes, 30 minutes before paclitaxel
Paclitaxel 135 mg/m²; administer by continuous intravenous infusion in a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 24 hours on day 1, every 3 weeks for 6 cycles (total dosage/cycle = 135 mg/m²)

Hydration before and after cisplatin:
≥1000 mL 0.45% sodium chloride injection; administer intravenously over a minimum of 2–4 hours. Encourage patients to increase oral intake of nonalcoholic fluids, and provide electrolyte replacement as needed (potassium, magnesium, sodium)
Cisplatin 50 mg/m²; administer intravenously in 50–250 mL 0.9% NS at a rate of 1 mg/min on day 2 after completing paclitaxel administration, every 3 weeks for 6 cycles (total dosage/cycle = 50 mg/m²)
Note: Begin cisplatin within 4 hours after completing paclitaxel administration

Supportive Care
Antiemetic prophylaxis
Emetogenic potential during paclitaxel administration is ***LOW***
Emetogenic potential on day 2 is ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Cisplatin Dose Levels	
Initial dosage	50 mg/m²
Dose level −1	37.5 mg/m²
Dose level −2	25 mg/m²
Paclitaxel Dose Levels	
Initial dosage	135 mg/m²
Dose level −1	110 mg/m²
Dose level −2	90 mg/m²

(*continued*)

Patient Population Studied

A study of women with advanced (stage IVB), recurrent, or persistent squamous cell carcinoma of the uterine cervix, 24% of whom had received prior chemotherapy and radiation

Efficacy (N = 130)

Complete response	15%
Partial response	21%
Overall response rate (ORR)	36%
ORR, prior chemoradiotherapy (n = 31)	32%
ORR, no prior chemoradiotherapy (n = 99)	37%
Progression-free survival	4.8 months
Progression-free survival, no prior therapy	4.9 months
Median survival	9.7 months
Median survival, no prior therapy	9.9 months

Toxicity (N = 129)

	% G1	% G2	% G3	% G4

Alopecia	11.6	52.7	0	0
Genitourinary	6.2	10.9	0.8	0
Renal	4.7	7	2.3	0

Treatment Modifications (*continued*)

Adverse Event	Dose Modification
Day 1 ANC <1500/mm³ *or* platelet count <100,000/mm³	Hold chemotherapy until ANC ≥1500/mm³ *and* platelet count ≥100,000/mm³
ANC <1500/mm³ *or* platelet count <100,000/mm³ persists ≥2 weeks beyond the scheduled start of cycle	Discontinue therapy
G4 thrombocytopenia	Reduce paclitaxel dosage by 1 level; continue with same cisplatin dosage
G3/4 ANC with fever*	
G3/4 ANC with fever despite paclitaxel dosage reduction by 1 dose level	Administer filgrastim with all subsequent courses
G3/4 ANC with fever despite paclitaxel dose reduction and filgrastim	Reduce paclitaxel dosage by 1 level or 20%; continue with same cisplatin dosage
G2 peripheral neuropathy	Reduce paclitaxel dosage by 2 dose levels
G3/4 peripheral neuropathy	Hold paclitaxel until neuropathy G ≤1; then reduce paclitaxel dosage by 2 dose levels. If G3/4 toxicity persists >2 weeks beyond scheduled start of next cycle, discontinue paclitaxel
G2 hepatic toxicity	Hold paclitaxel until toxicity G ≤1; then reduce paclitaxel dosage by 1 dose level
G3/4 hepatic toxicity	Hold paclitaxel until toxicity G ≤1; then reduce paclitaxel dosage by 1–2 dose levels. If G3/4 toxicity persists >2 weeks beyond scheduled start of cycle, discontinue paclitaxel
G2/3/4 nephrotoxicity	Hold cisplatin until serum creatinine ≤1.5 mg/dL (≤133 µmol/L); then resume treatment
	Discontinue cisplatin if creatinine >1.5 mg/dL (>133 µmol/L) >2 weeks beyond scheduled start of next cycle
G2 peripheral neuropathy or ototoxicity†	Reduce cisplatin dosage by 2 dose levels
G3/4 peripheral neuropathy or ototoxicity	Hold cisplatin until neuropathy G ≤1 then reduce cisplatin dosage by 2 dose levels. If G3/4 toxicity persists >2 weeks beyond scheduled start of next cycle, discontinue cisplatin
G4 gastrointestinal toxicity	Continue cisplatin at same dosage
Second event of G4 gastrointestinal toxicity	Reduce cisplatin dosage by 1 dose level

*Use filgrastim if thought beneficial
†G2 Ototoxicity consists of tinnitus and symptomatic hearing loss

Note: Management of paclitaxel hypersensitivity reaction:
1. Discontinue infusion
2. Wait for symptoms to resolve
3. If symptoms were not life-threatening, repeat premedications (dexamethasone, diphenhydramine, and cimetidine or ranitidine or famotidine) in preparation for restarting infusion
4. Administer 1 mL of the original paclitaxel solution diluted in 100 mL of the same base solution over 1 hour, *then*
5. Administer 5 mL of the original paclitaxel solution diluted in 100 mL of the same base solution over 1 hour, *then*
6. Administer 10 mL of the original paclitaxel solution diluted in 100 mL of the same base solution over 1 hour, *then*
7. Administer the remaining original solution at the original infusion rate

Therapy Monitoring

1. *Every 15 minutes for the first hour of the paclitaxel infusion:* Vital signs including blood pressure, respiratory rate, and temperature
2. *Once per week:* CBC with differential
3. *Before the start of a cycle:* CBC with differential, serum calcium, magnesium, potassium, bilirubin, and creatinine

REGIMEN FOR ADVANCED/ RECURRENT CERVICAL CANCER

CISPLATIN + GEMCITABINE

Burnett AF et al. Gynecol Oncol 2000;76:63–66 (GOG 204)

Gemcitabine 1000–1250 mg/m² per dose; administer intravenously diluted to a concentration ≥0.1 mg/mL in 0.9% sodium chloride injection (0.9% NS) over 30 minutes for 2 doses on days 1 and 8, every 21 days (total dosage/cycle = 2500 mg/m²)

Note: After gemcitabine administration, flush the patient's vascular access device with 75–125 mL of 0.9% NS

Hydration before and after cisplatin: ≥1000 mL 0.45% sodium chloride injection; administer by intravenous infusion over a minimum of 2–4 hours. Encourage patients to increase oral intake of non-alcoholic fluids, and provide electrolyte replacement as needed (potassium, magnesium, sodium)
Cisplatin 50 mg/m²; administer intravenously in 50–250 mL 0.9% NS over 60 minutes on day 1 after completing gemcitabine administration, every 21 days (total dosage/cycle = 50 mg/m²)

Note: Administer cisplatin on day 1 within 4 hours after completing gemcitabine

Supportive Care

Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed symptoms*
Emetogenic potential on day 8 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Phase II trial in patients with advanced, persistent, or recurrent squamous cell carcinoma of the cervix

Treatment Modifications

Cisplatin Dose Levels	
Initial dosage	50 mg/m²
Dose level −1	37.5 mg/m²
Dose level −2	25 mg/m²

Gemcitabine Dose Levels	
Initial dosage	1000 mg/m²
Dose level −1	800 mg/m²
Dose level −2	600 mg/m²

Gemcitabine Dosage Modification	
Total Bilirubin (mg/dL)	**% of Starting Gemcitabine Dosage**
≤2.0 (≤34.2 μmol/L)	100
2.1–3.0 (35.9–51.3 μmol/L)	50
>3.0 (>51.3 μmol/L)	25

Note: Gemcitabine dose reductions at any time after day 1 of cycle 1 will be continued throughout the rest of the study

Adverse Event	Dose Modification
Day 1 ANC <1500/mm³ *or* platelet count <100,000/mm³	Hold chemotherapy until ANC ≥1500/mm³ *and* platelet count ≥100,000/mm³
ANC <1500/mm³ *or* platelet count <100,000/mm³ that persists ≥3 weeks beyond the scheduled start of cycle	Discontinue therapy
>2-Weeks delay until ANC ≥1500/mm³ *and* platelet count ≥100,000/mm³	Reduce gemcitabine by 1 dose level
Day 8 ANC ≥1500/mm³ *or* platelet count ≥100,000/mm³	Administer day 1 gemcitabine dosage on day 8
Day 8 ANC 1000–1499/mm³ *or* platelet count 75,000–99,000/mm³	Reduce gemcitabine on day 8 by 1 dose level from day 1 level
Day 8 ANC <1500/mm³ *or* platelet count <100,000/mm³	Withhold day 8 gemcitabine dose; reduce gemcitabine dosage by 1 dose level in ensuing cycles on day 8
G4 thrombocytopenia	Reduce gemcitabine by 1 dose level; continue with same cisplatin dosage
G3/4 ANC with fever*	Reduce gemcitabine dosage by 1 dose level; continue with same cisplatin dosage
G3/4 ANC with fever despite 1 dose level reduction	Administer filgrastim with all subsequent courses
G3/4 ANC with fever despite gemcitabine dose reduction and filgrastim	Reduce gemcitabine dosage by 1 dose level or 20%; continue with same cisplatin dosage
G1 mucositis or diarrhea	Hold gemcitabine until toxicity resolves; then resume with same dosage
G2/3 mucositis or diarrhea	Hold gemcitabine until toxicity G ≤1; reduce subsequent dosages by 1 dose level

(*continued*)

Treatment Modifications (*continued*)

Adverse Event	Dose Modification
Mucositis or diarrhea that is G4 or that persists >2 weeks, or repeated episodes of persistent toxicity G ≥2	Hold gemcitabine until toxicity G ≤1; consider discontinuing gemcitabine
G2/3/4 nephrotoxicity	Hold cisplatin until serum creatinine ≤1.5 mg/dL (≤133 μmol/L) then resume treatment. If creatinine >1.5 mg/dL >2 weeks beyond scheduled start of next cycle, discontinue cisplatin
G2 peripheral neuropathy or ototoxicity†	Reduce cisplatin dosage by 2 dose levels
G3/4 peripheral neuropathy or ototoxicity	Hold cisplatin and gemcitabine until neuropathy G ≤1 then reduce cisplatin dosage by 2 dose levels. If G3/4 toxicity persists >2 weeks beyond scheduled start of next cycle, discontinue cisplatin
G4 gastrointestinal toxicity	Continue cisplatin at same dosage
Second event of G4 gastrointestinal toxicity	Reduce cisplatin dosage by 1 dose level

*Use filgrastim if thought beneficial
†G2 ototoxicity consists of tinnitus and symptomatic hearing loss. If neurotoxicity occurs, it will most likely be cisplatin-related

Efficacy (N = 17)

Complete response	5.9%
Partial response*	35.3%
Median survival patients with response	12 months
Median survival patients without response	7 months

*Six patients; 3 had received prior radiation therapy
GOG Response Criteria

Toxicity (N = 82 cycles)

	% G3	% G4
Hematologic		
Neutropenia	7.3	2.4
Anemia	1.2	1.2
Median leukocyte nadir	3145/mm^3	
Median platelet nadir	174,000/mm^3	
Nonhematologic		
Gastrointestinal	2.4	0

Therapy Monitoring

1. *Once per week:* CBC with differential
2. *Before the start of a cycle:* CBC with differential, serum calcium, magnesium, potassium, bilirubin, and creatinine

REGIMEN FOR ADVANCED/RECURRENT CERVICAL CANCER

CISPLATIN + IRINOTECAN

Chitapanarux I et al. Gynecol Oncol 2003;89:402–407

Irinotecan 60 mg/m² per dose; administer intravenously diluted in a volume of 5% dextrose injection (D5W) or 0.9% sodium chloride injection (0.9% NS) sufficient to produce a concentration within the range 0.12–2.8 mg/mL over 90 minutes for 3 doses on days 1, 8, and 15, every 28 days (total dosage/cycle = 180 mg/m²)

Hydration before and after cisplatin:
≥1000 mL 0.45% sodium chloride injection; administer intravenously over a minimum of 2–4 hours
Note: Encourage patients to increase oral intake of nonalcoholic fluids, and provide electrolyte replacement as needed (potassium, magnesium, sodium)

Cisplatin 60 mg/m²; administer intravenously in 100–500 mL 0.9% NS over 90 minutes on day 1 after completing irinotecan administration, every 28 days (total dosage per cycle = 60 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed symptoms*
Emetogenic potential on days 8 and 15 with irinotecan alone is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome
Atropine sulfate 0.25–1 mg administer subcutaneously or intravenously if abdominal cramping or diarrhea develop during or within 1 hour after irinotecan administration
- If symptoms are severe, add as primary prophylaxis at least 30 minutes before irinotecan during subsequent cycles
- For irinotecan, acute cholinergic syndrome may be characterized by abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

Diarrhea management
Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

(*continued*)

Toxicity (N = 30)

	% G1	% G2	% G3	% G4
Hematologic				
Neutropenia	26.7	26.7	30	—
Anemia	13.3	46.6	16.7	—
Thrombocytopenia	—	—	—	—
Nonhematologic				
Alopecia	50	50	—	—

Late-onset diarrhea	33.3	10	—	—
Nausea/vomiting	30	40	23.3	—
Renal	3.3	20	20	6.7

With respect to nonhematologic toxicity, renal dysfunction was the most significant; 2 patients developed G4 creatinine elevations

NCI, CTC, National Cancer Institute (USA) Common Toxicity Criteria, version 2.0. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]

Efficacy (N = 30)

Complete response	6.7%
Partial response	60%
Median survival	16.9 months
Median time to progression	13.4 months

WHO Criteria

Patient Population Studied

Chemotherapy-naïve women with metastatic or recurrent cervical cancer, with measurable disease, adequate hematopoietic, renal, and hepatic function, and with a WHO performance status of 0–2

Therapy Monitoring

1. *Before each cycle:* PE, CBC with differential, serum magnesium, BUN, creatinine, electrolytes, and liver function tests
2. *Weekly:* CBC with differential and serum creatinine
3. *Response evaluation:* After cycles 1 and 2 and every 2 cycles thereafter

(*continued*)

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Treatment Modifications

Adverse Event	Dose Modification
WBC <4000/mm^3, platelet count <100,000/mm^3, *or* diarrhea	Delay start of cycle by 1 week until WBC >4000/mm^3, platelet count >100,000/mm^3, *and* no diarrhea
Day 8 or 15 WBC <3000/mm^3 *or* platelet count <100,000/mm^3	Hold irinotecan
G ≥1 diarrhea	Hold irinotecan
If WBC <1000/mm^3, platelet count <50,000/mm^3, *or* diarrhea G ≥2 at any time in cycle	Reduce subsequent irinotecan dosage by 50%
Serum creatinine >1.5 × upper limits of normal	Reduce cisplatin dosage to 50 mg/m^2

REGIMEN FOR ADVANCED/ RECURRENT CERVICAL CANCER

PACLITAXEL PROTEIN-BOUND PARTICLES FOR INJECTABLE SUSPENSION (ALBUMIN-BOUND) (NAB-PACLITAXEL)

Alberts DS et al. Gynecol Oncol 2012;127:451–455

Paclitaxel protein-bound particles for injectable suspension) (albumin-bound) 125 mg/m^2 per dose (maximum single dose = 250 mg); administer intravenously over 30 minutes for 3 doses, on days 1, 8, and 15, every 28 days (total dosage/cycle = 375 mg/m^2; maximum dose/cycle = 750 mg)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
Nab-paclitaxel Dose Levels	
Starting dose	125 mg/m^2
Dosage level (–1)	100 mg/m^2
Dosage level (–2)	80 mg/m^2
Hematologic Toxicities	
On day 1 of a cycle ANC <1500 cells/mm^3 and the platelet count <100,000/mm^3	Withhold therapy until ANC ≥1500 /mm^3 and the platelet count is ≥100,000/mm^3. Delay therapy a maximum of 2 weeks
ANC still <1500 cells/mm^3 and platelet count still <100,000/mm^3 2 weeks after cycle start day	Discontinue therapy
First occurrence of febrile neutropenia or documented G4 neutropenia persisting ≥7 days	Reduce nab-paclitaxel dosage by 1 dose level during subsequent cycles
Recurrent febrile neutropenia or recurrent documented G4 neutropenia persisting ≥7 days after an initial dose reduction	Administer filgrastim
G4 thrombocytopenia	Reduce nab-paclitaxel dosage by 1 dose level during subsequent cycles
Non-hematologic Toxicities	
G ≥2 peripheral neuropathy	Reduce nab-paclitaxel dosage by 1 dose level to 100 mg/m^2 and delay start of subsequent therapy for a maximum of 2 weeks until recovered to G1
G ≥2 nephrotoxicity	Reduce nab-paclitaxel dosage by 1 dose level to 100 mg/m^2 and delay start of subsequent therapy for a maximum of 2 weeks until recovered to G1
G ≥3 elevations in SGOT (AST), SGPT (ALT), alkaline phosphatase, or bilirubin	Reduce nab-paclitaxel dosage by 1 dose level and delay start of subsequent therapy for a maximum of 2 weeks until recovered to G1
Nonhematologic toxicity with adverse effect on organ function G ≥2	Reduce nab-paclitaxel dosage by 1 dose level and delay start of subsequent therapy for a maximum of 2 weeks until recovered to G1 or pretherapy baseline
G3 hypersensitivity reactions	Retreat after administering standard paclitaxel premedication (steroids + histamine [H_1- and H_2-receptor] antagonists)
Any G3/4 toxicity with nab-paclitaxel 80 mg/m^2 per dose	Discontinue therapy

Patient Population Studied

Characteristics of Evaluable Patients (n = 35)

Characteristic	Number of Cases (%)
Age	
<40 y	6 (17.1)
40–49 y	15 (42.9)
50–59 y	10 (28.6)
60–69 y	3 (8.6)
>70 y	1 (2.9)
Race

SGOT (AST)	1 (2.9%)	0	0	0
Alkaline phosphatase	1 (2.9%)	0	0	0
Lymphatics	2 (5.7%)	2 (5.7%)	0	0

Efficacy (N = 35)

Partial response	10* (28.6%, 95% CI: 14.6%–46.3%)
Median duration of response	6.0 months (range: 1.5–9.2)
Stable disease	15 (42.9%)
Median duration of stable disease	5.8 months (range: 3.7–11.4 months)
Progressive disease	8 (22.9%)
Not evaluable	2 (5.7%)
Median progression-free survival	5.0 months
Median overall survival	9.4 months

*Five of the partial responses were documented in viscera (ie, liver in 2 patients, and 1 each in lung, pancreas, and bladder), whereas the other 5 partial responses occurred in the retroperitoneal nodes (3 patients), mediastinal nodes (1 patient) and intraperitoneal nodes (1 patient)

Treatment Monitoring

1. *Prior to the start of a cycle:* CBC with differential, LFTs, BUN, and creatinine
2. *Response Assessment:* Every 2 cycles

REGIMEN FOR ADVANCED/ RECURRENT/ PERSISTENT CERVICAL CANCER NOT CURABLE WITH STANDARD THERAPIES

PACLITAXEL + TOPOTECAN

Tewari KS et al. Gynecol Oncol SGO Abstract Suppl 2013:S5; SGO #1 (GOG 240)
Tiersten AD et al. Gynecol Oncol 2004;92:635–638

Prophylaxis against hypersensitivity reactions to paclitaxel with:

Dexamethasone 10 mg/dose; orally for 2 doses at 12 hours and 6 hours before paclitaxel, *or*
Dexamethasone 20 mg/dose; intravenously over 10–15 minutes, 30–60 minutes before paclitaxel on day 1 (total dose/cycle = 20 mg)
Diphenhydramine 50 mg, by intravenous injection 30–60 minutes before paclitaxel
Cimetidine 300 mg (or **Ranitidine** 50 mg, **Famotidine** 20 mg, or an equivalent histamine [H_2]-subtype receptor antagonist) administer intravenously over 15–30 minutes, 30–60 minutes before paclitaxel
Paclitaxel 175 mg/m²; administer intravenously, diluted in a volume of 0.9% Sodium Chloride Injection (0.9% NS) or 5% Dextrose Injection (D5W) sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 3 hours on day 1, every 21 days (total dosage/cycle = 175 mg/m²), *plus:*
Topotecan 0.75 mg/m² per dose; administer intravenously, diluted in 50–250 mL 0.9% NS or D5W over 30 minutes for 3 consecutive days, on days 1–3, every 21 days (total dosage/cycle = 2.25 mg/m²), *or*
Topotecan 1 mg/m² per dose; administer intravenously, diluted in 50–250 mL 0.9% NS or D5W over 30 minutes for 5 consecutive days, on days 1–5, every 21 days (total dosage/cycle = 5 mg/m²)

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
Day 1 ANC <1000/mm³ or platelet count <100,000/mm³	Delay therapy until ANC ≥1000/mm³ and platelet count is ≥100,000/mm³. Consider reducing topotecan dosage by 10–20% and paclitaxel dosage to 120–135 mg/m² based on dosages previously given. If treatment delay is >2 weeks, consider discontinuing therapy
G ≥2 arthralgias/myalgias	Add dexamethasone as secondary prophylaxis
G3 arthralgia/myalgia despite dexamethasone prophylaxis	Reduce paclitaxel dosage to 135 mg/m²
G2 neurotoxicity	Reduce paclitaxel dosage to 135 mg/m²
G3/4 neurotoxicity	Delay therapy until G ≤2, then reduce paclitaxel dosage to 100–120 mg/m²
G ≥2 AST (SGOT) or ALT (SGPT), or G ≥3 bilirubin	Stop paclitaxel
Moderate hypersensitivity during paclitaxel infusion	Patient may be retreated. Base a decision to retreat on reaction severity and a medically responsible care provider's judgment
Severe hypersensitivity during paclitaxel infusion	Discontinue therapy
Febrile neutropenia	Reduce topotecan and paclitaxel dosages by 25%
Bleeding associated with thrombocytopenia	
Pulmonary symptoms indicative of interstitial lung disease (eg, cough, fever, dyspnea, and/or hypoxia)	Discontinue topotecan and evaluate. If a new diagnosis of interstitial lung disease is confirmed topotecan should be discontinued

Efficacy (N = 13)

Tiersten AD et al. Gynecol Oncol 2004;92: 635–638

	Number (%)
Overall response	7 (54%)
Complete response	1 (8%)
Partial response	6 (46%)
Stable disease	3 (23%)
Progressive disease	3 (23%)

Efficacy*

Tewari KS et al. Gynecol Oncol SGO Abstract Suppl 2013: S5; SGO #1

	Cisplatin + Paclitaxel (N = 229)	Topotecan + Paclitaxel (N = 223)
Median OS	15 months	12.5 months
	HR = 1.20 (98.74% CI; 0.82–1.76) P (one-sided) = 0.880	
Overall response rate	38%	27.4%

*Topotecan + paclitaxel was shown to not be neither superior nor inferior to cisplatin + paclitaxel

(continued)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is LOW

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Monitoring

1. Prior to the start of a cycle: CBC with differential, LFTs, BUN, and creatinine
2. Response Assessment: Every 2 cycles

Patient Population Studied

Patient Demographics and Baseline Characteristics (N = 15)*

Tiersten AD et al. Gynecol Oncol 2004;92:635–638

	Number (%)
Age, Median (Range)	52 years (32–68 y)
Histologic type, n (%)	
Squamous cell carcinoma	9 (60%)
Adenocarcinoma	4 (27%)
Adenosquamous	2 (13%)
Prior chemotherapy*	10 (67%)
At time of recurrence*	5 (33%)
Prior radiotherapy	14 (93%)
At time of recurrence	
Pelvic recurrence	6 (40%)
Sites of metastases	
Lung	5 (33%)
Liver	3 (20%)
Pelvis	5 (33%)
Neck	1 (7%)
Psoas muscle	1 (7%)

**Note:* Eligible patients could not have received prior taxane or camptothecin therapy or >2 prior chemotherapy regimens

Toxicity

G3/4 Hematologic and Nonhematologic Toxicities Evaluable for Toxicity = 15 Patients (100%)/(86 Cycles)

Tiersten AD et al. Gynecol Oncol 2004;92:635–638

Adverse Event	Episodes, Number (%)
Hematologic	
Anemia	23 (26.7%)
Leukopenia	16 (18.6%)
Thrombocytopenia	6 (7%)
Febrile neutropenia	6 (7%)
Non-hematologic	
Neurotoxicity	3 (3.5%)
Diarrhea	2 (2.3%)
Pain	2 (2.3%)
Nausea/vomiting	1 (1.2%)
Elevated creatinine	1 (1.2%)
Tolerability	
Treatment delays due to toxicity*	3 (3.5%)
Dose reductions	3 patients (20%)†

*Five patients experienced treatment delays, but only 3 of the 10 cycles that were delayed were related to treatment toxicities (7 were the result of holidays or patient vacation)

†Dose successfully re-escalated in the subsequent cycle for 1 patient (affected drugs not specified)

REGIMEN FOR ADVANCED/ RECURRENT/ PERSISTENT CERVICAL CANCER NOT CURABLE WITH STANDARD THERAPIES

PACLITAXEL + CISPLATIN + BEVACIZUMAB

GOG 240: Tewari KS et al. J Clin Oncol 2013;31:[Abstract 3]

Prophylaxis against hypersensitivity reactions to paclitaxel with:

Dexamethasone 10 mg/dose; orally for 2 doses at 12 hours and 6 hours before paclitaxel, *or*
Dexamethasone 20 mg/dose; intravenously over 10–15 minutes, 30–60 minutes before paclitaxel on day 1 (total dose/cycle = 20 mg)
Diphenhydramine 50 mg, by intravenous injection 30–60 minutes before paclitaxel
Cimetidine 300 mg (or **Ranitidine** 50 mg, **Famotidine** 20 mg, or an equivalent histamine [H_2]-subtype receptor antagonist) intravenously over 15–30 minutes, 30–60 minutes before paclitaxel
Paclitaxel 135–175 mg/m² intravenously, diluted in a volume of 0.9% Sodium Chloride Injection (0.9% NS) or 5% Dextrose Injection (D5W) sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 3 hours on day 1, every 21 days (total dosage/cycle = 135–175 mg/m²)

Hydration before cisplatin: 1000 mL 0.9% NS; intravenously over a minimum of 1 hour before commencing cisplatin administration
Cisplatin 50 mg/m²; intravenously, diluted in 100–500 mL 0.9% NS over 30–90 minutes on day 1, every 21 days (total dosage/cycle = 50 mg/m²)

Hydration after cisplatin: Administer by intravenous infusion ≥1000 mL 0.9% NS over a minimum of 2 hours. Encourage patients to increase oral intake of non-alcoholic fluids, and provide electrolyte replacement as needed (potassium, magnesium, sodium)

Bevacizumab 15 mg/kg; intravenously, diluted in 100 mL 0.9% NS over 30–90 minutes on day 1, every 21 days (total dosage/cycle = 15 mg/kg)

(continued)

Treatment Modifications

Dose escalations are not recommended. Dosage reductions are based on toxicity encountered during a previous cycle

Adverse Event	Dose Modification
G≥2 arthralgias/myalgias	Add dexamethasone as secondary prophylaxis
G3 arthralgia/myalgia despite dexamethasone prophylaxis	Reduce paclitaxel dosage to 100–135 mg/m²
G2 neurotoxicity	Reduce paclitaxel dosage to 120–135 mg/m²
G3 neurotoxicity	Reduce paclitaxel dosage to 100–120 mg/m²
G3/4 neurotoxicity	Delay therapy until neurotoxicity abates to G ≤2, then reduce paclitaxel dosage to 100–120 mg/m²
Recurrent G3/4 neurotoxicity at a paclitaxel dosage of 100–120 mg/m²	Delay therapy until neurotoxicity abates to G ≤2, then reduce cisplatin dosage by 25%
G ≥2 AST (SGOT) or G ≥2 ALT (SGPT), or G ≥3 bilirubin	Withhold paclitaxel
Moderate hypersensitivity during paclitaxel infusion	Patient may be retreated. Base a decision to retreat on reaction severity and caregiver's discretion
Severe hypersensitivity during paclitaxel infusion	Discontinue therapy
Day 1 ANC <1500/mm³ or platelet count <100,000/mm³	Delay therapy until ANC ≥1500/mm³ and platelet count is ≥100,000/mm³. If treatment delay is >2 weeks, consider discontinuing therapy
Febrile neutropenia	Reduce cisplatin and paclitaxel dosages by 25%
Bleeding associated with thrombocytopenia	
Serum creatinine 1.6–2 mg/dL (141–177 µmol/L)	Reduce cisplatin dosage by 25%
Serum creatinine ≥2 mg/dL (≥177 µmol/L)	Hold cisplatin until serum creatinine is <2.0 mg/dL (<177 µmol/L)
Chest pain or arrhythmia during chemotherapy	Immediately stop chemotherapy and evaluate patient
Symptomatic arrhythmias or AV block ≥ second-degree, or documented ischemic event	Stop treatment
Gastrointestinal perforation	Discontinue bevacizumab permanently
Serious bleeding	
Wound dehiscence requiring medical intervention	
Nephrotic syndrome	
Hypertensive crisis	
Moderate to severe proteinuria or severe hypertension not controlled with medical management	Hold bevacizumab pending further evaluation (eg, 24-hour urine protein or work-up and treatment of hypertension)

Note: Bevacizumab use should be suspended at least several weeks before elective surgery and should not be resumed until a surgical incision is fully healed
AVASTIN® (bevacizumab) Solution for intravenous infusion; product label, March 2013. Genentech Inc., South San Francisco, CA

(*continued*)

Notes about bevacizumab administration: The duration of administration for the initial dose is 90 minutes. If administration is well tolerated, the administration duration may be decreased stepwise during subsequent administrations to 60 minutes and, finally, to a minimum duration of 30 minutes

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on a treatment day with cisplatin is **HIGH**. Potential for delayed emetic symptoms*

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Multicenter study. More than 70% of patients had previously received platinum-based therapy. Patients were randomly assigned to 1 of 4 treatment arms:

Arm I.	Paclitaxel and cisplatin on days 1 *or* 2, every 21 days
Arm II.	Paclitaxel on day 1 plus cisplatin and bevacizumab on days 1 *or* 2, every 21 days
Arm III.	Paclitaxel on day 1, and topotecan on days 1–3, every 21 days
Arm IV.	Paclitaxel and bevacizumab on day 1, and topotecan on days 1–3, every 21 days

Efficacy

(N = 425; Median Follow-up = 20.8 months)

	Cisplatin + Paclitaxel (N = 225)	Cisplatin + Paclitaxel + Bevacizumab (N = 227)
Complete response rate	6.2% (14)	12.3% (28)
Overall response rate	36%	48%
	2-sided p = 0.00807	
Median PFS	5.9 months	8.2 months
	HR = 0.67 (95% CI, 0.54–0.82; 2-sided p = 0.0002)	
Median OS*	13.3 months	17 months
	HR = 0.71 (95% CI, 0.54–0.94; p = 0.0035)	

CI, Confidence interval; HR, hazard ratio; OS, Overall survival; PFS, progression-free survival
*Advantage seen with bevacizumab in:
Patients between the ages of 48–56 years
Patients with recurrent/persistent disease
Patients with squamous histology
Patients with disease in the previously irradiated pelvis

Toxicity

	Cisplatin + Paclitaxel (N = 225)	Cisplatin + Paclitaxel + Bevacizumab (N = 227)
Treatment cycles, median (range)	6 (0–30)	7 (0–36)
Grade 5 adverse events	4 (1.8%)	4 (1.8%)
G ≥2 gastrointestinal, nonfistula	96 (44%)	114 (52%)
G ≥3 gastrointestinal fistula	0	7 (3%)
Gastrointestinal perforation (G ≥3)	0	5 (2%)
Thromboembolism	3 (1%)	18 (8%)
G ≥3 genitourinary fistula	0	6 (2%)
G ≥2 hypertension	4 (2%)	54 (25%)
G ≥3 proteinuria	0	4 (2%)
G ≥4 neutropenia	57 (26%)	78 (35%)
G ≥3 febrile neutropenia	12 (5%)	12 (5%)
G 3-4 bleeding	3 (1%)	12 (5%)
CNS bleeding (any grade)	0	0
G ≥2 pain	62 (28%)	71 (32%)

Treatment Monitoring

1. Prior to the start of a cycle: H&P; CBC with differential; serum LFTs; serum chemistries, including magnesium, potassium, and sodium; serum BUN and creatinine
2. Every week: CBC with differential and platelet count; monitor blood pressure at least weekly or more often as needed
3. Response Assessment: Every 2 cycles

9. Colorectal Cancer

Julia Lee Close, MD and Carmen Joseph Allegra, MD

Epidemiology

Incidence

Colon cancer: 96,830 (male: 48,450; female: 48,380. Estimated new cases for 2014 in the United States)

Rectum cancer: 40,000 (male: 23,380; female: 16,620. Estimated new cases for 2014 in the United States)
52.2 per 100,000 male, 39.3 per 100,000 female for colon and rectum cancer

Deaths: Estimated 50,310 in 2014 for colon and rectum cancer (male: 26,270; female: 24,040)

Median age at diagnosis: 69 years

Male to female ratio: 1.7:1

Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Stage at presentation:

Stage I:	15%
Stage II:	20–30%
Stage III:	30–40%
Stage IV:	20–25%

Skibber JM et al. Cancer of the colon. In: Devita VT Jr, Hellman S, Rosenberg SA, editors. Cancer: Principles and Practice of Oncology, 6th ed. Philadelphia: Lippincott Williams & Wilkins, 2001:1216–1270

Work-up

In situ and Stage I	H&P, carcinoembryonic antigen and (CEA), full colonoscopy, and pathology review
Stage II	H&P, CBC, serum electrolytes, LFTs, serum creatinine, BUN, and CEA. Full colonoscopy, CT scan of thorax and abdomen, and pelvis, pathology review *Rectal lesions:* MRI. Determine whether there is a loss of heterozygosity at chromosome 18q and ascertain the presence of microsatellite instability (MSI). Patient at high risk based on loss of heterozygosity at 18q and MSI status can be recommended for adjuvant treatment
Stage III	As above for stages I–II. If patient has potentially resectable disease, additional studies may be needed before laparotomy to confirm resectability, including spiral CT scan, contrast MRI, PET scan, angiography, and laparoscopy
Stage IV	As above plus KRAS status

de Gramont A et al. Gastrointest Cancer Res 2008,2: S2–S6

Skibber JM et al. Cancer of the colon. In: Devita VT Jr, Hellman S, Rosenberg SA, editors. Cancer: Principles and Practice of Oncology, 6th ed. Philadelphia: Lippincott Williams & Wilkins, 2001:1216–1270

Staging

Primary Tumor (T)

TX	Primary tumor cannot be assessed
T0	No evidence of primary tumor
Tis	Carcinoma in situ: intraepithelial or invasion of lamina propria*
T1	Tumor invades submucosa
T2	Tumor invades muscularis propria
T3	Tumor invades through the muscularis propria into pericolorectal tissues
T4a	Tumor penetrates to the surface of the visceral peritoneum†
T4b	Tumor directly invades or is adherent to other organs or structures‡,†

*Tis includes cancer cells confined within the glandular basement membrane (intraepithelial) or mucosal lamina propria (intramucosal) with no extension through the muscularis mucosae into the submucosa.
†Tumor that is adherent to other organs or structures, grossly, is classified cT4b. However, if no tumor is present in the adhesion, microscopically, the classification should be pT1-4a depending on the anatomical depth of wall invasion. The V and L classifications should be used to identify the presence or absence of vascular or lymphatic invasion whereas the PN site-specific factor should be used for perineural invasion.
‡Direct invasion in T4 includes invasion of other organs or other segments of the colorectum as a result of direct extension through the serosa, as confirmed on microscopic examination (for example, invasion of the sigmoid colon by a carcinoma of the cecum) or, for cancers in a retro-peritoneal or subperitoneal location, direct invasion of other organs or structures by virtue of extension beyond the muscularis propria (ie, respectively, a tumor on the posterior wall of the descending colon invading the left kidney or lateral abdominal wall; or a mid or distal rectal cancer with invasion of prostate, seminal vesicles, cervix or vagina).

(*continued*)

Five-Year Survival

	Colon	Rectal
I	>90%	>90%
II	75–85%	70–85%
IIIA	59%	55%
IIIB	42%	35%
IIIC	27%	24%
IV	<5%	<5%

A large proportion of colorectal cancer patients are potential candidates for adjuvant therapies for stage II or III disease.

Pathology

World Health Organization Classification

1. Adenocarcinoma (>90%)
2. Mucinous adenocarcinoma
3. Adenosquamous carcinoma
4. Small cell carcinoma
5. Medullary carcinoma
6. Signet ring adenocarcinoma
7. Squamous cell carcinoma
8. Undifferentiated

Skibber JM et al. Cancer of the colon. In: Devita VT Jr, Hellman S, Rosenberg SA, editors. Cancer: Principles and Practice of Oncology, 6th ed. Philadelphia: Lippincott Williams & Wilkins, 2001:1216–1270

Expert Opinion

Stage II colon cancer:

- Given the relatively low risk for recurrence for most patients with ***stage II*** colon cancer, the routine use of adjuvant chemotherapy for medically fit patients with stage II colon cancer is not recommended. The QUASAR trial is the only study to have shown a statistical benefit for fluorouracil/leucovorin
- Most experts recommend that adjuvant chemotherapy be considered for patients with ***high-risk stage II*** disease. Those considered at higher risk for recurrence include patients with:
  - Inadequately sampled nodes (<12)
  - Poorly differentiated histology, or
  - T4 lesions
  - Lymphatic/vascular invasion
  - Perforation
- Deficiency of mismatch repair proteins (MMR) is found in 15–20% of colon cancers. This deficiency has been associated with a low risk of recurrence. Only 1 retrospective study showed no or worse outcomes with fluorouracil, but this has never been validated by other studies. This tumor specific information needs to be considered in advising individual patients relative to adjuvant therapy

Stage III colon cancer:

- Systemic combined chemotherapy is the principal adjuvant therapy for ***stage III*** colon cancer
- The combinations of oxaliplatin with bolus or infusional fluorouracil/leucovorin
- (FOLFOX 4 or FLOX) have shown improved disease-free survival and overall survival compared with fluorouracil/leucovorin, and have become the standard
- Capecitabine can probably be used in place of bolus or infusional fluorouracil
- FOLFOX 4 or FLOX are associated with ~30% reduction in the risk of disease recurrence, and 22–32% reduction in mortality rate
- Trials testing the benefit of irinotecan, bevacizumab and cetuximab have all been negative in the adjuvant setting

Stage IV colon and rectal cancer:

- The choice of therapy is based on consideration of
  - The type and timing of the prior therapy that has been administered
  - The differing toxicity profiles of the constituent drugs
  - The possibility of resection of metastases
- Approximately 35% of patients have stage IV disease at presentation and 20% to 50% with stage II or III disease progress to stage IV
- Patients can be classified as potentially curable or noncurable
- Up to 60% of patients presenting with liver metastases who underwent a surgical resection were alive at 5 years in a report from Memorial Sloan-Kettering Cancer Center (MSKCC)
- Patients with previously untreated metastatic disease may be treated initially with FOLFOX (or XELOX) or FOLFIRI plus bevacizumab. The median survival approaches 2 years for patients with metastatic colorectal cancer treated initially with multi-agent therapy sets a benchmark
- Unfortunately, patients whose cancers harbor a BRAF mutation have a particularly poor outcome regardless of chemotherapeutic intervention
- Patients with progressive disease who have received fluorouracil–based therapy may be treated with chemotherapy consisting of FOLFIRI, irinotecan or FOLFOX (or XELOX) in addition to continuation of anti-vascular endothelial growth factor (VEGF) therapy or the addition of anti-epidermal growth factor receptor (EGFR) antibody therapy for those patients whose cancers do not contain a mutation in KRAS
- The oral anti-VEGF protein kinase inhibitor, regorafenib, has been shown to have activity in patients with disease that is refractory to the above listed agents

Rectal cancer:

- Preoperative chemoradiotherapy and postoperative chemoradiotherapy yield similar DFS and OS for patients with full thickness muscularis involvement T3), adjacent structure invasion (T4), and/or regional node involvement (N1/N2)
- Preoperative chemoradiotherapy, generally favored as a sphincter-sparing operation, is more likely to be technically feasible when compared to an upfront surgical approach
- Adjuvant chemotherapy is offered to patients who have undergone preoperative chemoradiotherapy
- Adjuvant chemotherapy for stages II and III is firmly established, albeit in the pre-neoadjuvant era. It remains the standard of care in the United States and Europe

Staging (*continued*)

Regional Lymph Node (N)

NX	Regional lymph nodes cannot be assessed
N0	No regional lymph node metastasis
N1	Metastasis in one to three regional lymph nodes
N1a	Metastasis in one regional lymph node
N1b	Metastasis in two to three regional lymph nodes
N1c	Tumor deposit(s) in the subserosa, mesentery, or nonperitonealized pericolic or perirectal tissues without regional nodal metastasis
N2	Metastasis in four or more regional lymph nodes
N2a	Metastasis in four to six regional lymph nodes
N2b	Metastasis in seven or more regional lymph nodes

Distant Metastasis (M)

M0	No distant metastasis
M1	Distant metastasis
M1a	Metastasis confined to one organ or site (eg, liver, lung, ovary, nonregional node)
M1b	Metastases in more than one organ/site or the peritoneum

ADJUVANT AND ADVANCED REGIMEN

BOLUS FLUOROURACIL + LEUCOVORIN (ROSWELL PARK REGIMEN)

Petrelli N et al. J Clin Oncol 1989;7:1419–1426
Wolmark N et al. J Clin Oncol 1999;17:3553–3559

Adjuvant therapy:
Leucovorin calcium 500 mg/m²; administer intravenously in 250 mL 0.9% sodium chloride injection (0.9% NS) over 2 hours once per week for 6 consecutive weeks (weeks 1–6), every 8 weeks (total dosage/cycle = 3000 mg/m²)
Fluorouracil 500 mg/m²; administer by intravenous injection over 1–2 minutes, starting 1 hour after leucovorin once per week for 6 consecutive weeks (weeks 1–6), every 8 weeks (total dosage/cycle = 3000 mg/m²)

Advanced colorectal cancer:
Leucovorin calcium 500 mg/m²; administer intravenously in 250 mL 0.9% NS over 2 hours once per week for 6 consecutive weeks (weeks 1–6), every 8 weeks (total dosage/cycle = 3000 mg/m²)
Fluorouracil 600 mg/m²; administer by intravenous injection over 1–2 minutes, starting 1 hour after leucovorin once per week for 6 consecutive weeks (weeks 1–6), every 8 weeks (total dosage/cycle = 3600 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:
Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:
A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count is <500/mm³ with or without accompanying fever in association with diarrhea
- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification*
Any G1 toxicity	Maintain dose
Any G2 toxicity	Hold treatment until toxicity resolves to G ≤1. If toxicity occurs after the fourth weekly dose, stop until the next cycle; then resume at same dosage. If diarrhea occurs, reduce fluorouracil to 400 mg/m² per dose
Any G3/4 toxicity	Hold treatment until toxicity resolves to G ≤1. If toxicity occurs after the fourth weekly dose, stop until next cycle; then resume with fluorouracil 400 mg/m² per dose. If diarrhea occurs, reduce fluorouracil to 350 mg/m² per dose
Further toxicity	Reduce fluorouracil to 300 mg/m² per dose. If diarrhea occurs, reduce fluorouracil to 250 mg/m² dose

*Leucovorin dosage remains constant at 500 mg/m² per dose

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population Studied

Patients with stage II (Dukes B) or III (Dukes C) colorectal cancer after potentially curative resection (duration of therapy was 4 cycles). Now, the standard regimen as adjuvant therapy is FOLFOX-4, 6 months For advanced disease this regimen has to be considered for special cases (old patients…)

Wolmark N et al. J Clin Oncol 1999;17:3553–3559

Efficacy (N = 691)

	5-Year DFS	5-Year Overall Survival
All patients	65%	74%
Stage II	75%	84%
Stage III	57%	67%

DFS, disease-free survival

Toxicity (N = 691)

Most Common Toxicities by Grade

  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Patient Population Studied

Patients with stage II or III colorectal cancer after potentially curative resection, or with advanced colorectal cancer.

Efficacy (N = 301)

ADJUVANT AND ADVANCED REGIMEN

CAPECITABINE

Twelves C et al. N Engl J Med 2005;352:2696–2704
Van Cutsem E et al. J Clin Oncol 2001;19:4097–4106

Capecitabine 1250 mg/m² per dose; administer orally with water within 30 minutes after a meal twice daily for 28 doses on days 1–14, every 3 weeks (total dosage/cycle = 35,000 mg/m²)

Notes:

- Capecitabine is given for 2 consecutive weeks followed by 1 week without treatment
- Doses are rounded down to approximate a calculated dose using combinations of 500-mg and 150-mg tablets
- In practice, treatment often is begun with capecitabine 1000 mg/m² per dose twice daily for 28 doses on days 1–14 (total dosage/cycle = 28,000 mg/m²). Dosage may be increased during subsequent cycles if initial treatment at a lesser dosage is tolerated

Supportive Care

INFUSIONAL FLUOROURACIL

Hansen RM et al. J Natl Cancer Inst 1996;88:668–674

Fluorouracil 300 mg/m² per day; administer by continuous intravenous infusion in 50–1000 mL 0.9% sodium chloride injection or 5% dextrose injection (total dosage/week = 2100 mg/m²). Treatment is continued indefinitely until toxicity/disease progression

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

***Latent or delayed onset diarrhea**:**

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count is <500/mm³ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

(*continued*)

Patient Population Studied

A study of 159 patients with previously untreated metastatic adenocarcinoma of the colon or rectum

Toxicity (N = 159)

Requiring Treatment Interruption

G2 stomatitis	35%
G3 stomatitis	5%
G2/3 hand-foot syndrome	36%
G3 vomiting and diarrhea	3%
G3/4 hematologic	6%
All toxicities	
None	2%
Mild	15%
Moderate	52%
Severe	27%
Life-threatening	4%
Lethal	1%

(*continued*)

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Treatment Modifications

Adverse Event	Dose Modification
G2 nonhematologic toxicity	Reduce fluorouracil dosage by 50 mg/m² per day
G3 nonhematologic toxicity	Reduce fluorouracil dosage by 100 mg/m² per day
Hematologic toxicity	No modifications

Therapy Monitoring

1. *Before each cycle:* H&P, CBC with differential, CEA serum electrolytes, and LFTs
2. *Weekly:* CBC with differential count
3. *Every 2–3 months:* CT scans to assess response

Efficacy (N = 159)

Overall response	28%
Complete response	5%
Median survival	13 months

METASTATIC DISEASE REGIMEN

SINGLE-AGENT IRINOTECAN (CPT-11)

Cunningham D et al. Lancet 1998;352:1413–1418

Irinotecan 350 mg/m²; administer intravenously over 90 minutes in 250 mL 5% dextrose injection (D5W) or 0.9% sodium Chloride injection (0.9% NS), on day 1, every 3 weeks (total dosage/cycle = 350 mg/m²)

Note: Reduce dosage to 300 mg/m² for patients ≥70 years of age or whose WHO performance status = 2 (total dosage/4-week cycle = 300 mg/m²)

Alternative

Pitot HC. Oncology 1998;12(8 Suppl 6):48–53

Irinotecan 100–125 mg/m²; administer intravenously over 90 minutes in 250 mL 0.9% NS or D5W every week for 4 consecutive weeks every 6 weeks (total dosage/cycle = 400–500 mg/m²)

Note: Four weeks of treatment followed by 2 weeks without treatment

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome

Atropine sulfate 0.25–1 mg administer subcutaneously or intravenously if abdominal cramping or diarrhea develop during or within 1 hour after irinotecan administration

- If symptoms are severe, add as primary prophylaxis at least 30 min before irinotecan during subsequent cycles
- For irinotecan, acute cholinergic syndrome may be characterized by: abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

Diarrhea management

Latent or delayed onset diarrhea*:*

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count is <500/mm³ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Treatment Modifications

(Camptosar, irinotecan hydrochloride injection product label, July 2005. Pharmacia & Upjohn Company, Division of Pfizer, Inc., New York, NY)

Irinotecan—Once Every 3 Weeks

Notes:

- Dose modifications are based on the National Cancer Institute (USA) Common Toxicity Criteria. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed October 11, 2013]
- Before beginning a treatment cycle, patients should have baseline bowel function (similar to that before start of treatment) without antidiarrheal therapy for 24 hours, ANC ≥1500/mm^3, and platelet count ≥100,000/mm^3
- Treatment should be delayed 1–2 weeks to allow for recovery from treatment-related toxicities. If a patient has not recovered after 2 weeks, consider stopping therapy

Toxicity in Previous Cycle	Irinotecan Dosage at the Start of a 3-Week Cycle
Neutropenia/Thrombocytopenia	
G1 ANC (1500–1999/mm^3) or G1 thrombocytopenia	Maintain dose and schedule
G2 ANC (1000–1499/mm^3) or G2 thrombocytopenia	Maintain dose and schedule
G3 ANC (500–999/mm^3) or G3 thrombocytopenia	Reduce dosage by 50 mg/m^2
G4 ANC (<500/mm^3) or G4 thrombocytopenia	Reduce dosage by 50 mg/m^2
Febrile neutropenia	Hold until neutropenia resolves. Resume treatment with irinotecan dosage reduced by 50 mg/m^2

(continued)

Treatment Modifications (*continued*)

Toxicity in Previous Cycle	Irinotecan Dosage at the Start of a 3-Week Cycle
Diarrhea	
G1 (2–3 stools/day > baseline)	Maintain dose and schedule
G2 (4–6 stools/day > baseline)	Maintain dose and schedule
G3 (7–9 stools/day > baseline)	Reduce irinotecan dosage by 50 mg/m²
G4 (≥10 stools/day > baseline)	Reduce irinotecan dosage by 50 mg/m²
Other Nonhematologic Toxicities	
Any G1 toxicity	Maintain dose and schedule
Any G2 toxicity	Maintain dose and schedule
Any G3 toxicity	Reduce dosage by 50 mg/m²
Any G4 toxicity	Reduce dosage by 50 mg/m²

Weekly Irinotecan—4 of Every 6 Weeks

Notes:

- Dose modifications are based on the National Cancer Institute (USA) Common Toxicity Criteria. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed October 11, 2013]
- Before beginning a treatment cycle, patients should have baseline bowel function (similar to that before start of treatment) without antidiarrheal therapy for 24 hours, ANC ≥1500/mm³, and platelet count ≥100,000/mm³
- Treatment should be delayed 1–2 weeks to allow for recovery from treatment-related toxicities. If a patient has not recovered after 2 weeks, consider stopping therapy

Toxicity	Weekly Irinotecan Dosage Based on Intracycle Toxicity	Irinotecan Dosage at Start of a 6-Week Cycle
Neutropenia/Thrombocytopenia		
G1 ANC (1500–1999/mm³) or G1 thrombocytopenia	Maintain dose and schedule	Maintain dose and schedule
G2 ANC (1000–1499/mm³) or G2 thrombocytopenia	Decrease weekly dosage by 25 mg/m²	Maintain dose and schedule
G3 ANC (500–999/mm³) or G3 thrombocytopenia	Omit weekly dose until toxicity G ≤2, then reduce irinotecan dosage by 25 mg/m²	Reduce dosage by 25 mg/m²
G4 ANC (<500/mm³) or G4 thrombocytopenia	Omit weekly dose until toxicity G ≤2, then reduce irinotecan dosage by 50 mg/m²	Reduce dosage by 50 mg/m²
Febrile neutropenia	Omit weekly dose until neutropenia G ≤2, then reduce irinotecan dosage by 50 mg/m²	Reduce dosage by 50 mg/m²
Diarrhea		
G1 (2–3 stools/day > baseline)	Delay treatment until diarrhea resolves to baseline; then resume irinotecan treatment	Maintain dose and schedule
G2 (4–6 stools/day > baseline)	Delay until diarrhea resolves to baseline, then reduce irinotecan dosage by 25 mg/m²	Maintain dose and schedule
G3 (7–9 stools/day > baseline)	Delay until diarrhea resolves to baseline, then reduce irinotecan dosage by 25 mg/m²	Reduce dosage by 25 mg/m²
G4 (≥10 stools/day > baseline)	Delay until diarrhea resolves to baseline, then reduce irinotecan dosage by 50 mg/m²	Reduce dosage by 50 mg/m²

(*continued*)

Treatment Modifications (*continued*)

Toxicity	Weekly Irinotecan Dosage Based on Intracycle Toxicity	Irinotecan Dosage at Start of a 6-Week Cycle
Other Nonhematologic Toxicities		
Any G1 toxicity	Maintain dose and schedule	Maintain dose and schedule
Any G2 toxicity	Delay until toxicity resolves to G ≤1, then reduce irinotecan dosage by 25 mg/m²	Maintain dose and schedule

Cunningham D et al. Lancet 1998;352:1413–1418

Patient Population Studied

A study of 189 patients with metastatic colorectal cancer with documented disease progression within 6 months of fluorouracil-based treatment

Efficacy (N = 189)

	Irinotecan	Best Supportive Care
Partial response	4%	0.7%
Partial or minor response	10.5%	4.4%
Median survival	9.2 months	6.5 months

Therapy Monitoring

1. *Before each cycle:* H&P, CBC with differential, CEA, serum electrolytes, and LFTs
2. *Weekly:* CBC with differential count
3. *Every 2–3 months:* CT scans to assess response

METASTATIC DISEASE REGIMEN

IRINOTECAN + BOLUS FLUOROURACIL + LEUCOVORIN (IFL)

Saltz LB et al. N Engl J Med 2000;343:905–914

Irinotecan 125 mg/m² per dose; administer intravenously in 250 mL 5% dextrose injection (D5W) over 90 minutes, given weekly for 4 consecutive weeks (4 doses), every 6 weeks (total dosage/cycle = 500 mg/m²)
Leucovorin calcium 20 mg/m² per dose; administer by intravenous injection over 30 seconds, given weekly for 4 consecutive weeks (4 doses), every 6 weeks (total dosage/cycle = 80 mg/m²)
Fluorouracil 500 mg/m² per dose; administer by intravenous injection over 1–2 minutes after leucovorin, given weekly for 4 consecutive weeks (4 doses), every 6 weeks (total dosage/cycle = 2000 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome
Atropine sulfate 0.25–1 mg administer subcutaneously or intravenously if abdominal cramping or diarrhea develop during or within 1 hour after irinotecan administration
- If symptoms are severe, add as primary prophylaxis at least 30 min before irinotecan during subsequent cycles
- For irinotecan, acute cholinergic syndrome may be characterized by: abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

Diarrhea management
Latent or delayed onset diarrhea*:*
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:
Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg
Antibiotic therapy during latent or delayed onset diarrhea:
A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count is <500/mm³ with or without accompanying fever in association with diarrhea
- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care
Prophylaxis and treatment for mucositis/stomatitis
General advice:
- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

(*continued*)

(continued)

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Treatment Modifications

(Camptosar, irinotecan hydrochloride injection product label, July 2005. Pharmacia & Upjohn Company, Division of Pfizer, Inc., New York, NY)

	Dosage Levels		
	Initial	−1	−2
Irinotecan	125 mg/m²	100 mg/m²	75 mg/m²
Leucovorin	Racemic leucovorin calcium 400 mg/m² or levoleucovorin calcium 200 mg/m²		
Fluorouracil	500 mg/m²	400 mg/m²	300 mg/m²

Notes:

- Dose modifications are based on the National Cancer Institute (USA) Common Toxicity Criteria. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed October 11, 2013]
- Before beginning a treatment cycle, patients should have baseline bowel function (similar to that before start of treatment) without antidiarrheal therapy for 24 hours, ANC ≥1500/mm³, and platelet count ≥100,000/mm³
- Treatment should be delayed 1–2 weeks to allow for recovery from treatment-related toxicities. If a patient has not recovered after 2 weeks, consider stopping therapy
- If toxicity occurs despite 2 dose reductions (ie, on level −2) discontinue therapy

(continued)

Treatment Modifications (*continued*)

Toxicity	Weekly Dosage Based on Intracycle Toxicity	Dosage at the Start of a 6-Week Cycle
Neutropenia/Thrombocytopenia		
G1 ANC (1500–1999/mm³) or G1 thrombocytopenia	Maintain dose and schedule	Maintain dose and schedule
G2 ANC (1000–1499/mm³) or G2 thrombocytopenia	Reduce weekly dosages of irinotecan and fluorouracil by 1 dosages level	Maintain dose and schedule
G3 ANC (500–999/mm³) or G3 thrombocytopenia	Hold treatment until toxicity G ≤2, then reduce weekly dosages of irinotecan and fluorouracil by 1 dosage level	Reduce weekly dosages of irinotecan and fluorouracil by 1 dosage level
G4 ANC (<500/mm³) or G4 thrombocytopenia	Hold treatment until toxicity G ≤2, then reduce weekly dosages of irinotecan and fluorouracil by 2 dosage levels	Reduce weekly dosages of irinotecan and fluorouracil by 2 dosage levels
Febrile neutropenia	Hold treatment until toxicity resolves, then reduce weekly dosage by 1 dosage level	
Diarrhea		
G1 (2–3 stools/day > baseline)	Maintain dose and schedule	Maintain dose and schedule
G2 (4–6 stools/day > baseline)	Hold until diarrhea resolves to baseline, then reduce weekly dosages by 1 level	Maintain dose and schedule
G3 (7–9 stools/day > baseline)	Delay until diarrhea resolves to baseline, then reduce weekly dosages by 1 level	Reduce weekly dosages of irinotecan and fluorouracil by 1 dosage level
G4 (≥ 10 stools/day > baseline)	Delay until diarrhea resolves to baseline, then reduce weekly dosages by 2 levels	Reduce weekly dosages of irinotecan and fluorouracil by 2 dosage levels
Other Nonhematologic Toxicities		
Any G1 toxicity	Maintain dose and schedule	Maintain dose and schedule
Any G2 toxicity	Hold treatment until toxicity G ≤1, then reduce weekly dosages of irinotecan and fluorouracil by 1 dosage level	Maintain dose and schedule

Efficacy (N = 231)

(Intention-to-Treat Analysis)

Confirmed objective response	39%
Median duration of response	9.2 months
Median progression-free survival	7 months
Median overall survival	14.8 months

Toxicity (N = 225)

	% G3	% G4
Diarrhea	15.1	7.6
Vomiting	5.3	4.4
Mucositis	2.2	0
Neutropenia	29.8	24
Fever/neutropenia		7.1
Fever/infection		1.8
Therapy discontinued because of toxicity		7.6
Drug-related death		0.9

Patient Population Studied

A study of 231 patients with metastatic colorectal cancer who had not previously received chemotherapy except adjuvant therapy that was completed more than 12 months before study entry. Patients had not previously received pelvic radiation

Therapy Monitoring

1. *Before each cycle:* H&P, CBC with differential, CEA, serum electrolytes, and LFTs
2. *Weekly:* CBC with differential count and safety assessment
3. *Every 6 weeks × 4 (24 weeks), then every 12 weeks:* CT scans to assess response

METASTATIC DISEASE REGIMEN

LEUCOVORIN + INFUSIONAL FLUOROURACIL + IRINOTECAN (FOLFIRI)

Douillard JY et al. Lancet 2000;355:1041–1047
Tournigand C et al. J Clin Oncol 2004;22:229–237

Common to both alternative regimens (Douillard et al. and Tournigand et al.):
Irinotecan 180 mg/m²; administer intravenously over 90 minutes in 500 mL 5% dextrose injection (D5W) on day 1, every 2 weeks (total dosage/cycle = 180 mg/m²), *plus one of the following alternative regimens:*

Douillard et al. Lancet 2000;355:1041–1047

(Racemic) Leucovorin calcium 200 mg/m² per day; administer intravenously over 1 hour in 25–500 mL 0.9% sodium chloride injection (0.9% NS) or D5W for 2 consecutive days, on days 1 and 2, every 2 weeks (total dosage/cycle = 400 mg/m²) *followed by:*
Fluorouracil 400 mg/m² per day; administer by intravenous injection over 1–2 minutes after leucovorin for 2 consecutive days, on days 1 and 2, every 2 weeks, *followed by:*
Fluorouracil 600 mg/m² per day; administer by continuous intravenous infusion over 22 hours in 100–1000 mL 0.9% NS or D5W for 2 consecutive days, on days 1 and 2, every 2 weeks (total dosage/cycle = 2000 mg/m²)

or

Tournigand et al. J Clin Oncol 2004;22:229–237

Either: **(racemic) Leucovorin calcium** 400 mg/m² *or* **levoleucovorin calcium** 200 mg/m²; administer intravenously over 2 hours in 25–500 mL 0.9% NS or D5W on day 1, every 2 weeks (total dosage/cycle for racemic leucovorin = 400 mg/m², for levoleucovorin = 200 mg/m²), *followed by:*
Fluorouracil 400 mg/m²; administer by intravenous injection over 1–2 minutes after leucovorin on day 1, every 2 weeks, *followed by:*
Fluorouracil 2400 mg/m²; administer by continuous intravenous infusion over 46 hours in 100–1000 mL 0.9% NS or D5W, starting on day 1 every 2 weeks (total dosage/cycle = 2800 mg/m²)
- Infusional fluorouracil dosage may be increased to 3000 mg/m² by continuous intravenous infusion over 46 hours, starting on cycle 3, day 1, and repeated every 2 weeks in patients who do not develop adverse effects G >1 during the first 2 cycles (total dosage/cycle = 3400 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***MODERATE***
Emetogenic potential on day 2 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome
Atropine sulfate 0.25–1 mg administer subcutaneously or intravenously if abdominal cramping or diarrhea develop during or within 1 hour after irinotecan administration
- If symptoms are severe, add as primary prophylaxis at least 30 min before irinotecan during subsequent cycles
- For irinotecan, acute cholinergic syndrome may be characterized by: abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

(*continued*)

(*continued*)

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count is $<500/mm^3$ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Treatment Modifications

(Camptosar, irinotecan hydrochloride injection product label, July 2005. Pharmacia & Upjohn Company, Division of Pfizer, Inc., New York, NY)

	Dosage Levels		
	Initial	−1	−2
Irinotecan	180 mg/m²	150 mg/m²	120 mg/m²
Leucovorin	Racemic leucovorin calcium 400 mg/m² *or* levoleucovorin calcium 200 mg/m²		
Bolus fluorouracil	400 mg/m²	300 mg/m²	
Infusional fluorouracil	600 mg/m²	480 mg/m²	360 mg/m²
Infusional fluorouracil	2400 mg/m²	2000 mg/m²	1800 mg/m²

Notes:

- Dose modifications are based on the National Cancer Institute (USA) Common Toxicity Criteria. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed October 11, 2013]
- Before beginning a treatment cycle, patients should have baseline bowel function (similar to that before the start of treatment) without antidiarrheal therapy for 24 hours, ANC ≥1500/mm³, and platelet count ≥100,000/mm³
- Treatment should be delayed 1–2 weeks to allow for recovery from treatment-related toxicities. If a patient has not recovered after 2 weeks, consider stopping therapy

If toxicity occurs despite 2 dose reductions (ie, on level −2), discontinue therapy

Toxicity	Modifications for Irinotecan and Fluorouracil
Neutropenia/Thrombocytopenia	
G1 ANC (1500–1999/mm³) or G1 thrombocytopenia	Maintain dose and schedule
G2 ANC (1000–1499/mm³) or G2 thrombocytopenia	Reduce dosages by 1 dosage level
G3 ANC (500–999/mm³) or G3 thrombocytopenia	Hold treatment until toxicity resolves to G ≤2, then reduce dosages by 1 dosage level
G4 ANC (<500/mm³) or G4 thrombocytopenia	Hold treatment until toxicity resolves to G ≤2, then reduce dosages by 2 dosage levels
Febrile neutropenia	Hold treatment until neutropenia resolves, then reduce dosages by 2 dosage levels
Diarrhea	
G1 (2–3 stools/day > baseline)	Maintain dose and schedule
G2 (4–6 stools/day > baseline)	Delay until diarrhea resolves to baseline, then reduce dosage by 1 dosage level
G3 (7–9 stools/day > baseline)	Delay until diarrhea resolves to baseline, then reduce dosage by 1 dosage level
G4 (≥10 stools/day > baseline)	Delay until diarrhea resolves to baseline, then reduce dosage by 2 dosage levels

(*continued*)

Patient Population Studied

A study of 199 patients with previously untreated advanced colorectal cancer

Efficacy (N* = 169/198)

Confirmed overall response	40.8% (34.8%)†
Complete response	3.6% (3.0%)
Partial response	37.3% (31.8%)
Median time to progression	6.7 months
Median survival	17.4 months

*Evaluable = 169 patients; intention-to-treat = 198 patients. Both totals include patients receiving weekly and 2-weekly regimens

†Percent of evaluable patients (percent of intention-to-treat patients)

Douillard JY et al. Lancet 2000;355:1041–1047

Treatment Modifications (*continued*)

Toxicity	Modifications for Irinotecan and Fluorouracil
Other Nonhematologic Toxicities	
Any G1 toxicity	Maintain dose and schedule
Any G2 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage by 1 dosage level
Any G3 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage by 1 dosage level
Any G4 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage by 2 dosage levels
G2–4 mucositis	Decrease only fluorouracil by 20%

METASTATIC OR ADJUVANT REGIMEN

LEUCOVORIN + INFUSIONAL FLUOROURACIL + OXALIPLATIN (FOLFOX)

André T et al. N Engl J Med 2004;350:2343–2351
de Gramont A et al. J Clin Oncol 2000;18:2938–2947
Rothenberg ML et al. J Clin Oncol 2003;21:2059–2069
Tournigand C et al. J Clin Oncol 2004;22:229–237

FOLFOX-4 (de Gramont et al., Rothenberg et al., André et al.):
Oxaliplatin 85 mg/m²; administer intravenously over 2 hours in 250 mL 5% dextrose injection (D5W) on day 1, every 2 weeks, concurrently with leucovorin administration (total dosage/cycle = 85 mg/m²)

Note: Oxaliplatin must not be mixed with sodium chloride injection. Therefore, when leucovorin and oxaliplatin are given concurrently via the same administration set tubing, both drugs must be administered in D5W

Leucovorin calcium 200 mg/m² per day; administer intravenously over 2 hours in 25–500 mL D5W for 2 consecutive days, on days 1 and 2, every 2 weeks (total dosage/cycle = 400 mg/m²) *followed by:*
Fluorouracil 400 mg/m² per day; administer by intravenous injection over 1–4 minutes after leucovorin for 2 consecutive days, on days 1 and 2, every 2 weeks, *followed by:*
Fluorouracil 600 mg/m² per day; administer by continuous intravenous infusion over 22 hours in 100–1000 mL 0.9% sodium chloride injection (0.9% NS) or D5W for 2 consecutive days, on days 1 and 2, every 2 weeks (total dosage/cycle = 2000 mg/m²)

or

FOLFOX-6 (Tournigand et al.)
Oxaliplatin 100 mg/m²; administer intravenously over 2 hours in 500 mL D5W on day 1, every 2 weeks, concurrently with leucovorin administration (total dosage/cycle = 100 mg/m²)

Note: Oxaliplatin must not be mixed with sodium chloride injection. Therefore, when leucovorin and oxaliplatin are given concurrently via the same administration set tubing, both drugs must be administered in D5W
Either: **(racemic) Leucovorin calcium** 400 mg/m² *or* **levoleucovorin calcium** 200 mg/m²; administer intravenously over 2 hours in 25–500 mL 0.9% NS or D5W on day 1, every 2 weeks (total dosage/cycle for racemic leucovorin = 400 mg/m², for levoleucovorin = 200 mg/m²), *followed by:*

Fluorouracil 400 mg/m²; administer by intravenous injection over 1–2 minutes after leucovorin on day 1, every 2 weeks, *followed by:*
Fluorouracil 2400 mg/m²; administer by continuous intravenous infusion over 46 hours in 100–1000 mL 0.9% NS or D5W, starting on day 1 every 2 weeks (total dosage/cycle = 2800 mg/m²)
- Infusional fluorouracil dosage may be increased to 3000 mg/m² by continuous intravenous infusion over 46 hours, starting on cycle 3, day 1, and repeated every 2 weeks in patients who do not develop adverse effects G >1 during the first 2 cycles (total dosage/cycle = 3400 mg/m²)

Note: The fluorouracil loading dose (400 mg/m²) can be omitted for better hematologic tolerance

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***MODERATE***
Emetogenic potential on day 2 is ***LOW to MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

WHO Criteria

Therapy Monitoring

1. *Before each cycle:* H&P, CBC with differential, CEA serum electrolytes, and LFTs
2. *Every 2–3 months:* CT scans to assess response in patients presenting with advanced colorectal cancer

METASTATIC DISEASE REGIMEN

LEUCOVORIN + BOLUS FLUOROURACIL + IRINOTECAN (IFL) + BEVACIZUMAB

Hurwitz H et al. N Engl J Med 2004;350:2335–2342

Bevacizumab 5 mg/kg; administer intravenously in 100 mL 0.9% sodium chloride injection (0.9% NS) every 2 weeks (total dosage/6-week cycle = 15 mg/kg)

Note: Administration duration for the initial dose is 90 minutes. If administration is well tolerated, the administration duration may be decreased stepwise during subsequent administrations to 60 minutes and, finally, to a minimum duration of 30 minutes

Irinotecan 125 mg/m² per dose; administer intravenously in 250 mL 5% dextrose injection (D5W) over 90 minutes, weekly for 4 consecutive weeks, every 6 weeks (total dosage/6-week cycle = 500 mg/m²)
Leucovorin calcium 20 mg/m² per dose; administer intravenously over 2 hours in 25–500 mL 0.9% NS or D5W, weekly for 4 consecutive weeks, every 6 weeks (total dosage/6-week cycle = 80 mg/m²), *followed by:*
Fluorouracil 500 mg/m² per dose; administer by intravenous injection over 1–2 minutes, after leucovorin, weekly for 4 consecutive weeks, every 6 weeks (total dosage/cycle = 2000 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential with or without bevacizumab is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome
Atropine sulfate 0.25–1 mg administer subcutaneously or intravenously if abdominal cramping or diarrhea develop during or within 1 hour after irinotecan administration
- If symptoms are severe, add as primary prophylaxis at least 30 min before irinotecan during subsequent cycles
- For irinotecan, acute cholinergic syndrome may be characterized by: abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

Diarrhea management
***Latent or delayed onset diarrhea**:**
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

(*continued*)

Patient Population Studied

First-line therapy of metastatic colorectal cancer. Exclusion criteria included prior chemotherapy or biologic therapy for metastatic disease, although adjuvant or radiosensitizing use of fluoropyrimidines with or without leucovorin or levamisole was permitted

Efficacy (N = 402)

Overall response rate	44.8%
Complete response	3.7%
Partial response	41%
Median survival	20.3 months
Progression-free survival	10.6 months

RECIST criteria (Response Evaluation Criteria in Solid Tumors. Therasse P et al. J Natl Cancer Inst 2000;92:205–216)

(*continued*)

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count is $<500/mm^3$ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Toxicity (N = 393)

Adverse events occurred with greater incidence (≥2%) among patients who received bevacizumab 1 bolus IFL than those who received bolus IFL 1 placebo

Toxicity	% of Patients
Any G3/4 toxicity	85
Cardiovascular	
Any thrombosis	19.4
Deep venous thrombosis	8.9
Pulmonary embolus	3.6
Any hypertension	22.4
G3 hypertension	11
Digestive	
G3/4 diarrhea	32.4
Hematologic	
G3/4 leukopenia	37
Other Toxicities (G1–4)	
Proteinuria	26.5
G2/3 proteinuria	3.1/0.8

Therapy Monitoring

1. *Before each cycle:* H&P, CBC with differential, serum electrolytes, CEA BUN, creatinine, and LFTs. Urine for protein analysis including 24-hour urine for protein if needed
2. *Twice per week initially, then at a minimum of once per week:* Blood pressure
3. *Every 6 weeks for the first 24 weeks:* CT scans to assess response

Treatment Modifications

Adverse Event	Dose Modification
Gastrointestinal perforation, serious bleeding	Discontinue bevacizumab permanently
Wound dehiscence requiring medical intervention	
Nephrotic syndrome	
Hypertensive crisis	
Moderate to severe proteinuria	Hold bevacizumab pending further evaluation (eg, 24-hour urine protein or work-up and treatment of hypertension)
Severe hypertension not controlled with medical management	

Note: Bevacizumab should be suspended at least several weeks before elective surgery and should not be resumed until a surgical incision is fully healed

Information from product label:
http://www.gene.com/gene/products/information/pdf/avastin-prescribing.pdf or http://www.fda.gov/cder/approval/index.htm

Standard intracycle and intercycle dose modifications of irinotecan and fluorouracil, according to the package insert, were permitted in patients with treatment-related adverse events. Suggestions include the following:

(Camptosar, irinotecan hydrochloride injection product label, July 2005. Pharmacia & Upjohn Company, Division of Pfizer, Inc, New York, NY)

	Dosage Levels		
	Initial	−1	−2
Irinotecan	125 mg/m²	100 mg/m²	75 mg/m²
Leucovorin	20 mg/m²		
Fluorouracil	500 mg/²	400 mg/m²	300 mg/m²

Notes:
- Dose modifications are based on the National Cancer Institute (USA) Common Toxicity Criteria http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed October 11, 2013]
- Before beginning a treatment cycle, patients should have baseline bowel function (present before start of treatment) without antidiarrheal therapy for 24 hours, ANC ≥1500/mm³, and platelet count ≥100,000/mm³
- Treatment should be delayed 1–2 weeks to allow for recovery from treatment-related toxicities. If a patient has not recovered after 2 weeks, consider stopping therapy
- If toxicity occurs despite 2 dose reductions (ie, on level −2) discontinue therapy

Toxicity	Weekly Dosage Based on Intracycle Toxicity	Dosage at Start of a 6-Week Cycle
Neutropenia/Thrombocytopenia		
G1 ANC (1500–1999/mm³) or G1 thrombocytopenia	Maintain dose and schedule	Maintain dose and schedule
G2 ANC (1000–1499/mm³) or G2 thrombocytopenia	Reduce weekly dosages of irinotecan and leucovorin by 1 dosage level	Maintain dose and schedule
G3 ANC (500–999/mm³) or G3 thrombocytopenia	Hold treatment until toxicity G ≥2, then reduce weekly dosages of irinotecan and leucovorin by 1 dosage level	Reduce weekly dosages of irinotecan and leucovorin by 1 dosage level
G4 ANC (<500/mm³) or G4 thrombocytopenia	Hold treatment until toxicity G ≤2, then reduce weekly dosages of irinotecan and leucovorin by 2 dosage levels	Reduce weekly dosages of irinotecan and leucovorinz by 2 dosage levels
Febrile neutropenia	Hold treatment until toxicity resolves, then reduce weekly dosages of irinotecan and leucovorin by 1 dosage level	

(*continued*)

Treatment Modifications (*continued*)

Toxicity	Weekly Dosage Based on Intracycle Toxicity	Dosage at Start of a 6-Week Cycle
Diarrhea		
G1 (2–3 stools/day > baseline)	Maintain dose and schedule	Maintain dose and schedule
G2 (4–6 stools/day > baseline)	Hold until diarrhea resolves to baseline, then reduce weekly dosages of irinotecan and leucovorin by 1 dosage level	Maintain dose and schedule
G3 (7–9 stools/day > baseline)	Delay until diarrhea resolves to baseline, then reduce weekly dosages of irinotecan and leucovorin by 1 dosage level	Reduce weekly dosages of irinotecan and leucovorin by 1 dosage level
G4 (≥10 stools/day > baseline)	Delay until diarrhea resolves to baseline, then reduce weekly dosages of irinotecan and leucovorin by 2 dosage levels	Reduce weekly dosages of irinotecan and leucovorin by 2 dosage levels
Other Nonhematologic Toxicities		
Any G1 toxicity	Maintain dose and schedule	Maintain dose and schedule
Any G2 toxicity	Hold treatment until toxicity G ≤1, then reduce weekly dosages of irinotecan and leucovorin by 1 dosage level	Maintain dose and schedule
Any G3 toxicity	Hold treatment until toxicity G ≤1, then reduce weekly dosages of irinotecan and leucovorin by 1 dosage level	Reduce weekly dosages of irinotecan and leucovorin by 1 dosage level
Any G4 toxicity	Hold treatment until toxicity G ≤1, then reduce weekly dosages of irinotecan and leucovorin by 2 dosage levels	Reduce weekly dosage by 2 dosage levels for irinotecan and leucovorin levels
G2–4 mucositis	Reduce fluorouracil by 1 dosage level (do not alter irinotecan)	

Goldberg RM et al. J Clin Oncol 2004;22:23–30
Saltz LB et al. N Engl J Med 2000;343:905–914

METASTATIC DISEASE REGIMEN

CETUXIMAB

Cunningham et al. N Engl J Med 2004;351:337–345
Saltz LB et al. J Clin Oncol 2004;22:1201–1208

Warning: Despite the use of prophylactic antihistamines, severe infusion reactions occur with the administration of cetuximab in about 3% of patients, rarely with fatal outcome (<1 in 1000). Approximately 90% of severe infusion reactions are associated with initial cetuximab administration and are characterized by the rapid onset of airway obstruction (bronchospasm, stridor, hoarseness), urticaria, and/or hypotension. Exercise caution with every cetuximab infusion

Notes:

1. Test doses do not reliably predict hypersensitivity reactions to cetuximab administration and are not recommended
2. Mild to moderate infusion reactions
   - Interrupt or slow the cetuximab infusion rate
   - Permanently decrease administration rate by 50%
   - Give antihistamine prophylaxis before repeated treatments
3. Severe reactions
   - Immediately interrupt cetuximab therapy
   - Administer epinephrine, glucocorticoids, intravenous antihistamines, bronchodilators, and oxygen as needed
   - Permanently discontinue further treatment

Cetuximab premedication:
Administer a H_1-receptor antagonist (eg, diphenhydramine 50 mg) intravenously 30–60 minutes before starting cetuximab administration. Hypersensitivity prophylaxis should be administered for subsequent cetuximab doses based on clinical judgment and presence and severity of infusion reactions during prior exposures

Initial cetuximab dose:
Cetuximab 400 mg/m²; administer intravenously over 120 minutes (maximum infusion rate = 5 mL/min [10 mg/min]) as a single dose (total initial dosage = 400 mg/m²), followed after an interval of 1 week by:

Weekly maintenance cetuximab doses:
Cetuximab 250 mg/m²; administer intravenously over 60 minutes (maximum infusion rate = 5 mL/min [10 mg/min]) every week (total weekly dosage = 250 mg/m²)

Notes:

- Cetuximab is intended for direct administration and should not be diluted
- Maximum infusion rate = 5 mL (10 mg)/min (300 mL/h, or 600 mg/h)
- Administer cetuximab through a low protein-binding inline filter with pore size = 0.22 μm
- Use 0.9% sodium chloride injection to flush vascular access devices after administration is completed

Supportive Care

Antiemetic prophylaxis
*Emetogenic potential is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

(*continued*)

Patient Population Studied

A study of patients with metastatic colorectal cancer whose tumor expresses EGFR and whose disease had progressed after receiving an irinotecan-containing regimen

Efficacy

	Cetuximab + Irinotecan	Cetuximab
Response	22.9%	10.8%
Progression-free survival	4.1 months	1.5 months

Cunningham et al. N Engl J Med 2004;351:337–345

Toxicity

	% G3/4	
Toxicity	Cetuximab + Irinotecan	Cetuximab Alone
Asthenia/ malaise	14	10
Abdominal pain	3	5
Fever	2	0
Infusion reaction	0	4
Acne-like rash	9	5
Nausea/ vomiting	7	4

(*continued*)

Diarrhea management

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode

If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

In the pivotal trial, cetuximab was given alone or in combination with irinotecan. All patients received a 20-mg test dose on day 1, then cetuximab was given at 400 mg/m² intravenously as an initial dose, followed by 250 mg/m² per week intravenously until disease progression or unacceptable toxicity. Cetuximab was added to irinotecan using the same dose and schedule for irinotecan on which the patient's tumor had previously progressed

Treatment Modifications

(ERBITUX [cetuximab] injection, for intravenous infusion, product label, August 2013. Manufactured by ImClone LLC, a subsidiary of Eli Lilly and Co., Branchburg, NJ. Distributed and Marketed by Bristol-Myers Squibb Company, Princeton, NJ, and Eli Lilly and Company., Indianapolis, IN)

Infusion Reactions	
Mild-moderate (G1/2) and nonserious G3/4	Permanently decrease administration rates by 50%
Serious (G3/4)	Immediately and permanently discontinue cetuximab

Severe (G3/4) Dermatologic Toxicity			
Occurrence	**Cetuximab**	**Improvement**	**Cetuximab Dosage**
First	Delay infusion 1–2 weeks	Yes	Continue at 250 mg/m²
		No	Discontinue
Second	Delay infusion 1–2 weeks	Yes	Decrease to 200 mg/m²
		No	Discontinue
Third	Delay infusion 1–2 weeks	Yes	Decrease to 150 mg/m²
		No	Discontinue
Fourth	Discontinue		

Information from the product label: http://www.erbitux.com/ (last accessed October 15, 2013)

Therapy Monitoring

1. *Before each cycle:* H&P, CBC with differential, CEA serum electrolytes, BUN, creatinine, and LFTs. Urine for protein analysis including 24-hour urine for protein if needed
2. *Every 6 weeks for the first 24 weeks:* CT scans to assess response
3. Monitor patients for 1 hour after completing cetuximab administration in a setting with resuscitation equipment and other agents necessary to treat anaphylaxis (eg, epinephrine, intravenous glucocorticoids and antihistamines, bronchodilators, and oxygen)
   - Monitor for longer periods to confirm resolution of signs and symptoms of hypersensitivity in patients who require treatment for infusion reactions
4. Interrupt cetuximab for acute onset or worsening of pulmonary symptoms (dyspnea, cough). Permanently discontinue cetuximab for confirmed Interstitial lung disease (ILD occurred in <0.5% of patients receiving cetuximab in clinical trials)
5. Instruct patients to limit sun exposure. Monitor for inflammation and infection involving the skin and nails
   - Dermatologic toxicities, including: acneform rash, skin drying and fissuring, paronychial inflammation, infectious sequelae (eg, *Staphylococcus aureus* sepsis, abscess formation, cellulitis, blepharitis, conjunctivitis, keratitis, cheilitis), and hypertrichosis have occurred in patients receiving cetuximab
   - Acneform rash occurred in 76–88% of patients who received cetuximab in clinical trials; severe acneform rash occurred in 1–17% of patients
   - Acneform rash usually develops within the first 2 weeks after starting therapy and resolves in a majority of the patients after treatment cessation, although in nearly half of patients studied rash continued beyond 28 days after treatment ceased

METASTATIC COLORECTAL CANCER REGIMEN

CETUXIMAB + FOLFOX-4

Bokemeyer C et al. J Clin Oncol 2009;27:663–671
Cunningham D et al. N Engl J Med 2004;351:337–345
de Gramont A et al. J Clin Oncol 2000;18:2938–2947

Warning:

1. Severe infusion reactions occurred with the administration of cetuximab in approximately 3% (17/633) of patients, rarely with fatal outcome (<1 in 1000)
2. Approximately 90% of severe infusion reactions are associated with the first infusion of cetuximab despite the use of prophylactic antihistamines
3. Infusion reactions are characterized by the rapid onset of airway obstruction (bronchospasm, stridor, hoarseness), urticaria, and/or hypotension
4. Caution must be exercised with every cetuximab infusion, as there were patients who experienced their first severe infusion reaction during later infusions
5. Provocative test doses do not reliably predict hypersensitivity reactions to cetuximab administration and are not recommended

Mild to moderate infusion reactions

- Interrupt or slow the cetuximab infusion rate
- Permanently decrease the administration rate by 50%
- Give antihistamine prophylaxis before repeated treatments

Severe reactions

- Immediately interrupt cetuximab therapy
- Administer epinephrine, glucocorticoids, intravenous antihistamines, bronchodilators, and oxygen as needed
- Permanently discontinue further treatment

Cetuximab premedication:
Diphenhydramine 50 mg by intravenous injection before cetuximab administration (other H_1-receptor antagonists may be substituted)

Initial cetuximab dose:
Cetuximab 400 mg/m²; administer intravenously over 120 minutes (maximum infusion rate = 5 mL/min [10 mg/min]) as a single dose (total initial dosage = 400 mg/m²)
Maintenance cetuximab doses:
Cetuximab 250 mg/m²; administer intravenously over 60 minutes (maximum infusion rate = 5 mL/min [10 mg/min]) every week (total weekly dosage = 250 mg/m²)

Notes:

- Cetuximab is intended for direct administration and should not be diluted
- Maximum infusion rate = 5 mL (10 mg)/min (300 mL/h, or 600 mg/h)
- Administer cetuximab through a low protein-binding inline filter with pore size = 0.22 μm
- Use 0.9% sodium chloride injection to flush vascular access devices after administration is completed

See Chapter 40 for more information about antineoplastic use

***FOLFOX-4** (de Gramont A et al.):*
Oxaliplatin 85 mg/m²; administer intravenously in 250 mL 5% dextrose injection (D5W) over 2 hours concurrently with leucovorin administration, on day 1 every 2 weeks, (total dosage/cycle = 85 mg/m²)
Note: Oxaliplatin must not be mixed with sodium chloride injection. Therefore, when leucovorin and oxaliplatin are given concurrently via a Y-connector, both drugs must be administered in D5W
Leucovorin calcium 200 mg/m² per dose; administer intravenously in 25–500 mL D5W over 2 hours on 2 consecutive days, on days 1 and 2, every 2 weeks (total dosage/cycle = 400 mg/m²), *followed by:*
Fluorouracil 400 mg/m² per dose; administer by intravenous injection over 1–2 minutes after leucovorin on 2 consecutive days, on days 1 and 2, every 2 weeks, *followed by:*
Fluorouracil 600 mg/m² per dose; administer by continuous intravenous infusion in 100–1000 mL 0.9% sodium chloride injection (0.9% NS) or D5W over 22 hours on 2 consecutive days, on days 1 and 2, every 2 weeks (total dosage/cycle = 2000 mg/m²)
Note: **Fluorouracil** boluses (400 mg/m² by intravenous injection) may be omitted for better hematologic tolerance

(continued)

(*continued*)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days with cetuximab is ***MINIMAL***
Emetogenic potential on days with oxaliplatin is ***MODERATE***
Emetogenic potential on days with fluorouracil and leucovorin alone is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

***Latent or delayed onset diarrhea**:**

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Patient Population Studied

463 patients with histologically confirmed, first occurrence of a nonresectable, EGFR-expressing metastatic colorectal cancer (mCRC) with a life expectancy of >12 weeks; an Eastern Cooperative Oncology Group Performance Status (ECOG-PS) >2. Patients were ineligible if they had a history of previous exposure to EGFR-targeted therapy or previous chemotherapy (except adjuvant treatment) for mCRC

Efficacy*

	ITT (N = 337)		KRAS WT (N = 134)		KRAS MT (N = 99)	
	F	F + C	F	F + C	F	F + C
Complete Response (%)	0.6	1	1	3	2	0
Partial Response (%)	35	44	36	57	45	33
Progression-free survival (months)	7.2	7.2	7.2	7.7	8.6	5.5
Percent progression-free at 3 months	85	83	78	93	87	78
Percent progression-free at 6 months	59	53	54	66	69	39
Percent progression-free at 9 months	34	34	27	47	42	20
Percent progression-free at 12 months	12	24	13	30	14	6

C, Cetuximab; F, FOLFOX-4 (oxaliplatin, leucovorin, and fluorouracil); ITT, intention to treat; MT, mutant; WT, wild type
*Modified WHO criteria

Therapy Monitoring

1. *Before each cycle:* H&P, CBC with differential, CEA if initially elevated, serum electrolytes, serum magnesium, and LFTs
2. *Every 2–3 months:* CT scans to assess response in patients presenting with advanced colorectal cancer

Treatment Modifications

ERBITUX (Cetuximab) product label, August 2013. Manufactured by ImClone Systems Incorporated, Branchburg, NJ. Distributed and marketed by Bristol-Myers Squibb Company, Princeton, NJ, and Eli Lilly and Company., Indianapolis, IN

Cetuximab Infusion Reactions

Mild/moderate (G1/2)	Permanently decrease administration rates by 50%

Skin reactions†,‡	0.6	18
Infusion-related reactions§	2	5

*National Cancer Institute (USA) Common Toxicity Criteria, version 2.0. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed October 11, 2013]

†No G4 adverse events

‡The special adverse event category skin reactions included the following *Medical Dictionary for Regulatory Activities 8.1* terms: acne, acne pustular, cellulitis, dermatitis acneiform, dry skin, erysipelas, erythema, face edema, folliculitis, growth of eyelashes, hair growth abnormal, hypertrichosis, nail bed infection, nail bed inflammation, nail disorder, nail infection, paronychia, pruritus, rash, rash erythematous, rash follicular, rash generalized, rash, macular, rash maculopapular, rash popular, rash pruritic, rash pustular, skin exfoliation, skin hyperpigmentation, skin necrosis, staphylococcal scalded skin syndrome, telangiectasia, wound necrosis, xerosis

§The special adverse event category infusion-related reactions included the following *Medical Dictionary for Regulatory Activities 8.1* terms: acute respiratory failure, apnea, asthma, bronchial obstruction, bronchospasm, cyanosis, dyspnea, dyspnea at rest, dyspnea exacerbated, dyspnea exertional, hypoxia, orthopnea, respiratory distress, respiratory failure, chills, hyperpyrexia, pyrexia, acute myocardial infarction, angina pectoris, blood pressure decreased, cardiac failure, cardiopulmonary failure, clonus, convulsion, epilepsy, hypotension, infusion-related reaction, loss of consciousness, myocardial infarction, myocardial ischemia, shock, sudden death and syncope, occurring on the first day of treatment; and anaphylactic reaction, anaphylactic shock, anaphylactoid reaction, anaphylactoid shock, drug hypersensitivity and hypersensitivity, occurring at any time during treatment

Notes: The median duration of cetuximab treatment was 24 weeks, with 84% of patients having a relative dose intensity (RDI) of ≥80%. Similar numbers of patients in both arms had RDIs of ≥80% for oxaliplatin (75% and 80% of patients receiving cetuximab plus FOLFOX-4 and FOLFOX-4, respectively) and FU (67% and 70% of patients, respectively). Reductions and delays in cetuximab dosing were primarily because of skin reactions, and delays in chemotherapy dosing were because of hematologic, GI, or neurologic reactions

METASTATIC COLORECTAL CANCER REGIMEN

CETUXIMAB + FOLFIRI

Van Cutsem E et al. N Engl J Med 2009;360:1408–1417

Warning:

1. Severe infusion reactions occurred with the administration of cetuximab in approximately 3% (17/633) of patients, rarely with fatal outcome (<1 in 1000)
2. Approximately 90% of severe infusion reactions are associated with the first infusion of cetuximab despite the use of prophylactic antihistamines
3. Infusion reactions are characterized by the rapid onset of airway obstruction (bronchospasm, stridor, hoarseness), urticaria, and/or hypotension
4. Caution must be exercised with every cetuximab infusion, as there were patients who experienced their first severe infusion reaction during later infusions
5. Provocative test doses do not reliably predict hypersensitivity reactions to cetuximab administration and are not recommended

Mild to moderate infusion reactions

- Interrupt or slow the cetuximab infusion rate
- Permanently decrease the administration rate by 50%
- Give antihistamine prophylaxis before repeated treatments

Severe reactions

- Immediately interrupt cetuximab therapy
- Administer epinephrine, glucocorticoids, intravenous antihistamines, bronchodilators, and oxygen as needed
- Permanently discontinue further treatment

Cetuximab premedication:

Diphenhydramine 50 mg; administer by intravenous injection before cetuximab administration (other H_1-receptor antagonists may be substituted)

Initial cetuximab dose:

Cetuximab 400 mg/m²; administer intravenously over 120 minutes (maximum infusion rate = 5 mL/min [10 mg/min]) as a single dose (total initial dosage = 400 mg/m²)

Maintenance cetuximab doses:

Cetuximab 250 mg/m²; administer intravenously over 60 minutes (maximum infusion rate = 5 mL/min [10 mg/min]) every week (total weekly dosage = 250 mg/m²)

Notes:

- Cetuximab is intended for direct administration and should not be diluted
- Maximum infusion rate = 5 mL (10 mg)/min (300 mL/h, *or* 600 mg/h)
- Administer cetuximab through a low protein-binding inline filter with pore size = 0.22 μm
- Use 0.9% sodium chloride injection to flush vascular access devices after administration is completed

See Chapter 40 for more information about antineoplastic use

Irinotecan 180 mg/m²; administer intravenously over 90 minutes in 500 mL 5% dextrose injection (D5W) on day 1, every 2 weeks (total dosage/cycle = 180 mg/m²), *plus:*
Either: **(racemic) leucovorin calcium** 400 mg/m² *or* **levoleucovorin calcium** 200 mg/m²; administer intravenously over 2 hours in 25–500 mL 0.9% sodium chloride injection (0.9% NS) or D5W on day 1, every 2 weeks (total dosage/cycle for racemic leucovorin = 400 mg/m², for levoleucovorin = 200 mg/m²), *followed by:*
Fluorouracil 400 mg/m²; administer by intravenous injection over 1–2 minutes after leucovorin on day 1, every 2 weeks, *followed by:*
Fluorouracil 2400 mg/m²; administer by continuous intravenous infusion over 46 hours in 100–1000 mL 0.9% NS or D5W, starting on day 1, every 2 weeks (total dosage/cycle = 2800 mg/m²)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on day 1 is ***MODERATE***
Emetogenic potential on day 2 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated
See Chapter 43 for more information

(*continued*)

(*continued*)

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome

Atropine sulfate 0.25–1 mg subcutaneously or intravenously if abdominal cramping or diarrhea develop during or within 1 hour after irinotecan administration

- If symptoms are severe, add as primary prophylaxis at least 30 minutes before irinotecan during subsequent cycles
- For irinotecan, acute cholinergic syndrome may be characterized by abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

Diarrhea management

Latent or delayed onset diarrhea:*

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Patient Population Studied

An open-label, multicenter study, comparing 14-day cycles of cetuximab plus FOLFIRI and FOLFIRI alone, randomized and treated 1198 patients. The primary end point was progression-free survival time. Inclusion criteria included histologically confirmed adenocarcinoma of the colon or rectum, first occurrence of metastatic disease that could not be resected for curative purposes, immunohistochemical evidence of tumor EGFR expression, and Eastern Cooperative Oncology Group (ECOG) Performance Status score of 2 or less. Exclusion criteria were previous exposure to an anti-EGFR therapy or irinotecan-based chemotherapy, previous chemotherapy for metastatic colorectal cancer, adjuvant treatment that was terminated 6 months or less before the start of treatment on trial

Efficacy (N = 1198)

	FOLFIRI (N = 599)	FOLFIRI + Cetuximab (N = 599)
Median progression-free survival	8 months	8.9 months
Median overall survival	18.6 months	19.9 months
Complete response	0.3%	0.5%
Partial response	38.4%	46.4%

Therapy Monitoring

1. *Before each cycle:* H&P, CBC with differential, CEA if initially elevated, serum electrolytes, serum magnesium, and LFTs
2. *Every 2–3 months:* CT scans to assess response in patients presenting with advanced colorectal cancer

Treatment Modifications

(ERBITUX [cetuximab] injection, for intravenous infusion, product label, August 2013. Manufactured by ImClone LLC, a subsidiary of Eli Lilly and Co., Branchburg, NJ. Distributed and Marketed by Bristol-Myers Squibb Company, Princeton, NJ), and Eli Lilly and Company., Indianapolis, IN

Cetuximab Infusion Reactions

Mild/moderate (G1/2)	Permanently decrease administration rates by 50%
Severe (G3/4)	Immediately and permanently discontinue

Cetuximab Dermatologic Toxicity—Severe (G3/4)

Occurrence	Cetuximab	Improvement	Cetuximab Dosage
First	Delay infusion 1–2 weeks	Yes	Continue at 250 mg/m²
		No	Discontinue
Second	Delay infusion 1–2 weeks	Yes	Decrease to 200 mg/m²
		No	Discontinue
Third	Delay infusion 1–2 weeks	Yes	Decrease to 150 mg/m²
		No	Discontinue
Fourth	Discontinue		

Information from the product label: www.erbitux.com/index.aspx (last accessed April 23, 2013)

Irinotecan and Fluorouracil

	Dosage Levels		
	Initial	−1	−2
Irinotecan	180 mg/m²	150 mg/m²	120 mg/m²
Leucovorin	Racemic leucovorin calcium 400 mg/m² *or* levoleucovorin calcium 200 mg/m²		
Fluorouracil injection	400 mg/m²	320 mg/m²	240 mg/m²
Infusional fluorouracil	2400 mg/m²	2000 mg/m²	1600 mg/m²

Notes:

- Dose modifications are based on the National Cancer Institute (USA) Common Toxicity Criteria. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed October 11, 2013]
- Before beginning a treatment cycle, patients should have baseline bowel function (similar to that before start of treatment) without antidiarrheal therapy for 24 hours, ANC ≥1500/mm³, and platelet count ≥100,000/mm³
- Treatment should be delayed 1–2 weeks to allow for recovery from treatment-related toxicities
- If a patient has not recovered after 2 weeks, consider stopping therapy. If toxicity occurs despite 2 dose reductions (ie, on level −2), discontinue therapy

Toxicity	Modifications for Irinotecan and Fluorouracil
Neutropenia/Thrombocytopenia	
G1 ANC (1500–1999/mm³) or G1 thrombocytopenia (75,000/mm³ to less than normal limits)	Maintain dose and schedule
G2 ANC (1000–1499/mm³) or G2 thrombocytopenia (≥50,000 to <75,000/mm³)	Reduce dosage by 1 dosage level
G3 ANC (500–999/mm³) or G3 thrombocytopenia (≥10,000 to <50,000/mm³)	Hold treatment until toxicity resolves to G ≤2, then reduce dosage by 1 dosage level
G4 ANC (<500/mm³) or G4 thrombocytopenia (<10,000/mm³)	Hold treatment until toxicity resolves to G ≤2, then reduce dosage by 2 dosage levels
Febrile neutropenia	Hold treatment until neutropenia resolves, then reduce dosage by 2 dosage levels

(*continued*)

Treatment Modifications (*continued*)

Toxicity	Modifications for Irinotecan and Fluorouracil
Diarrhea	
G1 (2–3 stools/day > baseline)	Maintain dose and schedule
G2 (4–6 stools/day > baseline)	Delay until diarrhea resolves to baseline then reduce dosage by 1 dosage level
G3 (7–9 stools/day > baseline)	Delay until diarrhea resolves to baseline then reduce dosage by 1 dosage level
G4 (≥10 stools/day > baseline)	Delay until diarrhea resolves to baseline then reduce dosage by 2 dosage levels
Other Nonhematologic Toxicities	
Any G1 toxicity	Maintain dose and schedule
Any G2 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage by 1 dosage level
Any G3 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage by 1 dosage level
Any G4 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage by 2 dosage levels
G2–4 mucositis	Decrease only fluorouracil by 20%

André T et al. Eur J Cancer 1999;35:1343–1347

Most Common G3/4 Adverse Events and Special Adverse Event Categories in the Safety Population, According to Treatment Group

MedDRA Preferred Term*	FOLFIRI (N = 602)	FOLFIRI + Cetuximab (N = 600)	*P*-Value
Any	61	79.3	<0.001
Neutropenia†	24.6	28,2	0.16
Leukopenia	5.1	7.2	0.15
Diarrhea	10.5	15.7	0.008
Fatigue	4.7	5.3	0.59
Rash	0	8.2	<0.001
Dermatitis acneiform	0	5.3	<0.001
Vomiting	5	4.7	0.80
Special Adverse Events			
Skin reactions			
All	0.2	19.7	<0.001
Acne-like rash	0	16.2	<0.001
Infusion-related reaction	0	2.5	<0.001

*Among the *Medical Dictionary for Regulatory Activities* (MedDRA, version 10.0) preferred terms, no grade 4 reactions were reported for dermatitis acneiform, acne-like rash, or all skin reactions
†Grade 3 or 4 febrile neutropenia was reported in 18 of the 600 patients (3.0%) receiving cetuximab plus FOLFIRI and in 13 of the 602 patients (2.2%) receiving FOLFIRI alone

METASTATIC COLORECTAL CANCER REGIMEN

PANITUMUMAB + BEST SUPPORTIVE CARE

Van Cutsem E et al. J Clin Oncol 2007;25:1658–1664

Panitumumab 6 mg/kg; administer intravenously in 0.9% sodium chloride injection (100 mL for doses ≤1000 mg; 150 mL for doses >1000 mg; product concentration should be <10 mg/mL) over 60–90 minutes on day 1, every 2 weeks (total dosage/cycle = 6 mg/kg)

Notes:

- Severe infusion reactions occur in approximately 1% of patients (anaphylactic reactions, bronchospasm, fever, chills, and hypotension). Dose adjustment or discontinuation of panitumumab is warranted depending on the severity of the reaction
- Panitumumab should always be administered by a rate controlling device via a low-protein-binding 0.22-μm inline filter
- Flush line before and after panitumumab with 0.9% sodium chloride injection
- Doses ≤1000 mg should be administered over 60 minutes; >1000 mg should be administered over 90 minutes
  - If tolerated, second and subsequent infusions may be administered over 30 minutes
- The routine use of an antihistamine prior to panitumumab administration is not recommended by the manufacturer; however, doing so may prevent infusion reactions

See Chapter 40 for more information about antineoplastic use

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MINIMAL** to **LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg; administer orally every 2 hours during waking hours, *plus*
Loperamide 4 mg; administer orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)

- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

(*continued*)

Patient Population Studied

A study of 463 patients with pathologic diagnosis of metastatic colorectal adenocarcinoma and radiologic documentation of disease progression during or within 6 months following the last administration of fluoropyrimidine, irinotecan, and oxaliplatin. A total of 231 patients were assigned to receive panitumumab + best supportive care (BSC) versus 232 patients assigned to BSC alone. To ensure adequate exposure to prior chemotherapy, average dose-intensity of irinotecan (>65 mg/m² per week) and of oxaliplatin (>30 mg/m² per week) were required. Other key eligibility criteria included: Eastern Cooperative Oncology Group (ECOG) Performance Status score of 0–2, 2 or 3 prior chemotherapy regimens for metastatic colorectal cancer, and 1% or more EGFR-positive membrane staining in evaluated tumor cells (primary or metastatic) by immunohistochemistry

Efficacy* (N = 463)

	Panitumumab + BSC (N = 231)	BSC (N = 232)
Median progression-free survival†	8 weeks	7.3 weeks
Mean progression-free survival (SE)†	13.8 (0.8) weeks	8.5 (0.5) weeks
Progression-free survival at week 8†	49%	30%
Overall survival	No significant difference observed between groups (HR,1.00; 95% CI, 0.82–1.22; $P = 0.81$)	
Overall response rate‡	10%	0%

*Assessed by modified RECIST criteria at weeks 8, 12, 16, 24, 32, 40, and 48, and every 3 months thereafter until disease progression (Response Evaluation Criteria in Solid Tumors. Therasse P et al. J Natl Cancer Inst 2000;92:205-216)

†Patients receiving panitumumab had a 46% decrease in the relative progression rate compared with patients receiving BSC (HR, 0.54; 95% CI, 0.44–0.66), and a 95%
CI for the difference in PFS rates favored panitumumab at all scheduled assessments from weeks 8–32; SE = Standard error

‡Median time to response was 7.9 (range: 6.7–15.6) weeks and median duration of response was 17.0 (range: 7.9–76.7) weeks; all responses were partial responses

(*continued*)

Persistent diarrhea:

Octreotide acetate (solution) 100–150 mcg; administer subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count $<500/mm^3$ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

Toxicities (N = 463)

	Panitumumab + BSC		BSC	
	% All Grades	% G3/4	% All Grades	% G3/4
Patients with at least 1 adverse event	100%	34.5	86	19.2
Erythema	64	5	1	0
Dermatitis acneiform	62	7	1	0
Pruritus	57	2	2	0
Skin exfoliation	24	2	0	0
Fatigue	24	4	15	3
Paronychia	24	1	0	0
Abdominal pain	23	7	17	4.7
Anorexia	22	3.5	18	2
Nausea	22	1	15	0
Diarrhea	21	1	11	0
Rash	20	1	1	0
Skin fissures	20	1	0	0
Constipation	19	3	9	1
Vomiting	18	2	12	1
Dyspnea	14	4.8	13	3
Pyrexia	14	0	12	2
Asthenia	14	3	12	2
Cough	14	0	7	0
Back pain	10	2	7	0
Edema peripheral	10	1	6	0
General physical health deterioration	10	7	3	2.1

Note: In the panitumumab group, 36% of patients had declines in blood magnesium levels versus 1% in the BSC group. Grade 3 or 4 hypomagnesemia occurred in 3% of patients and required magnesium supplementation

Treatment Modifications

Adverse Event	Dose Modification
G1/2 infusion reaction to panitumumab	Decrease infusion rate by 50% for duration of infusion
G3/4 infusion reaction to panitumumab	Immediately and permanently discontinue infusion
G3/4 or intolerable dermatologic reaction to panitumumab	Withhold panitumumab. If toxicity improves to G ≤2 and patient symptomatically improved after withholding no more than 2 doses, resume treatment at 50% of the original dose. If toxicity does not improve to G ≤2 within 1 month, permanently discontinue panitumumab *Note:* **If toxicities do not recur,** subsequent doses of panitumumab may be increased by increments of 25% of original dose until a 6-mg/kg dose is achieved
Recurrence of G3/4 or intolerable dermatologic reaction to panitumumab	Permanently discontinue infusion
Any G2/3/4 nonhematologic toxicity	Delay start of next cycle until the severity of all toxicities are G ≤1
ANC ≤1500/mm³ or platelet count ≤100,000/mm³	Delay start of next cycle until ANC >1500/mm³ and platelet count >100,000/mm³

Therapy Monitoring

1. *Before each cycle:* H&P, CBC with differential, CEA if initially elevated, serum electrolytes, serum magnesium, and LFTs
2. *Every 2–3 months:* CT scans to assess response in patients presenting with advanced colorectal cancer

METASTATIC COLORECTAL CANCER REGIMEN

PANITUMUMAB + FOLFOX-4

de Gramont A et al. J Clin Oncol 2000;18:2938–2947
Douillard J-Y et al. J Clin Oncol 2010;28:4697–4705

Panitumumab 6 mg/kg; administer intravenously in 0.9% sodium chloride injection (100 mL for doses ≤1000 mg; 150 mL for doses >1000 mg; product concentration should be <10 mg/mL) over 60–90 minutes on day 1 before FOLFOX-4 chemotherapy, every 2 weeks (total dosage/cycle = 6 mg/kg)

Notes:

- Severe infusion reactions occur in approximately 1% of patients (anaphylactic reactions, bronchospasm, fever, chills, and hypotension). Dose adjustment or discontinuation of panitumumab is warranted depending on the severity of the reaction
- Panitumumab should always be administered by a rate controlling device via a low-protein-binding 0.22-μm inline filter
- Flush line before and after panitumumab with 0.9% sodium chloride injection
- Doses ≤1000 mg should be administered over 60 minutes; >1000 mg should be administered over 90 minutes
- If tolerated, subsequent infusions may be administered over 30 minutes
- The routine use of an antihistamine prior to panitumumab administration is not recommended by the manufacturer; however, doing so may prevent infusion reactions

FOLFOX-4 (de Gramont A et al.):
Oxaliplatin 85 mg/m²; administer intravenously in 250 mL 5% dextrose injection (D5W) over 2 hours concurrently with leucovorin administration, on day 1, every 2 weeks, (total dosage/cycle = 85 mg/m²)

Note: Oxaliplatin must not be mixed with sodium chloride injection. Therefore, when leucovorin and oxaliplatin are given concurrently via a Y-connector, both drugs must be administered in D5W
Leucovorin calcium 200 mg/m² per dose; administer intravenously in 25–500 mL D5W over 2 hours on 2 consecutive days, on days 1 and 2, every 2 weeks (total dosage/cycle = 400 mg/m²), *followed by:*
Fluorouracil 400 mg/m² per dose; administer by intravenous injection over 1–2 minutes after leucovorin on 2 consecutive days, on days 1 and 2, every 2 weeks, *followed by:*
Fluorouracil 600 mg/m² per dose; administer by continuous intravenous infusion in 100–1000 mL 0.9% sodium chloride injection or D5W over 22 hours on 2 consecutive days, on days 1 and 2, every 2 weeks (total dosage/cycle = 2000 mg/m²)

Note: **Fluorouracil** boluses (400 mg/m² by intravenous injection) may be omitted for better hematologic tolerance

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***MODERATE***
Emetogenic potential on day 2 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

(continued)

Patient Population Studied

An open-label, multicenter, phase III trial comparing the efficacy of panitumumab-FOLFOX-4 with FOLFOX-4 alone in patients with ***previously untreated*** metastatic colorectal cancer (mCRC) according to tumor *KRAS* status. Patients with Eastern Cooperative Oncology Group Performance Status 0 or 1 versus 2 were randomly assigned (1:1) to receive either panitumumab-FOLFOX-4 or FOLFOX-4. The primary objective of the study was to assess the treatment effect on progression-free survival (PFS) of the addition of panitumumab to FOLFOX-4 as initial therapy for mCRC in patients with wild-type (WT) *KRAS* tumors and also in patients with mutant (MT) *KRAS* tumors. The study was amended to compare PFS (primary end point) and overall survival (secondary end point) according to *KRAS* status before any efficacy analyses

Treatment Modifications

Adverse Event	Dose Modification
G1/2 infusion reaction to panitumumab	Decrease infusion rate by 50% for duration of infusion
G3/4 infusion reaction to panitumumab	Immediately and permanently discontinue infusion
G3/4 or intolerable dermatologic reaction to panitumumab	Withhold panitumumab. If toxicity improves to G ≤2 and patient symptomatically improved after withholding no more than 2 doses, resume treatment at 50% of original dose. If toxicity does not improve to G ≤2 within 1 month, permanently discontinue panitumumab *Note:* **If toxicities do not recur**, subsequent doses of panitumumab may be increased by increments of 25% of original dose until a 6-mg/kg dose is achieved

(continued)

(*continued*)

Diarrhea management

***Latent or delayed onset diarrhea**:**

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count $<500/mm^3$ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Treatment Modifications (*continued*)

Adverse Event	Dose Modification
Recurrence of G3/4 or intolerable dermatologic reaction to panitumumab	Permanently discontinue infusion
Any G2/3/4 nonhematologic toxicity	Delay start of next cycle until the severity of all toxicities are G ≤1
ANC $\leq 1500/mm^3$ or platelet count $\leq 100{,}000/mm^3$	Delay start of next cycle until ANC $>1500/mm^3$ and platelet count $>100{,}000/mm^3$
G3/4 Nonneurologic	Reduce fluorouracil and oxaliplatin dosages by 20%
G3/4 ANC	Reduce oxaliplatin dosage by 20%
Persistent (≥14 days) paresthesias	Reduce oxaliplatin dosage by 20%
Temporary (7–14 days) painful paresthesias	
Temporary (7–14 days) functional impairment	
Persistent (≥14 days) painful paresthesias	Discontinue oxaliplatin
Persistent (≥14 days) functional impairment

2. *Every 2–3 months:* CT scans to assess response in patients presenting with advanced colorectal cancer

METASTATIC COLORECTAL CANCER REGIMEN

PANITUMUMAB + FOLFIRI

Douillard JY et al. Lancet 2000;355:1041–1047
Peeters M et al. J Clin Oncol 2010;28:4706–4713
Tournigand C et al. J Clin Oncol 2004;22:229–237

Panitumumab 6 mg/kg; administer intravenously in 0.9% sodium chloride injection (100 mL for doses ≤1000 mg; 150 mL for doses >1000 mg; product concentration should be <10 mg/mL) over 60–90 minutes on day 1 before FOLFIRI chemotherapy, every 2 weeks (total dosage/cycle = 6 mg/kg)

Notes:
- Severe infusion reactions occur in approximately 1% of patients (anaphylactic reactions, bronchospasm, fever, chills, and hypotension). Dose adjustment or discontinuation of panitumumab is warranted depending on the severity of the reaction
- Panitumumab should always be administered by a rate-controlling device via a low-protein-binding 0.22-μm inline filter
- Flush line before and after panitumumab with 0.9% sodium chloride injection
- Doses ≤1000 mg should be administered over 60 minutes; >1000 mg should be administered over 90 minutes
- If tolerated, subsequent infusions may be administered over 30 minutes
- The routine use of an antihistamine prior to panitumumab administration is not recommended by the manufacturer; however, doing so may prevent infusion reactions

Irinotecan 180 mg/m²; administer intravenously over 90 minutes in 500 mL 5% dextrose injection (D5W) on day 1, every 2 weeks (total dosage/cycle = 180 mg/m²), *plus:*
Either: (**racemic) leucovorin calcium** 400 mg/m² *or* **levoleucovorin calcium** 200 mg/m²; administer intravenously over 2 hours in 25–500 mL 0.9% sodium chloride injection (0.9% NS) or D5W on day 1, every 2 weeks (total dosage/cycle for racemic leucovorin = 400 mg/m², for levoleucovorin = 200 mg/m²), *followed by:*
Fluorouracil 400 mg/m²; administer by intravenous injection over 1–2 minutes after leucovorin on day 1, every 2 weeks, *followed by:*
Fluorouracil 2400 mg/m²; administer by continuous intravenous infusion over 46 hours in 100–1000 mL 0.9% NS or D5W, starting on day 1, every 2 weeks (total dosage/cycle = 2800 mg/m²)

Supportive Care

Antiemetic prophylaxis
Emetogenic potential on day 1 is ***MODERATE***
Emetogenic potential on day 2 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome
Atropine sulfate 0.25–1 mg subcutaneously or intravenously if abdominal cramping or diarrhea develop during or within 1 hour after irinotecan administration
- If symptoms are severe, add as primary prophylaxis at least 30 minutes before irinotecan during subsequent cycles
- For irinotecan, acute cholinergic syndrome may be characterized by abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

Diarrhea management
***Latent or delayed onset diarrhea**:**
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

(*continued*)

(*continued*)

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count $<500/mm^3$ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Treatment Modifications

Adverse Event	Dose Modification
G1/2 infusion reaction to panitumumab	Decrease infusion rate by 50% for duration of infusion
G3/4 infusion reaction to panitumumab	Immediately and permanently discontinue infusion
G3/4 or intolerable dermatologic reaction to panitumumab	Withhold panitumumab. If toxicity improves to G ≤2 and patient symptomatically improves after withholding no more than 2 doses, resume treatment at 50% of the original dose. If toxicity does not improve to G ≤2 within 1 month, permanently discontinue panitumumab *Note:* **If toxicities do not recur**, subsequent doses of panitumumab may be increased by increments of 25% of original dose until a 6-mg/kg dose is achieved
Recurrence of G3/4 or intolerable dermatologic reaction to panitumumab	Permanently discontinue panitumumab
Any G2/3/4 nonhematologic toxicity	Delay start of next cycle until the severity of all toxicities are G ≤1
ANC ≤1500/mm³ or platelet count ≤100,000/mm³	Delay start of next cycle le until ANC >1500/mm³ and platelet count >100,000/mm³

(*continued*)

Treatment Modifications (*continued*)

	Dosage Levels		
	Initial	−1	−2
Irinotecan	180 mg/m²	150 mg/m²	120 mg/m²
Leucovorin	Racemic leucovorin calcium 400 mg/m² or levoleucovorin calcium 200 mg/m²		
Fluorouracil injection	400 mg/m²	320 mg/m²	240 mg/m²
Infusional fluorouracil	2400 mg/m²	2000 mg/m²	1600 mg/m²

Notes:

- Dose modifications are based on the National Cancer Institute (USA) Common Toxicity Criteria. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed October 11, 2013]
- Before beginning a treatment cycle, patients should have baseline bowel function (similar to that before start of treatment) without antidiarrheal therapy for 24 hours, ANC ≥1500/mm³, and platelet count ≥100,000/mm³
- Treatment should be delayed 1–2 weeks to allow for recovery from treatment-related toxicities
- If a patient has not recovered after 2 weeks, consider stopping therapy
- If toxicity occurs despite 2 dose reductions (ie, on level −2), discontinue therapy

Toxicity	Modifications for Irinotecan and Fluorouracil
Neutropenia/Thrombocytopenia	
G1 ANC (1500–1999/mm³) or G1 thrombocytopenia (75,000/mm³ to less than normal limits)	Maintain dose and schedule
G2 ANC (1000–1499/mm³) or G2 thrombocytopenia (≥50,000 to <75,000/mm³)	Reduce dosage by 1 dosage level
G3 ANC (500–999/mm³) or G3 thrombocytopenia (≥10,000 to <50,000/mm³)	Hold treatment until toxicity resolves to G ≤2, then reduce dosage by 1 dosage level
G4 ANC (<500/mm³) or G4 thrombocytopenia (<10,000/mm³)	Hold treatment until toxicity resolves to G ≤2, then reduce dosage by 2 dosage levels
Febrile neutropenia	Hold treatment until neutropenia resolves, then reduce dosage by 2 dosage levels
Diarrhea	
G1 (2–3 stools/day > baseline)	Maintain dose and schedule
G2 (4–6 stools/day > baseline)	Delay until diarrhea resolves to baseline then reduce dosage by 1 dosage level
G3 (7–9 stools/day > baseline)	Delay until diarrhea resolves to baseline then reduce dosage by 1 dosage level
G4 (≥10 stools/day > baseline)	Delay until diarrhea resolves to baseline then reduce dosage by 2 dosage levels
Other Nonhematologic Toxicities	
Any G1 toxicity	Maintain dose and schedule
Any G2 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage by 1 dosage level
Any G3 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage by 1 dosage level
Any G4 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage by 2 dosage levels
G2–4 mucositis	Decrease only fluorouracil by 20%

	Wild-Type (WT) KRAS		Mutant (MT) KRAS	
	FOLFIRI (N = 294)	FOLFIRI + Panitumumab (N = 303)	FOLFIRI (N = 248)	FOLFIRI + Panitumumab (N = 238)
Progression-free survival	3.9 months	5.9 months	4.9 months	5.0 months
Overall survival	12.5 months	14.5 months	11.1 months	11.8 months
Overall response rate	10%	35%	14%	13%

*RECIST (Response Evaluation Criteria in Solid Tumors. Therasse P et al. J Natl Cancer Inst 2000;92:205-216)

Patient Population Studied

A study of 1186 patients with Eastern Cooperative Oncology Group (ECOG) Performance Status of 0, 1, or 2 and a diagnosis of adenocarcinoma of the colon or rectum. ***Only one prior chemotherapy regimen for metastatic colorectal cancer (mCRC) consisting of first-line fluoropyrimidine-based chemotherapy was allowed.*** Patients were excluded if they previously received irinotecan or anti-EGFR therapy. Radiographically confirmed disease progression must have occurred during or within 6 months after first-line chemotherapy

Toxicity* (N = 539†)

	% G3/4
Any G3/4 event	68.6
Skin toxicity	34.5
Neutropenia	16.9
Diarrhea	13.5
Mucositis	8.3
Hypokalemia	5.4
Pulmonary embolism	4.1
Hypomagnesemia	3.7
Dehydration	3.3
Paronychia	2.8
Febrile neutropenia	1.7
Panitumumab infusion-related reaction‡	<1

*NCI CTCAE, National Cancer Institute (USA) Common Terminology Criteria for Adverse Events, version 3. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]
†Includes patients with WT KRAS and MT KRAS who were treated with panitumumab
‡Grade 3 panitumumab-related infusion reactions occurred in 2 patients; these patients did not receive additional panitumumab treatment

Therapy Monitoring

1. *Before each cycle:* H&P, CBC with differential, CEA if initially elevated, serum electrolytes, serum magnesium, and LFTs
2. *Every 2–3 months:* CT scans to assess response in patients presenting with advanced colorectal cancer

SECOND-LINE COLORECTAL CANCER REGIMEN

ziv-AFLIBERCEPT + FOLFIRI

Van Cutsem E et al. J Clin Oncol 2012;30:3499–3506

ziv-Aflibercept 4 mg/kg; administer intravenously over 60 minutes in a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) sufficient to produce a concentration within the range 0.6–8 mg/mL on day 1, every 2 weeks (total dosage/cycle = 4 mg/kg), *followed by:*
Irinotecan 180 mg/m^2; administer intravenously over 90 minutes in 500 mL D5W on day 1, every 2 weeks (total dosage/cycle = 180 mg/m^2), *plus:*
Either: **(racemic) leucovorin calcium** 400 mg/m^2 *or* **levoleucovorin calcium** 200 mg/m^2; administer intravenously in 25–500 mL 0.9% NS or D5W over 2 hours on day 1, every 2 weeks (total dosage/cycle for racemic leucovorin = 400 mg/m^2, for levoleucovorin = 200 mg/m^2), *followed by:*
Fluorouracil 400 mg/m^2; administer by intravenous injection over 1–2 minutes after leucovorin on day 1, every 2 weeks, *followed by:*
Fluorouracil 2400 mg/m^2; administer by continuous intravenous infusion over 46 hours in 100–1000 mL 0.9% NS or D5W, starting on day 1 every 2 weeks (total dosage/cycle = 2800 mg/m^2)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***MODERATE***
Emetogenic potential on day 2 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome
Atropine sulfate 0.25–1 mg subcutaneously or intravenously if abdominal cramping or diarrhea develop during or within 1 hour after irinotecan administration
- If symptoms are severe, add as primary prophylaxis at least 30 minutes before irinotecan during subsequent cycles
- For irinotecan, acute cholinergic syndrome may be characterized by abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

Diarrhea management
Latent or delayed onset diarrhea*:*
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:
Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg
Antibiotic therapy during latent or delayed onset diarrhea:
A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea
- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

(*continued*)

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Patient Population Studied

Patients with an Eastern Cooperative Oncology Group (ECOG) Performance Status (PS) of 0–2 and histologically or cytologically proven colorectal adenocarcinoma with metastatic disease not amenable to potentially curative treatment were randomly assigned (1:1) to receive either ziv-aflibercept or placebo followed by combination chemotherapy with the FOLFIRI regimen. Although disease progression was to have been documented either during or after completion of a single prior oxaliplatin-containing regimen, patients were not selected for the timing of their progression. Patients who experienced relapse within 6 months of completion of oxaliplatin-based adjuvant therapy were eligible. Prior bevacizumab was permitted, but not prior irinotecan. Patients with a history of major surgery within 28 days were not allowed to participate

Dose Modifications

Note: Adjust each treatment component individually and/or delay cycle (up to 2 weeks) in the event of toxicity

Adverse Event	Dose Modification
Severe hemorrhage	Discontinue ziv-aflibercept
Gastrointestinal perforation	
Compromised wound healing	
Fistula formation	
Hypertensive crisis or hypertensive encephalopathy	
Arterial thromboembolic events	
Nephrotic syndrome or thrombotic microangiopathy (TMA)	
Reversible posterior leukoencephalopathy syndrome (RPLS)	
Recurrent or severe hypertension	Hold ziv-aflibercept until hypertension abates to G ≤1, and permanently reduce ziv-aflibercept dosage to 2 mg/kg
Proteinuria of 2 g/24 h	Hold ziv-aflibercept and resume when proteinuria is ≤2 g/24 h
Recurrent proteinuria	Hold ziv-aflibercept and resume when proteinuria is ≤2 g/24 h, and permanently reduce ziv-aflibercept dosage to 2 mg/kg
Planned surgery	Suspend ziv-aflibercept at least 4 weeks prior to elective surgery

Irinotecan and Fluorouracil

	Dosage Levels		
	Initial	−1	−2
Irinotecan	180 mg/m²	150 mg/m²	120 mg/m²
Leucovorin	Racemic leucovorin calcium 400 mg/m² or levoleucovorin calcium 200 mg/m²		
Fluorouracil injection	400 mg/m²	320 mg/m²	240 mg/m²
Infusional fluorouracil	2400 mg/m²	2000 mg/m²	1600 mg/m²

Notes:

- Dose modifications are based on the NCI CTCAE, National Cancer Institute (USA) Common Terminology Criteria for Adverse Events, version 3. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]
- Before beginning a treatment cycle, patients should have baseline bowel function (similar to that before start of treatment) without antidiarrheal therapy for 24 hours, ANC ≥1500/mm³, and platelet count ≥100,000/mm³
- Treatment should be delayed 1–2 weeks to allow for recovery from treatment-related toxicities
- If a patient has not recovered after 2 weeks of withholding ziv-aflibercept, consider stopping therapy. If toxicity occurs despite 2 dose reductions (ie, on level −2), discontinue therapy

(*continued*)

Dose Modifications (*continued*)

Toxicity	Modifications for Irinotecan and Fluorouracil
Neutropenia/Thrombocytopenia	
G1 ANC (1500–1999/mm^3) or G1 thrombocytopenia (75,000/mm^3 to less than normal limits)	Maintain dose and schedule
G2 ANC (1000–1499/mm^3) or G2 thrombocytopenia (≥50,000 to <75,000/mm^3)	Reduce dosage by 1 dosage level
G3 ANC (500–999/mm^3) or G3 thrombocytopenia (≥10,000 to <50,000/mm^3)	Hold treatment until toxicity resolves to G ≤2, then reduce dosage by 1 dosage level
G4 ANC (<500/mm^3) or G4 thrombocytopenia (<10,000/mm^3)	Hold treatment until toxicity resolves to G ≤2, then reduce dosage by 2 dosage levels
Febrile neutropenia	Hold treatment until neutropenia resolves, then reduce dosage by 2 dosage levels
Diarrhea	
G1 (2–3 stools/day > baseline)	Maintain dose and schedule
G2 (4–6 stools/day > baseline)	Delay until diarrhea resolves to baseline, then reduce dosage by 1 dosage level

SECOND-LINE COLORECTAL CANCER REGIMENS

BEVACIZUMAB AFTER FIRST PROGRESSION
BEVACIZUMAB + FOLFIRI

Bevacizumab 5 mg/kg; administer intravenously in 100 mL 0.9% sodium chloride Injection (0.9% NS) every 2 weeks (total dosage/cycle = 15 mg/kg)

Note: Administration duration for the initial dose is 90 minutes. If administration is well tolerated, the administration duration may be decreased stepwise during subsequent administrations to 60 minutes and, finally, to a minimum duration of 30 minutes

FOLFIRI *(Tournigand C et al. J Clin Oncol 2004;22:229–237):*

Irinotecan 180 mg/m²; administer intravenously over 90 minutes in 500 mL 5% dextrose injection (D5W) on day 1, every 2 weeks (total dosage/cycle = 180 mg/m²), *plus:*
Either: **(racemic) leucovorin calcium** 400 mg/m² *or* **levoleucovorin calcium** 200 mg/m²; administer intravenously over 2 hours in 25–500 mL 0.9% NS or D5W on day 1, every 2 weeks (total dosage/cycle for racemic leucovorin = 400 mg/m², for levoleucovorin = 200 mg/m²), *followed by:*
Fluorouracil 400 mg/m²; administer by intravenous injection over 1–2 minutes after leucovorin on day 1, every 2 weeks, *followed by:*
Fluorouracil 2400 mg/m²; administer by continuous intravenous infusion over 46 hours in 100–1000 mL 0.9% NS or D5W, starting on day 1, every 2 weeks (total dosage/cycle = 2800 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***MODERATE***
Emetogenic potential on day 2 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome
Atropine sulfate 0.25–1 mg subcutaneously or intravenously if abdominal cramping or diarrhea develop during or within 1 hour after irinotecan administration
- If symptoms are severe, add as primary prophylaxis at least 30 minutes before irinotecan during subsequent cycles
- For irinotecan, acute cholinergic syndrome may be characterized by: abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

Diarrhea management
***Latent or delayed onset diarrhea**:**
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:
Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg
Antibiotic therapy during latent or delayed onset diarrhea:
A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm³ with or without accompanying fever in association with diarrhea
- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

Wadler S et al. J Clin Oncol 1998;16:3169–3178

(*continued*)

(*continued*)

BEVACIZUMAB + FOLFOX-4

Bevacizumab 5 mg/kg; administer intravenously in 100 mL 0.9% sodium chloride Injection (0.9% NS) every 2 weeks (total dosage/cycle = 15 mg/kg)

Note: Administration duration for the initial dose is 90 minutes. If administration is well tolerated, the administration duration may be decreased stepwise during subsequent administrations to 60 minutes and, finally, to a minimum duration of 30 minutes

FOLFOX-4 *(de Gramont A et al. J Clin Oncol 2000;18:2938–2947):*
Oxaliplatin 85 mg/m^2; administer intravenously in 250 mL 5% dextrose injection (D5W) over 2 hours concurrently with leucovorin administration, on day 1, every 2 weeks, (total dosage/cycle = 85 mg/m^2)

Note: Oxaliplatin must not be mixed with sodium chloride injection. Therefore, when leucovorin and oxaliplatin are given concurrently via a Y-connector, both drugs must be administered in D5W

Leucovorin calcium 200 mg/m^2 per dose; administer intravenously in 25–500 mL D5W over 2 hours on 2 consecutive days, on days 1 and 2, every 2 weeks (total dosage/cycle = 400 mg/m^2), *followed by:*
Fluorouracil 400 mg/m^2 per dose; administer by intravenous injection over 1–2 minutes after leucovorin on 2 consecutive days, on days 1 and 2, every 2 weeks, *followed by:*
Fluorouracil 600 mg/m^2 per dose; administer by continuous intravenous infusion in 100–1000 mL 0.9% NS or D5W over 22 hours on 2 consecutive days, on days 1 and 2, every 2 weeks (total dosage/cycle = 2000 mg/m^2)

Note: **Fluorouracil** boluses (400 mg/m^2 by intravenous injection) may be omitted for better hematologic tolerance

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days with cetuximab is ***MINIMAL***
Emetogenic potential on days with oxaliplatin is ***MODERATE***
Emetogenic potential on days with fluorouracil and leucovorin is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed onset diarrhea*:*
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)
- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

(*continued*)

(continued)

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Treatment Modifications

Fluorouracil and Oxaliplatin

Any G2/3/4 nonhematologic toxicity	Delay start of next cycle until the severity of all toxicities are G ≤1
ANC ≤1500/mm^3 or platelet count ≤100,000/mm^3	Delay start of next cycle until ANC >1500/mm^3 and platelet count >100,000/mm^3
G3/4 Nonneurologic	Reduce fluorouracil and oxaliplatin dosages by 20%
G3/4 ANC	Reduce oxaliplatin dosage by 20%
Persistent (≥14 days) paresthesias	Reduce oxaliplatin dosage by 20%
Temporary (7–14 days) painful paresthesias	
Temporary (7–14 days) functional impairment	
Persistent (≥14 days) painful paresthesias	Discontinue oxaliplatin
Persistent (≥14 days) functional impairment	

Adapted in part from de Gramont A et al. J Clin Oncol 2000;18:2938–2947

(continued)

Treatment Modifications (*continued*)

Irinotecan and Fluorouracil

	Dosage Levels		
	Initial	−1	−2
Irinotecan	180 mg/m²	150 mg/m²	120 mg/m²
Leucovorin	Racemic leucovorin calcium 400 mg/m² or levoleucovorin calcium 200 mg/m²		
Fluorouracil injection	400 mg/m²	320 mg/m²	240 mg/m²
Infusional fluorouracil	2400 mg/m²	2000 mg/m²	1600 mg/m²

Notes:

- Dose modifications are based on the National Cancer Institute (USA) Common Toxicity Criteria. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed October 11, 2013]
- Before beginning a treatment cycle, patients should have baseline bowel (similar to that before start of treatment) function without antidiarrheal therapy for 24 hours, ANC ≥1500/mm³, and platelet count ≥100,000/mm³
- Treatment should be delayed 1–2 weeks to allow for recovery from treatment-related toxicities
- If a patient has not recovered after 2 weeks, consider stopping therapy. If toxicity occurs despite 2 dose reductions (ie, on level −2), discontinue therapy

Toxicity	Modifications for Irinotecan and Fluorouracil
Neutropenia/Thrombocytopenia	
G1 ANC (1500–1999/mm³) or G1 thrombocytopenia (75,000/mm³ to less than normal limits)	Maintain dose and schedule
G2 ANC (1000–1499/mm³) or G2 thrombocytopenia (≥50,000 to <75,000/mm³)	Reduce dosage by 1 dosage level
G3 ANC (500–999/mm³) or G3 thrombocytopenia (≥10,000 to <50,000/mm³)	Hold treatment until toxicity resolves to G ≤2, then reduce dosage by 1 dosage level
G4 ANC (<500/mm³) or G4 thrombocytopenia (<10,000/mm³)	Hold treatment until toxicity resolves to G ≤2, then reduce dosage by 2 dosage levels
Febrile neutropenia	Hold treatment until neutropenia resolves, then reduce dosage by 2 dosage levels
Diarrhea	
G1 (2–3 stools/day > baseline)	Maintain dose and schedule
G2 (4–6 stools/day > baseline)	Delay until diarrhea resolves to baseline then reduce dosage by 1 dosage level
G3 (7–9 stools/day > baseline)	Delay until diarrhea resolves to baseline then reduce dosage by 1 dosage level
G4 (≥10 stools/day > baseline)	Delay until diarrhea resolves to baseline then reduce dosage by 2 dosage levels
Other Nonhematologic Toxicities	
Any G1 toxicity	Maintain dose and schedule
Any G2 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage by 1 dosage level
Any G3 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage by 1 dosage level
Any G4 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage by 2 dosage levels
G2–4 mucositis	Decrease only fluorouracil by 20%

Efficacy

Tumor Response by RECIST*

	Bevacizumab + Chemotherapy (n = 404)	Chemotherapy Alone (n = 406)
Complete response	1 (<1%)	2 (<1%)
Partial response	21 (5%)	14 (3%)
Stable disease	253 (63%)	204 (50%)
Progressive disease	87 (22%)	142 (35%)
Missing/not assessable	42 (10%)	44 (11%)

Data are number (%)
*Includes only those patients with one or more measurable lesion at baseline. (RECIST, Response Evaluation Criteria in Solid Tumors. Therasse P et al. J Natl Cancer Inst 2000;92:205–216)

Response Durations

	Bevacizumab + Chemotherapy (n = 404)	Chemotherapy Alone (n = 406)
Median follow-up (months)	11.1 (6.4–15.6)	9.6 (IQR 5.4–13.9)
Median overall survival (months)	11.2 (95%CI 10.4–12.2)	9.8 (95%CI 8.9–10.7)
	HR 0.81 (95% CI 0.69–0.94); P = 0.0062	
Median progression-free survival (months)	5.7 (5.2–6.2)	4.1 (95% CI 3.7–4.4)
	HR 0.68 (95% CI 0.59–0.78); P <0.0001	
Median overall survival from start of first-line treatment* (months)	23.9 (95% CI 22.2–25.7)	22.5 (21.4–24.5)
	HR 0.90 (95% CI 0.77–1.05); P = 0.17	
Median overall treatment exposure (months)	4.2 (IQR 2.0–7.2)	3.2 months (1.7–5.2)
Treatment duration with bevacizumab (months)	3.9 (1.8–6.9)	N /A

Exploratory Subgroup Analysis According to *KRAS* Status (n = 616)

Progression-free survival KRAS wild type	HR 0.61, 95% CI 0.49–0.77; P <0.0001†
Progression-free survival KRAS mutant	HR 0.70, 95% CI 0.56–0.89; P = 0.003†
Overall survival KRAS wild type	HR 0.69, 95% CI 0.53–0.90; P = 0.005*,‡
Overall survival KRAS mutant	HR 0.92, 95% CI 0.71–1.18; P = 0.50‡

*Retrospectively documented
†Better outcome with bevacizumab
‡Treatment by *KRAS* status interaction test was negative for both progression-free survival ($P = 0.4436$) and overall survival ($P = 0.1266$), indicating there is no evidence treatment effect is dependent on *KRAS* mutational status.

Toxicity

Incidence of Grades 3–5 Adverse Events Occurring in ≥2% of Patients Given Chemotherapy with or without Bevacizumab After Disease Progression Following First-Line Bevacizumab-Based Treatment (Safety Population*)

	Bevacizumab + Chemotherapy (n = 401)	Chemotherapy Alone (n = 409)
Neutropenia	65 (16%)	52 (13%)
Leucopenia	16 (4%)	12 (3%)
Asthenia	23 (6%)	17 (4%)
Fatigue	14 (3%)	10 (2%)
Diarrhea	40 (10%)	34 (8%)
Vomiting	14 (3%)	13 (3%)
Nausea	13 (3%)	11 (3%)
Decreased appetite	5 (1%)	9 (2%)
Mucosal inflammation	13 (3%)	4 (1%)
Abdominal pain	15 (4%)	12 (3%)
Polyneuropathy	12 (3%)	6 (1%)
Peripheral neuropathy	5 (1%)	10 (2%)
Hypokalemia	9 (2%)	8 (2%)
Dyspnea	6 (1%)	12 (3%)
Pulmonary embolism	10 (2%)	8 (2%)
Hypertension	7 (2%)	5 (1%)
Bleeding or hemorrhage	8 (2%)	1 (<1%)
Venous thromboembolic events	19 (5%)	12 (3%)
Gastrointestinal perforation	7 (2%)	3 (<1%)
Subileus	8 (2%)	2 (<1%)
Patients who discontinued any treatment because of adverse events	63 (16%)†	36 (9%)

*The safety population = 810 patients given ≥1 dose of study drug, including 407 patients in the chemotherapy group and 403 in the chemotherapy plus bevacizumab group. Two patients assigned to chemotherapy plus bevacizumab were not given bevacizumab and for the safety analyses, were assigned to the chemotherapy group

†A total of 53 (13%) patients discontinued chemotherapy only or both bevacizumab and chemotherapy and 10 (2%) discontinued bevacizumab

Patient Population Studied

Prospective, randomized, open-label, phase III study that enrolled patients if they had: (a) histologically confirmed, measurable metastatic colorectal cancer; (b) Eastern Cooperative Oncology Group (ECOG) Performance Status 0–2; (c) tumor disease according to RECIST criteria evaluated by investigator up to 4 weeks prior to start of study treatment; (d) previous treatment with bevacizumab plus standard first-line chemotherapy including a fluoropyrimidine plus either oxaliplatin or irinotecan; and (e) they were not candidates for primary metastasectomy. Patients were excluded if they: (a) had a diagnosis of progressive disease for more than 3 months after the last bevacizumab administration; (b) had first-line progression-free survival of less than 3 months; and (c) were given less than 3 months (consecutive) of first-line bevacizumab

LATE-STAGE METASTATIC COLORECTAL CANCER REGIMEN

REGORAFENIB

Grothey A et al. Lancet 2013;381:303–312

Regorafenib 160 mg/day; administer orally for 21 consecutive days, days 1–21, every 28 days (total dose/28-day cycle = 3360 mg)

Notes:

Regorafenib tablets must be stored in the manufacturer's original container at room temperature between 20° and 25°C (68° and 77°F)

- Regorafenib must not be repackaged in other vials or pill boxes
- Regorafenib containers should be tightly closed after doses are removed
- The bottle in which regorafenib is packaged contains a desiccant, which should remain in the container

Regorafenib containers should be labeled to identify the date on which they were first opened

- Any unused regorafenib tablets are to be discarded 28 days after the container was initially opened

Regorafenib should be taken about the same time each day

- If a dose is missed, it should be taken on the same day it was to have been taken; that is, patients should not take more than 1 dose on a single day to make up for 1 or more doses missed on previous days

Tablets should be swallowed whole (no breaking, crushing, or chewing)

Regorafenib is taken with a low-fat breakfast that contains less than 30% fat. Two examples of low-fat breakfasts are:

1. Two slices of white toast with 1 tablespoon of low-fat margarine and 1 tablespoon of jelly, and 8 ounces of skim milk (319 calories and 8.2 g fat); *or*
2. One cup of cereal, 8 ounces of skim milk, 1 slice of toast with jam, apple juice, and 1 cup of coffee or tea (520 calories and 2 g fat)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on is ***MINIMAL–LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

(*continued*)

Dose Modifications

Starting Dose = 160 mg Regorafenib

Adverse Event	Dose Modification
First occurrence of G2 hand-foot skin reaction (HFSR) (palmar-plantar erythrodysesthesia [PPE]) of any duration at a regorafenib dose of 160 mg	Reduce regorafenib at a daily dose of 120 mg
G3 HFSR (PPE) at a regorafenib dose of 160 mg	Discontinue therapy for a minimum of 7 days until toxicity resolves to G ≤1 and resume regorafenib at a daily dose of 120 mg
G3/4* adverse reaction at a regorafenib dose of 160 mg (except hepatotoxicity)	Discontinue regorafenib until toxicity resolves to G ≤1 and resume regorafenib at a daily dose of 120 mg
G3 aspartate aminotransferase (AST)/alanine aminotransferase (ALT) elevation at a regorafenib dose of 160 mg	Resume only if the potential benefit outweighs the risk of hepatotoxicity. Resume at a regorafenib at a daily dose of 120 mg
Recurrence of G2 HFSR at the 120 mg dose	Discontinue therapy for a minimum of 7 days until toxicity resolves to G ≤1 and resume regorafenib at a daily dose of 80 mg
G3/4* adverse reaction at the 120 mg dose (except hepatotoxicity)	Discontinue regorafenib until toxicity resolves to G ≤1 and resume regorafenib at a daily dose to 80 mg
G3 HFSR (PPE) at a regorafenib dose of 120 mg	Discontinue therapy for a minimum of 7 days until toxicity resolves to G ≤1 and resume regorafenib at a daily dose of 80 mg
G2 HFSR (PPE) does not improve within 7 days despite dose reduction to 120 mg	

(*continued*)

(continued)

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg; administer orally every 2 hours during waking hours, *plus*
Loperamide 4 mg; administer orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)

- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide acetate (solution) 100–150 mcg; administer subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count $<500/mm^3$ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Dose Modifications *(continued)*

Adverse Event	Dose Modification
Symptomatic G2 hypertension	Discontinue therapy a minimum of 7 days until symptoms resolve to G ≤1 and resume regorafenib at a daily dose of 80 mg
Failure to tolerate 80 mg daily	Permanently discontinue regorafenib
Any occurrence of AST or ALT >20 times the upper limit of normal (ULN)	
Any occurrence of AST or ALT >3 times ULN with concurrent bilirubin >2 times ULN	
Recurrence of AST or ALT >5 times ULN despite dose reduction to 120 mg	

*For any G4 adverse reaction, only resume if the potential benefit outweighs the risks

Adverse Events

- Dose modifications were required in 378 (76%) of 500 patients assigned to receive regorafenib
- 100 patients (20%) required ≥1 dose reduction
- 352 (70%) required ≥1 dose interruption)
- Adverse events were the most common reason for dose modification

Treatment-Related Adverse Events Occurring in ≥5% of Patients in Either Group from Start of Treatment to 30 Days After End of Treatment (Safety Population)

	Regorafenib (n = 500)			Placebo (n = 253)

Patient Population Studied

Randomized, placebo-controlled, phase III study involving 114 centers in 16 countries. Patients had to have (a) histologic or cytologic documentation of adenocarcinoma of the colon or rectum; (b) have received locally and currently approved standard therapies; and (c) have disease progression during or within 3 months after the last administration of the last standard therapy or to have stopped standard therapy because of unacceptable toxic effects. Because available standard therapies varied it had to include as many of the following as were licensed: a fluoropyrimidine, oxaliplatin, irinotecan, and bevacizumab; and cetuximab or panitumumab for patients who had *KRAS* wild-type tumors. Eastern Cooperative Oncology Group (ECOG) Performance Status of 0 or 1; life expectancy of at least 3 months

	Regorafenib	Placebo
Median OS (months)*	6.4 (IQR 3.6–11.8)	5.0 (IQR 2.8–10.4)
	HR 0.77, 95% CI 0.64–0.94; $P = 0.0052$	
OS rate at 3 months	80.3%	72.7%
OS rate at 6 months	52.5%	43.5%
OS rate at 9 months	38.2%	30.8%,
OS rate at 12 months	24.3%	24.0%
Median PFS (months)†	1.9 (IQR 1.6–3.9)	1.7 (IQR 1.4–1.9)
	HR 0.49, 95% CI 0.42–0.58; $P<0.0001$	
ORR	1.0%	0.4%
CR	0	0
PR	1.0%	0.4%
	$P = 0.19$	
Disease control‡	207 (41%)	38 (15%)
	($P<0.0001$)	
Median duration of SD (months)‡	2.0 (IQR 1.7–4.0)	1.7 (IQR 1.4–1.9)

*Regorafenib showed an apparent benefit in 24 of 25 subgroups, the exception being the group of patients with primary disease in colon and rectum, which was based on only a few events. Compared with placebo, regorafenib had a greater effect on overall survival in the subgroup of patients with colon cancer (HR 0.70, 95% CI 0.56–0.89) than in those with rectal cancer (0.95, 0.63–1.43)

†For PFS, all subgroup analyses significantly favored regorafenib compared with placebo, except for patients from eastern Europe, for whom the difference was not significant. Regorafenib had much the same effect on PFS in patients with colon cancer (HR 0.55, 95% CI 0.45–0.67) and those with rectal cancer (0.45, 95% CI 0.33–0.62)

‡Disease control = PR + SD assessed at least 6 weeks after randomization

RECTAL CANCER REGIMEN

ADJUVANT OR NEOADJUVANT CHEMOTHERAPY + RADIATION

O'Connell MJ et al. N Engl J Med 1994;331:502–507

Chemotherapy Before or After Radiation

Fluorouracil + calcium leucovorin (Roswell Park, Mayo Clinic, or infusional fluorouracil) or FOLFOX
Note: Systemic chemotherapy is usually administered 4 weeks before or after surgery or chemoradiotherapy

Radiation + Chemotherapy

Fluorouracil 225 mg/m² per day; administer by continuous intravenous infusion over 24 hours in 50–1000 mL 0.9% sodium chloride injection or 5% dextrose injection, daily throughout radiation therapy (total dosage/week = 1575 mg/m²)
Radiation therapy 180 cGy per fraction for 25 fractions (total dose = 4500 cGy), directed at the initial pelvic field, followed by a minimum boost of 540 cGy, to the entire tumor bed, the immediately adjacent lymph nodes, and 2 cm of adjacent tissues (the perineum was excluded after it had received 4500 cGy in patients with abdominoperineal resection). A second boost of 360 cGy was allowed to a smaller field in patients with good-to-excellent displacement of the small bowel out of the field

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care
Prophylaxis and treatment for mucositis/stomatitis
General advice:
- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:
- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:
- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

(continued)

(continued)

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Patient Population Studied

A study of patients with surgically resected stage II or III rectal cancer with the inferior edge of tumor at or below the level of sacral promontory or within 12 cm of the anal verge

Efficacy (N = 328)

Bolus fluorouracil for 2 cycles ± semustine before and after RT with fluorouracil by continuous infusion during radiation

4-Year relapse-free survival	63%
4-Year overall survival	70%

O'Connell MJ et al. N Engl J Med 1994;331:502–507

Treatment Modifications

Adverse Event	Dose Modification
G ≥3 Gastrointestinal toxicity	Interrupt radiation treatments. Resume when the toxicities decrease to G ≤2
G ≥3 Hematologic toxicity	
G ≥3 Gastrointestinal toxicity	Interrupt fluorouracil infusion. Resume when the toxicities decrease to G ≤2
G ≥3 Hematologic toxicity	

Therapy Monitoring

1. *Before each cycle and weekly during RT:* H&P, CBC with differential, serum electrolytes, BUN, creatinine, and LFTs
2. *Every 2–3 months:* CT scans to assess response

LOCALLY ADVANCED RECTAL CANCER

CHEMORADIOTHERAPY WITH CAPECITABINE

Hofheinz R-D et al. Lancet Oncol 2012;13:579-588

Adjuvant Therapy

Before radiation therapy:

Capecitabine 1250 mg/m² per dose; administer orally twice daily (approximately every 12 hours, within 30 minutes after a meal) for 14 consecutive days, on days 1–14 (28 doses), every 21 days (weeks 1 and 4), for 2 cycles (total dosage/cycle = 35,000 mg/m²)

Throughout radiation therapy:

Capecitabine 825 mg/m² per dose; administer orally twice daily (approximately every 12 hours, within 30 minutes after a meal) continually throughout and coincident with the duration of radiation therapy (weeks 8 through 12 or 13; total dosage/week = 11,550 mg/m²), *plus:*
Radiotherapy to a total dose of 50.4 Gy delivered in conventional daily 1.8-Gy fractions on 5 days per week, over 5–6 weeks

Notes:

- Radiotherapy and capecitabine are started on the same day and capecitabine is stopped on the last day of radiotherapy
- Three-dimensional conformal techniques with high-energy photons (6–25 MeV) and belly boards were used. The clinical target volume included the entire macroscopic tumor with a minimum margin of 5 cm, the mesorectum (plus 1.0- to 1.5-cm margin lateral to the pelvic brim), and the iliac and presacral lymph nodes up to the L5–S1 junction (or L4–L5 junction in the case of extensive lymph-node involvement)

After radiation therapy:

Capecitabine 1250 mg/m² per dose; administer orally twice daily (approximately every 12 hours, within 30 minutes after a meal) for 14 consecutive days, on days 1–14 (28 doses) every 21 days (weeks 15, 18, and 21), for 3 cycles (total dosage/cycle = 35,000 mg/m²)

Notes:

- Phenytoin and coumarin-derivative anticoagulant doses may need to be reduced when either drug is administered concomitantly with capecitabine. In patients receiving concomitant capecitabine and oral coumarin-derivative anticoagulant therapy, the INR or prothrombin time should be monitored frequently in order to adjust the anticoagulant dose

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential with capecitabine alone is **MINIMAL–LOW***
*Emetogenic potential during chemoradiotherapy is at least **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
G1 toxicity	Continue capecitabine and maintain dose level
First episode of G2 toxicity	Interrupt capecitabine treatment until adverse effects abate to G ≤1. Then, administer same dose in the next cycle
Second episode of G2 toxicity	Interrupt capecitabine treatment until adverse effects abate to G ≤1. Then, administer 75% dose in the next cycle
Third episode of G2 toxicity	Interrupt capecitabine treatment until adverse effects abate to G ≤1. Then, administer 50% dose in the next cycle
Fourth episode of G2 toxicity	Discontinue therapy
First episode of G3 toxicity	Interrupt capecitabine treatment until adverse effects abate to G ≤1. Then, administer 75% dose in the next cycle
Second episode of G3 toxicity	Interrupt capecitabine treatment until adverse effects abate to G ≤1. Then, administer 50% dose in the next cycle
Third episode of G3 toxicity	Discontinue therapy
First episode of G4 toxicity	Discontinue capecitabine treatment unless continued therapy deemed to be in the patient's best interest. In the latter case, interrupt treatment until adverse effects abate to G ≤1. Then, administer 50% dose in the next cycle

(continued)

Diarrhea management

Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg; administer orally every 2 hours during waking hours, *plus*
Loperamide 4 mg; administer orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998; 16:3169–3178

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of nonalcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultrasoft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial brand, nonalcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population Studied

A noninferiority, phase 3 trial comparing fluorouracil with capecitabine for perioperative treatment of patients with locally advanced rectal cancer. Patients had histologically confirmed adenocarcinoma of the rectum (defined as a distal tumor border <16 cm from the anal verge, measured by rigid rectoscopy), with no evidence of distant metastases (identified by abdominal ultrasound or CT scan and chest radiograph)

Adjuvant cohort: Had undergone R0 resection (ie, leaving no residual tumor) for pT3–4 N_{any} or pT_{any} $N_{positive}$ nonmetastatic rectal cancer. TME was mandatory for tumors in the lower two-thirds of the rectum, with PME being permitted for those in the upper third, provided a distal margin of at least 5 cm without coning was observed

Neoadjuvant cohort: Had to have a clinical cT3–4 N_{any} or cT_{any} $N_{positive}$ tumor staged by endoscopic ultrasound, provided the lower border of the tumor was 0–16 cm from the anal verge (measured by rigid rectoscopy) and the primary tumor was deemed R0 resectable by TME or PME on the basis of clinical assessment (pelvic CT or MRI were done at the discretion of the local investigators)

Treatment Monitoring

1. *Before starting:* History and physical examination, CEA determination, CBC with differential and serum chemistries
2. *During treatment:* CBC with differential and serum chemistries before each treatment cycle
3. *Tumor assessments:* Abdominal computed tomography, magnetic resonance imaging, or ultrasound, at baseline, every 6 months initially, and annually thereafter. CEA levels every 3 months initially and every 6 months thereafter

ADJUVANT THERAPY
STAGE III COLON CANCER
CAPECITABINE + OXALIPLATIN (XELOX)

Haller DG et al. J Clin Oncol 2011;29:1465–1471

Oxaliplatin 130 mg/m²; administer intravenously in 250–500 mL 5% dextrose injection over 2 hours on day 1, every 3 weeks, for 8 cycles (total dosage/cycle = 130 mg/m²), *plus*
Capecitabine 1000 mg/m² per dose; administer orally twice daily (approximately every 12 hours, within 30 minutes after a meal) for 14 consecutive days, on days 1–14 (28 doses), every 3 weeks for 8 cycles (total dosage/cycle = 28,000 mg/m²)

Notes: Capecitabine monotherapy was continued in patients who refused or discontinued oxaliplatin because of toxicity
XELOX was compared to 2 fluorouracil and leucovorin (folinic acid) (FU/FA) regimens given either for 6 cycles over 24 weeks or 4 cycles over 32 weeks (Haller DG et al. J Clin Oncol 2005;23:8671–8678)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***MODERATE***
Emetogenic potential on days with capecitabine alone is ***MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)
For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine
Pyridoxine may provide relief for discomfort/pain associated with PPE, although the mechanism through which this occurs remains unclear
- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Diarrhea management
Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg; administer orally every 2 hours during waking hours, *plus*
Loperamide 4 mg; administer orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)
- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Rothenberg ML et al. J Clin Oncol 2001; 19:3801–3807
Wadler S et al. J Clin Oncol 1998; 16:3169–3178

Oral care

Treatment Modifications

Adverse Event	Dose Modification
ANC nadir $<1000/mm^3$ *or* platelet nadir $<50,000/mm^3$ after treatment	Delay treatment until ANC is $\geq 1000/mm^3$ *and* platelet count is $\geq 50,000/mm^3$, then decrease oxaliplatin dosage by 25%, and decrease daily capecitabine dosages by 50% during subsequent cycles.* Alternatively, consider using hematopoietic growth factors
Persistent G1/G2 neuropathy	Delay oxaliplatin 1 week. After toxicity resolves, resume oxaliplatin at a dosage decreased to 100 mg/m^2 during subsequent cycles
"Transient" G3/4 neuropathy (7–14 days)	Hold oxaliplatin. After toxicity resolves, resume oxaliplatin at a dosage decreased to 100 mg/m^2 during subsequent cycles
Persistent G3/4 neuropathy	Discontinue oxaliplatin
G3/4 diarrhea or stomatitis despite capecitabine dose reductions	Reduce oxaliplatin dosage to 100 mg/m^2
G3/4 nonhematologic adverse events other than renal function and neurotoxicity	Reduce oxaliplatin and capecitabine dosages by 25% during subsequent cycles
G2 stomatitis, diarrhea, or nausea	Hold capecitabine; resume capecitabine at full dosage after resolution of toxicity
Second episode of G2 stomatitis, diarrhea, or nausea	Hold capecitabine; resume capecitabine with dosage reduced by 25% after toxicity resolves
Third episode of G2 stomatitis, diarrhea, or nausea	Hold capecitabine; resume capecitabine with dosage reduced by 50% after toxicity resolves
Fourth episode of G2 stomatitis, diarrhea, or nausea	Discontinue capecitabine
G3 stomatitis, diarrhea, or nausea	Hold capecitabine. If G3 toxicity is adequately controlled within 2 days, resume capecitabine at full dosage when toxicity abates to G $\leq$1. If G3 toxicity takes >2 days to be controlled, resume capecitabine with dosage reduced by 25% after toxicity abates to G $\leq$1
Second episode of G3 stomatitis, diarrhea, or nausea	Hold capecitabine. If G3 toxicity is controlled adequately within 2 days, then resume capecitabine with dosage reduced by 50% after toxicity abates to G $\leq$1

(continued)

Treatment Modifications (*continued*)

Adverse Event	Dose Modification
Third episode of G3 stomatitis, diarrhea, or nausea	Discontinue capecitabine
G4 stomatitis, diarrhea, or nausea	Discontinue capecitabine. Resume capecitabine with dosage reduced by 50% after toxicity resolves
G1 capecitabine-associated PPE†	Begin pyridoxine 50 mg orally 3 times daily and continue capecitabine without dose modification
G2 capecitabine-associated PPE†	Begin pyridoxine 50 mg orally 3 times daily and withhold capecitabine. Resume capecitabine with dosage reduced by 15% after toxicity resolves
G3 capecitabine-associated PPE†	Begin pyridoxine 50 mg orally 3 times daily and withhold capecitabine. Resume capecitabine with dosage reduced by 30% after toxicity resolves
Recurrent G3 capecitabine-associated PPE†	Begin pyridoxine 50 mg orally 3 times daily and withhold capecitabine. Resume capecitabine with dosage reduced by 50% after toxicity resolves

*Treatment delays for unresolved adverse events of >3 weeks duration warrant discontinuation of treatment
†PPE, Palmar plantar erythrodysesthesia (hand-foot syndrome)

Efficacy

The authors concluded "The addition of oxaliplatin to capecitabine improves DFS in patients with stage III colon cancer. XELOX is an additional adjuvant treatment option for these patients."

	XELOX	FU/FA
3-year DFS	70.9% (95% CI, 67.9% to 73.9%)	66.5% (95% CI, 63.4% to 69.6%)
4-year DFS	68.4% (95% CI, 65.3% to 71.4%)	62.3% (95% CI, 59.1% to 65.5%)
5-year DFS	66.1% (95% CI, 62.9% to 69.4%)	59.8% (95% CI, 56.4% to 63.1%)
3-year RFS	72.1%	67.5%

Patient Population Studied

Patients with histologically confirmed stage III colon carcinoma (T1-4/N1-2/M0), defined as a tumor located ≥15 cm from the anal verge or above the peritoneal reflection. Surgery with curative intent was performed in all patients ≤8 weeks before random assignment, by which time full recovery from surgery was required

Staging

TNM Category	FIGO Stage*	Primary Tumor (T)
TX		Primary tumor cannot be assessed
T0		No evidence of primary tumor
Tis		Carcinoma *in situ* (preinvasive carcinoma)
T1	I	Tumor confined to corpus uteri
T1a	IA	Tumor limited to endometrium or invades less than one-half of the myometrium
T1b	IB	Tumor invades one-half or more of the myometrium
T2	II	Tumor invades stromal connective tissue of the cervix but does not extend beyond uterus†
T3a	IIIA	Tumor involves serosa and/or adnexa (direct extension or metastasis)
T3b	IIIB	Vaginal involvement (direct extension or metastasis) or parametrial involvement
T4	IVA	Tumor invades bladder mucosa and/or bowel mucosa (bullous edema is not sufficient to classify a tumor as T4)

*FIGO staging no longer includes stage 0 (Tis)
†Endocervical glandular involvement only should be considered as stage I and not stage II

TNM Category	FIGO Stage	Regional Lymph Nodes (N)
NX		Regional lymph nodes cannot be assessed
N0		No regional lymph node metastasis
N1	IIIC1	Regional lymph node metastasis to pelvic lymph nodes
N2	IIIC2	Regional lymph node metastasis to para-aortic lymph nodes, with or without positive pelvic lymph nodes

TNM Category	FIGO Stage	Distant Metastasis (M)
M0		No distant metastasis (no pathologic M0; use clinical M to complete stage group)
MI	IVB	Distant metastasis (includes metastasis to inguinal lymph nodes intraperitoneal disease, or lung, liver, or bone. It excludes metastasis to paraaortic lymph nodes, vagina, pelvic serosa, or adnexa)

IVa	19.9
IVb	17.2

Expert Opinion

Over the past decade there has been considerable evolution in the management of endometrial cancer. Fortunately, the large majority of patients present with early stage disease, and in these patients surgical resection are undertaken with curative intent. Recent reports have questioned the routine use of postoperative external beam radiation therapy in patients with an intermediate risk of recurrence, and a definitive answer to the role of radiation requires further investigation

However, it is the place of cytotoxic chemotherapy in the treatment of advanced, metastatic, and recurrent endometrial cancer that has undergone the greatest change. Once considered a relatively *chemoresistant* malignancy, it is now recognized that objective responses can be observed in ≥50% of patients with measurable disease[1,2] following treatment with several combination chemotherapy regimens including:

- Cisplatin + doxorubicin
- Cisplatin + doxorubicin + paclitaxel
- Paclitaxel + carboplatin

A number of single agents have documented activity (>15–20% objective response rates) in this malignancy including:

- Paclitaxel
- Doxorubicin
- Topotecan
- Cisplatin
- Carboplatin

Unfortunately, because of the relative rarity of metastatic endometrial cancer, there have been no phase III trials directly comparing the utility of these individual drugs that might help guide routine clinical management

Older randomized trials had revealed the potential for combination chemotherapy to improve objective response rates and progression-free survival in metastatic or recurrent endometrial cancer. The Gynecologic Oncology Group (GOG) 177 trial established doxorubicin + cisplatin followed by paclitaxel (TAP) as the standard for systemic treatment of stage III-IV and recurrent endometrial cancer.[1] However, TAP was associated with substantially more toxicity compared than the comparator arm, doxorubicin + cisplatin (AP). G2/3 neurotoxicity in 39% of patients who received TAP compared with 5% of those given AP, and 24% of patients who received TAP discontinued treatment because of toxicities compared with 9% of patients who received AP. As a result, TAP often was not utilized

An earlier report suggested the activity of a paclitaxel + carboplatin (TC) combination without doxorubicin might be similar to TAP but with less toxicity.[2,3] The TC combination had a high objective response rate in endometrial cancer and a relatively favorable side-effect profile. These results provided the rationale for GOG 209, in which TAP and TC were compared in 1300 women with advanced or recurrent endometrial cancer. Patients were randomly assigned to receive either:

- TAP: Doxorubicin 45 mg/m² + cisplatin 50 mg/m² (day 1), followed by paclitaxel 160 mg/m² (day 2) every 21 days with hematopoietic growth factor support for a maximum of 7 cycles, *or*
- TC: Paclitaxel 175 mg/m² + carboplatin AUC = 6 mg/mL/min (day 1) every 21 days for a maximum of 7 cycles
  - Paclitaxel 135 mg/m² and carboplatin AUC = 5 mg/mL/min were given to women with a history of pelvic/spine irradiation

Designed as a noninferiority trial, the study had 2 primary objectives:

1. Determine whether TC was therapeutically equivalent (noninferior) to TAP with respect to overall survival
2. Determine whether TC has a more favorable toxicity profile

A test for homogeneity suggested a consistent effect of treatment with TC across all prespecified subgroups. At interim analysis the authors concluded: "TC is not inferior to TAP in terms of PFS and OS. . . .Overall, the toxicity profile favors TC. Thus, TC as prescribed in this study is an acceptable backbone for further trials in combination with 'targeted' therapies."

GOG 209 Interim Analysis

Miller D et al. Randomized phase III noninferiority trial of first-line chemotherapy for metastatic or recurrent endometrial carcinoma: a Gynecologic Oncology Group study [abstract]. Gynecol Oncol 2012;125:771

	TAP	TC	
	Interim Efficacy Analysis		
PFS	14 months	14 months	HR = 1.03
OS	38 months	32 months	HR = 1.01

(*continued*)

(*continued*)

Expert Opinion (*continued*)

GOG 209 Interim Analysis (*continued*)

Safety/Tolerability			
Discontinued therapy for toxicity*	17.6%	11.9%	
Neutropenia and fever	7%	6%	P = 0.01
G1 sensory neuropathy	26%	19%	*P* <0.01
G3/4 thrombocytopenia	22.8%	12.8%	*P* <0.001
G3/4 neutropenia	**52.1%**	**79.7%**	***P* <0.001**
G3/4 other hematologic	30.6%	21.2%	*P* <0.001
G3/4 nausea	8.9%	5.6%	*P* = 0.024
G3/4 vomiting	7.0%	3.5%	*P* = 0.006
G3/4 diarrhea	5.7%	2.0%	*P* <0.001
G3/4 stomatitis	1.3%	0.2%	*P* = 0.019
G3/4 creatinine elevation	1.9%	0.6%	*P* = 0.044

TAP = Doxorubicin + cisplatin, followed by paclitaxel with growth factor support.
TC = paclitaxel + carboplatin
*About two-thirds of patients in each group completed 7 planned cycles, and another 10% completed 6 cycles. The most common reason for discontinuation was completion of protocol specified therapy

It should also be noted that a combination chemotherapy regimen (cisplatin + doxorubicin) has been demonstrated in a phase III trial to improve survival compared to whole abdominal radiotherapy when employed as initial treatment following surgical cytoreduction in women with stage III and IV (maximum 2-cm residual disease) endometrial cancer.[4] Based on existing data, many clinicians currently elect to employ 4–6 cycles of systemic chemotherapy, followed by local pelvic radiation in women whose major disease manifestations are principally confined to the pelvic region. The intent of the radiation is to reduce the risk of disease local recurrence in this specific clinical setting. Future randomized trials will hopefully define the utility of a combined chemotherapy-plus-radiotherapy approach in advanced and metastatic endometrial cancer

Certain subpopulations of endometrial cancer have long been known to be responsive to therapy with progesterone.[5] Clinical features that would predict for a patient who may respond to this treatment option include:

1. Low-grade cancer (grade 1)
2. Evidence of progesterone receptors within the primary tumor specimen
3. Long disease-free interval (eg, >1–2 years) between the diagnosis of endometrial cancer and documented disease recurrence
4. Nonvisceral metastatic disease

Perhaps the single most important factor to consider in this setting is tumor grade. Patients with high-grade endometrial cancers are unlikely to respond to hormonal manipulation. Conversely, it may be quite reasonable to initially attempt to treat a patient with a low-grade metastatic endometrial cancer with progesterone before administering chemotherapy

Summary:

1. Primary treatment for localized (stages I, II) endometrial cancer is surgery. In appropriately selected patients, postoperative radiation is delivered to reduce the risk of local relapse. For patients unable to undergo surgery (eg, significant preexisting cardiac dysfunction), external beam radiation therapy may substitute as the primary treatment modality
2. In stage III, stage IV, or recurrent endometrial cancer, the current "standard-of-care" should be considered combination chemotherapy following an attempt at optimal surgical resection (principally in the stage III setting). The regimen-of-choice remains to be defined, but options include cisplatin + doxorubicin + paclitaxel, carboplatin + paclitaxel, or cisplatin + doxorubicin
3. Patients unable to receive combination chemotherapy (eg, secondary to clinically relevant preexisting comorbidity) may be treated with one of several previously noted cytotoxic agents with known biological activity in metastatic endometrial cancer
4. In carefully selected patients (criteria described above), prior to the delivery of cytotoxic chemotherapy, treatment with a progesterone agent may reasonably be attempted

REGIMEN FOR ADVANCED OR RECURRENT ENDOMETRIAL CARCINOMA

DOXORUBICIN + CISPLATIN (AC)

Randall ME et al. J Clin Oncol 2006;24:36–44

Prehydration for cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS) by intravenous infusion over 2 hours
Note: Encourage patients to increase oral intake of non-alcoholic fluids, and provide electrolyte replacement as needed (potassium, magnesium, sodium)

Doxorubicin 60 mg/m²; administer by slow intravenous injection over 3–5 minutes on day 1, every 21 days (total dosage/cycle = 60 mg/m²)
- Maximum allowable total cumulative lifetime doxorubicin dosage = 420 mg/m²; that is, no more than 7 repeated treatment cycles
- Doxorubicin may be given during hydration for cisplatin

Cisplatin 50 mg/m²; administer intravenously in 250 mL 0.9% NS over 1 hour after doxorubicin on day 1, every 21 days (total dosage per cycle = 50 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential: ***HIGH. Potential for delayed symptoms***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event*	Dose Modification
Doxorubicin 60 mg/m² *and* ANC <1500/mm³ *or* platelet count <100,000/mm³	Reduce doxorubicin dosage to 45 mg/m²†
Doxorubicin 45 mg/m² *and* ANC <1500/mm³ *or* platelet count <100,000/mm³	Reduce doxorubicin dosage to 30 mg/m²†
Doxorubicin 30 mg/m² *and* ANC <1500/mm³ *or* platelet count <100,000/mm³	Reduce doxorubicin dosage to 15 mg/m²†
Doxorubicin 15 mg/m² *and* ANC <1500/mm³ *or* platelet count <100,000/mm³	Discontinue doxorubicin
Treatment interruption caused by myelosuppression exceeding 6 weeks	Discontinue doxorubicin
Decline in cardiac ejection fraction of 20% from baseline, or development of congestive heart failure or other life-threatening cardiac problems	Discontinue doxorubicin; continue cisplatin
Serum creatinine ≥2.0 mg/dL (≥177 μmol/L)	Hold cisplatin

*Consider growth factor support for myelosuppression
†Reinstitute dose if myelosuppression resolves

Patient Population Studied

A study of 422 women with stages III or IV endometrial carcinoma with a maximum of 2 cm of postoperative residual disease who were randomly allocated to receive whole abdominal radiation or doxorubicin and cisplatin

Efficacy (N = 194)

Initial Site of Recurrence	No (%)

Reason for Treatment Discontinuation (N = 194)*

	N	Percent
Completed treatment	123	63.4
Progression	18	9.3
Patient refusal	14	7.2
Toxicity	33	17.0
Death	4	2.1
Other	2	1.0

*Based on 7 cycles of doxorubicin + cisplatin followed by 1 cycle of cisplatin alone

Therapy Monitoring

1. Physical examination, CBC and differential count, and serum creatinine before each chemotherapy cycle
2. Evaluation of ejection fraction immediately before cycle 6 (or earlier, if clinically indicated)
3. Efficacy assessment every 2 to 3 cycles

REGIMEN FOR ADVANCED OR RECURRENT ENDOMETRIAL CARCINOMA

PACLITAXEL + CARBOPLATIN (TC)

Sorbe B et al. Int J Gynecol Cancer 2008;18:803–808

Premedication for paclitaxel:
Dexamethasone 20 mg per dose; administer orally or intravenously in 10–50 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) for 2 doses, 12–14 hours and 6–7 hours before starting paclitaxel

Diphenhydramine 50 mg, by intravenous injection 30 minutes before starting paclitaxel

Ranitidine 50 mg; administer intravenously over 30–60 minutes, 30 minutes before starting paclitaxel

Paclitaxel 175 mg/m²; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a solution with concentration within the range 0.3–1.2 mg/mL over 3 hours on day 1 every 3 weeks (total dosage/cycle = 175 mg/m²)

Carboplatin* AUC = 5 mg/mL • min; administer intravenously in 50–150 mL D5W over 60 minutes, on day 1, every 3 weeks (total dosage/cycle calculated to produce an AUC = 6 mg/mL • min) (see equation below)

*Carboplatin dose is based on Calvert et al's formula to achieve a target area under the plasma concentration versus time curve (AUC) [AUC units = mg/mL • min]

$$\text{Total carboplatin dose (mg)} = (\text{target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be calculated from the equation of Cockcroft and Gault:

$$\text{For males, Clcr} = \frac{(140 \pm \text{age [years]}) \times \text{body weight [kg]}}{72 \times (\text{serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times \text{body weight [kg]}}{72 \times (\text{serum creatinine [mg/dL]})} \times 0.85$$

Note: On October 8, 2010, the U.S. Food and Drug Administration (FDA) identified a potential safety issue with carboplatin dosing based on recent changes in the measurement of serum creatinine. By the end of 2010, all clinical laboratories in the USA will use the standardized Isotope Dilution Mass Spectrometry (IDMS) method to measure serum creatinine, which could result in an overestimation of the GFR in some patients with normal renal function. A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula could exceed an expected exposure (AUC) and result in increased drug-related toxicity

Provided actual GFR measurements are made to assess renal function, carboplatin can be safely dosed according to the Calvert formula described in product labeling

If GFR (or creatinine clearance) is estimated based on serum creatinine measurements by the IDMS method, the FDA recommended for patients with normal renal function capping an estimated GFR at 125 mL/min for any targeted AUC value. No greater estimated GFR values should be used

U.S. FDA. Carboplatin dosing. [online] May 23, 2013. Available from: http://www.fda.gov/AboutFDA/CentersOffices/OfficeofMedicalProductsandTobacco/CDER/ucm228974.htm [accessed February 26, 2014]

(*continued*)

Patient Population Studied

A prospective, phase II, multicenter study evaluating carboplatin and paclitaxel in the treatment of patients with primary advanced or recurrent endometrial carcinoma. Sixty-six patients were enrolled: 18 with primary advanced tumors and 48 with recurrences. All histologic types and tumor grades were allowed

Efficacy (N = 66)

Complete response	29%
Partial response	38%
Median progression-free survival	14 months
3-Year progression-free survival	18.2%
5-Year progression-free survival	12.5%
Median overall survival	26 months
3-Year overall survival	33.3%
5-Year overall survival	20.3%
Primary Advanced Cases (N = 18)	
Complete response	50%
Partial response	33%
Median progression-free survival	14 months
Median survival	19 months
Recurrent Cases (N = 48)	
Complete response	21%
Partial response	40%
Median progression-free survival	14 months
Median survival	27 months

Assessment: Clinical examination, gynecologic examination under anesthesia, transvaginal and transabdominal ultrasound, and computerized tomography were used in the evaluation of the tumor status. WHO response criteria were used to evaluate tumor

Note: Prior radiotherapy was not associated with response rate (P = 0.565), PFS rate (P = 0.420), or OS rate (P = 0.637) in this study

(*continued*)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential: **HIGH**. **Potential for delayed symptoms***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Toxicity (N = 66)

Adverse Events	% of Patients			
	Grade (%)			
	1	2	3	4
Hematologic				
Anemia	40.9	43.9	—	—
Neutropenia*	25.8	15.2	4.5	3.0
Thrombocytopenia	47	3.0	1.5	3.0
Nonhematologic				
Infection/fever	—	—	—	—
Renal	42.2	—	—	—
Cardiac	7.6	—	—	—
Neurologic†	37.9	31.8	13.6	—
Nausea/vomiting	39.4	16.7	4.5	1.5

*In 6 cases (9.1%), chemotherapy was stopped because of this toxicity

†In 13 cases (19.7%), therapy was prematurely stopped because of this toxicity

In 2 cases, allergic reactions prohibited completion of therapy

NCI CTC, National Cancer Institute (USA) Common Toxicity Criteria, version 2.0. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]

Therapy Monitoring

1. Physical examination, CBC and serum creatinine before each chemotherapy cycle
2. Efficacy assessment every 2–3 cycles

Treatment Modifications

Adverse Event	Dose Modification
At start of a cycle ANC ≤1000/mm^3 *or* platelet count ≤100,000/mm^3	Delay start of cycle up to 2 weeks until ANC >1000/mm^3 *and* platelet count >100,000/mm^3
ANC ≤1000/mm^3 *or* platelet count ≤100,000/mm^3 for more than 2 weeks but less than 3 weeks after scheduled start of next cycle	Reduce paclitaxel and carboplatin dosages by 20% (140 mg/m^2 and AUC = 4, respectively)
At start of a cycle ANC ≤1000/mm^3 *or* platelet count ≤100,000/mm^3 despite dose reduction	Delay start of cycle up to 2 weeks until ANC >1000/mm^3 *and* platelet count >100,000/mm^3, then administer filgrastim or pegfilgrastim after completing chemotherapy without changing chemotherapy dosages
Serum creatinine >2 mg/dL (>177 µmol/L) or G ≥3 peripheral neuropathy	Delay start of cycle up to 2 weeks; if serum creatinine does not decrease to ≤2 mg/dL (≤177 µmol/L) or G peripheral neuropathy within that 2-week period, discontinue therapy

REGIMEN

PACLITAXEL, DOXORUBICIN, CISPLATIN (TAP)

Fleming GF et al. J Clin Oncol 2004;22:2159–2166

Prehydration for cisplatin: 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously over at least 2 hours

Notes: Encourage patients to increase oral intake of non-alcoholic fluids, and provide electrolyte replacement as needed (potassium, magnesium, sodium)

Doxorubicin may be administered during hydration for cisplatin

Doxorubicin 45 mg/m^2 (maximum single dose = 90 mg); administer by slow intravenous injection over 3–5 minutes on day 1 every 21 days (total dosage/cycle = 45 mg/m^2; maximum dose/cycle = 90 mg)

Followed immediately afterward by:
Cisplatin 50 mg/m^2 (maximum single dose = 100 mg); administer intravenously in 250 mL 0.9% sodium chloride injection (0.9% NS) over 1 hour on day 1 after doxorubicin administration, every 21 days (total dosage/cycle = 50 mg/m^2; maximum dose/cycle = 100 mg)
Paclitaxel 160 mg/m^2 (maximum single dose = 320 mg); administer by intravenous infusion in a volume of 0.9% NS or 5% dextrose injection sufficient to produce a concentration within the range of 0.3–1.2 mg/mL over 3 hours on day 2, every 21 days (total dosage/cycle = 160 mg/m^2; maximum dose/cycle = 320 mg)

Notes:
- No modifications to starting drug doses based on age or history of pelvic radiation therapy
- Women with a BSA >2 m^2 received treatment as if their BSA was equal to only 2 m^2

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1: ***HIGH****. Potential for delayed symptoms*
Emetogenic potential on day 2: ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL, by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- For daily filgrastim, continue use until ANC ≥10,000/mm^3 on 2 consecutive daily measurements

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
G3/4 thrombocytopenia or G4 ANC	Reduce cisplatin and paclitaxel dosages by 20%
G3 peripheral neuropathy	Hold therapy until neuropathy G ≤1. Restart therapy with paclitaxel and cisplatin dosages reduced by 20%
Recurrent G3 neurologic toxicity	Discontinue therapy
LVEF <45% or a fall in LVEF ≥20% from baseline	Discontinue therapy
Toxicity-related delay in administration of >3 weeks	Discontinue therapy

Patient Population Studied

Chemotherapy-naïve women with histologically documented measurable stage III or stage IV or recurrent endometrial carcinoma of any cell type plus a GOG performance status of 0–2

Efficacy (N = 134)

Complete response	22%
Partial response	35%
Median progression-free survival	8.3 months
Median overall survival	15.3 months

Toxicity (N = 131)

	% of Patients		
	G2	G3	G4
Nonhematologic			
Auditory	7	0	0
LVEF	10	2	0
Pulmonary	5	2	0
DVT	1	6	0
Constitutional	31	10	2
Vomiting	23	10	2
Diarrhea	8	8	1
Mucositis or stomatitis	7	1	0
Genitourinary/renal	3	3	1
Metabolic	8	12	7
Sensory neuropathy	27	12	0
Hematologic			
Neutropenia	13	23	36
Thrombocytopenia	21	20	2

Therapy Monitoring

1. *Every cycle:* Pelvic examination and serum electrolytes, calcium, magnesium, BUN, and creatinine
2. *Every other cycle:* Tumor measurements by radiologic examination
3. *Every third cycle:* Left ventricular ejection fraction

11. Esophageal Cancer

Jimmy Hwang, MD and John Marshall, MD

Epidemiology

Incidence: 18,170 (male: 14,660; female: 3,510. Estimated new cases for 2014 in the United States)
7.7 per 100,000 male, 1.8 per 100,000 female
Deaths: Estimated 15,450 in 2014 (male: 12,450; female: 3,000)
Median age at diagnosis*: Squamous cell esophageal carcinoma: 53.4 years
Adenocarcinoma of the esophagus: 62.6 years
Male to female ratio: 3:1 for squamous cell carcinoma and 7:1 for adenocarcinoma
Stage at presentation: Locoregional disease: 50%
Distant metastasis: 50%

*Kelsen DP et al. Textbook of Gastrointestinal Oncology: Principles and Practice. Lippincott Williams & Williams, 2001
Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Pathology

Upper to midthoracic esophagus:	Predominantly squamous cell carcinoma
Distal esophagus and GE junction:	Predominantly adenocarcinoma
Other rare pathology:	Basaloid-squamous carcinoma (1.9%)* or small cell carcinomas

Especially in white men, the incidence of adenocarcinoma of the GE junction has risen significantly in the United States, whereas that of squamous cell carcinoma has slightly decreased. In the 1960s, squamous cell cancer accounted for 90% or more of esophageal cancer.† Data from 1996 suggested that they occur with equal frequency, and in 2004 the trend has changed further so that adenocarcinoma now accounts for at least 75% of esophageal cancers. This is thought to be related to increase in body mass index and Barrett esophagus

*Abe K et al. Am J Surg Pathol 1996;20:453–461
†Daly JM et al. National Cancer Data Base Report on Esophageal Carcinoma. Cancer 1996;78:1820–1828

Work-up

1. H&P, esophagogastroduodenoscopy, CBC, serum electrolytes, BUN, creatinine, LFTs and mineral panel, PET scan ± CT scan, of chest and abdomen
2. Endoscopic ultrasound is highly recommended if there is no evidence of distant metastases, with FNA if indicated
3. For locoregional cancer at or above the carina, a bronchoscopy must be considered
4. In selected patients with local-regional GE junction cancer, a laparoscopic staging of the peritoneal cavity may be warranted
5. In patients with locoregional cancer, PET/CT scan is strongly recommended. Suspicious metastatic cancer should be confirmed
6. In addition, for patients with locoregional cancer (stages I–III), a multidisciplinary evaluation is required, including nutritional assessment. The need for supplementation depends on the severity of dysphagia, and the overall nutritional status (>10% weight loss). Enteral nutritional support is preferred (PEG is avoided if surgery is a consideration)

Staging

Primary Tumor (T)

TX	Primary tumor cannot be assessed
T0	No evidence of primary tumor
Tis	High-grade dysplasia
T1	Tumor invades lamina propria or submucosa
T2	Tumor invades muscularis propria
T3	Tumor invades adventitia
T4a	Resectable cancer invades adjacent structures such as pleura, pericardium, diaphragm
T4b	Unresectable cancer invades adjacent structures such as aorta, vertebral body, trachea

Regional Lymph Nodes (N) (Any periesophageal lymph node from cervical nodes to celiac nodes)

NX	Regional lymph nodes cannot be assessed
N0	No regional lymph node metastases
N1	1–2 positive regional lymph nodes
N2	3–6 positive regional lymph nodes
N3	≥7 positive regional lymph nodes

Metastases

M0	No distant metastases
M1	Distant metastases

Grade

1	Well-differentiated
2	Moderately differentiated
3	Poorly differentiated
4	Undifferentiated

(*continued*)

Staging (*continued*)

Cancer Location

Upper thoracic	20–25 cm from incisors
Middle thoracic	>25–30 cm from incisors
Lower thoracic	>30–40 cm from incisors
Esophagogastric junction	Includes cancers whose epicenter is in the distal thoracic esophagus, esophagogastric junction, or within the proximal 5 cm of the stomach (cardia) that extend into the esophagogastric junction or distal thoracic esophagus (Siewert III). These stomach cancers are stage grouped similarly to adenocarcinoma of the esophagus

Staging Groupings for Esophageal Adenocarcinoma

Expert Opinion

Management of localized/locally advanced disease:
A distinction must be made between the treatment of localized/locally advanced *esophageal squamous cell carcinoma* and *esophageal adenocarcinoma*

Squamous cell carcinoma:
- Treatment should be surgery or radiation with concurrent chemotherapy
- The role of preoperative or postoperative radiation with concurrent chemotherapy is unclear

Adenocarcinoma:
- Treatment should be multimodality with surgery
  - Preoperative radiation with concurrent chemotherapy, followed by surgery
  - Perioperative chemotherapy (MAGIC: Cunningham D et al. N Engl J Med 2006;355:11–20)
  - Postoperative chemotherapy and radiation (INT 116: Macdonald JS et al. N Engl J Med 2001;345:725–730)

Chemotherapy:
There is no single standard chemotherapy for esophageal cancer
Squamous cell carcinoma:
- No single standard chemotherapy regimen

Adenocarcinoma:
- Tend to be grouped with gastric and gastroesophageal adenocarcinomas
  - Combination chemotherapy with platinum and fluoropyrimidine is the community standard, as defined by the regimen that is most commonly used. In patients with good functional status, a third drug is typically added. Options as that third drug may include trastuzumab (in HER-2 amplified disease); epirubicin (especially in the United Kingdom), and docetaxel
- **Docetaxel, cisplatin, and infusional fluorouracil (DCF)**
  - The "reference standard," but too toxic in the general population to be considered a "community standard"
  - Variations of DCF are under evaluation, but their efficacy compared to DCF is unclear
- The role of **"targeted therapies"** is uncertain
  - **Trastuzumab:** The ToGA study (Van Cutsem et al. J Clin Oncol 2009;27 Suppl:18s [abstract LBA4509], and Bang Y-J et al. Lancet 2010;376:687–697) evaluated the potential role of trastuzumab in *HER-2–positive* gastroesophageal adenocarcinomas. Although the addition of trastuzumab to cisplatin and fluoropyrimidine combinations improved survival, it is possible that the addition of other "third drugs," such as epirubicin or docetaxel, to a platinum and fluoropyrimidine backbone could produce a similar survival benefit in this patient population
  - **EGFR TKIs:** The differences in response rates to EGFR TKIs between esophageal (11%; Ferry DR et al. Clin Cancer Res 2007;13:5869–5875), gastroesophageal junction (9%; Dragovich T et al. J Clin Oncol 2006;24:4922–4927) and gastric adenocarcinomas (zero; Dragovich T et al. J Clin Oncol 2006;24:4922–4927) emphasizes potential differences among these disease locations. In addition, there may be a difference in disease control by histology (Janmaat ML et al. J Clin Oncol 2006;24:1612–1619). It is difficult to project survival in patients with metastatic disease, as available studies allowed both histologies, and many include gastric, gastroesophageal cancers

Palliative approaches include:
- Stents
- Photodynamic therapy
- Radiation
- Chemotherapy

Locoregional cancer defined as:
- Potentially resectable, or
- Unresectable, which includes T4 lesion, supraclavicular adenopathy, and celiac nodal metastasis in patients with upper or mid-thoracic esophageal cancer

REGIMEN

FLUOROURACIL + CISPLATIN + RADIATION

Herskovic A et al. N Engl J Med 1992;326:1593–1598
Minsky BD et al. J Clin Oncol 2002;20:1167–1174 (INT 0123; RTOG 94-05)

Hydration before cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously at ≥100 mL/hour before and after cisplatin administration. Also encourage patients to increase oral intake of non-alcoholic fluids. Monitor serum electrolytes and replace as needed (potassium, magnesium, sodium)
Mannitol diuresis: May be given to patients who have received adequate hydration. A dose of 12.5–25 g mannitol can be administered by intravenous injection before cisplatin or prepared as an admixture in the same container as cisplatin. Continued intravenous hydration is essential In an inpatient or "day hospital" setting, additional mannitol can be administered in the form of an infusion: 100–200 mL 20% mannitol injection administered intravenously over 4–8 hours. This can be done either during or immediately after cisplatin, but requires maintenance of adequate intravenous fluid input during and for hours after mannitol administration

Cisplatin 75 mg/m²; administer intravenously in 50–250 mL of 0.9% NS at a rate of 1 mg/minute, on day 1 during weeks 1, 5, 9, and 13 (total dosage per 28-day cycle [1 dose] = 75 mg/m²)
Fluorouracil 1000 mg/m² per day; administer by continuous intravenous infusion in 500–1000 mL 0.9% NS or 5% dextrose injection over 24 hours for 4 consecutive days on days 1–4 during weeks 1, 5, 9, and 13 (total dosage per 28-day cycle [4 doses] = 4000 mg/m²)
Radiation 1.8 Gy/day for 5 days/week
Starts concurrently with chemotherapy
Planned cumulative dose = 50.4 Gy (duration of planned treatment is 5 weeks, 3 days)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential on days with cisplatin is **HIGH**. Potential for delayed symptoms*
*Emetogenic potential on days with fluorouracil + radiation and radiation alone is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A clinical trial of 236 patients with AJCC clinical stage T1–4 N0–1 M0 primary squamous cell or adenocarcinoma of the cervical, mid, or distal esophagus selected for a nonsurgical (definitive chemoradiation) approach. Patients received combined modality therapy consisting of chemotherapy with concurrent radiation therapy. Patients were randomized to receive either 64.8 Gy or 50.4 Gy. The higher radiation dose did not increase survival or local/regional control

Notes

1. Doses for this regimen and other data based on Minsky et al
2. Patients who cannot tolerate cisplatin are treated with carboplatin (AUC = 5 mg/mL • min)

Therapy Monitoring

1. *Weekly:* H&P
2. *Before each cycle:* CBC with differential and serum electrolytes, BUN, creatinine, and magnesium
3. *Response evaluation:* 5–6 weeks after completion of therapy

Efficacy (N = 109)

Median duration of response	4.2 months
Alive/no failure	25%
Locoregional failure at 2 years	52%
Distant failure	16%
Treatment-related death	2%

Toxicity (N = 109/99)

Grade	% Acute Toxicities	% Late Toxicities
1	1	20
2	26	22
3	43	24
4	26	13
5	2	0

Maximum toxicity per patient based on RTOG morbidity scale. N = 109 for acute toxicity and 99 for late toxicity

Treatment Modifications

Adverse Event	Dose Modification
G3/4 toxicity	A minimum 1-week treatment delay. Resume when toxicity is grade ≤2. Continue radiation if toxicity is unrelated to radiation therapy (RT)
If during weeks 1, 5, 9, or 13, day 1: ANC ≥2000/mm³ but <3000/mm³ *or* platelets ≥75,000/mm³ but <100,000/mm³	Reduce cisplatin and fluorouracil dosages by 25%; continue RT
If during weeks 1, 5, 9, or 13, day 1: ANC <2000/mm³ *or* platelets <75,000/mm³	Hold chemotherapy and RT until toxicity resolves, then reduce cisplatin and fluorouracil dosages by 50%
ANC <1000/mm³ *or* platelets ≤75,000/mm³ between cycles on days chemotherapy is not administered	Reduce cisplatin and fluorouracil dosages by 50%
Serum creatinine = 1.6–2.0 mg/dL (141–177 µmol/L)	Reduce cisplatin dosage by 50%
Creatinine >2.0 mg/dL (>177 µmol/L	Discontinue cisplatin; continue RT
G3/4 stomatitis during fluorouracil treatment	Do not administer additional fluorouracil during that cycle. Reduce all subsequent fluorouracil dosages by 25%
G3/4 stomatitis on days chemotherapy not administered	Reduce all subsequent fluorouracil dosages by 25%
G ≥3 RT-related toxicity	Hold RT, and resume when toxicity is G ≤2

REGIMEN

WEEKLY IRINOTECAN + CISPLATIN + CONCURRENT RADIOTHERAPY

Ilson DH et al. J Clin Oncol 2003;21:2926–2932
Enzinger PC et al. Proc Am Soc Clin Oncol 2006;24:194s [abstract 4064]

Weeks 1 to 5: Induction chemotherapy therapy once weekly on weeks 1, 2, 4, and 5; rest on week 3

Hydration with cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose/0.45% sodium chloride injection (D5W/0.45% NS); administer intravenously over 2–4 hours as tolerated before starting cisplatin administration. Also, encourage patients to increase oral intake of non-alcoholic fluids. Monitor serum electrolytes and replace as needed (potassium, magnesium, sodium)

Cisplatin 30 mg/m² per dose; administer intravenously in 50–500 mL 0.9% NS over 30 minutes for 4 doses on weeks 1, 2, 4, and 5 (total dosage during induction = 120 mg/m²), *followed by:*
Irinotecan 65 mg/m² per dose; administer intravenously in 250 mL 0.9% NS or 5% dextrose injection (D5W) over 30 minutes for 4 doses after cisplatin, during weeks 1, 2, 4, and 5 (total dosage during induction = 260 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***HIGH***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome
Atropine sulfate 0.25–1 mg administered subcutaneously or intravenously if abdominal cramping or diarrhea develop during or within 1 hour after irinotecan administration
- If symptoms are severe, add as primary prophylaxis at least 30 minutes before irinotecan during subsequent cycles
- For irinotecan, acute cholinergic syndrome is characterized by abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

Weeks 6 and 7: Two-week rest period
Weeks 8 to 14: Chemoradiotherapy:
Chemotherapy—weekly each Monday of weeks 8, 9, 11, and 12
Radiation therapy—1.8 Gy daily; total dose of 50.4 Gy

Hydration with cisplatin: ≥1000 mL 0.9% NS or D5W/0.45% NS; administer intravenously over 2–4 hours as tolerated before starting cisplatin administration. Also, encourage patients to increase oral intake of non-alcoholic fluids. Monitor serum electrolytes and replace as needed (potassium, magnesium, sodium)
Cisplatin 30 mg/m² per dose; administer intravenously in 50–500 mL 0.9% NS over 30 minutes for 4 doses during weeks 8, 9, 11, and 12 (total dosage during induction = 120 mg/m²), *followed by:*
Irinotecan 65 mg/m² per dose; administer intravenously in 250 mL 0.9% NS or D5W over 30 minutes for 4 doses after cisplatin, during weeks 8, 9, 11, and 12 (total dosage during induction = 260 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***HIGH***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

(*continued*)

(continued)

Thromboprophylaxis
Low-dose **warfarin** 1 mg/day; administer orally beginning 3 days before the initiation of combined chemoradiotherapy and continuing until 4 weeks after completion of combined chemoradiotherapy

Acute cholinergic syndrome
Atropine sulfate 0.25–1 mg subcutaneously if abdominal cramping or diarrhea develop within 1 hour after irinotecan infusion
- If symptoms are severe, add as primary prophylaxis during subsequent cycles
- For irinotecan, acute cholinergic syndrome is characterized by abdominal cramps, diarrhea, diaphoresis, hypotension, bradycardia, rhinitis, increased salivation, visual disturbances, and lacrimation

Radiation therapy (notes):
- Delivered with megavoltage equipment (15 MV) using a multiple-field technique. Patients treated 5 days per week at 1.8 Gy/day to a total dose of 50.4 Gy
- All fields treated each day
- Portal films of at least 2 fields obtained each week or more often if needed
- Treatment delivered to 4 fields (anterior-posterior, posterior-anterior, and opposed laterals) such that dose does not vary by more than 5% over the entire target volume
- Dose prescribed to the isodose line to cover the volume at risk
- Use lung inhomogeneity corrections
- Superior and inferior borders of the radiation field should be 5 cm beyond the primary tumor
- Lateral, anterior, and posterior borders of the field should be ≥2 cm beyond the borders of the primary tumor
- Tumor size defined by EUS, barium swallow or CT scan (whichever is larger)
- Primary and regional lymph nodes included in radiation field

Week 18: Surgery after 4-week rest period

Treatment Modifications

Adverse Event	Dose Modifications*
During Induction Chemotherapy	
WBC <2000/mm³, ANC <1000/mm³, platelet count <75,000/mm³, serum creatinine >1.6 mg/dL (>141 μmol/L), or G3/4 diarrheal toxicity	Delay chemotherapy until WBC ≥2000/mm³, ANC ≥1000/mm³, platelet count ≥75,000/mm³, serum creatinine ≤1.6 mg/dL (≤141 μmol/L), and diarrheal toxicity G ≤2
If the fourth treatment (week 5) of induction therapy is delayed more than 1 week because of hematologic or diarrheal toxicity	Do not administer fourth treatment (week 5) of induction therapy (shortened to 3 treatment weeks); proceed to combined chemoradiotherapy after a minimum 2-week rest period
WBC <2000/mm³, ANC <1000/mm³, platelet count <75,000/mm³, serum creatinine >1.6 mg/dL (>141 μmol/L), or G3/4 diarrheal toxicity after the second treatment (week 2)	Reduce irinotecan dosage to 50 mg/m² • dose to permit delivery of a third and final induction course
Serum creatinine >1.6 mg/dL (<141 μmol/L) but ≤2 mg/dL (≤177 μmol/L)	Reduce cisplatin dosage to 15 mg/m² • dose
During Chemoradiotherapy	
Serum creatinine >1.6 mg/dL (>141 μmol/L) but ≤2 mg/dL (≤177 μmol/L)	Reduce cisplatin dosage to 15 mg/m² • dose

Note: Do not reduce irinotecan dosage during combined chemoradiotherapy

Patient Population Studied

Squamous cell carcinoma, adenocarcinoma, or poorly differentiated non–small cell carcinoma of the esophagus, which was locally advanced. Staged by computed tomography (CT) scan and endoscopic ultrasound (EUS). Included clinical stages II to III disease (T_1 N_1 M_0, T_{2-4} N_{0-1} M_0). Patients with T1N0 disease excluded. For tumors of the gastroesophageal junction, at least 50% of the tumor had to involve the distal esophagus

Efficacy* (N = 19)

All Patients	
CCR† or PCR‡	6/19 (32%) (95% confidence interval, 13–55%)§
Median OS	25 months (range: 8.6–35.2 months); 8 (42%) alive and free of disease at a median follow-up of 21 months
Patients with CCR or PCR	4/6 free of disease at a median follow-up of 26.7 months
Patients with viable cancer at surgery	4/10 free of disease at a median follow-up of 19.2 months
Documented recurrent disease	6 patients—3 recurrences of distant disease only; 3 first site of recurrence locoregionally (anastomotic recurrence, n = 1; mediastinal nodal recurrence, n = 2)

Dysphagia at Baseline (N = 16)	
Resolved	10/16 (62%)
Improved	3/16 (19%)
No change or worsening	3/16 (19%)

Surgical Resection Not Undertaken (4/19; 21%)	
Metastatic disease in abdominal lymph nodes outside radiotherapy field	2 (11%)
Clinical complete response (negative posttreatment endoscopy with negative biopsy); 1 durable 34+ months after therapy initiated	2 (11%)
Death of probable locally recurrent disease, with fatal hematemesis, 2 years after initiation of therapy	1 (7%)

Surgical Resection Undertaken (15/19; 79%)	
Complete resections with negative margins	14 (73%)
PCR	4 (21%)
Evidence of down-staging at surgery	11 (58%)

Surgical Complications	
Anastomotic leak	4/15 (27%)
Wound infection	3/15 (20%)
Postoperative death	1/15 (7%) (Protracted postoperative complications including diaphragmatic wound dehiscence)

*Modified WHO
†CCR: Clinical complete response
‡PCR: Pathologic complete response
§Seen at all irinotecan dose levels, including 2 PCR in 3 patients at 40 mg/m² · dose, 2 CCR at 50 mg/m² · dose and 65 mg/m² · dose, and 2 PCR in 6 patients treated at 80 mg/m² · dose

Therapy Monitoring

1. Complete blood counts with differential leukocyte counts at least weekly
2. LFTs, serum BUN, and creatinine before each chemotherapy administration
3. Assessment of response after induction chemotherapy and after chemoradiotherapy

Adverse Event (N = 19)

CTCAE

REGIMEN

OXALIPLATIN + PROTRACTED INFUSION FLUOROURACIL AND EXTERNAL BEAM RADIATION THERAPY (EBRT) PRIOR TO SURGERY

Leichman L et al. Proc Am Soc Clin Oncol 2009;27:205s [abstract 4513]

Neoadjuvant combined modality therapy:
Oxaliplatin 85 mg/m² per dose; administer intravenously in 250–500 mL 5% dextrose injection (D5W) over 2 hours for 3 doses on days 1, 15, and 29 (total dosage/course = 255 mg/m²)
Protracted infusion fluorouracil 180 mg/m² per day; administer by continuous intravenous infusion in 50–1000 mL 0.9% sodium chloride injection (0.9% NS) or D5W over 24 hours for 35 consecutive days, days 8–43 (total dosage/35-day course = 6300 mg/m²)
External beam radiation therapy 180 cGy/day starting day 8, on 5 days/week for 25 fractions, to a total dose 4500 cGy

Esophagectomy:
Two to 4 weeks after completing neoadjuvant combined modality therapy

Adjuvant chemotherapy (optional after recovery from surgery):
Oxaliplatin 85 mg/m² per dose; administer intravenously in 250–500 mL D5W over 2 hours for 3 doses on days 1, 15, and 29 (total dosage/course = 255 mg/m²)
Protracted infusion fluorouracil 180 mg/m² per day; administer by continuous intravenous infusion in 50–1000 mL 0.9% NS or D5W over 24 hours for 35 consecutive days, days 8–43 (total dosage/35-day course = 6300 mg/m²)
Note: Postoperative chemotherapy was not given to all patients; not given to patients with pathologic complete response. In study reported, <50% received postoperative chemotherapy. The investigators recommended completing *all* therapy before surgery

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential on days with oxaliplatin is **MODERATE**, on days with fluorouracil without EBRT is **LOW**, and on days with fluorouracil + EBRT is **LOW–MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Clinical stages II/III esophageal adenocarcinoma, Zubrod PS ≤2 and tumor <2 cm into the gastric cardia

Treatment Modifications

Adverse Event	Dose Modifications*
Inadequate hematologic recovery at time of oxaliplatin administration (absolute neutrophil count <1500/mm³ or platelet count <10,0000/mm³)	Delay therapy 1 week
Persistent G2 or any G3 neuropathy	Reduced oxaliplatin dosage by 25%

Adverse Event (N = 90)

Toxicity Grade (G)	Percent of Patients
Any G3 toxicity	43%
Any G4 toxicity	18%
Any G gastrointestinal toxicity	39%
Any G flu-like/fatigue	22%
Any G pulmonary toxicity	17%
Any G hematologic toxicity	16%
Any G mucositis toxicity	14%
Any G neurologic toxicity	3%
Death due to protocol*	4.5%

*Two a result of neoadjuvant combined modality therapy, two to surgery

Efficacy (N = 90)

Patients undergoing surgery	77 (86%)
Pathologic complete response	30 (33%)
Cancer in situ or T1N0M0	9 (10%)

Therapy Monitoring

1. Complete blood counts with differential leukocyte counts at least weekly
2. LFTs, serum BUN, and creatinine before each chemotherapy administration
3. Assessment of response after neoadjuvant combined modality therapy and after surgery

ADVANCED ESOPHAGEAL *OR* JUNCTIONAL CANCER PRE-OPERATIVE CHEMORADIOTHERAPY REGIMEN

CARBOPLATIN + PACLITAXEL + CONCURRENT RADIOTHERAPY

van Hagen P et al. N Engl J Med 2012;366:2074–2084

Hypersensitivity prophylaxis before paclitaxel:
Dexamethasone 20 mg per dose; administer orally for 2 doses: the first dose between 12 and 14 hours before starting paclitaxel, and a second dose 6–7 hours before starting paclitaxel
• Alternatively, give **Dexamethasone** 10 mg; administer intravenously 30 minutes before starting paclitaxel
Diphenhydramine 50 mg; administer by intravenous injection 30 minutes before starting paclitaxel
Ranitidine 50 mg; administer intravenously in 25–100 mL of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W), over 15–30 minutes, 30–60 minutes before starting paclitaxel
Paclitaxel 50 mg/m^2 per dose; administer intravenously diluted in 0.9% NS or D5W to a concentration within the range 0.3–1.2 mg/mL over 60 minutes before carboplatin for 5 doses on days 1, 8, 15, 22, and 29 (total dosage/course = 250 mg/m^2), *with:*
Carboplatin AUC = 2 mg/mL · min* per dose; administer intravenously diluted in 0.9% NS or D5W to a concentration >0.5 mg/mL over 60 minutes after paclitaxel for 5 doses on days 1, 8, 15, 22, and 29 (total course includes 5 doses each calculated to produce an AUC = 2 mg/mL · min*)

*Carboplatin dose is based on a formula described by Calvert et al. to achieve a target area under the plasma concentration versus time curve (AUC)

$$\text{Total carboplatin dose (mg)} = (\text{target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be estimated from the equation of Cockcroft and Gault, thus:

$$\text{For males, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})} \times 0.85$$

Calvert AH et al. J Clin Oncol 1989;7:1748–1756
Cockcroft DW, Gault MH. Nephron 1976;16:31–41
Jodrell DI et al. J Clin Oncol 1992;10:520–528
Sorensen BT et al. Cancer Chemother Pharmacol 1991;28:397–401

Note: On October 8, 2010, the U.S. Food and Drug Administration (FDA) identified a potential safety issue with carboplatin dosing based on recent changes in the measurement of serum creatinine. By the end of 2010, all clinical laboratories in the United States began using the standardized isotope dilution mass spectrometry (IDMS) method to measure serum creatinine, which could result in an overestimation of the GFR in some patients with normal renal function. A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula could exceed an expected exposure (AUC) and result in increased drug-related toxicity

Provided actual GFR measurements are made to assess renal function, carboplatin can be safely dosed according to the Calvert formula described in product labeling

If GFR (or creatinine clearance) is estimated based on serum creatinine measurements by the IDMS method, the FDA recommends for patients with normal renal function capping an estimated GFR at 125 mL/min for any targeted AUC value. No greater estimated GFR values should be used

U.S. Food and Drug Administration (FDA) Carboplatin dosing. [online] October 8, 2010. Available from: http://www.fda.gov/AboutFDA/CentersOffices/OfficeofMedicalProductsandTobacco/CDER/ucm228974.htm [accessed February 26, 2014]

Radiation Therapy
External beam radiation, using 3D conformal radiation technique

Fractionation Schedule
Administer a total dose of 41.4 Gy in 23 fractions of 1.8 Gy, 5 fractions per week, starting the first day of the first cycle of chemotherapy

Position of the Patient
Supine position. Assess reproducibility by orthogonal laser beams

(*continued*)

(continued)

Definitions of Target Volumes and Critical Structures
Define gross tumor volume (GTV) as the primary tumor and any enlarged regional lymph nodes, and draw on each relevant CT slice. Use available information including physical examination, endoscopy, EUS, and CT-thorax/abdomen to determine the GTV. The planning target volume (PTV) should provide a proximal and distal margin of 4 cm. In case of tumor extension into the stomach, use a distal margin of 3 cm. Provide a 2-cm radial margin around the GTV to include the area of subclinical involvement around the GTV and to compensate for tumor motion and setup variations. Contour both lungs. Contour the heart on all slices; include the infundibulum of the right ventricle and the apex of both atria in its cranial border and exclude the great vessels as much as possible. Define the caudal border as the lowest part of the left ventricle's inferior wall that is distinguishable from the liver. Contour the spinal canal to represent the spinal cord

Simulation Procedure
Prior to the start of the irradiation make a planning CT scan from the cricoid to L1 vertebra with a slice thickness of 5 mm, with the patient in treatment position. Determine the isocenter at the planning CT

Radiation Technique
Use a multiple-field technique. Give treatment with a combination of anterior/posterior, oblique or lateral field. Use customized blocks or a multileaf collimator to shape the treatment fields. Have all patients undergo 3D planning. Use beams-eye-view (BEV) to ensure optimal target volume coverage and optimal normal tissue sparing. Choose the most appropriate technical solutions (eg, beam quality, field arrangement, conformal therapy planning) as long as they comply with ICRU 50/62 safety margins and homogeneity requirements

Normal Tissue Tolerance
Obtain Dose-Volume- Histograms (DVHs) of both lungs, the heart, and spinal cord for all patients. Use DVHs primarily to document normal tissue damage. Use DVHs to help select the most appropriate treatment plan. Minimize the risks for severe pneumonitis for patients by the use of BEV planning and field-shaping (with optimal sparing of both lungs). Do not exceed spinal cord tolerance (50 Gy)

External Beam Equipment
Use megavoltage equipment with photon energies ≥6 MV. Use a multileaf collimator or individually shaped blocks to shape the irradiation portal according to the planning target volume

Dose Specification
Specify the prescription dose at the ICRU 50/62 reference point, which will be the isocenter for most patients. Ensure the daily prescription dose will be 1.8 Gy at the ICRU reference point and ensure the 95% isodose encompasses the entire planning target volume (PTV). Do not exceed the prescription dose by >7% (ICRU 50/62 guidelines) at the maximum to the PTV. Use tissue density inhomogeneity correction

Treatment Verification
Obtain portal images during the first fraction of all fields. On indication repeat portal images

Note: The median time between the end of chemoradiotherapy and surgery was 6.6 weeks (inter quartile range: 5.7 to 7.9)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **HIGH** on days with chemotherapy with potential for delayed symptoms*
*Emetogenic potential with radiation therapy alone is **LOW–MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Dose Modification

Adverse Event	Treatment Modification
WBC <1000/mm³ and/or platelets <50,000/mm³ on days 8, 15, 22, and 29	Delay chemotherapy by 1 week until WBC count is >1000/mm³ and platelet count is >50,000/mm³
Febrile neutropenia (ANC <500/mm³ and fever >38.5°C [>101.3°F])	Hold chemotherapy
Severe bleeding requiring ≥2 platelet transfusions	Hold chemotherapy
Hypersensitivity: Mild symptoms (eg flushing, rash, pruritus)	Complete paclitaxel infusion. Supervise at bedside. No treatment required
Hypersensitivity: Moderate symptoms (eg rash, flushing, mild dyspnea, chest discomfort, mild hypotension)	Stop paclitaxel infusion, give IV antihistamine (clemastine 2 mg or diphenhydramine 50 mg IV, or equivalent antihistamine) and dexamethasone (10 mg IV). After symptoms abate, resume paclitaxel infusion at a rate of 20 mL/hour for 15 minutes, then 50 mL/hour for 15 minutes. Then, if symptoms of hypersensitivity do not recur, at full dose-rate until infusion is completed
Hypersensitivity: Severe symptoms (one or more of the following): respiratory distress requiring treatment, generalized urticaria, angioedema, hypotension requiring therapy	Stop paclitaxel infusion, give IV antihistamine and steroid as above. Add epinephrine or bronchodilators if indicated, discontinue therapy
Creatinine ≤1.5 × the upper limit of normal on the day of retreatment	Continue therapy
Creatinine is >1.5 × the upper limit of normal	Establish intravenous hydration the evening preceding treatment at a flow rate sufficient to correct volume deficits and produce a urine flow ≥50 mL/hour. Repeat serum creatinine measurement in the morning. If repeated serum creatinine result is ≤1.5 × the upper limit of normal → proceed with treatment. Stop chemotherapy if the repeated serum creatinine result is >1.5 × the upper limit of normal
Mucositis with oral ulcers or protracted vomiting despite antiemetic premedication	Delay chemotherapy one week
G ≤2 neurotoxicity	Continue therapy
G >2 neurotoxicity	Discontinue chemotherapy
Asymptomatic bradycardia or isolated and asymptomatic ventricular extrasystoles	Continue therapy under continuous cardiac monitoring
First-degree AV block	Continue therapy under continuous cardiac monitoring
Symptomatic arrhythmia or AV block (except first degree) or other heart blocks	Continue therapy under continuous cardiac monitoring. Stop paclitaxel, manage arrhythmia according to standard practice, until patient goes off protocol.
G4 radiation induced esophagitis	Hold both chemotherapy and radiotherapy until the esophagitis is G ≤3

Efficacy

	Chemoradiotherapy + Surgery (N = 161)	Surgery Alone (N = 161)	P
R0 resection achieved	148 (92%)	111 (69%)	<0.001
Median number of lymph nodes resected	15	18	0.77
≥1 positive lymph node in resection specimen	50 (31%)	120 (75%)	<0.001
Median disease-free survival	Not reached	24.2 months	<0.001 HR, 0.498 95% CI 0.357–0.693
Median overall survival (ITT)	49.4 months	24.0 months	0.003 HR, 0.657 95% CI 0.495–0.871
1-Year overall survival rate	82%	70%	HR, 0.665 95% CI 0.500--0.884
2-Year overall survival rate	67%	50%	
3-Year overall survival rate	58%	44%	
5-Year overall survival rate	47%	34%

*Adverse events according to NCI CTCAE, National Cancer Institute (USA) Common Terminology Criteria for Adverse Events, version 3. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]

†168/171 patients treated with chemoradiotherapy underwent surgery

‡Includes pneumonia (isolation of pathogen from sputum culture and a new or progressive infiltrate on CXR), serious atelectasis (lobar collapse on chest radiograph), pneumothorax (collection of air, requiring drainage), pleural effusion (collection of fluid, requiring drainage), pulmonary embolus (detected on spiral CT or V/Q mismatch on scintigraphy), and acute respiratory failure (partial pressure of arterial oxygen <60 mm Hg while breathing ambient air)

§Including arrhythmia (any change in rhythm requiring treatment), myocardial infarction, and left ventricular failure (marked pulmonary edema on CXR)

Patient Population Studied

Patients with histologically confirmed, potentially curable squamous-cell carcinoma, adenocarcinoma, or large-cell undifferentiated carcinoma of the esophagus or esophagogastric junction (ie, tumors involving both the cardia and the esophagus on endoscopy) were eligible for inclusion in the study. The upper border of the tumor had to be ≥3 cm below the upper esophageal sphincter. Patients who had proximal gastric tumors with minimal invasion of the esophagus were excluded. The length and width of the tumor could not exceed 8 cm and 5 cm, respectively. Only patients with tumors of clinical stage T1N1 or T2-3N0-1 and no clinical evidence of metastatic spread (M0), according to the International Union against Cancer tumor–node–metastasis (TNM) classification, were enrolled. Eligible patients had a World Health Organization performance status score ≤2 and had lost ≤10% of body weight

Treatment Monitoring

1. Tumor assessment every 2 cycles
2. CBC with differential and serum creatinine: weekly while receiving chemotherapy; and at completion of chemoradiotherapy
3. During the first year after treatment completed, see patients every 3 months. In the second year, every 6 months, and then at the end of each year until 5 years after treatment

ADVANCED ESOPHAGEAL (and GASTRIC) CANCER FIRST-LINE THERAPY REGIMEN

CISPLATIN + CAPECITABINE

Kang Y-K et al. Ann Oncol 2009;20:666–673

Hydration before cisplatin: 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously over a minimum of 1 hour before commencing cisplatin administration
Cisplatin 80 mg/m^2; administer intravenously in 50–500 mL 0.9% NS over 2 hours on day 1, every 3 weeks (total dosage/cycle = 80 mg/m^2)
Hydration after cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 2 hours. Monitor and replace magnesium and other electrolytes as needed. Encourage patients to increase their intake of nonalcoholic fluids
Capecitabine 1000 mg/m^2 per dose; administer orally twice daily with water within 30 minutes after a meal for 14 consecutive days (28 doses) on days 1–14, every 3 weeks (total dosage/cycle = 28,000 mg/m^2)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed symptoms*
Emetogenic potential with capecitabine alone is ***MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care
Risk of mucositis/stomatitis is HIGH
General advice:
- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- Probiotics containing *Lactobacillus* sp. may be beneficial in preventing diarrhea

Patients with intact oral mucosa:
- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultrasoft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, nonalcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:
- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in 1 quart (~950 mL) of warm water. Follow with a plain-water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Treatment Modifications

Adverse Event	Dose Modification
ANC nadir <1000/mm³ *or* platelet nadir <50,000/mm³ after treatment	Delay treatment until ANC ≥1000/mm³ *and* platelet ≥50,000/mm³, then decrease cisplatin dosage by 25%, and decrease daily capecitabine dosages by 50% during subsequent cycles*. Alternatively, consider using hematopoietic growth factors
Serum creatinine >1.5 mg/dL (>133 μmol/L), but <3 mg/dL (<265 μmol/L) *or* creatinine clearance >40 mL/min but <60 mL/min (>0.66 mL/s, but <1 mL/s)	Delay treatment until serum creatinine ≤1.5 mg/dL (≤133 μmol/L), then decrease cisplatin dosage by 50%*
Serum creatinine >3 mg/dL (>265 μmol/L) *or* creatinine clearance <40 mL/min (<0.66 mL/s)	Stop cisplatin
Persistent G2 neuropathy	Hold cisplatin until toxicity resolves to G ≤1; reduce dose by 25% for subsequent cycles
Transient G3/4 neuropathy (duration 7–14 days)	Hold cisplatin. Resume cisplatin after toxicity resolves with dosage reduced by 25% for subsequent cycles
Persistent G3/4 neuropathy	Discontinue cisplatin
G3/4 nonhematologic adverse events other than renal function and neurotoxicity	Reduce cisplatin and capecitabine dosages by 25% for subsequent cycles
G2 stomatitis, diarrhea, or nausea	Hold capecitabine; resume capecitabine at full dosage after resolution of toxicity
Second episode of G2 stomatitis, diarrhea, or nausea	Hold capecitabine; resume capecitabine with dosage reduced by 25% after resolution of toxicity
Third episode of G2 stomatitis, diarrhea, or nausea	Hold capecitabine; resume capecitabine with dosage reduced by 50% after resolution of toxicity
Fourth episode of G2 stomatitis, diarrhea, or nausea	Discontinue capecitabine
G3 stomatitis, diarrhea, or nausea, first episode	Hold capecitabine; if G3 toxicity is adequately controlled within 2 days, resume capecitabine at full dosage when toxicity resolves to G ≤1. If G3 toxicity takes >2 days to be controlled, resume capecitabine with dosage reduced by 25% after toxicity resolves to G ≤1
Second episode of G3 stomatitis, diarrhea, or nausea	Hold capecitabine; if G3 toxicity is controlled adequately within 2 days, then resume capecitabine with dosage reduced by 50% after toxicity resolves to G ≤1
Third episode of G3 stomatitis, diarrhea, or nausea	Discontinue capecitabine
G4 stomatitis, diarrhea, or nausea	Withhold capecitabine. Resume capecitabine with dosage reduced by 50% after toxicity resolves
G1 capecitabine-associated PPE†	Begin pyridoxine 50 mg orally 3 times daily and continue capecitabine without dose modification
G2 capecitabine-associated PPE†	Begin pyridoxine 50 mg orally 3 times daily and withhold capecitabine. Resume capecitabine with dosage reduced by 15% after toxicity resolves
G3 capecitabine-associated PPE†	Begin pyridoxine 50 mg orally 3 times daily and withhold capecitabine. Resume capecitabine with dosage reduced by 30% after toxicity resolves
Recurrent G3 capecitabine-associated PPE†	Begin pyridoxine 50 mg orally 3 times daily and withhold capecitabine. Resume capecitabine with dosage reduced by 50% after toxicity resolves

*Treatment delays for unresolved adverse events of >3 weeks duration warrant discontinuation of treatment
†PPE, Palmar plantar erythrodysesthesia (hand-foot syndrome)

Efficacy

	Capecitabine + Cisplatin	Fluorouracil + Cisplatin	Hazard Ratio (95%CI)	P Value
Median progression-free survival	5.6 months	5.0 months	0.81 (0.63–1.04)	<0.001*
Median overall survival	10.5 months	9.3 months	0.85 (0.64–1.13)	0.008*

*For noninferiority versus 1.25
†95% CI in parentheses
‡Odds ratio (95% CI)

Patient Population Studied

Patients with histologically confirmed measurable advanced gastric cancer, a Karnofsky performance status of seventy or more, no previous chemotherapy other than neoadjuvant or adjuvant regimens, no radiotherapy to target lesions, and adequate hepatic, cardiac, and renal function, the latter defined as an estimated creatinine clearance ≥60 mL/min estimated with the Cockcroft and Gault formula

Treatment Monitoring

1. Tumor assessment every 2 cycles
2. CBC with differential before the start of a new cycle

Toxicity

Treatment-Related Adverse Events (in >15% of patients) by NCI-CTC*

REGIMEN

IRINOTECAN + CISPLATIN

Ilson DH et al. J Clin Oncol 1999;17:3270–3275

Hydration before cisplatin: 5% dextrose/0.9% sodium chloride injection (D5W/0.9% NS) or 0.9% NS ≥500 mL; administer intravenously over a minimum of 1 hour. Also encourage patients to increase oral intake of non-alcoholic fluids. Monitor serum electrolytes and replace as needed (potassium, magnesium, sodium)

Cisplatin 25–30 mg/m² per dose; administer intravenously in 25–100 mL 0.9% sodium chloride injection (0.9% NS) over 30–60 minutes weekly for 4 consecutive weeks (4 doses) on days 1, 8, 15, and 22, followed by 20 days (days 23–42) without cisplatin (total dosage/cycle = 100–120 mg/m²) *followed by:*

Irinotecan 50–65 mg/m² per dose; administer intravenously in a volume of 5% dextrose injection (D5W) sufficient to produce a solution with concentration of 0.12–2.8 mg/mL over 30 minutes, weekly, for 4 consecutive weeks (4 doses) on days 1, 8, 15, and 22, followed by 20 days (days 23–42) without irinotecan (total dosage/cycle = 200–260 mg/m²)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on days of chemotherapy is **HIGH**. Potential for delayed symptoms*

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome

Atropine sulfate 0.25–1 mg administer subcutaneously or intravenously if abdominal cramping or diarrhea develop during or within 1 hour after irinotecan administration

- If symptoms are severe, add as primary prophylaxis at least 30 minutes before irinotecan during subsequent cycles
- For irinotecan, acute cholinergic syndrome may be characterized by: abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

Diarrhea management

Latent or delayed onset diarrhea:*

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

Ciprofloxacin 500 mg orally every 12 hours if absolute neutrophil count <500/mm³ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807; Wadler S et al. J Clin Oncol 1998;16:3169–3178

(*continued*)

Patient Population Studied

A study of 35 patients with advanced (unresectable or metastatic) esophageal adenocarcinoma or squamous cell carcinoma with good performance status

Efficacy (N = 35)

Complete response	6%
Partial response	51%
Minor response	20%
Stable disease	20%
Disease progression	3%
Median duration of response	4.2 months

Treatment Modifications

Adverse Event	Dose Modification
G3/4 diarrhea or mucositis	Reduce irinotecan dosage by 10 mg/m² per dose
G4 fatigue >3 days	
On the day of retreatment if ANC <1000/mm³, WBC <3000/mm³, *or* platelet <100,000/mm³	Hold treatment until ANC ≥1000/mm³, WBC ≥3000/mm³, *and* platelet ≥100,000/mm³ No dosage reductions for treatment delays ≤1 week. Reduce irinotecan dosage by 10 mg/m² per dose if treatment is delayed >2 weeks, for febrile neutropenia, or for bleeding from thrombocytopenia
If blood counts on day 22 do not permit administering the fourth week of planned chemotherapy	Shorten treatment to a 5-week cycle: 3 consecutive weeks of treatment (days 1, 8, and 15), followed by 20 consecutive days without chemotherapy (days 16–35)
Serum creatinine >1.7 mg/dL (>150 µmol/L), but <2.0 mg/dL (<177 µmol/L)	Reduce cisplatin dosage to 15 mg/m² per dose
G ≥2 diarrhea or mucositis on treatment days	Hold treatment for 1 week

Note: If toxicities warrant holding either drug, both drugs are held
One-week treatment delays are common owing to leukocyte counts <3000/mm³ and ANC <1000/mm³ on treatment days

(continued)

Oral care

- Encourage patients to maintain intake of non-alcoholic fluids

If mucositis or stomatitis is present:

- Rinse mouth several times a day with ¼ teaspoon (1.25 g) each of baking soda and table salt in one quart of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols

Toxicity (N = 35)

	% G1/2	% G3/4
Hematologic

Increased bilirubin	3	0

NCI, CTC, National Cancer Institute (USA) Common Toxicity Criteria, version 2.0. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]
Reported as percent of patients experiencing toxicity at any time during therapy

Therapy Monitoring

1. *Pretreatment:* Complete H&P, 12-lead ECG, CBC, PT, PTT, serum electrolytes, BUN, creatinine, mineral panel and LFTs, urinalysis, chest x-ray, ± double-contrast barium esophagram, and chest and abdominal CT
2. *Before each cycle:* CBC and serum electrolytes, magnesium BUN, creatinine, mineral panel, and LFTs, with weekly intracycle CBC and serum creatinine
3. *Response evaluation:* After the first and second cycles and after every second cycle thereafter

Notes

Alternate infusion schedule of 2 weeks on and 1 week off may be better for some patients (days 1 and 8 every 21 days)

REGIMEN

EPIRUBICIN + CISPLATIN + FLUOROURACIL (ECF)

Findlay M et al. Ann Oncol 1994;5:609–616
Ross P et al. J Clin Oncol 2002;20:1996–2004

All chemotherapy is given through a central vascular access device
Warfarin 1 mg/day; administer orally continuously (prophylaxis against vascular access device occlusion)
Epirubicin 50 mg/m^2; administer by intravenous injection over 3–5 minutes just before cisplatin on day 1 every 3 weeks for up to 8 cycles (total dosage/3-week cycle = 50 mg/m^2)
Hydration before cisplatin: 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously over 80 minutes (~750 mL/hour) with:
Furosemide 40 mg; administer orally or intravenously, followed by 500 mL 0.9% NS; administer intravenously over 40 minutes (~750 mL/hour)
Cisplatin 60 mg/m^2; administer intravenously in 1000 mL 0.9% NS with mannitol 20 g over 4 hours on day 1, every 3 weeks for up to 8 cycles (total cisplatin dosage/3-week cycle = 60 mg/m^2) *followed by:*
Hydration after cisplatin: 1000 mL 0.9% NS; administer intravenously over 6 hours (~167 mL/hour)
Fluorouracil 200 mg/m^2 per day; administer by continuous intravenous infusion in 500–1000 mL 0.9% NS or 5% dextrose injection over 24 hours, daily, for up to 24 weeks, starting on the same day as the first dose of epirubicin and cisplatin (total dosage/3-week cycle = 4200 mg/m^2)
General hydration: Encourage patients to increase oral intake of non-alcoholic fluids. Monitor serum electrolytes and replace as needed (potassium, magnesium, sodium)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed symptoms*
Emetogenic potential on days with fluorouracil alone is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)
Use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamines, or pyridoxine 50 to 200 mg/day

Diarrhea management
Latent or delayed-onset diarrhea*:*
Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg every 2 hours while awake; every 4 hours during sleep
Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®) two tablets four times daily until control has been achieved.

Persistent diarrhea:
Octreotide acetate (solution) 100–150 mcg; administer subcutaneously 3 times daily.

Antibiotic therapy during latent or delayed-onset diarrhea:
A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449

†WHO criteria (Findlay M et al. Ann Oncol 1994;5:609–616; N = 139)

Treatment Modifications

Adverse Event	Dose Modification
Palmar/plantar erythema (PPE)	Add oral pyridoxine 50 mg 3 times daily. If PPE does not improve, discontinue fluorouracil for 1 week, then restart at fluorouracil 150 mg/m² per day (25% decrease)
G1/2 mucositis or diarrhea	Hold fluorouracil until toxicity resolves, then restart at fluorouracil 150 mg/m² per day (25% reduction)
G3/4 mucositis or diarrhea	Hold fluorouracil until toxicity resolves, then restart at fluorouracil 100 mg/m² per day (50% reduction)
Creatinine clearance ≥60 mL/min (≥1 mL/s)†	Cisplatin 60 mg/m² (100%)
Creatinine clearance 40–60 mL/min (0.66–1 mL/s)†	Cisplatin X mg/m² where X = absolute value of creatinine clearance
Creatinine clearance <40 mL/min (<1 mL/s)†	Hold cisplatin
EF* ≥50%	Epirubicin 50 mg/m² per dose
EF* <50%	Not eligible to receive epirubicin
First episode of ANC <2000/mm³ *or* platelets <100,000/mm³ on the day of epirubicin + cisplatin treatment	Delay treatment for 1 week, or until ANC is ≥2000/mm³ *and* platelet count is ≥100,000/mm³
Second episode of ANC <2000/mm³ *or* platelets <100,000/mm³ on the day of epirubicin + cisplatin treatment, or febrile neutropenia after previous treatment	Delay treatment until ANC is ≥2000/mm³ and platelet count is ≥100,000/mm³ then reduce epirubicin dosage to 38.5 mg/m² per dose (25% reduction) in subsequent cycles

*Obtain baseline multigated cardiac scan to determine left ventricular ejection fraction (EF) for evidence of cardiovascular disease
†Creatinine clearance as a measure of glomerular filtration rate (GFR)

Therapy Monitoring

1. *Before each chemotherapy cycle:* CBC with differential, platelet count, serum electrolytes, magnesium BUN, creatinine, LFTs, and mineral panel
2. *Response evaluation:* After cycles 3, 6, and 8, CT scan and endoscopy
3. Obtain a baseline multigated cardiac scan to determine left ventricular ejection fraction for evidence of cardiovascular disease

REGIMEN

FLUOROURACIL + CISPLATIN

Bleiberg H et al. Eur J Cancer 1997;33:1216–1220

Hydration before cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously at ≥100 mL/hour before and after cisplatin administration. Also encourage patients to increase oral intake of non-alcoholic fluids. Monitor serum electrolytes and replace as needed (potassium, magnesium, sodium)

Cisplatin 75–100 mg/m^2; administer intravenously in 250 mL 0.9% NS over 60 minutes, given on day 1 every 3 weeks (total dosage/cycle = 75–100 mg/m^2)

Take home: Potassium and magnesium oral supplements to use as needed, guided by laboratory monitoring

Fluorouracil 750–1000 mg/m^2 per day; administer by continuous intravenous infusion in 2000 mL 0.9% NS or 5% dextrose injection over 24 hours on days 1–5 every 3 weeks (total dosage/cycle = 3750–5000 mg/m^2)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on day 1 is HIGH. Potential for delayed symptoms

Emetogenic potential on days with fluorouracil alone is LOW

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care

- Encourage patients to maintain intake of non-alcoholic fluids

If mucositis or stomatitis is present:

- Rinse mouth several times a day with ¼ teaspoon (1.25 g) each of baking soda and table salt in one quart of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols

Diarrhea management

Latent or delayed-onset diarrhea*:

Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then* **Loperamide** 2 mg every 2 hours while awake; every 4 hours during sleep

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®) two tablets four times daily until control has been achieved.

Persistent diarrhea:

Octreotide acetate (solution) 100–150 mcg; administer subcutaneously 3 times daily.

Antibiotic therapy during latent or delayed-onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449; Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807; Wadler S et al. J Clin Oncol 1998;16:3169–3178

Patient Population Studied

A study of 44 patients with advanced squamous cell carcinoma of the esophagus

Therapy Monitoring

1. *Before each cycle:* H&P, chest x-ray, CBC with differential, serum electrolytes, BUN, creatinine, and mineral panel
2. *Response evaluation:* Every 2 cycles

Notes

1. This regimen should be used in selected patients with good performance status
2. Also used for metastatic adenocarcinoma of the distal esophagus and GE junction
3. Patients who cannot tolerate cisplatin can be treated with carboplatin (AUC = 5 mg/mL · min)

Treatment Modifications

Adverse Event	Dose Modification
ANC nadir <1000/mm^3 *or* platelet nadir <50,000/mm^3 after treatment	Delay treatment until ANC >1000/mm^3 *and* platelet >50,0000/mm^3, then decrease cisplatin dosage by 25% and decrease daily fluorouracil dosages by 50% in subsequent cycles*
Serum creatinine >1.5 mg/dL (133 µmol/L), but <3 mg/dL (265 µmol/L) *or* creatinine clearance >40 mL/min, but <60 mL/min	Delay treatment until serum creatinine <1.5 mg/dL (133 µmol/L), then decrease cisplatin dosage by 50%*
Serum creatinine >3 mg/dL (265 µmol/L) *or* creatinine clearance <40 mL/min	Stop cisplatin
G >2 Stomatitis or diarrhea	Decrease fluorouracil dosage by 50%

*Treatment delays for unresolved adverse events of ≥3 weeks warrant discontinuation of treatment

Efficacy (N = 34)

Complete response	3%
Partial response	32%
Stable disease	29%
Disease progression	18%
Early death	15%
Median failure free survival	7 months

Toxicity (N = 44)

	% G3/4
Hematologic	
Leukopenia	14
Thrombocytopenia	14
Nonhematologic	
Nausea/vomiting*	27
Vascular thrombosis	9
Mucositis	5
Diarrhea	2

*The high rate of nausea and vomiting observed in the original 1997 study should be reduced considerably by using currently available serotonin receptor (5-HT$_3$) antagonist and other antiemetics

WHO criteria

REGIMEN

DOCETAXEL + CISPLATIN + FLUOROURACIL (DCF)

Ajani JA et al. Proc Am Soc Clin Oncol 2003;22:249 [abstract 999]

Docetaxel 75 mg/m²; administer intravenously in a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) sufficient to produce a solution with concentration within the range 0.3–0.74 mg/mL over 60 minutes, given on day 1 every 3 weeks (total dosage/cycle = 75 mg/m²)

Hydration with cisplatin: ≥1000 mL 0.9% NS; administer intravenously at ≥100 mL/hour before and after cisplatin administration. Also encourage patients to increase oral intake of non-alcoholic fluids. Monitor serum electrolytes and replace as needed (potassium, magnesium, sodium)

Cisplatin 75 mg/m²; administer intravenously in 25–250 mL of 0.9% NS over 15–60 minutes, given on day 1 every 3 weeks (total dosage/cycle = 75 mg/m²)

Fluorouracil 750 mg/m² per day; administer by continuous intravenous infusion in 250–1000 mL of 0.9% NS or D5W over 24 hours for 5 consecutive days, on days 1–5 every 3 weeks (total dosage/cycle = 3750 mg/m²)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on day 1 is ***HIGH****. Potential for delayed symptoms*

Emetogenic potential on days 2–5 is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with one of the following:

Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection, or
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL, by subcutaneous injection for one dose

- Begin use from 24–72 h after myelosuppressive chemotherapy is completed
- Continue daily Filgrastim use until ANC ≥ 10,000/mm³ on two measurements separated temporally by ≥12 hours
- Discontinue daily Filgrastim use at least 24 hours before administering myelosuppressive treatment. Do not administer Pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider concomitant use of cotrimoxazole during periods of neutropenia, and in anticipation of mucositis
- Antiviral—anti-herpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Oral care

Risk of mucositis/stomatitis is HIGH

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

(continued)

Treatment Modifications

Adverse Event	Dose Modification
G3/4 hematologic adverse events	Use hematopoietic growth factors or decrease doses of docetaxel, cisplatin, and fluorouracil by 25% for subsequent cycles
G3/4 nonhematologic adverse events	Reduce doses of docetaxel, cisplatin, and fluorouracil by 25% for subsequent cycles

Patient Population Studied

A study of 115 patients with metastatic or locally unresectable gastric or gastroesophageal junction adenocarcinoma and measurable or evaluable disease

Toxicity (N = 115)

	% Patients
Any G3/4 adverse events	82
Complicated neutropenia	30
Death rate from all causes within 30 days after the last treatment	11.7

Efficacy (N = 115)

Overall response rate	39%
One year survival	44%
Time to progression	5.2 months
Median overall survival	10.2 months

(*continued*)

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Diarrhea management

Latent or delayed-onset diarrhea*:

Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg; administer orally every 2 hours during waking hours, *plus*
Loperamide 4 mg; administer orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)

- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement in chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide acetate (solution) 100–150 mcg; administer subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed-onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Therapy Monitoring

1. *Before each cycle:* H&P, CBC with differential, serum electrolytes, BUN, creatinine, and mineral panel
2. *Response evaluation:* Every 2 cycles

Notes

1. Reported DCF data reflects interim analysis
2. This regimen is not recommended for patients with WHO/ECOG performance status >1
3. For patients who cannot tolerate cisplatin, DCF is not recommended; however, substitutes such as oxaliplatin or carboplatin have been used
4. Primary prophylaxis with filgrastim or pegfilgrastim may also be considered for qualifying patients

REGIMEN

OXALIPLATIN + FLUOROURACIL + LEUCOVORIN (FOLFOX)

Mauer AM et al. Ann Oncol 2005;16:1320–1325

Oxaliplatin 85 mg/m^2; administer intravenously in 250–500 mL 5% dextrose injection (D5W) over 2 hours on day 1, every 14 days (total dosage/cycle = 85 mg/m^2)
Leucovorin 500 mg/m^2 per day; administer by intravenous infusion in 10–500 mL 0.9% sodium chloride injection (0.9% NS) or D5W over 2 hours for 2 doses on days 1 and 2, every 14 days (total dosage/cycle = 1000 mg/m^2); *followed each day by:*
Fluorouracil 400 mg/m^2 per day; administer by intravenous push or infusion in 10–100 mL 0.9% NS or D5W over 2–15 minutes for 2 doses on days 1 and 2, every 14 days; *followed immediately afterward by:*
Fluorouracil 600 mg/m^2 per day; administer by continuous intravenous infusion over 22 hours in 50–1000 mL 0.9% NS or D5W for 2 doses on days 1 and 2, every 14 days (total dosage/cycle = 2000 mg/m^2)

Note:
- Patients were counseled to avoid exposure to cold liquids or air because the acute neurotoxicity encountered with oxaliplatin appears to be exacerbated by exposure to cold

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH***
Emetogenic potential on day 2 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care
- Encourage patients to maintain intake of non-alcoholic fluids

If mucositis or stomatitis is present:
- Rinse mouth several times a day with ¼ teaspoon (1.25 g) each of baking soda and table salt in one quart of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols

Diarrhea management
***Latent or delayed-onset diarrhea**:**
Loperamide 4 mg; administer orally initially after the first loose or liquid stool, then **Loperamide** 2 mg every 2 hours while awake; every 4 hours during sleep
Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®) two tablets four times daily until control has been achieved.

Persistent diarrhea:
Octreotide acetate (solution) 100–150 mcg; administer subcutaneously 3 times daily.

Antibiotic therapy during latent or delayed-onset diarrhea:
A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Patient Population Studied

Recurrent or metastatic cancer of the esophagus or gastric cardia. Prior treatment with a single chemotherapy regimen and radiotherapy allowed. Eastern Cooperative Oncology Group (ECOG) performance status of 0, 1, or 2. Laboratory measures required at study entry: creatinine ≤1.5 times the institutional upper limit of normal or creatinine clearance ≥50 mL/min; bilirubin ≤1.5 mg/dL; and glutamic–oxaloacetic transaminase less than 2 times the institutional limit of normal

Adverse Events (N = 35)

Hematologic Toxicity

Toxicity Grade	G1	G2	G3	G4	G5
Leukopenia	6	14	7	1	0
Neutropenia	2	3	12	10	1
Thrombocytopenia	14	2	2	1	0
Anemia	17	9	3	0	0

Nonhematologic Toxicity

Neuropathy, sensory	13	8	1	0	—
Respiratory	0	4	1	0	—
Infection	1	1	1	0	—
Creatinine elevation	0	0	0	1*	—

*Reversible renal insufficiency secondary to oxaliplatin-induced hemolysis
NCI CTC, National Cancer Institute (USA) Common Toxicity Criteria, version 2.0. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]

Treatment Modifications

Adverse Event	Dose Modifications*
Inadequate hematologic recovery by day 15 (ANC <1500/mm^3 *or* platelet count <100,000/mm^3)	Delay therapy 1 week
G4 neutropenia or thrombocytopenia	Reduce oxaliplatin and fluorouracil dosages 25% in subsequent cycle
G3/4 stomatitis or diarrhea	Reduce oxaliplatin and fluorouracil dosages by 25% in the subsequent cycle after recovery to baseline
Persistent G2 or any G3 neuropathy	Reduce oxaliplatin dosages by 25%
Febrile or prolonged neutropenia	Administer prophylactic granulocyte colony stimulating factor in subsequent cycles

*Based on the worst toxicity observed during the previous course

Efficacy (N = 35)*

	Number (%)
Complete response	1 (2.5%)
Partial response	13 (37%)
Overall RR, all patients†	40% (95% CI, 24–57%)
Overall RR, chemotherapy-naïve patients	45% (95% CI, 27–64%)
Overall RR, previously treated patients	0 (95% CI, 0–53%)
Stable disease (≥4 cycles of chemotherapy)	10 (29%)
Progressive disease	10 (29%)
Not evaluated	1 (2.5%)
Median PFS, all patients	4.6 months (95% CI, 2.2–6.8)
Median PFS, chemotherapy-naïve patients	4.9 months‡
Median PFS, previously treated patients	1.7 months‡
1-Year PFS probability	0.15
Median OS, all patients	7.1 months (95% CI, 5.9–10.9)
Median OS, chemotherapy-naïve patients	7.6 months§
Median OS, previously treated patients	2.1 months§
1-Year survival probability	0.31 (95% CI, 0.17–0.47)
2-Year survival probability	0.11

*WHO Criteria
†Histology of responding patients: adenocarcinoma (13) adenosquamous (1)
‡$p = 0.0009$; log rank test
§$p = 0.011$; log-rank test

Therapy Monitoring

1. Complete blood counts with differential leukocyte counts at least weekly
2. LFTs, serum BUN, and creatinine before each cycle of chemotherapy
3. Assessment of response after every 4 cycles of therapy

REGIMEN

EPIRUBICIN + OXALIPLATIN + CAPECITABINE (EOC, EOX)

Cunningham D et al. N Engl J Med 2008;358:36–46
Cunningham D et al. N Engl J Med 2010;362:858–859
Sumpter K et al. Br J Cancer 2005;92:1976–1983

Epirubicin 50 mg/m²; administer by intravenous injection over 3–20 minutes on day 1, every 3 weeks, for a maximum of 8 cycles (total dosage/cycle = 50 mg/m²)
Oxaliplatin 130 mg/m²; administer intravenously in 250–500 mL 5% dextrose injection over 2 hours on day 1, every 3 weeks, for a maximum of 8 cycles (total dosage/cycle = 130 mg/m²)
Capecitabine 625 mg/m² per dose; administer orally with water within 30 minutes after a meal twice daily, continually during a 3-week cycle for a maximum of 8 cycles (daily dosage = 1250 mg/m²; total dosage/cycle = 26,250 mg/m²)

Supportive Care

Antiemetic prophylaxis
Emetogenic potential on day 1 is ***MODERATE***
Emetogenic potential on days with capecitabine alone is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Thromboprophylaxis
Low-dose **warfarin** 1 mg/day; administer orally

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)
Use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamines, or pyridoxine 50 to 200 mg/day

Diarrhea management
***Latent or delayed-onset diarrhea**:**
Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then* **Loperamide** 2 mg every 2 hours while awake; every 4 hours during sleep
Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®) two tablets four times daily until control has been achieved.

Persistent diarrhea:
Octreotide acetate (solution) 100–150 mcg; administer subcutaneously 3 times daily.

Antibiotic therapy during latent or delayed-onset diarrhea:
A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm³

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Treatment Modifications

Adverse Event	Dose Modifications
Inadequate hematologic recovery (ANC <1000/mm³ *or* platelet count <75,000/mm³) on day 1 of repeated cycles	Delay oxaliplatin 1 week
G2–4 thrombocytopenia or G3/4 neutropenia in previous cycle	Delay start of oxaliplatin until toxicity is resolved, then reduce oxaliplatin dosage to 100 mg/m² in subsequent cycles

(*continued*)

Patient Population Studied

Adenocarcinoma, squamous cell carcinoma, or undifferentiated carcinoma of the esophagus, gastroesophageal junction, or stomach that was locally advanced (inoperable) or metastatic. Eastern Cooperative Oncology Group performance status of 0–2. Major exclusion criteria were previous chemotherapy or radiotherapy (unless the latter was adjuvant treatment with relapse outside the radiotherapy field)

Efficacy

Compete response	3.9%
Partial response	44%
Median progression-free survival	7 months
1-Year survival rate	46.8%
Median survival	11.2 months
Median survival—metastatic disease	10 months

Adverse Events (N = 227–232)

	% All Grades	% G3/4
Hematologic Toxicities		
Anemia	64.1	8.6
Thrombocytopenia	21.1	5.2
Neutropenia	62.9	27.6
Febrile neutropenia	9.8	7.8
Nonhematologic Toxicities		
Diarrhea	61.7	11.9
Stomatitis	38.1	2.2
Hand-foot syndrome	39.3	3.1
Nausea and vomiting	78.9	11.4
Peripheral neuropathy	83.7	4.4
Lethargy	96.1	24.9
Alopecia	74.2	28.8
Thromboembolism	7.5	NA
Death within 60 days	6.1	

Treatment Modifications (*continued*)

Adverse Event	Dose Modifications
G2 stomatitis, diarrhea, or nausea	Hold capecitabine; resume capecitabine at full dose after resolution of toxicity
Second episode of G2 stomatitis, diarrhea, or nausea	Hold capecitabine; resume capecitabine with dosage reduced by 25% after resolution of toxicity
Third episode of G2 stomatitis, diarrhea, or nausea	Hold capecitabine; resume capecitabine with dosage reduced by 50% after resolution of toxicity
Fourth episode of G2 stomatitis, diarrhea, or nausea	Discontinue capecitabine
G3 stomatitis, diarrhea, or nausea	Hold capecitabine; if G3 toxicity is adequately controlled within 2 days, resume capecitabine at full dosage when toxicity resolves to G ≤1. If G3 toxicity takes >2 days to be controlled, then resume capecitabine with dosage reduced by 25% after toxicity resolves to G ≤1
Second episode of G3 stomatitis, diarrhea, or nausea	Hold capecitabine; if G3 toxicity controlled adequately within 2 days then resume capecitabine with dosage reduced by 50% after toxicity resolves to G ≤1
Third episode of G3 stomatitis, diarrhea, or nausea	Discontinue capecitabine
G4 stomatitis, diarrhea, or nausea	Withhold capecitabine. Resume capecitabine with dosage reduced by 50% after toxicity resolves
G1 capecitabine-associated PPE*	Begin pyridoxine 50 mg orally 3 times daily and continue capecitabine without dose modification
G2 capecitabine-associated PPE*	Begin pyridoxine 50 mg orally 3 times daily and withhold capecitabine. Resume capecitabine with dosage reduced by 15% after toxicity resolves
G3 capecitabine-associated PPE*	Begin pyridoxine 50 mg orally 3 times daily and withhold capecitabine. Resume capecitabine with dosage reduced by 30% after toxicity resolves
Recurrent G3 capecitabine-associated PPE*	Begin pyridoxine 50 mg orally 3 times daily and withhold capecitabine. Resume capecitabine with dosage reduced by 50% after toxicity resolves
Persistent G1 or G2 neuropathy	Delay oxaliplatin 1 week. Resume oxaliplatin after toxicity resolves at a dosage decreased to 100 mg/m² during subsequent cycles
G3/4 neuropathy	Hold oxaliplatin
"Transient" G3/4 neuropathy (duration, 7–14 days)	Hold oxaliplatin. Resume oxaliplatin after toxicity resolves at a dosage decreased to 100 mg/m² during subsequent cycles
Persistent G3/4 neuropathy	Discontinue oxaliplatin†
Laryngeal dysesthesia	Administer subsequent oxaliplatin infusions over a 6-hour period
G3/4 diarrhea or stomatitis despite capecitabine dose reductions	Reduce oxaliplatin dosage to 100 mg/m²

*PPE, Palmar plantar erythrodysesthesia (hand-foot syndrome)
†Consider substituting carboplatin

Therapy Monitoring

1. Complete blood counts with differential leukocyte counts at least weekly
2. LFTs, serum BUN, and creatinine before each cycle of chemotherapy
3. Assessment of response after every 4 cycles of therapy

REGIMEN

IRINOTECAN + FLUOROURACIL + LEUCOVORIN (FOLFIRI)

Dank M et al. Ann Oncol 2008;19:1450–1457
Pozzo C et al. Ann Oncol 2004;15:1773–1781

Irinotecan 80 mg/m² per dose; administer intravenously in 250 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 30 minutes for 6 weekly doses on days 1, 8, 15, 22, 29, and 36, every 7 weeks (total dosage during induction = 480 mg/m²), *followed by:*
Leucovorin 500 mg/m² per dose; administer intravenously in 25–500 mL 0.9% NS or D5W over 2 hours for 6 weekly doses on days 1, 8, 15, 22, 29, and 36, every 7 weeks (total dosage/cycle = 3000 mg/m²), *followed by*
Fluorouracil 2000 mg/m² per dose; administer by continuous intravenous infusion over 22 hours in 50–1000 mL 0.9% NS or D5W for 6 weekly doses on days 1, 8, 15, 22, 29, and 36, every 7 weeks (total dosage/cycle = 12,000 mg/m²)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

- **Filgrastim** (G-CSF) 5 mcg/kg per day, by subcutaneous injection from day 4 until ANC recovery (>1000/mm³) was recommended for treatment and secondary prophylaxis in patients who developed febrile neutropenia, neutropenia and infection, or neutropenia G ≥3 of >7 days duration during a previous cycle

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome

Atropine sulfate 0.25–1 mg; administer subcutaneously or intravenously if abdominal cramping or diarrhea develop during or within 1 hour after irinotecan administration

- If symptoms are severe, add as primary prophylaxis at least 30 minutes before irinotecan during subsequent cycles
- For irinotecan, acute cholinergic syndrome may be characterized by abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Concomitant diarrhea and vomiting, fever, or Karnofsky performance status <70%:

- Hospitalize the patient for IV hydration

Antibiotic therapy during latent or delayed-onset diarrhea:

Ciprofloxacin 500 mg orally every 12 hours if absolute neutrophil count is <500/mm³ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807; Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

- Encourage patients to maintain intake of non-alcoholic fluids

If mucositis or stomatitis is present:

- Rinse mouth several times a day with ¼ teaspoon (1.25 g) each of baking soda and table salt in one quart of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols

Treatment Modifications

Dose Levels	
Irinotecan	
Level 0	80 mg/m²
Level −1	65 mg/m²
Level −2	50 mg/m²
Fluorouracil	
Level 0	2000 mg/m²
Level −1	1750 mg/m²
Level −2	1500 mg/m²

Adverse Event	Dose Modifications*
Inadequate hematologic recovery by start of next cycle (ANC <1500/mm³ or platelet count <100,000/mm³)	Delay start of next treatment cycle up to 2 weeks
G >1 diarrhea	Delay start of next treatment cycle up to 2 weeks; treat as needed
Persistent G ≥1 toxicity after a 2-week delay or recurrent toxicity after more than 2-dose reductions, or G4 stomatitis or G3/4 peripheral neurotoxicity/ototoxicity	Discontinue therapy
Any toxicity G >2 except alopecia and anemia	Reduce irinotecan and fluorouracil dosages by 1 dose level
Second episode of isolated febrile neutropenia or G3/4 neutropenia lasting >7 days, despite filgrastim	Reduce irinotecan by 1 dose level
G3 stomatitis lasting >48 hours	Reduce fluorouracil by 1 dose level
G4 diarrhea, diarrhea with concomitant grade 3/4 neutropenia without fever, or diarrhea with fever or infection	Administer oral fluoroquinolones; reduce irinotecan and/or fluorouracil by 1 dose level
G2–4 acute cholinergic syndrome	Reduce irinotecan dosage by 1 dose level; administer atropine during subsequent cycles
Delayed diarrhea	Reduce irinotecan and/or fluorouracil 1 dose by level; administer loperamide
Febrile neutropenia, neutropenia and infection, or neutropenia G3/4 lasting more than 7 days	Administer filgrastim in subsequent cycles starting on day 4 and continue until ANC >1000/mm³

Patient Population Studied

Adenocarcinoma (including diffuse type, intestinal type and linitis) of the esophagogastric junction, with measurable or evaluable metastatic disease or locally recurrent disease with 1 or more measurable lymph node. A Karnofsky performance status (KPS) >70%. Must have finished prior radiotherapy and surgery 6 and 3 weeks, respectively. Previous adjuvant or neoadjuvant chemotherapy was allowed if completed >12 months before first relapse

Efficacy*

Response rate	31.8%
Median time to treatment failure†	4 months
Median time to progression	5 months
Median response duration	7.6 months
Median overall survival	9 months

*WHO Criteria

†TTF was influenced by the discontinuation of therapy. The majority of these discontinuations occurred within the first 2 months of treatment. The most frequent causes of discontinuation were asthenia, diarrhea, and infection

Adverse Event*

Toxicity	% All Grades	% G3/4
Hematologic		
Leukopenia	64.5	16.3
Neutropenia	66.1	24.8
Febrile neutropenia, neutropenia, and infection	4.8	4.8

Creatinine elevation	9.3	0.6
Fever in absence of infection	14.4	1.8
Infection	7.2	3

*National Cancer Institute of Canada–Clinical Trials Group Expanded Common Toxicity Criteria

Therapy Monitoring

1. Complete blood counts with differential leukocyte counts at least weekly
2. LFTs, serum BUN, and creatinine before each cycle of chemotherapy
3. Assessment of response every 7–8 weeks

REGIMEN

CISPLATIN + CAPECITABINE ± TRASTUZUMAB

Bang Y-J et al. Lancet 2010;376:687–697

Hydration with cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously at ≥100 mL/hour before and after cisplatin administration. Also, encourage patients to increase oral intake of non-alcoholic fluids. Monitor serum electrolytes and replace as needed (potassium, magnesium, sodium)

Cisplatin 80 mg/m²; administer intravenously in 100–250 mL 0.9% NS over 60 minutes on day 1, every 3 weeks, for 6 cycles (total dosage/cycle = 80 mg/m²)

Capecitabine 1000 mg/m² per dose; administer orally twice daily (approximately every 12 hours) with water within 30 minutes after a meal for 28 doses on days 1–14, every 3 weeks, for 6 cycles (total dosage/cycle = 28,000 mg/m²)

Trastuzumab

- **Initial dose: Trastuzumab** 8 mg/kg; administer intravenously in 250 mL 0.9% NS over 90 minutes (total dosage during cycle 1 = 8 mg/kg), *followed after 3 weeks by:*
- **Subsequent doses: Trastuzumab** 6 mg/kg per dose; administer intravenously in 250 mL 0.9% NS over 30–90 minutes (total dosage/cycle = 6 mg/kg)

Notes: Trastuzumab treatment continues every 3 weeks until disease progression, unacceptable toxicities, or patient withdrawal
An optimal sequence for drug administration is suggested by experimental evidence, but has not been proved in clinical trials (Li X-L. Cancer Invest 2010;28:1038–1047)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on day 1 is ***HIGH***

Emetogenic potential on days with capecitabine alone is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Trastuzumab infusion reactions:

- A symptom complex most commonly consisting of chills and/or fever may occur in as many as 40% of patients during the first infusion of trastuzumab. These symptoms occur infrequently with subsequent trastuzumab infusions. Other signs and/or symptoms may include nausea, vomiting, pain (in some cases at tumor sites), rigors, headache, dizziness, dyspnea, hypotension, rash, and asthenia. Although the symptoms are usually mild to moderate in severity, infrequently, trastuzumab may need to be discontinued
- When such a symptom complex is observed, it can be treated with or without reduction in the rate of trastuzumab infusion, and:
  - **Acetaminophen** 650 mg; administer orally
  - **Diphenhydramine** 25–50 mg administer orally or by intravenous injection, and
  - **Meperidine** 12.5–25 mg; administer by intravenous injection every 10 minutes if needed for shaking chills (generally, cumulative doses >50 mg are not needed; use with caution in persons with moderate or more severely impaired renal function)

Treatment plan notes:

- LVEF assessment (MUGA or echocardiography) every 3 months in patients receiving trastuzumab

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

Use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamines, or pyridoxine 50 to 200 mg/day

(*continued*)

Patient Population Studied

Patients with measurable or nonmeasurable histologically confirmed inoperable locally advanced, recurrent, or metastatic adenocarcinoma of the stomach or gastroesophageal junction with defined HER2+ status who had not previously received treatment for metastatic disease. New immunohistochemistry scoring criteria (Hofmann M et al. Histopathology 2008;52:797–805) determined eligibility. Patients whose tumor samples scored 3+ on immunohistochemical staining for HER2 or if samples were FISH positive (HER2:CEP17 ratio ≥2) were eligible to participate

(*continued*)

Diarrhea management

Latent or delayed onset-diarrhea*:

Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg every 2 hours while awake; every 4 hours during sleep
Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®) two tablets four times daily until control achieved.

Persistent diarrhea:

Octreotide acetate (solution) 100–150 mcg; administer subcutaneously 3 times daily.

Antibiotic therapy during latent or delayed-onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count $<500/mm^3$

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

- Encourage patients to maintain intake of non-alcoholic fluids

If mucositis or stomatitis is present:

- Rinse mouth several times a day with ¼ teaspoon (1.25 g) each of baking soda and table salt in one quart of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols

Therapy Monitoring

1. LVEF assessments at baseline and at least every 12 weeks
2. Complete blood counts and leukocyte differential counts at least weekly
3. LFTs, serum BUN, and creatinine before each cycle of chemotherapy
4. Assessment of response every 6 weeks

Treatment Modifications

Adverse Event	Dose Modifications*
Inadequate hematologic recovery by day 21 (absolute neutrophil count $<1500/mm^3$ *or* platelet count $<100,000/mm^3$)	Delay cisplatin and capecitabine for 1 week or until myelosuppression resolves
Recurrent treatment delay because of myelosuppression	Delay cisplatin and capecitabine for 1 week *or* until myelosuppression resolves, *then* decrease cisplatin and capecitabine dosage by 25% during subsequent treatments
Capecitabine	
G2 stomatitis, diarrhea, or nausea	Hold capecitabine; resume capecitabine at full dose after resolution of toxicity
Second episode of G2 stomatitis, diarrhea, or nausea	Hold capecitabine; resume capecitabine with dosage reduced by 25% after resolution of toxicity
Third episode of G2 stomatitis, diarrhea, or nausea	Hold capecitabine; resume capecitabine with dosage reduced by 50% after resolution of toxicity
Fourth episode of G2 stomatitis, diarrhea, or nausea	Discontinue capecitabine
G3 stomatitis, diarrhea, or nausea	Hold capecitabine; if G3 toxicity is adequately controlled within 2 days, then on resolution of toxicity to G ≤2, resume capecitabine at full dosage. If G3 toxicity takes >2 days to be controlled, then on resolution of toxicity to G ≤2, resume capecitabine with dosage decreased by 25%
Second episode of G3 stomatitis, diarrhea, or nausea	Hold capecitabine; if G3 toxicity is adequately controlled within 2 days, then on resolution of toxicity to G ≤2, resume capecitabine with dosage reduced by 50%
Third episode of G3 stomatitis, diarrhea, or nausea	Discontinue capecitabine
G4 stomatitis, diarrhea, or nausea	Discontinue capecitabine or on resolution of toxicity resume capecitabine with dosage reduced by 50%
G1 capecitabine-associated plantar palmar erythema (PPE)	Begin pyridoxine 50 mg 3 times daily and continue capecitabine without dose modification
G2 capecitabine-associated PPE	Begin pyridoxine 50 mg 3 times daily; withhold capecitabine until symptoms resolve, then resume capecitabine with dosage reduced by 15%

(*continued*)

Treatment Modifications (*continued*)

Adverse Event	Dose Modifications*
G3 capecitabine-associated PPE	Begin pyridoxine 50 mg 3 times daily; withhold capecitabine until symptoms resolve, then resume capecitabine with dosage reduced by 30%
Recurrent G3 capecitabine-associated PPE	Begin pyridoxine 50 mg 3 times daily; withhold capecitabine until symptoms resolve, then resume capecitabine with dosage reduced by 50%
Cisplatin	
Reduction in creatinine clearance* to ≤60% of on study value	Delay therapy 1 week. If creatinine clearance does not recover to pretreatment values, then consider reducing cisplatin dose
Creatinine clearance* 40 to 60 mL/min (0.66–1 mL/s)	Consider reducing cisplatin so that dose in milligrams equals the creatinine clearance* value in mL/min†
Creatinine clearance* <40 mL/min (<0.66 mL/s)	Hold cisplatin
Clinically significant ototoxicity	Discontinue cisplatin
Persistent (>14 days) peripheral neuropathy without functional impairment	Decrease cisplatin dose by 50%
Clinically significant sensory loss—persistent (>14 days) peripheral neuropathy with functional impairment	Discontinue cisplatin
Trastuzumab	
Trastuzumab toxicity was managed by treatment interruptions	

*Creatinine clearance used as a measure of glomerular filtration rate
†This also applies to patients with creatinine clearance (GFR) of 40 to 60 mL/min at the outset of treatment

Efficacy

	Chemotherapy + Trastuzumab (N = 294)	Chemotherapy Alone (N = 290)
Median overall survival	13.8 months (95% CI, 12–16 months)	11.1 months (95% CI, 10–13 months)
Median PFS	6.7 months (95% CI, 6–8 months)*	5.5 months (95% CI, 5–6 months)†
Duration of response	6.9 months (95% CI, 6–8 months)*	4.8 months (95% CI, 4–6 months)†
Overall tumor response rate	139 (47%)	100 (35%)
CR	16 (5%)	7 (2%)
PR	123 (42%)	93 (32%)

*N = 139
†N = 100

Post-hoc exploratory analysis

	High HER2 Expression (IHC 2+ & FISH+ or IHC 3+)		Low HER2 Expression (IHC 0 or 1+ and FISH+)	
	Chemotherapy + Trastuzumab	Chemotherapy Alone	Chemotherapy + Trastuzumab	Chemotherapy Alone
Hazard ratio	0.65 (95% CI, 0.51–0.83)		1.07 (95% CI, 0.70–1.62)	
Median OS	16.0 months	11.8 months	10 months	8.7 months

IHC, HER2 immunohistochemistry
There was evidence of a significant interaction test (p = 0.036) between treatment and the 2 HER2 subgroups (high HER2 expression vs. low HER2 expression)

Adverse Events

(NCI-CTCAE, National Cancer Institute (USA) Common Terminology Criteria for Adverse Events, version 3.0 and serious adverse events according to International Conference on Harmonisation guidelines). Available at: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]

Adverse events of all grades (>5%) and G3/4 (≥1%) plus adverse events of any grade with >5% difference between groups

	Trastuzumab + Chemotherapy (N = 294)		Chemotherapy Alone (N = 290)	
	All Grades	G3/4	All Grades	G3/4
Any adverse event	292 (99%)	201 (68%)	284 (98%)	198 (68%)
Gastrointestinal Disorders				
Nausea	197 (67%)	22 (7%)	184 (63%)	21 (7%)

Chills	23 (8%)	1 (<1%)	0	0
Hypokalemia	22 (7%)	13 (4%)	13 (4%)	7 (2%)
Dehydration	18 (6%)	7 (2%)	16 (6%)	5 (2%)
Dyspnea	9 (3%)	1 (<1%)	16 (6%)	5 (2%)

Serious Adverse Events

	Trastuzumab + Chemotherapy (N = 294)	Chemotherapy Alone (N = 290)
Serious adverse events	95 (32%)	81 (28%)
Adverse events leading to dose modifications or treatment interruption	246 (84%)	237 (82%)
60-day mortality	15 deaths (5%)	20 deaths (7%)
Treatment-related mortality	10 deaths (3%)	3 deaths (1%)
Severe infusion reactions (G ≥3; eg, allergic reaction or hypersensitivity, chills, arthralgia, dyspnea)	17 (6%)	NR
Cardiac adverse events	17 (6%)	18 (6%)
G3/4	4 patients, 9 events	9 patients, 9 events
Cardiac dysfunction (LVEF decrease ≥10%, or decrease to absolute LVEF <50%)	11 (5%)*	2 (1%)†

*N = 237
†N = 187

12. Gastric Cancer

Jonas W. Feilchenfeldt, MD and Manish A. Shah, MD

Epidemiology

Incidence: 22,220 (male: 13,730; female: 8,490. Estimated new cases for 2014 in the United States)
10.4 per 100,000 male, 5.3 per 100,000 female
The incidence of gastric cancer varies with different geographic regions

Deaths: Estimated 10,990 in 2014 (male: 6,720; female: 4,270)

Median age: 69 years

Male to female ratio: ~2:1

Stage at Presentation

Localized	24%
Regional	30%
Distant	35%

Kamangar F et al. J Clin Oncol 2006;24:2137–2150
Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Work-up

1. Multidisciplinary evaluation
2. History and physical examination
3. CBC and chemistry profile
4. CT abdomen with contrast; CT/ultrasound pelvis in women pelvis
5. Chest imaging*
6. Esophagogastroduodenoscopy (EGD)
7. PET-CT or PET scan (optional)
8. Endoscopic ultrasound (EUS) (optional)
9. *Helicobacter pylori* test† (optional)

*A combined CT scan of chest and abdomen is a pragmatic option
†Chey WD et al. Am J Gastroenterol 2007;102:1808–1825

Locoregional (M0):

1. Medically fit (medically able to tolerate major abdominal surgery), potentially resectable
2. Medically fit (medically able to tolerate major abdominal surgery), unresectable
3. Medically unfit. Laparoscopy is performed to evaluate for peritoneal spread when considering chemoradiation or surgery. Laparoscopy is not indicated if a palliative resection is planned

Stage IV (M1):

1. No further work-up necessary

Note: PET-CT may have a role for monitoring chemotherapy response

Pathology

Borrman Classification
Gross appearance is the basis for the first classification system of stomach cancers. Any of the 4 types may coexist:

Type I: Polypoid
Type II: Fungating
Type III: Ulcerated
Type IV: Infiltrative

Lauren Classification
Pattern of local invasion based on histologic features:

1. Intestinal: composed of cohesive neoplastic cells that form glands and tubular structures
2. Diffuse: scattered neoplastic cells that invade individually with minimal intercellular cohesion
3. Unclassified

World Health Organization Classification

1. Intraepithelial neoplasia—adenoma
2. Carcinoma
3. Adenocarcinoma (intestinal type, diffuse type)
4. Papillary adenocarcinoma
5. Tubular adenocarcinoma
6. Mucinous adenocarcinoma
7. Signet ring cell carcinoma
8. Adenosquamous carcinoma
9. Squamous cell carcinoma
10. Undifferentiated carcinoma
11. Others

Pathologic Staging

Primary Tumor (T)

TX	Primary tumor cannot be assessed
T0	No evidence of primary tumor
Tis	Carcinoma *in situ*: intraepithelial tumor without invasion of the lamina propria
T1	Tumor invades lamina propria, muscularis mucosae, or submucosa
T1a	Tumor invades lamina propria or muscularis mucosae
T1b	Tumor invades submucosa
T2	Tumor invades muscularis propria
T3	Tumor penetrates subserosal connective tissue without invasion of visceral peritoneum or adjacent structures*,†,‡
T4	Tumor invades serosa (visceral peritoneum) or adjacent structures*,‡
T4a	Tumor invades serosa (visceral peritoneum)
T4b	Tumor invades adjacent structures

*A tumor may penetrate the muscularis propria with extension into the gastrocolic or gastrohepatic ligaments, or into the greater or lesser omentum, without perforation of the visceral peritoneum covering these structures. In this case, the tumor is classified T3. If there is perforation of the visceral peritoneum covering the gastric ligaments or the omentum, the tumor should be classified T4

†The adjacent structures of the stomach include the spleen, transverse colon, liver, diaphragm, pancreas, abdominal wall, adrenal gland, kidney, small intestine, and retroperitoneum

‡Intramural extension to the duodenum or esophagus is classified by the depth of the greatest invasion in any of these sites, including the stomach

Regional Lymph Nodes (N)

NX	Regional lymph node(s) cannot be assessed
N0	No regional lymph node metastasis*
N1	Metastasis in 1 to 2 regional lymph nodes
N2	Metastasis in 3 to 6 regional lymph nodes
N3	Metastasis in 7 or more regional lymph nodes
N3a	Metastasis in 7 to 15 regional lymph nodes
N3b	Metastasis in 16 or more regional lymph nodes

*A designation of pN0 should be used if all examined lymph nodes are negative, regardless of the total number removed and examined

Distant Metastasis (M)

	No distant metastasis (no pathologic M0; use clinical M to complete stage group)
M1	Distant metastasis

Staging

Group	T	N	M
0	Tis	N0	M0
IA	T1	N0	M0
IB	T2	N0	M0

Edge SB, Byrd DR, Compton CC, Fritz AG, Greene FL, Trotti A, editors. AJCC Cancer Staging Manual. 7th ed. New York: Springer; 2010

Washington K. Ann Surg Oncol 2010;17:3077–3079

Treatment and Survival by Stage

Stage	Treatment	5-Year Survival Rate
Stage 0 (in situ)	Surgery	>90%
Stage IA	Surgery	60–80%
Stage IB	Surgery ± adjuvant therapy	50–60%
Stage II	Surgery + adjuvant therapy	30–50%
Stage IIIA	Surgery + adjuvant therapy	~20% (distal tumors)
Stage IIIB	Surgery + adjuvant therapy	~10%
Stage IV	Palliative chemotherapy, radiation therapy	~5%

Expert Opinion

1. Diffuse gastric histology and peritoneal spread may adversely affect the motility of the gastrointestinal tract. Consider promotility agents
2. Common sites of metastatic spread:

   Lymphatic: M1 lymph nodes include paraaortic nodes. Supradiaphragmatic and mediastinal nodes may also be involved. Rare involvement of the left supraclavicular nodes occurs via the thoracic duct

   Blood-borne hematogenous: Distant metastases to the liver, lungs, bone, and skin. Either hematogenous spread or neoplastic seeding of the peritoneum, mesentery, and omentum can result in massive bilateral involvement of the ovaries (Krukenberg tumor)
3. For locally advanced, non-metastatic disease, several studies demonstrate benefit with adjuvant therapy:
   - perioperative chemotherapy
   - post-operative chemoradiation
   - post-operative chemotherapy (preferred in Asia)
4. All tumors should be examined for HER2 status. HER2 positive patients should receive cisplatin/capecitabine and trastuzumab based therapy
5. In second line, either single agent docetaxel or single agent irinotecan can be administered

Bonin SR et al. Gastric cancer. In: Pazdur R et al. eds. Cancer Management: A Multidisciplinary Approach, 7th ed. The Oncology Group, 2003:259–270
D' Angelica M et al. Patterns of initial recurrence in completely resected gastric adenocarcinoma. Ann Surg 2004;240:808–816

6. **New tool for treatment monitoring: 18-fluorodeoxyglucose-PET**
   a. Although no data exist to routinely perform a PET-CT for staging purposes, the MUNICON trial points to a role of PET in predicting response to treatment in localized disease
   b. The trial included 119 patients with locally advanced adenocarcinoma of the esophagogastric junction who underwent staging with PET prior to initiating treatment. PET was repeated after 2 weeks of chemotherapy. Tumors with a decrease of 35% of standard uptake values (SUVs) were considered "responders." Difference of overall survival between responders and nonresponders was significant at censured follow-up of 2.3 years

Lordick F et al. Lancet Oncol 2007;8:797–805

7. A study reporting poor prognostic factors in locally advanced and metastatic esophagogastric cancer analyzed prognostic factors based on three randomized trials (N = 1080):

Ross P et al. J Clin Oncol 2002;20:1996–2004
Tebbutt NC et al. Ann Oncol 2002;13:1568–1575
Webb A et al. J Clin Oncol 1997;15:261–267

Multivariate Baseline Prognostic Model

Factors	Hazard Ratio	99% CI	p-Value
Performance status 2–3	1.575	1.251–1.981	<0.0001
Liver metastasis	1.409	1.139–1.743	<0.0001
Peritoneal metastasis	1.329	1.013–1.743	0.007
Alkaline phosphatase ≥100 units/L	1.412	1.136–1.755	<0.0001

Multivariate Logistic Regression Model for Tumor Response to Chemotherapy

Factors	Risk Ratio	99% CI	p-Value
Performance Status 2–3	0.469	0.280–0.787	<0.001
Peritoneal metastasis	0.475	0.254–0.889	0.002
Alkaline phosphatase ≥100 units/L	0.655	0.433–0.992	0.009

Chau I et al. J Clin Oncol 2004;22:2395–2403

Surgical Options

Resectable Tumors

1. Tis or T1* limited to mucosa (T1a)
   - Gastrectomy (endoscopic resection in experienced centers)
2. T1b-T3†
   - Distal gastrectomy
   - Subtotal gastrectomy (preferred for distal gastric cancers)
   - Total gastrectomy

Notes:
- Gastric resection should encompass the regional lymph nodes (D1), with a desired goal of removing/examining ≥15 lymph nodes‡,§
- Consider placing a feeding jejunostomy tube especially if postoperative chemoradiation appears a likely recommendation

Criteria of unresectability
Locoregionally advanced

1. Level 3 or 4 lymph node highly suspicious on imaging or confirmed by biopsy
2. Invasion or encasement of major vascular structures
3. Distant metastasis or peritoneal seeding (including positive peritoneal cytology)

ADJUVANT CHEMORADIATION REGIMEN

FLUOROURACIL + LEUCOVORIN + RADIATION

Macdonald JS et al. N Engl J Med 2001;345:725–730

Following curative surgery, patients receive 5 cycles of chemotherapy and concomitant radiotherapy spanning cycles 2 and 3 (based on a regimen described by Poon MA et al. J Clin Oncol 1989;7:1407–1418)

Cycle 1, neoadjuvant chemotherapy only:
Leucovorin 20 mg/m^2 per day; administer intravenously in 25–100 mL of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 5–15 minutes for 5 consecutive days on days 1–5 (total dosage/cycle = 100 mg/m^2)
Fluorouracil 425 mg/m^2 per day; administer intravenously in 25–100 mL 0.9% NS or D5W over 5–30 minutes after leucovorin for 5 consecutive days on days 1–5 (total dosage/cycle = 2125 mg/m^2)

Cycles 2 and 3, chemotherapy plus radiation:
Starts 28 days after the start of cycle 1 (ie, day 29)
Leucovorin 20 mg/m^2 per day; administer intravenously in 25–100 mL of 0.9% NS or D5W over 5–15 minutes for 4 consecutive days on days 1–4 during the first week of radiation therapy (total dosage during the first week of combined chemoradiation = 80 mg/m^2)
Fluorouracil 400 mg/m^2 per day; administer intravenously in 25–100 mL of 0.9% NS or D5W over 5–30 minutes after leucovorin for 4 consecutive days on days 1–4 during the first week of radiation therapy (total dosage during first week of combined chemoradiation = 1600 mg/m^2)
Radiation 180 cGy/day for 5 days/week for 5 consecutive weeks (total dose 4500 cGy in twenty-five 180-cGy fractions)

- Radiation fields must be evaluated carefully
- One-third of patients require field adjustments (INT-0116 study)

Leucovorin 20 mg/m^2 per day; administer intravenously in 25–100 mL of 0.9% NS or D5W over 5–15 minutes for 3 consecutive days on days 3–5 during the fifth week of radiation therapy (total dosage during the fifth week of combined chemoradiation = 60 mg/m^2)
Fluorouracil 400 mg/m^2 per day; administer intravenously in 25–100 mL of 0.9% NS or D5W over 5–30 minutes after leucovorin for 3 consecutive days on days 3–5 during the fifth week of radiation therapy (total dosage during the fifth week of combined chemoradiation = 1200 mg/m^2)

Cycles 4 and 5, chemotherapy only:
Starts 1 month after completing radiation therapy
Leucovorin 20 mg/m^2 per day; administer intravenously in 25–100 mL of 0.9% NS or D5W over 5–15 minutes on days 1–5, every 4 weeks for 2 cycles (total dosage/cycle = 100 mg/m^2)
Fluorouracil 425 mg/m^2 per day; administer intravenously in 25–100 mL of 0.9% NS or D5W over 5–30 minutes after leucovorin on days 1–5 every 4 weeks, for 2 cycles (total dosage/cycle = 2125 mg/m^2)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **LOW** for chemotherapy alone*
*Emetogenic potential is at least **MODERATE** during chemoradiation*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

(continued)

Patient Population Studied

A study of 556 evaluable patients with stage IB-IV M0 gastric cancer who had undergone curative surgery were randomly assigned to receive adjuvant chemoradiation or observation alone. Patients had completely recovered from resection and were no longer losing weight

Efficacy (N = 281)*

Median overall survival	36 months
3-Year disease-free survival	48%
Median relapse free survival	30 months
Local recurrence	19%
Regional relapse†	65%
Distant Relapses	33%

*Intention-to-treat analysis
†Typically, abdominal carcinomatosis

Therapy Monitoring

1. *Prior to each cycle:* Interval history with emphasis on clinical toxicities, physical examination, CBC with differential, serum creatinine, and LFTs
2. *Response evaluation:* Clinical follow-up at 3-months intervals for 2 years, then at 6-months intervals for 3 years, and yearly thereafter. Follow-up consists of physical examination, CBC, liver function tests, chest radiography, and CT as clinically indicated

Cessation of Chemoradiotherapy (N = 281)

Reason	No. of Patients (%)
Protocol treatment completed	181 (64)
Toxic effects	49 (17)
Patient declined further treatment	23 (8)
Progression of disease	13 (5)
Death	3 (1)
Other	12 (4)

(*continued*)

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE, although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Toxicity (N = 273)

(Grade ≥3)

	No. of Patients (%)
Hematologic	148 (54)
Gastrointestinal	89 (33)
Influenza-like symptoms	25 (9)
Infection	16 (6)
Neurologic	12 (4)
Cardiovascular	11 (4)
Pain	9 (3)
Metabolic	5 (2)
Hepatic	4 (1)
Lung-related	3 (1)
Death*	3 (1)

*One patient died from a cardiac event, 1 from pulmonary fibrosis, and 1 from sepsis complicating myelosuppression

Treatment Modifications

Dose modification as clinically indicated based on the most significant toxicity
Recommendations apply to all 5 chemotherapy cycles

Dosage level −1	Fluorouracil 350 mg/m^2
Dosage level −2	Fluorouracil 300 mg/m^2

Adverse Event	Dose Modification
Myelosuppression/ Thrombocytopenia	Consider reducing chemotherapy doses during subsequent cycles
Hand-foot syndrome (palmar-plantar erythrodysesthesia)	Interrupt fluorouracil therapy until symptoms resolve. Reduce fluorouracil dosage or discontinue fluorouracil
Mucositis	Interrupt fluorouracil therapy until symptoms resolve. Reduce fluorouracil dosage or discontinue fluorouracil
Diarrhea	Interrupt fluorouracil therapy until symptoms resolve. Reduce fluorouracil dosage or discontinue fluorouracil

ADJUVANT REGIMEN PRE- AND POSTOPERATIVE

EPIRUBICIN (E) + CISPLATIN (C) + FLUOROURACIL (F)

Cunningham D et al. N Engl J Med 2006;355:11–20. Comment in: N Engl J Med 2006;355:76–77, N Engl J Med 2006;355:1386–1388, ACP J Club 2007;146:2, Nat Clin Pract Oncol 2007;4:76–77

Pre- and postoperative chemotherapy: Administer 3–4 cycles of the chemotherapy regimen neoadjuvantly, with the last cycle given 3–6 weeks before surgery. Give 3–4 cycles of the chemotherapy regimen adjuvantly starting 6–12 weeks after surgery

Prior to starting chemotherapy: In patients with a history of ischemic heart disease measure left ventricular ejection fraction by multiple gated acquisition (MUGA) scanning or echocardiography. Omit epirubicin if the left ventricular ejection fraction is <50%

Epirubicin 50 mg/m^2; administer intravenously over 3–20 minutes on day 1 every 3 weeks (total dosage/cycle = 50 mg/m^2)
Hydration before cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously over a minimum of 3 hours
Mannitol 12.5–25 g; administer by intravenous injection or intravenous infusion over 5–15 minutes before starting cisplatin

- Mannitol may be given to patients who have received adequate hydration. Continued intravenous hydration is essential to ensure diuresis
- Mannitol may be prepared as an admixture (in the same container) with cisplatin

Cisplatin 60 mg/m^2; administer intravenously in 100–500 mL 0.9% NS over 30–60 minutes on day 1 every 3 weeks (total dosage/cycle = 60 mg/m^2)

Hydration after cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 3 hours. Encourage increased oral fluid intake. Goal is to achieve a urine output of ≥100 mL/hour. Monitor and replace magnesium and other electrolytes as needed
Fluorouracil 200 mg/m^2 per day; administer by continuous intravenous infusion over 24 hours in 50–1000 mL 0.9% NS or 5% dextrose injection for 21 consecutive days, on days 1–21 (total dosage/cycle = 4200 mg/m^2)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed emetic symptoms*
Emetogenic potential on days 2–21 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
***Latent or delayed-onset diarrhea**:**
Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg; administer orally every 2 hours during waking hours, *plus*
Loperamide 4 mg; administer orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
Myelosuppression/ thrombocytopenia	Consider reducing chemotherapy dosages during subsequent cycles
Hand-foot syndrome (palmar-plantar erythrodysesthesia)	Interrupt fluorouracil therapy until symptoms resolve. Reduce fluorouracil dosage or discontinue fluorouracil
Mucositis	Interrupt fluorouracil therapy until symptoms resolve. Reduce fluorouracil dosage or discontinue fluorouracil
Diarrhea	Interrupt fluorouracil therapy until symptoms resolve. Reduce fluorouracil dosage or discontinue fluorouracil
Reduction in creatinine clearance* to ≤60% of on study value	Delay therapy 1 week. If creatinine clearance does not recover to pretreatment values, then consider reducing cisplatin dosage
Creatinine clearance* 40–60 mL/min (0.66–1 mL/s)	Consider decreasing the amount of cisplatin administered, so the cisplatin dose in milligrams equals the creatinine clearance* value in mL/min†
Creatinine clearance* <40 mL/min (<0.66 mL/s)	Hold cisplatin
Left ventricular fraction less than 50%	Omit or discontinue epirubicin
Clinically significant ototoxicity	Discontinue cisplatin
Clinically significant sensory loss	Discontinue cisplatin

*Creatinine clearance is used as a measure of glomerular filtration rate (GFR)
†This also applies to patients with creatinine clearance (GFR) = 40–60 mL/min (0.66–1 mL/s) before starting or restarting treatment

(*continued*)

Alternatively, a trial of **Diphenoxylate hydrochloride 2.5 mg with Atropine sulfate** 0.025 mg (eg, Lomotil®)

- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Therapy Monitoring

1. *Before each cycle:* CBC with differential, blood urea nitrogen, electrolytes, serum creatinine, and LFTs
2. In patients with a history of ischemic heart disease, evaluate serially left ventricular ejection fraction with MUGA scanning or echocardiography

Patient Population Studied

Clinical trial of 503 patients with operable GI cancers (distal esophagus, GE junction, or gastric) randomly assigned to surgery only or perioperative chemotherapy consisting of 3 cycles of chemotherapy with the ECF regimen followed after 3–6 weeks by surgery, and then another 3 cycles of chemotherapy initiated 6–12 weeks after surgery. The surgical control arm underwent a surgical intervention within 6 weeks after randomization. The trial demonstrated significantly improved progression-free and overall survival in the chemotherapy arm

Toxicity

	Preoperative % G3/4	Postoperative % G3/4
Neutropenia	23.8	27.8
Leukopenia	11.5	11.1
Anemia	4.7	0.7
Thrombocytopenia	0.4	3.0
Nausea	6.4	12.3
Vomiting	5.6	10.1
Stomatitis	4.3	3.6
Diarrhea	2.6	3.6
Skin effects	3.4	1.5
Neurologic effects	3.8	3.6

Chemotherapy Administration/Tolerance	
Completed preoperative chemotherapy	86% of patients initially assigned to chemotherapy (215/250); 90.7% of those who started chemotherapy (215/237)*
Began postoperative chemotherapy	54.8% of patients initially assigned to chemotherapy (137/250); 65.6% of those who had surgical resection (137/209)†
Completed postoperative chemotherapy	41.6% of patients initially assigned to chemotherapy; 75.9% of those who started (104/137)

*Reasons for not completing 3 preoperative cycles (N = 250): toxic effects (12 patients), patient request (3), problems with a Hickman catheter (3), early cancer-related death (2), and other (2)

†Reasons for not starting postoperative chemotherapy (N = 209) after completing the first 3 cycles were disease progression or early death (37 patients), patient choice (11), postoperative complications (10), problems with a Hickman catheter (4), previous toxic effects (3), lack of response to preoperative treatment (2), and worsening coexisting disease (2)

Efficacy

Surgical and Pathologic Results

Variable	Perioperative-Chemotherapy Group (N = 250)	Surgery Group (N = 253)
Extent of Resection According to Surgeon		
Curative Surgery	69.3%	66.4%
Palliative Surgery	18%	28%
D1 resection (distal + total)	17.8%	18.5%
D2 resection (distal + total)	42.5%	40.4%
Pathology Reports		
Tumor stage (all patients)		
T1	15.7%	8.3
T2	36.0%	28.5
T3	43.6%	54.9%
T4	4.7%	8.3%
Nodal status (patients with gastric cancer)		
N0	31.3%	26.9
N1	53.3%	43.6%
N2	14.1%	21.8%
N4	1.5%	7.7%

Progression-Free Survival and Overall Survival

Months	0	12	24	36	48	60	72
Progression-free Survival							
ECF → S → ECF (N = 250)	100%	64%	40%	27%	19%	13%	9.2%*
S (N = 253)	100%	49%	23%	17%	11%	6%	3.2%
Overall Survival							
ECF → S → ECF (N = 250)	100%	67%	44%	32%	21%	15%	11%*
S (N = 253)	100%	61%	32%	20%	12%	7.1%	3.6%

ECF, Epirubicin + cisplatin + fluorouracil; S, surgery
*Statistically significant

ADJUVANT REGIMEN

ADJUVANT CAPECITABINE AND OXALIPLATIN FOR GASTRIC CANCER AFTER D2 GASTRECTOMY

Bang Y-J et al. Lancet 2012;379:315–321

Capecitabine 1000 mg/m² per dose; administer orally twice daily for 14 consecutive days, on days 1–14, every 3 weeks for 8 cycles (total dosage/cycle = 28,000 mg/m²), *plus:*
Oxaliplatin 130 mg/m²; administer intravenously in 250–500 mL 5% dextrose injection over 2 hours on day 1, every 3 weeks, for 8 cycles (total dosage/cycle = 130 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on Day 1 is ***MODERATE***
Emetogenic potential on days with capecitabine alone is ***MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)
For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE, although the mechanism through which this occurs remains unclear
- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Diarrhea management
Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg; administer orally every 2 hours during waking hours, *plus*
Loperamide 4 mg; administerorally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)
- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Treatment Modifications

Adverse Event	Dose Modification
ANC nadir $<1000/mm^3$ *or* platelet nadir $<50{,}000/mm^3$ after treatment	Delay treatment until ANC $\geq 1000/mm^3$ *and* platelet $\geq 50{,}000/mm^3$, then decrease oxaliplatin dosage by 25%, and decrease daily capecitabine dosages by 50% during subsequent cycles*. Alternately consider using hematopoietic growth factors
Persistent G1/G2 neuropathy	Delay oxaliplatin 1 week. Resume oxaliplatin after toxicity resolves at a dosage decreased to 100 mg/m^2 during subsequent cycles
"Transient" G3/4 neuropathy (7–14 days duration)	Hold oxaliplatin. Resume oxaliplatin after toxicity resolves at a dosage decreased to 100 mg/m^2 during subsequent cycles
Persistent G3/4 neuropathy	Discontinue oxaliplatin
G3/4 diarrhea or stomatitis despite capecitabine dose reductions	Reduce oxaliplatin dosage to 100 mg/m^2
G3/4 nonhematologic adverse events other than renal function and neurotoxicity	Reduce cisplatin and capecitabine dosages by 25% for subsequent cycles
G2 stomatitis, diarrhea, or nausea	Hold capecitabine; resume capecitabine at full dosage after resolution of toxicity
Second episode of G2 stomatitis, diarrhea, or nausea	Hold capecitabine; resume capecitabine with dosage reduced by 25% after resolution of toxicity
Third episode of G2 stomatitis, diarrhea, or nausea	Hold capecitabine; resume capecitabine with dosage reduced by 50% after resolution of toxicity
Fourth episode of G2 stomatitis, diarrhea, or nausea	Discontinue capecitabine
G3 stomatitis, diarrhea, or nausea	Hold capecitabine. If G3 toxicity is adequately controlled within 2 days, resume capecitabine at full dosage when toxicity resolves to G ≤1. If G3 toxicity takes >2 days to be controlled, resume capecitabine with dosage reduced by 25% after toxicity resolves to G ≤1
Second episode of G3 stomatitis, diarrhea, or nausea	Hold capecitabine; if G3 toxicity is controlled adequately within 2 days, then resume capecitabine with dosage reduced by 50% after toxicity resolves to G ≤1
Third episode of G3 stomatitis, diarrhea, or nausea	Discontinue capecitabine
G4 stomatitis, diarrhea, or nausea	Withhold capecitabine. Resume capecitabine with dosage reduced by 50% after toxicity resolves
G1 capecitabine-associated PPE†	Begin pyridoxine 50 mg orally 3 times daily and continue capecitabine without dose modification
G2 capecitabine-associated PPE†	Begin pyridoxine 50 mg orally 3 times daily and withhold capecitabine. Resume capecitabine with dosage reduced by 15% after toxicity resolves
G3 capecitabine-associated PPE†	Begin pyridoxine 50 mg orally 3 times daily and withhold capecitabine. Resume capecitabine with dosage reduced by 30% after toxicity resolves
Recurrent G3 capecitabine-associated PPE†	Continue pyridoxine 50 mg orally 3 times daily and withhold capecitabine. Resume capecitabine with dosage reduced by 50% after toxicity resolves

*Treatment delays for unresolved adverse events of >3 weeks duration warrant discontinuation of treatment
†PPE, palmar plantar erythrodysesthesia (hand-foot syndrome)

Efficacy

[Study Compared Adjuvant CAPE-OX After Surgery vs Surgery Only]

	Surgery Only (N = 515)	Surgery + CAPE-OX (N = 520)
Relapsed, developed a new gastric cancer, or died by time of data cutoff	163 (32%)	106 (20%)
3-year disease-free survival (DFS)	59% (95% CI, 53–64)	74% (95% CI, 69–79)
	HR 0.56, 95% CI 0.44–0.72; p <0.0001	
3-year DFS, stage II	71% (95% CI, 64–78)	85% (95% CI, 79–90)
3-year DFS, stage IIIa	51% (95% CI, 42–60)	66% (95% CI, 57–75)
3-year DFS stage IIIb	33% (95% CI, 15–51)	61% (95% CI, 48–73)
Deaths by time of data cutoff	85 (17%)	65 (13%)
3-year overall survival	78% (95% CI, 74–83)	83% (95% CI, 79–87)
	HR 0.72, 95% CI 0.52–1.00; p = 0.0493	
Recurrence or new gastric cancer	155 (30%)	96 (18%)
Peritoneal recurrence	56 (11%)	47 (9%)
Locoregional recurrence	44 (8.5%)	21 (4%)
Recurrence at distant sites	78 (15%)	49 (9.4%)

CAPE-OX, capecitabine and oxaliplatin

Toxicity

Adverse events reported by ≥10% of patients (safety population*)

Capecitabine and Oxaliplatin (N = 496)

	All Grades	Grades 3/4
Patients with ≥1 adverse event	490 (99%)	279 (56%)
Nausea	326 (66%)	39 (8%)

Weight decreased	59 (12%)	1 (<1%)
Peripheral sensory neuropathy	50 (10%)	3 (<1%)

Data are n (%)
*Patients who received ≥1 dose of capecitabine or oxaliplatin

Treatment Monitoring

1. *Before each cycle:* Physical examination with attention to clinical toxicities, CBC with differential, serum magnesium, and LFTs
2. *Efficacy Assessments:* Every two cycles

Patient Population Studied

Patients with histologically confirmed gastric adenocarcinoma without evidence of metastatic disease. Only patients whose tumors were American Joint Committee on Cancer/Union Internationale Contre le Cancer (AJCC/UICC) stage II (T2N1, T1N2, T3N0), IIIA (T3N1, T2N2, T4N0), or IIIB (T3N2) were eligible. All patients had curative D2 gastrectomy and achieved R0 resection ≤6 weeks before randomization. At least 15 lymph nodes were examined. All surgeons were experienced (>50 procedures per year), standard operating procedures were predefined, and surgery was photographed

Patient Characteristics (N = 520)

Age (years)	56.1 (11.1)
Men	373 (72%)
Karnofsky performance status 90–100	90%
Time since surgery (months)	1.14 (0.17)

ADVANCED DISEASE REGIMEN

EPIRUBICIN + CISPLATIN + FLUOROURACIL (ECF)

Webb A et al. J Clin Oncol 1997;15:261–267

Epirubicin 50 mg/m²; administer by intravenous injection over 3–20 minutes on day 1, every 3 weeks, for a maximum of 8 cycles (total dosage/3-week cycle = 50 mg/m²)

Hydration before cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously over a minimum of 3–4 hours. Monitor and replace magnesium/electrolytes as needed
Mannitol diuresis: **Mannitol** may be given to patients who have received adequate hydration. A bolus dose of 12.5 g mannitol can be administered as an intravenous injection before starting cisplatin or in the same container as cisplatin. Continued hydration is essential
Cisplatin 60 mg/m²; administer intravenously in 100–500 mL of 0.9% NS over 30–60 minutes on day 1, every 3 weeks, for a maximum of 8 cycles (total dosage/3-week cycle = 60 mg/m²)

Hydration after cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 3–4 hours. Also, encourage increased oral intake of non-alcoholic fluids. Goal is to achieve a urine output of ≥100 mL/hour
Fluorouracil 200 mg/m² by continuous intravenous infusion in 50–1000 mL 0.9% NS, or 5% dextrose injection over 24 hours, starting on cycle 1, day 1, continuously for a maximum duration of 6 months (total dosage/3-week cycle = 4200 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed emetic symptoms*
Emetogenic potential on days 2–21 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed-onset diarrhea*:
Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg; administer orally every 2 hours during waking hours, *plus*
Loperamide 4 mg; administer orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

(*continued*)

Efficacy (N = 111–126)

	N = 111	N = 126 (Intent to Treat)
Complete response	6%	5.5%
Partial response	39%	34%
Stable disease	21%	18%
Progressive disease	20%	17%

Insufficient Treatment	
Early death	6%
Toxic death	1%

Median failure-free survival	7.4 months

WHO criteria

Patient Population Studied

A trial of 274 patients with previously untreated advanced esophagogastric cancer randomized to receive epirubicin, cisplatin, and fluorouracil (ECF; N = 137) compared with fluorouracil, doxorubicin, and methotrexate (FAMTX; N = 137). The ECF regimen resulted in a survival and response advantage, tolerable toxicity, and better quality of life, and cost-effectiveness

(*continued*)

Alternatively, a trial of **Diphenoxylate hydrochloride 2.5 mg with Atropine sulfate** 0.025 mg (eg, Lomotil®)

- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids

If mucositis or stomatitis is present:

- Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
- Do not use mouthwashes that contain alcohols

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief; starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Treatment Modifications

Adverse Event	Dose Modification
Plantar/palmar erythema (PPE)	Give pyridoxine 50 mg orally 3 times daily. If PPE does not improve, hold fluorouracil for 1 week, then resume with fluorouracil 150 mg/m^2 per day by continuous infusion
G ≤1/2 mucositis or diarrhea	Interrupt chemotherapy until mucositis and diarrhea resolve, then resume fluorouracil with daily dosage reduced by 50 mg/m^2
G3/4 mucositis or diarrhea	Interrupt chemotherapy until mucositis and diarrhea resolve, then resume fluorouracil with daily dosage reduced by 100 mg/m^2
Creatinine clearance 40–60 mL/min (0.66–1 mL/s)	Reduce cisplatin so that dose in milligrams equals the creatinine clearance value in mL/min
Creatinine clearance <40 mL/min (<0.66 mL/s)	Hold cisplatin
Day 1 WBC <2000/mm^3 *or* platelet count <100,000/mm^3	Delay cisplatin and epirubicin for 1 week or until myelosuppression resolves
Second treatment delay because of myelosuppression	Delay cisplatin and epirubicin for 1 week, or until myelosuppression resolves, then decrease epirubicin dosage by 25% during subsequent treatments
Sepsis during an episode of neutropenia	

Findlay M et al. Ann Oncol 194;5:609–616

National Cancer Institute (USA) Common Toxicity Criteria, version 2.0. Available at: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed October 25, 2013]

Therapy Monitoring

1. *Before each cycle:* Physical examination with attention to clinical toxicities, CBC with differential, serum sodium, potassium, magnesium, creatinine, BUN, and LFTs
2. *Before repeated cisplatin treatments:* Monitor serum creatinine with estimated creatinine clearance (CrCl), or measure CrCl with either a 12- or a 24-hour urine collection

Note: Prior to starting chemotherapy: In patients with a history of ischemic heart disease, measure left ventricular ejection fraction by multiple gated acquisition (MUGA) scanning or echocardiography. Omit epirubicin if the left ventricular ejection fraction is <50%

ADVANCED DISEASE REGIMEN

DOCETAXEL + CISPLATIN + FLUOROURACIL (DCF)

van Cutsem E et al. J Clin Oncol 2006;24:4991–4997

Docetaxel 75 mg/m²; administer intravenously diluted in a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) sufficient to produce a docetaxel concentration within the range 0.3–0.74 mg/mL over 60 minutes on day 1, every 3 weeks (total dosage/cycle = 75 mg/m²)

Hydration before cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 3 hours
Mannitol 12.5–25 g; administer by intravenous injection or infusion over 5–15 minutes before starting cisplatin. Mannitol may be given to patients who have received adequate hydration. Continued intravenous hydration is essential to insure diuresis. Mannitol may be prepared as an admixture (in the same container) with cisplatin
Cisplatin 75 mg/m²; administer intravenously in 100–250 mL 0.9% NS over 1–3 hours on day 1, every 3 weeks (total dosage/cycle = 75 mg/m²)

Hydration after cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 3 hours. Encourage increased oral intake of non-alcoholic fluids. Goal is to achieve a urine output of ≥100 mL/hour. Monitor and replace magnesium and other electrolytes as needed
Fluorouracil 750 mg/m² per day; administer by continuous intravenous infusion in 50–1000 mL 0.9% NS or D5W over 24 hours for 5 consecutive days, on days 1–5, every 3 weeks (total dosage/cycle = 3750 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed emetic symptoms*
Emetogenic potential on days 2–5 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed-onset diarrhea:*
Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg; administer orally every 2 hours during waking hours, *plus*
Loperamide 4 mg; administer orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)
- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily

(*continued*)

Treatment Modifications

- Cycle delays occurred in 64% of patients. Dose reductions occurred in 41% of patients
- Fluorouracil dose was most commonly reduced in comparison with docetaxel and cisplatin

Dosage Level		
Docetaxel	Level −1	55 mg/m²
Cisplatin	Level −1	60 mg/m²
Fluorouracil	Level −1	500 mg/m² per day for 5 days

Adverse Event	Dose Modification
G3/4 diarrhea or stomatitis	Reduce fluorouracil by 1 dose level
Reduction in creatinine clearance* to <60% of on-study value	Delay therapy 1 week. If creatinine clearance does not recover to pretreatment values, then reduce cisplatin by 1 dose level
Creatinine clearance* 40–60 mL/min (0.66–1 mL/s)	Consider decreasing the amount of cisplatin administered, so the cisplatin dose in milligrams equals the creatinine clearance* value in mL/min†
Creatinine clearance* <40 mL/min (<0.66 mL/s)	Hold cisplatin
Peripheral neuropathy	Delay therapy 1 week. If symptoms do not resolve to G ≤1, reduce cisplatin and or docetaxel by 1 dose level
G3/4 peripheral neurotoxicity or ototoxicity	Discontinue therapy

*Creatinine clearance is used as a measure of glomerular filtration rate (GFR)
†This also applies to patients with creatinine dearance (GFR) of 40–60 mL/min (0.66–1 mL/s) before starting or restarting treatment
Note: Other dose modifications as clinically indicated based on the most significant toxicity

(*continued*)

- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Efficacy

Response Rate	
Overall response rate	36.7% (95% CI, 30.3–43.4%)
Complete response	2%
Partial response	35%
No change/stable disease	30%
Progressive disease	17%
Not assessable	16%
Progression-free and Overall Survival	
Time to disease progression	5.6 months (95% CI, 4.9–5.9 months)
Median overall survival	9.2 months (95% CI, 8.4–10.6 months)
Patients alive at 1 year	40%
Patients alive at 2 years	18%

WHO Criteria

Patient Population Studied

A trial of 445 evaluable patients with metastatic or locally recurrent, unresectable gastric carcinoma randomly assigned to receive DCF or cisplatin and fluorouracil (CF). The DCF regimen resulted in a significantly longer time to progression, survival and higher response rate than CF, but G3/4 adverse events were significant in both arms

Toxicity (N = 221)

Adverse Events	% G3/4	% All Grades
Hematologic Toxicities

Vomiting	14	61
Anorexia	10	45
Death Rate		
Death rate from all causes within 30 days after last chemotherapy		10.4%

*The most common adverse event leading to cycle delay

Notes:

- Cycle delays occurred in 64% of patients
- Dose reductions occurred in 41% of patients
- Of patients who withdrew consent, 46% had a G3/4 adverse event in the last cycle before withdrawing consent

National Cancer Institute (USA) Common Toxicity Criteria, version 2.0. Available at: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed October 25, 2013]

Therapy Monitoring

1. *Before each cycle:* Physical examination, CBC with differential, serum electrolytes, magnesium, calcium, creatinine, BUN, and LFTs
2. *Response evaluation:* Every 2 cycles

ADVANCED DISEASE REGIMENS

EPIRUBICIN (E), CISPLATIN (C), FLUOROURACIL (F), OXALIPLATIN (O), CAPECITABINE (X) ECF, ECX, EOF, AND EOX

Cunningham D et al. N Engl J Med 2008;358:36–46. Comment in: N Engl J Med 2008;358:1965, Nat Clin Pract Gastroenterol Hepatol 2008;5:414–415, N Engl J Med 2010;362:858–859

REAL-2 study conclusion: Capecitabine and oxaliplatin are as effective as fluorouracil and cisplatin, respectively, in patients with previously untreated esophagogastric cancer

ECF Regimen

Epirubicin 50 mg/m²; administer intravenously over 3–20 minutes on day 1 before cisplatin, every 3 weeks, for a maximum of 8 cycles (total dosage/cycle = 50 mg/m²)

Hydration before cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously over a minimum of 3 hours
Cisplatin 60 mg/m²; administer intravenously in 100–500 mL 0.9% NS over 30–60 minutes on day 1, every 3 weeks, for a maximum of 8 cycles (total dosage/cycle = 60 mg/m²)

Hydration after cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 3 hours. Encourage increased oral fluid intake. Goal is to achieve a urine output ≥100 mL/hour. Monitor and replace magnesium and other electrolytes as needed
Fluorouracil 200 mg/m² per day; administer by continuous intravenous infusion over 24 hours in 50–1000 mL 0.9% NS or 5% dextrose injection (D5W) for 21 consecutive days, on days 1–21, every 3 weeks, for a maximum of 8 cycles (total dosage/cycle = 4200 mg/m²)

ECX Regimen

Epirubicin 50 mg/m²; administer intravenously over 3–20 minutes on day 1 before cisplatin, every 3 weeks, for a maximum of 8 cycles (total dosage/cycle = 50 mg/m²)

Hydration before cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 3 hours
Cisplatin 60 mg/m²; administer intravenously in 100–500 mL 0.9% NS over 30–60 minutes on day 1, every 3 weeks, for a maximum of 8 cycles (total dosage/cycle = 60 mg/m²)

Hydration after cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 3 hours. Encourage increased oral fluid intake. Goal is to achieve a urine output ≥100 mL/hour. Monitor and replace magnesium and other electrolytes as needed
Capecitabine 625 mg/m² per dose; administer orally, twice daily for 21 consecutive days, on days 1–21, every 3 weeks, for a maximum of 8 cycles (total dosage/cycle = 26,250 mg/m²)

• The first 80 patients received capecitabine 500 mg/m² per dose, twice daily

EOF Regimen

Epirubicin 50 mg/m²; administer intravenously over 3–20 minutes on day 1 before oxaliplatin, every 3 weeks, for a maximum of 8 cycles (total dosage/cycle = 50 mg/m²)
Oxaliplatin 130 mg/m²; administer intravenously in 250 mL D5W over 2 hours on day 1, every 3 weeks, for a maximum of 8 cycles (total dosage/cycle = 130 mg/m²)
Note: Oxaliplatin must not be mixed with sodium chloride solutions

Fluorouracil 200 mg/m² per day; administer by continuous intravenous infusion in 50–1000 mL 0.9% NS or D5W over 24 hours for 21 consecutive days, on days 1–21, for a maximum of 8 cycles (total dosage/cycle = 4200 mg/m²)

EOX Regimen

Epirubicin 50 mg/m²; administer intravenously over 3–20 minutes on day 1 before oxaliplatin, every 3 weeks, for a maximum of 8 cycles (total dosage/cycle = 50 mg/m²)
Oxaliplatin 130 mg/m²; administer intravenously in 250 mL D5W over 2 hours on day 1, every 3 weeks, for a maximum of 8 cycles (total dosage/cycle = 130 mg/m²)
Note: Oxaliplatin must not be mixed with sodium chloride solutions

Capecitabine 625 mg/m² per dose; administer orally, twice daily for 21 consecutive days, on days 1–21, every 3 weeks, for a maximum of 8 cycles (total dosage/cycle = 26,250 mg/m²)

• The first 80 patients received capecitabine 500 mg/m² per dose, twice daily

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
Plantar-palmar erythema (PPE)	Give pyridoxine 50 mg orally 3 times daily. If PPE does not improve, hold fluorouracil or capecitabine for 1 week, then resume treatment at 75% of the dosage at which symptoms occurred
G1/2 mucositis or diarrhea	Interrupt chemotherapy until mucositis and diarrhea resolve, then resume fluorouracil or capecitabine at 75% of the dosage at which symptoms occurred
G3/4 mucositis or diarrhea	Interrupt chemotherapy until mucositis and diarrhea resolve, then resume fluorouracil or capecitabine at 50% of the dosage at which symptoms occurred
Creatinine clearance* 40–60 mL/min (0.66–1 mL/s)	Decrease the amount of cisplatin administered, so the cisplatin dose in milligrams equals the creatinine clearance* value in mL/min†
Creatinine clearance* <40 mL/min (<0.66 mL/s)	Hold cisplatin
Day 1 WBC <2000/mm³ *or* platelet count <100,000/mm³	Delay cisplatin, oxaliplatin, and epirubicin for 1 week or until myelosuppression resolves
Second treatment delay caused by myelosuppression	Delay cisplatin, oxaliplatin, and epirubicin for 1 week, or until myelosuppression resolves, then decrease cisplatin, oxaliplatin, and epirubicin dosages by 25% during subsequent treatments
Sepsis during an episode of neutropenia	
Peripheral neuropathy	Delay therapy 1 week. If symptoms do not resolve to G ≤1, reduce cisplatin or oxaliplatin dosage by 25%

*Creatinine clearance is used as a measure of glomerular filtration rate (GFR)
†This also applies to patients with creatinine clearance (GFR) of 40–60 mL/min before starting or restarting treatment

Findlay M et al. Ann Oncol 1994;5:609–616

(continued)

Supportive Care

‡A diagnosis of thromboembolism was made only in the per-protocol population
§Death within 60 days after randomization was evaluated only in the intention-to-treat population
National Cancer Institute (USA) Common Toxicity Criteria, version 2.0, were used in grading adverse events. Available at: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed October 25, 2013]

Patient Population Studied

The REAL-2 study was a trial of 1002 patients with previously untreated advanced esophagogastric cancer who were randomly assigned to 1 of 4 combination chemotherapy regimens, including epirubicin, cisplatin, and fluorouracil (ECF; N = 263); epirubicin, cisplatin, and capecitabine (ECX; N = 250); epirubicin, oxaliplatin, and fluorouracil (EOF; N = 245); and epirubicin, oxaliplatin, and capecitabine (EOX; N = 244). The primary endpoint was noninferiority in overall survival for the triplet therapies containing capecitabine or fluorouracil, and for those containing oxaliplatin or cisplatin. Progression-free survival and response rates did not differ significantly among the regimens. Adverse effects associated with capecitabine and fluorouracil were similar. In comparison with cisplatin, oxaliplatin-containing regimens had less associated G3 or G4 neutropenia, alopecia, renal toxicity, and thromboembolism but higher rates of G3 or G4 diarrhea and peripheral neuropathy. The investigators concluded capecitabine and oxaliplatin are as effective as fluorouracil and cisplatin, respectively, in patients with previously untreated esophagogastric cancer

Therapy Monitoring

1. *Before each cycle:* Physical examination, CBC and differential counts, clotting analysis, LFTs, serum creatinine and (estimated or measured) creatinine clearance
2. In patients with a history of ischemic heart disease, measure left ventricular ejection fraction by MUGA scanning or echocardiography prior to starting therapy and at intervals thereafter
3. Baseline chest radiography and computed tomography of the chest, abdomen, and pelvis, with or without upper gastrointestinal endoscopy within 28 days before treatment commences

Note: Prior to starting therapy: In patients with a history of ischemic heart disease, measure left ventricular ejection fraction by multiple gated acquisition (MUGA) scanning or echocardiography. Omit epirubicin if the left ventricular ejection fraction is <50%

ADVANCED DISEASE REGIMEN

IRINOTECAN + CISPLATIN

Ajani JA et al. Cancer 2002;94:641–646

Irinotecan 65 mg/m²; administer intravenously by intravenous infusion diluted in 5% dextrose injection (D5W) to a concentration within the range 0.12–2.8 mg/mL over 90 minutes every week for 4 consecutive weeks, weeks 1–4, every 6 weeks (total dosage/cycle = 260 mg/m²)

Hydration before cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously over a minimum of 3 hours
Cisplatin 30 mg/m²; administer intravenously in 100–500 mL 0.9% NS over 60 minutes, every week after irinotecan for 4 consecutive weeks, weeks 1–4, every 6 weeks (total dosage/cycle = 120 mg/m²)

Hydration after cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 3 hours. Encourage increased oral fluid intake. Goal is to achieve a urine output of ≥100 mL/hour. Monitor and replace magnesium and other electrolytes as needed
Note: Irinotecan and cisplatin are administered weekly for 4 consecutive weeks followed by a recovery period of 2 weeks without treatment

Supportive Care

Antiemetic prophylaxis

Emetogenic potential: ***HIGH****. Potential for delayed emetic symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed-onset diarrhea*:

Loperamide 4 mg orally initially, then 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize patient for IV hydration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose = 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

Ciprofloxacin 500 mg orally every 12 hours if absolute neutrophil count <500/mm³ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807; Wadler S et al. J Clin Oncol 1998;16:3169–3178

Acute cholinergic syndrome

Atropine sulfate 0.25–1 mg subcutaneously

- If symptoms are severe, add as primary prophylaxis during subsequent cycles
- For irinotecan, acute cholinergic syndrome is characterized by abdominal cramps, diarrhea, diaphoresis, hypotension, bradycardia, rhinitis, increased salivation, visual disturbances, and lacrimation

Patient Population Studied

A phase II trial of 36 evaluable patients with advanced untreated gastric or gastroesophageal junction carcinoma

Efficacy (N = 36)

Complete response	11%
Partial response	47%
Minor response	14%
Progressive disease	22%
Stable disease	6%
Median time to progression	24 weeks (95% CI, 16–32 weeks)
Median survival	9 months (95% CI, 7.5–10.5 months)

Toxicity (N = 36)

	% G1	% G2	% G3	% G4
Nonhematologic Toxicity				
Diarrhea	27	21	17	5
Fatigue	13	16	27	14
Myalgia	13	2	2	0
Nausea	18	32	15	1
Emesis	22	19	4	2
Neuropathy	6	2	0	0
Alopecia	36	33	0	0
Dizziness	1	2	0	0
Hematologic Toxicity				
Neutropenia	15	18	12	15
Febrile neutropenia	0	3	4	0

Note: One treatment-related death occurred in an elderly patient associated with neutropenia, sepsis, and multiple organ failure

Treatment Modifications

First modification	Consider changing the administration schedule to day 1 and day 8, every 21 days	
Subsequent modifications		
Cisplatin	Initial dose level	30 mg/m^2
	First dose reduction	20 mg/m^2
Irinotecan	Initial dose level	65 mg/m^2
	First dose reduction	50 mg/m^2
	Second dose reduction	40 mg/m^2

Adverse Event	Dose Modification
If on cycle day 1, WBC <3000/mm^3, ANC <1000/mm^3, platelet count <100,000/mm^3, serum creatinine >1.5 mg/dL (>133 μmol/L), and nonhematologic toxicity G ≥2	Hold irinotecan and cisplatin for 1 week, then resume treatment when WBC ≥3000/mm^3, ANC ≥1000/mm^3, platelet count ≥100,000/mm^3, serum creatinine <1.5 mg/dL (<133 μmol/L), and nonhematologic toxicity G ≤1
If on cycle day 1, a second episode of nonhematologic adverse event G ≥2 nonhematologic adverse event, or serum creatinine ≥1.8 mg/dL (≥159 μmol/L)	Hold cisplatin and irinotecan for 1 week, then resume at cisplatin dose decreased by one level if serum creatinine is <1.5 mg/dL (<133 μmol/L)
G4 neutropenia (with or without fever)	Add primary prophylaxis with filgrastim during all subsequent cycles
Febrile neutropenia despite filgrastim support	Hold treatment until adverse event resolves, then resume chemotherapy with irinotecan or cisplatin dosage reduced by 1 dose level
G3/4 nonhematologic adverse events (except nausea or vomiting), G3/4 diarrhea despite loperamide, G4 ANC, or thrombocytopenia during cycle 1	
Reduction in creatinine clearance* to ≤60% of on-study value	Delay therapy for 1 week. If creatinine clearance does not recover to pretreatment values, consider reducing cisplatin dosage
Creatinine clearance* 40–60 mL/min (0.66–1 mL/s)	Consider decreasing the amount of cisplatin administered, so the cisplatin dose in milligrams equals the creatinine clearance* value in mL/min†
Creatinine clearance* <40 mL/min (<0.66 mL/s)	Hold cisplatin
Peripheral neuropathy	Delay therapy for 1 week. If symptoms do not resolve to G ≤1, reduce cisplatin dose by 25%
G3/4 peripheral neurotoxicity or ototoxicity	Discontinue therapy

*Creatinine clearance is used as a measure of glomerular filtration rate (GFR)
†This also applies to patients with creatinine clearance (GFR) = 40–60 mL/min (0.66–1 mL/s) before starting or restarting treatment

Modified from Ajani JA et al. Cancer 2002;94:641–646 and Saltz LB et al. J Clin Oncol 1998;16:3858–3865

Therapy Monitoring

1. *Cycle 1:* CBC with differential, serum electrolytes, magnesium, calcium, creatinine, BUN, and LFTs on days 1 and 22
2. *Before repeated cycles:* Physical examination, CBC with differential, serum electrolytes, magnesium, calcium, creatinine, BUN, and LFTs

ADVANCED DISEASE REGIMEN

CISPLATIN + FLUOROURACIL (FUP)

Vanhoefer U et al. J Clin Oncol 2000;18:2648–2657

Fluorouracil 1000 mg/m²; administer by continuous intravenous infusion in 50–1000 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 24 hours for 5 consecutive days, on days 1–5, every 28 days (total dosage/cycle = 5000 mg/m²)

Hydration before cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 3 hours

Optional mannitol diuresis: **Mannitol** 12.5–25 g; administer by intravenous injection or infusion over 5–15 minutes before starting cisplatin

- Mannitol may be given to patients who have received adequate hydration
- Mannitol may be prepared as an admixture (in the same container) with cisplatin

Cisplatin 100 mg/m²; administer intravenously in 100–500 mL of 0.9% NS over 1 hour on day 2, every 28 days (total dosage/cycle = 100 mg/m²)

Hydration after cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 3 hours. Encourage increased oral fluid intake. Goal is to achieve a urine output of ≥100 mL/hour. Monitor and replace magnesium and other electrolytes as needed

Optional mannitol diuresis: **Mannitol** 20–50 g; administer intravenously over 2–5 hours after cisplatin

- Administer through a hydrophilic inline filter with pore size ≤5 μm to prevent infusion of mannitol crystals
- Continuing intravenous administration of fluids is essential for effective diuresis, particularly if mannitol is administered before, during, or after cisplatin

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days 1 and 3–5 is LOW

Emetogenic potential on day 2 is HIGH. Potential for delayed emetic symptoms

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed-onset diarrhea*:

Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg; administer orally every 2 hours during waking hours, *plus*
Loperamide 4 mg; administer orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)

- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily

(*continued*)

Efficacy

Eligible Patients with Measurable Disease (N = 81)	
Partial response	20% (95% CI, 11.5–30)
No change	43%
Progressive disease	21%
Early death	6%*
Not assessable	10%
Intention-to-Treat Analyses (N = 134)	
Progression-free survival	4.1 months (95% CI, 3.8–5.4 months)
Median survival	7.2 months (95% CI, 6.3–9.0 months)
Probability at 1 year for survival	27% (95% CI, 19–35%)

*Disease, 1%; toxicity, 1%; other, 4%
WHO Response Criteria

Toxicity (N = 127)

Adverse Event	% Patients with G3 or G4
Leukopenia	17
Neutropenia	35
Thrombocytopenia	9
Infection	5
Nausea/vomiting	26
Mucositis	12
Diarrhea	6
Renal	2
Peripheral neuropathy	<1
Alopecia	16
Treatment-related death in 2 patients	

WHO criteria

(*continued*)

- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population

The EORTC trial 40902 of 245 eligible patients with advanced adenocarcinoma of the stomach randomized to receive sequential high-dose methotrexate, fluorouracil, and doxorubicin (FAMTX) versus etoposide, leucovorin, and fluorouracil (ELF) versus infusional fluorouracil and cisplatin (FUP). The overall response rate in patients with measurable disease was 12% (FAMTX), 9% (ELF), and 20% (FUP)

Therapy Monitoring

1. *Before each cycle:* Physical examination, CBC with differential, serum electrolytes, magnesium, calcium, creatinine, BUN, and LFTs
2. *Response evaluation:* Every 2 cycles

Treatment Modifications

Dosage Levels		
Cisplatin	Initial dosage	100 mg/m²
	Level −1	75 mg/m²
	Level −2	50 mg/m²
Fluorouracil	Initial dosage	1000 mg/m² per day for 5 days
	Level −1	800 mg/m² per day for 5 days
	Level −2	600 mg/m² per day for 5 days

Adverse Event	Dose Modification
Plantar-palmar erythema (PPE)	Give pyridoxine 50 mg orally 3 times daily. If PPE does not improve, hold fluorouracil for 1 week, then resume fluorouracil at 1 dose level less than that at which symptoms occurred
G1/2 mucositis or diarrhea	Interrupt chemotherapy until mucositis and diarrhea resolve, then resume fluorouracil at 1 dose level less than that at which symptoms occurred
G3/4 mucositis or diarrhea	Interrupt chemotherapy until mucositis and diarrhea resolve, then resume fluorouracil at 2 dose levels less than that at which symptoms occurred
Reduction in creatinine clearance* to ≤60% of on-study measurement	Delay therapy for 1 week. If creatinine clearance does not recover to pretreatment values, then decrease cisplatin dosage by 1 dose level
Creatinine clearance* 40–60 mL/min (0.66–1 mL/s)	Consider decreasing the amount of cisplatin administered, so the cisplatin dose in milligrams equals the creatinine clearance* value in mL/min†
Creatinine clearance* <40 mL/min (<0.66 mL/s)	Hold cisplatin
Peripheral neuropathy	Delay therapy for 1 week. If symptoms do not resolve to G ≤1, reduce cisplatin by 1 dose level
G3/4 peripheral neurotoxicity or ototoxicity	Discontinue therapy

Other modifications as clinically indicated based on the most significant toxicity
*Creatinine clearance is used as measure of glomerular filtration rate (GFR)
†This also applies to patients with creatinine clearance (GFR) of 40–60 mL/min (0.66–1 mL/s) before starting or restarting treatment

ADVANCED DISEASE REGIMENS

CISPLATIN + FLUOROURACIL (CF)
IRINOTECAN + FLUOROURACIL (IF)

Dank M et al. Ann Oncol 2008;19:1450–1457

Cisplatin + Fluorouracil (CF):

Hydration before cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously over a minimum of 3 hours

Optional mannitol diuresis: **Mannitol** 12.5–25 g; administer by intravenous injection or infusion over 5–15 minutes before starting cisplatin
- Mannitol may be given to patients who have received adequate hydration
- Mannitol may be prepared as an admixture (in the same container) with cisplatin

Cisplatin 100 mg/m²; administer intravenously in 100–500 mL 0.9% NS over 1–3 hours on day 1, every 28 days (total dosage/cycle = 100 mg/m²)

Hydration after cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 3 hours. Encourage increased oral fluid intake. Goal is to achieve a urine output of ≥100 mL/hour. Monitor and replace magnesium and other electrolytes as needed

Optional mannitol diuresis: **Mannitol** 20–50 g; administer intravenously over 2–5 hours after cisplatin
- Administer through a hydrophilic inline filter with pore size ≤5 μm to prevent infusion of mannitol crystals
- Continuing intravenous fluid administration is essential for effective diuresis, particularly if mannitol is administered before, during, or after cisplatin

Fluorouracil 1000 mg/m² per day; administer by continuous intravenous infusion in 50–1000 mL 0.9% NS or 5% dextrose injection over 24 hours for 5 consecutive days, on days 1–5, every 28 days (total dosage/cycle = 5000 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed emetic symptoms*
Emetogenic potential on days 2–5 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Irinotecan + Fluorouracil (IF):

Note: IF provides a platinum-free frontline treatment alternative for metastatic gastric cancer

Irinotecan 80 mg/m² per dose; administer intravenously diluted in D5W to a concentration within the range 0.12–2.8 mg/mL over 30 minutes, weekly, for 6 consecutive weeks followed by a 1-week rest (total dosage/7-week cycle = 480 mg/m²), *followed by:*
Leucovorin 500 mg/m² per dose; administer intravenously in 25–250 mL 0.9% NS or D5W over 2 hours, weekly, for 6 consecutive weeks followed by a 1-week rest (total dosage/7-week cycle = 3000 mg/m²), *followed by:*
Fluorouracil 2000 mg/m² per dose; administer intravenously in 50–1000 mL 0.9% NS or D5W over 22 hours, weekly, for 6 consecutive weeks followed by a 1-week rest
(total dosage/7-week cycle = 12,000 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential: ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

(continued)

(continued)

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome associated with irinotecan

Atropine sulfate 0.25–1 mg subcutaneously

- If symptoms are severe, add as primary prophylaxis during subsequent cycles
- For irinotecan, acute cholinergic syndrome is characterized by: abdominal cramps, diarrhea, diaphoresis, hypotension, bradycardia, rhinitis, increased salivation, visual disturbances, and lacrimation

Supportive Care for both CF and IF regimens:

Diarrhea management

Latent or delayed-onset diarrhea:*

Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg; administer orally every 2 hours during waking hours, *plus*
Loperamide 4 mg; administer orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)

- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide acetate (solution) 100–150 mcg; administer subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed-onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols

(continued)

(continued)

- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE, although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Treatment Modifications (*continued*)

Treatment Modifications for Cisplatin + Fluorouracil (CF)

Adverse Event	Modification
ANC <1000/mm^3, *or* platelet count <100,000/mm^3, *or* diarrhea on day 1 of any cycle	Delay treatment for up to 2 weeks until ANC ≥1000/mm^3, platelet count is ≥100,000/mm^3, and diarrhea resolves. Resume treatment with cisplatin or fluorouracil dosages decreased by 1 dosage level if ANC recovers within 2 weeks after the planned retreatment date. If toxicity does not resolve within 2 weeks, permanently discontinue treatment
G4 neutropenia with or without fever	Give filgrastim during subsequent cycles from day 6 until ANC recovers to 5,000/mm^3 on a single measurement, or is >1000/mm^3 on two measurements separated by ≥1 day. Consider decreasing the cisplatin dosage by 1 dosage level during subsequent cycles
Febrile neutropenia, *or* neutropenia and infection, *or* G3/4 neutropenia for >7 days	Give filgrastim during subsequent cycles from day 6 until ANC recovers to ≥5,000/mm^3 on a single measurement, or is >1000/mm^3 on two measurements separated by ≥1 day
G1/2 mucositis/stomatitis	Withhold treatment until mucositis/stomatitis resolves, then resume treatment. Consider decreasing fluorouracil dosage by 1 dosage level
G3 mucositis/stomatitis of >48 hours duration	Withhold treatment until mucositis/stomatitis resolves, then resume treatment with fluorouracil dosage decreased by 1 dosage level
G4 mucositis/stomatitis	Permanently discontinue treatment
G1 diarrhea (2–3 stools/day > baseline)	Maintain cisplatin and fluorouracil dosages and schedules. Treat with loperamide or other antidiarrheal agents
G2 diarrhea (4–6 stools/day > baseline)	Withhold treatment and treat with loperamide or other antidiarrheal agents until diarrhea resolves to baseline. Then resume treatment with fluorouracil dosage decreased by 1 dosage level
G3 diarrhea (7–9 stools/day > baseline)	
G4 diarrhea (≥10 stools/day > baseline)	Withhold treatment and treat with loperamide or other antidiarrheal agents until diarrhea resolves to baseline. Then resume treatment with fluorouracil dosage decreased by 2 dosage levels
If on day 1 of a cycle, serum creatinine is >1.8 mg/dL (>159 μmol/L), or other non-hematological adverse event G ≥2	Withhold cisplatin for 1 week. Then, if serum creatinine has decreased to <1.5 mg/dL (<133 μmol/L), resume treatment with cisplatin dosage decreased by 1 dosage level
Decrease in creatinine clearance to ≤60% of on-study value*	Delay treatment for 1 week. If creatinine clearance does not recover to pre-treatment values, resume treatment with cisplatin dosage decreased by 1 dosage level
Creatinine clearance <40 mL/min (<0.66 mL/s)	Withhold cisplatin
G2 peripheral neuropathy	Delay treatment for 1 week. If neuropathy has not abated to G ≤1 after a 1-week delay, resume treatment with cisplatin dosage decreased by 1 dosage level
G3/4 peripheral neuropathy or ototoxicity	Permanently discontinue treatment
Concomitant vomiting with diarrhea, fever, or decreased performance status	Hospitalization for intravenous hydration and supportive care
G1 palmar-plantar erythrodysesthesia (PPE, hand-foot syndrome)	Give pyridoxine 50 mg orally 3 times daily. Continue fluorouracil without modification
G2/3 PPE	Give pyridoxine 50 mg orally 3 times daily. After PPE signs and symptoms resolve, resume fluorouracil at 1 dosage level less than that at which symptoms occurred
Recurrent G3 PPE (at dosage level –1)	Continue pyridoxine 50 mg orally 3 times daily. After PPE signs and symptoms resolve, resume fluorouracil at 1 dosage level less than that at which symptoms occurred
>2 Dosage reductions required	Permanently discontinue treatment

(*continued*)

Treatment Modifications (*continued*)

Treatment Modifications for Irinotecan + Fluorouracil (IF)

Adverse Event	Modification
ANC <1500/mm^3, platelet count <100,000/mm^3, or diarrhea G >1	Delay treatment for up to 2 weeks. Resume treatment with irinotecan and fluorouracil dosages decreased by 1 dosage level if ANC recovers to ≥1500/mm^3, platelet count is ≥100,000/mm^3, and diarrhea resolves within 2 weeks after the planned retreatment date
G4 neutropenia with or without fever	Give filgrastim on the days between repeated treatments, but discontinue filgrastim at least 24 hours before resuming treatment. Consider decreasing the irinotecan dosage by 1 dosage level during subsequent cycles
G3/4 neutropenia (duration >7 days)	Withhold treatment until neutropenia has resolved. Resume treatment with irinotecan dosage decreased by 1 dosage level. Give filgrastim on the days between repeated treatments, but discontinue filgrastim at least 24 hours before resuming treatment
Febrile neutropenia	Withhold treatment until fever and neutropenia are resolved, then resume treatment at the same dosages previously given. Consider secondary prophylaxis with filgrastim on the days between repeated treatments, but discontinue filgrastim at least 24 hours before resuming treatment
Febrile neutropenia, second episode despite filgrastim use	Withhold treatment until fever and neutropenia are resolved, then resume treatment with irinotecan dosage decreased by 1 dosage level. Continue filgrastim on the days between repeated treatments, but discontinue filgrastim at least 24 hours before resuming treatment
G1/2 mucositis/stomatitis	Withhold treatment until mucositis/stomatitis resolves, then resume treatment. Consider decreasing fluorouracil dosage by 1 dosage level
G1 diarrhea (2–3 stools/day > baseline)	Maintain irinotecan and fluorouracil dosages and schedules. Treat with loperamide or other antidiarrheal agents
G2 diarrhea (4–6 stools/day > baseline)	Withhold treatment and treat with loperamide or other antidiarrheal agents until diarrhea resolves to baseline. Then resume treatment with irinotecan dosage decreased by 1 dosage level
G3 diarrhea (7–9 stools/day > baseline)	
G4 diarrhea (≥10 stools/day > baseline)	Withhold treatment and treat with loperamide or other antidiarrheal agents until diarrhea resolves to baseline. Then resume treatment with irinotecan dosage decreased by 2 dosage levels
Diarrhea persisting >48 h, despite loperamide	Hospitalization, broad-spectrum antibiotic treatment (eg, a fluoroquinolone), and replace loperamide with alternative antidiarrheal agents
G3/4 neutropenia with diarrhea, *or* diarrhea with fever or infection	Withhold treatment until toxicities have resolved then resume treatment with irinotecan and/or fluorouracil dosages decreased by 1 dosage level
Diarrhea concomitant with vomiting, fever, or decreased performance status (Karnofsky scale <70%; ECOG>2)	Hospitalization for intravenous hydration and supportive care
G3 mucositis/stomatitis of >48 hours duration	Withhold treatment until mucositis/stomatitis resolves, then resume treatment with fluorouracil dosage decreased by 1 dosage level
G4 mucositis/stomatitis	Discontinue treatment
G1 palmar-plantar erythrodysesthesia (PPE, hand-foot syndrome)	Give pyridoxine 50 mg orally 3 times daily. Continue fluorouracil without modification
G2/3 PPE	Give pyridoxine 50 mg orally 3 times daily. After PPE signs and symptoms resolve, resume fluorouracil at 1 dosage level less than that at which symptoms occurred
Recurrent G3 PPE (recurrence at dosage level –1)	Continue pyridoxine 50 mg orally 3 times daily. After PPE signs and symptoms resolve, resume fluorouracil at 1 dosage level less than that at which symptoms occurred
>2 Dosage reductions required	Permanently discontinue treatment

Other Non-hematological Toxicities (CF and IF regimens)

Any G1 toxicity not specifically addressed above	Continue treatment at the same dosages and on the same schedules
Any G2/3 toxicity not specifically addressed above	Withhold treatment until toxicity resolves to G ≤1 or for up to 2 weeks. Then, resume treatment with the dosages of suspected contributing agents decreased by 1 dosage level or 25%. If toxicity does not resolve to G ≤1 within 2 weeks, discontinue treatment
Any G4 toxicity not specifically addressed above	Withhold treatment until toxicity resolves to G ≤1 or for up to 2 weeks. Then, resume treatment with the dosages of suspected contributing agents decreased by 2 dosage levels or 50%. If toxicity does not resolve to G ≤1 within 2 weeks, discontinue treatment

Other modifications as clinically indicated based on the most significant toxicity
*Creatinine clearance is used as measure of glomerular filtration rate

Ajani JA et al. Cancer 2002;94:641–646 and Saltz LB et al. J Clin Oncol 1998;16:3858–3865
Pozzo C et al. Ann Oncol 2004;15:1773–1781

ADVANCED DISEASE REGIMEN

HER2-POSITIVE ADVANCED GASTRIC CANCER
CISPLATIN + TRASTUZUMAB WITH CAPECITABINE *OR* FLUOROURACIL

Bang Y-J et al. Lancet 2010;376:687–697

Either:
Capecitabine 1000 mg/m² per dose; administer orally twice daily for 14 consecutive days, on days 1–14 (28 doses), every 3 weeks for 6 cycles, (total dosage/cycle = 28,000 mg/m²)
OR
Fluorouracil 800 mg/m² per day; administer by continuous intravenous infusion in 50–1000 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection over 24 hours for 5 consecutive days, on days 1–5, every 3 weeks, for 6 cycles (total dosage/cycle = 4000 mg/m²)
With:
Hydration before cisplatin: 1000 mL 0.9% NS; administer intravenously over a minimum of 1 hour before commencing cisplatin administration
(optional) **Mannitol** 12.5–25 g; administer by intravenous injection or intravenous infusion over 5–15 minutes before starting cisplatin
- Mannitol may be given to patients who have received adequate hydration. Continued hydration is essential to ensure diuresis
- Mannitol may be prepared as an admixture (in the same container) with cisplatin

Cisplatin 80 mg/m²; administer intravenously in 50–500 mL 0.9% NS over 30–60 minutes on day 1, every 3 weeks, for 6 cycles (total dosage/cycle = 80 mg/m²)
Hydration after cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 2 hours. Monitor and replace magnesium and other electrolytes as needed. Encourage patients to increase their intake of non-alcoholic fluids
Trastuzumab: Administer intravenously in 250 mL 0.9% NS every 3 weeks for 6 cycles
Loading Dose: **Trastuzumab** 8 mg/kg; administer over 90 minutes as a loading dose on cycle 1, day 1 only (total dosage during the 1st cycle = 8 mg/kg), *then:*
Maintenance Doses: **Trastuzumab** 6 mg/kg; administer over 30 minutes on day 1, every 21 days for 5 cycles (total dosage/cycle = 6 mg/kg)

Note: Assess left ventricular ejection fraction (LVEF) prior to initiating trastuzumab and at regular intervals during treatment
Crossover to trastuzumab at the time of disease progression was not allowed

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential on days with cisplatin is **HIGH**. Potential for delayed emetic symptoms*
*Emetogenic potential on days with capecitabine or fluorouracil is **LOW***
*Emetogenic potential on days with trastuzumab alone is **MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed-onset diarrhea*:
Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg; administer orally every 2 hours during waking hours, *plus*
Loperamide 4 mg; administer orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

(*continued*)

(*continued*)

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)
- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Trastuzumab infusion reactions
- A symptom complex most commonly consisting of chills and/or fever may occur in as many as 40% of patients during the first infusion of trastuzumab. These symptoms occur infrequently with subsequent trastuzumab infusions. Other signs and/or symptoms may include nausea, vomiting, pain (in some cases at tumor sites), rigors, headache, dizziness, dyspnea, hypotension, rash, and asthenia. Although the symptoms are usually mild to moderate in severity, infrequently, trastuzumab may need to be discontinued
- When such a symptom complex is observed, it can be treated with or without reduction in the rate of trastuzumab infusion, and:
  - **Acetaminophen** 650 mg; administer orally
  - **Diphenhydramine** 25–50 mg administer orally or by intravenous injection, and
  - **Meperidine** 12.5–25 mg; administer by intravenous injection every 10 minutes if needed for shaking chills (generally, cumulative doses >50 mg are not needed; use with caution in persons with moderate or more severely impaired renal function)

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)
For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE, although the mechanism through which this occurs remains unclear
- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day

Oral care
Prophylaxis and treatment for mucositis/stomatitis
General advice:
- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:
- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:
- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque

Advise patients who develop mucositis to:
- Choose foods that are easy to chew and swallow
- Take small bites of food, chew slowly, and sip liquids with meals
- Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
- For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
- Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Treatment Modifications

Adverse Event	Dose Modification
ANC nadir <1000/mm³ *or* platelet nadir <50,000/mm³ after treatment	Delay treatment until ANC ≥1000/mm³ *and* platelet ≥50,000/mm³, then decrease cisplatin dosage by 25%, and decrease daily capecitabine or fluorouracil dosages by 50% during subsequent cycles*. Alternatively, consider using hematopoietic growth factors
Serum creatinine >1.5 mg/dL (>133 μmol/L), but <3 mg/dL (<265 μmol/L) *or* creatinine clearance >40 mL/min (>0.66 mL/s) but <60 mL/min (<1 mL/s)	Delay treatment until serum creatinine ≤1.5 mg/dL (≤133 μmol/L), then decrease cisplatin dosage by 50%*
Serum creatinine >3 mg/dL (>265 μmol/L) *or* creatinine clearance <40 mL/min (<0.66 mL/s)	Stop cisplatin
Persistent G2 neuropathy	Hold cisplatin until toxicity resolves to G ≤1; reduce cisplatin dosage by 25% for subsequent cycles
Transient G3/4 neuropathy (duration 7–14 days)	Hold cisplatin. Resume cisplatin after toxicity resolves with dosage reduced by 25% for subsequent cycles
Persistent G3/4 neuropathy	Discontinue cisplatin
G3/4 nonhematologic adverse events other than renal function and neurotoxicity	Reduce cisplatin and capecitabine dosages by 25% for subsequent cycles
G2 stomatitis, diarrhea, or nausea	Hold capecitabine or fluorouracil; resume capecitabine or fluorouracil at full dosage after resolution of toxicity
Second episode of G2 stomatitis, diarrhea, or nausea	Hold capecitabine or fluorouracil; resume capecitabine or fluorouracil with dosage reduced by 25% after resolution of toxicity
Third episode of G2 stomatitis, diarrhea, or nausea	Hold capecitabine or fluorouracil; resume capecitabine or fluorouracil with dosage reduced by 50% after resolution of toxicity
Fourth episode of G2 stomatitis, diarrhea, or nausea	Discontinue capecitabine or fluorouracil
G3 stomatitis, diarrhea, or nausea	Hold capecitabine or fluorouracil; if G3 toxicity is adequately controlled within 2 days, resume capecitabine at full dosage when toxicity resolves to G ≤1
G3 stomatitis, diarrhea, or nausea	Hold capecitabine or fluorouracil; if G3 toxicity takes >2 days to be controlled, resume capecitabine or fluorouracil with dosage reduced by 25% after toxicity resolves to G ≤1
Second episode of G3 stomatitis, diarrhea, or nausea	Hold capecitabine or fluorouracil; if G3 toxicity is controlled adequately within 2 days, then resume capecitabine or fluorouracil with dosage reduced by 50% after toxicity resolves to G ≤1
Third episode of G3 stomatitis, diarrhea, or nausea	Discontinue capecitabine or fluorouracil
G4 stomatitis, diarrhea, or nausea	Discontinue capecitabine or fluorouracil. Resume capecitabine or fluorouracil with dosage reduced by 50% after toxicity resolves
G1 capecitabine-associated PPE†	Begin pyridoxine 50 mg orally 3 times daily and continue capecitabine without dose modification
G2 capecitabine-associated PPE†	Begin pyridoxine 50 mg orally 3 times daily and withhold capecitabine. Resume capecitabine with dosage reduced by 15% after toxicity resolves

(*continued*)

Patient Population Studied

Patients with histologically confirmed inoperable locally advanced, recurrent, or metastatic adenocarcinoma of the stomach or gastro-esophageal junction. Tumors were centrally tested for HER2 status with immunohistochemistry and fluorescence *in situ* hybridization. Patients were eligible if their tumor samples were scored as 3+ on immunohistochemistry or if they were FISH positive (HER2:CEP17 ratio ≥2). Major exclusion criteria included a history of cardiac disease

Patient Characteristics Trastuzumab + Chemotherapy (N = 293)

Age (years)	59.4 (10.8)
ECOG performance status	
0–1	264 (90%)
2	30 (10%)
Men	226 (77%)

Locally advanced	10 (3%)
Metastatic	284 (97%)

(*continued*)

Treatment Modifications (*continued*)

Adverse Event	Dose Modification
G3 capecitabine-associated PPE*	Begin pyridoxine 50 mg orally 3 times daily and withhold capecitabine. Resume capecitabine with dosage reduced by 30% after toxicity resolves
Recurrent G3 capecitabine-associated PPE*	Continue pyridoxine 50 mg orally 3 times daily and withhold capecitabine. Resume capecitabine with dosage reduced by 50% after toxicity resolves
Mild or moderate infusion reaction due to trastuzumab	Decrease the rate of trastuzumab infusion
Infusion reaction characterized by dyspnea or clinically significant hypotension	Interrupt the trastuzumab infusion. Monitor patients until symptoms completely resolve. After symptoms resolve restart the infusion at a slower rate
Severe or life-threatening infusion reactions due to trastuzumab—anaphylaxis, angioedema, interstitial pneumonitis, or acute respiratory distress syndrome	Discontinue trastuzumab
≥16% absolute decrease in LVEF from pretreatment values	Withhold trastuzumab dosing for at least 4 weeks. Trastuzumab may be resumed if, within 4–8 weeks, the LVEF returns to normal limits and the absolute decrease from baseline is ≤15%
LVEF below institutional limits of normal and ≥10% absolute decrease in LVEF from pretreatment values	
Persistent (>8 weeks) LVEF decline or suspension of trastuzumab dosing on more than 3 occasions for cardiomyopathy	Permanently discontinue trastuzumab

*Treatment delays for unresolved adverse events of >3 weeks duration warrant discontinuation of treatment
†PPE, Palmar plantar erythrodysesthesia (hand-foot syndrome)

Treatment Monitoring

1. CBC with differential, serum electrolytes, magnesium and calcium, BUN, and creatinine before the start of a new cycle
2. Tumor assessment every two cycles
3. LVEF assessment (MUGA or echocardiography) every 3 months in patients receiving trastuzumab

ADVANCED DISEASE REGIMENS

SINGLE-AGENT DOCETAXEL *OR* SINGLE-AGENT IRINOTECAN IN SECOND LINE

Kang JH et al. J Clin Oncol 2012;30:1513–1518

Docetaxel 60 mg/m²; administer intravenously in a volume of 0.9% sodium chloride injection or 5% dextrose injection (D5W) sufficient to produce a docetaxel concentration within the range 0.3–0.74 mg/mL over 60 minutes on day 1, every 3 weeks (total dosage/cycle = 60 mg/m²)
OR
Irinotecan 150 mg/m²; administer intravenously in 500 mL D5W over 90 minutes on day 1, every 2 weeks (total dosage/cycle = 150 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential with docetaxel is ***LOW***
Emetogenic potential with irinotecan is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Acute cholinergic syndrome
Atropine sulfate 0.25–1 mg; administer subcutaneously or intravenously if abdominal cramping or diarrhea develops during or within 1 hour after irinotecan administration
- If symptoms are severe, add as primary prophylaxis at least 30 min before irinotecan during subsequent cycles
- For irinotecan, acute cholinergic syndrome may be characterized by abdominal cramping, diarrhea, diaphoresis, hypotension, flushing, bradycardia, rhinitis, increased salivation, meiosis, and lacrimation

Diarrhea management
Latent or delayed-onset diarrhea*:*
Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg; administer orally every 2 hours during waking hours, *plus*
Loperamide 4 mg; administer orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)
- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:
Octreotide acetate (solution) 100–150 mcg; administer subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed-onset diarrhea:
A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm³ with or without accompanying fever in association with diarrhea
- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

(continued)

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Toxicity

Maximum Grade Adverse Events per Patient

	Docetaxel (N = 66)		Irinotecan (N = 60)		Best Supportive Care (N = 62)	
Adverse Event	% All G	% G3/4	% All G	% G3/4	% All G	% G3/4
Neutropenia	62%	15%	58%	18%	13%	2%
Anemia	76%	30%	77%	32%	61%	23%
Thrombocytopenia	24%	2%	22%	3%	5%	0%
Fatigue	38%	26%	22%	10%	40%	27%
Anorexia	17%	6%	33%	5%	47%	10%
Nausea	21%	5%	32%	3%	32%	6%
Diarrhea	14%	3%	15%	8%	18%	5%
Stomatitis	15%	3%	18%	5%	5%	2%

Treatment Modifications

Docetaxel

Adverse Event	Dose Modification
G4 neutropenia for >7 days, alone, or accompanied by fever >38°C (>100.4°F)	Reduce docetaxel dosage by 25% in all subsequent treatments
G4 thrombocytopenia	After platelet count recovers, resume docetaxel with dosage decreased by 25%
G4 vomiting not controlled by antiemetics	Reduce docetaxel dosage by 25%
G ≥3 diarrhea	
G ≥3 neuropathy	Discontinue therapy

Irinotecan

	Dosage Levels		
	Initial	−1	−2
Irinotecan	150 mg/m²	120 mg/m²	90 mg/m²

Notes:

- Dose modifications are based on National Cancer Institute (USA) Common Terminology Criteria for Adverse Events, version 3.0. Available at: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]
- Before beginning a treatment cycle, patients should have baseline bowel function without antidiarrheal therapy for 24 hours, ANC ≥1500/mm³, and platelet count ≥100,000/mm³
- Treatment should be delayed 1–2 weeks to allow for recovery from treatment-related toxicities
- If a patient has not recovered after 2 weeks, consider stopping therapy. If toxicity occurs despite 2 dose reductions (ie, on level −2), discontinue therapy

Adverse Event	Dose Modifications
Neutropenia/Thrombocytopenia	
G1 ANC (1500–1999/mm³) or G1 thrombocytopenia (75,000/mm³ to less than normal limits)	Maintain dose and schedule
G2 ANC (1000–1499/mm³) or G2 thrombocytopenia (≥50,000 to <75,000/mm³)	Reduce dosage by 1 dosage level
G3 ANC (500–999/mm³) or G3 thrombocytopenia (≥10,000 to <50,000/mm³)	Hold treatment until toxicity resolves to G ≤2, then reduce dosage by 1 dosage level
G4 ANC (<500/mm³) or G4 thrombocytopenia (<10,000/mm³)	Hold treatment until toxicity resolves to G ≤2, then reduce dosage by 2 dosage levels
Febrile neutropenia	Hold treatment until neutropenia resolves, then reduce dosage by 2 dosage levels
Diarrhea	
G1 (2–3 stools/day greater than baseline)	Maintain dose and schedule
G2 or G3 (4–9stools/day greater than baseline)	Delay until diarrhea resolves to baseline, then reduce dosage by 1 dosage level
G4 (≥10 stools/day greater than baseline)	Delay until diarrhea resolves to baseline, then reduce dosage by 2 dosage levels
Other Nonhematologic Toxicities	
Any G1 toxicity	Maintain dose and schedule
Any G2 or G3 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage by 1 dosage level
Any G4 toxicity	Hold treatment until toxicity resolves to G ≤1, then reduce dosage by 2 dosage levels

HR, hazard ratio

Treatment Monitoring

1. CBC with differential, serum electrolytes, magnesium and calcium, BUN, creatinine, and liver function tests before the start of a new cycle
2. Tumor assessment every two cycles

13. Gestational Trophoblastic Neoplasia

John R. Lurain, MD

Epidemiology

Incidence:*
Hydatidiform mole: 1 in 1000–2000 pregnancies (United States and Europe)
Choriocarcinoma: 1 in 20,000–40,000 pregnancies (United States and Europe)
Gestational trophoblastic neoplasia (GTN) lesions are nearly always disorders of the reproductive years. The incidence is higher in women <20 years and >40 years

*The reported incidence of hydatidiform mole and choriocarcinoma varies widely throughout the world, being greatest in Asia, Africa, and Latin America, and substantially lower in North America and Europe
Lurain JR. Am J Obstet Gynecol 2010;203:531–539

Pathology

Hydatidiform Mole

Benign (80%)	GTN (20%)
Complete hydatidiform mole	Invasive mole (18%)
Partial hydatidiform mole	Choriocarcinoma (2%)*
	Placental site trophoblastic tumor (rare)
	Epithelioid trophoblastic tumors (rare)

**Note:* Half of all choriocarcinomas occur in association with nonmolar pregnancies

Gestational Trophoblastic Neoplasia

- Potential for local invasion and metastases
- Most commonly develops after a molar pregnancy, but can arise de novo after any gestational experience: spontaneous or induced abortion, ectopic pregnancy, or preterm or term pregnancy
- The most common sites of metastases are lungs (80%), brain (10%) liver (10%), and vagina (~5%)

Hancock BW et al. Gestational Trophoblastic Disease, 3rd ed, 2009

Staging

FIGO Anatomic Staging System for GTN

Stage	Extent of GTN
I:	Confined to the uterus
II:	Extends outside the uterus, but is limited to the genital structures (adnexa, vagina, broad ligament)
III:	Extends to the lungs, with or without known genital tract involvement
IV:	All other metastatic sites

(continued)

Work-up

Once a diagnosis of GTN has been made, it is necessary to determine the extent of disease

Once the initial work-up is completed, patients are categorized (see Staging below)

1. H&P
2. Serum hCG

Note: For staging purposes, the hCG level that is important is that obtained immediately before instituting treatment and not the hCG obtained at the time of the previous molar evacuation

3. CBC, LFT, serum electrolytes, BUN, creatinine, PTT, and PT
4. Chest x-ray
5. CT of chest, abdomen, and pelvis
6. MRI brain (especially in patients with lung lesions. Asymptomatic patients with a normal chest x-ray are unlikely to have brain metastasis)
7. TSH, T_4 (elevations of thyroid tests are not common in patients with GTN but can occur mostly in association with hydatidiform mole)

Lurain JR. American J Obstet Gynecol 2011;204:11–18

Staging (*continued*)

FIGO Scoring System* (Modified WHO Scoring System)

[*Note:* This scoring system does not apply to patients with placental-site trophoblastic tumors]

Prognostic Factor	0	1	2	4
Age (years)	≤39	>39	—	—
Antecedent pregnancy	Hydatidiform mole	Abortion	Term pregnancy	—
Interval from index pregnancy	<4 months	4–6 months	7–12 months	>12 months
Pretreatment hCG level (IU/L)	<1000	1000–10,000	>10,000–100,000	>100,000
Largest tumor size including uterus	—	3–4 cm	≥5 cm	—
Sites of metastases	Lung†	Spleen, kidney	GI tract	Brain, liver
Number of metastases identified†	0	1–4	5–8	>8
Previous ineffective chemotherapy	—	—	Single drug	≥2 drugs

*FIGO staging system includes a modification of the WHO prognostic index score for risk assessment
†Chest x-ray is used to count the number of metastases for risk score assessment

Note: Total score for a patient is obtained by adding individual scores for each prognostic factor

Total Score	Risk
0–6	Low risk
≥7	High risk

Both **FIGO Anatomic Staging System** and the **Modified WHO score should be** used. By convention, the FIGO stage is depicted by a Roman numeral and is followed by the Modified WHO Score depicted by an Arabic numeral. The 2 values are separated by a colon (eg, III:9)

Kohorn EI:. Int J Gynecol Cancer 2001;11:73–77
Ngan HYS et al. Int J Gynaecol Obstet 2003;83:175–177

Survival

GTN can be cured predictably even in the presence of widespread metastases. Overall survival is >95%, with survival rates approaching 100% for stage I and stages II/III with WHO score <7 and 80–90% for stage IV or WHO score >7 disease

Expert Opinion

Nonmetastatic GTN

1. Patients with nonmetastatic GTN (FIGO stage I) should be treated with single-agent methotrexate or dactinomycin chemotherapy. Several different outpatient chemotherapy protocols have been used, yielding excellent and fairly comparable results. Hysterectomy may be used as part of primary therapy in patients who no longer desire to preserve fertility
2. Cure is anticipated in 100% of patients with nonmetastatic GTN. Approximately 85–90% of patients will be cured by the initial single-agent chemotherapy regimen. Most of the remaining patients will be placed into permanent remission with an alternate single agent. Multiagent chemotherapy is needed in approximately 2%, and hysterectomy is required in fewer than 5% of patients to achieve cure
   a. Methotrexate given intravenously for 5 days every 2 weeks* results in the highest primary remission rate of approximately 90%
   b. Methotrexate + leucovorin (folinic acid) given over 8 days every two weeks†§ is reported to have decreased toxicity (especially stomatitis), but is also more expensive, less convenient, and associated with a more frequent need for a change in chemotherapy (20–25%) to achieve remission

(*continued*)

Expert Opinion (*continued*)

c. Methotrexate 30–50 mg/m^2 by intramuscular injection once weekly
Methotrexate 100 mg/m^2 per dose by intravenous injection over 5–30 seconds, followed by:
Methotrexate 200 mg/m^2 by intravenous infusion in 25–1000 mL 0.9% NS or D5W over 12 hours
Leucovorin 15 mg/dose by intramuscular injection or orally every 12 hours for 4 doses starting 24 hours after beginning the methotrexate
- These treatment protocols are NOT recommended because of the lower primary remission rates of 53–70% and the more frequent need for multiagent chemotherapy to achieve remission

d. Dactinomycin given on a 5-day regimen every 2 weeks[**] or once every 2 weeks[††] are acceptable alternatives to methotrexate
- Dactinomycin generally causes more nausea and alopecia than methotrexate and produces vesicant injury if extravasation into perivascular tissues occurs. Therefore, dactinomycin is most often used as secondary therapy in the presence of methotrexate resistance or as primary therapy when patients have hepatic or renal compromise or effusions contraindicating the use of methotrexate

Low-Risk Metastatic GTN

1. Patients categorized as having low-risk metastatic GTN (FIGO stages II and III, score <7) can usually be treated successfully with sequential single-agent chemotherapy[*], with:
   - A 5-day methotrexate or dactinomycin regimen[ᶜ]
   - An 8-day methotrexate and leucovorin regimen
2. When resistance to sequential single-agent chemotherapy develops, multiagent chemotherapy as for high-risk disease should be given. Hysterectomy may become necessary to eradicate persistent, chemotherapy-resistant disease in the uterus, or it may be performed as adjuvant treatment coincident with the initiation of chemotherapy to shorten the duration of treatment if fertility preservation is not desired
3. Cure rate for low-risk metastatic GTN approaches 100%. Because approximately 30–50% of patients in this category develop resistance to the first chemotherapeutic agent, it is important to carefully monitor patients for evidence of drug resistance so that a change in chemotherapy can be made at the earliest possible time. Eventually, 5–15% of patients treated with sequential single-agent chemotherapy will require multiagent chemotherapy or surgery to achieve remission

High-Risk Metastatic GTN

1. Patients with high-risk metastatic GTN (FIGO stage IV or score ≥7) should be treated initially with multiagent chemotherapy with or without adjuvant surgery or radiation therapy. The EMA/CO protocol, or some variation of it, is currently the treatment of choice for high-risk metastatic GTN because of low toxicity allowing adherence to treatment schedule and relatively high complete response rates of 70–80%[‡‡,§§]
2. When central nervous system metastases are present, whole-brain irradiation (3000 cGy in 200-cGy fractions), or surgical excision with stereotactic irradiation in selected patients, is usually given simultaneously with the initiation of systemic chemotherapy. During radiotherapy, the methotrexate infusion dosage in the EMA/CO protocol is increased to 1000 mg/m^2 and 30 mg of leucovorin is given every 12 hours for 3 days starting 32 hours after the methotrexate infusion began. Reported cure rates with brain metastases are 50–80%, depending on patient symptoms as well as number, size, and location of brain lesions
3. Adjuvant surgical procedures, especially hysterectomy and pulmonary resection for chemotherapy-resistant disease, as well as procedures to control hemorrhage, are important components in the management of high-risk GTN. Almost 50% of high-risk patients treated with EMA/CO will require 1 or more operations in order to affect cure
4. Cure rates for high-risk metastatic GTN of 80–90% are now achievable with intensive multimodality treatment with EMA/CO chemotherapy, along with adjuvant radiotherapy or surgery when indicated. Approximately 30% of high-risk patients will fail to benefit not achieve a complete response from first-line therapy or relapse from remission. Salvage therapy with platinum-containing drug combinations, such as:

   Etoposide + cisplatin/etoposide + methotrexate + dactinomycin (EP/EMA),
   Bleomycin + etoposide + cisplatin (BEP),
   Etoposide + ifosfamide + cisplatin (VIP), or ifosfamide + carboplatin + etoposide (ICE), and
   Paclitaxel + cisplatin alternating with paclitaxel + etoposide (TP/TE),
   often in conjunction with surgical resection of sites of persistent tumor, will result in cure of most of these high-risk patients with resistant disease

REGIMEN FOR LOW-RISK GTN

METHOTREXATE

Lurain JR, Elfstrand EP. Am J Obstet Gynecol 1995;172:574–579
Roberts JP, Lurain JR. Am J Obstet Gynecol 1996;174:1917–1924

Methotrexate 0.4 mg/kg (maximum daily dose = 25 mg) per day; administer by intravenous injection daily for 5 consecutive days on days 1–5, every 2 weeks (total dosage/14-day cycle = 2 mg/kg, maximum dose/14-day cycle = 125 mg)

Recommendations:

1. Administer treatment courses as often as toxicity permits, usually every 14 days
2. Encourage increased oral fluid intake or, if NPO, give parenteral hydration
3. Avoid drugs that can alter methotrexate elimination, such as nonsteroidal antiinflammatory drugs, omeprazole (and possibly other proton pump inhibitors), penicillins, probenecid, and salicylates
4. Administer 2 additional cycles after the first normal hCG level

Note: Determination of GFR before treatment does not predict for methotrexate clearance and potential toxicity, but serum creatinine that is within normal limits and a GFR >60 mL/min are generally accepted as adequate renal function

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days 1–5: ***MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

See Chapter 47 for more information

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols

Therapy Monitoring

1. *Every other week:* PE, CBC with differential, serum electrolytes, LFTs, serum creatinine, BUN, and hCG
2. *Methotrexate levels:* Not routinely performed
3. *Complete remission:* Three consecutive weekly hCG levels within normal range
4. *Resistance to treatment:* hCG plateau over 2 consecutive treatments or a hCG rise after any treatment
5. *Following remission:* hCG levels are obtained monthly for 12 months, and every 3 months during the second year

Patient Population Studied

Retrospective review of 253 patients with nonmetastatic gestational trophoblastic tumors (invasive mole [209] or choriocarcinoma [44]) treated from 1962 to 1990. Antecedent pregnancy was hydatidiform mole (230), abortion (16), and term or preterm delivery (7). A mean of 4.7 courses (range: 1–7) of single-agent methotrexate was administered

Efficacy (N = 253)

Treatment	% Complete Response
Methotrexate alone	89.3*
Methotrexate + dactinomycin	8.7
Multiagent chemotherapy or surgery	2.0
Survival	100

*Six patients (2.4%) had a relapse 1–9 months after achieving a complete response. All were placed into a permanent remission with additional chemotherapy

Toxicity (N = 253)

Stomatitis	G3 (16 patients) mild to moderate (many)
Conjunctivitis	3 patients
Pleuritic/peritoneal pain	3 patients
Hair loss	None
Nausea/vomiting	Not common
Toxicity requiring dose reduction	11 patients (4.3%)
Toxicity requiring change in therapy*	12 patients (4.7%)

*Reasons: G3 stomatitis (5), rash and stomatitis (4); prolonged neutropenia (2), elevated LFTs (1)

Treatment Modifications

Adverse Event	Dose Modification
G ≤1 toxicity	Continue therapy if easy to manage
G2 toxicity	Consider a 20% reduction in methotrexate dosage
G ≥3 toxicity	Discontinue methotrexate and institute other therapy

REGIMEN FOR LOW-RISK GTN

METHOTREXATE WITH LEUCOVORIN

Bagshawe KD et al. Br J Obstet Gynaecol 1989;96:795–802
Berkowitz RS et al. Gynecol Oncol 1986;23:111–118
Wong LC et al. Am J Obstet Gynecol 1985;152:59–62

Methotrexate 1 mg/kg (maximum daily dose = 50 mg) per dose; administer by intramuscular injection for 4 doses on days 1, 3, 5, and 7, every 2 weeks (total dosage/14-day cycle = 4 mg/kg, or a maximum total dose of 200 mg)

Leucovorin calcium 0.1 mg/kg; administer orally or by intramuscular injection for 4 doses on days 2, 4, 6, and 8, at 30 hours after each dose of methotrexate, every 2 weeks (total dosage/cycle = 0.4 mg/kg)

Notes:

1. Administer treatment courses as often as toxicity permits after a minimum rest period of 7 days (usually every 14 days)
2. Encourage increased oral fluid intake or, if NPO, give parenteral hydration
3. Avoid drugs that can alter methotrexate elimination, such as nonsteroidal antiinflammatory drugs, omeprazole (and possibly other proton pump inhibitors), penicillins, probenecid, and salicylates
4. Administer 2 additional cycles after the first normal hCG level

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days 1, 3, 5, and 7: ***MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Patients with low-risk GTN

Efficacy (N = 348)

Outcome	% of Patients
Changed treatment for drug resistance	20
Relapsed	4
Survival	99.7

One death attributed to concurrent non-Hodgkin lymphoma
Bagshawe KD et al. Br J Obstet Gynaecol 1989;96:795–802

Treatment Modifications

Adverse Event	Dose Modification
G ≤1 toxicity	Continue therapy if easy to manage
G2 toxicity including LFTs	Consider a 20% reduction in methotrexate dosage
G ≥3 toxicity including LFTs	Discontinue methotrexate and institute other therapy

Toxicity (N = 185)

Toxicity	% of Patients
Hepatotoxicity; normalized in 1 week	14.1
Granulocytopenia without infection or need for antibiotics	5.9; no secondary infections
Thrombocytopenia without need for platelets	1.6; without infections
Pleuritic chest pain	3.1
Nausea/vomiting	1; requiring intravenous therapy
Alopecia	0
Toxicity requiring change in therapy*	6

Berkowitz RS et al. Gynecol Oncol 1986;23:111–118
Bagshawe KD et al. Br J Obstet Gynaecol 1989;96:795–802

Therapy Monitoring

1. *Every morning before methotrexate:* CBC and LFTs
2. *Every other week:* PE, CBC with differential, serum electrolytes, LFTs, serum creatinine, BUN, and hCG
3. *Methotrexate levels:* Not routinely performed
4. *Complete remission:* Three consecutive weekly hCG levels within normal range
5. *Resistance to treatment:* hCG plateau over 2 consecutive treatments or a hCG rise after any treatment
6. *Following remission:* hCG levels are obtained monthly for 12 months and every 3 months during the second year

REGIMEN FOR LOW-RISK GTN

DACTINOMYCIN

Osathanondh R et al. Cancer 1975;36:863–866

Dactinomycin 12 mcg/kg per day; administer by intravenous injection over 1–2 minutes for 5 consecutive days on days 1–5, every 2 weeks (total dosage/cycle = 60 mcg/kg)

Notes:

1. Therapy was reinstituted only when and if the human chorionic gonadotropin (hCG) level reached a plateau for 2 consecutive weeks, or again increased
2. Patients who did not respond after 2 consecutive cycles were classified as having resistant disease

Alternate regimen:

Dactinomycin 1.25 mg/m^2; administer by intravenous injection over 1–2 minutes, on day 1 every 2 weeks (total dosage/cycle = 1.25 mg/m^2)

Petrilli ES et al. Cancer 1987;60:2173–2176

Note: This is an acceptable regimen for the treatment of nonmetastatic postmolar GTN, but should not be used for metastatic disease, known choriocarcinoma or as secondary therapy to treat methotrexate-resistant disease

Supportive Care

Antiemetic prophylaxis—first regimen
Emetogenic potential on days 1–5: ***MODERATE***

Antiemetic prophylaxis—alternate regimen
Emetogenic potential: ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Efficacy (N = 70*)

	Nonmetastatic GTN (N = 31)			Metastatic GTN (N = 39)		
	Non-CCA	CCA	Total	Non-CCA	CCA	Total
CR†	93%	100%	94%	76%	56%	67%

*CCA, choriocarcinoma
†CR (complete response) = hCG in normal range for 3 consecutive weeks off therapy

Treatment Modifications

Adverse Event	Dose Modification
WBC <3000/mm^3	Hold dactinomycin until WBC >3000/mm^3
ANC <1500/mm^3	Hold dactinomycin until ANC >1500/mm^3
Platelet count <100,000/mm^3	Hold dactinomycin until platelet >100,000/mm^3
Hepatotoxicity before or during treatment (LFTs ≥3 × ULN)	Hold dactinomycin until LFTs ≤1.5 × ULN
Increasing hCG level	Discontinue dactinomycin
Plateau in hCG levels after 2 cycles of dactinomycin	Discontinue dactinomycin

Patient Population Studied

A study of 70 patients (previously untreated) with nonmetastatic (31) and metastatic (39) gestational trophoblastic disease accrued from 1965 to 1973

Toxicity (N = 32)

Toxicity	% of Patients
Hematologic	
WBC <2500/mm^3	25
ANC <1500/mm^3	38
Platelets <100,000/mm^3	16
Nonhematologic	
SGOT (AST) >50 units/L	22
Nausea and vomiting	66
Stomatitis	38
Skin rash	34
Alopecia	44

Goldstein DP et al. Obstet Gynecol 1972;39:341–345

Therapy Monitoring

1. *Every other week:* PE, CBC with differential, serum electrolytes, LFTs, serum creatinine, BUN, and hCG
2. *Complete remission:* Three consecutive weekly hCG levels within normal range
3. *Resistance to treatment:* hCG plateau over 2 consecutive treatments or a hCG rise after any treatment
4. *Following remission:* hCG levels are obtained monthly for 12 months and every 3 months during the second year

Notes

1. In current practice, dactinomycin is most frequently used as secondary therapy after the development of methotrexate resistance, rather than as primary therapy, because it causes more nausea and alopecia than methotrexate and produces local tissue injury if extravasation occurs while administered
2. Appropriate as primary therapy for patients with liver or renal disease or with large effusions that are relative contraindications to methotrexate

REGIMEN FOR HIGH-RISK GTN

ETOPOSIDE + METHOTREXATE + DACTINOMYCIN + CYCLOPHOSPHAMIDE + VINCRISTINE (EMA/CO)

Bower M et al. J Clin Oncol 1997;15:2636–2643
Escobar PF et al. Gynecol Oncol 2003;91:552–557
Kim SJ et al. Gynecol Oncol 1998;71:247–253
Lu W-G et al. Int J Gynecol Cancer 2008;18:357–362
Turan T et al. Int J Gynecol Cancer 2006;16:1432–1438

EMA component (days 1–3):
Dactinomycin 0.5 mg (fixed dose) per day; administer by intravenous injection over 1–2 minutes for 2 consecutive days on days 1 and 2, every 2 weeks (total dose/cycle = 1 mg)
Etoposide 100 mg/m^2 per day; administer intravenously diluted in 0.9% sodium chloride injection (0.9% NS) to a concentration within the range of 0.2–0.4 mg/mL over 60 minutes for 2 consecutive days on days 1 and 2, every 2 weeks (total dosage/cycle = 200 mg/m^2)
Methotrexate 100 mg/m^2; administer intravenously by injection or in 25 mL 0.9% NS or 5% dextrose injection (D5W) over 5 minutes, given on day 1, *followed immediately afterward by*:
Methotrexate 200 mg/m^2; administer intravenously in ≥1000 mL 0.9% NS over 12 hours on day 1, every 2 weeks (total dosage/cycle = 300 mg/m^2)
Note: See dose adjustment for patients with documented CNS metastases, below
Leucovorin calcium 15 mg; administer orally or by intramuscular injection every 12 hours for 4 doses on days 2 and 3, beginning 24 hours after the start of methotrexate infusion, every 2 weeks (total dose/cycle = 60 mg). *Note:* See dose adjustment for CNS metastases below

CO component (day 8):
Vincristine 0.8 mg/m^2 (maximum dose, 2 mg); administer by intravenous injection over 1–2 minutes, given on day 8, every 2 weeks (total dosage/cycle = 0.8 mg/m^2; maximum dose/cycle = 2 mg)
Cyclophosphamide 600 mg/m^2; administer intravenously in 250 mL 0.9% NS over 30 minutes, given on day 8, every 2 weeks (total dosage/cycle = 600 mg/m^2)

CNS treatment for patients with documented cranial metastases:
3000-cGy whole-brain radiation; administer in fifteen 200-cGy fractions given 5 times per week for 3 weeks
Dexamethasone as needed, 4 mg; administer orally every 6 hours while radiation is administered, tapering over 2–4 weeks after the completion of radiation
Alternative approach: Surgical excision followed by stereotactic radiation

Methotrexate 1000 mg/m^2; administer by continuous intravenous infusion over 24 hours in 1000 mL 0.9% NS on day 1, every 2 weeks (total dosage/cycle = 1000 mg/m^2)
Leucovorin calcium 30 mg; administer orally, intramuscularly, or intravenously every 12 hours for 6 doses on days 2–4, beginning 32 hours after the start of methotrexate infusion, every 2 weeks (total dose/cycle = 180 mg)

Note: During CNS therapy, the methotrexate regimen given during the *EMA component* is replaced with **Methotrexate** 1000 mg/m^2 by continuous intravenous infusion over 24 hours *for 2–3 cycles,* and the leucovorin calcium dose is increased to 30 mg/dose

Encourage increased oral fluid intake or, if NPO, give parenteral hydration

Duration of therapy:
Repeat EMA alternating weekly with CO to serologic remission (serum hCG <5 IU/L), then administer for an additional 4–8 weeks (2–4 cycles) of therapy. In the report by Escobar et al. of 45 high-risk GTT patients, 4–7 cycles were administered with a mean of 5.5 cycles

Supportive Care
Antiemetic prophylaxis—EMA/CO
Emetogenic potential on days 1 and 2: MODERATE–HIGH

Antiemetic prophylaxis—during methotrexate for CNS treatment
Emetogenic potential: MODERATE
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

(continued)

Treatment Modifications

Adverse Event	Dose Modification
WBC <3000/mm^3, platelets <100,000/mm^3, or liver transaminases >1.5 × ULN	Hold therapy until WBC ≥3000/mm^3, platelets ≥100,000/mm^3, and liver transaminases ≤ 1.5 × ULN
More than 1 treatment delay for WBC <3000/mm^3	Administer filgrastim 300 mcg/day subcutaneously on days 9–14 of all subsequent cycles
Hgb <10 g/dL	Transfuse as needed and administer erythropoietin
Peripheral neuropathy G > 2	Discontinue vincristine

Patient Population Studied

Women with high-risk GTN. Almost one-half had received prior chemotherapy

(continued)

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Efficacy (N = 272)

All Patients		Prior Therapy: No	Prior Therapy: Yes
Complete response	78.3%*	78%	79%
Progressive disease	17.2%†	14%	21%
Early deaths	4.5%	8%	—
Cumulative overall 5-year survival rate		86%	
Disease-specific 5-year survival rate		88%	

*Sixteen of 213 patients suffered relapse after attaining a complete response

†Forty-seven patients developed resistance to EMA/CO. Sixteen of 21 (76%) patients without prior therapy and 17/26 (65%) patients with prior therapy underwent successful salvage treatment and were alive and in remission at the time of publication

Bower M et al. J Clin Oncol 1997;15:2636–2643

(N = 45)

All Patients		Prior Therapy: No	Prior Therapy: Yes
Initial complete response	71%	76%	65%
Successful salvage therapy	20%*	—	—
Died of disease	9%	—	—
Survival†	91%	92%	90%

*All achieved remission with cisplatin-based therapy

†Median follow-up 36 months

Escobar PF et al. Gynecol Oncol 2003;91:552–557

Toxicity (N = 257 cycles)

	% Cycles: G1	G2	G3
Anemia	0.8	8.5	5.8
Neutropenia	6.6	5.4	1. 6
Thrombocytopenia	1.6	—	—
Alopecia	All patients		

Gastrointestinal toxicity (nausea, vomiting, diarrhea, and stomatitis) occurred in some patients, but was G3 requiring hospitalization in only 1 patient

Bower M et al. J Clin Oncol 1997;15:2636–2643

(N = 272):
Two cases of AML FAB subtypes M1 and M5

Escobar PF et al. Gynecol Oncol 2003;91:552–557

Therapy Monitoring

1. *Every other week:* PE, CBC with differential, serum electrolytes, LFTs, serum creatinine, BUN, and hCG
2. *Methotrexate levels:* Not routinely performed
3. *Complete remission:* Three consecutive weekly hCG levels within normal range
4. *Resistance to treatment:* hCG plateau over 2 consecutive treatments or a hCG rise after any treatment
5. *Following remission:* hCG levels are obtained monthly for 12 months and every 3 months during the second year

REGIMEN FOR REFRACTORY GTN

ETOPOSIDE + METHOTREXATE + DACTINOMYCIN/ETOPOSIDE + CISPLATIN (EP/EMA)

Lurain JR, Bahareh N. Gynecol Oncol 2005;97:618–623 *(discussion only, the regimen is not described)*
Mao Y et al. Int J Gynaecol Obstet 2007;98:44–47
Newlands ES et al. J Clin Oncol 2000;18:854–859

EP component (day 1)
Etoposide 150 mg/m^2; administer intravenously diluted in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) to a concentration within the range of 0.2–0.4 mg/mL over 60 minutes, on day 1, every 2 weeks
Cisplatin 25 mg/m^2; administer intravenously in 1000 mL 0.9% NS over 4 hours every 4 hours for 3 doses (total duration of continuous infusion is 12 hours) on day 1, every 2 weeks (total dosage/2-week cycle = 75 mg/m^2)
Hydration after cisplatin: Encourage increased oral intake of nonalcoholic fluids if possible. Monitor and replace magnesium, potassium, and other electrolytes as needed

EMA component (days 8–10)
Dactinomycin 0.5 mg (fixed dose); administer by intravenous injection over 1–2 minutes, on day 8 every 2 weeks (total dose/2-week cycle = 0.5 mg)
Etoposide 100 mg/m^2; administer intravenously in 0.9% NS or D5W to a concentration within the range of 0.2–0.4 mg/mL over 60 minutes, on day 8, every 2 weeks (total dosage/2-week cycle = 250 mg/m^2 [sum of EP + EMA regimens])
Methotrexate 100 mg/m^2; administer intravenously by injection or in 25 mL 0.9% NS or D5W over 5 minutes, given on day 8, *followed immediately afterward by:*
Methotrexate 200 mg/m^2; administer intravenously in ≥1000 mL 0.9% NS over 12 hours on day 8 every 2 weeks (total dosage/2-week cycle = 300 mg/m^2)

Leucovorin calcium 15 mg; administer orally, intravenously, or by intramuscular injection every 12 hours for 4 doses on days 9 and 10, beginning 24 hours after the start of methotrexate infusion, every 2 weeks (total dose/cycle = 60 mg)

Recommendations:
1. EP and EMA components of treatment are alternated at weekly intervals
2. Encourage increased oral fluid intake or, if NPO, give parenteral hydration
3. Avoid concomitant use of drugs that can alter methotrexate elimination, such as nonsteroidal antiinflammatory drugs, omeprazole (and perhaps other proton pump inhibitors), penicillins, probenecid, and salicylates

Supportive Care
Antiemetic prophylaxis—EP regimen
Emetogenic potential: ***HIGH*** *Potential for delayed symptoms*

Antiemetic prophylaxis—EMA regimen
Emetogenic potential: ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection
- Begin use on day 9 (24 hours after myelosuppressive chemotherapy is completed)
- Discontinue use at least 24 hours before myelosuppressive treatment resumes

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
WBC count <2000/mm^3, *and* platelet count <75,000/mm^3	Hold therapy until WBC count ≥2000/mm^3 *and* platelet count ≥75,000/mm^3
Serum creatinine >1.5 × ULN	Measure or estimate creatinine clearance (CrCl) and reduce cisplatin dose by the same percentage as the reduction in CrCl from baseline
G ≥2 mucositis	Double the dose of leucovorin and double the duration of administration (8 doses) before considering methotrexate dose reduction
Any treatment delay for WBC count <2000/mm^3	Administer filgrastim 300 mcg/day, subcutaneously on days 9–14 of all subsequent cycles

Patient Population Studied

A study of 42 women with high-risk GTN refractory to or relapsing after EMA/CO chemotherapy. Patients either (1) had improvement while receiving EMA/CO but a persistently low hCG level or (2) developed a reelevation of hCG after having a complete response to prior treatment with EMA/CO

Efficacy

Response	Alive in Remission
hCG Plateau on EMA/CO* (n = 22)	
—	21 (95%)
Resistant to or Relapsed After EMA/CO† (n = 12)	
12 (100%)	9 (75%)
Placental Site Trophoblastic Tumor (n = 8)	
—	4 (50%)
All Patients (N = 42)	
—	34 (81%)

*hCG sufficiently close to normal range, but not possible to evaluate response
†>1 log decline in hCG

Surgical Procedures in Patients Receiving EP/EMA

	Effect on hCG Response		
Operation	Decreased	None	Not assessed
Hysterectomy	2	4	4
Thoracotomy	1	3	5
Craniotomy	2	0	1
Total	5 (23%)	7 (32%)	10 (45%)

Toxicity*

	% G3	% G4
Hematologic (n = 25)		
Anemia	20	—
Leukopenia	48	20
Thrombocytopenia	24	16

Ten patients (40%) had multiple G3/4 toxicities

Nonhematologic (n = 22)		
Elevated BUN	32%	9%

*Complete results on patients treated before 1988 were no longer available. In the 42 patients:
- Treatment delays because of myelosuppression were observed in 37/42 patients (88%)
- Dose reductions were required in 16/42 patients (38%)
- Filgrastim was administered to 13/42 patients (31%)

NCI, CTC, National Cancer Institute (USA) Common Toxicity Criteria, version 2.0. At: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]

Therapy Monitoring

1. *Every other week*: PE, CBC with differential, serum electrolytes, LFTs, serum creatinine, BUN, and hCG
2. *Methotrexate levels:* Not routinely performed
3. *Complete remission*: Three consecutive weekly hCG levels within normal range
4. *Resistance to treatment:* hCG plateau over 2 consecutive treatments or a hCG rise after any treatment
5. *Following remission:* hCG levels are obtained monthly for 12 months, and every 3 months during the second year

SALVAGE REGIMEN FOR RELAPSED GTN AND PSTT

PACLITAXEL + CISPLATIN/PACLITAXEL + ETOPOSIDE (TP/TE)

Wang J et al. Ann Oncol 2008;19:1578–1583

Day 1: TP component

Primary prophylaxis against hypersensitivity reactions to paclitaxel:

Dexamethasone 20 mg/dose; administer orally for 2 doses every 6 hours, starting approximately 12 hours before paclitaxel administration begins

Cimetidine 300 mg (or equivalent histaminergic receptor [H_2 subtype] antagonist); administer intravenously over 15–30 minutes + **diphenhydramine** 25–50 mg (or equivalent H_1 receptor antagonist); administer intravenously 30–60 minutes before starting paclitaxel administration

Paclitaxel 135 mg/m^2; administer intravenously in a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) sufficient to produce a solution with concentration within the range 0.3–1.2 mg/mL over 3 hours (total dosage/cycle for TP + TE = 270 mg/m^2)

Hydration before cisplatin: Administer intravenously ≥1000 mL 0.9% NS over a minimum of 2–4 hours

Cisplatin 60–75 mg/m^2 with 12.5 g **mannitol**; administer intravenously in 1000 mL 0.9% NS after paclitaxel over 2–3 hours (total dosage/cycle = 60–75 mg/m^2)

Hydration after cisplatin: Administer intravenously ≥1000 mL 0.9% NS over a minimum of 2–4 hours. Also encourage increased oral intake of non-alcoholic fluids. Monitor and replace magnesium and other electrolytes as needed

Day 15: TE component

Primary prophylaxis against hypersensitivity reactions to paclitaxel:

Dexamethasone 20 mg/dose; administer orally for 2 doses every 6 hours, starting approximately 12 hours before paclitaxel administration begins

Cimetidine 300 mg (or equivalent H_2 receptor antagonist); administer intravenously over 15–30 minutes + **diphenhydramine** 25–50 mg (or equivalent H_1 receptor antagonist); administer intravenously 30–60 minutes before starting paclitaxel administration

Paclitaxel 135 mg/m^2; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a solution with concentration within the range 0.3– 1.2 mg/mL over 3 hours, *followed by:*

Etoposide 150 mg/m^2; administer intravenously diluted in 0.9% NS to a concentration within the range of 0.2–0.4 mg/mL over at least 60 minutes (total dosage/cycle = 150 mg/m^2)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on day 1: **HIGH** Potential for delayed symptoms after cisplatin*

*Emetogenic potential on day 15: **LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated:

Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection,

- Begin use at least 24 hours after myelosuppressive chemotherapy is completed
- Discontinue use at least 24 hours before resuming myelosuppressive chemotherapy, or for a postnadir ANC ≥10,000/mm^3

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Recommendations:

1. TP and TE components of treatment are alternated at 2-week intervals
2. Encourage increased oral fluid intake or, if NPO, give parenteral hydration
3. *Duration of therapy:* Repeat TP alternating with TE to serologic remission (serum hCG <5 IU/L), then administer for an additional 8–16 weeks (2–4 cycles) of therapy

Treatment Modifications

Adverse Event	Dose Modification
WBC count <3000/mm^3 *and* platelet count <100,000/mm^3	Hold therapy until WBC count ≥3000/mm^3 *and* platelet count ≥100,000/mm^3
Serum creatinine >1.5 mg/dL (>133 μmol/L)	Measure or estimate creatinine clearance (CrCl) and reduce cisplatin dose by the same percentage as the reduction in CrCl from baseline
Platelet nadir <50,000/mm^3	Decrease doses of all drugs by 20%
Peripheral neuropathy G >2	Discontinue therapy or possibly substitute docetaxel 60 mg/m^2 for paclitaxel

Patient Population Studied

A trial in which 24 women with relapsed/refractory GTN or placental site trophoblastic tumor (PSTT) were treated with TP/TE: 16 had failed to benefit from previous chemotherapy, including 6 who had received cisplatin-containing regimens and 8 who had prior treatment-induced toxic effects

Efficacy (N = 24)

Category	Complete Response	Partial Response	Alive in Remission
Relapsed disease (N = 16)	3 (19%)	5 (31%)*	7 (44%)*
Prior treatment Toxic (N = 8)†	2 (25%)	2 (25%)§	6 (75%)‡
Total (N = 24)	5 (21%)	7 (29%)	13 (54%)

*Median follow-up = 25 months; 4 patients with PR entered remission/cured with subsequent surgery and/or chemotherapy
†Four not assessable for response because hCG already normal or close to normal at start
‡Median follow-up = 19 months
§Two patients (1 PR and 1 not assessable for response) entered remission/cured with subsequent surgery and/or chemotherapy

Toxicity (N = 24)

	% G1	% G2	% G3	% G4
Neutropenia			42	
Thrombocytopenia			13	
Anemia	8			
Neuropathy	17		4	
Nausea	13			

Therapy Monitoring

1. *Every other week:* Physical examination, CBC with differential, serum electrolytes, LFTs, serum creatinine, BUN, and hCG
2. *Complete remission:* Three consecutive weekly hCG levels within normal range
3. *Resistance to treatment:* hCG plateau over 2 consecutive treatments or a hCG rise after any treatment
4. *Following remission:* hCG levels are obtained monthly for 12 months and every 3 months during the second year

14. Head and Neck Cancers

Pol Specenier, MD, PhD and JB Vermorken, MD, PhD

Epidemiology

Incidence: Tongue 13,590 (male: 9,720; female: 3,870. Estimated new cases for 2014 in the United States)
Mouth 11,920 (male: 7,150; female: 4,770. Estimated new cases for 2014 in the United States)
Pharynx 14,410 (male:11,550; female: 2,860. Estimated new cases for 2014 in the United States)
Larynx 12,630 (male: 10,000; female: 2,630. Estimated new cases for 2014 in the United States)

Deaths: Tongue estimated 2,150 in 2014 (male: 1,450; female: 700)
Mouth estimated 2,070 in 2014 (male: 1,130; female: 940)
Pharynx estimated 2,540 in 2013 (male: 1,900; female: 640)
Larynx estimated 3,610 (male: 2,870 female: 740)

Median age: Oral cavity and pharynx 62 years
Tongue 61 years
Larynx 65 years
Male to female ratio: 2.5:1

Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Pathology

1. Squamous carcinomas (90%)
2. Lymphomas
3. Salivary gland tumors (adenocarcinoma, adenoid cystic carcinoma, mucoepidermoid carcinoma)
4. Sarcomas
5. Melanomas

Work-up

1. History and physical examination
2. ENT examination
3. Laryngoscopy with biopsy of suspicious lesions
4. CT and/or MRI of the head and neck
5. X-ray or CT of chest (to rule out metastatic disease or second primary tumor)
6. Needle biopsy of lymph node not associated with obvious primary tumor

Organ Site Specific Work-up

a. Ethmoid sinus: H&P, CT and/or MRI, CXR, pathology review if diagnosis with incomplete excision
b. Maxillary sinus: H&P, Head and neck CT with contrast ± MRI, CXR, dental/prosthetic consultation as indicated
c. Salivary glands: H&P, CT/MRI, CXR, pathology review
d. Lip, oral cavity: H&P, CT/MRI, parorex, biopsy, preanesthesia studies, dental evaluation
e. Hypopharynx: H&P, biopsy, CXR or chest CT, CT with contrast or MRI of primary and neck, examination under anesthesia with laryngoscopy/esophagoscopy, preanesthesia studies, dental evaluation, multidisciplinary consultation as indicated
f. Glottic larynx: Same work up as for hypopharynx + CT scan with contrast and thin cuts of the larynx or MRI of primary, speech and swallowing studies

Staging

Primary Tumor (T)

- Differs for each site
- For larynx and hypopharynx cancers, vocal cord paralysis indicates at least T3
- Local invasion of adjacent structures indicates T4

Regional Lymph Nodes (N)

NX	Regional lymph nodes cannot be assessed
N0	No regional lymph node metastasis
N1	Metastasis in a single ipsilateral lymph node, 3 cm or less in greatest dimension
N2	Metastasis in a single ipsilateral lymph node, more than 3 cm but not more than 6 cm in greatest dimension, or in multiple ipsilateral lymph nodes, none more than 6 cm in greatest dimension, or in bilateral or contralateral lymph nodes, none more than 6 cm in greatest dimension
N2a	Metastasis in a single ipsilateral lymph node, more than 3 cm but not more than 6 cm in greatest dimension
N2b	Metastasis in multiple ipsilateral lymph nodes, none more than 6 cm in greatest dimension
N2c	Metastasis in bilateral or contralateral lymph nodes, none more than 6 cm in greatest dimension
N3	Metastasis in a lymph node, more than 6 cm in greatest dimension

Distant Metastasis (M)

M0	No distant metastasis
M1	Distant metastasis

Staging Groups

(Cancers of Oral Cavity, Oropharynx, Hypopharynx, and Larynx*)

	T (Primary)	N	M
Stage 0	Tis	N0	M0
Stage I	T1	N0	M0
Stage II	T2	N0	M0
Stage III	T3	N0	M0
	T1	N1	M0
	T2	N1	M0
	T3	N1	M0
Stage IVA	T4a	N0	M0
	T4a	N1	M0
	T1	N2	M0
	T2	N2	M0
	T3	N2	M0
	T4a	N2	M0
Stage IVB	T4b	Any N	M0
	Any T	N3	M0
Stage IVC	Any T	Any N	M1

*The same for all primary sites, except nasopharynx

Edge SB, Byrd DR, Compton CC, Fritz AG, Greene FL, Trotti A, editors. AJCC Cancer Staging Manual. 7th ed. New York: Springer; 2010

Larynx: 5-Year Relative Survival by Stage at Diagnosis for All Races, Both Sexes

Stage at Diagnosis	5-Year Relative Survival (%)
Localized (confined to primary site)	76.1
Regional (spread to regional lymph nodes)	42.8
Distant (cancer has metastasized)	35.3

Oral Cavity and Pharynx: 5-Year Relative Survival by Stage at Diagnosis for All Races, Both Sexes

Stage at Diagnosis	5-Year Relative Survival (%)
Localized (confined to primary site)	82.7
Regional (spread to regional lymph nodes)	59.2
Distant (cancer has metastasized)	36.3

Tongue: 5-Year Relative Survival by Stage at Diagnosis for All Races, Both Sexes

Stage at Diagnosis	5-Year Relative Survival (%)
Localized (confined to primary site)	78.0
Regional (spread to regional lymph nodes)	60.9
Distant (cancer has metastasized)	35.2

Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Expert Opinion

Treatment

General: All patients should have access to a *multidisciplinary team* with expertise in all aspects of care for patients with head and neck cancer including:

1. Head and neck surgery
2. Radiation oncology
3. Medical oncology
4. Reconstructive surgery
5. Dentistry
6. Speech and swallowing therapy
7. Diagnostic radiology
8. Pathology
9. Nutrition support
10. Social work

Smoking cessation counseling is indicated

Resectable versus unresectable disease: The tumor is considered unresectable when a (team of) surgeons with particular expertise in head and neck cancer has serious doubts about the ability to remove the gross tumor with a reasonable likelihood of local control, even with the addition of adjuvant chemoradiation

Postoperative chemoradiation: Postoperative cisplatin-based chemoradiation using *cisplatin 100 mg/m² every 3 weeks* is superior to irradiation alone in patients with adverse risk factors in the resection specimen. Postoperative chemoradiation is:

1. Indicated in patients with extracapsular nodal spread and/or positive surgical margins
2. To be considered in patients with:
   - pT3 or pT4 primary
   - N2 or N3 nodal disease
   - Perineural invasion
   - Vascular tumor embolism

Postoperative chemoradiation should be started within 6 weeks after surgery. But note, combined modality treatment is associated with a substantial increase in adverse effects

Organ preservation: In some patients with resectable disease a combination of chemotherapy and definitive irradiation can spare a functional organ without sacrificing the probability of cure. Each patient should be evaluated by the multidisciplinary team in order to offer to a patient the best options

Definitive nonsurgical treatment for patients with unresectable disease or as organ preservation:

- *Concurrent chemoradiation using cisplatin 100 mg/m² every 3 weeks for 3 doses should still be considered the standard regimen*
- Cetuximab with irradiation can be used in patients who cannot tolerate cisplatin-based chemotherapy
- PET-CT imaging 12 weeks after the end of chemoradiation may help to select patients with initial N2 or N3 disease who achieved a complete response from combined modality treatment for whom elective neck dissection is unnecessary
- *Salvage surgery* is indicated in patients with residual tumor at the *primary site* whenever the disease is resectable at that time
- *Neck dissection* is indicated in cases of residual *disease in the neck*

Considerations in patients undergoing chemoradiation:

1. All patients for whom chemoradiation is planned should be evaluated and treated by a dentist before the start of treatment
2. Follow patients closely during chemoradiation with special attention to:
   - Hydration
   - Nutritional status
   - Electrolyte balance
3. Tube feeding is indicated in cases of a 10% decrease of body weight. Some centers prefer prophylactic tube feeding before the start of chemoradiation
4. Swallowing exercises during and after treatment are strongly advocated in order to diminish the risk of permanent disturbance of oral food intake
5. Adequate analgesic therapy often including opioids may be required

(*continued*)

Expert Opinion (*continued*)

Induction chemotherapy:

1. *TPF (docetaxel + cisplatin + fluorouracil) is to be considered the current standard induction chemotherapy regimen in cases where induction chemotherapy is considered appropriate*
2. Induction chemotherapy reduces the risk of distant metastases but should not be considered standard treatment pending the results of ongoing randomized phase III trials
3. Induction chemotherapy may be an option for specific patient categories

Recurrent/metastatic disease: Active single agents include:

1. Cisplatin
2. Carboplatin
3. Paclitaxel
4. Docetaxel
5. Fluorouracil
6. Methotrexate
7. Ifosfamide
8. Bleomycin
9. Cetuximab

Consideration in recurrent/metastatic disease:

1. Response rates with single cytotoxic agents range from 15–30% in nonrandomized trials
2. In randomized comparisons *platinum-based combination chemotherapy regimens (in particular cisplatin plus infusional fluorouracil) induce higher response rates than single-agent chemotherapy but at the cost of increased toxicity*
3. Addition of a taxane to cisplatin and fluorouracil doublet increases response rates but also adds to toxicity
4. The addition of cetuximab to cisplatin and fluorouracil improves survival without a significant increase in serious toxicities. *The combination of cisplatin + fluorouracil + cetuximab, therefore, is the preferred regimen in patients who are most likely to benefit from combination chemotherapy*
5. Single agent chemotherapy is still an option in patients with a decreased performance status or in a frail condition:
   - Weekly methotrexate is the best-studied regimen for that indication
   - Taxanes may be adequate alternatives
6. Outcomes with second-line chemotherapy are generally disappointing
7. Single-agent cetuximab is a reasonable option in patients with platinum-refractory disease who did not receive cetuximab as part of their initial treatment for recurrent/metastatic disease
8. Selected patients with a locoregional relapse may be salvaged by surgery or re-irradiation
   - Metastatic disease outside the head/neck area is present in only 10% at presentation, but 20% of those treated for cure with surgery and/or radiation or with chemoradiation develop metastatic disease outside the locoregional area, commonly concurrent with a locoregional recurrence
   - Patients cured of the initial tumor have a 2–6% per year incidence of second primary tumors, commonly diagnosed in the upper aerodigestive tract

Thyroid function: Patients who received thyroid gland irradiation are prone to the development of hypothyroidism. Thyroid stimulating hormone should be followed every 6–12 months for the lifetime of affected patients

CONCOMITANT CHEMORADIATION REGIMENS

CISPLATIN WITH RADIATION THERAPY

Adelstein DJ et al. J Clin Oncol 2003;21:92–98
Forastiere AA et al. N Engl J Med 2003;349:2091–2098

Pretreatment:
Dental evaluation; percutaneous feeding tube; nutrition evaluation

Chemoradiation

As noted in the Expert Opinion section: Concurrent chemoradiation using cisplatin every 3 weeks for 3 doses should still be considered the standard regimen

Hydration before, during, and after cisplatin administration ± mannitol:
- *Pre-cisplatin hydration* with 1000 mL 0.9% sodium chloride injection (0.9% NS); administer with potassium and magnesium supplementation as needed based on pretreatment laboratory results
- *Mannitol diuresis:* May be given to patients who have received adequate hydration. A dose of **mannitol** 12.5–25 g may be administered by intravenous injection or a short infusion before or during cisplatin administration, or prepared as an admixture with cisplatin. Continued intravenous hydration is essential
- *Continued mannitol diuresis:* In an inpatient or day-hospital setting, one may administer additional mannitol in the form of an intravenous infusion: **mannitol** 10–40 g; administer intravenously over 1–4 hours. This can be done either during or immediately after cisplatin, but requires maintenance of adequate intravenously administered fluids during and for hours after mannitol administration
- *Post-cisplatin hydration* with ≥1000 mL 0.9% NS; administer with potassium and magnesium supplementation as needed based on measured values

Cisplatin 100 mg/m²; administer intravenously in 50–1000 mL 0.9% NS over 60 minutes on day 1, every 3 weeks for 3 cycles during radiation (total dosage/cycle = 100 mg/m²)
Radiation therapy at least 70 Gy to primary site and clinically positive nodes given in daily (Monday–Friday) fractions of 2 Gy/day over 7 weeks; at least 50 Gy to entire neck

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care (mucositis prophylaxis and management)
Risk of mucositis/stomatitis is HIGH
General advice:
- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:
- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification*
Creatinine clearance <50 mL/min (<0.83 mL/s)	Ineligible for therapy
Day 1, 22, or 43 ANC <1500/mm³ *or* platelets <100,000/mm³	Delay cisplatin until ANC >1500/mm³ *and* platelets >100,000/mm³, for up to 3 weeks. Discontinue cisplatin if recovery has not occurred after a 3-week delay
ANC nadir <500/mm³	Reduce cisplatin dosage to 75 mg/m²
Platelet nadir <25,000/mm³	
G1 neurotoxicity or ototoxicity	
Serum creatinine 1.5–2.0 mg/dL (133–177 µmol/L)	Hold cisplatin†, then reduce dosage to 75 mg/m²
ANC nadir <500/mm³ with a cisplatin dosage of 75 mg/m²	Reduce cisplatin dosage to 50 mg/m²
Platelet nadir <25,000/mm³ with a cisplatin dosage of 75 mg/m²	
G2 neurotoxicity or ototoxicity	
Serum creatinine 2.1–3.0 mg/dL (186–265 µmol/L)	Hold cisplatin†, then reduce dosage to 50 mg/m²
ANC nadir <500/mm³ with a cisplatin dosage of 50 mg/m²	Discontinue cisplatin
Platelet nadir <25,000/mm³ with a cisplatin dosage of 50 mg/m²	
Serum creatinine >3.0 mg/dL (>265 µmol/L)	
G3/4 neurotoxicity or ototoxicity	

*The use of colony-stimulating factors is discouraged
†Hold cisplatin dosage until serum creatinine <1.5 mg/dL (<133 µmol/L) or within 0.2 mg/dL (17.7 µmol/L) of baseline

(continued)

- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Efficacy

Larynx Preservation Regimen (N = 172)*

Complete response	90.6%
Laryngeal preservation at median 3.8 years follow-up	84%
2-Year estimated overall survival	74%
2-Year estimated laryngectomy-free survival†	66%
2-Year estimated disease-free survival	61%
5-Year estimated overall survival	54%
5-Year estimated laryngectomy-free survival†	45%
5-Year estimated disease-free survival	36%
Percent receiving >95% of planned RT dose	91%
Moderate‡ or worse speech impairment at 2 year§	11%
Moderate‡ or worse speech impairment at 1 year§	6%
Able to swallow only soft foods or liquids at 1 year	23%
Able to swallow only soft foods or liquids at 2 years	15%
Unable to swallow at 1 year	3%

*Forastiere AA et al. N Engl J Med 2003;349:2091–2098
†Composite endpoint on which the sample size of the trial was predicated. Either laryngectomy or death from any cause constituted treatment failure
‡Difficulty in pronouncing some words and being understood on the telephone
§*Note:* Information on speech and swallowing was available from only 78% of patients who were disease-free and had an intact larynx

Efficacy

Patients with Unresectable Squamous Cell Head and Neck Cancer (N = 87)*

Complete response	40.2%
3-Year overall survival	37%
Median Survival	19.1 months
3-Year disease-specific survival	51%
Compliance	85.1%
Distant metastasis as first site of recurrence	21.8%

*Adelstein DJ et al. J Clin Oncol 2003;21:92–98

Patient Population Studied

Organ preservation: Patients with previously untreated stage III or stage IV squamous cell carcinoma of the glottic or supraglottic larynx, the surgical treatment of which would require total laryngectomy. The disease had to be considered curable with surgery and postoperative radiation therapy. Karnofsky performance status (PS) at least 60%; adequate organ function; creatinine clearance at least 50 mL/min (≥0.83 mL/s)
Unresectable: Patients with stages III/IV unresectable squamous cancer excluding nasopharyngeal cancer, or cancers of the paranasal sinuses or parotid glands. ECOG PS 0–1, adequate organ function

Toxicity (N = 266)

Organ Preservation (n = 171); Unresectable (n = 95)

Toxicity	% G3/4/5 Toxicity	
	Organ Preservation	Unresectable
Hematologic Leukopenia Anemia Thrombocytopenia	47	42 18 3
Mucosal	43	45
Pharyngeal/esophageal	35	—
Nausea or vomiting	20	16
Laryngeal	18	—

Renal/genitourinary	4	8
Neurologic	5	—
Other (not specified)	40	—
G5 toxicity	5	4

*Within radiation field

Therapy Monitoring

1. *Before cisplatin and weekly after treatment:* CBC with differential, serum electrolytes, calcium, and magnesium
2. *Weekly follow-up recommended during therapy:* Attention to signs and symptoms of dehydration as supplemental hydration and nutritional support often are required
3. *Every 4–6 months:* Thyroid function studies

CONCOMITANT CHEMORADIATION REGIMENS

CISPLATIN + PACLITAXEL WITH RADIATION THERAPY

Garden AS et al. Preliminary results of RTOG 97–03. J Clin Oncol 2004;22:2856–2864

Pretreatment:
Dental evaluation; percutaneous feeding tube; nutrition evaluation
Premedication:
Dexamethasone 8–20 mg; administer by intravenous injection or short intravenous infusion 30 minutes before paclitaxel
Diphenhydramine 50 mg; administer by intravenous injection 30–60 minutes before paclitaxel
Ranitidine 50 mg; administer intravenously over 5–20 minutes, 30–60 minutes before paclitaxel
Paclitaxel 30 mg/m^2 per dose; administer intravenously in a volume of 0.9% sodium chloride injection (0.9% NS), or 5% dextrose injection (D5W) sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 3–24 hours weekly, on day 1, for 7 consecutive weeks (total dosage/7-week cycle = 210 mg/m^2)
Optional: **Dexamethasone** 4 mg; administer orally every 6 hours for 4 doses following paclitaxel with glucose monitoring if indicated
Cisplatin 20 mg/m^2 per dose; administer intravenously in 100–1000 mL 0.9% NS over 15–60 minutes weekly on day 2, for 7 consecutive weeks (total dosage/7-week cycle = 140 mg/m^2)
Radiation at least 70 Gy to primary site and clinically positive nodes given in daily (Monday–Friday) fractions of 2 Gy/day over 7 weeks

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential on days with paclitaxel is **LOW***
*Emetogenic potential on days with cisplatin is **HIGH***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care (mucositis prophylaxis and management)
Risk of mucositis/stomatitis is MODERATE
General advice:
- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:
- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Efficacy (N = 77)

Complete response	82%
Estimated 2-year disease-free survival	51.3%
Estimated 2-year overall survival	66.6%

Patient Population Studied

A study of 77 patients with stage III or stage IV M0 squamous cancer of oral cavity, oropharynx, or hypopharynx, previously untreated, assigned to 1 of 3 arms in a randomized phase II RTOG trial. ECOG PS at least 70% and adequate organ function are required

Therapy Monitoring

1. *Weekly:* CBC with differential, serum electrolytes, calcium, and magnesium. Weekly follow-up recommended during therapy with attention to signs and symptoms of dehydration because supplemental hydration and nutritional support are often required
2. *Every 4–6 months:* Thyroid function studies

CONCOMITANT CHEMORADIATION REGIMENS

CARBOPLATIN + FLUOROURACIL WITH RADIATION THERAPY

Calais G et al. J Natl Cancer Inst 1999;91:2081–2086

Pretreatment:
Dental evaluation; percutaneous feeding tube; nutrition evaluation
Carboplatin 70 mg/m² per day; administer intravenously in 50–100 mL 5% dextrose injection (D5W) or 0.9% sodium chloride injection (0.9% NS) over 15–30 minutes for 4 consecutive days, given on days 1–4, every 3 weeks (total dosage/cycle = 280 mg/m²)
Fluorouracil 600 mg/m² per day; administer by continuous intravenous infusion in 50–1000 mL 0.9% NS or D5W over 24 hours for 4 consecutive days, given on days 1–4, every 3 weeks (total dosage/cycle = 2400 mg/m²)
Radiation 2 Gy/day, 5 fractions per week to tumor and clinically positive nodes to a total dose of 70 Gy

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is MODERATE
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed onset diarrhea:*
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:
Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg
Antibiotic therapy during latent or delayed onset diarrhea:
A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm³ with or without accompanying fever in association with diarrhea
- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Wadler S et al. J Clin Oncol 1998;16:3169–178

Oral care (mucositis prophylaxis and management)
Risk of mucositis/stomatitis is HIGH
General advice:
- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications

(continued)

Patient Population Studied

A study of 109 patients with previously untreated stage III or stage IV squamous cell carcinoma of the oropharynx without evidence of distant metastases. Patients were assigned to the chemoradiation arm of a randomized phase III trial with Karnofsky PS at least 60% and adequate organ function

Efficacy (N = 109)

Locoregional control	66%
3-Year overall survival	51%
3-Year disease-free survival	42%
Median survival	29.2 months

Therapy Monitoring

1. *Weekly:* CBC with differential, serum electrolytes, calcium, and magnesium. Weekly follow-up recommended during therapy with attention to signs and symptoms of dehydration because supplemental hydration and nutritional support are often required
2. *Every 4–6 months:* Thyroid function studies

(*continued*)

- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste

CONCOMITANT CHEMORADIATION REGIMEN

CISPLATIN WITH RADIATION THERAPY FOLLOWED BY CISPLATIN + FLUOROURACIL

Al-Sarraf M et al. J Clin Oncol 1998;16:1310–1317

Pretreatment:
Dental evaluation; percutaneous feeding tube; nutrition evaluation
Hydration before, during, and after cisplatin administration ± mannitol:
- *Pre-cisplatin hydration* with 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously with potassium and magnesium supplementation as needed based on pretreatment laboratory results
- *Mannitol diuresis:* May be given to patients who have received adequate hydration. A dose of **mannitol** 12.5–25 g may be administered by intravenous injection or a short intravenous infusion before or during cisplatin administration, or prepared as an admixture with cisplatin. Continued intravenous hydration is essential
- *Continued mannitol diuresis:* In an inpatient or day-hospital setting, one may administer additional mannitol in the form of an intravenous infusion: **mannitol** 10–40 g; administer intravenously over 1–4 hours. This can be done either during or immediately after cisplatin, but requires maintenance of adequate intravenously administered fluids during and for hours after mannitol administration
- Post-cisplatin hydration with ≥1000 mL 0.9% NS; administer intravenously with potassium and magnesium supplementation as needed based on measured values

During radiation therapy:
Cisplatin 100 mg/m² per dose; administer intravenously in 25–1000 mL 0.9% NS over 15–20 minutes every 21 days for 3 cycles, given on days 1, 22, and 43 of radiation therapy (total dosage/cycle = 100 mg/m²)
Radiation 1.8–2 Gy/day, 5 fractions per week to tumor and clinically positive nodes to a total dose of 70 Gy. A total of 50 Gy to entire neck is recommended

After radiation therapy:
Note: Start 4 weeks after radiation therapy or the last dose of cisplatin, regardless of response to cisplatin + radiation
Cisplatin 80 mg/m² per dose; administer intravenously in 25–1000 mL 0.9% NS over 15–30 minutes every 4 weeks for 3 cycles, given on days 71, 99, and 127 (total dosage/cycle = 80 mg/m²)
Fluorouracil 1000 mg/m² per day; administer by continuous intravenous infusion in 100–1000 mL 0.9% NS or 5% dextrose injection over 24 hours for 4 consecutive days every 4 weeks for 3 cycles (96-hour infusion; on days 71–74, 99–102, and 127–130) (total dosage/cycle = 4000 mg/m²)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential during radiation therapy on days with cisplatin is **HIGH**. Potential for delayed symptoms*
*Emetogenic potential after radiation therapy on days with cisplatin is **HIGH**. Potential for delayed symptoms*
*Emetogenic potential after radiation therapy on days with fluorouracil alone is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
ANC <2000/mm³ *or* platelet count <100,000/mm³	Hold chemotherapy until ANC ≥2000/mm³ *and* platelet count ≥100,000/mm³
ANC nadir ≥1500/mm³ *or* platelet count nadir ≥75,000/mm³	No dose modification
ANC nadir 1000–1499/mm³ *and/or* platelet nadir 50,000–74,999/mm³	Reduce cisplatin dosage to 80 mg/m²
ANC nadir <1000/mm³ *and/or* platelet nadir <50,000/mm³	Hold chemotherapy until ANC >2000/mm³ *and* platelet >100,000/mm³ and then reduce cisplatin dosage to 60 mg/m²
Serum creatinine ≤2.0 mg/dL (≤177 μmol/L) *or* creatinine clearance ≥60 mL/min (≥1.00 mL/s)	No dose modification
Serum creatinine 2.1–4 mg/dL (186–354 μmol/L) *or* creatinine clearance 40–59 mL/min (0.66–0.98 mL/s)	Hold cisplatin dosage until serum creatinine <1.5 mg/dL (<133 μmol/L), then reduce cisplatin dosage to 80 mg/m²
Serum creatinine >4 mg/dL (>354 μmol/L) *or* creatinine clearance <40 mL/min (<0.66 mL/s)	Discontinue cisplatin
G ≥2 diarrhea (4–6 stools/day > baseline)	Hold fluorouracil until diarrhea resolves to baseline
G ≥2 mucositis	Hold fluorouracil until toxicity resolves to G ≤1
G ≥2 neurotoxicity	Hold cisplatin until neurotoxicity resolves to G ≤1
G3/4 neurotoxicity	Discontinue cisplatin

(continued)

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count $<500/mm^3$ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care (mucositis prophylaxis and management)

Risk of mucositis/stomatitis is MODERATE–HIGH

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population Studied

A study of 78 patients with stage III or stage IV nasopharyngeal cancer without evidence of systemic metastasis and no history of previous radiation therapy or chemotherapy. Patients were randomized to the combined modality arm of a 2-arm randomized phase III trial

Efficacy (N = 78)

Complete remission	49%
3-Year overall survival	78%
Median overall survival	>2.7 years
Estimated 3-year progression-free survival	69%

Therapy Monitoring

1. *Weekly:* CBC with differential, serum electrolytes, calcium, and magnesium. Weekly follow-up recommended during therapy with attention to signs and symptoms of dehydration, as supplemental hydration and nutritional support are often required
2. *For 2 days, starting the day after cisplatin administration, and as needed:* Serum electrolytes and magnesium
3. *Every 4–6 months:* Thyroid function studies

Toxicity (N = 78/53)

	% G3/4 Toxicities	
	Chemotherapy + Radiation (N = 78)	Adjuvant Chemotherapy (N = 53)
Hematologic		
Anemia	0	5.7
Leukopenia	29.5	22.6
Granulocytopenia	6.4	3.8
Thrombocytopenia	1.3	0
Nonhematologic		
Stomatitis	37.2	20.8
Nausea	17.9	9.4
Vomiting	14.1	1.9
Impaired hearing	11.5	11.3
Weight loss	6.4	0
Infection	2.6	1.9
Renal	0	0
Desquamation, RT field	2.6	N/A

No grade 5 toxicities with either part of regimen

ADVANCED DISEASE INDUCTION CHEMOTHERAPY FOLLOWED BY CHEMORADIATION

DOCETAXEL + CISPLATIN + FLUOROURACIL (TPF) *OR* CISPLATIN + FLUOROURACIL (PF)

Posner MR et al. N Engl J Med 2007;357:1705–1715

Induction Chemotherapy

(Three cycles of TPF or PF)

As noted in the Expert Opinion section: **TPF (docetaxel + cisplatin + fluorouracil)** is to be considered the current standard induction chemotherapy regimen in cases where induction chemotherapy is considered appropriate

Hydration before, during, and after cisplatin administration ± mannitol:

- *Pre-cisplatin hydration* with 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously with potassium and magnesium supplementation as needed based on pretreatment laboratory results
- *Mannitol diuresis:* May be given to patients who have received adequate hydration. A dose of **mannitol** 12.5–25 g may be administered by intravenous injection or a short intravenous infusion before or during cisplatin administration, or prepared as an admixture with cisplatin. Continued intravenous hydration is essential
- *Continued mannitol diuresis:* In an inpatient or day-hospital setting, one may administer additional mannitol in the form of an intravenous infusion: **mannitol** 10–40 g; administer intravenously over 1–4 hours. This can be done either during or immediately after cisplatin, but requires maintenance of adequate intravenously administered fluids during and for hours after mannitol administration
- *Post-cisplatin hydration* with ≥1000 mL 0.9% NS; administer intravenously with potassium and magnesium supplementation as needed based on measured values

TPF induction chemotherapy:

Dexamethasone 8 mg/dose; administer orally or intravenously twice daily for 6 doses starting the day before docetaxel administration (total dose/cycle = 48 mg)

- As prophylaxis against docetaxel-related hypersensitivity reactions, skin toxic effects, and fluid retention

Docetaxel 75 mg/m²; administer intravenously in a volume of 0.9% NS or 5% dextrose injection (D5W) sufficient to produce a docetaxel concentration within the range 0.3–0.74 mg/mL over 60 minutes on day 1, every 21 days for 3 cycles (total dosage/cycle = 75 mg/m²), *followed by:*
Cisplatin 100 mg/m²; administer intravenously in 50–1000 mL 0.9% NS over 0.5–3 hours on day 1, every 21 days for 3 cycles (total dosage/cycle = 100 mg/m²), *followed by:*
Fluorouracil 1000 mg/m² per day; administer in 50–1000 mL 0.9% NS or D5W by continuous intravenous infusion over 24 hours for 4 consecutive days, on days 1–4, every 21 days for 3 cycles (total dosage/cycle = 4000 mg/m²)
Prophylactic antibiotics days 5–14

or

PF induction chemotherapy:

Cisplatin 100 mg/m²; administer intravenously in 50–1000 mL 0.9% NS over 0.5–3 hours on day 1, every 21 days for 3 cycles (total dosage/cycle = 100 mg/m²), *followed by*
Fluorouracil 1000 mg/m² per day; administer intravenously in 50–1000 mL 0.9% NS or D5W by continuous infusion over 24 hours for 5 consecutive days, days 1–5, every 21 days for 3 cycles (total dosage/cycle = 5000 mg/m²)

Note: Induction chemotherapy is discontinued in case of (a) disease progression; (b) a reduction in tumor after 2 cycles <25% (WHO) or <30% (RECIST); or (c) unacceptable toxicity

Supportive Care for Patients Receiving Either TPF or PF Chemotherapies

Antiemetic prophylaxis

*Emetogenic potential on day 1 is **HIGH**. Potential for delayed symptoms*
*Emetogenic potential on days with fluorouracil alone is **LOW***
See Chapter 39 for antiemetic recommendations

(*continued*)

(*continued*)

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count $<500/mm^3$ with or without accompanying fever in association with diarrhea

Antibiotics should also be administered if patient is hospitalized with

- prolonged diarrhea and should be continued until diarrhea resolves

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

Risk of mucositis/stomatitis is HIGH

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

(*continued*)

(*continued*)

For Patients Who Receive TPF Chemotherapy

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with 1 of the following:

Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*

Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose

- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis
  - Posner et al gave antibiotic prophylaxis to patients who received the TPF regimen for 10 days starting on cycle day 5. Choice of antibiotics was not specified
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

For Patients Who Receive PF Chemotherapy

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
  - Posner et al gave antibiotic prophylaxis only to patients who received the TPF regimen: patients who received the PF regimen did not receive antimicrobial primary prophylaxis
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Chemoradiation

(Follows Induction Chemotherapy)

Seven weeks of chemoradiation: Starting between days 22 and 56 of induction chemotherapy cycle 3 (3–8 weeks after the start of cycle 3 of induction chemotherapy)

Radiotherapy:

70–74 Gy to primary tumor in 5 daily fractions/week of 2 Gy/fraction

At least 50 Gy to uninvolved lymph nodes

At least 60–74 Gy to involved lymph nodes

Concurrent chemotherapy:

Carboplatin* (calculated dose) AUC = 1.5 mg/mL • min per dose; administer intravenously diluted to concentrations as low as 0.5 mg/mL with either D5W or 0.9% NS over 1 hour, once weekly for up to 7 doses during the course of radiotherapy (total dose/week calculated to produce a target AUC = 1.5 mg/mL • min)

*Carboplatin dose is based on a formula described by Calvert et al. to achieve a target area under the plasma concentration versus time curve (AUC)

$$\text{Total Carboplatin Dose (mg)} = (\text{target AUC}) \times (\text{GFR} + 25)$$

(*continued*)

(*continued*)

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be estimated from the equation of Cockcroft and Gault, thus:

$$\text{For males, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})} \times 0.85$$

Calvert AH et al. J Clin Oncol 1989;7:1748–1756
Cockcroft DW, Gault MH. Nephron 1976;16:31–41
Jodrell DI et al. J Clin Oncol 1992;10:520–528
Sorensen BT et al. Cancer Chemother Pharmacol 1991;28:397–401

Note: On October 8, 2010, the U.S. FDA identified a potential safety issue with carboplatin dosing based on recent changes in the measurement of serum creatinine. By the end of 2010, all clinical laboratories in the United States were required to use the standardized Isotope Dilution Mass Spectrometry (IDMS) method to measure serum creatinine, which can result in an overestimation of the GFR in some patients with normal renal function. A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula can exceed an expected exposure (AUC) and result in increased drug-related toxicity

Provided actual GFR measurements are made to assess renal function, carboplatin can be safely dosed according to the Calvert formula described in product labeling

If GFR (or creatinine clearance) is estimated based on serum creatinine measurements by the IDMS method, the FDA recommended for patients with normal renal function capping an estimated GFR at 125 mL/min for any targeted AUC value. No greater estimated GFR values should be used

U.S. FDA. Carboplatin dosing. [online] Available from: http://www.fda.gov/AboutFDA/CentersOffices/OfficeofMedicalProductsandTobacco/CDER/ucm228974.htm [accessed February 26, 2014]

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days when carboplatin is administered is ***MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Dose Modification

Adverse Event	Dose Modifications
G3/4 hematologic toxicity	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 2 weeks, then discontinue therapy
G3/4 nonhematologic toxicity other than alopecia, fatigue, malaise, and nail changes (exceptions: neurotoxicity, ototoxicity, and mucositis as detailed below)	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. If toxicity does not resolve to G ≤1 within 2 weeks, then discontinue therapy
G3/4 neurotoxicity or ototoxicity	Discontinue therapy
G4 mucositis and diarrhea	Discontinue therapy
Febrile neutropenia or infection	Administer filgrastim during subsequent cycles
Delay in ANC recovery beyond day 28	
G4 neutropenia ≥7 days	
ANC <2000/mm^3; platelet count <100,000/mm^3; or hemoglobin <10 g/dL)	Withhold start of RT
Incomplete resolution of mucositis	

Efficacy*

	TPF† (N = 255)	PF† (N = 246)	Hazard Ratio or P-Value

†TPF, Docetaxel + cisplatin + fluorouracil; PF, cisplatin + fluorouracil

Surgery

(Elective Neck Dissection)
Elective neck dissection 6–12 weeks after end of chemoradiation for patients with initial N2 disease and a partial response to induction chemotherapy, N3 disease, or residual disease after chemoradiation

Patient Population Studied

A study of 539 patients with measurable, nonmetastatic, stage III or IV, histologically proven, previously untreated squamous cell carcinoma of the oral cavity, larynx, oropharynx, or hypopharynx with a tumor deemed to be unresectable (because of tumor fixation, involvement of the nasopharynx, or fixed lymph nodes), or of low surgical curability on basis of advanced tumor stage (3 or 4) or regional node stage (2–3, except T1N2), or if a patient was a candidate for organ preservation. WHO performance status 0 or 1. Adequate organ function and age ≥18 years

Therapy Monitoring

1. *Pretreatment evaluation:* Medical history and tumor assessment by clinical evaluation and imaging studies
2. *Toxicity assessment:* Weekly during treatment with chemotherapy
3. *Tumor assessment:* After cycles 2 and 3; then, 6–12 weeks after chemoradiation

Toxicity

	TPF*	PF*

*TPF, Docetaxel + cisplatin + fluorouracil; PF, cisplatin + fluorouracil

ADVANCED DISEASE
INDUCTION CHEMOTHERAPY FOLLOWED BY RADIOTHERAPY

DOCETAXEL + CISPLATIN + FLUOROURACIL (TPF) *OR*
CISPLATIN + FLUOROURACIL (PF)

Vermorken JB et al. N Engl J Med 2007;357:1695–1704

Induction Chemotherapy

(Three Cycles of TPF or PF)

As noted in the Expert Opinion section: **TPF (docetaxel + cisplatin + fluorouracil)** is to be considered the current standard induction chemotherapy regimen in cases where induction chemotherapy is considered appropriate

Hydration before, during, and after cisplatin administration ± mannitol:

- *Pre-cisplatin hydration* with 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously with potassium and magnesium supplementation as needed based on pretreatment laboratory results
- *Mannitol diuresis:* May be given to patients who have received adequate hydration. A dose of **mannitol** 12.5–25 g may be administered by intravenous injection or a short infusion before or during cisplatin administration, or prepared as an admixture with cisplatin. Continued intravenous hydration is essential
- *Continued mannitol diuresis:* In an inpatient or day-hospital setting, one may administer additional mannitol in the form of an intravenous infusion: **mannitol** 10–40 g; administer intravenously over 1–4 hours. This can be done either during or immediately after cisplatin, but requires maintenance of adequate intravenously administered fluids during and for hours after mannitol administration
- *Post-cisplatin hydration* with ≥1000 mL 0.9% NS; administer intravenously with potassium and magnesium supplementation as needed based on measured values

Docetaxel + Cisplatin + Fluorouracil (TPF)

Premedication:
Dexamethasone 8 mg/dose; administer orally or intravenously twice daily for 6 doses starting the day before docetaxel administration (total dose/cycle = 48 mg)
- As prophylaxis against docetaxel-related hypersensitivity reactions, skin toxic effects, and fluid retention

Induction chemotherapy:
Docetaxel 75 mg/m²; administer intravenously in a volume of 0.9% NS or 5% dextrose injection (D5W) sufficient to produce a docetaxel concentration within the range 0.3–0.74 mg/mL over 60 minutes on day 1, every 3 weeks for up to 4 cycles (total dosage/cycle = 75 mg/m²), *followed by:*
Cisplatin 75 mg/m²; administer intravenously in 50–1000 mL 0.9% NS over 60 minutes on day 1, every 3 weeks for up to 4 cycles (total dosage/cycle = 75 mg/m²), *followed by:*
Fluorouracil 750 mg/m² per day; administer in 50–1000 mL 0.9% NS or D5W by continuous intravenous infusion over 24 hours for 5 consecutive days, on days 1–5, every 3 weeks for up to 4 cycles (total dosage/cycle = 3750 mg/m²)

or

Cisplatin + Fluorouracil (PF)

Induction chemotherapy:
Cisplatin 100 mg/m²; administer intravenously in 50–1000 mL 0.9% NS over 60 minutes on day 1, every 3 weeks for up to 4 cycles (total dosage/cycle = 100 mg/m²), *followed by:*
Fluorouracil 1000 mg/m² per day; administer in 50–1000 mL 0.9% NS or D5W by continuous intravenous infusion over 24 hours for 5 consecutive days, on days 1–5, every 3 weeks for up to 4 cycles (total dosage/cycle = 5000 mg/m²)

Supportive Care for Patients Receiving Either TPF or PF Chemotherapies
Antiemetic prophylaxis
*Emetogenic potential on day 1 is **HIGH**. Potential for delayed symptoms*
*Emetogenic potential on days with fluorouracil alone is **LOW***
See Chapter 39 for antiemetic recommendations

Diarrhea management
Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode

(*continued*)

(continued)

- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

Risk of mucositis/stomatitis is MODERATE

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

For Patients Who Receive TPF Chemotherapy

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

- Particularly in patients who do not receive antibiotic prophylaxis

See Chapter 43 for more information

(continued)

Radiotherapy

Starting within 4–7 weeks after completion of chemotherapy

Radiotherapy: Conventional fractionation (66–70 Gy) *or* Accelerated irradiation (70 Gy]) *or* Hyperfractionated irradiation (74 Gy)

Surgery

(Elective Neck Dissection)

Elective neck dissection can be considered before radiotherapy and again 3 months after the completion of radiotherapy

Dose Modification

Adverse Event	Dose Modification
G3/4 hematologic toxicity	Hold chemotherapy up to 2 weeks until toxicity resolves to G ≤1. If toxicity has not resolved to G ≤1 within 2 weeks, discontinue therapy
G3/4 nonhematologic toxicity other than alopecia, fatigue, malaise, and nail changes (exceptions: neurotoxicity, ototoxicity and mucositis as detailed below)	
G3/4 neurotoxicity or ototoxicity	Discontinue therapy
G4 mucositis and diarrhea	
Febrile neutropenia or infection	Administer filgrastim in subsequent cycles
Delay in ANC recovery beyond day 28	
G4 neutropenia ≥7 days	
ANC <2000/mm^3, platelet count <100,000/mm^3, *or* hemoglobin <10 g/dL	Withhold start of RT
Incomplete resolution of mucositis	

Patient Population Studied

A study of 358 patients with measurable, nonmetastatic stages III or IV, histologically or cytologically proven, previously untreated squamous cell carcinoma of the oral cavity, larynx, oropharynx, or hypopharynx, with a tumor considered to be unresectable by a multidisciplinary team. WHO performance status 0 or 1, adequate organ function, and ages 18–70 years

(continued)

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis
  - Vermorken et al gave antibiotic prophylaxis to patients who received the TPF regimen from cycle days 5–15
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

For Patients Who Receive PF Chemotherapy
Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
  - Vermorken et al gave antibiotic prophylaxis only to patients who received the TPF regimen
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Efficacy

	TPF* (N = 181)	PF* (N = 177)
Median progression-free survival, months	11	8.2
Estimated 3-year progression-free survival	17%	14%
Median overall survival, months	18.8	14.5
Estimated 3-year overall survival	37%	26%
Overall response rate after induction chemotherapy	68%	54%
Complete response rate after induction chemotherapy	8.5%	6.6%

*TPF, Docetaxel + cisplatin + fluorouracil; PF, cisplatin + fluorouracil

Therapy Monitoring

1. *Day 1 of each cycle:* Medical history and physical exam, CBC with differential, LFTs, electrolytes, BUN, and creatinine
2. *At end of cycles 2 and 4:* Diagnostic imaging

Toxicity

Adverse Events During Induction Chemotherapy	TPF* % G3/4 N = 179	PF* % G3/4 N = 173
Anemia	9.2	12.8
Thrombocytopenia	5.2	17.9
Neutropenia	76.9	52.5
Leukopenia	41.6	22.9
Febrile neutropenia	5.2	2.8

Vomiting	0.6	4.5
Diarrhea	2.9	3.4
Constipation	0	0.6
Lethargy	2.9	1.7
Weight loss	0	0.6
Gastrointestinal pain	0	0.6
Neurotoxicity	0.6	0.6
Hearing loss	0	2.8
Local toxic effect	0.6	0.6
Toxic deaths	2.3	5.5

*TPF, Docetaxel + cisplatin + fluorouracil; PF, cisplatin + fluorouracil

ADVANCED DISEASE CHEMORADIATION IN UNRESECTABLE DISEASE

CISPLATIN ALONE *OR*

CISPLATIN + FLUOROURACIL

Adelstein DJ et al. J Clin Oncol 2003;21:92–98

Chemoradiation

As noted in the Expert Opinion section: Chemoradiation concurrent with cisplatin 100 mg/m² every 3 weeks × 3 doses should still be considered the standard regimen

Hydration before, during, and after cisplatin administration ± mannitol:

- *Pre-cisplatin hydration* with 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously with potassium and magnesium supplementation as needed based on pretreatment laboratory results
- *Mannitol diuresis:* May be given to patients who have received adequate hydration. A dose of **mannitol** 12.5–25 g may be administered by intravenous injection or a short infusion before or during cisplatin administration, or prepared as an admixture with cisplatin. Continued intravenous hydration is essential
- *Continued mannitol diuresis:* In an inpatient or day-hospital setting, one may administer additional mannitol in the form of an intravenous infusion: **mannitol** 10–40 g; administer intravenously over 1–4 hours. This can be done either during or immediately after cisplatin, but requires maintenance of adequate intravenously administered fluids during and for hours after mannitol administration
- *Post-cisplatin hydration* with ≥1000 mL 0.9% NS; administer intravenously with potassium and magnesium supplementation as needed based on measured values

Cisplatin 100 mg/m²; administer intravenously in 50–1000 mL 0.9% NS over 60 minutes on day 1, every 3 weeks for 3 cycles during radiation (total dosage/cycle = 100 mg/m²)
Radiation therapy administered to a total dose of 70 Gy given continually in single, daily, 2-Gy fractions over 7 weeks

Supportive Care

Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

or

Cisplatin 75 mg/m²; administer intravenously in 50–1000 mL 0.9% NS over 60 minutes on day 1, every 4 weeks for 3 cycles during radiation (total dosage/cycle = 75 mg/m²), *followed by:*
Fluorouracil 1000 mg/m² per day; administer in 50–1000 mL 0.9% NS or D5W by continuous intravenous infusion over 24 hours for 4 consecutive days, on days 1–4, every 4 weeks for 3 cycles during radiation (total dosage/cycle = 4000 mg/m²)

Concurrent radiation therapy, at a rate of 2 Gy/day, split as follows:
- *First chemotherapy cycle:* A total of 30 Gy administered as 15 daily fractions of 2 Gy/fraction, 5 days/week, starting on day 1 of cycle 1

(*continued*)

Patient Population Studied

A study of 295 patients with a histologically confirmed diagnosis of squamous cell or undifferentiated stage III or IV, nonmetastatic, carcinoma of the head and neck, excluding tumors originating in the nasopharynx, paranasal sinus, or parotid gland
Unresectability was predefined for each tumor site as follows:
- *Hypopharynx:* tumor extension across the midline of the posterior pharyngeal wall or fixed to the cervical spine
- *Larynx:* direct extension into surrounding muscle or skin or greater than 3 cm subglottic extension
- *Oral cavity:* functional reconstruction not possible
- *Base of tongue:* extension into the root of tongue or refusal of total glossectomy
- *Tonsil:* extension into the pterygoid region as manifested by clinical trismus or demonstrated radiographically, or tumor extension across the midline of the pharyngeal wall or direct invasion into the soft tissue of the neck

Adequate organ function and an ECOG performance score ≤1 were required

Dose Modification

Note: It is anticipated that radiation therapy will continue despite the development of significant mucositis and or myelosuppression

Adverse Event	Dose Modification
G3/4 hematologic toxicity	Hold chemotherapy for up to 3 weeks until toxicity resolves to G ≤1. If toxicity has not resolved to G ≤1 within 3 weeks, do not administer next cycle
G3/4 nonhematologic toxicity other than alopecia, fatigue, malaise, and nail changes (exceptions: neurotoxicity, ototoxicity, and mucositis as detailed below)	
G3/4 neurotoxicity or ototoxicity	Discontinue chemotherapy
G4 mucositis	

(continued)

- *Third chemotherapy cycle:* A total of 30–40 Gy administered as 15–20 daily fractions of 2 Gy/fraction, 5 days/week, starting on day 1 of cycle 3
- Administer 30–40 Gy for a total dose of 60–70 Gy depending on response

Note: The radiation therapy break is planned to allow for the possibility of surgical resection in patients whose disease is rendered resectable after the first 2 courses of chemotherapy and the first 30 Gy of radiation. Patients who do not achieve a complete response after the first 2 courses of chemotherapy and the first 30 Gy of radiation, or whose disease remains unresectable complete chemoradiation without surgery
As a result of the break, almost 7 additional weeks were required to complete treatment

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on day 1 is **HIGH**. Potential for delayed symptoms*
*Emetogenic potential on days with fluorouracil ± RT is **LOW–MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care

Risk of mucositis/stomatitis is HIGH

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Efficacy

	Cisplatin + Radiation N = 95	Cisplatin + Fluorouracil + Radiation N = 94
Complete response rate	40.2%	49.4%*
Estimated 3-year survival	37%	27%
Median overall survival, months	19.1	13.8
Disease-specific survival rates	51%	41%

*Includes patients undergoing mid-course surgical resection

G3–5 Toxicity

	Cisplatin + Radiation N = 95	Cisplatin + Fluorouracil + Radiation N = 94	p-Value
Nausea/vomiting	15	8	
Mucositis/dysphagia	43	44	
Leukopenia	40	29	<0.001
Thrombocytopenia	3	3	
Anemia	17	18	
Renal	8	0	0.01
Skin	7	2	
Feeding tube	49	48	
Toxic death	4	2	
All G3–5	85	72	0.02
Treatment regimen compliance*	85.1%	73%	0.05

*As measured by treatment completion

Therapy Monitoring

1. *Day 1 of each cycle:* Medical history and physical exam, CBC with differential, LFTs, electrolytes, BUN, and creatinine
2. *Diagnostic imaging:* At treatment completion and 3 months later

CHEMORADIATION WITH CISPLATIN IN UNRESECTABLE DISEASE

CHEMORADIATION FOR LARYNX PRESERVATION CISPLATIN WITH RADIATION THERAPY

Forastiere AA et al. N Engl J Med 2003;349:2091–2098

As noted in the Expert Opinion section: Concurrent chemoradiation using cisplatin 100 mg/m² every 3 weeks × 3 doses should still be considered the standard regimen

Chemoradiation

Hydration before, during, and after cisplatin administration ± mannitol:

- *Pre-cisplatin hydration* with 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously with potassium and magnesium supplementation as needed based on pretreatment laboratory results
- *Mannitol diuresis:* May be given to patients who have received adequate hydration. A dose of **mannitol** 12.5–25 g may be administered by intravenous injection or a short infusion before or during cisplatin administration, or prepared as an admixture with cisplatin. Continued intravenous hydration is essential
- *Continued mannitol diuresis:* In an inpatient or day-hospital setting, one may administer additional mannitol in the form of an intravenous infusion: **mannitol** 10–40 g; administer intravenously over 1–4 hours. This can be done either during or immediately after cisplatin, but requires maintenance of adequate intravenously administered fluids during and for hours after mannitol administration
- *Post-cisplatin hydration* with ≥1000 mL 0.9% NS; administer intravenously with potassium and magnesium supplementation as needed based on measured values

Cisplatin 100 mg/m²; administer intravenously in 50–1000 mL 0.9% NS over 60 minutes on day 1, every 3 weeks for 3 cycles during radiation (total dosage/cycle = 100 mg/m²)
Radiotherapy 70 Gy given in 35 fractions of 2 Gy/fraction over 7 weeks to the primary tumor and clinically positive nodes; 50 Gy in fractions of 2 Gy to the entire neck

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on days with cisplatin is **HIGH**. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care

Risk of mucositis/stomatitis is HIGH

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

(*continued*)

(continued)

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Induction Chemotherapy Followed By Radiotherapy

Cisplatin 100 mg/m²; administer intravenously in 50–1000 mL 0.9% NS over 60 minutes on day 1, every 3 weeks for 3 cycles (total dosage/cycle = 100 mg/m²), *followed by:*
Fluorouracil 1000 mg/m² per day; administer in 50–1000 mL 0.9% NS or D5W by continuous intravenous infusion over 24 hours for 5 consecutive days on days 1–5, every 3 weeks for 3 cycles (total dosage/cycle = 5000 mg/m²)

After 2 cycles of cisplatin + fluorouracil, evaluate extent of response and disease status in the neck with indirect laryngoscopy and CT imaging of the neck

- If evaluation reveals a complete or partial response of the primary tumor and no sign of progression in the neck, a third course of cisplatin plus fluorouracil is given, followed by radiotherapy
- If evaluation reveals less than partial response of the primary tumor or with progression in the neck, laryngectomy followed by adjuvant radiotherapy is recommended

Radiotherapy, 70 Gy given in 35 fractions of 2 Gy/fraction over 7 weeks to the primary tumor and clinically positive nodes; 50 Gy in fractions of 2 Gy to the entire neck

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on days with cisplatin is **HIGH** Potential for delayed symptoms*
*Emetogenic potential on days with fluorouracil alone is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care

Risk of mucositis/stomatitis is HIGH

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

(continued)

(continued)

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Surgery

Patients with either a single lymph node ≥3 cm or with multiple lymph node metastases on initial clinical staging of the neck should undergo neck dissection 8 weeks after completing radiotherapy. Laryngectomy should be performed in patients who had histologically proven persistent or recurrent carcinoma after the completion of treatment, or who had an inadequate response after 2 courses of induction chemotherapy

Toxicity

G3/4 Toxicity

	Induction Chemotherapy (Cisplatin + Fluorouracil) → RT (N = 168)		Radiotherapy Alone (N = 156)		Chemoradiation (Cisplatin + RT) (N = 171)	
	% G3	% G4	% G3	% G4	% G3	% G4
Hematologic	26	26	8	6.5	37	10
Infection	2.5	2.5	1	—	4	—
Mucositis	16	4	23	1	37	5
Pharyngeal/ esophageal	—	—	19	—	35	—
Laryngeal	—	—	13	0.5	17	1
Radiation dermatitis	—	—	10	—	6	1
Nausea/vomiting	12	2	—	—	16	1
Renal/ genitourinary	2	—	1	—	3.5	0.5
Neurologic	2.5	0.5	—	—	5	0.5
Other	12	4	10	1	34	6.5
Overall maximal	37	29	42	8	58	19

Note: Deaths caused by treatment occurred in 3% of the group assigned to induction cisplatin plus fluorouracil followed by radiotherapy, 3% of the group assigned to RT alone, and 5% percent of the group assigned to radiotherapy with concurrent cisplatin

Patient Population Studied

A study of 547 patients with biopsy-proven, previously untreated, stage III or IV squamous cell carcinoma of the larynx for whom surgical treatment would require total laryngectomy. Excluded were patients with large T4 tumors, defined as tumors penetrating through the cartilage or extending >1 cm into the base of tongue, and patients with a stage T1 primary tumor. Karnofsky performance score of ≥60 and adequate organ function were required

Dose Modification

Note: It is anticipated that radiation therapy will continue despite the development of significant mucositis and or myelosuppression

Adverse Event	Dose Modification
G3/4 hematologic toxicity	Hold chemotherapy up to 3 weeks until toxicity resolves to G ≤1. If toxicity has not resolved to G ≤1 within 3 weeks, do not administer next cycle
G3/4 nonhematologic toxicity other than alopecia, fatigue, malaise, and nail changes (exceptions: neurotoxicity, ototoxicity and mucositis as detailed below)	
G3/4 neurotoxicity or ototoxicity	Discontinue chemotherapy
G4 mucositis	

Efficacy

	Induction Chemotherapy (Cisplatin + Fluorouracil) → RT (N = 168)	Radiotherapy Alone (N = 156)	Chemoradiation (Cisplatin + RT) (N = 171)
Larynx Preservation Rate			
at 2 years	84%	67%	72%
Estimated Laryngectomy-free Survival			
at 2 years	59%	53%	66%
at 5 years	43%	38%	45%
Estimated Overall Survival			
at 2 years	76%	75%	74%
at 5 years	55%	56%	54%
Estimated Disease-free Survival			
at 2 years	52%	44%	61%
at 5 years	38%	27%	36%

Therapy Monitoring

1. *Day 1 of each cycle:* Medical history and physical exam, CBC with differential, LFTs, electrolytes, BUN, and creatinine
2. *Posttreatment reevaluation:* 8 weeks after the completion of therapy by examination of the head and neck and CT imaging. If persistent disease is suspected, perform the examination while the patient is under anesthesia so that direct laryngoscopy can be performed
3. *Scheduled follow-up visits:* Complete examination of the head and neck, with evaluation for late toxicity

HIGH-RISK PATIENTS

POSTOPERATIVE CHEMORADIATION WITH CISPLATIN

Bernier J et al. N Engl J Med 2004;350:1945–1952
Cooper JS et al. N Engl J Med 2004;350:1937–1944

Chemoradiation

Note: Among high-risk patients with resected head and neck cancer, the chemoradiation therapy regimen described significantly improved the rates of local and regional control and disease-free survival. However, compared to RT alone, chemoradiation is associated with a substantial increase in adverse effects

Hydration before, during, and after cisplatin administration ± mannitol:

- *Pre-cisplatin hydration* with 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously with potassium and magnesium supplementation as needed based on pretreatment laboratory results
- *Mannitol diuresis:* May be given to patients who have received adequate hydration. A dose of **mannitol** 12.5–25 g may be administered by intravenous injection or a short infusion before or during cisplatin administration, or prepared as an admixture with cisplatin. Continued intravenous hydration is essential
- *Continued mannitol diuresis:* In an inpatient or day-hospital setting, one may administer additional mannitol in the form of an intravenous infusion: **mannitol** 10–40 g; administer intravenously over 1–4 hours. This can be done either during or immediately after cisplatin, but requires maintenance of adequate intravenously administered fluids during and for hours after mannitol administration
- *Post-cisplatin hydration* with ≥1000 mL 0.9% NS; administer intravenously with potassium and magnesium supplementation as needed based on measured values

Cisplatin 100 mg/m²; administer intravenously in 50–1000 mL 0.9% NS over 60 minutes on day 1, every 3 weeks for 3 cycles during radiation (total dosage/cycle = 100 mg/m²)
Radiotherapy 60–66 Gy in 30–33 fractions of 2 Gy/fraction given continually over 6–6.6 weeks

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on days with cisplatin is **HIGH**. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm³ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Wadler S et al. J Clin Oncol 1998;16:3169–31378

(*continued*)

(continued)

Oral care

Risk of mucositis/stomatitis is HIGH

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population Studied

EORTC 22931

A study of 334 patients with previously untreated, histologically proven, squamous cell carcinoma of the oral cavity, oropharynx, hypopharynx, or larynx with: (a) tumor stage pT3 or pT4 and any nodal stage except T3N0 of the larynx with negative resection margins, (b) N2/N3 disease, (c) T1/2N1/N2 disease with extranodal spread, (d) positive section margins, (e) perineural involvement, (f) vascular involvement, or (g) oral cavity or oropharyngeal tumors with involvement of lymph nodes at levels IV or V. Adequate organ function, WHO performance status of 0–2, and age ≥18 years

RTOG 9501/Intergroup

A study of 459 patients with squamous cell carcinoma of the oral cavity, oropharynx, larynx, or hypopharynx, who underwent macroscopically complete resection but had at least 1 high-risk characteristic defined as: (a) invasion of at least 2 lymph nodes, (b) extracapsular extension of nodal disease, or (c) microscopically involved mucosal margins of resection. Adequate organ function and Karnofsky performance status of ≥60 were required

Dose Modification

Note: Continuity of radiotherapy should be maintained if at all possible. Keep to a minimum interruptions resulting from treatment-related adverse effects

Adverse Event	Dose Modification
On day 12 of any cycle, ANC $<1000/mm^3$ *or* platelet count $<75{,}000/mm^3$	Hold cisplatin until ANC $>1000/mm^3$ *and* platelet count $>75{,}000/mm^3$
G1/2 neurotoxicity	Reduce cisplatin dosage to 60 mg/m²
G3/4 neurotoxicity or ototoxicity	Discontinue cisplatin
Creatinine clearance 40–50 mL/min (0.66–0.83 mL/s)	Reduce cisplatin dosage to 75 mg/m²
Creatinine clearance <40 mL/min (<0.66 mL/s)	Discontinue cisplatin

Efficacy

EORTC* (Bernier J et al. N Engl J Med 2004;350:1945–1952)

	Radiotherapy	Chemoradiation
Median progression-free survival, months‡	23	55
Median overall survival, months	32	72
Estimate of 5-year		
Progression-free survival	36%	47%
Overall survival	40%	53%
Cumulative incidence of loco-regional relapse	31%	18%

RTOG/INTERGROUP† (Cooper JS et al. N Engl J Med 2004;350:1937–1944)

	Radiotherapy N = 210	Chemoradiation N = 206
Estimated 2-year rate of local regional control‡	72%	82%
First site of treatment failure		
Local regional recurrence	29%	16%
Distant metastasis	23%	20%
Overall survival	No significant difference Hazard ratio for death = 0.84; 95% CI = 0.65–1.09; P = 0.19	

*Median follow up was 60 months
†Median follow up was 46 months
‡Primary end point. *Note:* Only 8 local and regional recurrences were observed beyond 2 years

HIGH-RISK PATIENTS

POSTOPERATIVE CHEMORADIATION WITH CISPLATIN + FLUOROURACIL

Fietkau R et al. Proc Am Soc Clin Oncol 2006;24(18S, Part 1 of 2):281s (abstract 5507)

Chemoradiation

Hydration before, during, and after cisplatin administration:

- *Pre-cisplatin hydration* with 500–1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously with potassium and magnesium supplementation as needed based on pretreatment laboratory results
- *Post-cisplatin hydration* with 500–1000 mL 0.9% NS; administer intravenously with potassium and magnesium supplementation as needed based on measured values

Cisplatin 20 mg/m² per day; administer intravenously in 50–1000 mL 0.9% NS over 60 minutes for 5 consecutive days, on days 1–5, every 4 weeks for 2 cycles during radiation (total dosage/cycle = 100 mg/m²), *and*
Fluorouracil 600 mg/m² per day; administer in 50–1000 mL 0.9% NS or D5W by continuous intravenous infusion over 24 hours for 5 consecutive days, on days 1–5, every 4 weeks for 2 cycles during radiation (total dosage/cycle = 3000 mg/m²)
Radiotherapy (50 Gy in case of pN0, 56 Gy in case of pN+ without extracapsular spread, 64 Gy in case of pN+ with extracapsular spread)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on days with cisplatin is **HIGH**. Potential for delayed symptoms*
*Emetogenic potential on days with fluorouracil alone is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm³ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

Risk of mucositis/stomatitis during chemoradiation is MODERATE–HIGH

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications

(*continued*)

(*continued*)

- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population Studied

A study of 440 patients with pTR1, PT4, or ≥3 positive lymph nodes, or extracapsular spread and no macroscopic residual tumor

Dose Modification

Note: Continuity of radiotherapy should be maintained if at all possible. Keep to a minimum interruptions resulting from treatment-related adverse effects

Adverse Event	Dose Modification
G3/4 hematologic toxicity attributable to chemotherapy	Hold chemotherapy
G3/4 nonhematologic toxicity other than alopecia, fatigue, malaise, and nail changes attributable to chemotherapy (exception: mucositis as detailed below)	
G4 mucositis	Discontinue therapy

G3/4 Toxicity (%)

Adverse Event	Radiotherapy	Chemoradiation
Mucositis	12.6	20.8
Dermatitis	8.9	13.1
Leukopenia	0	4.4
Thrombocytopenia	0	1.7
Serum creatinine >1.5 × upper limit of normal range	1.2	6.4
Infections	6.9	8.8

Efficacy

	Radiotherapy	Chemoradiation
5-Year locoregional control	61.9%	83.3%
5-Year rate free of distant metastases	68%	70%
5-Year disease survival	50.1%	62.4%
5-Year survival	48.6%	58.1%

Therapy Monitoring

1. *Days 1 and 29:* Medical history and physical exam, CBC with differential, LFTs, electrolytes, BUN, and creatinine
2. *Posttreatment reevaluation:* 8 weeks after the completion of therapy by examination of the head and neck and CT imaging. If persistent disease is suspected, perform the examination while the patient is under anesthesia so that direct laryngoscopy can be performed
3. *Scheduled follow-up visits:* Complete examination of the head and neck, with evaluation for late toxicity

INITIAL OR METASTATIC DISEASE REGIMEN

CETUXIMAB ± RADIATION

Bonner JA et al. N Engl J Med 2006;354:567–578

Premedication:
Diphenhydramine 50 mg (or an equivalent [H_1] antihistamine); administer by intravenous injection or as a short infusion 30 minutes prior to cetuximab administration

Note: Severe infusion reactions can occur with the administration of cetuximab Approximately 90% of severe reactions were associated with the first infusion despite the use of prophylactic antihistamines

Initial dose:
Cetuximab 400 mg/m^2; administer intravenously over 120 minutes (maximum infusion rate = 5 mL [10 mg] per min) 1 week prior to radiation therapy

Maintenance doses:
Cetuximab 250 mg/m^2 per dose; administer intravenously over 60 minutes (maximum infusion rate = 5 mL [10 mg] per min), weekly ± **radiation**
Note: If administering radiation, administer cetuximab weekly for the duration of radiation

Radiation Regimens Used in the Randomized Trial

Regimen	Total Radiation Dose	Once-Daily Fractions	Twice-Daily Fractions
Once daily	70.0 Gy 35 fractions	2.0 Gy/fraction 5 fractions/week 7 weeks	Not applicable
Twice daily	72.0–76.8 Gy 60–64 fractions	Not applicable	1.2 Gy/fraction; 10 fractions/week for 6.0–6.5 weeks
Concomitant boost	72.0 Gy 42 fractions	32.4 Gy 1.8 Gy/fraction 5 fractions/week for 3.6 weeks	*Morning dose:* 21.6 Gy; 1.8 Gy/fraction; 5 fractions/week; 2.4 weeks *Afternoon dose:* 18.0 Gy; 1.5 Gy/fraction; 5 fractions/week; 2.4 weeks

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential with cetuximab is **MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care
Risk of mucositis/stomatitis is HIGH
General advice:
- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:
- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:
- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols

(*continued*)

(*continued*)

- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Dose Modification

Infusion Reaction Severity	Cetuximab Dosage
G1/2	Reduce dosage by 50%
G3/4	Discontinue cetuximab

		Subsequent Treatment Modifications by Outcome	
Severe Acneiform Rash*	Cetuximab	Improvement	No improvement
First occurrence	Delay repeated treatment for 1–2 weeks	Resume with cetuximab 250 mg/m² weekly	Discontinue cetuximab
Second occurrence		Resume with cetuximab 200 mg/m² weekly	
Third occurrence		Resume with cetuximab 150 mg/m² weekly	
Fourth occurrence		Discontinue cetuximab	

*In patients with mild and moderate skin toxicity treatment should continue without dose modification

Efficacy (N = 211)

	Radiotherapy Alone (N = 213)	Radiotherapy Plus Cetuximab (N = 211)
Locoregional Control		
Median duration (months)	14.9	24.4
Median Duration of Locoregional Control According to Site (Months)		
Oropharynx	23	49
Larynx	11.9	12.9
Hypopharynx	10.3	12.5
Median Duration of Locoregional Control According to Stage		
Stage III	16.2	38.9
Stage IV	13.5	20.9
Progression-Free Survival

Anemia	13	6	3	1

*With the exception of acneiform rash and infusion-related events, the incidence rates of G3–5 reactions were similar in the 2 treatment groups

Note: Four patients discontinued cetuximab because of hypersensitivity reactions after the test dose or first dose

Notes

1. *Indications:*

Cetuximab, in combination with radiation therapy, is indicated for the treatment of locally or regional advanced squamous cell carcinoma of the head and neck

Bonner JA et al. N Engl J Med 2006;354:567–578

Cetuximab as a single agent is indicated for the treatment of patients with recurrent or metastatic squamous cell carcinoma of the head and neck after prior platinum based therapy has failed

Trigo J et al. Proc Am Soc Clin Oncol 2004;23:488s [abstract 5502]

Evaluated the efficacy of cetuximab monotherapy in 103 patients with platinum-refractory, recurrent or metastatic squamous cell carcinoma of the head and neck in a multicenter phase II study. An initial dose of cetuximab 400 mg/m^2 was followed by cetuximab 250 mg/m^2 weekly, until disease progression, with an option to switch to cetuximab plus the same platinum agent on which patients' disease had previously progressed after disease progression occurred with cetuximab monotherapy. Drug-related adverse events in >10% of patients included skin rash/acne 80% (1% G3), fatigue 24% (4% G3), fever/chills 19% (2% G3), nail changes 15% (all G1/2), and nausea 13% (1% G3). There was 1 treatment-related death as a result of a hypersensitivity reaction in a patient for whom mechanical ventilation was not suitable. Preliminary efficacy data were as follows: 5 CR, 12 PR, 38 SD, 47 PD, and 1 not assessable, for an overall objective response rate of 16.5% (95% CI, 9.9–25.1%). The disease control rate was 53.4% (95% CI, 43.3–63.3%). Median TTP and median survival were 85 days and 175 days, respectively

METASTATIC DISEASE REGIMEN

METHOTREXATE
(See also CISPLATIN + FLUOROURACIL AND CARBOPLATIN + FLUOROURACIL)

Note: These 3 regimens were compared in a randomized trial. The Efficacy and Toxicity tables provide the comparative data

Forastiere AA et al. J Clin Oncol 1992;10:1245–1251

Methotrexate 40 mg/m²; administer by intravenous injection over 15–30 seconds, or as a short infusion in 10–100 mL 0.9% sodium chloride injection or 5% dextrose injection over 5–15 minutes every week, continually (total dosage/week = 40 mg/m²)

Note: Increase methotrexate dosage to 50 mg/m² weekly if patients experience only grade 0 (zero) mucositis or myelosuppression after 40 mg/m² per week

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care (mucositis prophylaxis and management)

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population Studied

A randomized comparison of 3 treatments: (a) single-agent methotrexate; (b) cisplatin plus fluorouracil; and (c) carboplatin plus fluorouracil. The study enrolled 277 patients with recurrent and metastatic squamous cell carcinoma of the head and neck. The primary objective was to compare separately the response rates of each regimen. Eligible patients had histologically proven squamous cell carcinoma of the head and neck that was either recurrent after attempted cure with surgery and radiation therapy or newly diagnosed disease with distant metastases. Patients with recurrent disease had not previously received chemotherapy for treatment of the recurrence, although they could have received induction chemotherapy ≥6 months before study entry. All patients were required to have measurable disease; a life expectancy of at least 12 weeks; a performance status of 0, 1, or 2 on the SWOG criteria; and a 24-hour creatinine clearance >50 mL/min (>0.83 mL/s)

Treatment Modifications

Adverse Event	Dose Modification
G ≥ 2 Hematologic or nonhematologic toxicity	Reduce methotrexate dosage by 10 mg/m²

Therapy Monitoring

Weekly: CBC with differential. Serum creatinine and LFTs as needed

Notes

Median duration of therapy is 8 weeks

Efficacy*

	Methotrexate (N = 87)	Cisplatin + Fluorouracil (N = 85)	Carboplatin + Fluorouracil (N = 86)

METASTATIC DISEASE REGIMEN

CISPLATIN + FLUOROURACIL

(See also Methotrexate and Carboplatin + Fluorouracil)

Note: These 3 regimens were compared in a randomized trial. The Efficacy and Toxicity tables provide the comparative data

Forastiere AA et al. J Clin Oncol 1992;10:1245–1251

Hydration before, during, and after cisplatin administration ± mannitol:

- *Pre-cisplatin hydration* with 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously with potassium and magnesium supplementation as needed based on pretreatment laboratory results
- *Mannitol diuresis:* May be given to patients who have received adequate hydration. A dose of **mannitol** 12.5–25 g may be administered by intravenous injection or a short infusion before or during cisplatin administration, or prepared as an admixture with cisplatin. Continued intravenous hydration is essential
- *Continued mannitol diuresis:* In an inpatient or day-hospital setting, one may administer additional mannitol in the form of an intravenous infusion: **mannitol** 10–40 g; administer intravenously over 1–4 hours. This can be done either during or immediately after cisplatin, but requires maintenance of adequate intravenously administered fluids during and for hours after mannitol administration
- Post-cisplatin hydration with ≥1000 mL 0.9% NS; administer intravenously with potassium and magnesium supplementation as needed based on measured values

Cisplatin 100 mg/m^2; administer intravenously in 25–250 mL of 0.9% NS over 15–30 minutes, given on day 1 every 21 days (total dosage/cycle = 100 mg/m^2)
Fluorouracil 1000 mg/m^2 per day; administer by continuous intravenous infusion in 100–1000 mL 0.9% NS or 5% dextrose injection over 24 hours for 4 consecutive days (96-hour infusion), given on days 1–4 every 21 days (total dosage/cycle = 4000 mg/m^2)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on days with cisplatin is **HIGH**. Potential for delayed symptoms*
*Emetogenic potential on days with fluorouracil alone is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
G ≥2 Mucosal or skin toxicity	Reduce fluorouracil dosage by 20%
G ≥2 Diarrhea (4–6 stools/day > baseline)	Hold fluorouracil until diarrhea resolves to baseline
G3 myelosuppression	Reduce cisplatin dosage by 25%. Do not change fluorouracil dosage
G4 myelosuppression	Reduce cisplatin dosage by 40%. Do not change fluorouracil dosage
Creatinine clearance <50 mL/min (<0.83 mL/s)	Do not administer therapy
Serum creatinine >1.5 mg/dL (>133 µmol/L) or 20% higher than baseline if >1.5 mg/dL (>133 µmol/L)	Hold cisplatin dose until serum creatinine <1.5 mg/dL (<133 µmol/L) or within 0.2 mg/dL (17.7 µmol/L) of baseline
Serum creatinine 1.5–2.0 mg/dL (133–177 µmol/L) immediately before a cycle	Hold cisplatin*, then reduce cisplatin dosage by 25% during subsequent cycles
Serum creatinine 2.1–3.0 mg/dL (186–265 µmol/L) immediately before a cycle	Hold cisplatin*, then reduce cisplatin dosage by 50% during subsequent cycles
Serum creatinine >3.0 mg/dL (>265 µmol/L) immediately before a cycle	Hold cisplatin
G2 neurotoxicity or ototoxicity	Hold cisplatin until neurotoxicity resolves to G ≤1
G3/4 neurotoxicity or ototoxicity	Discontinue chemotherapy

*Hold cisplatin until serum creatinine <1.5 mg/dL (<133 µmol/L), or within 0.2 mg/dL (17.7 µmol/L) of baseline

(*continued*)

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care (mucositis prophylaxis and management)

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Efficacy*

	Methotrexate (N = 87)	Cisplatin + Fluorouracil (N = 85)	Carboplatin + Fluorouracil (N = 86)
Complete response	2	6	2
Partial response	8	26	19
Stable disease/no response	50	37	42
Increasing disease	32	16	25
Assumed no response†	8	15	12

*WHO Criteria
†Early death or not assessable

Patient Population Studied

A randomized comparison of 3 treatments: (a) single-agent methotrexate; (b) cisplatin plus fluorouracil; and (c) carboplatin plus fluorouracil. The study enrolled 277 patients with recurrent and metastatic squamous cell carcinoma of the head and neck. The primary objective was to compare separately the response rates of each regimen. Eligible patients had histologically proven squamous cell carcinoma of the head and neck that was either recurrent after attempted cure with surgery and radiation therapy or newly diagnosed disease with distant metastases. Patients with recurrent disease had not previously received chemotherapy for treatment of the recurrence, although they could have received induction chemotherapy ≥6 months before study entry. All patients were required to have measurable disease; a life expectancy of at least 12 weeks; a performance status of 0, 1, or 2 on the SWOG criteria; and a 24-hour creatinine clearance >50 mL/min (>0.83 mL/s)

Therapy Monitoring

1. *Before each cycle:* PE, CBC, LFTs, serum electrolytes, calcium, and magnesium
2. *One week after treatment:* Serum electrolytes, calcium, and magnesium
3. *Weekly follow-up recommended during at least the first cycle:* Attention to signs and symptoms of dehydration as supplemental hydration is often required

Toxicity*

METASTATIC DISEASE REGIMEN

CARBOPLATIN + FLUOROURACIL

(See also Methotrexate and Cisplatin + Fluorouracil)

Note: These 3 regimens were compared in a randomized trial. The Efficacy and Toxicity tables provide the comparative data

Forastiere AA et al. J Clin Oncol 1992;10:1245–1251

Carboplatin 300 mg/m²; administer intravenously in 50–500 mL 5% dextrose injection (D5W) or 0.9% sodium chloride injection (0.9% NS) over at least 15 minutes, given on day 1, every 28 days (total dosage/cycle = 300 mg/m²)
Fluorouracil 1000 mg/m² per day; administer by continuous intravenous infusion in 100–1000 mL 0.9% NS or D5W over 24 hours for 4 consecutive days (96-hour infusion), given on days 1–4, every 28 days (total dosage/cycle = 4000 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days with carbop atin is HIGH. Potentia! for delayed symptoms
Emetogenic potential on days with fluorouracil alone is LOW
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:
Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg
Antibiotic therapy during latent or delayed onset diarrhea:
A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm³ with or without accompanying fever in association with diarrhea
- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

METASTATIC DISEASE REGIMEN

CISPLATIN

Jacobs C et al. J Clin Oncol 1992;10:257–263

Hydration before, during, and after cisplatin administration ± mannitol:

- *Pre-cisplatin hydration* with 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously with potassium and magnesium supplementation as needed based on pretreatment laboratory results
- *Mannitol diuresis:* May be given to patients who have received adequate hydration. A dose of **mannitol** 12.5–25 g may be administered by intravenous injection or a short infusion before or during cisplatin administration, or prepared as an admixture with cisplatin. Continued intravenous hydration is essential
- *Continued mannitol diuresis:* In an inpatient or day-hospital setting, one may administer additional mannitol in the form of an intravenous infusion: **mannitol** 10–40 g; administer intravenously over 1–4 hours. This can be done either during or immediately after cisplatin, but requires maintenance of adequate intravenously administered fluids during and for hours after mannitol administration
- *Post-cisplatin hydration* with ≥1000 mL 0.9% NS; administer intravenously with potassium and magnesium supplementation as needed based on measured values

Cisplatin 100 mg/m²; administer intravenously in 25–250 mL of 0.9% NS over 15–20 minutes every 21 days (total dosage/cycle = 100 mg/m²)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **HIGH**. Potential for delayed symptoms*

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 84 patients with unresectable recurrent disease or newly diagnosed distant metastatic disease who had received no prior chemotherapy, who were randomized to the cisplatin alone arm of a 3-arm phase III randomized trial. WHO performance status <4 and good organ function were required. Thirty-six percent had performance status of 2 or 3

Efficacy (N = 83)

Complete response	3.6%
Partial response	13.3%
Median duration of response	2 months
Median survival	5.7 months

Toxicity (N = 83)

	% G1/2	% G3/4
Hematologic		
Neutropenia	35	1
Thrombocytopenia	11	1
Anemia (Hgb <8 g/dL)	NR	11
Nonhematologic		
Vomiting	54	18
Diarrhea	17	0
Mucositis	3	2
Ototoxicity	3	1
Magnesium <1.5 mg/dL		= 22%
Creatinine >2 mg/dL (>177 μmol/L)		= 14%
G >1 cardiovascular toxicity		= 5%
Alopecia		= 4%

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Before each cycle:* serum electrolytes, creatinine, calcium, magnesium, and liver function tests

Treatment Modifications

Adverse Event	Dose Modification
Creatinine clearance <50 mL/min (<0.83 mL/s)	Ineligible for therapy
Day 1 ANC <1500/mm³ *or* platelets <100,000/mm³	Delay cisplatin until ANC >1500/mm³ *and* platelets >100,000/mm³ for up to 3 weeks. Discontinue cisplatin if recovery has not occurred after a 3-week delay
ANC nadir <500/mm³	Reduce dosage to 75 mg/m²
Platelet nadir <25,000/mm³	
G1 neurotoxicity or ototoxicity	
Serum creatinine 1.5–2.0 mg/dL (133–177 μmol/L)	Hold cisplatin*, then reduce dosage to 75 mg/m²
ANC nadir <500/mm³ with a cisplatin dosage of 75 mg/m²	Reduce dosage to 50 mg/m²
Platelet nadir <25,000/mm³ with a cisplatin dosage of 75 mg/m²	
G2 neurotoxicity or ototoxicity	
Serum creatinine 2.1–3.0 mg/dL (186–265 μmol/L)	Hold cisplatin*, then reduce cisplatin dosage to 50 mg/m²
ANC nadir <500/mm³ with a cisplatin dosage of 50 mg/m²	Discontinue cisplatin
Platelet nadir <25,000/mm³ with a cisplatin dosage of 50 mg/m²	
Serum creatinine >3.0 mg/dL (>265 μmol/L)	
G3/4 neurotoxicity or ototoxicity	

*Hold cisplatin until serum creatinine <1.5 mg/dL (<133 μmol/L) or within 0.2 mg/dL (17.7 μmol/L) of baseline

METASTATIC DISEASE REGIMEN

DOCETAXEL

Catimel G et al. Ann Oncol 1994;5:533–537

Premedication:
Dexamethasone 8 mg; administer orally twice daily for 3 days (6 doses), starting the day before docetaxel administration (total dose/cycle = 48 mg)
optional **Diphenhydramine** 25–50 mg; administer by intravenous injection 30–60 minutes before docetaxel
Docetaxel 100 mg/m^2; administer intravenously after dilution in a volume of 0.9% sodium chloride injection or 5% dextrose injection sufficient to produce a final docetaxel concentration within the range 0.3–0.74 mg/mL over 60 minutes every 21 days (total dosage/cycle = 100 mg/m^2)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care (mucositis prophylaxis and management)
Risk of mucositis/stomatitis is MODERATE
General advice:
- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:
- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:
- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque

(*continued*)

Patient Population Studied

A trial of 40 patients with unresectable recurrent disease following attempted cure with surgery and/or radiation therapy (may have received neoadjuvant chemotherapy) or newly diagnosed with distant metastases treated in a phase II trial. Performance status WHO ≤2, age <75 years, and adequate organ function were required

Efficacy (N = 37)

Complete response	5.4%
Partial response	27%
Stable disease	35%
Median duration of response	6.5 months

Toxicity (N = 39 Patients/166 Cycles)

	G1/2 (% Cycles)	G3/4 (% Cycles)
Hematologic		
Leukopenia	23 (43)	74 (48)
Neutropenia	5 (20)	87 (61)
Anemia	74 (61)	5 (1)
Thrombocytopenia	13 (5)	0 (0)
Nonhematologic		
Skin toxicity	46	7.5
Asthenia	46	23
Peripheral neuropathy	41	—
Nausea	33	2.5
Edema	30.7	—
Vomiting	28.5	2.5
Stomatitis	25.6	13
Diarrhea	25.6	2.5
Phlebitis	23	—
Hypersensitivity	20.5	2.5
Myalgia	13	—

(continued)

- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Treatment Modifications

Adverse Event	Dose Modification
G ≥2 cutaneous toxicity without recovery to G ≤1 at time of retreatment	Reduce docetaxel dosage 25%
G ≥2 peripheral neuropathy without recovery to G ≤1 at time of retreatment	
G4 granulocytopenia lasting more than 7 days or associated with fever >38.5°C (>101.3°F)	
G3/4 nonhematologic toxicity	

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *During dexamethasone:* monitor glucose if indicated

METASTATIC DISEASE REGIMEN

GEFITINIB *OR* ERLOTINIB (ORAL EPIDERMAL GROWTH FACTOR INHIBITORS)

Cohen EEW et al. J Clin Oncol 2003;21:1980–1987
Soulieres D et al. J Clin Oncol 2004;22:77–85

Gefitinib 500 mg; administer orally once daily, continually (total dose/week = 3500 mg)

or

Erlotinib 150 mg; administer orally once daily, continually (total dose/week = 1050 mg)
Note: Patients unable to swallow tablets or those with silicone-based feeding tubes may dissolve gefitinib or erlotinib tablets in water

Supportive Care

Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—consider use during neutropenia and for anticipated mucositis
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Gefitinib: 52 patients with recurrent or metastatic disease considered ineligible for curative surgery or radiation therapy who had received ≤1 prior systemic therapy. Performance status ECOG ≤2 and adequate organ function were required
Erlotinib: 115 patients with locally recurrent and/or metastatic head and neck squamous cell carcinoma regardless of their HER1/EGFR status. ECOG performance status 0–2

Efficacy (N = 47/115)

	Gefitinib (N = 47)	Erlotinib (N = 115)
Complete response	2.1%	0
Partial response	8.5%	4.3%
Stable disease	42.6%	38.3%
Median duration of response	1.6 months	
Median time to progression	3.4 months	9.6 weeks
Median survival	8.1 months	6 months
1-Year survival	29.2%	20%

Treatment Modifications

Adverse Event	Dose Modification
Gefitinib	
G2 Skin rash, nausea, or diarrhea	Hold gefitinib until toxicity G ≤1
Repeat G2 skin rash, nausea, or diarrhea	Reduce gefitinib dose to 250 mg/day
Other nonhematologic G2 toxicities	Hold gefitinib until toxicity G ≤1, then reduce dose to 250 mg/day
Any G3/4 toxicity	Hold gefitinib until toxicity resolves to G ≤1, then resume with dose reduced to 250 mg daily
Toxicity not resolved to G ≤1 after interrupting treatment for 2 weeks, or a second dose reduction indicated	Discontinue treatment
Erlotinib	
G2 skin rash	Hold erlotinib until toxicity G ≤1
Repeat G2 skin rash	Reduce erlotinib dose to 100 mg/day
Other nonhematologic G2/3 toxicities	Hold erlotinib until toxicity G ≤1, then reduce erlotinib dose to 100 mg/day
G4 toxicity	Discontinue erlotinib
Treatment for 4 weeks at the same daily dose without adverse effects attributed to erlotinib	Escalate the daily dose in 50-mg/day increments to a maximum daily dose of 250 mg (stepwise increases from 150 mg/day to 200 mg/day to 250 mg/day)

Toxicity (N = 50/115)

	Gefitinib (N = 50)		Erlotinib (N = 115)	
	% G1/2	% G3/4	% G1/2	% G3/4

Dyspnea	6	0	N/A	
Keratitis	4	0	N/A	
↑AST	12	0		
↑ALT	4	0	24	2
↑Alkaline phosphatase	4	0		
↑Creatinine	2	0	10	
Hypercalcemia	14	6		

Therapy Monitoring

1. *Every 8 weeks:* Tumor response evaluation
2. *Shortness of breath:* Stop gefitinib and evaluate for pneumonitis

Notes

Protocol for managing rash:

- Mild soap and lukewarm water to wash affected area
- Moisturize area with mild lotion
- Limit direct sun exposure. Use a sunscreen appropriate for sensitive skin (SPF15 or higher)
- Avoid over-the-counter acne treatments
- Avoid applying cosmetic products

METASTATIC DISEASE REGIMEN

DOCETAXEL + CISPLATIN

Glisson BS et al. J Clin Oncol 2002;20:1593–1599

Premedication:
Dexamethasone 8 mg; administer orally or intravenously twice daily for 3 days starting the day before docetaxel infusion (total dose/cycle = 48 mg)

Hydration before, during, and after cisplatin administration ± mannitol:
- *Pre-cisplatin hydration* with 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously with potassium and magnesium supplementation as needed based on pretreatment laboratory results
- *Mannitol diuresis:* May be given to patients who have received adequate hydration. A dose of **mannitol** 12.5–25 g may be administered by intravenous injection or a short infusion before or during cisplatin administration, or prepared as an admixture with cisplatin. Continued intravenous hydration is essential
- *Continued mannitol diuresis:* In an inpatient or day-hospital setting, one may administer additional mannitol in the form of an intravenous infusion: **mannitol** 10–40 g; administer intravenously over 1–4 hours. This can be done either during or immediately after cisplatin, but requires maintenance of adequate intravenously administered fluids during and for hours after mannitol administration
- *Post-cisplatin hydration* with ≥1000 mL 0.9% NS; administer intravenously with potassium and magnesium supplementation as needed based on measured values

Docetaxel 75 mg/m²; administer intravenously diluted in a volume of 0.9% NS or 5% dextrose injection sufficient to produce a docetaxel concentration within the range 0.3–0.74 mg/mL over 60 minutes, on day 1, every 21 days (total dosage/cycle = 75 mg/m²), *followed by*
Cisplatin 75 mg/m²; administer intravenously in 25–250 mL 0.9% NS over 30 minutes on day 1, every 21 days (total dosage/cycle = 75 mg/m²)

Supportive Care

Antiemetic prophylaxis
*Emetogenic potential is **HIGH**. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care (mucositis prophylaxis and management)
Risk of mucositis/stomatitis is LOW–MODERATE
General advice:
- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:
- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
ANC <1500/mm³ *or* platelets <100,000/mm³ at the time of chemotherapy administration	Delay chemotherapy until ANC > 1500/mm³ *and* platelets >100,000/mm³. Discontinue if recovery has not occurred after a 3-week delay
Creatinine clearance <50 mL/min (<0.83 mL/s)	Do not administer therapy
Serum creatinine >1.5 mg/dL (>133 µmol/L) *or* 20% higher than baseline value if baseline was >1.5 mg/dL (>133 µmol/L)	Hold cisplatin until serum creatinine <1.5 mg/dL (<133 µmol/L) *or* within 0.2 mg/dL (17.7 µmol/L) of baseline
Serum creatinine 1.5–2.0 mg/dL (133–177 µmol/L) immediately before a cycle	Hold cisplatin*, then reduce cisplatin dosage by 25% during subsequent cycles
Serum creatinine 2.1–3.0 mg/dL (186–265 µmol/L) immediately before a cycle	Hold cisplatin*, then reduce cisplatin dosage by 50% during subsequent cycles
Serum creatinine >3.0 mg/dL (>265 µmol/L) immediately before a cycle	Hold cisplatin
G2 neurotoxicity or ototoxicity	Hold cisplatin until neurotoxicity resolves to G ≤1
G3/4 neurotoxicity or ototoxicity	Discontinue chemotherapy

*Hold cisplatin until serum creatinine <1.5 mg/dL (<133 µmol/L) or within 0.2 mg/dL (17.7 µmol/L) of baseline

(*continued*)

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population Studied

A study of 36 patients with recurrent disease or disease deemed incurable, who had not previously received chemotherapy for recurrent disease and had never received a taxane, were entered in a multicenter phase II trial. Performance status ECOG 0–1 and adequate organ function were required, including creatinine clearance ≥50 mL/min (≥0.83 mL/s)

Efficacy (N = 36)

Complete response	6%
Partial response	34%
Stable disease	34%
Median duration of response	4.9 months
Median time to response	5 weeks
Median time to treatment failure	3 months
Median survival	9.6 months
1-Year survival	28%
2-Year survival	19%

Toxicity (N = 35/36)

	% G1/2	% G3/4

NR, Not reported
National Cancer Institute Common Toxicity Criteria

Therapy Monitoring

1. *Weekly:* CBC with differential
2. *Before each cycle:* Serum electrolytes, creatinine, calcium, magnesium, LFTs, and urinalysis
3. *During dexamethasone:* monitor glucose if indicated

METASTATIC DISEASE REGIMEN

PACLITAXEL + CARBOPLATIN

Pivot X et al. Oncology 2001;60:66–71

Premedication:
Prednisone 60 mg; administer orally twice daily for a total of 4 doses, starting the day before chemotherapy (total dose/cycle = 240 mg), *or*
Dexamethasone 20 mg/dose; administer orally for 2 doses at 12–14 hours and 6–7 hours before starting paclitaxel administration (total dose/cycle = 40 mg), *or*
Dexamethasone 20 mg; administer intravenously 30 minutes before starting paclitaxel administration (total dose/cycle = 20 mg)
Cimetidine 300 mg (*or* **Ranitidine** 50 mg *or* **Famotidine** 20 mg or an equivalent histamine receptor [H2]-subtype antagonist); administer intravenously over 15–30 minutes, 30–60 minutes before paclitaxel
Diphenhydramine 50 mg; administer by intravenous injection, 30–60 minutes before paclitaxel
Paclitaxel 175 mg/m^2; administer by intravenous infusion in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 3 hours on day 1, every 21 days (total dosage/cycle = 175 mg/m^2), *followed by:*
Carboplatin (calculated dose) AUC = 6 mg/mL • min; administer by intravenous infusion in 500 mL of 0.9% NS over 2 hours on day 1, every 21 days (total dosage/cycle calculated to produce an AUC of 6 mg/mL • min)

An equation for calculating carboplatin doses developed by Chatelut et al accounts for inter-individual carboplatin clearance (CL) based on patient-specific factors for weight, age, and sex (Chatelut E et al. J Natl Cancer Inst 1995;87:573–580):

$$\text{CL(females)} = (0.134 \times \text{wt}) + \frac{\left[(218 \times \text{wt}) \times (1 - 0.00457 \times \text{age}) \times 0.686\right]}{\text{serum creatinine}}$$

$$\text{CL(males)} = (0.134 \times \text{wt}) + \frac{\left[(218 \times \text{wt}) \times (1 - 0.00457 \times \text{age})\right]}{\text{serum creatinine}}$$

Weight is expressed in kilogram units, age in years, serum creatinine in micromoles/L (micromoles/L = mg/dL × 88.4), and the value for sex is 0 (zero) for males and 1 (one) for females

A carboplatin dose (in milligrams) is calculated from a target area under the plasma concentration versus time curve (AUC) and a value for carboplatin clearance (CL) appropriate for a female or male patient:

$$\text{Carboplatin dose (mg)} = \text{CL (mL/min)} \times \text{AUC (mg • min/mL)}$$

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **HIGH**. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL, by subcutaneous injection for one dose
- Begin use from 24–72 h after myelosuppressive chemotherapy is completed
- Continue daily Filgrastim use until ANC ≥10,000/mm^3 on two measurements separated temporally by ≥12 hours
- Discontinue daily Filgrastim use at least 24 hours before administering myelosuppressive treatment. Do not administer Pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis
- Antifungal—consider concomitant use of cotrimoxazole during periods of neutropenia, and in anticipation of mucositis
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care
Risk of mucositis/stomatitis is MODERATE
General advice:
- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications

(*continued*)

(*continued*)

- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population Studied

A study of 27 patients with unresectable recurrent disease or distant metastatic disease. Previous radiation treatment and concomitant or induction chemoradiation were allowed. ECOG performance status 0–2 and adequate organ function were required, including creatinine clearance ≥45 mL/min (≥0.75 mL/s)

Efficacy (N = 27)

Complete response	7.4%
Partial response	22.2%
Stable disease	11.1%
Median duration of response	4.4 months
Median survival	7.2 months

National Cancer Institute Common Toxicity Criteria

Therapy Monitoring

1. *Before each cycle:* CBC with differential, serum electrolytes, calcium, magnesium, and LFTs
2. *Weekly:* CBC with differential

Treatment Modifications

Adverse Event	Dose Modification
G3/4 mucositis	Reduce paclitaxel dosage by 20%
G3 thrombocytopenia	Reduce paclitaxel dosage by 20%
G4 thrombocytopenia	Reduce paclitaxel dosage by 50%
G4 neutropenia >5 days	Reduce paclitaxel dosage by 20%
ANC <1500/mm³ *or* platelets <100,000/mm³ at the time of chemotherapy administration	Delay chemotherapy until ANC >1500/mm³ *and* platelets >100,000/mm³. Discontinue chemotherapy if recovery has not occurred after a 2-week delay
Creatinine clearance (Clcr) <45 mL/min (<0.75 mL/s)	Delay treatment until Clcr >45 mL/min (>0.75 mL/s). Discontinue therapy if has not recovered by 6 weeks
G2 neurotoxicity	Hold paclitaxel until neurotoxicity resolves to G ≤1
G 3/4 neurotoxicity	Discontinue chemotherapy

RECURRENT/METASTATIC DISEASE

PLATINUM-REFRACTORY TUMORS SINGLE-AGENT CETUXIMAB

Vermorken JB et al. J Clin Oncol 2007;25:2171–2177

Cetuximab premedication:
Diphenhydramine 50 mg; administer by intravenous injection or infusion before cetuximab administration (other H_1-receptor antagonists may be substituted)

Initial cetuximab dose:
Cetuximab 400 mg/m²; administer intravenously over 120 minutes (maximum infusion rate = 5 mL [10 mg] per min) as a single loading dose (total initial dosage = 400 mg/m²)

Maintenance cetuximab doses:
Cetuximab 250 mg/m² per dose; administer intravenously over 60 minutes (maximum infusion rate = 5 mL [10 mg] per min) every week, continually (total weekly dosage = 250 mg/m²)

Notes:
Cetuximab is intended for direct administration and should not be diluted
Maximum infusion rate = 5 mL (10 mg)/min
Administer cetuximab through a low protein-binding inline filter with pore size = 0.22 μm
Use 0.9% sodium chloride injection to flush vascular access devices after administration is completed

Note: Continue cetuximab single-agent therapy for at least 6 weeks. If tumors appear to respond to treatment and disease stability (SD) is attained, treatment may be continued until progressive disease (PD), clinical deterioration, or unacceptable adverse events are observed

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A study of 103 patients with measurable metastatic and/or recurrent histologically proven squamous cell carcinoma of the head and neck with documented disease progression within 30 days after a minimum of 2 cycles and a maximum of 6 cycles of chemotherapy: cisplatin-based (≥60 mg/m² per cycle) or carboplatin-based (≥300 mg/m², or dose based on target AUC ≥4 mg/mL • min per cycle). Adequate organ function, a Karnofsky performance status ≥60, and age ≥18 years were required

Therapy Monitoring

1. *Pretreatment evaluation:* Medical history and tumor assessment by clinical evaluation and imaging studies
2. *Response evaluation:* Every 6 weeks

Dose Modifications

Adverse Event	Treatment Modifications
Progressive disease, clinical deterioration, or unacceptable toxicity	Discontinue treatment
First occurrence G3 skin toxicity	Hold cetuximab up to 2 weeks
Second occurrence G3 skin toxicity	Reduce cetuximab dosage to 200 mg/m²
Third occurrence G3 skin toxicity	Reduce cetuximab dosage to 150 mg/m²
Fourth occurrence G3 skin toxicity	Discontinue cetuximab

Efficacy (N = 103)

Overall response rate	0
Complete response rate	13%
Stable disease	33%
Progressive disease	37%
Disease not assessable	18%
Median time to progression	70 days
Median overall survival	178 days

Toxicity (N = 103)*

Adverse Event	% All Grades	% G3/4
Rash	49	1
Acne	26	0
Asthenia	24	4
Nail disorder	16	0
Dry skin	14	0
Fever	14	1

Infusion-related reactions	6	1
Treatment-related death	1 Patient	

*Common Toxicity Criteria, version 2.0, (U.S.) National Cancer Institute

RECURRENT/METASTATIC DISEASE: PLATINUM-REFRACTORY TUMORS

CISPLATIN- *OR* CARBOPLATIN-BASED CHEMOTHERAPY + CETUXIMAB

Baselga J et al. J Clin Oncol 2005;23:5568–5577

Cetuximab premedication:
Diphenhydramine 50 mg; administer by intravenous injection or infusion before cetuximab administration (other H_1-receptor antagonists may be substituted)

Initial cetuximab dose:
Cetuximab 400 mg/m²; administer intravenously over 120 minutes (maximum infusion rate = 5 mL [10 mg] per min) as a single loading dose (total initial dosage = 400 mg/m²)

Maintenance cetuximab doses:
Cetuximab 250 mg/m² per dose; administer intravenously over 60 minutes (maximum infusion rate = 5 mL [10 mg] per min) every week, continually (total weekly dosage = 250 mg/m²)

Notes:
Cetuximab is intended for direct administration and should not be diluted
Maximum infusion rate = 5 mL (10 mg) per minute
Administer cetuximab through a low protein-binding inline filter with pore size = 0.22 μm
Use 0.9% sodium chloride injection to flush vascular access devices after administration is completed
One hour after completing cetuximab administration, either cisplatin *or* carboplatin is given

Note: In the study reported by Baselga et al, carboplatin or cisplatin were administered at the same doses, routes of administration, and every 3- or 4-week schedules utilized in the regimens subjects had received during which they developed disease progression

Suggested Cisplatin and Carboplatin Regimens

(Vermorken JB et al. N Engl J Med 2008;359:1116–1127)

Cisplatin + Fluorouracil Regimen

Hydration before, during, and after cisplatin administration ± mannitol:
- *Pre-cisplatin hydration* with 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously with potassium and magnesium supplementation as needed based on pretreatment laboratory results
- *Mannitol diuresis:* May be given to patients who have received adequate hydration. A dose of **mannitol** 12.5–25 g may be administered by intravenous injection or a short infusion before or during cisplatin administration, or prepared as an admixture with cisplatin. Continued intravenous hydration is essential
- *Continued mannitol diuresis:* In an inpatient or day-hospital setting, one may administer additional mannitol in the form of an intravenous infusion: **mannitol** 10–40 g; administer intravenously over 1–4 hours. This can be done either during or immediately after cisplatin, but requires maintenance of adequate intravenously administered fluids during and for hours after mannitol administration
- *Post-cisplatin hydration* with ≥1000 mL 0.9% NS; administer intravenously with potassium and magnesium supplementation as needed based on measured values

Cisplatin 100 mg/m²; administer intravenously in 50–1000 mL 0.9% NS over 60 minutes on day 1 at least one hour after completing cetuximab doses, every 3 weeks (total dosage/cycle = 100 mg/m²), *followed by:*

Fluorouracil 1000 mg/m² per day; administer in 50–1000 mL 0.9% NS or D5W by continuous intravenous infusion over 24 hours for 4 consecutive days on days 1–4, every 3 weeks (total dosage/cycle = 4000 mg/m²)

Carboplatin + Fluorouracil Regimen

Carboplatin* (calculated dose) AUC = 5 mg/mL • min per dose; administer by intravenous infusion diluted to concentrations as low as 0.5 mg/mL with either D5W or 0.9% NS over 1 hour, on day 1 at least one hour after completing cetuximab doses, every 3 weeks (total dose/cycle calculated to produce a target AUC = 5 mg/mL • min), *followed by:*

Fluorouracil 1000 mg/m² per day; administer in 50–1000 mL 0.9% NS or D5W by continuous intravenous infusion over 24 hours for 4 consecutive days, on days 1–4, every 21 days for 4 cycles (total dosage/cycle = 4000 mg/m²)

*Carboplatin dose is based on a formula described by Calvert et al. to achieve a target area under the plasma concentration versus time curve (AUC)

$$\text{Total Carboplatin Dose (mg)} = (\text{target AUC}) \times (\text{GFR} + 25)$$

(*continued*)

(*continued*)

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be estimated from the equation of Cockcroft and Gault, thus:

$$\text{For males, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})} \times 0.85$$

Calvert AH et al. J Clin Oncol 1989;7:1748–1756
Cockcroft DW, Gault MH. Nephron 1976;16:31–41
Jodrell DI et al. J Clin Oncol 1992;10:520–528
Sorensen BT et al. Cancer ChemotherPharmacol 1991;28:397–401

Note: On October 8, 2010, the U.S. FDA identified a potential safety issue with carboplatin dosing based on recent changes in the measurement of serum creatinine. By the end of 2010, all clinical laboratories in the United States were required to use the standardized Isotope Dilution Mass Spectrometry (IDMS) method to measure serum creatinine, which can result in an overestimation of the GFR in some patients with normal renal function. A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula can exceed an expected exposure (AUC) and result in increased drug-related toxicity

Provided actual GFR measurements are made to assess renal function, carboplatin can be safely dosed according to the Calvert formula described in product labeling

If GFR (or creatinine clearance) is estimated based on serum creatinine measurements by the IDMS method, the FDA recommends, for patients with normal renal function, capping an estimated GFR at 125 mL/min for any targeted AUC value. No greater estimated GFR values should be used

U.S. FDA. Carboplatin dosing. [online] October 8, 2010. Available from: http://www.fda.gov/AboutFDA/CentersOffices/OfficeofMedicalProductsandTobacco/CDER/ucm228974.htm [accessed February 26, 2014]

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days with cetuximab alone is ***MINIMAL***
Emetogenic potential on days with cisplatin or carboplatin is ***HIGH****. Potential for delayed symptoms*
Emetogenic potential on days with fluorouracil alone is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care

Risk of mucositis/stomatitis is MODERATE

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

(*continued*)

(*continued*)

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population Studied

A study of 98 patients with measurable, stage III or IV squamous cell carcinoma of the head and neck, who were not candidates for local therapy, with disease progression after a minimum of 2 and a maximum of 4 cycles of cisplatin- or carboplatin-based chemotherapy. Adequate organ function, a Karnofsky performance status of ≥60, and age ≥18 years were required

Efficacy (N = 96)

Overall response rate	10%
Complete response rate	0
Partial response rate	10%
Stable disease	43%
Progressive disease	28%
Not assessable	19%
Median overall survival, days	183
Median time to progression, days	85

Toxicity (N = 96)*

Adverse Event	% All Grades	% G3/4
Skin reactions	80	3
Acne-like rash	72	3
Asthenia	65	19
Mucositis	18	2
Diarrhea	16	0
Fever	40	3
Nausea/vomiting	57	6
Respiratory disorder	32	13
Hypersensitivity reactions	3	0
Heart failure	2	0
Thromboembolism	2	2
Bleeding	24	8

*Common Toxicity Criteria, version 2.0, (U.S.) National Cancer Institute

Therapy Monitoring

1. *Pretreatment evaluation:* Medical history and tumor assessment by clinical evaluation and imaging studies
2. *Response evaluation:* Every 6 weeks

Treatment Modifications

Adverse Event	Dose Modification
First occurrence G3 skin toxicity	Hold cetuximab up to 2 weeks
Second occurrence G3 skin toxicity	Reduce cetuximab dosage to 200 mg/m²
Third occurrence G3 skin toxicity	Reduce cetuximab dosage to 150 mg/m²
Fourth occurrence G3 skin toxicity	Discontinue cetuximab
G ≥2 mucosal or skin toxicity	Reduce fluorouracil dosage by 20%
G ≥2 diarrhea (4–6 stools/day greater than baseline)	Hold fluorouracil until diarrhea resolves to baseline
G3 myelosuppression	Reduce cisplatin dosage by 25% or carboplatin dosage by 20%. Do not change fluorouracil dosage
G4 myelosuppression	Reduce cisplatin dosage by 40% or carboplatin dosage by 20%. Do not change fluorouracil dosage
Creatinine clearance <50 mL/min (<0.83 mL/s)	Do not administer therapy
Serum creatinine >1.5 mg/dL (>133 μmol/L), or 20% greater than baseline if baseline was >1.5 mg/dL	Hold cisplatin dosage until serum creatinine <1.5 mg/dL (<133 μmol/L) or within 0.2 mg/dL (17.7 μmol/L) of baseline
Serum creatinine 1.5–2.0 mg/dL (133–177 μmol/L) immediately before a cycle	Hold cisplatin*, then reduce cisplatin dosage by 25% during subsequent cycles
Serum creatinine 2.1–3.0 mg/dL (186–265 μmol/L) immediately before a cycle	Hold cisplatin*, then reduce cisplatin dosage by 50% during subsequent cycles
Serum creatinine >3.0 mg/dL (>265 μmol/L) immediately before a cycle	Hold cisplatin
G2 neurotoxicity or ototoxicity	Hold cisplatin until neurotoxicity resolves to G ≤1
G3/4 neurotoxicity or ototoxicity	Discontinue chemotherapy
G ≥3 nausea/vomiting despite use of a serotonin ($5HT_3$) receptor antagonist + dexamethasone + aprepitant, consistent with published guidelines (see Chapter 39)	Reduce cisplatin dosage or carboplatin dose, or discontinue the platinating agent

*Hold cisplatin until serum creatinine <1.5 mg/dL or within 0.2 mg/dL of baseline

RECURRENT/METASTATIC DISEASE: ADVANCED DISEASE

CISPLATIN + PACLITAXEL
CISPLATIN + FLUOROURACIL

Gibson MK et al. J Clin Oncol 2005;23:3562–3567

Cisplatin + Paclitaxel

Premedication for paclitaxel
Dexamethasone 20 mg/dose; administer orally or intravenously for 2 doses at 12–14 hours and 6–7 hours before starting paclitaxel (total dose/cycle = 40 mg), *or*
Dexamethasone 20 mg; administer intravenously 30 minutes before administering paclitaxel (total dose/cycle = 20 mg)

plus

Diphenhydramine 50 mg; administer intravenously 30 minutes before administering paclitaxel
Cimetidine 300 mg (*or* **Ranitidine** 50 mg *or* **Famotidine** 20 mg *or* an equivalent histamine receptor [H_2]-subtype antagonist); administer intravenously in 20–50 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 15–20 minutes, 30 minutes before administering paclitaxel

Hydration before, during, and after cisplatin administration ± mannitol:

- *Pre-cisplatin hydration* with 1000 mL 0.9% NS; administer intravenously with potassium and magnesium supplementation as needed based on pretreatment laboratory results
- *Mannitol diuresis:* May be given to patients who have received adequate hydration. A dose of **mannitol** 12.5–25 g may be administered by intravenous injection or a short infusion before or during cisplatin administration, or prepared as an admixture with cisplatin. Continued intravenous hydration is essential
- *Continued mannitol diuresis:* In an inpatient or day-hospital setting, one may administer additional mannitol in the form of an intravenous infusion: **mannitol** 10–40 g; administer intravenously over 1–4 hours. This can be done either during or immediately after cisplatin, but requires maintenance of adequate intravenously administered fluids during and for hours after mannitol administration
- *Post-cisplatin hydration* with ≥1000 mL 0.9% NS; administer intravenously with potassium and magnesium supplementation as needed based on measured values

Paclitaxel 175 mg/mg; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range 0.3–1.2 mg/mL over 3 hours on day 1, every 21 days (total dosage/cycle = 175 mg/m^2), *followed by:*
Cisplatin 75 mg/m^2; administer intravenously in 50–1000 mL 0.9% NS over 60 minutes on day 1, every 21 days (total dosage/cycle = 75 mg/m^2)

Notes: Treatment is continued for at least 6 cycles in patients who continue to respond
Carboplatin (target AUC = 6 mg/mL • min) may be substituted for cisplatin in patients who develop G ≥2 neuropathy or renal impairment (creatinine clearance <50 mL/min [<0.83 mL/s])

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Cisplatin + Fluorouracil

Hydration before, during, and after cisplatin administration ± mannitol:

- *Pre-cisplatin hydration* with 1000 mL0.9% sodium chloride injection (0.9% NS); administer intravenously with potassium and magnesium supplementation as needed based on pretreatment laboratory results
- *Mannitol diuresis:* May be given to patients who have received adequate hydration. A dose of **mannitol** 12.5–25 g may be administered by intravenous injection or a short infusion before or during cisplatin administration, or prepared as an admixture with cisplatin. Continued intravenous hydration is essential

(*continued*)

(continued)

- *Continued mannitol diuresis:* In an inpatient or day-hospital setting, one may administer additional mannitol in the form of an intravenous infusion: **mannitol** 10–40 g; administer intravenously over 1–4 hours. This can be done either during or immediately after cisplatin, but requires maintenance of adequate intravenously administered fluids during and for hours after mannitol administration
- *Post-cisplatin hydration* with ≥1000 mL 0.9% NS; administer intravenously with potassium and magnesium supplementation as needed based on measured values

Cisplatin 100 mg/m²; administer intravenously in 50–1000 mL 0.9% NS over 60 minutes on day 1, every 21 days (total dosage/cycle = 100 mg/m²)
Fluorouracil 1000 mg/m² per day; administer in 50–1000 mL 0.9% NS or 5% dextrose injection by continuous intravenous infusion over 24 hours for 4 consecutive days, on days 1–4, every 21 days (total dosage/cycle = 4000 mg/m²)

Notes: Treatment is continued for at least 6 cycles in patients who continue to respond. Carboplatin (target AUC = 6 mg/mL • min) may be substituted for cisplatin in patients who develop G ≥2 neuropathy or renal impairment (creatinine clearance <50 mL/min [<0.83 mL/s])

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on days with cisplatin or carboplatin is **HIGH**. Potential for delayed symptoms*
*Emetogenic potential on days with fluorouracil alone is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm³ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Wadler S et al. J Clin Oncol 1998;16:3169–3178

Oral care

Risk of mucositis/stomatitis is HIGH

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

(continued)

(*continued*)

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population Studied

A study of 218 patients with measurable or assessable histologically confirmed squamous cell carcinoma of the head and neck (excluding nasopharyngeal carcinoma) not curable with surgery or radiation. Prior chemotherapy for recurrent disease was not allowed. Prior chemotherapy delivered as part of initial curative therapy was allowed; treatment with paclitaxel or fluorouracil had to be completed more than 12 months before study entry and treatment with cisplatin had to be completed more than 6 months before study entry. Age ≥18 years, adequate organ function, and ECOG performance status ≤1 were required

Efficacy

	Cisplatin + Fluorouracil	Cisplatin + Paclitaxel
Complete response	6.7%	7%
Partial response	23.1%	19%
Stable disease	55.8%	54%
Progressive disease	3.8%	6%
Not assessable	10.6%	14%
Median overall survival, months	8.7	8.1
1-Year survival	41.4%	32.4%

Therapy Monitoring

1. *Pretreatment evaluation:* Medical history and tumor assessment by clinical evaluation and imaging studies
2. *Response evaluation:* Every 2 cycles

Toxicity

Adverse Event	Cisplatin + Fluorouracil % G3/4/5 N = 106	Cisplatin + Paclitaxel % G3/4/5 N = 108
Anemia	33	13
Thrombocytopenia	23	4
Neutropenia	67	55
Leukopenia	63	35
Infection	21*	13*
Genitourinary	3	1
Stomatitis	31	0
Mucositis	1	0
Diarrhea	6	1
Nausea	19	18
Vomiting	18	10

Cardiac	3†	4
Metabolic	15	10
Dehydration	5	4
Liver	1	3
Hypotension	2	5
Neurosensory	4	5
Neuromotor	3	4
Toxic deaths	7	5

*Includes 4% G5 toxicities
†Includes 1% G5 toxicities

Dose Modifications

Adverse Event	Dose Modification
G4 toxicity	Withhold treatment until G ≤1
G2 hepatic toxicity	Withhold treatment until G ≤1
G3 hepatic toxicity	Withhold treatment until G ≤1, then reduce paclitaxel dosage by 20%
Neutrophil count $<1500/mm^3$	Withhold treatment until ANC is $\geq 1500/mm^3$
Platelet count $<100{,}000/mm^3$	Withhold treatment until platelet count is $\geq 100{,}000/mm^3$
Nadir thrombocytopenia G4	Reduce dosages of all agents by 20%
G4 neutropenia ≥5 days	Reduce dosages of all agents by 20%
Febrile neutropenia requiring hospitalization and antibiotics	Reduce dosages of all agents by 20%
G ≥2 mucosal or skin toxicity	Reduce fluorouracil dosage by 20%
G3 mucositis	Reduce paclitaxel and fluorouracil dosages by 20%
G ≥2 diarrhea (4–6 stools/day greater than baseline)	Hold fluorouracil until diarrhea resolves to baseline
Creatinine clearance ≤50 mL/min (≤0.83 mL/s)	Replace cisplatin with carboplatin AUC = 6 mg/mL · min
G2 neuropathy	Replace cisplatin with carboplatin AUC = 6 mg/mL · min; do not alter paclitaxel dosage
G2 neuropathy lasting ≥1 cycle after substituting carboplatin for cisplatin	Reduce paclitaxel dosages by 20%
G3 neuropathy	Discontinue therapy

RECURRENT/METASTATIC DISEASE

CISPLATIN *OR* CARBOPLATIN WITH FLUOROURACIL + CETUXIMAB

Vermorken JB et al. N Engl J Med 2008;359:1116–1127

Cetuximab premedication:
Diphenhydramine 50 mg; administer by intravenous injection or infusion before cetuximab administration (other H_1-receptor antagonists may be substituted)

Initial cetuximab dose:
Cetuximab 400 mg/m²; administer intravenously over 120 minutes (maximum infusion rate = 5 mL [10 mg] per min) as a single loading dose (total initial dosage = 400 mg/m²)

Maintenance cetuximab doses:
Cetuximab 250 mg/m² per dose; administer intravenously over 60 minutes (maximum infusion rate = 5 mL [10 mg] per min) every week (total weekly dosage = 250 mg/m²)

Notes:
Cetuximab is intended for direct administration and should not be diluted
Maximum infusion rate = 5 mL (10 mg)/min
Administer cetuximab through a low protein-binding inline filter with pore size = 0.22 μm
Use 0.9% sodium chloride injection to flush vascular access devices after administration is completed
One hour after completing cetuximab administration, either cisplatin *or* carboplatin is given

Cisplatin-Containing Regimen

Hydration before, during, and after cisplatin administration ± mannitol:

- *Pre-cisplatin hydration* with 1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously with potassium and magnesium supplementation as needed based on pretreatment laboratory results
- *Mannitol diuresis:* May be given to patients who have received adequate hydration. A dose of **mannitol** 12.5–25 g may be administered by intravenous injection or a short infusion before or during cisplatin administration, or prepared as an admixture with cisplatin. Continued intravenous hydration is essential
- *Continued mannitol diuresis:* In an inpatient or day-hospital setting, one may administer additional mannitol in the form of an intravenous infusion: **mannitol** 10–40 g; administer intravenously over 1–4 hours. This can be done either during or immediately after cisplatin, but requires maintenance of adequate intravenously administered fluids during and for hours after mannitol administration
- *Post-cisplatin hydration* with ≥1000 mL 0.9% NS; administer intravenously with potassium and magnesium supplementation as needed based on measured values

Cisplatin 100 mg/m²; administer intravenously in 50–1000 mL 0.9% NS over 60 minutes on day 1, every 3 weeks (total dosage/cycle = 100 mg/m²), *followed by:*

Fluorouracil 1000 mg/m² per day; administer in 50–1000 mL 0.9% NS or D5W by continuous intravenous infusion over 24 hours for 4 consecutive days, on days 1–4, every 3 weeks (total dosage/cycle = 4000 mg/m²)

Carboplatin-Containing Regimen

Carboplatin* (calculated dose) AUC = 5 mg/mL • min per dose; administer by intravenous infusion diluted to concentrations as low as 0.5 mg/mL with either D5W or 0.9% NS over 1 hour, on day 1, every 3 weeks (total dose/cycle calculated to produce a target AUC = 5 mg/mL • min), *followed by:*

Fluorouracil 1000 mg/m² per day; administer in 50–1000 mL 0.9% NS or D5W by continuous intravenous infusion over 24 hours for 4 consecutive days, on days 1–4, every 3 weeks for 4 cycles (total dosage/cycle = 4000 mg/m²)

*Carboplatin dose is based on a formula described by Calvert et al. to achieve a target area under the plasma concentration versus time curve (AUC)

$$\text{Total Carboplatin Dose (mg)} = (\text{target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be estimated from the equation of Cockcroft and Gault, thus:

$$\text{For males, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})}$$

(*continued*)

(*continued*)

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times (\text{body weight [kg]})}{72 \times (\text{serum creatinine [mg/dL]})} \times 0.85$$

Calvert AH et al. J Clin Oncol 1989;7:1748–1756
Cockcroft DW, Gault MH. Nephron 1976;16:31–41
Jodrell DI et al. J Clin Oncol 1992;10:520–528
Sorensen BT et al. Cancer Chemother Pharmacol 1991;28:397–401

Note: On October 8, 2010, the U.S. FDA identified a potential safety issue with carboplatin dosing based on recent changes in the measurement of serum creatinine. By the end of 2010, all clinical laboratories in the United States were required to use the standardized Isotope Dilution Mass Spectrometry (IDMS) method to measure serum creatinine, which can result in an overestimation of the GFR in some patients with normal renal function. A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula can exceed an expected exposure (AUC) and result in increased drug-related toxicity

Provided actual GFR measurements are made to assess renal function, carboplatin can be safely dosed according to the Calvert formula described in product labeling

If GFR (or creatinine clearance) is estimated based on serum creatinine measurements by the IDMS method, the FDA recommends, for patients with normal renal function, capping an estimated GFR at 125 mL/min for any targeted AUC value. No greater estimated GFR values should be used

U.S. FDA. Carboplatin dosing. [online] October 8, 2010. Available from: http://www.fda.gov/AboutFDA/CentersOffices/OfficeofMedicalProductsandTobacco/CDER/ucm228974.htm [accessed February 26, 2014]

Treatment duration:
Until evidence of disease progression or unacceptable toxicity for a maximum of 6 cycles of chemotherapy. Cetuximab may be continued as a single agent until unacceptable toxicity or disease progression

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days with cetuximab alone is ***MINIMAL***
Emetogenic potential on days with cisplatin or carboplatin is ***HIGH****. Potential for delayed symptoms*
Emetogenic potential on days with fluorouracil alone is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)
- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

(*continued*)

(*continued*)

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

	PFC (N = 222)	**PF (N = 220)**	**Odds Ratio (p-Value)**
Overall response rate	36%	20%	2.23 (<0.001)

*WI-IO
†PFC, Cisplatin or carboplatin with fluorouracil + cetuximab; PF, cisplatin or carboplatin with + fluorouracil

Treatment Modifications

Adverse Event	Dose Modification
First occurrence G3 skin toxicity	Hold cetuximab up to 2 weeks
Second occurrence G3 skin toxicity	Reduce cetuximab dosage to 200 mg/m²
Third occurrence G3 skin toxicity	Reduce cetuximab dosage to 150 mg/m²
Fourth occurrence G3 skin toxicity	Discontinue cetuximab
G ≥2 mucosal or skin toxicity	Reduce fluorouracil dosage 20%
G ≥2 diarrhea (4–6 stools/day greater than baseline)	Hold fluorouracil until diarrhea resolves to baseline
Creatinine clearance ≤50 mL/min (≤0.83 mL/s)	Replace cisplatin with carboplatin AUC = 5 mg/mL·min
G3 myelosuppression	Reduce cisplatin dosage by 25% or carboplatin dosage by 20%. Do not change fluorouracil dosage
G4 myelosuppression	Reduce cisplatin dosage by 40% or carboplatin dosage by 20%. Do not change fluorouracil dosage
Creatinine clearance <50 mL/min (<0.83 mL/s)	Do not administer therapy
Serum creatinine >1.5 mg/dL (>133 µmol/L) or 20% higher than baseline if baseline was >1.5 mg/dL	Hold cisplatin dosage until serum creatinine <1.5 mg/dL (<133 µmol/L) or within 0.2 mg/dL (17.7 µmol/L) of baseline
Serum creatinine 1.5–2.0 mg/dL (133–177 µmol/L) immediately before a cycle	Hold cisplatin*, then reduce cisplatin dosage by 25% during subsequent cycles
Serum creatinine 2.1–3.0 mg/dL (186–265 µmol/L) immediately before a cycle	Hold cisplatin*, then reduce cisplatin dosage by 50% during subsequent cycles
Serum creatinine >3.0 mg/dL immediately before a cycle	Hold cisplatin
G2 neurotoxicity or ototoxicity	Hold cisplatin until neurotoxicity resolves to G ≤1
G3/4 neurotoxicity or ototoxicity	Discontinue chemotherapy
G ≥3 nausea/vomiting despite use of a serotonin (5-HT_3) receptor antagonist + dexamethasone + aprepitant, consistent with published guidelines (see Chapter 39)	Reduce cisplatin dosage or carboplatin dose, or discontinue the platinating agent

*Hold cisplatin until serum creatinine <1.5 mg/dL (<133 µmol/L) or within 0.2 mg/dL (17.7 µmol/L) of baseline

†PFC, Cisplatin or carboplatin with fluorouracil + cetuximab; PF, cisplatin or carboplatin with fluorouracil

Therapy Monitoring

1. *Pretreatment evaluation:* Medical history and tumor assessment by clinical evaluation and imaging studies
2. *Response evaluation:* Every 2 cycles

RECURRENT/METASTATIC DISEASE

WEEKLY DOCETAXEL

Guardiola E et al. Eur J Cancer 2004;40:2071–2076

Premedication for docetaxel
Dexamethasone 8 mg/dose; administer orally for 3 doses at 12 hours, 3 hours, and 1 hour before starting docetaxel (total dose/cycle = 24 mg)

Docetaxel 40 mg/m²; administer intravenously in a volume of 0.9% sodium chloride injection or 5% dextrose injection sufficient to produce a docetaxel concentration within the range 0.3–0.74 mg/mL over 60 minutes every 7 days (total dosage/week = 40 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed onset diarrhea*:*
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep
- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg with **Atropine sulfate** 0.025 mg (eg, Lomotil®)
- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:
Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg
Antibiotic therapy during latent or delayed onset diarrhea:
A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm3 with or without accompanying fever in association with diarrhea
- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

(*continued*)

Patient Population Studied

A study of 57 patients with measurable recurrent and/or metastatic squamous cell carcinoma of the head and neck. Excluded were patients with adenocarcinoma, undifferentiated nasopharyngeal carcinoma, or known brain metastasis. Prior chemotherapy for recurrent disease was not allowed. Prior chemotherapy delivered as part of initial curative therapy was allowed. Age ≥18 years, adequate organ function, and performance status ≤2 were required

Efficacy (Comparator = Weekly Methotrexate)*

	Docetaxel (N = 37)	Methotrexate (N = 20)
Overall response rate	27%	15%
Median time to progression, months	1.97	1.5
Median overall survival, months	3.7	3.9

*WHO

Dose Modifications

Adverse Event	Dose Modification
G4 toxicity	Withhold treatment until G ≤1
Neutrophil count <1500/mm³	Withhold treatment until ANC is ≥1500/mm³
Platelet count <100,000/mm³	Withhold treatment until platelet count is ≥100,000/mm³
G3 mucositis	Reduce docetaxel dosage by 20%
G2 neuropathy	Reduce docetaxel dosage by 20%
G3 neuropathy	Discontinue therapy

Therapy Monitoring

1. *Pretreatment evaluation:* Medical history and tumor assessment by clinical evaluation and imaging studies
2. *Toxicity:* Assess weekly
3. *Response evaluation:* Every 2 cycles

(continued)

Oral care (prophylaxis and management of mucositis)

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Toxicity (Comparator = Weekly Methotrexate)*

	Docetaxel		Methotrexate

*NCI Common Toxicity Criteria and UICC

RECURRENT/METASTATIC DISEASE

METHOTREXATE *OR* CISPLATIN + FLUOROURACIL *OR* CARBOPLATIN + FLUOROURACIL

Forastiere AA et al. J Clin Oncol 1992;10:1245–1251

Note: Combination chemotherapy (cisplatin + fluorouracil or carboplatin + fluorouracil) resulted in improved response rates but was associated with increased toxicity and no improvement in overall survival
Note: Other regimens for cisplatin + fluorouracil or carboplatin + fluorouracil can be found in other areas of this chapter

Methotrexate

Methotrexate 40 mg/m²; administer intravenously in 25–500 mL of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 1 hour every 7 days (total dosage/week = 40 mg/m²)

Supportive Care for Patients Receiving Weekly Methotrexate
Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Oral care
Risk of mucositis/stomatitis is LOW–MODERATE
General advice:
- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:
- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:
- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
- Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

(*continued*)

Cisplatin + Fluorouracil

Hydration before, during, and after cisplatin administration ± mannitol:

- *Pre-cisplatin hydration* with 1000 mL 0.9% NS; administer intravenously with potassium and magnesium supplementation as needed based on pretreatment laboratory results
- *Mannitol diuresis:* May be given to patients who have received adequate hydration. A dose of **mannitol** 12.5–25 g may be administered by intravenous injection or a short infusion before or during cisplatin administration, or prepared as an admixture with cisplatin. Continued intravenous hydration is essential
- *Continued mannitol diuresis:* In an inpatient or day-hospital setting, one may administer additional mannitol in the form of an intravenous infusion: **mannitol** 10–40 g; administer intravenously over 1–4 hours. This can be done either during or immediately after cisplatin, but requires maintenance of adequate intravenously administered fluids during and for hours after mannitol administration
- *Post-cisplatin hydration* with ≥1000 mL 0.9% NS; administer intravenously with potassium and magnesium supplementation as needed based on measured values

Cisplatin 100 mg/m²; administer intravenously in 25–250 mL 0.9% NS over 15–30 minutes on day 1, every 21 days (total dosage/cycle = 100 mg/m²)
Fluorouracil 1000 mg/m² per day; administer in 50–1000 mL 0.9% NS or D5W by continuous intravenous infusion over 24 hours for 4 consecutive days, on days 1–4, every 21 days (total dosage/cycle = 4000 mg/m²)

Carboplatin + Fluorouracil

Carboplatin 300 mg/m²; administer by intravenous infusion diluted to concentrations as low as 0.5 mg/mL with either D5W or 0.9% NS over at least 15 minutes on day 1, every 28 days (total dosage/cycle = 300 mg/m²)
Fluorouracil 1000 mg/m² per day; administer in 50–1000 mL 0.9% NS or D5W by continuous intravenous infusion over 24 hours for 4 consecutive days, on days 1–4, every 28 days (total dosage/cycle = 4000 mg/m²)

Supportive Care for Patients Receiving Fluorouracil with Either Cisplatin or Carboplatin

Antiemetic prophylaxis
*Emetogenic potential on days with cisplatin or carboplatin is **HIGH**. Potential for delayed symptoms*
*Emetogenic potential on days with fluorouracil alone is **LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed onset diarrhea*:
Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Persistent diarrhea:
Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg
Antibiotic therapy during latent or delayed onset diarrhea:
A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm³ with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

Oral care

Risk of mucositis/stomatitis is HIGH

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Patient Population Studied

A study of 261 eligible patients with histologically proven locally recurrent or metastatic squamous cell carcinoma of the head and neck. Prior chemotherapy for recurrent or metastatic disease was not allowed. Prior induction chemotherapy as part of the initial treatment was allowed provided it was completed at least 6 months before enrollment. Adequate organ function, life expectancy ≥12 weeks, and a performance status 0–2 according to SWOG criteria were required

Toxicity*

	PF (N = 85)†		CF (N = 86)†		MTX (N = 87)†	
Toxicity	% G1/2	% G3/4	% G1/2	% G3/4	% G1/2	% G3/4

*SWOG criteria

†PF, Cisplatin + fluorouracil; CF, carboplatin + fluorouracil; MTX, methotrexate

Dose Modification

Adverse Event	Dose Modification
G0 mucositis or myelosuppression	Increase methotrexate dosage to 50 mg/m² weekly
G ≥2 toxicity including stomatitis and dermatitis	Reduce methotrexate dosage by 10 mg/m² weekly
G ≥2 mucosal or skin toxicity	Reduce fluorouracil dosage by 20%
G ≥2 diarrhea (4–6 stools/day greater than baseline)	Hold fluorouracil until diarrhea resolves to baseline
G3 myelosuppression	Reduce cisplatin dosage by 25% or carboplatin dosage by 20%. Do not change fluorouracil dosage
G4 myelosuppression	Reduce cisplatin dosage by 40% or carboplatin dosage by 20%. Do not change fluorouracil dosage
Creatinine clearance <50 mL/min (<0.83 mL/s)	Do not administer therapy
Serum creatinine >1.5 mg/dL (>133 μmol/L) or 20% higher than baseline if baseline was >1.5 mg/dL	Hold cisplatin dosage until serum creatinine <1.5 mg/dL (<133 μmol/L) or within 0.2 mg/dL (17.7 μmol/L) of baseline
Serum creatinine 1.5–2.0 mg/dL (133–177 μmol/L) immediately before a cycle	Hold cisplatin*, then reduce cisplatin dosage by 25% during subsequent cycles
Serum creatinine 2.1–3.0 mg/dL (186–265 μmol/L) immediately before a cycle	Hold cisplatin*, then reduce cisplatin dosage by 50% during subsequent cycles
Serum creatinine >3.0 mg/dL (>265 μmol/L) immediately before a cycle	Hold cisplatin
G2 neurotoxicity or ototoxicity	Hold cisplatin until neurotoxicity resolves to G ≤1
G3/4 neurotoxicity or ototoxicity	Discontinue chemotherapy
G0/1 myelosuppression	Increase carboplatin dosage by 20% to 360 mg/m² on the same administration schedule

*Hold cisplatin until serum creatinine is <1.5 mg/dL (<133 μmol/L) or within 0.2 mg/dL (17.7 μmol/L) of baseline

Efficacy

	PF* (N = 87)	CF* (N = 86)	MTX* (N = 88)
Overall response rate	32%†	21%†	10%†
Complete response rate	6%	2%	2%
Progressive disease	16%	25%	32%
Median response duration, months	4.2	5.1	4.1
Median survival, months	6.6	5	5.6
Patients alive at 9 months	31%	30%	27%

*PF, Cisplatin + fluorouracil; CF, carboplatin + fluorouracil; MTX, methotrexate
†PF vs. MTX (P <0.001); CF vs. MTX (P = 0.05)

Therapy Monitoring

1. *Pretreatment evaluation:* Medical history and tumor assessment by clinical evaluation and imaging studies
2. *Toxicity:* Assess weekly during at least the first cycle with attention to signs and symptoms of dehydration as supplemental hydration is often required
3. *Laboratory analyses:* Weekly CBC, serum electrolytes, LFTs, calcium, and magnesium
4. *Response evaluation:* Every 6–8 weeks

15. Hepatocellular Carcinoma

Tim Greten, MD, PhD and Nadine Abi-Jaoudeh, MD

Epidemiology

Incidence*: 16 cases per 100,000 population
worldwide: 626,000 cases per year
Deaths (worldwide): 598,000 per year
Median age* (Asia and Western Europe): 50–60 years
Male to female ratio: ~2.4:1

Stage at presentation
Stage A: 35%
Stage B: 25%
Stage C: 10%
Stage D: 30%

*The incidence and age of hepatocellular carcinoma vary widely according to geographic location. The distribution also differs among ethnic groups and regions within the same country

Forner et al. Lancet 2012;379:1245–1255
Llovet JM et al. J Natl Cancer Inst 2008;100:698–711
Parkin DM et al. CA Cancer J Clin 2005;55:74–108

Work-up

1. Alpha-fetoprotein (AFP)
2. Liver function test (see Child-Pugh classification)
3. Ultrasound and abdominal/chest spiral CT and/or dynamic liver MRI
4. Specific clinical scenarios such as selection for liver transplantation may also require bone scintigraphy to exclude bone metastases, but there are no robust data supporting the cost-efficiency of this policy

Diagnostic Criteria for HCC: Non-invasive criteria (Restricted to cirrhotic patients)
1. Radiological criteria: (arterial hypervascularization/washout in portal phase)
   Two coincident imaging techniques, nodule <2 cm
   One imaging technique, nodule >2 cm
2. Combined criteria: one imaging technique associated with AFP
   Focal lesion >2 cm with arterial hypervascularization

Bruix J, Sherman M. Hepatology 2005;42:1208–1236
Forner A et al. Hepatology 2008;47:97–104

Pathology

Hepatocellular carcinoma	99%
Fibrolamellar hepatocellular carcinoma	<1%

Nakashima T, Kojiro M. Hepatocellular Carcinoma. Tokyo, Japan: Springer Verlag, 1987

Staging

Primary Tumor (T)

TX	Primary tumor cannot be assessed
T0	No evidence of primary tumor
T1	Solitary tumor without vascular invasion
T2	Solitary tumor with vascular invasion or multiple tumors none more than 5 cm
T3a	Multiple tumors more than 5 cm
T3b	Single tumor or multiple tumors of any size involving a major branch of the portal vein or hepatic vein
T4	Tumor(s) with direct invasion of adjacent organs other than the gallbladder or with perforation of visceral peritoneum

Regional Lymph Nodes (N)

NX	Regional lymph nodes cannot be assessed
N0	No regional lymph node metastasis
N1	Regional lymph node metastasis

Distant Metastasis (M)

M0	No distant metastasis (no pathologic M0; use clinical M to complete stage group)
M1	Distant metastasis

Expert Opinion

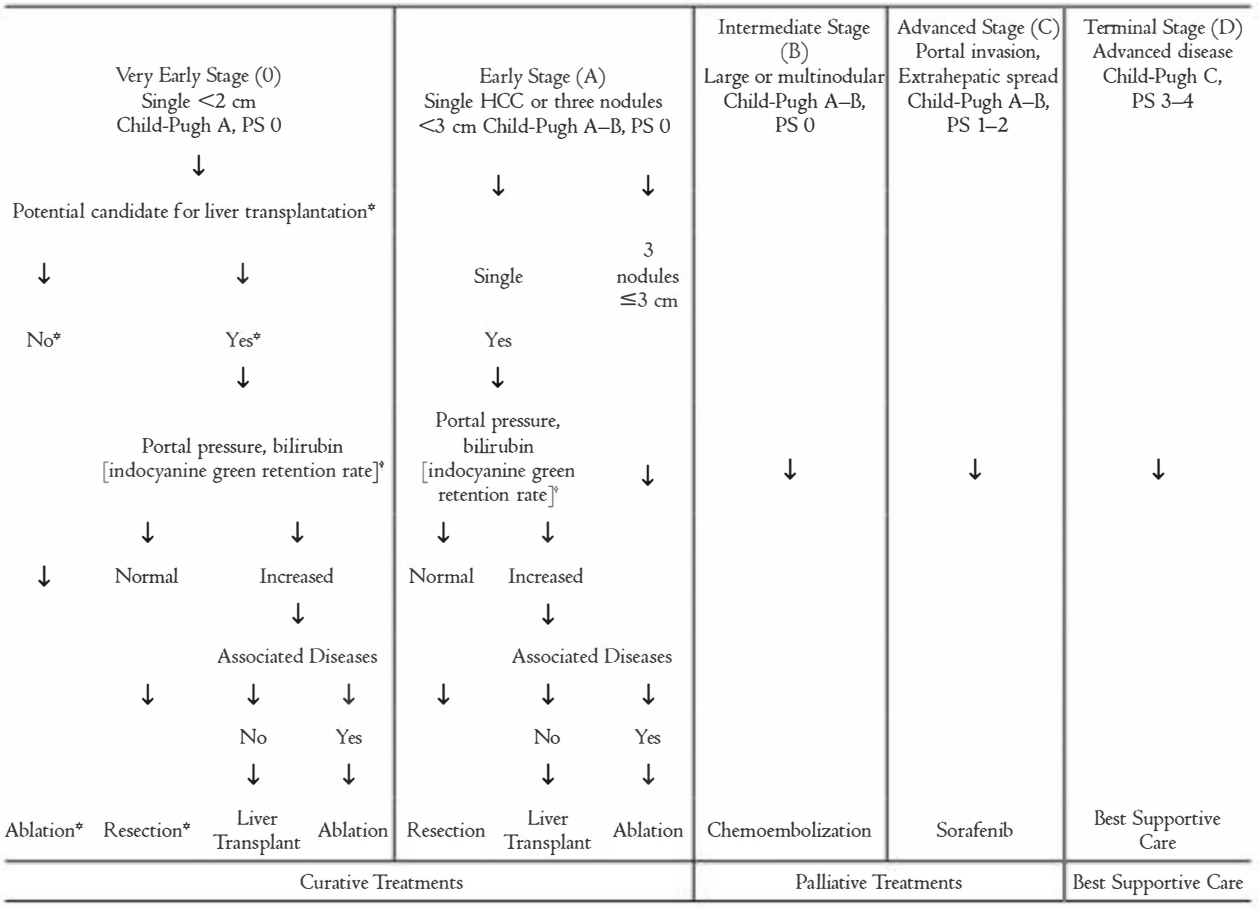
TREATMENT ACCORDING TO STAGE

European Association for the Study of the Liver (EASL)/European Organization for Research and Treatment of Cancer (EORTC) Guidelines J. Hepatol 2012;56:908–943

1. ***Stage 0–A***
   Patients diagnosed at an early stage (BCLC A) should be considered for one of the options that can achieve complete response: resection, liver transplantation from cadaveric or live donor, and percutaneous ablation by ethanol injection or radiofrequency
2. ***Stage B***
   Chemoembolization
3. ***Stage C***
   Sorafenib
4. ***Stage D***
   Symptomatic treatment

Hepatocellular Carcinoma—BCLC Staging and Treatment Strategy

Adapted from Forner et al, Lancet 2012;379:1245–1255



*Very Early Stage (BCLC0) patients are considered for resection only if transplant available. If transplant not an option, ablation first-line option and surgery justified only in patients with contraindication to ablation or in whom ablation fails. If patients eligible for transplant, then strategy of transplantation depending on risk of recurrence as per tumor pathology favors resection as the first-line approach. Analysis of resected tumor would distinguish BCLC 0 with marginal risk of recurrence (no need to transplant) and more advanced disease with microscopic vascular invasion or satellites that favor transplantation because of high risk of recurrence

†Selection of candidates for resection: In Japan it often relies on indocyanine green retention rate, whereas portal pressure and bilirubin are variables used in Europe and the USA. Clinically relevant portal hypertension defined as a hepatic vein pressure gradient > 10 mm Hg, but also confirmed by esophageal varices or splenomegaly with a platelet count $<100 \times 10^9$/L. Bruix and Sherman, Hepatology 2011;53:1020–1022; Llovet et al. Semin Liver Dis 2005;25:181–200

Expert Opinion (*continued*)

Therapeutic Strategies/Options

Adapted from Forner A et al. Lancet 2012;379:1245–1255

Procedure/Treatment	Benefit	Level of Evidence	Comment
Surgical Treatments			
Surgical resection	Increased survival	3ii A	• Treatment of choice in 5–10% without cirrhosis and one tumor. High rate of CRs; potential for cure • 5-year survival: ~70% without portal hypertension and normal bilirubin; 50% with portal hypertension; <50% if bilirubin increased
Adjuvant treatments	Controversial	1 A–D	• Tumor recurrence 70% at 5 y. Includes early (true) recurrence, usually in first 2 years > resection, and late (*de novo*) tumors • No effective neo-adjuvant or adjuvant treatments
Liver transplantation	Increased survival	3ii A	• Most effective option to prevent intrahepatic recurrence; recurrence rate <25%. One tumor ≤5 cm or ≤3 cm without vascular invasion or extra-hepatic spread ~75% 4-year survival; <15% recurrence rates • Can offer to patients treated with resection but with a high risk of recurrence according to pathologic analysis
Adjuvant treatments	Treatment response	3 Diii	• If transplant donors wait >6 months, trans-arterial chemoembolization and ablation are done, even though effectiveness is unproven
Loco-Regional Treatments—Image-Guided Tumor Ablation			
Percutaneous treatment [injection of chemicals (ethanol, acetic acid) or temperature modification (radiofrequency (RFA), microwave, laser)]	Increased survival	3ii A	• First-line technique now radiofrequency ablation (RFA) • Both ethanol and RFA highly effective in HCC <2 cm, but effectiveness of ethanol falls in 2–5 cm tumors • Effectiveness limited by (1) tumor size—ablation not recommended for tumors >5 cm; and (2) tumor location—with RFA avoid tumors located in subcapsular region, vicinity of major blood vessels or biliary tree, near to bowel or heart • Side-effects more frequent after RFA • Better disease control with RFA than ethanol could translate into better outcomes
Radiofrequency ablation (RFA)	Increased survival	1ii A	
Other modalities	Treatment response	2 D	
Combined modalities		3ii D	
Loco-Regional Treatments—Image-Guided Transcatheter Tumor Treatment			
Chemoembolization	Increased survival	1ii A	• Best candidates patients with compensated Child-Pugh A with asymptomatic multifocal or large hepatocellular tumors not amenable to resection (BCLC stage B) • >50% of patients have objective response that translates into improved in survival • Portal vein thrombosis, even if segmental, predicts poor tolerability and worse outcome
Radioembolization [Internal radiotherapy, ^{131}I, ^{90}Y]	Treatment response	3ii Diii	• Anti-tumor activity but survival benefit not proven • Role not yet defined
Systemic Treatments			
Sorafenib	↑ survival	1i A	• Non-curative treatment that improves survival
Hormonal compounds [Tamoxifen, Octreotide, Antiandrogen, Seocalcitiol]	No survival benefit	1i A	• Completely ineffective
Systemic chemotherapy		1i A	• Marginal activity; frequently toxic
Immunotherapy		1ii A	

Evidence-based classification adapted from the National Cancer Institute
1 = Randomized controlled trial or meta-analysis [1i = Double-blinded, 1ii = Non-blinded]; 2 = Non-randomized controlled trial; 3 = Case series [3i = Population-based, 3ii = Non-population-based, consecutive, 3iii = Non-population-based, non-consecutive]. A = Survival endpoint. B = Cause-specific mortality. C = Quality of life. D = Indirect surrogates [Di = Disease-free survival, Dii = Progression-free survival, Diii = Tumor response]

(*continued*)

Expert Opinion (*continued*)

Surgical Resection

- Best candidates patients with small solitary tumors and well-preserved liver function
- Tumor recurrence 70% at 5 years. Includes true recurrence, usually within the first 2 years after resection, and *de novo* tumors
- "Early" (true) recurrence: Microvascular invasion, poor histological differentiation, satellites, and multifocal disease predict early recurrence
- Late (*de novo*) recurrence: Depends mainly on carcinogenic effect of underlying chronic liver disease. Estimated by liver function variables related to inflammatoryactivity, evolutionary stage, or both
- No effective neo-adjuvantor adjuvant treatment options to reduce risk of recurrenceare available

Llovet et al. Semin Liver Dis 2005;25:181–200
Sala et al. Liver Transpl 2004;10:1294–1300

Liver Transplantation

- Most beneficial for patients deemed poor candidates for resection, especially those within Milano criteria (solitary tumor ≤5 cm and up to three nodules ≤3 cm)
- Donor shortage limits applicability
- Excellent results achieved in era with prompt availability of organs. Shortage of donors has imposed delay before transplantation, and tumor can progress and impede transplantation. Delays impair effectiveness of transplantation when considered according to intention
- When waiting >6 months, ablation and trans-arterial chemoembolization are done, even though effectiveness is unproven
- No role for systemic chemotherapy prior to transplantation

Percutaneous Ablation

- Induces tumor necrosis by injection of chemicals (eg, ethanol, acetic acid) or temperature modification (ablation by radio frequency (RFA), microwave, or laser)
  Note: Cryoablation resulted in shock and hepatic failure, and laser is not yet approved by the FDA
- Most ablation procedures done percutaneously, but can also done intraoperatively
- First-line technique is now radiofrequency ablation (RFA). Both ethanol injection and RFA highly effective in HCC <2 cm, but effectiveness of ethanol falls in 2–5 cm tumors
- Effectiveness limited by
  1. Tumor size: All ablation not recommended for tumors >5 cm
  2. Tumor location: With RFA avoid some tumors located in subcapsular region, vicinity of major blood vessels or biliary tree, near to bowel or heart
- Better disease control with RFA than ethanol could translate into better outcomes
- Side-effects more frequent after RFA
- Survival > ablation in Child-Pugh A patients is 50–75% at 5 years, paralleling surgical resection. Has challenged resection as the first-line treatment in patients with small solitary HCCs. Ablation nearly 100% effective in HCCs <2 cm and survival almost identical after resection or ablation
- RFA is associated with less treatment-associated morbidity than resection

Expert Opinion (*continued*)

Image-Guided Transcatheter Tumor Treatment—Chemoembolization

- Best candidates for trans-arterial chemoembolization are patients with compensated Child-Pugh A with asymptomatic multifocal or large hepatocellular carcinomas not amenable to resection (ie, BCLC stage B)
- >50% of patients have an objective response, and this translates into improvement in survival
- After initial success with transarterial chemoembolization, treated tumors re-vascularize and can be re-treated. However, in the long term, control is lost
- Median survival in old series almost 2 years but with better selection and optimum treatment, median survival >3 years
- Portal vein thrombosis, even if segmental, is a predictor of poor tolerability and impaired outcome
- No standard regimen established
- Extra systemic therapy between/following TACE procedures failed to improve outcome and is not recommended

Lammer et al. Cardiovasc Intervent Radiol 2010;33:41–52
Lin et al. Gastroenterology 1988;94:453–456
Llovet et al. Lancet 2002;359:1734–1739
Pelletier et al. J Hepatol 1990;11:181–184

Image-Guided Transcatheter Tumor Treatment—Radioembolization

- Radioembolization with yttrium-90 (Yt^{90})-labeled spheres has anti-tumor activity. There are no randomized controlled trials comparing this option with any other established treatment. A retrospective comparison to chemoembolization (TACE) found that radioembolization and chemoembolization had similar survival rates; however, radioembolization had longer time to progression and less toxicity than chemoembolization [Salem R et al. Gastroenterology 2011;140:497–507]

Salem et al. Gastroenterology 2010;138:52–64
Sangro et al. Hepatology 2011;54:868–878

Systemic Treatment—Sorafenib

- 602 patients in a multicenter, randomized, double-blind placebo-controlled trial
- Median OS in sorafenib group 10.7 months (95% CI 9.4–13.3) versus 7.9 months (6.8–9.1) in placebo group (hazard ratio 0.69, 95% CI 0.55–0.87; p = 0.0001)
- Median PFS 5.5 months for sorafenib versus 2.8 months for placebo (0.58, 0.45–0.74; p <0.001)
- No difference in median time to symptomatic progression (4.1 months vs 4.9 months; p = 0.77)
- Overall incidence of treatment-related adverse events (predominantly grade 1 or 2 in severity) 80% in sorafenib group and 52% in placebo group
- Findings have been replicated by a randomized controlled trial in Asia
- These results have established sorafenib as the standard of care for advanced HCC

EXTRAHEPATIC COLLATERAL VESSELS SUPPLYING HEPATOCELLULAR CARCINOMAS

Kim HC et al. Radiographics 2005;25(Suppl 1):S25–S39

- Extra-hepatic collateral arteries commonly supply hepatocellular carcinomas especially if the tumors are large or peripherally located
- Development of these vessels can interfere with effective tumor control with transcatheter arterial chemoembolization (TACE)
- When both the hepatic artery and extra-hepatic collateral vessels supply a tumor, additional extra-hepatic collateral vessel chemoembolization should be attempted to increase the therapeutic efficacy of TACE
- Extrahepatic collateral vessels originated from thirteen different sources (see Table): Considering the broad contact between the liver and the diaphragm, it is not surprising that diaphragmatic blood supplies, including the inferior phrenic, internal mammary, and intercostal arteries, are major sources of collateral circulation. Exophytic growth and extra-capsular HCC infiltration can cause omental adhesion. Direct contact or invasion into other organs, including the stomach, colon, adrenal gland, and kidney, may create blood supply to the tumor from these organs

(*continued*)

Expert Opinion (*continued*)

- Extrahepatic collateral vessels suspected when:
  1. A tumor grows exophytically or invades adjacent organs
  2. A tumor is in contact with the ligaments and bare area of the liver
  3. A hypertrophied extrahepatic collateral vessel is observed on a computed tomographic (CT) scan
  4. A peripheral defect of iodized oil retention within a tumor is seen during chemoembolization or on a follow-up CT scan
  5. A local recurrence develops at the peripheral portion of the treated tumor during follow-up
  6. A sustained elevation in serum α-fetoprotein level is noted despite adequate embolization of the hepatic artery
- Outcomes:
  1. 2104 such vessels observed in 1622 sessions in 860 (27%) patients
  2. TACE performed via 1556 extrahepatic collateral vessels (74%) in 732 patients in 1281 sessions
  3. Multiple extrahepatic collateral vessels embolized in 221 patients (two vessels in 186 patients, three vessels in 27, four vessels in six, and five vessels in two)

Extra-Hepatic Collateral Vessels Supplying HCC in 3179 Patients

Collateral Vessel	Observed Vessels	Embolized Vessels*

REGIMEN

CHEMOEMBOLIZATION WITH DOXORUBICIN

Llovet JM et al. Lancet 2002;359:1734–1739

Doxorubicin dose adjusted to serum bilirubin concentration (see table below) prepared as an emulsion with 10 mL of ethiodized oil injection administered intra-arterially followed by mechanical obstruction achieved by intra-arterial injection of gelatin sponge fragments suspended in radiologic contrast media until flow stagnation occurred. Chemoembolization was performed at baseline, repeated 2 months and 6 months later, and then every 6 months until disease progression observed

Notes:

• Doxorubicin dosage was based on serum total bilirubin concentration as per the table below:

Total Bilirubin		
(μmol/L)	(mg/dL)	Doxorubicin Dosage
<25.6	<1.5	75 mg/m²
25.6–51.3	1.5–3	50 mg/m²
51.3–85.5	3–5	25 mg/m²

• Extra-hepatic arterial supply of HCC is important. See section on **Extrahepatic collateral vessels supplying hepatocellular carcinomas** [Kim HC, Chung JW, Lee W, Jae HJ, Park JH, Radiographics 2005;25(Suppl 1):S25–S39]

• The mean numbers of treatment sessions were 3.08 (95% CI 2.4–3.5; range 0–7) for embolization and 2.8 (2.3–3.2; 1–8) for chemoembolization ($p = 0.5$)

GENERAL GUIDELINES

Prior to embolization:

• **Hydration**
  ▪ Start intravenous **hydration** with 0.9% sodium chloride injection (0.9% NS)
  ▪ Continuous 0.9% NS 100 mL/h beginning a minimum of 6 hours prior to procedure

• **Antibiotic prophylaxis** not always required but may be considered with the first doses given before embolization:
  ▪ **Metronidazole** 500 mg; administer intravenously prior to procedure followed by 500 mg every 12 hours × 3 doses, *plus*
  ▪ **Cefazolin** 1000 mg; administer intravenously prior to procedure followed by **Cefazolin** 500 mg; administer intravenously every 8 hours × 5 doses

• **Antiemetic primary prophylaxis**

Give a serotonin receptor ($5HT_3$) antagonist plus a high-potency glucocorticoid
  ▪ **Ondansetron** 16 mg; administer intravenously or 24 mg orally, *plus*
  ▪ **Dexamethasone** 10–12 mg; administer intravenously or orally 30–60 minutes before the procedure

Post-embolization syndrome:

• The triad of abdominal pain, vomiting, and fever that frequently occurs 24–72 hours after chemoembolization is commonly referred to as post-embolization syndrome

• Post-embolization syndrome uniformly responds to supportive care including analgesics and antiemetics

• Use care administering acetaminophen (paracetamol) and non-steroidal anti-inflammatory drugs in patients with liver cirrhosis

After embolization:

• Continue intravenous **hydration** with 0.9% NS or another clinically appropriate fluid until patient resumes adequate oral fluid intake

• Provide **analgesic support** with parenterally administered opioid medications (**morphine, hydromorphone, fentanyl**) after chemoembolization until patient is able to continue analgesic treatment with oral products

• Continue **antiemetic prophylaxis** with a $5HT_3$ antagonist plus a high-potency glucocorticoid:
  ▪ **Ondansetron** 8 mg; administer intravenously or orally every 8 hours, *plus*
  ▪ **Dexamethasone** 8 mg; administer intravenously or orally every 8 hours for 2–3 days

• **Filgrastim** (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection
  ▪ May be used for patients who develop an ANC <500/mm³, neutropenia and fever, or documented infections during neutropenia
  ▪ Discontinue filgrastim at least 24 hours before a chemoembolization procedure

Patient Population Studied

A total of 903 patients were screened and 791 excluded due to early HCC, advanced liver disease, vascular invasion, extra-hepatic spread, and end-stage cancer. 112 patients with intermediate BCLC stage (stage B or C) randomized to conservative treatment (n = 35), embolization (n = 37), or chemoembolization (n = 40)

Efficacy

1. Chemoembolization induced objective responses sustained for at least 6 months in 35% (14) of cases, and was associated with a significantly lower rate of portal vein invasion than conservative treatment
2. Probability of portal vein invasion reduced from 58% in control to 17% in patients with chemoembolization
3. Survival probabilities at 1 year and 2 years were 75% and 50% for embolization, and 82% and 63% for chemoembolization
4. Patients who achieved objective responses sustained for at least 6 months had probabilities of survival at 1, 2, and 3 years of 96%, 77%, and 47%, respectively ($p = 0.002$ compared with patients with treatment failure, and $p = 0.006$ vs control group)
5. Treatment allocation was the sole baseline variable independently related to survival (odds ratio 0.45 [95% CI 0.25–0.81], $p = 0.02$) in the Cox's regression model. Inclusion of treatment response identified this variable as an independent predictor (odds ratio 0.59 [0.44–0.81], $p = 0.0007$) together with constitutional syndrome (0.46 [0.25–0.86], $p = 0.04$)
6. There were no differences in intention-to-treat survival between non-responders and the control group (1-year survival 65% vs 63%; 2-year survival 41% vs 26%, $p = 0.3$)

	Embolization (n = 37)	Chemoembolization (n = 40)*	Control (n = 35)*

Patient's decision	2	4	6
Death on treatment	4	3	7
Other (lung cancer, percutaneous ethanol injection)	2	0	2
Treatment discontinuation	29 (78%)	31 (77%)	60 (78%)
Active treatment at end of follow-up	8 (22%)	9 (23%)	17 (22%)

*There were no significant differences between groups

Toxicity (N = 40)

Adverse Event	Number of Patients
Cholecystitis	2
Leukopenia	2
Ischemic biliary stricture	1
Hepatic infarction	1
Spontaneous bacterial peritonitis	1
Bacteremia	1
Septic shock	1
Allergic dermatitis	1
Severe alopecia	1

Other complications associated with TACE procedures in general:
- Hepatic artery occlusion: 4%
- Damage to the hepatic artery: pseudoaneurysm (rare), occlusion, and dissection
- Treatment was discontinued in 60 (78%) patients

Therapy Monitoring

1. Days 7 and 14 after TACE and then monthly: CBC and LFTs
2. Response assessment using computed tomography (CT) every 3 months

REGIMEN

CHEMOEMBOLIZATION WITH CISPLATIN

Lo C-M et al. Hepatology 2002;35:1164–1171

Chemoembolization: Cisplatin (1 mg/mL) emulsified with ethiodized oil injection in equivalent volumes (1:1)

- Administer cisplatin intra-arterially via the left or right hepatic artery as appropriate for tumor vascularization. If selective catheterization is not possible, the cisplatin emulsion is injected into the hepatic artery, distal to the gastroduodenal artery
- The emulsion is injected slowly under fluoroscopic monitoring to a maximum volume of 60 mL (≤30 mg cisplatin) at a controlled rate to prevent retrograde flow, followed by mechanical obstruction achieved by intra-arterial injection of gelatin sponge pellets 1 mm in diameter mixed with gentamicin 40 mg
- Chemoembolization is repeated every 2–3 months until comorbid pathologies, adverse events, or disease progression are observed

Notes:

- Extra-hepatic arterial supply of HCC is important. See section on **Extrahepatic collateral vessels supplying hepatocellular carcinomas** [Kim HC, Chung JW, Lee W, Jae HJ, Park JH. Radiographics 2005;25(Suppl 1):S25–S39]
- Forty patients assigned to the chemoembolization group received a total of 192 courses of chemoembolization, with each patient receiving a median of 4.5 courses (range, 1–15). Ninety-four courses (49%) of the chemoembolization were performed by selective injection into the right or left hepatic artery. The median volume of cisplatin-ethiodized oil emulsion injected in 1 course was 20 mL (range, 2–60), and the dosage was significantly related to the tumor size ($r = 0.70$; $P < 0.001$)

Two patients were scheduled for continuation of chemoembolization as of the date of the latest follow-up. The remaining 38 patients had treatment stopped because of progressive disease (12 patients), death (7 patients), poor liver function (6 patients), adverse effects (6 patients), patient refusal (3 patients), arteriovenous shunting (2 patients), and hepatic artery thrombosis (2 patients)

The most common clinical adverse effect was a self-limiting syndrome consisting of fever, abdominal pain, and vomiting. The median hospital stay for each course of treatment was 2 days (range, 1–21)

GENERAL GUIDELINES

Prior to embolization:

- **Hydration**
  - Start intravenous **hydration** with 0.9% sodium chloride injection (0.9% NS)
  - Continuous 0.9% NS 100 mL/h beginning a minimum of 6 hours prior to procedure
- **Antibiotic prophylaxis** not always required but may be considered with the first doses given before embolization:
  - **Metronidazole** 500 mg; administer intravenously prior to procedure followed by **Metronidazole** 500 mg; administer intravenously every 12 hours × 3 doses, *plus*
  - **Cefazolin** 1000 mg; administer intravenously prior to procedure followed by **Cefazolin** 500 mg; administer intravenously every 8 hours × 5 doses
- **Antiemetic primary prophylaxis**

  Give a serotonin receptor ($5HT_3$) antagonist plus a high-potency glucocorticoid
  - **Ondansetron** 16 mg; administer intravenously or 24 mg orally, *plus*
  - **Dexamethasone** 10–12 mg; administer intravenously or orally 30–60 minutes before the procedure

Post-embolization syndrome:

- The triad of abdominal pain, vomiting, and fever that frequently occurs 24–72 hours after chemoembolization is commonly referred to as post-embolization syndrome
- Post-embolization syndrome uniformly responds to supportive care including analgesics and antiemetics
- Use care administering acetaminophen (paracetamol) and non-steroidal anti-inflammatory drugs in patients with liver cirrhosis

After embolization:

- Continue intravenous **hydration** with 0.9% NS or another clinically appropriate fluid until patient resumes adequate oral fluid intake
- Provide **analgesic support** with parenterally administered opioid medications (**morphine, hydromorphone, fentanyl**) after chemoembolization until patient is able to continue analgesic treatment with oral products
- Continue **antiemetic prophylaxis** with a $5HT_3$ antagonist plus a high-potency glucocorticoid:
  - **Ondansetron** 8 mg; administer intravenously or orally every 8 hours, *plus*
  - **Dexamethasone** 8 mg; administer intravenously or orally every 8 hours for 2–3 days
- **Filgrastim** (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection
  - May be used for patients who develop an ANC $<500/mm^3$, neutropenia and fever, or documented infections during neutropenia
  - Discontinue filgrastim at least 24 hours before a chemoembolization procedure

Treatment Modifications

Withhold or discontinue chemoembolization for:
- Hepatic artery thrombosis
- Main portal vein thrombosis
- Arteriovenous shunting
- Hepatic encephalopathy
- Ascites not controlled by diuretics
- Variceal bleeding within the last 3 months
- Serum total bilirubin >50 μmol/L (>2.9 mg/dL)
- Serum albumin <28 g/L (<2.8 g/dL)
- Prothrombin time 4 seconds > control

Patient Population Studied

A study of 80 patients with Okuda Stages I–II HCC and no contraindications for chemoembolization; 40 assigned to chemoembolization and 39 assigned to control

Baseline Characteristics of the Study Patients According to the Treatment Group

	Chemoembolization (N = 40)	Control (N = 39)

*The most common clinical adverse effect was a self-limiting syndrome consisting of fever, abdominal pain, and vomiting. The median hospital stay for each course of treatment was 2 days (range, 1–21)

Therapy Monitoring

1. Days 7 and 14 after TACE and then monthly: CBC and LFTs
2. Response assessment using computed tomography (CT) every 3 months

REGIMEN

DEB-TACE: TRANSARTERIAL CHEMOEMBOLIZATION (TACE) USING DRUG-ELUTING BEADS (DEB)

Lammer J et al. Cardiovasc Intervent Radiol 2010;33:41–52

Transarterial chemoembolization using drug-eluting beads (DEB), an embolizing device that slowly releases chemotherapy to decrease systemic toxicity

Pretreatment approach:

- A baseline angiography of the celiac trunk, superior mesenteric artery, and hepatic artery is performed using a peripheral arterial approach
- Antibiotic prophylaxis is not required but may be considered

Note: Extra-hepatic arterial supply of HCC is important. See section on **Extrahepatic collateral vessels supplying hepatocellular carcinomas** [Kim HC, Chung JW, Lee W, Jae HJ, Park JH. Radiographics 2005;25(Suppl 1):S25–S39]

Drug-eluting beads (DEB) [BioCompatibles Ltd., UK] with a diameter ranging between 300 and 700 micrometers are loaded with **doxorubicin** and mixed with an equal volume of contrast media. Additional unloaded spheres are used to complete the embolization procedure

Doxorubicin 150 mg (bilirubin <1.5 mg/dL; <25.7 μmol/L)

Loading process to obtain a final loading dose of 150 mg doxorubicin per two 2-mL vials of beads:

- Begin about 2 hours before the TACE is planned
- Reconstitute a vial containing doxorubicin 50 mg with 2 mL of sterile water for injection. Mix well to obtain a clear red doxorubicin solution with concentration = 25 mg/mL
- Remove as much of the solution as possible from a vial of beads using a syringe with a small-gauge needle
- Using a syringe and needle, add 2 mL of reconstituted doxorubicin solution directly to the vial of beads
- Agitate the beads in the doxorubicin solution occasionally to encourage mixing. The dark red color of the suspension should become slightly pink and the beads, which are initially blue, should become red, indicating that doxorubicin has been loaded into the beads

  Note: Although the solution retains a red color, the doxorubicin will be loaded. Loading will take a minimum of 20 minutes for the smallest beads and up to 120 minutes for the largest beads
- Prior to use, transfer the beads loaded with doxorubicin to a syringe and add an equal volume of non-ionic contrast media. Invert the syringe gently to obtain an even suspension of beads

Note: Beads should only be loaded with doxorubicin HCl; liposomal formulations of doxorubicin are not suitable for loading into beads. A dose of up to 37.5 mg doxorubicin per mL of beads can be loaded. The maximum recommended total dose of doxorubicin per procedure is 150 mg. Beads loaded with doxorubicin may be stored for up to 24 hours at 2°–8°C (35.6°–46.4°F) in the presence or absence of non-ionic contrast media. Two hours of dwell time for 500–700 μmol DEB has been reported to allow for loading of more than 90% of 100 mg doxorubicin in the beads (Lewis AL et al. J Vasc Interv Radiol 2006;17:1335–1343)

TACE Procedure:

- The vascular network associated with the lesion is carefully evaluated using high-resolution imaging prior to beginning the embolization procedure
- **Highly selective catheterization** is performed with a 3-French microcatheter in order to obtain complete obstruction of the nourishing arteries and avoid damage to non-tumoral liver
- Beads are available in a range of sizes and care should be taken to choose the appropriate size of the bead that best matches the pathology (ie, vascular target/vessel size) and provides the desired clinical outcome
- A delivery catheter is chosen based on the size of the target vessel. Beads can tolerate temporary compression of 20–30% in order to facilitate passage through a delivery catheter

(*continued*)

Patient Population Studied

A trial in which 212 patients with Child-Pugh A/B cirrhosis (76% male, 59% HCV) with HCC unsuitable for resection without portal invasion or extra-hepatic spread and less than 50% liver involvement received chemoembolization with doxorubicin loaded DEB at doses adjusted for bilirubin and body surface (range: 47–150 mg). Patients were excluded if they had another primary tumor, advanced liver disease (bilirubin levels >3 mg/dL, AST or ALT >5 × upper limit of normal or >250 U/L), advanced tumoral disease (vascular invasion or extrahepatic spread, or diffuse HCC, defined as >50% liver involvement), or contraindications for doxorubicin administration. In this international, multicenter, prospective, randomized single-blind, phase II study patients were randomized to receive doxorubicin with DC Bead or conventional TACE defined as 50–75 mg/m² doxorubicin emulsified in ethiodized oil followed by particle embolization with an embolic agent of choice

Therapy Monitoring

1. Days 7 and 14 after TACE and then monthly: CBC and LFTs
2. Response assessment using computed tomography (CT) every 3 months

(*continued*)

- The delivery catheter is introduced into the target vessel according to standard techniques. The catheter tip is positioned as close as possible to the treatment site to avoid inadvertent occlusion of normal vessels
- Because the beads are not radiopaque, monitoring the embolization under fluoroscopic visualization necessitates adding contrast medium to the DEB suspension
- Care should be taken to ensure proper suspension of the beads in the contrast medium to enhance distribution during injection
- Beads are drawn into a syringe and slowly injected
- After completion of the treatment, the catheter is removed while maintaining gentle suction so as not to dislodge beads still within the catheter lumen
- The embolization end point will be to achieve complete occlusion of the neovascularity, avoiding, however, complete stasis in the afferent artery, which could lead to endothelial damage and subsequent thrombosis precluding future treatments

Note: Treatment is given at 2-monthly intervals, with a maximum of three chemoembolization (at baseline, 2 months, and 4 months) with a 6-month follow-up

GENERAL GUIDELINES

Prior to embolization:

- **Hydration**
  - Start intravenous **hydration** with 0.9% sodium chloride injection (0.9% NS)
  - Continuous 0.9% NS 100 mL/h beginning a minimum of 6 hours prior to procedure
- **Antibiotic prophylaxis** not always required but may be considered with the first doses given before embolization:
  - **Metronidazole** 500 mg; administer intravenously prior to the procedure followed by **Metronidazole** 500 mg; administer intravenously every 12 hours × 3 doses, *plus*
  - **Cefazolin** 1000 mg; administer intravenously prior to the procedure followed by **Cefazolin** 500 mg; administer intravenously every 8 hours × 5 doses
- **Antiemetic primary prophylaxis**

  Give a serotonin receptor ($5HT_3$) antagonist plus a high-potency glucocorticoid
  - **Ondansetron** 16 mg; administer intravenously *or* 24 mg orally, *plus*
  - **Dexamethasone** 10–12 mg; administer intravenously or orally 30–60 minutes before the procedure

Post-embolization syndrome:

- The triad of abdominal pain, vomiting, and fever that frequently occurs 24–72 hours after chemoembolization is commonly referred to as post-embolization syndrome
- Post-embolization syndrome uniformly responds to supportive care including analgesics and antiemetics
- Use care administering acetaminophen (paracetamol) and non-steroidal anti-inflammatory drugs in patients with liver cirrhosis

After embolization:

- Continue intravenous **hydration** with 0.9% NS or another clinically appropriate fluid until patient resumes adequate oral fluid intake
- Provide **analgesic support** with parenterally administered opioid medications (**morphine, hydromorphone, fentanyl**) after chemoembolization until the patient is able to continue analgesic treatment with oral products
- Continue **antiemetic prophylaxis** with a $5HT_3$ antagonist plus a high-potency glucocorticoid:
  - **Ondansetron** 8 mg; administer intravenously or orally every 8 hours, *plus*
  - **Dexamethasone** 8 mg; administer intravenously or orally every 8 hours for 2–3 days
- **Filgrastim** (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection
  - May be used for patients who develop an ANC $<500/mm^3$, neutropenia and fever, or documented infections during neutropenia
  - Discontinue filgrastim at least 24 hours before a chemoembolization procedure

Efficacy

Response Rates

Tumor Response Rate at 6 Months	DC Bead (N = 93)*	cTACE (N = 108)*
Objective response	48/93 (51.6%)	47/108 (43.5%)
	one-sided P = 0.11†	
Complete response	25/93 (26.9%)	24/108 (22.2%)
Partial response	23/93 (24.7%)	23/108 (21.3%)
Stable disease	11/93 (11.8%)	9/108 (8.3%)
Disease control rate	59/93 (63.4%)	56/108 (51.9%)
	two-sided P = 0.11	
Progressive disease	30/93 (32.3%)	44/108 (40.7%)
Advanced disease patients‡		
Objective response, advanced disease‡	32/61 (52.4%)	25/72 (34.7)
	Chi-square P = 0.038	
Complete response, advanced disease‡	15/61 (24.5%)	10/72 (13.9%)
	Chi-square P = 0.091

REGIMEN

SORAFENIB

Llovet JM et al. N Engl J Med 2008;359:378–90
Cheng et al. Lancet Oncol 2009;10:25–34

Sorafenib 400 mg per dose; administer orally, twice daily, continually (total dose/week = 5600 mg)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential: LOW

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed-onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®)

- Initial adult dose is two tablets four times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as two tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed-onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

Patient Population Studied

Llovet JM et al. N Engl J Med 2008;359:378–390

Multicenter, phase 3, double-blind, placebo-controlled trial. Six hundred two patients with advanced hepatocellular carcinoma who had not previously received systemic treatment were randomly assigned to receive either sorafenib (n = 299) or placebo (n = 303). The study population consisted of patients with advanced-stage hepatocellular carcinoma. Patients were classified as having advanced disease if they were not eligible or had disease progression after surgical or locoregional therapies. Eligibility criteria also included (a) Eastern Cooperative Oncology Group performance status score ≤2; (b) Child-Pugh liver function class A; (c) prothrombin time international normalized ratio ≤2.3 or prothrombin time ≤6 sec greater than control; (d) albumin, ≥2.8 g/dL; (e) total bilirubin ≤3 mg/dL (≤51.3 micromol/L); and (f) alanine aminotransferase and aspartate aminotransferase ≤5 times the upper limit of the normal range

Cheng et al. Lancet Oncol 2009;10:25–34

Patients with advanced (unresectable or metastatic) hepatocellular carcinoma who had not received previous systemic therapy were eligible for this trial. Eligibility criteria also included ECOG PS of 0/1/2; Child-Pugh liver function class A; and a life expectancy ≥12 weeks; albumin concentration of at least 28 g/L; total bilirubin concentration of 51.3 µmol/L or less; alanine aminotransferase concentration of five times the upper limit of normal (ULN) or less. Patients who had received previous local therapy, such as surgery, radiotherapy, hepatic arterial embolization, chemoembolization, radiofrequency ablation, percutaneous injection, or cryoablation, were eligible for enrolment in the study, provided that either the target lesion increased in size by 25% or more, or the target lesion had not been treated with local therapy. Furthermore, the local therapy must have been stopped at least 4 weeks before study entry. Patients with recurrent disease after previous resection were considered eligible for the study. Exclusion criteria included previous or concomitant systemic therapy (including new, molecularly targeted therapies)

*Plus–minus values are means ± SD. None of the differences between the two study groups were significant (P ≥0.05)
†To convert the values for bilirubin to micromoles per liter, multiply by 17.1. BCLC denotes
‡One patient in the sorafenib group had a BCLC score of D and a Child-Pugh class of C
§Patients may have received more than one type of therapy. There was no significant difference between groups in the number of patients who had received previous palliative or curative therapy or previous adjuvant or neoadjuvant therapy (P ≥0.05)
¶Radiotherapy was applied to extrahepatic metastatic lesions in all patients except five in the sorafenib group and three in the placebo group

Dose Modifications

Adverse Event	Dose Modification
G3/4 or persistent G2 drug-related adverse event	Decrease sorafenib to 400 mg daily*
G3/4 or persistent G2 drug-related adverse event on 400 mg daily	Decrease sorafenib to 400 mg every other day
G3/4 or persistent G2 drug-related adverse event on 400 mg every other day	Discontinue sorafenib

*A recent study in patients with thyroid cancer reduced doses initially from 400/400 daily to 400/200 each day before reducing the dose to 400 daily (Brose MS et al. Proc Am Soc Clin Oncol Annual Meeting 2013 [Abstract 4])

Efficacy

Llovet JM et al. N Engl J Med 2008;359:378–390

Outcome	Sorafenib	Placebo	HR/p-value
Median overall survival, months [95% CI]	10.7 months [9.4–13.3]	7.9 months [6.8–9.1]	0.69 (0.55–0.87) <0.001
1-year survival rate	44%	33%	0.009
Time to symptomatic progression*, median [95% CI]	4.1 Months [3.5–4.8]	4.9 months [4.2–6.3]	1.08 (0.88–1.31) 0.77
Time to radiologic progression, median [95% CI]	5.5 months [4.1–6.9]	2.8 months [2.7–3.9]	0.58 (0.45–0.74) <0.001
Level of Response†			
Complete response	0	0	NA
Partial response	2%	1%	0.05
Stable disease	71%	67%	0.17
Disease control rate‡	43%	32%	0

*Symptomatic progression was defined as a decrease of 4 or more points from the baseline score on the Functional Assessment of Cancer Therapy–Hepatobiliary Symptom Index 8 (FHSI8), deterioration to a score of 4 in Eastern Cooperative Group performance status, or death, whichever occurred first
†Response was measured according to RECIST
‡Percentage of patients with CR/PR/SD according to RECIST maintained for 28 days

Therapy Monitoring

At screening and every 6 weeks: Tumor measurements by computed tomography or magnetic resonance imaging

16. HIV-Related Malignancies

Bruce J. Dezube, MD

Kaposi Sarcoma (KS)

Epidemiology of KS

Incidence/100,000	
United States	
Males:	2.1
Females:	0.11
Africa	
Males:	39.3
Females:	21.8

Stage at Presentation in HAART Era (Based on ACTG* Modified TIS Staging)

Poor risk: 25%
Good risk: 75%

*ACTG: AIDS Clinical Trials Group
Deaths caused by AIDS since advent of HAART have decreased by more than 50%

Nasti G et al. J Clin Oncol 2003;21:2876–2882

Pathology

1. All KS is caused by human herpesvirus 8 (HHV-8), also called the Kaposi sarcoma-associated herpesvirus (KSHV), a gamma herpesvirus first identified in 1994
2. Pathology shows a highly vascular tumor with spindle-shaped cells staining positive for KSHV

Moore PS, Chang Y. N Engl J Med 1995;332:1181–1185

Work-up

1. Biopsy to confirm diagnosis
2. HIV serology
3. CD4 and HIV-1 viral load
4. Assessment of tumor extent:
   - Physical examination of the skin and lymph nodes
   - Chest x-ray
   - Chest CT scan not routinely indicated unless x-ray is abnormal
   - For GI symptoms, work-up as indicated
   - Fecal occult blood testing

Di Lorenzo G et al. Lancet Oncol 2007;8:167–176

Staging (Validated ACTG TIS Staging for AIDS-KS)*

Good Risk: Stage 0 (Stage 0: All criteria below must be satisfied)	Poor Risk: Stage 1 (Stage 1: If any of the criteria are present)
Tumor (T)	
Confined to skin and/or lymph nodes	Tumor-associated edema or ulceration Extensive oral KS Gastrointestinal KS KS in other nonnodal viscera
Immune System (I)*	
CD4 cells >150/mm^3	CD4 cells <150/mm^3
Systemic Illness (S)	
• No history of opportunistic infection or thrush	• History of opportunistic infections, thrush, or both
• No B symptoms persisting >2 weeks, including 1. Unexplained fever 2. Night sweats 3. >10% involuntary weight loss 4. Diarrhea	• B symptoms present
• Performance status >70 (Karnofsky scale)	• Performance status <70 (Karnofsky scale) • Other HIV-related illness (eg, neurologic disease, lymphoma)

Staging example:
A patient with KS restricted to the skin, CD4 count of 10 cells/mm^3, and a history of *Pneumocystis jirovecii* (formerly, *P. carinii*) pneumonia would be $T_0\ I_1\ S_1$

*According to the AIDS Clinical Trials Group (ACTG). Staging takes into account tumor extent (T), immune status (I), and systemic illness (S)

Notes:

1. In the HAART era, immune status may not be prognostically predictive. However, in patients with resistant HIV, immune status may be relevant
2. In the HAART era, poor prognosis is T_1S_1. All other stages are considered good prognosis

Krown SE et al. J Clin Oncol 1997;15:3085–3092
Nasti G et al. J Clin Oncol 2003;21:2876–2882

Survival

Stage	3-Year Survival (%)
$T_0\ S_0$	88
$T_1\ S_0$	80
$T_0\ S_1$	81
$T_1\ S_1$	53

Nasti G et al. J Clin Oncol 2003;21:2876–2882

Expert Opinion

Kaposi sarcoma, as an AIDS-presenting manifestation in antiretroviral therapy (ART) naïve patients, often responds to ART. However, not all patients achieve lesion resolution with ART. In addition to ART, radiotherapy or surgery can be used to treat isolated lesions

Systemic chemotherapy may be required if lesions do not regress with primary ART therapy, diffuse involvement of a large portion of an extremity or in widespread, bulky, or rapidly progressive disease with visceral organ involvement. Early systemic chemotherapy may help to suppress or prevent immune reconstitution inflammatory syndrome (IRIS)-associated flares

Despite the lack of randomized trials demonstrating superiority, pegylated liposomal doxorubicin can be used as first-line therapy of choice unless there is a cardiac contraindication. For patients who progressed while receiving pegylated liposomal doxorubicin or for those who do not respond there are several options for second-line therapy including the use of paclitaxel

KS REGIMEN (HIV REGIMENS)

HIGHLY ACTIVE ANTIRETROVIRAL THERAPY (HAART)

HAART should be considered as fundamental oncologic care in patients with AIDS-KS. Unless there is some overwhelming reason not to administer it, HAART should be given in essentially all AIDS-KS patients

Antiretroviral drugs are classified according to the type of compound and the part of the viral life cycle that a drug inhibits. The HAART regimen generally comprises a combination of 3 or more drugs from at least 2 different classes as defined by these criteria. The treatment goal is potent inhibition of HIV replication to levels <50 copies HIV mRNA/μL. HAART should be considered part of the fundamental oncologic therapy for AIDS-KS

Guidelines for the use of antiretroviral therapy can be found at www.aidsinfo.nih.gov (U.S. Department of Health and Human Services)

or

Thompson MA et al. JAMA 2012;308:387–402 (International Antiviral Society-USA panel)

Note: In patients for whom chemotherapy is planned, avoid zidovudine if possible, as it may aggravate myelosuppression

Efficacy

1. For initial therapy of KS, a trial of HAART is reasonable in many cases. Up to 74% of treatment-naïve cases (ie, never previously treated for either HIV or KS) can have a substantial tumor response to HAART
2. Responses may be seen within 3–6 months
3. Patients most likely to respond are those with:
   - Minimal tumor burden
   - HIV viral load suppression to very low levels
   - CD4 cell increases ≥150 cells/mm^3 above pretreatment levels
4. Response durations can be long-lasting, although progressive diseases may occur early
5. Beware of KS flare as a result of immune reconstitution inflammatory syndrome (IRIS). Such flares are treated with chemotherapy

Treatment Modifications

Antiretroviral drugs should be managed by physicians with expertise in the care of patients with HIV disease. Certain drug combinations can be antagonistic and should not be used. Dose modifications must be done with caution because inadequate plasma drug levels increase the potential to develop resistant mutant HIV. At least 3 medications are required for HAART: If toxicity requiring dosing cessation is ascribed to 1 medication, patients should be instructed to stop all medications to avoid resistance

Patient Population Studied

Patients without previous HIV or KS therapy

Therapy Monitoring

1. *Monthly for first 3 months:* Clinical evaluation, assessment of tumor burden, HIV-1 viral loads, immunologic assessment (CD4 cells) CBC with differential, liver function tests, BUN, creatinine, amylase, and lipase
2. *Every 3 months after first 3 months (if clinically improving):* Clinical evaluation, assessment of tumor burden, viral titers, immunologic assessment (CD4 cells), CBC with differential, liver function tests, BUN, creatinine, amylase, and lipase

KS REGIMEN

LOCAL THERAPY: RADIATION THERAPY, INTRALESIONAL THERAPY, CRYOTHERAPY (LIQUID NITROGEN, ALITRETINOIN GEL (TOPICAL ALL-*TRANS*-RETINOIC ACID)), PHOTODYNAMIC THERAPY

Von Roenn JH. Hematol Oncol Clin North Am 2003;17:747–762
Ramirez-Amador et al. Oral Oncol 2002;38:460–467

Important to administer HAART to all patients

Radiation therapy:
Dosing varies; radiation therapy may be more toxic in HIV patients

Intralesional therapy:
Vinblastine 0.1 mL of 0.1 mg/mL (or 0.2 mg/mL per 1 cm^2 of lesion surface area); administer intralesionally every 1–2 weeks,

or

3% Sodium tetradecyl sulfate (Sotradecol) injection 0.1–0.3 mL; administer intralesionally every 1–2 weeks

Cryotherapy (liquid nitrogen):
Liquid nitrogen is effective for treatment of small cosmetically disturbing lesions, particularly in the face. Liquid nitrogen is applied to the lesion to achieve a thaw time of approximately 40 seconds. High response rates lasting from 6 weeks to 6 months have been reported. Treatment-related hypopigmentation may be cosmetically unacceptable, particularly in dark-skinned patients

Alitretinoin gel:
Alitretinoin 0.1% gel; apply topically to affected areas 3–5 times per day; avoid application to normal skin and mucosal surfaces

Supportive Care (for therapy listed above):
Antiemetic prophylaxis
Emetogenic potential: ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Photodynamic therapy:
Photodynamic therapy utilizes the activation by light of a photosensitizing drug that preferentially accumulates in tumor tissue, such as Kaposi sarcoma. Drugs that have been used include **porfimer sodium** (Photofrin) and **thiazine compounds** (methylene blue and toluidine blue)

Note: Limited role for surgical resection

Toxicity

Radiation therapy:
Burning sensation during treatment; chronic lymphedema

Intralesional injections:
Painful

Cryotherapy:
Avoid in dark-skinned patients; permanently destroys melanocytes, leaving a white spot

Alitretinoin gel:
Can cause local irritation

Photodynamic therapy:
Erythema and edema in the treatment field

Patient Population Studied

Most studies were conducted before the widespread use of HAART in patients with minimal disease

Efficacy

1. Rarely useful except with limited disease
2. Local recurrence is common
3. Patients who benefit favorably from HAART may have better long-term outcome in terms of tumor recurrence
4. Patients who derive no benefit from HAART are likely to have new tumors or recurrent tumors relatively quickly in the treatment fields

Radiation therapy:
For limited disease, can be effective

Intralesional injections:
Useful for small lesions of cosmetic import. Not feasible for multiple lesions

Cryotherapy:
Not feasible for multiple lesions

Alitretinoin gel:
Reported response rate up to 40%
May be most useful for patients with minimal disease

Photodynamic therapy:
Effective palliative treatment for limited disease

Treatment Modifications

1. HIV infection may render certain tissues more vulnerable to toxic effects of radiation
2. Radiation therapy of oral disease should be reserved for symptomatic oral KS because of the high incidence of radiation-induced mucositis

Therapy Monitoring

Monitor for efficacy; no specific monitoring required

KS REGIMEN

DAUNORUBICIN CITRATE LIPOSOME INJECTION (LIPOSOMAL DAUNORUBICIN)

Gill PS et al. J Clin Oncol 1996;14:2353–2364

Important to administer HAART to all patients

Daunorubicin citrate liposome injection 40 mg/m²; administer intravenously in a volume of 5% dextrose injection equivalent to the volume of liposomal daunorubicin over 60 minutes every 2 weeks (total dosage/cycle = 40 mg/m²)

Ancillary medications: Secondary prophylaxis for neutropenia at discretion of investigator

Pegfilgrastim 6 mg; administer subcutaneously starting 24–48 hours after chemotherapy is completed. Most patients do not require growth factor support (eg, pegfilgrastim). Filgrastim may be used as an alternative

Supportive Care

Antiemetic prophylaxis

Emetogenic potential: LOW

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Advanced AIDS-KS pre-HAART. A prospective randomized phase III trial of 232 patients randomly assigned to receive liposomal daunorubicin 40 mg/m² or a combination chemotherapy regimen of doxorubicin 10 mg/m², bleomycin 15 units, and vincristine 1 mg (ABV). Both regimens were administered every 2 weeks

Efficacy (N = 116)

Complete response	2.6%
Partial response	22.4%
Median response duration	175 days
Median survival	369 days

Treatment Modifications

Treatment proceeds as planned if pretreatment ANC is ≥750/mm³ and platelet count ≥75,000/mm³

Adverse Event	Dose Modification
ANC ≤750/mm³	Delay liposomal daunorubicin until ANC recovery above this level Consider adding pegfilgrastim during subsequent cycles
Cardiac toxicity (≥20% reduction in ejection fraction)	Discontinue therapy
Pulmonary toxicity	Discontinue therapy
Liver dysfunction*	Dosage modifications indicated, but not specified

*DaunoXome (daunorubicin citrate liposome injection) labeling indicates dose modifications for increased bilirubin, but some protease inhibitors (eg, indinavir, atazanavir) cause mild hyperbilirubinemia; dose adjustment may not be required in this setting

Toxicity (N = 116)

	% G1/2	% G3/4
Hematologic*		
Neutropenia	12/55	36/15
Leukopenia	12/79	33/5
Thrombocytopenia	93/12	0/1
Anemia	62/55	9/2
Nonhematologic		
Fatigue	43	6
Fever	42	5
Diarrhea	34	4
Nausea	51	3
Vomiting	20	3
Abdominal pain	20	3
Dyspnea	23	3
Headache	22	3
Anorexia	21	2
Cough	26	2
Neuropathy	12	1
Alopecia	8	
Back pain/flushing/chest tightness	14	
Reduced ejection fraction†	0	

*Some patients experienced toxicity on ≥1 cycle
†Occurred within 5 minutes of infusion; subsided if discontinued; did not recur if resumed at slower rate

Therapy Monitoring

1. *Before therapy:* CBC with differential, LFTs, BUN, serum creatinine, and ejection fraction
2. *Before each cycle:* CBC with differential LFTs. BUN and serum creatinine
3. *Cumulative daunorubicin or doxorubicin dosage ≥ 500 mg/m²:* Ejection fraction

Notes

1. Trial conducted in the pre-HAART era. Of patients, 95% received antiretroviral drugs as monotherapy or 2 drugs concurrent with liposomal daunorubicin
2. Chronic therapy may be required; patients responding to HAART may have long-term progression-free survival and require fewer (eg, 4–6) cycles of chemotherapy

KS REGIMEN

DOXORUBICIN HCl LIPOSOME INJECTION (LIPOSOMAL DOXORUBICIN)

Northfelt DW et al. J Clin Oncol 1998;16:2445–2451

Important to administer HAART to all patients

Doxorubicin HCl liposome injection 20 mg/m^2; administer intravenously in 250 mL 5% dextrose injection over 60 minutes every 3 weeks (total dosage/cycle = 20 mg/m^2)

Premedication: Generally not required

Supportive Care

Antiemetic prophylaxis

Emetogenic potential: ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated with 1 of the following:

Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*

Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose

- Begin use from 24--72 hours after myelosuppressive chemotherapy is completed
- Most patients do not require growth factor support

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Hand-foot reaction (palmar-plantar erythrodysesthesia, PPE)

For patients who develop a hand-foot reaction, use topical emollients (eg, Aquaphor®), topical or orally administered steroids, antihistamine agents (H_1-receptor antagonists), or pyridoxine

Pyridoxine may provide relief for discomfort/pain associated with PPE although the mechanism through which this occurs remains unclear

- The suggested pyridoxine starting dose is 50 mg/day, which may be increased to a maximum of 200 mg/day
- Patients who develop G1/2 PPE while receiving doxorubicin HCl liposome injection may receive a fixed daily dose of pyridoxine 200 mg. This may allow for treatment to be completed without dosage reduction, treatment delay, or recurrence of PPE

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

(*continued*)

Patient Population Studied

A trial of 258 patients pre-HAART with advanced AIDS-KS randomly assigned to either pegylated-liposomal doxorubicin 20 mg/m^2 or a doxorubicin, bleomycin, and vincristine (ABV) regimen. Both regimens were administered every 14 days for 6 cycles

Efficacy* (N = 133)

Complete response	0.8%
Partial response	45.1%
• Flattening of lesions	37%
• Decreased sum of products of largest perpendicular diameters	6%
• Reduced number and flattening of lesions	1%
• Reduced size and flattening of lesions	1%
Median response duration	90 days
Median survival	160 days

*Modified AIDS Clinical Trials Group

Treatment Modifications

Adverse Event	Dose Modification
G3 toxicity other than granulocytopenia	Delay treatment for up to 14 days
ANC <750/mm^3 on cycle day 1	Delay treatment until ANC recovers
Palmar-plantar erythrodysesthesia	Delay treatment. May require dosage reductions

Although Doxil (doxorubicin HCl liposome injection) product labeling indicates dose modifications for increased bilirubin, some protease inhibitors (eg, indinavir, atazanavir) cause a mild hyperbilirubinemia, in which cases, dose adjustment may not be necessary

(*continued*)

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque
- Advise patients who develop mucositis to:
  - Choose foods that are easy to chew and swallow
  - Take small bites of food, chew slowly, and sip liquids with meals
  - Encourage soft, moist foods such as cooked cereals, mashed potatoes, and scrambled eggs
  - For trouble swallowing, soften food with gravies, sauces, broths, yogurt, or other bland liquids
  - Avoid sharp, crunchy foods; hot, spicy or highly acidic foods (eg, citrus fruits and juices); sugary foods; toothpicks; tobacco products; alcoholic drinks

Toxicity (N = 133)*,†

	% G3/4
At least one G3/4 toxicity	92
Hematologic

*WHO Criteria
†Percent of patients experiencing G3/4 toxicity
‡44% received G-CSF or GM-CSF
§Flushing, chest pain, dyspnea, difficulty swallowing, hypotension, back pain
¶One death because of cardiomyopathy

Therapy Monitoring

1. *Before therapy:* CBC with differential, LFTs, BUN and serum creatinine, and cardiac ejection fraction
2. *Before each cycle:* CBC with differential, LFTs, BUN, serum creatinine, and response assessment
3. *Cumulative daunorubicin or doxorubicin dosage ≥500 mg/m²:* Ejection fraction

Notes

1. Trial conducted in the pre-HAART era
2. Chronic therapy may be required; patients responding to HAART may have long-term progression-free survival and require fewer (eg, 4–6 cycles) of chemotherapy

REGIMEN

PACLITAXEL (TAXOL)

Gill PS et al. J Clin Oncol 1999;17:1876–1883
Saville MW et al. Lancet 1995;346:26–28

Important to administer HAART to all patients

Premedication: Primary prophylaxis against hypersensitivity reactions from paclitaxel:
Dexamethasone 20 mg; administer intravenously prior to paclitaxel (reduce to 8 mg if no hypersensitivity reactions occur during cycle 1), *plus:*
Diphenhydramine 50 mg; administer by intravenous injection 30 minutes before paclitaxel, *and:*
Ranitidine 50 mg or an equivalent dose of an alternative histamine (H_2) receptor antagonist; administer intravenously in 25–100 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 5–30 minutes, 30 minutes before paclitaxel
Paclitaxel 135 mg/m^2; administer intravenously, in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range of 0.3–1.2 mg/mL, over 3 hours every 21 days (total dosage/cycle = 135 mg/m^2)

or

Premedication: Primary prophylaxis against hypersensitivity reactions from paclitaxel:
Dexamethasone 10 mg/dose for 2 doses; administer orally, 14 and 7 hours prior to paclitaxel, *plus*
Diphenhydramine 50 mg; administer by intravenous injection 30 minutes before paclitaxel, *and:*
Ranitidine 50 mg; administer intravenously in 25–100 mL 0.9% sodium chloride injection or 5% dextrose injection over 5–30 minutes, 30 minutes before paclitaxel
Paclitaxel 100 mg/m^2; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range of 0.3–1.2 mg/mL, over 3 hours every 21 days (total dosage/cycle = 100 mg/m^2)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential: ***MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated with 1 of the following:

Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose

- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Most patients do not require growth factor support

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of herpes simplex virus

See Chapter 47 for more information

Oral care

Prophylaxis and treatment for mucositis/stomatitis

General advice:

- Encourage patients to maintain intake of non-alcoholic fluids
- Evaluate patients for oral pain and provide analgesic medications
- Consider histamine (H_2-subtype) receptor antagonists (eg, ranitidine, famotidine), or a proton pump inhibitor for epigastric pain
- *Lactobacillus* sp.-containing probiotics may be beneficial in preventing diarrhea

Patients with intact oral mucosa:

- Clean the mouth, tongue, and gums by brushing after every meal and at bedtime with an ultra-soft toothbrush with fluoride toothpaste
- Floss teeth gently every day unless contraindicated. If gums bleed and hurt, avoid bleeding or sore areas, but floss other teeth
- Patients may use saline or commercial bland, non-alcoholic rinses
  - Do not use mouthwashes that contain alcohols

(*continued*)

Patient Population Studied

Data from phase-II trials with advanced KS in highly immunosuppressed patients treated pre-HAART

Efficacy

Objective responses (Saville et al.)	71%
Objective responses (Gill et al.)	59%
Median response duration (Saville et al.)	2.5 months
Median duration of response (Gill et al.)	10.4 months

Treatment Modifications

Adverse Event	Dose Modification
G4 hematologic toxicity	Decrease paclitaxel dosage by 25%

Saville MW et al. Lancet 1995;346:26–28

Adverse Event	Dose Modification
Cycle, day 1 ANC <1000/mm^3, or platelet count <50,000/mm^3	Delay treatment until ANC >1000/mm^3, and platelet count >50,000/mm^3
ANC <500/mm^3 for 7 days	Reduce paclitaxel dosage by 20%
G1/2 peripheral neuropathy*	Reduce paclitaxel dosage by 20%
G3/4 peripheral neuropathy*	Discontinue therapy
Total bilirubin >3.0 mg/dL (>51.3 μmol/L)	Delay treatment until bilirubin <3.0 mg/dL (<51.3 μmol/L), then reduce dosage by 20%
Liver transaminases >5 times the upper limit of normal range	Delay treatment until liver transaminases <3 times the upper limit of normal, then reduce dosage by 20%

*Increased neuropathy reported when using stavudine

Gill PS et al. J Clin Oncol 1999;17:1876–1883

(*continued*)

If mucositis or stomatitis is present:

- Keep the mouth moist utilizing water, ice chips, sugarless gum, sugar-free hard candies, or a saliva substitute
- Rinse mouth several times a day to remove debris
  - Use a solution of ¼ teaspoon (1.25 g) each of baking soda and table salt (sodium chloride) in one quart (~950 mL) of warm water. Follow with a plain water rinse
  - Do not use mouthwashes that contain alcohols
- Foam-tipped swabs (eg, Toothettes®) are useful in moisturizing oral mucosa, but ineffective for cleansing teeth and removing plaque

Gill PS et al. J Clin Oncol 1999;17:1876–1883 (N = 56) (Southwest Oncology Group Toxicity Criteria)
Welles L et al. J Clin Oncol 1998;16:1112–1121

Therapy Monitoring

Before each cycle: CBC with differential, LFTs, BUN, serum creatinine, and physical examination with careful attention to peripheral nerves

Notes

1. Chronic therapy may be required
2. Active in patients who did not benefit from other therapies

KS REGIMEN

INTERFERON ALFA-2B

Krown SE. Curr Opin Oncol 2001;13:374–381
Krown SE et al. J Interferon Cytokine Res 2002;22:295–303
Von Roenn JH. Hematol Oncol Clin North Am 2003;17:747–762

Important to administer HAART to all patients

Premedications:

1. Primary antipyretic prophylaxis:
   Acetaminophen 650–1000 mg; administer orally,
   or
   Ibuprofen 400–600 mg; administer orally starting 1 hour before interferon, then every 4–6 hours as needed
2. Secondary antiemetic prophylaxis:
   If required for treating emetic symptoms, use as primary prophylaxis with subsequent interferon doses.
   See Chapter 39 for antiemetic recommendations

Low dose: **Interferon alfa-2b** 1 million IU once daily; administer subcutaneously or intramuscularly with antiretroviral therapy

Intermediate dose: **Interferon alfa-2b** 10 million IU once daily; administer subcutaneously or intramuscularly with antiretroviral therapy

Supportive Care

Antiemetic prophylaxis

Emetogenic potential: ***MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
G ≤2 constitutional symptoms	Administer analgesics, antihistamines, antiemetics, antidiarrheal agents, and other supportive measures, including hematopoietic growth factors
G3 constitutional and CNS toxicities; elevations in AST, and thrombocytopenia	Interrupt interferon alfa-2b dosing
G2 cardiac toxicity, stomatitis, and renal, bladder, pulmonary, allergic, or mucocutaneous toxicities	Interrupt interferon alfa-2b dosing
Recurrent toxicities or development of major opportunistic infection after dosage reduction	Discontinue interferon alfa-2b administration

Patient Population Studied

Patients with HIV-related KS

Efficacy

- Response rates to interferon as a single agent vary from 20% to 60%
- Multiple studies combining interferon and zidovudine reported response rates of 40% or higher

	Low-Dose Group*	Intermediate-Dose Group†
CR/CCR/PR‡	40%	55%
Complete response‡	3%	9%
Clinical Complete response‡	11%	12%
Partial response‡	26%	33%
Stable disease	37%	27%
Progressive disease	17%	3%
Not evaluable	5%	15%
Median time to response	24.6 weeks	40 weeks
Estimated median response duration	110 weeks	110 weeks

*Interferon alfa-2b 1 million IU once daily; administer by subcutaneous injection with didanosine 125–200 mg administer orally every 12 hours
†Interferon alfa-2b 10 million IU once daily; administer by subcutaneous injection with didanosine 125–200 mg administer orally every 12 hours
‡CR, no residual lesion, confirmed by biopsy; CCR, no residual lesion without biopsy confirmation; PR, 50% reduction in size, number or nodularity of cutaneous lesions, or complete resolution of cutaneous lesions with persistent tumor-associated edema

Krown SE et al. J Interferon Cytokine Res 2002;22:295–303

Toxicity

Low-dose group: 35 patients treated with interferon alfa-2b 1 million units; administer subcutaneously or intramuscularly once daily with didanosine* 125–200 mg orally every 12 hours

Intermediate-dose group: 33 patients treated with interferon alfa-2b 10 million units; administer subcutaneously or intramuscularly once daily with didanosine* 125–200 mg orally every 12 hours

*125 mg if weight <60 kg; 200 mg if weight ≥60 kg. Other antiretroviral therapies were subsequently substituted for or added to didanosine

	Low-Dose Group*	Intermediate-Dose Group†
	% G3/4	% G3/4
Neutropenia	3	21
Hyperamylasemia‡	9	18
Anemia	<10	<10
Thrombocytopenia	<10	<10
Elevated LFT	<10	<10
Hypertriglyceridemia	<10	<10

*Interferon alfa-2b 1 million IU, subcutaneously or intramuscularly once daily with didanosine 125–200 mg, orally every 12 hours
†Interferon alfa-2b 10 million IU, subcutaneously or intramuscularly once daily with didanosine 125–200 mg, orally every 12 hours
‡Difference between low and intermediate doses is significant

Notes:

- Grades 2/3 chills, fatigue, and fever occurred significantly more often in the intermediate-dose group than in the low-dose group
- Additional adverse events included cough, dyspnea, headache, anorexia, myalgias, and rash
- The majority of treatment withdrawals occur in the first 4 months of treatment, after which discontinuation of therapy because of toxicity is unusual

Krown SE et al. J Interferon Cytokine Res 2002;22:295–303

Therapy Monitoring

1. *Every 2 weeks initially, then once per month:* CBC with differential and serum electrolytes, BUN, creatinine, LFTs, and mineral panel
2. *Response evaluation:* Patients are evaluated for response every 4–8 weeks

Notes

1. In the era of HAART and with the advent of liposomal chemotherapy (Doxil, DaunoXome), interferon alfa has a very limited role in KS management
2. Combine interferon alfa-2b with HAART for best outcome
3. Patients with CD4 counts ≥200/mm^3 have better responses than those whose CD4 counts are <200/mm^3
4. High interferon alfa-2b doses may be associated with better efficacy, but because of the complexity of interactions regarding the status of underlying HIV disease and response potential, not all patients require high doses

HIV-Related Lymphoma (ARL)

Epidemiology

Incidence

- 43 cases/10,000 person-years in HIV-positive individuals
- Approximately 3% of HIV-infected patients develop ARL as the AIDS-defining diagnosis
- 10–15% of patients with AIDS develop ARL
- Since the advent of HAART, ARL has decreased by 50% owing to CD4 cell preservation; however, incidence within CD4 strata has not been changed by HAART

Stage at presentation

- More than 60% have advanced stages III–IV disease with B-cell symptoms
- Extranodal involvement common
- Among HIV-infected patients with non-Hodgkin lymphoma (NHL), 80% of NHL are aggressive; by comparison, 30% of non–HIV-associated lymphomas are aggressive

Besson C et al. Blood 2001;98:2339–2344

Pathology

Distribution of histologic subtypes tracks with CD4 cells and has been influenced by HAART-induced immune preservation. Specifically, since HAART, fewer immunoblastic subtypes are seen

1. Diffuse large B-cell lymphoma (DLBCL): 70%
   - Centroblastic: 20–30% associated with Epstein-Barr virus (EBV)
   - Immunoblastic: 80% associated with EBV
   - Primary central nervous system lymphoma: 100% associated with EBV
2. Burkitt lymphoma: 20%
   - 0–50% associated with EBV
3. Other (eg, primary effusion lymphoma [PEL], plasmablastic lymphoma [PBL], often of the oral cavity): 10%
   - 70% associated with EBV

Jaffe ES, Harris NL, Stein H, Vardiman JW. World Health Organization Classification of Tumors: Pathology & Genetics: Tumors of Haematopoietic and Lymphoid Tissues. Lyon, France: IARC Press, 2001:351

Work-up

1. Assessment of hematologic and biochemical parameters
2. CT scans of chest, abdomen, and pelvis
3. Bone marrow biopsy
4. Lumbar puncture for cytology and cell count
5. CD4 cell count
6. FDG-PET scans are very useful, if available

If primary brain lymphoma is suspected:

1. Brain biopsy is the gold standard
2. Must rule out peripheral disease
3. Slit-lamp exam of optic nerve
4. Minimally invasive diagnosis combining FDG-PET (or SPECT) with assessment of EBV presence in the CSF by polymerase chain reaction can be used in some cases rather than biopsy
   - If both tests are positive: 100% positive predictive value for primary brain lymphoma
   - If both tests are negative: 100% negative predictive value for brain lymphoma
   - If these tests are discordant: Biopsy is required to establish the diagnosis

Antinori A et al. J Clin Oncol 1999;17:554–560
Levine AM. Semin Oncol 1990;17:104–112

Staging

Ann Arbor Staging System for Lymphomas

Stage	Description
I	Single lymph node region
IE	Single extralymphatic organ or site
II	Two or more lymph node regions on the same side of the diaphragm
IIE	Single extranodal site + adjacent nodes
III	Nodal regions on both sides of the diaphragm (III)
IIIE	Nodal regions on both sides of the diaphragm + single extranodal site
IIIS	Nodal regions on both sides of the diaphragm + involvement of spleen
IIISE	Nodal regions on both sides of the diaphragm + single extranodal site + involvement of spleen
IV	Diffuse or disseminated involvement of one or more extralymphatic organs Bone marrow involvement Liver involvement Brain involvement

Absence of associated symptoms is designated A
Presence of symptoms is designated B. B symptoms include unexplained fevers, >10% unexplained weight loss, sweats

Survival

Overall survival is generally poor in most reports, but has improved since the advent of HAART:

1. *Diffuse large B-cell lymphoma (DLCBL):*
   - Pre-HAART 4–18 months
   - Since HAART 21 months
   - Recent phase II trial of dose-adjusted (DA)-EPOCH demonstrated survival equivalent to non-AIDS, bcl-2–negative DLBCL
2. *PEL:* Median survival approximately 4–6 months with therapy
3. *PBL:* Initial reports suggested poor survival as a result of low CR, but clinical heterogeneity of these cases is becoming more evident, and some may have favorable outcome
4. CD4 cell count is the primary prognostic determinant

Besson C et al. Blood 2001;98:2339–2344
Castillo J et al. Am J Hematol 2008;83:804–809

REGIMEN

ETOPOSIDE + PREDNISONE + VINCRISTINE + CYCLOPHOSPHAMIDE + DOXORUBICIN ± RITUXIMAB (DOSE-ADJUSTED EPOCH ± R: DA-EPOCH ± R)

Little RF et al. Blood 2003;101:4653–4659

Important Note: **Most specialists recommend continuing HAART for patients already on a stable regimen. However, in some centers, HAART is suspended until all cycles are completed, and then optimized on/after day 6 of final cycle**

Premedication for Rituximab—All Cycles
Acetaminophen 650 mg; administer orally 30–60 minutes before starting rituximab, *plus*
Diphenhydramine 25 mg; administer intravenously 30–60 minutes before starting rituximab

Rituximab 375 mg/m^2; administer intravenously in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W), diluted to a concentration within the range 1–4 mg/mL, day 1 every 21 days for a maximum of 6 cycles (total dosage/cycle = 375 mg/m^2)

Note: Caution is advised particularly if patient's CD4 count is <50/mm^3

Rituximab administration:
- Infuse initially at 50 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/hour every 30 minutes as tolerated to a maximum rate of 400 mg/hour. During subsequent treatments if previous rituximab administration was well tolerated, start at 100 mg/hour and increase by 100 mg/hour every 30 minutes as tolerated to a maximum rate of 400 mg/hour

Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate

Etoposide 50 mg/m^2 per day; administer by continuous intravenous infusion over 24 hours,* for 4 consecutive days, on days 1–4, every 21 days, for a maximum of 6 cycles (total dosage/cycle = 200 mg/m^2)

Doxorubicin 10 mg/m^2 per day; administer by continuous intravenous infusion over 24 hours,* for 4 consecutive days, on days 1–4, every 21 days, for a maximum of 6 cycles (total dosage/cycle = 40 mg/m^2)

Vincristine 0.4 mg/m^2 per day; administer by continuous intravenous infusion over 24 hours,* for 4 consecutive days, on days 1–4, every 21 days, for a maximum of 6 cycles (total dosage/cycle = 1.6 mg/m^2)

**Note:* See Special Instructions below for preparing a 3-in-1 admixture with etoposide, doxorubicin, and vincristine

Prednisone 60 mg/m^2 per day; administer orally for 5 consecutive days, on days 1–5 every 21 days for a maximum of 6 cycles (total dosage/cycle = 300 mg/m^2)

Cyclophosphamide; administer intravenously in 100 mL 0.9% NS or D5W over 30 minutes on day 5 after completing etoposide + doxorubicin + vincristine administration, every 21 days for a maximum of 6 cycles (total initial dosage/cycle = 187–375 mg/m^2)

Note: Baseline CD4+ lymphocyte count determines cycle 1 cyclophosphamide dosage

Baseline CD4 + Count	Cyclophosphamide Dosage
<100/mm^3	187 mg/m^2
≥100/mm^3	375 mg/m^2

Note: After cycle 1, cyclophosphamide dosage is increased or decreased in increments of 187 mg/m^2 (to a maximum 750 mg/m^2) to achieve an ANC nadir of ≅500/mm^3

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
ANC nadir during previous cycle ≥500/mm^3	Increase cyclophosphamide dosage in increments of 187 mg/m^2 per cycle to a maximum of 750 mg/m^2 per cycle
ANC nadir during previous cycle <500/mm^3	Reduce cyclophosphamide dosage by 187 mg/m^2
Platelet count nadir during previous cycle <25,000/mm^3	Reduce cyclophosphamide dosage by 187 mg/m^2

Patient Population Studied

Phase II trial of 39 patients with previously untreated ARL. Median CD4 cells/mm^3: 198 (range: 3–1182). Median potential follow-up of 53 months

Efficacy (without Rituximab)

Complete response	74%
Partial response	13%
Complete response (CD4+ cells >100/mm^3)	87%
Complete response (CD4+ cells ≤100/mm^3)	56%
At 53 Months' Potential Follow-up	
Disease-free survival of patients achieving a CR	92%
Overall survival	60%
Overall survival (CD4+ cells >100/mm^3)	87%
Overall survival (CD4+ cells ≤100/mm^3)	16%

(continued)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on Days 1–4 is ***MINIMAL***

Emetogenic potential on Day 5 is ***MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with one of the following:

Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection, or
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL, by subcutaneous injection for one dose

- Begin use from 24–72 h after myelosuppressive chemotherapy is completed
- Continue daily Filgrastim use until ANC ≥5000/mm^3 after the leukocyte nadir
- Discontinue daily Filgrastim use at least 24 hours before administering myelosuppressive treatment. Do not administer Pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider concomitant use of cotrimoxazole during periods of neutropenia, and in anticipation of mucositis
- Antiviral—anti-herpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Additional prophylaxis

Add a **proton pump inhibitor** during prednisone use to prevent gastritis and duodenitis
Give **stool softeners and/or laxatives** during and after vincristine administration

CNS therapy

CNS prophylaxis:

Cytarabine 50 mg per dose; administer intrathecally in a volume of **preservative-free** 0.9% sodium chloride injection equivalent to the amount of CSF removed (eg, 3–10 mL) via lumbar puncture, intraventricular catheter or reservoir (eg, Ommaya) once weekly for 4 consecutive weeks (total dose/4-week course = 200 mg)

or

Methotrexate 12 mg per dose; administer intrathecally in a volume of **preservative-free** 0.9% sodium chloride injection equivalent to the amount of CSF removed via lumbar puncture, intraventricular catheter, or reservoir on days 1 and 5, every 21 days, during cycles 3, 4, 5, and 6 (total dose/cycle = 24 mg)

CNS treatment (confirmed CNS disease)*:

Methotrexate 6 mg per dose, *plus*
Cytarabine 30 mg per dose, *plus*
Hydrocortisone 15 mg per dose

Induction: All 3 drugs are given together twice weekly for at least 4 consecutive weeks, or for 2 weeks after CSF specimens show no evidence of lymphoma. Administer intrathecally in a volume of **preservative-free** 0.9% sodium chloride injection equivalent to the amount of CSF removed via lumbar puncture, intraventricular catheter, or reservoir. Total doses/week: **methotrexate** = 12 mg; **cytarabine** = 60 mg; **hydrocortisone** = 30 mg

Consolidation: All 3 drugs are given together once weekly for 6 weeks. Administer intrathecally in a volume of **preservative-free** 0.9% sodium chloride injection equivalent to the amount of CSF removed via intraventricular catheter or reservoir. Total doses/week: **methotrexate** = 6 mg; **cytarabine** = 30 mg; **hydrocortisone** = 15 mg

Maintenance: All 3 drugs are given together, once monthly for 6 months. Administer intrathecally in a volume of **preservative-free** 0.9% sodium chloride injection equivalent to the amount of CSF removed. Total doses/month: **methotrexate** = 6 mg; **cytarabine** = 30 mg; **hydrocortisone** = 15 mg

**Note:* Monotherapy with methotrexate or cytarabine may be feasible in patients with sensitive disease

(continued)

Toxicity*† (N = 209 Cycles/39 Patients)

	% of Cycles
Hematologic	
G4 neutropenia (ANC <500/mm^3)	30‡
Febrile neutropenia	13
G3/4 anemia	17
G3/4 thrombocytopenia	21
Nonhematologic	
G3/4 constipation	3
G3/4 stomatitis	3
G3 neuropathy	2 patients

*ECOG criteria
†Despite filgrastim 5 mcg/kg per day

Therapy Monitoring

1. *Day 1 each cycle:* CBC with differential count, LFTs, BUN, and serum creatinine
2. *Twice-weekly during chemotherapy*: CBC with differential
3. *Cycle 4 and at end of cycle 6:* CD4+ cell count (modify prophylaxis or therapy for opportunistic infections in response to findings)
4. *After cycles 4 and 6:* Tumor restaging
5. *End of cycle 6:* Viral load
6. *Every 3 months thereafter:* CD4+ cell count and viral load as baseline to starting/resuming HAART

Note

Carriers of hepatitis B receiving rituximab should be monitored closely for clinical and laboratory signs of active HBV infection and for signs of hepatitis during and for up to several months following rituximab therapy

(*continued*)

***CNS treatment (confirmed CNS disease)*:**
Cytarabine liposome injection (DepoCyt) may be given as an alternative. The advantage of DepoCyt is that less frequent administrations are necessary

Induction: Cytarabine liposome injection 50 mg; administer intrathecally (intraventricular or lumbar puncture) every 14 days for 2 doses (weeks 1 and 3)

Consolidation therapy: Cytarabine liposome injection 50 mg; administer intrathecally (intraventricular or lumbar puncture) every 14 days for 3 doses (weeks 5, 7, and 9) followed by 1 additional dose at week 13

Maintenance: Cytarabine liposome injection 50 mg; administer intrathecally every 28 days for 4 doses (weeks 17, 21, 25, and 29)

Patients should receive **dexamethasone** 4 mg twice daily; administer either orally or intravenously, for 5 consecutive days, beginning on the day of cytarabine liposome injection

- DepoCyt product labeling includes a **Boxed Warning** indicating chemical arachnoiditis occurs commonly in association with DepoCyt use, characterized by nausea, vomiting, headache, and fever
- If left untreated, chemical arachnoiditis may be fatal
- The incidence and severity of chemical arachnoiditis symptoms can be reduced by a brief course of dexamethasone begun at the time DepoCyt is administered

Special Instructions

General instructions:
To prepare a 3-in-1 admixture with etoposide + doxorubicin + vincristine, dilute all 3 drug products in 0.9% sodium chloride injection (0.9% NS) as follows:

Total Dose of Etoposide	Volume of 0.9% NS
≤130 mg	500 mL
>130 mg	1000 mL

Etoposide (base) + doxorubicin + vincristine 3-in-1 admixtures:
Etoposide 50 mg/m², doxorubicin hydrochloride 10 mg/m², and vincristine sulfate 0.4 mg/m² admixtures diluted in 0.9% NS to produce a final etoposide concentration <250 mcg/mL, in polyolefin-lined infusion bags are stable and compatible for 72 hours at 23°–25°C (73.4°–77°F), and at 31°–33°C (87.8°–91.4°F) when protected from exposure to light

Wolfe JL et al. Am J Health Syst Pharm 1999;56:985–989

Etoposide Phosphate + doxorubicin + vincristine 3-in-1 admixtures:
Etoposide phosphate, doxorubicin hydrochloride, and vincristine sulfate admixtures diluted in 0.9% NS, to produce a final etoposide concentration <250 mcg/mL in polyolefin-lined infusion bags are stable and compatible for up to 124 hours at 2°–6°C (35.6°–42.8°F) and 35°–40°C (95°–104°F) in the dark and under fluorescent light. In admixtures stored at 35°–40°C (95°–104°F) and exposed to light, the initial drug concentrations decreased slightly, but remain within acceptable concentrations

Yuan P et al. Am J Health Syst Pharm 2001;58:594–598

A 3-in-1 admixture does not prevent microbial growth after exposure to bacterial and fungal contamination. With respect to product sterility, expiration dating should be determined by the aseptic techniques used in preparation and local and national guidelines

REGIMEN

CYCLOPHOSPHAMIDE + DOXORUBICIN + VINCRISTINE + PREDNISONE (CHOP) ± RITUXIMAB (CHOP ± RITUXIMAB)

Kaplan DL et al. Blood 2005;106:1538–1543

Important to note that most specialists recommend continuing HAART for patients already on a stable regimen. However, in some centers, HAART is suspended until all cycles are completed and then optimized on/after day 6 of final cycle

Rituximab premedication

Acetaminophen 650 mg; administer orally 30 minutes before rituximab

Diphenhydramine 50 mg; administer by intravenous injection 30 minutes before rituximab

Rituximab 375 mg/m^2; administer intravenously in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W), diluted to a concentration within the range 1–4 mg/mL, on day 1, every 21 days, for a maximum of 6 cycles (total dosage/cycle = 375 mg/m^2)

Note: Caution is advised particularly if a patient's CD4+ cell count is <50/mm^3

Notes on rituximab administration:

- Infuse initially at 50 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/hour every 30 minutes as tolerated to a maximum rate of 400 mg/hour. During subsequent treatments, if previous rituximab administration was well tolerated, start at 100 mg/hour and increase by 100 mg/hour every 30 minutes as tolerated to a maximum rate of 400 mg/hour
- Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypertension, and other serious adverse events. Resume rituximab administration after adverse events abate

Cyclophosphamide 750 mg/m^2; administer intravenously in 100 mL of 0.9% NS or D5W over 30 minutes, on day 1, every 21 days (total dosage/cycle = 750 mg/m^2)

Doxorubicin 50 mg/m^2; administer by slow intravenous injection over 3–5 minutes, on day 1, every 21 days (total dosage/cycle = 50 mg/m^2)

Vincristine 1.2 mg/m^2; administer by slow intravenous injection over 1–2 minutes, on day 1, every 21 days (total dosage/cycle = 1.2 mg/m^2)

Prednisone 100 mg/day; administer orally for 5 consecutive days, on days 1–5, every 21 days (total dose/cycle = 500 mg)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential: HIGH. Potential for delayed symptoms

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with one of the following:

Filgrastim (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection, *or*

Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL; administer by subcutaneous injection for 1 dose

- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial
  - Consider a fluoroquinolone during expected periods of neutropenia, or no prophylaxis
  - *P. jirovecii* prophylaxis is recommended
    - Cotrimoxazole (trimethoprim 80 mg and sulfamethoxazole 400 mg) once daily

      or
    - Aerosolized pentamidine once monthly
  - *Mycobacterium avium/intracellulare* complex prophylaxis for patients with CD4+ counts <100/mm^3
    - Azithromycin 1200 mg/dose; administer orally once weekly

(*continued*)

Patient Population Studied

A 2:1 randomization trial with 95 patients randomized to receive the CHOP-rituximab arm and 47 patients the CHOP arm. Median CD4+ lymphocyte count was 133 cells/mm^3; 79% of patients had stages III/IV disease

Efficacy (N = 47)

47 Patients Treated with CHOP

Complete response	50%
Median time to response	9 weeks

Treatment Modifications

Adverse Event	Dose Modification
ANC <1000/mm^3 for 3 consecutive days or febrile neutropenia	Administer pegfilgrastim in subsequent cycles if not already given in cycle 1; reduce cyclophosphamide and doxorubicin dosages by 25%
Platelet count <75,000/mm^3	Reduce cyclophosphamide and doxorubicin dosages by 25%

Toxicity* (N = 47)

	% Patients
G3/4 neutropenia	17
Fever and ANC <100/mm^3	8.5
Death caused by infection	2

*National Cancer Institute (USA) Common Toxicity Criteria, version 2.0. Available at: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]

(*continued*)

Note: Fluoroquinolone prophylaxis therapy is particularly important for patients treated with combination rituximab and chemotherapy.

- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of herpes simplex virus infection

See Chapter 47 for more information

Additional prophylaxis

Add a **proton pump inhibitor** during prednisone use to prevent gastritis and duodenitis

Give **stool softeners** and/or laxatives during and after vincristine administration

Therapy Monitoring

1. *Day 1 of each cycle:* CBC with differential count
2. *Twice-weekly during chemotherapy:* CBC with differential
3. *Every 2 cycles:* Tumor restaging

Note

Carriers of hepatitis B receiving rituximab should be monitored closely for clinical and laboratory signs of active hepatitis B virus infection and for signs of hepatitis during and for several months following rituximab therapy

17. Leukemia, Acute Lymphoblastic (ADULT)

Michael M. Boyiadzis, MD, MHSc, Ivan Aksentijevich, MD, and Judith Karp, MD

Epidemiology

Incidence: 6,020 (male: 3,140; female: 2,880. Estimated new cases for 2014 in the United States)
1.7 per 100,000 male and female per year (1.9 per 100,000 male, 1.5 per 100,000 female)

Deaths: Estimated 1,440 in 2014 (male: 810; female: 630)

Median age: B-cell lymphoblastic leukemia/lymphoma: 12 years
T-cell lymphoblastic leukemia/lymphoma: 18 years
Lymphoblastic leukemia/lymphoma unknown lineage: 12 years
Age-specific incidence patterns are characterized by a peak between the ages of 2 and 4 years and again during the sixth decade

Male to female ratio: 1.33

Dores GM. Blood 2012;119:34–43
Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Work-up

1. H&P
2. CBC, leukocyte differential, platelets, electrolytes, liver function tests, PT, PTT, fibrinogen, LDH, uric acid
3. Bone marrow biopsy/aspirate
4. HLA typing for patients who are candidates for allogeneic hematopoietic cell transplantation
5. Cardiac scan if prior cardiac history or prior anthracycline use
6. CT/MRI of head if neurologic symptoms
7. CT chest for T-ALL patients

Pathology

Common Chromosomal and Molecular Abnormalities in ALL

Cytogentics	Gene	Frequency in Adults	Frequency in Children
Hyperdiploidy	–	7%	25%
Hypodiploidy	–	2%	1%
t(9;22)(q34;q11) Philadelphia chromosome (Ph)	*BCR-ABL1*	25%	3%
t(12;21)(p13;q22)	*TEL-AML1*	2%	22%
t(v;11q23), e.., t(4;11), t(9;11), t11;19)	*MLL*	10%	8%
t(1;19)	*E2A-PBX1*	3%	5%
t(5;14)(q31;q32)	*IL3-IGH*	<1%	<1%
t(8;14), t(2;8), t(8;22)	*c-MYC*	4%	2%
t(1;14)(p32;q11)	*TAL-1**	12%	7%
t(10;14)(q24;q11)	*HOX11**	8%	1%
t(5;14)(q35;q32)	*HOX11L2**	1%	3%

*Abnormalities observed exclusively in T-cell lineage ALL; all other occur exclusively or predominately in B-cell linage ALL

Prognostic Factors for Risk Stratification of Adult ALL

Characteristics	High Risk Factors
Age	>35 years
Leukocytosis	>30,000 mm^3 (B lineage) >100,000 mm^3 (T lineage)
Karyotype	t(9;22), t(4;11) (q21;q23), complex, hypodiploid
Therapy response	Time to morphology CR >4weeks Persistent minimal residual disease (MRD)

Expert Opinion

Treatment regimens for acute lymphoblastic leukemia (ALL) have evolved empirically into complex schemes that use numerous agents in various doses, combinations, and schedules, and few of the individual components have been tested rigorously in randomized trials. However, the backbone of chemotherapy for ALL remains the sequence of induction, consolidation, and maintenance

Remission induction: Most regimens include steroids, vincristine, an anthracycline, and usually asparaginase. Cyclophosphamide and cytarabine are often added. The combination of these agents results in CR rate to 80–90%; thus, treating physicians should use a regimen with which they are familiar and have experience in providing supportive care. See table below for different adult ALL regimens

Consolidation: Eradication of minimal residual disease during hematologic remission is the primary aim of the consolidation phase. It is difficult to assess the value of individual components of treatment because the number, schedule, and combination of antineoplastic drugs vary considerably among studies. Consolidation therapy typically consists of several cycles of treatment similar to, but often less intensive than, the drugs, dosages, and administration schedules given during induction, and consolidation usually is better tolerated than induction

Maintenance: Maintenance therapies are important for patients not undergoing allogeneic hematopoietic cell transplantation (allo-HCT). Maintenance regimens consist of combinations of mercaptopurine, methotrexate, vincristine, and steroids given continually for 2–3 years. Patients with the genetic defect of thiopurine methyltransferase (TPMT) are more sensitive to myelosuppressive effects of mercaptopurine and should be consider for testing for TPMT gene polymorphisms

Myeloablative allo-HCT should be considered for adult patients with ALL in first clinical remission (CR) for all disease risk groups. Allo-HCT provides a significant improvement in overall and leukemia-free survival in younger patients (ages <35 years), standard risk, patients with Philadelphia chromosome (Ph)-negative ALL compared with less-intensive chemotherapy regimens. In older (ages >35 years) patients with standard risk, Ph-negative ALL, a higher treatment related mortality diminishes the significant survival advantage with allo-HCT

Cooperative group analysis have consistently demonstrated superior outcomes for adolescent and young adult (AYA) patients with ALL when treated with pediatric versus adult ALL regimens. Thus AYA patients should be treated with pediatric-based treatment protocols in clinical trials

Note: Mature B-cell ALL: Patients with mature B-cell ALL (Burkitt cell leukemia, L3) experience improvement in survival rate when high doses of cyclophosphamide, methotrexate, and cytarabine are incorporated early in treatment. The probability of leukemia-free survival improved with standard ALL induction from 35% to 60–70% with these agents. No maintenance therapy is given to patients with mature B-cell ALL since relapse occurs early and most patients are cured after approximately 1.5 years

Philadelphia chromosome-positive acute lymphoblastic leukemia: Patients with Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph+ ALL) are a distinct disease subgroup comprising 20–30% of adults. Chemotherapy regimens that have combined tyrosine kinase inhibitors (TKIs) offer enhanced CR rates and a greater opportunity for patients to proceed to allo-HCT. The potential benefits of allo-HCT in patients with Ph+ ALL have been described in several studies. For patients who receive allo-HCT DFS and OS always appear better than would be expected with chemotherapy alone. For patients who are too old or unfit for allo-HCT, TKIs should be continued without interruption in addition to whatever components of standard maintenance therapy can be tolerated

Patients with relapsed ALL have a poor prognosis with standard salvage therapy. Response rates to salvage chemotherapy range from 30–70% but are generally short-lived with a median survival of 6 months. Patients in second CR should be considered for allo-HCT

Studies in adults with ALL have demonstrated the strong correlation between minimal residual disease (MRD) and risks of relapse. The timing of MRD assessment varies depending on the ALL regimen protocol being used, and may occur during or after completion of initial induction therapy. For MRD evaluation by multicolor flow cytometry, sampling of bone marrow mononuclear cells is preferred over peripheral blood samples. For MRD evaluation by RQ-PCR, sampling of bone marrow mononuclear cells is preferred. The minimal limit of assay sensitivity (to declare MRD negativity) should be $<1 \times 10^4$, <0.01%)

Results of Clinical Trials in Adult ALL (*continued*)

Study	Year	N	Median Age (Range [Years])	SCT	CR Rate	Early Death	Survival
Total of all studies (using weighted mean)		7393			84%	7%	35%

Ph+, SCT in Philadelphia chromosome positive-ALL; PO, prospective SCT in all patients with donors; PR, SCT according to prospective risk model; HR, prospective SCT in a study for high-risk patients only; NR, not reported

Central nervous system involvement: Up to 10% of adults with ALL present with CNS involvement at the time of diagnosis. The cumulative risk of CNS leukemia in patients who do not receive prophylaxis can be as high as 50%. Factors associated with increased risks for CNS leukemia in adults include mature B-cell immunophenotype, T-cell immunophenotype, high presenting WBC count, and elevated serum LDH levels. CNS involvement should be evaluated by lumbar puncture at the appropriate timing in accordance with the specific treatment protocol used and when LP is performed intrathecal therapy administered concomitantly. Adult patients with ALL and CNS involvement at diagnosis require CNS-directed therapy starting at the same time as induction therapy. Treatment and prophylaxis of CNS involvement may consist of intrathecally administered methotrexate either alone or combined with intrathecally administered cytarabine or corticosteroids and/or intravenously administered high-dose cytarabine, high-dose cytarabine methotrexate. With the incorporation of adequate systemic chemotherapy and intrathecal chemotherapy regimens, it is possible to avoid the use of upfront cranial irradiation except for cases of overt CNS leukemia at presentation and reserve the use of irradiation for salvage therapy settings. Allo-HCT is indicated in patients with isolated CNS relapse and is probably the only curative approach for some patients, because of the high risk of occult marrow contamination at the time of CNS progression

PROPHYLAXIS AGAINST TUMOR LYSIS SYNDROME

HYDRATION, URINARY ALKALINIZATION, AND ALLOPURINOL ADMINISTRATION

Hydration with 2500–3000 mL/m² per day as tolerated; administer intravenously to maintain urine output ≥100 mL/m² per hour (or ≥2 mL/kg per hour in persons whose body weight is <50 kg)

Urinary alkalinization with **sodium bicarbonate** injection added to intravenously administered fluids

- The amount of sodium bicarbonate added to intravenously administered fluids should produce a solution with sodium content not greater than the concentration of sodium in 0.9% sodium chloride injection (≤154 mEq/L):

Sodium Bicarbonate is Added to a Solution to Increase Urine pH within a Range 6.5 to ≤7

Base Solution Sodium Content	Sodium Bicarbonate Additive	Total Sodium Content
0.45% Sodium Chloride Injection (0.45% NS)		
77 mEq/L	50–75 mEq	127–152 mEq/L
0.2% Sodium Chloride Injection (0.2% NS)		
34 mEq/L	100–125 mEq	134–159 mEq/L
5% Dextrose injection (D5W)		
0	125–150 mEq	125–150 mEq/L
D5W/0.45% NS		
77 mEq/L	50–75 mEq	127–152 mEq/L
D5W/0.2% NS		
34 mEq/L	100–125 mEq	134–159 mEq/L

Notes:

- Hydration rate may be decreased at the completion of chemotherapy administration
- Urinary alkalization increases the solubility and excretion of uric acid and its oxypurine precursors (hypoxanthine and xanthine) and helps avoid uric acid crystallization in renal tubules; however, alkalinization is not uniformly recommended because:
  1. It favors precipitation of calcium phosphate in renal tubules, a concern in patients with concomitant hyperphosphatemia
  2. A metabolic alkalemia may result from the administration of bicarbonate that can worsen the neurologic manifestations of hypocalcemia
- Discontinue sodium bicarbonate administration (while continuing hydration) if serum bicarbonate concentration is >30 mEq/L (>30 mmol/L) or urine pH >7.5

Allopurinol

- Administer orally or intravenously starting 12 hours to 3 days (preferably, 2–3 days) before starting cytoreductive chemotherapy
- Hyperuricemia develops within 24 to 48 hours after initiating chemotherapy when the excretory capacity of the renal tubules for uric acid is exceeded
- In the presence of an acid pH, uric acid crystals form in the renal tubules, leading to intraluminal renal tubular obstruction, an acute renal obstructive uropathy, and renal dysfunction
- ***Initial dosage***
  Allopurinol 100 mg/m² per dose; administer orally every 8 hours (maximum daily dose = 800 mg), *or*
  Allopurinol 3.3 mg/kg per dose; administer orally every 8 hours (maximum daily dose = 800 mg), *or*
  Allopurinol 200–400 mg/m² per day; administer intravenously (maximum daily dose = 600 mg) in a volume of 5% dextrose injection or 0.9% sodium chloride injection sufficient to yield a concentration not greater than 6 mg/mL. The duration for administering individual doses should be informed by the volume to be given
  - Allopurinol may be administered as a single daily dose, or the total daily dose may be divided equally for administration at 6-, 8-, or 12-hour intervals
- **Maintenance doses** should be based on serum uric acid determinations performed approximately 48 hours after initiation of allopurinol therapy, and periodically thereafter
- Continue administering allopurinol until leukemic blasts have been cleared from the peripheral blood

(*continued*)

(*continued*)

Notes:

• Allopurinol dose adjustments for impaired renal function:

Creatinine Clearance	Oral Allopurinol Dose
10–20 mL/min (0.17–0.33 mL/s)	200 mg/day
3–10 mL/min (0.05–0.17 mL/s)	100 mg/day
<3 mL/min (<0.05 mL/s)	100 mg every 36–48 hours

• Allopurinol does not remove uric acid already present

• The incidence of allergic reactions is increased in patients receiving amoxicillin, ampicillin, or thiazide diuretics

Rasburicase

• Rasburicase is recombinant urate oxidase (uricase) produced by genetically modified *Saccharomyces cerevisiae* that express urate oxidase cDNA cloned from a strain of *Aspergillus flavus*

• Uricase enzymes catalyze uric acid oxidation to allantoin, which is at least 5-times more soluble than uric acid

• Rational utilization

▪ Rasburicase should be considered among initial interventions against hyperuricemia in patients with high peripheral WBC counts, rapidly increasing blasts counts, high uric acid, or with evidence of impaired renal function; that is:

Burkitt leukemia	
WBC count ≥100,000/mm^3	
WBC count <100,000/mm^3 + LDH ≥2 × ULN	
WBC count <100,000/mm^3 + LDH <2 × ULN +	acute kidney injury *or* normal renal function + uric acid > ULN, *or* potassium > ULN, *or* phosphorus > ULN
ULN, upper limit of normal	

See Chapter 46, *Oncologic Emergencies*

Rasburicase 0.2 mg/kg per dose intravenously in a total volume of 50 mL 0.9% sodium chloride injection over 30 minutes once daily for up to 5 consecutive days is often used, but much less is usually sufficient (See Chapter 46, Oncologic Emergencies) (dosage and administration recommendations published in U.S. Food and Drug Administration product labeling, January 2011)

• Rasburicase has demonstrated effectiveness in prophylaxis and treatment for hyperuricemia and acute increases in uric acid associated with cytoreductive therapies at dosages <0.2 mg/kg based on body weight, with fixed doses, and after administration of from 1–3 doses

See Chapter 46 for more information

Treatment Stratified by Patient Age

<60 years	≥60 years
Cyclophosphamide 1200 mg/m²; administer intravenously in 100–250 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 15–30 minutes on day 1 (total dosage/course = 1200 mg/m²) **Daunorubicin** 45 mg/m² per day; administer by intravenous injection over 3–5 minutes for 3 consecutive days, on days 1–3 (total dosage/course = 135 mg/m²) **Prednisone** 60 mg/m² per day; administer orally, continually, for 21 consecutive days, on days 1–21 (total dosage/course = 1260 mg/m²)	**Cyclophosphamide** 800 mg/m²; administer intravenously in 100–250 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 15–30 minutes on day 1 (total dosage/course = 800 mg/m²) **Daunorubicin** 30 mg/m² per day; administer by intravenous injection over 3–5 minutes for 3 consecutive days, on days 1–3 (total dosage/course = 90 mg/m²) **Prednisone** 60 mg/m² per day; administer orally, continually, for 7 consecutive days, on days 1–7 (total dosage/course = 420 mg/m²)

All Patients

Vincristine 2 mg per dose; administer by intravenous injection over 1–2 minutes for 4 doses, on days 1, 8, 15, and 22 (total dose/course = 8 mg)
Asparaginase 6000 IU/m² per dose; administer intramuscularly, or intravenously in 10–50 mL 0.9% NS or D5W over at least 30 minutes for 6 doses, on days 5, 8, 11, 15, 18, and 22 (total dosage/course = 36,000 IU/m²)
Filgrastim 5 mcg/kg per day; administer by subcutaneous injection for at least 7 consecutive days. Start on day 4, at least 12 hours after the last dose of daunorubicin, and continue after the ANC nadir until the ANC is ≥1000/mm³ on 2 consecutive days (measurements ≥24 hours apart)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on day 1 is ***HIGH****. Potential for delayed symptoms*
Emetogenic potential on days 2 and 3 is ***MODERATE***
Emetogenic potential on days with asparaginase ± vincristine is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with:
Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection
- Begin use on day 4
- Continue daily filgrastim use for at least 7 days, and until ANC ≥1000/mm³ on 2 measurements separated temporally by ≥24 hours
- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
- Antibacterial—consider fluoroquinolone prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

(continued)

Patient Population Studied

102 patients (median age 35 years) with newly diagnosed ALL

Efficacy (N = 102)

Induction Course	
Complete CR (n = 97*)	90%
≥60 years (n = 21)	81%
<60 years (n = 76)	89%
Refractory disease (n = 102)	8%
Died during induction (n = 102)	5%
DFS, median	2.3 years
DFS Ph+ patients, median	0.8 years
Overall survival, median	2.4 years

*Among 102 patients randomly assigned to receive filgrastim during induction and early intensification courses, 97 patients were eligible for comparisons with patients who did not receive filgrastim

(continued)

(continued)

Courses IIA and IIB, early intensification (2 courses, each is 4 weeks in duration)

Methotrexate 15 mg; administer intrathecally via lumbar puncture in 3–15 mL *preservative-free* 0.9% sodium chloride injection (PF 0.9% NS) on day 1, every 4 weeks for 2 courses (total dose/course = 15 mg)
Cyclophosphamide 1000 mg/m^2; administer intravenously in 100–250 mL 0.9% NS or D5W over 15–30 minutes on day 1, every 4 weeks for 2 courses (total dosage/course = 1000 mg/m^2)
Mercaptopurine 60 mg/m^2 per day, administer orally, continually, for 14 consecutive days, days 1–14, every 4 weeks for 2 courses (total dosage/course = 840 mg/m^2)
Cytarabine 75 mg/m^2 per dose; administer by subcutaneous injection for 8 doses on days 1–4 and days 8–11, every 4 weeks for 2 courses (total dosage/course = 600 mg/m^2)
Vincristine 2 mg per dose; administer by intravenous injection over 1–2 minutes for 2 doses, on days 15 and 22, every 4 weeks for 2 courses (total dose/course = 4 mg)
Asparaginase 6000 IU/m^2 per dose; administer intramuscularly, or intravenously in 10–50 mL 0.9% NS or D5W over at least 30 minutes for 4 doses, on days 15, 18, 22, and 25, every 4 weeks for 2 courses (total dosage/course = 24,000 IU/m^2)
Filgrastim 5 mcg/kg per day; administer by subcutaneous injection for at least 14 consecutive days. Start on day 2, and continue after the ANC nadir until the ANC is ≥5000/mm^3 on 2 consecutive days (measurements ≥24 hours apart)

Note: In all cases, filgrastim should be discontinued at least 2 days before cyclophosphamide administration resumed on the first day of the second early intensification course

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on Day 1 is ***MODERATE***
Emetogenic potential on days with cytarabine is ***LOW***
Emetogenic potential on days with mercaptopurine alone is ***MINIMAL–LOW***
Emetogenic potential on days with asparaginase ± vincristine is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with:
Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection
- Begin use on day 2
- Continue daily filgrastim use for at least 14 days, and until ANC ≥5000/mm^3 on 2 measurements separated temporally by ≥24 hours
- Priority was given to starting the second course (Course IIB) 28 days after the first began
  - For patients whose ANC recovers to ≥1000/mm^3 and platelet count ≥50,000/mm^3 28 days after starting the first course (Course IIA), the second course of therapy began on the 29th day of Course IIA even if they had not yet recovered an ANC ≥5000/mm^3 by day 27
- Discontinue daily filgrastim use at least 2 days before restarting myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Course III, CNS prophylaxis and interim maintenance (1 course, 12 weeks in duration)

Cranial irradiation 2400 cGy (total dose), delivered during 12 consecutive days, days 1–12
Methotrexate 15 mg per dose; administer intrathecally via lumbar puncture in 3–15 mL preservative-free 0.9% sodium chloride injection for 5 doses, on days 1, 8, 15, 22, and 29 (total dose/course = 75 mg)

(continued)

Efficacy (N = 102) *(continued)*

Adverse Effects of Remission Induction

	Grades 3 & 4 or Grade 5 Toxicity
WBC (<1000/mm^3)	98
Platelets (<25,000/mm^3)	97
Hemoglobin (<6.5 g/dL)	93
Infection	78
Nausea	23
Bilirubin (>1.5 times NL)	44
Transaminase (>5 times NL)	35
Malaise/fatigue (PS >2)	16
Motor neuropathy	18
Pain	21
Hyperglycemia (>250 mg/dL)	33
Hypofibrinogenemia (<0.5 times NL)	26

Adverse Effects of Intensification and Maintenance

Grades 3 & 4 Toxicities	Intensification	Maintenance
Leucopenia	97	75
Thrombocytopenia	84	32
Anemia	84	26
Hemorrhage	4	0
Infection	49	25
Nausea/vomiting	17	8
Stomatitis	9	7
Diarrhea	3	1
Hepatic	28	30
Pulmonary	5	4
Cardiac	1	6
Genitourinary	2	1
CNS	13	6
Peripheral nervous system	12	7
Skin	1	2
Allergy	1	1

Data from 197 newly diagnosed ALL patients who were treated with the same chemotherapy regimen but did not receive filgrastim Larson RA et al. Blood 1995;85:2025–2037

(continued)

Mercaptopurine 60 mg/m² per day; administer orally, continually, for 70 consecutive days, days 1–70 (total dosage/course = 4200 mg/m²)
Methotrexate 20 mg/m² per dose; administer orally, for 5 doses, on days 36, 43, 50, 57, and 64 (total dosage/course = 100 mg/m²)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
- Antibacterial—*P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Course IV, late intensification (1 course, 8 weeks in duration)

Doxorubicin 30 mg/m² per dose; administer by intravenous injection over 3–5 minutes for 3 doses, on days 1, 8, and 15 (total dosage/course = 90 mg/m²)
Vincristine 2 mg per dose; administer by intravenous injection over 1–2 minutes for 3 doses, on days 1, 8, and 15 (total dose/course = 6 mg)
Dexamethasone 10 mg/m² per day; administer orally, continually, for 14 consecutive days, days 1–14 (total dosage/course = 140 mg/m²)
Cyclophosphamide 1000 mg/m²; administer intravenously in 100–250 mL 0.9% NS or D5W over 15–30 minutes on day 29 (total dosage/course = 1000 mg/m²)
Thioguanine 60 mg/m² per day; administer orally, continually, for 14 consecutive days, days 29–42 (total dosage/course = 840 mg/m²)
Cytarabine 75 mg/m² per dose; administer by subcutaneous injection for 8 doses on days 29–32 and days 36–39 (total dosage/course = 600 mg/m²)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential on Days 1, 8, 15, and 29 is **MODERATE***
*Emetogenic potential on Days 30–32 and 36–39 is **LOW***
*Emetogenic potential on days with thioguanine alone is **MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
- *During the intervals between doses of doxorubicin, and the interval from days 16 through 28*
- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

(continued)

Therapy Monitoring

1. CBC with differential daily during and after chemotherapy until recovery of ANC >500/mm³. Platelets every day while in hospital until patients no longer require platelet transfusions
2. Serum electrolytes, mineral panel, and uric acid, at least daily during active treatment until the risk of tumor lysis is past
3. Amylase and fibrinogen levels prior to asparaginase administration. If fibrinogen level is <100 mg/dL (<1 g/L) consider prophylactic administration of cryoprecipitate
4. Bone marrow aspirate and biopsy at day 29 of the initial induction course. After a patient achieves a CR, bone marrow biopsy and aspirate should be performed at the end of each consolidation cycle (or at the very least, every other cycle), and every 3 months during maintenance therapy

Treatment Modifications

Adverse Events	Treatment Modifications
Creatinine 1.5–2 mg/dL (133–177 µmol/L)	Reduce methotrexate dosage by 25%
Creatinine >2 mg/dL (>177 µmol/L)	Reduce methotrexate dosage by 50%
Creatinine >3 mg/dL (>265 µmol/L)	Reduce daunorubicin dosage by 50%
Total bilirubin 3–5 mg/dL (51–86 µmol/L)	Reduce daunorubicin dosage by 50% Reduce methotrexate dosage by 25%
Total bilirubin >3 mg/dL (>51 µmol/L)	Reduce vincristine dosage by 50%
Total bilirubin >5 mg/dL (>86 µmol/L)	Hold daunorubicin Hold methotrexate

(continued)

Course V, prolonged maintenance (courses are 4 weeks in duration and are repeated until 24 months after diagnosis)
Vincristine 2 mg per dose; administer by intravenous injection over 1–2 minutes, on day 1, every 4 weeks (total dose/course = 2 mg)
Prednisone 60 mg/m² per day; administer orally, continually, for 5 consecutive days, on days 1–5, every 4 weeks (total dosage/course = 300 mg/m²)
Mercaptopurine 60 mg/m² per day; administer orally, continually, for 28 consecutive days, days 1–28, every 4 weeks (total dosage/course = 1680 mg/m²)
Methotrexate 20 mg/m² per dose; administer orally, for 4 doses, on days 1, 8, 15, and 22, every 4 weeks (total dosage/course = 80 mg/m²)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
- Antibacterial—*P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Asparaginase Toxicity Management

Stock W et al. Leuk Lymphoma 2011;52:2237–2253

Toxicity	Grade 2	Grade 3	Grade 4
Hypersensitivity Urticaria, wheezing, laryngospasm, hypotension, etc.	For urticaria without bronchospasm, hypotension, edema, or need for parenteral intervention, continue asparaginase	For wheezing or other symptomatic bronchospasm with or without urticaria, indicated parenteral intervention, angioedema, or hypotension, discontinue asparaginase. If erwinia asparaginase is available, replace pegaspargase with erwinia asparaginase	For life-threatening consequences or indicated urgent intervention, discontinue asparaginase. If erwinia asparaginase is available, replace pegaspargase with erwinia asparaginase
Hypertriglyceridemia	If serum triglyceride level <1000 mg/dL (<11.3 mmol/L), continue asparaginase but follow patient closely for evolving pancreatitis	Hold asparaginase for triglyceride >1000 mg/dL (>11.3 mmol/L); follow closely for pancreatitis; resume asparaginase at prior dose level after patient's triglyceride level returns to normal range	Hold asparaginase for triglyceride >1000 mg/dL (>11.3 mmol/L); follow closely for pancreatitis; resume asparaginase at prior dose level after patient's triglyceride level returns to normal range
Hyperglycemia, ketoacidosis	Continue asparaginase for uncomplicated hyperglycemia	For hyperglycemia requiring insulin therapy, hold asparaginase (and glucocorticoid therapy) until blood glucose regulated with insulin; resume asparaginase at prior dose level	For hyperglycemia with life-threatening consequences or indicated urgent intervention, hold asparaginase (and glucocorticoid therapy) until blood glucose is regulated with insulin; resume asparaginase and do not make up for missed doses
Hyperammonemia-related fatigue	Continue asparaginase	Reduce asparaginase dose by 25%; resume full dose when toxicity is grade ≤2; make up for missed doses	Reduce asparaginase dose 50%; resume full dose when toxicity grade 2; make up for missed doses
Pancreatitis	Continue asparaginase for asymptomatic amylase or lipase elevation >3 × ULN (chemical pancreatitis) or only radiologic abnormalities; observe closely for rising amylase or lipase levels	Continue pegaspargase for non-symptomatic chemical pancreatitis but observe patient closely for development of symptomatic pancreatitis for early treatment. Hold native asparaginase for amylase or lipase elevation >3 × ULN until enzyme levels stabilize or are declining. Permanently discontinue asparaginase for symptomatic pancreatitis	Permanently discontinue all asparaginase for clinical pancreatitis (vomiting, severe abdominal pain) with amylase or lipase elevation >3 × ULN for >3 days and/or development of pancreatic pseudocyst

(continued)

Asparaginase Toxicity Management (*continued*)

Toxicity	Grade 2	Grade 3	Grade 4
Increased hepatic transaminases	For alanine or glutamine aminotransferase elevation >3–5 × ULN, continue asparaginase	For alanine or glutamine aminotransferase elevation >5–20 × ULN, delay next dose of asparaginase until transaminasemia is grade <2	For alanine or glutamine aminotransferase elevation >20 × ULN, discontinue asparaginase if toxicity reduction to grade <2 takes >1 week
Hyperbilirubinemia	Continue asparaginase if direct bilirubin <3.0 mg/dL (<51 μmol/L)	If direct bilirubin is 3.1–5.0 mg/dL (53–86 μmol/L), hold asparaginase and resume when direct bilirubin is <2.0 mg/dL Consider switching to native asparaginase	If direct bilirubin is >5.0 mg/dL (>86 μmol/L), discontinue all asparaginase and do not make up for missed doses
Non-CNS thrombosis	For abnormal laboratory findings without clinical correlates, continue asparaginase	Withhold asparaginase until acute toxicity and clinical signs resolve and anticoagulant therapy is stable or completed. Do not withhold asparaginase for abnormal laboratory findings without a clinical correlate	Withhold asparaginase until acute toxicity and clinical signs resolve and anticoagulant therapy is stable or completed
Non-CNS hemorrhage	For bleeding in conjunction, with hypofibrinogenemia, withhold asparaginase until bleeding is grade ≤1. Do not withhold asparaginase for abnormal laboratory findings without a clinical correlate	Withhold asparaginase until bleeding is grade ≤1, until acute toxicity and clinical signs resolve, and coagulant replacement therapy is stable or completed	Withhold asparaginase until bleeding is grade ≤1, until acute toxicity and clinical signs resolve, and coagulant replacement therapy is stable or completed
CNS thrombosis	For abnormal laboratory findings without a clinical correlate, continue asparaginase	Discontinue all asparaginase; if CNS symptoms and signs are fully resolved and significant asparaginase remains to be administered, may resume asparaginase therapy at a lower dose and/or longer intervals between doses	Permanently discontinue all asparaginase
CNS hemorrhage	Discontinue asparaginase; do not withhold asparaginase for abnormal laboratory findings without a clinical correlate	Discontinue all asparaginase; if CNS symptoms and signs are fully resolved and significant asparaginase remains to be administered, may resume asparaginase therapy at a lower dose and/or longer intervals between doses	Permanently discontinue all asparaginase

Grade according to the National Cancer Institute Common Terminology Criteria for Advance Events version 4, with the exception of pancreatitis

Notes

1. An additional group of 96 patients in a study reported by Larson et al. (Blood 1998;92:1556–1564) did not receive filgrastim after assignment to treatment. The median time to recover neutrophils ≥1000/mm^3 during the remission induction course was 16 days for patients assigned to receive filgrastim and 22 days for patients assigned to placebo. Patients who received filgrastim had significantly shorter durations of neutropenia and thrombocytopenia and fewer days in hospital compared with patients who received placebo
2. Among patients assigned to receive filgrastim, more achieved CR and fewer experienced death during remission induction than those who received placebo. Overall toxicity was not lessened by the use of filgrastim. After a median follow-up of 4.7 years there was no significant difference in the overall survival between the two groups
3. Larson et al. (Blood 1995:85:2025–2037) performed lumbar puncture at diagnosis of ALL only in symptomatic patients. Patients with CNS leukemia should receive intrathecal therapy via lumbar puncture or an intraventricular reservoir (eg, Ommaya) weekly until CNS clearance with

   Methotrexate 15 mg + Hydrocortisone sodium succinate 50 mg per dose; administer intrathecally once weekly, alternating with:

   Cytarabine 100 mg + Hydrocortisone sodium succinate 50 mg per dose; administer intrathecally once weekly

   - Doses may be given in a volume of 0.9% Sodium Chloride Injection WITHOUT antimicrobial preservatives (preservative-free) equal to the volume of CSF removed for chemical or cytological evaluations
   - Intrathecal chemotherapy is given twice weekly; alternating doses of either methotrexate + hydrocortisone or cytarabine + hydrocortisone
   - Alternating intrathecal chemotherapy doses are separated by at least 3 days
4. Patients should continue systemic treatment as specified in the regimen

REGIMEN

HYPER-CVAD

Kantarjian H et al. Cancer 2004;101:2788–2801
Kantarjian HM et al. J Clin Oncol 2000;18:547–561

Dose-intensive chemotherapy
The dose-intensive phase consists of 8 cycles of hyper-CVAD alternating with high-dose methotrexate and cytarabine every 3–4 weeks (when the WBC count is >3000/mm^3 and platelet count is >60,000/mm^3)

Hyper-CVAD (cycles 1, 3, 5, and 7)
Cyclophosphamide 300 mg/m^2 per dose; administer intravenously over 3 hours in 500 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) every 12 hours for 6 doses on days 1–3, for 4 cycles, cycles 1, 3, 5, and 7 (total dosage/cycle = 1800 mg/m^2)

Mesna 600 mg/m^2 per 24 hours; administer by continuous intravenous infusion in 1000 mL 0.9% NS for approximately 69 hours for 4 cycles, cycles 1, 3, 5, and 7 (total dosage/cycle ~1725 mg/m^2)
- Mesna administration starts concurrently with cyclophosphamide on day 1 and continues until 6 hours after the last dose of cyclophosphamide is completed (69 hours)

Vincristine 2 mg/dose; administer by intravenous injection over 1–2 minutes for 2 doses, on days 4 and 11, for 4 cycles, cycles 1, 3, 5, and 7 (total dose/cycle = 4 mg)

Doxorubicin 50 mg/m^2; administer intravenously via central venous access in 25–250 mL 0.9% NS or D5W over 2 hours on day 4, for 4 cycles, cycles 1, 3, 5, and 7 (total dosage/cycle = 50 mg/m^2)

Dexamethasone 40 mg per day; administer orally, or intravenously in 25–150 mL 0.9% NS or D5W over 15–30 minutes for 8 doses, on days 1–4 and days 11–14, for 4 cycles, cycles 1, 3, 5, and 7 (total dose/cycle = 320 mg)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on Days 1–4 is ***MODERATE***
Emetogenic potential on Days 11 is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with:
Filgrastim (G-CSF) 5 mcg/kg per dose; administer by subcutaneous injection every 12 hours, starting on day 5 (24 hours after doxorubicin)
- Continue filgrastim administration until postnadir WBC count >3000/mm^3 and platelet count is >60,000/mm^3. If platelet recovery is delayed, filgrastim is continued until the WBC count >30,000/mm^3
- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

(*continued*)

Patient Population Studied

288 newly diagnosed ALL patients (median age: 40 years)

Efficacy (N = 288)

CR	92%
CR <30 years	99%
CR >60 years	80%
Resistant disease	3%
Died during induction	5%
5-Year estimated survival rate	38%
5-Year CR rate	38%
CR for Ph+ ALL	91%
5-Year survival for Ph+ ALL	12%

(*continued*)

High-dose methotrexate + cytarabine (cycles 2, 4, 6, and 8)
Hydration: with a solution containing a total amount of sodium not >0.9% NS (ie, ≤154 mEq sodium/1000 mL) by intravenous infusion during methotrexate administration and for at least 24 hours afterward

- Commence fluid administration 2–12 hours before starting methotrexate, depending on patient's fluid status
- Urine output should be at least 100 mL/hour before starting methotrexate infusion
- Maintain hydration at a rate that maintains urine output ≥100 mL/hour until the serum methotrexate concentration is <0.1 μmol/L
- Urine pH should be increased within the range ≥7.0 to ≤8.0 to enhance methotrexate solubility and ensure elimination
- Adverse effects attributable to methotrexate are related to systemic methotrexate concentrations *and* the duration for which concentrations are maintained

Sodium bicarbonate 50–150 mEq/1000 mL is added to parenteral hydration solutions to maintain urine pH ≥7.0 to ≤8.0

Base Solution Sodium Content	Sodium Bicarbonate Additive	Total Sodium Content
0.45% Sodium Chloride Injection (0.45% NS)		
77 mEq/L	50–75 mEq	127–152 mEq/L
0.2% Sodium Chloride Injection (0.2% NS)		
34 mEq/L	100–125 mEq	134–159 mEq/L
5% Dextrose injection (D5W)		
0	125–150 mEq	125–150 mEq/L
D5W/0.45% NS		
77 mEq/L	50–75 mEq	127–152 mEq/L
D5W/0.2% NS		
34 mEq/L	100–125 mEq	134–159 mEq/L

Methotrexate 200 mg/m^2; administer intravenously over 2 hours, on day 1, *followed by:*
Methotrexate 800 mg/m^2; administer intravenously over 24 hours, on day 1, for 4 cycles, cycles 2, 4, 6, and 8 (total dosage/cycle, bolus + infusion = 1000 mg/m^2)

Note: For logistical practicality and efficiency, parenteral admixtures containing methotrexate may include a portion or all of the fluid and sodium bicarbonate needed to meet hydration and urinary alkalinization requirements during methotrexate administration

Leucovorin calcium 15 mg per dose; administer intravenously in 25–250 mL 0.9% NS or D5W over 15–30 minutes, starting 48 hours after methotrexate administration began (22 hours after methotrexate administration ends), every 6 hours for 8 doses (total dosage/cycle = 120 mg)

(*continued*)

Dose Modifications During the Induction Phase

Adverse Effect	Dose Modification
Total bilirubin >2 mg/dL (>34 μmol/L)	Reduce vincristine doses to 1 mg
Total bilirubin 2–3 mg/dL (34–51 μmol/L)	Reduce doxorubicin dosage by 25%
Total bilirubin 3–4 mg/dL (51–68 μmol/L)	Reduce doxorubicin dosage by 50%
Total bilirubin 3–5 mg/dL (51–86 μmol/L)	Reduce methotrexate dosage by 25%
Total bilirubin >4mg/dL (>68 μmol/L)	Reduce doxorubicin dosage by 75%
Total bilirubin >5 mg/dL (>86 μmol/L)	Hold methotrexate
Creatinine 1.5–2 mg/dL (133–177 μmol/L)	Reduce methotrexate dosage by 25%
Bilirubin level 3–5 mg/dL (51–86 μmol/L)	Reduce MTX dose by 25%
Bilirubin >5 mg/dL (>86 μmol/L)	Hold MTX
Creatinine >2 mg/dL (>177 μmol/L)	Reduce methotrexate dosage by 50% Reduce cytarabine dosage to 1000 mg/m^2

(continued)

Note: If serum methotrexate concentrations are:

Hours After *Starting* Methotrexate	Methotrexate Concentration	Leucovorin Regimen
Hour 24	>20 µmol/L (>2 × 10^{-5} mol/L)	Increase **leucovorin** dosages to 50 mg/dose; administer intravenously in 25–250 mL 0.9% NS or D5W over 15–30 minutes every 6 hours until serum methotrexate concentrations are <0.1 µmol/L (<1 × 10^{-7} mol/L)
Hour 48	>1 µmol/L (>1 × 10^{-6} mol/L)	
Hour 72	>0.1 µmol/L (>1 × 10^{-7} mol/L, *or* >100 nmol/L)	

Cytarabine

Patient ages <60 years: **Cytarabine** 3000 mg/m² per dose; administer intravenously in 50–500 mL 0.9% NS or D5W over 2 hours every 12 hours for 4 doses on days 2 and 3, for 4 cycles, cycles 2, 4, 6, and 8 (total dosage/cycle [not including intrathecal cytarabine] = 12,000 mg/m²)

Patient ages ≥60 years: **Cytarabine** 1000 mg/m² per dose; administer intravenously in 50–500 mL 0.9% NS or D5W over 2 hours every 12 hours for 4 doses on days 2 and 3, for 4 cycles, cycles 2, 4, 6, and 8 (total dosage/cycle [not including intrathecal cytarabine] = 4000 mg/m²)

Methylprednisolone 50 mg; administer intravenously twice daily for 6 doses, on days 1–3 (total dose/cycle = 300 mg)

Filgrastim 5 mcg/kg per dose; administer subcutaneously, every 12 hours, starting on day 4 (24 hours after the last dose of chemotherapy) and continue until postnadir WBC count >3000/mm³ and platelet count is >60,000/mm³. If platelet recovery is delayed, filgrastim is continued until the WBC count >30,000/mm³

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on Days 1–3 is ***MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with:

Filgrastim (G-CSF) 5 mcg/kg per dose; administer by subcutaneous injection every 12 hours, starting on day 4 (24 hours after the last dose of cytarabine)

- Continue filgrastim administration until postnadir WBC count >3000/mm³ and platelet count is >60,000/mm³. If platelet recovery is delayed, filgrastim is continued until the WBC count >30,000/mm³
- Discontinue daily filgrastim use at least 24 hours before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is HIGH

Antimicrobial primary prophylaxis is recommended:

- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

(continued)

Toxicity (N = 288)

Induction Chemotherapy (First Course of Hyper-CVAD Therapy)	
Myelosuppression	
Median time to ANC >1000/mm³	19 days
Median time to platelets >100,000/mm³	22 days
Hospitalization	54%
Sepsis	11%
Pneumonia	16%
Fungal infection	4%
Fever of unknown origin	37%
Neurotoxicity	64%
Moderate–severe mucositis	4%
Moderate–severe diarrhea	3%
Disseminated intravascular coagulopathy	3%
Induction deaths	5%

Consolidation Courses (Second Course of Hyper-CVAD Therapy)	
Pneumonia	4%
Hospitalization	16%
Neurotoxicity	7%
Mucositis	1%
Diarrhea	1%
Sepsis	10%
Fever of unknown origin	8%

(continued)

(continued)

Keratitis prophylaxis
Steroid ophthalmic drops (prednisolone 1% or dexamethasone 0.1%) administer by intraocular instillation daily until 24 hours after high-dose cytarabine is completed

Maintenance phase
Mercaptopurine 50 mg/dose; administer orally on an empty stomach, continually, 3 times daily for 2 years (total dose/4 weeks = 4200 mg)
Methotrexate 20 mg/m^2 per dose; administer orally, once weekly for 2 years (total dosage/4 weeks = 80 mg/m^2)
Vincristine 2 mg; administer by intravenous injection over 1–2 minutes, once monthly for 2 years (total dose/month = 2 mg)
Prednisone 200 mg per day; administer orally, continually, for 5 consecutive days every month, starting on the day vincristine is given (total dose/month = 1000 mg)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Toxicity (N = 288) *(continued)*

High-Dose Methotrexate + Cytarabine Therapy	
Sepsis	8%
Pneumonia	5%
Fever of unknown origin	22%
Neurotoxicity	5%
Minor infections	4%
Hospitalization	36
Mucositis	4%
Rash and desquamation of palms and feet	2%
Diarrhea	1%

Therapy Monitoring

1. CBC with differential daily during and after chemotherapy until recovery of ANC >500/mm^3. Platelets every day while in hospital until patient no longer requires platelet transfusions
2. Serum electrolytes, mineral panel, and uric acid, at least daily during active treatment until the risk of tumor lysis is past
3. Bone marrow aspirate and biopsy at day 29 of the initial induction course. After patient achieves a CR, bone marrow biopsy and aspirate should be performed at the end of each consolidation cycle (or at the very least, every other cycle), and every 3 months during maintenance therapy

Notes

1. In the studies reported by Kantarjian et al. (J Clin Oncol 2000;18:547–561), patients underwent a diagnostic LP on day 2 of the first course of treatment
   a. Patients with CNS disease at the time of diagnosis receive intrathecal therapy with:
      - **Methotrexate;** administer intrathecally 12 mg/dose via lumbar puncture *or* 6 mg/dose intraventricularly via indwelling ventricular reservoir catheter (eg, Ommaya) twice weekly until cerebrospinal fluid cell counts normalize and cytology becomes negative for malignant disease, *then:*
      - **Methotrexate;** administer intrathecally 12 mg/dose via lumbar puncture *or* 6 mg/dose intraventricularly via indwelling ventricular reservoir catheter on day 2 of each remaining treatment cycle, plus
      - **Cytarabine** 100 mg/dose; administer intrathecally via lumbar puncture *or* intraventricularly via indwelling ventricular reservoir catheter on day 8 of each remaining treatment cycle
   b. Patients with cranial nerve root involvement received radiation 24–30 Gy in 10–12 fractions to the base of the skull or whole brain
   c. Patients with no evidence of CNS disease should receive intrathecal prophylaxis based on prognostic factors for CNS leukemia

CNS Prophylaxis

	Risk Categories		
Risk Factors	**High**	**Low**	**Unknown**
LDH	>600 units/L	Within normal limits	unknown
Proliferative index (% $S+G_2M$)	≥14%		
Histology	Mature B-cell ALL	Not applicable	

	Administration Schedule by Risk Category		
Regimen for Intrathecal Prophylaxis	**High Risk**	**Unknown Risk**	**Low Risk**
Methotrexate; administer intrathecally 12 mg/dose via lumbar puncture *or* 6 mg/dose intraventricularly (via Ommaya reservoir) on day 2 of each cycle indicated, *plus* **Cytarabine** 100 mg administer; intrathecally via lumbar puncture or intraventricularly on day 8 of each cycle indicated	For 8 cycles, cycles 1–8	For 4 cycles, cycles 1–4	For 2 cycles, cycles 1 & 2

2. Patients with mature B-cell ALL received no maintenance therapy
3. Patients who receive high-dose cytarabine need to be closely monitored for changes in renal function. Renal dysfunction is highly correlated with increased risk of cerebellar toxicity associated with cytarabine. Patients need to be monitored for nystagmus, dysmetria, and ataxia before each cytarabine dose
4. Hyper-CVDA + Rituximab (Thomas DA et al. J Clin Oncol 2010;28:3880–3889): two hundred eighty-two adolescents and adults with de novo Philadelphia chromosome (Ph)–negative precursor B-lineage ALL were treated with standard or modified hyper-CVAD regimens. The latter incorporated standard-dose rituximab if CD20 expression ≥20%. The complete remission (CR) rate was 95% with 3-year rates of CR duration (CRD) and survival (OS) of 60% and 50%, respectively. In the younger (age <60 years) CD20-positive subset, rates of CRD and OS were superior with the modified hyper-CVAD and rituximab regimens compared with standard hyper-CVAD (70% *v* 38%; P <.001% and 75% *v* 47%, P = .003). In contrast, rates of CRD and OS for CD20-negative counterparts treated with modified versus standard hyper-CVAD regimens were similar (72% *v* 68%, P = not significant [NS] and 64% *v* 65%, P = NS, respectively). Older patients with CD20-positive ALL did not benefit from rituximab-based chemoimmunotherapy (rates of CRD 45% *v* 50%, P = NS and OS 28% *v* 32%, P = NS, respectively), related in part to deaths in CR. The incorporation of rituximab into the hyper-CVAD regimen improve outcome for younger patients with CD20-positive Ph-negative precursor B-lineage ALL.

REGIMEN

LINKER REGIMEN

Linker C et al. J Clin Oncol 2002;20:2464–2471

Treatment consisted of a total of 7 courses given in the order 1A → 1B → 1C → 2A → 2B → 2C → 3C, followed by maintenance chemotherapy

Induction (course 1A): DVP/Asp

Daunorubicin 60 mg/m² per day; administer by intravenous injection over 3–5 minutes for 3 consecutive days, on days 1–3 (total dosage/course after 3 doses = 180 mg/m²)
Note: If day 14 bone marrow evaluation reveals residual leukemia, give a fourth dose of daunorubicin on day 15 (total dosage/course after 4 doses = 240 mg/m²)

Vincristine

Patient age ≤40 years: **Vincristine** 1.4 mg/m² per dose; administer by intravenous injection over 1–2 minutes for 4 doses on days 1, 8, 15, and 22 (total dosage/course = 5.6 mg/m²)
Patient age >40 years: **Vincristine** 1.4 mg/m² per dose (maximum single dose = 2 mg), administer by intravenous injection over 1–2 minutes for 4 doses on days 1, 8, 15, and 22 (total dosage/course = 5.6 mg/m²; maximum dose/course = 8 mg)

Prednisone 60 mg/m² per day; administer orally, continually, for 28 consecutive days, on days 1–28 (total dosage/course = 1680 mg/m²)

Asparaginase 6000 IU/m² per day; administer intramuscularly, or intravenously in 10–50 mL 0.9% sodium chloride injection or 5% dextrose injection over at least 30 minutes for 12 consecutive days on days 17–28 (total dosage/course = 72,000 IU/m²)

CNS Prophylaxis and Treatment

1. Patients received CNS prophylaxis with methotrexate administered intrathecally during the initial diagnostic lumbar puncture. Five additional doses began with the first course of postremission chemotherapy with repeated doses delivered at weekly intervals as tolerated
2. Patients with CNS disease at diagnosis received intensified CNS therapy: 10 intrathecal treatments, and cranial irradiation 18 Gy was given after bone marrow remission was achieved

Methotrexate 12 mg per dose; administer intrathecally via lumbar puncture in 3–12 mL preservative-free 0.9% sodium chloride injection

	Prophylaxis	Treatment
Methotrexate (12 mg/dose)		
Total number of doses	6*	10*
Total dose/all courses	72 mg	120 mg
Cranial irradiation	None	1800 cGy after bone marrow CR

*First dose is given at the start of Induction Course 1A
Second and subsequent doses start concurrently with post-CR chemotherapy, and continue on a weekly schedule

(*continued*)

Patient Population Studied

84 newly diagnosed ALL adult patients (median age 27 years)

Efficacy (N = 84)

Induction	
Complete remission (CR) 1 Treatment-related death 5 Patients had resistant disease	93%
5-Year event-free survival	48% ± 13%
Overall survival	47%
5-Year event-free survival for patients achieving remission	52%
5-Year DFS for patients achieving remission	54%

(continued)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days when daunorubicin is given is ***MODERATE–HIGH***

Emetogenic potential on days when vincristine or asparaginase ± vincristine are given is ***MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with:

Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection

- If only 3 doses of daunorubicin are given, begin filgrastim use on day 14. If a fourth dose of daunorubicin is given (on day 15) postpone instituting filgrastim use until 24 hours after daunorubicin was administered
- Continue daily filgrastim use until ANC >1500/mm^3 on two measurements separated temporally by ≥24 hours
- Discontinue daily filgrastim use at least 24 hours before commencing the next course of myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is HIGH

Antimicrobial primary prophylaxis is recommended:

- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Consolidation (courses 1B and 2B): high-dose cytarabine + etoposide (HDAC/etoposide)

Cytarabine 2000 mg/m^2 per day; administer intravenously in 100–1000 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 2 hours for 4 consecutive days on days 1–4 (total dosage/course = 8000 mg/m^2)

Etoposide 500 mg/m^2 per day; administer intravenously diluted in 0.9% NS or D5W to a concentration within the range of 0.2–0.4 mg/mL over 3 hours for 4 consecutive days on days 1–4 (total dosage/course = 2000 mg/m^2)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is at least ***MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with one of the following:

Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL, by subcutaneous injection for 1 dose

- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Continue daily filgrastim use until ANC >1500/mm^3 on 2 measurements separated temporally by ≥24 hours
- Discontinue daily Filgrastim use at least 24 hours before commencing the next course of myelosuppressive treatment. Do not administer pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is HIGH

Antimicrobial primary prophylaxis is recommended:

- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

(continued)

Therapy Monitoring

1. CBC with differential daily during and after chemotherapy until recovery of ANC >500/mm^3. Platelets every day while in hospital until patients no longer require platelet transfusions
2. Electrolytes, mineral panel, and uric acid at least daily during active treatment until the risk of tumor lysis is past
3. Amylase and fibrinogen levels prior to asparaginase administration. If fibrinogen level is <100 mg/dL (<1 g/L) consider prophylactic administration of cryoprecipitate
4. Bone marrow aspirate and biopsy at day 29 of the initial induction course. After a patient achieves a CR, bone marrow biopsy and aspirate should be performed at the end of each consolidation cycle (or at the very least, every other cycle), and every 3 months during maintenance therapy

(continued)

Keratitis prophylaxis
Steroid ophthalmic drops (prednisolone 1% or dexamethasone 0.1%); administer by intraocular instillation daily until 24 hours after high-dose cytarabine is completed

Consolidation (course 2A): DVP/Asp
Daunorubicin 60 mg/m² per day; administer by intravenous injection over 3–5 minutes for 3 consecutive days on days 1–3 (total dosage/course = 180 mg/m²)

Vincristine
Patients age ≤40 years: **Vincristine** 1.4 mg/m² per dose; administer by intravenous injection over 1–2 minutes for 3 doses on days 1, 8, and 15 (total dosage/course = 4.2 mg/m²)
Patients age >40 years: **Vincristine** 1.4 mg/m² per dose (maximum single dose = 2 mg); administer by intravenous injection over 1–2 minutes for 3 doses on days 1, 8, and 15 (total dosage/course = 4.2 mg/m²; maximum dose/course = 6 mg)

Prednisone 60 mg/m² per day; administer orally, continually, for 21 consecutive days on days 1–21 (total dosage/course = 1260 mg/m²)

Asparaginase 12,000 IU/m² per dose; administer intramuscularly, or intravenously in 10–50 mL 0.9% sodium chloride injection or 5% dextrose injection over at least 30 minutes, for 3 doses/week (eg, Monday, Wednesday, and Friday), for a total of 6 doses during 2 consecutive weeks (total dosage/course = 72,000 IU/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on days when daunorubicin is given is ***MODERATE–HIGH***
Emetogenic potential on days when vincristine or asparaginase ± vincristine are given is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day, by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Continue daily filgrastim use until ANC >1500/mm³ on 2 measurements separated temporally by ≥24 hours
- Discontinue daily filgrastim use at least 24 hours before commencing the next course of myelosuppressive treatment. Do not administer pegfilgrastim within 14 days before administering myelosuppressive treatment

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Consolidation (courses 1C, 2C, and 3C): high-dose methotrexate + mercaptopurine
Hydration with methotrexate:
Administer 1500–3000 mL/m² per day. Use a solution containing a total amount of sodium not greater than 0.9% sodium chloride injection (ie, 154 mEq/1000 mL); administer by intravenous infusion during methotrexate administration and for at least 24 hours afterward
- Commence fluid administration 2–12 hours before starting methotrexate, depending upon a patient's fluid status
- Urine output should be at least 100 mL/hour before starting methotrexate infusion
- Maintain hydration at a rate that maintains urine output of at least 100 mL/hour until the serum methotrexate concentration is <0.05 µmol/L
- Adverse effects attributable to methotrexate are related to systemic methotrexate concentrations *and* the duration for which concentrations are maintained

(continued)

Treatment Modifications

Adverse Events	Treatment Modifications
Creatinine 1.5–2 mg/dL (133–177 µmol/L)	Reduce methotrexate dosage by 25%
Creatinine >2 mg/dL (>177 µmol/L)	Reduce methotrexate dosage by 50%
Creatinine >3 mg/dL (>265 µmol/L)	Reduce daunorubicin dosage by 50%
Total bilirubin 3–5 mg/dL (51–86 µmol/L)	Reduce daunorubicin dosage by 50% Reduce methotrexate dosage by 25%
Total bilirubin >3 mg/dL (>51 µmol/L)	Reduce vincristine dosage by 50%
Total bilirubin >5 mg/dL (>86 µmol/L)	Hold daunorubicin Hold methotrexate

(*continued*)

Sodium bicarbonate 50–150 mEq/1000 mL is added to parenteral hydration solutions to maintain urine pH ≥7.0 to ≤8.0

Base Solution Sodium Content	Sodium Bicarbonate Additive	Total Sodium Content
0.45% Sodium Chloride Injection (0.45% NS)		
77 mEq/L	50–75 mEq	125–152 mEq/L
0.2% Sodium Chloride Injection (0.2% NS)		
34 mEq/L	100–125 mEq	134–159 mEq/L
5% Dextrose Injection (D5W)		
0	125–150 mEq	125–150 mEq/L
D5W/0.45% NS		
77 mEq/L	50–75 mEq	125–152 mEq/L
D5W/0.2% NS		
34 mEq/L	100–125 mEq	134–159 mEq/L

Methotrexate 220 mg/m^2; administer intravenously over 1 hour (loading dose, or *bolus*), every 2 weeks on days 1 and 15, *followed by*

Methotrexate 60 mg/m^2 per hour; administer by continuous intravenous infusion for 36 hours, every 2 weeks on days 1 and 15 (total dosage/administration event, bolus + infusion = 2380 mg/m^2; total dosage/course = 4760 mg/m^2)

Note: For logistical practicality and efficiency, parenteral admixtures containing methotrexate may include a portion or all of the fluid and sodium bicarbonate needed to meet hydration and urinary alkalinization requirements during methotrexate administration

Leucovorin calcium 50 mg/m^2 per dose; administer intravenously in 25–250 mL 0.9% NS or D5W over 15–30 minutes starting immediately after methotrexate is completed (37 hours after methotrexate administration began), every 6 hours for 3 doses, every 2 weeks on days 2 and 16, *and then:*

Leucovorin calcium 50 mg/dose; administer orally starting 6 hours after the last intravenously administered dose of leucovorin. Continue administration every 6 hours until serum methotrexate concentrations are <0.05 μmol/L (<5 × 10^{-8} mol/L, or <50 nmol/L), every 2 weeks

Mercaptopurine 75 mg/m^2 per day; administer orally, continually, for 28 consecutive days on days 1–28 (total dosage/course = 2100 mg/m^2)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days when methotrexate is given is ***MODERATE***

Emetogenic potential on days when mercaptopurine alone is given is ***MINIMAL–LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is HIGH

Antimicrobial primary prophylaxis is recommended:

- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

(*continued*)

(*continued*)

Maintenance Therapy

Mercaptopurine 75 mg/m² per day; administer orally, continually, until complete remission is sustained for 30 months (total dosage/week = 525 mg/m²)

Methotrexate 20 mg/m² per dose; administer orally once weekly until complete remission is sustained for 30 months (total dosage/week = 20 mg/m²)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MINIMAL–LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is HIGH

Antimicrobial primary prophylaxis is recommended:

- Antibacterial—*P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Adverse Effects

Median Number of Days to Hematologic Recovery

	Courses			
	Induction 1A DVP/Asp n = 84	1B HDAC/Etoposide n = 79	2A DVP/Asp n = 59	2B HDAC/Etoposide n = 53
ANC >500/mm³	18	19	16	20
ANC >1000/mm³	23	20	17	20
No. of days with ANC <500/mm³	14	12	5	12
Platelets				
>20,000/mm³	15	19	1	22
>50,000/mm³	18	21	20	27
>100,000/mm³	22	24	29	29
No. of platelet transfusions	4	3	0	4
No. of RBC transfusions	6	7	2	6

11 Patients experienced a peak serum total bilirubin >3 mg/dL, 1 had a peak total bilirubin > 10 mg/dL

Asparaginase Toxicity Management

Stock W et al. Leuk Lymphoma 2011;52:2237–2253

Toxicity	Grade 2	Grade 3	Grade 4
Hypersensitivity Urticaria, wheezing, laryngospasm, hypotension, etc.	For urticaria without bronchospasm, hypotension, edema, or need for parenteral intervention, continue asparaginase	For wheezing or other symptomatic bronchospasm with or without urticaria, indicated parenteral intervention, angioedema, or hypotension, discontinue asparaginase. If erwinia asparaginase is available, replace pegaspargase with erwinia asparaginase	For life-threatening consequences or indicated urgent intervention, discontinue asparaginase. If erwinia asparaginase is available, replace pegaspargase with erwinia asparaginase
Hypertriglyceridemia	If serum triglyceride level <1000 mg/dL (<11.3 mmol/L), continue asparaginase but follow patient closely for evolving pancreatitis	Hold asparaginase for triglyceride >1000 mg/dL (>11.3 mmol/L); follow closely for pancreatitis; resume asparaginase at prior dose level after patient's triglyceride level returns to normal range	Hold asparaginase for triglyceride >1000 mg/dL (>11.3 mmol/L); follow closely for pancreatitis; resume asparaginase at prior dose level after patient's triglyceride level returns to normal range
Hyperglycemia, ketoacidosis	Continue asparaginase for uncomplicated hyperglycemia	For hyperglycemia requiring insulin therapy, hold asparaginase (and glucocorticoid therapy) until blood glucose regulated with insulin; resume asparaginase at prior dose level	For hyperglycemia with life-threatening consequences or indicated urgent intervention, hold asparaginase (and glucocorticoid therapy) until blood glucose is regulated with insulin; resume asparaginase and do not make up for missed doses
Hyperammonemia-related fatigue	Continue asparaginase	Reduce asparaginase dose by 25%; resume full dose when toxicity is grade ≤2; make up for missed doses	Reduce asparaginase dose 50%; resume full dose when toxicity grade 2; make up for missed doses
Pancreatitis	Continue asparaginase for asymptomatic amylase or lipase elevation >3 × ULN (chemical pancreatitis) or only radiologic abnormalities; observe closely for rising amylase or lipase levels	Continue pegaspargase for non-symptomatic chemical pancreatitis but observe patient closely for development of symptomatic pancreatitis for early treatment. Hold native asparaginase for amylase or lipase elevation >3 × ULN until enzyme levels stabilize or are declining. Permanently discontinue asparaginase for symptomatic pancreatitis	Permanently discontinue all asparaginase for clinical pancreatitis (vomiting, severe abdominal pain) with amylase or lipase elevation >3 × ULN for >3 days and/or development of pancreatic pseudocyst
Increased hepatic transaminases	For alanine or glutamine aminotransferase elevation >3–5 × ULN, continue asparaginase	For alanine or glutamine aminotransferase elevation >5–20 × ULN, delay next dose of asparaginase until transaminasemia is grade <2	For alanine or glutamine aminotransferase elevation >20 × ULN, discontinue asparaginase if toxicity reduction to grade <2 takes >1 week
Hyperbilirubinemia	Continue asparaginase if direct bilirubin <3.0 mg/dL (<51 μmol/L)	If direct bilirubin is 3.1–5.0 mg/dL (53–86 μmol/L), hold asparaginase and resume when direct bilirubin is <2.0 mg/dL Consider switching to native asparaginase	If direct bilirubin is >5.0 mg/dL (>86 μmol/L), discontinue all asparaginase and do not make up for missed doses
Non-CNS thrombosis	For abnormal laboratory findings without clinical correlates, continue asparaginase	Withhold asparaginase until acute toxicity and clinical signs resolve and anticoagulant therapy is stable or completed. Do not withhold asparaginase for abnormal laboratory findings without a clinical correlate	Withhold asparaginase until acute toxicity and clinical signs resolve and anticoagulant therapy is stable or completed
Non-CNS hemorrhage	For bleeding in conjunction, with hypofibrinogenemia, withhold asparaginase until bleeding is grade ≤1. Do not withhold asparaginase for abnormal laboratory findings without a clinical correlate	Withhold asparaginase until bleeding is grade ≤1, until acute toxicity and clinical signs resolve, and coagulant replacement therapy is stable or completed	Withhold asparaginase until bleeding is grade ≤1, until acute toxicity and clinical signs resolve, and coagulant replacement therapy is stable or completed

(continued)

Asparaginase Toxicity Management (*continued*)

Toxicity	Grade 2	Grade 3	Grade 4
CNS thrombosis	For abnormal laboratory findings without a clinical correlate, continue asparaginase	Discontinue all asparaginase; if CNS symptoms and signs are fully resolved and significant asparaginase remains to be administered, may resume asparaginase therapy at a lower dose and/or longer intervals between doses	Permanently discontinue all asparaginase
CNS hemorrhage	Discontinue asparaginase; do not withhold asparaginase for abnormal laboratory findings without a clinical correlate	Discontinue all asparaginase; if CNS symptoms and signs are fully resolved and significant asparaginase remains to be administered, may resume asparaginase therapy at a lower dose and/or longer intervals between doses	Permanently discontinue all asparaginase

Grade according to the National Cancer Institute Common Terminology Criteria for Advance Events version 4, with the exception of pancreatitis

REGIMEN

ALL TRIAL: MRC UKALL XII/ECOG E2993

Rowe JM et al. Blood 2005;106:3760–3767

Induction therapy

Induction—Phase 1 (weeks 1–4)

Daunorubicin 60 mg/m² per dose; administer by intravenous injection over 3–5 minutes for 4 doses on days 1, 8, 15, and 22 (total dosage/4-week course = 240 mg/m²)
Vincristine 1.4 mg/m² per dose; administer by intravenous injection over 1–2 minutes for 4 doses on days 1, 8, 15, and 22 (total dosage/4-week course = 5.6 mg/m²)
Prednisone 60 mg/m² per day; administer orally, continually, for 28 consecutive days on days 1 to 28 (total dosage/4-week course = 1680 mg/m²)
• Daily prednisone doses may be given in a single dose or ≥2 divided doses

Methotrexate 12.5 mg; administer intrathecally in 3–12 mL preservative-free 0.9% sodium chloride injection on day 15 (total dose/4-week course = 12.5 mg)
Asparaginase 10,000 IU/dose; administer intramuscularly, or intravenously in 10–50 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) for 12 consecutive days, on days 17 to 28 (total dose/4-week course = 120,000 IU)

Induction—Phase 2 (weeks 5–8)

(Regardless of whether residual leukemia is present at the end of phase 1)
Cyclophosphamide 650 mg/m²; administer intravenously in 100–1000 mL 0.9% NS or D5W over 15–60 min for 3 doses on days 1, 15, and 29 (total dosage/4-week course = 1950 mg/m²)
Cytarabine 75 mg/m² per dose; administer intravenously in 25–250 mL 0.9% NS or D5W over 15–60 min for 16 doses on days 1–4, 8–11, 15–18, and 22–25 (total dosage/4-week course = 1200 mg/m²)
Mercaptopurine 60 mg/m² per day; administer orally, continually, for 28 consecutive days on days 1 to 28 (total dosage/4-week course = 1680 mg/m²)
Methotrexate 12.5 mg per dose; administer intrathecally in 3–12 mL preservative-free 0.9% sodium chloride injection for 4 doses on days 1, 8, 15, and 22 (total dose/4-week course = 50 mg)

Notes: A diagnostic spinal tap was performed on all patients. If CNS leukemia was present at diagnosis, methotrexate was administered intrathecally via lumbar puncture or through a ventricular reservoir (eg, Ommaya) every week until blast cells were no longer present in the spinal fluid. In addition, 2400 cGy of cranial irradiation and 1200 cGy to the spinal cord were administered concurrently during induction, phase 2. For patients with CNS leukemia at presentation, intrathecal methotrexate was not administered during phase 2

Intensification therapy

Hydration for methotrexate: 6–18 hours before the anticipated start of methotrexate, start intravenous hydration containing sodium bicarbonate ($NaHCO_3$) to alkalinize a patient's urine to pH ≥7.0, but ≤8.0, at a rate that achieves a urine output ≥100 mL/hour
Options recommended to initially produce an alkaline urine, include:

Fluid	Administration Rate	Sodium Bicarbonate Content (per 1000 mL)
0.45% NS	150–250 mL/hour	50–75 mEq
0.2% NS		100–125 mEq
D5W /0.45% NS		50–75 mEq
D5W/0.2% NS		100–125 mEq
D5W		150 mEq

D5W, 5% Dextrose injection; NS, sodium chloride injection

Notes: Urine alkalinization to pH ≥7.0 to ≤8.0 and urine output ≥100 mL/hour often initially require more $NaHCO_3$ and more rapid hydration rates than will be required to maintain either or both parameters after they are achieved

(continued)

Population Studied

Of patients from 15 to 59 years of age newly diagnosed with ALL, 1521 received identical induction therapy, irrespective of risk assessment, including central nervous system (CNS) prophylaxis and treatment of CNS disease, if present at diagnosis. Philadelphia chromosome (Ph)-positive patients were considered the highest risk group. Patients who were Ph-negative were considered at high risk if any of the following were present: age ≥35 years; time to CR >4 weeks or WBC count >30 × 109/L for B-lineage ALL and >100 × 109/L for T-lineage ALL. Ph-negative patients who had none of these risk factors were considered at standard risk. After induction therapy, all patients younger than 50 years of age who had a human leukocyte antigen (HLA)–compatible sibling were assigned to undergo allogeneic transplantation. All other patients were randomly assigned between autologous transplantation and standard consolidation/maintenance therapy. Patients who were Ph-positive were offered a search for a matched unrelated donor if they did not have a histocompatible family donor

(*continued*)

The amount of sodium bicarbonate added to intravenously administered fluids should produce a solution with sodium content not greater than the concentration of sodium in 0.9% sodium chloride injection (≤154 mEq/L)

Methotrexate 3000 mg/m²; administer intravenously in one of the solutions identified above in admixture with 25–75 mEq $NaHCO_3$ over 4 hours after urine pH ≥7.0 to ≤8.0 and urine output >100 mL/hour are confirmed for 3 doses on days 1, 8, and 22 (total dosage/course = 9000 mg/m²)

- Temporarily interrupt hydration while methotrexate is administered
  - The methotrexate product should contain volume and sodium bicarbonate content equivalent to what was being given in intravenous hydration to maintain urine pH ≥7.0 to ≤8.0 and output >100 mL/hour
- Order daily serum methotrexate levels timed to start 24 hours after methotrexate administration begins and continue daily measurements until the serum methotrexate level is ≤0.05 μmol/L
- Continue hydration with urine alkalinization (pH ≥7.0 to ≤8.0) until serum methotrexate level is ≤0.05 μmol/L

Leucovorin calcium 100 mg/m² per dose (preferred), or **levoleucovorin calcium** 50 mg/m² per dose; administer intravenously in 25–250 mL 0.9% NS or D5W over 10–30 minutes every 6 hours starting 24 hours after methotrexate administration began, and continue for at least 6 doses or until serum methotrexate concentrations are ≤0.5 μmol/L, whichever occurs later

When the methotrexate level is <0.5 μmol/L, parenterally administered leucovorin or levoleucovorin may be replaced with leucovorin administered orally (10 mg/m², or a fixed 25-mg dose for patients whose body surface area is <2.5 m²), until the serum methotrexate level is ≤0.05 μmol/L

Asparaginase 10,000 IU/dose; administer intramuscularly, or intravenously in 10–50 mL 0.9% NS or D5W intravenously or intramuscularly for 3 doses on days 2, 9, and 23 (total dose/course = 30,000 IU)

Consolidation therapy
Cytarabine 50 mg/dose; administer intrathecally in 3–12 mL preservative-free 0.9% sodium chloride injection weekly for 4 weeks, *with:*
Cranial irradiation 2400 cGy
Consolidation—Cycle 1
Cytarabine 75 mg/m² per day; administer intravenously in 25–250 mL 0.9% NS or D5W over 15–60 minutes for 5 consecutive days on days 1–5 (total dosage/cycle = 375 mg/m²)
Etoposide 100 mg/m² per day; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range, 0.2–0.4 mg/mL over at least 60 minutes for 5 consecutive days on days 1–5 (total dosage/cycle = 500 mg/m²)
Vincristine 1.4 mg/m² per dose; administer intravenously over 1–2 minutes for 4 doses on days 1, 8, 15, and 22 (total dosage/cycle = 5.6 mg/m²)
Dexamethasone 10 mg/m² per day; administer orally, continually, for 28 consecutive days on days 1 to 28 (total dosage/cycle = 280 mg/m²)
Consolidation—Cycle 2 (starts 4 weeks after cycle 1)
Cytarabine 75 mg/m² per day; administer intravenously in 25–250 mL 0.9% NS or D5W over 15–60 minutes for 5 consecutive days on days 1–5 (total dosage/cycle = 375 mg/m²)
Etoposide 100 mg/m² per day; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range, 0.2–0.4 mg/mL over at least 60 minutes for 5 consecutive days on days 1–5 (total dosage/cycle = 500 mg/m²)
Consolidation—Cycle 3 (starts 4 weeks after cycle 2)
Daunorubicin 25 mg/m² per dose; administer by intravenous injection over 3–5 minutes for 4 doses on days 1, 8, 15, and 22 (total dosage/4-week course = 100 mg/m²)
Cyclophosphamide 650 mg/m²; administer intravenously in 100–1000 mL 0.9% NS or D5W over 15–60 min on day 29 (total dosage/4-week course = 650 mg/m²)
Cytarabine 75 mg/m² per dose; administer intravenously in 25–250 mL 0.9% NS or D5W over 15–60 minutes for 8 doses on days 31–34 and 38–41 (total dosage/4-week course = 600 mg/m²)
Thioguanine 60 mg/m² per day; administer orally, continually, for 14 consecutive days on days 29–42 (total dosage/4-week course = 840 mg/m²)

(*continued*)

(*continued*)

Consolidation—Cycle 4 (8 weeks after the conclusion of cycle 3)
Cytarabine 75 mg/m² per day; administer intravenously in 25–250 mL 0.9% NS or D5W over 15–60 minutes for 5 consecutive days on days 1–5 (total dosage/cycle = 375 mg/m²)
Etoposide 100 mg/m² per day; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a concentration within the range, 0.2–0.4 mg/mL over at least 60 minutes for 5 consecutive days on days 1–5 (total dosage/cycle = 500 mg/m²)

Maintenance therapy (continues for a total of 2.5 years after the start of intensification therapy)
Cytarabine 50 mg/dose; administer intrathecally in 3–12 mL preservative-free 0.9% sodium chloride injection on 4 occasions 3 months apart during maintenance therapy (total of 4 doses = 200 mg)
Vincristine 1.4 mg/m²; administer by intravenous injection over 1–2 minutes every 3 months (total dosage/3-month period = 1.4 mg/m²)
Prednisone 60 mg/m²; administer orally for 5 consecutive days every 3 months (total dosage/3-month period = 300 mg/m²)
Mercaptopurine 75 mg/m²; administer orally, continually each day (total dosage/week = 525 mg/m²)
Methotrexate 20 mg/m²; administer orally or intravenously once a week (total dosage/week = 20 mg/m²)

Supportive Care
Antiemetic Prophylaxis During Induction–Phase 1
Emetogenic potential on days 1, 8, and 15 is ***MODERATE***
Emetogenic potential on days with asparaginase (days 17–28) is ***MINIMAL***

Antiemetic Prophylaxis During Induction–Phase 2
Emetogenic potential on days with cyclophosphamide (days 1, 15, and 29) is ***MODERATE***
Emetogenic potential on days with cytarabine without cyclophosphamide is ***LOW***
Emetogenic potential on days with mercaptopurine alone is ***MINIMAL–LOW***

Antiemetic Prophylaxis During Intensification
Emetogenic potential on days with methotrexate (days 1, 8, and 22) is ***MODERATE***
Emetogenic potential on days with asparaginase (days 2, 9, and 23) is ***MINIMAL***

Antiemetic Prophylaxis During Consolidation, Cycle 1
Emetogenic potential on days 1–5 is ***LOW***
Emetogenic potential on days 8 and 15 is ***MINIMAL***

Antiemetic Prophylaxis During Consolidation, Cycle 2
Emetogenic potential on days 1–5 is ***LOW***

Antiemetic Prophylaxis During Consolidation, Cycle 3
Emetogenic potential on days 1, 8, 15, and 29 is ***MODERATE***
Emetogenic potential on days with cytarabine is ***LOW***
Emetogenic potential on days with thioguanine alone is ***LOW***

Antiemetic Prophylaxis During Consolidation, Cycle 4
Emetogenic potential on days 1–5 is ***LOW***

Antiemetic Prophylaxis During Maintenance
Emetogenic potential on days methotrexate is given is ***MINIMAL–LOW***
Emetogenic potential all other days is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is HIGH
Antimicrobial primary prophylaxis is recommended:
- Antibacterial—consider fluoroquinolone prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Efficacy

	No.	CR, %	5-Year Survival, %	5-Year Survival for Patients in CR, %
All patients	1521	91	38	41
Ph+	293	83	25	28
Ph−	1153	93	41	44
Standard risk*	533	97	54	57
High risk*	590	90	29	35
Unknown risk	30	84	23	

*Risk stratification at diagnosis based on age and WBC count only
Overall survival (OS) rates at 5 years in this study were 38% for all patients, 41% for Ph-negative patients, and 25% for Ph-positive patients
In subsequent reports (Goldstone AH et al. Blood 2008;111:1827–1833), the 5 year OS in 1913 ALL patients was 39% and 43% for patients with Ph-negative ALL. In Ph-positive patients (Fielding AK et al. Blood 2009;113:4489–4496), the OS was 44% after sib allo-HSCT, 36% after MUD, and 19% after chemotherapy

Treatment Modifications

Adverse Events	Treatment Modifications
Creatinine 1.5–2 mg/dL (133–177 μmol/L)	Reduce methotrexate dosage by 25%
Creatinine >2 mg/dL (>177 μmol/L)	Reduce methotrexate dosage by 50%
Creatinine >3 mg/dL (>265 μmol/L)	Reduce daunorubicin dosage by 50%
Total bilirubin 3–5 mg/dL (51–86 μmol/L)	Reduce daunorubicin dosage by 50% Reduce methotrexate dosage by 25%
Total bilirubin >3 mg/dL (>51 μmol/L)	Reduce vincristine dosage by 50%
Total bilirubin >5 mg/dL (>86 μmol/L)	Hold daunorubicin Hold methotrexate

Toxicity

Overall mortality rates for induction therapy were 4.7% (54 of 1153 patients) for Ph-negative patients and 5.5% (16 of 293 patients) for Ph-positive patients. Twenty-nine patients died of infection, most significantly caused by *Aspergillus* (7 patients). Five patients died of hemorrhage (3 pulmonary, 2 cerebral), 2 patients died of thromboses (possibly related to asparaginase), and 1 patient died from tumor lysis. The remaining 10 patients died of causes described as multiorgan failure, which might also have been related to an infectious etiology

Asparaginase Toxicity Management

Stock W et al. Leuk Lymphoma 2011;52:2237–2253

Toxicity	Grade 2	Grade 3	Grade 4
Hypersensitivity Urticaria, wheezing, laryngospasm, hypotension, etc.	For urticaria without bronchospasm, hypotension, edema, or need for parenteral intervention, continue asparaginase	For wheezing or other symptomatic bronchospasm with or without urticaria, indicated parenteral intervention, angioedema, or hypotension, discontinue asparaginase. If erwinia asparaginase is available, replace pegaspargase with erwinia asparaginase	For life-threatening consequences or indicated urgent intervention, discontinue asparaginase. If erwinia asparaginase is available, replace pegaspargase with erwinia asparaginase
Hypertriglyceridemia	If serum triglyceride level <1000 mg/dL (<11.3 mmol/L), continue asparaginase but follow patient closely for evolving pancreatitis	Hold asparaginase for triglyceride >1000 mg/dL (>11.3 mmol/L); follow closely for pancreatitis; resume asparaginase at prior dose level after patient's triglyceride level returns to normal range	Hold asparaginase for triglyceride >1000 mg/dL (>11.3 mmol/L); follow closely for pancreatitis; resume asparaginase at prior dose level after patient's triglyceride level returns to normal range
Hyperglycemia, ketoacidosis	Continue asparaginase for uncomplicated hyperglycemia	For hyperglycemia requiring insulin therapy, hold asparaginase (and glucocorticoid therapy) until blood glucose regulated with insulin; resume asparaginase at prior dose level	For hyperglycemia with life-threatening consequences or indicated urgent intervention, hold asparaginase (and glucocorticoid therapy) until blood glucose is regulated with insulin; resume asparaginase and do not make up for missed doses
Hyperammonemia-related fatigue	Continue asparaginase	Reduce asparaginase dose by 25%; resume full dose when toxicity is grade ≤2; make up for missed doses	Reduce asparaginase dose 50%; resume full dose when toxicity grade 2; make up for missed doses
Pancreatitis	Continue asparaginase for asymptomatic amylase or lipase elevation >3 × ULN (chemical pancreatitis) or only radiologic abnormalities; observe closely for rising amylase or lipase levels	Continue pegaspargase for non-symptomatic chemical pancreatitis but observe patient closely for development of symptomatic pancreatitis for early treatment. Hold native asparaginase for amylase or lipase elevation >3 × ULN until enzyme levels stabilize or are declining. Permanently discontinue asparaginase for symptomatic pancreatitis	Permanently discontinue all asparaginase for clinical pancreatitis (vomiting, severe abdominal pain) with amylase or lipase elevation >3 × ULN for >3 days and/or development of pancreatic pseudocyst
Increased hepatic transaminases	For alanine or glutamine aminotransferase elevation >3–5 × ULN, continue asparaginase	For alanine or glutamine aminotransferase elevation >5–20 × ULN, delay next dose of asparaginase until transaminasemia is grade <2	For alanine or glutamine aminotransferase elevation >20 × ULN, discontinue asparaginase if toxicity reduction to grade <2 takes >1 week
Hyperbilirubinemia	Continue asparaginase if direct bilirubin <3.0 mg/dL (<51 μmol/L)	If direct bilirubin is 3.1–5.0 mg/dL (53–86 μmol/L), hold asparaginase and resume when direct bilirubin is <2.0 mg/dL Consider switching to native asparaginase	If direct bilirubin is >5.0 mg/dL (>86 μmol/L), discontinue all asparaginase and do not make up for missed doses
Non-CNS thrombosis	For abnormal laboratory findings without clinical correlates, continue asparaginase	Withhold asparaginase until acute toxicity and clinical signs resolve and anticoagulant therapy is stable or completed. Do not withhold asparaginase for abnormal laboratory findings without a clinical correlate	Withhold asparaginase until acute toxicity and clinical signs resolve and anticoagulant therapy is stable or completed
Non-CNS hemorrhage	For bleeding in conjunction, with hypofibrinogenemia, withhold asparaginase until bleeding is grade ≤1. Do not withhold asparaginase for abnormal laboratory findings without a clinical correlate	Withhold asparaginase until bleeding is grade ≤1, until acute toxicity and clinical signs resolve, and coagulant replacement therapy is stable or completed	Withhold asparaginase until bleeding is grade ≤1, until acute toxicity and clinical signs resolve, and coagulant replacement therapy is stable or completed

(continued)

Asparaginase Toxicity Management (*continued*)

Toxicity	Grade 2	Grade 3	Grade 4
CNS thrombosis	For abnormal laboratory findings without a clinical correlate, continue asparaginase	Discontinue all asparaginase; if CNS symptoms and signs are fully resolved and significant asparaginase remains to be administered, may resume asparaginase therapy at a lower dose and/or longer intervals between doses	Permanently discontinue all asparaginase
CNS hemorrhage	Discontinue asparaginase; do not withhold asparaginase for abnormal laboratory findings without a clinical correlate	Discontinue all asparaginase; if CNS symptoms and signs are fully resolved and significant asparaginase remains to be administered, may resume asparaginase therapy at a lower dose and/or longer intervals between doses	Permanently discontinue all asparaginase

Grade according to the National Cancer Institute Common Terminology Criteria for Advance Events version 4, with the exception of pancreatitis

Monitoring Therapy

1. CBC with differential daily during and after chemotherapy until recovery of ANC >500/mm^3. Platelets every day while in hospital until patient no longer requires platelet transfusions
2. Metabolic panel and uric acid, at least daily during active treatment until the risk of tumor lysis is past
3. Amylase and fibrinogen levels prior to asparaginase administration. If fibrinogen level is <100 mg/dL (<1 g/L) consider prophylactic administration of cryoprecipitate
4. Bone marrow aspirate and biopsy after phase 1 and phase 2 of induction therapy. After a patient achieves a CR, bone marrow biopsy and aspirate should be performed at the end of each consolidation cycle (or at the very least, every other cycle), and every 3 months during maintenance therapy

Notes: A diagnostic spinal tap was performed on all patients

If CNS leukemia was present at diagnosis, methotrexate administered intrathecally via lumbar puncture or through a ventricular reservoir (eg, Ommaya) was given weekly until blast cells were no longer present in the spinal fluid. In addition, 2400 cGy of cranial irradiation and 1200 cGy to the spinal cord were administered concurrently during phase 2. For patients with CNS leukemia at presentation, intrathecal methotrexate was not administered during phase 2

In a subsequent analysis (Fielding AK et al. Blood 2007;109:944–950) of the MRC UKALL XII/ECOG E2993 study, among 1372 patients with ALL who entered remission, 609 (44%) relapsed at a median of 11 months after the start of treatment. Most (556 [91%]) patients relapsed within the bone marrow, the sole site of relapse in most (90%) of those patients. A group of 45 (8%) patients relapsed solely at extramedullary sites

Most patients (81%) relapsed within 2 years after diagnosis, although a significant minority (19%) relapsed >2 years after diagnosis. Of the 440 chemotherapy-treated patients, 349 relapsed within 2 years after diagnosis, and 87 relapsed later. Those on chemotherapy who relapsed within 2 years can be considered "relapses on therapy" because the duration of therapy was set to be 18 months from the point of initiation of the consolidation therapy (ie, 23 months)

The median survival after relapse was 24 weeks. Survival at 1 year was 22% (95% CI = 18–25%), and 7% (95% CI = 4–9%) at 5 years. Only 42 of 609 patients who relapsed remain alive without further relapse

Factors predicting a good outcome after salvage therapy were young age (OS of 12% in patients <20 years vs. OS of 3% in patients >50 years; 2P <0.001) and short duration of first remission (CR1) (OS of 11% in those with a CR1 >2 years vs. OS of 5% in those with a CR1 <2 years; 2P <0.001). Patients treated with HSCT had a superior OS (15% [95% CI = 0–35%] for autograft [n = 13], 16% [95% CI = 7–26%] for matched unrelated donor transplantation [n = 65], and 23% [95% CI = 10–36%] for sibling allograft [n = 42]) to those receiving chemotherapy alone (n = 182) whose OS was only 4% (95% CI = 1–7%) at 5 years

REGIMEN

LIPOSOMAL VINCRISTINE SULFATE

O'Brien S et al. J Clin Oncol 2013;31:676–683

Vincristine sulfate liposome injection 2.25 mg/m² per dose; administer intravenously in (total volume [q.s.]) 100 mL 0.9% sodium chloride or 5% dextrose injection over 60 minutes for 4 doses on days 1, 8, 15, and 22, every 28 days (total dosage/cycle = 9 mg/m²)

- Liposomal vincristine sulfate doses are calculated from actual body surface area, and are not capitated

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

G ≥3 adverse effects (severe symptoms; limiting self-care activities of daily living [ADL]*) or persistent G2 (moderate symptoms; limiting instrumental ADL)† peripheral neuropathy:	Interrupt vinCRIStine sulfate LIPOSOME If the peripheral neuropathy remains at G ≥3, discontinue liposomal vincristine sulfate If the peripheral neuropathy recovers to G ≤2, continue treatment with liposomal vincristine sulfate dosage decreased to 2 mg/m² per dose
Persistent G2 peripheral neuropathy after the first dose reduction to 2 mg/m²	Interrupt liposomal vincristine sulfate for up to 7 days If the peripheral neuropathy increases to G ≥3, discontinue liposomal vincristine sulfate If peripheral neuropathy recovers to G ≤1, continue treatment with liposomal vincristine sulfate dosage decreased to 1.825 mg/m² per dose
Persistent G ≥2 peripheral neuropathy after a second dose reduction to 1.825 mg/m²	Interrupt liposomal vincristine sulfate for up to 7 days If the peripheral increases to G ≥3, discontinue liposomal vincristine sulfate If the toxicity recovers to G ≤1, continue treatment with liposomal vincristine sulfate dosage decreased to 1.5 mg/m² per dose
If neutropenia, thrombocytopenia, or anemia G ≥3 develop, consider dose modification or reduction as well as supportive care measures.	
Reduce liposomal vincristine sulfate dosages or interrupt treatment for hepatic toxicity	

Severity grading for adverse events is based on the National Cancer Institute (NCI) Common Terminology Criteria for Adverse Events (CTCAE) v3.0. Available at: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]

**Self-care ADL* refers to bathing, dressing and undressing, feeding self, using the toilet, taking medications, and not bedridden

†*Instrumental ADL* refers to preparing meals, shopping for groceries and clothes, using telephone, managing money, etc.

Patient Population Studied

Sixty-five adults (median age: 31 years; range: 19–83 years) with Ph-negative ALL in second or greater relapse, or whose disease had progressed following 2 or more leukemia therapies

Efficacy

CR/CRi rate was 20% and overall response rate was 35%

Median OS, overall, 4.6 months (range: <1 month to >25 months), and 7.7 months (range: 2.4 to >23.3 months) among patients who achieved a CR/CRi.

Therapy Monitoring

CBC with differential leukocyte count, renal and hepatic function tests prior to each dose of liposomal vincristine sulfate

Bone marrow biopsy on day 28 of treatment courses 1 and 2 and every second treatment course thereafter

Toxicity

Notes:

- Liposomal vincristine sulfate is a vinca alkaloid indicated for the treatment of adult patients with Philadelphia chromosome-negative (Ph−) acute lymphoblastic leukemia (ALL) in second or subsequent relapse, or whose disease has progressed following 2 or more antileukemia therapies
- Liposomal vincristine sulfate is contraindicated in patients with demyelinating conditions including Charcot-Marie-Tooth syndrome
- Neurologic toxicity: Monitor patients for peripheral, motor, and sensory, central and autonomic neuropathy, and reduce, interrupt, or discontinue treatment if signs or symptoms present
  - Patients with preexisting severe neuropathy should be treated with liposomal vincristine sulfate only after careful risk-benefit assessment

REGIMEN

NELARABINE

Gökbuget N et al. Blood 2011;118:3504–3511

Nelarabine 1500 mg/m² per dose; administer intravenously (without dilution) over 2 hours for 3 doses on days 1, 3, and 5, every 21 days (total dosage/cycle = 4500 mg/m²)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Study of 126 relapsed/refractory patients (85% T-cell acute lymphoblastic leukemia (T-ALL), 15% T-cell lymphoblastic lymphoma), median age 33 years (range: 18–81 years) treated with nelarabine

Treatment Modifications

Nelarabine administration should be discontinued for neurologic adverse reactions of NCI Common Terminology Criteria for Adverse Events grades ≥2. Treatment may be delayed for other toxicities

Therapy Monitoring

1. Weekly and before a treatment cycle: CBC with differential, renal, and hepatic function
2. Response evaluation: bone marrow biopsy every 2 cycles

Efficacy (N = 126)

	Result after Cycle 1 (%)	Overall Result after 1–3 Cycles (%)
CR	32	36
PR	19	10
Failure	47	52
Death on therapy	1	1
Withdrawal	2	2

- Patients with CR after 1 cycle (N = 36) tended to have a better 3-year survival (32% ± 8%) compared with those who later achieved a CR (N = 9; 11% ± 10%; $P = 0.06$)
- The probability of survival after 1 year was 24% (SE ± 3%) and after 3 years 12% (SE ± 3%) with a median survival of 6 months
- The 3-year survival of patients with failure or PR after nelarabine (N = 81) compared with patients who achieved a CR (N = 45) was 4% (SE ± 2%) versus 28% (SE ± 7%), respectively ($P < 0.0001$)
- A total of 36 of 45 patients (80%) who achieved a CR after nelarabine subsequently received stem cell transplantation (SCT) in continuous CR. Four patients died in CR (11%) related to transplantation (GVHD N = 1, infection N = 3) and 20 patients relapsed (56%). The probability of survival 3 years after transplantation in 36 patients transplanted in CR after nelarabine is 31% (SE ± 8%), and the relapse-free survival at 3 years is 37% (SE ± 9%). The median time to relapse after SCT was 4 months (range: 1–24) months. In patients alive after SCT, the median survival was 41 months (range: 13–85 months)
- Survival probability at 3 years was 36% (SE ± 8%) in the 36 patients transplanted in CR after nelarabine. In comparison, CR patients without transplantation in CR after nelarabine (N = 9) survival probability was zero and failure or PR was 4% (SE ± 2%; N = 81) after 3 years ($P < 0.0001$)

Toxicity

Hematologic	G 3–4 (%)
Leukopenia	41
Granulocytopenia	37
Thrombocytopenia	17

Neurotoxicity

	Incidence, N (%) of Cycles	G 1	G 2	G 3	G 4
		Number of Cycles			
Cognitive disturbance	9 (4)	3	0	1	5
Confusion	9 (4)	3	0	3	3
Consciousness impaired	1 (0.5)	0	0	1	0
Dizziness	13 (6)	7	2	2	2
Fatigue	1 (0.5)	1	0		0
Guillain-Barré–like syndrome	1 (0.5)	0	0	1	0
Hallucination	4 (2)	0	0	2	2
Insomnia	2 (1)	1	0	1	0
Memory impaired	7 (3)	2	1	1	3
Mood alteration	12 (6)	7	1	4	0
Neuropathy increased	5 (2)	2	2	1	0
Restlessness	4 (2)	1	2	0	1
Somnolence	1 (0.5)	0	0	1	0
Tremor	4 (2)	1	1	2	0

- Neurologic toxicities of any degree were observed after 26 cycles (13%) in 20 patients (16%). The majority of events were G1 or G2. In 4% of the cycles (N = 4) and 7% of the patients (N = 9), G3/4 neurotoxicities were observed
- In 1 patient, treatment had to be stopped because of a Guillain-Barré–like syndrome with tetraparesis, hallucinations, and reduced vigilance, which developed at day 3 of the first cycle. The symptoms improved slowly after nelarabine was withdrawn

Notes

- Nelarabine is indicated for the treatment of patients with T-cell acute lymphoblastic leukemia and T-cell lymphoblastic lymphoma whose disease has not responded to or has relapsed following treatment with at least 2 chemotherapy regimens
- Severe neurologic adverse reactions have been reported with the use of nelarabine, including altered mental states, such as severe somnolence, central nervous system effects, such as convulsions, and peripheral neuropathy, ranging from numbness and paresthesias to motor weakness and paralysis. There have also been reports of adverse reactions associated with demyelination, and ascending peripheral neuropathies similar to Guillain-Barré syndrome

  Full recovery from adverse reactions has not always occurred with cessation of therapy with nelarabine. Close monitoring for neurologic adverse reactions is strongly recommended
- DeAngelo DJ et al. (Blood 2007;109: 5136–5142) also reported their experience with 26 refractory/relapsed patients with T-cell acute lymphoblastic leukemia (T-ALL) and 13 patients with T-cell lymphoblastic lymphoma whose median age was 34 years (range: 16–66 years). Treatment consisted of **nelarabine** 1500 mg/m² per dose intravenously over 2 hours for 3 doses on days 1, 3, and 5, every 21 days (total dosage/cycle = 4500 mg/m²). The investigators reported a complete remission rate of 31% (95% confidence interval [CI], 17%, 48%), and an overall response of 41% (95% CI, 26%, 58%). The principal toxicities were G3 or G4 neutropenia and thrombocytopenia, which occurred in 37% and 26% of patients, respectively. Only one G4 neurologic adverse event occurred, a reversible depressed level of consciousness. The median disease-free survival (DFS) was 20 weeks (95% CI, 11%, 56%), and the median overall survival was 20 weeks (95% CI, 13%, 36%). The 1-year overall survival was 28% (95% CI, 15%, 43%)

18. Leukemia, Acute Myeloid

Michael M. Boyiadzis, MD, MHSc, Ivan Aksentijevich, MD, and Judith Karp, MD

Epidemiology

Incidence: 18,860 (male: 11,530; female: 7,330. Estimated new cases for 2014 in the United States)
3.7 per 100,000 male and female per year (4.5 per 100,000 male, 3.1 per 100,000 female)
Deaths: Estimated 10,460 in 2014 (male: 6,010; female: 4,450)
Median age: 67 years (median age for acute promyelocytic leukemia: 40 years)
Male to female ratio: 1.48

Dores GM. Blood 2012;119:34–43
Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Work-up

- H&P
- CBC and leukocyte differential counts, platelets, electrolytes, liver function tests, PT, PTT, INR, fibrinogen, LDH, uric acid
- Bone marrow biopsy with cytogenetics, immunophenotyping, and molecular studies (including c-KIT, FLT3-ITD, NPM, CEBPA)
- HLA typing for patients who are candidates for allogeneic hematopoietic stem cell transplantation
- Cardiac scan if prior cardiac history or prior anthracycline use
- Lumbar puncture if neurologic symptoms (LP should be performed if a mass/lesion is not detected on imaging studies)

Pathology

WHO Classification of Acute Myeloid Leukemia

1. **AML with recurrent genetic abnormalities**
   - AML with t(8;21)(q22;q22) (RUNX1-RUNX1T1)
   - AML with inv(16)(p13.1q22) or t(16;16)(p13.1;q22) (CBFB-MYH11)
   - APL with t(15;17)(q22;q12); PML-RARA
   - AML with t(9;11)(p22;q23); MLLT3-MLL
   - AML with t(6;9)(p23;q34); DEK-NUP214
   - AML with inv(3)(q21q26.2) or t(3;3)(q21;q26.2); RPN1-EVI1
   - AML (megakaryoblastic) with t(1;22)(p13;q13); RBM15-MKL1
   - AML with mutated NPM1
   - AML with mutated CEBPA
2. **AML with MDS-related features**
3. **Therapy-related AML**
4. **AML not otherwise specified**
   - AML minimal with differentiation
   - AML without maturation
   - AML with maturation
   - Acute myelomonocytic leukemia
   - Acute monoblastic and monocytic leukemia
   - Acute erythroid leukemia
   - Acute megakaryoblastic leukemia
   - Acute basophilic leukemia
   - Acute panmyelosis with myelofibrosis
5. **Myeloid proliferation related to Down syndrome**
   - Transient abnormal myelopoiesis
   - Myeloid leukemia associated with Down syndrome

Swerdlow SH et al., eds. WHO Classification of Tumours of Haematopoietic and Lymphoid Tissues, 4th ed. Lyon, France: International Agency for Research on Cancer Press; 2008

Response Criteria for Acute Myeloid Leukemia

Morphologic leukemia-free state
Bone marrow <5% blasts in an aspirate with spicules
No blasts or Auer rods or persistence of extramedullary disease

Complete remission
Patient achieves a morphologic leukemia-free state, *and*
Absolute neutrophil count >1000/mm^3
Platelets ≥100,000/mm^3
No residual evidence of extramedullary disease
Morphologic CR–patient independent of transfusions
Cytogenetic CR–cytogenetics normal (in those with previously abnormal cytogenetics)
Molecular CR–negative molecular studies in patients with APL or Ph+ leukemia

Patients who fail to achieve a complete response are considered treatment failures
Relapse following a complete response is defined as reappearance of leukemic blasts in the peripheral blood or the finding of more than 5% blasts in the bone marrow, not attributable to another cause

Cheson BD et al. J Clin Oncol 2003;21:4642–4649

Risk Stratification

Risk Status	Cytogenetics	Molecular Abnormalities
Better-risk	inv(16) or t(16;16) t(8;21) t(15;17)	normal cytogenetics with NPM1 mutation or isolated CEBPA mutation in the absence of FLT3-ITD
Intermediate risk	normal cytogenetics +8 t(9;11) other nondefined	t(8;21), inv (16), t(16;16) with c-kit mutation
Poor risk	complex −5,5q,−7,7q− 11q23 –non t(9;11) inv(3), t(3;3) t(6;9) t(9;22)	normal cytogenetics with flt3-itd mutation

O'Donnell MR et al. J Natl Compr Canc Netw 2011;9:280–317

Expert Opinion

Acute Myeloid Leukemia

- Three days of an anthracycline and 7 days of cytarabine (the "3+7" induction regimen) currently remains the standard for newly diagnosed patients with AML (excluding APL) who can tolerate intensive chemotherapy. Bone marrow biopsy/aspirate should be performed 7–10 days after completion of therapy. If the bone marrow is hypoplastic (defined as cellularity <10--20% and residual blasts <5–10%), a repeated bone marrow should be performed until count recovery when the remission status can be assessed. If the bone marrow has residual blasts, then a second course of therapy can be administered; this can be identical to the first induction course, escalation to high-dose cytarabine or non–cross-resistant antileukemic regimens (eg, mitoxantrone and etoposide). Young patients without comorbidities who are refractory to initial induction regimens should be considered for allogeneic hematopoietic cell transplantation (HCT) using a myeloablative regimen
- The choice of postremission therapy must be determined by the prognostic group, most importantly, the cytogenetics/molecular studies at presentation. In patients with favorable cytogenetics/molecular studies intensive postremission therapy should be administered. The use of peripheral autologous hematopoietic cell transplantation should be considered in experienced centers that have demonstrated a consistently low morbidity and therapy-related mortality
- Postremission with intensive therapy should be considered in patients with core-binding factor AML (CBF-AML) characterized by t(8;21)(q22;q22); *RUNX1-RUNX1T1* and inv(16)(p13.1q22) or t(16;16)(p13.1;q22); and *CBFB-MYH11* (activating *KIT* mutations are found in approximately one-third of CBF-AML, and are associated with a significantly inferior outcome in most but not all studies; a clinical trial or allo-HCT should be consider for these patients). Similar to CBF-AML, repetitive cycles of high-dose cytarabine is a reasonable first-line strategy in patients with normal karyotype and mutated NPM1 or CEBPA^{dm} without FLT3-ITD
- In patients with AML with intermediate-risk cytogenetics, allo-HCT should be considered if a HLA-matched donor is available. There is no added benefit in receiving additional high-dose postremission therapy prior to allo-HCT if there is no delay in the HCT. Allo-HCT should also be considered in patients with cytogenetically normal karyotype whose leukemic cells have FLT-3 ITD. For patients with poor cytogenetics or molecular abnormalities, patients with prior myelodysplasia allo-HCT should also be considered
- Older patients with good performance status, minimal comorbidity, and good risk cytogenetics or molecular mutations, may benefit from standard therapies regardless of chronologic age. Patients deemed unfit to received intensive chemotherapy may be managed by one of the following options: best supportive care, subcutaneously administered cytarabine, azacitidine, decitabine, or clofarabine. Patients in first relapse after a CR duration >6–12 months can be retreated with either the induction regimen they last received or a high-dose cytarabine-containing regimen; after a second CR, patients should be considered for an allo-HCT. For patients in first relapse after a short CR duration (<6 months) a non–cross-resistant antileukemic regimen should be used, and, after a second CR, patients should be considered for an allo-HCT

(*continued*)

Expert Opinion (*continued*)

Evaluation for CNS Leukemia

- Leptomeningeal involvement is much less frequent (<5%) in AML than in ALL; thus, routine lumbar puncture is not recommended during routine diagnostic work-up. However, if neurologic symptoms are present at diagnosis, an initial MRI/CT should be first performed to rule out bleeding or mass effect. If the lumbar puncture is positive, intrathecal chemotherapy with cytarabine or methotrexate is recommended, concurrent with induction chemotherapy. Intrathecal chemotherapy is given twice per week until cerebrospinal fluid cytology shows no blasts, and then weekly for 4–6 weeks. Liposomal cytarabine has a longer half-life than conventional formulations (cytarabine injection; Cytarabine for Injection, USP) and offers the benefit of less-frequent (once weekly) administration. Screening for occult CNS should be considered in AML patients in remission with M4 or M5 morphology, biphenotypic leukemia, or WBC >100,000/mm^3 at diagnosis

Acute promyelocytic leukemia (APL)

- APL is a medical emergency primarily because of bleeding, which continues to represent a major cause of early death. Once the diagnosis is suspected on the basis of clinical findings and the peripheral blood smear (even without waiting for a bone marrow examination), and before the diagnosis is confirmed by cytogenetic or molecular studies, tretinoin (all *trans*-retinoic acid; ATRA) should be given emergently, both to resolve the coagulopathy as well as to initiate induction therapy
- The concurrent administration of tretinoin plus cytotoxic chemotherapy produces a complete remission (CR) in 80–95% of patients of all ages with APL. Tretinoin plus anthracyclines either alone or with cytarabine for induction (in high risk patients, WBC>10,000/mm^3) is the current standard of care. The combination of all-trans retinoic acid + arsenic trioxide has provided the opportunity to minimize and even eliminate standard cytotoxic chemotherapy from initial treatment regimens without compromising the excellent outcomes achieved by anthracycline-containing protocols
- The goal of consolidation therapy for APL is the conversion of a morphologic and cytogenetic remission into a durable molecular remission. Molecular remission often requires at least 2 cycles of consolidation
- Two or 3 cycles of an anthracycline, either daunorubicin or idarubicin, are administered until a molecular CR is achieved. Tretinoin is also given for 1 to 2 weeks with each cycle of consolidation. In patients with high-risk disease (WBC >10,000/mm^3), either intermediate- or high-dose cytarabine may be administered. The choice of regimen should be influenced by risk group, age, and cardiovascular risk. Patients should be treated according to regimens established from large clinical trials, and one should use a regimen consistently through all components not mixing induction from one trial with consolidation from a different trial
- Mercaptopurine + methotrexate have been used as maintenance therapy, which continues for 1–2 years. The addition of tretinoin in maintenance improved disease-free survival and relapse rates. However, as consolidation regimens have evolved to incorporate tretinoin or arsenic trioxide, the role of these agents in maintenance needs to be defined, especially in low-risk patients who achieve molecular CR after consolidation
- Bone marrow biopsy should be done after peripheral blood counts recover from induction therapy to determine whether a CR by morphology has been achieved. Monitoring RT-PCR for the PML-RAR-α fusion transcript to document molecular remission should be performed on a marrow sample at completion of consolidation. Subsequent monitoring of patients by PCR can be done with peripheral blood at a minimum of every 2 months for 2 years to detect molecular relapse

Adès L et al. J Clin Oncol 2006;24:5703–5710

Sanz MA et al. Blood 2010;115:5137–5146

Supportive Care

Hyperleukocytosis in AML

- The frequency of hyperleukocytosis (conventionally and arbitrarily defined as a WBC count >100,000/mm^3) ranges from 5% to 13% in adult patients with AML
- Symptoms may arise from the involvement of any organ, but intracranial hemorrhages and respiratory failure account for the majority of deaths. In many patients, leukostasis becomes evident a few days after diagnosis, and sometimes after the first leukocytoreduction. Clinical deterioration and death may occur after the blast count has been significantly reduced, which suggests that although leukocytoreduction is an important step in the management of leukostasis, additional measures are needed to prevent leukostasis-related deaths

Treatment

- Prompt leukocytoreduction, initiation of chemotherapy, and supportive care
- Leukocytoreduction can be achieved by the use of hydroxyurea. Hydroxyurea should be started immediately in all patients with hyperleukocytotic AML. Hydroxyurea given at dosages up to 50–60 mg/kg per day orally until WBCs are <10,000–20,000/mm^3
- Leukopheresis is also an option for the initial management of hyperleukocytosis. The disadvantage of leukopheresis is that it requires the placement of a large caliber central venous catheter in patients who may be thrombocytopenic and coagulopathic, and it may also worsen their thrombocytopenia. There are no guidelines that identify the absolute WBC count to be achieved by leukopheresis that correlates with reversal of the signs and symptoms of leukostasis

PROPHYLAXIS AGAINST TUMOR LYSIS SYNDROME

HYDRATION + URINARY ALKALINIZATION + ADMINISTRATION OF ALLOPURINOL

Hydration with 2500–3000 mL/m² per day as tolerated; administer intravenously to maintain urine output ≥100 mL/hour (or ≥2 mL/kg per hour in persons whose body weight is <50 kg)

Urinary alkalinization with sodium bicarbonate injection added to intravenously administered fluids

- The amount of sodium bicarbonate added to intravenously administered fluids should produce a solution with sodium content not greater than the concentration of sodium in 0.9% sodium chloride injection (≤154 mEq/L):

Sodium Bicarbonate is Added to a Solution to Increase Urine pH within a Range 6.0 to ≤7

Base Solution Sodium Content	Sodium Bicarbonate Additive	Total Sodium Content
0.45% Sodium Chloride Injection (0.45% NS)		
77 mEq/L	50–75 mEq	127–152 mEq/L
0.2% Sodium Chloride Injection (0.2% NS)		
34 mEq/L	100–125 mEq	134–159 mEq/L
5% Dextrose Injection (D5W)		
0	125–150 mEq	125–150 mEq/L
D5W/0.45% NS		
77 mEq/L	50–75 mEq	127–152 mEq/L
D5W/0.2% NS		
34 mEq/L	100–125 mEq	134–159 mEq/L

Notes:

- Hydration rate may be decreased at the completion of chemotherapy administration
- Urinary alkalization increases the solubility and excretion of uric acid and its oxypurine precursors (hypoxanthine and xanthine) and helps avoid uric acid crystallization in renal tubules; however, alkalinization is not uniformly recommended because:
  1. It favors precipitation of calcium/phosphate in renal tubules, a concern in patients with concomitant hyperphosphatemia
  2. A metabolic alkalemia may result from the administration of bicarbonate that can worsen the neurologic manifestations of hypocalcemia

Allopurinol

- Administer orally or intravenously starting 12 hours to 3 days (preferably 2–3 days) before starting cytoreductive chemotherapy
- Hyperuricemia develops within 24–48 hours after initiating chemotherapy when the excretory capacity of the renal tubules is exceeded
- In the presence of an acid pH, uric acid crystals form in the renal tubules, leading to intraluminal renal tubular obstruction, an acute renal obstructive uropathy, and renal dysfunction

Initial dosage

- Allopurinol 100 mg/m² per dose; administer orally every 8 hours (maximum daily dose = 800 mg), *or*
- Allopurinol 3.3 mg/kg per dose; administer orally every 8 hours (maximum daily dose = 800 mg), *or*
- Allopurinol 200–400 mg/m² per day; administer intravenously (maximum daily dose = 600 mg) in a volume of 5% dextrose injection or 0.9% sodium chloride injection sufficient to yield a concentration not greater than 6 mg/mL. The duration for administering individual doses should be informed by the volume to be given
  - Allopurinol may be administered as a single daily dose, or the total daily dose may be divided equally for administration at 6-, 8-, or 12-hour intervals
- **Maintenance doses** should be based on serum uric acid determinations performed approximately 48 hours after initiation of allopurinol therapy, and periodically thereafter
- Continue administering allopurinol until leukemic blasts have been cleared from the peripheral blood

(*continued*)

(*continued*)

Notes:

• Allopurinol dose adjustments for impaired renal function:

Creatinine Clearance	Oral Allopurinol Dose
10–20 mL/min (0.17–0.33 mL/s)	200 mg/day
3–10 mL/min (0.05–0.17 mL/s)	100 mg/day
<3 mL/min (<0.05 mL/s)	100 mg every 36–48 hours

• The incidence of allergic reactions is increased in patients receiving amoxicillin, ampicillin, or thiazide diuretics

Rasburicase is recombinant urate oxidase (uricase) produced by genetically modified *Saccharomyces cerevisiae* that express urate oxidase cDNA cloned from a strain of *Aspergillus flavus*

• Uricase enzymes catalyze uric acid oxidation to allantoin, which is at least 5 times more soluble than uric acid

Rasburicase should be considered among initial interventions against hyperuricemia in patients with high peripheral WBC counts, rapidly increasing blasts counts, high uric acid, or with evidence of impaired renal function; that is:

WBC ≥100,000/mm^3	
WBC ≥25, 000 to <100,000/mm^3 *or* WBC <25,000/mm^3 + LDH ≥2× ULN	+ acute kidney injury *or* + normal renal function uric acid >ULN potassium or phosphorus >ULN

ULN, upper limit of normal

See Chapter 46, *Oncologic Emergencies*

Rasburicase 0.2 mg/kg per dose intravenously in a total volume of 50 mL 0.9% sodium chloride injection over 30 minutes once daily for up to 5 consecutive days is often used, but much less is usually sufficient (See Chapter 46, Oncologic Emergencies) (dosage and administration recommendations published in U.S. Food and Drug Administration product labeling, January 2011)

• Rasburicase has demonstrated effectiveness in prophylaxis and treatment for hyperuricemia and acute increases in uric acid associated with cytoreductive therapies at dosages <0.2 mg/kg based on body weight, with fixed doses, and after administration of from 1–3 doses

INDUCTION THERAPY FOR PREVIOUSLY UNTREATED ACUTE MYELOGENOUS LEUKEMIA REGIMEN

CYTARABINE + DAUNORUBICIN

Fernandez HF et al. N Engl J Med 2009;361:1249–1259

Cytarabine 100 mg/m² per day; administer by continuous intravenous infusion in 100–1000 mL 0.9% sodium chloride injection or 5% dextrose injection over 24 hours for 7 consecutive days on days 1–7 (total dosage/cycle = 700 mg/m²)

Daunorubicin 60–90 mg/m² per day; administer by intravenous injection over 3–5 minutes for 3 consecutive days on days 1–3 (total dosage/cycle = 180–270 mg/m²)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days 1–3 is ***MODERATE***

Emetogenic potential on days 4–7 is ***LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) should be considered in patients with severe infection or in elderly patients or in patients with slow bone marrow recovery. Begin use after bone marrow aplasia is confirmed and continue use until ANC recovers

Primary prophylaxis is indicated with one of the following:

Filgrastim (G-CSF) 5 mcg/kg per day; administer by subcutaneous injection, *or*

Sargramostim (GM-CSF) 250 mcg/m² per day; administer by subcutaneous injection

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is HIGH

Antimicrobial primary prophylaxis is recommended:

- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Patient Population Studied

Study of 657 patients who had untreated AML (ages: 17–60 years) who were randomized to receive 3 once-daily doses of daunorubicin at either the standard dose (45 mg/m² of body-surface area per day) or a high dose (90 mg/m² per day), combined with 7 daily doses of cytarabine 100 mg/m² per day by continuous intravenous infusion

Efficacy

Induction therapy: 57% in the standard-dose group *vs.* 71% in the high-dose group

In the standard-dose group, patients younger than the age of 50 years had a CR of 59.4% in comparison with CR of 74.3% in the high-dose group

High-dose daunorubicin (90 mg/m² per day) did not provide benefit in patients older than the age of 50 years or those with unfavorable cytogenetic profile

The median overall survival was 15.7 months in the standard-dose group and 23.7 months in the high-dose group

Toxicity

	Standard Dose (45 mg/m² · day) N = 318		High Dose (90 mg/m² · day) N = 315	
Adverse Events	G3	G4	G3	G4
Low hemoglobin	67	11	63	13
Low Blood Count				
Leukocytes	2	95	<1	98
Neutrophils	3	93	18	80
Platelets	16	81	18	80
Transfusions Required				
Platelets	55	5	57	6
PRBC	59	1	59	<1
Fatigue	5	<1	3	3
Fever	5	1	5	3
Rash or desquamation	5	<1	5	0
Anorexia	4	4	5	5
Nausea	6	<1	5	0
Hemorrhage with G3/4 low platelet count	8	1	10	1
Febrile neutropenia	32	3	31	4
Infection with G3/4 neutropenia	40	7	39	<1
Dyspnea	4	2	<1	3
Cardiac event*	5	2	4	3

*A reduced left ventricular ejection fraction was reported in none of 318 patients in the standard group and in 4 of 315 patients in the high-dose group

Notes: The death rates during induction therapy were 4.5% in the standard-dose group and 5.5% in the high-dose group (P = 0.60). Causes of death were infection (14 patients), pulmonary failure (6 patients), cardiac failure (4 patients), hemorrhage (3 patients), hypotension (2 patients), and ileus (1 patient)

Treatment Modifications

Adverse Events	Treatment Modifications
Creatinine >3 mg/dL (>265 μmol/L)	Reduce daunorubicin dosage by 50%
Total bilirubin 2.5–5 mg/dL (42.8–85.5 μmol/L)	
Total bilirubin >5 mg/dL (>85.5 μmol/L)	Hold daunorubicin

Therapy Monitoring

1. CBC with differential daily during induction chemotherapy and following therapy until neutrophil recovery (>500/mm^3) and patients achieve independence from platelet transfusions
2. Electrolytes, mineral panel, liver function tests daily, and uric acid at least daily during active treatment until risk of tumor lysis is past
3. Bone marrow aspirate/biopsy 7–10 days after chemotherapy is completed

INDUCTION THERAPY FOR PREVIOUSLY UNTREATED ACUTE MYELOGENOUS LEUKEMIA REGIMEN

CYTARABINE + IDARUBICIN

Vogler WR et al. J Clin Oncol 1992;10:1103–1111

Cytarabine 100 mg/m² per day; administer by continuous intravenous infusion in 100–1000 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 24 hours for 7 consecutive days, on days 1–7 (total dosage/cycle = 700 mg/m²)

Idarubicin 12 mg/m² per day; administer intravenously diluted to a concentration >0.01 mg/mL with 0.9% NS or D5W over 15–30 minutes for 3 consecutive days, on days 1–3 (total dosage/cycle = 36 mg/m²)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on Days 1–3 is ***MODERATE***
Emetogenic potential on Days 4–7 is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) should be considered in patients with severe infection or in elderly patients or in patients with slow bone marrow recovery. Begin use after bone marrow aplasia is confirmed and continue use until ANC recovers

Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Sargramostim (GM-CSF) 250 mcg/m² per day by subcutaneous injection
See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is HIGH

Antimicrobial primary prophylaxis is recommended:

- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Patient Population Studied

Study of 111 patients (median age: 60 years) with newly diagnosed AML

Efficacy (N = 105)

Induction CR 69%, Number in CR with 1 course: 77 %
Median time to CR: 42 days
Response by age group
Ages 15–50 years (N = 29): 86%
51–60 years (N = 24): 71%
>60 years (N = 52): 63%

Toxicity (N = 105)

Adverse Events	G1/2 %	G3/4 %
Nausea and vomiting	76	6
Diarrhea	57	16
Mucositis	43	7
Total bilirubin	36	9
SGOT (AST)	47	5
Alkaline phosphatase	52	5
Creatinine	29	2
Skin rash	41	5
Cardiac	5	11
Hair loss	37	40

	Mean Duration of Aplasia (Days)
WBC <1000/mm³	31.2
Platelets <50,000/mm³	35.1

Therapy Monitoring

1. CBC with differential daily during induction chemotherapy and following therapy until neutrophil recovery (>500/mm³), and until patients achieve independence from platelet transfusions
2. Electrolytes, mineral panel, liver function tests daily, and uric acid at least daily during active treatment until risk of tumor lysis is past
3. Bone marrow aspirate/biopsy 7–10 days after chemotherapy is completed

Treatment Modifications

Adverse Events	Treatment Modifications
Creatinine >3 mg/dL (>265 µmol/L)	Reduce idarubicin dosage by 50%
Total bilirubin 2.6–5 mg/dL (44.5–85.5 µmol/L)	Reduce idarubicin dosage by 50%
Total bilirubin >5 mg/dL (>85.5 µmol/L)	Hold idarubicin

INTENSIVE POSTREMISSION CHEMOTHERAPY IN ADULTS WITH ACUTE MYELOID LEUKEMIA REGIMEN

HIGH-DOSE CYTARABINE

Mayer RJ et al. N Engl J Med 1994;331:896–903

Cytarabine 3000 mg/m² per dose; administer intravenously in 100–1000 mL 0.9% sodium chloride injection or 5% dextrose injection over 3 hours, every 12 hours for 6 doses (2 doses/day) on days 1, 3, and 5, every 28 days for 4 cycles (total dosage/cycle = 18,000 mg/m²)

Notes: Repeated cycles were initiated no sooner than 28 days after a previously administered cycle, or 1 week after patients achieved postnadir ANC >1500/mm³ and platelet counts >100,000/mm³, with the expectation the maximal interval between consecutive cycles would be ≤35 days

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on days of treatment is ***MODERATE–HIGH***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) should be considered in patients with severe infection or in elderly patients or in patients with slow bone marrow recovery. Begin use after bone marrow aplasia is confirmed and continue use until ANC recovers

Primary prophylaxis is indicated with one of the following:

Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*

Sargramostim (GM-CSF) 250 mcg/m² per day by subcutaneous injection

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is HIGH

Antimicrobial primary prophylaxis is recommended:

- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Keratitis prophylaxis

Steroid ophthalmic drops (prednisolone 1% or dexamethasone 0.1%) administer by intraocular instillation daily until 24 hours after high-dose cytarabine is completed

Treatment Modifications

Adverse Events	Treatment Modifications	
Neurologic toxicity	Hold cytarabine. Patients who develop CNS symptoms should not receive subsequent high-dose cytarabine	
The risk of neurotoxicity with high-dose cytarabine therapy is directly related to renal function throughout therapy	**Serum Creatinine**	**Cytarabine Dosage**
	<1.5 mg/dL (<133 μmol/L)	2000 mg/m²
	1.5–1.9 mg/dL (133–168 μmol/L), or an increase from baseline by 0.5–1.2 mg/dL (44–106 μmol/L)	1000 mg/m²
	≥2 mg/dL (≥177 μmol/L), or an increase of >1.2 mg/dL (>106 μmol/L)	100 mg/m² per day by continuous intravenous infusion over 24 hours for up to 6 days
In patients exhibiting rapidly rising creatinine as a result of tumor lysis	Hold cytarabine	

Patient Population Studied

Study of 596 patients in CR after induction chemotherapy (daunorubicin + cytarabine) who were randomly assigned to receive 4 cycles of cytarabine on one of three 5-day dosage schedules: low-dose or moderate-dose cytarabine administered by continuous intravenous infusion, or high-dose cytarabine administered intravenously intermittently

Efficacy

The likelihood of remaining alive and disease-free (DFS) after 4 years was 21% among subjects who received low-dose continuous infusion cytarabine, 25% in the moderate-dose group, and 39% among those who received high-dose cytarabine

The probability of remaining alive (survival) for 4 years after randomization was 31% for the group assigned to receive low-dose continuous infusion cytarabine, 35% for the group assigned to receive moderate-dose intermittent infusions, and 46% among patient who received high-dose cytarabine

The probability of remaining in continuous complete remission after 4 years among patients ≤60 years of age was 24% in the low-dose group, 29% in the moderate-dose group, and 44% in the high-dose group

In contrast, for patients older than 60 years of age, the probability of remaining disease-free after 4 years was ≤16% in each group

Subsequent analysis showed a disease-free survival rate of 60% for patients with good-risk cytogenetics, 30% with intermediate-risk cytogenetics, and 12% with poor-risk cytogenetics in patients who received high-dose cytarabine

Bloomfield CD et al. Cancer Res 1998;58:4173–4179

Toxicity

% of Patients Who Received 4 Planned Cycles	Cytarabine Regimens		
	LD CIVI	MD CIVI	High-Dose
All patients	76%	74%	56%
Patients, ages ≤60 years	78%	76%	62%

Cytarabine Regimens	Cycles During Which Patients Were Hospitalized	Serious CNS Toxicity	Deaths During Remission
LD CIVI	16%	0	1%
MD CIVI	59%	0	6%
High-Dose	71%	12%	5%

LD CIVI, Cytarabine 100 mg/m² per day by continuous intravenous infusion over 24 hours for 5 consecutive days on days 1–5; MD CIVI, cytarabine 400 mg/m² per day by continuous intravenous infusion over 24 hours for 5 consecutive days on days 1–5; High-Dose, 3000 mg/m² per dose by intravenous infusion over 3 hours, twice daily on days 1, 3, and 5, for 6 doses

Therapy Monitoring

1. CBC with differential and platelet counts daily during chemotherapy; electrolytes, LFTs, and mineral panel, daily during chemotherapy
2. *Out patient monitoring postchemotherapy:* CBC with differential, platelets, and electrolytes, 2–3 times weekly until counts recovery
3. *Between cycles:* Bone marrow biopsy/aspirate if peripheral blood counts are abnormal, or patients failure to recover counts after therapy. Bone marrow biopsy after recovery of counts following the last course of therapy

Notes:

1. This trial of postremission therapy for AML demonstrated a significant dose–response effect for cytarabine. Patients 60 years of age or younger who received high-dose cytarabine were more likely to remain in remission and to survive longer than patients in the same age group who received lower doses. Serious CNS abnormalities were reported only in the group given high-dose cytarabine, and were especially common in patients older than 60 years of age
2. Patients who receive high-dose cytarabine need to be closely monitored for changes in renal function. Renal dysfunction is highly correlated with an increased risk of cerebellar toxicity. Patients need to be monitored for nystagmus, dysmetria, and ataxia before each dose of cytarabine

ACUTE PROMYELOCYTIC LEUKEMIA (APL) INDUCTION REGIMEN

TRETINOIN (ALL *TRANS*-RETINOIC ACID) + IDARUBICIN

Sanz MA et al. Blood 2010;115:5137–5146

Tretinoin 22.5 mg/m² per dose; administer orally every 12 hours until hematologic CR (total dosage/week = 315 mg/m²)

Idarubicin 12 mg/m² per dose; administer intravenously diluted to a concentration >0.01 mg/mL in 0.9% sodium chloride injection or 5% dextrose injection over 15–30 minutes for 4 doses on days 2, 4, 6, and 8 (total dosage/induction course = 48 mg/m²)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on days with tretinoin alone is **MINIMAL–LOW***

*Emetogenic potential on days with idarubicin is **MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is HIGH

Antimicrobial primary prophylaxis is recommended:

- Antibacterial—consider fluoroquinolone prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Patient Population Studied

Study of 437 consecutive patients with genetic diagnosis of APL

Efficacy

Of 402 evaluable patients, 372 achieved morphologic CR (92.5%)*

The median time interval to CR was 39 days (range: 18–81 days)

Patients with WBC counts >10,000/mm³ and >50,000/mm³ had a poorer response rates (83% and 73%, respectively) compared with those with low- and intermediate-risk patients (99% and 96%, respectively; $P < 0.001$)

*The median time to reach neutrophil counts >1000/mm³ and platelet counts >50,000/mm³ was 24 days (range: 6–72 days) and 19 days (range: 4–80 days), respectively

Toxicity

Causes of induction deaths*
Hemorrhage: 3.7%
Infection: 1.5%
Differentiation syndrome: 1%

*Hemorrhage and infection accounted for most of the deaths during induction therapy (15 and 6 patients, respectively). Deaths caused by hemorrhage were caused by intracranial (12 patients, 80%), pulmonary (2 patients, 13%), and gastrointestinal hemorrhages (1 patient, 7%). Differentiation syndrome and acute myocardial infarction were contributing causes of death in 4 and 2 patients, respectively. The remaining 3 deaths were attributable to massive suprahepatic thrombosis, myocarditis, and cardiac failure, each of which occurred in 1 patient

Therapy Monitoring

1. CBC 2- to 3-times daily until resolution of coagulopathy, then daily
2. Fibrinogen, PT, and PPT, twice daily until resolution of coagulopathy, then daily
3. Electrolytes, mineral panel, and uric acid, at least daily during active treatment until risk of tumor lysis is past
4. Bone marrow biopsy should be done once the peripheral blood counts recover from induction to determine whether a CR by morphology has been achieved

Treatment Modifications

Adverse Events	Treatment Modifications
Creatinine >3 mg/dL (>265 μmol/L)	Reduce idarubicin dosage by 50%
Total bilirubin 2.6–5 mg/dL (44.5–85.5 μmol/L)	Reduce idarubicin dosage by 50%
Total bilirubin >5 mg/dL (>85.5 μmol/L)	Hold idarubicin
ATRA syndrome	Hold ATRA and treat with dexamethasone 10 mg intravenously every 12 hours for 3–5 days, then decrease the dexamethasone dose and administration schedule (taper) over a week to discontinue. Restart ATRA when symptoms and signs improve

Notes:

1. ATRA (all *trans*-retinoic acid) syndrome occurs in patients with APL after treatment initiation. It is characterized by fever, peripheral edema, pulmonary infiltrates, hypoxemia, respiratory distress, hypotension, renal and hepatic dysfunction, and serositis, resulting in pleural and pericardial effusions. Considering that this complex of symptoms is not specific to the use of retinoic acid but may occur during therapy with agents such as arsenic trioxide it is now referred as the "APL differentiation syndrome"

   Early recognition and aggressive management with dexamethasone (10 mg; administer intravenously every 12 hours for ≥3 days) has been effective in most patients. If the symptoms or signs are severe, ATRA is discontinued and resumed at resolution of symptoms and signs, but under the cover of steroids, because the syndrome may recur. Tretinoin can be restarted in most cases
2. Disseminated intravascular coagulation (DIC) is frequently present at diagnosis in patients with APL, or occurs soon after the initiation of cytotoxic chemotherapy. This complication constitutes a medical emergency, because, if left untreated, it can cause pulmonary or cerebrovascular hemorrhage in up to 40% of patients with a 10–20% incidence of early hemorrhagic death. Tretinoin therapy appears to shorten the duration of the coagulopathy
3. Platelets are transfused to maintain platelet counts >30,000–50,000/mm^3, and cryoprecipitate is administered to maintain the fibrinogen level >150 mg/dL (>1.5 g/L). Both products should be transfused multiple times a day if necessary to maintain respective levels during the first week therapy or longer until coagulopathy resolves

ACUTE PROMYELOCYTIC LEUKEMIA (APL) INDUCTION REGIMEN

TRETINOIN (ALL *TRANS*-RETINOIC ACID; ATRA) + ARSENIC TRIOXIDE

Lo-Coco F et al. N Engl J Med 2013;369:111–121
Comment in: N Engl J Med 2013;369:186–187

(Supplementary materials published online)

Induction:
Arsenic trioxide 0.15 mg/kg per day; administer intravenously in 100–250 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 2 hours, daily, continually, until hematological complete remission (HCR) *or* a maximum of 60 days (total dosage/week = 1.05 mg/kg); *plus*
Tretinoin 22.5 mg/m^2 per dose; administer orally twice daily, continually, until HCR *or* for a maximum of 60 days (total dosage/week = 315 mg/m^2)

Consolidation:
Arsenic trioxide 0.15 mg/kg per dose; administer intravenously in 100–250 mL 0.9% NS or D5W over 2 hours for 5 days/week, weekly for 4 consecutive weeks (weeks 1–4, 9–12, 17–20, and 25–28), followed by 4 consecutive weeks without arsenic trioxide treatment, for a total of 4 courses (total dosage/week = 0.75 mg/kg; total dosage/4-week course = 3 mg/kg); *plus*
Tretinoin 22.5 mg/m^2 per dose; administer orally twice daily for 2 consecutive weeks (28 doses during weeks 1–2, 5–6, 9–10, 13–14, 17–18, 21–22, and 25–26) followed by 2 consecutive weeks without tretinoin treatment for a total of 7 courses (total dosage/week = 315 mg/m^2; total dosage/2-week course = 630 mg/m^2)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential when arsenic trioxide is administered is **MODERATE***
*Emetogenic potential when tretinoin alone is administered is **MINIMAL–LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider concomitant use of cotrimoxazole during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Efficacy

	ATRA–Arsenic Trioxide Group (n = 77)	ATRA–Chemotherapy Group (n = 79)
Hematologic complete remission*	100%	95%
Two-year event-free survival rates†	97%	86%

*The median time to hematologic complete remission was 32 days (range: 22 to 68 days) in the ATRA–arsenic trioxide group and 35 days (range: 26 to 63 days) in the ATRA–chemotherapy group
†Two-year event-free survival rates were 97% in the ATRA–arsenic trioxide group and 86% in the ATRA–chemotherapy group (95% confidence interval for the difference, 2 to 22 percentage points; P <0.001 for noninferiority and P = 0.02 for superiority of ATRA–arsenic trioxide). Overall survival was also better with ATRA–arsenic trioxide (P = 0.02)

Toxicity

The differentiation syndrome, including moderate and severe forms, developed in 15 patients in the group who received tretinoin (ATRA)–arsenic trioxide (19%) and in 13 patients in the ATRA–chemotherapy group (16%) (P = 0.62)

Four patients in the ATRA–chemotherapy group died during induction therapy: 2 from differentiation syndrome, 1 from ischemic stroke, and 1 from bronchopneumonia

Grades 3 or 4 neutropenia lasting >15 days and G3 or G4 thrombocytopenia lasting >15 days occurred with significantly greater frequency during induction therapy and after each consolidation course in the ATRA–chemotherapy group than in the ATRA–arsenic trioxide group

A total of 43 of 68 patients in the ATRA–arsenic trioxide group (63%) and 4 of 69 patients in the ATRA–chemotherapy group (6%) had G3 or G4 hepatic toxic effects during induction or consolidation therapy or during maintenance therapy (only patients in the ATRA–chemotherapy group) (P <0.001)

Prolongation of the QTc interval occurred in 12 patients in the ATRA–arsenic trioxide group (16%) and in no patients in the ATRA–chemotherapy group (P <0.001)

Patient Population Studied

A phase 3, multicenter trial comparing ATRA plus chemotherapy with ATRA plus arsenic trioxide in patients with APL classified as low-to-intermediate risk (white-cell count, ≤10,000/mm^3). Patients (18–71 years of age), were randomly assigned to receive either ATRA plus arsenic trioxide for induction and consolidation therapy or standard ATRA–idarubicin induction therapy followed by 3 cycles of consolidation therapy with ATRA, plus chemotherapy and maintenance therapy with low-dose chemotherapy and ATRA

Treatment Modifications

QT prolongation QTc interval >450 msec for men and >460 msec for women	Withhold arsenic trioxide and replete electrolytes 1. After QTc normalizes, resume arsenic trioxide with dosage decreased by 50%: arsenic trioxide 0.075 mg/kg per day 2. If no further QTc prolongation occurs at the reduced dosage, escalate arsenic trioxide dosage to 0.11 mg/kg per day 3. If QTc prolongation does not occur after escalation to 0.11 mg/kg per day, arsenic trioxide dosage may again be escalated to 0.15 mg/kg per day (full dose)
Grades 3–4 hepatotoxicity (serum total bilirubin, AST, alkaline phosphatase)	Temporarily discontinue ATRA and/or arsenic trioxide After serum bilirubin, SGOT, and alkaline phosphatase decrease to <4× the upper limit of their normal ranges (ULN), treatment with ATRA and/or arsenic trioxide may resume at 50% of the dosages previously given for 7 days If toxicity does not recur during the 7 days after resuming ATRA and arsenic trioxide, drug administration may resume at full dosages If hepatotoxicity recurs, the drugs are permanently discontinued
Grades 3–4 nonhematologic toxicity	Withhold ATRA and arsenic trioxide until toxicities remit to G <2, then resume treatment with both agents at decreased dosages according to a pre-defined table of dose reduction

	Dosages	
Dose Levels	Arsenic Trioxide (mg/kg per day)	Tretinoin (ATRA) (mg/m² per dose, Twice Daily)
0 (starting dose)	0.15	22.5
−1	0.11	18.75
−2	0.10	12.5
−3	0.075	10

Therapy Monitoring

1. CBC, 2 to 3 times daily until resolution of coagulopathy, then daily
2. Fibrinogen, PT, and PTT, twice daily until resolution of coagulopathy, then daily
3. Electrolytes, mineral panel, and uric acid, at least daily during active treatment until risk of tumor lysis is past
4. Bone marrow biopsy should be done after peripheral blood counts recovers from induction to determine whether a CR by morphology has been achieved. Patients often remain molecularly positive at the end of induction even when their marrow shows morphologic remission
5. Arsenic trioxide monitoring

   Prior to initialing therapy: ECG for QTc interval assessment

   Serum electrolytes and creatinine

During therapy: maintain serum potassium concentration >4 mEq/L (>4 mmol/L)

Maintain serum magnesium concentration >0.74 mmol/L (>1.8 mg/dL, >1.48 mEq/L)

ECG weekly during induction

Notes:

Hu et al reported long-term follow-up (median: 70 months) for 85 patients with APL treated with ATRA + arsenic trioxide. Among 80 of 85 patients (94.1%) who achieved CR with a median of 27 days (range: 15–38 days), 5 experienced early deaths within 15 days after starting induction therapy as a result of intracranial hemorrhage (3 patients), retinoic acid syndrome (1 patient), or disseminated intravascular coagulation (1 patient)

Kaplan-Meier estimates of the 5-year event-free survival and overall survival (OS) for all patients were 89.2% ± 3.4% and 91.7% ± 3.0%, respectively, and the 5-year relapse-free survival and OS for patients who achieved CR (n = 80) were 94.8% ± 2.5% and 97.4% ± 1.8%, respectively

Hu J et al. Proc Natl Acad Sci USA 2009;106: 3342–3347
Shen Z-X et al. Proc Natl Acad Sci USA 2004;101: 5328–5335

ACUTE PROMYELOCYTIC LEUKEMIA (APL) RELAPSED PATIENTS REGIMEN

ARSENIC TRIOXIDE

Soignet SL et al. J Clin Oncol 2001;19:3852–3860

Arsenic trioxide 0.15 mg/kg per day; administer intravenously in 100–250 mL 5% dextrose injection (D5W) or 0.9% sodium chloride injection (0.9% NS) over 2 hours until bone marrow remission or to a cumulative maximum of 60 doses (total dosage/week = 1.05 mg/kg; maximum dosage during induction = 9 mg/kg [60 doses])

or

Arsenic trioxide 0.15 mg/kg per dose administer intravenously in 100–250 mL D5W or 0.9% NS over 2 hours for 5 days/week (eg, Monday through Friday) until bone marrow remission or to a cumulative maximum of 60 doses (total dosage/week = 0.75 mg/kg; maximum dosage during induction = 9 mg/kg [60 doses])

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider concomitant use of cotrimoxazole during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Patient Population Studied

Study of 40 patients with either relapsed and/or refractory acute promyelocytic leukemia

Efficacy

CR: 85%
Median time to clinical CR: 59 days

Treatment Modifications

Adverse Events	Treatment Modifications
APL syndrome	Hold arsenic trioxide and treat with dexamethasone 10 mg intravenously every 12 hours for 3–5 days, then decrease the dexamethasone dose and schedule (taper) over a week to discontinue. Restart arsenic trioxide when symptoms and signs improve
Drug-related toxicity G ≥3, or nonhematologic toxicity G4	Hold therapy until resolution of the toxic event or recovery to baseline. Restart treatment at 50% of the preceding dose on the same administration schedule. If the toxic event does not recur within 3 days after restarting at a reduced dosage, continue treatment at the original dosage If the same toxicity recurs, discontinue arsenic trioxide

Toxicity (N = 40)

Adverse Events	All Grades	G4
Nausea	75%	—
Vomiting	58%	—

QTc prolongation	40%	—
APL syndrome*	25%	—
Peripheral neuropathy	43%	—

There were no treatment-related deaths
*Treatment with arsenic trioxide for remission induction is associated with the development of symptoms identical to retinoic acid syndrome. Considering the complex of symptoms is not specific to the use of retinoic acid, it is now referred as the APL syndrome

Therapy Monitoring

1. CBC twice weekly, or more frequently based on transfusion requirements
2. Chemistry, LFTs, and electrolytes, twice weekly
3. Bone marrow
4. EKG daily for 7 days to assure QTc stability, then monitor weekly

Notes:

Careful monitoring to maintain serum electrolytes in the upper range of normal will lessen the risk of cardiac arrhythmias:

Calcium ≥2.25 mmol/L (≥4.5 mEq/L, ≥9 mg/dL)
Potassium ≥4 mmol/L (≥4 mEq/L)
Magnesium ≥0.9 mmol/L (≥1.8 mEq/L, ≥2.2 mg/dL)

19. Leukemia, Chronic Lymphocytic

Patricia Kropf, MD and Kenneth Foon, MD

Epidemiology

Incidence: 15,720 (male: 9,100; female: 6,620. Estimated new cases for 2014 in the United States) 4.3 per 100,000 male and female per year (5.9 per 100,000 male, 3.1 per 100,000 female)
Deaths: Estimated 4,600 in 2014 (male: 2,800; female: 1,800)
Median age: 70 years
Male to female ratio: 1.3:1

Stage at Presentation (Rai):

Stage 0:	31%
Stage I/II:	59%
Stages III/IV:	10%

Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Work-up

Essential

1. Medical history and PE: attention to node-bearing areas, including the Waldeyer ring, and to size of liver and spleen
2. Performance status
3. B-symptoms
4. Laboratory work-up: CBC with differential, LDH, comprehensive metabolic panel
5. Hepatitis B testing if CD20 monoclonal antibody contemplated
6. MUGA scan/echocardiogram if anthracycline-based regimen is indicated
7. Pregnancy testing in women of child-bearing age (if chemotherapy planned)
8. Unilateral bone marrow biopsy + aspirate

Useful in certain circumstances

1. Quantitative immunoglobulins
2. β_2-Microglobulin
3. Reticulocyte count, haptoglobin, direct Coombs test
4. Uric acid
5. Chest, abdomen, and pelvis CT scans prior to initiation of therapy

Informative for prognostic and/or therapy determination

1. Cytogenetics/FISH analysis to detect: t(11q;v), +12, del(11q), del(13q), del(17p)
2. Determination of CD38 and Zap 70 expression
3. Immunoglobulin heavy-chain variable gene (IGHV) mutation status

Diagnosis

NCI-working group diagnostic criteria

1. Absolute lymphocytosis in the peripheral blood with a count of $\geq 5 \times 10^9$ B lymphocytes and cells morphologically mature in appearance
2. The clonality of the B cells must be confirmed by flow cytometry
3. The monoclonal B-cell lymphocytes express low levels of surface immunoglobulins, simultaneously with CD5, CD23, CD19, and CD20

Hallek M et al. Blood 2008;111:5446–5456

Prognosis

Poor risk factors

1. Advanced clinical stage
2. Rapid lymphocyte doubling time (<6 months)
3. Diffuse bone marrow involvement
4. High LDH, β_2-microglobulin
5. 17p and 11q deletions (normal karyotype and trisomy 12 have an intermediate prognosis, while 13q deletion has a good prognosis)*
6. Expression of CD38 (>30%)
7. Unmutated IGHV genes
8. Zap-70 expression (>30%)

Expert Opinion

Chronic lymphocytic leukemia (CLL) is one of the most common leukemias in the Western world, characterized by the monoclonal proliferation of mature B lymphocytes in the blood, lymph nodes, and marrow. The diagnosis requires a count of over 5000 circulating CLL type cells per cubic millimeter. The median overall survival in patients with CLL is about 10 years. The individual prognosis, however, is extremely variable. In some patients, the disease runs an indolent course and life expectancy is near normal, while in others, the disease progresses rapidly with an aggressive clinical course resulting in refractory disease and shortened overall survival. The diagnosis of CLL does not imply the need for treatment; rather, a number of indications justify the need for patient-specific therapy

Treatment by Stage:

- Asymptomatic early stage disease (Rai 0, Binet A) should be monitored without therapy unless there is evidence of disease progression
- Intermediate (stages I and II) and high risk (stages III and IV) according to the modified Rai classification or at Binet stage B or C usually benefit from the initiation of treatment. Some of these patients (in particular, Rai intermediate risk or Binet stage B) can be monitored without therapy until they have evidence for progressive or symptomatic disease

Indications for treatment include:

- Evidence of progressive marrow failure as manifested by the development or worsening anemia (hemoglobin <11 g/dL) and/or thrombocytopenia (platelets $<100 \times 10^9$/L)
- Constitutional symptoms: A minimum of any one of the following disease-related symptoms must be present:
  a. Unintentional weight loss ≥10% within the previous 6 months
  b. Significant fatigue; that is, Eastern Cooperative Oncology Group performance status 2 or worse (cannot work or unable to perform usual activities)
  c. Fevers >100.5°F (>38.0°C) for ≥2 weeks without other evidence of infection
  d. Night sweats for more than 1 month without evidence of infection
- Massive, progressive, or symptomatic splenomegaly
- Massive, progressive, or symptomatic lymphadenopathy
- Autoimmune hemolytic anemia and/or thrombocytopenia that is poorly responsive to corticosteroids or other second-line treatments (splenectomy, intravenous immunoglobulin, and/or immunosuppressive agents, rituximab, or alemtuzumab)
- Rapidly increasing lymphocytosis with an increase of >50% over 2 months or lymphocyte doubling time of <6 months[1]

Note: Recurrent bacterial infections are very common in patients with CLL, but we do not view this as a reason to treat the underlying CLL unless any of the above mentioned criteria for initiating therapy exist. We would first attempt therapy with intravenous gamma globulin (IVIG) monthly for the prevention of recurrent bacterial infections. If IVIG is not successful in preventing recurrent bacterial infections then we would initiate therapy

Isolated hypogammaglobulinemia, or monoclonal or oligoclonal paraproteinemia do not constitute a basis for initiating therapy. Patients with CLL may present with a markedly elevated leukocyte count; however, the symptoms associated with leukocyte aggregates that develop in patients with acute leukemia rarely occur in patients with CLL. Therefore, the absolute lymphocyte count should not be used as the sole indicator for initiating treatment

Therapy: There are multiple treatment options available for patients with CLL, however, there is not one treatment that is considered the "standard of care" for all patients. The choice of therapy depends upon patient characteristics including age, performance status, and the expected clinical course based upon disease risk factors

(continued)

Expert Opinion (*continued*)

Choice of Therapy

- Patient characteristics, such as age and performance status, allow practioners to define the goal of therapy. Data suggest that improved therapies lead to improved overall survival.[2] In addition, research has shown that obtaining minimal residual disease improves survival.[3] Complete response is the most beneficial response with respect to long-term disease control, and complete responses are seen in about 50–80% of patients treated with chemoimmunotherapies, albeit at increased toxicity
- In young, fit patients, the goal of therapy is a complete response. We recommend fludarabine, cyclophosphamide, rituximab (FCR), or bendamustine and rituximab (BR) as frontline therapy, given for 6 cycles, based on high complete remission rates and improved progression-free survival.[4,5,6,7] Alternative options include low-dose fludarabine, and cyclophosphamide with high-dose rituximab (FCR-Lite)[8] or pentostatin, cyclophosphamide, rituximab (PCR)[9]. Both regimens are associated with superb efficacy data and perhaps less toxicity, although phase III data directly comparing the regimens are lacking. Recently, long-term results of the FCR-lite regimen were released revealing that patients treated with this regimen enjoyed a median progression-free survival of 5.8 years (the median overall survival has not yet been reached).[10] In young, fit patients with del (17p) or del (11q), we recommend FCR as initial therapy or treatment on a clinical trial. In addition, such patients should be considered for an allogeneic transplant in first remission. Patients who harbor del (17p) or del (11q) are at high risk of not responding to initial therapy or relapsing soon thereafter
- In older patients, such as those over 70 years of age, or in unfit patients who cannot tolerate aggressive therapy, the goal is the palliation of symptoms using a treatment regimen with a favorable toxicity profile. In such cases, we recommend treatment with single agent chlorambucil[11], which is palliative and has an acceptable toxicity profile. Other options include bendamustine with or without rituximab, single agent rituximab or ofatumumab[12,13,14]
- In determining the most appropriate treatment for patients with CLL, one must take into account the anticipated progression rate based on disease characteristics. To date, there are no data showing that in patients with aggressive disease, early intervention positively impacts survival. Therefore, even in the context of high risk features, we advocate an approach of "expectant observation." High risk features includes those patients with chromosomal del 11q, 17p deletion, lymphocyte doubling time <12 months, unmutated immunoglobulin heavy chain variable region genes, ZAP-70 (>20% positive), and CD38 (>30% positive)[1,15]
- With respect to stem cell transplant, transplant in the treatment of CLL continues to be defined. Due to the high relapse rates following autologous hematopoietic stem cell transplant (auto-HSCT) we believe that auto-HSCT for CLL should only be offered in the context of a clinical trial and should be considered early during the patient's clinical course, thus avoiding multiple therapies that may impair the ability to harvest the patient's stem cells or damage the patient's stem cells
- With respect to allogeneic stem cell transplant, an allogeneic transplant should only be considered in patients with exceptionally poor cytogenetics such as those patients who harbor del (17p) or del (11q), or those who are resistant to conventional therapy with fludarabine-based regimens. An allogeneic transplant is generally limited to younger patients (age <60) with a good performance status[16,17,18]
- Therapy of CLL may change dramatically in the next few years as highly active small molecules that target the B-cell receptor and BCL-2 should be approved. Lenalidomide, a small molecule with potent immunomodulatory activity, has activity in CLL and may also be approved for treatment of CLL in the near future[19]

CLL REGIMEN

FLUDARABINE + CYCLOPHOSPHAMIDE + RITUXIMAB (FCR)

Hallek M et al. Lancet 2010;376:1164–1174

Prophylaxis Against Tumor Lysis Syndrome—Cycle 1
Allopurinol 300 mg/day; administer orally or intravenously for 7 consecutive days, days 1–7

Premedication for rituximab—All Cycles
Acetaminophen 650 mg; administer orally 30–60 minutes before starting rituximab, *plus*
Diphenhydramine 25 mg; administer intravenously 30–60 minutes before starting rituximab

4-Week Cycles

Cycle 1	Cycles 2–6
Rituximab 375 mg/m²; administer intravenously on day 0 (total dosage/cycle = 375 mg/m²)	**Rituximab** 500 mg/m²; administer intravenously on day 1 (total dosage/cycle = 500 mg/m²)

Rituximab is diluted in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) to a concentration within the range of 1–4 mg/mL

Notes on rituximab administration:
- During a first cycle, initiate rituximab infusion at a rate of 50 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, the administration rate may be increased by 50 mg/hour every 30 minutes as tolerated, to a maximum rate of 400 mg/hour. Subsequently, if previous administration was well tolerated, start at 100 mg/hour, and escalate the rate as tolerated in increments of 100 mg/hour every 30 minutes to a maximum rate of 400 mg/hour
- Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypotension, and other serious adverse events. Resume rituximab administration at a slower rate after adverse events abate

Cycles 1–6

Cyclophosphamide 250 mg/m² per day; administer intravenously in 25–250 mL 0.9% NS or D5W over 10–30 minutes daily for 3 consecutive days on days 1–3 (total dosage/cycle = 750 mg/m²)

Fludarabine 25 mg/m² per day; administer by intravenous infusion in 100–125 mL 0.9% NS or D5W over 20–30 minutes daily for 3 consecutive days on days 1–3 (total dosage/cycle = 75 mg/m²)

- Fludarabine and cyclophosphamide administration begin 1 day after completing rituximab administration only during the first cycle
- During cycles 2–6, the day on which rituximab is given (day 1) and the first day on which fludarabine and cyclophosphamide are administered coincide

Supportive Care
Antiemetic prophylaxis
Emetogenic potential on Cycle 1, Day 0 is ***LOW***
Emetogenic potential on Cycle 1, Days 1–3 is ***MODERATE***
Emetogenic potential on Cycles 2–6, Days 1–3 is ***MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed

See Chapter 43 for more information

(*continued*)

Patient Population Studied

Study of 408 treatment naïve patients (ages: 30–81 years) with active chronic lymphocytic leukemia

Efficacy (N = 408)

Overall response	90%
Complete response	44%
Progression-free survival	median 51.8 months
Overall survival at 3 years	87%

Adverse Events (N = 404)

Toxicities Associated with FCR

	Grade 3 or Grade 4 %
Neutropenia	34
Thrombocytopenia	7
Anemia	5
Autoimmune hemolytic anemia	<1
Infections, total	25

Treatment Modifications

ANC ≤1000/mm³ or platelet ≤80,000/mm³ after the first treatment cycle	Treatment postponed until toxicity resolves. If delay >1 week, restart treatment with dose reduction of the cyclophosphamide dosage to 200 mg/m² per day and fludarabine dosage to 20 mg/m² per day. If further dose reduction is needed reduce the cyclophosphamide dosage to 150 mg/m² per day and fludarabine dosage to 15 mg/m² per day The rituximab dose is not reduced
Major infection	Reduce cyclophosphamide dosage to 200 mg/m² per day and fludarabine dosage to 20 mg/m² per day. If further dose reduction is needed reduce the cyclophosphamide dosage to 150 mg/m² per day and fludarabine dosage to 15 mg/m² per day The rituximab dose is not reduced

(continued)

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider concomitant use with a broad-spectrum antibacterial (eg, cotrimoxazole) and during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Infusion reactions associated with rituximab

Fevers, chills, and rigors

1. Interrupt rituximab administration for severe symptoms, and give:
   - **Acetaminophen** 650 mg; administer orally for fever. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Diphenhydramine** 25–50 mg; administer orally or by intravenous injection for pruritus, hypotension, or angioedema. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Meperidine** 12.5–25 mg; administer by intravenous injection every 10–20 minutes as needed for shaking chills (generally, cumulative doses >100 mg are not needed; use repeated doses with caution in persons with moderate or more severely impaired renal function)
2. If rituximab administration was interrupted, resume infusion at a slower rate than the maximum rate previously attempted. Rate escalation may be reattempted at smaller incremental steps with close monitoring. Do not exceed the maximum recommended rate of 400 mg/hour

Dyspnea or wheezing without allergic findings (urticaria, or tongue or laryngeal edema)

1. Interrupt rituximab administration immediately
2. Give **hydrocortisone** 100 mg by intravenous injection (or an alternative steroid with equivalent glucocorticoid potency)
3. Give a **histamine (H_2)-receptor antagonist** (ranitidine 50 mg, cimetidine 300 mg, or famotidine 20 mg) intravenously over 15–30 minutes

After symptoms resolve, resume rituximab administration at 25 mg/hour with close monitoring. Do not increase the administration rate

Therapy Monitoring

1. *Prior to each cycle:* CBC with differential and serum electrolytes, BUN, creatinine, and LFTs
2. *Response evaluation:* every 2–3 cycles

ALTERNATIVE REGIMEN

FLUDARABINE + CYCLOPHOSPHAMIDE WITH HIGH-DOSE RITUXIMAB

Foon KA et al. J Clin Oncol 2009;27:498–503
Foon KA et al. Blood 2012;119:3184–3185

4-Week Cycles

Cycle 1	Cycles 2–6
Rituximab 375 mg/m²; administer intravenously on day 1, *plus* **Rituximab** 500 mg/m²; administer intravenously on day 14 (total dosage during the first cycle = 875 mg/m²)	**Rituximab** 500 mg/m²; administer intravenously on days 1 and 14 (total dosage/cycle = 1000 mg/m²)
Rituximab is diluted in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) to a concentration within the range of 1–4 mg/mL	

Notes on rituximab administration:

- During a first cycle, initiate rituximab infusion at a rate of 50 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, the administration rate may be increased by 50 mg/hour every 30 minutes as tolerated, to a maximum rate of 400 mg/hour. Subsequently, if previous administration was well tolerated, start at 100 mg/hour, and escalate the rate as tolerated in increments of 100 mg/hour every 30 minutes to a maximum rate of 400 mg/hour
- Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypotension, and other serious adverse events. Resume rituximab administration at a slower rate after adverse events abate

Cycle 1	Cycles 2–6
Cyclophosphamide 150 mg/m² per day; administer intravenously in 25–250 mL 0.9% NS or D5W over 15–60 minutes daily for 3 consecutive days on days 2–4 (total dosage during cycle 1 = 450 mg/m²)	**Cyclophosphamide** 150 mg/m² per day; administer intravenously in 25–250 mL 0.9% NS or D5W over 15–60 minutes daily for 3 consecutive days on days 1–3 (total dosage/cycle = 450 mg/m²)
Fludarabine 20 mg/m² per day; administer by intravenous infusion in 100–125 mL 0.9% NS or D5W over 30 minutes, daily for 3 consecutive days on days 2–4 (total dosage during cycle 1 = 60 mg/m²)	**Fludarabine** 20 mg/m² per day; administer by intravenous infusion in 100–125 mL 0.9% NS or D5W over 30 minutes, daily for 3 consecutive days on days 1–3 (total dosage/cycle = 60 mg/m²)

After 6 cycles of combined chemoimmunotherapy, rituximab 500 mg/m² was administered once every 3 months until relapse

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential on Cycle 1, Day 1 is **LOW***
*Emetogenic potential on Cycle 1, Days 2–4 is **MODERATE***
*Emetogenic potential on Cycles 2–6, Days 1–3 is **MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is indicated with one of the following:

Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose

- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed

See Chapter 43 for more information

(*continued*)

Patient Population Studied

Study of 50 patients (median age: 58 years) with active chronic lymphocytic leukemia

Efficacy (N = 48)

Complete response	77%
Partial response	23%

Median duration of complete response: 22.3 months (range: 5.2–42.3 months)

(continued)

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider concomitant use with a broad-spectrum antibacterial (eg, cotrimoxazole) and during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Infusion reactions associated with rituximab

Fevers, chills, and rigors

1. Interrupt rituximab administration for severe symptoms, and give:
   - **Acetaminophen** 650 mg; administer orally for fever. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Diphenhydramine** 25–50 mg; administer orally or by intravenous injection for pruritus, hypotension, or angioedema. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Meperidine** 12.5–25 mg; administer by intravenous injection every 10–20 minutes as needed for shaking chills (generally, cumulative doses >100 mg are not needed; use repeated doses with caution in persons with moderate or more severely impaired renal function)
2. If rituximab administration was interrupted, resume infusion at a slower rate than the maximum rate previously attempted. Rate escalation may be reattempted at smaller incremental steps with close monitoring. Do not exceed the maximum recommended rate of 400 mg/hour

Dyspnea or wheezing without allergic findings (urticaria, or tongue or laryngeal edema)

1. Interrupt rituximab administration immediately
2. Give **hydrocortisone** 100 mg by intravenous injection (or an alternative steroid with equivalent glucocorticoid potency)
3. Give a **histamine (H_2)-receptor antagonist** (ranitidine 50 mg, cimetidine 300 mg, or famotidine 20 mg) intravenously over 15–30 minutes

After symptoms resolve, resume rituximab administration at 25 mg/hour with close monitoring. Do not increase the administration rate

CLL REGIMEN

CHLORAMBUCIL

Rai KR et al. N Engl J Med 2000;343:1750–1757

Premedication: **Allopurinol** 300 mg/day; administer orally for 9 consecutive days, starting the day before chlorambucil is administered, every 28 days
- Continue use during the first 3 cycles
- Use may continue for additional cycles if clinically appropriate

Chlorambucil 40 mg/m²; administer orally on day 1 (single dose), every 28 days for a maximum of 12 cycles (total dosage/cycle = 40 mg/m²)

Alternative Chlorambucil Regimens
Dighiero G et al. N Engl J Med 1998;338:1506–1514

Chlorambucil 0.3 mg/kg per day; administer orally for 5 consecutive days on days 1–5, every 28 days (total dosage/28-day cycle = 1.5 mg/kg), *or*
Chlorambucil 0.1 mg/kg per day; administer orally continually for 28 consecutive days on days 1–28, every 28 days (total dosage/28-day cycle = 2.8 mg/kg)
- Continue treatment until clinical resistance develops

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is ***NOT*** *indicated*
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Patient Population Studied

Study of 181 previously untreated patients with stages I–IV CLL

Efficacy (N = 181)

Complete response	4%
Partial response	33%
Stable or progressive disease	63%
Median duration of response	14 months
Median survival	56 months

Toxicity (N = 178)

(CALGB Expanded Common Toxicity Criteria)

Toxicity	% Patients with G3/4
Thrombocytopenia	14
Neutropenia	19
Infection	9
Any G3/4 toxicity	44

Grade 3, Severe side effect; Grade 4, life-threatening side effect

Treatment Modification

Adverse Event	Treatment Modification
Hematologic toxicity G ≥3	Reduce chlorambucil dose 25%. For recurrent hematologic toxicity (G ≥3), further reduce chlorambucil dose an additional 25%. May cautiously re-escalate dose in subsequent cycles
Nonhematologic toxicity G ≥3	Reduce chlorambucil dose 25%. May cautiously re-escalate dose in subsequent cycles

Toxicity N = 161

Percentage of Patients with Hematologic Toxicity

	% G3 or G4
Neutropenia	23
Thrombocytopenia	19

Percentage of Patients with Nonhematologic Toxicity During Any Cycle

	% G1/2	% G3/4
Infection	4.3	1.9
Fatigue	7.5	1.2
Nausea/vomiting	34.8	1.8
Diarrhea	8.7	1.2
Rash	6.8	2.5
Hypersensitivity	3.8	1.2

Therapy Monitoring

1. *Prior to each cycle:* CBC with differential and serum electrolytes, BUN, creatinine, and LFTs
2. *Response evaluation:* every 2–3 cycles

Notes

1. Recommended as frontline therapy
2. Chlorambucil may be combined with rituximab

CLL REGIMEN

BENDAMUSTINE + RITUXIMAB

Fisher K et al. J Clin Oncol 2011;29:3559–3566

Premedication for Rituximab—All Cycles
Acetaminophen 650 mg orally 30–60 minutes before starting rituximab, *plus*
Diphenhydramine 25 mg intravenously 30–60 minutes before starting rituximab

4-Week Cycles

Cycle 1	Cycles 2–6
Rituximab 375 mg/m²; administer intravenously on day 0 (total dosage/cycle = 375 mg/m²)	**Rituximab** 500 mg/m²; administer intravenously on day 1 (total dosage/cycle = 500 mg/m²)
Rituximab is diluted in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) to a concentration within the r ange of 1–4 mg/mL	

Notes on rituximab administration:
- During the first cycle, initiate rituximab infusion at a rate of 50 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, the administration rate may be increased in 50-mg/hour increments every 30 minutes as tolerated, to a maximum rate of 400 mg/hour. Subsequently, if previous administration was well tolerated, start at 100 mg/hour, and escalate the rate as tolerated in increments of 100 mg/hour every 30 minutes to a maximum rate of 400 mg/hour
- Interrupt rituximab administration for fever, chills, edema, congestion of the head and neck mucosa, hypotension, and other serious adverse events. Resume rituximab administration at a slower rate after adverse events abate

Bendamustine HCl 70 mg/m² per day; administer intravenously in a volume of 0.9% NS or D2.5W/0.45% sodium chloride injection sufficient to produce a solution within the concentration range 0.2–0.6 mg/mL, over 30 minutes for 2 consecutive days, on days 1 and 2, every 4 weeks for up to 6 cycles depending on response and toxicity (total dosage/cycle = 140 mg/m²)

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential with rituximab alone is **MINIMAL***
*Emetogenic potential on days with bendamustine is **MODERATE***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
*Primary prophylaxis is **NOT** indicated*
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider use during neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Dose Modifications

G4 hematologic toxicity or G ≥2 nonhematologic toxicities during second and subsequent cycles	Delay retreatment with bendamustine until ANC is ≥1000/mm³ and platelet count is ≥75,000/mm³, and nonhematologic toxicities remit to G ≤1, then resume bendamustine at 50 mg/m² per day on days 1 and 2, every 4 weeks. Consider reescalating bendamustine dosage to 70 mg/m² per dose only if G4 hematologic or G ≥2 nonhematologic toxicities do not recur after at least 1 cycle at 50 mg/m² per day on days 1 and 2
Recurrence of G4 hematologic toxicity or G ≥2 nonhematologic toxicities with bendamustine at 50 mg/m² per dose	Delay retreatment with bendamustine until ANC is ≥1000/mm³ and platelet count is ≥75,000/mm³, and nonhematologic toxicities remit to G ≤1, then resume bendamustine at 25 mg/m² per day on days 1 and 2, every 4 weeks. Consider reescalating bendamustine dosage to 50 mg/m² per dose only if G4 hematologic or G ≥2 nonhematologic toxicities do not recur after at least 1 cycle at 25 mg/m² per day on days 1 and 2

Infections	10	12.8	0	0
Other nonhematologic toxicities	9	11.5	2	2

Patient Population Studied

Seventy-eight patients with relapsed and/or refractory CLL; 22 patients had fludarabine refractory disease; 14 patients had deletion of 17p

Monitoring Therapy

1. Prior to each cycle: CBC with differential and serum electrolytes, BUN, creatinine, and liver function tests
2. A response assessment may be performed after 2 cycles and/or at the completion of therapy. This may include peripheral blood flow cytometry and/or a bone marrow biopsy and aspirate

CLL REGIMEN

OFATUMUMAB

Coiffier B et al. Blood 2008;111:1094–1100

Premedications before each ofatumumab dose:
Acetaminophen 1000 mg; administer orally 30 minutes to 2 hours before starting ofatumumab
Cetirizine 10 mg (or equivalent H_1 receptor antagonist); administer orally 30 minutes to 2 hours before starting ofatumumab
Prednisolone 100 mg (or another glucocorticoid at an equipotent dose); administer intravenously 30 minutes to 2 hours before starting ofatumumab

- Prednisolone 100 mg (*or glucocorticoid equivalent*) should be given prior to ofatumumab during weeks 1, 2, and 9
- Glucocorticoid doses may be gradually decreased during weeks 3–8 if an infusion reaction G ≥3 did not occur with preceding ofatumumab doses
- For doses 10–12, give prednisolone 50–100 mg/dose (*or glucocorticoid equivalent*) if an infusion reaction G ≥3 did not occur with preceding ofatumumab doses

Initial Ofatumumab Dose (week 1):
Ofatumumab 300 mg; administer intravenously in a total volume of 1000 mL 0.9% sodium chloride injection (0.9% NS), *followed 1 week later by:*

Subsequent Ofatumumab Doses (weeks 2–8, 12, 16, 20, and 24):
Ofatumumab 2000 mg/dose; administer intravenously in a total volume of 1000 mL 0.9% NS, weekly for 7 consecutive weeks (weeks 2–8), *followed 4 weeks later by:*
Ofatumumab 2000 mg/dose; administer intravenously in a total volume of 1000 mL 0.9% NS every 4 weeks for 4 doses (weeks 12, 16, 20, and 24)

Ofatumumab administration rates:
Initial dose (Ofatumumab 0.3 mg/mL)

	Administration Rate	
Interval After Starting Administration	(mL/h)	(mg/h)
0–30 min	12	3.6
31–60 min	25	7.5
61–90 min	50	15
91–120 min	100	30
>120 min	200	60

Second dose (Ofatumumab 2 mg/mL)

	Administration Rate	
Interval After Starting Administration	(mL/h)	(mg/h)
0–30 min	12	24
31–60 min	25	50
61–90 min	50	100
91–120 min	100	200
>120 min	200	400

(*continued*)

Treatment Modification

Adverse Event	Treatment Modification
Grade 4 infusion reaction	Do not resume the infusion
Grades 1, 2, or 3 infusion reactions	If an infusion reaction resolves or remains G ≤2, resume the infusion with the following modifications according to the initial grade of the infusion reaction • G1 or G2: Infuse at 50% of the previous infusion rate • G3: Infuse at 12 mL/hour After resuming the infusion the rate may be increased according to the recommended ofatumumab administration rates (above), based on patient tolerance

Efficacy (N = 33)

Objective Response Rate (%)

Cohort A	1(33)
Cohort B	0
Cohort C	13(50)

Patient Population Studied

Thirty-three patients with relapsed or refractory B-cell CLL who had already received treatment with rituximab. Patients received once weekly infusions of ofatumumab. Patients were divided into 3 cohorts based on the dose of ofatumumab:

A. One 100-mg dose followed after 1 week by 3 weekly 500-mg doses; N = 3
B. One 300-mg dose followed after 1 week by 3 weekly 1000-mg doses; N = 3
C. One 500-mg dose followed after 1 week by 3 weekly 2000-mg doses; N = 27

(*continued*)

Doses 3–12 (Ofatumumab 2 mg/mL)

Interval After Starting Administration	Administration Rate (mL/h)	Administration Rate (mg/h)
0–30 min	25	50
31–60 min	50	100
61–90 min	100	200
91–120 min	200	400
>120 min	400	800

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

*Primary prophylaxis is **NOT** indicated*

See Chapter 43 for more information

Risk of Fever and Neutropenia is HIGH

Antimicrobial primary prophylaxis is recommended:

- Antibacterial—*Pneumocystis jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—recommended
- Antiviral—antiherpes antivirals (eg, acyclovir)

See Chapter 47 for more information

Monitoring Therapy

1. *Every week:* PE, CBC with differential, serum electrolytes, and creatinine
2. *Response evaluation:* after the sixth weekly infusion (lab work and physical exam only) and at the completion of therapy

Notes

1. Progressive multifocal leukoencephalopathy (PML), including fatal PML, can occur with ofatumumab. Consider PML in any patient with new onset of or changes in preexisting neurologic signs or symptoms. Discontinue ofatumumab if PML is suspected and initiate evaluation including neurologic consult, brain MRI and lumbar puncture
2. Hepatitis B Infection (HBV) and reactivation may occur in patients following treatment with ofatumumab. Screen patients at high risk for HBV prior to initiating therapy. Closely monitor carriers of hepatitis B for clinical and laboratory signs of active HBV during treatment and for 12 months following the last infusion of ofatumumab

Toxicities

Grades 3 and 4 adverse events according to NCI Common Terminology Criteria for Adverse Events (CTCAE), version 3.0

	No. of Patients	No. of Events
Total no. subjects with G3 or G4 adverse events	10	18
Thrombocytopenia	3	4
Neutropenia	2	2
Anemia, NOS	1	1
Infection	3	3
Pyrexia	2	2
Pain NOS	1	1
Nervous system disorders	2	2
Angina	1	1
Cytolytic hepatitis	1	1
Hypoxia	1	1

Infusion-related toxicities decreased with time

Other Treatment-Related Events	% G1/2	% G3/4
Infections	28	27
Septicemia	4	11
CMV reactivation	3	4
Neutropenia	30% during weeks 5/6	
Thrombocytopenia	In first 2 weeks	

CLL REGIMEN

FLUDARABINE + RITUXIMAB

Byrd JC et al. Blood 2003;101:6–14
Woyach JA et al. J Clin Oncol 2011;29:1349–1355

Premedication:
Allopurinol 300 mg/day; administer orally for 14 consecutive days on days 1–14
Acetaminophen 650 mg; administer orally 30 minutes before rituximab
Diphenhydramine 50 mg; administer by intravenous injection 30 minutes before rituximab

Fludarabine 25 mg/m^2 per day; administer by intravenous infusion in 100–125 mL 5% dextrose injection (D5W) or 0.9% sodium chloride injection (0.9% NS) over 20–30 minutes for 5 consecutive day on days 1–5, every 28 days for 6 cycles (total dosage/cycle = 125 mg/m^2)

Cycle 1: Rituximab 375 mg/m^2 per dose; administer by intravenous infusion in a volume of D5W or 0.9% NS sufficient to produce a concentration within the range 1–4 mg/mL for 2 doses on days 1 and 4 (total dosage/cycle 1 = 750 mg/m^2)

Cycles 2–6: Rituximab 375 mg/m^2; administer by intravenous infusion in a volume of D5W or 0.9% NS sufficient to produce a concentration within the range 1–4 mg/mL on day 1, every 28 days for 5 cycles (total dosage/cycle = 375 mg/m^2)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***MINIMAL***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis may be indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider concomitant use with cotrimoxazole, during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

Infusion reactions associated with rituximab
Fevers, chills, and rigors

1. Interrupt rituximab administration for severe symptoms, and give:
   - **Acetaminophen** 650 mg; administer orally for fever. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Diphenhydramine** 25–50 mg; administer orally or by intravenous injection for pruritus, hypotension, or angioedema. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Meperidine** 12.5–25 mg; administer by intravenous injection every 10–20 minutes as needed for shaking chills (generally, cumulative doses >100 mg are not needed; use repeated doses with caution in persons with moderate or more severely impaired renal function)
2. If rituximab administration was interrupted, resume infusion at a slower rate than the maximum rate previously attempted. Rate escalation may be reattempted at smaller incremental steps with close monitoring. Do not exceed the maximum recommended rate of 400 mg/hour

Dyspnea or wheezing without allergic findings (urticaria, or tongue or laryngeal edema)

1. Interrupt rituximab administration immediately
2. Give **hydrocortisone** 100 mg by intravenous injection (or an alternative steroid with equivalent glucocorticoid potency)
3. Give a **histamine (H_2) receptor antagonist** (ranitidine 50 mg, cimetidine 300 mg, or famotidine 20 mg) intravenously over 15–30 minutes

After symptoms resolve, resume rituximab administration at 25 mg/hours with close monitoring. Do not increase the administration rate

Patient Population Studied

Study of 104 previously untreated patients with symptomatic CLL

Efficacy (N = 104)

Overall response rate	84%
Complete response rate	38%
Estimated 5-year progression-free survival	28%
Median overall survival	85 months

Adverse Events (N = 51)

Hematologic Toxicity (Modified NCI Criteria for CLL)

Toxicity	% G1/2	% G3/4
Neutropenia	8	76
Thrombocytopenia	47	20
Anemia	65	4
Infection	43	20

Nonhematologic Toxicity (NCI CTC)

Toxicity	% G1/2	% G3/4
Nausea	48	0
Vomiting	16	0
Myalgias	28	0
Fatigue/malaise	62	0
Dyspnea/hypoxemia*	12	14
Hypotension*	10	6
Fever*	32	0
Chills/rigors*	36	0
G3/4 pulmonary toxicity	3 cases	
Thrombocytopenic purpura	1 case	
Pure red cell aplasia	1 case	

*Infusion-related toxicities occurred in 100% of patients during the first administration of rituximab. Usually G1/2, although 20% experienced G3/4. Only 2 patients (4%) experienced infusion-related adverse events during a second administration

Treatment Modifications

Adverse Event	Treatment Modification
Fludarabine-Related Toxicities	
G3 neutropenia, thrombocytopenia, or anemia	Delay treatment until recovery to within 20% of baseline, then resume treatment with dosage of fludarabine reduced by 25%
G4 neutropenia, thrombocytopenia, or anemia	Delay treatment until recovery to within 20% of baseline, then resume treatment with dosage of fludarabine reduced by 50%
Infection without G3/4 neutropenia	Hold treatment until infection resolves, then restart at the same dosages
Evidence of autoimmune hemolytic anemia or thrombocytopenia	Replace rituximab and fludarabine with alternative treatment as appropriate
Grade ≥2 nonhematologic adverse events attributable to fludarabine, except nausea, vomiting, fatigue, diarrhea, infusion-related fever, or chills	Reduce fludarabine dosage by 50%
G3/4, or irreversible G2 nonhematologic toxicity	Reduce fludarabine dosage by 50%, or consider withdrawing fludarabine

Therapy Monitoring

1. *Before each cycle:* CBC with differential and serum electrolytes, creatinine, and LFTs
2. *Response evaluation:* every 3 cycles

Note

Recommended as initial therapy for patients with CLL. This regimen is increasingly used in combination with cyclophosphamide

CLL REGIMEN

PENTOSTATIN + CYCLOPHOSPHAMIDE + RITUXIMAB

Lamanna N et al. J Clin Oncol 2006;24:1575–1581

Hydration: ≥1500 mL 0.9% sodium chloride injection (0.9% NS) at ≥100 mL/hour before cyclophosphamide every 21 days

Premedication:
Allopurinol 300 mg/day administer orally for 9 consecutive days, starting the day before chemotherapy treatment begins, every 21 days
- Continue use during the first 2 cycles
- Use may continue for additional cycles if clinically appropriate

Cycles 1–6:
Cyclophosphamide 600 mg/m^2; administer by intravenous infusion in 50–150 mL 5% dextrose injection (D5W) or 0.9% NS over 15–60 minutes, on day 1, every 3 weeks for up to 6 cycles (total dosage/cycle = 600 mg/m^2), *followed by:*

Pentostatin 4 mg/m^2; administer by intravenous infusion in 25–50 mL D5W or 0.9% NS, over 20–30 minutes, on day 1, every 3 weeks for up to 6 cycles (total dosage/cycle = 4 mg/m^2)

Cycles 2–6:
Rituximab 375/m^2; administer by intravenous infusion in a volume of D5W or 0.9% NS sufficient to produce a concentration within the range 1–4 mg/mL, on day 1 of cycles 2–6 after pentostatin administration is completed, every three weeks for 5 cycles (total dosage/cycle = 375 mg/m^2)

Filgrastim; administer by subcutaneous injection, daily, starting on cycle day 3 and continuing until patient achieves a single postnadir ANC >5000/mm^3, or an ANC >1500/ mm^3 on 2 consecutive days

Filgrastim doses are based on a patient's body weight as follows:

Body Weight	Filgrastim Dose
≤70 kg	300 mcg/day
>70 kg	480 mcg/day

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is MODERATE
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is INTERMEDIATE
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—consider a fluoroquinolone or no prophylaxis; *P. jirovecii* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—consider concomitant use with cotrimoxazole, during periods of neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir, famciclovir, valacyclovir)

See Chapter 47 for more information

(*continued*)

Treatment Modifications

Adverse Event	Treatment Modification
Serum creatinine >2 mg/dL (>177 µmol/L) or increased by 20% above baseline	Hold treatment until serum creatinine ≤2 mg/dL (≤177 µmol/L) or is <20% greater than baseline result, or creatinine clearance ≥50 mL/min (≥0.83 mL/s)
G2 toxicity	Hold drug until G ≤1 then restart at same dose
Repeated G2 toxicity	Hold drug until G ≤1 then restart at with all drug dosages decreased by 25%
G3/4 toxicity	Hold drug until G ≤1 then restart with all drug dosages decreased by 25–50%
Patient whose disease does not achieve at least a PR after 3 cycles	Therapy considered ineffective and discontinued

Efficacy (N = 32)

Complete response	25%
Partial response	47%
Stable disease	3%
Median response duration	25 months
Median survival	44 months

(continued)

Infusion reactions associated with rituximab

Fevers, chills, and rigors

1. Interrupt rituximab administration for severe symptoms, and give:
   - **Acetaminophen** 650 mg; administer orally for fever. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Diphenhydramine** 25–50 mg; administer orally or by intravenous injection for pruritus, hypotension, or angioedema. For persistent or recurrent symptoms, repeat administration every 4–6 hours as needed during rituximab administration
   - **Meperidine** 12.5–25 mg; administer by intravenous injection every 10–20 minutes as needed for shaking chills (generally, cumulative doses >100 mg are not needed; use repeated doses with caution in persons with moderate or more severely impaired renal function)
2. If rituximab administration was interrupted, resume infusion at a slower rate than the maximum rate previously attempted. Rate escalation may be reattempted at smaller incremental steps with close monitoring. Do not exceed the maximum recommended rate of 400 mg/hour

Dyspnea or wheezing without allergic findings (urticaria, or tongue or laryngeal edema)

1. Interrupt rituximab administration immediately
2. Give **hydrocortisone** 100 mg by intravenous injection (or an alternative steroid with equivalent glucocorticoid potency)
3. Give a **histamine (H_2)-receptor antagonist** (ranitidine 50 mg, cimetidine 300 mg, or famotidine 20 mg) intravenously over 15–30 minutes
4. After symptoms resolve, resume rituximab administration at 25 mg/hour with close monitoring. Do not increase the administration rate

Patient Population Studied

Study of 32 previously treated patients with CLL. Patients had previously received from 1–7 regimens (median: 2). In 32% of patients, disease was refractory to prior fludarabine

Toxicity (N = 32)

Hematologic Toxicity (NCI Working Group Guidelines)

Toxicity	% G3/4
Anemia	9
Thrombocytopenia	16
Neutropenia	53

Nonhematologic Toxicity (NCI CTC)

Toxicity	% G3/4
Infection	28
Nausea	3
Vomiting	0
Constipation	0
Hepatic toxicity	0
Renal toxicity	0
Neurotoxicity	0

Therapy Monitoring

1. *Before each cycle:* CBC with differential and serum electrolytes, BUN, creatinine, and LFTs
2. *Response evaluation:* every 3 cycles

CLL REGIMEN

IBRUTINIB

Byrd JC et al. N Engl J Med 2013;369:32–42

Ibrutinib 420 mg/day orally, continually (total dose/week = 2940 mg)
Note: Administration with food increases ibrutinib exposure approximately 2-fold compared with administration after overnight fasting (IMBRUVICA [ibrutinib] capsules, for oral use; November 2013 product label. Janssen Biotech, Inc. Horsham, PA-C, USA)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is ***NOT*** *indicated*
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management
Latent or delayed-onset diarrhea*:*
Loperamide 4 mg; administer orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg every 2 hours while awake; every 4 hours during sleep
Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil®) two tablets four times daily until control has been achieved

Persistent diarrhea:
Octreotide acetate (solution) 100–150 mcg; administer subcutaneously 3 times daily

Antibiotic therapy during latent or delayed-onset diarrhea:
A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count $<500/mm^3$

*Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178
Abigerges D et al. J Natl Cancer Inst 1994;86:446–449

Oral care
Encourage patients to maintain intake of non-alcoholic fluids
If mucositis or stomatitis is present:
- Rinse mouth several times a day with 1/4 teaspoon (1.25 g) each of baking soda and table salt in one quart of warm water. Follow with a plain water rinse
- Do not use mouthwashes that contain alcohols

Patient Population Studied

Byrd JC et al. N Engl J Med 2013;369:32–42

Patients with a diagnosis of relapsed or refractory CLL or small lymphocytic lymphoma, defined according to the International Workshop on Chronic Lymphocytic Leukemia and World Health Organization classifications. Those enrolled were deemed to be in need of treatment. The first and second cohorts were required to have received ≥2 previous therapies, including a purine analog. A third cohort included patients with high-risk disease that did not respond to a chemoimmunotherapy regimen or whose disease progressed within 24 months after completion of the regimen

Treatment Monitoring

1. *Before treatment:* physical examination; CBC with differential; assessment of serum chemistry; and bone marrow aspiration and biopsy as indicated
2. *Assessment of efficacy:* Every 2 to 3 cycles

Efficacy (N = 85)

Byrd JC et al. N Engl J Med 2013;369:32–42

Subgroup	Number	ORR (95% CI)*
All patients	85	71% (60–80)

Negative	49	65% (50–78)
IGHV (immunoglobulin variable-region heavy-chain gene)		
Mutated	12	33% (10–65)
Unmutated	69	77% (65–86)
β_2-Microglobulin		
≤3 mg/L	39	72% (55–85)
>3 mg/L	41	68% (52–82)

*Only patients who received ibrutinib and had at least one post-baseline assessment

Dose Modification

Toxicity Occurrence	CLL Dose Modification After Recovery Starting Dose = 420 mg
First	Restart at 420 mg daily
Second	Restart at 280 mg daily
Third	Restart at 140 mg daily
Fourth	Discontinue ibrutinib

Interrupt ibrutinib therapy for any Grade 3 or greater nonhematological, Grade 3 or greater neutropenia with infection or fever, or Grade 4 hematological toxicities. Once the symptoms of the toxicity have resolved to Grade 1 or baseline (recovery), ibrutinib therapy may be reinitiated at the starting dose. If the toxicity reoccurs, reduce dose by one capsule (140 mg per day). A second reduction of dose by 140 mg may be considered as needed. If these toxicities persist or recur following two dose reductions, discontinue ibrutinib

CLL REGIMEN

OBINUTUZUMAB + CHLORAMBUCIL

Goede et al. N Engl J Med 2014;370:1101–1110

Chlorambucil 650 0.5 mg/kg; administer orally on days 1 and 15 of each 28-day cycle (total dose per cycle: 1 mg/kg)
Obinutuzumab administer as an intravenous infusion in 100–250 mL of 0.9% normal saline (NS) to a final concentration of 0.4–4 mg/mL every 28 days as follows:

Day 1, Cycle 1:	100 mg	Administer at 25 mg/hr over 4 hours. Do not increase the infusion rate
Day 2, Cycle 1:	900 mg	Administer at 50 mg/hr. The rate of the infusion can be escalated in increments of 50 mg/hr every 30 minutes to a maximum rate of 400 mg/hr
Days 8 and 15, Cycle 1:	1000 mg	Infusions can be started at a rate of 100 mg/hr and increased by 100 mg/hr increments every 30 minutes to a maximum of 400 mg/hr
Day 1, Cycles 2–6:	1000 mg	

Premedicate with glucocorticoid acetaminophen and anti-histamine

Premedication for Obinutuzumab Infusion to Reduce Infusion-Related Reactions (IRR)

Day of Treatment Cycle	Patients Requiring Premedication	Premedication	Administration
Cycle 1: Day 1, Day 2	All patients	Intravenous glucocorticoid: 20 mg dexamethasone or 80 mg methylprednisolone*	Completed at least 1 hour prior to obinutuzumab infusion
		650–1000 mg acetaminophen	At least 30 minutes before obinutuzumab infusion
		Anti-histamine (eg, diphenhydramine 50 mg)	
Cycle 1: Day 8, Day 15 Cycles 2–6: Day 1	All patients	650–1000 mg acetaminophen	≥30 minutes before obinutuzumab infusion
	IRR (≥G1) with previous infusion	Anti-histamine (eg, diphenhydramine 50 mg)	≥30 minutes before obinutuzumab infusion
	G3 IRR with previous infusion OR lymphocyte count >25 × 10^9/L prior to next treatment	Intravenous glucocorticoid: 20 mg dexamethasone or 80 mg methylprednisolone*	Completed ≥1 hour prior to obinutuzumab infusion

*Hydrocortisone not recommended; has not been effective in reducing rate of infusion reactions
Adapted from: gene.com/download/pdf/gazyva_prescribing.pdf

Notes:

- Hepatitis B Virus (HBV) reactivation, in some cases resulting in fulminant hepatitis, hepatic failure, and death, can occur in patients receiving CD20-directed cytolytic antibodies, including obinutuzumab. Screen all patients for HBV infection before treatment initiation. Monitor HBV positive patients during and after treatment with obinutuzumab. Discontinue obinutuzumab and concomitant medications in the event of HBV reactivation
- Progressive multifocal leukoencephalopathy (PML), including fatal PML, can occur in patients receiving obinutuzumab
- Obinutuzumab can cause severe and life-threatening infusion reactions. Symptoms may include hypotension, tachycardia, dyspnea, and respiratory symptoms (eg, bronchospasm, larynx and throat irritation, wheezing, laryngeal edema). Other common symptoms include nausea, vomiting, diarrhea, hypertension, flushing, headache, pyrexia, and chills
- ***Two-thirds of patients experienced a reaction to the first 1000 mg infused of obinutuzumab. Infusion reactions can also occur with subsequent infusions***
- Premedicate patients before each infusion. Closely monitor patients during the entire infusion. Infusion reactions occur within 24 hours of receiving obinutuzumab
- Hypotension may occur as an infusion reaction. Consider withholding antihypertensive treatments for 12 hours prior to and during each obinutuzumab infusion, and for the first hour after administration until blood pressure is stable

Dose Modifications

Adverse Event	Dose Adjustment
G1/2 obinituzumab infusion reactions	Interrupt or reduce the rate of the infusion and manage symptoms
G3 obinituzumab infusion reactions	Interrupt obinituzumab until resolution of symptoms
G4 obinituzumab infusion reactions including but not limited to anaphylaxis, acute life-threatening respiratory symptoms, or other life-threatening infusion reactions	Stop the obinituzumab infusion. Permanently discontinue obinituzumab
Patient who develops PML	Discontinue obinutuzumab therapy and consider discontinuation or reduction of any concomitant chemotherapy or immunosuppressive therapy
G3/4 neutropenia	Strongly recommended to receive antimicrobial prophylaxis throughout the treatment period. Antiviral and antifungal prophylaxis should be considered

Efficacy

Metric	Obinutuzumab + Chlorambucil [O + C]	Rituximab + Chlorambucil [R + C]	Chlorambucil-Alone [CA]
ORR 3 months > the end of treatment	77.3–78.4%	65.1–65.7%	31.4%
	O + C vs R + C: P <0.001		
	O + C vs CA: P < 0.001		
		R + C vs CA: P <0.001	
CR 3 months > the end of treatment	55–57.7	58.1–58.4	—
PR 3 months > the end of treatment	20.7–22.3	7.0–7.3	31.4
Median PFS	26.7 months	16.3 months	11.1 months
	O + C vs CA: HR for progression or death, 0.18; 95% CI, 0.13–0.24; P <0.001		
		R + C vs CA: HR, 0.44; 95% CI, 0.34–0.57; P <0.001	
Median PFS	26.7 months	15.2 months	
	O + C vs R + C: HR, 0.39; 95% CI, 0.31–0.49; P <0.001		
Rate negative MRD in bone marrow	19.5%	2.6%	
	O + C vs R + C: P <0.001		
Rate negative MRD in peripheral blood	37.7%	3.3%	
	O + C vs R + C: P <0.001		
Rates of death	8–9%	12%	20%,
	O + C vs CA: HR for death, 0.41; 95% CI, 0.23–0.74; P = 0.002		
	O + C vs R + C: HR, 0.66; 95% CI, 0.41–1.06; P = 0.08		

CI, confidence interval; CR, complete response; HR, hazard ratio; MRD, minimal residual disease; ORR, overall response rates; PFS, progression-free survival; PR, partial r esponse

Toxicity

Adverse Events of Grade 3 or Higher, Safety Population*

	Obinutuzumab–Chlorambucil vs. Chlorambucil Alone		Obinutuzumab–Chlorambucil vs. Rituximab–Chlorambucil	
	Obinutuzumab–Chlorambucil (N = 241)	Chlorambucil Alone (N = 116)	Obinutuzumab–Chlorambucil (N = 336)	Rituximab–Chlorambucil (N = 321)
Event	Number of Patients (percent)

Thrombocytopenia	27 (11)	5 (4)	35 (10)	10 (3)
Leukopenia	13 (5)	0	15 (4)	3 (1)
Infections	27 (11)	16 (14)	40 (12)	44 (14)
Pneumonia	8 (3)	4 (3)	13 (4)	17 (5)
Febrile neutropenia	4 (2)	5 (4)	8 (2)	4 (1)

*The safety population included all patients who received at least one dose of study medication. Shown are adverse events of grade 3, 4, or 5 with an incidence of 3% or higher in any treatment group, irrespective of whether the event was considered related or unrelated to treatment by the investigators

Patient Population Studied

Open-label study that enrolled patients with CD20-positive CLL that was diagnosed according to the criteria of the International Workshop on Chronic Lymphocytic Leukemia. Previously untreated patients requiring treatment (ie, those with Binet stage C or symptomatic disease) were included. Enrolled patients were required to have a clinically meaningful burden of coexisting conditions, as reflected by a score higher than 6 on the Cumulative Illness Rating Scale (CIRS) (range, 0 to 56, with higher scores indicating worse health status) or a creatinine clearance of 30 to 69 mL per minute as assessed with the use of the Cockcroft–Gault formula

Treatment Modifications

1. *Before treatment:* physical examination; CBC with differential; assessment of serum chemistry; and bone marrow aspiration and biopsy as indicated
2. *Assessment of efficacy:* Every 2 to 3 cycles

20. Leukemia, Chronic Myelogenous

Michael W.N. Deininger, MD, PhD and Brian J. Druker, MD

Epidemiology

Incidence: 5,980 (male: 3,130; female: 2,850. Estimated new cases for 2014 in the United States)
Deaths: Estimated 810 in 2014 (male: 550; female: 260)
Median age: 65 years
Male to female ratio: 1.7:1

Phase at presentation:
Chronic phase: 85–90%
Accelerated phase and blast crisis: 10–15%

Cervantes F et al. Haematologica 1999;84:324–327
O'Brien SG et al. N Engl J Med 2003;348:994–1004
Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)

Pathology

Peripheral blood findings at diagnosis: median (range)

1. *WBC:* 174,000/mm^3 (15–850/mm^3)
2. *Hemoglobin:* 10.3 g/dL (4.9–16.6 g/dL)
3. *Platelet count:* 430,000/mm^3 (17–3182/mm^3)
4. Left-shifted white cell differential, basophilia, and eosinophilia
5. *Blasts:* <15%—chronic phase

Bone marrow findings at diagnosis

1. Increased cellularity
2. Increased myeloid-to-erythroid ratio with full myeloid maturation
3. Blasts <15%—chronic phase
4. Basophilia
5. Megakaryocyte hyperplasia
6. Reticulin fibrosis

Cytogenetics and molecular diagnostics

1. Philadelphia (Ph) chromosome including variant translocations (90%)
2. *BCR-ABL* translocation by FISH (95%)*
3. *BCR-ABL* transcripts by RT-PCR (95%)*
4. Chromosomal abnormalities in addition to the Ph chromosome (clonal evolution)†:
   (Associated with disease progression, usually absent in the chronic phase at diagnosis)

Trisomy 8	52.9%
Second Philadelphia chromosome	50.7%
Isochromosome 17	35.8%
Trisomy 19	24.3%

*Approximately 5% of patients with morphologically and clinically typical CML are negative for BCR-ABL by FISH and RT-PCR; these patients constitute a heterogeneous group with a poorer prognosis that is usually unresponsive to imatinib. The data given here do not apply to this group of patients
†Clonal evolution is associated with a less-favorable response to standard drug therapy (imatinib), regardless of disease phase, but is not an independent prognostic variable. In patients treated with nonimatinib therapies, isochromosome 17 is an adverse prognostic factor in multivariate analysis

Thiele J et al. Leuk Lymphoma 2000;36:295–308

Work-up

History and physical examination

1. CBC and leukocyte differential counts, platelets, electrolytes, liver function tests
2. HLA typing for patients who are candidates for allogeneic hematopoietic cell transplantation
3. Bone marrow aspirate and biopsy (bone marrow cytogenetics can detect chromosomal abnormalities other than Ph chromosome that are not detectable using peripheral blood)
4. BCR-ABL1 transcript levels by quantitative reverse transcriptase polymerase reaction (QPCR) before initiation of treatment.
5. If collection of bone marrow is not feasible, fluorescence in situ hybridization (FISH) on a peripheral blood specimen with dual probes for BCR and ABL1 genes

Classification of Disease: Phases of Disease

Chronic phase:
1. Bone marrow and peripheral blood blasts <15%
2. Peripheral blood promyelocytes and blasts combined <30%
3. Peripheral blood basophils <20%
4. Platelets >100,000/mm^3

Accelerated phase:
1. Bone marrow and peripheral blood blasts 15–30%
2. Peripheral blood promyelocytes + blasts ≥30% (but blasts alone <30%)
3. Peripheral blood basophils ≥20%
4. Platelets ≤100,000/mm^3 (unless related to therapy)

Blast crisis:
1. Bone marrow or peripheral blood blasts ≥30%
2. Myeloid immunophenotype: MPO-positive
3. Lymphoid immunophenotype: TdT-positive

Cytogenetic abnormalities in addition to the Philadelphia chromosome (typically, isochromosome 17, trisomy 8, trisomy 19, second Ph chromosome) are considered indicative of accelerated phase by some authors, even in the absence of other defining criteria. Adverse prognostic significance is best documented for isochromosome 17

CML Extras

Calculation of Relative Risk

Adapted from Hasford J et al. Blood 2011;118:686–692

Study	Calculation		Risk Definition by Calculation
Sokal et al. 1984*		Exp 0.0116 × (age − 43.4)	Low risk: <0.8
	+	0.0345 × (spleen − 7.51)	Intermediate risk: 0.8–1.2
	+	0.188 × [(platelet count ÷ 700)^2 − 0.563]	
	+	0.0887 × (myeloblasts − 2.10)	High risk: >1.2
Euro Hasford et al. 1998†		0.666 when age ≥50 y	Low risk: ≤780
	+	(0.042 × spleen)	Intermediate risk: 781–1480
	+	1.0956 when platelet count >1500 × 10^{9}L	
	+	(0.0584 × myeloblast)	High risk: >1480
	+	0.20399 when basophils >3%	
	+	(0.0413 × eosinophils) × 100	
EUTOS Hasford et al. 2011‡		Spleen × 4	Low risk: ≤87
	+	Basophils × 7	High risk: >87

Calculation of the risk requires use of clinical and hematologic data at diagnosis, prior to any treatment:
- Age is given in years
- Spleen is given in centimeters below the costal margin (maximum distance)
- Myeloblasts, eosinophils, and basophils are given in percent of peripheral blood differential

Relative risk for the Sokal calculation is expressed as exponential of the total; that for the Hasford calculation is expressed as the total × 1000

To calculate Sokal and Euro risk score, go to:
http://www.leukemia-net.org/content/leukemias/cml/cml_score/index_eng.html
To calculate EUTOS risk score, go to:
http://www.leukemia-net.org/content/leukemias/cml/eutos_score/index_eng.html

*Sokal et al. Blood 1984;63:789–799. Risk according to Sokal et al. defined based on patients treated with conventional chemotherapy.
†Hasford et al. J Natl Cancer Inst. 1998;90:850–858. Risk according to Hasford et al. defined based on patients treated with rIFNα-based regimens

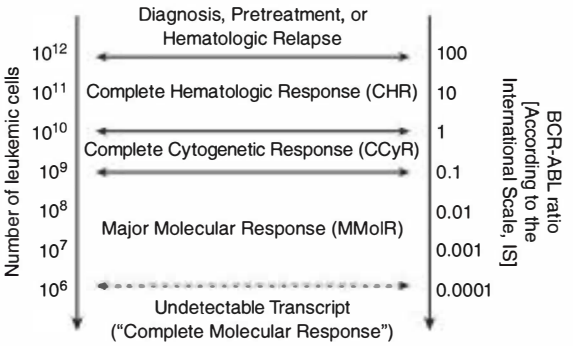
CML Extras (*continued*)

Approximate relationship between response, the putative number of leukemic cells, and the level of BCR-ABL transcripts
[Adapted from Baccarani M et al. Blood 2006;108:1809–1820]



Response Definitions and Monitoring

Adapted from Baccarani et al. Blood 2013;122:872–884

	Complete Hematologic Response (CHR)*	Cytogenetic Response (CyR)†	Molecular Response (MolR)‡
Definitions	• Normalization of blood counts: ▪ Platelet count <450,000/mm^3 ▪ WBC <10,000/mm^3; ▪ Differential without immature granulocytes and <5% basophils • Spleen not palpable • Disappearance of CML symptoms	Percent of 20 marrow metaphases with Philadelphia chromosome (Ph) detected by karyotyping: • Complete (CCyR)* = 0% • Partial/Major (MCyR) = 1–35% • Minor CyR = 36%–65% • Minimal CyR = 66%–95% • None = >95%	"Complete (CMR, CMolR)" = Transcript not detectable§ Major (MMolR)* = ≥3 $\log_{10}$ reduction in *BCR-ABL1* transcripts (≤0.10% IS)
Monitoring	• Check CBC every 2 weeks until CHR achieved and confirmed • Once CHR achieved check CBC every 3 months unless otherwise required	• Check CyR at 3, 6, 12 months and then at least every 6 months until CCyR achieved and confirmed • Once CCyR achieved check every 12 months	• Check every 3 months • Perform mutational analysis in case of failure, suboptimal response, or >5-fold increase in transcript level

*Complete HR, complete CCyR, and major MolR should be confirmed on at least 2 occasions
†CyR is evaluated by morphologic cytogenetics of at least 20 marrow metaphases. FISH of peripheral blood cells should be used only if marrow metaphases cannot be obtained
‡MolR is assessed on peripheral blood cells. Following quantitative real time PCR (qRT-PCR) analysis, the *BCR-ABL1*/control gene transcript ratio is determined using the International Scale (IS) standardized baseline. The international scale for measuring MolR is that proposed by Hughes et al. Blood 2006;108:28–37
§There is no universal definition of complete molecular response (CMR, CMolR). Some of the studies used define CMR as a negative (undetectable) result on a nested PCR assay; however, this is problematic owing to test variability. Others suggest that CMR be defined as undetectable *BCR-ABL1* mRNA in 2 consecutive samples with a 4.5-log detection limit. This definition may become inadequate once sensitivity increases beyond the 4.5-log levels. It may be best to indicate test sensitivity and avoid the term CMR

(*continued*)

CML Extras (*continued*)

Recommendations for Cytogenetic and Molecular Monitoring

Adapted from Baccarani et al. Blood 2013;122:872–884

At diagnosis	Chromosome banding analysis (CBA) of marrow cell metaphases
	FISH in case of Ph negativity to identify variant, cryptic translocations
	Qualitative PCR (identification of transcript type)
During treatment	Quantitative real-time PCR (RQ-PCR) for the determination of *BCR-ABL1* transcripts level on the international scale, to be performed every 3 months until an MMR (BCR-ABL ≤0.1%, or $MR^{3.0}$) has been achieved, then every 3–6 months *and/or*
	CBA of marrow cell metaphases (at least 20 banded metaphases), to be performed at 3, 6, and 12 months until a CCyR has been achieved, then every 12 months. Once a CCyR is achieved, FISH on blood cells can be done. If adequate molecular monitoring can be ensured, cytogenetics can be spared
Failure, progression	RQ-PCR, mutational analysis, and CBA of marrow cell metaphases. Immunophenotyping in BP
Warning	Molecular and cytogenetic tests to be performed more frequently. CBA of marrow cell metaphases recommended in case of myelodysplasia or CCA/Ph^- with chromosome 7 involvement

CCA/Ph^- clonal chromosome abnormalities in Ph^- cells; FISH, fluorescence in situ hybridization

Note: The responses can be assessed either with molecular tests alone or with cytogenetic tests alone, depending on the local laboratory facilities, but whenever possible, both cytogenetic and molecular tests are recommended until a CCyR and an MMR are achieved. Then RQ-PCR alone may be sufficient. Mutational analysis by conventional Sanger sequencing is recommended in case of progression, failure, and warning. In case of failure, warning, and development of myelodysplastic features (unexpected leucopenia, thrombocytopenia, or anemia), CBA of marrow cell metaphases is recommended

Definition of the Response to TKIs (Any TKI) as First-Line Treatment [Previously Untreated Patients in Early Chronic Phase (ECP) CML]

Adapted from Baccarani et al. Blood 2013;122:872–884

Time	Failure*	Warning†	Optimal
Diagnosis/Baseline	NA	High risk *or* CCA/Ph^+, major route‡	NA
3 months on TKI treatment	No CHR *and/or* Ph^+ >95%	BCR-ABL1 >10% *and/or* Ph^+ 36–95%	BCR-ABL1 ≤10% *and/or* Ph^+ ≤35%
6 months on TKI treatment	BCR-ABL1 >10% *and/or* Ph^+ >35%	BCR-ABL1 1–10% *and/or* Ph^+ 1–35%	BCR-ABL1 <1% *and/or* Ph^+ 0%
12 months on TKI treatment	BCR-ABL1 >1% *and/or* Ph^+ >0%	BCR-ABL1 >0.1–1%	BCR-ABL1 ≤0.1%
Then, and at any time	Loss of CHR Loss of CCyR Confirmed loss of MMR§ New mutation CCA/Ph^+	CCA/Ph^- (−7 or 7q−)	BCR-ABL1 ≤0.1%

CCA, clonal chromosomal abnormalities; CCyR, complete cytogenetic response, Philadelphia chromosome (Ph) not detected by karyotyping in 20/20 marrow metaphases; CHR, complete hematologic response; CyR, cytogenetic response; NA, not applicable

*Failure implies patient should be moved to other treatments when available

†Warning implies that the characteristics of the disease and the response to treatment require more frequent monitoring to permit timely changes in therapy in case of treatment failure. Such patients may become eligible for other treatments

‡Major route abnormalities include trisomy 8, trisomy Ph (+der(22)t(9;22)(q34;q11)), isochromosome 17 (i(17)(q10)), trisomy 19 and ider(22)(q10)t(9;22)(q34;q11)

§To be confirmed on 2 occasions, at least 1 of which with BCR-ABL ≥1%

(*continued*)

CML Extras (*continued*)

Definitions of the Response to Second-Line Therapy in Case of Failure of Imatinib

Adapted from Baccarani et al. Blood 2013;122:872–884

	Failure	Warning	Optimal
Diagnosis/Baseline	NA	No CHR or loss of CHR on imatinib *or* Lack of CyR to first-line TKI *or* High risk	NA
3 months on TKI treatment	No CHR *or* Ph^+ >95% *or* New mutations	BCR-ABL1 >10% *and/or* Ph^+ 65–95%	BCR-ABL1 ≤10% *and/or* Ph^+ <65%
6 months on TKI treatment	BCR-ABL1 >10% *and/or* Ph^+ >65% *and/or* New mutations	Ph^+ 35–65%	BCR-ABL1 ≤10% *and/or* Ph^+ <35%
12 months on TKI treatment	BCR-ABL1 >10% *and/or* Ph^+ >35% *and/or* New mutations	BCR-ABL1 1–10% *and/or* Ph^+ 1–35%	BCR-ABL1 <1% *and/or* Ph^+ 0
Then, and at any time	Loss of CHR *or* Loss of CCyR or PCyR New mutations Confirmed loss of MMR* CCA/Ph^+	CCA/Ph^- (−7 or 7q−) *or* BCR-ABL1 >0.1%	BCR-ABL1 ≤0.1%

CCA/Ph^+, clonal chromosome abnormalities in Ph^+ cells; CCA/Ph^-, clonal chromosome abnormalities in Ph^- cells; MMR, BCR-ABL1 ≥0.1% = MR3.0 or better; NA, not applicable

*In 2 consecutive tests, of which 1 with a BCR-ABL transcripts level ≥1%

Note: These definitions are mainly based on data reported for nilotinib and dasatinib, but can be used provisionally also for bosutinib and ponatinib, until more data are available. These definitions cannot apply to the evaluation of the response to third-line treatment.

Expert Opinion

FDA-Approved Indications and Usage

1. Imatinib is approved for:
   - *Newly diagnosed adult* and pediatric patients with CML* in chronic phase
   - Patients with CML in blast crisis (BC), accelerated phase (AP), or in chronic phase (CP) after failure of interferon-α therapy
   - Adult patients with relapsed or refractory Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph^+ ALL)
   - Pediatric patients with Ph^+ ALL in combination with chemotherapy
2. Dasatinib is approved for:
   - *Newly diagnosed adults* with CML in chronic phase
   - Adults with chronic-, accelerated-, or myeloid or lymphoid blast-phase CML with resistance or intolerance to prior therapy that included imatinib
   - Adults with Ph^+ ALL with resistance or intolerance to prior therapy
3. Nilotinib is approved for:
   - *Newly diagnosed adults* with CML in chronic phase
   - Adults with chronic- or accelerated-phase CML with resistance or intolerance to prior therapy that included imatinib
4. Bosutinib is approved for:
   - Adult patients with chronic-, accelerated-, or blast-phase CML with resistance or intolerance to prior therapy
5. Ponatinib is approved for:
   - T315I-positive CML (chronic phase, accelerated phase, or blast phase) or T315I-positive Ph^+ ALL
   - Chronic-phase, accelerated-phase, or blast-phase CML or Ph^+ ALL for whom no other tyrosine-kinase inhibitor therapy is indicated
6. Omacetaxine Mepesuccinate is approved for:
   - Adult patients with chronic- or accelerated-phase CML with resistance and/or intolerance to 2 or more tyrosine kinase inhibitors (TKIs)

*According to the WHO, chronic myeloid leukemia (CML) is defined by the presence of the Ph chromosome or the BCR-ABL fusion gene in the context of a myeloproliferative neoplasm. Therefore the qualification "Ph chromosome-positive CML" is unnecessary

(*continued*)

Expert Opinion (*continued*)

Treatment options:

1. In the opinion of some, imatinib remains the standard drug therapy regimen for the initial treatment of all phases of CML. Other agents are considered second-line and are reserved for patients who are intolerant of or whose disease is resistant to imatinib. In the opinion of others, nilotinib and dasatinib represent better first-line options than imatinib. But everyone agrees that the availability of 3 first-line therapies provides clinicians with a range of options for managing intolerance and resistance
2. Although imatinib is an excellent therapy, it is not perfect: with 8 years of follow-up, 16% of IRIS patients discontinued treatment for insufficient efficacy and 6% for adverse events. These outcomes led many to ask whether first-line use of more potent tyrosine kinase inhibitors (TKIs), such as dasatinib and nilotinib, could reduce the rate of failures. Promising results in single-arm studies with both dasatinib and nilotinib led to randomized trials comparing dasatinib to imatinib (**D**asatinib versus **i**matinib study in treatment **n**aïve CML patients [**DASISION**] study) and nilotinib to imatinib (Evaluating nilotinib efficacy and safety in clinical trials of newly **d**iagnosed Ph-positive CML patients [**ENESTnd**] study). Both studies found dasatinib and nilotinib superior to imatinib with respect to:
   - Complete cytogenetic responses (CCyR)
   - Major molecular responses (MMR), and
   - Complete molecular responses (CMR)

   These observations led to their approval for first-line therapy of CML-CP
3. Dasatinib and nilotinib provide several advantages
   - Response milestones are achieved sooner and in a greater proportion of patients
   - Progression to advanced disease is reduced (statistically significant for nilotinib)

   However, the numerical advantages are slight, overall survival is not significantly different, and some late side effects have been observed for the second-generation inhibitors (nilotinib: peripheral occlusive arterial disease, POADs; dasatinib: pulmonary hypertension). Thus, longer follow-up will be necessary, before a general recommendation can be made
4. Dasatinib and nilotinib control the majority of BCR-ABL1 mutations that confer resistance to imatinib, with partially complementary exceptions. The choice between dasatinib and nilotinib can be partially rationalized based on BCR-ABL genotype (kinase domain mutation analysis) and patient history (side-effects profile). However, the 2 agents have not been compared in a prospective study. Patients with the T315I mutation of BCR-ABL do not respond to either agent
5. Bosutinib is active against several BCR-ABL1 mutants that confer resistance to nilotinib and dasatinib, and is approved for the treatment of adult patients with chronic-, accelerated-, or blast-phase CML with resistance or intolerance to prior therapy
6. The most problematic point mutation is the BCR-ABL^{T315I} "gatekeeper" mutation. BCR-ABL^{T315I} is insensitive to imatinib, dasatinib, nilotinib, and bosutinib
7. Ponatinib was demonstrated to have in vitro activity against BCR-ABL1^{T315I} and other resistant mutants. However, certain T315I-inclusive compound mutants exhibit high-level resistance. The extent to which T315I-inclusive compound mutations (eg, BCR-ABL1$^{E255V/T315I}$) reduce the effectiveness of ponatinib remains to be established. Ponatinib has demonstrated considerable clinical activity in patients with and without BCR-ABL^{T315I}, especially in the chronic phase of CML, but safety concerns prevents its use in second-line therapy, except in the case of BCR-ABL^{T315I}
8. Interferon-α may be considered in exceptional cases, but is generally ineffective in patients with disease resistant to tyrosine kinase inhibitors
9. Hydroxyurea is used for lowering excessively high white blood cell counts if the diagnosis is uncertain, and in the case of intolerance or resistance to tyrosine kinase inhibitors. Hydroxyurea is considered a palliative regimen, as it does not usually induce lasting responses
10. Although the Sokal score was developed in patients treated with chemotherapy, it also predicts the likelihood of achieving a complete cytogenetic response to imatinib (91% vs. 84% vs. 69% at 48 months for low-, intermediate-, and high-risk patients, respectively). Complete cytogenetic response is associated with a favorable outcome
11. The definitions of disease phases given above were used in the clinical trials of imatinib that led to regulatory approval. They are widely, but not universally, accepted
12. AML- or ALL-type chemotherapy is indicated for tyrosine kinase inhibitor-resistant CML in myeloid and lymphoid blast crisis, respectively. No data from controlled trials are available that demonstrate superiority of one regimen over another. All efforts should be made to proceed to allogeneic hematopoietic cell transplantation as soon as possible. Complete hematologic remission is achieved in 40–60% of patients

CML REGIMEN

IMATINIB

Deininger MWN et al. J Clin Oncol 2003;21:1637–1647

Chronic phase CML:

Initial dose:

Imatinib 400 mg/day; administer orally, continually, with the largest meal of the day (total dose/week = 2800 mg)

Dose escalation:

Escalate to **Imatinib** 600 mg/day; administer orally, continually, with the largest meal of the day (total dose/week = 4200 mg), if patient has not reached:

1. Complete hematologic response at 3 months, *or*
2. <95% Ph-negative metaphases at 6 months, *or*
3. <35% Ph-negative metaphases at 12 months

Accelerated phase and blast crisis CML

Initial dose:

Imatinib 600 mg/day; administer orally, continually, with the largest meal of the day (total dose/week = 4200 mg)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is MINIMAL–LOW

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Efficacy (Chronic phase, N = 553)*

Complete hematologic response	98%
Complete cytogenetic response	87%
Partial cytogenetic response (1–35% Ph^+ metaphases)	5%
Freedom from progression to accelerated phase or blast crisis	93%

*Projected rates at 60 months

Druker BJ et al. N Engl J Med 2006;355:2408–2417

Treatment Modifications

Hematologic Toxicity (No Modifications for Anemia)	
G1/2	No dose modifications
G3	Hold imatinib until toxicity resolves to grade 1*, then restart at 400 mg/day
Recurrent G3	Hold imatinib until toxicity resolves to grade 1, then restart at 300 mg/day
G4	Withhold imatinib until toxicity resolves to grade 1, then restart at 300 mg/day
Recurrent G4	Hold imatinib until toxicity resolves to grade 1, then restart at 300 mg/day†
Nonhematologic Toxicity	
G1	No dose modifications
G2/3	Hold imatinib until toxicity resolves to grade 1, then restart at 400 mg/day
Recurrent G2/3	Hold imatinib until toxicity resolves to grade 1, then restart at 300 mg/day
G4	Hold imatinib until toxicity resolves to grade 1, then restart at 300 mg/day
Recurrent G4	Discontinue imatinib

*Consider filgrastim for persistent neutropenia
†No dose reduction to <300 mg/day

Deininger MWN et al. J Clin Oncol 2003;21: 1637–1647

Therapy Monitoring

1. *CBC:* Weekly; every 2 weeks after achievement of complete hematologic response; every 4–6 weeks after achievement of a complete cytogenetic response
2. *Blood chemistry:* Weekly; every 4–8 weeks after achievement of complete hematologic response
3. *Bone marrow cytogenetics:* Every 3 months until complete cytogenetic response, then at 12- to 24-month intervals
4. *Quantitative RT-PCR for BCR-ABL from peripheral blood or bone marrow:* Every 3–6 months after achievement of complete cytogenetic response

Patient Population Studied

Study of 553 patients with newly diagnosed CML in chronic phase

Toxicity (In >10% of patients, N = 553)

Toxicity	% G1/2	% G3/4
Superficial edema	54.6	0.9

Insomnia	12.2	—

O'Brien SG et al. N Engl J Med 2003;348:994–1004

Notes

In patients who develop disease progression while receiving imatinib, the option of allogeneic stem cell transplantation should be reevaluated

CML REGIMEN

DASATINIB

Shah NP et al. J Clin Oncol 2008;26:3204–3212

Chronic phase CML:
Initial dose:
Dasatinib 100 mg/day; administer orally, continually, with or without a meal (total dose/week = 700 mg)
Dose escalation:
Escalate to **dasatinib** 140 mg/day; administer orally, continually, with or without a meal in case of insufficient response (total dose/week = 980 mg)

Accelerated phase and blast crisis CML:
Initial dose:
Dasatinib 140 mg/day; administer orally, continually, with or without meal (total dose/week = 980 mg)
Dose escalation:
Escalate to **dasatinib** 180 mg/day; administer orally, continually, with or without a meal in case of insufficient response (total dose/week = 1260 mg)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is MINIMAL–LOW
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Study of 166 patients with CML in chronic phase resistant to or intolerant of imatinib

Therapy Monitoring

1. *CBC:* Weekly; every 2 weeks after achievement of complete hematologic response; every 4–6 weeks after achievement of complete cytogenetic response
2. *Blood chemistry:* Weekly; every 4–8 weeks after achievement of complete hematologic response
3. *Bone marrow cytogenetics:* Every 3 months until complete cytogenetic response, then at 12–24 months intervals
4. *Quantitative RT-PCR for BCR-ABL from peripheral blood or bone marrow:* Every 3–6 months after achievement of complete cytogenetic response

Efficacy (Chronic phase, N = 166)

Complete hematologic response*	90%
Complete cytogenetic response†	41%
Partial cytogenetic response† (1–35% Ph^+ metaphases)	18%
Freedom from progression to accelerated phase or blast crisis	93%

*51% of patients were in CHR at entry
†20% of patients were in major cytogenetic response at entry

Shah NP et al. J Clin Oncol 2008;26:3204–3212

Toxicity (In >10% of patients, N = 166)

Toxicity	% G1/2	% G3/4
Anemia	79	10
Leukocytopenia	43	16
Neutropenia	30	33
Thrombocytopenia	38	22
Fluid retention	20	1
Superficial edema	14	0
Pleural effusion	6	1
Headache	30	<1

Myalgia	11	0
Dyspnea	9	1
Peripheral edema	10	0

Shah NP et al. J Clin Oncol 2008;26:3204–3212

Treatment Modifications

Hematologic Toxicity: Chronic Phase (No Modifications for Anemia)	
G1/2	No dose modifications
ANC <500/mm³*	Hold dasatinib until ANC ≥1000/mm³ Recovery within 7 days: resume at 100 mg/day Recovery within >7 days or first recurrence: resume at 80 mg/day Second recurrence: discontinue
Platelet count <50,000/mm³	Hold dasatinib until platelet count is ≥50,000/mm³ Recovery within ≤7 days: resume at 100 mg/day Recovery within >7 days or first recurrence: resume at 80 mg/day Second recurrence: discontinue drug
Platelet count <25,000/mm³	Hold dasatinib until platelet count is ≥50,000/mm³ and resume at 80 mg/day First recurrence: Hold dasatinib until platelet count is ≥50,000/mm³ and resume at 80 mg/day Second recurrence: discontinue drug
Hematologic Toxicity: Accelerated or Blastic Phase	
G1–3	No dose modifications
G4–first occurrence	If cytopenia is unrelated to leukemia (bone marrow assessment), hold dasatinib until recovery to platelet count ≥20,000/mm³ and ANC ≥1000/mm³ and resume at 140 mg/day†
G4–second occurrence	Hold dasatinib until recovery to platelet count ≥20,000/mm³ and ANC ≥1000/mm³, and resume at 100 mg/day
G4–third occurrence	Hold dasatinib until recovery to platelet count ≥20,000/mm³ and ANC ≥1000/mm³, and resume at 80 mg/day
Nonhematologic Toxicity	
G1	No dose modifications
G2/3	Hold dasatinib until toxicity resolves to grade 1, then restart at 100 mg/day
Recurrent G2/3	Hold dasatinib until toxicity resolves to grade 1, then restart at 80 mg/day
G4	Hold dasatinib until toxicity resolves to grade 1, then restart at 80 mg/day
Recurrent G4	Discontinue dasatinib

*Consider filgrastim for persistent neutropenia
†Consider dose escalation to 180 mg/day in case of leukemia-related cytopenia
http://packageinserts.bms.com/pi/pi_sprycel.pdf (last accessed Dec. 19, 2011)

CML REGIMEN

NILOTINIB

le Coutre P et al. Blood 2008;111:1834–1839

Chronic phase CML:
Nilotinib 400 mg; administer orally twice daily, continually, at least 2 hours after the last and 1 hour before the next meal

Accelerated phase CML:
Nilotinib 400 mg; administer orally twice daily, continually, at least 2 hours after the last and 1 hour before the next meal

Note: Dose escalation is not indicated

Supportive Care

Antiemetic prophylaxis
Emetogenic potential is MINIMAL–LOW
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Study of 280 patients with CML in chronic phase resistant to or intolerant of nilotinib

Toxicity (In >10% of patients, N = 280)

Toxicity	% G1/2	% G3/4
Thrombocytopenia	NR	29
Neutropenia	NR	29
Rash	25	3
Pruritus	23	1
Headache	17	2
Fatigue	18	1
Constipation	12	0
Diarrhea	9	2
Vomiting	11	<1
Nausea	23	1

LeCoutre P et al. Blood 2008;111:1834–1839

Therapy Monitoring

1. *CBC:* Weekly; every 2 weeks after achievement of complete hematologic response; every 4–6 weeks after achievement of complete cytogenetic response
2. *Blood chemistry:* Weekly; every 4–8 weeks after achievement of complete hematologic response
3. *Bone marrow cytogenetics:* Every 3 months until complete cytogenetic response, then at 12–24-month intervals
4. *Quantitative RT-PCR for BCR-ABL from peripheral blood or bone marrow:* Every 3–6 months after achievement of complete cytogenetic response

Efficacy (Chronic phase, N = 280)

Complete hematologic response*	74%
Complete cytogenetic response*	31%
Partial cytogenetic response* (1–35% Ph* metaphases)	16%

*Only patients without response at baseline

le Coutre P et al. Blood 2008;111:1834–1839

Notes

1. Hypokalemia and hypophosphatemia should be corrected before initiating nilotinib therapy and serum electrolyte levels monitored during nilotinib treatment
2. EKG monitoring for QT prolongation is indicated at baseline, within 7 days after initiating therapy or changing the dose, and periodically thereafter
3. The Fridericia correction of the QT interval (QTcF) should be used for all calculations

Treatment Modifications

Hematologic Toxicity (No Modifications for Anemia)	
G1/2	No dose modifications
G3/4	Hold nilotinib until toxicity resolves to grade 2 Recovery within 2 weeks: restart at 400 mg twice daily Recovery within >2 weeks: restart at 400 mg/day
Nonhematologic Toxicity (Noncardiac)	
G1/2	No dose modifications
G3/4	Hold nilotinib until toxicity resolves to grade 1, then restart at 400 mg/day If tolerated, consider re-escalation to 400 mg twice daily
QT Prolongation	
QTcF >480 msec	Hold nilotinib and correct any hypokalemia and/or hypomagnesemia QTcF <450 msec and within 20 msec of baseline within 2 weeks: resume at 400 mg twice daily QTcF 450–480 msec: resume at 400 mg/day; if recurrence of QTcF >480 msec, discontinue nilotinib

http://www.pharma.us.novartis.com/product/pi/pdf/tasigna.pdf (last accessed, Dec. 19, 2011)

REFRACTORY PHILADELPHIA CHROMOSOME-POSITIVE CML REGIMEN

PONATINIB (ICLUSIG)

Cortes JE et al. N Engl J Med 2012;367:2075–2088

Ponatinib hydrochloride 45 mg/day; administer orally with or without food, continually for 28 consecutive days, on days 1–28, every 4 weeks (total dose/28-day cycle = 1260 mg)

Notes:

- On the basis of safety, pharmacokinetic, and pharmacodynamic data, 45 mg of ponatinib was determined to be the maximum tolerated dose
- The optimal dose of ponatinib has not been identified. In clinical trials, the starting dose of ponatinib was 45 mg administered orally once daily. However, 59% of the patients required dose reductions to 30 mg or 15 mg once daily during the course of therapy
- More safety information will become available with additional analysis and follow-up
- ***Start dosing with 45 mg once daily. Consider reducing the dose of ponatinib for CP CML and AP CML patients who have achieved a major cytogenetic response***
- ***The recommended dose should be reduced to 30 mg once daily when administering ponatinib with strong CYP3A subfamily inhibitors***

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

United States Food and Drug Administration (US FDA)

Safety Announcement, 12-20-2013

The U.S. Food and Drug Administration (FDA) is requiring several new safety measures for the leukemia drug Iclusig (ponatinib) to address the risk of life-threatening blood clots and severe narrowing of blood vessels. Once these new safety measures are in place, the manufacturer of Iclusig is expected to resume marketing to appropriate patients. Healthcare professionals should review these additional safety measures and carefully consider them when evaluating the risks and benefits of Iclusig for each patient

The required safety measures involve label changes to narrow the indication, provide additional warnings and precautions about the risk of blood clots and severe narrowing of blood vessels, revise recommendations about dosage and administration of Iclusig, and update the patient Medication Guide. We are also requiring a risk evaluation and mitigation strategy (REMS). In addition, the manufacturer of Iclusig, ARIAD Pharmaceuticals, must conduct postmarket investigations to further characterize the drug's safety and dosing

On October 31, 2013, FDA requested and ARIAD agreed to voluntarily suspend marketing of Iclusig. FDA's request resulted from FDA's investigation, which revealed a steady increase in the number of serious vascular occlusion events identified through continued safety monitoring of the drug. This observation represented a significant change in the safety profile of Iclusig as the proportion of patients on the drug experiencing vascular occlusion events such as blood clots and severe narrowing of blood vessels was significantly greater than the proportion reported at the time of its approval in December 2012

During the marketing suspension, Iclusig treatment has been available through single patient or emergency investigational new drug applications (INDs). Patients should continue to receive Iclusig under their authorized IND until marketing of Iclusig is resumed. FDA is working closely with ARIAD on the new safety measures and anticipates these will be in place by the end of January 2014. Once that process is complete, patients being treated under these INDs can be transitioned back to receiving the marketed Iclusig product. In more detail, the new safety measures for Iclusig include the following:

- The indications for use are limited to:
  - Treatment of adult patients with T315I-positive chronic myeloid leukemia (chronic phase, accelerated phase, or blast phase) or T315I-positive Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph^+ ALL)
  - Treatment of adult patients with chronic phase, accelerated phase, or blast phase chronic myeloid leukemia or Ph^+ ALL for whom no other tyrosine kinase inhibitor (TKI) therapy is indicated
- The *Warnings and Precautions* in the label are revised to describe the vascular occlusion events. This includes a description of the observed arterial and venous thrombosis and occlusions that have occurred in at least 27%—more than 1 in every 4—of patients treated with Iclusig

(*continued*)

(*continued*)

- The *Dosage and Administration* recommendations are revised to state that the optimal dose of Iclusig has not been identified. The recommended starting dose remains 45 mg administered orally once daily with or without food; however, additional information is included regarding dose decreases and discontinuations
- The patient Medication Guide is revised to include additional safety information consistent with the safety information in the revised drug label
- The Iclusig REMS will inform prescribers about the approved indications for use and the serious risk of vascular occlusion and thromboembolism associated with the drug
- We urge healthcare professionals and patients to report side effects involving Iclusig to the FDA MedWatch program, using the information in the "Contact FDA" box at the bottom of this page

European Medicines Agency Recommendations

November 22, 2013

Following a review of the data on the risk of occlusive vascular events with Iclusig, the European Medicines Agency has concluded that healthcare professionals may continue to use ponatinib in its authorized indication with increased caution. The Agency has made the following recommendations:

- Iclusig should not be used in patients with a history of heart attack or stroke, unless the potential benefits of treatment outweigh the risks
- The cardiovascular status of patients should be assessed and cardiovascular risk factors actively managed before starting treatment with Iclusig. Cardiovascular status should continue to be monitored and optimized during treatment
- Hypertension should be controlled during treatment with Iclusig and healthcare professionals should consider interrupting treatment if hypertension is not controlled
- Patients should be monitored for evidence of vascular occlusion or thromboembolism, and treatment should be interrupted immediately if this occurs

The recommendations are based on a review of data from clinical studies, including 2 ongoing studies (a phase I dose-finding study and a pivotal phase II study), which showed a higher incidence of arterial and venous thrombotic events in patients treated with Iclusig than was observed at the time of marketing authorization. In the phase I study, preliminary analysis of follow-up data from September 2013 showed a rate of serious occlusive vascular events of 22% (18 out of 81 patients) while in a preliminary analysis of data from the phase II study the rate was 13.8% (62 out of 449 patients). Median treatment duration was 2.7 years in the phase I study and 1.3 years in the phase II study

In addition, in a recently discontinued phase III study that compared Iclusig with imatinib with a median treatment duration of 3 months, there was a higher number of occlusive vascular events reported in the Iclusig arm, although the data from this study are still preliminary

The reported events from the studies include cardiovascular, cerebrovascular, peripheral vascular and venous thrombotic events. These events were seen in patients with and without risk factors but were seen more frequently in older patients and patients with a history of ischaemia (such as heart attacks) and strokes, high blood pressure, diabetes or blood fat disorders

Changes in Prescribing Information for Iclusig (Ponatinib) as of 12/2013 in Accordance with FDA Guidelines:

Boxed Warning

WARNING: VASCULAR OCCLUSION, HEART FAILURE, and HEPATOTOXICITY

Vascular Occlusion:

- Arterial and venous thrombosis and occlusions have occurred in at least 27% of Iclusig-treated patients, including fatal myocardial infarction, stroke, stenosis of large arterial vessels of the brain, severe peripheral vascular disease, and the need for urgent revascularization procedures. Patients with and without cardiovascular risk factors, including patients age 50 years or younger, experienced these events
- Monitor for evidence of thromboembolism and vascular occlusion. Interrupt or stop Iclusig immediately for vascular occlusion. A benefit–risk consideration should guide a decision to restart Iclusig therapy

Heart Failure:

- Heart failure, including fatalities, occurred in 8% of Iclusig-treated patients. Monitor cardiac function. Interrupt or stop Iclusig for new or worsening heart failure

Hepatotoxicity:

- Hepatotoxicity, liver failure and death have occurred in Iclusig-treated patients. Monitor hepatic function. Interrupt Iclusig if hepatotoxicity is suspected

1. Indications and Usage

Iclusig (ponatinib) is a kinase inhibitor indicated for the:

- Treatment of adult patients with T315I-positive chronic myeloid leukemia (CML) (chronic phase, accelerated phase, or blast phase) and T315I-positive Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph^+ ALL)
- Treatment of adult patients with chronic phase, accelerated phase, or blast phase chronic myeloid leukemia or Ph^+ ALL for whom no other tyrosine kinase inhibitor (TKI) therapy is indicated

These indications are based upon response rate. There are no trials verifying an improvement in disease-related symptoms or increased survival with Iclusig

(*continued*)

(continued)

2. Dosage and Administration

2.1. Recommended Dosing

- The optimal dose of Iclusig has not been identified. In clinical trials, the starting dose of Iclusig was 45 mg administered orally once daily. However, 59% of the patients required dose reductions to 30 mg or 15 mg once daily during the course of therapy
- Start dosing with 45 mg once daily. Consider reducing the dose of Iclusig for CP CML and AP CML patients who have achieved a major cytogenetic response
- Consider discontinuing Iclusig if response has not occurred by 3 months (90 days)
- Iclusig may be taken with or without food. Tablets should be swallowed whole

3. Warnings and Precautions

3.1. Vascular Occlusion

Arterial and venous thrombosis and occlusions, including fatal myocardial infarction, stroke, stenosis of large arterial vessels of the brain, severe peripheral vascular disease, and the need for urgent revascularization procedures have occurred in at least 27% of Iclusig-treated patients from the phase 1 and phase 2 trials. Iclusig can cause fatal and life-threatening vascular occlusion within 2 weeks of starting treatment. Iclusig can also cause recurrent or multisite vascular occlusion

In the dose-escalation (phase 1) clinical trial, 48% (31/65) of patients with CML or Ph^+ ALL developed vascular occlusive events. The median time to onset of the first vascular occlusion event was 5 months. Iclusig can cause fatal and life-threatening vascular occlusion in patients treated at dose levels as low as 15 mg per day

Patients with and without cardiovascular risk factors, including patients age 50 years or younger, experienced these events. Vascular occlusion adverse events were more frequent with increasing age and in patients with prior history of ischemia, hypertension, diabetes, or hyperlipidemia (see Table)

Vascular Occlusion Incidence in Iclusig-Treated Patients in Phase II Trial According to Risk Categories

	Prior History of Ischemia, Hypertension, Diabetes, or Hyperlipidemia	No History of Ischemia, Hypertension, Diabetes, or Hyperlipidemia
Age: 49 or younger	18% (6/33)	12% (13/112)
Age: 50 to 74 years	33% (50/152)	18% (20/114)
Age: 75 and older	56% (14/25)	46% (6/13)
All age groups	33% (70/210)	16% (39/239)
Total	24% (109/449)	

Arterial Occlusion and Thrombosis

Arterial occlusion and thrombosis occurred in at least 20% (91/449) of Iclusig-treated patients with some patients experiencing events of more than 1 type. Patients have required revascularization procedures (cerebrovascular, coronary, and peripheral arterial) because of vascular occlusion from Iclusig

Cardiac vascular occlusion, including fatal and life-threatening myocardial infarction and coronary artery occlusion has occurred in 12% (55/449) of Iclusig-treated patients, Patients have developed heart failure concurrent or subsequent to themyocardial ischemic event

Cerebrovascular occlusion, including fatal stroke has occurred in 6% (27/449) of Iclusig-treated patients. Iclusig can cause stenosis over multiple segments in major arterial vessels that supply the brain (eg, carotid, vertebral, middle cerebralartery)

Peripheral arterial occlusive events, including fatal mesenteric artery occlusion and life-threatening peripheral arterial disease have occurred in 8% (36/449) of Iclusig-treated patients. Patients have developed digital or distal extremity necrosis and have required amputations

Clinicians should consider whether the benefits of Iclusig treatment are expected to exceed the risks of therapy. ***In patients suspected of developing arterial thrombotic events, interrupt or stop Iclusig. A benefit–risk consideration should guide a decision to restart Iclusig therapy***

Venous Thromboembolism

Venous thromboembolic events occurred in 5% (23/449) of Iclusig-treated patients, including deep venous thrombosis (8 patients), pulmonary embolism (6 patients), superficial thrombophlebitis (3 patients), and retinal vein thrombosis (2 patients). ***Consider dose modification or discontinuation of Iclusig in patients who develop serious venous thromboembolism***

3.2. Heart Failure

Fatal and serious heart failure or left ventricular dysfunction occurred in 5% of Iclusig-treated patients (N = 22). Eight percent of patients (N = 35) experienced any grade of heart failure or left ventricular dysfunction. Monitor patients for signs or symptoms consistent with heart failure and treat as clinically indicated, including interruption of Iclusig. ***Consider discontinuation of Iclusig in patients who develop serious heart failure***

(continued)

(continued)

3.3. Hypertension

Treatment-emergent hypertension occurred in 67% of patients (300/449). Eight patients (2%) treated with Iclusig in clinical trials experienced treatment-emergent symptomatic hypertension as a serious adverse reaction, including hypertensivecrisis. Patients may require urgent clinical intervention for hypertension associated with confusion, headache, chest pain, or shortness of breath. In patients with baseline systolic BP <140 mm Hg and baseline diastolic BP <90 mm Hg, 78% (220/282) experienced treatment-emergent hypertension; 49% (139/282) developed Stage 1 hypertension (defined as systolic BP ≥140 mm Hg or diastolic BP ≥90 mm Hg) while 29% developed Stage 2 hypertension (defined as systolic BP ≥160 mm Hg or diastolic BP ≥100 mm Hg). In 131 patients with Stage 1 hypertension at baseline, 61% (80/131) developed Stage 2 hypertension. ***Monitor and manage blood pressure elevations during Iclusig use and treat hypertension to normalize blood pressure. Interrupt, dose reduce, or stop Iclusig if hypertension is not medically controlled***

3.4. Neuropathy

Peripheral and cranial neuropathy have occurred in Iclusig-treated patients. Overall, 13% (59/449) of Iclusig-treated patients experienced a peripheral neuropathy event of any grade (2%, grade 3/4). In clinical trials, the most common peripheral neuropathies reported were peripheral neuropathy (4%, 18/449), paresthesia (4%, 17/449), hypoesthesia (2%, 11/449), and hyperesthesia (1%, 5/449). Cranial neuropathy developed in 1% (6/449) of Iclusig-treated patients (<1% grade 3/4)

Of the patients who developed neuropathy, 31% (20/65) developed neuropathy during the first month of treatment. Monitor patients for symptoms of neuropathy, such as hypoesthesia, hyperesthesia, paresthesia, discomfort, a burning sensation, neuropathic pain or weakness. ***Consider interrupting Iclusig and evaluate if neuropathy is suspected***

3.5. Ocular Toxicity

Serious ocular toxicities leading to blindness or blurred vision have occurred in Iclusig-treated patients. Retinal toxicities including macular edema, retinal vein occlusion, and retinal hemorrhage occurred in 3% of Iclusig-treated patients

Conjunctival or corneal irritation, dry eye, or eye pain occurred in 13% of patients. Visual blurring occurred in 6% of the patients. Other ocular toxicities include cataracts, glaucoma, iritis, iridocyclitis, and ulcerative keratitis. ***Conduct comprehensive eye exams at baseline and periodically during treatment***

Treatment Modifications

Adverse Event	Treatment Modification
1st arterial thrombotic event	Interrupt and consider discontinuation of ponatinib
2nd arterial thrombotic event	Discontinue ponatinib
1st episode of G3/4 hepatotoxicity	Interrupt and then reduce or discontinue ponatinib
2nd episode of G3/4 hepatotoxicity	Discontinue ponatinib
First occurrence of ANC <1 × 10^9/L or platelet <50 × 10^9/L	Interrupt ponatinib and resume initial 45 mg dose after recovery to ANC ≥1.5 × 10^9/L and platelet ≥75 × 10^9/L
Second occurrence of ANC <1 × 10^9/L or platelet <50 × 10^9/L	Interrupt ponatinib and resume at 30 mg after recovery to ANC ≥1.5 × 10^9/L and platelet ≥75 × 10^9/L
Third occurrence of ANC <1 × 10^9/L or platelet <50 × 10^9/L	Interrupt ponatinib and resume at 15 mg after recovery to ANC ≥1.5 × 10^9/L and platelet ≥75 × 10^9/L
Elevation of liver transaminase >3 × ULN (G ≥2) at a ponatinib dose of 45 mg	Discontinue ponatinib and monitor hepatic function. Resume ponatinib at 30 mg after recovery to G ≤1 (<3 × ULN)
Elevation of liver transaminase >3 × ULN (G ≥2) at a ponatinib dose of 30 mg	Discontinue ponatinib and monitor hepatic function. Resume ponatinib at 15 mg after recovery to G ≤1 (<3 × ULN)
Elevation of liver transaminase >3 × ULN (G ≥2) at a ponatinib dose of 15 mg	Discontinue ponatinib
Elevation of liver transaminase >3 × ULN (G ≥2) concurrent with an elevation of bilirubin >2 × ULN and alkaline phosphatase <2 × ULN	Discontinue ponatinib
Asymptomatic G1/2 elevation of serum lipase	Consider interruption or dose reduction of ponatinib
Asymptomatic G3/4 elevation of lipase (>2 × ULN) or asymptomatic radiologic pancreatitis (G2 pancreatitis) at a ponatinib dose of 45 mg	Interrupt ponatinib and resume at 30 mg after recovery to G ≤1 (<1.5 × ULN)
Asymptomatic G3/4 elevation of lipase (>2 × ULN) or asymptomatic radiologic pancreatitis (G2 pancreatitis) at a ponatinib dose of 30 mg	Interrupt ponatinib and resume at 15 mg after recovery to G ≤1 (<1.5 × ULN)
Asymptomatic G3/4 elevation of lipase (>2 × ULN) or asymptomatic radiologic pancreatitis (G2 pancreatitis) at a ponatinib dose of 15 mg	Discontinue ponatinib

(continued)

Treatment Modifications (*continued*)

Adverse Event	Treatment Modification
Symptomatic G3 pancreatitis at a ponatinib dose of 45 mg	Interrupt ponatinib and resume at 30 mg after complete resolution of symptoms and after recovery of lipase elevation to G ≤1
Symptomatic G3 pancreatitis at a ponatinib dose of 30 mg	Interrupt ponatinib and resume at 15 mg after complete resolution of symptoms and after recovery of lipase elevation to G ≤1
Symptomatic G3 pancreatitis at a ponatinib dose of 15 mg	Discontinue ponatinib
G4 pancreatitis	Discontinue ponatinib

Notes:
Arterial Thrombosis: Cardiovascular, cerebrovascular, and peripheral vascular thrombosis, including fatal myocardial infarction and stroke have occurred in ponatinib-treated patients. In clinical trials, serious arterial thrombosis occurred in 8% of ponatinib-treated patients. Interrupt and consider discontinuation of ponatinib in patients who develop arterial thrombotic events
Hepatic Toxicity: Hepatotoxicity, liver failure and death have occurred in ponatinib-treated patients. Monitor hepatic function prior to and during treatment. Interrupt and then reduce or discontinue ponatinib for hepatotoxicity

NA denotes not applicable
*Sequencing data were not available for 3 patients with chronic-phase CML; all 3 had a complete hematologic response, 2 had a major cytogenetic response (both complete), and 1 had a major molecular response
†Sequencing data were not available for 1 patient with accelerated-phase CML and 1 patient with blast-phase CML; the former patient had a major hematologic response
‡Of these patients, 26 had a complete hematologic response at baseline, and all 26 remained in complete hematologic response during the study
§At baseline, 1 patient had a complete hematologic response and a molecular relapse. This patient had a major molecular response during the study. Eight patients had a partial cytogenetic response at entry; of these patients, 7 had a complete cytogenetic response during the study, and 1 maintained a partial cytogenetic response
¶Molecular response 4 was defined as at least a 4-log reduction, or a transcript ratio of BCR-ABL to ABL ≤0.01% (expressed as a percentage on the International Scale) in peripheral blood, as measured on quantitative reverse-transcriptase–polymerase-chain-reaction assay. Molecular response 4.5 indicates that the ratio is <0.0032%

*Treatment-related AEs were graded by the NCI Common Terminology Criteria for Adverse Events (v.3) and defined as events investigators deemed to have a possible, probable, or definite relationship to ponatinib. Listed are treatment-related AEs reported in ≥10% of patients, along with any G ≥3 or serious events
†Rash includes erythematous and papular rash
‡A G1 increase in the lipase level deemed probably not related to ponatinib occurred in 1 patient
§Included in this category is 1 patient who had 3 events of pancreatitis (all G2; all serious) that were deemed to either not related or probably not related to ponatinib. One event was changed to G3 and possibly related to ponatinib after the database cutoff

Patient Population Studied

Patients with a diagnosis of CML whose disease had relapsed or was resistant to standard care, or for which no standard care was available or acceptable. Ph-positive disease was classified and characterized as relapsed or refractory disease on the basis of standard criteria. In addition, patients were required to have an Eastern Cooperative Oncology Group performance status of 2 or lower

Treatment Monitoring

1. Complete blood counts (CBCs) and leukocyte differential counts should be performed weekly during the first 3 cycles, then every second week during subsequent cycles
2. Serum ALT, AST, alkaline phosphatase, lipase, and (pancreatic) amylase at baseline and weekly during the first 2 cycles, then every second week during subsequent cycles

REFRACTORY PHILADELPHIA CHROMOSOME–POSITIVE CML REGIMEN

BOSUTINIB

Khoury H-J et al. Blood 2012;119:3403–3412

Bosutinib 500 mg/day; administer orally with food, continually (total dose/week = 3500 mg)

Notes:

1. If a dose is missed by more than 12 hours, the patient should skip the dose and resume taking the usual prescribed dose on the following day
2. Consider dose escalation from 500 mg daily to 600 mg once daily with food in patients who do not reach complete hematologic response (CHR) by week 8 or a complete cytogenetic response (CCyR) by week 12, and who did not have G ≥3 adverse reactions
3. *Use in Hepatic Impairment:* In patients with pre-existing mild, moderate, and severe hepatic impairment (Child-Pugh classes A, B, and C, respectively), the recommended dose of bosutinib is 200 mg daily. A daily dose of 200 mg in patients with hepatic impairment is predicted to result in systemic exposure (area under the concentration curve; AUC) similar to the AUC seen in patients with normal hepatic function receiving 500 mg daily. However, there are no clinical data for efficacy at the dose of 200 mg once daily in patients with hepatic impairment and CML
4. *Concomitant Use With CYP3A Inhibitors:* Avoid the concomitant use of strong or moderate CYP3A subfamily and/or P-glycoprotein (P-gp, ABCB1, MDR1) inhibitors with bosutinib as an increase in bosutinib plasma concentration is expected
   a. Strong CYP3A inhibitors include: boceprevir, clarithromycin, conivaptan, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, posaconazole, ritonavir, saquinavir, telaprevir, voriconazole, and telithromycin
   b. Moderate CYP3A inhibitors include: amprenavir, aprepitant, atazanavir, ciprofloxacin, crizotinib, darunavir, diltiazem, erythromycin, fluconazole, fosamprenavir, grapefruit products, imatinib, and verapamil
5. *Concomitant Use With CYP3A Inducers:* Avoid the concomitant use of strong or moderate CYP3A inducers with bosutinib as a large reduction in exposure is expected
   a. Strong CYP3A inducers include: carbamazepine, phenobarbital, phenytoin, rifabutin, rifampin, and St. John's Wort
   b. Moderate CYP3A inducers include: bosentan, efavirenz, etravirine, modafinil, and nafcillin

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MINIMAL–LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Treatment Modification
AST/ALT >5 × ULN	Withhold bosutinib until AST/ALT ≤2.5 × ULN, then resume use at 400 mg once daily
AST/ALT >5 × ULN >4 weeks	Discontinue bosutinib
AST/ALT ≤3 × ULN concurrently with bilirubin elevations >2 × ULN and alkaline phosphatase <2 × ULN (Hy's law case definition)	Discontinue bosutinib
G3/4 diarrhea (≥7 stools/day over baseline/ pretreatment)	Withhold bosutinib until recovery to G ≤1 and resume at 400 mg once daily
Other G3/4 nonhematologic toxicity	Withhold bosutinib until recovery to G ≤1, then resume use at 400 mg once daily. If clinically appropriate, consider re-escalating the dose of bosutinib to 500 mg once daily
1st episode of ANC <1000 × 10^6/L or platelets <50,000 × 10^6/L with recovery in <2 weeks	Withhold bosutinib until ANC ≥1000 × 10^6/L and platelets ≥50,000 × 10^6/L Resume treatment with bosutinib at the same dose
2nd episode of ANC <1000 × 10^6/L or platelets <50,000 × 10^6/L with recovery in <2 weeks	Withhold bosutinib until ANC ≥1000 × 10^6/L and platelets ≥50,000 × 10^6/L then resume bosutinib at a dose 100 mg less than the dose previously administered
ANC <1000 × 10^6/L or platelets <50,000 × 10^6/L with recovery in <2 weeks	Withhold bosutinib until ANC ≥1000 × 10^6/L and platelets ≥50,000 × 10^6/L, then resume bosutinib use at a dose 100 mg less than the dose previously administered
Fluid retention (pericardial effusion, pleural effusion, pulmonary edema, and/or peripheral edema)	Monitor and manage patients using standards of care. Interrupt, decrease the dose, or discontinue bosutinib as necessary

DAS, dasatinib; IM, imatinib; NI, nilotinib; CHR, complete hematologic response

*Includes 3 patients who previously received all 3 inhibitors and 1 patient with NI intolerance

†Evaluable patients had a baseline disease assessment. Patients with CHR at baseline were evaluable for hematologic response and were considered responders if they maintained their response at 2 consecutive postbaseline assessments ≥4 weeks apart

‡Evaluable patients had a baseline disease assessment. Patients with CCyR at baseline were considered nonresponders for assessment of cytogenetic response

§Because of logistical constraints, patients from sites in China, India, Russia, and South Africa were not assessed for molecular response. MMR indicates ≥3 log reduction from standardized baseline Bcr-Abl: Abl ratio, and CMR, undetectable Bcr-Abl, with a sensitivity of ≥5 log. Molecular response was not assessed according to the International Scale

(*continued*)

Patient Population Studied

Study patients represented a subpopulation of adults with a confirmed diagnosis of Ph+ chronic-phase CML who previously received treatment with imatinib followed by dasatinib and/or nilotinib. All had an Eastern Cooperative Oncology Group performance status of 0 or 1, and no allogeneic hematopoietic stem cell transplantation within 3 months before starting study treatment. All patients had previously received imatinib and developed primary or acquired resistance or intolerance to imatinib, and had also received and developed resistance or intolerance to dasatinib and/or nilotinib. Resistance was defined as failure to achieve or maintain any of the following with previously administered treatments: hematologic improvement within 4 weeks, CHR after 12 weeks, any cytogenetic response by 24 weeks, or MCyR by 12 months. Acquired resistance was defined as loss of a MCyR or any hematologic response. Patients could also have resistance related to Bcr-Abl mutations. Intolerance was defined as an inability to take a protein kinase inhibitor because of drug-related G4 hematologic toxicity lasting more than 7 days, drug-related G3/4 nonhematologic toxicity, persistent G2 toxicity that did not respond to dose reduction and medical management, or loss of previously attained response on lower doses of protein kinase inhibitor therapy with an inability to receive a higher dose because of drug-related toxicity at higher doses

Phase 1/2, open-label, multicenter, 2-part study. The phase 1 (part 1) dose-escalation study enrolled patients with chronic phase CML previously treated with only imatinib. It determined the part 2 starting dose of bosutinib 500 mg/day, despite not reaching a study-defined maximum tolerated dose. Part 2 of the study evaluated the efficacy and safety of bosutinib across multiple patient subpopulations, including those with chronic-phase CML who had been previously treated with imatinib and dasatinib and/or nilotinib. The primary analysis in the subpopulation of patients with chronic-phase CML previously treated with multiple protein kinase inhibitors was MCyR by 24 weeks

*Patients with >1 mutation may be counted in both the P-loop and non–P-loop categories
†P-loop mutations include those from positions 248 to 255
‡Non–P-loop mutations include those from positions 244 to 247 and >255

Treatment Monitoring

1. Complete blood counts (CBCs) and leukocyte differential counts should be performed weekly during the first month after starting bosutinib, and at least monthly thereafter
2. Serum hepatic enzymes monthly during the first 3 months after starting bosutinib, and as clinically indicated thereafter. Increase the frequency of monitoring if hepatic transaminases increase after starting treatment

Toxicity

Dose interruptions and reductions resulting from AEs were required for 63% and 48% of patients, respectively. Twenty-four (20%) patients discontinued bosutinib because of AEs as shown in Table

	IM + DAS Resistant (n = 37)	IM + DAS Intolerant (n = 50)	IM + NI Resistant (n = 27)	IM + DAS + NI (n = 4)*	Total (n = 118)

†Two patients had G3/4 pleural effusions on bosutinib (at days 597 and 967 of treatment), but neither discontinued bosutinib because of a pleural effusion
‡No patient with dasatinib intolerance related to cardiovascular events, gastrointestinal events, musculoskeletal events, or skin disorders experienced the same toxicity as a G3/4 AE on bosutinib

REFRACTORY PHILADELPHIA CHROMOSOME–POSITIVE CML REGIMEN

Chronic or accelerated phase chronic CML with resistance and/or intolerance to 2 or more tyrosine kinase inhibitors (TKIs)

OMACETAXINE MEPESUCCINATE

Cortes J et al. Am J Hematol 2013;88:350–354
Cortes J et al. Blood 2012;120:2573–2580

Omacetaxine mepesuccinate 1.25 mg/m^2 per dose by subcutaneous injection:

Induction regimen schedule

Doses are given twice daily for 14 consecutive days, on days 1–14, every 28 days until patients achieve a hematologic response (total dosage/28-day cycle = 35 mg/m^2)

Maintenance regimen schedule

Doses are given twice daily for 7 consecutive days, on days 1–7, every 28 days for as long as patients experience clinical benefit from treatment (total dosage/28-day cycle = 17.5 mg/m^2)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

The efficacy of omacetaxine mepesuccinate was evaluated using a combined cohort of adult patients with CML from 2 trials. The combined cohort consisted of patients who had received 2 or more approved TKIs and had, at a minimum, documented evidence of resistance or intolerance to dasatinib and/or nilotinib. Resistance was defined as 1 of the following: no complete hematologic response (CHR) by 12 weeks (whether lost or never achieved); or no cytogenetic response by 24 weeks (ie, 100% Ph-positive [Ph$^+$]) (whether lost or never achieved); or no major cytogenetic response (MCyR) by 52 weeks (ie, ≥35% Ph$^+$) (whether lost or never achieved); or progressive leukocytosis. Intolerance was defined as 1 of the following: (a) G3/4 nonhematologic toxicity that did not resolve with adequate intervention; (b) G4 hematologic toxicity lasting more than 7 days; or (c) any G ≥2 toxicity unacceptable to the patient. Patients with NYHA class III or IV heart disease, active ischemia, or other uncontrolled cardiac conditions were excluded

A total of 76 patients with chronic phase CML were included in the efficacy analysis. The demographics were: median age 59 years, 30% were 65 years of age or older. All had previously received 2 or more TKIs, including imatinib. Thirty-six (47%) patients had failed treatment with imatinib, dasatinib, and nilotinib. Most patients had also received prior non-TKI treatments, most commonly hydroxyurea (54%), interferon (30%), and/or cytarabine (29%)

Treatment Modifications

G4 neutropenia (ANC <0.5 × 10^9/L) or G3 thrombocytopenia (<50 × 10^9/L) during a cycle	Delay start of next cycle until ANC ≥1 × 10^9/L and platelet count ≥50 × 10^9/L. Also, for the next cycle, reduce the number of dosing days by 2 days (eg, to 12 or 5 days)
G3/4 non-hematologic toxicity	Interrupt and/or delay omacetaxine mepesuccinate until toxicity is G ≤1. Also, for the next cycle, reduce the number of dosing days by 2 days (eg, to 12 or 5 days)
G2 AE unresponsive to supportive care	Interrupt treatment until G ≤1 then resume omacetaxine mepesuccinate at full dose
G ≥3 AE unresponsive to supportive care	Interrupt treatment until G ≤1 then resume omacetaxine mepesuccinate reducing the number of treatment days by 2 in subsequent cycles

Toxicity

Adverse Reactions Occurring in at Least 10% of Patients (Chronic Myeloid Leukemia–Chronic Phase)

Epistaxis	16 (15)	1 (1)
Skin and Subcutaneous Tissue Disorders		
Alopecia	16 (15)	0
Rash	11 (10)	0

Notes:
Safety data were evaluated in 163 patients, including 108 patients with CML-CP and 55 patients with CML-AP who received at least 1 dose of omacetaxine mepesuccinate and an additional 4 patients with CML-CP from another open-label, single-arm trial. Ten deaths were reported within 30 days after the last omacetaxine mepesuccinate dose. Four of these were attributed to progressive disease, 4 to cerebral hemorrhage, 1 to multiorgan failure, and 1 to unknown causes

Efficacy

The accelerated FDA approval was based on combined data from 2 open-label single-arm trials enrolling patients with CML in chronic phase (CML-CP) or in accelerated phase (CML-AP). The efficacy population included 76 patients with CML-CP who had received 2 or more prior TKIs, including imatinib

Efficacy Results for Patients with CP CML

The efficacy end point was based on MCyR

	Patients (N = 76)
Primary Response–MCyR	
Total with MCyR, n (%)	14 (18.4)
95% confidence interval	(10.5%–29%)
Cytogenetic Response, n (%)	
Confirmed complete	6 (7.9)
Confirmed partial	3 (3.9)
Mean time to MCyR onset (N = 14)	3.5 months
Median duration of MCyR (N = 14)	12.5 months (Kaplan-Meier estimate)

Cytogenetic response evaluation is based on standard cytogenetic analysis (at least 20 metaphases)
Complete: no Ph^+ cells; Partial: >0 to 35% Ph^+ cells

Treatment Monitoring

1. Complete blood counts (CBCs) should be performed weekly during induction and initial maintenance cycles
2. After initial maintenance cycles, monitor CBCs every 2 weeks, or as clinically indicated
3. Monitor blood glucose concentrations frequently, especially in patients with diabetes or risk factors for diabetes

CML REGIMEN

HYDROXYUREA

Hehlmann R et al. Blood 1994;84:4064–4077

Starting dose: **Hydroxyurea** 40 mg/kg; administer orally after meals, continually, as a single daily dose or divided into 2 doses (total dosage/week [initially] = 280 mg/kg)

1. Optimal dose is determined **empirically**, with very frequent monitoring of CBC (eg, every 3 days)
2. A dose of 1000–2000 mg/day is frequently sufficient for patients with WBC <100,000/mm^3. With higher WBCs and a need to rapidly lower WBC, hydroxyurea 6000–8000 mg/day may be required initially
3. Total daily dose depends on disease activity and is extremely variable (range: hydroxyurea 500–15,000 mg/day)
4. Therapeutic goal is normalization of the WBC (target: 5000–10,000/mm^3). This may require significantly higher or lower doses than the initial dose. If response is insufficient, aggressiveness of dose escalation must match aggressiveness of the disease. Frequent monitoring of WBC is mandatory during changes to the regimen
   a. Slowly rising WBC or failure to achieve therapeutic target: increase total daily hydroxyurea dose 25–50%, assess effect after 5–7 days before further escalation
   b. Rapidly rising WBC: increase total daily hydroxyurea dose by 50–100%, assess effect of dose increase for 3 days before further dose escalation
5. Very high doses carry a risk of prolonged aplasia

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is MINIMAL–LOW

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Study of 194 patients with newly diagnosed CML in chronic phase

Efficacy (N = 194)

5-year survival: 45%

Toxicity*

Hematologic side effects

1. Neutropenia and anemia are common, whereas thrombocytopenia is rare
2. Cytopenias are usually rapidly reversible (within 3–4 days)
3. High doses and/or failure to interrupt treatment despite cytopenia may result in prolonged aplasia

Relatively common nonhematologic side effects

1. Gastrointestinal symptoms (stomatitis, anorexia, nausea, vomiting, diarrhea)
2. Acute skin reactions (rash, ulceration, dermatomyositis-like changes, erythema)

Rare, nonhematologic side effects

1. Chronic skin reactions (hyperpigmentation, atrophy of skin and nails, skin cancer, alopecia)
2. Headache, drowsiness, convulsions
3. Fever, chills, asthenia
4. Renal and hepatic impairment

**Important note:* A comprehensive and detailed analysis of nonhematologic toxicity from a controlled trial is not available

Therapy Monitoring

1. *CBC:* At least weekly at first, then every 2–4 weeks after achieving stable blood counts
2. *Blood chemistry profile:* Every 6 months
3. *Bone marrow morphology and cytogenetics:* Every 6 months

Treatment Modifications

Hematological Toxicity	
G1	No dose modifications. G1 WBC or ANC are acceptable or even desirable
G2 or G3	Hold hydroxyurea until toxicity resolves to G1, then restart at 75% of initial dose
Recurrent G2/3	Hold hydroxyurea until toxicity resolves to G1, then restart at 50% of initial dose
G4	Hold hydroxyurea until toxicity resolves to G1, then restart at 25% of initial dose
Recurrent G4	Hold hydroxyurea until toxicity resolves to G1, then restart at 50% of the previous dose
Nonhematologic Toxicity	
G1	No dose modifications
G2/3	Hold hydroxyurea until toxicity resolves to G1, then restart at initial dose
Recurrent G2/3	Hold hydroxyurea until toxicity resolves to G1, then restart at 75% of initial dose
G4	Hold hydroxyurea until toxicity resolves to G1, then restart at 50% of dose previously administered
Recurrent G4	Discontinue hydroxyurea

Notes

1. Hydroxyurea is the drug of choice when a rapid reduction of the white cell count is clinically mandated, but the diagnosis of BCR-ABL-positive CML has not been established
2. Hydroxyurea may be indicated in cases of imatinib intolerance or resistance

CML REGIMEN

INTERFERON ALFA

Baccarani M et al. Blood 2002;99:1527–1535
Hehlmann R et al. Blood 1994;84:4064–4077

Premedication:
Acetaminophen 500–650 mg/dose; administer orally, every 4 to 6 hours as needed

Target dose of Interferon alfa:
Interferon alfa-2a 5 million IU/m² per day; administer subcutaneously, continually (preferably at bedtime) (total dosage/week = 35 million IU/m²)

or

Interferon alfa-2b 5 million IU/m² per day; administer subcutaneously, continually (preferably at bedtime) (total dosage/week = 35 million IU/m²)

Typical dose of Interferon alfa:
5 million IU/m² per day. To increase tolerability, interferon alfa should be started at low doses (eg, 1.5 million IU/m² per day), with gradual increases over several weeks until the target dose is achieved

Supportive Care
Antiemetic prophylaxis
Emetogenic potential is MINIMAL–LOW
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Notes

Interferon alfa is reserved for patients who are intolerant of imatinib, nilotinib, and dasatinib. Patients whose disease is resistant to these drugs usually do not respond to interferon alfa

On October 1, 2007, Hoffmann-La Roche, Inc. (Nutley, NJ) announced interferon alfa-2a (Roferon-A®) would be discontinued from the U.S. market

In 1989, interferon alfa-2a received orphan drug designation from the U.S. Food and Drug Administration for the treatment of chronic myelogenous leukemia and other oncological diseases

Patient Population Studied

Patients with newly diagnosed CML in chronic phase:
n = 263
(Baccarani M et al. Blood 2002;99:1527–1535)

n = 194
(Hehlmann R et al. Blood 1994;84:4064–4077)

Efficacy (N = 263)

Complete or partial hematologic response	74%
Complete cytogenetic response	7.6%
Partial cytogenetic response	10.3%
5-year survival	65%

Baccarani M et al. Blood 2002;99:1527–1535

Treatment Modifications

The practical management of patients receiving interferon alfa is complex. The simplified dose modification schema shown below is only a minimal guideline

Nonhematologic Toxicity	
G1	No dose reduction
G2	Reduce interferon alfa dosage by 25%
G3/4	Stop interferon alfa. Restart at 50% of the previously administered dose after toxicity resolves. If resumption is tolerated, increase to 75% of the dose that produced G3/4 toxicity
Hematologic Toxicity	
G1/2	No dose reduction
G3	Reduce interferon alfa dosage in 25% decrements until abates to grade <3
G4	Stop interferon alfa. Restart at a dosage decreased by 50% when toxicity resolves; increase dosage to 75% of the dose that produced G4 toxicity if tolerated

Modified from: O'Brien S et al. Leuk Lymphoma 1996;23:247–252

Toxicity

Toxicity	% (All Grades)
Fever	92
Asthenia or fatigue	88
Myalgia	68
Chills	63

Sleep disturbances	11
Paresthesia	8
Dyspnea	8
Cardiac dysrhythmia	7
Involuntary movements	7
Dry skin	7
Pruritus	7
Visual disturbances	6

Roferon-A (interferon alfa-2a, recombinant) product label, October 2004. Hoffmann-La Roche Inc., Nutley, NJ

Therapy Monitoring

1. *CBC:* Weekly; every 3–4 weeks after achievement of complete hematologic response, if counts are stable; every 4–6 weeks after achievement of complete cytogenetic response
2. *Blood chemistry:* Twice weekly; every 4–6 weeks after achievement of complete hematologic response
3. *Bone marrow cytogenetics:* Every 6 months; every 6–12 months after achievement of complete cytogenetic response
4. *Quantitative RT-PCR for BCR-ABL from peripheral blood or bone marrow:* Every 3 months

21. Leukemia, Hairy Cell

Martin S. Tallman, MD

Epidemiology

Incidence: 2% of all leukemia (approximately 600–800 new patients per year in the United States)
Median age: 52 years
Male to female ratio: Approximately 4:1

Bernstein L et al. Cancer Res 1990;50:3605–3609
Staines A, Cartwright RA. Br J Haematol 1993;85:714–717

Pathology

Peripheral blood findings at diagnosis

1. Pancytopenia: 50%
2. "Leukemic" phase with a WBC >1000/mm^3: 10–20%
3. Monocytopenia
4. Hairy cells identified in most patients, but the number is usually low and may be difficult to identify in the peripheral blood because of low numbers and staining technique

Bone marrow findings at diagnosis

1. Hypercellularity
2. Hairy cell infiltration: diffuse, patchy, or interstitial

   Diffuse infiltration: Often results in complete effacement of bone marrow

   Patchy infiltration: Subtle small clusters of hairy cells present focally or throughout the bone marrow

   Interstitial Infiltration: Hairy cells do not form well-defined discreet aggregates, but merge almost imperceptibly with surrounding normal hematopoietic tissue
3. Hairy cell nuclei are usually round, oval, or indented, and are widely separated from each other by abundant, clear or lightly eosinophilic cytoplasm. Rarely hairy cells can be convoluted or spindle shaped
4. Extravasated blood cells create blood lakes in the bone marrow similar to those observed in the spleen
5. Mast cells are often numerous
6. Reticulin stain of the bone marrow almost always shows moderate to marked increase in reticulin fibers
7. Approximately 10--20% of patients show a hypocellular bone marrow

Immunophenotyping, cytogenetics, and molecular diagnostic studies

1. *Cytochemical studies:* Tartrate-resistant acid phosphatase **(TRAP)** stain. However, TRAP is not specific for HCL
2. *Hairy cell immunophenotype:* CD19(+), CD20(+), CD22(+), CD79B(+), CD5(−), CD10(−), CD11C(+), CD25 Sub(+), FMC(+), CD103(+), CD45(+)
3. *Clonal cytogenetics:* Abnormalities in approximately two-thirds of patients. Chromosomes 1, 2, 5, 6, 11, 14, 19, and 20 are most frequently involved. Chromosome 5 is altered in approximately 40%, most commonly as a trisomy 5, pericentric inversion, and interstitial deletions involving band 5q13. However, the identification of cytogenetic abnormalities in a patient with a definite diagnosis of HCL is usually not important as it does not influence, as far as is currently determined, prognosis or therapy

(*continued*)

Work-up

1. H&P
2. CBC with differential, serum electrolytes, BUN, creatinine, LFTs, and uric acid
3. Bone marrow aspirate and biopsy for tartrate-resistant acid phosphatase (TRAP) (although TRAP is not required for the diagnosis, has been largely abandoned, and has been supplanted by immunophenotyping) and morphologic review; immunophenotyping by flow cytometry with B-cell–associated antibodies, including CD20, CD79A, or DBA.44

Differential Diagnosis

Other small B-cell lymphoproliferative disorders associated with splenomegaly:

1. Prolymphocytic leukemia
   a. Marked elevation in the WBC
   b. Characteristic morphology of the prolymphocytes
   c. Different immunophenotypic profile
2. Splenic marginal zone lymphoma (splenic lymphoma with villous lymphocytes)
   a. Cells do not usually exhibit TRAP positivity
   b. Bone marrow infiltrates are demarcated sharply
   c. Different immunophenotypic profile; CD103(−)
3. HCL variant
   a. Morphologic features between hairy cells and prolymphocytes
   b. Usually associated with leukocytosis/lack of monocytopenia
   c. Absence of CD25 expression
4. Systemic mastocytosis
   a. Mast cells are negative for B-cell markers, and positive for tryptase

Prognosis

Therapy with purine analogs: pentostatin (2′-deoxycoformycin) or cladribine (2-chlorodeoxyadenosine)

Complete remission	70–90%
Peripheral remission	10–20%
No response	5–10%
Relapse rate	5–25%
Estimated 5-year survival rate	85–90%
5–10-year survival rate	80–90%

Expert Opinion

A diagnosis of HCL by itself is not necessarily an indication to initiate treatment. If a patient is maintaining safe peripheral blood counts, the conservative approach is to "watch and wait" until counts decrease

Treatment is indicated when a patient has developed life-threatening cytopenias (absolute neutrophil count $<1000/mm^3$, hemoglobin <11 g/dL, or platelet count $<100,000/mm^3$), or in the presence of symptomatic splenomegaly or constitutional symptoms attributable to the disease

There is no clear advantage to either purine analog as initial treatment for patients with previously untreated HCL with respect to long-term outcome. The ease of administration of cladribine, which requires only a single course of therapy, may offer some advantages

Patients should be followed closely during treatment and for several months after completion of therapy, with special attention to appropriate surveillance and treatment for infection resulting from myelosuppression. An improvement in peripheral blood counts after purine nucleoside analog treatment may require weeks and sometimes months. Bone marrow biopsy to confirm a complete response is usually performed 3 months after the completion of therapy. However, if the peripheral blood counts return to normal, splenomegaly resolves and the patient is asymptomatic, one can argue not to carry out another bone marrow biopsy as the results will likely not influence further therapy. Even if the marrow demonstrates a small amount of HCL, further therapy is not indicated outside the context of a clinical trial exploring the potential benefits of additional therapy for residual disease

For patients who do not respond to initial therapy with a purine analog, the suggested therapeutic option is treatment with a different purine analog. However, the lack of excellent response to one purine analog is exceedingly uncommon and would prompt a reevaluation of the diagnosis

If relapse is suspected, the bone marrow should be reexamined before restarting therapy. In patients who achieved an initial, durable complete response to a purine analog lasting longer than 1 year, a reasonable course of action would be to retreat the patient either with the same agent or an alternative purine analog. If there was an initial remission of short duration (eg, <1 year), a repeated course of the original therapy is unlikely to result in a second remission of equivalent or longer duration. Retreatment with a second cycle of cladribine or pentostatin leads to a second complete remission in up to 70% of patients

The anti-CD20 antibody rituximab has been evaluated in patients with relapsed/refractory HCL and should be considered in patients who are not eligible to enroll in a clinical trial. Clinical trials using the truncated *Pseudomonas* exotoxin-linked recombinant anti-CD22 antibody (BL22) have shown high response rates in patients with previously treated HCL

Tallman MS et al. Blood 1992;80:2203–2209
Tallman MS et al. Blood 1996;88:1954–1959

Cladribine 0.1 mg/kg per day; administer by continuous intravenous infusion in 100–500 mL 0.9% sodium chloride injection, (0.9% NS), over 24 hours for 7 consecutive days (total dosage/cycle = 0.7 mg/kg)

or

Cladribine 0.14 mg/kg per day; administer intravenously in 100–500 mL of 0.9% NS over 2 hours for 5 consecutive days (total dosage/cycle = 0.7 mg/kg)

or

Cladribine 0.15 mg/kg per dose; administer intravenously in 100–500 mL 0.9% NS over 3 hours once weekly for 6 consecutive weeks (total dosage/cycle = 0.9 mg/kg)

Chacko J et al. Br J Haematol 1999;105:1145–1146
Lauria F et al. Blood 1997;89:1838–1839

Supportive Care

Antiemetic prophylaxis

See Chapter 39 for antiemetic recommendations

Emetogenic potential is ***MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is not indicated

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis is not clearly indicated. However, the following can be considered:

- Antibacterial—consider a fluoroquinolone during neutropenia *or*
- Antifungal—consider use during neutropenia
- Antiviral—antiherpes antivirals (eg, acyclovir) as patients may develop herpes viral infections as a result of their underlying disease even without the influence of purine analog therapy

See Chapter 47 for more information

Optional: **Allopurinol** 300 mg/day; administer orally, beginning on the first day of cladribine administration and continue for 2 weeks. Tumor lysis is uncommon and allopurinol need not be routinely administered. In addition, cutaneous disorders have occasionally been reported when cladribine used with allopurinol

Therapy Monitoring

1. Every other day for the week of therapy, then weekly for the next 7 weeks: CBC and serum electrolytes, BUN, creatinine, LFTs, and uric acid
2. *Three months after the completion of therapy:* Bone marrow aspirate and biopsy
3. *Long-term follow-up:* CBC every 3–6 months for 2 years, and then every 6 months for 3 years

Treatment Modifications

Cladribine Dose	No Modification
Platelet count <15,000/mm^3	Administer platelets
Symptomatic anemia or hemoglobin <7 g/dL	Administer packed red blood cells

Patient Population Studied

Patients with newly diagnosed as well as relapsed and refractory disease

Efficacy

Complete remission rate	75–90%
Partial remission rate	5–20%
Relapse rate	5–50%

Toxicity (N = 895)

Peripheral vein chemical phlebitis*	12%

*Tallman MS et al. Blood 1992;80:2203–2209 (N = 26)

Notes

Cladribine may be administered to patients with relapsed or refractory disease

REGIMEN

PENTOSTATIN (2′-DEOXYCOFORMYCIN, DCF)

Grever M et al. J Clin Oncol 1995;13:974–982

Hydration: 5% Dextrose/0.9% sodium chloride injection or 5% dextrose/0.45% sodium chloride injection; administer intravenously 1000 mL before and at least 500 mL after pentostatin administration

Pentostatin 4 mg/m^2; administer intravenously over 20–30 minutes in 25–50 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) every 2 weeks until complete remission (total dosage per 2-week course = 4 mg/m^2)

then

Pentostatin 4 mg/m^2; administer intravenously over 20–30 minutes in 25–50 mL 0.9% NS or D5W every 2 weeks for 2 courses (total dosage per 2-week course = 4 mg/m^2)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis should be considered in patients with:

ANC <500/mm^3 or in patients with history of recurrent episodes of fever and neutropenia

Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose

- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed

Antimicrobial prophylaxis

Risk of fever and neutropenia is INTERMEDIATE

Antimicrobial primary prophylaxis is not clearly indicated

- Antibacterial—no prophylaxis
- Antifungal—no prophylaxis
- Antiviral—antiherpes antivirals (eg, acyclovir) as patients may develop herpes viral infections as a result of their underlying disease even without the influence of purine analog therapy

Allopurinol: Tumor lysis is uncommon and allopurinol need not be routinely administered

Patient Population Studied

Study of 154 patients with previously untreated hairy cell leukemia

Efficacy

Complete remission rate	70–80%
Partial remission rate	5–20%
Relapse rate	10–25%

Toxicity (N = 154)

Toxicity	% G3	% G4
Allergy/rash	2.6	0
Nausea/vomiting/anorexia	12	0
Chills/fever	1.3	0
Diarrhea	1.3	0
Neurologic	0.7	0
Hepatic	0.7	0
Renal	0.7	0
Anemia	0.7	0
Granulocytopenia (G4)	5.2	14
Thrombocytopenia	2.6	0

Suspected infection during induction	53%
Systemic antibiotics during induction	27%

Treatment Modifications

Toxicity	Treatment Modification
Serum creatinine >20% over baseline	Hold pentostatin until serum creatinine returns to baseline or creatinine clearance on a 24-hour urine collection is >50 mL/min (>0.83 mL/s)
New or suspected infection	Hold pentostatin until successful therapy being administered
G2 nonhematologic toxicity	Reduce pentostatin by 33% after toxicity G ≤1
G3 nonhematologic toxicity	Reduce pentostatin by 50% after toxicity G ≤1
G4 nonhematologic toxicity	Discontinue pentostatin

Therapy Monitoring

1. *Two to 3 times per week during therapy:* CBC and serum electrolytes, BUN, creatinine, LFTs, and uric acid
2. *Three months after the completion of therapy:* Bone marrow aspirate and biopsy
3. *Long-term follow-up:* CBC every 3–6 months for 2 years, and then every 6 months for 3 years

REGIMEN

RITUXIMAB

Hagberg H, Lundholm L. Br J Haematol 2001;115:609–611
Lauria F et al. Haematologica 2001;86:1046–1050
Nieva J et al. Blood 2003;102:810–813

Premedication:

1. **Acetaminophen** 650–1000 mg; administer orally, 30–60 minutes before rituximab
2. **Diphenhydramine** 25–50 mg; administer orally or by intravenous injection 30–60 minutes before rituximab

Rituximab 375 mg/m^2 per week; administer intravenously in 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) diluted to a concentration within the range of 1–4 mg/mL for 4 consecutive weeks (total dosage per 4-week course = 1500 mg/m^2)

or

Rituximab 375 mg/m^2 per week; administer intravenously in 0.9% NS or D5W diluted to a concentration within the range of 1–4 mg/mL for 8 consecutive weeks with an additional 4 weekly doses (maximum of 12 doses) if a patient does not achieve a complete remission, but shows signs of continual improvement (total dosage per 8-week and 12-week courses = 3000 mg/m^2 and 4500 mg/m^2, respectively)

Thomas DA et al. Blood 2003;102:3906–3911

Rituximab infusion rates:

First dose: Start at an initial rate of 50 mg/hour. If hypersensitivity or infusion reactions do not occur during the first 30 minutes, increase the rate by 50 mg/hour every 30 minutes, to a maximum rate of 400 mg/hour

Subsequent doses: If previous administration was well tolerated, start at 100 mg/hour, and, if tolerated, increase by 100 mg/hour every 30 minutes, to a maximum rate of 400 mg/hour

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—*P. jiroveci* prophylaxis is recommended (eg, cotrimoxazole)
- Antifungal—not indicated
- Antiviral—not indicated, unless patient previously had an episode of HSV

See Chapter 47 for more information

Optional: **Allopurinol** 300 mg/day; administer orally, beginning on the first day of rituximab administration and continuing for 2 weeks. Tumor lysis is uncommon and allopurinol need not be routinely administered

Patient Population Studied

Relapsed or refractory HCL

Efficacy

Thomas DA et al. Blood 2003;102:3906–3911

Overall response rate	80%
Complete response rate	53%
Partial response rate	27%*
No response	20%

*Includes 2 additional patients who achieved complete remission by hematologic parameters but had residual marrow disease (1–5% hairy cells)
Duration of response: With median follow-up of 32 months, 5 of 12 patients had progression of disease at 8, 12, 18, 23, and 39 months from the start of therapy

Toxicity (N = 15)

Thomas DA et al. Blood 2003;102:3906–3911

Toxicity	No. of Patients	G	Dose No.
Fever and chills	9	1	1
Nausea and vomiting	4	1	1, 2
Hypotension*	1	1	1
Palpitations*	1	2	1, 2
Shortness of breath*	1	2	1
Myalgia	1	3	All 8
Fatigue	2	1, 2	1, 2
Back pain	1	1	1
Rash	1	1	1
Infection	0	—	—

*Infusional events associated with the first dose. Rapid resolution occurred with temporary cessation of the infusion

Therapy Monitoring

1. *Weekly prior to each dose of rituximab:* CBC
2. *One to 3 months after the completion of therapy:* Bone marrow aspirate and biopsy with immunophenotyping
3. *Long-term follow-up:* CBC every 3–6 months for 2 years, and then every 6 months for 3 years

Treatment Modifications

Fever, chills, hypotension, and other toxicities:
Slow or interrupt rituximab administration

Severe hypersensitivity reactions:
1. Interrupt administration
2. **Diphenhydramine** 25–50 mg; administration by intravenous injection is recommended
3. Additional treatment with diphenhydramine, bronchodilators, intravenous hydrocortisone, and/or intravenous hydration may be indicated
4. Resume infusion at a 50% reduction in rate when symptoms have completely resolved
5. Medications for the treatment of hypersensitivity reactions should be available for immediate use in the event of a reaction during administration (eg, intravenous fluids, epinephrine, antihistamines, glucocorticoids, and O_2)
6. In many cases, the infusion can be resumed at a 50% reduction in rate when symptoms have completely resolved

Notes

1. Patients requiring close monitoring during first and all subsequent infusions include those with preexisting cardiac and pulmonary conditions, prior clinically significant cardiopulmonary adverse events, or circulating malignant cells $>25{,}000/mm^3$ with or without evidence of high tumor burden
2. No clear benefit of 12 doses versus 4 doses

212. Chapter Title

Enriqueta Felip, MD, PhD and Rafael Rosell, MD

Epidemiology

Incidence: 224,210 (male: 116,000; female: 108,210. Estimated new cases for 2014 in the United States)
61.4 per 100,000 male and female per year (74.3 per 100,000 men, 51.9 per 100,000 women)
Deaths: Estimated 159,260 in 2014 (male: 86,930; female: 72,330)
Median age: 61.4 years
Male-to-female ratio: ~1:1

Stage at Presentation
Localized (confined to primary site): 15%
Regional (spread to regional lymph nodes): 22%
Distant (cancer has metastasized): 57%

Siegel R et al. CA Cancer J Clin 2014;64:9–29
Surveillance, Epidemiology and End Results (SEER) Program, available from http://seer.cancer.gov (accessed in 2013)
Weir HK et al. J Natl Cancer Inst 2003;95:1276–1299

Pathology

Lung cancer is divided into 2 major classes:

1. Non–small cell lung cancer (NSCLC): 75–85%
   - Squamous cell carcinoma
   - Adenocarcinoma
   - Large-cell carcinoma
2. Small cell lung cancer (SCLC) 15–25%

Brambilla E et al. Eur Respir J 2001;18:1059–1068

Non–Small Cell Lung Cancer (NSCLC)

Work-up

1. History and physical examination including performance status and weight loss
2. Chest x-ray, PA and lateral
3. CT scan of chest and upper abdomen including adrenals
4. CBC, serum electrolytes, BUN, creatinine, calcium, magnesium, and LFTs
5. CT scan and/or MRI of brain if neurologic history or examination is abnormal
6. Bone scan if there is bone pain, elevated calcium level, or elevated alkaline phosphatase level
7. Assessment of perioperative risks for potential candidates for surgery, including pulmonary function tests (PFTs)

Stages I–II	a. Bronchoscopy b. FDG-PET scan
Stages IIIA–IIIB	a. Bronchoscopy b. FDG-PET scan c. MRI of the chest in superior sulcus tumors d. MRI of brain e. Bone scan f. Mediastinal lymph node biopsy if CT scan shows nodes >1 cm *Invasive tests:* Mediastinoscopy, thoracoscopy, transbronchial needle aspiration, and endoscopic ultrasound and needle aspiration
Stage IV	Biopsy for otherwise potentially resectable patient with isolated adrenal mass or liver lesion

Staging

Primary Tumor (T)

TX	Primary tumor cannot be assessed
T0	No evidence of primary tumor
Tis	Tis Carcinoma in situ
T1	Tumor ≤3 cm in greatest dimension, surrounded by lung or visceral pleura, without bronchoscopic evidence of invasion more proximal than the lobar bronchus (ie, not in the main bronchus)*
T1a	Tumor ≤2 cm in greatest dimension
T1b	Tumor >2 cm but ≤3 cm in greatest dimension
T2	Tumor >3 cm but ≤7 cm or tumor with any of the following features (T2 tumors with these features are classified T2a if ≤5 cm) Involves main bronchus, ≥2 cm distal to the carina Invades visceral pleura (PL1 or PL2) Associated with atelectasis or obstructive pneumonitis that extends to the hilar region but does not involve the entire lung
T2a	Tumor >3 cm but ≤5 cm in greatest dimension
T2b	Tumor >5 cm but ≤7 cm in greatest dimension
T3	Tumor >7 cm or one that directly invades any of the following: parietal pleural (PL3) chest wall (including superior sulcus tumors), diaphragm, phrenic nerve, mediastinal pleura, parietal pericardium; or tumor in the main bronchus (<2 cm distal to the carina* but without involvement of the carina; or associated atelectasis or obstructive pneumonitis of the entire lung or separate tumor nodule(s) in the same lobe
T4	Tumor of any size that invades any of the following: mediastinum, heart, great vessels, trachea, recurrent laryngeal nerve, esophagus, vertebral body, carina, separate tumor nodule(s) in a different ipsilateral lobe

*The uncommon superficial spreading tumor of any size with its invasive component limited to the bronchial wall, which may extend proximally to the main bronchus, is also classified as T1a

Distant Metastases (M)

M0	No distant metastasis (no pathologic M0; use clinical M to complete stage group)
M1	Distant metastasis
M1a	Separate tumor nodule(s) in a contralateral lobe; tumor with pleural nodules or malignant pleural (or pericardial) effusion*
M1b	Distant metastasis

*Most pleural (and pericardial) effusions with lung cancer are caused by tumor. In a few patients, however, multiple cytopathologic examinations of pleural (pericardial) fluid are negative for tumor, and the fluid is nonbloody and is not an exudate. Where these elements and clinical judgement dictate that the effusion is not related to the tumor, the effusion should be excluded as a staging element and the patient should be classified as M0

Regional Lymph Nodes (N)

NX	Regional lymph nodes cannot be assessed
N0	No regional lymph node metastasis
N1	Metastasis in ipsilateral peribronchial and/or ipsilateral hilar lymph nodes and intrapulmonary nodes, including involvement by direct extension
N2	Metastasis in ipsilateral mediastinal and/or subcarinal lymph node(s)
N3	Metastasis in contralateral mediastinal, contralateral hilar, ipsilateral or contralateral scalene, or supraclavicular lymph node(s)

Staging Groups

Group	T	N	M
Occult	TX	N0	M0
0	Tis	N0	M0
IA	T1a	N0	M0
	T1b	N0	M0
IB	T1a	N0	M0

	T1b	N3	M0
	T2a	N3	M0
	T2b	N3	M0
	T3	N3	M0
	T4	N2	M0
	T4	N3	M0
IV	Any T	Any N	M1a
	Any T	Any N	M1b

Edge SB, Byrd DR, Compton CC, Fritz AG, Greene FL, Trotti A, editors. AJCC Cancer Staging Manual. 7th ed. New York: Springer; 2010

5-Year Relative Survival Rates

All stages	15%
Stage I	56%
Stage II	32%
Stage III	9%
Stage IV	2%

More information at http://www.seer.cancer.gov

Expert Opinion

1. Surgery is the standard treatment in stages I–II disease. Radiation therapy should be considered in medically inoperable stages I–II disease (inadequate pulmonary function tests or comorbid diseases)
2. Four cycles of adjuvant cisplatin-based chemotherapy (a doublet combination) is recommended in patients with pathologic stages II–III. Cisplatin-based chemotherapy may be considered in selected patients with stage IB disease (tumor size >4 cm)
3. Preoperative chemotherapy is the treatment of choice for resectable stage IIIA disease. Platinum-based chemotherapy and thoracic radiation therapy is the standard treatment for unresectable stage III. Concurrent chemoradiation appears to be better than sequential chemoradiation
4. Platinum-based chemotherapy prolongs survival, improves symptom control, and yields superior quality of life in stage IV disease. First-line chemotherapy should be a 2-drug combination regimen. No specific new agent–platinum combination is clearly superior (cisplatin or carboplatin in combination with any of the following: paclitaxel, docetaxel, gemcitabine, vinorelbine). Non–platinum-containing regimens may be used as alternatives to platinum-based combinations
5. For elderly patients or patients with ECOG PS (performance status) 2, available data support the use of single-agent chemotherapy as first-line treatment
6. Docetaxel, pemetrexed, or erlotinib treatment should be considered in patients with advanced NSCLC who experience disease progression after first-line chemotherapy
7. Gefitinib, erlotinib and afatinib are three options available for patients whose tumors harbor EGFR mutations

Pfister DG et al. J Clin Oncol 2004;22:330–353
Winton TL et al. N Engl J Med 2005;352:2589–2597

REGIMEN

PACLITAXEL + CARBOPLATIN

Kelly K et al. J Clin Oncol 2001;19:3210–3218

Premedication (primary prophylaxis against hypersensitivity reactions from paclitaxel):
Dexamethasone 20 mg/dose for 2 doses; administer orally the evening before and the morning of chemotherapy prior to paclitaxel, *plus*:
Diphenhydramine 50 mg for 1 dose; administer by intravenous injection 30 minutes before paclitaxel, *and*:
Ranitidine 50 mg or **cimetidine** 300 mg for 1 dose; administer intravenously in 25–100 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 5–30 minutes, 30 minutes before paclitaxel
Paclitaxel 225 mg/m^2; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a solution with concentration within the range 0.3–1.2 mg/mL over 3 hours on day 1, every 3 weeks (total dosage/cycle = 225 mg/m^2)
Carboplatin (calculated dose) AUC = 6 mg/mL • min; administer intravenously in 50–150 mL D5W over 15–30 minutes, on day 1, every 3 weeks (total dosage/cycle calculated to produce an AUC = 6 mg/mL • min) (see equation below)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential: ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Continue filgrastim until ANC >10,000/mm^3 on 2 consecutive daily measurements

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Additional Supportive Care
Dexamethasone 8 mg/dose orally every 12 hours for 6 doses after chemotherapy if G ≥2 arthralgias/myalgias occur
Add a **proton pump inhibitor** during dexamethasone use to prevent gastritis and duodenitis

---

Note: Carboplatin dose is based on Calvert's formula to achieve a target area under the plasma concentration versus time curve (AUC) [AUC units = mg/mL • min]

$$\text{Total carboplatin dose (mg)} = (\text{Target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be calculated from the equation of Cockcroft and Gault:

$$\text{For males, Clcr} = \frac{(140 - \text{age [years]}) \times \text{body weight (kg)}}{72 \times (\text{Serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times \text{body weight (kg)}}{72 \times (\text{Serum creatinine [mg/dL]})} \times 0.85$$

Sorensen BT et al. Cancer Chemother Pharmacol 1991;28:397–401

(*continued*)

Treatment Modifications

Adverse Event	Dose Modification
ANC nadir <500/mm^3, platelet nadir <50,000/mm^3, or febrile neutropenia	Reduce carboplatin dosage to AUC = 5 if previous cycle dose was AUC = 6; or to AUC = 4 if previous cycle dose was AUC = 5
ANC nadir <500/mm^3, platelet nadir <50,000/mm^3, or febrile neutropenia after 2 carboplatin dose reductions (AUC in previous cycle = 4)	Reduce paclitaxel dosage to 200 mg/m^2, and decrease carboplatin dosage to AUC = 3
Day 1 ANC <1500/mm^3 or platelets <100,000/mm^3	Delay chemotherapy until ANC >1500/mm^3 and platelets >100,000/mm^3, for maximum delay of 2 weeks
Delay of >2 weeks in reaching ANC >1500/mm^3 and platelet nadir >100,000/mm^3	Discontinue therapy
G2 neurotoxicity	Reduce paclitaxel dosage to 200 mg/m^2
G3 neurotoxicity	Reduce paclitaxel dosage to 175 mg/m^2
G2 arthralgia/myalgia despite dexamethasone prophylaxis	Reduce paclitaxel dosage to 200 mg/m^2
G3 arthralgia/myalgia despite dexamethasone prophylaxis	Reduce paclitaxel dosage to 175 mg/m^2
G ≥2 AST or G ≥3 total bilirubin	Hold paclitaxel
Moderate hypersensitivity	Patient may be retreated
Severe hypersensitivity	Discontinue therapy
Chest pain or arrhythmia during chemotherapy	Immediately stop chemotherapy and evaluate the patient
Symptomatic arrhythmias, or ≥2-degree AV block, or an ischemic event	Discontinue therapy

(*continued*)

Note: A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula could exceed an expected exposure (AUC) and result in increased drug-related toxicity. The FDA recommends capping an estimated GFR at 125 mL/min for any targeted AUC value. No greater estimated GFR values should be used [online] May 23, 2013. Available from: http://www.fda.gov/AboutFDA/CentersOffices/OfficeofMedicalProductsandTobacco/CDER/ucm228974.htm [accessed February 26, 2014]

Patient Population Studied

A randomized comparison with vinorelbine + cisplatin in 206 patients with advanced, previously untreated NSCLC

Efficacy (N = 203)*

Response rate (CR + PR)	25%
Median progression-free survival	4 months
Median survival	8.6 months
1-year survival	38%
2-year survival	15%

Therapy Monitoring

1. *Before each cycle:* H&P, PS evaluation, CBC with differential, LFTs, BUN, and creatinine
2. *Every week:* CBC with differential and platelet count
3. *Response evaluation:* Every 2–3 cycles

REGIMEN

PACLITAXEL + CISPLATIN

Rosell R et al. Ann Oncol 2002;13:1539–1549

Premedication (primary prophylaxis against hypersensitivity reactions from paclitaxel):
Dexamethasone 20 mg/dose for 2 doses; administer orally the evening before and the morning of chemotherapy before paclitaxel, *plus:*
Diphenhydramine 50 mg; administer by intravenous injection, 30 minutes before paclitaxel, *and:*
Ranitidine 50 mg or **cimetidine** 300 mg; administer intravenously in 25–100 mL 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) over 5–30 minutes, 30 minutes before paclitaxel
Paclitaxel 200 mg/m²; administer intravenously in a volume of 0.9% NS or D5W sufficient to produce a solution with concentration within the range 0.3–1.2 mg/mL over 3 hours on day 1, every 21 days (total dosage/cycle = 200 mg/m²)

Hydration before cisplatin: Administer by intravenous infusion ≥1000 mL 0.9% NS over a minimum of 2–4 hours
Cisplatin 80 mg/m²; administer intravenously in 100–250 mL 0.9% NS over 30 minutes, on day 1, every 21 days (total dosage/cycle = 80 mg/m²)
Hydration after cisplatin: Administer by intravenous infusion ≥1000 mL 0.9% NS over a minimum of 2–4 hours. Encourage patients to increase oral intake of non-alcoholic fluids. Monitor serum electrolytes and replace as needed (potassium, magnesium, sodium)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential: ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Continue filgrastim until ANC >10,000/mm³ on 2 consecutive daily measurements

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Additional Supportive Care
Dexamethasone 8 mg/dose orally every 12 hours for 6 doses after chemotherapy if G ≥2 arthralgias/myalgias occur
Add a **proton pump inhibitor** during dexamethasone use to prevent gastritis and duodenitis

Patient Population Studied

A randomized comparison with paclitaxel + carboplatin in 309 patients with advanced (Stages III/IV) NSCLC not previously treated

Efficacy (N = 284)*

Complete Response	1%
Partial Response	27%
Median progression-free survival†	4.2 months
Median survival†	9.8 months
Estimated 1-year survival	38%
2-Year survival	15%

*WHO criteria
†Intention-to-treat analysis

Toxicity (N = 302)

Hematologic

	% G3/4
Neutropenia	51
Leukopenia	16
Anemia	9
Infections	5
Febrile neutropenia	4
Thrombocytopenia	2

Nonhematologic

	% Severe
Nausea/vomiting	14
Asthenia	10
Arthralgia/myalgia	9
Peripheral neuropathy*	7
Diarrhea	2
Hypersensitivity	1
Renal*	1

*Grade 3

Treatment Modifications

Dose escalations are not permitted. Dosage reductions are based on toxicity encountered during a previous cycle

Adverse Event	Dose Modification
G ≥2 arthralgias/myalgias	Add dexamethasone as secondary prophylaxis
Day 1 ANC <1500/mm^3 or platelet count <100,000/mm^3	Delay therapy until ANC >1500/mm^3 and platelet count >100,000/mm^3. If >2-week delay, the decision to retreat is based on caregiver's discretion
Febrile neutropenia	Reduce cisplatin and paclitaxel dosages by 25%
Bleeding associated with thrombocytopenia	
Serum creatinine 1.6–2.0 mg/dL (141–177 μmol/L)	Reduce cisplatin dosage by 25%
Serum creatinine >2.0 mg/dL (>177 μmol/L)	Hold cisplatin until serum creatinine ≤2.0 mg/dL (≤177 μmol/L)
G3/4 neurotoxicity	Delay therapy until G ≤2
Moderate hypersensitivity reactions	Decision to retreat based on severity and caregiver's discretion
Severe hypersensitivity reactions	Stop treatment
Symptomatic arrhythmias or AV block ≥ second-degree, or documented ischemic event	
G ≥2 AST (SGOT) or G ≥3 total bilirubin	Stop paclitaxel

Therapy Monitoring

1. *Before each cycle:* H&P, PS evaluation, CBC with differential, serum electrolytes, magnesium, LFTs, BUN, and creatinine
2. *Every week:* CBC with differential and platelet count
3. *Response evaluation:* Every 2–3 cycles

REGIMEN

GEMCITABINE + CISPLATIN

Sandler AB et al. J Clin Oncol 2000;18:122–130

Gemcitabine 1000 mg/m²; administer intravenously in 50–250 mL 0.9% sodium chloride injection (0.9% NS) over 30–60 minutes, on days 1, 8, and 15, every 28 days (total dosage/cycle = 3000 mg/m²). On day 1, administer after or during hydration for cisplatin and follow with cisplatin

Hydration before cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 2–4 hours

Cisplatin 100 mg/m²; administer intravenously in 100–250 mL 0.9% NS over 30–120 minutes, on day 1 every 28 days (total dosage/cycle = 100 mg/m²)

Hydration after cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 2–4 hours. Also encourage patients to increase oral intake of non-alcoholic fluids. Monitor serum electrolytes and replace as needed (potassium, magnesium, sodium)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential on day 1 is HIGH. Potential for delayed symptoms

Emetogenic potential on days 8 and 15 is LOW

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A randomized comparison with single-agent cisplatin in 260 patients with advanced (Stages III/IV) previously untreated NSCLC

Efficacy (N = 260)

Complete response	1.2%
Partial response	29.2%
Estimated median progression-free survival	5.6 months
Estimated median survival	9.1 months
Estimated 1-year survival	39%

Toxicity (N = 260)*

	% G3	% G4
Hematologic		
Granulocytopenia	21.5	35.3
Thrombocytopenia	25	25.4
Anemia	21.9	3.1

Neurologic (motor)	11.5	0
Dyspnea	4	3
Increased transaminases	2	1
Increased bilirubin	0.8	0.8

*WHO criteria

Treatment Modifications

Adverse Event	Dose Modification
ANC <1500/mm³, or platelets <100,000/mm³	Hold chemotherapy until ANC >1500/mm³ and platelets >100,000/mm³
Febrile granulocytopenia that requires antibiotics	Reduce cisplatin and gemcitabine dosages by 25% in subsequent cycles
Bleeding associated with thrombocytopenia	
Intracycle: G1/2 nonhematologic toxicity or G1–3 nausea or vomiting	100% gemcitabine dosage on days 8 and 15
Intracycle: G3 nonhematologic toxicity, except nausea, vomiting, and alopecia	Reduce gemcitabine dosage by 25% on days 8 and 15, or hold treatment at clinician's discretion
Intracycle: G4 nonhematologic toxicity	Hold gemcitabine
Day 1 serum creatinine 1.6–2.0 mg/dL (141–177 µmol/L)	Reduce cisplatin dosage by 25%
Day 1 serum creatinine >2.0 mg/dL (>177 µmol/L)	Hold cisplatin until serum creatinine ≤2.0 mg/dL (≤177 µmol/L)
G3/4 neurotoxicity	Delay treatment until toxicity resolves to G1
Treatment delay >2 weeks	Discontinue therapy according to clinician's discretion

Therapy Monitoring

1. *Each cycle on day 1:* H&P, performance status reevaluation, CBC with differential and platelet count, serum electrolytes, magnesium, serum creatinine, hepatic transaminases, and bilirubin
2. *Cycle days 8 and 15*: CBC with differential and platelet count
3. *Response evaluation:* Every 2–3 cycles

REGIMEN

DOCETAXEL + CISPLATIN

Fossella F et al. J Clin Oncol 2003;21:3016–3024

Prophylaxis for fluid retention and hypersensitivity reactions from docetaxel:
Dexamethasone 8 mg/dose; administer orally twice daily for 3 days, starting the day before docetaxel is administered (total dose/cycle = 48 mg)

Hydration before cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously over a minimum of 2–4 hours
Docetaxel 75 mg/m²; administer intravenously in a volume of 0.9% NS or 5% dextrose injection (D5W) sufficient to produce a solution with concentration within the range 0.3–0.74 mg/mL over 1 hour on day 1, every 3 weeks (total dosage/cycle = 75 mg/m²), *followed immediately by:*
Cisplatin 75 mg/m²; administer intravenously in 100–250 mL 0.9% NS over 1 hour on day 1, every 3 weeks (total dosage/cycle = 75 mg/m²)

Hydration after cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 2–4 hours. Encourage patients to increase oral intake of non-alcoholic fluids. Monitor serum electrolytes and replace as needed (potassium, magnesium, sodium)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential: ***HIGH****. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is indicated with one of the following:
Filgrastim (G-CSF) 5 mcg/kg per day by subcutaneous injection, *or*
Pegfilgrastim (pegylated filgrastim) 6 mg/0.6 mL by subcutaneous injection for 1 dose
- Begin use from 24–72 hours after myelosuppressive chemotherapy is completed
- Continue filgrastim until ANC >10,000/mm³ on 2 consecutive daily measurements

See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A multicenter, international, prospective, open-label, randomized phase III comparison with vinorelbine + cisplatin in 408 patients with locally advanced or recurrent (Stage IIIB) or metastatic (Stage IV) NSCLC

Efficacy (N = 408)

Complete response	2.0%
Partial response	29.7%
Overall median survival	11.3 months
1-year survival	46%
2-year survival	21%

Therapy Monitoring

1. *Each cycle on day 1:* H&P, PS evaluation, CBC with differential, serum electrolytes, magnesium, BUN, creatinine, and LFTs
2. *Every week:* CBC with differential and platelet count
3. *Response evaluation:* Every 2–3 cycles

Toxicity (N = 406)*

†G3/4 adverse event in >5% of patients

Treatment Modifications

Adverse Event	Dose Modification
ANC <1500/mm³ or platelet count <100,000/mm³	Hold chemotherapy until ANC >1500/mm³ and platelets >100,000/mm³
Febrile granulocytopenia that requires antibiotics	Reduce cisplatin and docetaxel dosages by 25% during subsequent cycles*
Bleeding associated with thrombocytopenia	
Day 1 serum creatinine 1.6–2.0 mg/dL (141–177 µmol/L)	Reduce cisplatin dosage* by 25%
Day 1 serum creatinine >2.0 mg/dL (>177 µmol/L)	Hold cisplatin until serum creatinine ≤2.0 mg/dL (≤177 µmol/L)
G3/4 neurotoxicity	Delay treatment
Treatment delay ≥2 weeks	Discontinue therapy or according to clinician's criteria

*A maximum of 2 docetaxel or cisplatin dosage reductions are permitted

REGIMEN

VINORELBINE + CISPLATIN

Wozniak AJ et al. J Clin Oncol 1998;16:2459–2465

Vinorelbine 25 mg/m²; administer intravenously in a volume of 0.9% sodium chloride injection (0.9% NS) or 5% dextrose injection (D5W) sufficient to produce a solution with concentration within the range 0.5–3 mg/mL over 6–10 minutes, once weekly for 4 weeks (total dosage/cycle = 100 mg/m²)

Hydration before cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 2–4 hours

Cisplatin 100 mg/m²; administer intravenously in 100–250 mL 0.9% NS over 1 hour on day 1, every 4 weeks (total dosage/cycle = 100 mg/m²)

Hydration after cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 2–4 hours. Encourage patients to increase oral intake of non-alcoholic fluids. Monitor serum electrolytes and replace as needed (potassium, magnesium, sodium)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential: **HIGH**. Potential for delayed symptoms*

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis may be indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A randomized comparison with cisplatin of 206 patients with advanced previously untreated NSCLC

Efficacy

Complete response	2%
Partial response	24%
Median progression-free survival	4 months
Median survival	8 months
1-Year survival	36%
2-Year survival	12%

Toxicity (N = 204)*

Hematologic	% G3	% G4

Hearing	4
Vision	1
Neurologic (peripheral)	2
Neurologic (central)	2
Renal	5
Phlebitis/thrombosis	3

*SWOG criteria

Treatment Modifications

Treatment day ANC must be ≥1500/mm³ and platelets ≥100,000/mm³ to treat on schedule at 100% dosages

Adverse Event	Dose Modification
Treatment day ANC 1000–1499/mm³ or platelets 75,000–99,999/mm³	Reduce cisplatin and vinorelbine dosages by 50%
Treatment day ANC <1000 or platelets <75,000/mm³	Hold cisplatin* and vinorelbine
Treatment delay >2 weeks but <3 weeks	Reduce subsequent cisplatin and vinorelbine dosages by 50%
Fever or sepsis with neutropenia in any cycle	
ANC nadir <500/mm³ or platelet nadir <50,000/mm³	Reduce cisplatin dosage by 50% in subsequent cycles
Serum creatinine ≥1.6 mg/dL (≥141 µmol/L), but creatinine clearance ≥50 mL/min (≥0.83 mL/s)	Reduce cisplatin dosage by 50%
Creatinine clearance <50 mL/min (<0.83 mL/s)	Hold cisplatin*
Serum total bilirubin 2.1–3.0 mg/dL (35.9–51.3 µmol/L)	Reduce vinorelbine dosage by 50%
Serum total bilirubin >3.0 mg/dL (>51.3 µmol/L)	Reduce vinorelbine dosage by 75%
Treatment delay >4 weeks	Discontinue therapy

*If cisplatin treatment is held for any period of time, reduce cisplatin dosage 50% when treatment resumes

Therapy Monitoring

1. *Before repeated cycles:* H&P, PS evaluation, Serum creatinine and calculated creatinine clearance; serum electrolytes, magnesium, hepatic transaminases, and bilirubin
2. *Weekly:* CBC with differential and platelet count
3. *Response evaluation:* Every 2–3 cycles

REGIMEN

CISPLATIN + PEMETREXED

Scagliotti GV et al. J Clin Oncol 2008; 26:3543–3551

Ancillary medications:
Folic acid 350–1000 mcg/day; administer orally beginning 1–2 weeks before the first dose of pemetrexed and continuing until 3 weeks after the last dose of pemetrexed
Cyanocobalamin (vitamin B_{12}) 1000 mcg; administer intramuscularly every 9 weeks, beginning 1–2 weeks before the first dose of pemetrexed
Dexamethasone 4 mg; administer orally twice daily for 3 consecutive days, starting the day before pemetrexed administration to decrease the risk and severity of severe skin rash associated with pemetrexed

Hydration before cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS); administer intravenously over a minimum of 2–4 hours
Pemetrexed 500 mg/m²; administer intravenously in 100 mL 0.9% NS over 10 minutes on day 1 every 21 days for a maximum of 6 cycles (unless there was earlier evidence of disease progression or intolerance of the study treatment) (total dosage/cycle = 500 mg/m²)
Cisplatin 75 mg/m²; administer intravenously in 100–250 mL 0.9% NS over 1 hour on day 1, every 21 days for a maximum of 6 cycles (unless there was earlier evidence of disease progression or intolerance of the study treatment) (total dosage/cycle = 75 mg/m²)

Hydration after cisplatin: ≥1000 mL 0.9% NS; administer intravenously over a minimum of 2–4 hours

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential: **HIGH**. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Treatment Modifications

Adverse Event	Dose Modification
Day 1 dose reduction of pemetrexed, or cisplatin required	Reduced dose is administered during subsequent treatment cycles
Patients with 2 dose reductions on day 1 who experience toxicity requiring a third dose reduction	Discontinue therapy
Toxicity G ≥2	Delay start of next cycle up to 42 days

Toxicity* (N = 839)

Toxicity	% G3/4
Neutropenia	15.1%
Anemia	5.6%
Thrombocytopenia	4.1%
Febrile neutropenia	1.3%
Nausea	7.2%
Vomiting	6.1%
Fatigue	6.7%
Alopecia, any grade	11.9%
Dehydration, any grade	3.6%

*NCI CTC, National Cancer Institute (USA) Common Toxicity Criteria, version 2.0. Available at: http://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm [accessed December 7, 2013]

Patient Population Studied

Noninferiority, phase III, randomized study comparing the overall survival between treatment arms in 1725 chemotherapy-naïve patients with histologically or cytologically confirmed NSCLC, classified as stage IIIB not amenable to curative treatment or stage IV and an Eastern Cooperative Oncology Group (ECOG) performance status of 0–1. A total of 862 patients were treated with cisplatin + pemetrexed

Efficacy (N = 862)

Objective response rate*	30.6%
Duration of response	4.5 months
Median overall survival	10.3 months
Median progression-free survival	4.8 months
1-year survival	43.5%
2-year survival	18.9%

*RECIST

Therapy Monitoring

Baseline, every other cycle, and then every 6 weeks:
History and physical examination; assessment by imaging techniques

NSCLC WITH ALK GENE REARRANGEMENT REGIMEN

CRIZOTINIB

Kwak EL et al. N Engl J Med 2010;363:1693–1703
Shaw AT et al. Lancet Oncol 2011;12:1004–1012

Crizotinib 250 mg/dose; administer orally twice daily, continually, with or without food (total dose/week = 3500 mg; total dose/28-day cycle = 14,000 mg)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is at least ***MODERATE***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

*Abigerges D et al. J Natl Cancer Inst 1994;86:446–449
Rothenberg ML et al. J Clin Oncol 2001;19:3801–3807
Wadler S et al. J Clin Oncol 1998;16:3169–3178

(*continued*)

Dose Adjustments

Adverse Event	Dose Modification
Hematologic Toxicity*	
G3 hematologic toxicity	Withhold until recovery to G ≤2, then resume at the same dose schedule
G4 hematologic toxicity	Withhold until recovery to G ≤2, then resume at 200 mg twice daily
G4 hematologic toxicity at a dose of 200 mg twice daily	Withhold until recovery to G ≤2, then resume at 250 mg once daily
G4 hematologic toxicity at a dose of 250 mg once daily	Permanently discontinue crizotinib
Non-hematologic Toxicity	
G3/4 alanine aminotransferase (ALT) or aspartate aminotransferase (AST) elevation with G ≤1 total bilirubin	Withhold until recovery to G ≤1 or baseline, then resume at 200 mg twice daily
G3/4 ALT or AST elevation with G ≤1 total bilirubin on a dose of 200 mg twice daily	Withhold until recovery to G ≤1 or baseline, then resume 250 mg once daily
G3/4 ALT or AST elevation with G ≤1 total bilirubin on a dose of 250 mg once daily	Permanently discontinue crizotinib
G2/3/4 ALT or AST elevation with concurrent G2/3/4 total bilirubin elevation (in the absence of cholestasis or hemolysis)	Permanently discontinue crizotinib
Any Grade pneumonitis†	Permanently discontinue crizotinib
G3 QTc prolongation	Withhold until recovery to G ≤1, then resume at 200 mg twice daily
G3 QTc prolongation on a dose of 200 mg twice daily	Withhold until recovery to G ≤1 or baseline, then resume 250 mg once daily
G3 QTc prolongation on a dose of 250 mg once daily	Permanently discontinue crizotinib
Grade 4 QTc prolongation	Permanently discontinue crizotinib

*Except lymphopenia (unless associated with clinical events, eg, opportunistic infections)
†Not attributable to NSCLC progression, other pulmonary disease, infection, or radiation effect

(*continued*)

Notes:

1. Detection of ALK-positive NSCLC using an FDA-approved test indicated for this use is necessary for selection of patients for treatment with crizotinib
2. Assessment for ALK-positive NSCLC should be performed by laboratories with demonstrated proficiency in the specific technology being utilized. Improper assay performance can lead to unreliable test results

Drugs That May Increase Crizotinib Plasma Concentrations

Coadministration of crizotinib with strong CYP3A inhibitors increases crizotinib plasma concentrations

- Avoid concomitant use of strong CYP3A inhibitors, including but not limited to atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, troleandomycin, and voriconazole
- Avoid grapefruit or grapefruit juice which may increase plasma concentrations of crizotinib
- Exercise caution with concomitant use of moderate CYP3A inhibitors

Drugs That May Decrease Crizotinib Plasma Concentrations

Coadministration of crizotinib with strong CYP3A inducers decreases crizotinib plasma concentrations

- Avoid concurrent use of strong CYP3A inducers, including but not limited to carbamazepine, phenobarbital, phenytoin, rifabutin, rifampin, and St. John's Wort

Patient Population Studied

Eighty-two patients with advanced ALK-positive NSCLC who had received crizotinib in the phase 1 clinical trial. For all patients, ALK positivity was confirmed by fluorescence in situ hybridization (FISH). ALK FISH was done before trial enrolment, using the initial diagnostic or surgical specimen, or a repeat biopsy specimen obtained for the purposes of genetic testing. These patients were mainly young (median age: 51 years [range: 25–78 years]), never smokers with adenocarcinoma histology. Among the 82 patients, 50 (61%) were enrolled at U.S. study sites, 26 (32%) at the Korean site, and the remaining 6 (7%) in Australia. Because the protocol placed no restriction on the number of previous therapies, the number varied widely among patients, ranging from 0 to 7 previous lines (median: 2) of therapy for metastatic disease. Seventy-three (89%) of 82 patients had received at least 1 previous therapy for metastatic disease. An additional 36 patients with advanced, ALK-positive NSCLC who had not received crizotinib were identified through retrospective and prospective screening efforts

Treatment Monitoring

1. *Monthly and as clinically indicated:* Complete blood counts (CBC) including differential white blood cell counts and liver function tests
2. *If G3/4 clinical or laboratory abnormalities are observed or if fever or infection occurs:* Frequent monitoring of complete blood counts (CBC) including differential white blood cell counts and liver function tests
3. Consider periodic monitoring with electrocardiograms (ECGs) and electrolytes in patients with congestive heart failure, bradyarrhythmias, electrolyte abnormalities, or who are taking medications that are known to prolong the QT interval

**Includes edema, edema localized, and peripheral edema

††Includes chest pain, chest discomfort, and musculoskeletal chest pain

‡‡Includes nasopharyngitis, rhinitis, pharyngitis, and upper respiratory tract infection

§§Includes balance disorder, dizziness, and presyncope

‖‖Includes burning sensation, dysesthesia, hyperesthesia, hypoesthesia, neuralgia, paresthesia, peripheral neuropathy, peripheral motor neuropathy, and peripheral sensory neuropathy

***Although most events were G1, G2 motor neuropathy and G3 peripheral neuropathy were reported in 1 patient each

ADVANCED NSCLC REGIMEN

WEEKLY *nab*-PACLITAXEL + CARBOPLATIN

Socinski MA et al. J Clin Oncol 2012;30:2055–2062

Paclitaxel protein-bound particles for injectable suspension (*nab*-paclitaxel) 100 mg/m² per dose; administer intravenously over 30 minutes, once weekly for 3 doses, on days 1, 8, and 15 every 3 weeks (total dosage/cycle = 300 mg/m²)

Carboplatin [calculated dose] AUC = 6 mg/mL · min*; administer intravenously diluted to concentrations as low as 0.5 mg/mL with either 5% dextrose injection or 0.9% sodium chloride injection over 15–30 minutes on day 1, every 3 weeks (total dosage/cycle calculated to produce an AUC = 6 mg/mL · min)

*Carboplatin dose is based on a formula described by Calvert et al. to achieve a target area under the plasma concentration versus time curve (AUC)

Recommendations for Initial *nab*-paclitaxel Dosage in Hepatically Impaired Patients

	SGOT (AST) Levels		Total Bilirubin Levels	*nab*-Paclitaxel Dosage*
Mild	<10 × ULN	*and*	> ULN to ≤1.25 × ULN	100 mg/m²
Moderate	<10 × ULN	*and*	1.26–2 × ULN	75 mg/m²
Severe	<10 × ULN	*and*	2.01–5 × ULN	50 mg/m²†
	>10 × ULN	*or*	>5 × ULN	Do not administer

*A need for dosage adjustments during repeated treatment cycles should be based on individual tolerance for previous treatment
†Increase dose to 75 mg/m² during subsequent courses, as tolerated

$$\text{Total carboplatin dose (mg)} = (\text{Target AUC}) \times (\text{GFR} + 25)$$

In practice, creatinine clearance (Clcr) is used in place of glomerular filtration rate (GFR). Clcr can be estimated from the equation of Cockcroft and Gault, thus:

$$\text{For males, Clcr} = \frac{(140 - \text{age [years]}) \times \text{body weight (kg)}}{72 \times (\text{Serum creatinine [mg/dL]})}$$

$$\text{For females, Clcr} = \frac{(140 - \text{age [years]}) \times \text{body weight (kg)}}{72 \times (\text{Serum creatinine [mg/dL]})} \times 0.85$$

Calvert AH et al. J Clin Oncol 1989;7:1748–1756
Cockcroft DW, Gault MH. Nephron 1976;16:31–41
Jodrell DI et al. J Clin Oncol 1992;10:520–528
Sorensen BT et al. Cancer Chemother Pharmacol 1991;28:397–401

Note: On October 8, 2010, the U.S. Food and Drug Administration (FDA) identified a potential safety issue with carboplatin dosing based on recent changes in the measurement of serum creatinine. By the end of 2010, all clinical laboratories in the United States began using the standardized isotope dilution mass spectrometry (IDMS) method to measure serum creatinine, which could result in an overestimation of the GFR in some patients with normal renal function. A carboplatin dose calculated with an IDMS-measured serum creatinine result using the Calvert formula could exceed an expected exposure (AUC) and result in increased drug-related toxicity

Provided actual GFR measurements are made to assess renal function, carboplatin can be safely dosed according to the Calvert formula described in product labeling

If GFR (or creatinine clearance) is estimated based on serum creatinine measurements by the IDMS method, the FDA recommends for patients with normal renal function capping an estimated GFR at 125 mL/min for any targeted AUC value. No greater estimated GFR values should be used

U.S. FDA. Carboplatin dosing. [online] October 8, 2010. Available from: http://www.fda.gov/AboutFDA/CentersOffices/OfficeofMedicalProductsandTobacco/CDER/ucm228974.htm [accessed February 26, 2014]

ADVANCED-STAGE NON–SMALL CELL LUNG CANCER (CHEMOTHERAPY-NAÏVE) REGIMEN

CISPLATIN + PEMETREXED

Scagliotti VG et al. J Clin Oncol 2008;26:3543–3551

Ancillary medications:
Folic acid 350–1000 mcg per day orally beginning 1–2 weeks before the first dose of pemetrexed and continuing until 3 weeks after the last dose of pemetrexed
Cyanocobalamin (vitamin B_{12}) 1000 mcg intramuscularly every 9 weeks, beginning 1–2 weeks before the first dose of pemetrexed
Dexamethasone 4 mg orally twice daily for 3 consecutive days, starting the day before pemetrexed administration to decrease the risk and severity of severe skin rash associated with pemetrexed

Hydration before cisplatin: ≥1000 mL 0.9% sodium chloride injection (0.9% NS) by intravenous infusion over a minimum of 2–4 hours

Pemetrexed disodium 500 mg/m² intravenously in 100 mL 0.9% NS over 10 minutes on day 1 every 3 weeks for a maximum of 6 cycles (unless there was earlier evidence of disease progression or intolerance of the study treatment) (total dosage/cycle: = 500 mg/m²)
Cisplatin 75 mg/m² intravenously in 100–250 mL 0.9% NS over 1 hour on day 1 every 3 weeks for a maximum of 6 cycles (unless there was earlier evidence of disease progression or intolerance of the study treatment) (total dosage/cycle = 75 mg/m²)
Hydration after cisplatin: ≥1000 mL 0.9% NS by intravenous infusion over a minimum of 2–4 hours

Supportive Care
Antiemetic prophylaxis
*Emetogenic potential is **HIGH**. Potential for delayed symptoms*
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

Chemotherapy-naïve patients with histologically or cytologically confirmed NSCLC who were classified as stage IIIB not amenable to curative treatment or stage IV, and an Eastern Cooperative Oncology Group performance status of 0 or 1. Prior radiation therapy was permitted if it was completed at least 4 weeks before study treatment and patients had fully recovered from its acute effects. Exclusion criteria included peripheral neuropathy NCI CTC G ≥1

Treatment Modifications

Adapted in part from Alimta (pemetrexed for injection) Lyophilized Powder, for Solution for Intravenous Use; 05/2013 product label. Lilly USA, LLC, Indianapolis, IN

Nadir ANC <500/mm³ and nadir platelets ≥50,000/mm³	75% of previous pemetrexed dose and 75% of previous cisplatin dose
Nadir platelets <50,000/mm³ without bleeding regardless of nadir ANC	75% of previous pemetrexed dose and 75% of previous cisplatin dose
Nadir platelets <50,000/mm³ with bleeding*, regardless of nadir ANC	50% of previous pemetrexed dose and 50% of previous cisplatin dose
Any G3/4 toxicities except mucositis	Withhold treatment until toxicity resolves to the same or less than pretreatment status. Resume treatment with 75% of the previously administered pemetrexed and cisplatin dosages
Any G3/4 toxicities except mucositis after two dose reductions	Discontinue therapy
Any diarrhea requiring hospitalization (irrespective of grade) or G3/4 diarrhea	Withhold treatment until toxicity resolves to the same or less than pretreatment status. Then, resume treatment with 75% of the previously administered pemetrexed and cisplatin dosages
Any diarrhea requiring hospitalization (irrespective of grade) or G3/4 diarrhea after 2 dose reductions	Discontinue therapy
G3/4 mucositis	Withhold treatment until toxicity resolves to the same or less than pretreatment status. Then, resume treatment with pemetrexed dosage decreased by 50% and the same cisplatin dosage (100%) previously given

(*continued*)

Treatment Modifications (*continued*)

G3/4 mucositis after 2 dose reductions	Discontinue therapy
G1 neurotoxicity	Continue pemetrexed and cisplatin treatment at 100% of the previously administered dosages
G2 neurotoxicity	Withhold treatment until toxicity resolves to the same or less than pretreatment status. Then, resume treatment with the same pemetrexed dosage (100%) previously given and cisplatin dosage decreased by 50%
G3/4 neurotoxicity	Discontinue therapy

*These criteria meet the NCI Common Toxicity Criteria (CTC, 1998) version 2.0 definition of G ≥2 bleeding

Toxicity

	Cisplatin + Pemetrexed	Cisplatin + Gemcitabine	P
G3/4 neutropenia,	15%	27%	≤0.001
G3/4 anemia	6%	10%	≤0.001
G3/4 thrombocytopenia	4%	13%	≤0.001
Febrile neutropenia	1%	4%	0.002
Alopecia (all grades)	12%	21%	<0.001
G3/4 nausea	7%	4%	0.004
Transfusions	16.4%	28.9%	<0.001
RBC transfusions	16.1%	27.3%	<0.001
Platelet transfusions	1.8%	4.5%	0.002
Erythropoietin administration	10.4%	18.1%	<0.001
Granulocyte-colony stimulating factor administration	3.1%	6.1%	0.004
Deaths attributed to drug toxicity	1.0%	0.7%	

Treatment Monitoring

1. *Monthly and as clinically indicated:* Complete blood counts (CBC) including differential white blood cell counts and liver function tests
2. *If G3/4 clinical or laboratory abnormalities are observed or if fever or infection occurs:* Frequent monitoring of complete blood counts (CBC) including differential white blood cell counts and liver function tests

REGIMEN

DOCETAXEL

Shepherd FA et al. J Clin Oncol 2000;18:2095–2103

Prophylaxis for fluid retention and hypersensitivity reactions from docetaxel:
Dexamethasone 8 mg/dose; administer orally twice daily for 3 days, starting the day before docetaxel is administered (total dose/cycle = 48 mg)
Docetaxel 75 mg/m²; administer intravenously in a volume of 0.9% sodium chloride injection or 5% dextrose injection sufficient to produce a solution with concentration within the range 0.3–0.74 mg/mL over 1 hour on day 1, every 3 weeks (total dosage/cycle = 75 mg/m²)

Supportive Care
Antiemetic prophylaxis
Emetogenic potential: ***LOW***
See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis
Primary prophylaxis is NOT indicated
See Chapter 43 for more information

Antimicrobial prophylaxis
Risk of fever and neutropenia is LOW
Antimicrobial primary prophylaxis to be considered:
- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A randomized comparison with best supportive care of 55 patients with advanced (Stages III/IV) NSCLC previously treated with platinum-containing chemotherapy

Efficacy (N = 55)

Complete response	—
Partial response	7.1%
Median survival	7.5 months
1-Year survival	37%

Toxicity (N = 55)

	% G3/4
Neutropenia	67.3
Anemia	5.5
Febrile neutropenia	1.8
Thrombocytopenia	0
Pulmonary	20
Asthenia	18.2
Infection	5.5
Nausea	3.6
Vomiting	3.6
Diarrhea	1.8
Neuromotor	1.8
Neurosensory	1.8

Treatment Modifications

Adverse Event	Dose Modification
G4 neutropenia for >7 days, alone, or accompanied by fever >38°C (>100.4°F)	Reduce docetaxel dosage by 25% in all subsequent treatments
G4 thrombocytopenia	Resume docetaxel after platelet count recovers with docetaxel dosage decreased by 25%
G4 vomiting not controlled by antiemetics	Reduce docetaxel dosage by 25%
G ≥3 diarrhea	
G ≥3 neuropathy	Discontinue therapy

Therapy Monitoring

1. *Before treatment:* H&P, PS evaluation, CBC with differential, and LFTs
2. *Weekly:* CBC with differential and platelet count
3. *Response evaluation:* Every 2–3 cycles

REGIMEN

VINORELBINE (ELDERLY PATIENTS)

Gridelli C et al. J Natl Cancer Inst 2003;95:362–372

Vinorelbine 30 mg/m² per dose; administer intravenously in a volume of 0.9% sodium chloride injection or 5% dextrose injection sufficient to produce a solution with concentration within the range 0.5–3 mg/mL over 6–10 minutes for 2 doses, on days 1 and 8 every 3 weeks for a maximum of 6 cycles (total dosage/cycle = 60 mg/m²)

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***MINIMAL***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Patient Population Studied

A randomized comparison of gemcitabine + vinorelbine in 233 patients ages 70 years and older with advanced (Stages IIIB/IV) untreated NSCLC

Efficacy (Intent-to-Treat, N = 233)

Response rate	18%
Median survival	36 weeks
6-month survival	60%
Estimated 1-year survival	38%

*WHO criteria

Treatment Modifications

Adverse Event	Dose Modification
Days 1 and 8 ANC ≥1500/mm³, platelet count ≥100,000/mm³, and no organ toxicity (other than alopecia)	Vinorelbine given at 100% dosage
Days 1 and 8 ANC <1500/mm³, platelet count <100,000/mm³, or organ toxicity (other than alopecia)	Delay treatment for up to 2 weeks
Serum total bilirubin 2.1–3.0 mg/dL (35.9–51.3 µmol/L)	Reduce vinorelbine dosage by 50%
Serum total bilirubin >3.0 mg/dL (51.3 µmol/L)	Reduce vinorelbine dosage by 75%

Therapy Monitoring

1. *Days 1* and *8:* CBC with differential and platelet count. Serum electrolytes, BUN, creatinine, and LFTs
2. *Weekly:* CBC with differential and platelet count
3. *Response evaluation:* Every 2–3 cycles

MAINTENANCE THERAPY—ADVANCED NSCLC REGIMEN

MAINTENANCE PEMETREXED

Ciuleanu T et al. Lancet 2009;374:1432-1440

Ancillary medications:

Folic acid 350–1000 mcg per day; administer orally beginning 1–2 weeks before the first dose of pemetrexed and continuing until 3 weeks after the last dose of pemetrexed

Cyanocobalamin (vitamin B_{12}) 1000 mcg; administer intramuscularly every 9 weeks, beginning 1 to 2 weeks before the first dose of pemetrexed

Dexamethasone 4 mg; administer orally twice daily for 3 consecutive days (6 doses), starting the day before pemetrexed administration to decrease the risk and severity of severe skin rash associated with pemetrexed (total dose/cycle = 24 mg)

Pemetrexed disodium 500 mg/m²; administer intravenously in 100 mL 0.9% sodium chloride injection over 10 minutes on day 1, every 21 days until disease progression (total dosage/cycle = 500 mg/m²), *plus*

Best Supportive Care

Supportive Care

Antiemetic prophylaxis

Emetogenic potential is ***LOW***

Treatment Modifications

Adapted in part from Alimta (pemetrexed for injection) Lyophilized Powder, for Solution for Intravenous Use; 05/2013 product label. Lilly USA, LLC, Indianapolis, IN

Nadir ANC <500/mm³ and nadir platelets ≥50,000/mm³	75% of the previous pemetrexed dose
Nadir platelets <50,000/mm³ without bleeding regardless of nadir ANC	75% of the previous pemetrexed dose
Nadir platelets <50,000/mm³ with bleeding*, regardless of nadir ANC	50% of the previous pemetrexed dose
Any G3/4 toxicities except mucositis	Withhold treatment until toxicity resolves to the same or less than pretreatment status. Then, resume treatment with pemetrexed dosage decreased by 75%
Any G3/4 toxicities except mucositis after two dose reductions	Discontinue therapy
Any diarrhea requiring hospitalization (irrespective of grade) or G3/4 diarrhea	Withhold treatment until toxicity resolves to the same or less than pretreatment status. Then, resume treatment with pemetrexed dosage decreased by 75%

(*continued*)

Patient Population Studied

Patients were enrolled no earlier than 21 days and no later than 42 days after the first day of their last cycle of induction therapy. Inclusion criteria included an Eastern Cooperative Oncology Group performance status of 0 or 1, histologic or cytologic diagnosis of stage IIIB (with pleural effusion, positive supraclavicular lymph nodes, or both) or stage IV non–small cell lung cancer before induction therapy, and adequate organ function. Patients must not have progressed during four 21-day cycles of 1 of the following 6 initial doublet chemotherapy regimens: gemcitabine + carboplatin, gemcitabine + cisplatin, paclitaxel + carboplatin, paclitaxel + cisplatin, docetaxel + carboplatin, or docetaxel + cisplatin. Induction regimens did not include pemetrexed. Previous radiotherapy was completed ≥4 weeks before study enrollment

Patient Characteristics

Sex	
Men	73%
Women	27%

NSCLC REGIMEN
PATIENTS WITH TUMORS HARBORING EGFR MUTATIONS

GEFITINIB

Maemondo M et al. N Engl J Med 2010;362:2380–2388

Gefitinib 250 mg per day; administer orally with or without food, continually (total dose/week = 1750 mg)*

*Gefitinib availability in the United States is limited to participation in the Iressa Access Program. Postmarket Drug Safety Information for Patients and Providers may be acquired online from the U.S. Food and Drug Administration at http://www.fda.gov/Drugs/DrugSafety/PostmarketDrugSafetyInformationforPatientsandProviders/ucm110476.htm (last accessed June 7, 2013) or from AstraZeneca

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MINIMAL-LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
- Rehydrate orally with fluids and electrolytes during a diarrheal episode
- If a patient develops blood or mucus in stool, dehydration, or hemodynamic instability, or if diarrhea persists >48 hours despite loperamide, stop loperamide and hospitalize the patient for IV hydration

Alternatively, a trial of **Diphenoxylate hydrochloride** 2.5 mg **with Atropine sulfate** 0.025 mg (eg, Lomotil)

- Initial adult dose is 2 tablets 4 times daily until control has been achieved, after which the dose may be reduced to meet individual requirements. Control may often be maintained with as little as 2 tablets daily
- Clinical improvement of acute diarrhea is usually observed within 48 hours. If improvement of chronic diarrhea after treatment with a maximum daily dose of 8 tablets is not observed within 10 days, control is unlikely with further administration

Persistent diarrhea:

Octreotide 100–150 mcg subcutaneously 3 times daily. Maximum total daily dose is 1500 mcg

Antibiotic therapy during latent or delayed onset diarrhea:

A fluoroquinolone (eg, **Ciprofloxacin** 500 mg orally every 12 hours) if absolute neutrophil count <500/mm^3 with or without accompanying fever in association with diarrhea

- Antibiotics should also be administered if patient is hospitalized with prolonged diarrhea and should be continued until diarrhea resolves

Dose Adjustments

Summary of product characteristics for IRESSA 250-mg film-coated tablets. Available at: http://www.iressa.com/ [accessed March 21, 2014]

Acute onset of new or progressive pulmonary symptoms, such as dyspnea, cough, or fever	Interrupt treatment with gefitinib pending diagnostic evaluation
Interstitial lung disease (ILD)	Discontinue gefitinib and institute appropriate treatment as necessary
Hepatic failure or gastrointestinal perforation	Discontinue gefitinib
Dehydration, severe bullous, blistering or exfoliative skin conditions, or acute worsening ocular disorders	Interrupt or discontinue gefitinib
G1/2 diarrhea	Interrupt gefitinib temporarily and institute loperamide therapy. Resume gefitinib if symptoms resolve to G ≤1
G3/4 diarrhea	Discontinue or interrupt gefitinib temporarily. Institute symptomatic therapy. If the patient is receiving benefit from gefitinib, and treatment is interrupted only temporarily, resume gefitinib only if symptoms resolve to G ≤1
G3/4 diarrhea despite loperamide	Discontinue gefitinib
G1/2 skin reaction	Interrupt gefitinib temporarily and institute symptomatic therapy; resume gefitinib if symptoms resolve to G ≤1
G3/4 skin reaction	Discontinue or interrupt gefitinib temporarily. Institute symptomatic therapy. If the patient is receiving benefit from gefitinib, and treatment is interrupted only temporarily, resume gefitinib only if symptoms resolve to G ≤1
Total bilirubin >3 × ULN and/or transaminases a >5 × ULN in the setting of normal pretreatment values	Interrupt or discontinue gefitinib

Notes: Gefitinib plasma concentrations may increased by administration concurrently with potent inhibitors of CYP3A4 activity (eg, clarithromycin, itraconazole, ketoconazole, posaconazole, protease inhibitors, telithromycin, voriconazole). The increase may be clinically relevant as adverse reactions are related to dose and exposure. Patients who receive gefitinib concomitantly with potent CYP3A4 inhibitors should be closely monitored for adverse reactions referable to gefitinib
Gefitinib systemic concentrations also may be increased in individuals with CYP2D6 poor metabolizer genotypes

Complete or partial response	84 (73.7)	35 (30.7)	<0.001
Stable disease	18 (15.8)	56 (49.1)	<0.001
Progressive disease	11 (9.6)	16 (14.0)	<0.001
Response could not be evaluated	1 (0.9)	7 (6.1)	

	Gefitinib (N = 114)	Carboplatin + Paclitaxel (N = 114)	HR [95%CI]; P Value
Median progression-free survival (interim analysis)	10.4 months	5.5 months	0.36 [0.25–0.51]; <0.001
Median progression-free survival (final analysis)	10.8 months	5.4 months	0.30 [0.22–0.41]; <0.001
1-year progression-free survival rate	42.1%	3.2%	
2-year progression-free survival rate	8.4%	0%	
Median overall survival*	30.5 months	23.6 months	
2-year survival rate	61.4%	46.7%	P = 0.31

	Men	Women	HR [95%CI]; P Value
Median progression-free survival	6.5 months	6.0 months	0.68 [0.51–0.92; 0.01

	Exon 19 Deletion	L858R Point Mutation	P Value
Median progression-free survival	11.5 months	10.8 months	0.90
Response rate	82.8%)	67.3%)	

*Neither sex nor clinical stage had a significant effect on overall survival

Treatment Monitoring

1. *Weekly, then monthly, then every 3 months:* History and physical exam, pulse O_2
2. *Weekly, then monthly, then every 3 months:* Serum creatinine, LFTs

NSCLC REGIMEN
PATIENTS WITH TUMORS HARBORING EGFR MUTATIONS

ERLOTINIB

Rosell R et al. Lancet Oncol 2012;13:239–246

Erlotinib 150 mg per day; administer orally at least 1 hour before or 2 hours after food, continually (total dose/week = 1050 mg)

Supportive Care

Antiemetic prophylaxis

*Emetogenic potential is **MINIMAL-LOW***

See Chapter 39 for antiemetic recommendations

Hematopoietic growth factor (CSF) prophylaxis

Primary prophylaxis is NOT indicated

See Chapter 43 for more information

Antimicrobial prophylaxis

Risk of fever and neutropenia is LOW

Antimicrobial primary prophylaxis to be considered:

- Antibacterial—not indicated
- Antifungal—not indicated
- Antiviral—not indicated unless patient previously had an episode of HSV

See Chapter 47 for more information

Diarrhea management

Latent or delayed onset diarrhea*:

Loperamide 4 mg orally initially after the first loose or liquid stool, *then*
Loperamide 2 mg orally every 2 hours during waking hours, *plus*
Loperamide 4 mg orally every 4 hours during hours of sleep

- Continue for at least 12 hours after diarrhea resolves
- Recurrent diarrhea after a 12-hour diarrhea-free interval is treated as a new episode
