System GC

DA Cowan, personal communication (2003).

In this system, the drugs are chromatographed as tertiary bases or trifluoroacetyl derivatives.

- *Column*: 3% OV-17 on 80–100 mesh Chromosorb W HP glass (2 m × 3 mm i.d).
- *Temperature programme*: 170°C for 2 min to 270°C at 16°/min for 8 min.
- *Carrier gas*: N_2, 30 mL/min.
- *Reference compounds*: *n*-Alkanes with an even number of carbon atoms.
- *Retention indices*: The retention indices given for system GC are those of the tertiary bases or of trifluoroacetyl derivatives.

Analgesics (non-narcotic) and non-steroidal anti-inflammatory drugs

Analgesics (non-narcotic) and non-steroidal anti-inflammatory drugs (NSAIDs) are acidic and/or neutral drugs and, although water soluble, are readily extracted at pH 5 (sodium acetate or phosphate buffer) into polar solvents, such as ethyl acetate or diethyl ether. Recovery can be improved by 'salting out' using excess solid sodium chloride. Many are arylacetic (indometacin), arylpropionic (ibuprofen), salicylic

(diflunisal) or fenamic (mefenamic acid) acid derivatives, and thus require the formation of suitable derivatives prior to GC (data for methyl derivatives are given in Table 40.9; the values given for system GD are retention times of methyl derivatives relative to *n*-$C_{16}H_{34}$). This is most pertinent at low concentrations or with packed columns, while at higher concentrations peaks may tail, and there is thus a tendency for retention time to increase with concentration. Capillary columns, especially those with higher phase ratios, give better peaks for underivatised phenols. The arylpropionic acid derivatives are chiral, with the non-steroidal anti-inflammatory (NSAI) activity usually residing in the *S*-enantiomer, but these are usually marketed as racemates and undergo enantiomeric inversion *in vivo*. Separation of NSAI enantiomers has been reviewed (Davies 1997).

Systems GA or GB, described above, may be used, or systems GD and GL.

System GD

In this system, the substances are chromatographed as their methyl derivatives.

- *Column*: 3% SE-30 on 80–100 mesh Chromosorb G (acid-washed and dimethyldichlorosilane-treated) glass (2 m × 3 mm i.d).
- *Temperature programme*: 120°C for 2 min to 260°C at 10°/min for 5 min.
- *Carrier gas*: N_2, 40 mL/min.
- *Reference compound*: Hexadecane (*n*-$C_{16}H_{34}$).
  Note: Free carboxylic acids and phenols will not generally give peaks, although large quantities may give tailing peaks.
- *Retention indices and relative retention times*: The values given for system GD are retention times of methyl derivatives relative to *n*-$C_{16}H_{34}$.

System GL

In this system (Maurer *et al.* 2001), the substances are chromatographed as their methyl derivatives after extractive methylation. Equal volumes of urine and phase-transfer reagent (0.02 mol/L tetrahexylammonium hydrogensulfate in 1 mol/L phosphate buffer, pH 12) are incubated with three volumes of 1 mol/L methyl iodide in toluene on a shaker at 50°C for 30 min. The organic phase is eluted on a diol solid-phase cartridge (conditioned with methanol, then toluene) using diethyl ether–ethyl acetate (95 : 5 v/v). After evaporation to dryness at 60°C, the residue is reconstituted in ethyl acetate for injection.

- *Column:* HP1 (methyl-PSX) fused-silica capillary (12 m × 0.2 mm i.d. 0.33 μm).
- *Injector:* 280°C splitless mode.
- *Temperature programme:* 100°C for 2 min to 310°C at 30°/min for 8 min.
- *Carrier gas:* He, 1 mL/min.
- *Retention indices* are given in Table 40.9.

Anticholinergics

The anticholinergics comprise a chemically diverse group of drugs, although most can be extracted successfully from biological specimens under mildly alkaline conditions. Some (atropine, hyoscine) are

Table 40.9 GC retention data and mass spectral data for analgesics (non-narcotic) and NSAIDs (ET, ethyl; Me, methyl)

relatively unstable and produce several artefacts, either from hydrolysis during extraction or from thermal degradation in the GC. The quaternary ammonium compounds (e.g. emepromium bromide) are not amenable to gas chromatography. Systems GA or GB, previously described, may be used. Retention indices and relative retention times are given in Table 40.10.

Anticonvulsants and barbiturates

Most barbiturates and anticonvulsants are acidic or mildly basic drugs and are extracted readily from aqueous medium into organic solvents. Although phenobarbital requires pH 7 or less for good recovery in liquid–liquid extractions, the other barbiturates and anticonvulsants (such as carbamazepine and phenytoin) may be extracted from aqueous

solutions at pH values as high as 11. There is little to be gained in terms of sensitivity by using NPD over FID, especially for barbiturates, but the former is more specific and excludes fatty acids, which can be problematic in decomposing samples. For GC, some investigators prefer to methylate, either during the extraction (iodomethane–tetramethylammonium hydroxide in dimethyl sulfoxide) (Liu *et al.* 1994), or by flash methylation in the injection port (trimethylphenylammonium hydroxide in ethyl acetate) (Brugmann 1981). This method is sometimes considered unreliable for quantitative analysis, and is arguably only necessary when using packed chromatography columns. Data for the methyl derivatives are therefore given where they are available. When using packed columns for GC, the medium- and higher-polarity phases, such as *-1310, *-2100, DEGS and waxes, are useful, although methylation allows the use of some more non-polar phases such as *-1 (Stern, Caron 1977).

Systems GA and GB, previously described, may be used, or systems GE, GF and GAJ.

System GE

Quantitative analysis of underivatised antiepileptic drugs (Supelco 1979).

- *Column*: 2% SP-2110 and 1% SP-2510-DA on 100–120 mesh Supelcoport glass (1 m × 2 mm i.d.).
- *Temperature programme*: 120°C to 250°C at 16°/min.
- *Carrier gas*: N_2, 50 mL/min.
- *Reference compound*: Phenytoin. *Note:* This system separates cholesterol from all drugs in the group.
- *Retention indices and relative retention times*: The values given for system GE are retention times relative to phenytoin.

System GF

(Flanagan, Berry 1977).

- *Column*: 3% Poly A103 on 80–100 mesh Chromosorb W HP glass (1 m × 4 mm i.d.).
- *Temperature*: 200°C.
- *Carrier gas*: N_2, 60 mL/min.
- *Reference compounds*: *n*-Alkanes with an even number of carbon atoms.

System GAJ

Data generated by the author.

- *Column:* DB1301 capillary (25 m × 0.32 mm i.d., 0.25 µm).
- *Temperature programme:* 100°C to 235°C at 35°/min for 3.6 min to 290°C at 8°/min for 3.5 min.
- *Carrier gas:* He, 1.5 mL/min.
- *Reference compound:* Methylphenobarbital.
- *Detection* by FID and NPD split.
- *Retention indices and relative retention times* are given in Table 40.11. The values given for system GAJ are retention times relative to methylphenobarbital.

Antidepressants

Antidepressants (tricyclics, selective serotonin reuptake inhibitors (SSRIs), monoamine oxidase inhibitors (MAOIs)) can be extracted readily under mildly basic conditions (pH 10) into many solvents, such as ethyl acetate, hexane, diethyl ether. Less polar solvents, such as hexane, limit the extraction of hydroxylated metabolites. An acidified (0.05 mol/L H_2SO_4) back extraction is a useful clean-up procedure

where sensitivity is important. Chromatography of primary and secondary amines is poor on packed columns, but is adequate on well-maintained capillary columns, particularly those of low–medium polarity such as PSX-5 (see Table 40.3). Some authors prefer to chromatograph the secondary amines and hydroxylated metabolites as acetylated derivatives, prepared by heating the dried residue with acetic anhydride and pyridine (3 : 2, v/v) (Maurer, Bickeboeller-Friedrich 2000). Others employ an enzymatic hydrolysis procedure to improve recovery of both parent drug and metabolites, although the additional sensitivity gained is often negated by the increased analytical time in the emergency setting. Acid hydrolysis is quicker, but some relevant compounds are destroyed under these conditions.

System GA, GF or GB, described above, may be used, or system GM.

System GM

System GM (Dawling *et al.* 1990) is ideal for plasma samples, since the isothermal conditions allow high throughput and the limited resolution of hydroxylated metabolites is not important as these do not constitute a significant fraction of the extract from plasma. Conditions are given for both packed and capillary column systems.

- *Column:* 3% SP2250 on Supelcoport 80–100 mesh glass (2.1 m × 2 mm i.d.).
- *Temperature:* 265°C.
- *Carrier gas:* He, 25 mL/min.
- *Column:* HP-50 + fused silica capillary (25 m × 0.53 mm i.d., 1 μm).
- *Temperature:* 250°C.
- *Carrier gas:* He, 7 mL/min.
- *Reference compound:* Iprindole.
- *Quantification:* NPD.
- *Retention indices*, relative retention to iprindole, are given in Table 40.12. Only the metabolites known to occur in urine and/or plasma specimens are included in this list; the list in De Zeeuw (2002) is more extensive.

Antihistamines

Antihistamines are a diverse group of drugs that includes the ethanolamines (diphenhydramine), ethylenediamines (pyrilamine), alkylamines (hydroxyzine), phenothiazines (promethazine) and piperidines (chlorphenamine). Many share common metabolites with other members of

[a]Racemate.

their class, which may compromise the identification of the parent drug ingested. Some authors advocate the preparation of acetylated derivatives, particularly to analyse the hydroxylated metabolites, but to identify them in biological fluids this is an unnecessary additional step.

Systems GA, GB, GC or GF, described above, may be used. The retention indices and principal ions are given in Table 40.13.

Benzodiazepines

The analysis of benzodiazepines in biological specimens is hampered by their high potency and resultant low plasma concentrations, and by their inter-connected metabolic pathways. Several benzodiazepines appear in urine almost exclusively as glucuronide-conjugated metabolites, and these can be hydrolysed with glucuronidase (1000 U glucurase/mL of urine at 60°C for 1–2 h), although some can degrade with prolonged heating. Extraction can be performed at any pH between 3 and 12, but basic extracts (pH 9–11) give cleaner chromatograms. The extraction solvent should be moderately polar (ethyl acetate is appropriate), and TMS derivatives form easily in 20–30 min at 60°C using 50% bis(trimethylsilyl)trifluoroacetamide (BSTFA) with 1% trimethylchlorosilane (TMCS) in acetonitrile. These derivatives markedly improve peak shape and sensitivity. All compounds except 7-aminonitrazepam show electron-capture responses with high sensitivity. However, quantitation by ECD is problematic as it has a narrow linear range, and a multiple point calibration is essential. Alternatively, for most compounds a nitrogen detector (NPD) gives adequate sensitivity with a much improved linear range, although it is not advisable to make TMS derivatives if using this detector. MS detection is required to confirm the identity. System GA or GB, described above, may be used or system GG. The retention indices and principal ions are given in Table 40.14.

System GG

M Möller, personal communication

- *Column*: 2.5% OV-17 on 80–100 mesh Chromosorb G, treatment and dimensions as for system GA.
- *Column temperature, carrier gas, reference compounds*: As for system GA.
- *Retention indices*: The retention indices of benzodiazepines have been shown to be dependent on column temperature (Schuetz, Westenberger 1978, 1979). The values given by these authors are about 50 RI units above those generally quoted. The values given below should therefore be checked before use by chromatographing a few sample compounds.

Table 40.13 GC retention data and mass spectral data for antihistamines (BP, benzophenone; CBPH, chlorobenzophenone)

[a]Does not form a TMS derivative.
[b]No electron-capture response.

Hydrolysis of benzodiazepines (preparation of benzophenones)
Boil an aqueous solution (or urine) with concentrated hydrochloric acid (1 part to 10 parts urine or solution) for 30–60 min. Cool, and neutralise with solid $KHCO_3$ or adjust the pH to 8–9 with 10 mol/L KOH. Mix with an equal volume of petroleum ether for 10 min. Centrifuge and evaporate the upper organic phase to dryness at 60°C. The reconstituted extract can be used for GC or other analytical procedures such as TLC (Chapter 39). Data are also presented here for some acetylated hydrolysis products (treatment of the dried residue with acetic anhydride and pyridine (3 : 2) for 30 min at 60°C (Maurer, Pfleger 1987). Not all benzodiazepines make benzophenones when hydrolysed by acid, and a number of other degradation products are furnished. The α-OH-metabolites of alprazolam, brotizolam and triazolam are partly altered by the elimination of formaldehyde. Hydrolysis products of bis-desethylflurazepam and di-OH-tetrazepam are dehydrated; OH-bromazepam, lorazepam and oxazepam form artefacts by rearrangement; the nor-metabolites of clobazam are cleaved and rearranged to benzimidazole derivatives; tetrazepam, and its two hydroxylated metabolites, are transformed into a pair of *cis*- and *trans*-isomeric hexahydroacridone derivatives.

Since the metabolism of benzodiazepines is complex, assays that convert drugs and metabolites into hydrolysis products are not ideal, because they do not permit unequivocal identification of the parent compound. After acid hydrolysis, care must be taken to ensure that the acid is neutralised prior to extraction or before injecting the solvent onto the chromatograph, otherwise the column deteriorates rapidly. The retention indices and principal ions are given in Table 40.15.

Cardioactive drugs

Cardioactive drugs (beta-blockers, calcium channel antagonists, angiotensin-converting enzyme (ACE) inhibitors, etc.) are a diverse group of

chemicals that require different analytical strategies. The calcium channel antagonists of the phenylalkylamine class (e.g. verapamil) and the benzothiazines (e.g. diltiazem) chromatograph well on standard GC phases (X-1 or X-5) after solvent extraction under mildly basic conditions (pH 10–12). As a rule, the beta-blockers (those with names that end in '-olol') are more water soluble and often require 'salting out' of aqueous solution at mildly basic conditions (pH 10–12) with an excess of solid sodium chloride. When subjected to GC they have a tendency to produce artefacts by loss of water and/or their amino-alkyl side-chain. Although they chromatograph reasonably well on capillary columns such as X-1 or X-5, they often give tailing peaks on packed columns, and various derivatisation strategies have been employed to overcome this. Simultaneous preparation of *N*-TFA and *O*-TMS derivatives have been described (Leloux *et al.* 1989; Lho *et al.* 1990), and cyclic boronates may be formed from phenyl or *n*-butylboronic acids using either triethylamine or pyridine catalysts (Lee *et al.* 1998). Acetylation of acid-hydrolysed sample extracts is described using acetic anhydride with a pyridine catalyst; although this process results in the complete destruction of some of the parent compounds, data for many metabolites are given (Maurer, Pfleger 1986). The ACE inhibitors (those with names that end in '-pril') have a free carboxylic acid group, and acquire a second such group by enzymatic hydrolysis of their ethyl ester link ('prilates'). Neither of these groups of compounds, nor the dihydropyridine calcium channel antagonists (e.g. nifedipine), chromatographs in their native state, but GC has been applied successfully to their analysis following extractive methylation. Here, equal volumes of urine and phase-transfer reagent (0.02 mol/L tetrahexylammonium hydrogensulfate in 1 mol/L phosphate buffer pH 12) are incubated with three volumes of 1 mol/L methyliodide in toluene on a shaker at 50°C for 30 min. The organic phase is eluted on a diol solid-phase cartridge (conditioned with methanol, then toluene) using diethyl ether–ethyl acetate (92.5 : 7.5, v/v). After evaporation to dryness at 60°C, the residue is reconstituted in ethyl acetate for injection.

Systems GA and GB, described above, can be used, and system GP chromatographs many of the drug metabolites as their methyl derivatives (Maurer *et al.* 1998; Maurer, Arlt 1999).

System GP

- *Column:* HP1 (methyl-PSX) fused silica capillary (12 m × 0.2 mm i.d., 0.33 μm)
- *Injector:* 280° splitless mode.
- *Temperature programme:* 100°C for 3 min to 310°C at 30°/min for 8 min.
- *Carrier gas:* He, 1 mL/min.
- *Retention indices and principal ions* are given in Table 40.16.

Coumarins and other anticoagulants

Coumarins are extracted fairly readily from acidic solution, especially when 'salted out' with solid sodium chloride; the coumarin structure is

not amenable to GC without prior derivatisation. Maurer and Arlt (1998) describe an extractive methylation procedure from aqueous alkali (5 mL) using iodomethane in toluene (5 mL of 0.5 mol/L) and 150 µL of a phase-transfer reagent (tetrahexylammonium hydrogensulfate (THA), 4.5 g in 50 mL of 0.5 mol/L NaOH). Removal of excess THA was achieved by passing the toluene layer through a solid-phase extraction (SPE) cartridge and eluting with diethyl ether–ethyl acetate (92.5 : 7.5, v/v), which enables GC with MS. System GA, described above, is used, and the retention indices and principal ions are given in Table 40.17. Anticoagulants of the heparin family (e.g. enoxaparin) are not included as these peptides cannot be chromatographed.

Diuretics

As a group, the diuretics chromatograph poorly on packed columns, and only marginally better on capillaries because of the presence of one or

more sulfonamide (SO_2–NH_2) or carboxylic acid groups. However, they can be methylated easily, and then systems GA or GB, described above, may be used effectively. The diuretics can be extractively alkylated from aqueous alkali (5 mL) using iodomethane in toluene (5 mL of 0.5 mol/L) and 150 µL of a phase-transfer reagent. Tetrahexylammonium hydrogensulfate (4.5 g in 50 mL 0.5 mol/L NaOH) is far superior to tetrabutylammonium hydroxide (TBAH) and tetrapentylammonium hydroxide (TPAH) (Carreras *et al.* 1994). Removal of excess THA was achieved by passing the toluene layer through an SPE cartridge and eluting with diethyl ether–ethyl acetate (92.5 : 7.5, v/v). Alternatively, diuretics can be extracted from aqueous acidic solution into ethyl acetate, and the evaporated residue heated with 10% methyl iodide in acetone and 100 mg solid K_2CO_3 for 6 h at 60°C, and the resultant extract applied directly to the chromatograph. The former method tends to produce more completely substituted derivatives than the latter, which gives a more varied pattern of substituted derivatives. Although good sensitivity for plasma samples can be obtained with an NPD, the use of a mass spectrometer is required to confirm the identity (Lisi *et al.* 1991; Yoon *et al.* 1990).

System GA or GB, described above, can be used, as can systems GX and GY.

System GX

The details are taken from Carreras *et al.* (1994).

- *Column:* 5%-phenyl-PSX (X-5) (25 m × 0.2 mm i.d., 0.33 µm).
- *Temperature programme:* 230°C to 320°C at 35°/min (drugs elute isothermally).
- *Carrier gas:* He, 1 mL/min.
- *Retention indices and times* (min) are given in Table 40.18.

System GY

The details are taken from Lisi *et al.* (1991).

- *Column:* methyl-PSX (X-1) (25 m × 0.22 mm i.d., 0.1 µm).
- *Temperature programme:* 130°C to 320°C at 40°/min for 3 min.
- *Injection:* Split 10 : 1.
- *Carrier gas:* H_2, 1 mL/min.
- *Retention indices and times* (min) are given in Table 40.18.

Essential oils, flavours and fragrances

Essential oils, flavours and fragrances are complex mixtures of many components, so Table 40.19 is representative of the most common ones only. For a more extensive list, the reader is referred to specialist texts (Adams 1995). In addition, many small esters and ketones are contributory and can be detected via the system described in the section below on volatile substances. Essential oils, once thought innocuous, are now recognised as a potential cause of serious poisonings, especially in children, and are encountered in highly concentrated forms with increasing frequency in everyday use as vehicles for medicines, aromatherapy and handicraft supplies. Since most natural flavours occur in predominantly one enantiomeric form, and the majority of synthetic flavours are racemates, chiral analysis of enantiomeric proportions is an effective way to determine the authenticity of flavours. The catalogues of chromatography column suppliers show many examples of chiral separations; some examples are found on-line at www.restek.com. Systems GA and GB, described above, can be used, as can systems GN and GO (Supelco 2000).

System GN

- *Column:* Supelcowax 10 (Wax10) (10 m × 0.25 mm i.d., 0.25 μm).
- *Temperature programme:* 50° for 2 min, to 280° at 2°/min
- *Carrier gas:* He, 25 cm/s.
- *Retention times* (min) are given in Table 40.19.

System GO

- *Column:* SPB-5 (5%-phenyl-PSX, X-5) (30 m × 0.25 mm i.d. 0.25 μm).
- *Temperature programme:* 75° for 8 min to 200° at 4°/min.
- *Carrier gas:* He, 25 cm/s.
- *Retention times* (min) are given in Table 40.19.

Narcotic analgesics, opiates and opioids

Many laboratories perform specific assays for opiates for federal or legal purposes; these are generally limited to codeine, morphine and more recently 6-monoacetyl morphine (MAM) (Paul *et al.* 1999).

However, for clinical purposes a wider range of analytes is desirable and can include codeine, dihydrocodeine, hydrocodone, hydromorphone, oxycodone and oxymorphone. All assays involve a hydrolysis step (acidic or enzymatic – see earlier discussion for an evaluation of these) to cleave the glucuronide conjugates, followed by a basic extraction (often using solid-phase or acidic back extraction for cleanliness). Derivatisation is possible with a number of reagents (PFP, TMS, TFA or AC derivatives are the most common) (Chen *et al.* 1990; Grinstead 1991; Maurer, Pfleger 1984), and retention data for some of these are included in Table 40.20. The derivatising reagent is selected on the basis of personal preference for a desired separation or the formation of unique ions on MS fragmentation. Analysis of hydromorphone, oxycodone and oxymorphone is complicated by the possibility that several structurally different

derivatives will form in non-reproducible proportions from the automerisation of the enol and keto forms. However, these compounds can be stabilised in their keto forms by incubating with hydroxylamine or methoxyamine–pyridine, and then yield only a single derivatised oxime product (Broussard *et al.* 1997; Meatherall 1999).

Systems GA, GB, GC or GF, described previously may be used. For plasma, system GM, described previously, is a rapid isothermal packed-column method with good sensitivity on NPD. Table 40.20 gives retention indices, or relative retention times to iprindole for GF.

Non-amfetamine stimulants and hallucinogens

Non-amfetamine stimulants and hallucinogens have a variety of clinical and toxic actions. Extraction of cocaine is straightforward under basic conditions, and most metabolites, except benzoylecgonine, can be detected in the clinical setting without derivatisation. For regulated testing, quantification of benzoylecgonine is required, and most laboratories use TMS as the derivatising reagent. As a result of the recent interest in other metabolites that may have clinical importance, data for these and their TMS derivatives are also included in Table 40.21.

For analysis of cannabis metabolites, hydrolysis of conjugates with 10 mol/L potassium hydroxide is usually performed on urine prior to weakly acidic extraction (pH 6.5); TMS is the derivative of choice. Phencyclidine (PCP) analysis is complicated by the low concentration present, although extraction is straightforward and derivatisation is required only for metabolite measurement (Nakahara *et al.* 1997). Chromatographic confirmation of lysergide (LSD) is hampered by the low concentrations and acidic nature of the metabolites, which necessitates both derivatisation (TMS) and tandem MS (Nelson, Foltz 1992). Systems GA or GB may be used. Table 40.21 gives the retention indices (reference compounds are the alkanes with an even number of carbon atoms).

Table 40.21 GC retention data and mass spectral data for non-amfetamine stimulants and hallucinogens (AC, acetyl; PFP, pentafluoropropionate; TFA, trifluoroacetyl; TMS, trimethylsilyl)

Oral hypoglycaemics

Oral hypoglycaemics constitute three chemical classes: biguanides (metformin), sulfonylureas (chlorpropamide) and thiazolidenediones (rosiglitazone). The latter two classes contain sulfur, and the sulfonylureas also share structural similarities with the thiazide diuretics (see above) and the sulfonamide antibiotics (see later). Sulfonylureas and their metabolites are not amenable to GC because of their acidity and polarity. Extractive methylation has been employed, but the use of standard conditions leads to the formation of unstable compounds, and in addition there may be thermal decomposition during chromatography. Thus, the formation of common fragments (superscripts a to f in Table 40.22; HH Maurer, personal communication, 2003) complicates

[(a)–(f)]Hydrolysis artefacts common to several sulfonylureas.

identification of the parent compound and limits the application as a screening tool. For this purpose, HPLC may be more applicable (Maurer *et al.* 2002). However, stable *N*-methyl (sulfonamide nitrogen) derivatives can be formed by maintaining the extraction pH below 7, and by using TBAH as the ion-pairing reagent. With the alkylation pH above 10, and using TPAH as the counter-ion, there is almost complete hydrolysis to sulfonamide and amide artefacts (Hartvig *et al.* 1980). Thermal stability can also be achieved by the judicious choice of pairs of derivatising reagents: methyl iodide plus trifluoroacetic anhydride (TFAA) for parent compounds, and methyliodide plus heptafluorobutyric anhydride (HFBA) for the hydroxy and carboxy metabolites (Braselton *et al.* 1977). This strategy offers the additional advantage of an improved ECD response. The biguanides also present analytical difficulties, although successful chromatography is achieved by forming a triazine derivative by them reacting with *p*-nitrobenzoyl chloride, for which the retention data are given in Table 40.22 (Brohon, Nöel 1978; Paroni *et al.* 2000). Screening methods are not yet developed for the newer classes of drugs such as the alpha-glucosidase inhibitors, glinides, glitazones and gliptins, although LC-MS methods have been published for some of the individual compounds. Systems GA and GB may be used, and the reference compounds are *n*-alkanes with an even number of carbon atoms.

Pesticides

A comprehensive method for screening pesticides using systems GA and GK can be found in Chapter 16, Table 16.1. Systems GKA, GKB, GKC and GKD cater for a smaller set of compounds and these can be found in the Indexes of Analytical Data.

System GKA

(Osselton, Snelling 1986).

- *Column*: Chromosorb W HP 3% SE-30 on 80–100 mesh silanised glass (2 m × 4 mm i.d.).
- *Carrier gas*: O_2-free N_2, 50 mL/min.
- *Detector*: Flame ionisation and nitrogen–phosphorus.
- *Reference compound:* Straight-chain hydrocarbons

System GKB

(Osselton, Snelling 1986).

- *Column*: Chromosorb W HP 3% OV-7 on 80–100 mesh silanised glass (2 m × 4 mm i.d.).
- *Carrier gas*: O_2-free N_2, 50 mL/min.
- *Detector*: Flame ionisation and nitrogen–phosphorus.
- *Reference compound*: Straight-chain hydrocarbons.

System GKC

(Osselton, Snelling 1986).

- *Column*: Chromosorb W HP 3% OV-17 on 80–100 mesh silanised glass (2 m × 4 mm i.d.).
- *Carrier gas*: O_2-free N_2, 50 mL/min.
- *Detector*: Flame ionisation and nitrogen–phosphorus.
- *Reference compound*: Straight-chain hydrocarbons.

System GKD

(Junting, Chuichang 1991).

- *Column*: Fused silica HP-1, methyl silica gum (5 m × 0.53 mm i.d., 2.65 μm).
- *Temperature programme*: 190°C to 235°C at 10°/min.
- *Carrier gas*: N_2, 20 mL/min flow rate.
- *Detector*: Flame ionisation.

Phenothiazines and other tranquillisers

Phenothiazines and other tranquillisers can be extracted readily under mildly basic conditions (pH 10) into solvents such as ethyl acetate, hexane, butyl chloride and diethyl ether. An acidified (0.05 mol/L H_2SO_4) back extraction is a useful clean-up procedure where sensitivity is important. Chromatography of the primary and secondary amines is poor on packed columns, but is adequate on well-maintained capillary columns, particularly those of low-to-medium polarity, such as PSX-5 (see Table 40.3). Meprobamate is unstable in basic solution, and benefits from the use of mildly acidic (pH 5) extraction conditions. Some authors prefer to chromatograph the secondary amines and hydroxylated metabolites as acetylated derivatives, prepared by heating the dried residue with acetic anhydride and pyridine (3 : 2, v/v) (Maurer, Bickeboeller-Friedrich 2000). Others employ an enzymatic hydrolysis procedure to improve the recovery of both parent drug and metabolites, although the additional sensitivity gained is often negated by the increased analytical time in the emergency setting. Acid hydrolysis is quicker, but some relevant compounds are destroyed under these conditions. System GA or GB may be used (Table 40.23), and the reference compounds are *n*-alkanes with an even number of carbon atoms.

Laxatives

Table 40.24 lists the stimulant laxatives. Other types of laxatives, such as bulkers (bran), osmotic (PEG and lactulose), stool softeners and saline

(magnesium and other salts), are detected by other means (Duncan 2000) and are not discussed here. Stools may be analysed after homogenisation, or alternatively purgatives may be detected in urine, both after enzymatic hydrolysis to release conjugated metabolites. Extraction of hydrolysis products with chloroform–isopropanol (9 : 1) or other moderately polar solvents at the hydrolysis pH yields good recovery, and derivatisation (e.g. silylation, methylation or acetylation) improves chromatography, particularly of the more polar compounds such as rhein. Rhein is a product of many vegetable glycoside laxatives, including sennosides, aloes and cascara (except frangula, which is metabolised to emodin), which are hydrolysed by colonic bacteria to active aglycones prior to absorption (this is important to remember when analysing pharmaceutical products). System GA or GB may be used, and the reference compounds are *n*-alkanes with an even number of carbon atoms.

Solvents and other volatile compounds

Methods for the analysis and analytical data for solvents and other volatile substances are described in detail in Chapter 16. An ECD run in parallel with an FID produces the optimal detection rates, since many of the compounds of interest are halogenated. The low boiling point of these compounds requires their careful isolation from biological samples by headspace analysis, and the GC may benefit from cryogenic cooling (Flanagan *et al.* 1997; Sharp 2001). Standard capillary columns can be used (e.g. dimethyl-PSX), but chromatography and durability benefit from the use of a column with a high-phase ratio (3–5 µm film thickness). Other columns, such as an X-wax phase (a 0.25 µm film thickness is adequate here), or those specifically designed for volatiles, such as X-624 (3 µm film thickness), are used commonly (see Table 40.3 for details of these stationary phases). System GA or GI may be used and a more comprehensive method for screening volatiles can be found in Chapter 16, Table 16.3.

System GA, previously described, may be used, or system GI, below.

System GI

(Ramsey, Flanagan 1982).

- *Column*: 0.3% Carbowax 20M on 80-100 mesh Carbopak C glass, (2 m × 2 mm i.d.).
- *Temperature programme*: 35°C for 2 min to 175°C at 5°/min for at least 8 min.
- *Carrier gas*: N_2, 30 mL/min.

Steroids (Table 40.25)

System GAR

(CND Analytical, 1989).

- *Column:* Fused silica capillary with methylsilicone (12 m × 0.25 mm i.d., 0.25 µm).
- *Temperature programme:* 70°C to 150°C at 15°/min to 250°C at 25°/min.

System GAG

(Lurie *et al.* 1994).

- *Column*: Bonded DB-1 fused silica capillary, cross-linked (30 m × 0.25 mm i.d., 0.25 µm). Split ratio of 30 : 1.
- *Temperature programme*: 180°C to 230°C at 10°/min to 245°C at 1°/min to 295°C at 30°/min for 15 min.
- *Carrier gas*: H_2.
- *Detector*: Flame ionisation.

System GAI

(Ayotte *et al.* 1996).

- *Column*: HP-5 5% phenyl polymethyl siloxane capillary (25 m × 0.25 mm i.d., 0.33 µm).
- *Temperature programme*: 100° for 1 min to 220° at 16°/min to 301° at 20°/min for 5.5 min.
- *Carrier gas*: He.
- *Detection*: Mass-selective detector.
- *Retention time*: Relative to 17α-methyl-5α-androstan-3β,17β-diol.

Sulfonamides

Gas chromatography of sulfonamides is only possible after extractive *N*-methylation of the secondary amino group (Gyllenhaal *et al.* 1978) and some authors additionally prepare HFB or PFP derivatives of any primary amino groups (Tarbin *et al.* 1999). These latter derivatives may require the use of positive chemical ionisation MS (Reeves 1999). As with the oral hypoglycaemics, differences in methylation conditions may lead to hydrolysis, and a number of sulfonamides may yield products or metabolites that correspond to sulfanilamide derivatives. The main metabolites are the N^4-acetylacted derivatives, which are hydrolysed relatively easily back to the parent compound under acidic conditions. System GA or GJ (Gyllenhaal *et al.* 1978) may be used.

System GJ

- *Column:* 5% OV-17 on 80 to 100 mesh Gas-Chrom Q glass (1.5 m × 2 mm i.d.).
- *Temperature:* 250°.
- *Carrier gas:* N_2, 30 mL/min.
- *Relative retention times* are given in Table 40.26 (retention times of methyl derivatives are relative to griseofulvin).

Table 40.26 GC retention data and mass spectral data for the sulfonamides (AC, acetyl; Me, methyl)

CHAPTER

41 High Performance Liquid Chromatography

T Kupiec and P Kemp

Introduction

The ability to separate and analyse complex samples, both small and large molecules, is important to the biological and medical sciences. Classic column chromatography has evolved over the years, with chromatographic innovations introduced at roughly decade intervals. These techniques offered major improvements in speed, resolving power, detection, quantification, convenience and applicability to new sample types. The most notable of these modifications was high performance liquid chromatography (HPLC). Modern HPLC techniques became available in 1969; however, they were not widely accepted in the pharmaceutical industry until several years later. Once HPLC systems capable of quantitative analysis became commercially available, their usefulness in pharmaceutical analysis was fully appreciated.

By the 1990s, HPLC had begun an explosive growth that made it a popular analytical method judged by sales of instruments and also scientific importance. During the last decade developments in chromatographic supports and instrumentation for liquid chromatography have continued to evolve. The use of silica-based monolithic supports, elevated mobile phase temperatures and columns packed with particles $<2\,\mu m$ has resulted in better resolution and faster separations of complex mixtures. Ultra-fast HPLC is such an important topic that it has been given its own section in the chapter. This application has experienced phenomenal growth in the first decade of the twenty-first century.

Liquid chromatography's present popularity results from its convenient separation of a wide range of sample types, exceptional resolving power, speed and nanomolar detection levels. It is presently used in biological, forensic and pharmaceutical research and development:

- To purify synthetic or natural products
- To characterise metabolites
- To assay active ingredients, impurities, degradation products and in dissolution assays
- In pharmacodynamic and pharmacokinetic studies.

Improvements made in HPLC in recent years include:

- Changes in packing material, such as smaller particle size, new packing and column materials
- High-speed separation
- Micro-HPLC, automation and computer-assisted optimisation
- Improvements in detection methods, including the so-called hyphenated detection systems.

These innovations will be discussed in the appropriate sections of this chapter. Additionally, a few novel techniques are presented that have come to be used in the past few years. These techniques include denaturing high pressure liquid chromatography and ion chromatography.

Practical aspects of HPLC theory

The practical application of HPLC is aided by an awareness of the concepts of chromatographic theory, in particular the measurement of chromatographic retention and the factors that influence resolution.

Chromatographic principles

The retention of a drug with a given packing material and eluent can be expressed as a retention time or a retention volume, but both of these are dependent on flow rate, column length and column diameter. The retention is best described as a column capacity ratio (k), which is independent of these factors. The column capacity ratio of a compound (A) is defined by Equation (41.1):

$$k_A = \frac{V_A - V_0}{V_0} = \frac{t_A - t_0}{t_0} \qquad (41.1)$$

where V_A is the elution volume of A and V_0 is the elution volume of a non-retained compound (i.e. void volume). At constant flow rate, retention times (t_A and t_0) can be used instead of retention volumes. The injection of a solvent or salt solution can be used to measure V_0, but the solute used should always be recorded along with reported k data. The importance of selecting suitable solutes for the measurement of V_0 has been discussed (Wells, Clark 1981).

It is sometimes convenient to express retention data relative to a known internal standard (B). The ratio of retention times (t_A/t_B) can be used, but the ratio of adjusted retention times, $(t_A - t_0)/(t_B - t_0)$, is better when data needs to be transferred between different chromatographs (Ettre 1980).

Resolution is the parameter that describes the separation power of the complete chromatographic system relative to the particular components of the mixture. By convention, resolution (R) is expressed as the ratio of the distance between two peak maxima to the mean value of the peak width at the base line (Equation 41.2).

$$R = \frac{2(V_{R,2} - V_{R,1})}{W_1 + W_2} \qquad (41.2)$$

If we approximate peaks by symmetrical triangles, then if R is equal to or more than 1, the components are completely separated. If R is less than 1, the components overlap.

Sensitivity in chromatographic analysis is a measure of the smallest detectable level of a component in a chromatographic separation and is dependent on the signal-to-noise ratio in a given detector. Sensitivity can be increased by derivatisation of the compound of interest, optimisation of the chromatographic system or miniaturisation of the system. The limit of detection is normally taken as 3 times the signal-to-noise ratio and the limit of quantification as 10 times this ratio.

Chromatographic mechanisms

The systems used in chromatography are often described as belonging to one of four mechanistic types: adsorption, partition, ion exchange and size exclusion. *Adsorption chromatography* arises from interactions between solutes and the surface of the solid stationary phase. Generally, the eluents used for adsorption chromatography are less polar than the stationary phases and such systems are described as 'normal phase'. *Partition chromatography* involves a liquid stationary phase that is immiscible with the eluent and coated on an inert support. Partition systems can be normal phase (stationary phase more polar than eluent) or reversed-phase chromatography, referred to as RPC (stationary phase less polar than eluent). *Ion-exchange chromatography* involves a solid stationary phase with anionic or cationic groups on the surface to which solute molecules of opposite charge are attracted. *Size-exclusion chromatography* involves a solid stationary phase with controlled pore size.

Solutes are separated according to their molecular size, with the large molecules unable to enter the pores eluting first. However, this concept of four separation modes is an over-simplification. In reality, there are no distinct boundaries and several different mechanisms often operate simultaneously.

Other types of chromatographic separation have been described. *Ion-pair chromatography* is an alternative to ion-exchange chromatography. It involves the addition of an organic ionic substance to the mobile phase, which forms an ion pair with the sample component of opposite charge. This allows a reversed-phase system to be used to separate ionic compounds. *Chiral chromatography* is a method used to separate enantiomers, which can be achieved by various means. In one case, the mobile phase is chiral and the stationary phase is non-chiral. In another, the liquid stationary phase is chiral with the mobile phase non-chiral. Or, finally, the solid stationary phase may be chiral with a non-chiral mobile phase.

Hardware

HPLC instrumentation includes a pump, an injector, a column, a detector and a recorder or data system (Figure 41.1). The heart of the system is the column in which separation occurs. Since the stationary phase is composed of micrometer-sized porous particles, a high-pressure pump is required to move the mobile phase through the column. The chromatographic process begins by injecting the solute on to the top of the column. Separation of components occurs as the analytes and mobile phase are pumped through the column. Eventually, each component elutes from the column and is registered as a peak on the recorder. Detection of the eluting components is important; this can be either selective or universal, depending upon the detector used. The response of the detector to each component is displayed on a chart recorder or computer screen and is known as a chromatogram. To collect, store and analyse the chromatographic data, computers, integrators and other data-processing equipment are used frequently.

Mobile phase reservoir

The most common type of solvent reservoir is a glass bottle. Most of the manufacturers supply these bottles with special caps, Teflon tubing and filters to connect to the pump inlet and to the sparge gas (helium) used to remove dissolved air. When the mobile phase contains excessive gas that remains dissolved at the pressure produced by the column, the gas may come out of the solution at the column exit or in the detector, which results in sharp spikes. Spikes are created by microscopic bubbles that change the nature of the flowing stream to make it heterogeneous, while drift may occur as these microscopic bubbles gradually collect and combine in the detector cell. The main culprit is oxygen (from the air) that dissolves in polar solvents, particularly water. Degassing may be accomplished by one or a combination of the following methods: applying a vacuum to the liquid; boiling the liquid; placing the liquid in an ultrasonic bath; bubbling a fine stream of helium through the liquid (sparging); or using commercial on-line degassing units.

Pumps

High-pressure pumps are needed to force solvents through packed stationary-phase beds. Smaller bed particles (e.g. 3 µm) require higher pressures. There are many advantages to using smaller particles, but they may not be essential for all separations. The most important advantages are higher resolution, faster analyses and increased sample load capacity. However, only the most demanding separations require these advances in significant degrees. Many separation problems can be resolved with larger particle packings (e.g. 5 µm) that require less pressure.

Flow-rate stability is another important pump feature that distinguishes pumps. Constant-flow systems are generally of two basic types: reciprocating piston and positive displacement (syringe) pumps. The basic advantage of both systems is their ability to repeat elution volume and peak area, regardless of viscosity changes or column blockage, up to the pressure limit of the pump. Although syringe-type pumps have a pressure capability of up to 540 000 kPa (78 000 psi), they have a limited ability to form gradients. Reciprocating piston pumps can maintain a liquid flow for an indefinite length of time, while a syringe pump needs to be refilled after the syringe volume has been displaced. Dual-headed reciprocating piston pumps provide more reproducible and pulse-free delivery of solvent, which reduces detector noise and enables more reliable integration of peak area. Reciprocating pumps now dominate the HPLC market and are even useful for micro-HPLC applications, as they can maintain a constant flow at flow rates in µL/min ranges.

An additional pump feature found on the more elaborate pumps is external electronic control. Although it adds to the expense of the pump, external electronic control is a very desirable feature when automation or electronically controlled gradients are to be run. Alternatively, this becomes unnecessary when using isocratic methods. The degree of flow control also varies with the expense of the pump. More expensive pumps include such state-of-the-art technology as electronic feedback and multiheaded configurations.

Modern pumps have the following parameters:

- Flow-rate range, 0.01–10 mL/min
- Flow-rate stability, not more than 1% (short term)

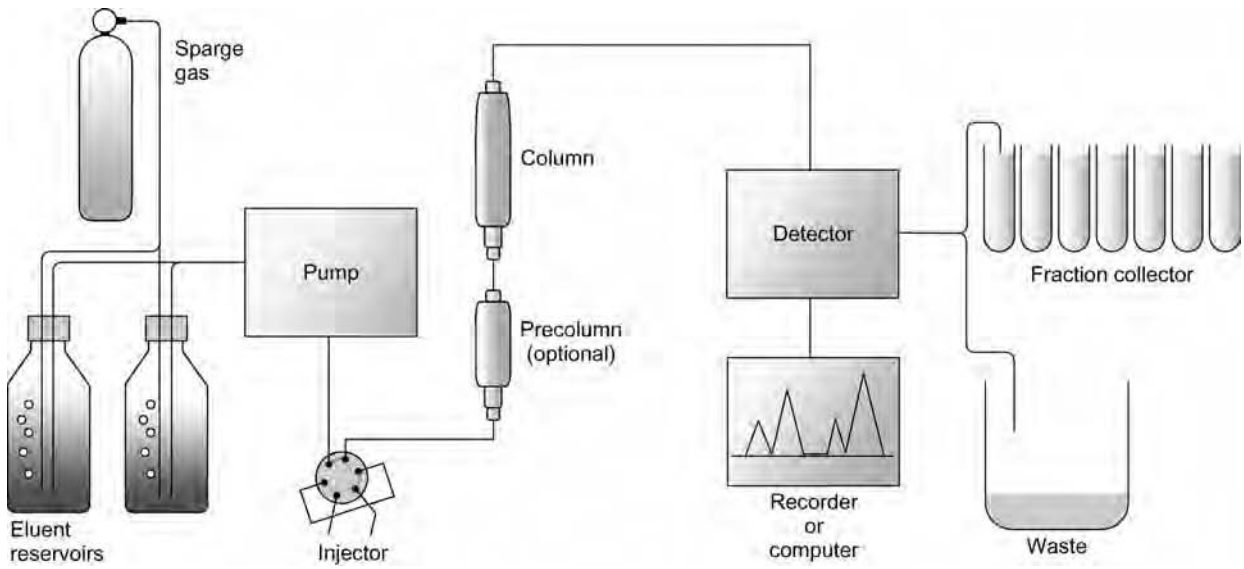

Figure 41.1 A typical HPLC system.

- For size exclusion chromatography (SEC), flow-rate stability should be <0.2%
- Maximum pressure, up to 34 500 kPa (5000 psi).

Injectors

An injector for an HPLC system should provide injection of the liquid sample within the range 0.1–100 mL of volume with high reproducibility and under high pressure (up to 27 600 kPa). The injector should also minimise disturbances to the flow of the mobile phase and produce minimum band broadening. Sample introduction can be accomplished in various ways. In most cases, the injection valve has replaced syringe injection. Valve injection offers rapid, reproducible and essentially operator-independent delivery of a wide range of sample volumes. The most common valve is a six-port Rheodyne valve in which the sample fills an external stainless-steel loop. A clockwise turn of the valve rotor places the sample-filled loop into the mobile-phase stream, which deposits the sample on to the top of the column. These valves can be operated manually or actuated via computer-automated systems. One minor disadvantage of valve injection is that the sample loop must be changed to obtain various sample volumes. However, this is a simple procedure that requires only a few minutes. Automatic sampling devices are incorporated in more sophisticated HPLC systems. These autosamplers have a piston-metering syringe-type pump to suck the preset sample volume into a line and transfer it to a sample loop of adequate size in a standard six-port valve. Most autosamplers are computer controlled and can serve as the master controller for the whole system.

In HPLC, liquid samples may be injected directly and solid samples need only be dissolved in an appropriate solvent. The solvent need not be the mobile phase, but frequently it is wise to choose the mobile phase to avoid detector interference, column–component interference, loss in efficiency or all of these. It is always best to remove particles from the sample by filtration or centrifugation, since continuous injections of particulate material eventually cause blockage of injection devices or columns.

Sample sizes may vary widely. The availability of highly sensitive detectors frequently allows the use of small samples that yield the highest column performance.

Thermostats

It is often advantageous to run ion-exchange, size-exclusion and reversed-phase columns above room temperature and to control precisely the temperature of liquid–liquid columns. Accordingly, column thermostats are a desirable feature in modern HPLC instruments. Temperature variation within the HPLC column should generally be held within $\pm 0.2^{\circ}$C. It is especially important to maintain a constant temperature in quantitative analysis, since changes in temperature can seriously affect peak-size measurement. It is often important to be able to work at higher temperatures for size-exclusion chromatography of some synthetic polymers because of solubility problems. High-velocity circulating air baths, which usually consist of high-velocity air blowers plus electronically controlled thermostats, are the most convenient for HPLC. Alternatively, HPLC columns can be jacketed and the temperature controlled by contact heaters or by circulating fluid from a constant-temperature bath. This latter approach is practical for routine analyses but is less convenient when columns must be changed frequently.

Column switches

These valve devices are used to divert the flow from one column to another within a single HPLC system. Column-switching techniques can be used during method development when several columns are to be evaluated for their efficiency, retention, etc. More recently, the use of column switching has been employed in the on-line analysis of biological matrices. Raw plasma or other sample matrix is injected directly onto the first column. Chromatographic conditions are optimised such that interfering substances are eluted from the column while the analytes of interest are retained. The column switch then diverts the eluent that contains the analytes of interest from the 'clean-up column' onto the analytical column, which then separates the analytes of interest for quantification or characterisation. Another use of column switches is in gradient chromatography for which high throughput is essential. The first column is switched off-line to re-equilibrate to initial conditions, while the second column is brought on-line for the next injection. This conserves valuable analysis time that would otherwise be wasted waiting for the column to re-equilibrate. The most up-to-date information on the use of column switching can be found by searching the current literature.

Detectors

Today, optical detectors are used most frequently in HPLC systems. These detectors pass a beam of light through the flowing column effluent as it passes through a flow-cell. Flow-cells are available in preparative, analytical and micro-analytical sizes The variations in light intensity, caused by ultraviolet (UV) absorption, fluorescence emission or change in refractive index (depending on the type of detector used) from the sample components that pass through the cell, are monitored as changes in the output voltage. These voltage changes are recorded on a strip-chart recorder and are often fed into an integrator or computer to provide retention time and peak-area data.

Most applications in drug analysis use detectors that respond to the absorption of UV radiation (or visible light) by the solute as it passes through the flow-cell. Absorption changes are proportional to concentration, following the Beer–Lambert Law. Flow-cells generally have path-lengths of 5–10 mm with volumes between 5 and 10 µL. These detectors give good sensitivities with many compounds, are not affected by slight fluctuations in flow rate and temperature, and are non-destructive, which allows solutes to be collected and further analysed if desired.

The simplest detectors are of the fixed-wavelength type and usually contain low-pressure mercury lamps that have an intense emission line at 254 nm. Some instruments offer conversion kits that allow the energy at 254 nm to excite a suitable phosphor to give a new detection wavelength (e.g. 280 nm). Variable-wavelength detectors have a deuterium lamp with a continuous emission from 180 nm to 400 nm and use a manually operated diffraction grating to select the required wavelength. Tungsten lamps (400–700 nm) are used for the visible region.

Many organic compounds absorb at 254 nm and hence a fixed-wavelength detector has many uses. However, a variable-wavelength detector can be invaluable to increase the sensitivity of detection by using the wavelength of maximum absorption. This is particularly useful when analysing proteins that absorb at 280 nm, or peptides that are detected commonly at 215 nm. Using a variable-wavelength detector can also increase the selectivity of detection by enhancing the peak of interest relative to interfering peaks.

Eluents must have sufficient transparency at the selected detection wavelength. Buffer salts can also limit transparency. The spectra of some drugs change with pH and the sensitivity and selectivity of an assay can sometimes be controlled by changing the eluent pH. The influence of such changes on the chromatography must also be considered.

Other commonly used detectors include diode array, refractive index (RI), fluorescence (FL), electrochemical (EC) and mass spectrometry (MS) detectors. Infrared (IR) and nuclear magnetic resonance (NMR) spectrometers may also be used as detectors.

Photodiode array detectors

The photodiode array detector (DAD) is an advanced type of UV detector. Depending on the wavelength, a tungsten lamp and a deuterium lamp are used as light sources. The polychromatic light beam is focused on a flow-cell (volume 8–13 µL) and subsequently dispersed by a holographic grating or quartz prism. The spectral light then reaches a chip that contains 100–1000 light-sensitive diodes arranged side by side. Each diode registers only a well-defined fraction of the information and in this way all wavelengths are measured at the same time. Note that, although having more diodes in an array increases the resolution of UV spectra, it lowers the absolute sensitivity since less radiation is absorbed by each individual diode. The wavelength resolution of up-to-date detectors is of the order of 1 nm per diode, with a wavelength accuracy of better than ± 1 nm and a sensitivity below 10^{-4} absorbency

units. All operations of the detector are controlled by computer: correction of fluctuations of the lamp energy, collection of signals (I_λ) from all the diodes, storage of the data of the mobile phase ($I_{0\lambda}$, measured at the start of the chromatogram) and calculation of the absorbance according to the Beer–Lambert Law from I_λ to $I_{0\lambda}$. The number of spectra recorded per second can be chosen from between 0.1 and 10; usually one spectrum per second is optimum with respect to chromatographic resolution and noise. At the end of the run, a three-dimensional spectrochromatogram (absorbance as a function of wavelength and time) is stored on the computer and can be evaluated qualitatively and quantitatively. A detailed description of the DAD operation is given in Huber and George (1993).

Diode array detection offers several advantages. Knowledge of the spectra of compounds of interest enables interfering peaks to be eliminated so that an accurate quantification of peaks of interest can be achieved despite less than optimal resolution. Simultaneous detection at two wavelengths allows calculation of an absorbance ratio. If this ratio is not constant across a peak, the peak is not pure, regardless of its appearance. An additional advantage of the DAD is the subtraction of a reference wavelength. This reduces baseline drift during gradient elution. HPLC-DAD systems linked to libraries of UV spectra are particularly useful in clinical and forensic toxicology in screening for drugs in biological samples (Herzler *et al.* 2003; Pragst *et al.* 2004) and its use in this context is described in detail later.

Refractive index detector

The RI detector is a universal detector, in that changes in RI (either positive or negative) that arise from the presence of a compound in the eluent are recorded. However, it is also the least sensitive detector (as much as 100 times less sensitive than UV detection). RI detectors may be used for excipients such as sugars in pharmaceuticals. Many factors influence RI and must be controlled during separation, such as temperature, eluent composition and pressure. The chromatography is best facilitated using a thermostatically controlled cabinet and high-quality pump to minimise pressure fluctuations.

Fluorescence detector

In FL detectors, the solute is excited with UV radiation and emits radiation at a longer wavelength. Most detectors allow the selection of both excitation and emission wavelengths. There are only a few drugs and natural compounds that have strong natural fluorescence (e.g. ergot alkaloids); however, many drug derivatives are fluorescent compounds. FL detection can offer great selectivity, since excitation and emission wavelengths as well as retention time can be used to identify drugs. Eluents must be chosen carefully when using FL detection. The eluent must neither fluoresce nor absorb at the chosen wavelengths. It is also necessary to consider the pH of the system, in that some drugs show fluorescence only in certain ionic forms.

Electrochemical detectors

EC detectors measure the current that results from the electrolytic oxidation or reduction of analytes at the surface of an electrode. These detectors are quite sensitive (down to 10^{-15} mole) and also quite selective. Two types of detector are available. The coulometric detector has a large electrode surface at which the electrochemical reaction is taken to completion. The amperometric detector has a small electrode with a low degree of conversion. Despite the difference in conversion rate, in practice these two types have approximately the same sensitivity. Eluents for EC detection must be electrically conductive. This is accomplished by the addition of inert electrolytes. EC detection is most easily used in the oxidative mode, as use in the reductive mode requires the removal of dissolved oxygen from the eluent.

`Hyphenated' techniques

The recent development of the so-called hyphenated techniques has improved the ability to separate and identify multiple entities within a mixture. These techniques include HPLC-MS, LC-MS(-MS), HPLC-IR and HPLC-NMR. These techniques usually involve chromatographic separation followed by peak identification with a traditional detector such as UV, combined with further identification of the compound with the MS, IR or NMR spectrometer.

Mass spectrometry as a detector for an HPLC system has gained wide popularity over the past few years. Advances in data systems and the simplification of the user interface have facilitated the ease of use of a mass spectrometer as an HPLC detector. The most common types of mass spectrometers used in HPLC are quadrupoles and ion traps. Tandem mass spectrometers (also called triple–quadrupoles) are also commonly available and are widely used in the pharmaceutical industry for the quantitative analysis of trace concentrations of drug molecules.

The process of mass analysis is essentially the same as in any other mass-spectrometric analyses that utilise quadrupole or ion-trap technology. The unique challenge to interfacing an HPLC system to a mass spectrometer is the need to convert a liquid-phase eluent into a gas phase suitable for mass spectral analysis. Modern mass spectrometers commonly utilise a technique known as atmospheric pressure ionisation (API) to accomplish this. API can be subdivided into electrospray (ion spray) ionisation (ESI) and atmospheric pressure chemical ionisation (APCI). Each technique has its own advantages. ESI is particularly useful for the analysis of a wide variety of compounds, especially proteins and peptides. APCI is also very well suited for the analysis of a large variety of compounds, particularly the less polar organic molecules. Both techniques are very rugged and well suited to pharmaceutical analysis.

An important consideration when using API is the need for volatile mobile phase modifiers in the chromatographic separation. Acetic acid, formic acid, etc., are commonly used as acidic modifiers. Ammonium formate and ammonium acetate salts can also be used when more pH control is required for the separation. Organic modifiers are most often methanol or acetonitrile. One very important issue that must be considered when developing a method using API (electrospray, in particular) is the phenomenon of ion suppression. Co-eluting contaminants compete with the analyte of interest for ionisation, which results in a loss of signal for the analyte of interest. This can be very problematic if extremely small quantities of analyte are to be measured (as is often the case when MS is being used). Additional sample clean-up or adjustment of the chromatography to prevent co-elution of the contaminant is often necessary to correct this problem.

LC-MS(-MS) is commonly used in the pharmaceutical industry and in forensic science to analyse trace concentrations of drug and/or metabolite. MS-MS offers the advantage of increased signal-to-noise ratio, which in turn lowers the limits of detection and quantification easily into the sub ng/mL range. MS-MS is also a very useful technique in the qualitative identification of previously unidentified metabolites of drugs, which thus makes MS-MS a very powerful technique in research laboratories. Several recently published studies have employed MS-MS as a high-throughput analytical technique in the pharmaceutical industry.

HPLC-IR has proved to be an effective method for detection of degradation products in pharmaceuticals. IR provides spectral information that can be used for compound identification or structural analysis. The IR spectra obtained after HPLC separation and IR analysis can be compared with the thousands of spectra available in spectral libraries to identify compounds, metabolites and degradation products. An advantage of IR spectroscopy is its ability to identify different isomeric forms of a compound based on the different spectra that result from alternative locations of a functional group on the compound. Unlike MS, IR is a non-destructive technique in which the original compound is deposited on a plate as pure, dry crystals and can be collected afterwards if desired.

HPLC-NMR is also growing in popularity for the identification of various components in natural products and other disciplines. Although a relatively new hyphenated system, HPLC-NMR has several applications on the horizon. The miniaturisation of the system and the possibility of measuring picomolar amounts of material are both areas currently attracting a large amount of attention. Also, in the future HPLC-NMR systems will be interfaced with other detectors, such as Fourier transform IR and mass spectrometers. This will provide a wide range of possibilities for further applications, which could include the analysis of mixtures of polymer additives and the ability to identify unknowns without first having to isolate them in a pure form.

Data systems

Since the detector signal is electronic, use of modern data-acquisition techniques can aid in the signal analysis. In addition, some systems can store data in a retrievable form for highly sophisticated computer analysis at a later time.

The main goal in using electronic data systems is to increase analysis accuracy and precision, while reducing operator attention. There are several types of data systems, which differ in terms of available features. In routine analysis, where no automation (in terms of data management or process control) is needed, a pre-programmed computing integrator may be sufficient. If higher control levels are desired, a more intelligent device is necessary, such as a data station or minicomputer. The advantages of intelligent processors in chromatographs are found in several areas. First, additional automation options become easier to implement. Second, complex data analysis becomes more feasible. These analysis options include such features as run-parameter optimisation and deconvolution (i.e. resolution) of overlapping peaks. Finally, software safeguards can be designed to reduce accidental misuse of the system. For example, the controller can be set to limit the rate of solvent switching. This acts to extend column life by reducing thermal and chemical shocks. In general, these stand-alone, user-programmable systems are becoming less expensive and increasingly practical.

Other more advanced features can also be applied to a chromatographic system. These include computer-controlled automatic injectors, multi-pump gradient controllers and sample fraction collectors. These added features are not found on many systems, but they do exist and can save much time and effort for the chromatographer.

Columns

Typical HPLC columns are 10, 15 and 25 cm in length and are fitted with extremely small-diameter (3, 5 or 10 μm) particles. The columns may be made of stainless steel, glass-lined stainless steel or polyetheretherketone (PEEK). The internal diameter of the columns is usually 4.0 or 4.6 mm for traditional detection systems (UV, FL, etc.); this is considered the best compromise of sample capacity, mobile phase consumption, speed and resolution. However, if pure substances are to be collected (preparative scale), larger-diameter columns may be needed. Smaller-diameter columns (2.1 mm or less) are often used when HPLC is coupled with MS. The smaller-diameter columns also have the advantage of consuming less solvent because of their lower optimal flow rates. HPLC systems sold today can often be plumbed with narrower tubing diameters to take advantage of the benefits of these smaller column diameters.

Packed capillary microcolumns are also gaining wider use when interfacing an HPLC system to a mass spectrometer and extremely low flow rates (nL/min) are needed to maximise sensitivity for the analysis of proteins and peptides.

Packing of the column tubing with small-diameter particles requires high skill and specialised equipment. For this reason, it is generally recommended that all but the most experienced chromatographers purchase pre-packed columns, since it is difficult to match the high performance of professionally packed HPLC columns without a large investment in time and equipment.

In general, HPLC columns are fairly durable and one can expect a long service life unless they are used in some manner that is intrinsically destructive, such as with highly acidic or basic eluents, or with continual injections of 'dirty' biological or crude samples. It is wise to inject some test mixture (under fixed conditions) into a column when it is new and to retain the chromatogram. If questionable results are obtained later, the test mixture can be injected again under specified conditions. The two chromatograms are compared to establish whether or not the column is still useful.

Column dimensions

The description of column dimensions and assignment of a category to a size vary greatly depending on the reference cited. The following categories were suggested by Rozing *et al.* (2001), and may be more stratified than other categories.

Preparative

Preparative columns generally are of larger bore than analytical columns. Some have inner diameters as large as 100 mm and may have lengths up to 600 mm. These columns are usually packed with packing materials of larger particle size that may range from 10 μm to 50 μm in particle size. The flow rate used with these columns normally exceeds 5 mL/min.

Normal bore

The normal bore for an analytical column can range from 3.9 mm to 5.0 mm inner diameter, but the most common is 4.6 mm. This diameter is the best compromise of sample capacity, mobile phase consumption, speed and resolution. The normal flow rate for this type of column is 1.5–5 mL/min.

Minibore

A minibore or narrow-bore column has an inner diameter of 2.1–3.9 mm. The flow rate for this column size ranges from 500 μL/min to 1500 μL/min.

Microbore

Microbore columns have a 1.0–2.1 mm inner diameter and have flow rates of 100–500 μL/min. These small columns save solvent, are popular when HPLC is interfaced with MS and provide increased sensitivity in situations of limited sample mass.

Capillary

Capillary columns have inner diameters of 50 μm to 1.0 mm and have a typical flow rate of 0.2–100 μL/min. So-called 'nanobore' columns usually fall into the lower end of this size range. The inner surface of these very narrow columns must be extremely smooth. Since this is difficult to obtain with stainless-steel columns, many of these columns are glass-lined stainless steel. Fused-silica columns also fall into this category.

Packing materials

Silica-based packing materials

Silica ($SiO_2 \cdot xH_2O$) is the most widely used substance for the manufacture of packing materials. It consists of a network of siloxane linkages (Si–O–Si) in a rigid three-dimensional structure that contains interconnecting pores. The size of the pores and the concentration of silanol groups (Si–OH) that line the pores can be controlled in the manufacturing process. Thus, a wide range of commercial products is available with surface areas that range from 100 m^2/g to 800 m^2/g and average pore sizes from 4 nm to 33 nm.

Spherical packing materials are now the only types being introduced for analytical HPLC. Irregularly shaped materials are still being used to pack preparative columns. The silanol groups on the surface of silica give it a polar character, which is exploited in adsorption chromatography using organic eluents. Silanol groups are also slightly acidic and hence basic compounds are adsorbed particularly strongly. Unmodified silicas can thus be used with aqueous eluents for the chromatography of basic drugs.

Silica can be altered drastically by reaction with organochlorosilanes or organoalkoxysilanes to give Si–O–Si–R linkages with the surface. The attachment of hydrocarbon chains to silica produces a non-polar surface suitable for RPC in which mixtures of water and organic solvents are used as eluents. The most popular material is octadecylsilica (ODS), which contains C_{18} chains, but materials with C_1, C_2, C_4, C_6, C_8 and C_{22} chains are also available. The latest silica-based bonded phase to be introduced is a long C_{30} phase, which has 24% carbon coverage to make it one of the most retentive phases available.

During manufacture, such materials may be reacted with a small monofunctional silane (e.g. trimethylchlorosilane) to further reduce the number of silanol groups that remain on the surface (end-capping). Recent advances in column technology include multiple reactant end-capping, use of Type B silica (high purity, low trace metals, low acidity) and encapsulating the surface with a polymeric phase. These silicas are often referred to as 'base-deactivated' and are especially useful in RPC in the pH range 4–8 when many basic compounds are partially ionised. Variations in elution order on different commercial packing materials of the same type (e.g. ODS) are often attributed to differences in surface coverage and the presence of residual silanol groups. For this reason it must not be assumed

that a method developed with one manufacturer's ODS column can be transferred easily to another manufacturer's ODS column.

Speciality silicas A vast range of materials have intermediate surface polarities that arise from the bonding to silica of organic compounds that contain groups such as phenyl, cyano, nitro, amino, fluoro, sulfono and diol. There are also miscellaneous chemical moieties bound to silica, as well as polymeric packings, designed to purify specific compounds.

Phenyl Propylphenylsilane ligands attached to the silica gel show weak dipole-induced dipole interactions with polar analytes. Usually this type of bonded phase is used for group separations of complex mixtures. Newer phases have phenyl backbones that allow π–π (stacking) interactions. These are recommended for peptide mapping applications. Amino compounds show some specific interactions with phenyl-modified adsorbents.

Cyano A cyano-modified surface is very slightly polar. Columns with this phase are useful for fast separations of mixtures that consist of very different components. These mixtures may show a very broad range of retention times on the usual columns.

Cyano-columns can be used in both normal-phase and reversed-phase modes of HPLC.

Amino Amino-phases are weak anion exchangers. This type of column is mainly used in normal-phase mode, especially for protein separation and also the selective retention of aromatic compounds.

Fluoro A newer type of silica packing has fluorinated surfaces. This phase is generally more hydrophilic than phases with hydrocarbons of similar chain length. It has increased retention and unique selectivity for halogenated organic compounds and lipophilic compounds.

Sulfono Sulfonic functional groups separate compounds on the basis of hydrophobic interactions. These packing materials allow the isocratic separation of mixtures that normally require gradient elution.

Diols Diols are slightly polar adsorbents for normal-phase separations. These are useful for separating complex mixtures of compounds with different polarities that usually have a strong retention on unmodified silica.

Miscellaneous Cyclodextrins, amylose, avidin, ristocetin, nitrophenylethyl, carbamate, ester, diphenylethyldiamine and Pirkle-type functional groups are all bound to silica packing material to enable enantiomeric separations. These columns are often referred to as chiral columns. Strong ion exchangers are also available, in which sulfonic acid groups or quaternary ammonium groups are bonded to silica. These packing materials are useful for separating proteins. There are also proprietary functional groups added to silica packing materials for a variety of uses. These include petrochemical analysis, environmental analysis, detection of DNA adducts, purification of double-stranded DNA, separation of cationic polymers and separation of nitro-aromatic explosives.

For size-exclusion chromatography, a special type of silica is available that has a narrow range of pore diameters. Size-exclusion chromatography can be complicated by adsorption, but this can be reduced by treating the surface with trimethylchlorosilane.

pH range The useful pH range for silica-based columns is 2–8, since siloxane linkages are cleaved below pH 2 while at pH values above 8 silica may dissolve. However, the pH range may be extended above 8 if a pre-column packed with microparticulate silica is included between the pump and injector to saturate the eluent before it enters the analytical column.

Zirconia packing materials

Zirconia is a metal oxide that is more chemically and thermally stable than silica. It can be used for separations conducted at temperatures as high as 200°C and is unaffected by changes in ionic strength or organic content of the mobile phase. Zirconia packings have a wider pH range and are especially useful for basic separations at pH 10 or higher, where silica gel starts to dissolve. Zirconia can be used for RPC and is extremely stable and efficient through surface modification with polymer or carbon coatings. Other chemical modifications of zirconia produce packing materials suitable for normal-phase or ion-exchange chromatography.

Polymer-based packing materials

Several packing materials based on organic polymers are available. For example, unmodified styrene–divinylbenzene co-polymers have a hydrophobic character and can be used for RPC. Although they traditionally give lower column efficiencies than ODS, this has improved greatly in the past few years. Polymeric materials are best when separation conditions require a mobile phase that can go beyond the upper pH limits of silica gel (usually pH 6.5–7), as they have the advantage of being stable over a wide pH range. Polymeric materials also provide selectivity and retention characteristics different from those of silica-based reversed-phase packings. They also avoid problems associated with residual silanol groups (e.g. peak tailing). Ion-exchange materials of the styrene–divinylbenzene type are also available in which sulfonic acids, carboxylic acids or quaternary ammonium groups are incorporated in the polymeric matrix.

Monolithic columns

Monoliths are chromatographic columns that are cast as continuous homogeneous phases rather than packed as individual particles, creating porous rods of polymerised silica that are mechanically stable. Monolithic phases have flow-through pores with macroporosity ($\sim$2 µm) and mesopores, which are diffusive pores with an average pore diameter that can be controlled. To create the column, a silica gel polymer is formed, which, after ageing, is dried into the form of a straight rod of highly porous silica with the bimodal pore structure. The rod is then encased (or clad) in a PEEK cover, ensuring that there is absolutely no void space between the silica and PEEK material. The pore structure yields a very large internal surface area and ensures high-quality separations. In addition, the high porosity of the column means that very high flow rates can be used with lower pressures. This enables separations in a fraction of the time needed when using a column with conventional packing materials.

Recently, a polymeric monolithic column was introduced. It contains a poly(glycidylmethacrylate–ethyleneglycol-dimethacrylate) co-polymer that has functional groups added to make various types of stationary phases.

Maintenance

An effective maintenance programme is essential to keep an HPLC system in proper working order. The maintenance programme should include preventive, periodic and necessary repairs of the HPLC system. This programme is essential to ensure that all the components of the system are in proper working condition. In this section, the general maintenance of columns, pumps, injection valves and detectors is discussed. For information on the functions and uses of these components, refer to the earlier sections of this chapter.

It is always recommended that the maintenance guidelines provided with the system should be consulted to ensure compliance with the manufacturers' suggestions. This guide should be used whenever maintenance is required.

Columns

The column is an essential key to good chromatography and its maintenance ensures proper functionality of the HPLC system. High back-pressures, poor resolution, non-uniform peak symmetry and decreasing retention times are several signs that may indicate that the column is in need of repair or is failing.

Column degradation is inevitable, but a column's life can be prolonged if it is maintained properly. Flushing of a column with a mobile phase of high elution strength after sample runs is essential. When a column is not in use, it should be capped to prevent it from drying out. Particulate samples should be filtered and, when possible, a guard column should be utilised. Column regeneration can instil some life into a column, but preventive maintenance is the vital key to prevent premature degradation.

Pumps

The pump forces the mobile phase through the HPLC system. A steady pump pressure is needed to ensure reproducibility and accuracy. Inability to build pressure, high pressures or leakage may indicate that the pump is not functioning correctly.

Pumps are typically known to be robust, but adequate maintenance must be performed to maintain that characteristic. Good maintenance practice includes replacing components, such as inlet check valves, outlet check valves, frits, pump seals and piston rods, on a routine schedule, based on the amount of usage. Proper maintenance of the pump system minimises downtime.

Injection valves

Injection valves play the role of directing injected volumes into the mobile phase, where they then travel on to the column. Proper valve function is a necessity to ensure reproducibility between injections. The symptoms of injection valve failure are low pump pressure, leakage or inadequate inert gas pressure to the switch valve.

The seals of the injection valve may eventually falter, after numerous injections. Replacement of these seals is necessary to maintain system reproducibility with respect to injections made.

Detectors

Detector maintenance is generally performed as needed. Baseline drift, erratic baseline and decreasing response may be indicators of a failing detector.

A malfunctioning or contaminated flow cell can also cause baseline drift. The cell should be flushed regularly with water to remove salts when using mobile phases of high salt concentration. An organic mobile phase of high elution strength should be used to remove any organic residue that may remain in the cell. An erratic baseline can occur because of an air bubble in the flow cell. Increasing the flow rate may push the bubble out of the cell. Decreasing responses can also result from a decrease in lamp intensity.

Eluent preparation

The quality of solvents and inorganic salts is an important consideration. Soluble impurities can give noisy baselines and spurious peaks or can build up on the surface of the packing material, eventually changing chromatographic retention. Furthermore, the eluate may need to be collected for further experimentation and all contamination must be avoided. In addition, particulate matter should be removed, otherwise pump filters, frits and tubing can become blocked.

There is now commercially available a wide range of HPLC-grade solvents that are free from particulate matter, have low residues on evaporation and have guaranteed upper limits of UV-absorbing and fluorescent impurities. However, if a detector is not to be operated at its maximum sensitivity, analytical grade solvents may be used. A general rule of thumb is to use the highest purity of solvent that is available and practical depending on the particular application.

Air dissolved in the mobile phase can lead to problems. The formation of a bubble in a pump head usually reduces or stops eluent flow, while bubbles formed in the detector can give spurious peaks. One commonly used remedy is to degas the eluent using an in-line vacuum chamber. HPLC solvents are pumped from the reservoirs into a vacuum chamber in line with the HPLC eluent flow. This method ensures continuous and efficient degassing of the mobile phase. Vacuum degassing can also be performed off-line by applying a weak vacuum to the mobile phase reservoir while sonicating. Off-line techniques do not offer the advantage of continuous degassing throughout the analysis. Eluents can also be degassed by purging with helium, which has a very low solubility and drives the air out. This technique can be performed on-line and be controlled by the HPLC system, or off-line. Care must always be taken when degassing eluents that contain volatile components to avoid changing the composition.

It is convenient to prepare eluents as volume-plus-volume mixtures of solvents (i.e. the volume of each solvent is measured separately and then they are mixed). Volume changes can occur when solvents are mixed (e.g. methanol and water show a contraction in volume), which must be remembered if the volume of only one solvent is measured and the second solvent is added to make up to volume.

True pH values can be measured only in aqueous solutions and any measurements made with a pH meter in aqueous–organic solvents should be described as 'apparent pH'. In general, the apparent pH of a buffer solution rises as the proportion of organic solvent in the aqueous mixture increases. When an eluent is prepared it is usually best to dissolve the required buffer salts in water at the appropriate concentrations, adjust the pH and then mix this solution (v/v) with the organic solvents.

Separation techniques

Isocratic

When the mobile-phase composition does not change throughout the course of the run, it is said to be isocratic. A mixed mobile phase can be delivered at a constant ratio by the pumps themselves or the solvent mixture can be prepared prior to analysis and pumped through a single reservoir. This is the simplest technique and should be the method of first choice when developing a separation.

Gradient elution

HPLC can be performed with changes in composition over time (gradient elution). The elution strength of the eluent is increased during the gradient run by changing polarity, pH or ionic strength. Gradient elution can be a powerful tool to separate mixtures of compounds with widely different retentions. A direct comparison can be drawn with temperature programming in gas chromatography (GC; see Chapter 40).

Eluent gradients are usually generated by combining the pressurised flows from two pumps and changing their individual flow rates with an electronic controller or data system, while maintaining the overall flow rate constant. Alternatively, a single pump with a low sweep volume can be used in combination with a proportioning valve, which controls the ratio of two liquids that enter the pump from two liquid reservoirs. Equipment and data systems that allow the gradient to take almost any conceivable form (e.g. step gradients, concave and convex gradient curves) are commonly available. The gradient can be programmed to return the system to the original eluent composition for the next analysis.

While most, if not all, commercially available pumps are capable of performing reliable gradient elutions, there are some potential difficulties. The technique can be very time-consuming, as the column must be reconditioned with the initial eluent between runs. This drawback can be overcome by utilising a column-switching apparatus (see earlier in this chapter). In addition, drifting of the detector response and the appearance of spurious peaks that arise from solvent impurities may occur. While isocratic elution is usually favoured over gradients for simplicity, gradient elution can be a very important and useful technique in the separation of complex mixtures.

Recently, the use of 'fast gradient' separation has enabled the implementation of high-throughput analysis in laboratories with a high sample load.

Derivatisation

Derivatisation involves a chemical reaction that alters the molecular structure of the analyte of interest to improve detection and/or chromatography. In HPLC, derivatisation of a drug is not usually necessary to achieve satisfactory chromatography. This applies to compounds of all polarities and molecular weights and is an important advantage of HPLC over GC. Derivatisation is used to enhance the sensitivity and selectivity of detection when available detectors are not satisfactory for the underivatised compounds. Both UV-absorbing and fluorescent derivatives have been used widely. UV derivatisation reagents include *N*-succinimidyl-*p*-nitrophenylacetate (SNPA), phenylhydrazine and 3,5-dinitrobenzoyl chloride (DNBC), while fluorescent derivatives can be formed with reagents such as dansyl chloride (DNS-Cl), 4-bromomethyl-7-methoxycoumarin (BMC) and fluorescamine. The characteristics of a good derivative in HPLC are similar to those in GC (stability, low background, convenience, and so on).

Derivative formation can be carried out before the sample is injected on to the column (pre-column) or by on-line chemical reactions

between the column outlet and the detector. Such post-column reactions generally involve the addition of reagents to the eluent. With pre-column derivatisation there are no restrictions on reaction conditions (e.g. solvent, temperature) and a large excess of reagent can be used, as this can be separated from the derivatives during the chromatography. The major drawback of pre-column reactions is the need to obtain reproducible yields for accurate quantification, which is best achieved when the reactions proceed to completion. Furthermore, it is important that the products of pre-column derivatisation reactions be characterised fully. With post-column derivatisation, the reaction is well controlled by the flow rates of eluate and reagents, temperature, etc. Hence, it is less necessary for the reaction to proceed to completion or even for the chemistry to be understood as the system is calibrated by the injection of known quantities of the reference standards. A much more detailed discussion can be found in Snyder *et al.* (1997).

Chiral separation

Separation of compounds by chiral chromatography began in the early 1980s. At that time, the separation of enantiomeric compounds was one of the most challenging problems in chromatography. However, in recent years more than 100 chiral columns have been made available. These columns are based on several different approaches to solving the many enantiomeric separation problems. Chiral columns are used in a variety of different applications that range from pharmacokinetic and pharmacodynamic studies to measuring enantiomeric impurity of amino acids.

Chiral stationary phases (CSPs) are designed to separate optical isomers. The use of these columns provides an efficient and economical way to separate optical isomers by HPLC. CSPs are used both for resolving optical isomers to determine enantiomeric purity and for isolating enantiomerically pure compounds.

Figure 41.2 shows the separation of enantiomers of flurbiprofen. Enantiomers were separated on a CHIRALPAKbAD-RHTM column using methanol–0.1% trifluoroacetic acid (TFA) as the mobile phase. This separation was performed at 15°C to improve selectivity.

The columns can be categorised according to two criteria: class and origin. The class category is based on the structural properties of the chiral selector. The category is made up of five different column types: macrocyclic, polymeric, π–π associations, ligand exchange, miscellaneous) plus hybrids. The macrocyclic chiral columns have had the largest impact on analytical enantiomeric separations. The origin category separates columns according to their source and classifies them into three types: naturally occurring, semisynthetic and synthetic chiral selectors.

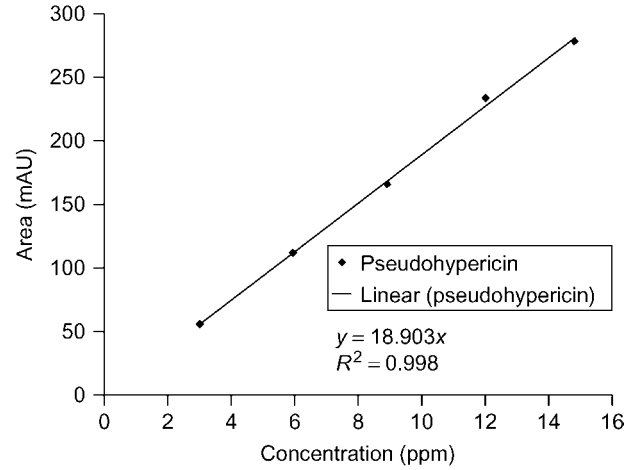

Figure 41.3 Example of a calibration curve for pseudohypericin.

High-speed/high-temperature HPLC

The speed of a chromatographic method directly affects the economy and operating cost of the separation. High-speed HPLC is accomplished by using short microbore columns packed with small particles (3 µm). In addition, the use of higher temperatures increases the speed of HPLC separations through the 5- to 10-fold decrease in eluent viscosity upon an increase of the eluent's temperature from 25°C to 200°C. High-temperature/high-speed HPLC is not universally useful because of several limitations. Silica-based stationary phases are unstable in aqueous media at temperatures above 50–60°C. Some detectors are also not able to tolerate high temperatures.

Quantitative analysis

The quantification methods incorporated in HPLC derive mostly from GC methods. The basic theory for quantification involves the measurement of peak height or peak area. To determine the concentration of a compound, the peak area or height is plotted versus the concentration of the substance (Figure. 41.3). For peaks that are well resolved, both peak height and peak area are proportional to the concentration. Three different calibration methods, each with its own benefits and

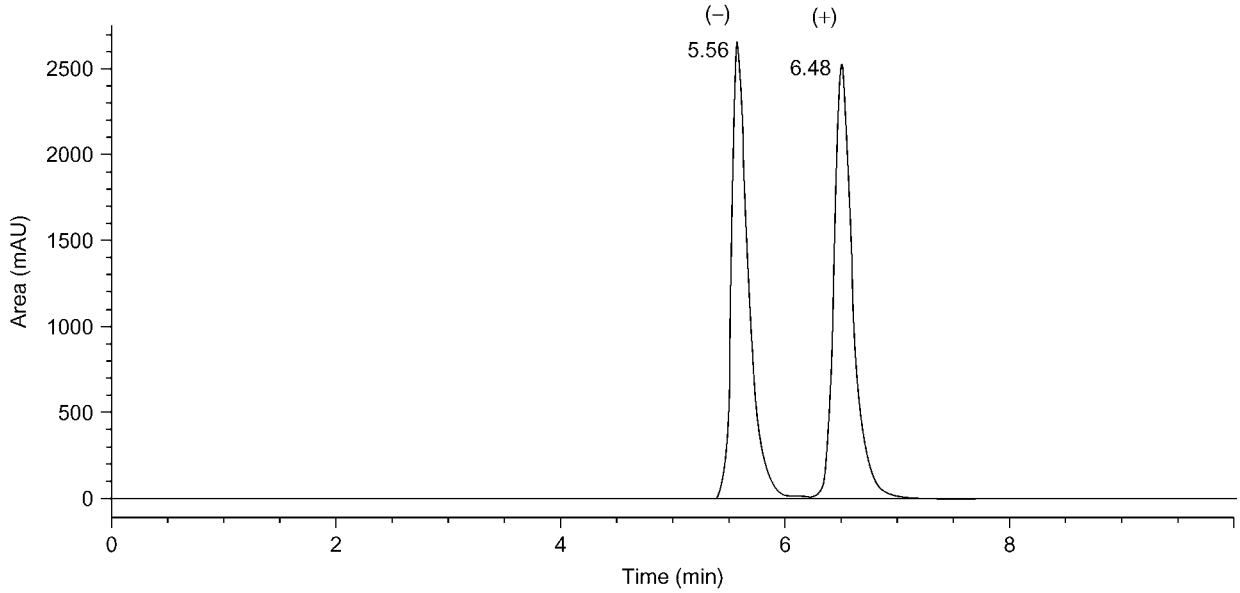

Figure 41.2 Chiral separation of the (+) and (−) enantiomers of flurbiprofen.

limitations, can be employed in quantitative analysis: external standard, internal standard and the standard addition method.

External standard

The external standard method is the simplest of the three methods. The accuracy of this method is dependent on the reproducibility of the injection of the sample volume. To perform this method, a standard solution of known concentration of the compound of interest is prepared. A fixed amount, which should be similar in concentration to the unknown, is injected. Peak height or area is plotted versus the concentration for each compound. The plot should be linear and go through the origin. The concentration of the unknown is then determined according to Equation (41.3).

$$\text{Concentration}_{\text{unknown}} = \left(\frac{\text{Area}_{\text{unknown}}}{\text{Area}_{\text{known}}}\right) \times \text{Concentration}_{\text{known}} \qquad (41.3)$$

The calibrator concentrations should cover the range of the likely concentration in the unknown sample. Only concentrations read within the highest and lowest calibration levels are acceptable. Concentrations read from an extrapolated regression line may not be accurate. This applies to all the quantification methods.

Internal standard

Although each method is effective, the internal standard method tends to yield the most accurate and precise results. In this method, an equal amount of an internal standard, a component that is not present in the sample, is added to both the sample and the standard solutions. The internal standard selected should be chemically similar to the analyte, have a retention time close to that of the analyte and derivatise in a similar way to the analyte. For biological samples, the internal standard should extract similarly to the analyte without significant bias towards the internal standard or the analyte. Additionally, it is important to ensure that the internal standard is stable and that it does not interfere with any of the sample components. The internal standard should be added before any preparation of the sample so that extraction efficiency can be evaluated. Quantification is achieved by using ratios of peak height or area of the component to the internal standard (Equation 41.4).

$$\text{Concentration}_{\text{unknown}} = \left(\frac{\text{Area}_{\text{internal standard in known}}}{\text{Area}_{\text{internal standard in unknown}}}\right) \times \left(\frac{\text{Area}_{\text{unknown}}}{\text{Area}_{\text{known}}}\right) \text{Concentration}_{\text{known}} \qquad (41.4)$$

Standard addition method

The third method for quantification is the standard addition approach. This is especially useful when there is a problem with interference from the sample matrix, since it cancels out these effects. To perform this quantification, the sample is divided into two portions, so that a known amount of the analyte (a spike) can be added to one portion. These two samples, the original and the original-plus-spike, are then analysed. The sample with the spike shows a larger analytical response than the original sample because of the additional amount of analyte added to it. The difference in analytical response between the spiked and unspiked samples results from the amount of analyte in the spike. This provides a calibration point to determine the analyte concentration in the original sample. The method has a drawback if only a small volume of sample is available. Equation (41.5) is used for this method.

$$\text{Amount}_{\text{unknown}} = \frac{\text{Area}_{\text{unspiked}}}{\text{Area}_{\text{spiked}}\text{Area}_{\text{unspiked}}} \times \text{Amount}_{\text{spiked}} \qquad (41.5)$$

Validation

It is important to use a validated HPLC method when carrying out analyses. Typical analytical characteristics evaluated in an HPLC validation may include precision, accuracy, specificity, limit of detection, limit of quantification, linearity and range. Some appropriate suggestions for LC validation for postmortem and body fluids samples are published in the *SOFT/AAFS Forensic Toxicology Laboratory Guidelines* (www.soft-tox.org). It is important to consider the guidelines of the US Food and Drug Administration (FDA; www.fda.gov/cder/guidance) and US Pharmacopoeia (USP; www.usp.org) when validating HPLC methods used for pharmaceutical samples. USP 24 section <1225> provides guidance on the validation of compendial methods including definitions and determination. International Conference on Harmonisation (ICH) guidelines (www.ich.org) provide suggestions concerning the validation of pharmaceuticals. Valuable sources of information providing regulatory guidance may be found on the FDA website at www.fda.gov/cder/guidance.

System suitability tests evaluate the function of the overall HPLC system. This includes all parts that make up a system, such as the instrument, reagents, packing material, details of the procedure and even the analyst. These tests imply that all the components of a system constitute a single system of which the overall function can be tested. These tests are very valuable and have been accepted in general application because reliable and reproducible chromatographic results are based on a wide range of specific parameters.

Most laboratories have a standard operating procedure that outlines the specifications of running a systems suitability test. For example, in pharmaceutical analysis at least five replicate injections should be made of a single solution that contains 100% of the expected active and excipient ingredient levels. The peak response is measured and the standard deviation of that response should not exceed the limit set by the testing monograph or 2%, whichever of the two is the lower. Using the USP method, the tailing factors of the analytes should be determined. The values should not exceed 2.0. Peak-to-peak resolutions are also determined by using the USP calculations, and the value should not be lower than 1.5. The system test should be used to ensure the quality of the data and of the analysis.

Ultra-high performance liquid chromatography

Analytical laboratories are consistently called upon to reduce turnaround times without affecting quality. In the forensic laboratory, decreased analytical time translates into a quicker dissemination of data to medical examiners and law enforcement agencies. For the pharmaceutical testing laboratory, demands for greater efficiency have spread industry wide, from drug discovery to clinical trials. There are many difficult applications dealing with the separation of a high number of analytes in complex sample matrices, such as proteomics, genomics and metabolomics. These difficult analyses require a high degree of efficiency and resolution within acceptable analysis times. A faster analysis potentially assists with moving a new drug out into the market in a more timely manner.

For decades, HPLC has been an integral component of analytical laboratories involved in comprehensive drug testing. Whether it is used to quantify active ingredients and/or excipients in the pharmaceutical laboratory, for pharmacokinetic studies or analysing for drugs in biological fluids in the forensic arena, HPLC continues to be a mainstay for the quantitative analysis of drugs. Newer techniques such as ultra-high performance liquid chromatography (UHPLC) have been developed to provide faster separation without compromising data quality. Improvements in detectors, column chemistries and hardware provide faster separations and data analysis without compromising data quality. This technique is known by many general names including ultra-high performance liquid chromatography or ultra-high pressure liquid chromatography (both of which are called UHPLC), high-speed liquid chromatography and fast liquid chromatography. Instrument manufacturers have come up with their own names for this technique. Examples include: Ultra Performance

Liquid Chromatography (UPLC; Waters); Rapid Resolution LC System (RRLC; Agilent); Xtreme Liquid Chromatography (X-LC; Jasco); Accela High Speed Chromatography System (Thermo). Whatever its name, this technology has advantages and disadvantages that should be considered by those laboratories thinking about adding it to their analytical capabilities.

In liquid chromatography, packing columns with small particles is a recognised method for simultaneous improvement of efficiency, optimum velocity and mass transfer. Martin and Synge (1941) proposed the use of smaller particles and high pressure differences across the entire column length as a means of achieving greater column efficiency. Halasz *et al.* (1975) demonstrated that the fastest HPLC separations could be obtained by using the smallest particle sizes. In recent years, particle sizes in columns have decreased from 10 µm to 2.5 µm. The advantages of 1–2 µm particles have been to increase sensitivity and column efficiency while reducing analysis time. This evolution of particle size has been governed by the van Deemter equation, which describes the relationship between linear velocity (flow rate) and plate height (HETP or column efficiency). The design and development of smaller particles presented a number of challenges including poor loading capacity and retention due to low surface area, limited pH ranges and poor mechanical strength.

The van Deemter equation (van Deemter 1956) indicates that the most efficient particle size is 1.7 µm at a high linear velocity. This relationship shows that, as particle size decreases, the flow rate (or linear velocity) required to attain maximum resolution increases. The increase in flow rate results in a proportional increase in back pressure, i.e. smaller particles require much higher operating pressures. The pressure required for percolating mobile phase through a column packed with small particles can be prohibitive for standard HPLC hardware. Halving the particle diameter results in a four fold increase in pressure. The significant increase in back pressure presented a challenge to conventional HPLC instrument systems. To address the increasing pressure requirements, MacNair *et al.* (1997) introduced UHPLC to overcome the pressure limitations that small particles impose on conventional pumping systems. This research showed that the pressures required to run at optimum flow rates are of the order of 20 000 psi, which translates into analysis times of less than 10 minutes.

The improved resolution with UHPLC may be optimised by reduction in particle size and bridging of the column packing. This characteristic is important in terms of sample throughput and sensitivity improvement. Resolution can be enhanced by the use of longer columns packed with small particles, although optimisation of mobile phase flow rate is not always possible. Relative to isocratic mode, UHPLC generates higher resolution separations in gradient mode. The maximum peak capacity for a 3-hour gradient is also substantially enhanced by a significant reduction of the column dead time in UHPLC compared with traditional approaches.

Some drawbacks of UHPLC include the need for a dedicated instrument, with optimised high-back-pressure pumps and an injector, acquisition rate of the detector, injection cycle time, dwell volume and system dead volume. At the high pressures necessary for UHPLC, columns may age faster if they are run routinely at greater than 12 000 psi. Intracolumn temperature gradients due to back pressure generated by frictional heat can also be problematic. This issue, especially critical for the 4.6 mm i.d. columns and/or when the pressure is close to or higher than 1000 bar, can usually be resolved by reducing the column inside diameter to 1.0–2.1 mm. The internal diameters of the connection tubing are very small (0.004–0.02 inch) and are less forgiving than those of traditional systems.

Applications

UHPLC is rapidly becoming an integral part of analytical laboratories from many disciplines. The benefits of decreased analysis time without sacrifice of quality have attracted the attention of contract pharmaceutical, forensic and research laboratories. Scientists have used this technology to improve the speed of conventional HPLC separations or to develop completely new UHPLC methods.

Method development in the pharmaceutical laboratory is often tedious and time-consuming. Optimisation of the various sample handling protocols and instrument parameters can be a daunting task. UHPLC technology has decreased method development time significantly. Many laboratories use UHPLC to rapidly develop an analytical method, then transfer, or scale, the analysis to conventional HPLC conditions for routine use. The theory behind scaling of chromatographic methods involves the use of mathematics to transform the UHPLC chromatographic conditions to conventional HPLC parameters.

The drug discovery process in the pharmaceutical industry continues to evolve, with complex drugs, metabolic profiles and extraction matrices requiring new technologies in the analytical laboratories to maintain progress. Toxic drug metabolites, for example, must be identified as early as possible in the discovery process so that poor compounds will not continue down the path to production. The rapid turnaround time, sensitivity and specificity of UHPLC coupled with mass spectrometry have provided researchers with a tool to identify potential problems quickly.

The use of UHPLC is not confined to the pharmaceutical industry. The forensic and environmental arenas have benefited from it as well. Recent research has shown UHPLC, coupled with mass spectrometry (UHPLC-MS), to be a rapid and sensitive method for the simultaneous detection of amfetamine and amfetamine-like stimulants, cocaine and metabolites, and the major metabolite of Δ^9-tetrahydocannabinol in surface water and urban wastewater (Bijlsma *et al.* 2009). Additional forensic research has also demonstrated the usefulness of UHPLC-MS for the detection of drugs of abuse in urine for doping control (Ventura *et al.* 2008; Badoud *et al.* 2010). Surface water and wastewater have been analysed for the presence of antibiotics using UHPLC and quadrupole time-of-flight mass spectrometry (Ibanez *et al.* 2009).

Saving time and money without sacrificing quality is a goal of any analytical laboratory. UHPLC continues to grow in popularity owing to the multiple analytical advantages described above. The expanding number of vendors of both instrumentation and column technology is evidence that UHPLC is becoming a valuable tool in a variety of analytical disciplines.

New emerging trends

Several new trends, including hyphenated systems and micro-HPLC, are discussed in other sections of this chapter. Two other trends that deserve mention, denaturing high performance liquid chromatography and ion chromatography, are described below.

Ion chromatography

Ion chromatography (IC) is a branch of liquid chromatography that has several unique characteristics to meet the needs of ion analysis. The eluents, or mobile phases, used are often acid, alkaline or high-saline solutions. The high-pressure pump used should consist of an entirely non-metallic flow path in order to deliver these eluents reliably without corrosion issues. The ion-exchange columns provide unique ion separation capabilities, and a conductivity detector is the primary detection device used for IC. Other detectors, such as ultraviolet/visible light absorbance (UV/VIS) and electrochemical detectors are often used as well. Like all forms of liquid chromatography, IC includes a pump, injection valve, separation column and detector. Figure 41.4 is a representation of a liquid chromatographic system used to determine ions. The hardware used to perform IC is similar to that used for HPLC, although it is typically made of inert polymer as corrosive acid and base solutions are frequently used in IC. A sample introduction device and the means to record the output signal are also required.

While a number of separation and detection set-ups can be used in IC, the most commonly used approach is the combination of an ion-exchange separation with suppressed conductivity detection, i.e. the concept first described by Small, Stevens and Bauman (Small *et al.* 1975). In an ion-exchange separation, ionic analytes are separated by virtue of their electrostatic attraction to a stationary phase that carries immobilised ion-exchange sites. The ion-exchange site carries a charge that is opposite to the charge on the analyte. For example, anions are

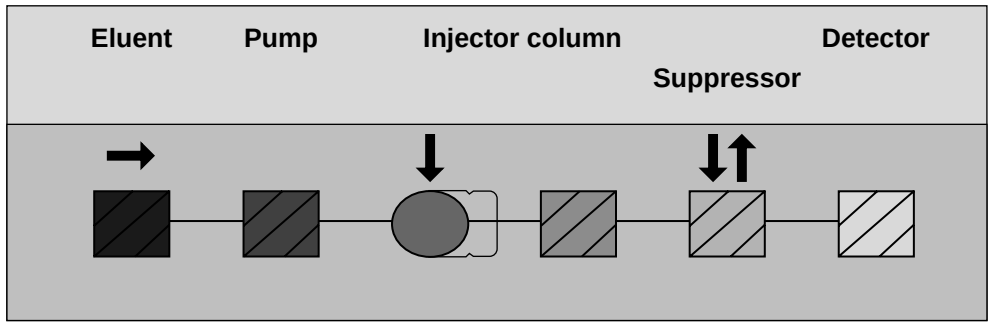

Figure 41.4 Elements of a liquid chromatography system used to determine ions.

separated using a column that carries positively charged ion-exchange sites. The more strongly an analyte interacts with the column, the longer the retention time. The relative affinity of the ion-exchange site for ions is dependent on the charge, charge density and hydrophobicity of the eluent and the analyte ion. Analytes are identified by their retention time and quantitatively determined (primarily) by peak area.

Components of an ion chromatograph

Eluent The function of the eluent (mobile phase) is primarily to provide counterions for the ion-exchange process. Secondary functions include providing a stable environment for the sample ions and providing kinetic flow of the sample ions through separation and detection. The most common eluents used in ion chromatography are sodium or potassium hydroxide or sodium or potassium carbonate/bicarbonate for anion determinations. For cations, methanesulfonic acid (MSA), sulfuric acid or nitric acid is most commonly used.

Pump The pump delivers liquid eluent to the resin-packed column. Modern pumps must deliver a minimum of detector noise while operating over a wide flow and pressure range. Because of the possibility of using strong acid and base eluents, the pump's wet components and system tubing are constructed from PEEK.

Injector A fixed length of tubing of known internal diameter constitutes the 'sample loop'. The sample loop can be filled either manually or by an autosampler. A high-pressure six-port or ten-port two-way valve is switched in-line into the flowing eluent stream and the loop contents are carried on to the ion-exchange guard and separator column.

Separation column (and guard column) The separation column provides stable support for stationary phase ions that act as active sites in the dynamic ion-exchange process. The active sites compete with the counterions in the mobile phase for retention of analytes. The choice of column is key to the separation of important analytes, capacity to retain any given sample component and analyte peak efficiency, i.e. minimal band broadening in the ion chromatographic separation process. The sample ions are separated into discrete bands as they move through the column. Different ions migrate at different rates, depending on their relative affinities for the resin. A guard column of shorter length serves to protect the separation column. It is typically packed with the same resin as the separation column or a neutral (non-functionalised) resin to remove possible hydrophobic contaminants.

Conductivity detector A conductivity detector measures the electrical conductance of analyte ions as they pass through a conductivity cell. Conductivity detection is the primary method of detection used in IC. The detector produces a signal depending on a chemical or physical property of an analyte. For optimal results, a detector must exhibit high sensitivity, low noise and a wide linear range. The conductivity detector is ideal for small inorganic and organic ions.

Chemical suppression technology is the breakthrough in IC that has allowed it to become a preferred technique for ions. The suppressor is a post-column reactor specific to IC, which allows more sensitive conductivity detection. Conductivity detection is a universal (bulk property) detector for IC as all ions are conductive. Chemical suppression provides a significant improvement in signal-to-noise ratio, making ion chromatography a truly practical tool.

Figure 41.5 illustrates the effect of chemical suppression in a typical ion-exchange separation of anions with conductivity detection. The effluent from the analytical column is monitored by conductivity as it passes immediately from the column; a chromatogram similar to that

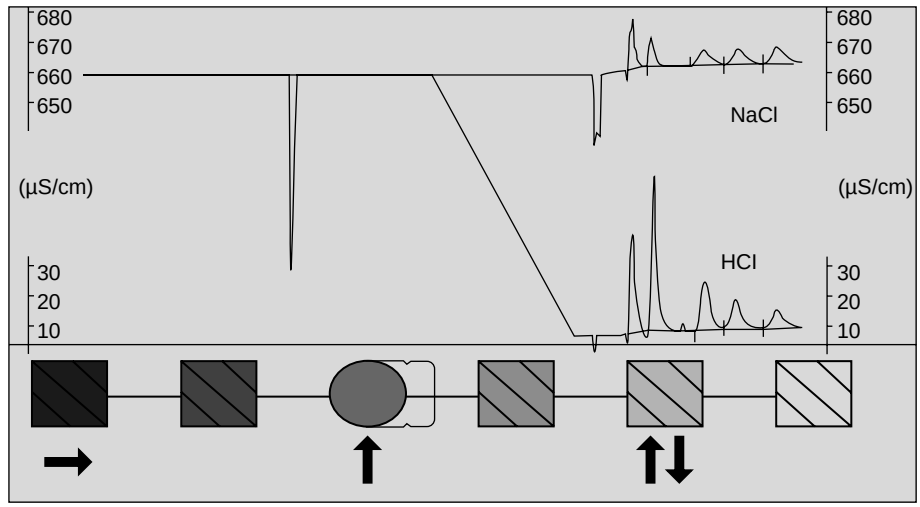

Figure 41.5 Effect of chemical suppression in ion-exchange chromatography of anions with conductivity suppression.

shown in the upper right area of the figure would be obtained. This chromatogram illustrates a very high background from the conductive eluent, a large counterion peak at the column void volume and analyte peaks with low response. In contrast, by passing the column effluent through a chemical suppressor, the chromatogram shown at the bottom is obtained. The chemical suppressor exchanges cations in the eluent for hydronium ions. The source of hydronium used in IC systems is dilute sulfuric acid. The hydronium ions then neutralise the carbonate ions in the eluent, resulting in fluoride, chloride and sulfate ions in carbonic acid, which is slightly dissociated resulting in typical background detector signals of 1–5 μS/cm. Counterions of the analytes, which are cationic and thus elute in the void, are also removed. This accounts for the absence of the large system peak after suppression. A third advantage is that the anions are now paired with hydronium counterions, resulting in a much larger response for these ions since they enter the conductivity detector cell in a more conductive form. The detector response for a peak using conductivity detection is proportional to the sum of the equivalent conductivity of the anion and its associated cation. The equivalent conductivities for anions and cations are typically between 35 and 80 S cm^2/mol. The hydronium ion, H_3O^+, with 350 S cm^2/mol and hydroxide ion (regenerants for cation separations) with 198 S cm^2/mol provide the only exceptions.

The use of suppression in IC results in an increase in detector response as much as 10-fold for anion methods. Suppressor design and performance have expanded the range of IC methods from packed-bed batch suppression to membrane-based continuous suppression. The first chemical suppressor was a batch suppressor and, while it delivered good signal-to-noise ratio, it had to be frequently removed from the chromatographic separation stream for regeneration. With modern technologies, automated micro-packed column suppressors automate the regeneration and rinsing of the suppressor channels. Figure 41.6 illustrates the analysis of anions using suppressed ion chromatography with conductivity detection.

Other detectors for ion chromatography

Amperometric detection Some inorganic and organic ion determinations are not well suited for conductivity detection. Amperometric detection is used to measure the current or charge resulting from oxidation or reduction of analyte molecules at the surface of a working electrode. For analytes that can be oxidised or reduced, detection is sensitive and highly selective since many potentially interfering species cannot be oxidised or reduced and therefore are not detected. When a single potential is applied to the working electrode, the detection method is DC amperometry. Pulsed amperometry (PAD) employs a repeating sequence of potentials. Separation of carbohydrates by high-pH anion exchange followed by PAD detection is used for the detection of wood sugars, mannitol, fucose, arabinose, rhamnose, galactose, glucose, sucrose, xylose, mannose, fructose and ribose (Cheng, Kaplan 2003). This use of IC is for evaluating pulping and biomass conversion operations.

Ultraviolet/visible light absorbance Commonly used in HPLC, UV/VIS is also used in IC as a detection device complementary to conductivity detection for the identification and quantification of aromatic and heterocyclic molecules, transition metals and certain inorganic ions. UV/VIS detection used in tandem with conductivity detection quantifies trace level analytes in the presence of interfering high-concentration ions by measuring the amount of light that they absorb at a specific wavelength. An example is measurement of nitrite ions in the presence of high chloride ions (high-saline solution) (Miura, Hamada 1999). UV/VIS detection using post-column reaction chemistry permits selective measurement of transition metals (Atanassova *et al.* 2004).

Mass spectrometry Combining IC separations with mass spectrometry detection using standard IC conditions improves MS performance because the suppressor removes high-ionic-strength eluents. IC with MS detection offers high specificity of analytes by avoiding co-elution interferences and background interferences. It is also possible to quantify target analytes and identify unknowns.

Examples of ion chromatography applications in the pharmaceutical industry

- Sodium in buffered nasal drops
- Chloride in dextrin injection (USP)
- Cations in artificial saliva
- Neomycin by pulsed amperometric detection
- Triethylamine in cefixime (USP method)
- Betanacol chloride – Assay (BP method)
- Chloride and sulfate in gabapentin
- Sodium in basalazide
- Acetate in pantoprazole sodium
- 2-Aminoethanol in pantoprazole sodium
- Residual TFA in bulk drugs
- Molybdenum in tinidazole
- Tetrafluoroborate in antibiotics
- Ethyl sulfate in indinavir sulfate (IP method with Supp. 3)

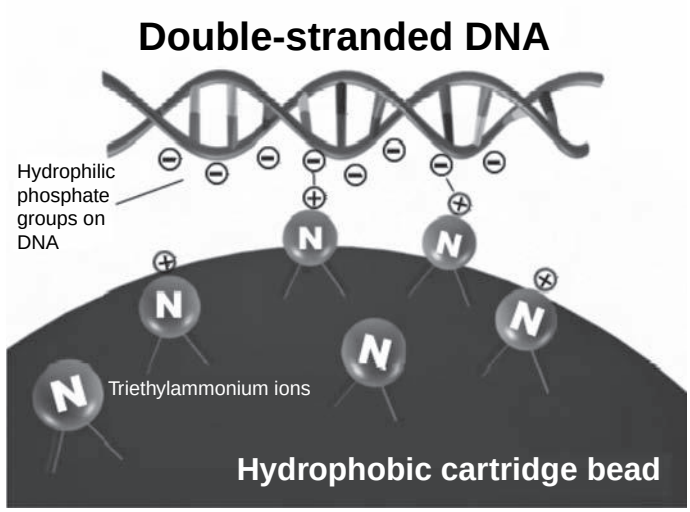

Figure 41.7 Interaction of DNA with the stationary phase in Denaturing HPLC.

- *N*-Methylpyrolidone in cefepime hydrochloride (USP Method)
- Sulfate and sulfamate in topiramate
- Pamidronic acid – assay
- Phosphate and phosphite as impurities in pamidronic acid
- Residual acetic acid and formic acid in ceftriaxone.

Denaturing high performance liquid chromatography

HPLC has also found applications in the field of molecular and clinical genetics in the form of denaturing HPLC (DHPLC). Some of the main applications of DHPLC include discovery of mutations and variations (Liu *et al.* 1998; Luquin *et al.* 2010), screening of genetic diseases (Kosaki *et al.* 2005; Costabile, Quach 2006) and purification and analysis of nucleic acid (Danielson *et al.* 2005). The technique is also finding important applications in forensic science, for example in pharmacogenomic investigations (Aquilante *et al.* 2006) and in DNA analyses (Budowle, van Daal 2009). A full account of the role of pharmacogenomics in forensic toxicology is given in Chapter 25.

For separations of DNA fragments, a specific combination of stationary and mobile phases is required. In general, the stationary phase is made of a C_{18} polystyrene–divinylbenzene bead polymer. Each of these beads is approximately 3 µm in size. The matrix is very hydrophobic. Binding of hydrophilic DNA can be highly efficient when the positive charges of the ion-pairing reagent TEAA (triethylammonium acetate) interact electrostatically with negatively charged DNA. The positively charged ammonium ion of TEAA interacts electrostatically with the phosphate groups on the DNA backbone. The triethyl groups are hydrophobic, and the result is that the hydrophilic DNA acquires a hydrophobic outer coating and can thus interact with the column matrix. Varying concentrations of acetonitrile in the mobile phase are used in order to elute the attached DNA fragments off the stationary phase. Figure 41.7 illustrates the interaction of DNA molecules with the stationary phase.

Detection of mutations in DNA fragments by DHPLC involves a process known as partial denaturation. In this process, heat is applied and the double-stranded DNA unwinds and separates into single strands by the breaking of hydrogen bonding between the cytosine/guanine and adenosine/thymine base-pairs. The sample is then cooled to allow the strands to re-hybridise (or anneal). If a mixture of two or more DNA fragments is heat denatured and allowed to cool, a combination of homoduplexes and heteroduplexes is formed. The homoduplexes represent the original components of the mixture, whereas the heteroduplexes are formed by cross-hybridisation of the different contributors of the mixture. Heteroduplexes derived from DNA fragments from a heterozygous individual have different denaturing (or melting) properties from those of perfectly matched homoduplexes formed from DNA fragments from a homozygous individual and it is this difference in temperature stability that is exploited by DHPLC. Thus, the annealed mixture is introduced onto a column heated to an optimum temperature (usually >50°C) to induce partial denaturation; with an increasing gradient of a non-polar solvent such as acetonitrile it is possible to separate the heteroduplexes and the homoduplexes. Heteroduplexes are generally retained less owing to their decreased interaction with the ion-pairing reagent and the fact that they are inherently unstable. An example of the use of DHPLC in investigating a genetic disorder is shown in Figure 41.8.

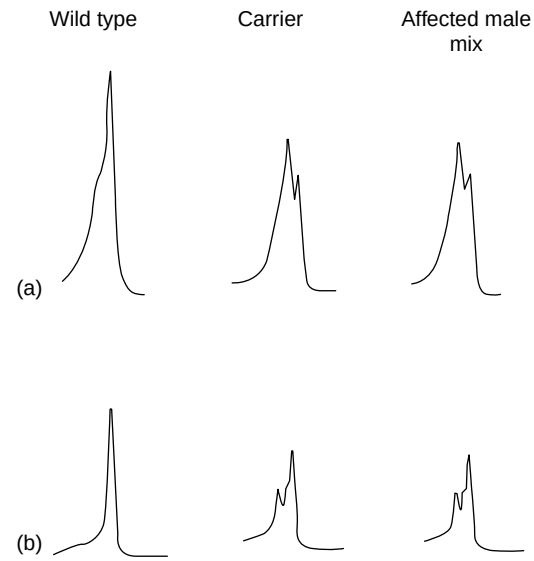

Figure 41.8 Partial denaturing HPLC chromatograms of DNA samples taken from two families (a and b) affected by the haemophilia A mutation. The wild-type DNA (predominant form) shows a homoduplex (a double-stranded molecule in which both strands are from the same source). The carrier DNA shows a heteroduplex (a double-stranded DNA molecule or a DNA–RNA hybrid where each strand is from a different source) as in the sample from an affected male derived after mixing with normal DNA. (From Lin *et al.* 2008.)

Most DHPLC systems have built-in features to perform analyses under non-denaturing, partially denaturing and fully denaturing conditions, depending upon the specific application. In order to effect each of the conditions listed, a column oven is employed that can vary column temperatures to within 0.1°C. Non-denaturing analysis allows for size-based separation and purification of double-stranded DNA and is usually carried out under a column temperature of around 50°C. Partially denaturing conditions (usually >50°C) are used for variation and single-nucleotide polymorphism (SNP) discovery and detection are based on DNA fragment sequence as described above. Fully denaturing temperatures (>70°C) can be used for the separation and analysis of oligonucleotides and nucleic acids as illustrated in Figure 41.9.

On-line sample preparation

The preparation of samples typically demands a large amount of time, work and cost in an analytical laboratory. The innovation of on-line sample preparation makes the process more efficient and reduces the cost. On-line sample preparation techniques usually involve direct elution of the extract from a solid-phase extraction cartridge into the system by the mobile phase. The on-line method gives superior analytical results and can be automated fully. Another benefit is that the sample preparation is reliable, reproducible and robust. This sample preparation method is also discussed in the column-switching section of this chapter.

Rapid screening

The need for high throughput in a laboratory environment is constantly increasing. The use of short, highly efficient, analytical columns, rapid gradients and column-switching apparatus in HPLC systems is helping to facilitate this. Sample turnaround time can often be reduced to a few minutes or less in highly automated and optimised systems. Other information on this topic is given earlier in this chapter in the sections on gradients and column switching.

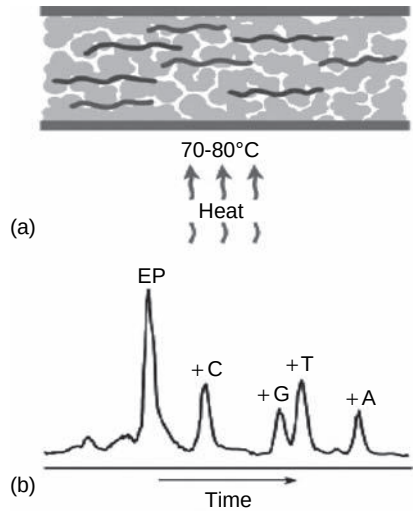

Figure 41.9 Principle of completely denaturing HPLC. (a) At column temperatures >70°C, double-stranded DNA fragments will denature completely. (b) The single-stranded components can then be resolved from each other even if they differ only in sequence and not in size. The chromatogram depicts the separation of an extension primer (EP) and the four possible isomeric products generated by single nucleotide extension sequencing. Resolution for any given pair of alleles can be optimised by varying column temperature. The order of elution of the alleles depends on the stationary phase used. On poly(styrene-divinylbenzene) monoliths, as depicted, extension products elute in the order C < G < T < A. On micropellicular alkylated poly(styrene-divinylbenzene) particles, in contrast, the elution order is G < C < A < T.

Systems for drug analysis

Eluent systems

A large number of eluent and/or packing material combinations have been used for drug analysis. However, currently most are performed on silica or one of the hydrocarbon-bonded silicas (usually ODS). Other types of packing are employed when these conventional materials fail. The majority of drug analyses can be carried out with the four types of system described next.

Silica with non-polar eluents

With silica normal-phase systems the principal mechanism is adsorption chromatography. Separation is controlled by the competition between solute molecules and molecules of the mobile phase for the adsorption sites on the silica surface. Polar groups are attracted most strongly to these sites and hence polar compounds are retained more strongly than non-polar ones. Retention can be decreased by increasing the polarity of the eluent.

Adsorption energies of numerous solvents on alumina (ε° values are given in Table 41.1) have been measured and this scale can be used as a good guide to the elution strengths of eluents on silica as well as alumina (Snyder 1968).

Mixtures of solvents can be employed to give elution strengths between those of the pure solvents. Furthermore, different solvent mixtures that have the same ε° value often give different separations of a group of compounds.

Water is strongly bound to silica and thus the water content of the eluent must be controlled strictly to maintain constant activity of the silica surface and hence reproducible retention times. This is most critical when the eluent is of very low polarity. However, because anhydrous systems are difficult to maintain, a low concentration of water can be used in the eluent, sufficient to deactivate the most active sites without deactivating the whole surface. Typical water concentrations range from 0.01% to 0.2% (v/v). The most satisfactory method used to prepare a solvent of known water content is to mix anhydrous and water-saturated solvents in known proportions. Anhydrous hydrocarbon or halo hydrocarbon solvents can be prepared by passing them through a bed of activated silica or alumina (200 μm) in a glass column. The problems associated with the control of water concentration mean

Table 41.1 ε° values for numerous solvents on alumina (Snyder 1968)

Solvent	ε°
Pentane	0.00
Hexane	0.01
Isooctane	0.01
Cyclohexane	0.04
Toluene	0.29
1-Chlorobutane	0.30
Ether	0.38
Chloroform	0.40
Methylene chloride	0.42
Tetrahydrofuran	0.45
Acetone	0.56
Ethyl acetate	0.58
Diethylamine	0.63
Acetonitrile	0.65
Isopropyl alcohol	0.82
Ethanol	0.88
Methanol	0.95
Acetic acid	Large
Water	Large

that commonly alcohols, such as methanol (0.01–0.5% v/v), are employed to moderate the silica surface (Engelhard 1977).

Silica with polar eluents

Several systems have been described that involve the use of silica with eluents of moderate-to-high polarity containing alcohols and/or water as major components. With such eluents, adsorption chromatography is most probably not the principal mechanism. The mechanisms are poorly understood, which makes the prediction of retention behaviour difficult; nevertheless, many of these systems are very useful for drug analysis.

An eluent that consists of methanol–ammonium nitrate buffer (90 : 10) is suitable for a wide range of basic drugs (e.g. amfetamines and opiates). Retention can be controlled by changes to the pH, ionic strength or methanol : water ratio, or by the addition of other organic solvents such as methylene chloride. With these alkaline eluents the silica surface must bear a negative charge and the principal mechanism is probably cation exchange.

Benzodiazepines can be chromatographed with methanol eluents that contain perchloric acid (typically 0.001 mol/L). Retention can be modified by the addition of other organic solvents (e.g. ether) or by changes to the acid concentration.

Both acidic and basic drugs can be chromatographed on silica using aqueous methanolic eluents that contain cetyltrimethylammonium bromide (Hansen 1981). Hydrophobic quaternary ammonium ions are strongly adsorbed on silica to give a dynamically coated stationary phase. Retention may be controlled by varying the concentration or nature of the quaternary ammonium ion, changing the ionic strength or pH of the buffer, or changing the concentration or nature of the organic component.

ODS with polar eluents

Eluents for RPC on ODS are usually mixtures of methanol or acetonitrile with an aqueous buffer solution. Retention is controlled mainly by the hydrophobic interactions between the drugs and the alkyl chains on the packing material. Retention increases as the analytes decrease in polarity (i.e. polar species are eluted first). Hence, the elution time is increased by increasing the polarity of the eluent (i.e. increasing the water content). The pH of the eluent and the pK_a of the drug are also important, since non-ionised species show greater retention. Thus, acids show an increase in retention as the pH is reduced, while bases show a decrease. It is important to use a buffer of sufficient capacity to cope with any injected sample size, otherwise tailing peaks can arise from changes in ionic form during chromatography. Phosphate buffers (0.05–0.2 mol/L) are widely used as they have a good pH range and low UV absorbance.

Drugs that contain basic nitrogen atoms sometimes show poor efficiencies and give tailing peaks caused by interactions with residual silanol groups on the packing material. This can often be improved by the addition of an amine or quaternary ammonium compound to the eluent, which competes with the analytes for adsorption sites on the silica. Amines of small molecular weight (e.g. diethylamine) can be used as part of the buffer system. Alternatively, low concentrations (0.001 mol/L) of long-chain hydrophobic modifiers (e.g. *N,N*-dimethyloctylamine) can be added to eluents together with conventional buffers.

Other hydrocarbon-bonded packing materials can be used in RPC. A decrease in retention is associated with a decrease in the alkyl chain length.

ODS with polar eluents that contain hydrophobic cations or anions

Drugs that bear positive or negative charges are retained poorly in reversed-phase systems. If the pH of the eluent cannot be changed to convert the drug into its non-ionised form, a hydrophobic ion of opposite charge can be added to form a neutral ion-pair and increase retention. Hence, for a basic drug an acidic eluent is chosen and a hydrophobic anion is added. This technique is referred to as reversed-phase ion-pair chromatography.

The sodium salts of alkylsulfonic acids (RSO_3^- Na^+, where R = pentyl, hexyl, heptyl or octyl) are used widely as ion-pair reagents for basic drugs, while quaternary ammonium compounds (e.g. tetrabutylammonium salts) are used for acidic drugs. Ion-pair reagents are generally added to eluents in the concentration range 0.001–0.005 mol/L, and within this range an increase in concentration leads to an increase in retention. When detergents such as sodium lauryl sulfate or cetyltrimethylammonium bromide are used as the ion-pair reagents, the method is sometimes referred to as 'soap chromatography'. With these salts, ions build up on the surface of the packing material and produce a stationary phase, which behaves like an ion exchanger. This type of mechanism has been described as 'dynamic ion exchange' and probably also occurs with less hydrophobic ion-pair reagents. It is virtually impossible to remove an ion-pair reagent completely from a hydrocarbon-bonded phase, and such columns should therefore not be re-used with other reversed-phase eluents.

Selection of chromatographic systems

Many different combinations of packing material and eluent may be suitable for the analysis of a particular compound or group of compounds and the final choice can be influenced by many factors. The time required to develop a new system can be shortened if it is possible to predict the way in which changes in eluent composition influence chromatographic retention. Systems that use hydrocarbon-bonded phases are particularly attractive from this viewpoint as a large range of parameters can be adjusted (pH, organic solvent, ionic strength, ion-pair reagents) with largely foreseeable consequences. Predictions for silica are generally less reliable. Silica is good for separating drugs that belong to different chemical classes, while hydrocarbon-bonded silicas are preferred for separations of drugs with closely related structures (e.g. barbiturates).

Most of the endogenous materials in biological extracts that can interfere with the analysis of a drug are fairly polar. In reversed-phase systems this material generally elutes before the drug and can obscure the drug peak. In these circumstances, reversed-phase ion-pair chromatography can be valuable to increase selectively the retention of the drug relative to the interfering peaks. Normal-phase systems that use silica do not generally suffer from this problem, as most of the endogenous material usually elutes after the drug. However, these slow-eluting compounds can lead to a noisy baseline or may remain adsorbed to the packing material and thus eventually lead to a loss in column performance.

The vast majority of compounds are separated using a silica-based column with C_{18}, and fine-tuning of the separation can be done by selecting a column with a shorter bonded phase, such as C_8 (see later).

Specially end-capped columns are available that are designed to minimise the tailing that is common with nitrogen-containing weak bases. These are often marketed as a 'basic' column (e.g. Metachem's MetaSil Basic). There are also specially end-capped columns designed to withstand extremely high concentrations of aqueous mobile phase (95–100%). These columns are end-capped with a hydrophilic moiety that ensures proper 'wetting' of the silica to prevent bonded-phase collapse. The columns are typically marketed as 'AQ' for aqueous (e.g. YMC's ODS-AQ).

Analysis of drugs in pharmaceutical preparations

HPLC has found widespread use for the quantitative analysis of drugs in preparations of pharmaceutical and illicit manufacture. Drug concentrations are generally high enough to allow dissolution of the sample (tablet, powder, ointment, etc.) in a suitable solvent followed by injection. UV, visible, FL, RI or mass spectrometric detection methods are used often. These techniques are well suited to provide specific data regarding the chemical composition of the sample in question (e.g. a UV spectrum, mass spectrum).

Within the pharmaceutical industry, HPLC is used at various stages of drug development, such as the optimisation of synthetic reactions and stability testing. Furthermore, it is used extensively for quality control during production to monitor the purity of drugs and excipients. HPLC systems can be automated easily (including injection and data handling), which allows large numbers of samples to be analysed rapidly and economically. HPLC is particularly valuable for the analysis of drugs that are polar (e.g. aspirin), thermally unstable (e.g. benzodiazepines) or present in oil-based formulations for which analysis by GC can be very difficult. Similarly, HPLC can be used for the forensic analysis of illicit preparations to aid the identification of an unknown drug by the measurement of retention times and UV spectra and

comparison to spectral libraries. Furthermore, as the technique can be non-destructive, depending on the detection system used, the eluted compounds can be collected for further analysis.

Example of a drug analysis system

Opiates have been separated by many methods in the past, and the system described here was developed for this purpose. The three opiates separated were morphine sulfate, hydrocodone bitartrate and oxycodone hydrochloride. The column used was a Phenomenex Luna C_{18} (2), $150 \times 4.60\,\text{mm} \times 5\,\mu\text{m}$. The mobile phase was 39 mmol/L dipotassium hydrogenphosphate (K_2HPO_4) and methanol in a 40 : 60 ratio. The final pH was 10 and the mobile phase flow rate was 1.0 mL/min. The retention times obtained (Figure 41.10) for morphine sulfate, hydrocodone bitartrate and oxycodone hydrochloride were 2.799, 4.696 and 6.143 min, respectively.

Analysis of drugs in biological fluids and tissues

Several factors determine the ability of HPLC to detect a drug among the endogenous compounds present in biological material. Clearly, selective detection of the drug relative to the endogenous material is advantageous. In addition, the stationary phase and/or mobile phase can be altered to separate the drug peak from interfering peaks (e.g. using ion-pair reagents). Finally, the sample may be extracted before HPLC to concentrate the drug relative to the endogenous material.

The chromatographic system and detector should always be chosen to minimise the time needed for sample preparation. The complexity of the sample preparation procedure is controlled by several factors, which include the nature of the sample (urine, blood, liver, etc.), the condition of the sample and the concentration of the drug. Interference from endogenous compounds is most acute when drug concentrations are low (e.g. in therapeutic drug monitoring), so more extensive sample preparation and more sensitive and specific detectors are often required. Such assays can be very susceptible to changes in the condition of the sample (e.g. a method developed for fresh blood may not be satisfactory for urine or hair samples), which can present severe difficulties in forensic toxicology. Thus, methods should be tested and validated with the most difficult samples that may be encountered. In contrast, the analysis by HPLC of biological samples that contain high drug concentrations (e.g. in fatal drug overdose) may require much less sample preparation and is less susceptible to changes in sample condition.

Sample preparation for HPLC is essentially the same as for other methods of drug analysis. A drug that is physically trapped within solid tissue (e.g. liver), or chemically bound to the surface of proteins, must be released; then the protein is precipitated to leave the drug in aqueous solution. The protein may be degraded by strong acids or enzymes, precipitated by various chemicals (e.g. tungstic acid, ammonium sulfate) or removed by ultrafiltration. Some drugs are destroyed by protein degradation methods, while ultrafiltration and precipitation can lead to drug losses through protein binding. No single procedure works well for all drugs and the method should be selected to give the maximum recovery of the drug being analysed.

When drug concentrations are high (typically μg/mL) and systems with polar mobile phases are used, the direct injection of deproteinised solutions may be acceptable. Proteins must be removed to protect the column from irreversible contamination. A rapid procedure is to: mix the biological fluid with at least two volumes of methanol or acetonitrile; centrifuge to remove the precipitated protein; evaporate the organic supernatant; and reconstitute the sample in a volume of mobile phase. Urine can be treated similarly to guard against the precipitation of salts on the column. Great care and consideration should be afforded when injecting minimally prepared biological samples on to a HPLC system. Particulates are more likely to become trapped in the system plumbing and a more rapid degradation of column performance may be observed from build-up of contaminants on the head of the column. To help maximise column performance and lifetime, it is good policy to use a guard column between the injector and analytical column. This is packed with the same material as the analytical column and replaced at frequent intervals. The configurations of guard columns range from easily replaceable and relatively inexpensive frit-like filters and/or cartridges to shorter versions of the analytical column itself. All are designed to protect the analytical column by acting as a trap for components that would otherwise irreversibly bind to the analytical column and thus decrease the usable life of the column.

Extraction of drugs and other analytes away from endogenous materials prior to analysis is a common procedure for all types of biological samples. This may also entail a concentration step, which increases the sensitivity of the method. Solvent extraction remains the most popular approach, as many factors can be modified to optimise the extraction. These modifications include changing the polarity of the organic solvent, the pH and ionic strength of the aqueous phase, and the use of ion-pairing agents. It is generally recommended that the collected organic phase be evaporated to dryness and the residue dissolved in a suitable solvent, typically something greater than or equal to the polarity and composition of the initial mobile phase before injection. Care must be taken that volatile drugs are not lost by evaporation and that lipid material in the residue does not prevent the drug from dissolving in the new solvent.

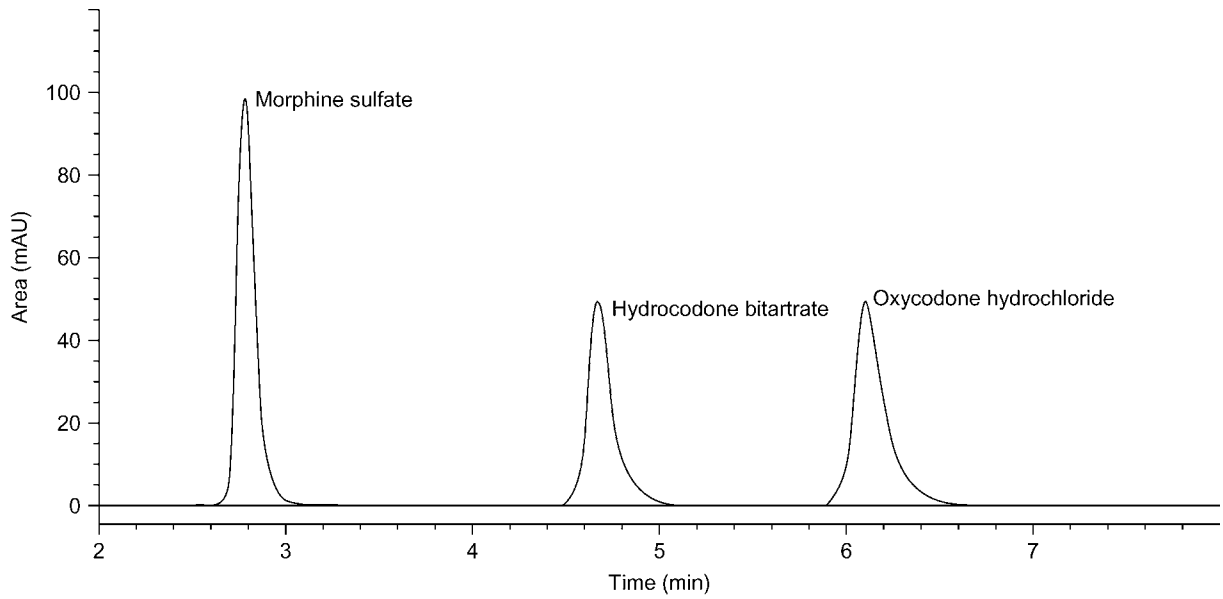

Figure 41.10 Separation of opiates by HPLC. Conditions for separation are described in the text.

Example protocol for the extraction of a wide variety of weak bases

- To 1 mL of plasma, urine or other homogenised matrix add 100 µL concentrated ammonium hydroxide.
- Extract the sample with 4 mL of a mixture of *n*-butyl chloride–acetonitrile (4 : 1) for 20 min.
- Centrifuge at high speed for 20–30 min to partition the phases.
- Carefully collect the organic phase into a clean tube.
- Evaporate the organic phase under a stream of air or nitrogen at 25–40°C, depending on the volatility of the analytes (a small volume of acidified methanol can be added to prevent the loss of amfetamine-type analytes).
- Reconstitute the residue in an HPLC mobile phase that is more polar than the LC mobile phase to be used for analysis (e.g. if the HPLC elution ratio is 60% aqueous, reconstitute the sample in a phase that is >60% aqueous). This ensures that, when injected, the sample is focused on the front end of the column and minimises band (peak) broadening.

An example of a chromatogram that utilises this extraction technique is shown in Figure 41.11. The urine was fortified with analytes and deuterated internal standards for amfetamine and methamfetamine (dashed chromatograms) and extracted as described above. The sample was eluted using a MetaSil Basic 3 × 100 mm × 3 µm column. The mobile phase was 85% (0.1% formic acid in water), 15% methanol, pumped isocratically at 0.2 mL/min. The instrument used was an Agilent 1100 LC/MSD with ESI.

SPE columns are also widely used to extract drugs from biological samples. The column is washed with suitable solvents to remove endogenous material before the drug is removed by passing through a solvent of higher elution strength. Such columns are usually attached to extraction manifolds utilising either positive or negative pressure to draw the liquids through the sorbent beds. Extraction selectivity can be controlled by adjustments to the biological fluid before extraction (e.g. pH, ionic strength) and the choice of washing solvents. Most, if not all, manufacturers of SPE columns offer methods and columns optimised for a particular drug class and/or matrix. As less traditional biological matrices are used for drug analysis (e.g. sweat, hair, oral fluids), some modifications of the sample preparation scheme are needed. Hair requires solubilisation prior to extraction; oral fluids and sweat may need to be isolated from their respective collection devices. Consideration of the pH and solubility may be needed prior to sample preparation, but in general the principles in place for the extraction of blood, urine, etc. apply to these alternative matrices. Some important issues unique to these matrices are:

- Sample volume is typically much less than blood or urine.
- The amount of drug extracted from a particular matrix may be much less than from traditional matrices, so that much more sensitive detectors (e.g. MS or MS–MS) are required.

Identification of drugs by HPLC with photodiode array detection and UV spectra library search

HPLC with DAD in combination with a UV spectra library has proved to be a very successful 'systematic toxicological analysis' (STA) technique for use in clinical and forensic toxicology (see Chapter 1). Any drugs or other poisons in the sample are identified by coincidence of the UV spectrum and of the retention time or another chromatographic retention parameter with the library data; one system and its use are described below (F Pragst and M Herzler, personal communication).

Chromatographic conditions

Since the method is used in combination with a database of UV spectra and retention parameters, the chromatographic conditions must be reproducible and the same as used to generate the database. The mobile phase must be suitable for the separation of a large variety of organic substances and must be transparent in the wavelength range used. These prerequisites are best met by reversed-phase columns (RP_8 or RP_{18}) and acidic acetonitrile–buffer mixtures as mobile phases. Systems described in the literature generally use either a gradient elution or two isocratic runs with different buffer : acetonitrile ratios.

Gradient elution has the advantages that strongly polar and non-polar substances can be analysed in one run, that peaks are not broadened with increasing retention time, and that the retention times of the toxicologically relevant compounds are distributed more evenly over the run time, but it has some disadvantages (see above). A system of HPLC retention indices was introduced by Bogusz *et al.* (1993) analogous to the Kovats indices used in GC and based on the retention times of the nitroalkanes.

Isocratic HPLC has the advantage of higher reproducibility of the retention times, greater ruggedness and a more economic use of the mobile phase by recycling. Disadvantages are an unfavourable distribution of the retention times of toxicologically relevant compounds with an increased number at the beginning of the chromatogram, and the need for a second mobile phase for non-polar compounds. Nevertheless, isocratic HPLC–DAD procedures are used successfully in many toxicological laboratories for screening purposes. Suitable experimental

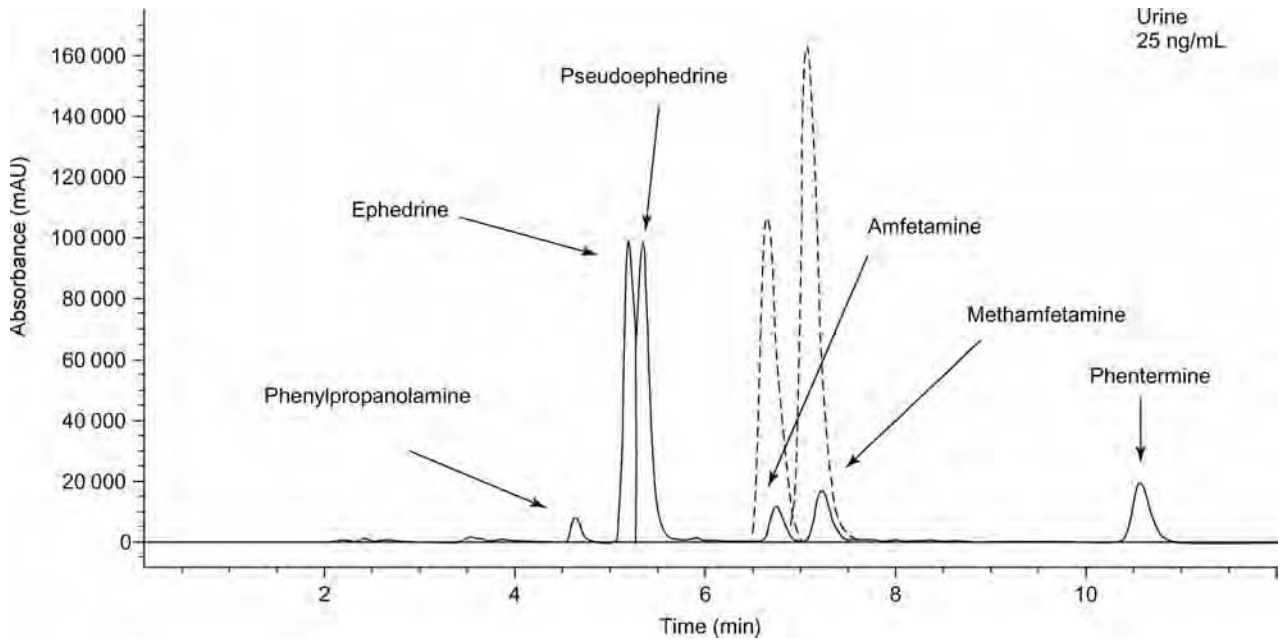

Figure 41.11 Separation of amfetamines by HPLC–MS. Conditions for separation are described in the text.

conditions, also used in the recording of an extensive UV spectra library, were as follows (Pragst *et al.* 2001):

- HPLC column: RP_8, end-capped, 5 µm, 250 × 4.0 mm
- Mobile phase A: 0.1 mol/L phosphate buffer pH 2.3–acetonitrile (67 : 33 v/v)
- Mobile phase B: 0.1 mol/L phosphate buffer pH 2.3–acetonitrile (33 : 67 v/v)
- Flow rate: 1 mL/min.

Standard compounds are histamine hydrochloride to measure the time of an unretained peak t_0 (dead time), 5-(4-methylphenyl)-5-phenylhydantoin (MPPH) to calculate relative retention times (RRTs) in mobile phase A, and 4-phenylbenzophenone to calculate RRTs in mobile phase B.

The UV spectra of a large number of compounds listed in this book were measured under these conditions. An overview of HPLC–DAD conditions used for STA is given in Pragst *et al.* (2001).

Retention parameters

Absolute retention times are not suitable for peak identification purposes, since they depend strongly on the configuration and experimental conditions of the HPLC device. Moreover, the capacity ratio k_A (see above) is sensitive to small fluctuations of the experimental conditions and is not suitable for an identification system used in different laboratories. Therefore, for gradient elution, retention indices are preferred (Bogusz *et al.* 1993). Under isocratic conditions RRTs related to a standard compound are more reproducible (Equation 41.6).

$$\mathrm{RRT_x} = \frac{t_x - t_0}{t_s - t_0} \tag{41.6}$$

where RRT_x is the RRT of compound x, t_x is the absolute retention time of compound x, t_0 is the retention time of an unretained peak, and t_s is the retention time of the standard compound.

The relatively small peak resolution of HPLC and the differences between charges of the reversed-phase material mean that the value of retention indices or of RRTs in the identification of a compound from a large number of candidates is rather limited. However, it is very useful for distinguishing between compounds with very similar UV spectra. In this way an RRT window can be chosen as a pre-selection parameter for the spectra library search.

UV spectral library search and specificity of UV spectra

Before peak identification a 'peak purity check' should be carried out. A pure peak means that it originates only from one compound and that the UV spectrum does not change over the whole peak width.

A UV spectral library search is based on the comparison of the spectrum of the unknown peak with all spectra of the library. This comparison is not confined to UV maxima and minima, but can comprise all absorbance–wavelength pairs measured by DAD. Mathematical models to assess spectral similarity use the description of the spectrum as a vector in n-dimensional space, where n is the number of absorbance–wavelength pairs measured. For the complete identity of two spectra, both vectors point in exactly the same direction, that is the angle between them is $\theta = 0°$. Different concentrations have an effect on vector length, but not on its direction in space. The similarity index (SI) is defined as $\cos\theta$ and is calculated with Equation (29.7):

$$\mathrm{SI_x} = \cos\theta_{\bar{s}_1 \cdot \bar{s}_2} = \frac{\bar{s}_1 \cdot \bar{s}_2}{|\bar{s}_1| \times |\bar{s}_2|} \tag{41.7}$$

where $\bar{S}_i$ is the vectorised spectrum of compound i.

UV spectra can be measured with extremely high reproducibility. Therefore, small differences between spectra measured under identical conditions indicate that they originate from different compounds. SI is 1.000 for completely identical spectra. However, in practice two spectra with SI >0.9990 can be regarded as identical. At small concentrations, and in the case of partly overlapping peaks, SI >0.990 may be a sufficient criterion for identity.

It was shown in a systematic study on the selectivity of an HPLC–DAD method (Herzler *et al.* 2003) that, from 2888 toxicologically relevant compounds, 2682 (93%) exhibited UV absorption above 195 nm. Out of these, 1619 (60.4%) had a unique UV spectrum and could be identified unambiguously. By inclusion of the retention time this proportion was increased to 84.2%. Large UV spectra libraries can be divided into sub-libraries, according to the retention parameter or the effect or use of the substance, to facilitate a faster and more specific library search. The result can also be supported by the presence of metabolites, while in doubtful cases complementary methods may be used for confirmation (e.g. MS).

As an example, in Figure 41.12 the results of the library search for a peak with RRT = 0.0811 in an intoxication case are shown. In this case a sub-library of all compounds with RRT = 0.601–0.900 was used. Hit 1 was promethazine with SI = 0.9992; hit 2 (promazine, SI = 0.9964) and hit 3 (dixyrazine, SI = 0.9961) also originated from compounds of the phenothiazine type. The small difference between the spectra of hits 1 and 2 may arise because in these two compounds the amino group of the side chain is separated from the phenothiazine ring by two and three saturated carbon atoms, respectively. Dixyrazine could clearly be excluded by the much smaller retention time. However, promethazine and promazine could not be distinguished by the RRT values stored in the database. Therefore, to confirm the library search result, promazine and promethazine standards were measured immediately after the sample, which resulted in an exact agreement with promethazine.

As a prerequisite for the optimal use of a commercially available UV spectral library, the same mobile phase must be used and the technical parameters of the DAD (wavelength accuracy and resolution) need to be (and stay) sufficient. This can be controlled by daily measurement of a compound with a vibration fine structure of the UV spectrum, such as benzene.

UV spectra and retention times of metabolites

The use of HPLC–DAD has the advantage that in many cases, metabolites can be attributed easily to the parent drug by the UV spectrum. Depending on the site of metabolism, the UV spectrum may be altered significantly (change of the UV-absorbing unsaturated part of the molecule, the chromophore) or it may be the same as (or very similar to) that of the parent drug (reaction at the aliphatic part of the molecule). As an example, in Figure 41.13 the spectrum of flunitrazepam is compared with that of its metabolites, 7-aminoflunitrazepam (strong change of the chromophore by transformation of the aromatically bound nitro group into the amino group) and 3-hydroxyflunitrazepam (no essential change of the chromophore by hydroxylation at the aliphatic carbon atom 3).

The retention times of drugs on reversed-phase columns are shifted in a typical way by metabolism. Metabolism to more hydrophilic products (e.g. hydroxylation, reduction of the nitro to an amino group; Figure 41.13) leads to a decrease in retention time, whereas deamination strongly increases retention time, particularly in an acidic mobile phase (removal of the strongly hydrophilic, protonated amino group). For many drugs, the chromatograms obtained from blood or urine extracts have a typical metabolite pattern that supports identification in the context of STA.

Sample pretreatment

Tablets, powders or residues in syringes can simply be dissolved in the mobile phase and analysed by HPLC-DAD without further treatment. The investigation of biological samples, such as whole blood (serum, plasma), stomach contents, urine or tissue samples, is more complicated. In these cases the drug must be separated from the biological matrix.

Although SPE has been much improved in the past decade, liquid–liquid extraction (LLE) is still preferred if HPLC-DAD is used for toxicological screening, since it is less susceptible to interferences, more reproducible and easier to handle for single samples. An important advantage of UV detection is that cholesterol and fatty acids, co-extracted to a high extent from human samples by lipophilic solvents, show no UV absorption and therefore, in contrast to GC-MS, do not interfere with the analysis. Moreover, derivatisation is not necessary. A sample pretreatment method by extraction with n-butyl chloride–acetonitrile (4 : 1), which can be used for a wide variety of basic compounds,

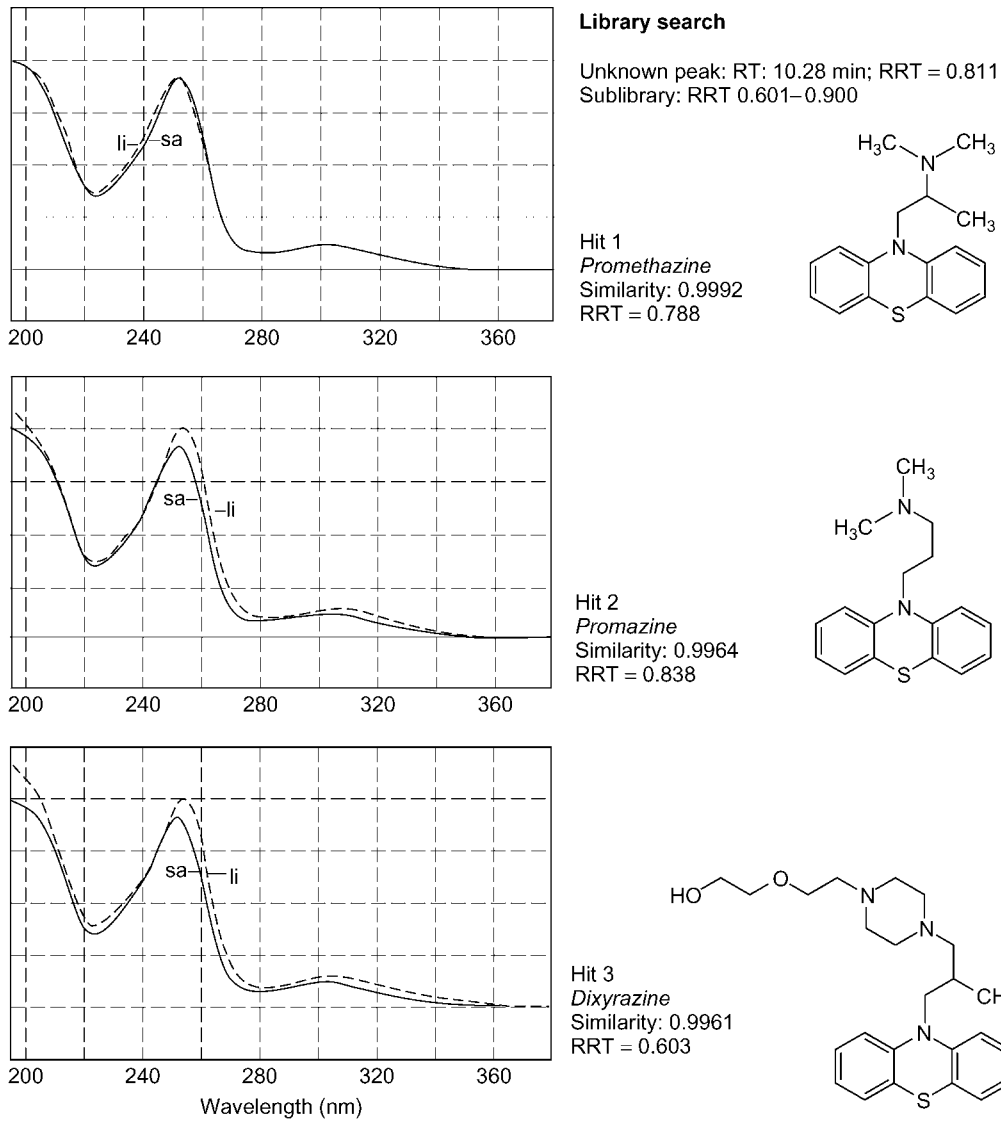

Figure 41.12 Results of the HPLC–DAD library search for a peak in the chromatogram of an alkaline extract of a lethal trimipramine–promethazine intoxication. Hit 1 (promethazine) was confirmed by exact agreement of the retention time with the reference compound measured immediately after the sample. sa, sample; li, library.

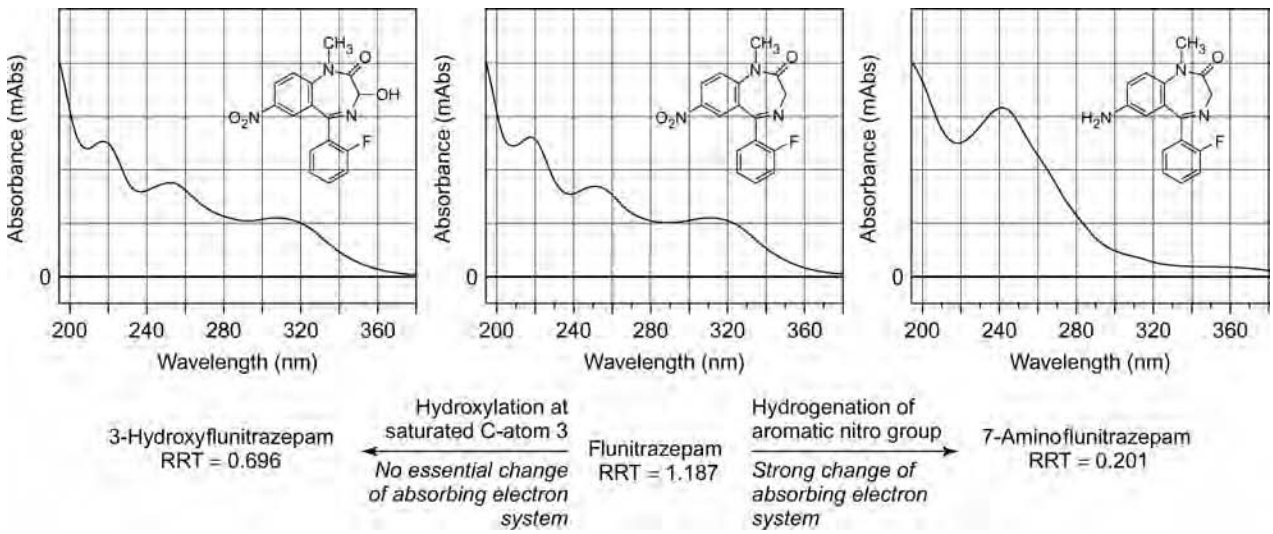

Figure 41.13 Change of the UV spectrum and the relative retention time (RRT) of flunitrazepam by metabolism.

is given above. For systematic toxicological screening of blood (serum, plasma) samples by HPLC-DAD, the measurement of two extracts obtained at pH 2 and pH 9 with dichloromethane and of the supernatant of a protein precipitation by acetonitrile has proved to be very useful (Pragst *et al.* 2002).

Preparation of a basic and an acidic methylene chloride extract

1. Dispense 500 µL of whole blood, serum or plasma into two 1.5-mL vials.
2. To vial 1 add 100 µL of a 0.2 mol/L solution of tri(hydroxymethyl) amine (basic extract).
3. To vial 2 add 100 µL of 0.1 mol/L hydrochloric acid (acidic extract).
4. To both vials add 400 µL of dichloromethane.
5. Vortex mix the vials for 1 min and centrifuge.
6. Withdraw 200 µL of the dichloromethane extract and evaporate the solvent at room temperature under a stream of nitrogen.
7. Dissolve the residue in 100 µL of mobile phase.
8. Analyse 50 µL of each extract (basic extract in mobile phase A and acidic extract in mobile phase B).

Protein precipitation by acetonitrile

1. To 500 µL of whole blood, serum or plasma add 500 µL of acetonitrile.
2. Vortex the mixture for 2 min and centrifuge.
3. Separate off the supernatant.
4. Analyse 50 µL in mobile phase A.

Protein precipitation is particularly useful for hydrophilic drugs, which are extracted poorly by the procedure mentioned above. These include paracetamol, salicylic acid and lamotrigine. The limits of detection are between 0.01 and 0.1 µg/mL for dichloromethane extraction (depending on the extinction coefficient and on the extraction yield) and between 0.1 and 1 µg/mL for protein precipitation.

Application example

In STA, the library search must be applied to all peaks of the HPLC-DAD chromatogram. As an example, the chromatogram at 225 nm of the basic extract from the blood sample of a lethal drug poisoning case and the UV spectra of the highest peaks are shown in Figure 41.14. To determine RRT, the standard compound (MPPH, peak no. 10, RRT = 1.000) was added. From the remaining 11 peaks of the chromatogram, 7 could be identified by both UV spectrum and RRT. As the result, a high overdose of trimipramine and promethazine was found to be the cause of death. The extensive metabolism indicated that there had been a long survival time after drug ingestion. The similarities between the UV spectra of the parent drugs (peaks 9 and 12) and some of their metabolites (peak 8, and peaks 6 and 11, respectively) are also demonstrated in this case. On the other hand, the sulfoxides of promethazine (peak 3) and desmethylpromethazine (peak 2) show completely changed spectra because of the transformation that takes place directly at the UV-absorbing phenothiazine ring. Caffeine (peak 1) is found in almost all samples. The poor separation of peaks 4, 5 and 7 meant that the UV spectra were not suitable for a library search.

Recommended HPLC systems

There are general screening methods based on gradient elution and retention indices that have proven value by many laboratories, and data from these are listed below (systems HA, HX, HZ, HY and HAA). Another (system HBK) is based on a combination of isocratic systems. The tabulated data are derived from systems in which groups of compounds have been chromatographed either as part of a general screening procedure or from systems that have been used specifically for that group of compounds. Other systems for the chromatography of individual compounds, especially those used for quantification, are given in the monographs.

Chromatographic retention data are presented as *k* values as well as retention times (RTs), retention indices (RIs) and relative retention times (RRTs).

Note In the tables, a dash indicates that no value is available for the compound, not that it does not elute.

General screens

System HA

Jane I *et al.* (1985). *J Chromatogr* 323: 191–225.

- *Column:* Silica Spherisorb S5W (125 × 4.9 mm i.d., 5 µm).
- *Mobile phase:* Solution containing 1.175 g (0.01 mol/L) ammonium perchlorate in 1 L methanol; adjust to pH 6.7 by the addition of 1 mL 0.1 mol/L sodium hydroxide in methanol.
- k *values:* Values for drugs in this system will be found in drug monographs and in the Indexes to Analytical Data; they are also included in the systems for specific groups of drugs that follow.

System HX

J Hartstra, JP Franke, RA de Zeeuw, personal communication.

- *Column:* Lichrospher 60 RP-Select B (125 × 4.0 mm i.d., 5 µm) with precolumn Lichrospher 60 RP-Select B (4 × 4.0 mm i.d., 5 µm).
- *Mobile phase:* (A:B) triethylammonium phosphate buffer (25 mmol/L, pH 3.0)–acetonitrile.
- *Elution programme:* (A:B) (100 : 0) to (30 : 70) in 30 min, hold 10 min, back to initial conditions in 3 min with equilibration for 10 min before next injection.
- *Flow rate:* 1 mL/min.
- *Detection:* DAD.
- *Standards:* Nitro-*n*-alkanes (C_1 to C_{11}) 10 µL in 10 mL acetonitrile.
- *RI values:* Values for drugs in this system will be found in the monographs and in the Indexes to Analytical Data; they are also included in the systems for specific groups of drugs that follow.

System HY

RK Watt, RA Waters, AC Moffat, unpublished information.

- *Column:* C_{18} symmetry (250 × 4.6 mm i.d., 5 µm).
- *Column temperature:* 40°C.
- *Mobile phase:* (A:B) sulfuric acid (0.5 mL 2.5 mol/L) in water (500 mL)–sulfuric acid (0.5 mL 2.5 mol/L) in acetonitrile (500 mL).
- *Elution programme:* (98 : 2) for 3 min to (2 : 98) over 23 min, hold for 10 min, back to initial conditions over 2 min with equilibration of 8 min before next injection.
- *Detection:* DAD.
- *Standards:* Nitro-*n*-alkanes (C_1 to C_{16}) 10 µL in 10 mL acetonitrile.
- *RI values:* Values for drugs in this system will be found in the monographs and in the Indexes to Analytical Data; they are also included in the systems for specific groups of drugs that follow.

System HZ

Conemans JMH *et al.* http://www.zanob.nl/pages/LSShowElementsPage_v2.asp?ListID=1650&elemid=29275&articleid=133751&token= (accessed 14 December 2010).

- *Column:* C_{18} end-capped LiChrospher 100 RP-18e (125 × 4.0 mm i.d., 5 µm), with precolumn LiChrocart 124-4.
- *Mobile phase:* Add 146 µL triethylamine and about 750 µL phosphoric acid to 530 mL water. Adjust pH to 3.3 using a 10% potassium hydroxide solution and finally add 470 mL acetonitrile.
- *Flow rate:* 0.6 mL/min.
- *Detection:* DAD.
- *Retention times:* Values for drugs in this system will be found in the monographs and in the Indexes to Analytical Data; they are also included in the systems for specific groups of drugs that follow.

System HAA

Gaillard Y, Pepin G. (1997). *J Chromatogr A* 763: 149–163.

- *Column:* C_8 Symmetry (250 × 4.6 mm i.d., 5 µm) with Symmetry C_{18} precolumn (20 mm).
- *Column temperature:* 30°C.
- *Mobile phase:* (A:B) phosphate buffer (pH 3.8)–acetonitrile.
- *Elution programme:* (85 : 15) for 6.5 min to (65 : 35) until 25 min to (20 : 80) for 3 min, and back to initial conditions for equilibration for 7 min.

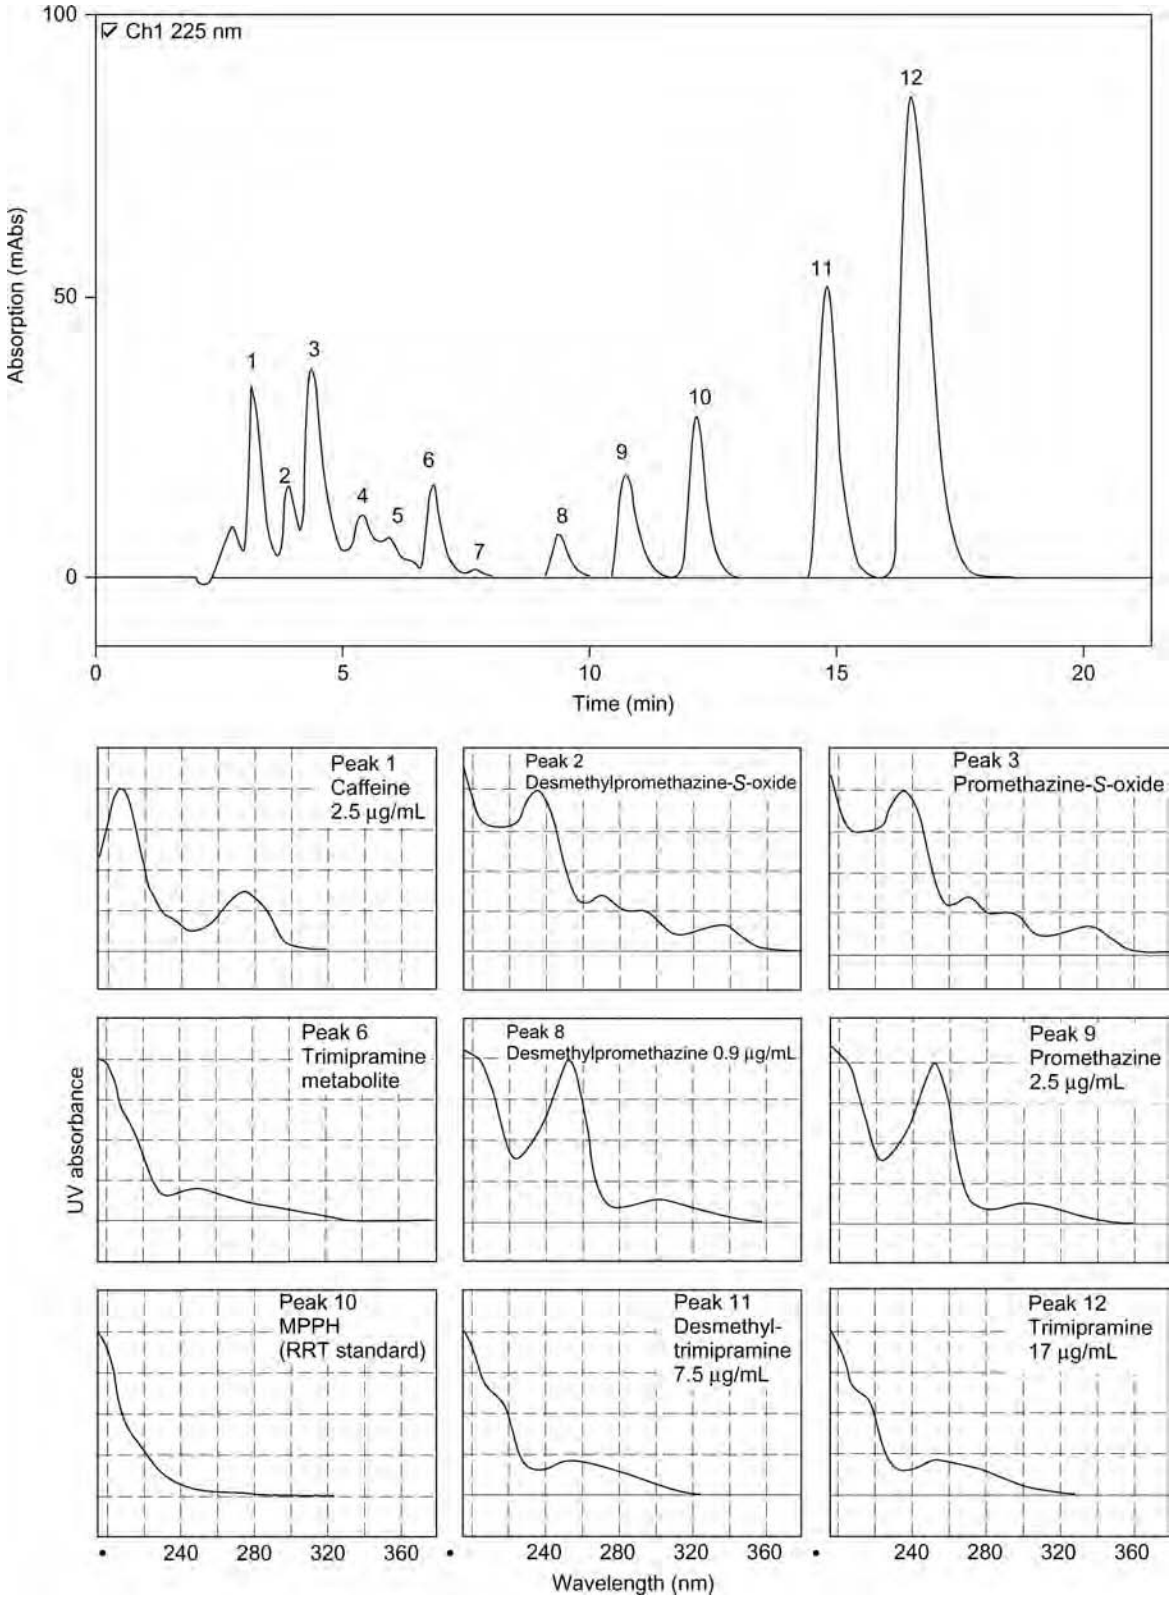

Figure 41.14 HPLC–DAD investigation of a combined trimipramine–promethazine poisoning. Chromatogram of a basic extract of a venous blood sample, UV spectra of the highest peaks, results of the library search and semiquantitatively determined concentrations.

- *Flow rate:* 1 mL/min for 6.5 min, then linear increase to 1.5 mL/min for 6.5–25 min and hold for 3 min (re-equilibration is made at 1.5 mL/min).
- *Detection:* DAD.
- *Retention times:* Values for drugs in this system will be found in the monographs and in the Indexes to Analytical Data; they are also included in the systems for specific groups of drugs that follow.

System HBK

Pragst F *et al.* (2001) *UV Spectra of Toxic Compounds*. Heppenheim: Verlag Dr Dieter Helm.

- *Column:* Lichrospher RP-8ec (250 × 4.0 mm i.d., 5 µm).
- *Mobile phase:* Three different composition are used: A: acetonitrile–phosphate buffer pH 2.3 (33 : 67). Internal standard: 5-(4-methylphenyl)-5-phenylhydantoin (for compounds eluting within 30 min). B: acetonitrile–phosphate buffer pH 2.3 (67 : 33). Internal standard: 4-phenylbenzophenone (for compounds eluting after 30 min). C: acetonitrile–phosphate buffer pH 2.3 (20 : 80). Internal standard: salicylamide (for compounds with RRTs below 0.2).
- *Flow rate:* 1 mL/min.
- *Detection:* DAD.
- *Note:* The phosphate buffer is prepared by dissolving 4.8 g phosphoric acid (85%) and 6.66 g potassium dihydrogenphosphate in 1 L water, adjust pH to 2.3. Values for drugs in this system will only be found in the Indexes to Analytical Data.

Amfetamines, other stimulants and anorectics

Systems HA, HX or HY previously described may be used, or Systems HB or HC below.

System HB

Gill R *et al.* (1981). *J Chromatogr* 218: 639–646.

- *Column:* ODS Hypersil (250 × 5 mm i.d., 5 µm).
- *Mobile phase:* Solution containing 19.60 g (0.2 mol/L) phosphoric acid and 7.314 g (0.1 mol/L) diethylamine in 1 L of a 10% v/v solution of methanol; adjust the pH to 3.15 by the addition of sodium hydroxide solution.

System HC

Law B *et al.* (1984). *J Chromatogr* 301: 165–172.

- *Column:* Silica Spherisorb (250 × 5 mm i.d., 5 µm).
- *Mobile phase:* Methanol–ammonium nitrate buffer solution (90 : 10). To prepare the buffer solution add 94 mL strong ammonia solution and 21.5 mL nitric acid to 884 mL water and adjust to pH 10 by the addition of strong ammonia solution.

Anticholinergics

The general screening systems, previously described, may be used or systems HAX and HAY below.

System HAX

Koves EM (1995). *J Chromatogr A* 692: 103–119.

- *Column:* Supelcosil LC-DP (250 × 4.6 mm i.d., 5 µm).
- *Eluent:* (A : B : C) Acetonitrile–phosphoric acid (0.025% v/v)–triethylamine buffer.
- *Isocratic elution:* (25 : 10 : 5).
- *Flow rate:* 0.6 mL/min.
- *Detection:* DAD (λ × 229 nm).
- *Note:* The triethylamine (TEA) buffer is prepared by adding 9 mL concentrated phosphoric acid and 10 mL TEA to 900 mL water, adjusted to pH 3.4 with diluted phosphoric acid and made up to 1 L with water.

System HAY

Koves EM (1995). *J Chromatogr A* 692: 103–119.

- *Column:* LiChrospher 100 RP-8 (250 × 4.0 mm i.d., 5 µm).
- *Eluent:* (A : B : C) as for System HAX.
- *Isocratic elution:* (60 : 25 : 15).
- *Flow rate:* 0.6 mL/min.
- *Detection:* DAD (λ × 229 nm).

Anticonvulsants and barbiturates

System HE

Christofides JA, Fry DE (1980). *Clin Chem* 26: 499–501.

- *Column:* Alkyl-silica SAS-Hypersil (125 × 4.5 mm i.d., 5 µm).
- *Mobile phase:* Acetonitrile–tetrabutylammonium phosphate, 0.005 mol/L, pH 7.5 (20 : 80).

System HG

Gill R *et al.* (1981). *J Chromatogr* 204: 275–284.

- *Column:* ODS Hypersil (150 × 4.6 mm i.d., 5 µm).
- *Mobile phase:* Methanol–0.1 mol/L sodium dihydrogenphosphate (11.998 g/L) (40 : 60); adjust to pH 3.5 by the addition of phosphoric acid.

System HH

Gill R *et al.* (1981). *J Chromatogr* 226; *Biomed Appl* 15: 117–123.

- *Column:* As for System HG, above.
- *Mobile phase:* As for System HG except that the mixture is adjusted to pH 8.5 by the addition of sodium hydroxide solution.

Antidepressants

The general screening systems, previously described, may be used or systems HF and HAZ below.

System HF

R Gill, unpublished data, after Kabra PM *et al.* (1981). *Clin Chim Acta* 111: 123–132.

- *Column:* ODS Hypersil (160 × 5 mm i.d., 5 µm).
- *Mobile phase:* Acetonitrile–phosphate buffer (pH 3.0; 30 : 70). To prepare the phosphate buffer, add 0.6 mL nonylamine to 1 L 0.01 mol/L sodium dihydrogenphosphate (1.1998 g/L) and adjust the pH to 3.0 by the addition of phosphoric acid.

System HAZ

Chiba K *et al.* (1995). *J Chromatogr B* 668: 77–84.

- *Column:* C_{18} (250 × 4.0 mm i.d., 5 µm).
- *Mobile phase:* (A : B : C) Water–methanol–triethylamine adjusted to pH 5.5 with phosphoric acid.
- *Isocratic elution:* (70 : 30 : 0.1).
- *Flow rate:* 0.7 mL/min.
- *Detection:* UV (λ = 240 nm).

Antivirals

The general screening systems, previously described, may be used or systems HAB and HAC below.

System HAB
Sparidans RW *et al.* (2000). *J Chromatogr B Biomed Sci Appl* 742: 185–192.

- *Column:* C_{18} Symmetry (100 × 4.6 mm i.d., 3.5 µm) with Symmetry C_{18} precolumn (20 × 3.8 mm, 5 µm).
- *Mobile phase:* Acetonitrile–sodium phosphate buffer (25 mmol/L, pH 6.8) (40 : 60).
- *Flow rate:* 1.5 mL/min.
- *Detection:* Fluorescence ($\lambda_{ex} = 270$ nm, $\lambda_{em} = 340$ nm).
- *Note:* 8 min after each injection, flush column for 5 min at 1.5 mL/min with acetonitrile–water (30 : 70). Equilibrate for about 8 min with the original eluent before injecting the next sample.

System HAC
Aymard G *et al.* (2000). *J Chromatogr B Biomed Sci Appl* 744: 227–240.

- *Column:* C_{18} Symmetry (250 × 4.6 mm i.d., 5 µm) with C_{18} precolumn (Guard-Pak, µBondapak).
- *Column temperature:* 37°C.
- *Mobile phase:* (A : B) Disodium hydrogenphosphate (0.04 mol/L) with 4% (v/v) octane sulfonic acid (0.25 mol/L)–acetonitrile.
- *Isocratic elution:* (50 : 50).
- *Flow rate:* 1.3 mL/min.
- *Detection:* DAD (λ = 261 nm between time 0 and 9 min; λ = 241 nm between time 9 and 20 min; λ = 254 nm between time 20 and end of the run (32 min).

Local anaesthetics

The general screening systems, previously described may be used, as well as system HQ or HR, below.

System HQ

Gill R *et al*. (1984). *J Chromatogr* 301: 155–163.

- *Column:* ODS Hypersil (160 × 5 mm i.d., 5 µm).
- *Mobile phase:* Methanol–water–1% v/v solution of phosphoric acid–hexylamine (30 : 70 : 100 : 1.4).

System HR

Gill R *et al*. (1984). *J Chromatogr* 301: 155–163.

- *Column:* As for System HQ above.
- *Mobile phase:* Methanol–1% v/v solution of phosphoric acid–hexylamine (100 : 100 : 1.4).

Steroids

System HATa

Walters MJ *et al.* (1990). *J Assoc Off Anal Chem* 73: 904–926.

- *Column:* ODS Zorbax (250 × 4.6 mm i.d., 5 µm), stainless steel.
- *Eluent:* (A) Methanol.
- *Isocratic elution:* (100).
- *Flow rate:* 1.5 mL/min.
- *Detection:* UV (λ = 240, 210 and 280 nm).

System HATb

Walters MJ *et al.* (1990). *J Assoc Off Anal Chem* 73: 904–926.

- *Column:* ODS Zorbax (250 × 4.6 mm i.d., 5 µm), stainless steel.
- *Eluent:* (A : B) Methanol–water.
- *Isocratic elution:* (75 : 25).
- *Flow rate:* 1.5 mL/min.
- *Detection:* UV (λ = 240, 210 and 280 nm).

System HAR

Lurie I *et al.* (1994). *J Forensic Sci* 39: 74–85.

- *Column:* ODS Zorbax (250 × 4.6 mm i.d., 5 µm).
- *Mobile phase:* (A : B) Water–methanol.
- *Gradient elution:* (30 : 70) to (0 : 100) over 15 min with 15 min hold.
- *Flow rate:* 1.0 mL/min.
- *Detection:* DAD.

System HT

Rose JQ, Jusko WJ (1979). *J Chromatogr Biomed Appl* 162: 273–280.

- *Column:* Silica Zorbax SIL (250 × 4.6 mm i.d., 5 µm).
- *Mobile phase:* Methylene chloride–methanol (97 : 3).

Additional systems

System HAD

Aymard *et al.* (2000). *J Chromatogr Biomed Sci Appl* 744: 227–240.

- *Column:* C_{18} Symmetry Shield (250 × 4.6 mm i.d., 5 µm) protected by 2 µm Upchurch filter.
- *Column temperature:* 30°C.
- *Mobile phase:* (A : B) M/15 potassium dihydrogenphosphate with 1% (v/v) octane sulfonic acid : acetonitrile. Mobile phase (MP) 1: (95 : 5) at flow rate 1 mL/min; MP 2: (80 : 20) at flow rate 1 mL/min; MP 3: (30 : 70) at flow rate 1.2 mL/min.
- *Eluent switching programme:* At injection, MP1 to the column. From time 12 min to 30 min, MP2 to the column. From time 30 min, MP3 to the column to rinse it. From time 35 min to 40 min, equilibration with MP1.
- *Detection:* DAD (λ = 260 nm).

k	*Compound*
2.7	Lamivudine
3.2	Didanosine
3.8	Stavudine
6.6	Zidovudine
8.1	Abacavir
11.1	Nevirapine

System HAF

Tanaka E *et al.* (1996). *J Chromatogr B Biomed Sci Appl* 682: 173–178.

- *Column:* ODS TSK-gel Super (100 × 4.6 mm i.d., 2 µm).
- *Mobile phase:* (A : B) Acetonitrile–5 mmol/L sodium dihydrogenphosphate (pH 6).
- *Isocratic elution:* (45 : 55).
- *Flow rate:* 0.65 mL/min.
- *Detection:* UV (λ = 254 nm).

Retention time (min)	*Compound*
5.3	Clonazepam
6.6	Bromazepam
9.1	Nitrazepam
13.7	Triazolam
15.0	Lorazepam
18.4	Etizolam
21.0	Chlordiazepoxide
29.8	Diazepam
32.2	Flutazolam

System HAV

Rutledge DR *et al.* (1994). *J Pharm Biomed Anal* 12: 135–140.

- *Column:* RP-short alkyl chain, silanol-deactivated (SCD 100; 250 × 4.6 mm i.d.), stainless steel.
- *Mobile phase:* (A : B) Methanol–0.04 mol/L dibasic potassium phosphate (pH 5.5).
- *Isocratic elution:* (50 : 50).
- *Flow rate:* 1 mL/min.
- *Detection:* UV (λ = 237 nm).

k	*Compound*
2.2	Celiprolol
2.3	Propranolol
3.6	Diltiazem deacetyldiltiazem
5.1	Diltiazem desmethyldiltiazem
6.1	Diltiazem
6.4	Imipramine
8.2	Verapamil

System HBA

Sastre-Toraño J, Guchelaar H-J (1998). *J Chromatogr B Biomed Sci Appl* 720: 89–97.

- *Column:* C_{18} base-deactivated silica (125 × 4.6 mm i.d., 5 µm) with base-deactivated C_{18} precolumn (20 × 4.6 mm i.d., 5 µm).
- *Eluent:* (A : B) Acetonitrile–50 mmol/L potassium dihydrogenphosphate (pH 7.5, containing 500 µL triethylamine).
- *Isocratic elution:* (60 : 40).
- *Flow rate:* 2 mL/min.
- *Detection:* Fluorescence (λ_{ex} = 255 nm, λ_{em} = 315 nm).

Retention time (min)	*Compound*
8.8	Erythromycin
15.7	Clarithromycin
17.1	Roxithromycin
20.7	Azithromycin

System HBB

Taninaka C *et al.* (2000). *J Chromatogr B Biomed Sci Appl* 738: 405–411.

- *Column:* C_{18} (250 × 6.0 mm i.d., 5 µm).
- *Eluent:* (A : B) Acetonitrile–50 mmol/L phosphate buffer (pH 7.2).
- *Isocratic elution:* (43 : 57).
- *Flow rate:* 1.7 mL/min.
- *Detection:* Electrochemical (working electrode: glassy carbon; reference electrode: Ag/AgCl).

Retention time (min)	*Compound*
6.8	Clarithromycin
6.8	Erythromycin
9.6	Azithromycin
16.3	Roxithromycin

System HAE

Proust V *et al.* (2000). *J Chromatogr B Biomed Sci Appl* 742: 453–458.

- *Column:* C_{18} (Lichrospher, 100 RP-18, 5 µm) with C_{18} precolumn (Lichrospher RP-18, 5 µm).
- *Mobile phase:* (A : B) Acetonitrile–25 mmol/L sodium phosphate modified with diethylamine (0.9%) and tetrahydrofuran (1%), pH 3.0.
- *Isocratic elution:* (44.8 : 55.2).
- *Flow rate:* 0.5 mL/min.
- *Detection:* UV (λ = 260 nm).

Retention time (min)	*Compound*
6.3	Delavirdine
7.0	Saquinavir
8.0	Nelfinavir
9.4	Amprenavir
22.2	Ritonavir
28.6	Efavirenz

System HAK

Le Guellec C *et al.* (1988). *J Chromatogr Sci Appl* 719: 227–233.

- *Column:* C_{18} Symmetry (250 × 4.6 mm i.d., 5 µm) with C_{18} precolumn Symmetry sentry.
- *Mobile phase:* (A : B) Acetonitrile–20 mmol/L potassium dihydrogenphosphate.
- *Elution programme:* (50 : 50) to (70 : 30) in 15 min.
- *Flow rate:* 1 mL/min.
- *Detection:* UV (λ = 313 nm).

Retention time (min)	*Compound*
4.7	Carbamazepine
6.2	Clonazepam
7.6	Nordazepam
9.3	Clobazamm
Not detected	Phenobarbital
Not detected	Phenytoin

System HAL

Boukhabza A *et al.* (1990). *J Chromatogr* 529: 210–216.

- *Column:* C_{18} Novapak (150 × 4.6 mm i.d., 5 µm).

- *Mobile phase:* (A : B : C) Acetonitrile–methanol–6 mmol/L phosphate buffer (pH 5.7).
- *Isocratic elution:* (30 : 10 : 60).
- *Flow rate:* 1.3 mL/min.
- *Detection:* DAD ($\lambda = 242$ nm).
- *Note:* The phosphate buffer stock solution is prepared using 94 mL 0.2 mol/L sodium dihydrogenphosphate added to 6 mL 0.2 mol/L disodium phosphate heptahydrate.

Retention time (min)	*Compound*
1.4	Barbital
1.45	Clonazepam 7-acetamidoclonazepam
1.55	Clonazepam 7-aminoclonazepam
2.0	Aprobarbital
2.4	Hexobarbital
3.7	Flunitrazepam M (nor)
4.4	Nordazepam oxazepam
4.4	Oxazepam
4.6	Nitrazepam
4.33	Clonazepam
5.1	Lorazepam
6.2	Flunitrazepam
6.3	Alprazolam
6.6	Triazolam
7.7	Chlordiazepoxide
7.8	Clobazam
7.9	Nordazepam
8.1	Bromazepam
8.2	Medazepam
13.2	Diazepam

System HAM

de Carvalho D, Lanchote VL (1991). *Ther Drug Monit* 13: 55–63.

- *Column:* C_{18} (150 × 4.0 mm i.d., 3 µm) with C_{18} precolumn (40 × 4.0 mm i.d., 3 µm).
- *Mobile phase:* (A : B) Water–acetonitrile.
- *Isocratic elution:* (50 : 50).
- *Flow rate:* 0.7 mL/min.
- *Detection:* UV ($\lambda = 313$ nm).

Retention time (min)	*Compound*
1.8	Theophylline
1.98	Caffeine
2.0	Paracetamol
2.2	Primidone
2.7	Sulfamethoxazole
2.8	Phenobarbital
3.1	Chlordiazepoxide
3.4	Diazepam
3.4, 4.4	Oxazepam
3.5	Phenytoin
4.2	Lorazepam
4.3	Clonazepam
4.5	Nitrazepam
9.0	Imipramine
9.1	Desipramine
10.3	Diazepam
Not detected	Alprazolam
Not detected	Bromazepam
Not detected	Clobazam
Not detected	Codeine
Not detected	Ephedrine
Not detected	Levomepromazine
Not detected	Lidocaine
Not detected	Medazepam
Not detected	Nortriptyline
Not detected	Propranolol
Not detected	Thioridazine
Not detected	Triazolam

CHAPTER

42 Capillary Electrophoresis

F Tagliaro, A Fanigliulo, J Pascali and F Bortolotti

Introduction

Since its introduction in the early 1980s, and particularly in the first decade of this century, capillary electrophoresis (CE) has established a prominent role in many areas of applied analytical chemistry. This is demonstrated by an increasing number of applications and scientific papers in biomedical sciences, toxicology, biopharmaceutics, biotechnology, and environmental and forensic science. The spread of this application relies on its peculiar features:

- Wide analytical applications (from inorganic ions to large DNA fragments and even viruses and cells)
- Variety of separation modes (electrophoretic, electrokinetic, chromatographic and more)
- Variety of detection systems (from ultraviolet (UV) spectroscopy to mass spectrometry (MS))
- High separation efficiency (up to millions of theoretical plates) and mass sensitivity (from femtomoles (10^{-15} moles) down to yoctomoles (10^{-21} moles)); minimal consumption of samples (in the order of nanolitres) and solvents (a few millilitres per day)
- Simple and inexpensive operation coupled with instrumental ruggedness.

Moreover, being based on specific separation mechanisms, CE has established itself as an independent analytical technique complementary to chromatography.

Capillary electrophoresis originated from the optimisation of basic electrophoretic principles traditionally applied using slab gels. The range of applications of CE soon extended to include hybrid separation mechanisms, partially borrowed from chromatography, and it has become a highly versatile and flexible tool in the hands of separation scientists. CE has been recognised as potentially admissible in the US courts as a form of evidence in accordance with the Daubert Standard (Kuffner *et al.* 1996).

Although CE has received major attention in molecular biology, clinical chemistry, analytical toxicology and other areas of forensic analysis, it is still 'in its infancy'. Forensic science laboratories have to deal with a range of diverse analytical problems involving, for example, gunshot residues, explosives, inks, dusts, soils, illicit drugs, poisons, DNA fragments and proteins and others, and CE has particular characteristics that make it applicable to all these areas. Forensic samples are often limited in quantity and heavily contaminated and must be conserved as far as possible in order to allow for further investigations. CE has great potential as a practical and productive investigation tool for analytical toxicologists and other forensic scientists dealing with such samples. In addition, scientists working in the fields of clinical and biochemical analysis, where analytical versatility, minimum use of sample volume and low operative costs are extremely important, derive considerable benefits from the technique.

This chapter builds on that contributed to the third edition of this publication by Professor David Perrett in that it aims to illustrate the basic principles of CE by giving a description of its instrumentation and of the different modes of separation and detection. A major addition is the presentation of recent review papers that cover important topics of CE applications in analytical toxicology and to which the readers are referred for more detailed information. Further, a selected number of applications of particular interest are discussed.

Theoretical aspects

Capillary electrophoresis can be defined as high-voltage electrophoresis (10–30 kV) carried out in a capillary-shaped separation compartment (typical dimensions: internal diameter 20–100 μm, length 20–100 cm). The geometry of this set-up, with respect to traditional slab gel electrophoresis, offers the neat advantages of minimal band diffusion and improved joule heating control, thus permitting the application of high voltages. The reduced zone broadening results in excellent separation efficiency, reaching up to 10^6 theoretical plates.

The CE separation mechanism, as in any form of electrophoresis, is based on the principle that charged species subjected to an electric field tend to migrate, driven by electrostatic force, towards the electrode with the opposite charge. Their velocity depends on their electrophoretic mobility (μ), which is specific for each individual ionic species on the basis of the mass-to-charge ratio, as described by Equation (42.1):

$$\mu_i = \frac{q_i}{6\pi\eta r_i} \tag{42.1}$$

where μ_i = ion mobility, q_i = ion charge, η = electrolyte solution viscosity, and r_i = ion effective radius.

When an electric field of strength E is applied, the ion migration velocity (v_i) will equal the product $\mu_i \times E$, causing the physical separation of the components of a mixture of molecules with different μ_i (Equation 42.2):

$$v_i = \mu_i \times E \tag{42.2}$$

where the electric field strength E is given by Equation (42.3):

$$\text{Electric field } (E) = \frac{\text{Applied voltage}}{\text{Distance between electrodes}} = \frac{V}{d} \tag{42.3}$$

An additional phenomenon known as *electroosmosis* takes place inside the separation capillary and results from the double electrical layer that builds up at the solid–liquid interface whenever a solid surface is in contact with a solution of ions. This ionic double layer is described by the so-called zeta potential ζ. The inner wall of capillaries, silica being the most common material of which the CE capillaries are made, exhibits an excess of surface charge, since it contains a great number of silanol groups (SiOH), which at pH values higher than 2 are ionised as SiO^-. The resulting negative charge of the wall surface tends to be compensated for by cations attracted from the solution, thus building up a double electric layer. When an electric potential difference is established between the ends of the capillary (i.e. when electrophoresis starts), all the cations in the solution migrate towards the cathode (the negative electrode) and anions move in the opposite direction. The migration towards the cathode of excess cations close to the capillary wall (being not compensated by migration of the corresponding anions stationary in the wall) drags water in the same direction, thus producing a measurable flow of liquid inside the capillary (typically tens of nanolitres per minute), termed 'electroosmotic flow' (EOF). Capillaries made of materials other than silica (e.g. Teflon), or with the wall coated with neutral or charged coatings (negative or positive), will display the same phenomenon, depending on the degree of ionisation of the wall surface. It is

important to point out that even 'neutral' capillaries may display a charged surface because of the adsorption on the wall of molecules present in the solution.

Electrophoretic migration and electroosmotic flow may have either the same or the opposite direction. Thus, they sum as vectors and induce ionised species to migrate with an apparent velocity (v) resulting from the sum of their intrinsic mobility (μ_i) and the mobility of the EOF (μ_{EOF}) (Equation 42.4):

$$v = (\mu_i + \mu_{EOF}) \times E \tag{42.4}$$

The set-up of a capillary electropherograph is usually with the detector close to the end of the capillary towards which the EOF is directed, and liquid flow will drag towards the detector all the solutes contained in the injected sample, excluding those with an electrophoretic counter-migration velocity higher than the EOF itself (small ions with high charge-to-mass ratio). Inside this flow of solvent, the ionic species migrate according to the respective μ_i, whereas neutral solutes (with $\mu_i = 0$) migrate all together at the velocity of the EOF.

In short, with the usual instrumental arrangement, having the injector at the anode end and the detector close to the cathode end of an uncoated fused-silica capillary (negatively charged at the inner wall), the cations with the highest mobility will arrive at the detector first, followed by the cations with progressively lower mobility (lower charge-to-mass ratio); subsequently, the bulk of the neutrals will appear at the detector, followed by the anions in reversed order of mobility (slow anions first, fast anions last). Only the fastest anions with electrophoretic mobility higher than that of the EOF will not be detected, because they will escape from the opposite end of the separation capillary.

The EOF, being driven by a force generated close to the capillary wall, has a peculiar 'piston-like' flow profile, which is particularly beneficial for molecular separations. In fact, it minimises band broadening, which is a typical drawback of capillary liquid chromatography, where the pressure-driven flow of the mobile phase, hindered by shear forces at the wall, yields a parabolic flow profile.

The coexistence of both electrophoretic and electrokinetic phenomena, which can be tuned separately and in combination to achieve molecular separation, is a unique feature of CE that can be exploited to perform a great variety of separations modes. In addition, interactions taking place between analytes and other molecules (e.g. complex-forming molecules, organic solvents, micelles, polymer gels) present in the medium in which separation occurs further contribute to differentiation of the migration velocities of different chemical species according to non-electrophoretic principles.

For a detailed explanation of the theoretical principles of CE, readers are referred to publications listed in the 'Further reading' section of this chapter, and particularly to the book by Ahuja and Jimidar (2008).

Finally, although quantification methods used in CE are similar to those applied in other forms of chromatography, in that they mainly use internal standardisation, two important differences must be emphasised. First, in CE most separations have an 'on-column' detection step. In this process, the velocity of the peaks crossing the detection window differs according to the respective ion mobilities of the analytes. As a result, the 'apparent peak width' of zones moving at different velocities will differ, even if the 'real band width' is the same. Consequently, two equal bands differing only in mobility will show different 'peak areas', because of the difference in their residence times inside the detector cell. To overcome this problem, for quantitative computations the ratio of peak area to migration time can be used instead of peak areas. An alternative is to use peak heights.

Second, since only minute amounts of sample (of the order of a few tens of nanolitres) are injected onto the separation capillary, it is difficult to handle these volumes with precision using current technology. This seriously restricts the use of external standardisation for quantitative methods. Thus, as for example with gas chromatography (GC), internal standardisation is much preferred.

Instrumental hardware

The outstanding feature of CE instrumentation is its basic simplicity. A schematic representation of a capillary electropherograph is given in Figure 42.1.

In brief, as in other chromatographic techniques, a CE analysis is based on three major steps: sample injection, separation and detection. As a consequence, a capillary electropherograph can be described as an assembly of the following components:

- An injection system
- A high-voltage power supply
- A separation capillary (generally located in a thermostatted compartment)
- A detector.

In CE, only a minute amount of sample can be introduced into the capillary, in order to maintain the separation efficiency. Overloading of samples causes peak broadening and peak distortion. Sample loading is limited by capillary dimensions. Typically, the length of the sample plug should not exceed 1–2% of the total capillary length and this corresponds to volumes of between 10 and 100 nL, for typical CE capillaries, which have an inner volume ranging between 1 and 4 µL.

Sample injection is achieved by replacing the inlet buffer reservoir with the sample vial for a few seconds. The forces driving sample introduction into the separation capillary may be brought about by applying pressure, voltage or both. The most common modes are hydrodynamic and electrokinetic injection.

Hydrodynamic injection is the most widely used and is carried out by the application of a positive pressure at the inlet end of the capillary, by the application of a vacuum at the terminal end or by exploiting siphoning between the two capillary ends. In this way, the amount of sample loaded is almost independent of the sample composition and is representative of the whole sample solution. Hydrodynamic injection is described by Equation (42.5):

$$V = \frac{\Delta P d^4 \pi t}{128 \eta L} \quad \text{(Hagen–Poiseuille equation)} \tag{42.5}$$

where V = sample volume, ΔP = applied pressure, d = capillary internal diameter, t = injection time, L = capillary length and η = buffer viscosity.

The typical applied pressure range is between 5 and 30 psi (1 psi = 69 mbar = 6.9 kPa) and injection times are between 5 and 20 seconds, although these parameters depend strongly on method optimisation. The advantages of this injection mode are reproducibility and suitability for quantitative analysis. However, it is subject to limited sensitivity owing to the tiny volume of sample introduced into the capillary and hence the limited mass of analytes that can be introduced into the capillary.

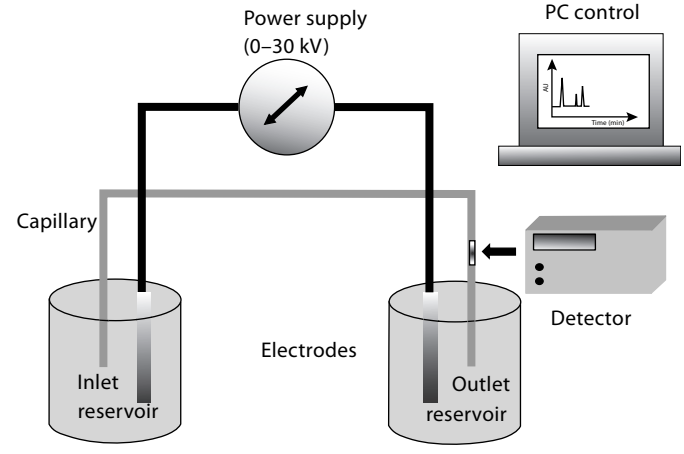

Figure 42.1 Schematic representation of a capillary electropherograph.

Electrokinetic injection is obtained by applying a voltage for a few seconds while the injection end of the capillary is dipped into the sample vial. In this way, analytes enter the separation capillary by both electrophoretic migration and the pumping effect of the EOF. The amount of sample introduced is given by Equation (42.6):

$$Q = \frac{(\mu_i + \mu_{EOF}) V \pi r^2 C t}{L} \quad (42.6)$$

where Q = grams or moles of injected amount, μ_i = analyte electrophoretic mobility, μ_{EOF} = EOF mobility, V = applied voltage, r = capillary radius, t = injection time, L = capillary length and C = analyte concentration.

It can be seen that, in electrokinetic injection, discrimination occurs on the basis of the electrophoretic mobility of the sample components, so that ionic species with mobilities towards the detector will be preferentially introduced with respect to neutral species and ions with the opposite charge. This results in selectivity and sensitivity enhancements for the analytes that are preferentially loaded, but also in delicate reproducibility, strongly affected by the sample composition. Electrokinetic injection is the injection mode exploited to realise 'sample stacking' procedures that allow large increases in analytical sensitivity, as discussed below with regard to sample pretreatment and sample enrichment.

Separation capillary

Fused silica is by far the most widely used material for CE capillaries, since it is chemically and electrically inert, physically resistant, UV transparent (for the needs of in-capillary UV detection) and displays good thermal conductivity (in order to ensure high dissipation of the joule heat). To achieve the necessary mechanical resistance, capillaries are externally coated with a protective polyimide layer, in a similar way to GC capillaries. This external layer is optically opaque and must be removed in the region where an optical detector is to be placed. This can easily be achieved by burning or scraping off the material in a capillary segment corresponding to the detection window. In-capillary optical detection has the advantage of avoiding any post-separation added volumes and consequent band broadening, but has disadvantages in terms of optical path length and cell geometry.

Typical ranges for inner and outer diameters of CE capillaries are 25–100 μm and 350–400 μm, respectively. Capillary length typically rages between 20 and 100 cm.

Fused-silica capillaries can be internally 'uncoated' (naked) or 'coated' with thin layers of polymers. The most common internal coatings include amines, polyacrylamide, cellulose, poly(vinyl alcohol)s, amino acids, surfactants, aryl pentafluoro compounds, poly (vinylpyrrolidinone) and poly(ethyleneamine). Also, liquid chromatography (C_2, C_8, C_{18}) or GC (poly(ethylene glycol) and phenyl methyl silicone) stationary phases can be used as capillary wall coatings.

An inherent problem in CE separations is reproducibility, since the EOF and consequently migration times of analytes are affected by the inner surface conditions. A common practice adopted to refresh the inner surface of uncoated silica capillaries and remove adsorbed materials is that of flushing with strong bases, which dissolve a thin layer of the silica surface. Usually, 1 mol/L sodium hydroxide solution is flushed through the capillary, followed by 0.1 mol/L sodium hydroxide solution and then by the separation buffer for final conditioning. The frequency of base conditioning during the experimental work depends on the nature of the samples, the buffer employed, the working pH, the background electrolyte (BGE) concentration and the nature of the capillary surface. Acid washing and flushing with solvents are less popular but effective practices, particularly when coated capillaries are used that would suffer from exposure to basic solutions.

Thermostatting is another key point to ensure reproducibility of capillary separations. Temperature variations due to joule heating should be minimised in CE analyses so as to minimise viscosity changes in both separation and injection. Thermostatting is better achieved by using a refrigerant fluid, but air streams are also effective when separations generate low currents.

Power supply

A high-voltage power supply is a fundamental part of a CE instrument. It should be capable of delivering up to 30 kV, with currents up to 200–300 μA. Because of the typical direction of the EOF (towards the cathode, in naked fused-silica capillaries), the standard polarity configuration has the anode (positive electrode) placed at the injection end of the capillary and the cathode (negative electrode) at the opposite end, close to the detector (a configuration known as 'normal polarity'). However, in many cases (e.g. when the EOF is directed towards the anode, because the capillary wall is coated with a positively charged wall modifier) the application of a 'reversed polarity' configuration is needed in order to allow the analytes to migrate to the detector. For this reason, dual-polarity power supplies that are capable of rapidly switching the electrode polarity are used in modern CE instrumentation.

CE separations are usually carried out at a constant potential, but separations at constant current can sometimes be needed. An advantage of constant-current mode is the possibility of compensating by automatic adjustments of the voltage for viscosity changes caused by inadequate temperature control.

Voltage programming, i.e. applying gradients of voltage or current during the analysis, has also been reported to improve separation efficiency in the case of complex samples, but the advantages of gradient application are not as important as in GC and high performance liquid chromatography (HPLC), where temperature or buffer composition gradients are the most popular mode for tuning separation.

Detectors

Although it might be expected that the detection of analytes directly inside the capillary through its transparent silica wall would be relatively simple, this is not the case. Inherently, the main problem related to detection is sensitivity, not in terms of detectable mass (picogram amounts of analytes are easily detectable inside the capillary with simple UV detectors), but in terms of concentration of analyte. Since only minute volumes (nanolitres) of samples can be introduced into the tiny separation compartment (i.e. the capillary, with a typical volume 1 μL), only very small amounts of analytes will reach the detector. On this basis, taking into account the high efficiency of CE (i.e. the ability to produce separations without generating dilution of the electrophoretic zones), it is mandatory to avoid zone broadening in order to achieve an acceptable sensitivity, either 'in-capillary' or 'off-capillary'. The way to achieve this is by limiting any 'dead volumes' in the system, particularly at the detection side, and increasing the response time of the detectors.

In the next subsections the most common CE detectors are described and their relative advantages and drawbacks discussed.

Optical methods

UV is the most commonly employed means of detection in CE instruments. Absorbance detection is usually performed 'in-capillary', with the optical beam focused directly into the capillary, crossing a transparent window made in it by removing the protective polyimide external coating. The limited optical path inside the capillary and the poor optical shape of the capillary section are the major factors negatively affecting sensitivity.

There are also other features peculiar to CE separation that have to be taken into account in quantitative analysis. As mentioned previously, detection in CE occurs when separation is still taking place, in contrast to chromatographic techniques where all analytes move at the same velocity in front of the detector, which is located after the separation column. In CE, the migration velocity differs from one analyte to another during detection such that their residence time in the detector is affected by their different velocities, and this affects the respective peak areas. To correct this artefact in quantitative analysis, peak areas in CE should be divided by their migration times.

Moreover, in CE the dynamic linear range of optical detection is less extended than in HPLC, particularly with UV detection, since deviations from the Beer–Lambert Law occur owing to the small size and curvature of the capillary cell.

Despite these limitations, UV detection is generally applicable, easy to perform and acceptably sensitive for most applications.

Capillary design and optical cell design may be optimised to improve sensitivity. Two examples are Z-shaped cells and bubble cells. In Z-cells, a double right angle, in the capillary region where detection takes place, results in an increased optical path length. The light beam runs axially for the length included between the two right angles. In bubble cells, solutes pass through an expanded region ('bubble') inside the capillary, where the analyte zone expands radially and, consequently, contracts longitudinally, increasing the path length without sacrificing separation.

The availability of multichannel, dispersive optical detectors (diode array detectors, DADs) for commercial CE instruments has greatly impacted CE instrumentation, allowing for enhanced information content at each analytical run and easier method development.

Fluorescence detection, mainly based on laser-induced fluorescence (LIF), has been proficiently applied both to fluorescent analytes and to molecules that can be made fluorescent after chemical derivatisation. In this case, sensitivity can be as high as 10^{-12} mol/L.

In the case of non-UV-absorbing ionised molecules, 'indirect detection' can be performed by introducing a detectable (UV-absorbing) additive, with the same charge as the analyte of interest and similar mobility to the running buffer. Displacement of the additive by the non-absorbing analyte will occur in the capillary in the zone of residence of the analyte and consequently a negative peak will be recorded by the detector (Beckers, Boček, 2003; Johns *et al.* 2003). Indirect detection, for instance, makes possible the determination of small organic and inorganic ions, most of which do not absorb UV light, using the UV detectors present in all commercial CE instruments.

Electrochemical detectors

Electrochemical (EC) detectors, particularly amperometric and conductimetric detectors, can be successfully coupled with CE. Electrochemical detection can be performed either 'in-capillary' or 'off-capillary'.

Amperometric detectors record the electronic current generated by an electrochemical reaction involving the analyte molecules, thus displaying, for oxidisable (or reducible) analytes, high sensitivity and good selectivity. This technique is mass sensitive and therefore independent of the cross-sectional pathlength of the capillary. Conductimetric detectors are simpler, although less selective, than amperometric detectors. Their application to CE allows direct detection of small ions, making possible ion analysis in a configuration resembling ion chromatography.

A general problem with EC detection in CE is the isolation of the separation circuit from the detection circuit to avoid interferences. A further problem of the EC detection mode is the necessity of using miniaturised electrodes, compatible with capillary dimensions. These devices are not commercially available so far, making EC detection (particularly amperometric) still reliant on home-made components.

Mass spectrometry

(See also Chapters 37 and 41.)

Hyphenation with mass spectrometry (CE-MS) is the latest major innovation in CE. In recent years the application of CE-MS has grown substantially, and now accounts for a large number of publications in the pharmaceutical, biotechnological, environmental and toxicological science literature (Schmitt-Kopplin, Frommberger 2003; Schmitt-Kopplin, Engelmann 2005).

The key issue when coupling CE with MS is the efficient transfer of ions from the CE capillary to the mass analyser without sacrifice of separation performance and sensitivity (Smith *et al.* 1988).

The electrospray ionisation (ESI) source has proved to be the most suitable for CE-MS coupling. This produces gas-phase ions from ions in solution, which are introduced into the mass spectrometer after being sprayed in a plume of droplets, as a result of a voltage applied on a holed metal tip. The ESI source is compatible with the CE-limited flows, since it is concentration sensitive and not mass sensitive. Other ion sources can be coupled with CE, for example atmospheric pressure chemical ionisation (APCI; Tanaka *et al.* 2003) and atmospheric pressure photoionisation (APPI; Mol *et al.* 2005), but the recent successful results of CE-MS interfacing are due to the development of the CE-ESI hyphenation.

Coupling CE with ESI involves joining a high-voltage-driven separation technique with a high-voltage-based molecule ionisation technique. Thus, it is necessary to ensure electrical continuity between the two systems while at the same time keeping the respective circuits independent. Second, a stable flow of ionised molecules must be constantly produced during analysis and therefore a BGE compatible with the ion source must be chosen.

CE can be interfaced with ESI with essentially two possible alternatives, as well described by Cai and Henion (1995): the 'sheath liquid' interface and the 'sheathless' interface. In the former case the electrical continuity is brought about by an additional aqueous/organic flow (the sheath liquid) of the order of magnitude of μL/min, which dilutes the liquid stream coming out of the separation capillary (nL/min). This accessory flow also ensures the onset of a stable ion spray. The diluting effect on the sample may be seen as a drawback in terms of sensitivity, but, on the other hand, it allows for the use of non-volatile BGEs or small amounts of additives or coating agents in the separation buffer (van Wijk *et al.* 2007).

In a sheathless interface, the electrical contact between the CE buffer and ion source is established by making the terminal end of the separation capillary conductive via several devices, such as stainless-steel connections, microelectrodes, conductive polymer coatings, and metal coatings of gold, silver, nickel or chromium. Unfortunately, the lack of reproducibility and robustness, due to delicate fabrication and manipulation of miniaturised components, limits its use on a large scale despite its advantages in terms of sensitivity (Smith 1990). Novel sheathless configurations have recently been designed, exploiting the results of the developments in nanospray and other miniaturised technology, with promising results (Janini *et al.* 2003; Kele *et al.* 2005).

Fast mass analysers with a high sampling rate along the electropherogram are required to follow the tiny, fast and closely moving CE peaks, which reflect the intrinsic high efficiency of this separation technique. CE has been hyphenated with almost all types of MS detector: magnetic sectors (Perkins, Tomer 1994), single and triple quadrupoles (Baidoo *et al.* 2003), ion traps (IT; McClean *et al.* 2000; Wey *et al.* 2000; Wey, Thormann 2001a; Iio *et al.* 2003), Fourier transform ion cyclotron resonance (FTICR; Hofstadler *et al.* 1994, 1996) and time-of-flight (TOF) mass spectrometers (Lazar *et al.* 1998a, 1998b; Ullsten 2004). At present, as in HPLC, ion traps remain the most widely employed detectors for CE because of their relative speed of scanning, relatively low cost and the possibility of performing multistep fragmentation experiments (MS^n).

The hyphenation of CE with TOF MS is seen as particularly promising, because of the high scan rate (10–200 μs per spectrum) and high sampling frequency of this detector (Lazar *et al.* 1998a, 1998b; 1999). TOF shows a particular advantage for toxicological analyses owing to the possibility of identifying molecules by determining their accurate mass and not requiring fragmentation databases.

Microchip CE

A specific advantage of CE is that instrumentation can easily be miniaturised in a microchip format, since a precise control of fluidics and other separation conditions can be obtained simply by changing the voltage and without the need of mechanical pumps, valves, etc. as in HPLC. CE microchips can also provide custom design, versatility, reduced consumption of reagents and sample, low waste generation, and increased analysis speed and portability. Because of the minimal amounts of sample injected, the most commonly used detection method is LIF, which offers the highest sensitivity. Microchip CE is mostly suitable for portable devices and fully automated analysers. Instrumentation based on this technique is now commercially available. Table 42.1, taken from the third edition of this work, gives an indication of the relative sensitivities of CE detectors towards various analytes in terms of mass and concentration limit of detection (LOD).

Modes of separation

A particular advantage of CE is the possibility of using the same hardware to perform different separation modes by simply adjusting a few

Table 42.1 Relative sensitivity of CE detection systems towards appropriate compounds

Detection mode	*LOD (moles injected)*	*LOD (mol/L)*	*Commercial availability*	*Comments*
UV/visible	10^{-13}–10^{-16}	10^{-3}–10^{-8}	Yes; DAD supplied with the major instruments	At <200 nm it is almost a universal detector; sensitivity is limited by capillary ID
Fluorescence	10^{-15}–10^{-17}	10^{-5}–10^{-9}	Yes – stand-alone add on	Limited to fluorescent compounds and derivatives; xenon lamp based
Laser-induced fluorescence	10^{-18}–10^{-22}	10^{-10}–10^{-16}	Yes	Very sensitive, but restricted to situations in which the wavelength of lasers matched the excitation wavelength of the analyte
Amperometric	10^{-18}–10^{-20}	10^{-5}–10^{-11}	No	Limited to electroactive species
Conductivity	10^{-15}–10^{-16}	10^{-4}–10^{-8}	Yes, but not currently manufactured	Universal towards ions, but lacks sensitivity
Mass spectrometry	10^{-15}–10^{-17}	10^{-8}–10^{-10}	Interfaces available from both CE and MS companies	Universal detection, but CE modes are limited
Indirect UV	10^{-10}–10^{-12}	10^{-2}–10^{-5}	Yes, with UV detector	Universal for ions, but lacks sensitivity
Indirect fluorescence	10^{-15}–10^{-17}	10^{-5}–10^{-6}	Yes, but requires fluorescent detector	Universal for ions, but lacks sensitivity

analytical parameters, such as running buffer composition or capillary surface. This is illustrated in Figure 42.2, which summarises how a CE method is developed by evaluating the effects of changing these parameters. This unique characteristic of CE makes it a highly flexible tool with which to tackle the large and varied spectrum of compounds that are typically encountered in toxicological analysis, e.g. small ions (CN^-, K^+), drugs, drug enantiomers, drug metabolites, proteins, peptides and DNA. The most common separation modes are described below.

Capillary zone electrophoresis

Capillary zone electrophoresis (CZE) is the basic mode of operation that can be applied in CE. Analytes migrate in discrete zones along the capillary under a high electric field (about 600–700 = V/cm), with different velocities, depending on their individual electrophoretic mobilities (μ).

The presence of the EOF produces an electrically driven flow of liquid, which, in fused-silica capillaries (exposing SiO^- groups), is directed from the anode to the cathode. The electroosmotic flow mobility (μ_{EOF}) is described by Equation (42.7):

$$\mu_{\mathrm{EOF}} = \frac{\varepsilon\zeta}{4\pi\eta} \tag{42.7}$$

where ε = dielectric constant, ζ = zeta potential and η = solution viscosity.

Because of the presence of the EOF, as already mentioned, both cationic and (most) anionic solutes will move towards the detector, which is typically located at the cathode end of the capillary. Neutral species will move, without separation, at the same velocity as the EOF.

The EOF can be modified, reduced almost to zero, or reversed by modifying buffer characteristics (pH, composition, ionic strength) and by using additives or capillary wall modifiers (coatings). Buffer ions should be chosen that are to be used within ±1 pH unit of their pK_a and carry low currents. All buffer systems absorb UV radiation, particularly in the 190–230 nm spectral region, i.e. the range of UV detection most commonly used in CE. Inorganic buffer systems such as phosphate and borate are preferable when low-wavelength UV detection is used. Table 42.2 gives physicochemical values for the buffers most commonly used in CE.

Capillary coating can be accomplished in a permanent way by chemical modifications of the capillary surface or, more commonly, by adding

HEPES, *N*-(2-hydroxyethyl)piperazine-*N'*-(2-ethanesulfonic acid); NA, not applicable; TRIS, tris(hydroxymethyl)aminomethane.
[a] All measurements obtained using AR-grade salts and usually the sodium salt.
[b] All determinations performed using 25 mmol/L solution at 25°C, except that the SDS solution was 75 mmol/L and those marked *for which 5 mmol/L was used.
[c] All values measured at the pK_a adjusted from the native pH with 25 mmol/L HCl or 25 mmol/L NaOH as appropriate.
[d] The native pH is the pH of the simple solution of the salt in water.
[e] Absorbance measured in a 1-cm silica cell against an empty silica cell.

modifiers to the running buffer (dynamic coating). A major advantage of dynamic coating is reproducibility, since it is continuously regenerated, the modifier always being present in the running buffer.

Although aqueous buffers are the standard separation electrolytes in CZE, the use of organic solvents as running media has been reported in several publications (Riekkola *et al.* 2000; Geiser, Veuthey 2009).

The advantages of non-aqueous capillary electrophoresis (NACE) are especially related to its suitability for molecules with poor solubility in water and to a change in selectivity with respect to aqueous buffers. Moreover, the high volatility of most organic solvents makes this technique particularly eligible for MS coupling. Several aspects of electrophoretic migration are changed in an organic medium. The most relevant are changes in the volume of solvated analyte ions and in the protonation equilibria of the analyte molecules owing to different dielectric constants, different acid–base properties and the different solvation power of organic solvents with respect to water. This results in a dramatic change in the pK_a of molecules that can be exploited to perform separations of molecules with similar pK_a values in aqueous buffers (Riekkola 2002). An additional advantage is the lower current generated on voltage application. The use of organic solvents, with small amounts of organic acids or buffer salts added, has proved to be effective in a wide range of applications (Porras *et al.* 2001; Scriba 2007).

Another special mode of CZE, known as complex-formation electrophoresis, can be used to achieve chiral separations. It is based on the addition of special modifiers to the running buffer, acting as chiral selectors. This technique is much less expensive and more efficient than chiral HPLC or GC, where expensive and delicate chiral stationary phases are needed. The chiral selectors most commonly used in CE are cyclodextrins (CDs) which are neutral cyclic oligosaccharides consisting of six, seven or eight glucose units, named α-, β- and γ-CD, respectively. Chiral selectivity is achieved by forming reversible inclusion complexes of different affinity constants with each of the two enantiomers of a chiral analyte. Since the mobility of the complex is different from that of the free drug, the chiral separation is achieved as a function of the affinity differences of the CD used for each of the two steric isomers (for a review see Scriba 2008). There is now increasing interest in the use of macrolytic antibiotics, which were first introduced as chiral selectors by Armstrong *et al.* in 1994. These exhibit a variety of interactions (inclusion, electrostatic, hydrogen bonding) and this enables high chiral resolution with a wider range of analytes (acidic, basic or neutral compounds). Six groups of antibiotics have been employed so far as chiral selectors in CE, namely glycopeptides, polypeptides, ansamycins, aminoglycosides and lincosamides. A comprehensive review of their application to the chiral analysis of pharmaceuticals such as NSAIDS, anticoagulants, beta-blockers, vasodilators and hormones has been given by Prokhorova *et al.* (2010).

Micellar electrokinetic chromatography

Micellar electrokinetic capillary chromatography (MEKC or MECC) was introduced by Terabe *et al.* (1984) to separate non-charged (neutral) analytes.

Micelles, made of anionic or cationic surfactants, have a net electrophoretic mobility because of their charged outer surface; in addition they can transport uncharged species along the capillary in their hydrophobic core. In MEKC, a micellar phase (formed by a surfactant at a concentration above its critical micelle concentration, CMC) with electrophoretic mobility opposite to the EOF is added to the running buffer. In this system, which resembles reversed-phase liquid chromatography, the separation occurs by the partitioning of neutral molecules between the BGE and the micelles, which act as a 'pseudo-stationary phase', moving slowly to the detector because of their electrophoretic mobility

opposite to the EOF. They therefore exert a retarding effect on the compounds that they interact with, while the EOF acts as a chromatographic mobile phase, driving the analytes towards the detector. In this system, the uncharged more polar analytes are excluded from the lipophilic core of the micelles and consequently migrate first, at a velocity matching that of the EOF. On the other hand, the most lipophilic compounds are highly retained by the micelles and move at a velocity matching the 'apparent' migration of the micelles towards the detector. The compounds with an intermediate polarity interact selectively with the micelles and are differentially retarded according to their individual degree of lipophilicity.

The most frequently used surfactant for MEKC is sodium dodecylsulfate (SDS), but cationic surfactants, such as cetyl trimethylammonium bromide (CTAB) or dodecyl trimethylammonium bromide (DTAB) are also used.

As in reversed-phase chromatography, the addition of organic modifiers (methanol, acetonitrile, etc.) to the running buffer can be used to modify selectively the 'elution' of the analytes.

MEKC can be seen as a very flexible mode of CE, capable of separating both neutral and charged species at the same time. Thus it proves to be a suitable tool for a wide range of applications and, particularly, for the analysis of drugs and other organic compounds.

Capillary electrochromatography

Capillary electrochromatography (CEC) is electrophoresis carried out inside a capillary containing a stationary phase, similar to a HPLC column. Thus, it can be seen as a kind of 'hybrid' technique between capillary liquid chromatography and capillary electrophoresis, exploiting different separation mechanisms, both chromatographic (partitioning of molecules between stationary and mobile phases) and electrophoretic (differential mobility of charged species in an electric field). As in MEKC, the driving force of the mobile phase is the EOF generated at the interface between the mobile phase and the stationary phase. The generation of the EOF inside the stationary phase achieves the advantage of minimised band spreading in comparison with capillary HPLC.

Although in theory CEC appears very efficient and selective, the limited availability and reproducibility of capillary columns has resulted in few applications being described.

Capillary isoelectric focusing

Capillary isoelectric focusing (CIEF) uses the basic principles of isoelectric focusing in a capillary format. In brief, under an electric field, a pH gradient is generated inside the capillary that is filled with a mixture of amphoteric species (known as ampholites). The separation in this case is not attained by migration differences but through the focusing of analytes in discrete zones of the capillary, on the basis of their isoelectric points. This technique is the gold standard for the separation of proteins (or other ampholites) which are differentiated with exceptional selectivity that is difficult to achieve with separation techniques simply based on charge-to-mass ratios or molecular weight differences.

In CIEF, proteins do not in fact migrate through the capillary, but settle (*focus*) inside the capillary where the local buffer pH equals their isoelectric points (pIs). In a subsequent step, an external force (e.g. pressure, electroosmosis) is applied to drive the discrete analyte zones out of the capillary towards the detector.

This mode of operation is particularly useful for the separation of isoforms of the same protein, which often differ only slightly in net charge or in mass-to-charge ratio, but exhibit different pIs.

Capillary isotachophoresis

Isotachophoresis means 'moving at the same velocity'. Capillary isotachophoresis (CITP) differs from CE in that the electric field is different in each section of the capillary. Ionic analytes are separated and migrate in discrete zones at the same speed between two ionic solutions, one with the highest mobility (the leading electrolyte) and the other with the lowest mobility (the terminating electrolyte) of all the analytes in the sample.

Because of its band-focusing ability, CITP can be used not only for direct separation but also for sample pretreatment with a concentration ability of up to 100–1000 times, followed by CZE analysis.

Capillary gel electrophoresis

Capillary gel electrophoresis (CGE) is electrophoresis performed in a capillary filled with a sieving medium, typically a linear or cross-linked polymer, where the separation mechanism is based on the different size of analytes. It is mainly applied for the separation of biopolymers in which, because of the similarity of the constituting monomeric units, values of charge-to-mass ratios are almost constant in spite of different molecular sizes. In these cases, the potential of plain electrophoretic separations is extremely poor and, consequently, an additional mechanism with different selectivity, i.e. molecular sieving, must be introduced into the separation process. CGE is typically used for DNA–RNA analysis and sequencing (e.g. in forensic DNA fingerprinting) and for the characterisation of proteins (resembling slab gel SDS–polyacrylamide electrophoresis, SDS-PAGE).

In CGE, entangled polymer solutions (linear polyacrylamide, hydroxyalkylcellulose, poly(vinyl alcohol), etc.) are often preferred to cross-linked gels.

Capillary immunoassay

Capillary immunoassay is a combination of immunochemistry and electrophoresis. In this analytical mode the selectivity relies on antigen–antibody recognition, whereas electrophoresis achieves the separation between the free and the bound antigen. The addition of excess antigen tagged with a label that is detectable by the detector of the CE instruments produces competition between labelled and native antigen for the binding sites on the antibody. Therefore, the amount of labelled antigen in the 'free fraction' will be inversely correlated with the concentration of the native antigen in the sample. Capillary immunoassay is rapid and versatile and appears to be particularly suitable for use as a screening method for drugs in biological fluids. Most publications on capillary immunoassay describe competitive immunometric methods to detect small concentrations of analytes in complex biological matrices. The introduction of labelled drugs as fluorescent tracers, which could be easily detected by LIF detectors, offers an opportunity to achieve high sensitivity. For example, Chen and Pentoney (1994) described an immunoassay technique coupled with CE separation for the analysis of digoxin in serum at clinically useful concentration levels of 10^{-10} mol/L. Thormann *et al.* (1998) proposed a screening method for the detection of urinary methadone by capillary electrophoretic immunoassay at a concentration of 10 ng/mL.

Sample pretreatment and sample injection

As previously discussed, the major drawback of CE is its moderate sensitivity in terms of analyte concentration because of the small sample volumes (typically ~10–50 nL) that can be injected into the separation capillary. In particular, for the most widely used detection method (UV absorbance) the sensitivity limit of CE is generally 10- to 100-fold higher than that of HPLC. Effective sample preconcentration techniques may overcome this limitation. Other problems in applying CE to biological samples are the high concentrations of inorganic constituents present in the samples, which cause electrodispersion and reduce the efficiency of separation, with resulting loss of resolution and sensitivity. Consequently, sample preparation, including clean-up and preconcentration, plays a key role in the application of CE to complex samples.

Basically, conventional sample clean-up and preconcentration methods, such as solid-phase extraction (SPE), solid-phase microextraction (SPME), liquid–liquid extraction (LLE), protein precipitation and dialysis can be applied before CE analysis. The prepared sample (usually purified and concentrated) is injected into a capillary; CE separation and analyte detection follow.

Off-line preconcentration methods can lower the detection limit of CE by 10- to 30-fold or even more, mainly owing to the higher purity of the injected material. Their main disadvantage is sample loss, because no more than 1% of the extracted sample is injected into the capillary. Moreover, sample loss and sample contamination may occur during the preconcentration process, especially when a large volume of sample is concentrated in a tiny volume of extract. It is therefore desirable to have on-line sample clean-up and preconcentration methods (Veraart *et al.* 1999; Simpson *et al.* 2008). On-line sample clean-up and concentration can be achieved using selective chromatographic sorbents packed inside the capillary injection end. This type of on-line coupling is also called in-line SPE-CE coupling. The sample enrichment procedure includes washing, wetting, conditioning, sorption, washing, filling and desorption, before CE separation. This compact SPE technique lowers the detection limit of CE by factors of 700–1000.

In some cases only nanolitre or low microlitre volumes of sample are available and this places constraints on the sample preparation options. For such samples, direct sample injection may be necessary, possibly coupled with on-capillary concentration or derivatisation. Sample-stacking techniques are the most frequently used 'on-capillary' concentration methods, since they do not need any preconcentration device to be connected to the capillary. In sample stacking, the sample is prepared in a low-conductivity buffer, while the CE running buffer has a relatively high concentration of salts (high conductivity). It is well known that the electrophoretic velocity of an ion in a low-conductivity matrix is higher than that in a high-conductivity matrix, because of a higher electric field (in the low conductivity medium). Therefore, when the ions electromigrate across a boundary between low- and high-conductivity matrices, they are subjected to a sudden slow down, resulting in stacking (concentration) of the sample zone at the interface between injection plug and separation buffer. One merit of sample stacking is that it can inject a larger sample plug into the capillary. In some experiments, more than half the capillary can be filled with sample plug (partial-filling techniques). Sample stacking can also be accomplished during electrokinetic injection when the inlet capillary is immersed in a sample vial with a low-conductivity matrix. This stacking mode is also called field-amplification sample stacking (FASS). Injection of a short plug of water before the sample is reported to be able to enhance the electric field at the injection point and thus to increase the stacking. Other concentration methods, such as acetonitrile stacking, sweeping and the use of a pH junction, are also based on the velocity difference of ions moving across the boundary of the sample plug and the running buffer. An overview of the approaches to sample preparation for capillary electrophoresis has been presented by Wu (2003).

Applications of CE to forensic and clinical drug analyses

Drugs

Capillary electrophoresis was introduced in the early 1990s for the determination of potentially toxic, illicit and abused drugs in both clandestine preparations and biological fluids. CZE and MEKC are the most commonly employed electrophoretic techniques in this regard (Boone, Ensing 2003). Single-wavelength UV, DAD, fluorescence and MS detectors are reported as being employed in most literature applications. CE has been claimed to offer advantages over chromatography for the separation of chiral drug families, e.g. amfetamines and ring-substituted amfetamines.

Shihabi *et al.* (1998) reviewed the application of CE in the clinical field of therapeutic drug monitoring and cited references for the analysis of antiepileptics, antiarrhythmics, cardiovascular drugs, analgesics, antiasthmatics, immunosuppresants, antitumour agents and antibiotics in serum and urine. Examples of drugs being analysed in serum or urine by chiral separation are also listed. Although CE has not, as yet, found widespread routine use in this area, it remains a promising approach and its versatility has been demonstrated recently by the development of a rapid method for the measurement of serum lithium concentrations (Pascali *et al.* 2010). In an early review, Boone *et al.* (1999) listed details for the CE analysis of over 200 drugs and metabolites in biological samples including the sample pretreatment methods applied and the detection limits achieved.

A detailed review of the use of electrophoretic and electrokinetic separation techniques for profiling of drugs and related products was published by Hilhorst *et al.* (2001). Other more recent reviews on the application of capillary electrophoretic/electrokinetic techniques in forensic toxicology were published by Thormann (2002), Anastos *et al.* (2005) and Tagliaro *et al.* (2007).

The use of CE as an alternative to the more traditional GC and HPLC techniques is justified by the minimal amount of sample required, making this approach suitable for specific applications such as single-cell analysis (Yeung 1999; Phillips 2001; Woods *et al.* 2004; Arcibal *et al.* 2007) and determination of samples prepared by microdialysis (Denoroy *et al.* 1998; O'Brien 2003).

One of the most interesting applications of CZE showing the suitability of this technique for comprehensive toxicological drug screening in biological samples was reported by Hudson *et al.* (1995). Hudson analysed 326 basic and neutral drugs by CZE using two phosphate running buffers at pH 2.5 and pH 9.5, with UV detection and electrokinetic injection. LODs lower than 10 ng/mL for most of the tested drugs were obtained in spiked blood samples.

Alnajjar *et al.* (2004) used fluorescence detection for the CE analysis of multiple drugs of abuse in biological fluids. Morphine, normorphine, 6-acetylmorphine and codeine were separated and quantified using native fluorescence, although with moderate sensitivity. Derivatisation with fluorescein isothiocyanate coupled with LIF detection provided sensitivities higher than those for GC and HPLC.

CZE was also applied by Zhang *et al.* (2007) for the analysis of the toxic alkaloids lappaconitine, bullatine A, atropine sulfate, atropine methobromide, scopolamine hydrobromide, anisodamine hydrobromide, brucine, strychnine, quinine sulfate and chloroquine in human blood and urine, using procaine hydrochloride as an internal standard. The separation employed a fused-silica capillary of 75 μm i.d. × 60 cm length and a buffer containing 100 mmol/L phosphate and 5% acetonitrile (pH 4.0). The sample was injected in a pressure mode and the separation was performed at a voltage of 16 kV. The compounds were detected by UV absorbance at wavelengths of 195 and 235 nm. Electrophoretic peaks could be identified either by the relative migration time or by their UV spectrum.

In-house coated capillaries (with poly(ethylene oxide)) were used in a very simple CZE method (running buffer 100 mmol/L phosphate pH 6.4; UV detection at 200 nm wavelength) for the analysis of morphine, codeine, methadone and EDDP (a methadone metabolite) in human urine, after acid hydrolysis and LLE. Using electrokinetic injection, LODs ranging from 50 ng/mL to 100 ng/mL were achieved, thus making the method suitable for practical application in urine drug testing (Di Pietro *et al.* 2006).

Because of its ability to separate both neutral and charged compounds and its relatively high peak capacity, MEKC has traditionally been preferred to CZE for the analysis of illicit drug preparations.

In a paper by Ishii *et al.* (2001), the ability of MEKC to simultaneously separate and detect cocaine congeners and sugars added as excipients to clandestine preparations was exploited for analysing batches of seized drugs without any sample preparation. Under appropriate separation conditions (15% (v/v) acetonitrile in 8 mmol/L Na_2HPO_4–5 mmol/L phthalate–10 mmol/L CTAB, pH 12.5; capillary fused silica, 75 μm i.d. × 85 cm effective length; voltage −27 kV) and using indirect/UV absorption (310 nm) detection, sugars and polyhydric alcohols (ribose, glucose, lactose, sucrose, mannitol, inositol), dissociated as anions, were detected as positive peaks migrating faster than the EOF, while benzoylecgonine, cocaine, *cis*-cinnamoylcocaine and *trans*-cinnamoylcocaine (bearing a positive charge) were detected as 'negative peaks' after the peak corresponding to the EOF.

MEKC has also been applied to the determination of lysergide (LSD). The main problems in LSD analysis arise from the low dosage of drug taken, its extensive metabolism and its thermal instability, all of which yield extremely low concentrations to be determined in both biological fluids and clandestine preparations. On-line preconcentration of LSD from urine samples was exploited by Fang *et al.* (2002). To increase

sensitivity, the authors combined the use of two sample enrichment techniques, namely sweeping-MEKC and cation-selective exhaustive injection (CSEI-sweep-MEKC). The sweeping MEKC technique involved the concentration of analytes at the interface with the MEKC separation buffer, by introducing the sample hydrodynamically into the capillary in a solvent free of pseudostationary phase (Quirino, Terabe 1999). CSEI-sweep-MEKC caused sample stacking with electrokinetic injection and sweeping, thus providing further improvements in sensitivity (Quirino, Terabe 2000). Fang reported a LOD (S/N>3) of about 16 ng/mL in spiked urine using the sweeping-MEKC method with fluorescence detection ($\lambda_{ex} = 320$ nm; $\lambda_{em} = 390$ nm), and a LOD of about 1 ng/mL with CSEI-sweep-MEKC. The sweeping-MEKC was also used for the online concentration and analysis of LSD in clandestine tablets (Fang *et al.* 2003).

LIF detection, using a He–Cd laser at 325 nm wavelength, has also been applied to the determination of LSD in specimens of human blood (Frost, Koehler 1998). The CE method used a citrate–acetate system as running buffer.

The use of DAD as a CE detector in routine methods has attracted particular attention in drug analysis. As expected from a multichannel detector, recording an entire signal spectrum enhances the capability of correct identification and determination of analytes and the possibility of studying the peak purity. An example of a CE-DAD application can be found in Nieddu *et al.* (2005). This rapid method realises the screening of a class of amfetamine designer drugs, comprising 10 methylenedioxy derivatives of amfetamines and phenethylamine in human blood. The detection limits and recoveries from blood samples were between 10 and 30 ng/mL and 81 and 90%, respectively.

CSEI was used by Meng *et al.* (2006) as an on-line concentration method for the high-sensitivity analysis of illicit amfetamines. Using this approach (CSEI with micellar sweeping), a LOD lower than 50 pg/mL was achieved, whereas using normal MEKC it was about 10 ng/mL. The quantitative reproducibility of CSEI-micellar sweeping for the analysis of amfetamine, metamfetamine and MDMA using a benzylamine internal standard was satisfactory (standard deviation around 10%). The method was also tested on hair samples.

Among multichannel detectors, mass-selective detectors have rapidly become the gold standard in toxicological analysis for both generic and specific determinations. Recently CE-MS coupling has begun to find applications in the field of drug analysis (Smyth 2006).

Benzodiazepines are a challenging class of drugs to assay in biological fluids and represent a typical example of the proficient use of MS detection based on its outstanding identification power and selectivity. A double-dynamic coating CZE method with IT-MS detection was developed by Vanhoenacker *et al.* (2004a) for the separation of six benzodiazepines in spiked urine, and MS^2 experiments were performed for confirmation. McClean *et al.* (2000) optimised a CZE-ESI-IT-MS method for the determination of selected 1,4-benzodiazepines, identified by sequential product ion fragmentation.

MS^3 fragmentation was also exploited by Wey *et al.* (2000) to unambiguously identify codeine, morphine, dihydrocodeine and their glucuronides in urine samples previously screened using opiate immunoassay.

The simultaneous detection and quantification of a number of abused drugs in human hair (namely 6-monoacetylmorphine, morphine, amfetamine, metamfetamine (MA), methylenedioxyamfetamine (MDA), methylenedioxymetamfetamine (MDMA), benzoylecgonine, ephedrine and cocaine) was obtained by Gottardo *et al.* (2007a) with a rapid CZE-ESI-IT-MS method (Figure 42.3). Ammonium formate (25 mmol/L), pH 9.5 and 15 kV separation were employed for the separation using a bare fused-silica capillary. Under field-amplified sample stacking conditions, LODs were below 0.1 ng/mg for all drugs in hair matrix and good linearity was achieved in the concentration range 0.025–5 ng for each analyte per mg of sample. The same group investigated the application of these separation conditions when coupling CE-ESI with a TOF detector (Gottardo *et al.* 2007b), in order to exploit the advantages of high mass accuracy and fast scanning capability of this technique. Drugs and metabolites were identified in hair samples, after a single extraction procedure, by exact mass and isotopic pattern matching (Figure 42.4). Analytical precision in real matrices proved acceptable in both within-day and day-to-day tests.

MS detection can also be usefully employed for the detection of poorly UV absorbing molecules, such as γ-hydroxybutyric acid (GHB). Gottardo *et al.* (2004) described the use of IT-MS detection coupled to CZE as a confirmation method for a previously developed CZE screening assay using indirect UV detection (Bortolotti *et al.* 2004). A detection limit of 20 μg/mL was obtained in urine, which required no pretreatment other than dilution with water (1 : 4).

A triple quadrupole MS was used as detector by Baidoo *et al.* (2003) to detect and quantify nicotine and eight of its metabolites in smokers' urine. Detection limits of 0.55 and 11.25 ng/mL were reported for nicotine and cotinine, respectively when sample-stacking electrokinetic injection was used.

An interesting use of CE-MS was reported by Vanhoenacker *et al.* (2004b), who used a double dynamic coating, already reported by Lurie *et al.* (2001) for CE-UV, in a method with IT-MS detection. The double coating was prepared by subsequent flushing of the capillary with a polycation buffer solution ('initiator') and a polyanion solution ('accelerator'), the latter of which also acted as the running buffer. Thus, a double-layer coating was achieved, producing a high and stable EOF, with a significant reduction in analysis time and an increase in reproducibility. The separation of five basic drugs, including amfetamine, ephedrine, trazodone, codeine and salbutamol, was reported.

An important field of application of CE in toxicological analysis is the chiral determination of amfetamine and its congeners (Heo *et al.* 2000), either alone or in combination with other drugs (Ramseier *et al.* 1999). CE is a particularly easy and cost-effective means of developing chiral analytical methods. Additionally, mass spectrometry is often the detector of choice in these methods in order to ensure good specificity and discrimination power (Ramseier *et al.* 2000; Boatto *et al.* 2005).

Amfetamine designer drugs challenge both GC and HPLC techniques owing to their thermal instability, on the one hand, and their poor retention on reversed-phase columns, on the other. The advantage of CZE lies in the possibility of simply adding the chiral selector to the running buffer, with no need for especially manufactured and expensive chiral columns or a precolumn derivatisation procedure to form diasteroisomers (for a review see Zaugg and Thormann 2000).

An example of enantioseparation and discrimination of amfetamines and other pharmaceutical drugs was given by Cherkaoui *et al.* (2001). The authors used CE coupled with ESI-MS and adopted the partial filling technique. This involves the introduction of a small amount of chiral selector solution in the separation capillary prior to sample injection, while the remaining capillary is filled with BGE free of chiral selector. Usually, analytes of interest are basic compounds, positively charged at an acidic pH, whereas an anionic chiral selector is chosen as additive. Under these conditions, an opposite migration of analyte and chiral selector is obtained. As a result, the two species undergo complex formation inside

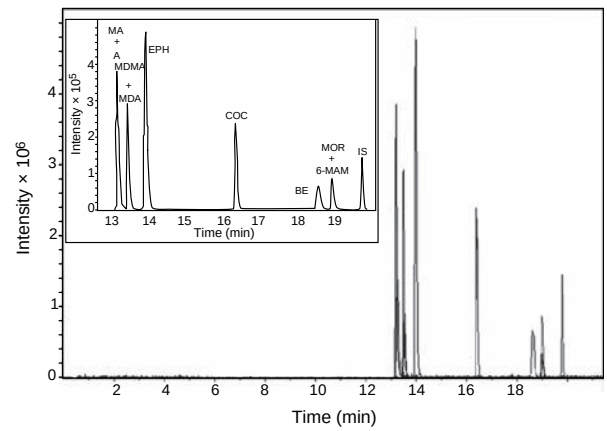

Figure 42.3 Toxicological analysis of drugs of abuse in hair using CZE-ion trap MS. Peak identification: A, amfetamine; MA, metamfetamine; MDA, methylenedioxyamfetamine; MDMA, methylenedioxymetamfetamine; EPH, ephedrine; COC, cocaine; BE, benzoylecgonine; MOR, morphine; 6-MAM, 6-acethylmorphine; IS, internal standard (folcodine). For analytical details, see text. (From *Gottardo et al.* 2007a, with permission.)

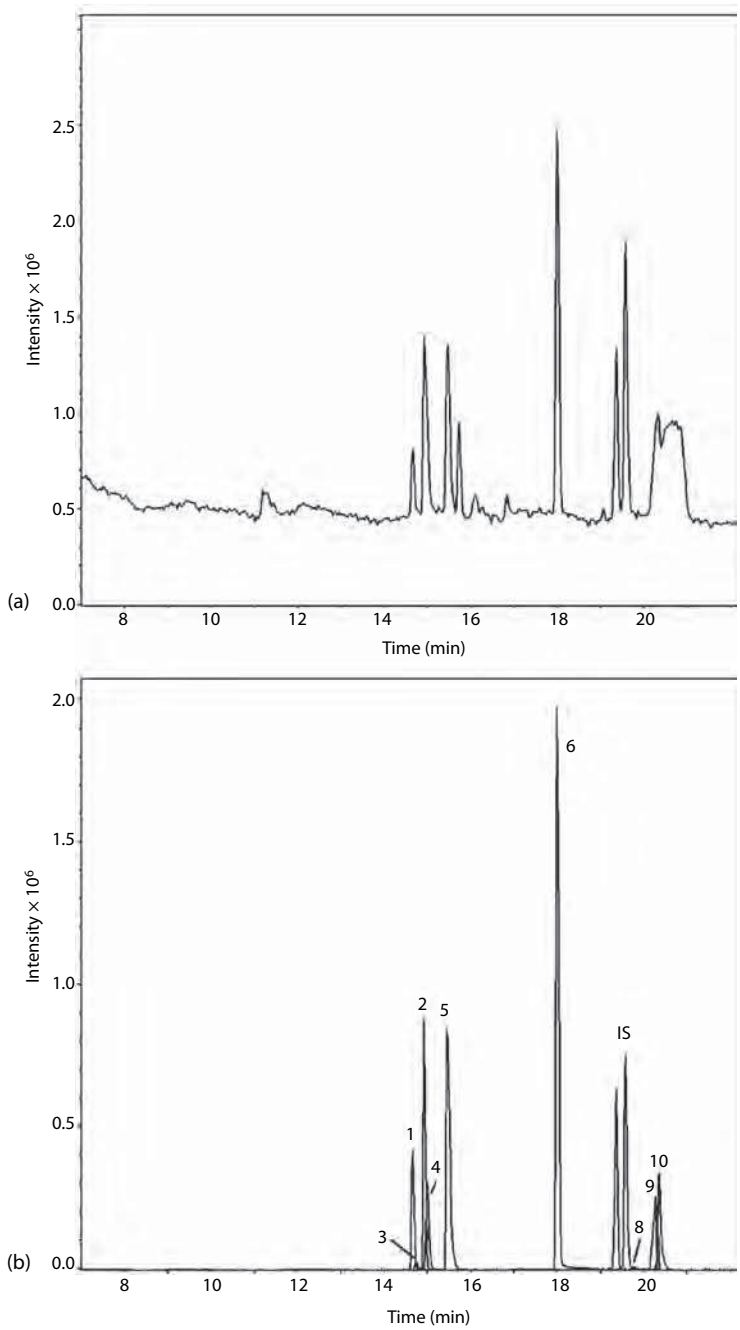

Figure 42.4 Toxicological analysis of drugs of abuse in hair using CZE-TOF MS. Peak identification: 1, MA, metamfetamine; 2, MDMA, methylenedioxymetamfetamine; 3, amfetamine; 4, MDA, methylenedioxyamfetamine; 5, ephedrine; 6, cocaine; 7, codeine; 8, benzoylecgonine; 9,6-acethylmorphine; 10, morphine, at a concentration of 0.2 ng/mg each drug; IS, internal standard (folcodine). For analytical details, see text. (From *Gottardo et al.* 2007b, with permission.)

the capillary, with resulting enantiomeric separation. When MS detection is used, the anionic chiral selector does not enter the MS ion source, because it is driven in the opposite direction by the applied voltage.

Iio *et al.* (2003) used the complete filling technique in which the chiral selector, a diluted mixture of 3 mmol/L β-cyclodextrin and 10 mmol/L heptakis(2,6-di-*O*-methyl)-β-cyclodextrin, was instead added directly to the BGE. This method achieved the enantioseparation of metamfetamine and its metabolites in human urine samples with detection limits (with MS) in the range 0.03–0.05 μg/mL.

Amfetamine, metamfetamine, MDA, MDMA and MDEA were also used as test compounds in a study by Souverain *et al.* (2006) on the different strategies for rapid chiral analysis using CE. The adoption of hydroxypropyl-β-cyclodextrin as the chiral selector was investigated using different approaches (short-end injection, high electric fields, external pressure application, dynamic coating of the capillary) with a view to decreasing analysis time and increasing sensitivity.

A general paper on the optimisation of chiral separations using dual neutral cyclodextrins (β-CD and dimethyl-β-CD) was published by Nhujak *et al.* (2005), showing the potential advantages of adding two chiral selectors to the running buffer.

As previously discussed, non-aqueous capillary electrophoresis (NACE) is particularly eligible for CE-MS coupling, because of the high volatility of most organic solvents, which is beneficial for ionisation. Moreover, the observed change in selectivity in comparison with

separations in aqueous buffer may offer additional practical advantages in resolution. A complete review on NACE-MS has been published by Scriba (2007), collecting all the published NACE-MS applications up to November 2006. The low number of papers reviewed is probably due to the difficulties in adopting a separation technique whose physical–chemical mechanisms are still scarcely understood.

Peri-Okonny *et al.* (2003) exploited NACE-MS for the separation of nine basic drugs, including tricyclic antidepressant and bronchodilator drugs, with 80 mmol/L acetate buffer dissolved in methanol–acetonitrile (80 : 20 v/v). The results showed improved efficiency compared with HPLC separation.

In a paper by Steiner and Hassel (2005), a few organic solvents (namely methanol, acetonitrile, DMSO, formamide, *N*-methylformamide and *N,N*-dimethylformamide) were compared against water for the preparation of ammonium acetate separation buffer. Selectivity, peak efficiency and average plate counts were evaluated in the separation of basic drugs. In the seven different solvents (including water), the shortest run time was obtained with acetonitrile, the best peak resolution with the amphiprotic solvents (especially methanol), best peak efficiency with methanol and formamide, and the most sensitive ESI-MS detection with acetonitrile and methanol, but with only a slight advantage compared with water.

Anderson *et al.* (2004) developed a NACE-MS method for the determination of lidocaine and two of its metabolites in human plasma. The effects of sheath liquid composition, drying gas temperature and nebulising gas pressure on separation efficiency were evaluated.

Fluoxetine and related compounds were analysed with NACE-MS by Cherkaoui and Veuthey (2002), using 25 mmol/L ammonium acetate–1 mol/L acetic acid in acetonitrile as the running buffer and a 30 kV separation voltage. A significant increase in sensitivity was obtained compared with UV detection. NACE-MS was also reported by Geiser *et al.* (2000) for separation of amfetamine derivatives in spiked urine, after LLE.

Although proposed as an attractive alternative to chromatography and supported by positive results, CE traditionally lacks sensitivity compared with chromatographic methods. However, on-line and off-line sample enrichment and stacking injection techniques have been employed successfully to enhance sensitivity.

As previously mentioned, CSEI was used by Meng *et al.* (2006) for the high-sensitivity analysis of illicit amfetamines and achieved a LOD of $<$50 pg/mL.

The FASS approach was reported by Zhang and Thormann (1998) and Wey *et al.* (1999) for the determination of opioids in biological fluids and by Manetto *et al.* (2000) for the determination of opiate drugs in hair. This on-line sample preconcentration method has also proved useful for the CE-MS analysis of opioids in urine (Wey, Thormann 2001b).

FASS with electrochemiluminescence detection has been used for the determination of diamorphine and cocaine on banknotes contaminated with illicit drugs (Xu *et al.* 2006), offering a new tool with which to produce evidence of the diffusion of these illicit compounds in the population. Acetic acid (10 mmol/L) was used to elute the drugs from the banknotes. The detection limits obtained were 18.5 ng/mL for diamorphine and 18.1 ng/mL for cocaine. No interference from other compounds present on the banknote surfaces was observed.

A miniaturised method of SPE based on a novel monolith phase (methacrylic acid–ethyleneglycol dimethacrylate) coupled to CZE was reported by Wei *et al.* (2006) for the rapid determination of diamorphine, 6-monoacetylmorphine, morphine, codeine, papaverine and narcotine in human urine. The extraction device was contained in a capillary tube. By applying FASS injection, detection limits of 7–20 ng/mL were achieved.

Reviews of applications of capillary electrophoresis in the analysis of metal-based drugs and pharmaceutical analyses have been published by Timerbaev (2007) and by Suntornsuk (2007).

Small ions

Capillary electrophoresis, which is also known in this application as capillary ion analysis (CIA), and used most often with indirect UV detection, can offer a simple alternative to ion chromatography for the analysis of small ions. The advantages of using electrophoresis can be summarised as versatility (the same instrument can easily be switched without hardware modifications from other applications to ion analysis) and robustness, since all the separation occurs in solution without the need for any interaction with a stationary phase. This avoids problems of column contamination from injected materials. Last, but not least, because its separation mechanisms are substantially different from those of chromatography, CE can be used to confirm the results of an ion chromatographic analysis. Several applications of CIA in the determination of ions of toxicological interest have been reported, as reviewed by Timerbaev and Keppler (2007).

A method for ion screening without quantification was developed by Gillette *et al.* (2006) for the detection of 29 different anions (including thiosulfate, bromide, chromate, iodide, chloride, sulfate, sulfite, sulfide, nitrite, nitrate, oxalate, perchlorate, azide, thiocyanate, chlorate, fluoride, chlorite and phthalate) in human biological samples. This CE method was based on a background electrolyte composed of 2.25 mmol/L pyromellitic acid, 1.6 mmol/L triethanolamine, 0.75 mmol/L hexamethonium hydroxide and 6.5 mmol/L NaOH at pH 7.7; negative voltage was applied. Samples of human blood, plasma, urine and intestinal contents were analysed after protein precipitation and SPE. Using direct and indirect UV detection (at 200 and 250 nm, respectively), screening for all 29 compounds could be carried out in less than 20 minutes with a LOD of about 1 μg/mL for each compound in pure aqueous solution.

The quantitative determination of bromide (an old antiepileptic drug, recently reconsidered for treating refractory epilepsy) in human serum was performed by a very simple CZE method using 90 mmol/L sodium tetraborate and 10 mmol/L sodium chloride (pH 9.24) as the background electrolyte and reversed polarity (Pascali *et al.* 2006). Owing to the absorption of radiation in the low UV range by bromide ions, direct UV detection (200 nm) could be applied and achieved high selectivity, since most anions do not absorb UV radiation. The method gained further selectivity, because the separation of bromide ions was effected counter to the EOF. Thus, direct injection of serum samples, after 1 : 10 dilution with water, could be carried out and the reported LOD and limit of quantification (LOQ) were 0.05 and 0.1 mmol/L, respectively.

Eight arsenic compounds were recently analysed by CE with indirect UV detection. Two different buffers were optimised for the separation of the anionic and cationic species with good results in terms of sensitivity (LODs in the order of 7.8–250 μg/mL for the anionic species) (Kitagawa *et al.* 2006).

An optimised dynamic coating system, the CElixirOA (Analis, Namur, Belgium), was used in a method aimed at the characterisation of inorganic ions in metamfetamine tablets, produced in clandestine laboratories. The characterisation of phosphate, phosphite and hypophosphite ions helps to distinguish the various phosphorus–iodine methods used in these laboratories for producing metamfetamine by reduction of pseudoephedrine. The method separated acetate, azide, bromide, carbonate, chlorate, chloride, chromate, fluoride, hypophosphite, iodide, nitrate, nitrite, perchlorate, phosphate, phosphite, sulfate, sulfite and thiocyanate, with LODs in the order of μg/mL and percentage relative standard deviations of normalised migration times under 0.1% (Knops *et al.* 2006).

In recent years, a new and interesting application for CIA has emerged, on the boundary between ion analysis, toxicology and biochemistry. It concerns the determination of minor metabolites of ethanol formed by its enzymatic conversion into ethyl glucuronide (EtG) and ethyl sulfate (EtS). In comparison with ethanol and acetaldehyde, the major ethanol metabolites, EtG and EtS, are detectable for longer in body fluids and tissues and consequently can be used as markers of recent alcohol intake when ethanol and acetaldehyde are no longer detectable.

Two papers from the group of Thormann (Krivankova *et al.* 2005; Mrazkova *et al.* 2006) have recently described the optimisation and application of a CZE method based on separation in pH 4.4 nicotinic acid–ε-aminocaproic acid BGE in polyacrylamide-coated capillaries, reversed polarity and indirect detection. The method allowed the simultaneous determination of lactate and acetate, which are organic ions potentially affected by ethanol ingestion. Because of a transient isotachophoretic phenomenon, producing a sample self-stacking effect,

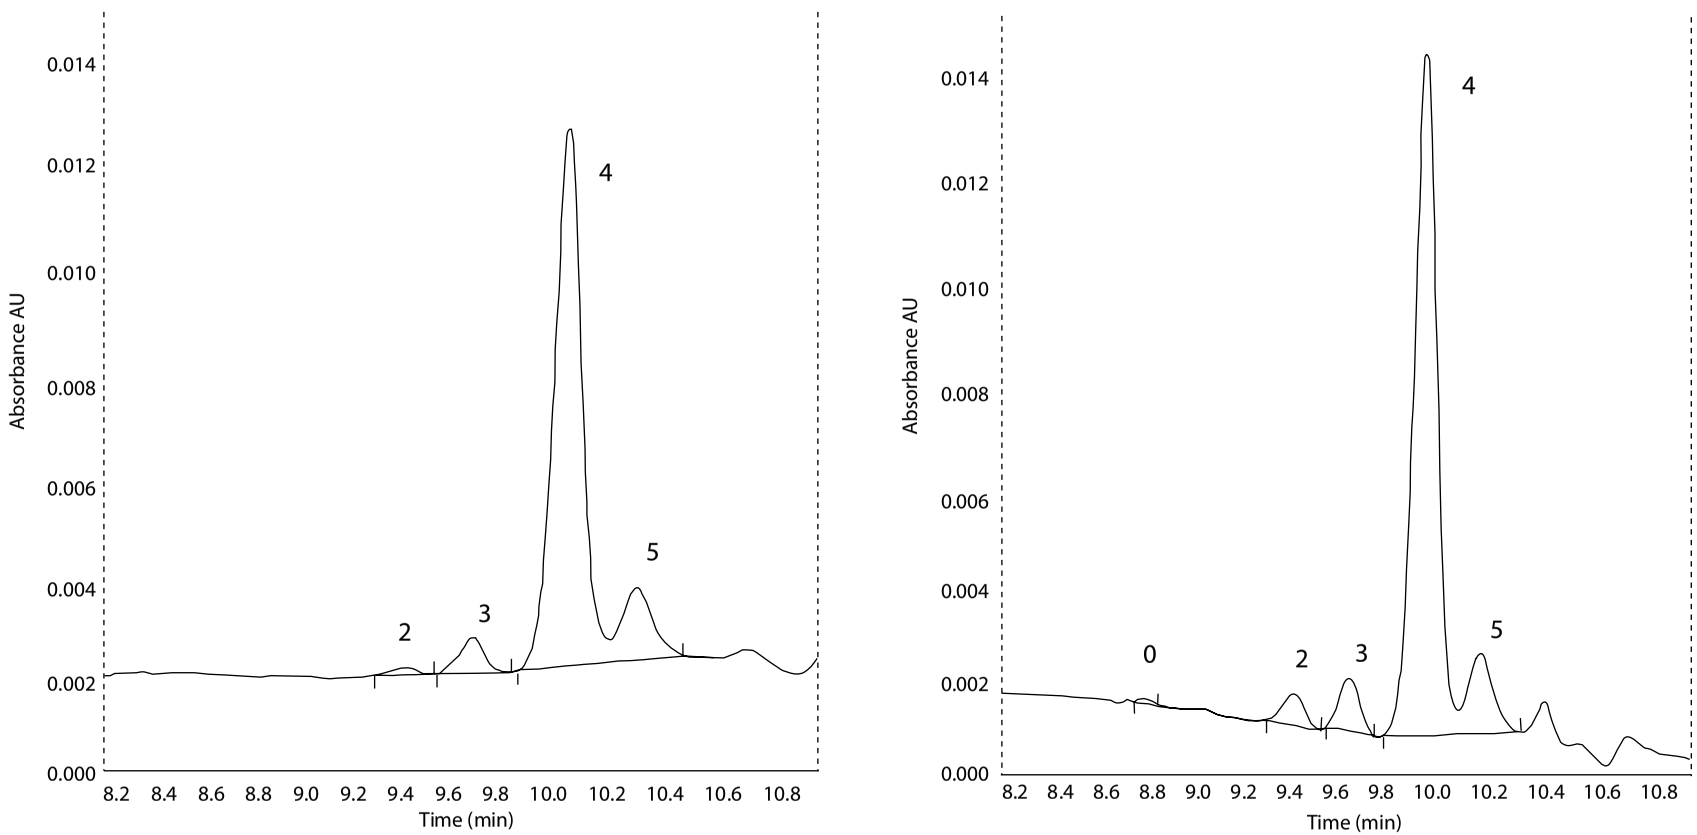

Figure 42.5 Transferrin (Tf) glycoform separation in serum with CE (for CDT analysis). On the left, analysis of a `normal' individual; on the right, analysis of an alcohol abuser. Peak identification: 0, asialo-Tf; 2, disialo-Tf; 3, trisialo-Tf; 4, tetrasialo-Tf; 5, pentasialo-Tf. Tf, human tranferrin.

a sensitivity of ~0.1 μg/mL for EtG could be achieved in untreated samples after only 1 : 1 dilution. This method was applied successfully to human serum, but no data were provided about its application to urine, which is the biological sample most often analysed for EtG.

Esteve-Turillas *et al.* (2006) and Fang *et al.* (2003) reported methods for EtS analysis in serum and urine. The BGE was composed of 15 mmol/L maleic acid, 1 mmol/L phthalic acid and 0.05 mmol/L CTAB. Again, negative polarity and indirect detection were applied and the selectivity of the method allowed for 1 : 5 dilution as the only sample pretreatment.

Proteins and peptides of toxicological interest

Since its introduction in 1930, protein analysis has always been a major field of application of electrophoresis and electrophoretic methods remain the basis of serum protein analysis. Although little attention has been paid to protein analysis in forensic toxicology, protein molecules have become attractive as biological markers of chronic alcohol abuse. Carbohydrate-deficient transferrin (CDT) has gained universal acceptance as one such marker and is assayed in many clinical and forensic laboratories world-wide (Arndt 2001).

CDT is the collective name of a group of minor isoforms of serum transferrin with a low degree of glycosylation, which include asialo-, monosialo- and disialo-transferrin (Tf). CDT concentrations increase after sustained alcohol intake (≥50–80 g/day), lasting for at least 7 days, and decrease, after cessation of drinking with a half-life of about 14 days.

First applied to CDT analysis in the second half of the 1990s, CE has rapidly gained acceptance and today is considered, along with HPLC, to be the most reliable method currently available (Bortolotti *et al.* 2006). An example of the separation of glycoforms of Tf by CE is shown in Figure 42.5.

Following the introduction of commercial reagents and multicapillary instrumentation, CE has become the most productive instrumental approach to routine protein and peptide analyses. Most CE methods are based on CZE separations using borate buffers with organic amines added (e.g. diaminobutane, spermine, diethylenetriamine) to hinder protein interactions with the capillary wall. Detection is always based on absorption of UV radiation at 200–214 nm wavelengths (Crivellente *et al.* 2000; Giordano *et al.* 2000; Lanz *et al.* 2002; Fermo *et al.* 2004). An interesting alternative was proposed by Wuyts *et al.* (2001), who described a CZE method using proprietary reagents containing polycations and polyanions (CEofix CDT buffer system, Analis, Namur, Belgium), which provided a dynamic double coating of the capillary. Further improvements of the results in terms of peak resolution were obtained using the same reagents by fine tuning of capillary length, temperature and voltage by the group of Thormann and his co-workers (Lanz and Thormann 2003; Lanz *et al.* 2004; Joneli *et al.* 2006).

Because of their high potential productivity, multicapillary systems, have rapidly replaced former methods (e.g. gel electrophoresis) in the routine analysis of DNA, RNA and serum proteins.

Toxins and venoms

Toxins and venoms are products of living organisms that may have a polypeptide nature, but which, in any case, are complex and very unstable molecules. For this reason they are often not amenable to chromatographic analysis. CE has been shown to offer interesting applications in this area (Weinberger 2001). Although no determinations in human fluids or tissues have so far been published, Bruggemann *et al.* (1996), described a method for the analysis of the principal toxins of *Amanita phalloides* (α-amanitin and β-amanitin) in body fluids. Although the method was successful when applied to the analysis of mushroom extracts, the detection limit did not offer sufficient sensitivity to cover the clinically relevant range of concentrations in biological fluids.

Conclusions

Claims that capillary electrophoresis has had limited success in terms of practical application ignore the fact that this technique has already gained a leading position in DNA analysis, where CE-based instruments in fully automated configurations are the standard tools for DNA fragment analysis and sequencing. CE is also rapidly gaining predominance in clinical protein analysis where multicapillary instrumentation is replacing cellulose acetate electrophoresis. In this area, the analysis of CDT is another example of the successful application of CE methods in routine laboratory practice. CE, particularly with multicapillary instruments, offers good separation performances, standardisation and simple documentation of results, together with full automation and unrivalled productivity.

In contrast to GC and HPLC, CE has not, as yet, achieved significant recognition as a valuable technique in drug analysis. In this area CE-MS is the configuration that most warrants attention since it fulfils the strictest forensic requirements of analytical toxicology, in terms of sensitivity, selectivity, identification power and reliability.

A major advantage of coupling CE technology to MS, which remains to be fully investigated, is associated with the miniaturisation of the separation capillary. This greatly reduces the number of ions that enter the ion source when compared with HPLC-MS and reduces to a minimum the risk of ion suppression, which is a major disadvantage associated with HPLC-MS. In addition, the speed of data production/acquisition of modern MS detectors (particularly TOF-MS) is fully compatible with the fast and narrow peaks typical of CE separations

In conclusion, CE technology shows considerable promise for future applications in analytical toxicology, particularly in combination with high-resolution MS techniques (Polettini 2008). The ease of use and robustness of CE-MS suggests a promising future for this fascinating analytical technique (Servais 2006).

CHAPTER

43 Atomic Absorption Spectroscopy, Inductively Coupled Plasma-Mass Spectrometry and Other Techniques for Measuring the Concentrations of Metals

A Taylor

Introduction

The development of flame atomic absorption spectrometry (AAS) (Walsh 1955) followed by electrothermal AAS (ETAAS), which is also known as graphite furnace AAS (GFAAS) (Massman 1968), brought about a new era in the quantitative measurement of metals. These techniques provided for considerably lower detection limits than had previously been achievable and an increase in the range of elements that could be measured (Taylor 2006a). Although widely used, AAS is essentially a single-element technique and separate measurements must be made if more than one metal is to be determined. Multi-element analyses using atomic emission spectrometry (AES), neutron activation analysis (NAA) and X-ray fluorescence (XRF) have been available for some years, but these either lack the sensitivity of AAS or require very specialised instrumentation that is not readily accessible.

The field of trace element analysis advanced dramatically when inductively coupled plasma–mass spectrometry (ICP-MS) was developed (Gray, Date 1983). Not only are the detection limits and speed of analysis equal to or better than those seen with AAS, but it is also a powerful multi-element technique. Within a single analysis most elements within the periodic table, including their individual isotopes, may be measured. However, the costs associated with the purchase and operation of ICP-MS and, more importantly, the interferences that were evident in the analysis of biological samples, prevented the widespread application of the technique to clinical, toxicological and forensic situations.

The use of collision and dynamic reaction cells with ICP-MS has largely overcome most of these interferences, and equipment costs have reduced so that ICP-MS is now the primary technique for measurement of metals and other elements in biological specimens. Other important recent advances include the use of techniques that separate different molecular conformations of an element (speciation), *in vivo* analyses involving NAA or, more usually, XRF, and analysis of solid samples to provide quantitative measurements and/or mapping of elemental distribution across a structure using laser ablation (LA) ICP-MS or XRF.

Preparation of samples for analysis

Sample preparation

A range of biological samples including serum, blood, urine, tissues and hair may be used to measure concentrations of metals (see Chapter 17). While there are some exceptions, most analytical systems for measuring metals require samples to be in a liquid form. Processes for preparation, therefore, are designed to ensure that the specimen is in a suitable form for introduction to the analytical instrument and with the analytes at concentrations that will produce a measurable response. At the same time the method should also reduce or eliminate possible interferences.

With instrument sampling systems that involve narrow capillary tubing it is necessary that the transfer rates of samples and calibration solutions be equal. The presence of components such as proteins and cells in serum and blood gives rise to viscosity that is absent in aqueous calibration solutions. Accordingly, assays may be subject to matrix interferences unless the flow rates of sample and calibration solution are matched (Example 43.1). When the concentrations of analyte(s) are high, dilution with water may be all that is needed. Alternatively, protein precipitation can be performed by addition of, for example, 10% (w/v) trichloroacetic acid followed by centrifugation.

Liquid–liquid extraction is a particularly useful approach with addition of a chelating agent to the sample (either a body fluid or a solution post digestion) followed by solvent extraction of the resulting complex. Interfering material is retained in the aqueous phase and, if the volume of solvent is less than that of the sample, analyte enrichment also occurs. A common method uses ammonium pyrrolidine dithiocarbamate (APDC) and 4-methyl-2-pentanone (methyl isobutyl ketone, MIBK), but various chelating agents and solvents have been employed (Example 43.2).

As with sample collection (see Chapter 28), contamination must be avoided throughout the sample preparation procedure. Equipment and

Example 43.1. Sample preparation: dilution of serum for measurement of selenium by ICP-MS

Prepare a 1 : 14 dilution by mixing 200 µL serum with:

- 200 µL 1% Triton X-100
- 200 µL internal standard
- 200 µL modifier (0.14 mol/L NH_3, 3 mmol/L $(NH_4)_2H_2EDTA$, 29 mmol/L $NH_4H_2PO_4$)
- 500 µL 6% v/v butan-1-ol
- 1.7 mL water.

The modifier and Triton X-100 reduce viscosity and prevent blockage of the nebuliser, the butan-1-ol reduces the concentration of interfering Ar adducts such as $^{40}Ar^{38}Ar$, and the internal standard compensates for variation in nebuliser and plasma performance during a run.

Example 43.2. Sample preparation: extraction and concentration of vanadium from urine for measurement by ETAAS

- Adjust 5 mL of test urine to pH 1–2 and pour this solution into a glass-stoppered tube.
- Add 0.5 mL of 5% cupferron solution, stopper, vortex for 30 s and allow to stand for 10 min.
- Add 1 mL water-saturated MIBK, stopper and vortex for 30 s. Mix by repeated inversions for 10 min.
- Centrifuge at 3000 rpm for 5 min to clarify the two layers.
- Take the clear organic layer into sample cups for measurement of vanadium by ETAAS.

reagents should be of the highest quality available and must be tested for cleanliness. All re-usable materials should be cleaned before use. Glassware should be first soaked in aqueous acid, for example 2–10% v/v hydrochloric acid or nitric acid, and then rinsed with copious volumes of purified water. Pure water has an electrical resistivity of more than 18 MΩ and, ideally, should be used at all times. Reagent blank and internal quality control (IQC) samples must be included in the analysis procedure. In addition to guarding against false high results, it is necessary to check for losses of analyte due to volatilisation, adsorption onto container surfaces, or the precipitation of insoluble complexes.

Analysis of tissues

Solid specimens have to be digested to give an aqueous solution prior to analysis. Acid digestion is most commonly used. Methods with addition of nitric acid, perchloric acid and hydrogen peroxide in varying combinations are widely employed and a number of possible procedures are available (Bazzi *et al.* 2005). Sulfuric acid may be included to achieve higher temperatures (Welz *et al.* 1987). Care must be exercised if using the potentially explosive perchloric acid.

Heating may be performed in conical flasks or beakers placed on a hot plate, or in tubes that fit an aluminium heating block. Care is necessary to prevent more volatile elements, especially mercury, being lost. Digestion is normally complete within 2–6 h. Microwave heating in sealed digestion vessels is widely used (Grinberg *et al.* 2005). Specially designed ovens include features to prevent damage from acid fumes and excessive pressure within digestion vessels. As many as 40 or more samples can be digested at the same time, often in less than 30 min and, because each vessel is sealed, there should be no loss of volatile elements (Example 43.3).

Example 43.3. Sample preparation: digestion of hair for measurement of lead with microwave heating

- Wash and dry with acetone and water (Ryabukhin 1978)
- Accurately weigh the sample (the weight taken will depend on sensitivity of technique and amount available)
- Transfer to the digestion vessel
- Add 2.0 mL water and 3.0 mL nitric acid. Seal and load into the oven
- Set pre-determined heating parameters, e.g. power, temperature, time
- Initiate the heating cycle
- Allow to cool
- Quantitatively transfer contents to a tube and make up to required volume

An alternative to acid digestion involves dissolution of the sample in a concentrated alkaline solution. Tetramethylammonium hydroxide (TMAH) is preferred and samples are simply mixed with the reagent and heated for a few hours. Putting 50 mg of dried tissue and 2 mL 50 g/L TMAH into a screw capped vial, complete solubilisation is achieved by heating at 90°C for 2 h with occasional shaking of the vials A third approach to sample destruction is dry ashing, in which the sample is heated in a muffle furnace, typically to 400–450°C, followed by cooling and dissolution of the ash in dilute acid. Loss of volatile elements must be considered and this technique cannot be used if mercury is to be measured. These techniques for preparation of solid samples can be applied to liquid specimens for elimination of matrix interferences and to effect analyte enrichment.

Techniques to extract metals from tissues in a way that preserves their natural chemical state for subsequent speciation analysis have been developed recently. These methods involve use of ultrasonication (Zhou, Mo 2009) or extraction into a solvent at a very high pressure, e.g. 6 MPa, at 125°C (Sanz *et al.* 2007). Enzymes such as proteases and lipase have also been found useful for disrupting tissues to release elements without transformation of the species (Kurek, Ruszczynska 2009).

Analyte enrichment

Techniques for pre-concentration (analyte enrichment) are included in methods when low detection limits are required. Some examples have been mentioned above, but others have been developed for the specific purpose of concentrating the analyte. These involve trapping from a relatively large sample and subsequent elution into a smaller volume. The methods used include (1) adsorption onto materials such as charcoal or silica, (2) use of ion-exchange resins either with or without functionalised groups to trap specific elements, and (3) size-exclusion chromatography (SEC) (Loreti, Bettmer 2004). Enrichment in this way can be off-line, but many methods incorporate on-line sample processing.

Experience with ion-exchange chromatography and SEC has led to a further important development in sample preparation – speciation. In some cases measurement of the total concentration of an element is inadequate and can be misleading. In such circumstances it is necessary to measure particular species such as Cr(III) and Cr(VI), or As(III), monomethylarsonic acid and dimethylarsinic acid (Mandal *et al.* 2004). Methods for speciation involving chromatographic separation or differential solvent extraction are used routinely (Taylor 2006a).

Colorimetry and fluorimetry

A number of compounds react with metal ions to give coloured products (Table 43.1), forming the basis for quantitative assays, although selectivity and sensitivity are usually poor. Colorimetric measurements of calcium and magnesium in serum and urine, analytes that are present at concentrations of the order of mmoles per litre in these fluids, is routine in clinical laboratories. Measurement of zinc and copper in serum is also possible and commercial kits are available that can be used on modern clinical chemistry analysers (Makino 1999). However, there are interferences from the serum matrix, and in external quality assurance (EQA) schemes the performance of these methods is unsatisfactory (Taylor 2006b).

Some of the complexes formed between metals and dye compounds also fluoresce, but compounds have been specially developed to exploit the fluorimetric potential for greater sensitivity and selectivity (Table 43.2). Nevertheless, in practice, only the measurement of selenium using 2,3-diaminonaphthylamine is of interest. Methods can be as sensitive as those involving AAS, but a much more complex sample

Table 43.1 Some compounds that react with metals to give coloured products

Reagent	*Metal*
Catechol violet	Al
Eriochrome cyanide R	Al
o-Cresolphthalein complexone	Ca, Mg
Methylthymol blue	Ca
Sodium diethyldithiocarbamate	Cu
2,2′-Bipyridyl	Fe
Dithizone	Pb, Hg
3,3′-Diaminobenzidine	Se
2-Carboxy-2′-hydroxy-5′-sulfoformazylbenzene (Zincon)	Zn
1-(2-Pyridylazo)-2-naphthol (PAN)	Zn

Table 43.2 Some compounds that react with metal ions to produce fluorescent products

Reagent	*Metal*
3-(2,4-Dihydroxyphenylazo)-2-hydroxy-5-chlorobenzenesulfonic acid (Lumogallion)	Al
8-Hydroxyquinoline	Be
2′,3,4′,5,7-Pentahydroxyflavone (Morin)	Mg
2,3-Diaminonaphthylamine	Se
3,3′-Diaminobenzidine	Se

preparation procedure involving acid digestion is needed. Hence, it is generally used only when there is no alternative.

Electrochemical methods

Anodic stripping voltammetry

Anodic stripping voltammetry (ASV) is a technique in which there is preconcentration of metals on to an electrode followed by selective oxidation during an anodic potential sweep. It is ideally suited to the analysis of dilute solutions where the sample volume is not a limiting factor. The sensitivity can be similar to that associated with AAS for 12–15 elements. A reference electrode and a thin-film mercury graphite electrode are placed in the sample and a negative potential is applied to the mercury electrode, typically for periods of 2–30 min. Cations in the sample are thereby caused to concentrate ('plate-out') on the surface of the mercury electrode (the anode). The direction of the potential is then reversed to give an increasingly larger positive potential over 2–30 s. As the voltage reaches the half-wave potential of an element, lead (Pb^{2+}) for example, all such ions are oxidised and discharged (stripped) from the anode, producing a current that can be measured (Figure 43.1).

The current produced is proportional to the number of ions appearing at that voltage and is compared with those given by calibration solutions. In its simplest form, the potential is scanned linearly as a function of time (linear sweep voltammetry). In differential pulse anodic stripping voltammetry (DPASV), the current is measured in pulses by taking two readings and recording the difference as the potential is increased. This reduces the background current and therefore increases the sensitivity of measurement. While ASV is not widely used in the analysis of biological specimens, a niche application has developed, especially in the USA, for measuring lead in blood. A chelating agent is added to mobilise lead bound to red cells and protein, and the measurement is performed using an instrument specifically designed for this application (Figure 43.2). The equipment is compact and can be used in any location. A very simple hand-held instrument, suitable for concentrations up to about 60 μg/dL, is available in which the electrode and sample container are provided as precalibrated disposable units. A problem associated with the precalibration process was identified, but this has since been resolved (Stanton *et al.* 2006).

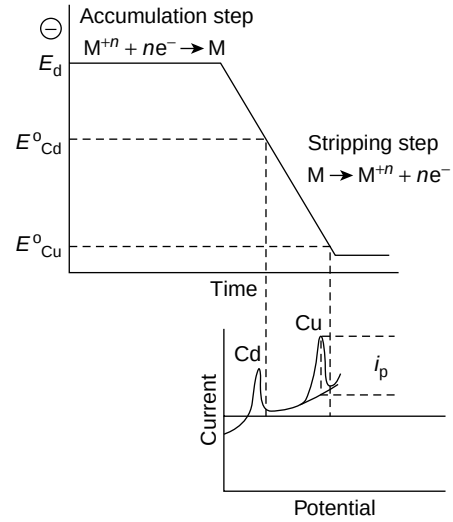

Figure 43.1 Principle of anodic stripping voltammetry illustrated by the potential–time waveform (top) for a solution containing cadmium and copper and the resulting voltammogram (bottom). E_d is the electrodeposition potential and E^o values are the respective oxidation potentials for the two elements. The current measured (i_p) is proportional to the concentration of copper in the sample. (Reproduced from http://www2.chemistry.msu.edu/courses/chem837/Anodic%20stripping%20Voltammetry.pdf.)

Ion-selective electrodes

Ion-selective electrodes (ISEs), of which the pH electrode is an example, are widely used to measure major cations (Na^+, K^+, Ca^{2+}) in biological specimens (Burnett *et al.* 2000). Electrodes for other metal ions and also for anions are available. In clinical laboratories, lithium (Li^+) is commonly measured in this way in plasma or serum (Greil, Steller 1992; Greffe, Gouget 1996). (Use of lithium-free blood collection tubes is essential.) Fluoride (F^-) may be measured in biological samples, not only to assess possible exposure to this poison or compounds giving rise to F^- by metabolism, but also in medicolegal work to establish that enough fluoride has been added to ensure inhibition of microbial growth (Shajani 1985; Kissa 1987).

ISEs are examples of membrane electrodes in which the membrane has physical or chemical properties that allow movement of only one kind of ion between the internal filling solution and any test solutions. If the activities of the ions in the two solutions are not equal, ions will move across the membrane towards the lower-activity solution, and the electric charge thus generated will oppose the migration of ions until equilibrium is established. The actual number of ions involved in these movements is small and does not involve a gradual interdiffusion between the two compartments. The potential established by the movement of ions is measured and is logarithmically related to the activity in the test solution. It is important to remember that it is *activity* and not concentration that is determined by an ISE.

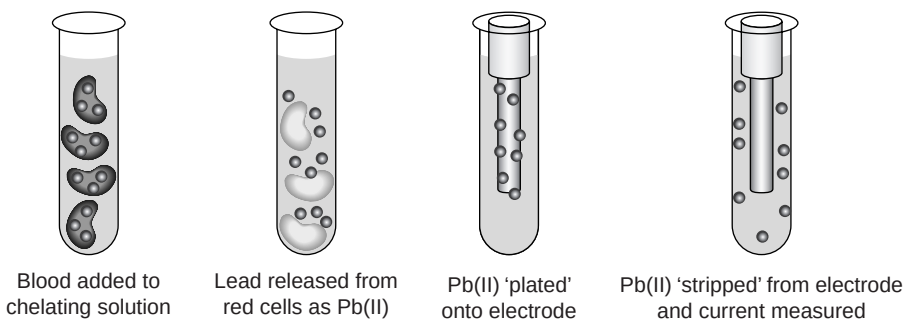

Figure 43.2 Measurement of lead in blood by anodic stripping voltammetry.

Membranes may be solid with a fixed ionic structure, e.g. glass that responds to Na^+, or a water-immiscible liquid containing dissolved material that will actively exchange the selected ions in solution. An effective calcium exchanger is a calcium salt of an alkyl phosphate dissolved in dioctylphenylphosphonate. The exchanger is prepared on a thin PVC layer to form the membrane. For a fluoride ISE, the membrane is a crystal of lanthanum fluoride (LaF_3) doped with europium fluoride (EuF_2) to provide holes in the crystal to allow the F^- ions to pass across.

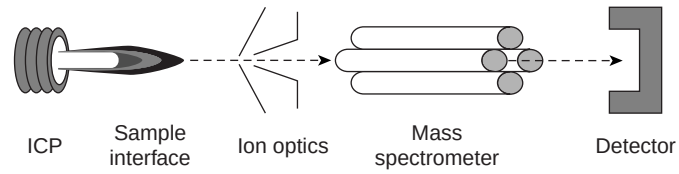

Figure 43.3 Components of an ICP-mass spectrometer.

Atomic spectrometry

Quantitative analytical atomic spectrometric techniques include inorganic MS, AAS, AES, atomic fluorescence spectrometry (AFS) and XRF. AAS, AES and AFS involve interactions between UV–visible light and the outer shell electrons of free, gaseous, uncharged atoms. In XRF, high-energy particles collide with inner shell electrons of atoms, initiating transitions that conclude with emission of X-ray photons. For inorganic MS, ionised analyte atoms are separated within electrical or magnetic fields according to their mass-to-charge (*m/z*) ratio.

Vapour generation procedures (see Vapour generation approaches below) were initially developed for AAS and later applied to other atomic spectrometric techniques.

Inductively coupled plasma–mass spectrometry

As a sample is taken to a high temperature, any organic component is destroyed and the thermal energy causes some or all of the inorganic elements to be ionised. When these ions are directed into a mass spectrometer they are separated by a mass filter according to the *m/z* ratio, and are then detected and counted using an electron multiplier. This process is generally described as *atomic* or *inorganic MS* (Hill 1999; Nelms 2005; Evans *et al.* 2009). Many elements can be measured virtually simultaneously and detection limits are in the range of a few µg/L or below. Elements that have hitherto been almost impossible to quantify can be measured reliably. The other major feature of mass spectrometry is the ability to measure isotopes of the same element (Al Saleh *et al.* 1993). The technique is now well established for analysis of biological specimens (Heitland, Köster 2004, 2006).

Various ion sources for inorganic MS have been employed, but most recent work makes use of a plasma, i.e. a volume of ionised gas, usually argon. The modules required for ICP-MS include sample introduction and ion generation, ion focusing, ion separation, ion detection, and data collection and display (Figure 43.3).

Plasma

Plasmas exist at temperatures of around 6000–10 000°C and in the instrument are constrained to the shape of a 'torch'. Figure 43.4 shows a radiofrequency induction coil around the tip of the torch. As power is supplied to the coil from an RF generator, oscillating electrical and magnetic fields are established at the end of the torch. The plasma is initiated by applying a high-voltage spark to the argon flowing through the ICP torch causing electrons to be stripped off the atoms, forming argon ions.

These ions are caught in the oscillating fields and collide with other argon atoms, forming an argon discharge or plasma that is sustained with the energy from the induction coil. This is known as an inductively coupled plasma (ICP) and samples are introduced via a nebuliser, from a vapour generation device (see Vapour generation approaches), by electrothermal vaporisation from a graphite atomiser, or by laser ablation of solid specimens (Figure 43.5).

Sample introduction

A range of sample introduction techniques have been developed (Figure 43.5) but the most widely used involve liquid samples converted to a fine aerosol using a nebuliser, followed by isolation of the fine droplets in a spray chamber. This provides for efficient ionisation in the plasma.

Samples are normally pumped at a rate of around 1 mL/min via a peristaltic pump into the nebuliser where the liquid is broken up into an aerosol by the pneumatic action of a flow of argon. As plasmas are inefficient at dissociating large droplets in the aerosol, the spray chamber – coupled to the nebuliser – functions to allow only the small droplets (~5–10 µm in diameter) to enter the plasma. Some spray chambers are externally cooled (typically to 2–5°C) to give thermal stability of the sample and to minimise the amount of solvent going into the plasma. This can have a number of beneficial effects such as a reduction of oxide species and the ability to aspirate volatile organic solvents.

The commonest spray chamber is the double-pass, in which the aerosol is directed into a central tube running the whole length of the chamber. Droplets greater than 10 µm in diameter fall out by gravity and exit through a drain tube at the end of the spray chamber. The fine droplets pass between the outer wall and the central tube and are then transported into the plasma torch. The cyclonic spray chamber operates

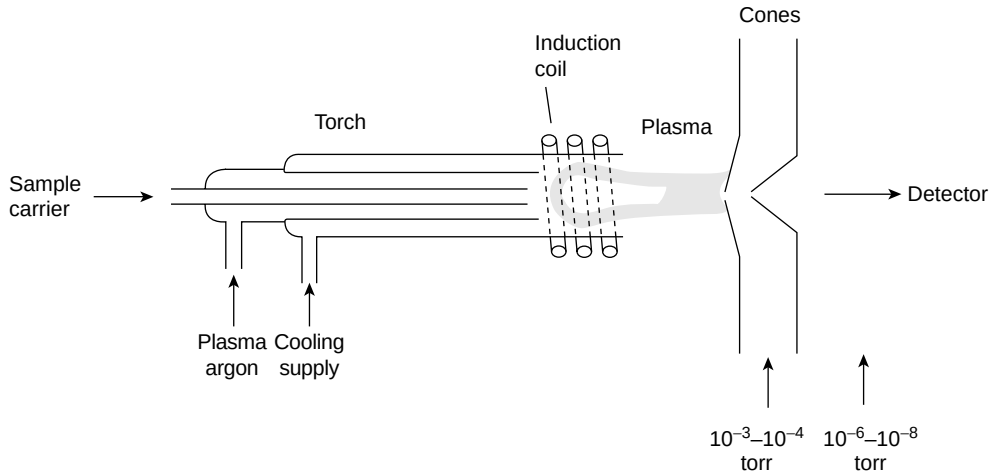

Figure 43.4 ICP torch.

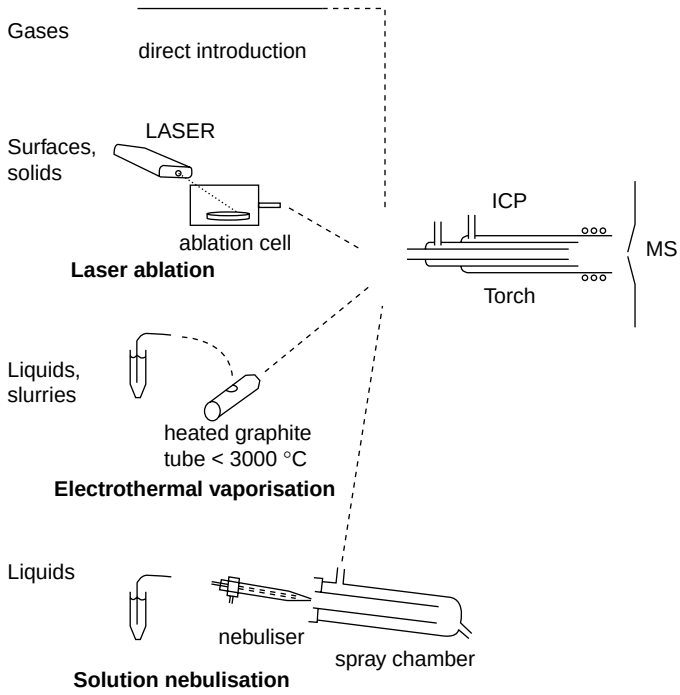

Figure 43.5 Sample introduction for ICP-MS.

by centrifugal force. Smaller droplets are carried with the gas stream into the ICP-MS set-up, while the larger droplets strike the walls and run to the drain. The types of nebulisers and spray chambers generally used for ICP-MS are listed in Table 43.3.

The plasma and ion generation

The plasma is responsible for the formation of analyte ions. This involves desolvation of the aerosol droplet to give the solid and then the gaseous form of the analyte. Any molecular forms are disintegrated/dissociated to leave the ground-state atom. The final step is removal of an outer shell electron, giving the ion. The ICP torch is interfaced to the mass analyser via two metallic cones (sampler and skimmer) with very small holes through which ions are extracted into the ion focusing unit. Because the orifice sizes of the sampler and skimmer cones used in ICP-MS are so small (~0.6–1.2 mm), they are susceptible to becoming blocked and the concentration of matrix components (dissolved solids) must generally be kept below 0.2%. The interface region accommodates the change from atmospheric pressure (101 kPa, 760 mmHg) in the plasma, to 2–3 mmHg (267–400 Pa) at the cones, down to 10^{-6} mmHg (0.000133 Pa) within the mass spectrometer.

Ion focusing and separation

Having passed through the sampler and skimmer cones into the spectrometer, the ion optics, a system of ion lenses, focus and direct ions to the entrance of the analyser for mass separation and measurement. Several analyser configurations are available commercially, although the most commonly used is the quadrupole mass filter.

The quadrupole design has four cylindrical metallic rods, typically 15–20 cm in length and about 1 cm in diameter. Figure 43.6 shows a cross-section of the quadrupole configuration. When a specific direct current (DC) field is applied to one pair of rods and a radiofrequency (RF) field to the opposite pair, the positive or negative bias on the rods will electrostatically steer the analyte ions of interest down the middle of the four rods to the end, where they emerge and produce an electrical pulse in the detector. Ions of other *m/z* ratios pass through the spaces between the rods and are ejected from the quadrupole. The settings are then changed so that ions at a different *m/z* ratio are measured and the process is repeated until all the analytes in a multi-element determination have been measured. While this represents a sequential analytical process, readings are made within milliseconds and a spectrum is presented as if measurements were simultaneous (Figure 43.7).

Limitations to the resolution achievable with quadrupole mass filters, 0.7–1.0 amu, require more powerful systems for certain applications. To exploit the full potential of the ICP-MS technique, a double-focusing sector field mass analyser is required (Figure 43.8). Such instruments provide up to 30 times greater ion resolution and offer higher sensitivity than a quadrupole ICP-MS. The units responsible for separation are an electrostatic analyser (ESA), followed by an electromagnet (in some instruments this order is reversed). Ions are sampled from the plasma and then accelerated in the ion optics region to a few kilovolts before entering the mass analyser. The ESA is dispersive with respect to ion energy while the magnetic field separates ions on the basis of ion energy and mass. By variation of the electric field and the magnetic field strength, ions are separated with much improved resolution. As with the quadrupole, readings are rapidly sequential.

Some commercial instruments employ time-of-flight (TOF) MS technology, which provides true simultaneous multi-element measurement. This is particularly useful for the analysis of rapid, transient multi-element signals, such as those generated by electrothermal vaporisation and laser ablation. Multi-collector instruments, with double-focusing sector field mass spectrometry, are used for applications requiring high-precision measurements, such as the determination of isotopic ratios.

Interferences

ICP-MS is subject to spectral interference caused by the presence of isotopes of either different elements (e.g. $^{64}Ni^{+}$ on $^{64}Zn^{+}$, $^{156}Gd^{2+}$ on $^{78}Se^{+}$) or ions formed from matrix components and the plasma gas (isobaric and polyatomic, respectively). Examples of polyatomic interferences that are important for analysis of biological samples include $^{40}Ar^{+}$ on ^{40}Ca, $^{31}P^{16}O_2{}^{+}$ on ^{63}Cu, $^{40}Ar^{35}Cl^{+}$ on ^{75}As and $^{40}Ar_2{}^{+}$ on ^{80}Se. These interferences can be avoided by counting a non-affected isotope if it is present with sufficient abundance, e.g. $^{82}Se^{+}$ in place of $^{80}Se^{+}$, $^{66}Zn^{+}$ in place of $^{64}Zn^{+}$. Sector field ICP-MS is not subject to most of these interferences, although there may be some loss of sensitivity at high resolution, which may lead to problems with

Table 43.3 Nebulisers and spray chambers used in ICP-MS

Unit/Design	*Advantages*	*Disadvantages*
Concentric nebuliser	Provides stable and sensitive readings	Unable to use samples with high dissolved solids, liable to blocking
Cross-flow nebuliser	Can use samples with higher dissolved solids. Rugged performance	Produces fewer small droplets and, therefore, less sensitive readings
Microflow nebuliser	Ideal for small samples, use flow rate of less than 0.1 mL/min	
	Low memory effects and low blanks	
Double-pass spray chamber	Rugged performance, suitable for most applications	
Cyclonic spray chamber	Good sampling efficiency with improved sensitivity and lower detection limits	Precision may be compromised

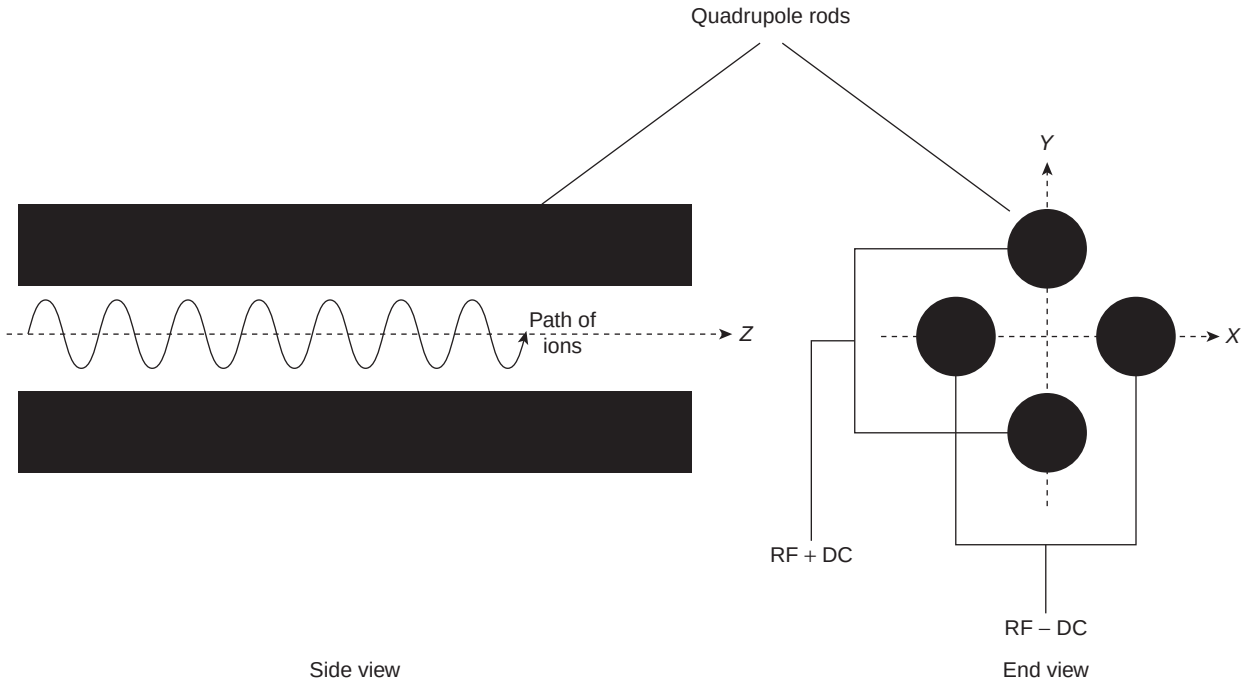

Figure 43.6 Cross-section of the quadrupole for ICP-MS.

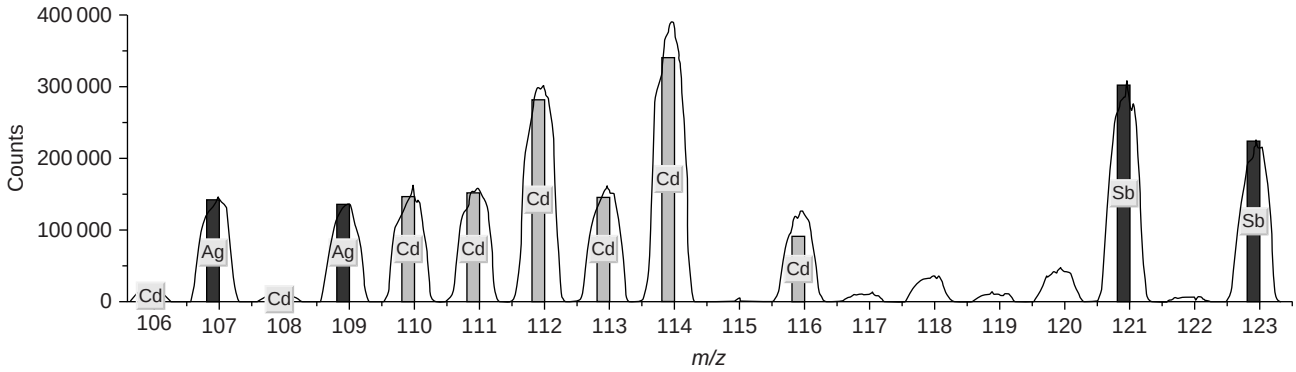

Figure 43.7 Example of an ICP-MS mass spectrum.

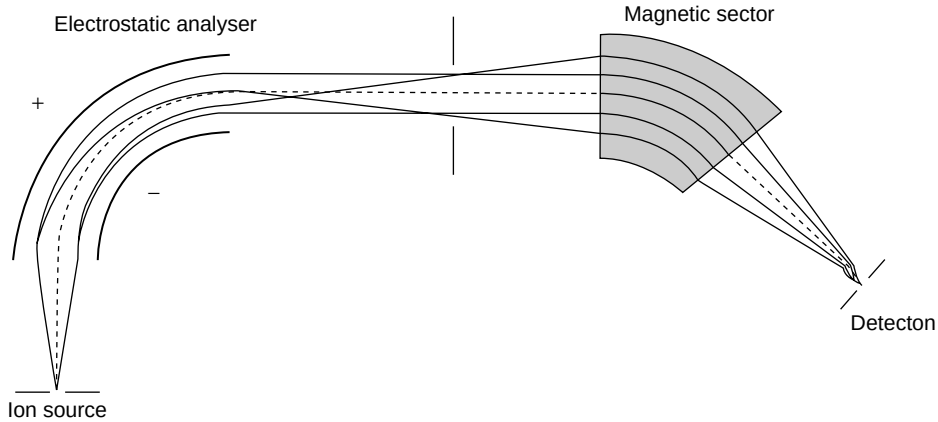

Figure 43.8 Sector field mass spectrometer.

some applications such as the measurement of blood selenium (Klaue, Blum 1999). The most usual procedure, however, is to use a collision, or dynamic reaction, cell.

This is a relatively new development for use in quadrupole MS instruments. The cell is a multipole – a quadrupole, a hexapole or an octapole – aligned between the ion optics and the quadrupole mass filter. Interactions between polyatomic ions and a gas fed into the cell greatly reduce spectral interferences. These interactions lead to the formation of secondary species, which are removed from the ion path on the basis of kinetic energy discrimination or mass discrimination so that only the analyte ion is transmitted to the detector.

The addition of nitrogen, helium, or methane to the carrier gas or an organic solvent to the diluent reduces some of the argon-based interferences (Branch *et al.* 1994). An alternative approach involves prior separation of analyte ions from those involved in the formation of polyatomic species. Separation may be achieved by vaporisation of the sample, for example by hydride generation or by electrothermal vaporisation, or by prior use of a chromatographic or other separation step such as liquid–liquid extraction.

Non-spectral interferences, associated with sample introduction and fluctuations in the inductively coupled plasma, are effectively eliminated by using an internal standard. This should be an element not present in the original sample, not subject to spectral interferences, and with mass and ionisation energy close to those of the analyte(s). Internal standards often used with biological specimens are scandium, indium and iridium for masses <80, 80–150 and >150 amu, respectively.

Applications

In most laboratories ICP-MS serves as a routine technique that affords high throughput, single- or multi-element analysis with very good sensitivity. It can, therefore, be applied to a wide range of investigations. Situations in which ICP-MS is particularly valuable are illustrated by the following studies.

Multi-element screening A welder developed neurological symptoms after working on a warship where the metal had been coated with non-standard paint. A urine sample was analysed with the ICP-MS instrument set in semi-quantitative mode, for a rapid scan to identify any elements present at abnormal levels. Metals identified as possibly of further interest were then quantified, but none was found at increased concentration (Taylor, 2009, unpublished observation).

Sensitivity Individuals from regions where there had been military action were concerned about possible exposure to uranium. With the exquisite sensitivity afforded by ICP-MS it was possible to demonstrate that concentrations of natural and depleted uranium in blood and urine samples were quite normal (Oeh *et al.* 2007).

Isotopic analysis Several children from one town had increased blood lead concentrations. Lead isotopes were measured in blood samples and a series of possible sources of exposure. The isotopic ratios of a 'market place' medicine with a high lead concentration matched the ratios determined in the blood samples. The public authorities arranged for the material to be removed from sale (Al Saleh *et al.* 1993).

Versatility Non-standard sample introduction and the excellent sensitivity of LA-ICP-MS were exploited to determine the profile of platinum along a single strand of hair from a patient treated with cisplatin. Each measurement corresponded to just a few days of growth and concentration peaks corresponded to discrete episodes of treatment (Stadlbauer *et al.* 2005).

General principles of AES, AAS and AFS

Atoms may exist at the most stable or *ground state* (E^0), having the lowest energy, or at any one of a series of *excited states* depending on how many electrons have been moved to higher energy levels, although it is usual to consider just the first transition (to E'). This may be visualised in an energy level diagram (Figure 43.9). It is important to understand that energy levels, and the differences (ΔE) between each energy level, are dependent on the composition of the atom and are unique to each element.

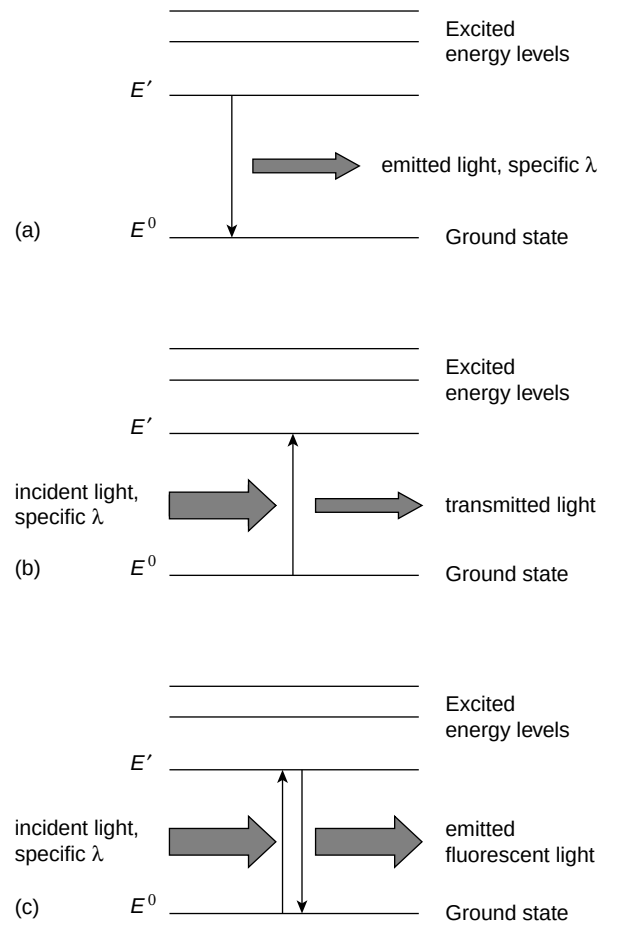

Figure 43.9 Energy-level diagrams to show transitions associated with (a) AES, (b) AAS and (c) AFS. The vertical arrows indicate absorption or emission of radiant energy (light).

The value of ΔE for movements of *outer shell electrons* in most elements corresponds to the energy equivalent to UV–visible radiation. The energy of a photon is represented as:

$$E = h\nu \tag{43.1}$$

where h is the Planck constant and ν is the frequency of the waveform corresponding to that photon. Furthermore, frequency and wavelength are related as:

$$\nu = \frac{c}{\lambda} \tag{43.2}$$

where c is the velocity of light and λ is the wavelength. Therefore:

$$E = \frac{hc}{\lambda} \tag{43.3}$$

and so the transition associated with each element, e.g. ΔE(Ca), is characterised by a unique wavelength.

Under appropriate conditions, outer shell electrons of vaporised, ground state atoms within the analytical system are excited by heating (thermal energy). As atoms return to the more stable ground state, this energy is lost. Some of this energy is in the form of emitted light that can be measured. The intensity of the light is proportional to the number of atoms present and in a quantitative system the process is *atomic emission spectrometry* (Figure 43.9a).

As light (i.e. radiant energy) of a specific wavelength enters an analytical system, outer shell electrons of corresponding vaporised ground

state atoms within the light path will be excited as the energy is absorbed. Consequently the amount of light transmitted through to the detector is reduced. The loss of light is proportional to the number of atoms present and the method is known as *atomic absorption spectrometry* (AAS) (Figure 43.9b).

Some of the radiant energy absorbed by ground-state atoms can be emitted as light as the atom returns to the ground state. This emission is known as resonance fluorescence and is again proportional to the number of atoms in the light path. The technique is known as *atomic fluorescence spectrometry* (AFS) (Figure 43.9c). This technique requires very bright light sources to generate useful amounts of fluorescence and in practice is limited to just a few elements.

It follows from equations 43.1–43.3 that the wavelengths of the absorbed and emitted light are the same, and are unique to any given element. This gives AAS, AES and AFS great specificity, so that one element can be measured accurately even in the presence of an enormous excess of a chemically similar element.

Atomic absorption spectrometry

Atomic absorption spectrometry can be used to measure more than 60 elements and is sufficiently sensitive to measure many of these elements at the concentrations present in biological specimens. The spectrometer consists of a light source, atomiser, monochromator, detector and readout/display. The essential requirement of a good light source for AAS is to provide a high-intensity, monochromatic output, which is achieved with hollow cathode or electrodeless discharge lamps. The monochromator, detector and display are similar to those of other spectrometers.

The *atomiser* is any device that will generate ground-state atoms as a vapour within the light path of the instrument. In the case of lead in blood, for example, the element is present bound to macromolecules within red cells and a small fraction in the blood plasma. Formation of the atomic vapour (atomisation) requires (1) removal of solvent (drying), (2) separation from anionic or other components of the matrix to give Pb^{2+} and (3) reduction ($Pb^{2+} + 2e^- \rightarrow Pb^0$). The necessary energy is supplied as heat, from either a flame or an electrically heated furnace. The uncharged lead atomic vapour, within the atomiser, then absorbs incident radiant energy coming from a lead-specific hollow cathode lamp.

Flame atomisation

The typical arrangement for flame AAS involves a *pneumatic nebuliser*, mixing chamber, and an air–acetylene laminar flame with a 10 cm path length (Figure 43.10). The sample uptake rate through the nebuliser is usually about 5 mL/min and aspiration for several seconds is necessary to achieve a steady signal. The sample emerges from the nebuliser as an aerosol with a wide range of droplet sizes, is mixed with the combustion gases and is transported to the flame for atomisation. As with the nebuliser used for ICP-MS, droplets of more than 10 µm diameter run to waste and only about 15% of the sample enters the flame. Hence, with the pneumatic nebuliser, the original sample undergoes dilution with the flame gases, a portion is lost in the mixing chamber and there is considerable thermal expansion (i.e. further dilution) within the flame. In addition to dispersion of sample through the flame, there are losses of atoms due to the formation of oxides or other species at the flame margins.

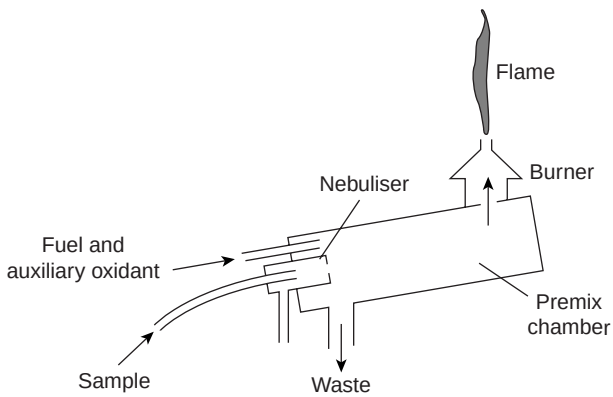

Figure 43.10 Pneumatic nebuliser for flame AAS.

Table 43.4 Advantages and disadvantages of pneumatic nebulisation

Advantages	*Disadvantages*
Rapid	Only about 15% of the sample enters the flame
Reproducible	Wide range of droplet sizes
Few interferences	Low atomic density of sample in the flame
Steady-state signal	Burner conditions impose limitations on nebuliser

The advantages and disadvantages of the pneumatic nebuliser–flame atomisation system are shown in Table 43.4. Because of its simplicity, speed and freedom from interferences, this approach is adopted whenever possible. The lowest analyte concentrations that can be measured are typically ~1 mg/L. Acetylene burns in air at ~2000°C. A nitrous oxide–acetylene flame, which reaches ~3000°C, is used for elements such as aluminium and chromium that form refractory oxides and do not atomise at the temperature of an air–acetylene flame.

Improved sensitivity is obtained when the limitations of pneumatic nebulisers listed above are overcome. This may be achieved with (1) use of atom traps that give a greater atom density within the light path, (2) by-passing the nebuliser so that all of the sample is atomised, and (3) introducing the sample as a single, rapid pulse rather than a continuous flow. Some accessories employ a combination of these features. Atom traps, e.g. the slotted quartz tube and the Delves cup system, are devices that effectively concentrate the analyte atoms in the flame by slowing down their dispersion so that more of the incident radiation is absorbed, increasing the sensitivity of the analysis. Traps are most effective with more volatile elements such as zinc, cadmium and lead (Delves 1970; Taylor, Brown 1983). These three approaches to improved sensitivity also feature in other atomisers used in AAS, AES and AFS.

Electrothermal atomisation

Various materials have been used to construct electrically heated furnaces to vaporise the analyte, but commercial instruments use a graphite tube and the technique is often called *graphite furnace atomisation*. Heating occurs when electrical contact is made to the ends of the tube and a voltage is applied; the resistance to the flow of current causes the furnace temperature to increase. A programme is used to increase the voltage and, consequently, the temperature, so that a solution placed inside the furnace is carefully dried, organic material is destroyed and the analyte ions are dissociated from anions. With a further rapid increase in temperature, analyte ions are vaporised and reduced to ground-state atoms for absorption of radiant energy and spectrophotometric measurement.

The atomisation temperatures achieved by these analysers can be up to 3000°C, allowing refractory elements such as aluminium and chromium to be measured. Typically only 10–50 µL of sample is needed for injection into the furnace and, because the entire sample is atomised within a small volume, a dense atom population is produced. The technique is very sensitive and analyte concentrations of a few µg/L can be measured. However, electrothermal atomisation AAS (ETAAS) is subject to greater potential interference than flame AAS (FAAS) and procedures to either eliminate or compensate for interferences are essential. Different forms of graphite (electrographite, pyrolytically coated graphite and total pyrolytic graphite) are used, and the design of the furnace and its mode of heating are optimised to promote atomisation and reduce interferences.

Interferences

Devices that involve flow of solutions, such as nebulisers or flow injection systems, will give inaccurate results if the samples and calibrators have different viscosities, as this causes rates of flow into the analyser to differ. If this occurs, internal standardisation, addition of standard or the addition of reagents to equalise analyte and calibrant flow rates can be used to improve accuracy. Thus, the viscosity of serum reduces the aspiration rates of samples compared with aqueous calibration solutions, giving low results if not adjusted. Sample viscosity can be reduced by dilution, but this may then give very low absorbance readings. Different strategies to overcome this problem in the measurement of serum copper and zinc are outlined in Example 43.4. Note that when the method includes several steps, the possibility for contamination to occur, especially with zinc, is increased. Whichever sample preparation method is used, it is important to measure the aspiration rates of samples and calibration solutions through the nebuliser pre-mix chamber to ensure that they are equivalent.

Table 43.5 Chemical modifiers used in ETAAS

Modifier	*Function*
Nickel Ammonium phosphate Palladium Ruthenium	Form a thermostable complex with the analyte ions to allow a higher ash temperature to be used and so remove interfering species
Gaseous oxygen	Assists the ashing of the organic matrix. Mediates formation of atoms via activation of the graphite surface
Nitric acid Ammonium nitrate	Promote low temperature volatilisation of halides to prevent analyte–chloride vapour phase interferences
Magnesium nitrate	Delays atomisation so that isothermal conditions can be established inside the furnace

Example 43.4. Techniques to match viscosities of sample and calibration solutions

- Prepare the calibration solution in the same matrix as the sample (matrix matching or standard additions).
- Prepare the calibration solutions in 2% v/v glycerol.
- Add 1 part 10% w/v trichloroacetic acid to 1 part serum or calibration solution. Mix well, centrifuge and remove the supernatant for analysis.
- Dilute the samples and calibrators with 5% v/v aqueous butan-1-ol.
- Dilute the mixture 5- to 10-fold in purified water.

Table 43.6 Approaches to eliminate non-atomic absorption in ETAAS

Technique	*Rationale*	*Examples*
Chemical modifiers	Promote the destruction of sample matrix. Delay atomisation of analyte	Oxygen, magnesium nitrate, diammonium hydrogen orthophosphate
Isothermal atomisation	Reduce vapour phase interactions by delaying atomisation until the furnace reaches constant temperature	L'Vov platform, graphite probe, novel furnaces
Background correction	Separately measure total and non-atomic absorption; difference = atomic absorption	Deuterium BC, Zeeman-effect BC, Smith-Heijfte BC

Chemical interactions may influence the rate of atomisation. During FAAS, calcium bound to phosphate in serum is not entirely separated at 2000°C and gives a lower result than an equivalent concentration in an aqueous calibrant. Addition of a releasing agent such as lanthanum (La^{3+}), which releases the calcium by binding preferentially to phosphate, avoids this interference.

Problems also occur in the graphite furnace. Components in the sample matrix can cause the analyte to become volatile and be lost during the ashing step, e.g. lead can be lost as lead chloride, $PbCl_2$. However, the most difficult problems are those that develop in the vapour phase as the samples are heated. Ground-state atoms are vaporised into a rapidly changing thermal environment where the gas-phase temperature is lower than that of the tube wall and the ends of the tube are at a lower temperature than the centre. Consequently, vaporised atoms may condense on the cooler parts of the tube and then revaporise as the gas-phase temperature increases to the analyte appearance temperature, giving double peaks. This is because the molecular species formed give non-atomic absorption. Compensation for non-atomic absorption is provided by using chemical modifiers to stabilise the atoms and/or to promote destruction of the matrix at an earlier stage of heating (Table 43.5), by using devices to establish isothermal atomisation conditions and by using background correction techniques (Table 43.6).

A typical method for the measurement of blood lead (Example 43.5) exploits each of these features. Matrix-matched calibration solutions are prepared in a sample of blood with a low concentration of lead. Samples are diluted 15-fold with a phosphate/Triton solution and introduced into the graphite tube furnace of the AAS set-up. Oxygen or air is bled into the furnace during the ash phase to facilitate the destruction of organic material. Background correction is essential to compensate for the non-atomic absorption.

Example 43.5. Measurement of lead in blood by electrothermal atomisation atomic absorption spectrometry

- Add whole blood (30 µL) to chemical modifier (0.05 % v/v Triton X-100 + 0.5 % (w/v) diammonium hydrogen orthophosphate (420 µL)).
- Mix well and introduce to furnace with deuterium or Zeeman-effect background correction.
- Heating programme (instrument: Thermo 939):

Phase	*Temperature (°C)*	*Hold time (s)*	*Ramp (°/s)*	*Gas*	*Gas setting*	*Remarks*
1	80	2	100	Ar	2	Drying
2	130	35	2	Ar	2	Drying
3	500	10	0	Air	2	Air ashing
4	600	15	10	Ar	3	Air/O_2 desorbed from furnace
5	1400	2	max.	Ar	0	Temperature control and read
6	2800	3	max.	Ar	3	Cool

Atomic emission and atomic fluorescence spectrometry

Atomic emission spectrometry

Flame atomic emission spectrometry (FAES; flame photometry) is convenient for the alkali metals at high concentrations, but AES is most useful with high-temperature energy sources when multi-element analyses can be undertaken. As indicated above, the heat source for atomisation and excitation to a higher energy level can be a flame. Historical alternatives include arcs and sparks, but modern instruments employ an argon plasma, as subsequently used for ICP-MS. Samples are normally introduced via a nebuliser but, as for ICP-MS and AAS, vapour generation (see below), electrothermal vaporisation from a graphite atomiser or laser ablation of solid specimens is also possible. Optical systems direct the emitted light either via a monochromator to a single detector or to an array of monochromators and detectors positioned around the plasma. With the first arrangement a sequential series of readings can be made with the monochromator driven to give each of the wavelengths of interest in turn. Simultaneous readings can be made with the second arrangement as each of the monochromators transmits light of different required wavelengths. A sequential reading instrument is less expensive than a simultaneous reading instrument, but more sample is required to take a series of readings. For most elements the analytical sensitivity for ICP-AES is similar or slightly superior to that obtained with FAAS.

At the high operating temperatures of the ICP, many energy transitions take place, giving rise to the potential for spectral interferences when emission of light from different elements occurs at wavelengths that are too close to be separated by the monochromator. Most of these spectral interferences are known so that, when interference is suspected, an alternative resonance line may be used for the measurement.

Atomic fluorescence spectrometry

Few commercial instruments for AFS are available and these are confined to the measurement of hydride-forming elements and mercury (see Vapour generation approaches). The components of the instrument are similar to those for AAS. Effective atomic fluorescence requires intense, stable light sources and these are difficult to construct reliably. Most success has been with electrodeless discharge lamps. The optical path of the emitted light is directed at 90° to that of the incident light so that only the emitted, fluorescent light reaches the detector. Very low detection limits can be achieved for the metalloid elements of groups 4–6 of the periodic table.

Vapour generation approaches

A family of chemical vapour generation techniques has been described (Tsalev 1999) where the analyte is separated from the matrix as an atomic or chemical vapour that is then transported to a suitable instrument for detection and measurement. Most practical applications involve either volatile hydride generation or the formation of mercury vapour, although some recent reports have demonstrated that it is possible to measure copper and zinc in this way (Matsumoto *et al.* 2007; He *et al.* 2008).

Hydride generation

Elements such as arsenic, selenium, antimony and bismuth form gaseous hydrides, e.g. arsine (AsH_3), and this can be exploited in an assay. Using simple instrumentation, a reducing agent, such as sodium borohydride, is added to a reaction flask containing an acidified sample. Hydrogen is formed, which reacts with the analyte and the gaseous hydride is evolved. The hydride is transferred by a flow of inert gas to an ICP for AES or MS, or to a heated silica tube positioned in the light path for AAS or AFS (Heilier *et al.* 2005). The tube is heated, by either an air–acetylene flame or an electric current, to a temperature that is sufficient to cause dissociation of the hydride and atomisation of the analyte (Figure 43.11). Of relevance to AAS, there is no loss of specimen in the nebuliser, all the atoms enter the light path within a few seconds and they are trapped within the silica tube, which retards their dispersion. Instrument development to give a continuous flow has simplified automation.

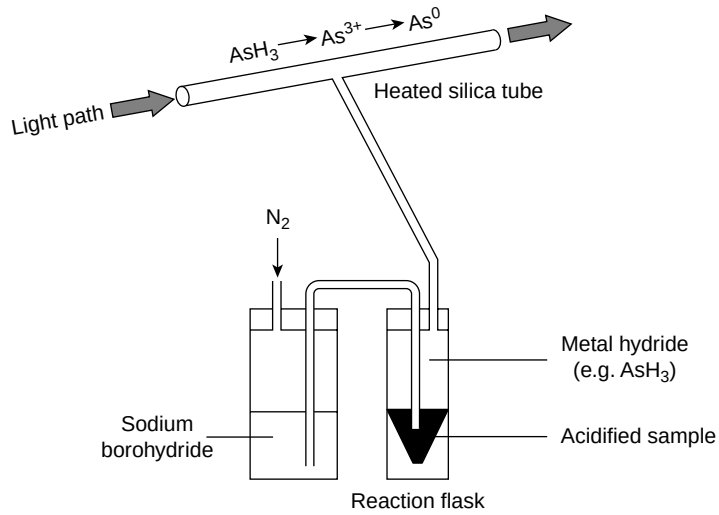

Figure 43.11 Hydride generation AAS.

Typically, the hydride-forming element will be present in a sample as a range of species (e.g. As(III), As(V), monomethylarsonic acid, dimethylarsinic acid, arsenobetaine). The rate of hydride formation is dependent on the species, so that to measure the total concentration of the element it is necessary to convert all of the different species present to the form that is the most reactive. This is usually achieved by heating with concentrated acids (Example 43.6) and then adding a reducing agent to give the reactive species (As(III), Se(IV), Sb(III), etc.).

Example 43.6. Preparation of sample for the measurement of total selenium concentrations (Welz *et al.* 1987)

- 1 g of blood, urine, tissue placed in a digestion tube. Add 5 mL HNO_3 and heat at 150°C for 30 min.
- Add 0.2 mL $HClO_4$ and 0.5 mL H_2SO_4. Heat at 150°C for 15 min, then at 200°C for 15 min, 250°C for 15 min.
- Heat for a further 20 min with the heater set at 320°C. Allow to cool to room temperature.
- To reduce Se(VI) to Se(IV), add 5 mL 50% v/v HCl. Heat at 90°C for 20 min.
- Cool, add 5 mL H_2O and take for the measurement.

Seafoods are a rich source of non-toxic organoarsenic species and urinary total arsenic concentrations will be high for several days following consumption of fish. It is possible to differentiate between dietary and non-dietary arsenic compounds by omitting the aggressive heating step and using a mild reducing agent to convert any As(III) metabolites to the hydride-forming species. The analysis will then reflect the exposure to toxic arsenic species (Cava-Montesinos *et al.* 2005; Leermakers *et al.* 2006).

Certain interferences are common to hydride generation whichever detector is used. If one hydride-forming element is present in the sample in large amounts it will consume the reducing agent so that other elements may not be detected (Welz, Stauss 1993). High concentrations of transition-element ions also inhibit hydride formation. If this is a problem, the use of masking agents, co-precipitation or chelation of the analyte followed by liquid–liquid extraction of the chelate can be used prior to the analysis (Welz, Melcher 1984).

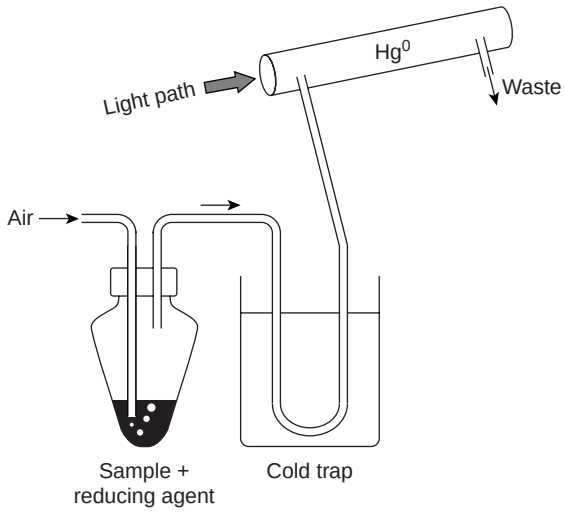

Figure 43.12 Cold vapour generation.

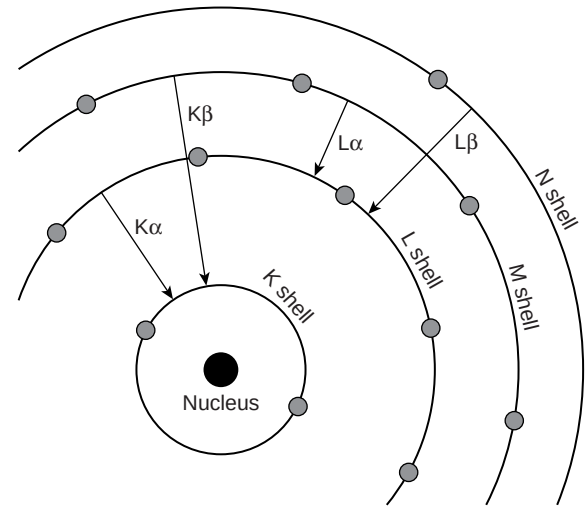

Figure 43.13 XRF electronic transitions in a calcium atom.

Mercury vapour generation

Mercury forms a vapour at ambient temperatures and this property is the basis for cold vapour generation. A reducing agent such as tin(II) chloride is added to the sample solution to convert Hg^{2+} to elemental mercury (Hg^0). Agitation or bubbling of gas through the solution causes rapid vaporisation of the atomic mercury, which is transferred to a flow-through cell placed in a light path (Figure 43.12). To break the carbon–mercury bond in any organomercury compounds present, potassium permanganate may be added to acidified urine and the sample incubated at room temperature overnight. Excess permanganate is destroyed by addition of hydroxylamine hydrochloride. The reducing agent is added to the sample immediately before connection to the vapour generation accessory (Example 43.7). As with hydride generation, the LOD is a few nanograms and instruments to perform both procedures have been developed.

Example 43.7. Measurement of mercury in urine by cold vapour generation AAS

- Place urine (1 mL) in a tube (4°C).
- Add 0.2 mL concentrated H_2SO_4 and 1.5 mL 6% w/v $KMnO_4$.
- Stand overnight and then add 0.3 mL 20% w/v hydroxylamine hydrochloride.
- Add 1 mL 20% w/v $SnCl_2$ in 50% v/v HCl to reduce Hg^{2+} to Hg^0.
- Connect to accessory and purge with air or inert gas to volatilise the analyte.

X-ray fluorescence

When solid samples are exposed to short-wavelength X-rays or to gamma rays (the primary radiation), an electron may be displaced, i.e. ionisation occurs. Energy associated with these rays is sufficient to displace electrons from the inner orbitals (K, L or M) of constituent atoms. The atomic structure is then unstable and the orbital vacancy is filled by an outer shell electron 'falling' into the hole. This event releases energy in the form of an X-ray photon. The energy (and hence wavelength) of the emitted photon is equal to the difference in the energy levels involved in the electron transition. This phenomenon is known as *X-ray fluorescence* (XRF).

The transitions are given names that describe the movement of electrons: L to K is Kα, M to K is Kβ, M to L is Lα (Figure 43.13).

The wavelength is characteristic of the atom (element) from which it originated, while the intensity of the emission is related to the concentration of the atoms in the sample (Janssens, Adams 1989; West *et al.* 2009). The spectrometer used to measure the emission may separate either the wavelengths of the radiation or the energies of the photons. Thus analytical XRF is described as wavelength-dispersive (WDXRF) or energy-dispersive (EDXRF). Total reflection XRF (TXRF) is usually described as a separate technique, although it may be considered as a variation of EDXRF (Klockenkämper, von Bohlen 1992). To perform an analysis, specimens are irradiated by high-energy photons, usually the polychromatic primary beam from an X-ray tube. To avoid having to use an elaborate power supply, radioactive isotopes such as ^{244}Cm, ^{241}Am, ^{55}Fe and ^{109}Cd may be used as sources. These have application to semi-portable instruments developed for *in vivo* XRF (Chettle 2006).

The signal may be complicated by contributions from the sample matrix, making calibration difficult. Techniques to overcome the interferences include the use of reference materials, matrix-matched standardisation and/or internal standardisation. In TXRF or when samples are prepared as very thin films, problems are reduced and simpler to resolve. In addition to the effect of the matrix, sensitivity is also influenced by wavelength, and lower-atomic-mass elements are more difficult to measure accurately.

With WDXRF the fluorescence energy is dispersed into individual spectral lines using an analyser crystal and the diffracted beams focused onto a photomultiplier tube. As with ICP-AES, readings may be taken sequentially, with a number of interchangeable crystals for measurement of the full range of elements, or simultaneously in a multichannel mode usually preset for specific analytes. Detection limits for light elements (silicon and below) are 10–100 times lower than with EDXRF. Resolution is good, although less so at shorter wavelengths. Sequential instruments require long analysis times to measure several elements compared with simultaneous instruments or EDXRF technology.

For EDXRF, X-ray emission is directed into a crystal detector. Pulses of current are generated with intensities that are proportional to the energy of the X-ray photons. The energies associated with the various elements in the sample are sorted electronically. Compared with WDXRF, lower-energy sources such as a low-power X-ray tube or radioactive element (^{244}Cm, ^{241}Am or ^{109}Cd) are employed. The detector has to be maintained in a vacuum at the temperature of liquid nitrogen (77 K). While analysis times are 10–30 times longer than with WDXRF, as a truly multi-element technique, the total time required for measurement is not necessarily increased.

If a collimated beam of X-rays is directed against an optically flat surface at a shallow angle (~5 minutes of arc), total reflection will occur.

This is the principle of TXRF in which the sample is exposed to both primary and total reflected beams, and is excited to fluoresce. Emitted radiation is detected and resolved as an energy-dispersive spectrum. As there is effectively no absorption by the matrix, measurement and calibration are much simpler and sensitivities are greater than with other X-ray techniques (Klockenkämper, von Bohlen 1992).

Applications of XRF include the analysis of solid samples such as artefacts, powders, dried tissues and fluids. Instruments to determine metals *in vivo* are being developed with particular interest in lead in bone. Elements such as silver and iron have been measured in skin. Reviews of recent developments and applications are published annually (West *et al.* 2009).

Catalytic methods

The concentration of an element can be measured from its catalytic role in a reaction, the rate of which is monitored using colorimetry or fluorimetry (Nakano *et al.* 1983). The decoloration of ceric sulfate by arsenious acid, which requires iodine as catalyst, was once used to measure iodine in serum when investigating thyroid function. Most other examples of this type of reaction involve the oxidation of a substrate by hydrogen peroxide:

- $H_2O_2 + KI \rightarrow I^{3-}$; catalysed by Mo
- *o*-Dianisidine oxidation by H_2O_2; catalysed by Cr(VI)
- Acid blue 45 oxidation by H_2O_2; catalysed by Mn.

Chemiluminescence for the measurement of metals is a special example of a catalytic technique. Oxidation of luminol by hydrogen peroxide at alkaline pH is accompanied by the emission of light. Chromium, cobalt, copper, iron and manganese have all been assayed in this way (Klopf, Nieman 1983). Such methods are very sensitive and can detect a few μg/L of analyte if interference from other metals can be excluded. However, these reactions have seldom been exploited in the analysis of biological samples. They are included here to illustrate the range of techniques available to the analyst.

Neutron activation analysis

Neutron activation analysis (NAA) can be used to measure several elements simultaneously. However, because access to an atomic reactor is required, the technique is generally used only for special projects. In summary, the sample is irradiated with neutrons which interact with the target nucleus via a non-elastic collision, causing neutron capture. This produces a compound nucleus with an unstable excited state which almost instantaneously reverts to a more stable configuration. In most cases, this more stable configuration is as a radioactive nucleus, which then decays by the emission of a range of radioisotopes that can be measured using conventional β- or γ-counters, dependent on the unique half-life of the radioactive nucleus. Although characteristic emissions from individual radioisotopes impart some selectivity, there may be interferences, especially from short-lived isotopes. Therefore, the sample is left for a specific decay period and/or post activation ion-exchange chromatography is often employed to isolate the element(s) of interest.

Up to 74 elements can be measured using NAA and it provides detection limits ranging from 0.1 ng/g to 1 mg/g. Heavier elements with larger nuclei have a larger neutron capture cross-section and are more likely to be activated. The analysis is non-destructive, requiring little or no sample preparation. However, it is an expensive technique requiring special equipment and highly trained operators. In order to attain good detection limits, irradiation times of several days may be needed. although NAA is essentially non-destructive, which means that the sample is available for further investigations, the irradiated samples remain radioactive for many years, requiring careful handling and disposal.

Separation science and metals

Chromatography

Chromatography has been used occasionally as the basic technique to determine metals, but conventional detectors lack the sensitivity for this to be a useful approach except where concentrations are unusually high. Ion chromatography is more usually associated with the measurement of anions, but it is possible to measure metal ions using anion exchange columns (Pohl *et al.* 1997). Methods usually involve derivatisation with a reagent such as 4-(2-pyridylazo)resorcinol and colorimetric detection, although other detection systems may be employed including AES and ICP-MS (Heitkemper *et al.* 2001). Detection limits of 0.02–0.5 ng using a 50 μL aqueous sample have been reported.

For measurements of metals, however, chromatography is important for two other applications. Sample preparation can include passage through a column prior to introduction to an ICP-mass spectrometer to eliminate spectral interferences. For example, Cl^- ions can be separated from the sample matrix to prevent formation of $^{40}Ar^{35}Cl^+$ in the plasma, which would otherwise interfere with the reading for ^{75}As (Sheppard *et al.* 1990). Chromatographic techniques are also widely used, together with atomic spectrometric methods, for metal speciation studies (see below).

Capillary electrophoresis

Capillary electrophoresis refers to a group of related separation techniques used for molecular separation within narrow-bore fused-silica capillaries. Capillary zone electrophoresis is the technique most widely used to separate metal-containing species and the two terms are generally used synonymously. The technique is applied almost exclusively to speciation studies.

The capillary, containing an electrolyte solution, has its ends placed in vials (inlet and outlet) also filled with electrolyte solution. The vials also contain electrodes connected to a high-voltage supply (Figure 43.14). The sample solution enters the capillary as a small plug

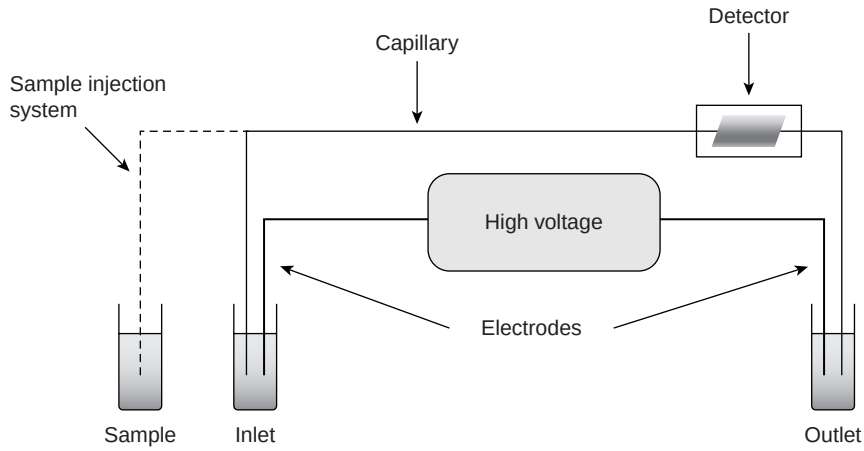

Figure 43.14 Capillary electrophoresis.

by capillary action or through application of pressure or voltage. As a high voltage (5–30 kV) is established across the capillary, zones of analyte form due to different electrophoretic mobilities (based on differences in charge, size and hydrophobicity) of ionic species and migrate toward the outlet side of the capillary. In fact, different ions can be separated when their charge/size ratio differs. For metal speciation investigations, the separated zones are fed into an appropriate detector, usually an ICP-mass spectrometer (Deng *et al.* 2008; Groessl *et al.* 2008; Nguyen, Moini 2008; Kuban *et al.* 2009)

Speciation

Knowing the total concentration of an element in a specimen is usually sufficient for most toxicological investigations, but sometimes this is inadequate or misleading. Non-toxic arsenic compounds derived from seafood may be present in blood and urine. Therefore, separation of arsenic species in a sample, to differentiate between dietary and other sources of exposure, may be vital in a poisoning incident. Similarly, separate determination of methylmercury and inorganic mercury in a sample, by selective measurement of the mercury species, will provide information about the source of exposure. Speciation analysis is also a feature of more fundamental work to investigate the metabolism of an element (Devos *et al.* 2002; Kremer *et al.* 2005) and is prominent in current literature (Taylor *et al.* 2009). Chromatography or electrophoresis is generally used for speciation prior to measurement. Detection is usually by AAS, AES, AFS or ICP-MS. Typically the separation and detection systems are linked in a tandem arrangement.

Apart from the examples for arsenic and mercury, other applications include separation of ionic species, e.g. Cr(III) and Cr(VI), investigation of metalloproteins in body fluid and cell fractions, studies of the metabolism of metal-containing drugs, and interactions between metals and nucleic acids. Identification of selenium species in yeast is a particularly topical challenge that is addressed by several research groups. All types of gas and liquid chromatography, capillary and polyacrylamide gel electrophoresis feature prominently among the techniques employed (Taylor *et al.* 2009).

Analyses involve any or all of the following steps: extraction (from tissue samples, for example), formation of a volatile derivative (for GC), separation and measurement. The extraction procedure should extract all the element in the sample and no species transformation should occur. Useful reviews of arsenic and selenium speciation are available (Francesconi, Kuehnelt 2004; Francesconi, Pannier 2004; Polatajko *et al.* 2006).

Summary

Analysts have an increasing range of techniques available for the quantitative measurement of metals in biological and other samples. Accurate measurements of a specific element, or a multi-element profile to indicate whether a metal is unexpectedly present or absent, can be provided in complex biological or other materials. For many years AAS and AES have been the most important techniques, but ICP-MS is increasingly the method of choice and it is likely that further developments will lead to greater sensitivity, analysis of smaller samples and more effective removal of interferences. XRF is proving a powerful technique, not only for powders or other solid materials; the number of applications is growing rapidly (West *et al.* 2009) and XRF could become equally in importance to ICP-MS in the future.

CHAPTER

44 Emerging Techniques

D Rudd

Introduction

Throughout history, analytical technologies and the associated methodologies have evolved, and will continue to evolve, to fulfil unmet needs. As technological advances are made, and as user requirements become ever more demanding, so techniques and methods are refined and more widely applied to meet these expectations.

It is unusual, but not impossible, to find examples of completely new analytical technologies being discovered. The pioneering days of analytical science, in this respect at least, may be behind us. Nevertheless, these are exciting times for the pharmaceutical analyst and this chapter attempts to capture the flavour of some of the more interesting newer developments, application areas and ways of working.

At the forefront of these newer approaches lies the 'Quality by Design' philosophy that is revolutionising pharmaceutical product and process development and manufacture (FDA 2004; ICH Topic Q8 (R2) 2009) and which is discussed in some detail below. This philosophy has resulted in increasing demands and the need for innovative approaches in the field of pharmaceutical analysis. This is exemplified by, but not restricted to, movement away from laboratory-based measurements to more process-based analytical applications. The consequences of this shift in emphasis are significant and are dealt with in this chapter in a variety of ways.

The chapter has the following structure:

- The 'Quality by Design' philosophy, as applied to pharmaceutical product and process development and manufacture, is described and the analytical contribution is highlighted.
- The evolution of some existing laboratory-based analytical techniques is discussed, specifically of those (ultra-high performance liquid chromatography, ion-mobility spectrometry and solid-state nuclear magnetic resonance spectroscopy) that lend themselves to newer ways of working as required by the modern-day pharmaceutical analyst. Some detail is provided in terms of an overview of the less familiar techniques, but broadly the emphasis is placed on more recent developments and applications, and an indication of the direction in which the techniques are moving.
- Dose-form-specific developments are described using examples of tablet imaging and dissolution and the monitoring of powder and suspension inhalation products. Some recent advances in automation approaches are given to illustrate activity in this area
- A major part of this chapter is devoted to process-based measurement techniques as this is the area that is currently seeing the more significant advances and novel applications.

  Such developments generally involve much more than simple transition of the laboratory-based technique into a process environment and, as a result, a number of traditional analytical steps (sampling, sample treatment, data processing, etc.) need to be considered differently. To that end, a lengthy discourse is provided to help the practising laboratory-based analyst identify and address areas of analytical science with which they may be less familiar. This section forms the basis for a draft ASTM (American Society for Testing and Materials) standard undergoing approval by ballot at the time of writing (American Society for Testing and Materials 2010).

  Newer process-based techniques are described, and these include passive and active acoustics), a range of spectroscopic techniques and imaging approaches. This section includes a detailed discussion of process tomography techniques since they offer some interesting, and less appreciated, opportunities for the characterisation and control of dynamic fluid systems, particularly at the manufacturing scale.

  The section on process-based measurement techniques concludes with reference to light-scattering applications and thermal effusivity and an overview of data collection and interpretation techniques and how they are being developed for non-laboratory applications.
- Examples of some field-based measurement techniques are given. These systems can provide capability for rapid identification of pharmaceutical materials, and often with surprisingly good quantitative performance.
- The dramatic emergence of rapid microbiological techniques is discussed; these, possibly more than any other group of analytical technologies, reflect the way in which demands for greater speed of analysis, quality of data and capability, etc. may be met.
- Finally, the growing importance of biopharmaceuticals and the associated need for analytical methods for their characterisation and quantification are addressed. Many major pharmaceutical companies expect biopharmaceutical products to occupy a significant portion of the new product portfolio in the next few years (GlaxoSmithKline 2010). In that event, some of the technologies described are likely to become particularly important.

It is hoped that the format and scope of this chapter will offer a useful, if necessarily limited, insight into a number of interesting and emerging analytical areas. Not all of these, of course, necessarily offer the advantages that are claimed by the main protagonists, and it will be interesting to see exactly which techniques realise their potential and which fall by the wayside.

Inevitably in this chapter, reference is made to a number of existing commercial analytical systems and suppliers. Generally, this should be recognised as a means to illustrate a specific approach or new development rather than an endorsement of that particular supplier, although the examples are chosen, of course, because of their suitability.

'Quality by Design' in the pharmaceutical industry

Traditional pharmaceutical development and manufacture is capable of producing high-quality, safe and efficacious medicines for the patient based on well-defined and well-controlled manufacturing processes. The quality of the finished product is generally established using laboratory-based analytical testing that demonstrates compliance of the batch from which laboratory samples are taken and tested against a predetermined quality specification.

While it is fair to say that this approach has been used successfully for many years, there are a number of perceived shortcomings that can result in incorrect assessment of product quality, potential risk to the patient and/or waste of expensive commercial material. For example, issues with analytical methodology, non-representative sampling schemes, inhomogeneity of material, etc. may all result in an erroneous assessment of the overall batch quality. In addition, minor deviations in the manufacturing process (either deliberate or adventitious) may result in change to some finished-product quality attributes and these may go undetected during the laboratory analytical testing, or may be detected and assigned an inappropriate level of significance.

These potential scenarios result in greater dependence being placed on the outcome of the laboratory analytical testing to demonstrate the

overall quality of the product whereas, in an ideal world, such testing would simply be confirmatory rather than pivotal in terms of establishing batch quality.

In order to overcome some of the shortcomings that have been highlighted, the pharmaceutical industry is now becoming increasingly aware of the importance of incorporating 'Quality by Design' principles into its product and process development activities (FDA 2004; ICH Topic Q8 (R2) 2009). Broadly, this means that greater emphasis is placed on the incorporation of sound scientific and engineering principles into product and process development such that robust, fit-for-purpose and well-understood processes are established and operated throughout the life cycle of the product.

The 'Quality by Design' approach generally embraces four distinct stages, reflecting the sequence of events that needs to be followed in order to develop and maintain product and process quality. Various terms are used by different organisations for each of these stages but, in general, the following represents a summary of the scope and objectives of each stage:

Design intent

Design intent effectively defines the required performance of the product and process, including final commercial requirements, and will be based on input from various customer sources. The key areas of performance are patient safety and efficacy. However, the design intent will also address the need for appropriate formulation and manufacturing technologies to ensure that the product is chemically and physically stable, and that it is manufactured using a robust process.

Design selection

The design selection stage involves the selection of the formulation, manufacturing unit operations, device, packaging and analytical methods for the commercial product that meet the design intent. A key output of design selection is an understanding of how the input materials, manufacturing operations and packaging design impact the quality of the final product.

Control definition

Control definition identifies the ways in which the quality of the final product may be achieved. The attributes and parameters that contribute to variability in quality will be established and appropriate controls defined.

Control verification

Control verification is the final stage of a 'Quality by Design' approach and allows continued verification of the suitability of the defined control strategy throughout the life cycle of the product and process. This usually takes the form of data trending activities to ensure that process parameters, operating ranges, predictive models, etc. are all consistently providing material of suitable quality or, if this is not the case, to offer refinement of the control strategy such that quality requirements continue to be met.

This approach provides a number of key advantages to the patient and to the manufacturer of the product:

- Product quality and performance are ensured through the design of effective and efficient manufacturing processes.
- Product and process specifications are based on a mechanistic understanding of how formulation and process factors affect product quality and performance.
- Continuous real-time quality assurance can be achieved and demonstrated.
- Process control strategies may be applied to ensure that deliberate or adventitious excursions in process operating conditions do not necessarily result in batch failures or production of sub-optimal material.

It is evident from this brief summary of the key advantages of a 'Quality by Design' approach that the analytical component is an integral part of successful implementation. For example, during development, analytical technologies will be required to help identify the relationships between formulation and process factors (the so-called 'critical process parameters' (ICH Topic Q8 (R2) 2009)) and the key indicators of product quality and performance (the 'critical quality attributes' (ICH Topic Q8 (R2) 2009)). Such analytical technologies (or, more exactly, the methodologies associated with the techniques) may need to be relatively sophisticated and, as such, may not be ideally suited for routine application throughout the life cycle of the product. However, this is not too problematic, as such relatively complex analytical technologies may be used during product and process development to establish a suitable degree of process understanding (that is, the identification of the relationships between critical process parameters and critical quality attributes), with simpler methodology being employed for subsequent routine monitoring.

Continuous real-time quality assurance depends on a more targeted application of a number of measurement and control technologies, including the use of robust and reproducible analytical methodology. Such applications are likely to be in-process (at-line, on-line or in-line), although it is possible to provide continuous real-time quality assurance using laboratory-based (off-line) measurement technologies. The important factor is that the overall analytical cycle time (that is, the interval between taking a sample and being able to react to the measurement made on that sample) should be short relative to the time scale of the process in order to allow real-time quality assurance to be achieved.

As indicated earlier, analytical methodology to support routine monitoring throughout the life cycle of the product needs to be robust, reproducible and well established, and these requirements dictate strongly the suitability of some emerging technologies. This will be considered later in this chapter.

To summarise this section, it is apparent that the pharmaceutical industry is currently embracing the incorporation of 'Quality by Design' principles into its product and process development activities in order to ensure improved product quality and increased efficiency of manufacture. The application of analytical technologies is an integral part of this 'Quality by Design' philosophy, with different technical requirements being identified during product and process development compared with routine manufacture. As a result, some analytical technologies lend themselves more easily to these different application areas, and this distinction must be borne in mind at all times when emerging techniques are being considered.

Laboratory-based analytical techniques

Some of the newer developments in existing laboratory-based analytical techniques are discussed, including the ways in which some of those techniques are evolving and being applied. Adoption of 'Quality by Design' principles to the analytical method itself, rather than the use of the method to aid application of such principles to pharmaceutical product and process development and manufacture, is also introduced (Borman *et al.* 2007).

'Quality by Design' for analytical methods

As discussed above, the pharmaceutical industry is beginning to incorporate 'Quality by Design' principles into the development and routine manufacture of drug substances and drug products. This is based on the need to deliver more robust manufacturing processes and to facilitate continuous improvement through more flexible regulatory approaches. In a similar vein, the application of 'Quality by Design' concepts to analytical methods has recently gained impetus in order to improve their overall robustness, transferability and potential for continuous improvement.

As described previously, the application of 'Quality by Design' principles begins with a set of predefined objectives (design intent). For a pharmaceutical product and manufacturing process, this will be defined as a set of 'critical quality attributes' (ICH Topic Q8 (R2) 2009) that describe the characteristics and limits with which the product must comply in order to be safe and efficacious. For an analytical method, the equivalent may be considered as the 'analytical target profile', which is the combination of all the desired method performance characteristics (e.g. precision, sensitivity, accuracy) and associated criteria such that it is fit for the intended purpose.

The definition of the 'analytical target profile' is based on the critical quality attributes requiring measurement in support of the process control strategy. For a quantitative test, the key requirement is that the method has adequate accuracy and precision over the range of intended use in the presence of any potential interferences. Determination of targets for precision needs to be based on the specification limits associated with that test and to ensure that the method contribution to the overall process capability is minimised.

Once the method performance requirements are understood and documented, appropriate analytical technique and method conditions may be chosen to achieve the desired performance (design selection). During this phase, information such as prior experience with similar measurements or matrices, regional limitations, availability of reagents or specific technologies in laboratories conducting the testing, and/or cycle time requirements to support process operations can be used to ensure that the method will both meet the predefined 'analytical target profile' and be operationally efficient in routine use.

The next step in the 'Quality by Design' process is to develop an understanding of the method (where the term 'understanding' is used to refer to an appreciation of the relationship between method inputs and the desired performance characteristics). Here a systematic approach needs to be adopted in which the various steps involved in the method (sampling, sample preparation, measurement, data interpretation, etc.) are defined using process mapping tools and then method factors that may influence the overall performance are identified through use of tools such as Ishikawa (Fishbone) diagrams (Tague 2004).

The method design phase then continues by evaluation of the impact of each factor on the desired method performance. Initially this involves assessment of the factors that are considered most likely to be important and, once these are identified, experimentation to understand which of these factors significantly influence performance and, in the case of continuous variables, the associated ranges that continue to provide acceptable data. Typically, experimental design approaches are used for resource efficiency and to understand any multivariate relationships that exist. For non-continuous factors (operator, batch of column packing, equipment model, etc.), it is not possible to explore fully the range of variations that will produce acceptable results. However, if considered potentially important, such factors should also be examined to determine, from a limited sample, whether specific control is required. Techniques such as Measurement System Analysis (Automotive Industry Action Group 2010) can also be used to understand the influence of such variables.

This systematic approach will generally produce a set of method operating instructions that provides a high probability that the method will operate robustly in routine use (control definition). Moreover, evidence of compliance with these method operating instructions will prove highly useful in any trouble-shooting exercises in the event that unexpected results are obtained.

It is also important to capture any understanding generated during this systematic approach and to maintain and update this knowledge as further experience is gained during routine use. This may identify additional or modified control requirements, particularly where automated data capture systems allow identified variables to be monitored (control verification).

In summary, the 'Quality by Design' approach, as applied to analytical methods, starts with predefined method performance objectives, followed by experimentation that provides an understanding of the relationship between method inputs and performance characteristics. In turn, this defines the required control strategy, application of which ensures that the expected analytical method performance is achieved throughout the life cycle on the basis of continued monitoring and refinement during routine usage.

General developments in the key laboratory-based analytical techniques

Ultra-high performance liquid chromatography

High performance liquid chromatographic (HPLC) techniques have been the mainstay of the pharmaceutical analytical laboratory for several decades. This reflects the ability of the technique to resolve drug molecules and associated impurities from the complex excipient mixtures introduced during product formulation and from the biological matrices that are encountered in drug metabolism studies. It is a curiosity to many, however, that a technique that has such wide utilisation in routine laboratory analysis and screening finds little application in the process measurement environment. There are examples of process-based HPLC applications, of course, but, relative to the level of use as a laboratory technique, these are limited in number. This is primarily due to the lack of robustness of HPLC equipment when used in manufacturing environments, coupled with the relatively long analysis times and sample preparation required.

Progress in laboratory-based liquid chromatographic technology and capability has been steady rather than spectacular over the last 30 years, with significant advances being made in equipment design and reliability, but more particularly in terms of stationary-phase performance. In more recent years, the development of column packing materials of progressively smaller particle size (typically below 2.5 μm) has allowed high-efficiency separations to be achieved without an associated increase in analysis times. This new development in liquid chromatography (ultra-high performance liquid chromatography or UPLC) has now found wide application in many routine pharmaceutical analytical laboratories, especially where sample numbers are very high or where rapid throughput is required.

More recently, practitioners of UPLC have begun to identify other advantages that rapid, highly efficient separation capability might provide. On-line application is now regarded more favourably compared with traditional HPLC in that real-time information can easily be obtained, and this lends itself to applications such as chemical reaction monitoring (Cormier, Jenkins 2010), *in situ* cleaning verification (Fekete *et al.* 2009) and preparative scale-up monitoring (Boughtflower 2008).

Developments in equipment continue to be necessary in order to keep pace with the evolution of column packing materials and the requirements that their improved performance demands. Rapid analysis times are driving improvements in sample injection technology and liquid-phase delivery systems, while detector performance (especially in terms of sampling frequency and resolution) remains crucial if optimised applications are required. Against this backdrop of continuous improvement in performance, it is important to remember that equipment robustness is equally critical if successful process-based applications are to be achieved. It may be that the emergence of packing materials of smaller particle size, coupled with the associated improvements in equipment, finally allows liquid chromatographic techniques to bridge the gap between well-established routine laboratory usage and the more demanding (in terms of analysis time and equipment robustness) process-based applications.

Ion-mobility spectrometry

Ion-mobility spectrometry (IMS) is a type of separation technique, similar to time-of-flight mass spectrometry (TOF-MS), that distinguishes ions of a given compound on the basis of their velocities through a drift tube under the influence of a weak electric field. The technique characterises chemical substances on the basis of their gas-phase ion mobilities and provides detection and quantification of trace analytes.

IMS analysis is carried out by injecting a sample solution onto a substrate and then allowing it to dry. The substrate is then heated, and this results in desorption or vaporisation of the sample into an inlet tube. Primary ion formation occurs through atmospheric pressure chemical ionisation (APCI) and, following many collisions, product ions are formed and gated into the drift tube. These ions travel through the drift tube at different velocities based on their size, shape and charge. In contrast to mass spectrometry, separation of ions is based on a size/charge relationship rather than the mass/charge (m/z) ratio.

IMS is usually subdivided into three distinct techniques. Typically, IMS refers to low-field (e.g. 100 V/cm) linear measurements. The technique is linear in that the ions travel at a constant velocity through a linearly decreasing field. Differential mobility spectrometry (DMS) and field asymmetric waveform IMS (FAIMS) are both high-field (e.g. 10 kV/cm or greater), non-linear ion measurements and involve field gradients across the drift tube and/or different instrument configurations to provide increased speed and flexibility or higher resolution.

IMS has been used for direct formulation analysis (O'Donnell *et al.* 2008), particularly for product authentication purposes, but is more usefully applied for cleaning verification. In addition, portable IMS devices are finding wide application in the area of health and safety as well as from a security perspective (see below).

The use of IMS instruments for cleaning verification of manufacturing equipment offers several advantages over methods currently used by pharmaceutical manufacturers. The low levels of quantification for drug substances and contaminants using IMS are generally in the range of 0.4 mg to 10 ng, making the technique comparable to HPLC and TOC (total organic carbon) methods. However, the increased specificity associated with IMS helps to avoid some of the 'false positives' that TOC and HPLC can indicate. Cycle times are reduced as a consequence of the speed of analysis and instrument set-up compared with HPLC, while the elimination of solvents and of column packing materials are added advantages.

Solid-state and quantitative nuclear magnetic resonance spectroscopy

Solid-state NMR (SSNMR) has historically been used in the pharmaceutical industry as a 'fingerprint' technique, supporting vibrational spectroscopy and powder X-ray diffraction techniques. However, the role of SSNMR has grown beyond this to an information-rich technique that can address unique solid-state challenges and serve as a first-line technique in many roles (Vogt 2010b). These changes have been driven by developments in hardware and pulse sequences, which now allow access to a range of nuclei of interest in pharmaceuticals using commercial instrumentation. Some of these nuclei, such as ^{1}H and ^{19}F, allow SSNMR to obtain (simultaneously) high sensitivity and specificity, opening up a range of applications to low-dose products (e.g. low-level polymorph detection), which are not possible with other techniques (Katrincic *et al.* 2009). New multidimensional SSNMR methods allow the extraction of detailed information about molecular structure and association in both crystalline and amorphous materials, leading to applications to co-crystals (Vogt *et al.* 2009) and amorphous dispersions (Pham *et al.* 2010). SSNMR methods have recently been used in combination with X-ray diffraction to determine the crystal structure of a pharmaceutical from a powder sample (Vogt *et al.* 2008), while the ability to probe subtle phenomena, such as dynamic motion in solids, static disorder in crystal structures and crystal defects, is also established (Vogt 2010a).

Looking further ahead, it is likely that SSNMR will be applied more extensively to the characterisation of formulations containing low levels of drug and structural studies on drug delivery systems. Technology and performance improvements should also facilitate investigation of biopharmaceutical solids, for example, where biomolecule–excipient interactions need to be better understood to ensure product performance and efficacy. However, the role of SSNMR has grown beyond this to an information-rich technique that can address unique solid-state challenges and serve as a first-line technique in many roles (Vogt 2010b).

Dose-form-specific developments

Magnetic resonance imaging for solid dose forms

Three-dimensional imaging of solid dose forms, especially those where controlled or modified delivery of the drug from the matrix is intended, can provide a valuable insight for the formulation development scientist. An understanding of hydration mechanisms and the modes of moisture ingress, for example, may allow better formulation development and optimisation of drug release performance for complex solid dose forms.

Historically, tablet imaging has been achieved by mapping physical and/or chemical properties of the intact dose form, generally using spectroscopic techniques and, while such an approach can provide useful information concerning drug and excipient distribution within the tablet matrix, destructive sampling may be involved. In addition, such applications are usually limited to dose forms in their dry state, making it difficult to investigate dynamic hydration mechanisms, for example, under conditions similar to those experienced during use by patients.

Magnetic resonance imaging (MRI) has been used successfully for several years to study hydration mechanisms and drug release from pharmaceutical products (Richardson *et al.* 2005), but applications have been limited by high equipment running costs and long experimental run times. However, such disadvantages are now being overcome with the use of low-field MRI systems that incorporate compact permanent magnet technology (see www.oxford-instruments.com 2010), allowing non-invasive and non-destructive imaging of whole tablets during the dissolution process.

Broadly, the MRI technique provides information on water (and lipid, where present) proton density (M_0) as well as mobility (generally described by the spin–lattice relaxation time, T_1, and the spin–spin relaxation time, T_2). The fact that different materials in a given matrix exhibit different values of these density and mobility parameters allows discrimination during measurement such that mapping of key components becomes possible despite the presence of other, potentially interfering species. As an example, MRI has been used to compare the degree of hydration of a gel matrix formulation (chlorpheniramine maleate tablets) with the corresponding drug release profile under traditional pharmacopoeial testing conditions (Nott 2008). More recently, some immediate-release and modified-release formulations have been studied using the technique in order to understand more fully the mechanisms whereby drug is released (Butler, Nott 2010).

These examples indicate that the MRI approach could be used not only for formulation development and optimisation, but also as a potential real-time release technique for tablet dissolution studies. In addition, MRI could offer an insight into the extent of water binding during granulation and/or drying processes, for example, thus providing an improved level of understanding for these manufacturing steps.

Next-generation dissolution testing

Laboratory-based dissolution testing continues to be the main technique for both development and routine assessment of drug release from oral solid dose products. However, it is recognised that opportunities exist for improvements in reliability, capability and efficiency, even allowing for the advances made in the field of automation of dissolution testing. As a consequence, a number of major pharmaceutical companies are collaborating with key vendors in an attempt to influence the design and promote the development of a 'next-generation' automated dissolution system that will meet the identified current and future needs.

At present, two different approaches, each with their own advantages and disadvantages, are being pursued within this collaboration. The first is the RoboDis system developed by ERWEKA in collaboration with Bayer Schering Pharma (see www.erweka.com 2010) and is based on a centrally configured Stäubli industrial robot that sequentially services all dissolution vessels. Currently this system employs fibreoptic technology for in-situ ultra violet (UV) measurement with a Zeiss spectrometer and Helma probe. The RoboDis system is well engineered and provides operation for up to 12 dissolution vessels, with video monitoring integrated into the control software. However, it lacks some flexibility, in that no media addition or exchange is currently possible and cycle times for sample analysis are fairly lengthy. On-line HPLC analysis of samples is also yet to be addressed.

The second approach features the SOTAX AT-70 (see www.sotax.com 2010), which has dedicated pumps, valves and tubing to service each of the six dissolution vessels separately. On-line UV and HPLC measurement, as well as media addition and exchange, is supported. Sample analysis times are fairly rapid, but there are large dead volumes associated with the complex network of tubing and valves, etc.

It is interesting to note that these current developments largely centre on the automation and general improvement of existing dissolution technology. While it is recognised that dissolution testing in its current form is an important element in the quality assessment of oral solid dose products from a regulatory perspective, it is nevertheless surprising that radically different approaches are not being considered for drug release monitoring. Perhaps the task of demonstrating drug release from oral solid dose products based, for example, on tablet imaging technology and/or assessment of the mechanical properties of the tablet would

Figure 44.1 Xelair series automated inhalation product testing system. (Courtesy of Astech Projects Ltd; www.astechprojects.co.uk.)

prove too problematic – in which case developments in this area are likely to remain limited to those of the type described above.

Dose content uniformity of the emitted dose for inhalation products

Reliable assessment of the dose emitted by metered-dose inhalers (MDIs) and dry powder inhalation products (DPIs) has always been an important aspect of the performance and quality assurance of such dose forms. Regulatory emphasis has increased in this area in recent years, making the need for reproducible and accurate measurement of emitted doses particularly important as a means of ensuring that patients receive the correct dose on a consistent basis.

To this end, the more recent developments in analytical technologies used to determine emitted doses have concentrated on reducing the variability and increasing the volume of data produced. As the regulatory requirements for testing the dose content are well defined (FDA 1998, 2002), technology developments have centred on improved control of product preparation (including shaking regimes for MDIs), actuation, dose collection and waste firing. It is considered likely that this emphasis on the automation part of the testing will be maintained in the future, rather than the introduction of innovative approaches for the determination of the emitted dose itself.

Available commercial systems for emitted dose testing generally reflect the manual process – that is, the priming of the actuation system of the inhalation product, the collection of doses, the firing of doses to waste, the collection of subsequent doses, the analytical manipulation of the collected doses, washing, etc. – but using a heavily automated approach for some or all of these steps. Examples include the Xelair range (see www.astechprojects.co.uk 2010) and the Process Master range (see www.rtslifescience.com 2010), both of which address a number of issues encountered with manual testing of inhalation products – namely, variability in data, productivity and safety aspects – and which also offer a more integrated approach across dose collection, sample treatment and analytical assessment.

Interestingly, systems such as the Xelair (illustrated in Figure 44.1) and Process Master (Figure 44.2) ranges can provide different levels of capability and complexity, allowing applications that extend from simple automation of individual stages of emitted dose testing through to fully automated, completely unattended operation involving large numbers of samples within distinctly different batch sets.

Further refinements are likely to be made with these systems, particularly in terms of the shaking and firing regimes (which seem to be a significant source of variability during manual testing), although the challenge may be one of replicating the most representative manual approach so that any large historical body of data on a given product is not immediately lost on introduction of an automated alternative.

Developments in automation

Advances in automation of analytical technologies continue to be made, although still along fairly traditional lines. The perceived advantages of automation (ability to deal with large numbers of samples; improved quality of data generated; productivity and efficiency; environmental and

Figure 44.2 Process Master automated inhalation product testing system. (Courtesy of RTS Life Science; www.rtslifescience.com.)

safety considerations, etc.) mean that developments generally centre on improvements in these areas, and there are several examples of these types of advances, some of which have been discussed earlier under the dose-form-specific developments (see www.astechprojects.co.uk 2010; www.erweka.com 2010; www.rtslifescience.com 2010; www.sotax.com 2010).

More ambitious advances in automation are less commonplace, but some of the potentially more interesting are discussed here.

Development of an automated generic extraction technology

Traditionally, laboratory automation is generally developed and applied to late-stage, established pharmaceutical products – and, in particular, to routine, high-volume and/or high-throughput testing. This makes sense, in that large numbers of samples are generally produced only at later stages of product development and beyond, allowing the heavy validation burden of any automated technology to be justified.

However, there is an advantage in being able to apply automated approaches to earlier development samples, especially those where the final details of the product type (dose, formulation, pack, etc.) are not fully established. The development of a generic, automated sample treatment stage for application to such product variants therefore has merit as a precursor to a number of different analytical measurement steps.

Recent industry/vendor collaborations have seen the development of such a generic extraction technology based first on the use of acoustic energy to form a localised, high-velocity jet of solute to provide an effective extraction process (see www.covarisinc.com 2010), and second on the use of a commercialised lyophilisation system (Faulkes 2008). Results have shown improved extraction times and extraction efficiencies for early stage formulations and the potential of the systems to deal with diverse formulation types and sub-optimal products (unusually hard tablets or dose forms with high moisture content, and so on).

Automated method development

The incorporation of 'Quality by Design' principles for the automated development of liquid chromatography methods, in particular, has received some attention in recent years. This represents one of the more intriguing aspects of automation development and opens up the more ambitious idea of using automated approaches for the development of pharmaceutical products and manufacturing processes.

At this stage, however, the application of automated 'Quality by Design' is restricted to liquid chromatography methods, one example of which is based on the integration of commercial software from S-Matrix with UPLC technology from Waters (see www.waters.com 2010). It will be interesting to see whether this approach represents the first step towards intelligent, automated development of pharmaceutical products and manufacturing processes, or a short-lived marriage of related, but non-enhancing technologies.

Laboratory on a chip

This much-heralded field of automation and miniaturisation continues to offer advances and, with such a significant level of support and underpinning research effort, seems destined to occupy a key position for the foreseeable future. Environmental considerations have only served to underline the advantages that development in microfluidics, for example, can bring to laboratory on a chip applications and a recent point-of-care disease diagnostic application (Gervais, Delamarche 2009) illustrates how complex analyses may be conducted with these devices. The successful incorporation of pumps, valves and reaction chambers into a robust miniature device, which requires very small sample volumes and yet provides high sensitivity and versatility, demonstrates how this approach can provide point-of-care, field-based or in-process automated analytical capability.

Process-based measurement techniques

Process measurement technologies represent the heart of successful monitoring and control. This section provides an overview of the key measurement techniques, many of which are now being used on a fairly regular basis within the pharmaceutical sector. The areas of development and applicability are also described. In addition, the important aspects of sampling and data processing are discussed in view of the differences arising in comparison with laboratory-based techniques.

Sampling aspects are part of a range of analytical performance topics that need to be considered for process-based measurement techniques, and the following section provides guidance for addressing some of these issues. Note that the content of this section is based on a draft standard undergoing approval by ballot within the ASTM at the time of writing (American Society for Testing and Materials 2010).

Performance assessment for process-based measurement techniques, including sampling considerations

With any process-based measurement system, before any meaningful conclusions can be drawn from the data obtained, it is important to recognise that various factors may affect instrument performance and/or data quality and that these factors need to be well understood and controlled, where necessary.

Generally, such factors may be classified as follows:

- Instrument configuration and performance qualification (PQ)
- Factors affecting measurement
- Influence of effective sample size.

Within each of these categories, there are a number of technique-specific and application-specific factors that will contribute (often adversely) to the quality of the measurement data obtained. It is important, therefore, to identify the technique-specific and application-specific factors that need to be considered to ensure that high-quality data are obtained. In this way, the user can be assured that meaningful conclusions can be drawn about the process or system under investigation, rather than having such conclusions clouded by excessive variability or lack of sensitivity, for example in the measurement system being used.

Instrument configuration and performance qualification

It is important to establish the basic operating configuration of the instrument and expected performance standards. This is likely to have been carried out during method development and, to some extent, will be independent of the intended application (although some applications will necessitate specific instrumental operating configurations). For example, if a spectroscopic measurement technique allows the averaging of multiple spectral measurements to improve the signal-to-noise ratio (SNR), the user can decide how many spectra will be averaged. Too many and the overall measurement cycle time may become excessively long, while too few will result in minimal improvement in the SNR. The final decision on the number of spectra to be averaged may, therefore, be a compromise between maximum measurement cycle time and minimum acceptable SNR – and these become critical parameters to consider as aspects of PQ before the measurement system is used in the chosen application.

Generally, all aspects of instrument configuration that could potentially affect the instrument performance (and also affect the quality of the data produced) are considered and a default operating configuration is established based on an expected level of instrument performance (e.g. maximum relative standard deviation (RSD) of not greater than 2% on 10 replicate measurements of a standard system or sample, minimum SNR of 10, minimum response of measurement to change in amount of analyte of 0.2 mV/mg, and so on). Naturally, it becomes possible to move away from any default operating configuration if the specific application requires a modified approach (e.g. an improved SNR is required, whereas extended measurement cycle times are acceptable), but this would be reflected in similarly modified performance expectations.

Broadly, during the PQ exercise, the expected level of instrument performance is established (and documented) and a default set of instrumental operating parameters is identified which is capable of providing this level of performance. Idealised test systems or reference materials may be used for basic PQ work – that is, a system or process that itself can be considered consistent and/or well characterised. In this way, the user can be sure that any examples of failure to meet the predefined levels of instrument performance are truly attributable to the measurement system and not to the process or material under investigation.

Factors affecting measurement

Once satisfactory instrumental performance has been established, it becomes possible to evaluate systematically those factors (many of which are application specific) that might also affect the quality of the measurement.

Many process-based measurement techniques (spectroscopic, acoustic, thermal, etc.) are often configured to provide relatively simplistic data outputs (spectroscopic absorbance, average acoustic signal level, average thermal effusivity, etc.). While this approach has some advantages in terms of ease of comprehension of data, it must be recognised that meaningful interpretation of such data relies heavily on the validity of the underlying assumptions being made.

Univariate data output of this type (single measurement values being displayed against time, for example), based as it is on contributions from a number of key variables (analyte concentration and particle size, etc. in the case of spectroscopic absorbance; granule compressibility, granule size and flow properties in the case of acoustic signal level; average analyte effusivity, influence of air and water, etc. in the case of thermal effusivity), is useful only when the influence of particular variables can be isolated. The underlying assumption is that the influences of all variables other than the one of interest are consistent, so that variations in the univariate data output can be attributed (perhaps correlated) with the one key variable of interest.

In order to draw such conclusions, it becomes necessary to confirm the validity of these underlying assumptions – and, if this has not been done or if this cannot be done, the reliance on over-simplified univariate data output must be seriously questioned. It then becomes necessary to interrogate the unprocessed measurement data using more sophisticated data processing techniques in order to de-convolute the respective influences of multiple key variables. This is relatively easy to do for many process-based measurement techniques but may prove to be difficult for others, rendering the specificity (or discriminating ability) of such techniques questionable.

In short, where measurements are made that are known to be influenced by a number of key variables, it is important to understand the contribution to the measurement signal from each of these variables (especially in terms of consistency or otherwise), before conclusions can be drawn about the relationship between the measurement signal and the key variable of interest.

For any given measurement technique, the factors affecting measurement will be different, but there are a number of considerations that occur across the range of most common process-based measurement techniques.

Sensitivity or response of sensor Whether this takes the form of light throughput in a fibreoptic probe, frequency response of an acoustic sensor or speed of response of a thermocouple, for example, sensor performance, reliability and consistency are important. Failure to meet predetermined levels of performance may be indicative of poor fabrication, deterioration, poor installation and/or alignment, fouling or poisoning.

In addition, a poor choice of measurement technique or sensors could give rise to an inadequate level of specificity (discriminating ability) – and this is a common cause of poor SNRs.

Interfacing of the measurement system with the process under investigation During method development, basic application-specific measurement parameters such as number of sensors, position of sensors and interfacing of sensors are established. For example, several spectroscopic sensors may be needed if suspension homogeneity is being monitored, whereas a single (far-reaching) acoustic sensor may be sufficient to determine granulation end point.

The method of interfacing (mechanical fixing, insertion, chemical coupling, etc.) may also be critical, and this needs to be defined sufficiently well within the documented process analytical method that the interfacing can be reproduced – and demonstrated to be satisfactory – from one piece of equipment to another, and possibly across different geographical locations and over a wide time interval to allow comparison of data generated under different conditions.

Influence of system or process under investigation Most process-based measurement applications involve the monitoring of dynamic systems. This means that the system or process under investigation is itself changing during the measurement cycle. Of course, some of these changes are the very thing that the analyst is interested in monitoring (e.g. analyte homogeneity during a powder blending process). However, other aspects of the system or process may also be changing (degree of compaction of powder systems, level of moisture, particle size, etc.) and, if these factors contribute significantly to the overall measurement signal – and yet are not the primary factors that the user is interested in monitoring – once again, erroneous conclusions will be drawn from the data obtained if the variations in these 'secondary' factors are not considered. This is why many process-based measurement applications depend critically on the ability to monitor systems and processes simultaneously using a combination of diverse measurement techniques, so that the influence of changes in 'secondary' factors can be understood. There is probably no measurement technique that is universally sensitive to the influence of all potential factors, making it impossible to understand the contributions of each factor from one measurement technique alone.

Influence of external (environmental) factors Traditionally, the performance of laboratory-based measurement techniques is generally unaffected by environmental factors. While such instruments will usually have an environmental operating specification (such as 'do not operate at temperatures above 50°C'), such constraints are seldom a problem in a well-ventilated, air-conditioned modern laboratory. However, the process-based measurement is likely to be made in a relatively harsh process environment, where significant variations in environmental factors such as temperature, humidity, noise levels (audio and ultrasonic), etc., can confound the measurement. Data quality can be assured only when such influences are controlled, minimised and/or understood.

Effective sample size

On-line and in-line process measurement applications do not involve physical sampling of the system or process. Measurements are generally made using sensors or probes in contact with, or inserted into, the system or process – or, in many cases, using non-contact 'interrogation' of the system or process using beams of radiation focused though observation windows fabricated into the process equipment.

However, even though there may be no physical removal of samples from the system or process, all such process measurement techniques are effectively sampling from the bulk of the material under investigation. This is based on the fact that such techniques have a limited field of view or operation, will penetrate a system or process to a finite depth, and can only make measurements at a defined rate.

To illustrate this point, consider a spectroscopic technique that produces data based on an illumination area of about 4 mm diameter and that penetrates to a depth of about 1 mm. This equates to an effective sample volume (assuming a cylindrical shape) of about 13 mm^3 and, provided that the average density of the system under investigation is known (say, about 0.4 g/cm), allows calculation of the effective sample mass that is being monitored during each measurement (in this example, about 5 mg). Combining this with the frequency of measurement (say, a scan once a second, with about 30 scans being averaged) means that an effective sample size of about 150 mg is being investigated. Clearly this level of scrutiny would be acceptable for a powder blending application where blend homogeneity at a scale approximating to the nominal tablet unit dose is being pursued.

As a general principle, the effective sample size can be calculated (or, at least, estimated) on the basis of the contributions from the factors discussed, that is:

- volume of the system or process being monitored (this, in turn, may need to be estimated on the basis of the area of examination and depth of penetration)
- density of the system or process being monitored; this may change during the measurement cycle, so an average value or estimate may be needed
- frequency of measurement: where multiple measurements are averaged, or the output from several sensors is combined, these factors should also be included.

The required effective sample size is specific to the particular application. For example, a powder blending application involving blend homogeneity determination needs to be conducted at a scale that is comparable to the nominal tablet unit dose level (e.g. 150–750 mg typically), whereas monitoring a tablet granulation process using acoustic emission at this scale would be wholly inappropriate – a much greater effective sample size (perhaps the whole batch) being required (meaning that multiple or continuous measurement may be necessary).

Acoustic techniques

While much of analytical science is generally concerned with the study of optical spectroscopy, the equivalent use of sound has so far received less attention. In a similar vein to electromagnetic radiation, sound energy may be emitted by physical and chemical processes, so some similarities exist between the study of optics and acoustics.

The analytical aspects of sound can be divided in to two main areas – active acoustics and passive acoustics (acoustic emission). In active acoustics, an acoustic wave is launched into the sample (material) of interest and the physical properties of the sample affect the velocity and attenuation of this acoustic wave. The velocity is a function of the density and compressibility of the material, while the attenuation also depends on additional viscoelastic and thermal properties.

Acoustic emission monitoring refers to the technique of detecting and analysing sound produced by a process or system. Often these sounds are well above the frequencies that can be detected by the human ear (frequencies up to ~15 kHz are audible). Processes that give rise to acoustic emission include boiling, gas evolution, mixing, grinding and fluidisation. Acoustic emissions produced by chemical reactions can reach frequencies of 1 MHz or greater (Wentzell, Wade 1989) and such emissions are usually monitored using piezoelectric transducers (Figure 44.3) responding in the region between 50 and 450 kHz. At these frequencies, attenuation is high and sound propagates only relatively short distances. This has the advantage that processes can be monitored with little interference from extraneous noise.

Acoustic emission

Acoustic emission is well known in the study of fracture mechanics and is used extensively by materials scientists. A large amount of research has been conducted on the use of acoustic emission for the routine inspection of aircraft wings, pressure vessels, load-bearing structures and components. Acoustic emission is also used in the engineering industry for the monitoring of machine tool wear.

Several workers (Betteridge *et al.* 1981; Belchamber *et al.* 1986; Wentzell, Wade 1989) have reported the use of acoustic emission in the study of chemical reactions. This includes the acoustic emission produced by effervescent reactions and that generated by crystalline phase changes. In the area of pharmaceuticals, it has been shown that acoustic emission is capable of monitoring the blending of powder materials (Tily *et al.* 1987; Holroyd 1989), that it is useful for the monitoring and end-point determination of a high-shear granulation process (Whitaker *et al.* 2000) and that it can be used to monitor chemical systems that may be difficult to observe by other means (Betteridge *et al.* 1981).

In most process applications of acoustic emission, there are many sources of sound, each producing short bursts of energy. This means that the detected signal, for instance on the wall of a vessel, is a complex mixture of many overlapping waveforms resulting from many sources and many propagation modes.

At interfaces, depending on the relative acoustic impedance of the two materials, much of the energy is reflected back towards the source. In a fluidised bed, for instance, acoustic emissions will be detected only from particles directly impacting on the walls of the bed close to the transducer.

The simplest way of studying the acoustic data is to examine changes in the 'average signal level' (ASL), an example of which is presented in Figure 44.4.

However, other information can be derived from examining the power spectrum of the ASL and this is calculated by performing a fast Fourier transform (FFT) on the digitised raw data record. Power spectra may be averaged to produce a reliable estimate of power spectral density or to give a 'fingerprint' of a particular process regime. This type of averaging is not possible on the raw acoustic signals or ASL records as they are essentially random and average to zero. Interpretation of the power spectrum is complicated by the fact that the acoustic signal originating in the system is distorted by several factors, including transmission, reflection and signal transfer characteristics.

The shape of the power spectrum (Figure 44.5) of the ASL record is a function of the process dynamics. Periodic processes show high power at certain discrete frequencies (e.g. mechanical stirring, periodic bubbling of a fluidised bed). Random processes show either flicker-type properties, where power is inversely proportional to frequency, or white noise-type properties in which power is independent of frequency (van der Ziel 1976). The amplitude of the power spectrum is also affected by the energy of the acoustic emissions produced by the process. For instance, if hard material is being processed, the acoustic emission produced by particle impact will be greater than that produced by soft material.

Most recently, acoustic emission techniques have been applied to the on-line determination of the particle size, flow properties and compression properties of material produced during a high-shear granulation process (Whitaker *et al.* 2000). This application is based on the fact that particle size and granule density changes achieved during granulation affect the acoustic emission signals and, as these physical properties have a direct effect on powder flow and compression properties, the value in monitoring and controlling these parameters becomes apparent. As a non-invasive, sensitive and relatively inexpensive technique, acoustic emission lends itself well to both development applications and more routine usage. Key physical properties can be monitored in real time, providing indications of process end points and/or 'process signatures' (that is, the batch-specific information that characterises the actual

operating conditions and performance of a pharmaceutical process), which can help to guarantee the quality of intermediate pharmaceutical materials, such as granulation output. In turn, re-creation of the process signatures associated with successful process performance can provide a non-subjective basis for process optimisation, process scale-up and technology transfer.

Active acoustics

Active ultrasound spectroscopy, based on its capability of establishing material characteristics that are not easily assessed using existing measurement approaches, may be considered as a powerful addition to the current range of analytical monitoring and control techniques. It is particularly useful when applied to fluid, rather than solid, systems.

Active ultrasound spectroscopy differs from passive acoustic emission in that an ultrasound signal is applied to the material under test. Ultrasound, transmitted by a transducer responding to electrical input, travels over a defined pathlength through the test material (as depicted schematically in Figure 44.6) to a receiving transducer, at which an electrical response is generated and digitised for processing into information about the test material. Generally, measurements of attenuation (loss in amplitude of the primary, longitudinal mode of ultrasound propagation in fluids, shown as the ratio of I to I_0 in Figure 44.6) and velocity (shown as V in Figure 44.6) are made and these can provide useful insight into viscoelastic properties, for example, of the test material. The practical implementation of this approach is shown in

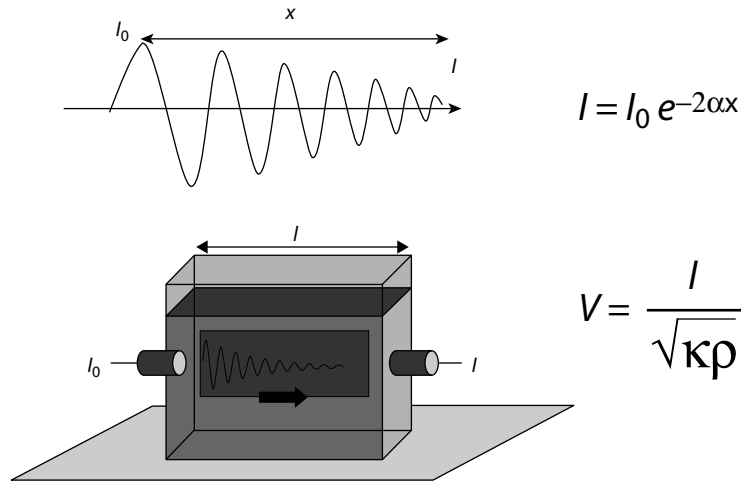

Figure 44.6 Schematic describing attenuation and velocity measurements in active ultrasound spectroscopy. α, absorbance coefficient; κ, compressibility; ρ, density. (Courtesy of Process Analysis & Automation; www.paa.co.uk.)

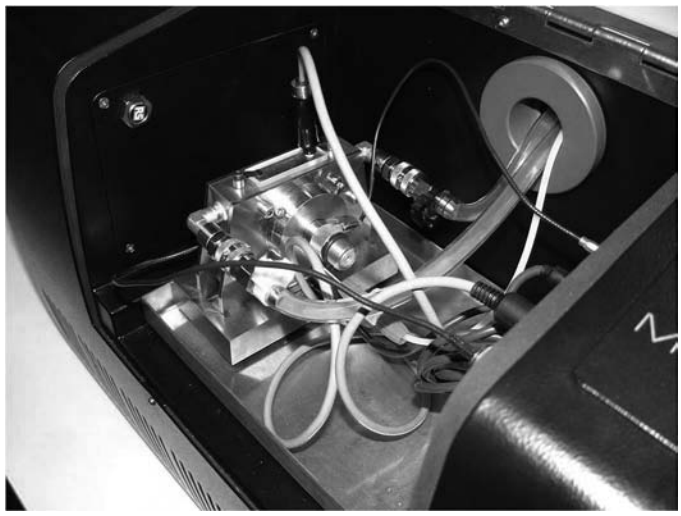

Figure 44.7 Sample cell from the ICHOS active ultrasound spectrometer. (Courtesy of Process Analysis & Automation; www.paa.co.uk.)

Figure 44.7, which depicts the active ultrasound sample cell from the commercially available ICHOS system (see www.paa.co.uk 2010).

It may be seen that active ultrasound spectroscopy offers the user flexibility of approach because, given an instrument of appropriate capability, there is the opportunity to define frequencies and other characteristics of the ultrasound waves used to probe the test material.

High-frequency ultrasound enables non-invasive analysis, with negligible transfer of energy to the sample. This can be important if, for example, fragile test materials are being investigated, e.g. during protein conformation studies or investigations into chemical and biochemical equilibria. An example of this is provided in Figure 44.8, which shows how changes in acid–base equilibria during a titration manifest themselves in the ultrasound domain. Information of this type may be used to determine reaction rate constants, equilibrium shifts and pK values, for example.

The active ultrasound process is also non-invasive in the sense that optically opaque samples, and those enclosed by vessels or pipework, can be tested *in situ*. The ultrasound source may be used in continuous signal mode or with a series of discrete, regular tone bursts. This latter approach allows precise scanning across a range of ultrasound frequencies, and can deliver more instantaneous sonic power into the medium as the system has time to recover between bursts.

Spectroscopic techniques

Terahertz spectroscopy

Terahertz radiation corresponds to the far infrared region of the electromagnetic spectrum (3–333 cm^{-1} or 100 GHz–10 THz), or parts thereof, residing between microwave and mid-infrared radiation. Rather than representing information originating from intramolecular vibrations in the mid-infrared region of the spectrum, terahertz radiation induces intermolecular non-covalent bond vibrations and translations in solids. As terahertz radiation directly probes interactions between molecules, it is intrinsically sensitive to changes in crystalline structure.

A photoconductive semiconductor antenna that generates broadband pulses of terahertz radiation by injecting charge carriers into the substrate using a femtosecond laser is used as the radiation source. After transmission through the sample material, the radiation is detected as a time-domain waveform.

After performing a Fourier transformation of both sample and reference waveforms into the frequency domain, the terahertz absorbance spectrum is calculated. For the structural image generation in terahertz pulsed imaging (TPI), the measured time delay originating from reflections at interfaces within the sample in the time-domain waveform is used to resolve the depth dimension. Spatial information (in horizontal and vertical dimensions) is obtained by point mapping of the sample. These TPI waveform data for each pixel can also be Fourier transformed to yield a fourth dimension that contains spectral information relating to the sample. Using this approach, the interrogated sample can be described in terms of structural information and chemical composition.

Applications to date fall into two main areas (Strachan *et al.* 2006): polymorph detection and quantification (usually carried out using terahertz pulsed spectroscopy) and tablet imaging (using TPI as described above). Demonstration of stability of polymorphic form in drug substances and pharmaceutical formulations is important from a quality perspective in terms of product efficacy and patient safety, and terahertz spectroscopy may have an important part to play in this respect. Similarly, the tablet imaging applications allow improved

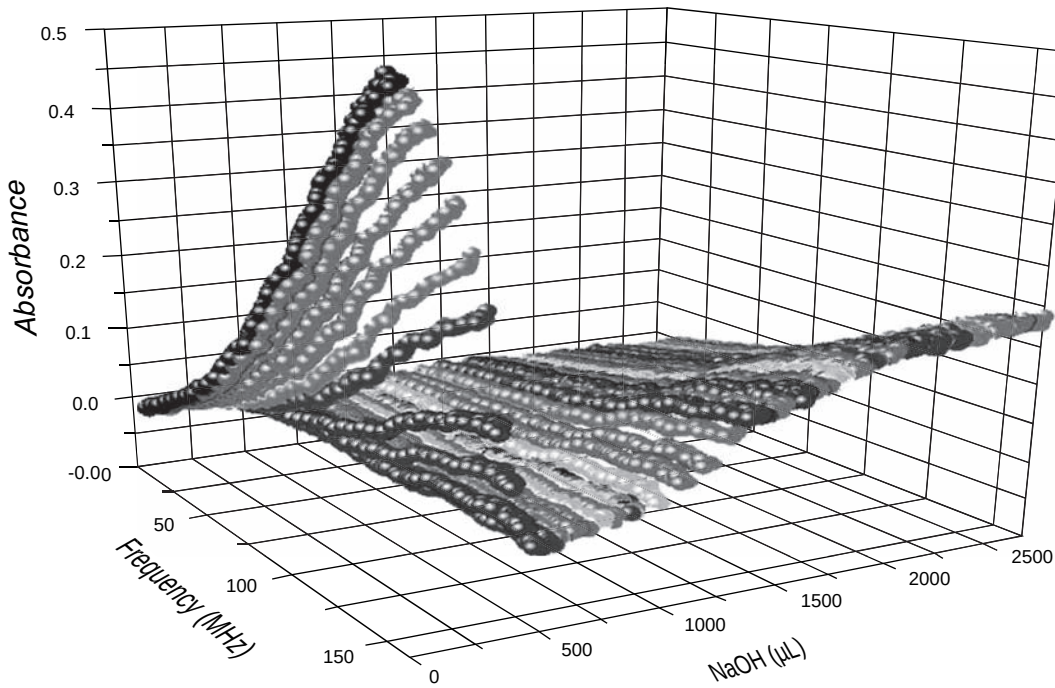

Figure 44.8 Acid–base titration monitored using active ultrasound spectroscopy. (Courtesy of Process Analysis & Automation; www.paa.co.uk.)

understanding and control of film-coating processes and/or some insight into the mechanical and physical characteristics of solid dose forms, which, in turn, may dictate the way in which the contained drug substance is released during treatment of the patient.

Despite the apparent attractions of terahertz spectroscopy, there is a feeling that the technique may not offer significantly unique advantages over other forms of infrared spectroscopy. While there are examples of undoubtedly successful applications of terahertz spectroscopy, it seems generally true that these may be equally well achieved using infrared or near-infrared spectroscopy, meaning that the technique is still looking for its unique place in the analytical toolkit. Couple this with the relative lack of maturity of the technique in terms of pharmaceutical applications, high cost of equipment and questions about instrument robustness (compared with near-infrared systems, for example) and it becomes clear that terahertz spectroscopy still has to win over a number of sceptics. Nevertheless, developments in instrument capability continue, meaning that the potential of the technique remains high.

Light-induced fluorescence

Light-induced fluorescence (LIF) is a well-established technique that can provide a number of advantages, especially in terms of selectivity and sensitivity, compared with other forms of spectroscopy (Lai *et al.* 2004). Specific excitation and emission wavelengths are associated with those individual molecules that exhibit fluorescence properties and, while these wavelength regions are often quite broad, the combination for a particular molecule may result in greatly improved selectivity. Moreover, the fluorescence process can result in very large gains in sensitivity compared with absorption spectroscopy, making the fluorescence technique highly advantageous in suitable applications. Some of these advantages can be offset, however, if scattered radiation (i.e. radiation from the excitation source) is not distinguished from the emitted fluorescence signal during detection. Failure to do this will result in significant loss of accuracy owing to non-specific signals being included in any analyte measurements.

Recent developments have seen the emergence of LED (light-emitting diode) array sensors as high-intensity, robust and versatile light sources for LIF applications. These small, self-contained, solid-state devices lend themselves well to process-based applications, especially manufacturing operations such as powder blending where interfacing of sensor-based LIF systems into a variety of large-scale blenders has been achieved successfully (Dickens 2010). The selectivity of the LIF sensor allows the monitoring system to be customised by the user to monitor the analyte of choice on the basis of its fluorescent spectral properties (using the excitation and emission wavelengths). This makes the technique ideal for monitoring relatively minor components (e.g. drug substances) in complex powder matrices (such as pharmaceutical formulations).

Extending this idea, an array of several sensors, each tailored to a specific analyte, allows multicomponent systems to be monitored simultaneously, provided that each of the analytes exhibits suitable fluorescence spectral properties. Portable devices are also available (see www.customsensors.com 2010), making the LIF technique potentially suitable for raw material identification and analysis as well as cleaning verification applications.

Transmittance Raman spectroscopy and deep Raman spectroscopy

Compared with other optical techniques, Raman spectra are relatively rich in features and can offer high chemical specificity. Physical changes, such as modifications to crystal structure or polymorphic form, are also detectable and, unlike infrared and terahertz spectroscopy, the technique is able to deal with systems containing high amounts of water.

Unlike conventional Raman spectroscopy (in which the signal is collected after back-scattering from the sample illumination area), the transmission Raman spectroscopy signal is collected from the opposite side of the sample (i.e. after transmission through the sample). This allows bulk assessment of the sample to be carried out, rather than the surface or subsurface interrogation that conventional Raman spectroscopy provides. Transmission Raman spectroscopy provides an additional benefit in that fluorescence interference and Raman signals from surface or near-surface layers are suppressed, meaning that analysis of drug content in fluorescing capsules, for example, becomes relatively easy compared with conventional Raman spectroscopy. Transmission Raman spectroscopy provides an additional benefit in that fluorescence interference and Raman signals from surface or near-surface layers are suppressed, meaning that analysis of drug content in fluorescing capsules, for example, becomes relatively easy compared with conventional Raman spectroscopy (see www.cobaltlight.com/sites/cobaltlight.com/files/CTN003%20-%20Transmission%20Raman%20Spectroscopy.pdf).

Current technical developments are exemplified by the TRS100 system produced by Cobalt Light Systems (see www.cobaltlight.com 2010). This instrument capitalises on the light-scattering properties of common pharmaceutical materials and offers a number of important application areas ranging from the characterisation of crystalline and amorphous forms of drug substance (including some quantitative aspects) through to complete and rapid non-destructive assay of intact solid dose products such as capsules and tablets, with no sample preparation required. Claims of high accuracy, good repeatability and rapid throughput of samples (typically 100 dose units in 5 minutes) for capsule and tablet assay applications make the system highly attractive for process control as well as offering a strong statistically based foundation for batch sanctioning.

A variation on conventional Raman spectroscopy that lends itself to some pharmaceutical applications is the spatially offset Raman spectroscopy (SORS) technique. This is based on the collection of the back-scattered Raman signal at spatial offsets from the incident radiation. Broadly, a laser excites the sample and the signal is collected at both the excitation point and an offset distance. The surface signal is then subtracted to reveal the spectrum of the contents. Greater spatial offsets result in Raman signals that are more representative of deeper sub-layers within the sample structure, making it possible to interrogate the contents of a diffusely scattering container, for example. Applications to date include the non-invasive detection of counterfeit drugs in plastic bottles and identification of tablets within an unopened blister pack. Greater spatial offsets result in Raman signals that are more representative of deeper sub-layers within the sample structure, making it possible to interrogate the contents of a diffusely scattering container, for example. Applications to date include the non-invasive detection of counterfeit drugs in plastic bottles and identification of tablets within an unopened blister pack (see www.cobaltlight.com/sites/cobaltlight.com/files/CAN002%20%20Counterfeit%20Drugs%20Detection%20Using%20SORS.pdf).

Process NMR spectroscopy

Chemical reaction monitoring using process-based NMR spectroscopy is commonplace and these applications are well reviewed elsewhere (Wawer *et al.* 2008; Edwards, Giammatteo 2010). More interestingly, the technique seems to have potential as part of a 'Quality by Design' strategy for the optimisation and control of drug substance manufacturing processes, where establishment of process parameter ranges can provide flexibility within the registered manufacturing process without compromising product quality. This approach, whereby small but controlled variations in the manufacturing process may be shown to produce material of acceptable quality – especially when supported by real-time analytical data that confirm the acceptability of these changes – represents the way in which process control and on-going verification need to be performed in the future.

While this philosophy is true for all real-time measurement techniques, process NMR is felt to occupy a key position for chemical reaction monitoring and control in view of the information that it can provide for important chemical and physical quality attributes.

Imaging techniques

Vibrational imaging

The term 'vibrational imaging' is generally applied to the use of near-infrared, mid-infrared and/or Raman spectroscopy to establish the presence and distribution of chemical species within a sample. Effectively, chemical imaging of this nature provides the user with an additional level

of information by combining material identification with spatial visualisation of its distribution. As such, there are a number of pharmaceutical applications ranging over blend homogeneity monitoring (El Hagrasy *et al.* 2001), tablet content uniformity determination (Gendrin *et al.* 2007), detection of polymorphism (Clark *et al.* 2007) and product authentication (Dubois *et al.* 2007). Different forms of spectroscopy are used depending on the nature of the chemical species that need to be mapped and there is generally a balance to be considered in terms of the level of scrutiny applied to any given sample. For example, highly detailed information may be obtained using microspectroscopy (i.e. the use of near-infrared, mid-infrared or Raman microscopes) and this can be useful for establishing chemical distributions within a tablet, although data acquisition times can be lengthy. In contrast, a manufacturing-scale powder blend monitoring application relies more on spatial mapping at the product target dose level (perhaps several tens of milligrams), so microscopy would be inappropriate. In terms of resolution, less detailed information is obtained in these circumstances, but data acquisition times are considerably shorter, allowing real-time process control as appropriate.

Different mapping strategies may be employed depending on the nature of the application and these can help to establish the distribution of minor components in a complex matrix or when dealing with rough-surfaced samples.

Current developments in vibrational chemical imaging technologies reflect the improvements in camera speed and capability, with wavelength ranges covering the visible to short-wave infrared (700–2500 nm) and acquisition rates of several hundred frames per second being used. Couple this with spatial resolutions of 1 mm or better and you have a powerful technology, not only for the types of application mentioned above (tablet content uniformity, powder blend monitoring, etc.), but also for more challenging examples such as film-coating quality assessment and quantification and the monitoring of outputs from processes such as continuous granulation and roller compaction.

Thermal imaging

Thermal imaging is a visualisation technique based on the principle that infrared radiation is emitted by all objects, with more radiation being emitted as the temperature of the object increases. When a system is viewed using a thermographic camera, differences in the thermal properties of materials associated with that system may allow visual distinction, in much the same way that objects appear differently coloured in the optical domain.

The principle of operation of thermal imaging devices is comparable to the way in which optical cameras work, with the obvious difference that the detection system within thermal cameras responds to the infrared region of the electromagnetic spectrum rather than the visible. High-resolution thermal cameras are widely available, with the capabilities and overall performance constantly being improved.

As with other imaging techniques, application to pharmaceutical manufacturing processes can be achieved by monitoring bulk systems in order to establish the degree of homogeneity (for example, during a powder blending operation) or to confirm that a reaction end point has been reached. Such monitoring techniques allow hot spots in vessels or regions of poor flow and inadequate mixing to be rapidly identified, allowing corrective action to be taken in real time.

At present, the overall resolution of commercially available thermal cameras is insufficient to provide the detailed image maps required for the monitoring and control of bulk pharmaceutical processes. The problem of how to achieve a detailed level of scrutiny across a large-scale manufacturing process, and with rapid data processing, is common to most imaging techniques, but it is likely that developments with thermal cameras will allow this issue to be addressed in the near future.

Process tomography

Tomography is the general name given to the imaging by sections of three-dimensional systems using sensors arranged around the periphery. Process tomography, where sectional images of systems such as pipes and vessels are obtained, is generally based on the electrical properties of the materials involved, although ultrasound is often used (particularly in the medical diagnostic field). In principle, any useful property may be exploited to obtain suitable images, but positron emission, electrical resistance, electrical impedance, electrical capacitance and magnetic induction are the most widely used at present. Figure 44.9 shows the type of information that can be obtained – in this case an electrical resistance image of a human hand, in which the wrist and five fingers can be seen clearly. This provides an idea of the level of resolution achievable and its suitability when applied to large, manufacturing-scale processes and chemical reactors.

To illustrate the basic principles and utility of tomographic techniques, electrical capacitance tomography (ECT) is chosen as an example for further description in this chapter. However, the general points discussed are applicable to other forms of process tomography.

A basic ECT system will consist of a capacitance sensor (an example of which is shown in Figure 44.10), a capacitance measuring unit and a computerised control system.

ECT is most successful when applied to materials such as oils, plastics, dry powders and, under favourable circumstances, aqueous systems

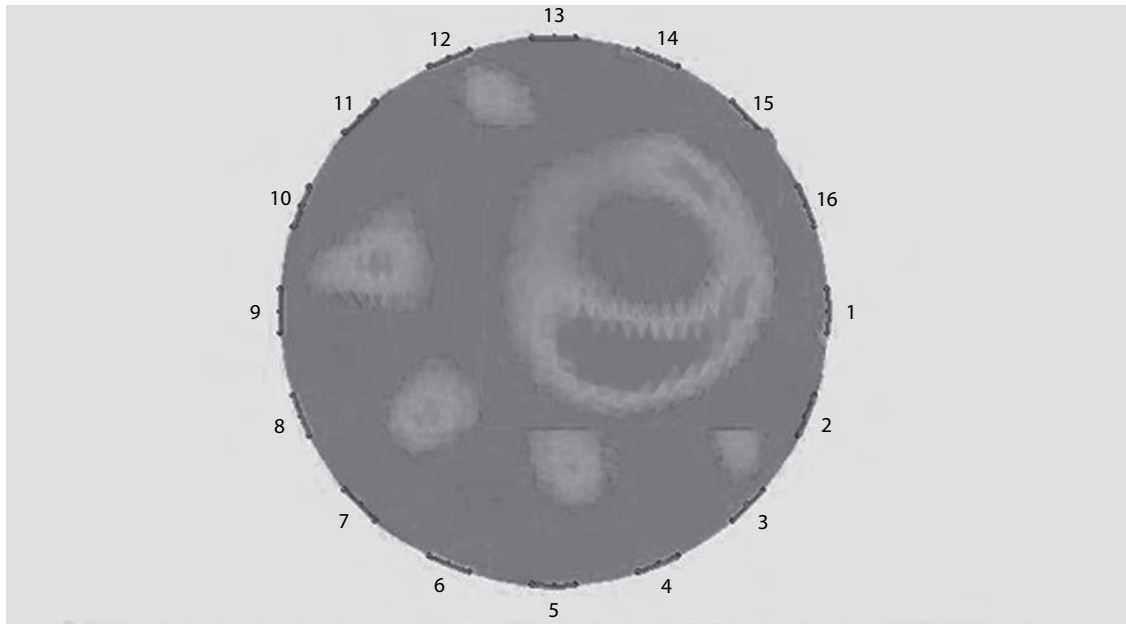

Figure 44.9 Electrical resistance tomography image of a wrist and five fingers. (Courtesy of Industrial Tomography Systems plc; www.itoms.com.)

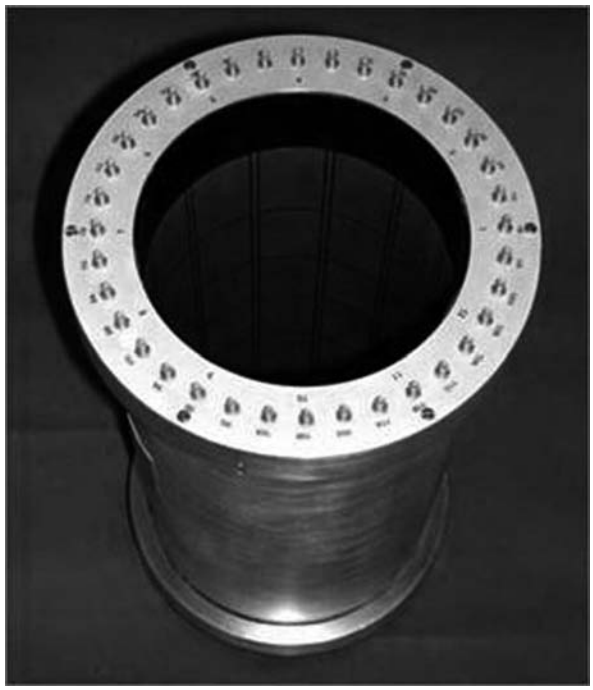

Figure 44.10 Electrical capacitance tomography sensor system. (Courtesy of Process Tomography Ltd; www.tomography.com.)

(all of which have low electrical conductivity). ECT allows information about the distribution of the contents of closed pipes or vessels to be obtained by measuring variations in the dielectric properties of the material inside the vessel. Typical information obtainable includes cross-sectional images of the vessel contents.

The cross-section to be imaged is surrounded by one or more circumferential sets of capacitance electrodes and the electrical capacitances between all combinations of the electrodes within each set are measured. This information is then used to construct an image of the contents of the cross-section of the vessel enclosed by the sensor, based on variations in the permittivity of the material inside the vessel. An example of the kind of image obtained is shown in Figure 44.11, which depicts a plastic tube inside a pipe.

In practice, the capacitance electrodes can be mounted either inside or outside the vessel. If the vessel wall is an electrical insulator such as plastic, then the electrodes are normally mounted on the outside surface of the pipe or vessel. In this case, the measurement is non-invasive and can be made intrinsically safe. The sensor is surrounded by an earthed shield that minimises the influence of external fields or objects.

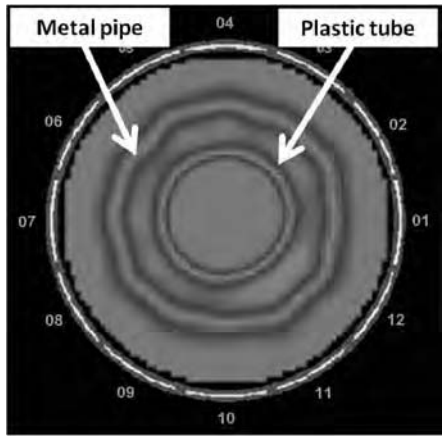

Figure 44.11 Process tomography image of a plastic tube inside a pipe. (Courtesy of Process Tomography Ltd; www.tomography.com.)

The number and size of the capacitance electrodes used depends on the application. A larger number of electrodes will give a higher-resolution image, but the measurement sensitivity will be low, although this can be increased by using longer electrodes, although at the expense of axial resolution. If high axial resolution is required, a small number of short electrodes can be used, together with separately excited axial guard electrodes, and these prevent the electric field from spreading excessively at each end of the sensor electrodes.

ECT images are normally of relatively low resolution (at present a 32×32 pixel grid is typical), but they can be captured at high speed. With existing technology, image data can be captured at 100 frames per second for a 12-electrode sensor and displayed on-line. Higher image capture rates (up to 300 frames per second) can be achieved for sensors with fewer electrodes.

The spatial resolution achievable depends on the size and radial position of the target object, together with its permittivity difference relative to that of the other material in the pipe. Typically, target objects (or local changes in permittivity) with a diameter of around 5% of that of the pipe or vessel can be detected provided that there is sufficient contrast between the permittivity of the target and the surrounding media. The accuracy of the ECT image depends on the method used for its reconstruction from the interelectrode capacitance measurements. At present, the only image-construction algorithm that is fast enough to be used for on-line image display is the linear back-projection method. This produces approximate images that are of acceptable quality for many applications. Other methods can be used to produce improved images off-line from captured capacitance measurements and these can often involve the use of iterative computational methods or the application of neural network techniques.

Pharmaceutical applications of process tomography to date include chemical reaction monitoring (Ricard *et al.* 2005), imaging of powders in a fluidised bed, allowing confirmation of satisfactory and uniform operation during the drying process (Yang 2010) and non-invasive check-weighing of bulk materials during pharmaceutical manufacture (see www.tomography.com 2010).

Light scattering

Developments in light-scattering techniques for pharmaceutical analysis seem relatively limited at present. The use of dynamic light scattering (DLS) to monitor protein aggregation is well established (see www.horiba.com 2010), and multi-angle light scattering (MLS) detector systems feature routinely where measurements of absolute molecular sizes are required (Johann 2005). However, significant advances in light-scattering instrumentation and application areas are considered unlikely at present, although any technology that provides insight into particle size aspects and conformation of large molecules and their potential for aggregation will always be considered useful.

Turbidity for metered-dose inhaler suspension monitoring

Many pharmaceutical products incorporate drug particles in suspension, using both aqueous-based and non-aqueous suspension matrices. Such products include MDIs, aqueous nasal sprays and some oral dose forms (e.g. syrups or reconstituted powders). For products of this type, drug concentration monitoring and particle sizing can be hindered by the presence of the suspension matrix, and elaborate sample manipulation is often required in order to eliminate measurement interference.

Direct measurement of drug content in suspension matrices depends heavily on the use of analytical measurement technologies that are not responsive to the components of the suspension. In this respect, it would be natural to assume that a high degree of discrimination or selectivity is required, and this is undoubtedly true in terms of achieving a distinction between the drug substance being analysed and the matrix in which it is suspended. However, beyond this distinction and, somewhat curiously, a high level of selectivity between different analyte molecules is much less important for pharmaceutical systems where a single drug substance is suspended, even in a complex matrix. In such cases, as long as the measurement technique provides sufficient discrimination for the drug substance under investigation, relatively poor selectivity can be tolerated, as no other drug molecules are present in the system. For this

reason, light-scattering techniques based on suspension turbidity have found favour recently when applied to MDI concentration monitoring (Marsh *et al.* 2010).

Most MDI products consist of one or, sometimes, two drugs suspended in non-aqueous media (usually volatile propellant systems). The relative simplicity of such formulations (where a single drug substance is present in a single-component suspension medium) means that properties such as suspension turbidity (the extent of which is directly attributable to the amount of drug present in the formulation matrix) can be monitored to establish overall drug concentration in bulk systems. Back-scattered light from simple near-infrared sources is generally used for systems that have relatively high levels of turbidity, whereas forward scattering is more frequently used for applications where the degree of turbidity is less. Good linearity of response may be obtained over a relatively large concentration range, making the technique ideal for real-time monitoring during filling operations, for example. In addition, flexible laboratory-based equipment and robust process-based versions are available commercially (see http://us.mt.com 2010), allowing development of suitable methodology and transfer to systems that are fully integrated into manufacturing production lines. Application to multicomponent MDIs (i.e. products that contain two different drugs) is also possible using dual-source turbidity systems with the irradiation wavelength of each source chosen specifically to match the spectral absorption characteristics of the two drugs.

Turbidity measurements also allow for some particle size trending in view of the fact that the degree and nature of the light scattering have some dependency on particle size.

Thermal effusivity

Thermal effusivity is a material property that combines the thermal conductivity, density and heat capacity of the material. The measurement of thermal effusivity values of materials is based on the principle that the material will exchange heat energy with its surroundings in a manner characterised by the relevant material properties. As a result, the technique can be used to differentiate between various components of a system on the basis of their heat transfer properties and this means that the composition of pharmaceutical formulations (for example) could be monitored during a blending and/or granulation process. Determination of the extent of mixing or blending using thermal effusivity is based on the uniformity of measurement across the bulk material. As with many other techniques, well-mixed materials will show a relatively low degree of variability when replicate measurements are made, whereas poor mixing will reveal itself in the form of high variation from sample to sample.

The thermal effusivity value of a pure material is characteristic of that material and, since measurements are essentially based on an averaging principle, it becomes possible to calculate the theoretical thermal effusivity values of multicomponent systems such as pharmaceutical formulations. Thus, mixing and blending processes may be monitored not only in terms of variability across the bulk material, but also by assessing how the average thermal effusivity value compares with the calculated end point. In principle, this provides a highly advantageous method for monitoring dynamic systems, allowing process control to be achieved on the basis of meeting defined requirements of homogeneity and/or overall composition.

Instrumentation is relatively simple (see www.ctherm.com 2010) and involves the application of a small amount of heat to the system under investigation, followed by measurement of the amount of heat reflected back to the sensor. A number of sensors may be used simultaneously (up to eight, typically), in order to allow assessment of the distribution or homogeneity of materials across bulk containers or vessels. This lends itself to process-based applications where monitoring equipment may be fixed directly onto powder blenders, for example Figure 44.12.

A number of practical issues seem inherent in this technique, however, and this has led to a general curtailing of the initial enthusiasm that prevailed in the pharmaceutical industry at one stage. First, the reliability of current instrumentation is questionable. Sensors need to be calibrated using reference materials (substances such as high-density polyethylene may be used) and differences in individual sensor performance (sensitivity, reproducibility, etc.) may adversely affect the conclusions when systems are monitored using multiple sensors. Second, the reliability of an individual thermal effusivity measurement depends on reproducible and adequate contact between the sensor and the bulk material. Variations in the degree of contact will result in variable and inaccurate data. This is regarded as a significant problem

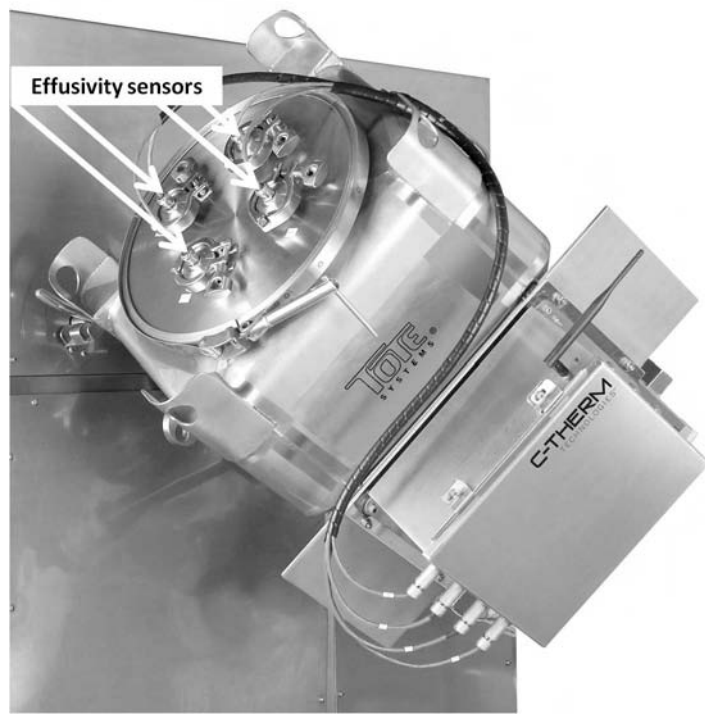

Figure 44.12 Thermal effusivity equipment for powder blend homogeneity monitoring. (Courtesy of C-Therm Technologies; www.ctherm.com.)

during mixing and blending applications, for example, where the extent of sensor contact is based entirely on the natural pressure that the bulk material exerts on the sensor when the blender is inverted. To allow a potentially critical variable to have such an uncontrolled influence on the reliability of the measurement would seem to require some considerable attention.

Finally, and perhaps most significantly of all, it is noted that the thermal effusivity values of common pharmaceutical materials are relatively similar to one another. Typically a range of 200–500 $W\,s^{1/2}/m^2\,K$ encompasses most common excipients, and it is likely that many drug substances exhibit similar thermal characteristics. Contrast this with the nominal values for water (about 1600 $W\,s^{1/2}/m^2\,K$) and air (about 5 $W\,s^{1/2}/m^2\,K$) and it becomes apparent that the presence of even relatively small amounts of these materials can be highly influential in terms of the overall average thermal effusivity value of a multicomponent system. As a result, questions may be raised about the effective 'selectivity' of the technique and its ability to distinguish between the apparent mixing of multicomponent systems as opposed to simple consolidation of particles (with attendant loss of interstitial air) or general drying, leading to an apparent increase in homogeneity according to the thermal effusivity data.

Until such fundamental questions are resolved, and despite the attractiveness of the general principle upon which the technique is based, thermal effusivity is likely to remain in the unproven category, with applications limited by the apparent lack of selectivity. It may find application, of course, where monitoring of water and/or air removal from pharmaceutical systems is important and this may explain the partial successes in monitoring of drying processes, lubrication of granules and particle consolidation during granulation and tablet compression. However, if such success is based simply on water and/or air removal, then it must be recognised that the capability of the technique is limited at best, and that it provides a relatively crude way of monitoring pharmaceutical processes almost independently of the nature and composition of the bulk materials.

Data collection and interpretation

As analytical technologies continue to evolve, it becomes progressively more important to ensure that advances are made in data collection and interpretation techniques. Currently, there are some interesting developments in two key areas associated with data generation and assessment:

- Synchronisation and integration of product and process data
- Data mining and data trending.

This section reviews some recent progress in these areas and attempts to indicate some possible future developments.

Synchronisation and integration of product and process data

The emergence of 'Quality by Design' principles in pharmaceutical development and manufacture has emphasised the importance of process understanding – that is, understanding the relationship between the critical quality attributes of the product and the process parameters (and input raw material attributes) of the manufacturing process. Development of process understanding is dependent, therefore, on collection of data associated with both the product and the manufacturing process. In this way, correlations and cause-and-effect relationships may be established, enabling suitable process control strategies to be developed and implemented to ensure good and consistent quality of product.

Generally, data collection systems associated with analytical instrumentation (laboratory-based information management systems or stand-alone measurement equipment) have been viewed separately from those that record the electromechanical measurements made on the manufacturing process (temperatures, flow rates, mixing times, etc.). The principle of 'Quality by Design' and the importance of developing process understanding highlight the need to synchronise and integrate these diverse measurements, thus allowing correlations between product and process data to be made with increased confidence.

Extensive industry/vendor collaboration in recent years has seen the development of a number of commercial products that address this need (as well as other requirements associated with the quality assurance of pharmaceutical products) and that may be exemplified by the SIPAT software produced by Siemens (see www.siemens.com 2010) or synTQ from Optimal (see www.optimal-ltd.co.uk 2010).

Software of this nature can provide the user with a common interface for all of the analytical systems (product and process analysers), process control systems, data analysis and reporting tools, etc. In this way, a fully integrated approach towards quality assurance and (potentially) real-time release of pharmaceutical products becomes possible, and this is particularly important as continuous processing begins to feature more prominently in pharmaceutical manufacture.

Data mining and data trending

Data mining involves the extraction of information from data-sets and usually results in features and relationships being identified within those data-sets. Groups, clusters, associations and patterns may be established, and significant features or characteristics identified, thus allowing predictions or subsequent additions, interpolations and extrapolations to be made.

Traditional approaches involving projection techniques such as PCA (principal components analysis) and PLSR (partial least squares regression or projection to latent structures regression, depending on your point of view) are now well established in the pharmaceutical industry, but recent developments include the application of genetic algorithms for variable selection in pharmaceutical development (Tabora *et al.* 2010) and locally weighted PLSR for powder blend uniformity monitoring (Kim *et al.* 2010). Generally, approaches of this type provide improved model accuracy and/or predictive capability and offer an indication of the application areas in which multivariate data interpretation techniques appear to be most useful.

Elsewhere, some of the machine learning approaches (e.g. artificial neural networks and support vector machines) are now being utilised extensively for establishing structure–activity relationships, but do not yet seem to be finding application to pharmaceutical model development and historical product and process characterisation. Several vendors, for example StatSoft (see www.statsoft.com 2010), offer products with this type of capability, and an increase in usage designed to establish trends and relationships in historical data-sets, stability studies and continuous process manufacturing data is considered likely.

Field-based measurement techniques

Near-infrared systems

Portable analytical systems are playing an increasingly important role in a number of different application areas. Raw material identification and analysis at the point of receipt is an important and long-established application and hand-held near-infrared (NIR) devices continue to evolve to support this type of usage.

Optoelectronic developments have allowed vendors to produce rugged, portable 'point and shoot' devices that now offer performance comparable to that of laboratory-based FT-NIR systems, and this is providing the user with high-resolution NIR capability and rapid spectral acquisition even under harsh field-based conditions. Examples include the microPHAZIR Rx system from Thermo Scientific (see www.ahurascientific.com 2010) and Axsun's Anavo device (see www.axsun.com 2010), both of which are similar in capability, but which differ in terms of the light source used. The advantage of Axsun's tunable diode laser over the tungsten light bulb favoured by Polychromix lies in the simplicity of design and elimination of power and cooling requirements, but perhaps at the expense of light throughput and battery and source life. Either way, the use of hand-held NIR devices for raw material identification and analysis, as well as some process monitoring applications, is now quite commonplace.

Other portable NIR systems include the briefcase-sized RxSpec 700Z from ASD (see www.asdi.com 2010), which is marketed as an anti-counterfeiting drug analyser and allows field agents to test drug samples on the spot to investigate authenticity.

Raman systems

Although NIR finds wide applicability in field-based raw material identification and analysis, Raman spectroscopy can offer some significant advantages in certain circumstances. The high specificity of the technique can provide increased confidence when attempting to identify or discriminate between chemically similar materials, but it is the ability to obtain high-quality spectra directly through a range of packaging materials that distinguishes Raman systems from alternative approaches (Perkin-Elmer 2010), although the quantitative aspects may be less impressive.

Ion-mobility spectrometry

Ion-mobility spectrometry (IMS) instruments are easy to use, as demonstrated by their widespread employment in military and aviation security applications.

For IMS, volatile samples are introduced by sampling the headspace of open containers or vapour streams from processing lines. Less volatile particulates are collected by wiping surfaces with an inert material followed by their thermal desorption directly into the instrument and, because sampling is accomplished without the use of solvents, manual processing or derivatisation, non-scientists can perform the measurements. This ease of use and portability of equipment, coupled with the sensitivity of detection and broad selectivity, has resulted in IMS becoming the current technique of choice for field-based security applications (Ewing *et al.* 2001).

Similarly, the technique lends itself to environmental and personal monitoring, especially in terms of exposure to drug substances or hazardous materials during pharmaceutical manufacture (Eiceman *et al.* 1995). A number of commercial units are currently available, allowing individual personal monitoring, as well as static field-based systems that provide more of an overview of general, rather than localised, exposure.

Field-based systems for fault detection and trace analysis of solvents and chemicals are also available, in particular using IMS to provide the sensitivity and quantitative elements that such applications require. Progress in this area involves the use of programmable systems that can be 'trained' to create a chemical fingerprint characteristic of the process or system under investigation, and that can then be used to detect anomalous events or out-of-range situations.

Such systems (see www.owlstonenanotech.com 2010) can provide point-of-use capability for reaction monitoring, as well as solvent estimation in drug substances and measurement of contaminants at trace levels and in real time.

Rapid microbiological techniques

Clinical and food industry microbiological laboratories have used rapid microbiological methods for many years because of the need for quick diagnosis of infectious diseases and the assessment of quality of perishable goods. In contrast, the pharmaceutical industry has seemed reluctant to adopt rapid microbiological methods, largely owing to the potential lack of acceptance by regulatory agencies, but these concerns have been alleviated in recent years as the 'Quality by Design' initiatives gather pace. As a result, many rapid microbiological methods have now become firmly established within the pharmaceutical sector, particularly for screening and other specialised applications, but the traditional culture-plate methods are generally still preferred for routine use. This is partly historical and reflects the fact that rapid microbiological methods do not necessarily give equivalent information to that obtained from the more traditional methods. As an example, some rapid microbiological methods (particularly those that do not rely on microbial growth) can detect a significantly wider range of organisms than existing more traditional methods, and this can cause obvious problems in terms of demonstrating equivalence of data during method validation programmes.

Unlike traditional culture-plate methods (which involve the growth of microorganisms in media), rapid microbiological methods rely on the instrumental detection of suitable markers. Broadly, rapid microbiological methods may be classified under three main headings: identification (where the types of microbial contaminants are specified), qualitative (where the presence or absence of microbial contamination is indicated), and quantitative (where the total level of contamination is estimated). Different technologies are employed in each of these application areas, with the most common involving nucleic acid-based detection (using DNA or RNA targets), antibody-based detection, biochemical, enzymatic detection, impedance methods and solid-state and flow cytometry.

Some current developments are now discussed.

Nucleic acid-based methods

Molecular-based methods are now being used to classify strains at the genetic level and as easy-to-use assays for the rapid detection of objectionable organisms. For example, molecular strain typing by sequencing or enzyme digestion patterns can allow comparison of strain against previously observed contaminants.

Nucleic acid amplification techniques (e.g. based on polymerase chain reaction) are also finding application and operate by amplifying and detecting the nucleic acid within the microbial cell rather than detecting the cell itself. Amplification tests may be tailored to detect only a single species or strain and therefore provide high sensitivity and selectivity. Equally, the use of commonly shared genetic sequences as amplification targets allows detection of much broader categories of organisms, thus providing a more universal identification system where necessary (Rodger *et al.* 2010).

Fluorescence-based methods

These methods utilise either the natural autofluorescence of a bacterial cell or the fluorescence resulting from the absorption or activation of a fluorescent dye. Sometimes a short pre-enrichment growth phase is required with this type of method in order to obtain adequate sensitivity but, in general, high selectivity can be achieved.

Oligonucleotide probes can be designed that offer differing levels of selectivity depending on the intended application. When such probes are labelled with fluorescent dyes or the enzyme horseradish peroxidase, for example, identification of single microbial cells is possible using fluorescence *in-situ* hybridisation (FISH). Development of group-specific probes continues (Amann, Fuchs 2008), allowing more reliable quantification of microbial populations *in situ* and in increasingly complex sample types.

Commercially, the Biovigilant system (see www.biovigilant.com 2010) offers a detection approach based on Mie scattering size information coupled with UV laser-induced fluorescence of certain metabolites inside microbial cells and spores. This combination of measurements greatly facilitates classification of microbes.

Bioluminescence methods

Adenosine triphosphate (ATP) bioluminescence methods are well accepted for rapid microbial screening, but can have limited effectiveness for biopharmaceuticals owing to the presence of non-microbial ATP in the sample matrix. Pre-treatment of the sample with proprietary reagents can help to overcome this problem, however, allowing more rapid detection of microbial contamination during manufacture (see www.celsis.com 2010a).

More recently, adenylate kinase (AK) has been used to achieve amplification of ATP bioluminescence, thereby providing confirmation of the absence of microorganisms, including slow-growing moulds, in pharmaceutical products within an overall cycle time of 18–24 h (see www.celsis.com 2010b) for microbial limit testing. Such technology can also be used for sterility testing (see www.celsis.com 2010c), with improvements in sample applicability and handling, reproducibility of detection and overall reduction in analytical cycle times compared with the traditional pharmacopoeial approach.

MALDI-TOF methods

Matrix-assisted laser desorption ionisation time-of-flight (MALDI-TOF) mass spectrometry can be used for the accurate identification of selected bacteria and fungi. Application of the technique to clinical samples has demonstrated excellent performance (Seng *et al.* 2009) and provides a

good indication that MALDI-TOF mass spectrometry could replace Gram staining and biochemical identification and become a reliable standard in medical microbiological laboratories in the next few years.

The emergence of biopharmaceuticals

The pharmaceutical industry has placed, and continues to place, great emphasis on the development of biopharmaceutical products in recent years in order to provide new forms of therapy or to address disease areas that are not adequately treated using conventional 'small' molecules.

This upsurge has presented a number of analytical challenges in terms of the physical and chemical characterisation of biopharmaceuticals and the control of the associated manufacturing processes in view of the relative complexity involved. Conventional 'small' molecules generally have well-defined structures, and the quality (potency, morphology, impurity levels, etc.) may be established with confidence. Biopharmaceuticals are less easy to characterise, however, and those that are chemically identical (some proteins, for example) may have different biological effects resulting from their structural folding patterns. In addition, the biopharmaceutical manufacturing process (involving host cell development, cell production, purification, etc.) is often difficult to operate reproducibly and the characteristics of the finished product (and hence efficacy, and safety) are likely to be influenced by small variations during production.

In view of this high level of complexity, a number of established analytical techniques have been and are being applied, with further development as necessary, for the characterisation of biopharmaceuticals and the associated manufacturing processes. Some of the major applications are now described.

Surface plasmon resonance spectroscopy

Traditionally surface plasmon resonance spectroscopy (SPR spectroscopy) has been used for measuring adsorption of materials onto planar (usually metal) surfaces and has found application in ligand binding studies, for example. For biopharmaceutical characterisation, biosensor-based SPR spectroscopy is being used as a replacement for traditional ELISA (enzyme-linked immunosorbent assay) technology for antibody detection as it offers the advantages of speed and simplicity, ease of automation and provision of label-free immunoassays (Gong 2009). More ambitiously, SPR spectroscopy provides the capability of therapeutic antibody screening based on mechanism of action, and can include a multiplexed approach to allow analysis of several multiple interactions in parallel (Corbin 2009).

The real-time capability of SPR spectroscopy lends itself to process-based application and allows product yield and integrity to be monitored and optimised (Hoffman 2010), as well as providing the basis for process development and control (Thillaivinayagalingam *et al.* 2010).

Quantitative polymerase chain reaction

The polymerase chain reaction (PCR) is widely used in a number of different application areas to produce multiple copies of a DNA sequence. After this amplification, end-point detection usually involves gel electrophoresis followed by staining, but this approach is fairly time-consuming, prone to interference and provides, at best, only qualitative information.

Quantitative PCR (qPCR) overcomes many of these shortcomings by performing the amplification and detection simultaneously, and allows instrumental measurement while the reaction is progressing. Quantitative PCR has been applied to address contamination of host cell DNA and viruses, as this is a critical step in ensuring biological purity of the organisms being used to express the required product (see www.home.agilent.com 2010).

In addition, a multiplex real-time qPCR assay method has been proposed recently that allows the viral clearance capacity of biopharmaceutical purification processes to be established and that may prove useful as a validation technique during process development and implementation (Lute *et al.* 2009).

Capillary electrophoresis and isoelectric focusing

Capillary electrophoresis techniques now play an important role in many biopharmaceutical development and quality control laboratories, with modern instrumentation offering considerable advantages over traditional slab gel methods.

General application areas include the determination of molecular purity, usually involving separations based on hydrodynamic size under denaturing conditions (Guo *et al.* 2008) or determination of the isoelectric point of proteins and establishing the charge heterogeneity due to post-translational modifications (see www.m-scan.co.uk 2010).

The modes of separation used in capillary electrophoresis techniques offer complementary information to that obtained using HPLC, for example, and this can provide a more complete approach to the characterisation of complex biopharmaceutical products (Girard 2009).

Cation-exchange chromatofocusing

Classically, cation-exchange chromatography is used to characterise charge heterogeneity in some classes of biopharmaceuticals (monoclonal antibodies, for example). The inherent heterogeneity of these species demands thorough characterisation, but traditional cation-exchange chromatography methods employing salt gradients can suffer from a lack of robustness and stability of performance owing to fluctuations in eluent composition.

Chromatofocusing is performed on an ion-exchange column and uses a pH gradient to achieve elution of the analytes of interest. Buffer composition and the shape of the pH gradient dictate the order and point of elution of the components of the sample. However, there are limitations in terms of robustness of performance, particularly owing to the chemical composition of elution buffers and when shallow pH gradients are used.

Chromatofocusing using gradual pH gradients (produced by the external mixing of two different elution buffers) can provide improved method performance and flexibility compared with existing approaches and this technique can be used for separation of monoclonal antibody charge species and determination of acidic species and isoform content (Rozhkova 2009).

Conclusion

It may be apparent from the brief review of developments, newer application areas and improved ways of working presented in this chapter that the field of pharmaceutical analysis is in the midst of quite a revolution. There may be few truly 'new' analytical technologies emerging, perhaps because the analytical toolbox is already quite well furnished with techniques suitable for most existing applications, but the change in emphasis that is being felt within the analytical community is providing the impetus for a great deal of innovative thinking.

No longer is the pharmaceutical analyst content simply to review the results of product and process development, or to establish product quality using traditional tests and methods. Now the emphasis is on gaining an improved understanding of pharmaceutical products and processes such that quality is ensured 'by design', and the on-going analytical assessment, mainly during this design and development phase, plays an integral part in obtaining this understanding. Control of drug substance manufacturing processes to ensure *and demonstrate* correct morphology, crystal habit, physical properties, etc. is as important now as establishing purity, for these are the aspects that will govern subsequent processability during product manufacture and final quality of the pharmaceutical product. Tablet hydration studies during formulation development will provide an insight into the mechanisms whereby the tablet releases the active ingredient and it is this, rather than the traditional laboratory dissolution test, that will aid design of a product of suitable quality.

Analytical techniques have evolved to meet these needs and will continue to do so. More established techniques are finding newer application areas. Different approaches are being adopted to establish aspects

of product and process understanding and final product quality. In all of this, the challenge for the pharmaceutical analyst is to keep sight of the real objectives and to choose the most appropriate techniques and methods, and the required analytical performance, that will achieve them. May the revolution continue.

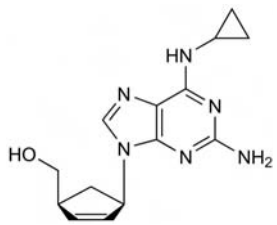
PART TWO

Monographs

Abacavir

Antiretroviral, Nucleoside Reverse Transcriptase Inhibitor
$C_{14}H_{18}N_6O$ = 286.3
CAS—136470-78-5

IUPAC Name [(1*S*,4*R*)-4-[2-Amino-6-(cyclopropylamino)purin-9-yl]cyclopent-2-en-1-yl]methanol
Synonyms (1*S*,4*R*)-4-[2-Amino-6-(cyclopropylamino)-9*H*-purin-9-yl]-2-cyclopentene-1-methanol; (–)-*cis*-4-[2-amino-6-(cyclopropylamino)-9*H*-purin-9-yl]-2-cyclopentene-1-methanol; 1592U89.
Proprietary Names *Epzicom*; *Kivexa*.



Chemical Properties White to off-white solid. White solid foam from acetonitrile. Mp 165°. Soluble in water (0.077 mg/L at 25°). pK_a 5.01 [Kumar *et al.* 1999]. Log *P* (octanol/sodium phosphate, pH 7.4) 1.22 [Kumar *et al.* 1999].

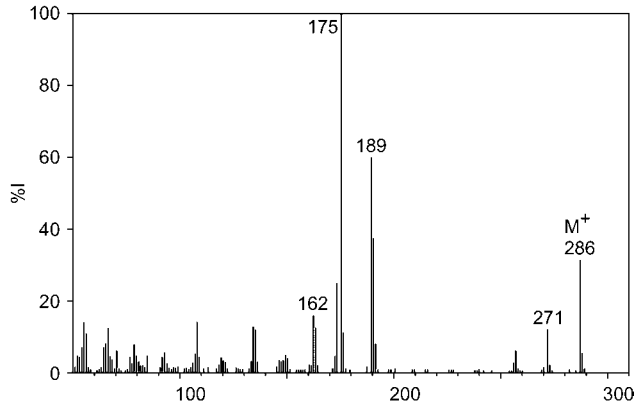
Abacavir Succinate

$C_{18}H_{24}N_6O_5$ = 404.4
CAS—168146-84-7
IUPAC Name [(1*R*)-4-[2-Amino-6-(cyclopropylamino)purin-9-yl]cyclopent-2-en-1-yl]methanol butanedioic acid

Abacavir Sulfate

$(C_{14}H_{18}N_6O)_2,H_2SO_4$ = 670.8
CAS—188062-50-2
IUPAC Name [(1*R*)-4-[2-Amino-6-(cyclopropylamino)purin-9-yl]cyclopent-2-en-1-yl]methanol sulfuric acid
Proprietary Names *Kivexa*; *Trizivir*; *Ziagen*.
Chemical Properties Log *P* (octanol/water, pH 7.1–7.3), 1.20 (25°).

High Performance Liquid Chromatography System HAB—RT 1.0 min; system HAD—*k* 8.10.
Ultraviolet Spectrum Aqueous alkali—217, 260, 285 nm.
Mass Spectrum Principal ions at *m/z* 175, 189, 190, 286, 173, 162, 271, 163.



Quantification

Plasma **HPLC** Column: Waters Symmetry C_{18} (100 × 4.6 mm i.d., 3.5 µm). Mobile phase: acetonitrile : phosphate buffer (pH 7.8, 85 : 15), flow rate 1.5 mL/min. UV detection (λ = 285 nm). Limit of quantification, 0.08 mg/L [Sparidans *et al.* 2001]. Column: Symmetry Shield C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : phosphate buffer + ion pair (50 : 50). UV detection (λ = 260 nm) [Aymard *et al.* 2000]. Column: Symmetry C_{18} (100 × 4.6 mm i.d., 3.5 µm). Temperature: 41°. Mobile phase: 25 mmol/L phosphate buffer (pH 7.0) : acetonitrile (85 : 15), flow rate 1.0 mL/min. UV detection (λ = 285 nm). Retention time: 4.8 min. Limit of quantification, 0.02 mg/L [Veldkamp *et al.* 1999]. Column: Phenomenex Luna C_{18} (150 × 4.6 mm i.d., 5 µm) Mobile phase: acetonitrile: water (83 : 17), flow rate 1.0 mL/min. UV detection (λ = 285 nm). Limit of quantification, 0.05 mg/L. [Ferrer *et al.* 2004].

LC-MS Column: Machery-Nagel Nucleosil C_{18}-100 (125 × 3 mm i.d., 3 µm). Mobile phase: 20 mmol/L ammonium acetate-0.1% aqueous acetic acid : acetonitrile, flow rate 0.4 mL/min. ESI, positive ion mode [Gehrig *et al.* 2007]. Column: Zorbax Eclipse XDB C_8 (150 × 2.1 mm i.d., 5 µm). Mobile phase: 10 mmol/L ammonium acetate (pH 6.3) : acetonitrile (30 : 70 for 1.5 min to 85 : 15 at 2 min), flow rate 0.25 mL/min. ESI, positive ion mode. Limit of detection not reported [Clark *et al.* 2004]. Column: Phenomenex Luna $C_8(2)$ (50 × 2.0 mm i.d., 5 µm). Mobile phases: 20 mmol/L DMHA (pH 7) and methanol : water (80 : 20), flow rate 0.2 mL/min. Limit of detection, <25 nmol/L [Fung *et al.* 2001].

CE Capillary: uncoated fused silica (50 µm i.d., 70 µm o.d.). Buffer: 40 µmol/L ammonium acetate (pH 9.2). SIM acquisition mode, *m/z* 288. Limit of detection, 1 µmol/L [Cai *et al.* 2003].

Urine **HPLC** Column: Phenomenex Kromasil octadecyl (150 × 3.2 mm i.d., 5 µm). Mobile phase: 25 mmol/L ammonium acetate buffer (pH 4.0) : methanol (95 : 5), flow rate 0.7 mL/min. UV detection (λ = 295 nm). Limit of quantification, 56 mg/L [Ravitch, Moseley 2001].

CSF **HPLC** See Urine [Ravitch, Moseley 2001].

Placenta **LC-MS** See Plasma [Clark *et al.* 2004].

Foetus **LC-MS** See Plasma [Clark *et al.* 2004].

Disposition in the Body Abacavir is extensively and rapidly absorbed after oral administration with a bioavailability of ~83%, depending on formulation [Chittick *et al.* 1999]. It is metabolised by alcohol dehydrogenase to 5′-carboxylic acid and by glucuronyl transferase to the 5′-glucuronide. It is mainly excreted in urine: 1.2% of a dose is excreted unchanged in urine, 30% as the 2 metabolites and 15% as an unidentified metabolite; 16% of the dose can also be detected in faeces [Yuen *et al.* 2008].

Therapeutic Concentration

Twelve HIV-infected adult patients were administered with single oral doses of 100, 300, 600, 900 and 1200 mg abacavir. Peak plasma concentrations of 0.6, 2.9, 4.7, 8.1 and 9.6 mg/L were reached for these doses, respectively, attained within 1.0–1.7 h [Kumar *et al.* 1999].

Abacavir was administered to 41 HIV-infected adult patients as an oral dose of 100, 300 or 600 mg twice daily for 12 weeks. Average peak plasma concentrations of 0.6, 2.2 and 4.4 mg/L were reached for these doses, respectively, attained within 1.0 h [Weller *et al.* 2000].

Abacavir was administered to 22 HIV-infected children, aged between 3 months and 13 years, either as a 4 or a 8 mg/kg dose. Peak plasma concentrations of 1.69 and 3.94 mg/L, respectively, were reached within 1.5 h [Hughes *et al.* 1999].

Toxicity Life-threatening hypersensitivity reactions have been reported, as well as life-threatening lactic acidosis and severe hepatomegaly with steatosis.

Half-life Adults, elimination half-life 0.9–1.7 h [Kumar *et al.* 1999], 0.8–1.0 h [Weller *et al.* 2000]. Children, 1.0 h [Hughes *et al.* 1999]. The half-life of the active intracellular anabolite, carbovir triphosphate, is >20 h [Yuen *et al.* 2008].

Volume of Distribution Apparent volume of distribution: adults 0.65–0.95 L/kg (57.6–77.6 L) [Weller *et al.* 2000]; children 1.82 L/kg (45.3 L) [Jullien *et al.* 2005].

Clearance Mean apparent clearance: adults 0.56 L/h/kg (single 1200 mg dose)–1.94 L/h/kg (single 100 mg dose) [Kumar *et al.* 1999]; children 1.6 L/h/kg (8 mg/kg dose)–1.1 L/h/kg (4 mg/kg dose) [Hughes *et al.* 1999], 0.9 L/h/kg (8 mg/kg dose) [Jullien *et al.* 2005].

Protein Binding ≈50% [Yuen *et al.* 2008].

Dose Adults: 300 mg (base) twice daily or 600 mg once daily. Children aged between 3 months and 16 years: 8 mg/kg body weight (maximum 300 mg) twice daily.

Acamprosate Calcium

Alcohol Deterrent

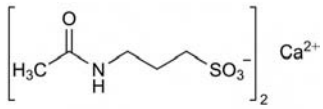
$Ca(C_5H_{10}NO_4S)_2 = 400.5$

CAS—77337-76-9 (acamprosate); 77337-73-6 (acamprosate calcium)

IUPAC Name Calcium 3-acetamidopropane-1–sulfonate

Synonyms Ca-AOTA; calcium 3-acetamido-1-propanesulfonate; calcium acetylhomotaurinate; calcium bisacetyl homotaurine.

Proprietary Names *Aotal*; *Campral.*



Chemical Properties A colourless crystalline powder. Mp 270°.

High Performance Liquid Chromatography System HAA—retention time 3.0 min.

Ultraviolet Spectrum Water—192 nm.

Quantification

Plasma **GC-MS** Column: fused-silica capillary coated with OV-1701 (25 m × 0.35 mm i.d., 0.2 µm). Temperature programme: 240° to 310° at 10°/min for 2 min. NICI, SIM acquisition mode at *m/z* 424. Retention time: 5.5 min [Girault *et al.* 1990]. Limit of detection, 0.001 mg/L [Girault *et al.* 1990].

HPLC Fluorescence detection. Limit of detection, 0.001 mg/L [Chabenat *et al.* 1987].

Disposition in the Body Absorption is slow after oral administration but sustained and shows large intersubject variability. Steady state concentrations are observed 7 days after administration. The drug crosses the blood–brain barrier. It is not significantly metabolised and is excreted unchanged in urine.

Therapeutic Concentration

Following single oral doses of 666 mg to 24 healthy subjects, aged 19 to 35 years, the mean maximum plasma concentration was 0.180 mg/L. Most of the dose was absorbed within 4 h [Girault *et al.* 1990].

Six healthy volunteers and 12 patients with moderate or severe chronic renal impairment were administered a single dose of 666 mg. Maximum peak plasma concentrations were 0.198 mg/L for the healthy individuals and 0.813 mg/L for those with severe impairment. These were observed at 6 and 23 h, respectively [Sennesael 1994].

Half-life Plasma 13 to 18 h (healthy individuals); 47 h (patients with severe renal impairment).

Clearance Plasma 184 L/h (healthy volunteers); 16 L/h (patients with moderate renal impairment); 66.5 L/h (severe impairment).

Protein Binding Not bound.

Note For a review of acamprosate calcium, see Wilde and Wagstaff [1997].

Dose Patients with a body weight <60 kg: 1.3 g daily. Patients with a body weight >60 kg: 2 g daily.

Chabenat C *et al.* (1987). Determination of calcium acetylhomotaurinate by liquid chromatography with fluorimetric and electrochemical detection. *J Chromatogr* 414: 417–422.

Acarbose

Antidiabetic

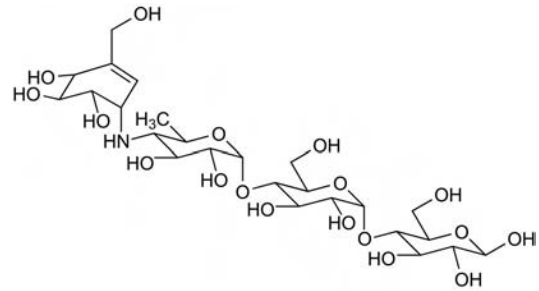
$C_{25}H_{43}NO_{18} = 645.6$

CAS—56180-94-0

IUPAC Name (2*R*,3*R*,4*R*,5*S*,6*R*)-5-[(2*R*,3*R*,4*R*,5*S*,6*R*)-5-[(2*R*,3*R*,4*S*,5*S*,6*R*)-3, 4-Dihydroxy-6-methyl-5-[[(1*S*,4*S*,5*S*,6*S*)-4,5, 6-trihydroxy-3-(hydroxymethyl)cyclohex-2-en-1-yl]amino]oxan-2-yl]oxy-3, 4-dihydroxy-6-(hydroxymethyl)oxan-2-yl] oxy-6-(hydroxymethyl)oxane-2,3, 4-triol

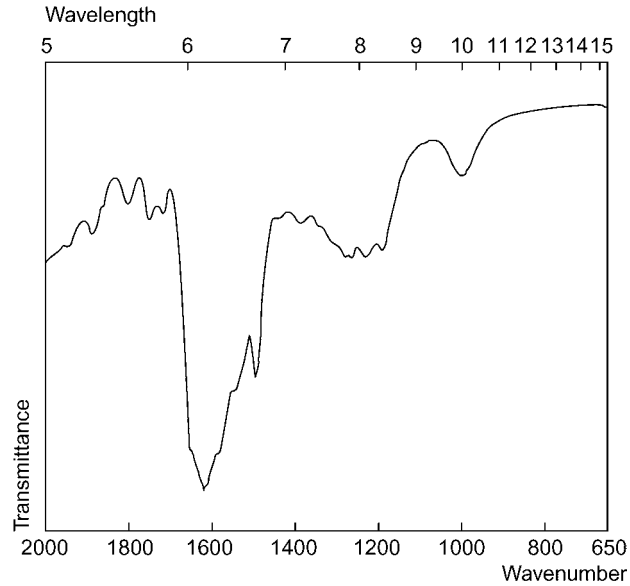
Synonyms Bay-g-5421; *O*-4,6-Dideoxy-4-[[(1*S*,4*R*,5*S*,6*S*)-4,5,6-trihydroxy-3-(hydroxymethyl)-2-cyclohexen-1-yl] amino]-α-D-glucopyranosyl-(1→4)-*O*-α-D-glucopyranosyl-(1→4)-D-glucose.

Proprietary Names *Glicobase*; *Glucobay*; *Glucor*; *Glumide*; *Prandase*; *Precose*.



Chemical Properties A white to off-white amorphous powder, which is soluble in water. pK_a 5.1. Log *P* (octanol/water), −8.08.

Infrared Spectrum Principal peaks at wavenumbers 1033, 1153, 1458 cm^{-1} (KBr disk).



Quantification

Plasma **Bioassay** Limit of detection, 5 µg/L [Ahr *et al.* 1989].

Urine **Bioassay** Limit of detection, 150 µg/L [Ahr *et al.* 1989].

Other **HPLC** In Pharmaceuticals. ELS detection. Limit of quantification, >15 mg/L, limit of detection, <5 mg/L [Cherkaoui *et al.* 1998]. Column: Nucleosil aminopropyl-bonded (250 × 4.6 mm, i.d. 5 µm). Mobile phase: methanol: dichloromethane (65:35). Detection: ELS. Retention time: 4.3 min [Cherkaoui *et al.* 1998].

Disposition in the Body Acarbose is metabolised by intestinal digestive enzymes and by the microbial flora of the gastrointestinal tract, where the majority of the active unchanged drug remains. The major metabolites are the 4-methylpyrogallol derivatives (sulfate, methyl and glucuronide conjugates) produced by biotransformation (mainly reduction and conjugation). 35% of an oral dose is absorbed as the metabolites and only 1 to 2% absorbed as the active drug. After intravenous administration, approximately 90% of a dose is excreted in urine within 48 h as the active drug (parent drug or active metabolite). After oral administration, <2% of the dose is recovered in urine as the active drug and 34% as metabolites, and approximately 50% as the unabsorbed drug in faeces (within 96 h post ingestion).

Therapeutic Concentration Patients with severe renal impairment, creatinine clearance <25 mL/min/1.73 m^2, have a peak plasma concentration of acarbose 5 times greater than those with normal renal function.

Six healthy volunteers were administered with a single oral 200 mg dose of acarbose. Peak plasma concentrations of 49.5 ± 27.0 µg/L were reached approx. 2 h after administration [Ahr *et al.* 1989].

Toxicity Acarbose is associated with hepatotoxicity and has low toxicity by ingestion, subcutaneous and intravenous routes. A 360 mg/kg body weight dose in women over a 60-day period and given intermittently in a number of separate and discrete doses can cause non-fatal toxic effects. Acarbose competitively and reversibly inhibits the α-glucosidase enzymes, glucoamylase, sucrase, maltase and isomaltase, found in the small intestine, and this delays hydrolysis of complex carbohydrates. It is unlikely to produce hypoglycaemia in overdose, but abdominal discomfort and diarrhoea may occur.

Bioavailability Systemic bioavailability is 0.5 to 1.7%.

Half-life Elimination half-life is 3.2 ± 0.9 h.

Volume of Distribution Steady state volume of distribution is 0.32 L/kg.

Clearance Total body clearance, 600 L/h.

Protein Binding Minimal protein binding with plasma concentrations of more than 1 µg/L and up to 98% with 0.008 µg/L.

Dose An initial dose of 25 mg three times a day is administered and can be increased to a maintenance dose of 50 to 100 mg three times daily. Doses up to 200 mg three times daily have been reported. Patients with a body weight ≤60 kg have a maximum dose of 50 mg three times a day.

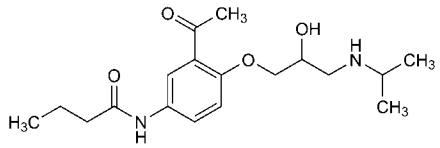
Acebutolol

β-*Adrenoceptor Antagonist*
$C_{18}H_{28}N_2O_4$ = 336.4
CAS—3751-730-9

IUPAC Name *N*-[3-Acetyl-4-[2-hydroxy-3-(propan-2-ylamino)propoxy]phenyl]butanamide
Synonyms (±)-3′-Acetyl-4′-(2-hydroxy-3-isopropylaminopropoxy)butyranilide; *N*-[3-acetyl-4-[2-hydroxy-3-[(1-methylethyl)amino]propoxy]butanamide.



Chemical Properties Crystals. Mp 119° to 123°. pK_a 9.4. Log *P* (octanol/water), 0.1 [Dohta *et al.* 2007], −0.40 [Krzek *et al.* 2006]. Extraction yield (chlorobutane), 0.05 [Demme *et al.* 2005]. Acebutolol is stable in plasma for more than 24 h at room temperature, after 3 freeze–thaw cycles and after storage at –20° for 1 month [Maurer *et al.* 2004]. Acebutolol is stable in plasma for at least 48 h at 4° and for at least 8 weeks at –80°. Stock standard solutions were stable for at least 3 months when kept at 4° [Umezawa *et al.* 2008].
Note For a study on the degradation of acebutolol in various concentrations of sodium hydroxide, see Kwiecień *et al.* [2008] and in hydrochloric acid, see Krzek *et al.* [2006].

Acebutolol Hydrochloride

$C_{18}H_{28}N_2O_4$,HCl = 372.9
CAS—34381-68-5
Proprietary Names *Acecor*; *Acetanol*; *Neptal*; *Prent*; *Sectral*. It is an ingredient of *Secadrex*.
Chemical Properties A white or slightly cream-coloured powder. Mp 141° to 143°.

Colour Tests Methanolic potassium hydroxide—yellow; Nessler's reagent—orange (slow); sulfuric acid—yellow.
Thin-layer Chromatography System TA—R_f 0.47; system TB—R_f 0.00; system TC—R_f 0.03; system TE—R_f 0.33; system TAE—R_f 0.13; system TAF—R_f 0.71; system TAG—R_f 0.06.

Plates: F_{254}. Solvent system: chloroform : methanol : ammonia (15 : 7 : 0.2). UV detection (λ = 240 nm). R_f 0.53 [Krzek *et al.* 2006;Kwiecień *et al.* 2008].

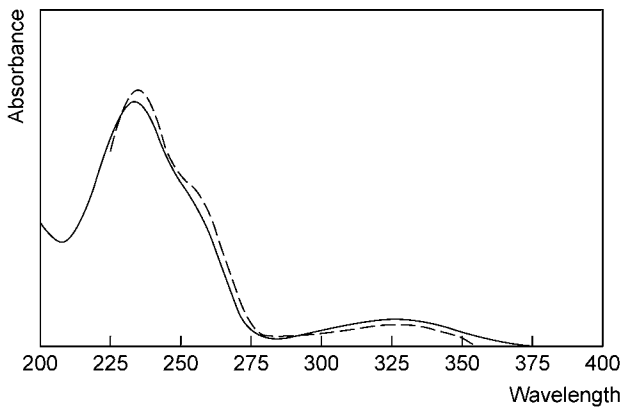
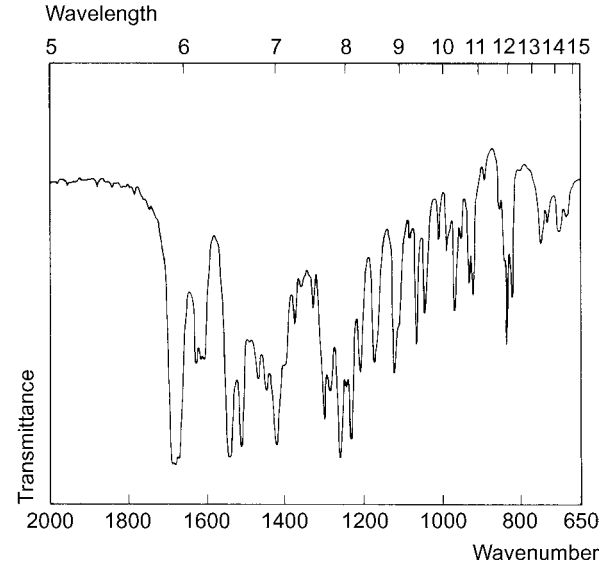
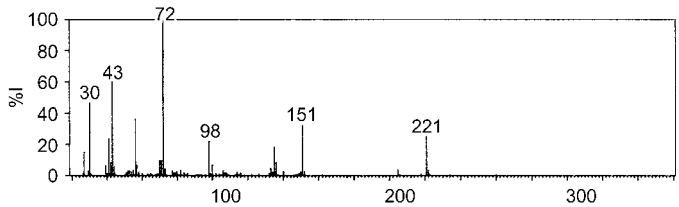
Ultra Performance Liquid Chromatography Column: Acquity C_{18} BEH (100 × 2.1 mm i.d., 1.7 µm). Mobile phase: 0.1% trifluoroacetic acid in water : 0.1% trifluoroacetic acid in acetonitrile (80 : 20 to 50 : 50 in 10 min), flow rate 0.5 mL/min. UV detection (λ = 270 nm). Retention time: 1.41 min. Limit of detection, not reported [Wren, Tchelitcheff 2006].
Ultraviolet Spectrum Aqueous acid—234 (A^1_1=655b), 320 nm (A^1_1=75b); methanol—235 (A^1_1=866a), 328 nm.



Infrared Spectrum Principal peaks at wavenumbers 1665, 1245, 1525, 1495, 1217, 1285 cm^{-1} (hydrochloride), KBr disk.



Mass Spectrum Principal ions at *m/z* 72, 43, 30, 56, 151, 221, 41, 98.



Quantification

Plasma **HPLC** Column: HyPurity C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: phosphate buffer (pH 3.8) : acetonitrile (90 : 10 to 65 : 35 at 25 min for 1 min), flow rate 1.0 mL/min. DAD (λ = 220 nm). Retention time: 14.5 min. Limit of quantification, 25 µg/L; limit of detection, 6 µg/L [Delamoye *et al.* 2004]. Column: Spherisorb ODS (250 × 4.6 mm i.d., 5 µm). Mobile phase: 0.1 mol/L phosphate buffer (pH 4.0) : acetonitrile (6 : 55), flow rate 1.0 mL/min. UV detection (λ = 243 nm). Limit of quantification, 20 µg/L for acebutolol and its metabolites [Buskin *et al.* 1982].

LC-MS Column: Shodex MSpak GF-310 4B (50 × 4.6 mm i.d., 6 µm). Mobile phase: 10 mmol/L ammonium formate : acetonitrile (100 : 0 for 3 min to 0 : 100 at 4 min for 5.5 min), flow rate 0.55 mL/min. ESI, positive ion mode. Retention time: 7.2 min. Limit of detection, 1 µg/L [Umezawa *et al.* 2008]. Column: Merck LiChroCART (125 × 2 mm i.d.). Mobile phase: 5 mmol/L aqueous ammonium formate (pH 3.0) : acetonitrile (80 : 20 for 2.2 min to 60 : 40 at 5.5 min to 10 : 90 at 8.0 min to 80 : 20 at 9.5 min for 0.5 min), flow rate 0.4 mL/min to 0.7 mL/min at 8 min to 0.65 mL/min at 9.5 min to 0.4 mL/min at 10.0 min. APCI, SIM acquisition mode. Limit of quantification, 0.1 mg/L, limit of detection, 0.01 mg/L [Maurer *et al.* 2004].

Urine **GC-MS** Column: Supelco Equity 1701 (10 m × 100 mm i.d., 0.1 µm). Temperature programme: 100° for 0.1 min to 300° at 2.1 min at 55°/min. Carrier gas: He, 0.6 mL/min. EI ionisation at 70 eV, full scan or SIM acquisition mode. Retention time: ~5.8 min. Limit of detection, 10 µg/L [Brunelli *et al.* 2006].

HPLC See Plasma [Buskin *et al.* 1982].

Other **LC-MS** Sewage. Column: Zorbax SB-C_8 (150 × 2.1 mm i.d., 3.5 µm). Mobile phase: water : acetonitrile : formic acid (94.5 : 5.0 : 0.5) : acetonitrile : formic acid (99.5 : 0.5; 100 : 0 to 75 : 25 in 13 min for 13 min), flow rate 0.2 mL/min. ESI, MRM acquisition mode. Retention time: 17.4 min. Limit of detection, 9 ng/L [Lee *et al.* 2007].

Disposition in the Body Absorbed after oral administration; bioavailability approx. 40%. The major active metabolite is the acetyl derivative diacetalol. After an oral dose, approximately 20 to 40% of the dose is excreted in the urine in 24 h, approximately 9 to 12% of the dose as unchanged drug and approximately 12 to 24% as diacetalol. Up to 60% of the dose is eliminated in the faeces as unchanged drug and diacetalol. After an IV dose, relatively more is excreted in the urine than in the faeces, and the proportion of unchanged drug in the urine is greater than after an oral dose.

Therapeutic Concentration

Ten healthy subjects ingested 200 mL grapefruit juice or water 3 times a day for 3 days and twice on day 4. On day 3, each subject ingested 400 mg acebutolol with the grapefruit juice or water. The grapefruit juice decreased the mean peak plasma concentration from 872 ± 207 to 706 ± 140 µg/L [Lilja *et al.* 2005].

After a single oral dose of 400 mg, administered to 8 subjects, a mean peak plasma concentration of 700 µg/L was attained in 2 h; a mean peak concentration of diacetalol of 800 µg/L was attained in 4 h [Gulaid *et al.* 1981].

Steady-state concentrations of 0.51 to 1.23 mg/L (mean, 0.7 mg/L) were reported during chronic oral administration of 300 mg every 6 to 8 h to 6 subjects; the concentration of diacetalol was 0.63 to 4.43 mg/L (mean, 2.2 mg/L) [Winkle *et al.* 1977].

Toxicity A fatal case of self-poisoning with acebutolol was reported with a post-mortem blood concentration of 34.7 µg/mL [Tracqui *et al.* 1992].
Bioavailability ~40%.

A

Half-life Plasma half-life acebutolol ~7 to 11 h, diacetalol ~12 h.
Volume of Distribution Approximately 1 to 3 L/kg.
Distribution in Blood Plasma : whole blood ratio, ~0.8.
Protein Binding Approximately 20%.
Dose The equivalent of 0.2 to 1.2 g of acebutolol daily.

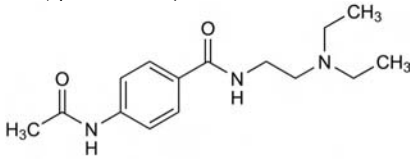
Acecainide

Antiarrhythmic
$C_{15}H_{23}N_3O_2$ = 277.4
CAS—32795-44-1

IUPAC Name 4-Acetamido-*N*-(2-diethylaminoethyl)benzamide
Synonyms *N*-Acetylprocainamide; NAPA.

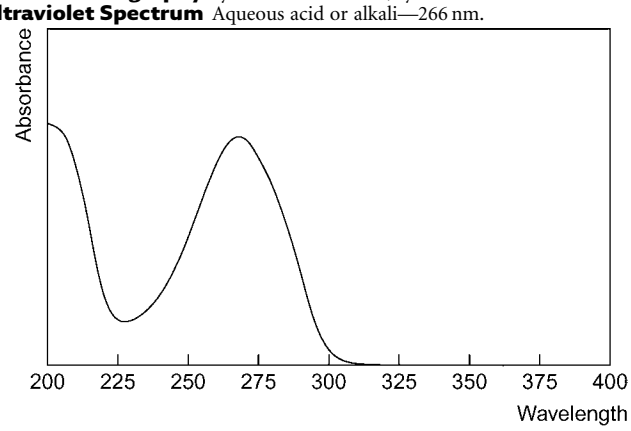


Chemical Properties Log *P* 1.99 [Hollosy *et al.* 2006].

Acecainide Hydrochloride

$C_{15}H_{23}N_3O_2$,HCl = 313.8
CAS—34118-92-8
Chemical Properties Crystals. Mp 190° to 193°.

Gas Chromatography System GA—RI 2550; system GB—RI 2724.
Ultraviolet Spectrum Aqueous acid or alkali—266 nm.



Infrared Spectrum Principal peaks at wavenumbers 1639, 1509, 1527, 1696, 1600, 1259 cm^{-1} (hydrochloride), KBr disk.
Mass Spectrum Principal ions at *m/z* 86, 58, 99, 56, 162, 132, 149, 205.
Quantification See also under Procainamide.
Plasma **GC** Column: Chromosorb W-HP 3% OV-17 (1.5 m × 1 mm i.d.). Temperature: 255°. Carrier gas: He, 5 mL/min. EI ionisation at 70 eV. Limit of detection, 500 µg/L [Strong *et al.* 1975].

HPLC Column: Ultrasphere octyl C_8 (250 × 4.6 mm i.d., 5 µm). Mobile phase: water : methanol : acetic acid : tetraethylammonium (78 : 22 : 1 : 0.01), flow rate 1.3 mL/min. UV detection (λ = 280 nm). Retention time: 6.7 min. Limit of quantification, 4 µg/L; limit of detection, 2 µg/L [Lessard *et al.* 1998].
Disposition in the Body Readily absorbed after oral administration; bioavailability approx. 85%. Up to 85% of a dose is excreted in the urine as unchanged drug in 48 h, with only 2 to 3% excreted as procainamide and <1% as the monodesethyl metabolite. Acecainide is the principal active metabolite of procainamide.
Therapeutic Concentration In plasma, usually in the range 10 to 30 mg/L. After a single oral dose of 1.5 g to nine subjects, peak plasma concentrations of 7.4 to 17.2 mg/L (mean, 12 mg/L), were attained in 1.5 to 4 h [Lee *et al.* 1976]. Following oral administration of 1 g four times a day to 8 subjects, steady-state plasma concentrations of 9.3 to 25.5 mg/L (mean, 18 mg/L) were reported [Atkinson *et al.* 1977].
Toxicity Toxic effects may occur at plasma concentrations within the therapeutic range.
Bioavailability Approximately 85%
Half-life Plasma half-life, approximately 6 to 9 h in normal subjects; increased in subjects with heart disease or renal impairment.
Volume of Distribution Approximately 1.5 L/kg.
Clearance Plasma clearance, approx. 3 mL/min/kg.
Protein Binding Approximately 10%.
Note For a review of the pharmacokinetics of acecainide, see Connolly and Kates [1982].
Dose Acecainide has been given in doses of 2 to 6 g daily.

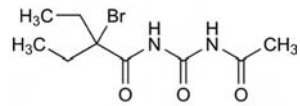
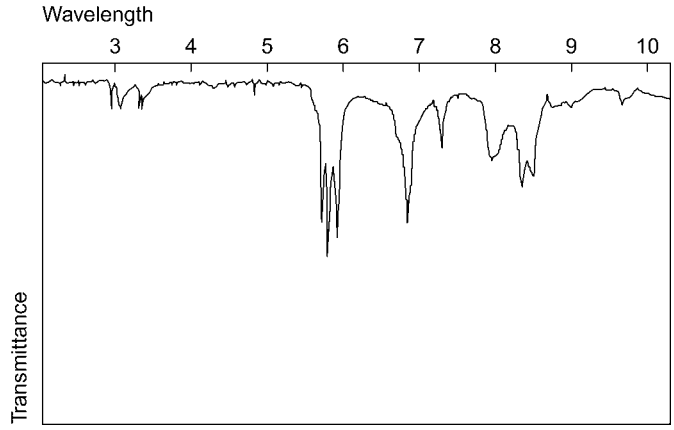
Acecarbromal

Sedative, Hypnotic
$C_9H_{15}BrN_2O_3$ = 279.1
CAS—77-66-7

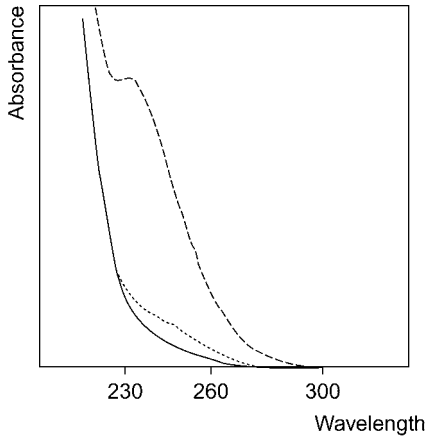
IUPAC Name *N*-(Acetylcarbamoyl]-2-bromo-2-ethylbutanamide
Synonyms *N*-[(Acetylamino)carbonyl]-2-bromo-2-ethylbutanamide; acetylbromodiethylacetylcarbamide; *N*-acetyl-*N*-bromodiethylacetylurea; *N*-acetyl-*N*′-α-bromo-α-ethylbutyrylcarbamide; acetylcarbromal.
Proprietary Names *Abasin*; *Sedamyl.*



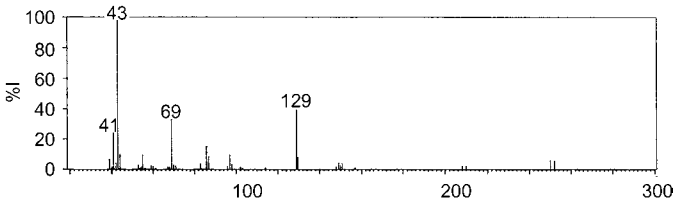
Chemical Properties Colourless crystals or white crystalline powder. Mp 109°. Soluble 1 in 1000 of water; soluble in ethanol, chloroform and ether.
Colour Test Nessler's reagent—brown-orange (slow).
Thin-layer Chromatography System TD—R_f 0.49; system TE—R_f 0.57; system TF—R_f 0.48; system TAD—R_f 0.60; system TAE—R_f 0.84; system TAF—R_f 0.84; system TAJ—R_f 0.61; system TAK—R_f 0.58; system TAL—R_f 0.90.
Gas Chromatography System GA—acecarbromal RI 1720, M (carbromal) RI 1513, M (desbromocarbromal) RI 1380.
High Performance Liquid Chromatography System HX—RI 429; system HY—RI 374.
Infrared Spectrum Principal peaks at wavenumbers 1776, 1730, 1183, 1267, 1149, 1236 cm^{-1} (Nujol mull).



Ultraviolet Spectrum Aqueous alkali—230 nm.



Mass Spectrum Principal ions at *m/z* 43, 129, 69, 41, 86, 97, 55, 44.



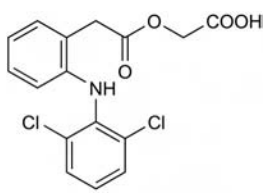
Quantification
Plasma **HPLC** Column: LiChrosorb Si 60 (30 cm × 3 mm i.d., 5 µm). Mobile phase: *n*-hexane : methylene chloride : ethanol (235 : 10.5 : 7.5), flow rate 1.2 mL/min. Retention time: 4.5 min. Limit of detection not reported [Hobel, Bender 1977].
Urine **GC-MS** Column: HP capillary (12 m × 0.2 mm i.d., 0.33 µm). Temperature programme: 100° to 310° at 30°/min. Carrier gas: He, 1 mL/min. EI ionisation at 70 eV, scan mode. Limit of detection, 10–20 µg/L [Maurer 1990].
HPLC See Plasma [Hobel, Bender 1977].
Dose 0.75 to 1.5 g daily.

Hobel M, Bender G (1977). Separation and quantitative determination of acecarbromal, carbromal, and bromisoval as well as their main metabolites by means of high-pressure liquid chromatographic analysis. *Arch Toxicol* 37: 307–312.
Maurer HH (1990). Identification and differentiation of barbiturates, other sedative-hypnotics and their metabolites in urine integrated in a general screening procedure using computerized gas chromatography-mass spectrometry. *J Chromatogr* 530: 307–326.

Aceclofenac

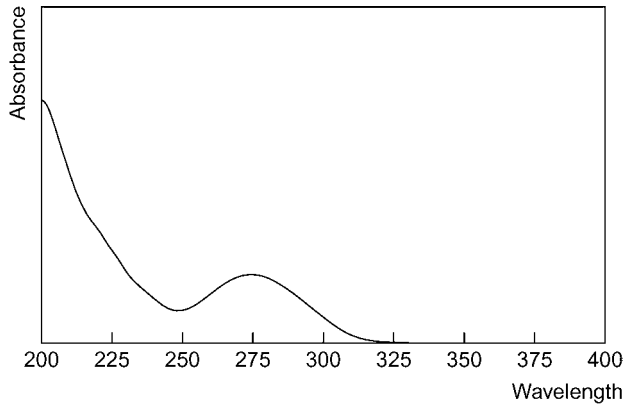
Antiinflammatory
$C_{16}H_{13}Cl_2NO_4 = 354.2$
CAS—89796-99-6

IUPAC Name 2-[2-[2-(2,6-Dichloroanilino)phenyl]acetyl]oxyacetic acid
Synonyms Aceclofenacum; 2-[(2,6-dichlorophenylamino)phenyl]acetoxyacetic acid; PR-82/3.
Proprietary Names *Airtal*; *Barcan*; *Biofenac*; *Difucrem*; *Falcol*; *Gerbin*; *Preservex*; *Sanein*; *Tresquim*.



Chemical Properties A white to almost white crystalline powder. Mp 149° to 150°. It is practically insoluble in water; soluble in alcohol and methyl alcohol; freely soluble in acetone and dimethylformamide.
Thin-layer Chromatography Plate: silica gel. Mobile phase: chloroform: methanol:acetic acid (90:10:1). Aceclofenac R_f 0.44; 4′-OH aceclofenac R_f 0.25 [Bort *et al.* 1996].
High Performance Liquid Chromatography System HZ—retention time 10.7 min.

Ultraviolet Spectrum Ethanol—275 nm.



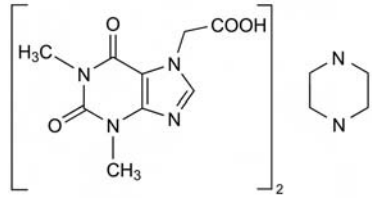
Quantification
Plasma **HPLC** UV detection (λ=278 nm). Limit of detection, 0.010 mg/L [Lee *et al.* 2000]. Column: Spherisorb ODS–2 C_{18} (200 × 4.6 mm, 5 µm). Mobile phase: 0.02% triethanolamine in 100 mmol/L phosphate buffer, pH 7.4:acetonitrile (75:25), flow rate 1.0 mL/min. UV detection (λ=282 nm). Retention time: aceclofenac, 23.4 min; 4′-hydroxyaceclofenac, 7.6 min [Bort *et al.* 1996]. Limit of detection, 6.5 mg/L [Bort *et al.* 1996].
Urine **HPLC** See Plasma [Bort *et al.* 1996].
Disposition in the Body Aceclofenac is well absorbed after oral administration and circulates mainly as the unchanged drug. It is metabolised in hepatocytes and microsomes to 4′-hydroxyaceclofenac, which can undergo further conjugation. Other metabolites also identified include diclofenac and 4-hydroxydiclofenac, and their hydroxylated derivatives. Aceclofenac penetrates into synovial fluid and concentrations here reach approximately 57% of those in plasma. 70% of an administered dose is excreted in urine as glucuronides of aceclofenac and diclofenac.
Therapeutic Concentration
Eight healthy, male, Caucasian volunteers, aged between 26 and 68 years, were orally administered a 100 mg dose of aceclofenac. Peak plasma concentrations of 7.6 ± 1.3 mg/L were reached within 2.6 ± 1.8 h [Bort *et al.* 1996].
Toxicity Type III hypersensitivity reactions have been reported.
Half-life Elimination half-life is approximately 4 h.
Volume of Distribution Apparent volume of distribution is ~25 L.
Protein Binding >99% protein bound.
Dose A usual dose of 100 mg twice daily is administered with a reduction to 100 mg daily for patients with hepatic impairment.

Bort R *et al.* (1996). Metabolism of aceclofenac in humans. *Drug Metab Dispos* 24(8): 834–841.
Lee HS *et al.* (2000). Simultaneous determination of aceclofenac and diclofenac in human plasma by narrowbore HPLC using column-switching. *J Pharm Biomed Anal* 23: 775–781.

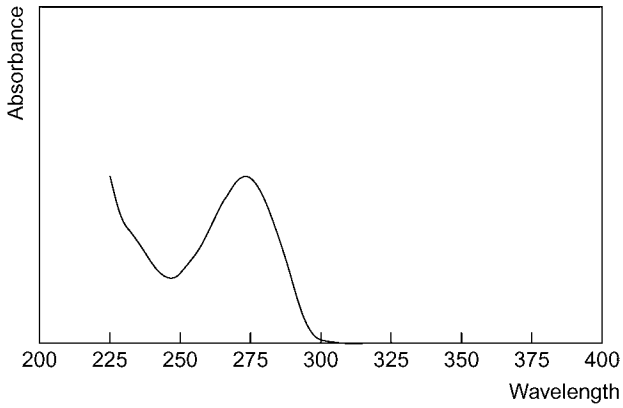
Acefylline Piperazine

Xanthine Bronchodilator
$(C_9H_{10}N_4O_4)_2,C_4H_{10}N_2 = 562.5$
CAS—18833-13-1

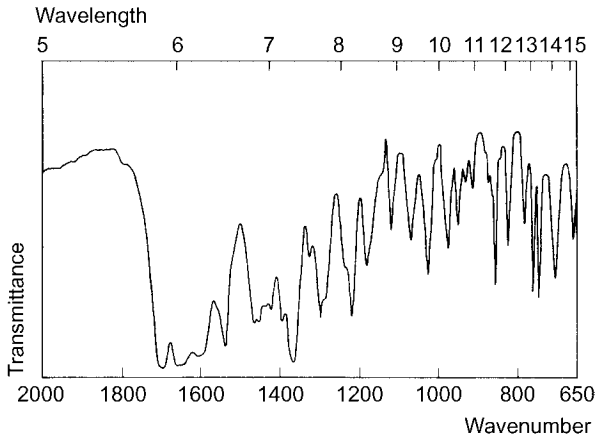
IUPAC Name 2-(1,3-Dimethyl-2,6-dioxopurin-7-yl)acetic acid; piperazine
Synonyms Acepifylline; Piperazine bis(theophyllin-7-ylacetate); piperazine theophylline ethanoate.
Proprietary Names *Dynaphylline*; *Etaphylline*; *Etophylate*.



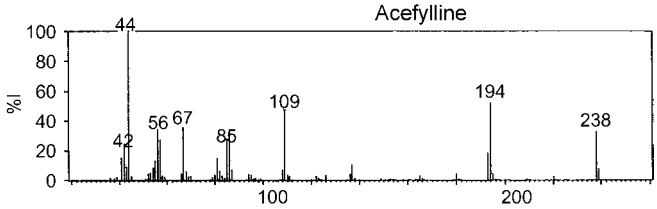
Chemical Properties A white crystalline powder. Mp 260°. Freely soluble in water; slightly soluble in ethanol.
Colour Test Amalic acid test—orange/violet.
Thin-layer Chromatography System TA—R_f 0.04; system TB—R_f 0.01; system TC—R_f 0.01; system TL—R_f 0.01 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—RI 1000.
Ultraviolet Spectrum Aqueous acid—274 nm (A^1_1=317a).



Infrared Spectrum Principal peaks at wavenumbers 1700, 1660, 1612, 1538, 1298, 1219 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 44, 194, 109, 67, 86, 238, 56, 85.



Quantification
Plasma **HPLC** UV detection. Limit of detection, 25 µg/L for theophylline-7-acetic acid [Sved *et al.* 1981].
Urine **GC** FID [Zuidema, Hilbers 1980].
Disposition in the Body Very poorly absorbed after oral administration. It is metabolised to theophylline-7-acetic acid but does not appear to be converted to theophylline.
Therapeutic Concentration Following a single oral dose of 1 g to 2 subjects, peak plasma concentrations of 0.28 and 0.14 µg/mL of theophylline-7-acetic acid were attained in 1.5 and 2 h, respectively [Sved *et al.* 1981].
Half-life Plasma half-life, theophylline-7-acetic acid about 1 to 2 h.
Volume of Distribution Theophylline-7-acetic acid 0.5 L/kg (single subject).
Clearance Plasma clearance, theophylline-7-acetic acid 7 mL/min/kg (single subject).
Dose 1.5 to 3 g daily.

Sved S *et al.* (1981). The assay and absorption kinetics of oral theophylline-7–acetic acid in the human. *Biopharm Drug Disp* 2: 177–184.

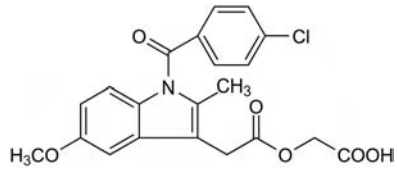
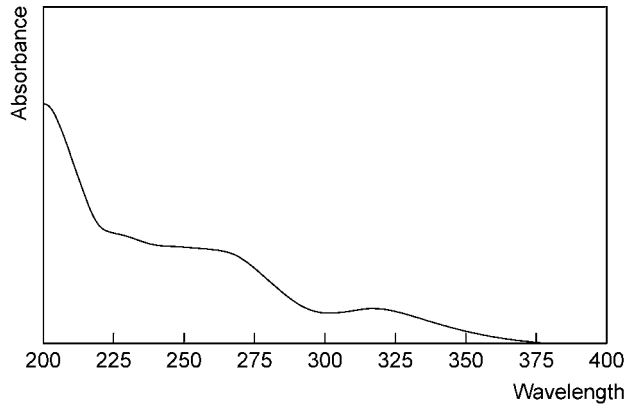
Acemetacin

NSAID
$C_{21}H_{18}ClNO_6$ = 415.8
CAS—53164-05-9
IUPAC Name 2-[2-[1-(4-Chlorobenzoyl)-5-methoxy-2-methylindol-3-yl]acetyl]oxyacetic acid
Synonyms 1-(4-Chlorobenzoyl)-5-methoxy-2-methyl-1*H*-indole-3-acetic acid carboxymethyl ester; TV-1322, TVX-1322.
Proprietary Names *Acemix*; *Altren*; *Emflex*; *Espledol*; *Oldan*; *Peran*; *Rantudil*; *Rheumibis*; *Rheutrop*; *Solart*; *Tilur*.



Chemical Properties Very fine, pale yellow crystals from petroleum ether. Mp 150° to 153°. pK_a 2.9. Log *P* (octanol/water), 4.13.
Gas Chromatography System GA—acemetacin RI 0, acemetacin-ME RI 3150, acemetacin-ET RI 3220, acemetacin art-ME_2 RI 2390.
Ultraviolet Spectrum



Mass Spectrum Principal ions at *m/z* 355, 139, 113, 371, 341, 415.
Quantification
Blood **HPLC** Column: Hypersil ODS (150 × 4.5 mm i.d., 5 µm). Mobile phase: methanol:0.02 mol/L potassium dihydrogen phosphate (57:43), pH 4.5, flow rate 1.25 mL/min. UV detection (λ = 245 nm). Retention time: acemetacin, 5.58 min; indometacin, 9.03 min [Notarianni, Collins 1987]. Limit of detection, 10 µg/L for acemetacin and indometacin, 20 µg/L for *p*-chlorobenzoic acid [Notarianni, Collins 1987]. UV detection. Limit of detection, 25 µg/L for acemetacin and indometacin [Schöllnhammer *et al.* 1986].
Plasma **HPLC** UV detection. Limit of detection, 25 µg/L for acemetacin and indometacin [Schöllnhammer *et al.* 1986].
Disposition in the Body Acemetacin is rapidly and well absorbed after oral administration. It is metabolised to indometacin (major metabolite) and *p*-chlorobenzoic acid (PCBA, minor metabolite and degradation product) by hydrolysis in the liver. The drug is eliminated by both hepatic and renal routes; the pharmacokinetics are unaffected by moderate renal or hepatic impairment.
Therapeutic Concentration
Following administration of 60 mg orally twice a day for 8 days to 10 young (mean age of 30.9 years, between 22 and 44) and 10 elderly subjects (mean 75.9 years, ranging between 68 and 80 years), mean peak plasma concentrations of 187 and 277 µg/L were reached after 2.6 and 2.5 h in the 2 groups, respectively, on day 8 of the study. The peak concentrations for the metabolite, indometacin, were 705 µg/L for the young and 804 µg/L for the elderly. These were observed at 3.1 and 2.9 h, respectively. Each individual suffered with osteoarthritis and was fasted overnight before administration of the drug with a standard breakfast [Jones *et al.* 1991].
Half-life Plasma, 1 h.
Dose 120 to 180 mg daily.

Jones RW *et al.* (1991). The comparative pharmacokinetics of acemetacin in young subjects and elderly patients. *Br J Clin Pharmacol* 31: 543–545.
Notarianni LJ, Collins AJ (1987). Method for the determination of acemetacin, a non-steroidal anti-inflammatory drug, in plasma by high-performance liquid chromatography. *J Chromatogr* 413: 305–308.

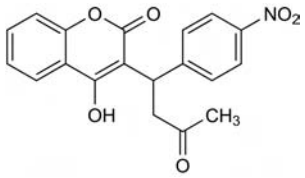
Acenocoumarol

Anticoagulant
$C_{19}H_{15}NO_6$ = 353.3
CAS—152-72-7
IUPAC Name 2-Hydroxy-3-[1-(4-nitrophenyl)-3-oxobutyl]chromen-4-one
Synonyms Acenocumarin; 4-hydroxy-3-[1-(4-nitrophenyl)-3-oxobutyl]-2*H*-1-benzopyran-2-one; nicoumalone; G-23350.

Proprietary Names *Sinthrome*; *Sintrom*.



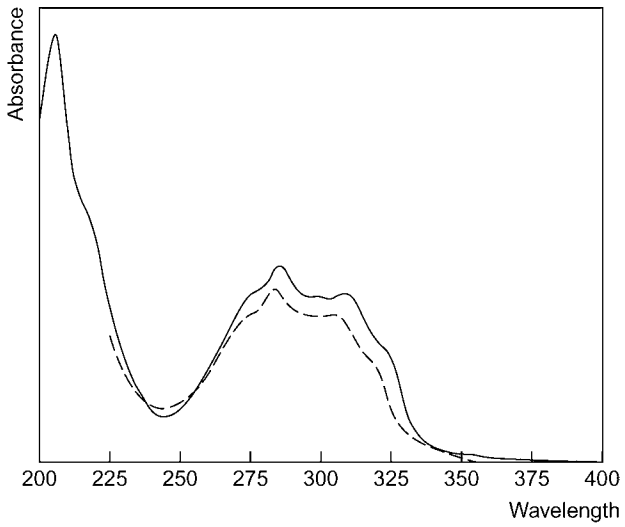
Chemical Properties An almost white to buff-coloured powder. Mp 196° to 199°. Sparingly soluble in water; soluble 1 in 400 of ethanol and 1 in 200 of chloroform; soluble in solutions of alkali hydroxides. pK_a 4.7. Log *P* (octanol/water), 2.0.

Thin-layer Chromatography System TB—R_f 0.00; system TD—R_f 0.52; system TE—R_f 0.16; system TF—R_f 0.48; system TAD—R_f 0.60; system TAE—R_f 0.92; system TAF—R_f 0.92; system TAJ—R_f 0.68; system TAK—R_f 0.51; system TAL—R_f 0.92 (acidified iodoplatinate solution, positive; acidified potassium permanganate solution, positive).

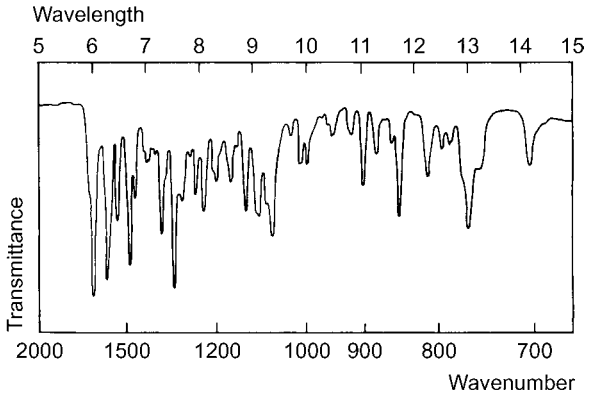
Gas Chromatography System GA—acenocoumarol-Me RI 3035; M (amino-)-Me_3 RI 2985; M (acetamido-)-Me_2 RI 3265; M (OH-)isomer 1-Me_2 RI 3350; M (OH-)isomer 2-Me_2 RI 3500.

High Performance Liquid Chromatography System HX—RI 563; system HZ—retention time 9.1 min; system HAA—retention time 20.1 min.

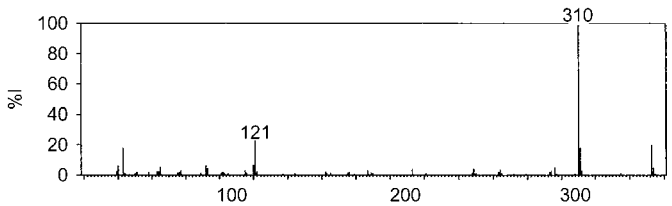
Ultraviolet Spectrum Methanol—283 (A^1_1=640a), 306 nm.



Infrared Spectrum Principal peaks at wavenumbers 1686, 1616, 1508, 1070, 762, 1570 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 310, 121, 353, 311, 43, 120, 92, 296.



Quantification

Plasma **TLC** Fluorescence detection. Limit of detection, 10 µg/L [van Kempen *et al.* 1978].

GC ECD detection. Limit of detection, 500 pg [Bianchetti *et al.* 1976].

GC-MS Limit of detection, 0.8 µg/L [Pommier *et al.* 1994].

HPLC Acenocoumarol enantiomers [Gill *et al.* 1988].

LC-MS Limit of detection, 10 µg/L [Kollroser, Schober 2002].

Serum **HPLC** UV detection. Limit of detection, 15 µg/L [de Wolff *et al.* 1980].

Disposition in the Body Acenocoumarol is readily absorbed after oral administration. It is extensively metabolised by reduction to a number of metabolites including the amino derivative, and the two diastereoisomers of 4-hydroxy-3-[1-(4-nitrophenyl)-3-hydroxybutyl]coumarin. Two further inactive metabolites, the 6-hydroxy- and 7-hydroxycoumarin derivatives have been identified in urine. About 50 to 60% of a dose is excreted in the urine in 48 h, mostly as metabolites, with less than 1% as unchanged drug; about 30% of a dose is eliminated in the faeces.

Therapeutic Concentration

Following a single oral dose of 10 mg to 3 subjects, peak plasma concentrations of about 0.3 mg/L were attained in 2 to 3 h; the amino metabolite was not detected in plasma [Thijssen, Baars 1983].

After a single oral dose of 12 mg to 2 subjects, peak plasma acenocoumarol concentrations of 0.17 and 0.41 mg/L were attained in 3 h; peak concentrations of the amino metabolite of 0.28 and 0.16 mg/L were reported after 6 to 10 h [Dieterle *et al.* 1977].

Following oral administration of 2.5 mg twice daily to 2 subjects, steady-state plasma concentrations of 0.02 to 0.07 mg/L were reported [Bianchetti *et al.* 1976].

Half-life Plasma half-life, about 8 h.

Volume of Distribution About 0.3 L/kg.

Clearance Plasma clearance, about 0.5 mL/min/kg.

Protein Binding About 98%.

Dose Maintenance, 1 to 8 mg daily.

Acepromazine

Phenothiazine, Tranquilliser

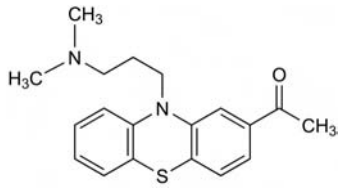
$C_{19}H_{22}N_2OS$ = 326.5

CAS—61-00-7

IUPAC Name 1-[10-[3-(Dimethylamino)propyl]phenothiazin-2-yl]ethanone

Synonyms Acetazine; acetylpromazine; 1522-CB; 1-[10-[3-(dimethylamino) propyl]-10*H*-phenothiazin-2-yl]ethanone.

Proprietary Name *Plégicil*



Chemical Properties An orange-coloured oil. Acepromazine is converted to 2-(1-hydroxyethyl)promazine in whole blood [Elliott, Hale 1999].

Acepromazine Maleate

$C_{19}H_{22}N_2OS,C_4H_4O_4$ = 442.5

CAS—3598-37-6

Proprietary Names *Atravet*; *Calmivet*; *Plégicil*; *PromAce*; *Sedalin*; *Vetranquil*. It is an ingredient of *Immobilon* (for large animals).

Chemical Properties A yellow crystalline powder. Mp 135° to 136°. Soluble 1 in 27 of water, 1 in 13 of ethanol and 1 in 3 of chloroform; slightly soluble in ether and light petroleum. pK_a 9.3. Log *P* (octanol/pH 7.4), 2.3.

Colour Tests Formaldehyde-sulfuric acid—blue-violet; Forrest reagent—red; FPN reagent—brown-orange; Liebermann's reagent—brown; Mandelin's test—green→red; Marquis test—yellow-green-red.

Thin-layer Chromatography System TA—R_f 0.48; system TB—R_f 0.26; system TC—R_f 0.24; system TE—R_f 0.63; system TAE—R_f 0.28; system TAG—R_f 0.12 (acidified iodoplatinate solution, positive).

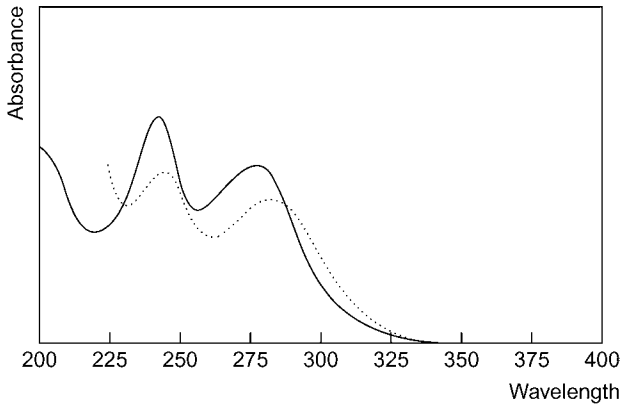
Gas Chromatography System GA—RI 2735 acepromazine, RI 2720 M (dihydro-)-H_2O; system GB—RI 2844 acepromazine, RI 2824 M (dihydro-)-H_2O, RI 3160 M (7-OH-); system GF—RI 3230.

Column: Fused silica capillary (1) J & W DB-1 (15 m × 0.32 mm, 0.25 μm), (2) J & W DB-1301 (15 m × 0.25 mm, 0.25 μm), (3) J & W DB-1 capillary (10 m × 0.18 mm, 0.4 μm). Temperature programme: 120° to 280° at 20°/min (1 and 2), 80° to 300° at 20°/min (3). Carrier gas: He. Detection: NPD (1 and 2); MS (*m/z* 41 to 550) (3). Retention time: 8.1 min (1); 9.4 min (2); 12.2 min (3) [Stowell 1998].

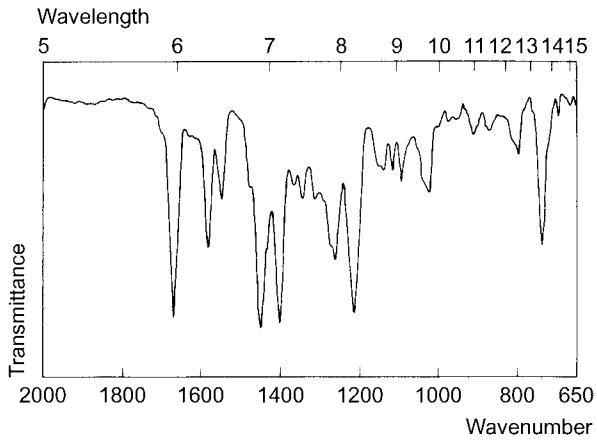
High Performance Liquid Chromatography System HA—*k* 4.1; system HY—RI 350; system HAA—RT 10.8 min.

Column: Spherisorb S5OD/CN (150 × 4.6 mm). Mobile phase: 0 to 70% acetonitrile in 15 min for 3 min, flow rate 2 mL/min. UV detection (λ = 200 to 595 nm). Retention time: 10.5 min [Elliott, Hale 1999].

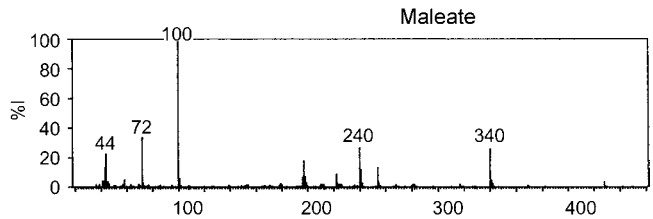
Ultraviolet Spectrum Aqueous acid—243 (A_1^1 = 765a), 279 nm; aqueous alkali—245, 283 nm.



Infrared Spectrum Principal peaks at wavenumbers 1675, 1220, 1265, 1587, 746, 1562 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 100, 72, 240, 340, 44, 197, 254, 43 (maleate).



Quantification

Blood **GC-MS** Column: J & W DB-1 (15 × 0.32 mm, 0.25 μm). Temperature programme: 120° to 280° at 20°/min. Carrier gas: He, 9 psi. NPD. Retention time: 8.1 min. Limit of detection not reported [Stowell 1998].

HPLC Column: Spherisorb S5OD/CN (150 × 4.6 mm i.d.). Mobile phase: 0 to 70% acetonitrile in 15 min, for 3 min, flow rate 2 mL/min. UV detection. Limit of detection, 5 μg/L [Elliott, Hale 1999]. Column: NovaPak C_{18} (300 × 3.9 mm i.d., 4 μm). Mobile phase: methanol : tetrahydrofuran : 10 mmol/L potassium dihydrogen phosphate (pH 2.6; 65 : 5 : 30), flow rate 0.8 mL/min. DAD. Limit of detection not reported [Tracqui *et al.* 1993].

Serum **LC-MS** Column: Betasil C_{18} reversed phase (150 × 4.6 mm i.d., 5 μm). Mobile phase: acetonitrile : 0.1% trifluoroacetic acid (50 : 50 for 2.5 min to 65 : 35 in 1 min for 2 min to 50 : 50 for 0.5 min), flow rate 0.6 mL/min. APCI, positive ion mode, SIM acquisition mode. Retention time, 4.5 min. Limit of quantification, 5.0 μg/L; limit of detection, 2.5 μg/L [Miksa *et al.* 2005].

Stomach Contents **GC-MS** See Blood [Stowell 1998].

Bile **GC-MS** See Blood [Stowell 1998].

Hair **LC-MS** Column: Xterra MS C_{18} reversed phase (50 × 2.1 mm i.d., 5 μm). Mobile phase: 2 mmol/L ammonium formate (pH 3.0) : 2 mmol/L ammonium formate (pH 3.0)-acetonitrile (10 : 90; 85 : 15 at 1 min to 70 : 30 at 6 min to 10 : 90 at 7 min to 85 : 15 at 8 min). ESI, positive ion mode. Limit of quantification, 10 ng/g, limit of detection, 5 ng/g [Gaulier *et al.* 2008].

Liver **GC-MS** See Blood [Stowell 1998].

Disposition in the Body Acepromazine is converted to 2-(1-hydroxyethyl)promazine by red blood cells, and 2-(1-hydroxyethyl)promazine, which may be the major unconjugated metabolite of acepromazine in humans.

Toxicity

A 43-year-old woman was found dead. Acepromazine was found in chest-cavity blood, the liver, brain and bile at concentrations of 0.6, 3.0, 0.4 and 6.5 mg/L, respectively. The stomach contents contained a total of 2.5 mg acepromazine [Stowell 1998].

A 28-year-old woman was found dead and toxicological analysis showed a blood concentration of 2.4 mg/L acepromazine and 3.29 mg/L zolpidem, urine concentration of 0.37 and 2.54 mg/L, respectively, and gastric contents concentration of 20.1 and 34.3 mg/L, respectively [Tracqui *et al.* 1993].

Note For a report of an overdose with Large Animal Immobilon (2.45 g/L etorphine hydrochloride and 10 g/L acepromazine maleate), see Sterken *et al.* [2004].

Dose Acepromazine has been given in doses of 6 to 60 mg daily.

Acetaldehyde

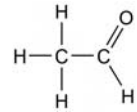
Aldehyde

C_2H_4O = 44.1

CAS—75-07-0

IUPAC Name Acetaldehyde

Synonyms Acetic aldehyde; aldehyde; ethanal; ethyl aldehyde.



Chemical Properties A colourless inflammable liquid. Mp −123.5°. Bp 21.0°. Refractive index, at 20°, 1.3316. Miscible with water, ethanol, and ether.

Colour Tests Potassium dichromate (Method 2)—green; Schiff's reagent—violet; sodium nitroprusside (method 2)—red.

Gas Chromatography System GA—RI 372; system GI—retention time 0.7 min.

Column: Alltech Carbowax megabore capillary (30 m × 0.54 mm, 1.2 μm). Carrier gas: He, 7.9 mL/min. Internal standard: 1-propanol. FID. Retention time: 1.44 min [McCarver-May, Durisin 1997].

Mass Spectrum Principal ions at *m/z* 29, 44, 43, 42, 26, 41, 28, 27.

Quantification

Blood **GC** FID head-space analysis. Limit of detection, 18 μg/L [Christensen *et al.* 1981].

Disposition in the Body Acetaldehyde is a major intermediate metabolite of ethanol and is also a metabolite of metaldehyde, paraldehyde and phenacetin. It undergoes further metabolism by oxidation to acetic acid and, eventually, to carbon dioxide and water. A minor pathway involves condensation with pyruvic acid to form acetoin.

Toxicity Acetaldehyde is more toxic than ethanol or acetic acid. The maximum permissible atmospheric concentration is 100 ppm.

Christensen JM *et al.* (1981). Determination of acetaldehyde in human blood by a gas chromatographic method with negligible artefactual acetaldehyde formation. *Clinica Chim Acta* 116: 389–395.

McCarver-May DG, Durisin L (1997). An accurate, automated, simultaneous gas chromatographic headspace measurement of whole blood ethanol and acetaldehyde for human in vivo studies. *J Anal Toxicol* 21: 134–141.

Acetanilide

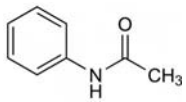
Analgesic

C_8H_9NO = 135.2

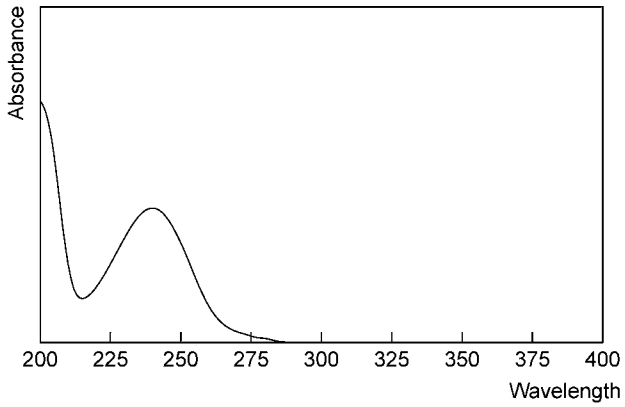
CAS—103-84-4

IUPAC Name *N*-Phenylacetamide

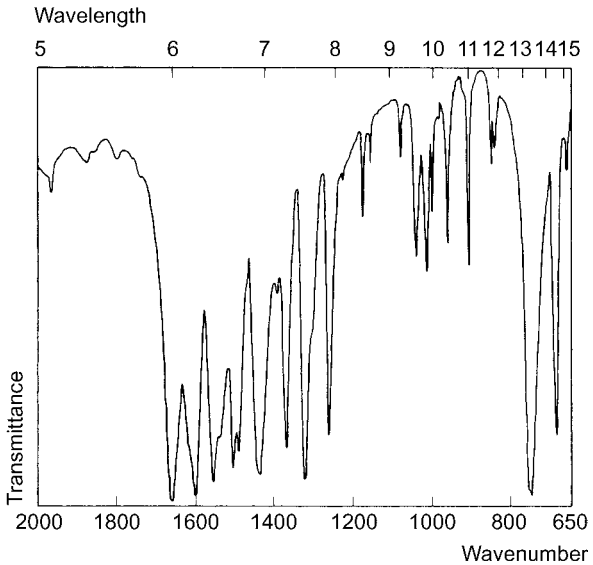
Synonyms Acetylaniline; acetylaminobenzene; antifebrin.



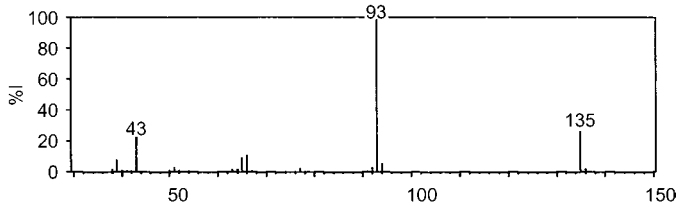
Chemical Properties Colourless shining lamellar crystals or white crystalline powder. Mp 113° to 115°. Soluble 1 in 200 of water, 1 in 20 of boiling water, 1 in 3.5 of ethanol, 1 in 8 of chloroform and 1 in 50 of ether; soluble in acetone. pK_a 0.6 (25°). Log *P* (octanol/water), 1.2.
Colour Test Liebermann's reagent—red→orange
Thin-layer Chromatography System TD—R_f 0.45; system TE—R_f 0.70; system TF—R_f 0.45; system TAD—R_f 0.52; system TAE—R_f 0.80; system TAF—R_f 0.84 (acidified potassium permanganate solution, positive).
Gas Chromatography System GA—acetanilide RI 1368, paracetamol RI 1687; system GB—RI 1400.
High Performance Liquid Chromatography System HA—*k* 0.1; system HD—acetanilide *k* 0.5, paracetamol *k* 0.1; system HW—acetanilide *k* 2.30, paracetamol *k* 0.32; system HY—RI 281.
Ultraviolet Spectrum Aqueous acid—239 nm ($A_1^1 = 815$a). No alkaline shift.



Infrared Spectrum Principal peaks at wavenumbers 1660, 1598, 752, 1538, 1315, 1500 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 93, 135, 43, 66, 65, 39, 94, 92; paracetamol 109, 151, 43, 80, 108, 81, 53, 52.



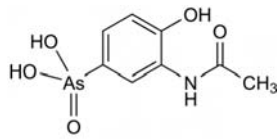
Quantification
Plasma **GC** Column: 3% OV-17 Gas Chrom Q 100-120. Temperature: 195°. Carrier gas: N_2, 50 mL/min. FID. Retention time: 2.5 min. Limit of detection, not reported [Buchanan *et al.* 1980].
Disposition in the Body Rapidly and completely absorbed after oral administration, with maximum plasma concentrations achieved after 1 to 2 h. It is distributed throughout the body. The main metabolic reaction is oxidation to paracetamol through which the analgesic and antipyretic effects of the drug are chiefly exerted; paracetamol is then conjugated with glucuronic acid or sulfate. A minor reaction is deacetylation of acetanilide to aniline. Approximately 0.1% of an oral dose is excreted unchanged in the urine in 24 h, approx. 4% as free paracetamol, 80% as paracetamol conjugates, and 0.05% as aniline. Approximately 0.1% of an oral dose may be eliminated in the faeces.
Toxicity The main toxic effect is the formation of methaemoglobin via production of aniline or other toxic metabolites.
Half-life Plasma half-life, approx. 1.5 h.
Volume of Distribution Approximately 0.7 L/kg.
Clearance Plasma clearance, approx. 6 mL/min/kg.
Protein Binding Not significantly bound.
Dose Acetanilide was formerly given in doses of 0.36 to 1.2 g daily.

Buchanan N *et al.* (1980). Acetanilide pharmacokinetics in kwashiorkor. *Br J Clin Pharmacol* 9: 525–526.

Acetarsone

Antiprotozoal
$C_8H_{10}AsNO_5 = 275.1$
CAS—97-44-9

IUPAC Name (3-Acetamido-4-hydroxyphenyl)arsonic acid
Synonyms Acetarsol; acetphenarsine; acetphenarsinum; [3-(Acetylamino)-4-hydroxyphenyl]arsonic acid; osarsolum.
Proprietary Names *Ehrlich 594*; *Fourneau 190*; *F—190*; *Gynoplix*; *Orarsan*; *Spirocid*; *Stovarsol*; *SVC*.

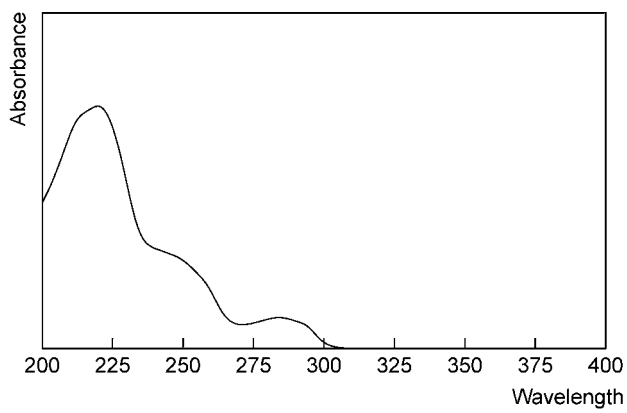


Chemical Properties A white crystalline powder. Mp about 240°, with decomposition. Practically insoluble in cold water, moderately soluble in boiling water; practically insoluble in ethanol; soluble in dilute alkalis. pK_a 3.7, 7.9, 9.3.

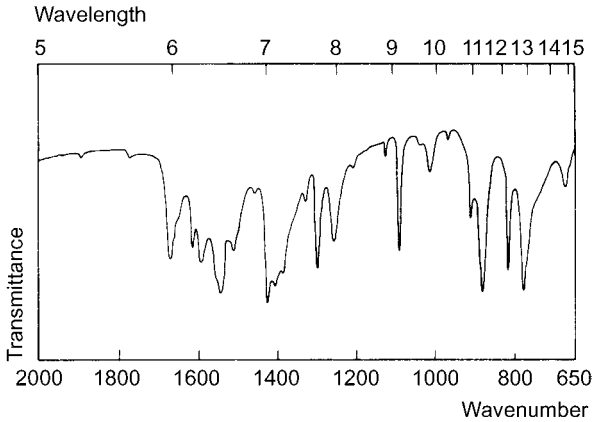
Acetarsone Sodium

$C_8H_9AsNNaO_5,5H_2O = 387.2$
CAS—5892-48-8 (anhydrous)
Chemical Properties White crystals or crystalline powder. Soluble 1 in 7 of water; practically insoluble in ethanol, chloroform and ether.

Ultraviolet Spectrum Aqueous acid—281 nm (A_1^1=94b);aqueous alkali—250 nm (A_1^1=567b), 299 nm (A_1^1=177b).



Infrared Spectrum Principal peaks at wavenumbers 887, 1538, 784, 823, 1297, 1584 cm^{-1} (KBr disk).

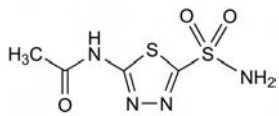


Dose Up to 500 mg daily for 10 days.

Acetazolamide

Antiglaucoma, Diuretic, Carbonic Anhydrase Inhibitor
$C_4H_6N_4O_3S_2$ = 222.3
CAS—59-66-5

IUPAC Name *N*-(5-Sulfamoyl-1,3,4-thiadiazol-2-yl)acetamide
Synonyms 6063; acetazolam; acetazoleamide; *N*-[5-(aminosulfonyl)-1,3,4-thiadiazol-2-yl]acetamide.
Proprietary Names *Acetamox*; *Atenezol*; *Défiltran*; *Diamox*; *Didoc*; *Diuriwas*; *Donmox*; *Edemox*; *Fonurit*; *Glaucomide*; *Glaupax*; *Inidrase*.

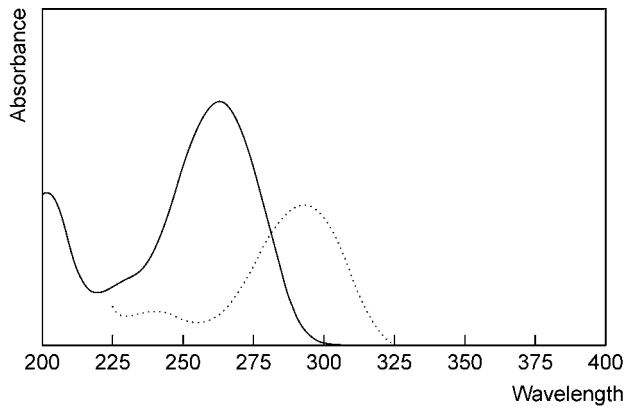


Chemical Properties A fine, white to yellowish-white crystalline powder. Mp about 260°, with decomposition. Soluble 1 in 1400 of water, 1 in 400 of ethanol, and 1 in 100 of acetone; practically insoluble in carbon tetrachloride, chloroform and ether. pK_a 7.2, 9.0 (25°).

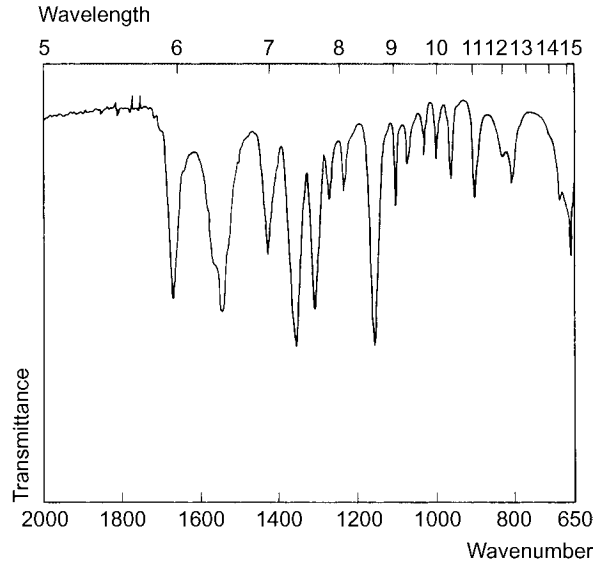
Acetazolamide Sodium

$C_4H_5N_4NaO_3S_2$ = 244.2
CAS—1424-27-7
Proprietary Names *Diamox Sodium*; *Vetamox*.
Chemical Properties Soluble in water.

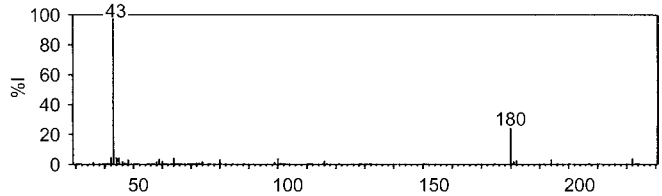
Colour Test Koppanyi-Zwikker test—red-violet (transient).
Thin-layer Chromatography System TA—R_f 0.85; system TD—R_f 0.04; system TE—R_f 0.03; system TF—R_f 0.31; system TAD—R_f 0.18; system TAE—R_f 0.84; system TAJ—R_f 0.18; system TAK—R_f 0.01; system TAL—R_f 0.60.
Gas Chromatography-Mass Spectrometry Column: fused silica capillary cross-linked 5% phenylmethylsilicone (25 m × 0.2 mm, 0.33 µm). Temperature programme of 230° to 320° at 35°/min. Injector: 280°. Detector: 300°. Carrier gas: He, 1 mL/min flow rate. Internal standard (IS): mefruside. (SIM acquisition mode at *m/z* 249 and *m/z* 85 for IS). Retention time: acetazolamide, 3.62 min (*k* 0.684); IS, 7.43 min (*k* 2.46) [Carreras *et al.* 1994].
High Performance Liquid Chromatography System HA—*k* 0.1; system HX—RI 268; system HY—RI 226; system HZ—retention time 1.9 min; system HAA—retention time 6.9 min.
Ultraviolet Spectrum Aqueous acid—265 nm (A^1_1=475a); aqueous alkali—240, 291 nm.



Infrared Spectrum Principal peaks at wavenumbers 1167, 1548, 1316, 1665, 671, 1115 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 43, 180, 42, 45, 44, 64, 100, 222.



Quantification
Blood **GC** ECD detection. Limit of detection, 10 pg [Wallace *et al.* 1977].
GC-MS Limit of detection, 25 pg [Kishida *et al.* 1981].
HPLC UV detection. Limit of detection, 50 µg/L [Chapron, White 1984].
Plasma **GC** ECD. Limit of detection, 10 pg [Wallace *et al.* 1977].
HPLC UV detection (λ=254 nm). Limit of detection, 5 µg/L [Zarghi, Shafaati 2002]. UV detection. Limit of detection, 50 µg/L [Chapron, White 1984].
Saliva **GC** ECD. Limit of detection, 10 pg [Wallace *et al.* 1977].
GC-MS Limit of detection, 25 pg [Kishida *et al.* 1981].
Urine **HPLC** UV detection. Limit of detection, 50 µg/L [Chapron, White 1984].
Disposition in the Body Acetazolamide is readily absorbed after oral administration. It binds tightly to carbonic anhydrase and will accumulate in tissues in which this enzyme is present, particularly in red blood cells and the renal cortex. About 70 to 90% of a dose is excreted in the urine as unchanged drug in 24 h but the renal clearance is increased if the urine is alkaline; small amounts of unchanged drug are excreted in the bile. The plasma:saliva ratio is about 100.
Therapeutic Concentration In plasma, usually in the range 10 to 15 mg/L.
Following a single oral dose of 250 mg to 5 subjects, peak plasma concentrations of 10 to 18 (mean 14) mg/L were attained in 1 to 3 h; peak erythrocyte concentrations of 13 to 29 mg/L were reached about 1 h after the peak plasma concentrations [Wallace *et al.* 1977].
A patient with type I diabetes and end-stage renal disease (ESRD) undergoing continuous ambulatory peritoneal dialysis (CAPD) was administered a 250 mg oral dose of acetazolamide after surgery for a detached retina. The concentration of acetazolamide in serum was measured prior to the dose and 12 additional times over a 24 hrs dosing period. The serum concentration at the beginning of the dosing period was 18 µg/mL and at the end 17 µg/mL with a maximum concentration of 27 µg/mL at 6.5 h. The therapeutic range was 5 to 10 µg/mL [Schwenk *et al.* 1994].
Toxicity Fatal cases of agranulocytosis, aplastic anaemia and thrombocytopenia have been reported.
Half-life Plasma half-life, about 13 h; blood and erythrocyte concentrations decrease more slowly.
Volume of Distribution About 0.2 L/kg.
Protein Binding About 90 to 95%.
Dose In the treatment of glaucoma 0.25 to 1 g daily.

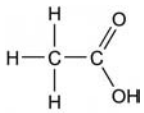
Acetic Acid Glacial

Acid
$CH_3{\cdot}COOH = 60.1$
CAS—64-19-7

IUPAC Name Acetic acid
Synonyms Acetic acid; acide acetique cristallisable; concentrated acetic acid



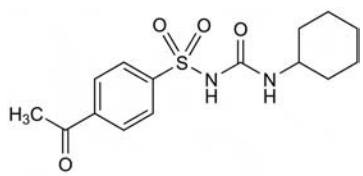
Chemical Properties A translucent crystalline mass or a clear colourless liquid. Mp 15°. Bp about 117°. Refractive index, at 20°, 1.3718. Miscible with water, ethanol, chloroform and ether. pK_a 4.8 (25°).
Colour Test Ferric chloride—red.
Mass Spectrum Principal ions at *m/z* 45, 29, 43, 60, 42, 28, 44, 41.
Quantification
Blood **GC** FID. Limit of detection, 1 µg/mL [Lester 1964].
Disposition in the Body Acetic acid occurs as a metabolite of ethanol and also of paraldehyde after its depolymerisation to acetaldehyde. It is further oxidised to carbon dioxide and water.
Toxicity The estimated minimum lethal dose is 5 mL and the maximum permissible atmospheric concentration is 10 ppm.

Lester D (1964). *Anal Chem* 36: 1810–1812.

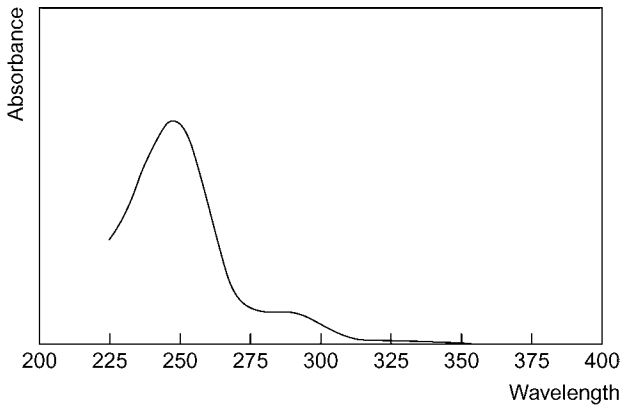
Acetohexamide

Antidiabetic
$C_{15}H_{20}N_2O_4S = 324.4$
CAS—968-81-0

IUPAC Name 1-(4-Acetylphenyl)sulfonyl-3-cyclohexylurea
Synonyms 4-Acetyl-*N*-[(cyclohexylamino)carbonyl]benzenesulfonamide; cyclamide; tsiklamid.
Proprietary Names *Dimelor*; *Dimeline*; *Dymelor*; *Ordimel*.

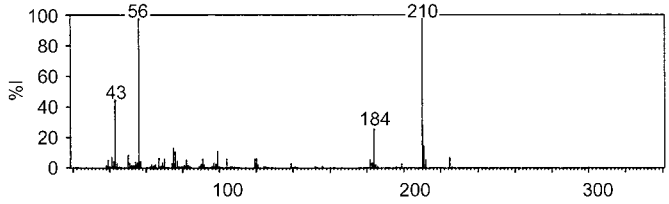


Chemical Properties A white crystalline powder. Mp 182° to 187°. Practically insoluble in water and ether; soluble 1 in 230 of ethanol and 1 in 210 of chloroform; soluble in pyridine and in dilute solutions of alkali hydroxides.
Colour Test Koppanyi-Zwikker test—violet.
Thin-layer Chromatography System TD—R_f 0.39; system TE—R_f 0.12; system TF—R_f 0.43; system TAD—R_f 0.53; system TAJ—R_f 0.60; system TAK—R_f 0.66; system TAL—R_f 0.91.
High Performance Liquid Chromatography System HY—RI 438.
Ultraviolet Spectrum Aqueous acid—247 nm (A_1^1=508b);aqueous alkali—249 nm (A_1^1=427a).



Infrared Spectrum Principal peaks at wavenumbers 1165, 1031, 1681, 1531, 905, 1264 cm^{-1} (Nujol mull).

Mass Spectrum Principal ions at *m/z* 210, 56, 43, 184, 211, 75, 99, 76.



Quantification
Plasma **Spectrofluorimetry** Limit of detection, 200 ng [Girgis-Takla, Chroneos 1979].
Biological Fluids **GC** FID [Kleber *et al.* 1977].
Disposition in the Body Readily absorbed after oral administration and rapidly metabolised to (−)-1-hydroxyhexamide which has about 2.5 times the hypoglycaemic activity of the unchanged drug. Minor metabolites include 4′-*trans*-hydroxyacetohexamide, 4′-*trans*-hydroxy-1-hydroxyhexamide and, to a lesser extent, the 4′-*cis*-, 3′-*cis*- and 3′-*trans*-isomers. About 80% of a dose is excreted in the urine in 24 h, mainly as metabolites.
Therapeutic Concentration In plasma, usually in the range 20 to 60 µg/mL. Following oral administration of 750 mg of 3 different tablet formulations to 8 subjects, mean peak plasma-acetohexamide concentrations of about 28, 40, and 44 mg/L were attained 2 h after a dose; mean peak plasma concentrations of (−)-1-hydroxyhexamide averaged about 30 mg/L [Kleber *et al.* 1977].
After daily oral doses of 0.5 g to 18 subjects, an average serum concentration of 42 mg/L was reported 3 to 5 h after the dose [Sheldon *et al.* 1965].
Toxicity Prolonged hypoglycaemia has been reported.
Half-life Plasma half-life, acetohexamide about 1.3 h, (−)-1-hydroxyhexamide about 5 h.
Protein Binding About 96%.
Note For a review of the pharmacokinetics of oral hypoglycaemic agents, see Balant [1981].
For a review of the relationship between the pharmacokinetics and pharmacodynamic effects of oral hypoglycaemic drugs, see Ferner and Chaplin [1987].
Dose 0.25 to 1.5 g daily.

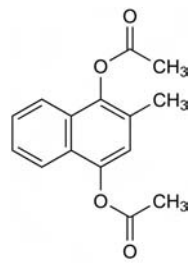
Acetomenaphthone

Vitamin K Activity
$C_{15}H_{14}O_4 = 258.3$
CAS—573-20-6

IUPAC Name (4-Acetyloxy-2-methylnaphthalen-1-yl) acetate
Synonyms Acetomenadione; 1,4-diacetoxy-2-methylnaphthalene; dihydrovitamin K_3; menadiol diacetate; vitamin-K_4.
Proprietary Names *Kapilin*; *Prokayvit Oral*; *Vitavel K*. It is an ingredient of *Pernivit*.



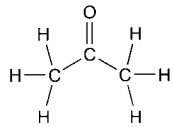
Chemical Properties A white crystalline powder. Mp 112° to 115°. Practically insoluble in water; slightly soluble in cold ethanol; soluble 1 in 3.3 of boiling ethanol; soluble in acetic acid.
Colour Test Liebermann's reagent—black.
Ultraviolet Spectrum Dehydrated alcohol—285 nm (A_1^1=245b), 322 nm (A_1^1=37b).
Infrared Spectrum Principal peaks at wavenumbers 1210, 1760, 1163, 1070, 775, 1030 cm^{-1} (KBr disk).
Dose 5 to 20 mg daily.

A

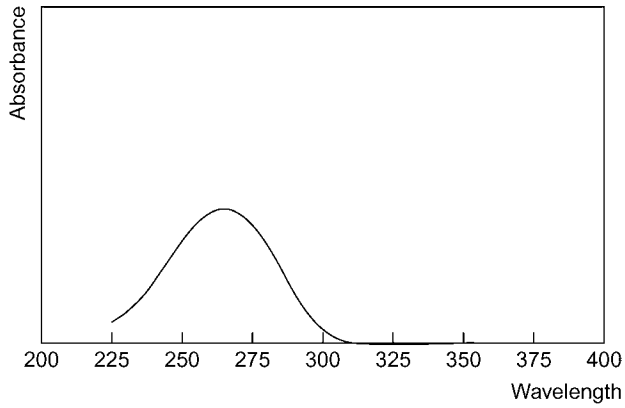
Acetone

Solvent
C_3H_6O = 58.08
CAS—67-64-1

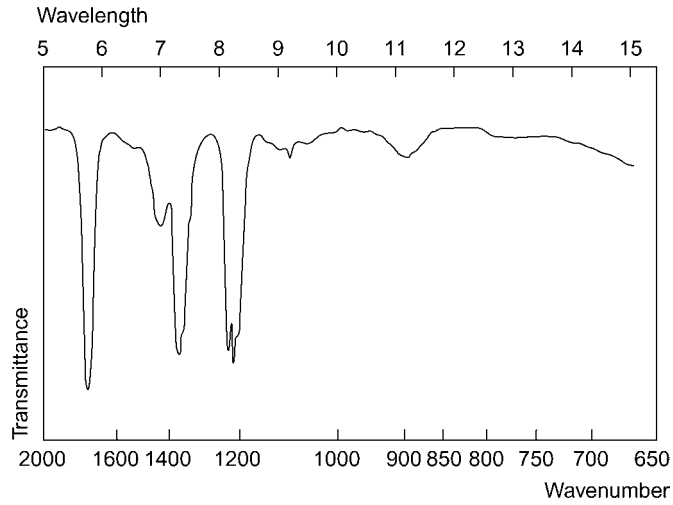
IUPAC Name Propan-2-one
Synonyms Cetona; dimethylformaldehyde; dimethyl ketone; β-ketopropane; 2-propanone; pyroacetic ether.



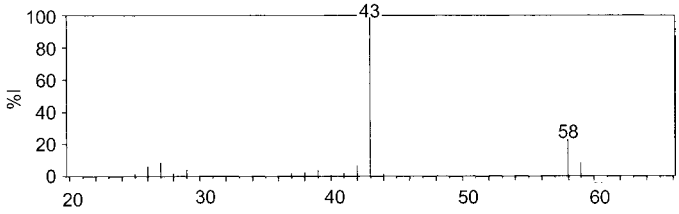
Chemical Properties A clear, colourless, volatile, mobile, inflammable liquid. Mp −94°. Bp approx. 56°. Refractive index 1.3591. Miscible with water, ethanol, chloroform and ether. Log *P* (octanol/water), −0.2.
Colour Test Sodium nitroprusside (method 1)—red.
Gas Chromatography System GA—RI 469; system GI—RT 2.5 min.
Ultraviolet Spectrum Aqueous acid—265 nm.



Infrared Spectrum Principal peaks at wavenumbers 1750, 1330 and 1200 cm^{-1}.



Mass Spectrum Principal ions at *m/z* 43, 58, 59, 27, 42, 26, 39, 29.



Quantification
Plasma **GC** Column: Chromosorb 102 (1.5 m × 4 mm i.d.). Temperature: 115°. Carrier gas: N_2, 50 mL/min. FID. Retention time: 7.3 min. Limit of detection, 0.1 mmol/L [Trotter *et al.* 1971].

HPLC Column: Pecosphere 3 × 3 C_{18} (33 × 4.6 mm i.d., 3 µm). Mobile phase: acetonitrile : water (45 : 55), flow rate 1.0 mL/min. UV detection. Retention time: 3 min. Limit of detection, 0.034 mmol/L [Brega *et al.* 1991].

Serum **GC** Column: Restek Rtx-200 (30 m × 0.53 mm i.d., 3 µm). Temperature programme: 40° for 1 min to 260° at 70°/min. Carrier gas: He, 80.1 mL/min. IS: *n*-propanol. FID. Retention time: acetone, 1.76 min; IS, 1.54 min Limit of quantification, 2.5 mg/L, limit of detection, 1.0 mg/L [Williams *et al.* 2000].
Urine **GC** Column: 10% SBS-100 (4.1 m × 3.2 mm i.d.). Temperature: 60°. Carrier gas: N_2. FID. Limit of detection not reported [Fujino *et al.* 1992].

HPLC Column: Pecosphere 3 × 3 C_{18} (33 × 4.6 mm i.d., 3 µm). Mobile phase: acetonitrile : water (45 : 55), flow rate 1.0 mL/min. UV detection. Limit of detection, 0.034 mmol/L [Brega *et al.* 1991].
Alveolar Air **GC** Column: BX100 (1 m × 3 mm i.d.). Temperature: 90°. FID. Limit of detection not reported [Fujino *et al.* 1992]. Column: Chromosorb 102 (1.5 m × 4 mm i.d.). Temperature: 115°. Carrier gas: N_2, 50 mL/min. FID. Retention time: 7.3 min. Limit of detection, 0.1 mmol/L [Trotter *et al.* 1971].
Disposition in the Body Acetone is absorbed through the lungs and skin. It is excreted in the urine and through the lungs; large amounts are mainly excreted unchanged but small doses may be oxidised to carbon dioxide or utilised in the body as acetate or formate. Acetone is the main metabolite of isopropyl alcohol; it occurs naturally in the blood and urine of diabetics.
Therapeutic Concentration

Observations were made for 89 non-occupationally exposed subjects and 3 groups of workers exposed to acetone or isopropanol on a daily basis. Acetone was detected in all samples from the non-exposed subjects at mean concentrations of 840 µg/L in blood, 842 µg/L in urine, 715 mg/L in alveolar air and 154 ng/L in environmental air. The morning after a shift, workers had concentrations of acetone in their blood and urine of 3.5 mg/L and 13 mg/L, respectively. This was after mean environmental air acetone exposure of 336 µg/L [Wang *et al.* 1994].

One-hundred and ten male workers exposed to acetone or acetate fibres had urine acetone concentrations of 2.4 ± 5.6 mg/L compared with 1.3 ± 2.4 mg/L in non-exposed workers [Satoh *et al.* 1995].

Toxicity Acetone is one of the solvents abused in 'glue-sniffing'. Severe toxic effects have been associated with blood concentrations of 200 to 300 mg/L; a blood concentration of 550 mg/L has been reported in a fatality. The maximum permissible atmospheric concentration is 1000 ppm. Exposure to 1600 ppm for about 15 min causes irritation to the eyes and nose. Up to 20 mL has been ingested without ill-effect.

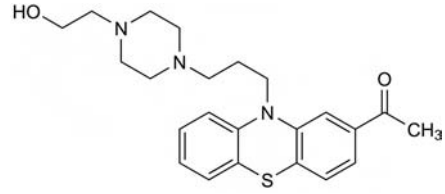
Acetophenazine

Antipsychotic, Tranquilliser
$C_{23}H_{29}N_3O_2S$ = 411.6
CAS—2751-68-0

IUPAC Name 1-[10-[3-[4-(2-Hydroxyethyl)piperazin-1-yl]propyl]phenothiazin-2-yl] ethanone
Synonyms Acephenazine; 1-[10-[3-[4-(2-hydroxyethyl)-1-piperazinyl]propyl]-10*H*-phenothiazin-2-yl]ethanone.

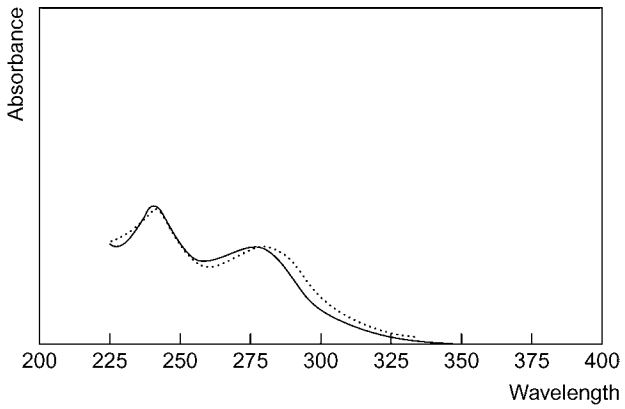


Acetophenazine Dimaleate

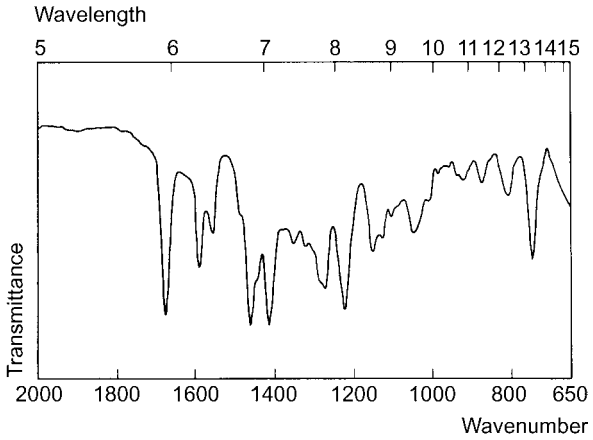
$C_{23}H_{29}N_3O_2S,2C_4H_4O_4$ = 643.7
CAS—5714-00-1
Proprietary Name *Tindal*
Chemical Properties A fine yellow powder. Mp about 165°, with decomposition. Soluble 1 in 10 of water, 1 in 260 of ethanol, 1 in 370 of acetone, 1 in 2850 of chloroform, 1 in 6000 of ether, and 1 in 11 of propylene glycol.

Colour Tests Formaldehyde–sulfuric acid—blue-violet; Forrest reagent—pink-orange; FPN reagent—orange; Liebermann's reagent—brown; Marquis test—red-violet.
Thin-layer Chromatography System TA—R_f 0.53; system TB—R_f 0.03; system TC—R_f 0.25; system TE—R_f 0.38; system TL—R_f 0.03; system TAE—R_f 0.34; system TAF—R_f 0.32; system TAJ—R_f 0.05; system TAK—R_f 0.00; system TAL—R_f 0.33(Dragendorff spray, positive; FPN reagent, pink; acidified iodoplatinate solution, positive; Marquis reagent, orange).
Gas Chromatography System GA—not eluted.

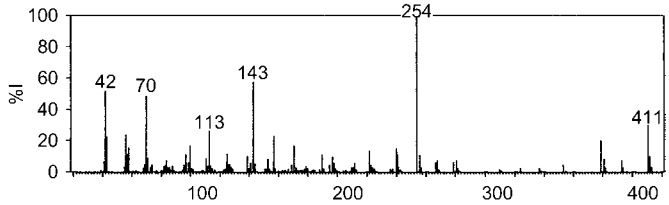
High Performance Liquid Chromatography System HA—*k* 1.9.
Ultraviolet Spectrum Aqueous acid—243 nm (A^1_1=500a), 278 nm.



Infrared Spectrum Principal peaks at wavenumbers 1670, 1220, 1265, 1587, 746, 1149 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 254, 143, 42, 70, 411, 113, 56, 157.

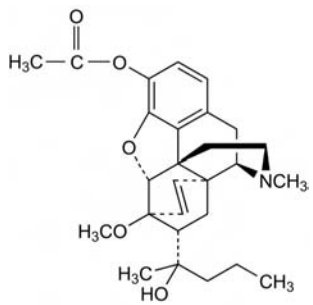


Dose 40 to 120 mg of acetophenazine maleate daily; up to 600 mg daily has been given.

Acetorphine

Narcotic Analgesic (Veterinary)
$C_{27}H_{35}NO_5$ = 453.6
CAS—25333-77-1

Synonym O^3-Acetyl-7,8-dihydro-7α-[1(*R*)-hydroxy-1-methylbutyl]-O^6-methyl-6,14-*endo*-ethenomorphine

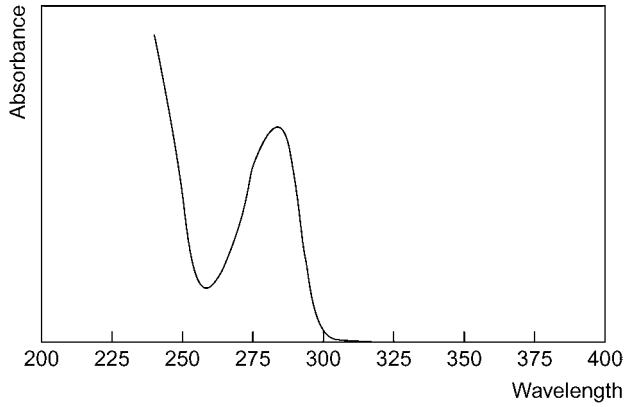


Chemical Properties Mp 193°. Soluble 1 in 4000 of water; freely soluble in ethanol, chloroform and ether.

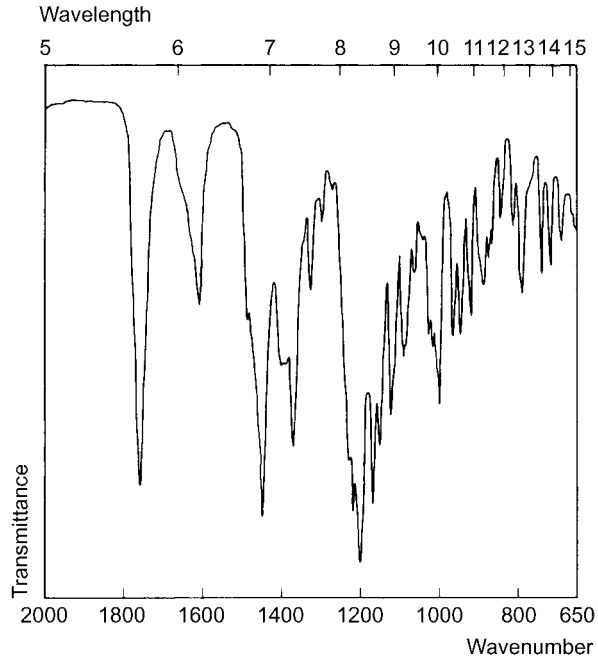
Caution It is dangerous to smell or taste this substance.

Acetorphine Hydrochloride
$C_{27}H_{35}NO_5$,HCl = 490.0
CAS—25333-78-2
Synonym M183
Chemical Properties A white, crystalline, hygroscopic powder. Mp 204°. It is hydrolysed in solution to etorphine and acetic acid.
Soluble 1 in 50 of water and 1 in 10 of ethanol.

Colour Test Marquis test—blue-grey→yellow-brown.
Thin-layer Chromatography System TA—R_f 0.72 (acidified iodoplatinate solution, positive; Marquis reagent, grey; acidified potassium permanganate solution, positive).
High Performance Liquid Chromatography System HA—*k* 0.4.
Ultraviolet Spectrum Aqueous acid—284 nm (A^1_1=45b).



Infrared Spectrum Principal peaks at wavenumbers 1200, 1218, 1168, 1760, 1150, 1122 cm^{-1} (acetorphine hydrochloride, KBr disk).



Acetylcholine Chloride

Parasympathomimetic
$C_7H_{16}ClNO_2$ = 181.7
CAS—60-31-1

IUPAC Name 2-Acetyloxyethyl(trimethyl)azanium chloride
Synonym 2-(Acetyloxy)-*N*,*N*,*N*-trimethylethanaminium chloride
Proprietary Names *Acecoline*; *Arterocoline*; *Miochol*; *Ovisot*.
Chemical Properties A white, very hygroscopic, crystalline powder. Mp about 150°. Very soluble in water yielding unstable solutions; very soluble in ethanol and propylene glycol; freely soluble in chloroform; practically insoluble in ether.

A

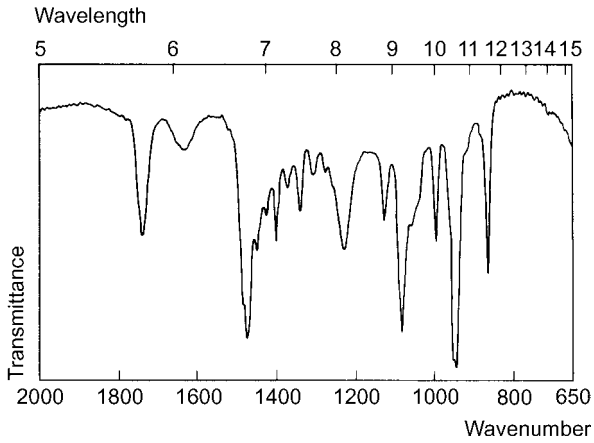
Acetylcholine Bromide

$C_7H_{16}BrNO_2$ = 226.1
CAS—66-23-9

Chemical Properties Deliquescent colourless crystals or white crystalline powder. Hydrolysed by hot water and alkalis. Mp 143°. Freely soluble in water; soluble in ethanol; practically insoluble in ether.

Thin-layer Chromatography System TA—R_f 0.02; system TN—R_f 0.70; system TO—R_f 0.60 (acidified iodoplatinate solution, positive).

Infrared Spectrum Principal peaks at wavenumbers 949, 1089, 869, 1231, 1000, 1740 cm^{-1} (KBr disk).



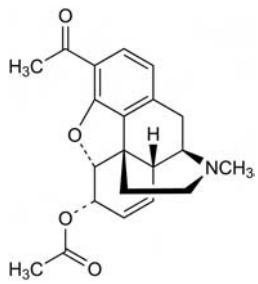
Mass Spectrum Principal ions at *m/z* 58, 43, 57, 149, 71, 42, 41, 55.

Dose Acetylcholine chloride is used as a 1% ophthalmic solution; it was formerly given parenterally in doses of 20 to 200 mg.

Acetylcodeine

Morphine Impurity
$C_{20}H_{23}NO_4$ = 341.4
CAS—6703-27-1

Synonym 3-*O*-Methyl-6-*O*-acetylmorphine



Chemical Properties Mp 134° to 135°. It is a contaminant of codeine and up to 12% may be found in illicit heroin. Stable for 48 h at 4°, 16 h at room temperature and after 3 freeze-thaw cycles [Brunet *et al.* 2008]. Stable in urine for 23 weeks [O'Neal, Poklis 1997].

Thin-layer Chromatography System TA—R_f 0.44; system TB—R_f 0.23; system TC—R_f 0.43; system TE—R_f 0.54; system TL—R_f 0.12; system TAE—R_f 0.26; system TAF—R_f 0.25; system TAJ—R_f 0.32; system TAK—R_f 0.05; system TAL—R_f 0.61.

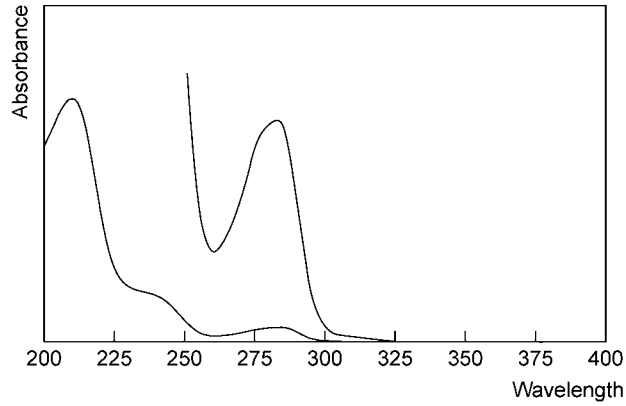
Gas Chromatography System GA—RI 2503; system GB—RI 2645; system GM—RRT 1.449 (relative to iprindole).

High Performance Liquid Chromatography System HC—*k* 0.78; system HS—*k* 0.50; system HX—RI 336.

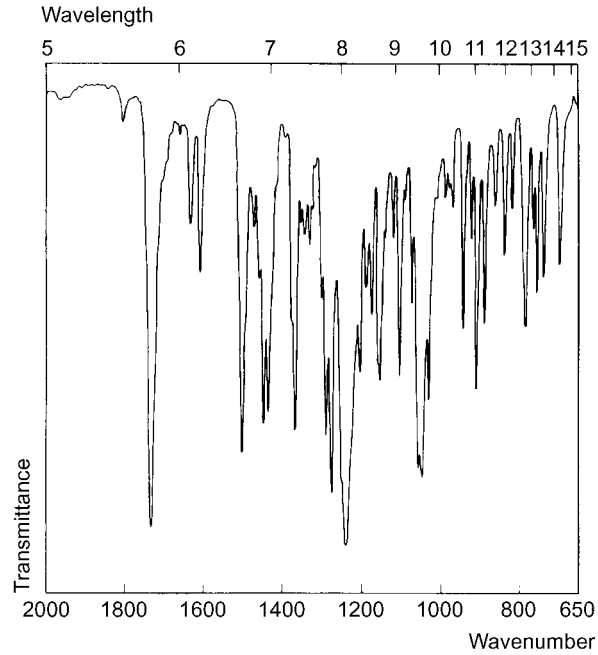
Column: aminopropyl-bonded silica (250 × 4.0 mm). Mobile phase: acetonitrile : 0.005 mol/L tetrabutylammonium phosphate (85 : 15), flow rate 1.0 mL/min. UV detection (λ = 284 nm). Relative retention time: 1.13. Limit of detection, 2.0 µg [Baker, Gough 1981].

Liquid Chromatography-Gas Chromatography Column: Zorbax Extend C_{18} (50 × 2.1 mm i.d., 3.5 µm). Mobile phase: 5 mmol/L ammonium formate-0.1% formic acid : acetonitrile (95 : 5 to 85 : 15 in 18 min, to 80 : 20 in 5 min, to 95 : 5 in 0.1 min), flow rate 0.4 mL/min. ESI, positive ion mode [Zhang *et al.* 2008].

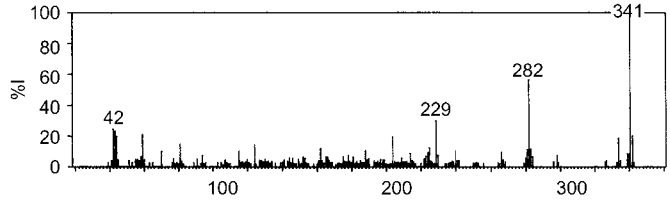
Ultraviolet Spectrum Aqueous acid—284 nm (A_1^1 = 37b)



Infrared Spectrum Principal peaks at wavenumbers 1233, 1731, 1272, 1042, 1055, 1501 cm^{-1}.



Mass Spectrum Principal peaks at *m/z* 341, 282, 229, 42, 43, 59, 342, 204 [Paul *et al.* 1985].



Quantification

Plasma **LC-MS** Column: Zorbax Bonus (150 × 4.6 mm i.d., 5 µm). Mobile phase: ammonium formate buffer (pH 4.0) : acetonitrile (97 : 3 for 2 min to 87 : 13 at 2.6 min to 84.5 : 15.5 at 8.0 min to 20 : 80 at 8.1 min until 11 min, to 97 : 3 at 11.1 min until 15 min). ESI, MRM acquisition mode. Retention time: 7.8 min. Limit of quantification, 5 µg/L [Rook *et al.* 2005; Rook *et al.* 2006].

Urine **GC-MS** Column: DB-5MS (25 m × 0.2 mm i.d., 0.33 µm). Carrier gas: He, 20.4 cm/s. Temperature programme: 180° for 1 min to 280° at 10°/min for 14 min. MSD, SIM acquisition mode. Limit of quantification, 0.2 µg/L, limit of detection, 0.1 µg/L [Brenneisen *et al.* 2002]. Column: DB-5MS (15 m × 0.25 mm i.d., 0.25 µm). Temperature programme: 170° for 1 min to 240° at 20°/min to 256° at 2°/min to 270° at 10°/min for 0.6 min. EI ionisation. Limit of quantification, 1 µg/L [Staub *et al.* 2001]. Column: HP-1 (12 m × 0.2 mm i.d., 0.33 µm). Temperature programme: 170° for 1 min to 280° at 10°/min. MSD, SIM acquisition mode. Limit of detection, 2 µg/L [O'Neal, Poklis 1998]. Limit of quantification, 1.0 µg/L, limit of detection, 0.5 µg/L [O'Neal, Poklis 1997]. Column: DB-5 (15 m × 0.25 mm i.d.). Carrier gas: He, 1.6 mL/min. EI ionisation at 70 eV. Retention time: 3.26 min [Paul *et al.* 1985].

LC-MS Column: Phenomenex C_{18} AQUA (150 × 2 mm i.d., 4 µm). Mobile phase: water-acetonitrile (98 : 2) and 5 mmol/L ammonium acetate : water-acetonitrile (10 : 90) and 5 mmol/L ammonium acetate (95 : 5 to 0 : 100 in 6 min for 4 min to 95 : 5 at 13 min for 6 min), flow rate 200 µL/min. ESI, positive ion mode, MRM acquisition mode. Limit of quantification, 1.16 µg/L, limit of detection, 0.35 µg/L [Musshoff *et al.* 2004]. Column: RP18 (125 × 3 mm i.d.). Mobile phase: acetonitrile: 0.05 mmol/L ammonium formate buffer (pH 3.0, 30 : 70), flow rate 0.4 mL/min. SIM acquisition mode, positive ion mode. Limit of detection, 2.0 µg/L [Bogusz *et al.* 2001].

Oral Fluid **GC-MS** Column: capillary (15 m × 0.25 mm i.d.). EI ionisation. Limit of quantification, 2.0 µg/L [Cone *et al.* 2007].

LC-MS Column: EXSIL BDS C_8 (50 × 3.2 mm i.d.). Mobile phase: 5% methanol in 4 mmol/L ammonium formate: 1% propan-2-ol and 0.05% formic acid in methanol (100 : 0 for 1 min to 5 : 95 over 3 min for 2 min to 100 : 0 over 0.1 min for 1 min. TIS, ESI, positive ion mode, MRM acquisition mode. Limit of quantification, 2 µg/L, limit of detection, 1 µg/L [Phillips, Allen 2006].

Sweat **GC-MS** Column: HP-5MS (30 m × 0.32 mm i.d., 0.25 µm). Carrier gas: He, 1.1 mL/min. Temperature programme: 100° for 0.5 min to 245° at 25°/min to 255° at 2°/min to 300° at 30°/min for 0.7 min. EI ionisation. Retention time: 11.1 min. Limit of detection, 5 ng/patch [Brunet *et al.* 2008].

Hair **GC-MS** Column: HP-5MS (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1.0 mL/min. Temperature programme: 180° for 1 min to 190° at 15°/min for 10 min to 250° at 5°/min to 290° at 30°/min for 2 min. Limit of quantification, 0.13 ng/mg, limit of detection, 0.02 g/mg [Musshoff *et al.* 2005; Musshoff *et al.* 2009]. Column: DB-5MS (15 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He. Temperature programme: 170° for 1 min to 240° at 20°/min to 256° at 2°/min to 270° at 10°/min for 0.6 min. SIM acquisition mode. Limit of quantification, 0.09 ng/mg [Girod, Staub 2001]. Column: HP5-MS 5% phenyl 95% methylsiloxane (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1.0 mL/min. Temperature programme: 60° for 1 min to 295° at 30°/min for 6 min. EI ionisation. Retention time: 10.1 min. Limit of quantification, 10 pg/mg [Kintz *et al.* 1998; Polettini *et al.* 1997].

Acetylcysteine

Mucolytic, Antidote (Parametamol)

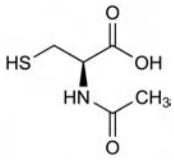
$C_5H_9NO_3S$ = 163.2

CAS—616-91-1

IUPAC Name (2*R*)-2-Acetamido-3-sulfanylpropanoate

Synonym *N*-Acetylcysteine

Proprietary Names *Airbron*; *Brunac*; *Fabrol*; *Fluimucil*; *Fluprowit*; *Mucocedyl*; *Mucolyticum*; *Mucolator*; *Mucomyst*; *Muco sanigen*; *Mucosil*; *Mucret*; *Nac*; *Neo-Flumucil*; *Parvolex*; *Tixair*.



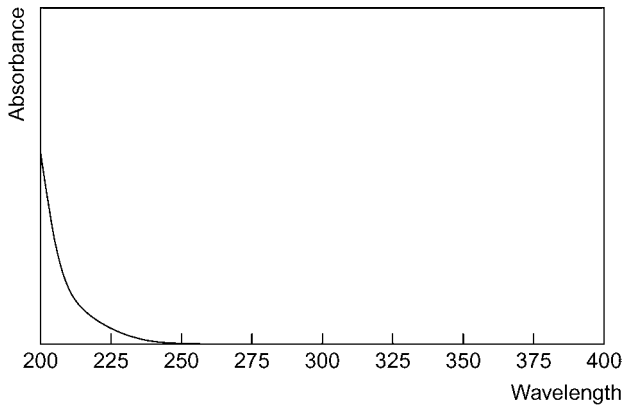
Chemical Properties A white, crystalline, deliquescent powder. Mp 104° to 110°. Soluble 1 in 8 of water and 1 in 2 of ethanol; practically insoluble in chloroform and ether. pK_a 9.5 (30°).

Thin-layer Chromatography System TE—R_f 0.00; system TF—R_f 0.00.

Gas Chromatography System GA—RI 1547.

High Performance Liquid Chromatography System HX—RI 149; system HY—RI 176; system HZ—RT 1.57 min.

Ultraviolet Spectrum No significant absorption, 230–360 nm.



Infrared Spectrum Principal peaks at wavenumbers 1530, 1300, 1230, 1275, 1580, 1715 cm^{-1} (Nujol mull).

Quantification

Plasma **HPLC** Column: Kromasil C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: methanol : water : tetrahydrofuran : triprotic citric acid–sodium hydroxide buffer (pH 6.6, 75 : 18 : 4 : 3), flow rate 0.5 mL/min. Fluorescence detection (λ_{ex} = 500 nm, λ_{em} = 510 nm). Limit of detection, 0.3 nmol/L [Guo *et al.* 2009]. Column: Nucleosil (250 × 4.6 mm i.d., 5 µm). Mobile phase: 10 mmol/L sodium dihydrogen phosphate-10 mmol/L 1-octanesulfonic acid in acetonitrile : water (9 : 91), flow rate 1.5 mL/min. UV detection (λ = 333 nm). Limit of detection, 170 nmol/L [Tsikas *et al.* 1998]. Column: C_{18} bonded reversed phase (250 × 0.46 mm i.d., 5 µm). Mobile phase: methanol : aqueous 0.05 mol/L trisodium citrate-0.001 mol/L EDTA buffer (pH 7.0, 30 : 70), flow rate 1.0 mL/min. UV detection (λ = 360 nm). Limit of detection, 60 µg/L [Lewis *et al.* 1984].

Urine **HPLC** See Plasma. Limit of detection, 200 mg/L [Lewis *et al.* 1984].

Disposition in the Body *N*-Acetylcysteine is readily absorbed after oral administration, peak plasma concentrations being attained in 2–3 h; concentrations in the lung are similar to those in plasma. Approximately 20% of a dose is excreted in the urine in 24 h. *N*-Acetylcysteine is primarily metabolised to cysteine.

Therapeutic Concentration

Five healthy male and female subjects with a mean age of 28.8 years were fasted overnight for 12 h and administered 600 mg *N*-acetylcysteine orally. *N*-Acetylcysteine was observed in plasma at a mean concentration of 4.6 µg/L after 60 min and 2.5 µg/L after 90 min. Cysteine was observed at a mean maximum concentration of 18.6 µg/L [Tsikas *et al.* 1998].

Nine male and female patients with cirrhosis, mean age 51.1 years (range, 40–74), and 6 healthy subjects with mean age 39.8 years (range, 28–61) were administered 600 mg *N*-acetylcysteine IV over 3 min. After 30 min, the peak plasma concentration was 60 mg/L for both groups; after 10 h, the plasma concentration was 4.5 mg/L for the patients and 1.5 mg/L for the healthy subjects [Jones *et al.* 1997].

Half-life Healthy subjects 2.6 h; patients with cirrhosis 4.9 h.

Volume of Distribution Healthy subjects 25.5 L; patients with cirrhosis 17.4 L.

Clearance Body clearance: healthy subjects, 6.5 L/h; patients with cirrhosis 4.5 L/h.

Protein Binding ≈78%.

Dose As a mucolytic, 600 mg daily by mouth. In the treatment of paracetamol overdosage, initially 150 mg/kg by rapid IV infusion.

Guo XF *et al.* (2009). Simultaneous analysis of plasma thiols by high-performance liquid chromatography with fluorescence detection using a new probe, 1,3,5,7-tetramethyl-8-phenyl-(4-iodoacetamido)difluoroboradiaza-s-indacene. *J Chromatogr A* 1216: 3874–3880.

Jones AL *et al.* (1997). Pharmacokinetics of *N*-acetylcysteine are altered in patients with chronic liver disease. *Aliment Pharmacol Ther* 11: 787–791.

Lewis PA *et al.* (1984). High-performance liquid chromatographic assay for *N*-acetylcysteine in plasma and urine. *J Pharm Sci* 73: 996–998.

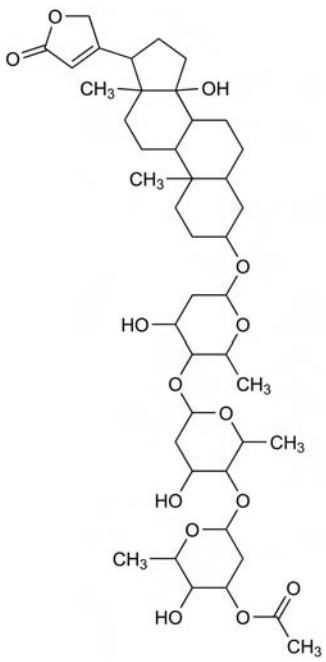
Tsikas D *et al.* (1998). Analysis of cysteine and *N*-acetylcysteine in human plasma by high-performance liquid chromatography at the basal state and after oral administration of *N*-acetylcysteine. *J Chromatogr B Biomed Sci Appl* 708: 55–60.

A

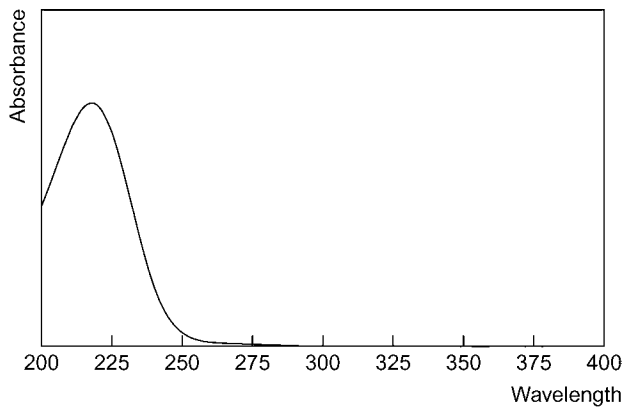
Acetyldigitoxin

Cardiac Glycoside
$C_{43}H_{66}O_{14}$ = 807.0
CAS—1111-39-3

IUPAC Name [(2*R*,3*R*,4*S*,6*S*)-3-Hydroxy-6-[(2*R*,3*S*,4*S*,6*S*)-4-hydroxy-6-[(2*R*,3*S*,4*S*,6*R*)-4-hydroxy-6-[[(3*S*,5*R*,8*R*,9*S*,10*S*,13*R*,14*S*,17*R*)-14-hydroxy-10,13-dimethyl-17-(5-oxo-2H-furan-3-yl)-1,2,3,4,5,6,7,8,9,11,12,15,16,17-tetradecahydrocyclopenta[a]phenanthren-3-yl]oxy]-2-methyloxan-3-yl] oxy-2-methyloxan-3-yl]oxy-2-methyloxan-4-yl] acetate
Synonyms 3β-[(*O*-3-*O*-Acetyl-2,6-dideoxy-β-D-*ribo*-hexopyranosyl-(1→4)-*O*-2,6-dideoxy-β-D-*ribo*-hexopyranosyl(1→4)-2,6-dideoxy-β-D-*ribo*-hexopyranosyl) oxy]-14-hydroxy-5β,14β-card-20(22)-enolide; acetyldigitoxoside; β-digitoxin monoacetate.
Proprietary Name *Acylanid(e)*



Chemical Properties A white hygroscopic crystalline powder. Mp 217° to 221°. Soluble 1 in 6100 of water, 1 in 63 of ethanol and 1 in 12 of chloroform; practically insoluble in ether and light petroleum; soluble in methanol.
Ultraviolet Spectrum No significant absorption, 230 to 360 nm.



Quantification

Plasma **LC-MS**. Limit of detection, 0.15 µg/L [Tracqui *et al.* 1997].
Disposition in the Body About 65% of a dose is absorbed after oral administration. It is slowly excreted in the urine, about 20% of a dose being excreted in 6 days; digitoxin accounts for about 60% of the urinary material. About 15 to 20% of a dose is eliminated in the faeces over a period of 18 days.
Half-life Plasma half-life, about 8 to 9 days.
Protein Binding In plasma, about 80%.
Dose Maintenance, 100 to 200 µg daily.

Tracqui A *et al.* (1997). High-performance liquid chromatography-ionspray mass spectrometry for the specific determination of digoxin and some related cardiac glycosides in human plasma. *J Chromatogr B Biomed Sci Appl* 692: 101–109.

Acetyldihydrocodeine

Cough Suppressant, Opioid Derivative
$C_{20}H_{25}NO_4$ = 343.4
CAS—3861-72-1

Synonym 4,5-Epoxy-3-methoxy-9a-methylmorphinan-6-yl acetate
Chemical Properties Soluble in water (510 mg/L). Log *P* (octanol/water), 2.50 [Meylan, Howard 1995].

Acetyldihydrocodeine Hydrochloride

$C_{20}H_{25}NO_4$,HCl = 379.9
Proprietary Name *Acetylcodone*

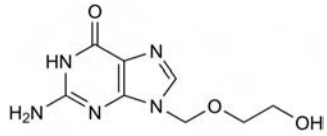
Colour Tests Ammonium molybdate test—green→blue (limit of detection, 0.1 µg); ammonium vandate test—faint grey-green (limit of detection, 1.0 µg); sulfuric acid-formaldehyde test—purple (limit of detection, 0.1 µg); Vitali's test—faint yellow/faint yellow/orange (limit of detection, 1.0 µg).
Thin-layer Chromatography System TA—R_f 0.26 (location reagent iodoplatinate spray positive reaction).
Gas Chromatography System G2/225—retention time 1.27 min (relative to codeine); system G4—retention time 0.95 min (relative to codeine).
Ultraviolet Spectrum Ethanol—284.5 nm; aqueous acid (0.05 N sulfuric acid)—283 nm; aqueous alkali (0.5 N sodium hydroxide)—283 nm.
Dose Given by mouth in a usual daily dose of 20 to 50 mg; no more than 20 mg should be taken as a single dose.

Meylan WM, Howard PH (1995). Atom/fragment contribution method for estimating octanol-water partition coefficients. *J Pharm Sci* 84: 83–92.

Aciclovir

Antiviral
$C_8H_{11}N_5O_3$ = 225.2
CAS—59277-89-3

IUPAC Name 2-Amino-9-(2-hydroxyethoxymethyl)-3H-purin-6-one
Synonyms Acycloguanosine; acyclovir; 2-amino-1,9-dihydro-9-(2-hydroxyethoxymethyl)-6*H*-purin-6-one; BW-248U.
Proprietary Names *Aciviran*; *Activir*; *Acyvir*; *Alovir*; *Avirase*; *Avyclor*; *Clovix*; *Cusiviral*; *Cycloviran*; *Dravyr*; *Efriviral*; *Esavir*; *Geavir*; *Maynar*; *Milavir*; *Neviran*; *Rexan*; *Sifiviral*; *Viclovir*; *Vipral*; *Virherpes*; *Virmen*; *Zovir*; *Zovirax*; *Zyclir.*

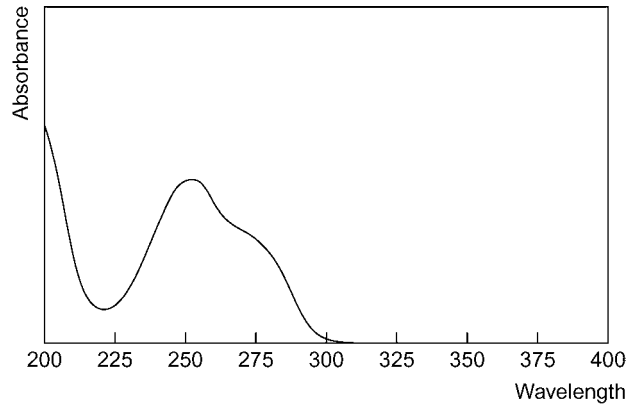


Chemical Properties A white to almost white crystalline powder. Mp 255°, with decomposition. It is sparingly to slightly soluble in water; practically insoluble or very slightly soluble in ethanol; dissolves in dilute solutions of mineral acids and alkali hydroxides; and is freely soluble in dimethyl sulfoxide. pK_a 2.3. Log *P* (octanol/water), −1.56.

Aciclovir Sodium

$C_8H_{10}N_5NaO_3$ = 247.2
CAS—69657-51-8
Proprietary Names *Cusiviral*; *Geavir*; *Herpotern*; *Maynar*; *Viclovir*; *Virherpes*; *Virmen*; *Zovirax*; *Zyclir.*
Chemical Properties A white crystalline powder. It is soluble 1 in 10 of water.

High Performance Liquid Chromatography System HAA—retention time 3.1 min.
Ultraviolet Spectrum Aqueous acid (0.2 mol/L H_2SO_4)—255 nm;basic—261 nm.



Infrared Spectrum Principal peaks at wavenumbers 1717, 1632, 1485, 1104 cm^{-1}.

Mass Spectrum Principal ions at *m/z* 151, 164, 45, 43, 165, 109, 110, 108.

Quantification

Plasma **HPLC** Column: C_8 Symmetry (150 × 4.6 mm, 5 µm). Mobile phase: acetate citrate buffer (0.1 mol/L) containing 3.7 mmol/L octane sulfonic acid:methanol (92:8 pH 3.0), flow rate 1 mL/min. UV detection (λ=250 nm). Retention time: 5.3 min [Poirier *et al.* 1999]. Limit of detection, 62.5 µg/L [Poirier *et al.* 1999]. Column: LiChrosorb RP-8 (250 × 4 mm i.d., 7 µm). Mobile phase: 1% acetonitrile in 0.02 mol/L disodium hydrogen orthophosphate, (pH 2.5) flow rate 1.2 mL/min. Fluorescence detection (λ_{ex}=270 nm, λ_{em}=380 nm). Retention time: 9.6 min [Peh, Yuen 1997].Limit of detection, 30 µg/L [Peh, Yuen 1997]. Column: ODS R-P Ultrasphere (75 × 4.6 mm, 3 µm). Mobile phase: 30 mmol/L phosphate buffer, pH 2.1 containing 5 mmol/L dodecyl sulfate and 18% acetonitrile, flow rate 1.5 mL/min. Fluorescence detection (λ_{ex}=285 nm, λ_{em}=380 nm). Retention time: aciclovir, 1.7 min; 9-carboxy-methoxymethylguanine, 1.5 min [Svensson *et al.* 1997]. Limit of detection, 0.12 µg/L [Svensson *et al.* 1997]. UV detection. Limit of detection, 10 µg/L [Swart *et al.* 1994].

Serum **HPLC** Column: RP-8 SymmetryShield (6 mm i.d., 5 µm). Mobile phase: acetonitrile: monoammonium phosphate buffer 0.025 mol/L (pH 4.0) (2:98), flow rate 1.0 mL/min. UV detection. Retention time: 9.7 min [Pham-Huy *et al.* 1999]. Limit of quantification, 200 µg/L, limit of detection, 50 g/L [Pham-Huy *et al.* 1999]. UV detection. Limit of detection, 50 µg/L [Nebinger, Koel 1993].

Urine **HPLC** Fluorescence detection (λ_{ex}=285 nm, λ_{em}=380 nm). Limit of detection, 0.60 µg/L [Svensson *et al.* 1997].

Note For an ELISA for the quantification of aciclovir see Tadepalli *et al.* [1986].

Disposition in the Body Aciclovir is poorly absorbed after oral administration. Peak plasma concentrations occur about 1.5 to 2.5 h after administration. It is excreted mostly unchanged through the kidney by both glomerular filtration and tubular secretion. 30 to 70% of an administered dose can be detected in urine. About 14% is excreted as the inactive metabolite 9-carboxymethoxymethylguanine (the main metabolite), and also 8-hydroxy-9-(2-hydroxyethoxymethyl)guanine has been detected (<0.2% of the dose). Faecal excretion accounts for about 2% of a dose. It is widely distributed into various tissues, including CSF where concentrations reach about 50% of those of plasma. It crosses the placenta and is distributed into breast milk. Aciclovir is removed by haemodialysis but not by peritoneal dialysis.

Therapeutic Concentration The trough serum therapeutic concentration range is 0.5 to 1.5 mg/L while the peak is 5 to 15 mg/L.

Single dose and multiple dosing studies were carried out on adult volunteers aged 45 to 60 years. Single dose studies involved administering intravenous doses of 0.5, 1.0, 2.5, 5.0, 10.0 and 15.0 mg/kg over a 1 h infusion period resulting in mean peak plasma concentrations of 1.0, 2.1, 4.2, 8.8, 14.6 and 22.7 mg/L, respectively. All concentrations were observed by the end of infusion. The mean peak and trough plasma concentrations measured after administration of 2.5 mg/kg intravenously over 1 h every 8 h were 5.1 and 0.5 mg/L, respectively. Following doses of 5.0, 10.0, and 15.0 mg/kg administered similarly, the mean peak and trough concentrations were: 9.8 and 0.7, 20.7 and 2.3, 23.6 and 2.0 mg/L, respectively. A study was also carried out on children, from birth up to 17 years old, who were administered a 250 or 500 mg/m^2 dose. The mean peak concentrations were 4 to 18 mg/L and 14 to 30 mg/L, respectively [Blum *et al.* 1982].

Bioavailability Oral, 20%.

Toxicity Nephrotoxicity may occur occasionally. The risk may be increased if large doses are given or if it is administered very rapidly or as a bolus. Neurotoxicity may also occur. Patients have ingested up to 20 g with no unexpected effects. If the solubility of aciclovir in intratubular fluid is exceeded (2.5 g/L), aciclovir may precipitate in the renal tubules and urine flow must therefore be maintained in cases of overdosage.

Severe neurological impairment and nonoliguric renal failure developed in a 68-year-old man a week after starting treatment with aciclovir 600 mg four times daily by mouth. On presentation the blood-aciclovir concentration was 18 mg/L. Intravascular volume depletion secondary to profuse diarrhoea and a history of chronic renal failure were contributory factors. Symptoms resolved on discontinuation of aciclovir and haemodialysis [Bradley *et al.* 1997].

Seven of 8 subjects treated with high-dose aciclovir (400 to 1200 mg/m^2/day) by i.v. infusion for cytomegalovirus pneumonia following bone-marrow transplant died. Plasma aciclovir concentrations at postmortem for 4 of the subjects were 0.018 to 0.2 mg/L. The following corresponding concentrations in various organs were reported: lung 0.023 to 0.28 mg/L, heart 0.027 to 0.25 mg/L, liver 0.022 to 0.31 mg/L, renal medulla 0.16 to 2.68 mg/L, renal cortex 0.13 to 2.62 mg/L, brain 0.142 mg/L, spinal cord 0.0063 to 0.118 mg/L [Wade *et al.* 1982].

Half-life Plasma, 2 to 3 h.

Volume of Distribution 4 to 55 L/1.73 m^2.

Clearance Plasma, 327 mL/min/1.73 m^2.

Protein Binding 9 to 33%.

Dose Up to 30 mg/kg body weight daily intravenously; up to 4 g daily by mouth.

Acipimox

Hyperlipidaemic, Nicotinic Acid Analogue

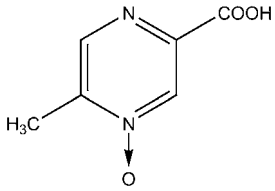
$C_6H_6N_2O_3$ = 154.1

CAS—51037-30-0

IUPAC Name 5-Methyl-4-oxidopyrazin-4-ium-2-carboxylic acid

Synonyms 2-Carboxy-5-methylpyrazine-4-oxide; K-9321; 6-methyl-1-oxidopyrazin-1-ium-2-carboxylic acid.

Proprietary Names *Olbemox*; *Olbetan*.



Chemical Properties Crystals. Mp 177° to 180°. Freely soluble in water, insoluble in ether. pK_a 3.25 [Ghabrial *et al.* 1991]. Log *P* (octanol/water), −0.52 [Meylan, Howard 1995].

Quantification

Urine **HPLC** Column: Whatman Partisil PAC 10 (250 × 3 mm i.d.). Mobile phase: citrate phosphate buffer (pH 2.5) : acetonitrile (80 : 20), flow rate 1.4 mL/min. UV detection (λ = 269 nm). Limit of detection not reported [Musatti *et al.* 1981].

Placenta **HPLC** Column: Novapak phenyl (4 µm). Mobile phase: 25 mmol/L dipotassium hydrogen phosphate buffer containing 40 mL/L methanol, 5 mmol/L tetrabutyl ammonium and 5 mmol/L triethylamine (pH 6.8), flow rate 3 mL/min. UV detection (λ = 264 nm). Limit of detection not reported [Ghabrial *et al.* 1991].

Disposition in the Body Acipimox is rapidly and completely absorbed from the gastrointestinal tract, reaching peak plasma concentrations in approx. 2 h. The drug is not significantly metabolised [Musatti *et al.* 1981] but the main metabolite is 5-methylpyrazine-2-carboxylic acid [Efthymiopoulos *et al.* 1993]. Approximately 90% of an administered dose is excreted unchanged in the urine [Musatti *et al.* 1981], although only 6% is excreted via this route in patients with severe renal failure [Bonadonna *et al.* 1985].

Therapeutic Concentration

Ten healthy volunteers were administered a single 250 mg acipimox dose followed by a dose 3 times daily for 6 days. After the single administration, the mean peak plasma concentration was 5.74 mg/L (2.56 to 8.38 mg/L) at 1.7 h (1 to 3 h). The elimination half-life was 1.15 h (0.79 to 1.48 h). These values were not significantly different after repeated doses [Efthymiopoulos *et al.* 1993].

Six uraemic patients on dialysis were given single oral doses of 50 mg acipimox. The mean peak plasma concentration was 1.6 mg/L at 2 h. During dialysis, the mean plasma levels declined rapidly [Bonadonna *et al.* 1985].

Four healthy male volunteers (aged 22 to 28 years; weight 66 to 75 kg) were administered 150, 250 or 400 mg acipimox at 1 week intervals according to a randomised sequence. Mean peak plasma concentrations were 1.75 ± 0.22, 3.57 ± 0.22, and 6.03 ± 0.63 mg/L, respectively, attained at 1.75 ± 0.25, 2 ± 0, and 1.25 ± 0.24 h, respectively. Six healthy male volunteers (aged 19 to 37 years; weight 60 to 83 kg) were administered one 250 mg capsule either on an empty stomach or after a 750 calorie breakfast. After a 1 week washout period, the same 6 men started oral treatment of 250 mg three times daily for 6 days with one capsule taken on the morning of the 7th day. Mean peak plasma levels were as follows:

	C_{max} (mg/L)	t_{max} (h)	$t_{1/2}$ (4-10) (h)
Fasting	4.24 ± 0.34	1.33 ± 0.21	1.95 ± 0.10
After food	3.74 ± 0.18	3.16 ± 0.16	1.90 ± 0.12
19th dose	6.01 ± 0.18	1.50 ± 0.22	1.92 ± 0.08

[Musatti *et al.* 1981]

A

Toxicity Diffusion through the human placenta is slow, which should afford the fetus some protection if acipimox is administered to the mother [Ghabrial *et al.* 1991].
Half-Life Healthy patients, 1.15 h; patients in renal failure and on haemodialysis, 2.6 h.
Clearance Approximately 220 mL/min.
Dose 500 to 750 mg daily in divided doses.

Bonadonna A *et al.* (1985). A pilot study of the pharmacokinetics and triglyceride lowering activity of acipimox in dialyzed uremic patients. *Int J Clin Pharmacol Ther Toxicol* 23: 112–114.

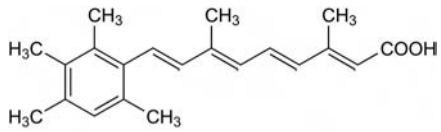
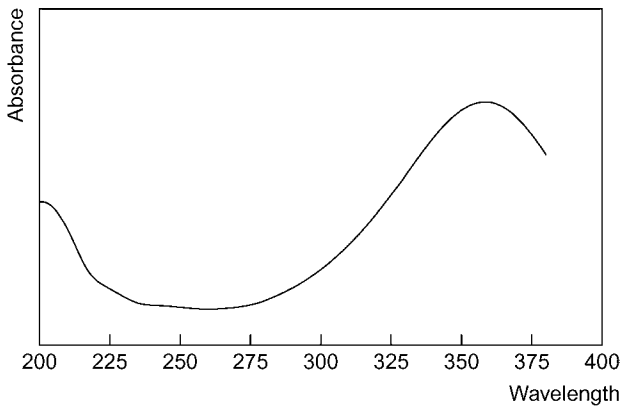
Acitretin

Dermatological Agent, Retinoid
$C_{21}H_{26}O_3$ = 326.4
CAS—55079-83-9

IUPAC Name (2*E*,4*E*,6*E*,8*E*)-9-(4-Methoxy-2,3,6-trimethylphenyl)-3,7-dimethylnona-2,4,6,8-tetraenoic acid
Synonyms Etretin; Ro-10-1670.
Proprietary Names *Neotigason*; *Soriatane*.



Chemical Properties A yellow to greenish-yellow powder. Mp 228° to 230°. Protect from light. pK_a 3.7. Log *P* (octanol/water), 6.4. The retinoids easily undergo photoisomerisation and oxidation, making it necessary to handle and store all substances and solutions in yellow dark-room light [Palmskog 1980]. Plasma samples spiked with 50 and 100 µg/L were stable for 2, 6, 10 and 24 h at ambient temperature and for 7, 21 and 90 days at –20° [Al Mallah *et al.* 1987]. Plasma samples stored at 10° were stable for at least 24 h [Wyss, Bucheli 1992].
Thin-layer Chromatography System TF—R_f 0.43.
High Performance Liquid Chromatography Column: Nucleosil RP C_{18} (250 × 4.2 mm i.d., 5 µm). Mobile phase: methanol-acetonitrile (7 : 3) : 1.5% acetic acid (85 : 15), flow rate 1.2 mL/min. UV detection (λ = 350 nm). Retention time: 13-*cis*-acitretin, 6.0 min; all-*trans*-acitretin, 6.9 min. Limit of quantification, 1 µg/kg [Laugier *et al.* 1994].
Ultraviolet Spectrum



Mass Spectrum Principal peaks at *m/z* 150, 326, 163, 203, 251, 281, 41, 311.
Quantification
Blood **HPLC** Column: Nucleosil C_{18} (250 × 4 mm i.d., 5 µm). Mobile phase: methanol : 1% aqueous acetic acid (85 : 15), flow rate 1.5 mL/min. UV detection (λ = 350 nm). Retention time: 8.9 min. Limit of detection not reported [Al Mallah *et al.* 1987].
Plasma **HPLC** Column: Nucleosil C_{18} reversed phase (250 × 4.2 mm i.d., 5 µm). Mobile phase: methanol-acetonitrile (7 : 3) : 1.5% acetic acid (85 : 15), flow rate 1.2 mL/min. UV detection (λ = 350 nm). Retention time: 6 and 6.9 min for 13-*cis*-acitretin and all-*trans*-acitretin, respectively. Limit of quantification, 1 µg/L [Laugier *et al.* 1994]. Column: Spherisorb ODS (1.5 µm). Mobile phase: 1% ammonium acetate-acetonitrile-acetic acid (30 : 70 : 3) : 1.7% ammonium acetate-acetonitrile-acetic acid (6 : 95 : 3) : acetonitrile-tetrahydrofuran-water (80 : 20 : 2; 100 : 0 : 0 through to 0 : 0 : 100). UV detection (λ = 230 nm). Limit of detection, 0.1 µg/L [Sturkenboom *et al.* 1994]. Column: Spherisorb ODS1 (250 × 4 mm i.d., 5 µm). Mobile phase: 10% ammonium acetate-glacial acetic acid-water-acetonitrile (4 : 3 : 300 : 700) : 10% ammonium acetate-glacial acetic acid-water-acetonitrile (4 : 1 : 146 : 850; 100 : 0 to 0 : 100 at 8 min for 3 min to 100 : 0 at 11.1 min), flow rate 1.0 mL/min. UV detection (λ = 360 nm). Limit of detection, 2 µg/L [Klein *et al.* 1992]. Column: Spherisorb ODS 1 (125 × 4 mm, 5 µm). UV detection (λ = 360 nm). Limit of quantification, 0.3 µg/L, limit of detection, 0.1 µg/L for acitretin and metabolites [Wyss, Bucheli 1992]. Column: Chromspher silica (150 × 4.6 mm i.d., 5 µm). Mobile phase: *n*-hexane: methylsalicylate : acetic acid (200 : 18 : 0.6). UV detection (λ = 360 nm). Limit of quantification, 3 to 4 µg/L [Meyer *et al.* 1991].

Suction Blister **HPLC** See Plasma [Laugier *et al.* 1994]
Disposition in the Body Acitretin is absorbed after oral administration and peak plasma concentrations occur after approximately 1 to 6 h. Administration with food increases bioavailability. The drug is widely distributed in the body. It undergoes extensive metabolism and interconversion by simple isomerisation to 13-*cis*-acitretin. Both acitretin and 13-*cis*-acitretin may be conjugated. An additional three metabolites have been identified. Etretinate has been detected following administration of acitretin; this may be a route of metabolism if there is concomitant alcohol consumption. It is excreted in urine and bile. Neither acitretin nor its 13-*cis* metabolite are removed by dialysis.
Therapeutic Concentration
Following administration of a single dose of acitretin (40 mg) to 6 subjects with psoriasis, aged between 23 and 76 years (mean, 52 years), peak plasma concentrations of 98 to 526 µg/L (mean, 241 µg/L) occurred after 0.6 to 3.0 h. The dose was administered after an overnight fast followed by an additional 3 h fast post-administration [Larsen *et al.* 1987].
Following administration of 50 mg acitretin to 18 healthy male subjects (18 to 40 years old) with or without food, peak plasma concentrations of 87 to 480 µg/L and 196 to 728 µg/L were measured, respectively. A mean peak plasma concentration of 245 and 416 µg/L was observed for the doses administered with food and without, respectively. Peak concentrations were reached between 2 and 5 h [McNamara *et al.* 1988].
Peak plasma concentrations of 229 to 408 µg/L occurred after 1.0 to 2.8 h in four subjects who were administered 40 mg acitretin daily for 3 months. This dose was ingested after an overnight fast followed by a 3 h additional fast post-administration. The individuals used in the study were aged 23 to 59 years (mean, 55 years) and suffered from severe psoriasis (healthy otherwise) [Larsen *et al.* 1988].
Toxicity Acitretin is teratogenic. Although acitretin has a relatively short half-life, etretinate has also been detected in the plasma of some patients taking acitretin. Since etretinate is also teratogenic and has a much longer half-life than acitretin, pregnancy must be avoided for at least 3 years after stopping acitretin therapy [Sturkenboom *et al.* 1994]. Plasma concentrations may be a poor guide to presence of etretinate in the body since etretinate concentrates in fatty tissues. The minimum plasma concentrations associated with teratogenicity are unknown.
A woman had taken a cumulative dose of 9.9 g acitretin but had stopped taking it 52 months previously. Etretinate concentrations of of 0.30 µg/L and 128.5 µg/kg were found in plasma and SC fat, respectively. Another woman who was still taking acitretin (cumulative dose, 1.075 g) had plasma and fat concentrations of 0.48 µg/L and 18.7 µg/kg etretinate, respectively [Maier, Hönigsmann 1996].
Bioavailability Approximately 60%.
Half-life Plasma, acitretin, 50 h; 13-*cis*-acitretin, 63 h.
Volume of Distribution Mean, 3.47 L/kg; range, 2.3 to 4.5 L/kg.
Clearance Plasma, 175.9 ± 81.4 mL/kg/h.
Protein Binding Greater than 99.9%.
Note For general data and references, see Brindley [1989] and Pilkington and Brogden [1992].
Dose Usually 25 to 50 mg daily.

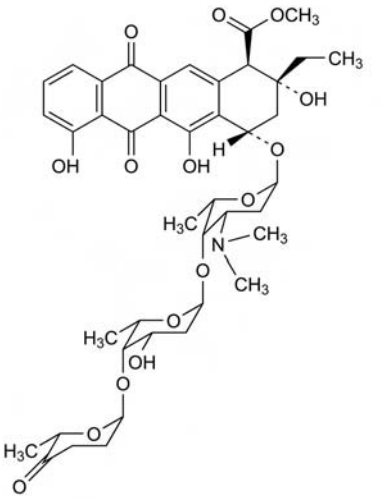
Wyss R, Bucheli F (1992). Use of direct injection precolumn techniques for the high-performance liquid chromatographic determination of the retinoids acitretin and 13-*cis*-acitretin in plasma. *J Chromatogr* 593: 55–62.

Aclarubicin

Antineoplastic
$C_{42}H_{53}NO_{15}$ = 811.8
CAS—57576-44-0

IUPAC Name Methyl (1*R*,2*R*,4*S*)-4-[(2*R*,4*S*,5*S*,6*S*)-4-(dimethylamino)-5-[(2*S*,4*S*,5*S*, 6*S*)-4-hydroxy-6-methyl-5-[(2*R*, 6*S*)-6-methyl-5-oxooxan-2-yl]oxy-oxan-2-yl]oxy-6-methyloxan-2-yl]oxy-2- ethyl-2,5,7-trihydroxy-6,11-dioxo-3,4-dihydro-1H-tetracene-1-carboxylate
Synonym Aclacinomycin A; [1*R*-(1α,2β,4β)]-2-ethyl-1,2,3,4,6,11-hexahydro-2,5,7-trihydroxy-6,11-di-oxo-4-[[2,3,6-trideoxy-4-*O*-[2,6-dideoxy-4-*O*-[(2*R*-*trans*)-tetrahydro-6-methyl-5-oxo-2*H*-pyran-2-yl]-α-L-*lyxo*-hexopyranosyl]-3-(dimethyl-amino)-α-L-*lyxo*-hexopyranosyl]oxy]-1-naphthacenecarboxylic acid methyl ester.

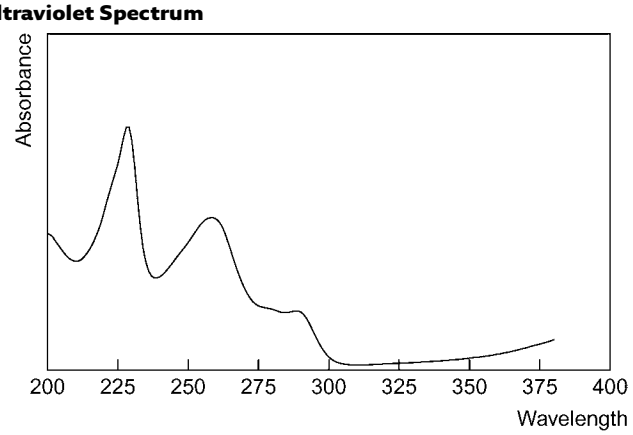


Chemical Properties It is soluble in chloroform and in ethyl acetate; insoluble in ether, in *n*-hexane and in light petroleum.

Aclarubicin Hydrochloride

$C_{42}H_{53}NO_{15}$,HCl = 848.3
Proprietary Names *Aclacin*; *Aclacinomycine*; *Aclaplastin*.

Ultraviolet Spectrum



Mass Spectrum Principal ions at *m/z* 113, 100, 71, 43, 73, 81, 96, 376.
Quantification
Serum **HPLC** Column: C_{18} μBondapak (300 × 4 mm i.d., 10 μm). Mobile phase: acetonitrile: methanol: water (40:90:70) acidified with orthophosphoric acid 85% (1.5 mL per 100 mL), flow rate 2 mL/min. UV detection (λ=254 nm). Retention time: 5.9 min [Erttmann 1983]. Limit of detection, 10.8 μg/L [Erttmann 1983].

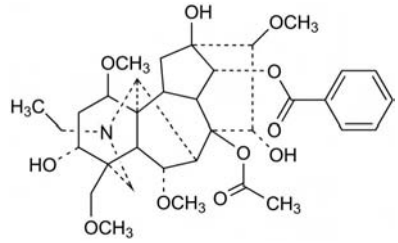
Disposition in the Body Aclarubicin is rapidly distributed following intravenous administration. It is rapidly and highly metabolised to biologically active glycosides and inactive aglycones. The metabolites are excreted mainly in urine, and small amounts may be excreted in faeces.
Therapeutic Concentration The mean peak concentration of the principal active metabolite is 130 μg/L and occurs at a mean time of 191 min after dosing.
Half-life Plasma, aclarubicin, 3 h; principal metabolite, 13 h.
Clearance Plasma, 1.6 to 8.8 L/min/m^2.
Volume of Distribution Apparent, 600 to 1900 L/m^2.
Dose 25 to 100 mg/m^2 as a single infusion every 3 to 4 weeks (maintenance therapy). Usual maximum total dose is 400 mg/m^2.

Erttmann R (1983). Determination of aclacinomycin A by reversed-phase high-performance liquid chromatography. *J Chromatogr* 277: 433–435.

Aconitine

Alkaloid, Diterpine
$C_{34}H_{47}NO_{11}$ = 645.7
CAS—302-27-2

Synonyms Acetylbenzoylaconine; (1α,3α,6α,14α,15α,16β)-20-ethyl-1,6,16-trimethoxy-4-(methoxymethyl)aconitane-3,8,13,14,15-pentol 8-acetate 14-benzoate.

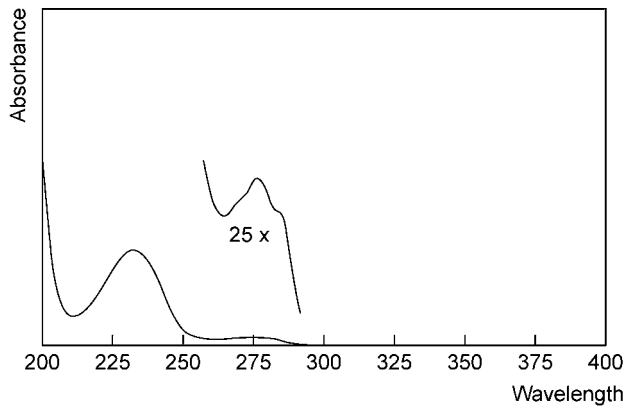


Chemical Properties An alkaloid present in species of *Aconitum*, including *A. napellus* agg. (Ranunculaceae). Colourless crystals or white crystalline powder. Mp 204°, with decomposition. Solubility (g/mL): 1 in 3300 water, 1 in 28 abs. alcohol, 1 in 2 chloroform, 1 in 50 ether, 1 in 7 benzene and slightly soluble in petroleum ether. In phosphate buffer (pH 7.4) at 37°, aconitine is converted *in vitro* to benzoylaconine and aconine over time [Mizugaki *et al.* 1998]. In extracts, aconitine was stable at high and low concentrations for more than 24 h, before and after 3 freeze–thaw cycles and after storage at –20° for 1 month [Beyer *et al.* 2007].

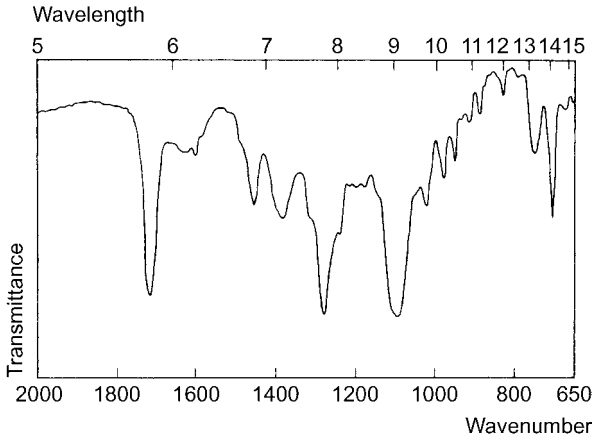
Aconitine Nitrate

$C_{34}H_{47}NO_{11}$,HNO_3 = 708.8
CAS—6509-18-8
Proprietary Names *Aconitysat*; *Bromofotyl*; *Herbadon*.
Chemical Properties Colourless crystals or white crystalline powder. Mp approx. 200°, with decomposition. Soluble 1 in 10 in boiling water; less soluble in cold water; soluble in alcohol. pK_a 8.1 (25°). Log *P* (octanol/water), 0.13.

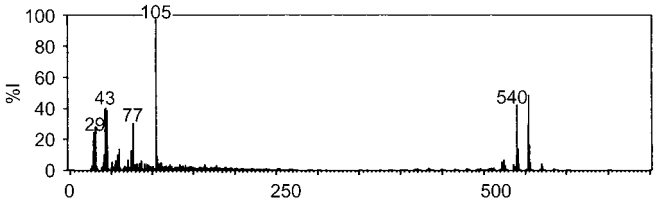
Thin-layer Chromatography System TA—R_f 0.68; system TB—R_f 0.11; system TC—R_f 0.39; system TE—R_f 0.75; system TL—R_f 0.58; system TAE—R_f 0.42; system TAF—R_f 0.68; system TAJ—R_f 0.06; system TAK—R_f 0.00; system TAL—R_f 0.24 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—not eluted.
Gas Chromatography-Mass Spectrometry Column: Fused silica cross-linked with 5% phenylsilicone (15 m × 0.25 mm i.d.). Temperature programme: 250° for 1 min to 320° at 16°/min. Carrier gas: He, 25 cm/s. SIM acquisition mode [Ito *et al.* 1997].
High Performance Liquid Chomatography System HX—RI 432.
Liquid Chomatography-Mass Spectrometry Column: Inertsil ODS-2 (150 × 0.32 mm i.d.). Mobile phase: acetonitrile : 0.3% trifluoroacetic acid solution (0 : 100 to 80 : 20 over 40 min) containing 0.8% glycerin, flow rate 5 μL/min. FAB. Retention time: 28.5 min. Limit of detection, ~1 pg [Ohta *et al.* 1998].
Ultraviolet Spectrum Aqueous acid—234 (A_1^1 = 233a), 275 nm.



Infrared Spectrum Principal peaks at wavenumbers 1092, 1273, 1713, 1235, 710, 1020 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 105, 554, 540, 43, 45, 77, 31, 29.



Quantification

Blood **GC-MS** Column: DB-5 fused silica capillary cross-linked with methyl 5% phenylsilicone. Temperature programme: 250° for 1° /min to 320° at 16°/min. Carrier gas: He, 25 cm/s. EI ionisation at 70 eV, SIM acquisition mode. Limit of detection, 10 pg for aconitine and mesaconitine [Ito *et al.* 1998].

HPLC Column: XTerra RP18150 (150 × 4.6 mm i.d., 5 μm). Mobile phase: 10 mmol/L ammonium hydrogen carbonate (pH 10.05) : acetonitrile (100 : 0 to 50 : 50 at 10 min for 15 min), flow rate 1 mL/min. UV detection (λ = 237 nm). Limit of detection, 0.1 ng [Wang *et al.* 2004]. Column: Spherisorb S5OD/CN (150 × 4.6 mm i.d.). Mobile phase: acetonitrile : water (0 : 100 to 70 : 30 at 15 min for 3 min), flow rate 2 mL/min. DAD (λ = 200–595 nm). Retention time: 3.78 min. Limit of detection, ~2 μg/L [Elliott 2002]. Column: L-column ODS (150 × 4.6 mm i.d.). Mobile phase: organic solvent mixed with a dilute acidic solution, flow rate 1 mL/min. UV detection (λ = 235 nm). Limit of detection, 1 ng for aconitine and other aconite alkaloids, [Ohta *et al.* 1997].

LC-MS Column: XTerra MS C_{18} (50 × 2.1 mm, 3.5 μm). Mobile phase: 2 mmol/L ammonium acetate : water : acetonitrile (10 : 80 : 10 for 0.5 min to 10 : 40 : 50 from 0.5 to 1.5 min to 10 : 50 : 40 for 1 min to 10 : 80 : 10 over 1 min), flow rate, 0.4 mL/min. ESI, positive ion mode. Retention time: 2.9 min. Limit of detection, 0.4 μg/L [Pullela *et al.* 2008]. Column: XTerra RP_8 (150 × 2.1 mm i.d., 3.5 μm). ESI, positive ion mode, MRM acquisition mode. Limit of quantification, 0.5 ng/g, limit of detection, 0.1 ng/g [Beike *et al.* 2004]. Column: Inertsil ODS-2 (150 × 0.32 mm i.d.). Mobile phase: acetonitrile : 0.3% trifluoroacetic acid solution (0 : 100 to 80 : 20 over 40 min) containing 0.8% glycerin, flow rate 5 μL/min. FAB. Retention time: 28.5 min. Limit of detection, ~1 μg/L [Ohta *et al.* 1998].

Plasma **LC-MS** Column: LiChroCART (125 × 2 mm i.d.). Mobile phase: 50 mmol/L aqueous ammonium formate (pH 3.5) : acetonitrile (90 : 10 for 2 min to 20 : 80 at 5 min for 2 min to 90 : 10 at 10 min), flow rate 0.4 mL/min for 2 min to 0.6 mL/min for 5 min to 0.4 mL/min for 3 min. APCI, positive ion mode, SIM acquisition mode or tandem MS, ESI, MRM acquisition mode. Limit of quantification, 50 and 0.1 μg/L for single-stage MS and tandem MS, respectively [Beyer *et al.* 2007]. Column: Shiseido UG80 C_{18}. Mobile phase: 20 mmol/L ammonium acetate : acetonitrile (70 : 30), flow rate 200 μL/min. ESI, positive ion mode. Limit of detection, 0.2 μg/L [Kaneko *et al.* 2006]. Column: Altima C_{18} (150 × 3 mm i.d., 3 μm). Mobile phase: 2 mmol/L formate buffer (pH 3.0) : acetonitrile (20 : 80), flow rate 400 μL/min. ESI, MRM acquisition mode. Limit of quantification, 0.02 μg/L, limit of detection, 0.01 μg/L [Moritz *et al.* 2005].

Serum **GC-MS** Column: DB-5 fused silica capillary cross-linked with methyl 5% phenylsilicone (15 m × 0.25 mm i.d.). Temperature programme: 250° for 1 min to 320° at 16°/min. Carrier gas: He, 25 cm/s. EI ionisation at 70 eV, SIM acquisition mode. Limit of detection, 10 pg [Mizugaki *et al.* 1998]. Column: DB-5 cross-linked with methyl 5% phenylsilicone (15 m × 0.25 mm i.d.). Carrier gas: He, 25 cm/s. Temperature programme: 250° for 1 min to 320° at 16°/min. EI ionisation at 70 eV, SIM acquisition mode. Limit of detection, 10 pg [Ito *et al.* 1997].

LC-MS Column: Xterra RP18 (150 × 2.1 mm i.d., 3.5 μm). Mobile phase: 0.1% formic acid in acetonitrile : 0.1% formic acid in aqueous solution (24 : 76), flow rate 0.2 mL/min. ESI, positive ion mode, SIM acquisition mode. Limit of detection not reported [Fujita *et al.* 2007]. Column: Eclipse XDB-C_{18}(150 × 2.1 mm i.d., 5 μm). Mobile phase: 10 mmol/L ammonium acetate (pH 7.0): acetonitrile containing 0.5% acetate (80 : 20 to 30 : 70 at 7 min to 20 : 80 at 14 min), flow rate 0.25 mL/min. ESI, positive ion mode. Limit of detection, 0.2–1 μg/L [Hayashida *et al.* 2003].

Urine **GC-MS** See Blood [Ito *et al.* 1998]. See Serum [Mizugaki *et al.* 1998].

HPLC See Blood [Elliott 2002; Wang *et al.* 2004]. Column: L-column ODS (150 × 4.6 mm i.d.). Mobile phase: organic solvent mixed with a dilute acidic solution, flow rate 1 mL/min. UV detection (λ = 235 nm). Limit of detection, 1 ng for aconitine and other aconite alkaloids [Ohta *et al.* 1997].

LC-MS See Blood [Pullela *et al.* 2008]. Column: XTerra (150 × 2.1 mm i.d.). Mobile phase: acetonitrile : water both containing 0.3% formic acid (25 : 75 for 5 min to 60 : 40 at 6.5 min for 3.5 min to 25 : 75 at 11 min), flow rate 300 μL/min. ESI, positive ion mode. Limit of detection not reported [Van Landeghem *et al.* 2007]. Column: Agilent Zorbax Eclipse XDB C_8 (150 × 4.5 mm i.d., 5 μm). Mobile phase: 0.2% formic acid in water : 0.2% formic acid in acetonitrile (70 : 30 to 50 : 50 in 20 min to 70 : 30 in 3 min), flow rate 0.5 mL/min. ESI, positive ion mode. Limit of detection, 2.5 μg/L [Lai *et al.* 2006]. Column: Hypersil BDS-C_{18}(150 × 4.6 mm i.d., 5 μm). Mobile phase: acetonitrile : water : formic acid (50 : 50 : 1), flow rate 0.5 mL/min. ESI, SRM acquisition mode. Limit of detection not reported [Zhang *et al.* 2005]. See Blood [Beike *et al.* 2004]. See Blood. Limit of detection, ~0.5 μg/L [Ohta *et al.* 1998].

Stomach Contents **LC-MS** See Blood [Beike *et al.* 2004].

Kidney **LC-MS** See Urine [Van Landeghem *et al.* 2007].

Liver **LC-MS** See Urine [Van Landeghem *et al.* 2007].

Other **LC-MS** Tuber Samples. See Plasma [Kaneko *et al.* 2006].

Disposition in the Body

Toxicity Aconitine affects both the heart and the CNS and is one of the most potent and quick-acting poisons. It is well absorbed from the gastrointestinal tract and death may occur within a few minutes. The estimated minimum lethal dose is 2 mg of aconitine, 5 mL of aconite tincture (25% v/v) or 1 g of aconite root, although recovery after ingestion of 10 mg of aconitine has been reported.

A 25-year-old individual ingested some pink flowers and some blackberries. The pink flowers were later identified as *A. napellus*. Postmortem femoral blood and urine had aconitine concentrations of 3.6 and 149 μg/L, respectively [Pullela *et al.* 2008].

A man in his fifties was poisoned with *A. napellus*. On re-analysis of samples 5 years later, his aconitine concentrations were 810 μg/L in urine and 6.5 and 1.3 μg/kg in his liver and kidneys, respectively [Van Landeghem *et al.* 2007].

A 21-year-old man ingested 3 homemade capsules containing 237 mg of root and 19 μg of aconitine. At 7, 9, 14 and 19 h post-ingestion, his plasma aconitine concentrations were 1.75, 0.75, 0.35, and 0.02 μg/L, respectively [Moritz *et al.* 2005].

Two cases of aconitine poisoning gave the following postmortem concentrations:

	Blood (μg/kg)	*Stomach contents (μg/kg)*	*Urine (μg/L)*
Case 1	10.0	3	NA
Case 2	12.1	NA	180

NA, not available [Beike *et al.* 2004].

In a fatality resulting from the deliberate ingestion of *A. napellus* extract, the following postmortem tissue concentrations of aconitine were reported: femoral blood 10.8 μg/L, urine 264 μg/L. The antemortem concentrations were 6 μg/L in the serum (estimate) and 334 μg/L in the urine [Elliott 2002].

A 61-year-old man developed nausea and diarrhoea 2 h after ingesting aconite, mistaken for edible grass. Resuscitation and antiarrhythmic drugs did not work. Ventricular tachycardia and fibrillation developed and lasted for 6 h. The man fell into a coma and died of brain oedema on the 6th day. No aconitine was detected in serum after 24 h. Urine was tested after 9, 13 and 18 h and aconitine levels were 14.9, 20.2 and 2.8 μg/L, respectively [Yoshioka *et al.* 1996].

Note But *et al.* [1994] describe 3 fatal cases of aconite poisoning and Dickens *et al.* [1994] describe a further 2. For a review of aconitine poisonings since the 1950s see Chan [1994], for a global perspective see Chan [2002] and see Chan *et al.* [1994] for cases specifically regarding Chinese herbal medicines.

Acriflavinium Chloride

Antiseptic

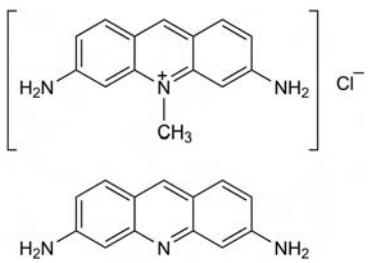
$C_{27}H_{25}Cl_2N_6 = 505.4$

CAS—8063-24-9

IUPAC Name Acridine-3,6-diamine; 10-methylacridin-10-ium-3,6-diamine; chloride; hydrochloride

Synonyms Acid trypaflavine; acriflavinium chloride hydrochloride.

Proprietary Names *Diacrid*; *Panflavin*.



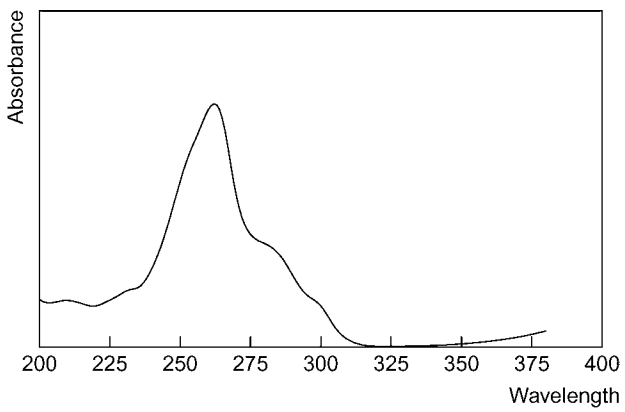
Chemical Properties An orange-red to red crystalline powder. A precipitate may form in aqueous solutions on dilution or on standing. Soluble 1 in about 3 of water and 1 in 40 of ethanol; practically insoluble in chloroform and ether. pK_a 9.1 (25°).

Note A mixture of 3,6-diamino-10-methylacridinium chloride hydrochloride and 3,6-diaminoacridine dihydrochloride, the latter being present to the extent of approximately one-third.

Colour Test Marquis test—yellow→red.

Thin-layer Chromatography System TA—four spots at R_f 0.07, R_f 0.22, R_f 0.28, R_f 0.62 (location under ultraviolet light, yellow-green fluorescence).

Ultraviolet Spectrum Aqueous acid—262 nm (A^1_1=1515a). No alkaline shift



Infrared Spectrum Principal peaks at wavenumbers 1631, 1590, 1171, 1181, 1316, 1242 cm^{-1}.

Acrivastine

Antihistamine

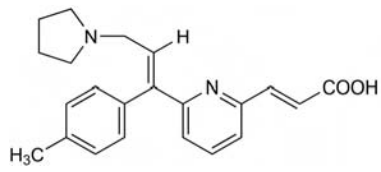
$C_{22}H_{24}N_2O_2 = 348.4$

CAS—87848-99-5

IUPAC Name (*E*)-3-[6-[(*E*)-1-(4-Methylphenyl)-3-pyrrolidin-1-ylprop-1-enyl] pyridin-2-yl]prop-2-enoic acid

Synonyms BW-270C; BW-825C; BW-A825C; (*E*)-3-{6-[(*E*)-3-Pyrrolidin-1-yl-1-*p*-tolylprop-1-enyl]-2-pyridyl}acrylic acid.

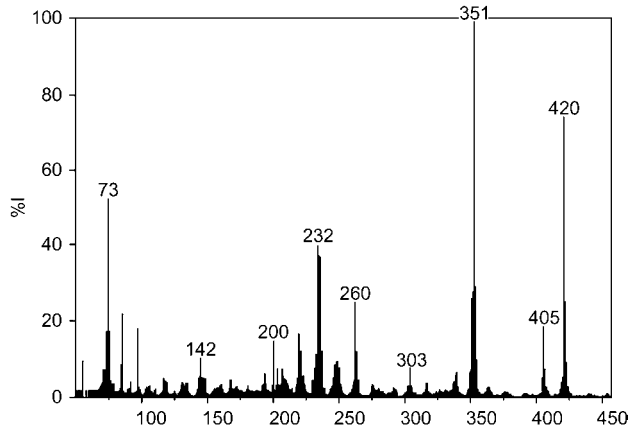
Proprietary Names *Benadryl*; *Semprex*.



Chemical Properties An odourless, white to pale cream crystalline powder. Mp 222°. It is slightly soluble in water; soluble in chloroform and ethanol. Log *P* (octanol/water), 2.83.

High Performance Liquid Chromatography Column: RP-C_{18} LiChrosorb (200 × 4.6 mm i.d., 5 µm). Mobile phase: water : acetonitrile : methanol : perchloric acid : *n*-octylamine (500:130:25:13:0.3), flow rate 3 mL/min. UV detection (λ=260 nm). Retention time: 6.6 min [Altuntas *et al.* 1998].

Mass Spectrum Principal ions at *m/z* 351, 420, 73, 232, 233, 260, 405, 200 (TMS derivative).



Quantification

Plasma **GC-MS** Limit of detection, about 2 µg/L for acrivastine and propionic acid metabolite [Chang *et al.* 1989].

Disposition in the Body Acrivastine is well absorbed after oral administration. Peak plasma concentrations are reached in about 1.5 h. It is does not cross the blood–brain barrier to a significant extent. The drug undergoes some metabolism to form a propionic acid analogue that has pharmacological activity and makes up approximately 10% of the total plasma drug concentration. About 60% of an administered dose is excreted unchanged in urine and 15 to 17% of this is detected as the metabolite.

Therapeutic Concentration

A mean peak plasma concentration of 73.1 (range, 48.1 to 101.0) µg/L was obtained 1.42 h (range, 0.75 to 2 h) after oral administration of a single dose of 4 mg to 12 healthy male subjects, aged between 20 and 42 years [Cohen *et al.* 1985].

Bioavailability 18%.

Half-life Plasma, 1.4 to 2.1 h (acrivastine); 2.3 h (metabolite).

Volume of Distribution 0.64 L/kg (single dose); 0.75 L/kg (multiple).

Clearance Total body, 4.41 ± 0.63 mL/min/kg.

Protein Binding 50%.

Note For a review of acrivastine see Brogden and McTavish [1991].

Dose 8 mg 3 times daily (in Europe and UK) or 4 times daily (USA).

Altuntas TG *et al.* (1998). Quantitative determination of acrivastine and pseudoephedrine hydrochloride in pharmaceutical formulation by high performance liquid chromatography and derivative spectrophotometry. *J Pharm Biomed Anal* 17: 103–109.

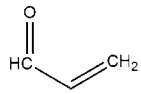
A

Acrolein

Aldehyde, Herbicide, Lachrymator
$C_3H_4O = 56.1$
CAS—107-02-8

IUPAC Name Prop-2-enal
Synonyms Acraldehyde; acrylaldehyde; acrylic aldehyde; aqualin (shell); 2-propenal.



Chemical Properties Colourless to slightly yellow liquid with a pungent odour. Mp −88°. Soluble in 2 to 3 parts water, in alcohol, in ether. Log *P* (octanol/water), −0.01 [Hansch *et al.* 1995]. Unstable, polymerises (especially under light or in the presence of alkali or strong acid) forming disacryl, a plastic solid. Stable in PBS for at least 2 h at 4° but in urine stable for 30 min at 4° [Sakura *et al.* 1998].

For the absorption spectrum, see O'Neil *et al.* [2006].

Quantification

Plasma **HPLC** Column: C_{18} RP ODS Uptisphere (150 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : imidazole buffer (pH 7.5, 30 : 70), flow rate 1.8 mL/min. Fluorescence detection (λ_{ex}=407 nm, λ_{em}=507 nm). Limit of quantification, 16.8 µg/L, limit of detection, 5.6 µg/L [Paci *et al.* 2000].

Urine **GC-MS** Column: DB-WAX capillary (30 m × 0.32 mm i.d., 0.5 µm). Carrier gas: He, 2.0 mL/min. EI ionisation, SIM acquisition mode. Retention time: 1.4 min. Limit of detection not reported [Takamoto *et al.* 2004]. Column: DB-WAX capillary (30 m × 0.32 mm i.d., 0.5 µm). Carrier gas: He, 2.0 mL/min. Temperature: 70°. EI ionisation, SIM acquisition mode. Limit of detection, 1.0 nmol/L [Takamoto *et al.* 2001]. Column: DB-1 capillary (60 m × 0.5 mm i.d., 0.25 µm). Carrier gas: He, 1.7 mL/min. Temperaature: 70°. SIM acquisition mode. Limit of detection, 1–5 nmol/L [Sakura *et al.* 1998].

HPLC Column: C_{18} (10 cm × 8 mm i.d., 10 µm). Mobile phase: 0.05 mol/L dibasic ammonium phosphate solution (pH 2.5) : acetonitrile : methanol (92 : 6 : 2), flow rate 3 mL/min. Fluorescence detection (λ_{ex}= 360 nm, λ_{em}= 495 nm). Retention time: 4.3 min. Limit of detection, 1.0 mg/L [Al Rawithi *et al.* 1993].

LC-MS Column: Luna C_8 (150 × 4.6 mm i.d., 3 µm). Mobile phase: 0.1% formic acid (pH 2.5) : acetonitrile (75 : 25 for 2 min to 50 : 50 within 6 min for 4 min to 0 : 100 in 2 min for 4 min to 75 : 25 in 4 min for 4 min), flow rate 0.3 mL/min. ESI, MRM acquisition mode. Retention time: 10.7 min. Limit of detection, 5 µg/L for 3-HPMA [Schettgen *et al.* 2008].

Saliva **HPLC** Column: C_{18} Synergi Phenomenex (50 × 4.6 mm i.d., 4 µm). Mobile phase: water-tetrahydrofuran (80 : 20) : acetonitrile- tetrahydrofuran (80 : 20, 100 : 0 to 20 : 80 in 20 min), flow rate 1.2 mL/min. UV detection (λ= 365 nm). Limit of detection, 10 pmol [Annovazzi *et al.* 2004].

CE Capillary: fused silica (57/50 cm total/effective length × 50 µm i.d.). Running buffer: 20 mmol/L sodium tetraborate (pH 9.0) containing 60 mmol/L SDS. UV detection (λ= 365 nm). Limit of detection, 0.6 pmol [Annovazzi *et al.* 2004].

Brain **LC-MS** Column: C_{18} reversed phase. Mobile phase: 0.1% formic acid in water : 0.1% formic acid in acetonitrile (95 : 5 for 2 min to 80 : 20 in 8 min to 30 : 70 in 20 min to 10 : 90 in 20 min to 5 : 95 in 5 min to 95 : 5), flow rate 4 µL/min. ESI. Limit of detection, 6.5 pg [Williams *et al.* 2005].

Expired Air Condensate **LC-MS** Column: Supelcosil LC-18-DB (75 × 4.6 mm i.d., 3 µm). Mobile phase: 20 mmol/L aqueous acetic acid : methanol (57 : 43 to 2 : 98 in 3.2 min for 2.5 min. ESI or APCI, negative ion mode, SRM acquisition mode. Limit of detection, 1.0 nmol/L [Andreoli *et al.* 2003].

Other **HPLC** Human Liver Microsomes. Column: LiChrosorb 100 RP-8 (125 × 3 mm i.d., 5 µm). Mobile phase: 0.5% phosphoric acid : acetonitrile (96 : 4), flow rate 0.4 mL/min. Fluorescence detection (λ_{ex}= 358 nm, λ_{em}= 505 nm). Retention time: 8 min. Limit of quantification, 10 µg/L, limit of detection, 5 µg/L [Bohnenstengel *et al.* 1997].

Disposition in the Body When glycerol is heated to 280° it decomposes to acrolein. It is one of the main components of mainstream cigarette smoke, and its local noxious and carcinogenic effects in the oral cavity and upper gastrointestinal tract are well known [Annovazzi *et al.* 2004]. It is also the metabolite of cyclophosphamide and ifosphamide [Kaijser *et al.* 1993], irritates mucous membranes, and is considered pathogenetically important in hemorrhagiccystitis [Takamoto *et al.* 2004].

Toxicity Potential symptoms of overexposure are irritation of eyes, skin and mucous membranes; decreased pulmonary function; delayed pulmonary edema; chronic respiratory disease [NIOSH, 1997).

LD_{50} (oral) in rats: 0.046 g/kg [O'Neil *et al.* 2006].

Uses Manufacture of colloidal forms of metals, making plastics, perfumes, warning agent in methyl chloride refrigerant. Has been used in military poison gas mixtures. Used in organic syntheses [O'Neil *et al.* 2006].

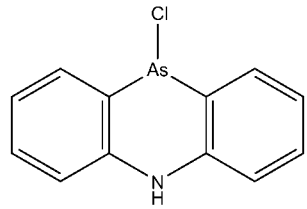
Adamsite

Chemical Warfare Agent, Organic Arsenical, Riot Control Agent
$C_{12}H_9AsClN = 277.6$
CAS—578-94-9

IUPAC Name 10-Chloro-5*H*-phenarsazinine
Synonyms 5-Aza-10-arsenaanthracene chloride; 10-chloro-5,10-dihydroarsacridine; 10-chloro-5,10-dihydrophenarsazine; diphenylaminechlorarsine; DM; phenazarsine chloride.



Chemical Properties Canary-yellow crystals from carbon tetrachloride; also reported as yellow to green solid. Dimorphous. The stable form occurs as orthorhombic crystals. Mp 195°. Bp 410° with decomposition. Sublimes readily. Practically insoluble in water (0.4 mg/L; also reported as 0.64 mg/L). Slightly soluble in benzene, xylene, carbon tetrachloride. Soluble in acetone (13 g/100 g at 15°). Corrodes iron, bronze, brass (The metastable form melts at 186° if monoclinic, and at 182° if triclinic) [Ludemann *et al.* 1969; Olajos, Salem 2001; O'Neil MJ *et al.* 2006]. Log *P* (octanol/water), 4.05 [Sanderson *et al.* 2008]. As a solid, the rate of hydrolysis is not significant owing to the formation of an oxide coating; however, the rate of hydrolysis is rapid when it is in the form of an aerosol. Hydrolysis products are hydrochloric acid and diphenylarsenious acid [Olajos, Salem 2001]. Fungal manganese peroxidase has been shown to be a useful biocatalyst to convert hazardous organopollutants that include adamsite [Haas *et al.* 2004].

Thin-layer Chromatography Plates: basic silica gel-G (250 µm). Solvent systems: (1) acetone : chloroform (20 : 80); (2) ethyl acetate : methanol (10 : 90). Locating reagent *o*-dianisidine and sulfuric acid. R_f values reported as follows:

Compound	*R_f value*		*Spot colour*
	System 1	**System 2**	
Adamsite	0.35	0.23	Orange
Diphenylcyanoarsine	0.65	—	Rose
Diphenylamine	0.08	0.15	Green
Adamsite oxide	—	0.38	Orange

Limit of quantification not reported [Ludemann *et al.* 1969].

High Performance Liquid Chromatography Column: C_{18} (250 × 3.0 mm i.d., 5 µm). Mobile phase: methanol : water (20 : 80 to 80 : 20 over 45 min to 100 : 0 over 1 min), flow rate 0.5 mL/min. UV detection (λ = 210 and 230 nm). Retention time: ~36 min. Limit of quantification not reported [Haas *et al.* 2004].

Disposition in the Body

Toxicity Adamsite is one of several compounds classified as vomiting agents, including diphenylchloroarsine (DA), diphenylcyanoarsine (DC) and chloropicrin. It is more toxic than other riot control compounds and is considered a potentially dangerous agent. The effects from adamsite begin approx. 30 min after the onset of exposure and may last an hour or two. In addition to other standard signs and symptoms of exposure to lachrymatory agents (eye and upper respiratory tract irritation, coughing, etc.), exposure to adamsite can cause unsteady gait, weakness in the limbs, and trembling, and even mental depression. Exposure to high concentrations may result in serious illness and even death [Olajos, Salem 2001]. The maximum 'safe' inhaled dose of adamsite for humans was reported as 100 mg•min/m^3; however, many of the experiments were terminated so as to not exceed the 'safe' dosage [Punte *et al.* 1962]. Human ocular irritancy thresholds and toxicity estimates are reported as follows: irritancy threshold 1 mg/m^3, intolerable concentration 5 mg/m^3, lethal concentration (10 min exposure) 650 mg/m^3. The inhalation toxicity of chemical warfare agents, military chemicals, and riot control agents is, by convention, expressed by the notation Ct. It is defined as the product of the concentration in mg/m^3 multiplied by the exposure time (t) in minutes (mg•min/m^3). The terms LCt_{50} and ICt_{50} describe the airborne dosages that are lethal (L) or incapacitating (I) to 50% of the exposed population. The estimated LCt_{50} for adamsite in humans is between 11 000 and 35 000 mg•min/m^3, whereas the ICt_{50} is reported as between 20 and 150 mg•min/m^3. Animal LCt_{50} estimates (mg•min/m^3) are reported as rat 3700, mouse 22400, and guinea pig 7900. Computed inhaled LD_{50} values (mg/kg) are reported as: rat 14.1, mouse 17.9, and guinea pig 2.4 [Olajos, Salem 2001]. LCt_{50} in fish (mg/L) is 0.44 [Sanderson *et al.* 2007].

Adenosine

Antiarrhythmic

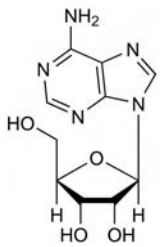
$C_{10}H_{13}N_5O_4 = 267.2$

CAS—58-61-7

IUPAC Name (2*R*,3*R*,4*S*,5*R*)-2-(6-Aminopurin-9-yl)-5-(hydroxymethyl)oxolane-3,4-diol

Synonyms Adenine nucleoside; adenine riboside; 6-amino-9-β-D-ribofuranosyl-9*H*-purine.

Proprietary Names *Adenocard*; *Adenocor*; *Adenoscan*; *Adenosin*; *Adrekar*; *Krenosin*.



Chemical Properties Adenosine is a white crystalline powder. Mp 234°, with decomposition >300°. Adenosine is soluble in water (approx. 8 g/L) and practically insoluble in alcohol. pK_a 3.5. Log *P* (octanol/water), −1.05. Extraction yield (chlorobutane), 0 [Demme *et al.* 2005].

Adenosine Triphosphate

$C_{10}H_{16}N_5O_{13}P_3 = 507.2$

CAS—56-65-5

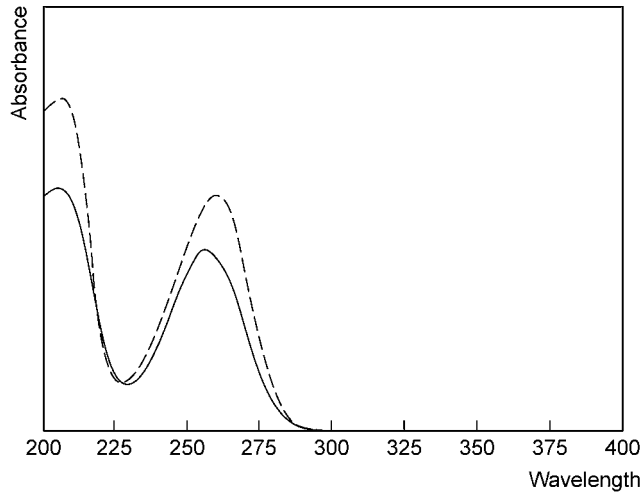
Synonyms Adenosine 5′-triphosphate; 5′-adenyldiphosphoric acid; adenylpyrophosphoric acid; ATP; adenosine 5′-(tetrahydrogen triphosphate).

Proprietary Names *Atepadene*; *Atepodin*; *Bio-Regenerat*; *Striadyne*.

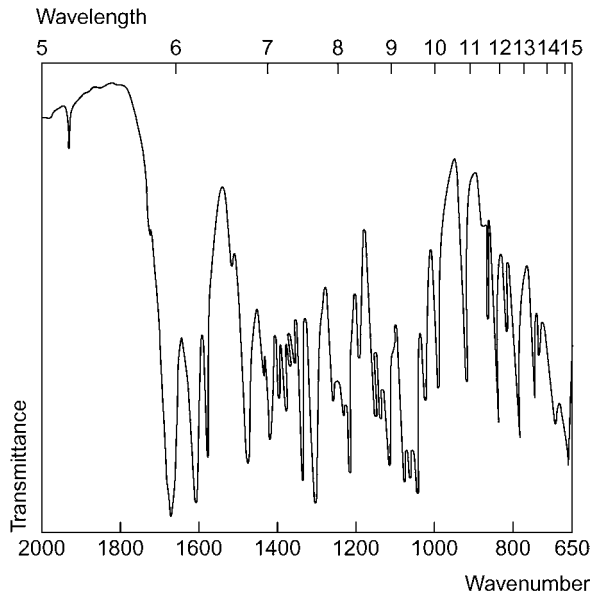
Thin-layer Chromatography Plate: octadecyl-modified silica treated with copper acetate and (2*S*,4*R*,2′*RS*)-4-hydroxyl-1-(2-hydroxydodecyl)proline (Chiral). Mobile phase: methanol : water : acetonitrile (50:50:50). R_f 0.8 [Feldburg, Reppuci 1987]. Plate: Whatman LK5DF. Mobile phase: IPA : water : ammonia (7:2:1). R_f 0.6. Plate: Whatman LHPKDF. Mobile phase: IPA : water : ammonia (7:2:1). R_f 0.7. Plate: Whatman LKC18DF. Mobile phase: IPA : water : DMSO (16:4:1). R_f 0.6. Plate: Whatman C2. Mobile phase: IPA : water : DMSO (16:4:1). R_f 0.8. Plate: Whatman SCX. Mobile phase: 0.1 mol/L ammonium hydrogen phosphate and 1 mol/L sodium chloride. R_f 0.7 [Sherma 1982]. Plate: silanised aminopropyl. Mobile phase: methanol : water (46:60) and sodium chloride (0.18 mol/L). R_f 0.8 [Hauck, Jost 1983].

High Performance Liquid Chromatography System HAA—retention time 2.7 min.

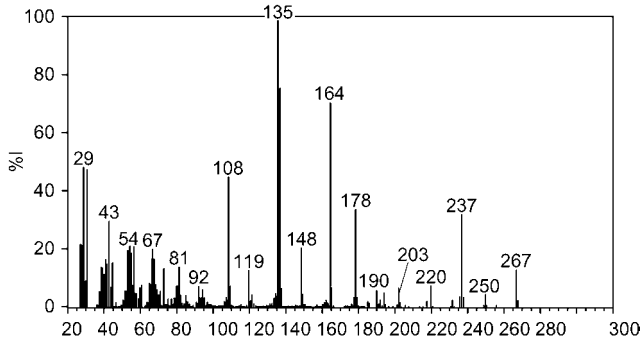
Ultraviolet Spectrum Aqueous acid (0.1 mol/L hydrochloric acid), alkali (0.1 mol/L sodium hydroxide) and water—209, 259 nm.



Infrared Spectrum



Mass Spectrum Principal ions at *m/z* 135, 136, 164, 29, 31, 108, 178, 237.



Disposition in the Body Extremely efficient re-uptake of adenosine from plasma by red blood cells and blood vessel endothelial cells. Once inside the blood cells, adenosine is phosphorylated, by adenosine kinase, to adenosine monophosphate (AMP). Alternatively, it is deaminated, by adenosine deaminase, to inactive inosine, which can be further degraded to hypoxanthine and then uric acid. Adenosine is almost completely eliminated after a single pass through the coronary circulation. It is naturally found in various forms in all cells of the body.

Therapeutic Concentration Administered dose is minute in comparison with adenosine concentrations already in the body and due to the efficient re-uptake, classic ADME studies are not possible.
Half-life 0.6 to 10 s.
Distribution in Blood Erythrocytes transport adenosine from the liver to tissues which cannot synthesise it.
Dose Initial dose is 6 mg (rapid IV bolus injection, administered over 1 to 2 s), followed by a saline flush. Up to 2 additional 12 mg boluses, within 1 to 2 min after initial dose, if necessary. A dose of 0.05 to 0.1 mg/kg body weight is effective in children with a maximum of 0.3 mg/kg.

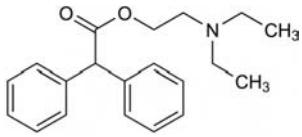
Adiphenine

Anticholinergic
$C_{20}H_{25}NO_2 = 311.4$
CAS—64-95-9

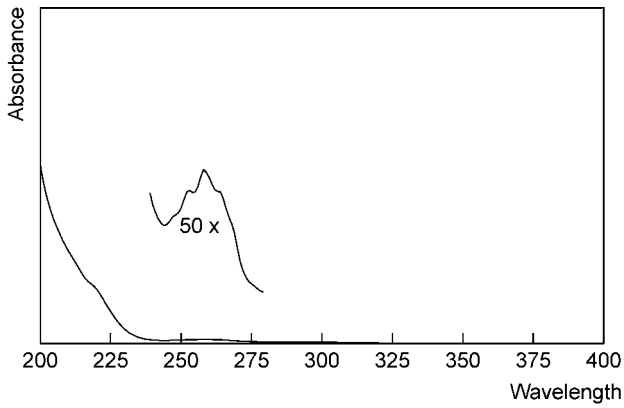
IUPAC Name 2-Diethylaminoethyl 2,2-diphenylacetate
Synonyms Diphacil; diphenylacetyldiethylaminoethanol; α-phenylbenzeneacetic acid 2-(diethylamino)ethyl ester.



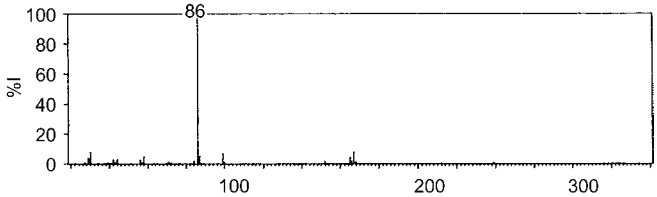
Adiphenine Hydrochloride

$C_{20}H_{25}NO_2,HCl = 347.9$
CAS—50-42-0
Synonym Spasmolytine
Proprietary Name *Trasentine*
Chemical Properties A white crystalline powder. Mp 112° to 115°. Soluble in water, ethanol and chloroform; practically insoluble in ether.

Colour Tests Liebermann's reagent—brown; Mandelin's test—green→blue.
Thin-layer Chromatography System TA—R_f 0.64; system TB—R_f 0.56; system TC—R_f 0.60; system TE—R_f 0.83; system TAE—R_f 0.49; system TL—R_f 0.51 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—RI 2186.
High Performance Liquid Chromatography System HA—*k* 1.8; system HX—RI 422.
Ultraviolet Spectrum Aqueous acid—253, 258 (A^1_1=14.5a), 264 nm.



Infrared Spectrum Principal peaks at wavenumbers 1736, 1145, 700, 1190, 1500, 746 cm^{-1} (KBr disk).
Mass Spectrum Principal ions at *m/z* 86, 30, 167, 99, 87, 58, 165, 29.

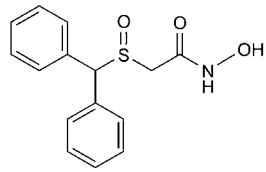


Dose Adiphenine hydrochloride has been given in doses of 225 to 450 mg daily.

Adrafinil

α-Adrenoceptor Agonist
$C_{15}H_{15}NO_3S = 289.4$
CAS—63547-13-7

IUPAC Name 2-Benzhydrylsulfinyl-*N*-hydroxyacetamide
Synonyms Adrafinilum; 2-(benzhydrylsulfinyl)acetohydroxamic acid; 2-[(diphenylmethyl)sulfinyl]-acetohydroxamic acid; 2-[(Diphenylmethyl)sulfinyl]-N-hydroxyacetamide.
Proprietary Name *Olmifon*



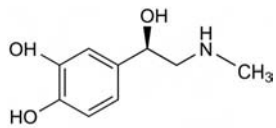
Chemical Properties White to off-white crystalline powder. Mp 154° to 160°. Slightly soluble in water (<1 g/L), more soluble in ethanol and soluble in methanol.
High Performance Liquid Chromatography System HAA—retention time 13.8 min.
Quantification
Other **LC-MS** Rat Serum. Column: Kromasil C_{18} (250 × 4.6 mm i.d., 5 μm). Mobile phase: acetonitrile : water: acetic acid (35 : 65 : 0.1), flow rate 1.0 mL/min. ESI, positive ion mode. Limit of quantification, 11.6 μg/L, limit of detection, 3.5 μg/L [Rao *et al.* 2008].
Disposition in the Body After oral administration, adrafinil is partly metabolised to its amide, 2-(benzhydrylsulfinyl)acetamide (2-[(diphenylmethyl)sulfinyl]acetamide; modafinil), which is also metabolised into its inactive acid and sulfone forms.
Toxicity Low toxicity.
Half-life Elimination half-life, adrafinil 1 h; modafinil 3 h.
Protein Binding To albumin, 80%.
Dose Between 600 mg and 1.2 g daily by mouth (for the elderly).

Rao RN *et al.* (2008). LC-ESI-MS determination and pharmacokinetics of adrafinil in rats. *J Chromatogr B Analyt Technol Biomed Life Sci* 873: 119–123.

Adrenaline

Sympathomimetic
$C_9H_{13}NO_3 = 183.2$
CAS—51-43-4

IUPAC Name 4-[(1*R*)-1-Hydroxy-2-(methylamino)ethyl]benzene-1,2-diol
Synonyms Epinephrine; epirenamine; levorenin; suprarenin.
Proprietary Names *Bronkaid Mistometer*; *Dyspné-Inhal*; *Epi-glaufrin*; *Epinal*; *Eppy*; *Glauposine*; *Primatene Mist*; *Simplene*; *Suprarenaline*; *Sus-Phrine*; *Vaponefrin*. It is an ingredient of *Asma-Vydrin*; *Brovon*; *Ganda*; *Isopto*; *Epinal*; *Riddovydrin Inhalant*; *Rybarvin*.



Chemical Properties A white or creamy-white crystalline powder or granules. It darkens in colour on exposure to air and light. It is unstable in neutral or alkaline solution. Mp ≈212°, with decomposition. Sparingly soluble in water; practically insoluble in ethanol, chloroform, ether, and light petroleum; freely soluble in solutions of mineral acids and boric acid solution, and in solutions of sodium or potassium hydroxide. pK_{a1} 8.7, pK_{a2} 10.2, pK_{a3} 12.0 (20°).

Adrenaline Acid Tartrate

$C_9H_{13}NO_3,C_4H_6O_6 = 333.3$
CAS—51-42-3
Synonyms Adrenaline bitartrate; adrenaline tartrate; epinephrine bitartrate.
Proprietary Names *E1*; *E2*; *Epitrate*; *Liadren*; *Lyophrin*; *Medihaler Epi*. It is an ingredient of *E-Pilo*; *Mydricaine*; *PE*; *Welder's Flash Drops*.
Chemical Properties A white to greyish-white or light brownish-grey, crystalline powder. It slowly darkens on exposure to air and light. Incompatible with alkalis. Mp 147° to 152°, with decomposition. Soluble 1 in 3 of water and 1 in 520 of ethanol; practically insoluble in chloroform and ether.

Adrenaline Hydrochloride

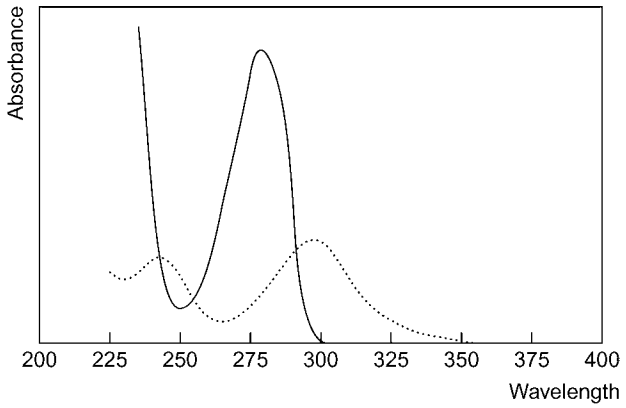
$C_9H_{13}NO_3,HCl = 219.7$
CAS—55-312

Proprietary Names *Epifrin*; *Glaucon*; *Glycirenan*. It is an ingredient of *Riddobron Inhalant*; *Riddofan*.
Colour Tests Ammoniacal silver nitrate—red-brown/red-brown; ferric chloride—green; folin–Ciocalteu reagent—blue; Marquis test—orange→violet; methanolic potassium hydroxide—pink-orange→brown; Nessler's reagent—black; palladium chloride—orange→brown; potassium dichromate (method 1)—green→brown.

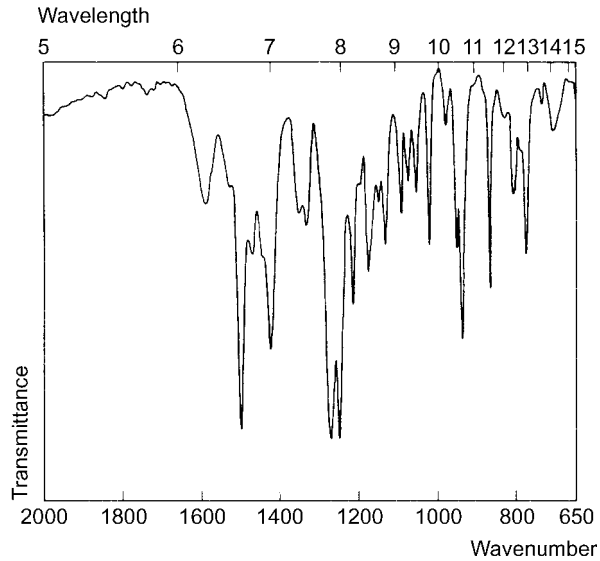
Thin-layer Chromatography System TA—R_f 0.00; system TB—R_f 0.00; system TC—R_f 0.01; system TE—R_f 0.13; system TAE—R_f 0.30; system TAG—R_f 0.00 (acidified potassium permanganate solution—positive).

High Performance Liquid Chromatography System HC—*k* 0.63; system HX—RI 30.

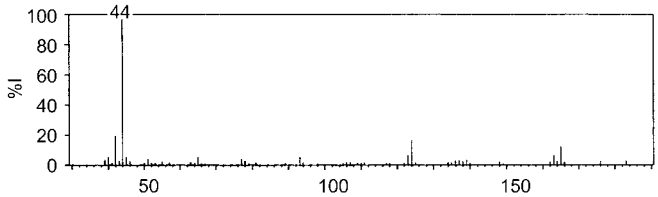
Ultraviolet Spectrum Aqueous acid—280 (A^1_1 = 155a); aqueous alkali—242, 297 nm.



Infrared Spectrum Principal peaks at wavenumbers 1253, 1274, 1500, 945, 1224, 871 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 44, 42, 124, 165, 163, 123, 93, 65.



Quantification

Plasma **GC** Column: 7% DC-11 on 80/100 mesh Gas Chrom P (1.8 m × 3.1 mm [6 ft × 0.125 in] o.d.). Carrier gas: He, 20 mL/min. Temperature: 115°. FID. Limit of detection, 0.1 pg [Lovelady, Foster 1975].

HPLC Column: PLRP-S 100 Å (150 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : 0.025 mol/L sodium phosphate-0.025 mol/L citric acid-0.001 mol/L heptane and sulfonic acid (pH 2.85), flow rate 0.75 mL/min. Fibre optic detection. Retention time: 210 s. Limit of detection, 3.5 ng/L [Ferreira *et al.* 2009]. Column: reversed phase (150 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : 0.025 mol/L sodium phosphate-0.025 mol/L citric acid-0.001 mol/L heptane (pH 2.8, 55 : 95), flow rate 0.75 mL/min. Electrochemical detection. Limit of detection, 3.4 ng/L [Silva *et al.* 2009]. Column: Deverosil RP Aqueous-AR-5 triacontylsilyl silica C_{30} (250 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : 10.5 g/L citric acid and 20 mg/L EDTA (pH 2.8, 2 : 98), flow rate 0.3 mL/min. Electrochemical detection. Retention time: 9.2 min. Limit of quantification, 20 ng/L, limit of detection, 10 ng/L [Machida *et al.* 2006]. Column: RP C_{18} Ultrasphere-ODS (250 × 4.6 mm i.d., 5 mm). Mobile phase: 0.1 mol/L citrate buffer, 0.3 mol/L disodium EDTA and 0.5 µmol/L sodium 1-octanesulfonic acid in methanol : water (pH 2.5, 7 : 93), flow rate 1.2 mL/min. Electrochemical detection. IS: isoproterenol. Retention time: noradrenaline 3.5 min, adrenaline 4.1 min, IS 9.6 min. Limit of detection, <10 pg [Wang *et al.* 1999].

Serum **GC** See Plasma [Lovelady, Foster 1975].

Urine **GC** See Plasma [Lovelady, Foster 1975].

HPLC See Plasma [Ferreira *et al.* 2009; Silva *et al.* 2009].

Note For spectrofluorimetry for the quantification of adrenaline, see O'Hanlon *et al.* [1970].

Disposition in the Body Adrenaline is rapidly destroyed in the gastrointestinal tract after oral administration; the effects of adrenaline after SC injection are produced within 5 min and appear more slowly than after IM injection. It is rapidly taken up by the heart, spleen, several glandular tissues and adrenergic nerves; only metabolites are detectable in CSF. The major metabolic reactions are oxidative deamination and *O*-methylation followed by reduction or by glucuronic acid or sulfate conjugation. Approximately 70–95% of an IV dose is excreted in the urine; of the excreted material, ~80% is *O*-methyl metabolites, 2% is catechol metabolites and only 1% is unchanged drug. The major urinary metabolite is 4-hydroxy-3-methoxymandelic acid (HMMA); other metabolites include 4-hydroxy-3-methoxyphenylacetic acid (homovanillic acid, HVA), conjugated metanephrine and 4-hydroxy-3-methoxyphenylglycol, together with minor amounts of 3,4-dihydroxymandelic acid in free or conjugated form and *N*-methyladrenaline.

Endogenous plasma concentrations of adrenaline in normal subjects are in the range 30–160 ng/L.

Toxicity The minimum SC lethal dose is ~4 mg, but recoveries have occurred after accidental overdosage with 16 mg SC and 30 mg IV, followed by immediate supportive treatment.

Protein Binding ~50%.

Dose 200 to 500 µg, SC or IM, as a single dose which may be repeated.

Adrenalone

Haemostatic, Sympathomimetic, Vasoconstrictor

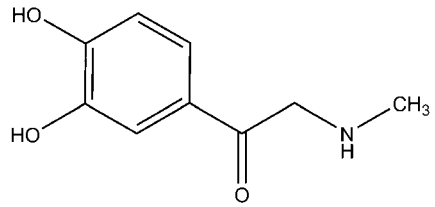
$C_9H_{11}NO_3$ = 181.2

CAS—99-45-6

IUPAC Name 1-(3,4-Dihydroxyphenyl)-2-(methylamino)ethanone

Synonyms Adrenone; 3,4-dihydroxy-α-methylaminoacetophenone; 3′,4′-dihydroxy-2-(methylamino)-acetophenone; 4-methylaminoacetopyrocatechol.

Proprietary Name *Stryphon*



Chemical Properties Mp 235.5°. Sparingly soluble in water. Log *P* (octanol/water), 0.47 [Meylan, Howard 1995].

Adrenalone Hydrochloride

$C_9H_{11}NO_3$,HCl = 217.7

CAS—62-13-5

Proprietary Names *Haemodan*; *Kephrine*; *Levorene*; *Stryphnnasal*.

Chemical Properties Crystals. Mp 243°. Freely soluble in water, soluble in alcohol, insoluble in ether.

Ultraviolet Spectrum Peaks at 205, 232, 280 and 312 nm.

Quantification

Other **HPLC** USP Adrenaline Injections. Column: Zorbax CN (250 × 4.6 mm i.d., 0.45 µm). Mobile phase: 5 mmol/L octane sulfonic acid sodium salt, 0.1 mmol/L sodium EDTA in 20 mL acetonitrile, and 10 mL methanol per litre of water (pH 3.5), flow rate 1.5 mL/min. Electrochemical detection followed by UV detection (λ = 254 nm). Retention time: 10.5 min. Limit of detection not reported [Kirchhoefer *et al.* 1985].

Dose In adults, IM or SC, 500 µg to 2 mg daily; orally, 2.5 mg to 10 mg daily.

Kirchhoefer RD *et al.* (1985). Analysis of USP epinephrine injections for potency, impurities, degradation products, and *d*-enantiomer by liquid chromatography, using ultraviolet and electrochemical detectors. *J Assoc Off Anal Chem* 68: 163–165.

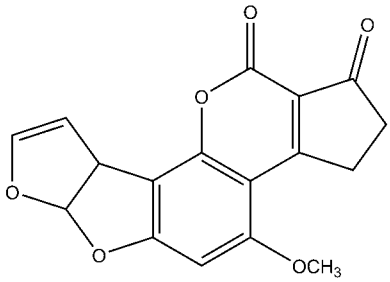
A

Aflatoxins B

Difuranocoumarin, Mycotoxin



Chemical Properties Aflatoxins are a closely related group of secondary fungal metabolites produced by *Aspergillus flavus, A. bombycis*, *A. ochraceoroseus*, *A. parasiticus, A. pseudotamari*, *A. nomius* and *Penicillium puberulum*, but not all strains of *A. flavus* and *A. parasiticus* produce aflatoxins. The four naturally occurring aflatoxins are aflatoxins B_1 (AFB_1), B_2 (AFB_2), G_1 (AFG_1) and G_2 (AFG_2), although AFB_1 is the most commonly occurring compound. Aflatoxins M_1 (AFM_1) and M_2 (AFM_2) are the 4-hydroxylated aflatoxin B derivatives found in the milk of cows fed contaminated meal. Further aflatoxins have been described, especially as mammalian biotransformation products of the major metabolites. Conditions for the growth and production of the naturally occurring aflatoxins in foodstuffs include a moisture content of 18 to 19.5% and a temperature of 25° to 40°. The next most important factor is the presence of zinc as a trace element (e.g. in groundnuts and corn). The B toxins are so named because they exhibit blue fluorescence under UV light [Bennett, Klich 2003; Denning 1987; Wild, Hall 2000]. Aflatoxins are freely soluble in moderately polar solvents (e.g. chloroform and methanol), especially in dimethyl sulfoxide, and also have some water solubility. They are very stable at high temperatures, with little or no destruction occurring under ordinary cooking conditions or during pasteurisation. The presence of the lactone ring in their structure makes the aflatoxins susceptible to alkaline hydrolysis. Acid treatments are also used frequently for their detoxification [McLean, Dutton 1995].

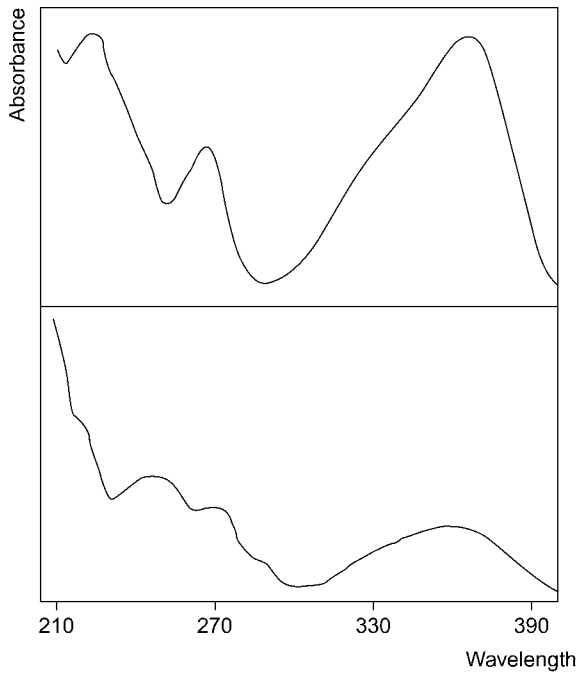
Aflatoxin B_1

$C_{17}H_{12}O_6$ = 312.3
CAS—1162-65-8
IUPAC Name (6a*R-cis*)-2,3,6a,9a-Tetrahydro-4-methoxycyclopenta[*c*]furo[3′,2′:4,5]furo[2,3-*h*][1]benzopyran-1,11-dione
Synonym AFB_1
Chemical Properties Crystals. Mp 268° to 269° [O'Neil *et al.* 2006].

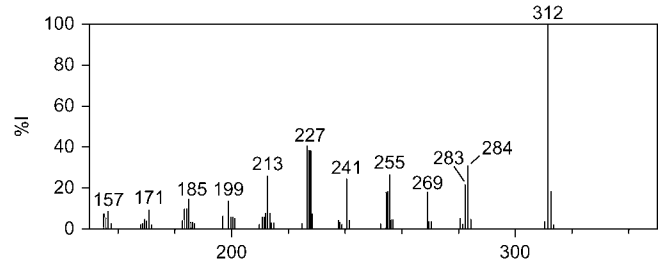
Aflatoxin B_2

$C_{17}H_{14}O_6$ = 314.3
CAS—7220-81-7
IUPAC Name (6a*R-cis*)-2,3,6a,8,9,9a-Hexahydro-4-methoxycyclopenta[*c*]furo[3′,2′:4,5]furo[2,3-*h*][1]benzopyran-1,11-dione
Synonym AFB_2
Chemical Properties The 8,9-dihydro derivative of AFB_1. Crystals. Mp 268° to 269° [O'Neil *et al.* 2006].

Ultraviolet Spectrum Ethanol—223, 362, 265 nm (AFB_1); 363,265 nm (AFB_2) [Dragsted *et al.* 1988].



Mass Spectrum Tsuboi *et al.* [1984].



Quantification

Blood **HPLC** Column: C_{18} (250 × 5.0 mm i.d., 5 µm). Mobile phase: water : acetonitrile (75 : 25), flow rate 2.0 mL/min. Fluorescence detection (λ_{ex} = 365 nm, λ_{em} = 418 nm). Limit of detection, AFB_1 250 ng/L, AFM_1 100 ng/L, AFM_2 30 ng/L [Abdulrazzaq *et al.* 2002]. Column: C_{18} (200 × 2.1 mm i.d., 5 µm). Mobile phase: acetonitrile : water (32 : 68), flow rate 0.2 mL/min. Fluorescence detection (λ_{ex} = 365 nm, λ_{em} = 432 nm). Relative retention times: AFB_1 1.60, AFB_2 1.29, AFG_1 1.22, AFG_2 1.00, AFM_1 0.776, AFB_{2a} 0.568, AFG_{2a} 0.493, AFM_{2a} 0.353 (relative to AFG_2, retention time: 19.1 min). Limit of detection, AFB_1 3 ng/L, AFB_2 10 ng/L, AFG_1 3 ng/L, AFG_2 10 ng/L [Chao *et al.* 1994].

Serum **HPLC** Column: C_{18} (150 × 4.6 mm i.d.). Mobile phase: methanol : water : acetonitrile (25 : 25 : 50), flow rate 0.8 mL/min. Fluorescence detection (λ_{ex} = 366 nm, λ_{em} = 418 nm). Retention time: AFB_1 2.5 min. Limit of quantification not reported [Lopez *et al.* 2002]. Column: C_{18} (125 × 4.0 mm i.d., 5 µm). Mobile phase: 0.02 mol/L sodium phosphate (pH 7.2) : methanol (100 : 0 for 2 min to 40 : 60 over 20 min), flow rate 1.0 mL/min. Fluorescence detection (λ_{ex} = 405 nm, λ_{em} = 470 nm). Retention time: aflatoxin–lysine adduct 18.2 min. Limit of quantification, 9.1 pg on-column [Sabbioni 1990]. Column: C_{18} (250 × 5.0 mm i.d., 5 µm). Mobile phase: water : methanol (50 : 50), flow rate 2.0 mL/min. Fluorescence detection (λ_{ex} = 365 nm, λ_{em} = 418 nm). Retention times: AFB_1 ~7.5 min, AFB_2~ 6.0 min, AFG_1 ~5.0 min, AFG_2 ~4.5 min, AFM_1 ~4.0 min, AFM_2 ~3.0 min, aflatoxicol ~11.0 min. Limit of detection, AFB_1 250 ng/L; AFG_1 500 ng/L; AFM_1 and aflatoxicol 100 ng/L; AFB_2, AFG_2, and AFM_2 25 ng/L [Lamplugh 1983].

Urine **TLC** Plates: silica gel G-HR (20 × 20 cm, 0.5 mm). Solvent system: acetone : chloroform : propan-2-ol (10 : 85 : 5). UV detection. R_f values: AFB_1 0.73, AFG_1 0.59, AFM_1 0.44, AFB_{2a} 0.39, AFG_{2a} 0.29, aflatoxicol-1 0.69, aflatoxicol-2 0.62, tetrahydrodeoxy-AFB_1 0.79. Limit of detection, AFB_1 90 ng/L, AFG_1 13 ng/L, AFM_1 27 ng/L, AFB_{2a} 125 ng/L, AFG_{2a} 73 ng/L, aflatoxicol-1 57 ng/L, aflatoxicol-2 42 ng/L, tetrahydrodeoxy-AFB_1 33 ng/L [Lovelace *et al.* 1982].

HPLC Column: C_{18} (150 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile-methanol (1 : 1) : 20 mmol/L ammonium acetate buffer (pH 3.9; 30 : 70), flow rate 1.2 mL/min. Fluorescence detection. Limit of detection, AFB_1 25 ng/L, AFB_2 0.35 ng/L, AFG_1 50 ng/L, AFG_2 0.8 ng/L, AFM_1 5 ng/L, AFQ_1 100 ng/L [Polychronaki *et al.* 2008]. Column: phenyl (100 × 8.0 mm i.d., 4 µm). Mobile phase: water containing 1 mmol/L potassium bromide and 1 mmol/L nitric acid : acetonitrile (70 : 30), flow rate 1.5 mL/min. Fluorescence detection (λ_{ex} = 365 nm, λ_{em} = 440 nm). Limit of quantification, AFB_1, AFB_2, AFG_1 and AFG_1 6.8 µg/L; AFM_1 and AFQ_1 18 µg/L; limit of detection, 1 ng/L [Kussak *et al.* 1995a; Kussak *et al.* 1998]. Column: C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: water containing 1 mmol/L potassium bromide and 1 mmol/L nitric acid : methanol : acetonitrile (60 : 20 : 20), flow rate 1.0 mL/min. Fluorescence detection (λ_{ex} = 365 nm, λ_{em} = 440 nm). Limit of detection, AFB_1, AFB_2, AFG_1 and AFG_2 50 ng/L [Kussak *et al.* 1993].

LC-MS Column: C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : methanol : water (20 : 20 : 60), flow rate 1.0 mL/min. ESI, positive ion mode, SIM and MRM acquisition modes. Retention times: AFB_1 11.7 min, AFB_2 9.7 min, AFG_1 8.7 min, AFG_2 7.5 min. Limit of detection, AFB_1 and AFB_2 2 pg, AFG_1 3 pg, AFG_2 8 pg on column [Kussak *et al.* 1995b].

Liver **TLC** Plates: silica kieselgel 60G (10 × 10 cm, 0.2 mm). Solvent systems: first direction, methanol : water : ether (94 : 4.5 : 1.5), second direction chloroform : acetone (97 : 3). R_f values not reported. Limit of quantification not reported [Apeagyei *et al.* 1986].

Other **TLC** Food Samples. Plates: precoated silica gel 60 (10 × 10 cm, 0.2 mm). Solvent systems: first direction, chloroform : acetone (9 : 1), second direction toluene : ethyl acetate : formic acid (5 : 4 : 1). UV detection. R_f values: first direction, AFB_1 0.62, AFB_2 0.56, AFG_1 0.48, AFG_2 0.40; second direction, AFB_1 0.22, AFB_2 0.20, AFG_1 0.15, AFG_2 0.12. Limit of detection, 1.2 µg/kg [Fernandez Pinto *et al.* 2001; Tapia 1985].

HPLC Rat Liver. Column: C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: 50 mmol/L sodium phosphate (pH 3.0)-methanol (75 : 25) : methanol (90 : 10 to 65 : 35 over 15 min, to 49 : 51 over 5 min), flow rate 1.0 mL/min. UV detection (λ = 365 nm). Retention times: AFB_1 21.6 min, AFG_1 19.9 min, AFM_1 16.3 min, AFQ_1 14.1 min, AFB_1-8,9-epoxide-glutathione *S*-transferase (AFBO-GSH) conjugate 9.2 min. Limit of quantification, AFB_1 25 pmol, AFBO-GSH 50 pmol [Kamdem *et al.* 2006]. Food Samples. Column: C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : methanol : water (1 : 3 : 6), flow rate 1.0 mL/min. Fluorescence detection (λ_{ex} = 360 nm, λ_{em} = 450 nm). Limit of quantification not reported [Sugita-Konishi *et al.* 2006]. Traditional Herbal Remedies Samples. Column: C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: water : methanol : acetonitrile (70 : 20 : 10), flow rate 1.0 mL/min. Fluorescence detection (λ_{ex} = 365 nm, λ_{em} = 450 nm). Limit of detection, AFB_1, AFG_1 and AFG_2 (trifluoroacetic acid [TFA] derivatives) 0.01 µg/kg [Ali *et al.* 2005]. Rice Samples (polished and cooked). Column: C_{18} (150 × 3.9 mm i.d.). Mobile phase:

methanol : acetonitrile : water (17 : 17 : 70), flow rate 1.0 mL/min. Fluorescence detection (λ_{ex} = 360 nm, λ_{em} = 440 nm). Limit of detection, AFB_1 (TFA derivative) 0.80 μg/kg [Park *et al.* 2005]. Spice Samples. Column: C_{18} (125 × 4.0 mm i.d., 5 μm). Mobile phase: water : methanol : acetonitrile (65 : 20 : 15). Fluorescence detection (λ_{ex} = 365 nm, λ_{em} = 430 nm). Limit of detection, AFB_1 0.1 μg/kg; AFB_2, AFG_1, and AFG_2 (TFA derivatives) 0.2 μg/kg [Fazekas *et al.* 2005]. Food Samples. Column: C_{18} (150 × 4.6 mm i.d., 5 μm). Mobile phase: water : acetonitrile (25 : 75), flow rate 0.7 mL/min. Fluorescence detection (λ_{ex} = 365 nm, λ_{em} = 435 nm). Limit of quantification, AFB_1 and AFB_2 0.13 μg/kg, AFG_1 0.5 μg/kg, AFG_2 2.5 μg/kg, limit of detection, AFB_1 and AFB_2 0.04 μg/kg, AFG_1 0.15 μg/kg, AFG_2 0.75 μg/kg [Blesa *et al.* 2004]. Beer Samples. Column: Lichrospher C_{18}. Mobile phase: water : acetonitrile : methanol (75 : 15 : 10), flow rate 1.0 mL/min. Fluorescence detection (λ_{ex} = 365 nm, λ_{em} = 425 nm). Limit of quantification, AFB_1 5 μg/L; AFB_2, AFG_1 and AFG_2 (TFA derivatives) 8 μg/L [Odhav and Naicker 2002]. Baby Food Samples. Column: C_{18} (250 × 4.6 mm i.d., 5 μm). Mobile phase: water : acetonitrile : methanol (6 : 2 : 3) containing 120 mg/L potassium bromide and 350 μL 4 mol/L nitric acid, flow rate 1.0 mL/min. Fluorescence detection (λ_{ex} = 360 nm, λ_{em} = 420 nm). Post-column bromination. Retention times: AFB_1, AFB_2, AFG_1, and AFG_2 11, 9, 8, and 6 min, respectively. Limit of quantification, 0.05 μg/kg [Stroka *et al.* 2001; Tam *et al.* 2006]. Airborne Dust Samples. Column: C_{18} (250 × 4.6 mm i.d.). Mobile phase: water : methanol : acetonitrile (60 : 20 : 20), flow rate 1.1 mL/min. Fluorescence detection (λ_{ex} = 365 nm, λ_{em} = 450 nm). Retention time: AFB_1 9.0 min. Limit of detection, 33 μg/L [Selim *et al.* 1998].

LC-MS Corn Silage Samples. Column: C_{18} (150 × 2.1 mm i.d., 5 μm). Mobile phase: acetonitrile : water with 0.5% acetic acid (pH 3, 5 : 95 to 50 : 50 over 15 min to 80 : 20 over 10 min), flow rate 0.3 mL/min. ESI, positive and negative ion modes, SIM acquisition mode. Retention times: AFB_1 15.4 min, citrinin 16.7 min, deoxynivalenol 6.9 min, fumonisin B_1 15.1 min, gliotoxin 14.2 min, ochratoxin A 20.3 min, zearalenone 20.4 min. Limit of quantification, AFB_1 5 ppb; limit of detection, AFB_1 1.5 ppb [Richard *et al.* 2007]. Food Samples. Column: C_{18} (150 × 4.6 mm i.d., 5 μm). Mobile phase: water : methanol (55 : 45), flow rate 0.7 mL/min. ESI, positive ion mode, SIM acquisition mode. Limit of detection, AFB_1 and AFG_1 0.07 μg/kg, AFB_2 and AFG_2 0.2 μg/kg [Blesa *et al.* 2004]. Cell Culture Samples. Column: LichroCart 250-3 Purospher C_{18}. Mobile phase: methanol : 10 mmol/L ammonium acetate containing 20 μmol/L sodium acetate (20 : 80 for 4 min, to 70 : 30 over 4 min for 18 min to 90 : 10 in 1 min for 4 min, flow rate 0.4 mL/min. ESI, positive ion mode, SIM acquisition mode. Retention times: AFG_2, AFG_1, AFB_2 and AFB_1 13.5 min, 13.8 min, 14.2 min and 14.5 min, respectively; citrinine, ochratoxin A, and sterigmatocystin also detected. Limit of quantification, 200 ng [Tuomi *et al.* 2001].

For methods for the analysis of aflatoxins in human tissues using normal phase HPLC, see Anukarahanonta and Chudhabuddhi [1983] and Siraj *et al.* [1981]. For a radioimmunoassay of AFB and AFG, see Tsuboi *et al.* [1984]. For ELISA methods for the detection of aflatoxins, see Blesa *et al.* [2004], Dragsted *et al.* [1988], Kim *et al.* [2001] and Lipigorngoson *et al.* [2003].

Disposition in the Body Following ingestion, AFB_1 is metabolised mainly by CYP1A2, CYP3A4 and CYP3A5 in the liver, generating several hydroxylated derivatives and a highly reactive epoxide (AFB_1-8,9-*exo*-epoxide) that binds to DNA to form the predominant 8,9-dihydro-8-(N^7-guanyl)-9-hydroxy-AFB_1 adduct, that damages DNA. Other metabolites are formed from AFB_1, including aflatoxicol (reductive metabolite; interconversion occurs in red blood cells), AFQ_1 (hydroxylated at position 3), AFM_1 (hydroxylated at position 4), and AFP_1 (position 4 methoxy group replaced by hydroxyl group). These metabolites and other naturally occurring aflatoxins (AFG_1, AFB_2, and AFG_2) are poorer substrates for epoxidation and, consequently, are less mutagenic, carcinogenic, and toxic than AFB_1. Urinary aflatoxin-N^7-guanine adducts and AFM_1, AFQ_1, AFP_1 metabolites together with serum aflatoxin–albumin adducts (aflatoxin–lysine) have been found to be useful biomarkers of aflatoxin exposure. Typically, urinary metabolites reflect recent exposure (2 to 3 days), whereas blood or serum aflatoxin–albumin adducts reflect exposure over a longer period (2 to 3 months). The metabolism of AFB_1 to the epoxide and to AFM_1 can be blocked by treatment with oltipraz, an antischistosomal drug, which induces the major aflatoxin detoxification enzyme glutathione-*S*-transferase. Aflatoxins are known to cross the placenta. The role of extrahepatic metabolism of AFB_1, particularly in the small intestine, may be important in modulating the toxic and carcinogenic effects *in vivo*. Lipoxygenase and prostaglandin H synthase may also make a significant contribution to AFB_1 metabolism in some extrahepatic organs.

Toxicity The disorders caused by aflatoxin consumption are loosely called aflatoxicoses. Acute aflatoxicosis results in death; chronic aflatoxicosis results in cancer, immune suppression, and other pathological conditions. AFB_1 is the most potent heptatocarcinogen known in mammals [Creppy 2002], included in category 1A by the International Agency for Research on Cancer [IARC 1993]. Exposure to aflatoxins is associated with increased risk of hepatocellular carcinoma, particularly in combination with hepatitis B virus [IARC 1993, 2002]. The maximum limit for AFB_1 and AFB_2 in foods is 4 μg/kg (or 4 μg/L) in the UK and 20 μg/kg (or 20 μg/L) in the USA [Creppy 2002]. The LD_{50} values for AFB_1 are 18.2 μg/50 g bodyweight oral dose in 1-day-old duckling and 9.50 mg/kg bodyweight IP dose in newborn mice; for AFB_2, the oral dose is 84.8 μg/50 g bodyweight in 1-day-old duckling [Buchi *et al.* 1973; Carnaghan *et al.* 1963]. The order of acute and chronic toxicity is $AFB_1 > AFG_1 > AFB_2 > AFG_2$, reflecting the role played by epoxidation of the 8,9-double bond and also the greater potency associated with the cyclopentenone ring of the B series compared with the 6-membered lactone ring of the G series [McLean, Dutton 1995; Wogan 1966]. Kwashiorkor, a form of protein energy malnutrition disease, may be a form of paediatric aflatoxicosis [de Vries *et al.* 1990; Hendrickse 1997; Lamplugh, Hendrickse 1982; Maxwell 1998; Peraica *et al.* 1999].

A group of 50 lactating mothers and their infants were screened for aflatoxin exposure. AFB_1 was detected in the serum and milk of 24 mothers at mean concentrations of 8.9 μg/L and 1.9 μg/L, respectively. The corresponding mean serum concentration in infants was 1.8 μg/L [Hassan *et al.* 2006].

An outbreak of hepatitis that affected 400 people, of whom 100 died, almost certainly resulted from aflatoxins. The outbreak was traced to maize that was heavily contaminated with *A. flavus*, and containing up to 15 mg/kg aflatoxins. Consumption of the affected adults was calculated to be 2 to 6 mg in a single day. From this value, a dose of the order of 10 to 20 mg was estimated as lethal for adults [Krishnamachari *et al.* 1975].

In an attempted suicide with purified AFB_1, a young woman ingested 5.5 mg AFB_1 over 2 days and, 6 months later, a total of 35 mg over 2 weeks. Following admission to hospital after each attempt, physical, radiological, and laboratory examinations were normal and liver biopsies appeared normal. A follow-up examination 14 years later did not reveal any signs or symptoms of disease. These findings suggest that the hepatotoxicity of AFB_1 may be lower in well-nourished persons or that the latent period for tumour formation exceeds 14 years [Peraica *et al.* 1999; Willis *et al.* 1980].

The possibility that IV heroin users might be exposed to aflatoxins was investigated. Four heroin samples submitted for analysis yielded AFB_1 in concentrations of 1.63, 4.31, 5.23 and 30.82 nmol/kg. Random urine samples obtained from 132 heroin addicts and from 99 normal adult volunteers were screened for AFB_1. Approximately 20% of the heroin users showed AFB_1, AFB_2, AFM_1, AFM_2 and aflatoxicol in their urine, in quantities that ranged from 0.73 to 29.09 nmol/L, whereas only 2 of the control urines showed any aflatoxins (AFB_2 at 0.13 and 0.24 nmol/L) [Hendrickse, Maxwell 1988; Hendrickse *et al.* 1989].

Postmortem concentrations of aflatoxins were reported following an outbreak in Malaysia where 17 people were taken ill following ingestion of contaminated noodles. Of these victims, 13 died; all were children (aged between 2.5 and 11 years old). The duration of survival ranged from 2 to 6 days, with a median of 4 days 4 h. Aflatoxin concentrations in tissues were reported as follows:

Victim	*Tissue sample (μg/kg)*					
	Liver	*Kidney*	*Spleen*	*Lung*	*Heart*	*Brain*
1	14.5 (AFM_1)	–	4.8 (AFM_1)	–	2.4 (AFB_1)	–

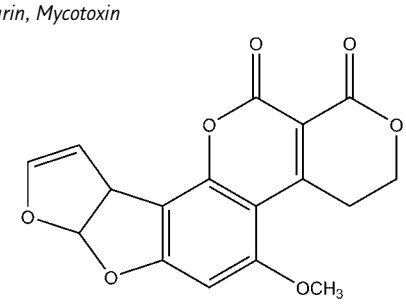
Aflatoxins G

Difuranocoumarin, Mycotoxin



Chemical Properties Aflatoxins G are a closely related group of secondary fungal metabolites produced by *Aspergillus bombycis*, *A. ochraceoroseus*, *A. parasiticus*,

A. pseudotamari, *A. nomius* and *Penicillium puberulum*. The 4 naturally occurring aflatoxins are aflatoxins B_1 (AFB_1), B_2 (AFB_2), G_1 (AFG_1) and G_2 (AFG_2). The G toxins are so named because they exhibit green fluorescence under UV light [Bennett, Klich 2003; Denning 1987; Wild, Hall 2000]. See Aflatoxins B for further properties.

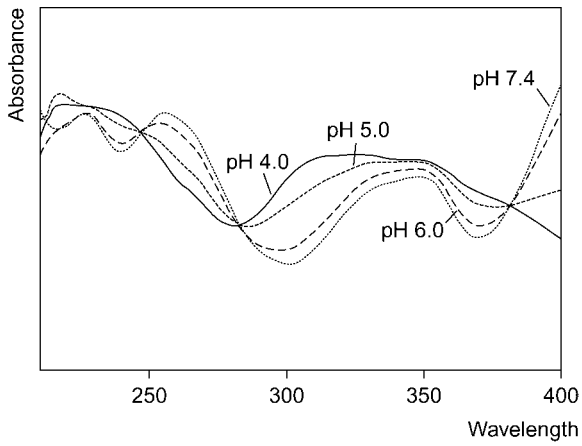
Aflatoxin G_1

$C_{17}H_{12}O_7 = 328.3$
CAS—1165-39-5
IUPAC Name (7a*R*,10a*S*)-3,4,7a,10a-Tetrahydro-5-methoxy-1*H*,12*H*-furo[3′,2′:4,5]furo[2,3-*h*]pyrano[3,4-*c*][1]benzopyran-1,12-dione
Synonym AFG_1
Chemical Properties Crystals. Mp 244° to 246° [O'Neil *et al.* 2006].

Aflatoxin G_2

$C_{17}H_{14}O_7 = 330.3$
CAS—7241-98-7
IUPAC Name (7a*R*,10a*S*)-3,4,7a,9,10,10a-*H*exahydro-5-methoxy-1*H*,12*H*-furo[3′,2′:4,5]furo[2,3-*h*]pyrano[3,4-*c*][1]benzopyran-1,12-dione
Synonym AFG_2
Chemical Properties The 9,10-dihydro derivative of AFG_1. Crystals. Mp 237° to 240° [O'Neil *et al.* 2006].

Ultraviolet Spectrum Ethanol—362, 243, 264, 257 nm (AFG_1); 363, 265 nm (AFG_2); 0.1 mol/L sodium phosphate buffer—(pH 7.4) 413, 255, 225, 346 nm; (pH 6.0) 413, 225, 255, 346 nm; (pH 5.0) 218, 345 nm; (pH 4.0) 326, 216 nm (*N*-α-acetyllysine–AFG_1 adduct) [Sabbioni and Wild 1991].



Quantification

See Aflatoxins B.
Note For a review of LC-MS methods for the analysis of aflatoxins in different media, see Zollner and Mayer-Helm [2006].

Disposition in the Body

Toxicity The LD_{50} values orally in 1-day-old duckling are 39.2 μg/50 g bodyweight for AFG_1 and 172.5 μg/50 g bodyweight for AFG_2 [Carnaghan *et al.* 1963]. See also Aflatoxins B. For epidemiological studies of AFG, AFB and AFM exposure to mothers and their lactating infants, see Polychronaki *et al.* [2008]. The maximum limit for AFG_1 and AFG_2 in foods is 4 μg/kg (or 4 μg/L) in the UK and 20 μg/kg (or 20 μg/L) in the US [Creppy 2002].

Postmortem AFG_1 concentrations in lung tissue of children who died from kwashiorkor were between 3.4 and 52.1 ng/g. AFG_2, AFM_1 and AFM_2 were also detected but at much lower concentrations. In another similar study, AFG_1 concentrations in kidney ranged between 7.9 and 42.5 ng/g. AFG_2 was detected more often but at much lower concentrations (between 0.006 and 0.9 ng/g) [Oyelami *et al.* 1997, 1998].
Note For a study investigating the use of an AFG_1–serum albumin adduct as a measure of human exposure to aflatoxins, see Sabbioni and Wild [1991].
Protein Binding AFG_1 is mainly bound to albumin.

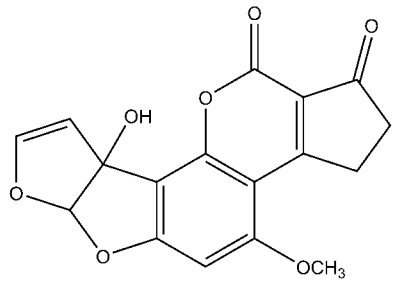
Aflatoxins M

Haemostatic, Sympathomimetic, Vasoconstrictor, Difuranocoumarin, Mycotoxin



Chemical Properties Aflatoxins M_1 (AFM_1) and M_2 (AFM_2) are the highly toxic 4-hydroxylated aflatoxin B derivatives found in the milk of cows fed contaminated meal. Aflatoxins are freely soluble in moderately polar solvents (e.g. chloroform and methanol), especially in dimethyl sulfoxide, and also have some water solubility. They are very stable at high temperatures, with little or no destruction occurring under ordinary cooking conditions or during pasteurisation. The presence of the lactone ring in their structure makes the aflatoxins susceptible to alkaline hydrolysis. Acid treatments are also used frequently for their detoxification [McLean, Dutton 1995]. See Aflatoxins B for further properties.

Aflatoxin M_1

$C_{17}H_{12}O_7 = 328.3$
CAS—6795-23-9
IUPAC Name (6a*R*,9a*R*)-2,3,6a,9a-Tetrahydro-9a-hydroxy-4-methoxycyclopenta[*c*]furo[3′,2′:4,5]furo[2,3-*h*][1]benzopyran-1,11-dione
Synonyms AFM_1; 4-hydroaflatoxin B_1.
Chemical Properties Crystals from methanol. Mp 299° with decomposition. Exhibits blue–violet fluorescence [O'Neil *et al.* 2006].

Aflatoxin M_2

$C_{17}H_{14}O_7 = 330.3$
CAS—6885-57-0
IUPAC Name 2,3,6a,8,9,9a-Hexahydro-9a-hydroxy-4-methoxycyclopenta[*c*]furo[3′,2′:4,5]furo[2,3-*h*][1]benzopyran-1,11-dione
Synonyms AFM_2; 4-hydroaflatoxin B_2.

Chemical Properties The 8,9-dihydro derivative of AFM_1. Crystals from methanol/chloroform. Mp 293° with decomposition. Exhibits violet fluorescence [O'Neil *et al.* 2006].
Ultraviolet Spectrum Ethanol—226, 357, 265 nm (AFM_1); 357, 221, 264 nm (AFM_2).

Quantification

Serum **HPLC** Column: C_{18} (150 × 4.6 mm i.d., 5 μm). Mobile phase: acetonitrile : water : methanol (33 : 62 : 5), flow rate 0.7 mL/min. Fluorescence detection (λ_{ex} = 365 nm, λ_{em} = 425 nm). Limit of detection, 1 μg/L [Okumura *et al.* 1993]. Column: C_{18} (250 × 5.0 mm i.d., 5 μm). Mobile phase: water : acetonitrile (75 : 25), flow rate 2.0 mL/min. Fluorescence detection (λ_{ex} = 365 nm, λ_{em} = 418 nm). Limit of detection AFM_1, 0.1 μg/L, AFM_2 0.03 μg/L, AFB_1 0.25 μg/L [Abdulrazzaq *et al.* 2002].
Urine **TLC** Plates: silica gel G-HR (20 × 20 cm, 0.5 mm). Solvent system: acetone : chloroform : propan-2-ol (10 : 85 : 5). UV detection. R_f values: AFB_1 0.73, AFG_1 0.59, AFM_1 0.44, AFB_{2a} 0.39, AFG_{2a} 0.29, aflatoxicol-1 0.69, aflatoxicol-2 0.62, tetrahydrodeoxy-AFB_1 0.79. Limit of detection, AFB_1 90 ng/L, AFG_1 13 ng/L, AFM_1 27 ng/L, AFB_{2a} 125 ng/L, AFG_{2a} 73 ng/L, aflatoxicol-1 57 ng/L, aflatoxicol-2 42 ng/L, tetrahydrodeoxy-AFB_1 33 ng/L [Lovelace *et al.* 1982].

HPLC Column: C_{18} (150 × 4.6 mm i.d., 5 μm). Mobile phase: acetonitrile-methanol (1 : 1) : 20 mmol/L ammonium acetate buffer (pH 3.9; 30 : 70), flow rate 1.2 mL/min. Fluorescence detection. Limit of detection, AFB_1 25 ng/L, AFB_2 0.35 ng/L, AFG_1 50 ng/L, AFG_2 0.8 ng/L, AFM_1 5 ng/L, AFQ_1 100 ng/L [Polychronaki *et al.* 2008]. Column: C_{18} (250 × 4.6 mm i.d., 5 μm). Mobile phase: 13% ethanol and 3% methanol in tetraethylammonium fluoride, flow rate 0.6 mL/min. Fluorescence detection (λ_{ex} = 365 nm). Retention time: 12 min. Limit of detection, 0.5 ng/L [Cheng *et al.* 1997]. Column: C_{18} (250 × 4.6 mm i.d.). Mobile phase: methanol : 0.01 mol/L potassium dihydrogen phosphate (1 : 1), flow rate 0.8 mL/min. Fluorescence detection (λ_{ex} = 365 nm, λ_{em} = 435 nm). Retention time: 4.0 min (trifluoroacetic acid derivative). Limit of detection, 0.01 ppb [Liu *et al.* 1990].
Faeces **HPLC** Column: C_{18} (220 × 4.6 mm i.d., 5 μm). Mobile phase: acetonitrile-methanol (1 : 1) : 20 mmol/L ammonium acetate buffer (pH 3.9, 30 : 70), flow rate 1.5 mL/min. Fluorescence detection (λ_{ex} = 366 nm, λ_{em} = 440 nm). Retention times: AFM_1 8.6 min, AFQ_1 7.8 min, AFB-N^7-guanine 4.6 min. Limit of detection, AFM_1 and AFB-N^7-guanine 5 ng/kg; AFQ_1 0.5 μg/kg [Mykkanen *et al.* 2005].
Other **TLC** Egg Samples. Plates: precoated silica gel 60 (20 × 20 cm). Solvent system: hexane : tetrahydrofuran : ethanol (95 : 4 : 1). UV detection. Limit of quantification, 0.04 μg/kg [Trucksess and Stoloff 1984]. Milk Samples (powdered and liquid). Plates: precoated silica G25HR. Solvent systems: toluene : ethyl acetate : ethyl ether : formic acid (25 : 35 : 40 : 5); plates are heated at 110° for 10 min and developed in hexane : acetone : chloroform. Fluorescence detection (*p*-anisaldehyde derivative). Limit of detection, 0.3 ng [Serralheiro, Quinta 1986]. Dog Liver Samples. Plates: precoated silica gel washed (developed) twice in chloroform : acetone (9 : 1) and once

A

in diethyl ether to remove impurities, activated at 105° for 1 h. Solvent systems: (1) chloroform: acetone: propan-2-ol (82.5 : 15 : 2.5); (2) chloroform : acetone (8 : 2); (3) benzene: ethyl acetate: acetone (50 : 4 : 6). R_f values: (1) AFM_1 0.48, aflatoxicol M_1 0.37, AFB_{2a} 0.43, aflatoxicol 0.78, AFB_1 0.83; (2) AFM_1 0.37, aflatoxicol M_1 0.28, AFB_{2a} 0.33, aflatoxicol 0.71, AFB_1 0.77; (3) AFM_1 0.06, aflatoxicol M_1 0.09, aflatoxicol 0.37, AFB_1 0.24. Limit of quantification not reported [Salhab *et al.* 1977].

HPLC Human Breast Milk. Column: C_{18} (220 × 4.6 mm i.d., 5 μm). Mobile phase: water : methanol : acetonitrile (66 : 17 : 17), flow rate 1.0 mL/min. Fluorescence detection (λ_{ex} = 360 nm, λ_{em} = 440 nm). Limit of detection, 4.2 ng/L [Polychronaki *et al.* 2006]. Column: C_{18} (250 × 4.0 mm i.d., 10 μm). Mobile phase: 2% acetic acid : acetonitrile : methanol (40 : 35 : 25), flow rate 1.0 mL/min. Fluorescence detection (λ_{ex} = 360 nm, λ_{em} = 430 nm). Retention times: AFM_1 3.1 min, ochratoxin A 7.3 min. Limit of quantification, 0.01 μg/L [Navas *et al.* 2005]. Column: C_{18} (220 × 4.6 mm i.d., 5 μm). Mobile phase: water-methanol-acetonitrile-acetic acid (77 : 15 : 8 : 0.05): water-methanol-acetonitrile-acetic acid (52 : 40 : 8 : 0.05; 100 : 0 for 12 min to 0 : 100 over 8 min for 8 min), flow rate 1.0 mL/min. Fluorescence detection (λ_{ex}= 365 nm, λ_{em}= 418 nm). Retention time: 23.3 min. Limit of detection, 10 ng/L [el Nezami *et al.* 1995]. Cheese Samples. Column: C_{18} (125 × 4.0 mm i.d., 4 μm). Mobile phase: water: acetonitrile (75 : 25), flow rate 1.0 mL/min. Fluorescence detection (λ_{ex}= 365 nm, λ_{em}= 440 nm). Retention time: 5.2 min. Limit of detection, 5 ng/kg [Peitri *et al.* 1997]. Milk Samples. Column: C_{18} (250 × 4.6 mm i.d., 5 μm). Mobile phase: water: acetonitrile: methanol (55 : 24 : 21 for 6 min, to 15 : 40 : 45 over 1 min for 3 min), flow rate 0.8 mL/min. Fluorescence detection (λ_{ex}= 360 nm, λ_{em}= 440 nm). Retention time: 7 min. Limit of quantification, 0.3 μg/L, limit of detection, 0.12 μg/L [Muscarella *et al.* 2007]. Column: C_{18} (250 × 4.6 mm i.d.). Mobile phase: water : acetonitrile : methanol (50 : 30 : 20), flow rate 0.8 mL/min. Fluorescence detection (λ_{ex} = 360 nm, λ_{em} = 430 nm). Retention time: 7.9 min. Limit of quantification, 10 ng/L, limit of detection, 3 ng/L [Diaz, Espitia 2006]. Column: C_{18} (250 × 4.6 mm i.d., 5 μm). Mobile phase: acetonitrile : water (25 : 75), flow rate 1.0 mL/min. Fluorescence detection (λ_{ex} = 365 nm, λ_{em} = 435 nm). Retention times: AFM_1 13.5 min, AFM_2 10.2 min, AFM_{2a} 5.1 min. Limit of detection, AFM_1 1 ng/kg, AFM_2 0.3 ng/kg, AFM_{2a} 0.2 ng/kg [Nakajima *et al.* 2004]. Column: C_{18} (250 × 4.6 mm i.d., 5 μm). Mobile phase: water : acetonitrile : methanol (60 : 22 : 18), flow rate 1.0 mL/min. Fluorescence detection. Limit of detection, 0.05 μg/L [Carvajal *et al.* 2003]. Column: C_{18} (150 × 4.0 mm i.d., 5 μm). Mobile phase: acetonitrile : water (25 : 75), flow rate 0.8 mL/min. Fluorescence detection (λ_{ex} = 365 nm, λ_{em} = 435 nm). Retention time: 7 min. Limit of detection, 5 μg/L [Roussi *et al.* 2002; Van Egmond and Dragacci 2001]. Milk, Dried Milk, and Yoghurt Samples. Column: C_{18} (125 × 4.0 mm i.d., 5 μm). Mobile phase: acetonitrile : water (28 : 72), flow rate 1.5 mL/min. Retention time: 5.5 min. Limit of detection, 1 ng/L [Galvano *et al.* 1998]. Pig Liver Samples. Column: C_{18} (150 × 4.6 mm i.d., 5 μm). Mobile phase: acetonitrile : water (25 : 75), flow rate 0.8 mL/min. Fluorescence detection (λ_{ex} = 365 nm, λ_{em} = 435 nm). Retention time: 8.3 min. Limit of detection, 1 μg/kg [Chiavaro *et al.* 2005]. Column: C_{18} (250 × 4.6 mm i.d., 10 μm). Mobile phase: acetonitrile : water (30 : 70), flow rate 1.0 mL/min. Fluorescence detection (λ_{ex} = 366 nm, λ_{em} = 430 nm). Limit of detection, 10 ng/kg [Tyczkowska *et al.* 1987]. Milk and Cheese samples. Column: C_{18} (250 × 4.6 mm i.d., 5 μm). Mobile phase: acetic acid : acetonitrile : propan-2-ol : water (2 : 10 : 10 : 78), flow rate 1.2 mL/min. Post-column derivatisation with *p*-bromophenacyl bromide. Fluorescence detection (λ_{ex} = 353 nm, λ_{em} = 423 nm). Retention time: 6 min. Limit of detection, 1 and 5 ng/kg for milk and cheese, respectively [Manetta *et al.* 2005].

LC-MS Rat Urine. Column: phenyl-hexyl (150 × 2.0 mm i.d., 3 μm). Mobile phase: water : acetonitrile both containing 0.1% formic acid (70 : 30 for 10 min to 5 : 95 over 0.1 min for 1.4 min), flow rate 0.325 mL/min. ESI, positive ion mode, MRM acquisition mode. Retention times: AFM_1 4 min, AFP_1 3.8 min, AFG_2 5.2 min, AFB_2 6.6 min, AFG_1 7 min, AFB_1 9 min. Limit of quantification, 392 fg on-column [Everley *et al.* 2007]. Cow Milk Samples. Column: C_{18} (250 × 4.6 mm i. d., 5 μm). Mobile phase: water-acetone (87 : 13) : methanol-acetone (87 : 13; 85 : 15 for 1 min to 15 : 85 over 10 min to 5 : 95 for 2 min), flow rate 1.0 mL/min. APPI, MRM acquisition mode. Retention time: 8.0 min. Limit of quantification, 6 ng/L [Cavaliere *et al.* 2006a]. Column: PRP-1 poly(styrene-divinylbenzene) (100 × 2.1 mm i.d., 3 μm). Mobile phase: 10 mmol/L 4-methylmorpholine aqueous solution (pH 9.7) : acetonitrile (80 : 20 to 0 : 100 over 6 min for 6.5 min), flow rate 0.2 mL/min. ESI, negative ion mode, SRM acquisition mode. Retention time: 9.3 min. Limit of detection, 0.59 ng/L with immunoaffinity column clean-up [Chen *et al.* 2005]. Cheese Samples. Column: C_{18} (100 × 2.1 mm i.d., 3.5 μm). Mobile phase: water : acetonitrile both containing 0.1% acetic acid (75 : 25 for 16 min to 10 : 90 for 24 min), flow rate 0.2 mL/min. ESI, positive ion mode, MRM acquisition mode. Retention times: AFM_1 4.7 min, AFG_2 6.4 min, AFB_2 8.2 min, AFG_1 8.6 min, AFB_1 11.3 min, penicillic acid 3.5 min, roquefortine C 4.2 min, mycophenolic acid 27.0 min, ochratoxin A 31.9 min. Limit of quantification, AFM_1, mycophenolic acid and ochratoxin A 0.3 μg/kg; roquefortine C 0.4 μg/kg; AFB_1, AFB_2, AFG_1 and AFG_2 0.8 μg/kg; penicillic acid 2.0 μg/kg. Limits of detection, 0.6, 0.8, 1.6 and 4.0 μg/kg, respectively [Kokkonen *et al.* 2005].

Note See Aflatoxins B for further methods. For a review of LC-MS methods for the analysis of aflatoxins in different media, see Cavaliere *et al.* [2006b] and Zollner and Mayer-Helm [2006]. For a comparison of methods using different extraction methods for AFM_1 in cheese, see Cavaliere *et al.* [2006b], and using different ionisation sources for LC-MS analysis, see Cavaliere *et al.* [2006a]. For a two-dimensional TLC method for the quantification of AFM_1 in milk, see Grosso *et al.* [2004], in cheese, see Bijl *et al.* [1987]. For a comparison of methods for the extraction and clean-up of AFM_1, see Shepherd *et al.* [1986].

Disposition in the Body AFM_1 is one of the major urinary metabolites found in subjects exposed to AFB_1 and its level correlates with the presence of AFB_1–serum albumin adducts. AFM_1 can be further activated to form AFM_1-8,9-epoxide, which binds to DNA and is excreted into urine in the form of AFM_1-N^7-guanine. Quantitative data on AFM_1 excretion into faeces are limited.

Toxicity The carcinogenic potency of AFM_1 is approx. 10-fold lower than that of AFB_1 [Creppy 2002]. It is classified as a probable human carcinogen in group 2B by the International Agency for Research on Cancer [IARC 1993]. The European regulatory limits for AFM_1 in milk are 0.05 μg/L for liquid milk and 0.5 μg/kg for milk powder. This was recently amended to include maximum permissible levels of 0.025 μg/kg AFM_1 for infant formulae, follow-on formulae, and dietary foods. The Codex Alimentarius Committee for Food Additives and Contaminants (CCFAC) recommend a limit of 0.5 μg/L for liquid milk and 5.0 μg/kg for milk powder. Exposure to AFM_1 accounts for a substantial part of the risk of hepatocellular carcinoma in men with chronic hepatitis B virus hepatitis [Sun *et al.* 1999]. For a study on AFM_1 absorption and cytotoxicity in a human intestinal *in vitro* model, see Caloni *et al.* [2006]. Kwashiorkor, a form of protein energy malnutrition disease, may be a form of paediatric aflatoxicosis, and exposure of neonates to AFM_1 present in breast milk should be monitored [Coulter *et al.* 1984, 1986; de Vries *et al.* 1990; Hendrickse 1997; Lamplugh, Hendrickse 1982; Maxwell 1998; Peraica *et al.* 1999]. The oral LD_{50} in 1-day-old ducklings is 16.6 μg/duckling for AFM_1 and 62.0 μg/duckling for AFM_2 [Holzapfel *et al.* 1966].

In a study investigating morbidity in neonates of 166 mothers exposed to aflatoxins, AFM_1 was detected in 113 (68%) of maternal blood samples (0.03 to 8.49 μg/L) and in 111 (67%) of cord blood samples (0.05 to 10.44 μg/L). No correlation was found between AFM_1 concentration and rates of jaundice or infection in neonates [Abdulrazzaq *et al.* 2004].

During a survey of the occurrence of aflatoxins in breast milk, a group of 445 women had AFM_1 concentrations ranging from 2 to 3 ng/L. Consequently, an average 3-month-old baby (bodyweight 4.5 kg) with a daily milk intake of approximately 500 to 700 mL, might receive a daily AFM_1 dose between 7.5 and 10.5 ng/kg bodyweight [Saad *et al.* 1995].

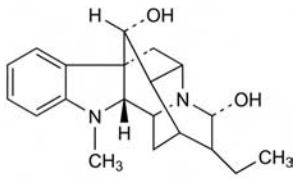
Ajmaline

Antiarrhythmic
$C_{20}H_{26}N_2O_2 = 326.4$
CAS—4360-12-7

Synonyms Ajmalan-17,21-diol; rauwolfine.
Proprietary Names *Aritmina*; *Cardiorythmine*; *Gilurytmal*; *Ritmos*; *Tachmalin*.



Chemical Properties An alkaloid obtained from the root of *Rauwolfia serpentina* (Apocynaceae). A white or slightly yellowish crystalline powder. Mp ~195°, with decomposition. Practically insoluble in water; freely soluble in ethanol, chloroform and glacial acetic acid; sparingly soluble in ether and methanol; soluble in dilute hydrochloric acid. pK_a 8.2. Extraction yield (chlorobutane), 0.5 [Demme *et al.* 2005]. Ajmaline is stable under acidic and basic conditions. There is no conversion of ajmaline into its more thermodynamically stable isomer isoajmaline or into sandwicine [Köppel *et al.* 1992].

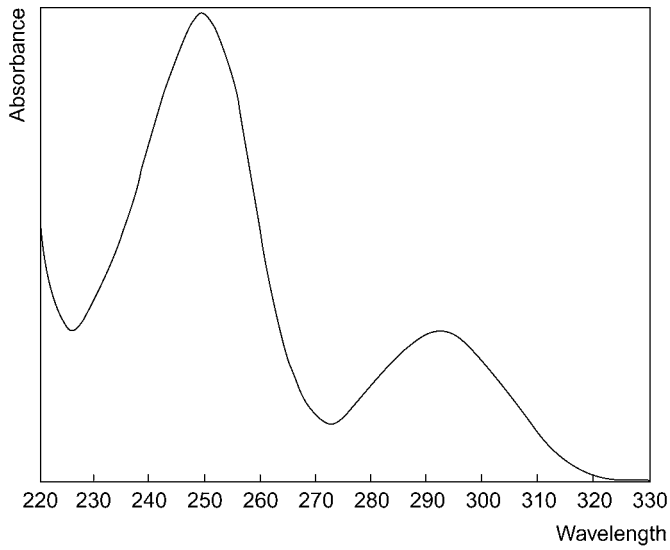
Ajmaline Hydrochloride
$C_{20}H_{26}N_2O_2,2HCl,2H_2O = 435.4$
Chemical Properties Crystals. Mp 140°. Soluble 1 in 40 of water.
Proprietary Name *Cardiorythmine*

Ajmaline Monoethanolate
$C_{20}H_{26}N_2O_2,C_2H_6O = 372.5$
CAS—60991-48-2
Chemical Properties A white or slightly yellowish crystalline powder. Practically insoluble in water; freely soluble in ethanol, chloroform and glacial acetic acid; sparingly soluble in ether and methanol.

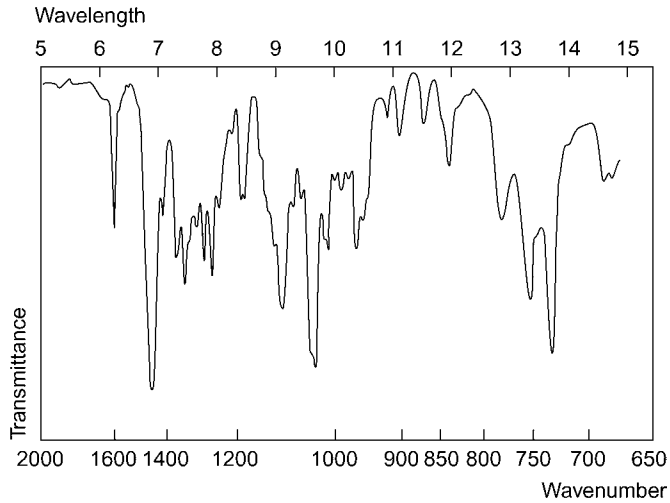
Colour Tests Liebermann's reagent—red; Mandelin's test—red; Marquis test—violet.

Thin-layer Chromatography System TA—R_f 0.62; system TB—R_f 0.07; system TE—R_f 0.56; system TAE—R_f 0.22 (acidified potassium permanganate solution, positive).
Gas Chromatography System GA—RI 2880.
High Performance Liquid Chromatography System HA—*k* 2.8 (tailing peak)); system HY—RI 277.

Column: RP-18e (100 × 4.6 mm i.d.). Mobile phase: acetonitrile : 0.01 mol/L phosphate buffer containing 0.5% glacial acetic acid (pH 3.0, 15 : 85 for 9 min to 25 : 75 for 1 min to 30 : 70 for 2 min to 35 : 65 for 18 min to 15 : 85 for 20 min), flow rate 1.0 mL/min. DAD. Retention time: 6.05 min. Limit of quantification, 19 mg/L; limit of detection, 6 mg/L [Srivastava *et al.* 2006]. Column: RP-18 (125 × 4 mm i.d., 5 µm). Column temperature: 40°. Mobile phase: methanol : 0.1 mol/L phosphate buffer (pH 3.5; 26 : 74), flow rate 1 mL/min. IS: detajmium. Detection: fluorescence (λ_{ex} = 247 nm, λ_{em} = 353 nm). Retention time: ajmaline 3.5 min, IS, 7.0 min [Oertel *et al.* 1998]. Column: Nucleosil C_{18} (120 × 4 mm i.d., 5 µm) Mobile phase: acetontrile : 0.07% orthophosphoric acid (22 : 78), flow rate 1.5 mL/min or aqueous 0.2 mol/L trifluoroacetic acid: acetonitrile (80 : 20), flow rate 1.1 mL/min. UV detection (λ = 254 nm). Retention time: ajmaline 5.88 min, isoajmaline 5.1 min, ajmaline *N*-oxide 4.35 min, dihydroajmaline 7.05 min [Köppel *et al.* 1992].
Ultraviolet Spectrum Aqueous acid—245 (A^1_1 = 223a), 289 nm. No alkaline shift.



Infrared Spectrum Principal peaks at wavenumbers 756, 741, 1103, 1092, 1046, 1280 cm^{-1}.



Quantification
Blood **GC-MS** Column: 3% OV-1 on Gas Chrom Q, 100/120 mesh (6 ft (180 cm) × 2 mm i.d.). Temperature: 250°. Carrier gas: He, 40 mL/min. EI ionisation. Limit of detection, 0.4 mg/L [Clemans *et al.* 1977].

HPLC Column: Zorbax CN (250 × 4.6 mm i.d.). Mobile phase: hexane : ethanol : ethanolamine (83.18 : 16.79 : 0.03), flow rate 1.5 mL/min. UV detection (λ = 235 nm). Retention time: 8.15 min. Limit of detection not reported [Ikeda *et al.* 1988].

Plasma **HPLC** Column: Nucleosil C_{18} (120 × 0.4 cm i.d., 5 µm). Mobile phase: acetonitrile : 0.07% orthophosphoric acid (22 : 78), flow rate 1.5 mL/min.

A

Fluorescence detection ($\lambda_{ex} = 296$ nm, $\lambda_{em} = 358$ nm). Retention time: ajmaline 5.88 min, isoajmaline and sandwicine 5.10 min, ajmaline *N*-oxide 4.35 min, and hydroajmaline 7.05 min. Limit of detection, 1 µg/L with extraction and 50 µg/L without [Köppel *et al.* 1992].

Gastric Contents **HPLC** See Blood [Ikeda *et al.* 1988].

Other **TLC** Dog Plasma. Plates: precoated (20 × 20 cm). Solvent system: benzene : acetic acid : methanol (86 : 7 : 7). R_f 0.20. Limit of detection, 0.1 µg [Dombrowski *et al.* 1975].

Note For a spectrofluorometric method for the determination of ajmaline in plasma, see Welman *et al.* [1977].

Disposition in the Body Variably absorbed after oral administration and mainly metabolised by the liver. The main metabolite is hydroxyajmaline *N*-oxide [Köppel *et al.* 1990].

Therapeutic Concentration

Six patients with acute myocardial infarction and ventricular arrhythmia were administered 20 mg/h IV ajmaline for 24 h. After 24 h, the plasma concentrations ranged from 0.25 to 0.95 mg/L [Köppel *et al.* 1992].

After IV injection of 50 mg to 1 subject, a plasma concentration of approx. 1.7 mg/L was reported at 1 min [Welman *et al.* 1977].

Toxicity

A 4-year-old girl died 3 h after ingestion of her mother's ajmaline tablets: seventeen 50 mg tablets were found missing. The ajmaline concentrations were determined to be 5.5 mg/L in her blood and 178.2 µg/g in her stomach contents (46.3 mg in total was found in the stomach). An estimated lethal dose of 100 to 500 mg/kg was reported [Ikeda *et al.* 1988].

A 57-year-old man ingested 1.0 g of ajmaline with suicidal intent. His blood concentrations and urinary excretion of ajmaline during the first 3 days post-ingestion were as follows:

Day	*Blood concentration (mg/L)*	*Urine*	
		mg/L	*mg/24 h*
1	3	1.26	35.3
2	0	0.609	6.09
3	0	0	0

[Almog *et al.* 1979].

In a fatality resulting from the ingestion of 2.5 g ajmaline and 300 mg diazepam, the following postmortem tissue concentrations of ajmaline were reported: blood 10 mg/L, liver 50 µg/g, urine 44 mg/L. A blood-alcohol concentration of 1590 mg/L was also reported [AR Alha 1966, personal communication].

Note For an account of a suicide attempt with ajmaline, see Jornod and Barrelet [1965].

Bioavailability Oral, 5%.

Half-life 1.5 h.

Volume of Distribution 2 to 3 L/kg.

Protein Binding 76%.

Dose Maintenance, 200 to 300 mg daily; therapeutic 150 to 400 mg daily.

Alacepril

ACE Inhibitor, Antihypertensive

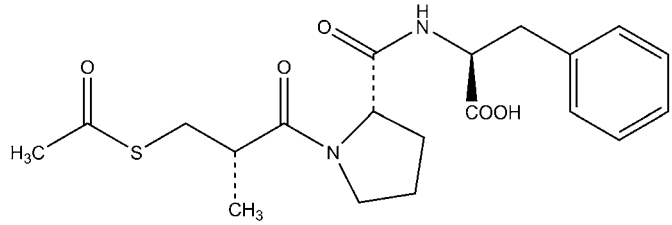
$C_{20}H_{26}N_2O_5S = 406.5$

CAS—74258-86-9

IUPAC Name (2*S*)-2-[[(2*S*)-1-[(2*S*)-3-Acetylsulfanyl-2-methylpropanoyl]pyrrolidine-2-carbonyl]amino]-3-phenylpropanoic acid

Synonyms 1-[(2*S*)-3-(Acetylthio)-2-methyl-1-oxopropyl]-l-prolyl-l-phenylalanine; 1-(*D*-3-acetylthio-2-methylpropanoyl)-l-prolyl-l-phenylalanine; DU-1219; *N*-[1-[(*S*)-3-mercapto-2-methylpropionyl]-l-prolyl]-3-phenyl-l-alanine acetate (ester).

Proprietary Name *Cetapril*



Chemical Properties Crystals. Mp 155° to 156° [O'Neil *et al.* 2006]. Captopril is stable in plasma and urine at approx. −20° for 30 days [Hayashi *et al.* 1985].

Quantification

Plasma **HPLC** Column: µBondapak C_{18} (300 × 4.0 mm i.d., 10 µm). Mobile phase: acetonitrile : ethanol : 1% acetic acid (45 : 11 : 75), flow rate 1.0 mL/min. UV detection ($\lambda = 254$ nm). Limit of detection, 10 µg/L for captopril [Hayashi *et al.* 1985].

Urine **HPLC** See Plasma. Limit of detection, 50 µg/L for captopril [Hayashi *et al.* 1985].

Disposition in the Body Alacepril thiolesterase catalyses the hydrolysis of alacepril to desacetylalacepril (DU-1227). Alacepril is also converted to captopril after absorption.

Therapeutic Concentration

Forty-seven patients with chronic renal failure or normal renal function were administered 6.25, 12.5, 25, or 50 mg alacepril. At a dosage of 25 mg/day, the plasma concentration of captopril ranged from 123 to 3010 mg/L, while serum creatinine levels ranged from 0.4 to 11.3 mg/L. There was a linear relationship between plasma concentrations of captopril and serum creatinine levels at all doses given. In patients with creatinine clearance (CL_{CR}) <10 mL/min who were administered 6.25, 12.5, or 25 mg/day alacepril, the plasma concentrations were 621 ± 99, 1055 ± 190, and 1679 ± 275 µg/L, respectively. A dosage of 25 mg/day resulted in a mean plasma concentration of 1993 ± 725 µg/L in patients on chronic haemodialysis, with a decrease to 1115 ± 415 µg/L after 4 h on haemodialysis [Nonoguchi *et al.* 2008].

Nine patients with chronic renal failure were administered 50 mg alacepril orally. Mean maximum plasma concentrations were 239, 1090, and 1433 µg/L for free captopril, protein-conjugated captopril, and total captopril attained at 1.1, 3.6, and 2.8 h, respectively. The mean peak plasma concentration, the time to peak plasma concentration, the elimination rate constant and the area under curve of free captopril did not differ from those in healthy subjects, although cumulative urinary excretion was significantly diminished. The same parameters of plasma protein-conjugated captopril and total captopril in the uraemic patient were 2 to 3 times greater than those in healthy subjects, while the elimination of total captopril in the urine was significantly decreased [Onoyama *et al.* 1986; Singlas, Fillastre 1991].

Seven healthy male subjects (aged 33 to 50 years) were given 50 mg alacepril orally in the fasting or fed state. Mean maximum plasma concentrations were 266, 513 and 764 µg/L for free captopril, protein-conjugated captopril and total captopril, respectively, attained at 1, 1.7 and 1.6 h, respectively, in the fasting state. The elimination half lives for free, protein-bound and total captopril were 1.9, 4.2 and 5 h, respectively. In the fed state, the half lives remained the same but the t_{max} for free captopril was prolonged to 1.9 h [Kelly, O'Malley 1990; Onoyama *et al.* 1985].

Note For a study investigating the efficacy of alacepril in combination with candesartan silextil in ovarian hyperstimulation syndrome, see Ando *et al.* [2003]. For a study of alacepril in decreasing atrial and brain natriuretic peptides in congestive heart failure, see Yoshimura *et al.* [1994]. For a study comparing the withdrawal of diuretics or ACE inhibitors as antihypertensive therapy in subjects with essential hypertension, see Takata *et al.* [1992].

Half-life In the fasted state: 1.9, 4.2 and 5 h for free, protein-bound and total captopril, respectively.

Dose Daily oral dose 25 to 75 mg, as a single dose or in two divided doses.

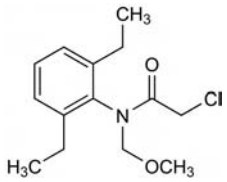
Alachlor

Herbicide

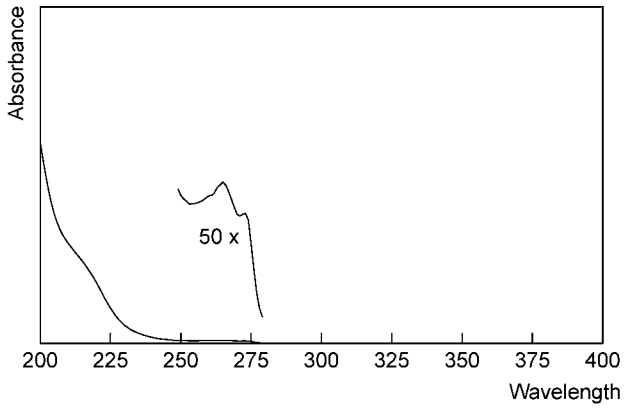
$C_{14}H_{20}ClNO_2$ = 269.8

CAS—15972-60-8

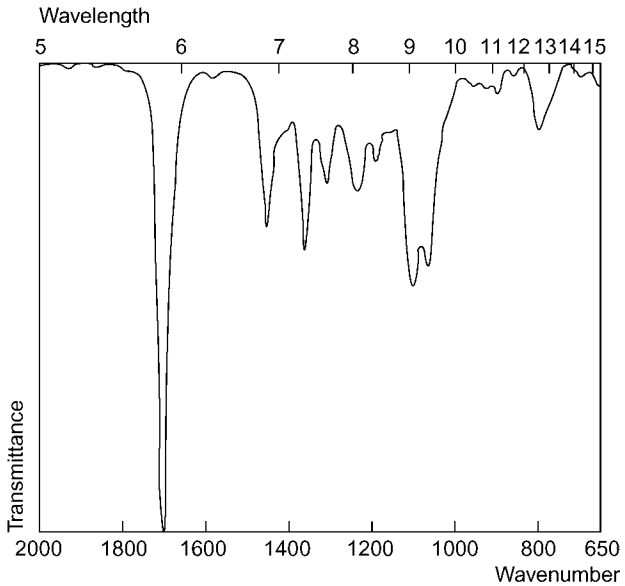
IUPAC Name 2-Chloro-*N*-(2,6-diethylphenyl)-*N*-(methoxymethyl)acetamide
Synonyms Alachlore; CP-50144; metachlor.
Proprietary Names *Alanex*; *Lasso*.



Chemical Properties A colourless to yellow crystalline solid. Mp 40° to 41°. It is soluble in water (240 mg/L at 25°), acetone, benzene, ethanol, ethyl acetate, diethyl ether and chloroform; sparingly soluble in heptane. Log *P* (octanol/water), 2.64, 2.92 and 3.52.
Thin-layer Chromatography System TX—R_f 0.40; system TY—R_f 0.45.
Gas Chromatography System GA—RI 1876.
Ultraviolet Spectrum Aqueous acid—265, 273 nm.



Infrared Spectrum Principal peaks at 1106, 1702, 1365, 1458 cm^{-1}.



Mass Spectrum Principal ions at *m/z* 45, 160, 188, 146, 237, 132, 117, 77.
Quantification
Serum **GC** Column: DB-1 (2 m × 0.25 mm i.d., 0.25 µm). Temperature programme: 120° for 0.3 min to 180° at 15°/min. Carrier gas: 1.9 mL/min. FID. Reference compounds: pentachlorophenol, heptadecanoic acid. Retention time: 2.75 min [Liu *et al.* 1994]. Limit of detection, 11.5 µg/L [Liu *et al.* 1994].

HPLC Limit of detection, <50 mg/L [Galati *et al.* 1998].

Note For an ELISA for the quantification of alachlor see Biagini *et al.* [1995].
Disposition in the Body Alachlor is absorbed through the skin and can be metabolised to 2,6-diethylbenzoquinoneimine (DEBQI) which is a carcinogenic metabolite and 2-chloro-*N*-(2,6-diethylphenyl)acetamide (CDEPA) which can subsequently be converted into DEBQI. Additionally, 2,6-diethylaniline (DEA), alachlor mercapturate and conjugated metabolites have been detected in urine. No free alachlor has been detected in urine.
Toxicity Alachlor may cause mild eye and skin irritations after exposure.

Biagini RE *et al.* (1995). Urinary biomonitoring for alachlor exposure in commercial pesticide applicators by immunoassay. *Bull Envir Contam Toxicol* 54(2): 245–250.

Liu Z *et al.* (1994). Comprehensive two-dimensional gas chromatography for the fast separation and determination of pesticides extracted from human serum. *Anal Chem* 66: 3086–3092.

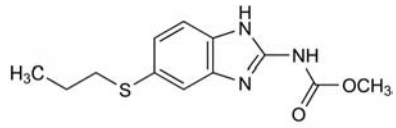
Albendazole

Anthelmintic (Veterinary)

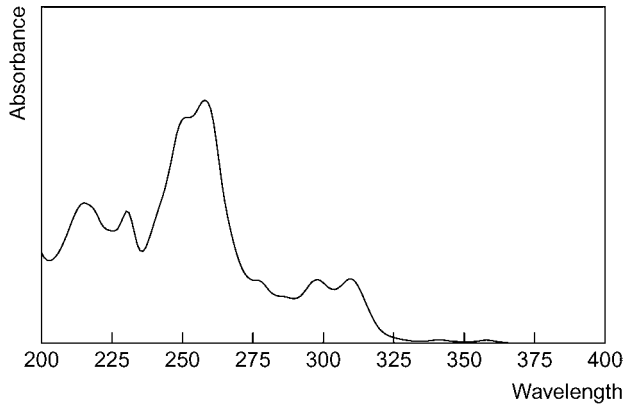
$C_{12}H_{15}N_3O_2S$ = 265.3

CAS—54965-21-8

IUPAC Name Methyl *N*-(6-propylsulfanyl-1H-benzimidazol-2-yl)carbamate
Synonym [5-(Propylthio)-1*H*-benzimidazol-2-yl]carbamic acid methyl ester.
Proprietary Names *Albenza*; *Eskazole*; *Proftril*; *Valbazen*; *Zental*.



Chemical Properties Colourless crystals. Mp 208° to 210°.
Ultraviolet Spectrum Aqueous acid—292 nm (A^1_1=370b); aqueous alkali—309 nm (A^1_1=742b).



High Performance Liquid Chromatography Column: amylose tris(3-dimethylphenyl carbamate) coated on silica gel substrate, Chiralpak AD (250 × 4.6 mm, 10 µm). Mobile phase: hexane: isopropanol: ethanol (81:14.25:4.74), flow rate 1.2 mL/min. Fluorescence detection (λ_{ex}=280 nm; λ_{em}=320 nm). Retention time: 8.5 min for albendazole; 13.7 (*trans*) 21.6 (*cis*) min for albendazole sulfoxide; 25.7 min for albendazole sulfone [Lanchote *et al.* 1998].
Quantification
Plasma **HPLC** Limit of quantification 10 µg/L and 7.5 µg/L for albendazole and metabolites, respectively [Chiap *et al.* 2000]. Column: RP C_{18} LiChroCART (125 × 4 mm, 5 µm). Mobile phase: acetonitrile: 0.25 N sodium acetate buffer (3:7), flow rate 1.5 mL/min. Internal standard (IS): mebendazole. UV detection (λ=290 nm). Retention time: 1.2 min for albendazole sulfoxide; 1.9 min for albendazole sulfone; 5.6 min for IS; 11.7 min for albendazole [Valois *et al.* 1994]. Limit of quantification, 40 µg/L for albendazole sulfoxide, and 10 µg/L for sulfone [Valois *et al.* 1994]. UV detection (λ=290 nm). Limit of detection, 14 µg/L for albendazole sulfoxide, and 30 µg/L for albendazole sulfone [Zeugin *et al.* 1990].
Disposition in the Body
Therapeutic Concentration

Thirteen subjects, male and female, with a mean age of 38.9 (15 to 64) years were administered a mean daily dose of 18.3 mg/kg albendazole (range 16.0 to 22.2 mg/kg). The mean peak plasma concentration of albendazole sulfoxide was 0.71 mg/L (range 0.36 to 1.52 mg/L) and albendazole sulfone was 0.06 (range 0.02 to 0.14) mg/L [Valois *et al.* 1994].

A patient with echinococcosis was administered 200 mg albendazole orally and a peak plasma concentration of 1.57 µmol/L was observed at 0.9 h [Zeugin *et al.* 1990].

Chiap P *et al.* (2000). Determination of albendazole and its main metabolites in ovine plasma by liquid chromatography with dialysis as an integrated sample preparation technique. *J Chromatogr A* 870(1–2): 121–134.

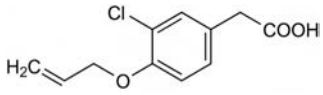
Alclofenac

Analgesic

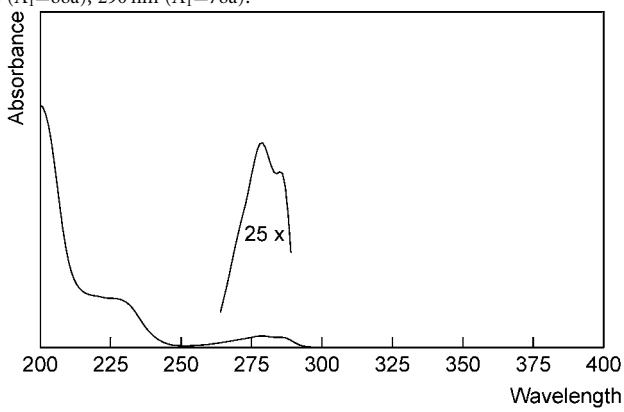
$C_{11}H_{11}ClO_3 = 226.7$

CAS—22131-79-9

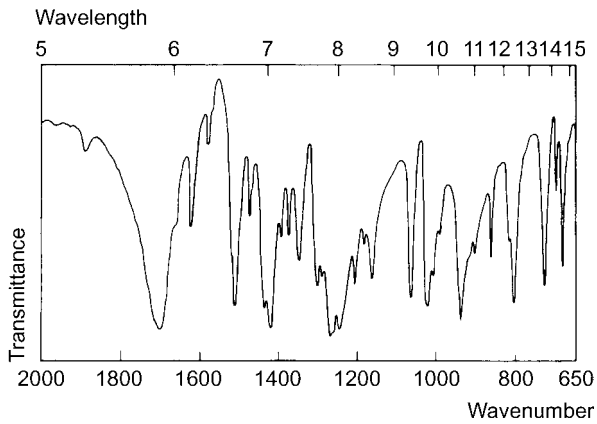
IUPAC Name 2-(3-Chloro-4-prop-2-enoxyphenyl)acetic acid
Synonym 3-Chloro-4-(2-propenyloxy)benzeneacetic acid.
Proprietary Names *Allopydin*; *Epinal*; *Mervan*; *Reufenac*; *Zumaril*.



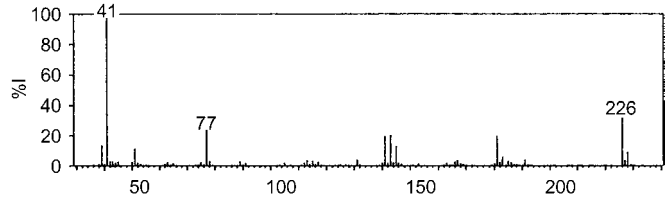
Chemical Properties A white or slightly yellowish-white crystalline powder. Mp about 91°. Slightly soluble in water; soluble 1 in 3 of ethanol, 1 in 4 of chloroform, and 1 in 6 of ether. pK_a 4.6.
Thin-layer Chromatography System TD—R_f 0.18; system TE—R_f 0.04; system TF—R_f 0.28; system TG—R_f 0.12; system TAD—R_f 0.33; system TAJ—R_f 0.17; system TAK—R_f 0.70; system TAL—R_f 0.90 (Lucy Tenger reagent, orange).
Gas Chromatography System GD—(methyl derivative)RRT 1.13.
High Performance Liquid Chromatography System HD—*k* 2.6; system HV—retention time 0.61 relative to meclofenamic acid.
Ultraviolet Spectrum Aqueous acid—277 (A^1_1=77b); dehydrated alcohol—282 (A^1_1=88a), 290 nm (A^1_1=78a).



Infrared Spectrum Principal peaks at wavenumbers 1258, 1689, 1235, 933, 1016, 1500 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 41, 226, 77, 143, 181, 141, 39, 145.



Quantification
Plasma **GC** FID. Alclofenac and 2 metabolites [Roncucci *et al.* 1971].
Urine **GC** See Plasma [Roncucci *et al.* 1971].
HPLC Limit of quantification, 1 mg/L [Delbeke *et al.* 1993].
Disposition in the Body Alcofenac is variably absorbed after oral or rectal administration and distributed into the synovial fluid. It is metabolised by glucuronic acid conjugation; there is some conjugation with glycine, deallylation to form 3-chloro-4-hydroxyphenylacetic acid, and hydroxylation to form 3-chloro-4-(2,3-dihydroxypropyloxy)phenylacetic acid which may be methylated; an epoxide metabolite has also been identified. Up to about 90% of an oral dose is excreted in the urine in 24 h, mostly as unchanged drug and the glucuronide conjugate.
Therapeutic Concentration
After an oral dose of 1 g to 10 subjects, a mean peak plasma concentration of 136 mg/L was attained in about 1 h; concentrations in the synovial fluid reached a mean peak of 32 mg/L in 2 h [Thomas *et al.* 1975].
Half-life Plasma half-life, 1.5 to 5.5 h (mean 2.5 h).
Volume of Distribution About 0.1 L/kg.
Protein Binding About 99%.
Note For a review of the pharmacokinetics of alclofenac, see Brogden *et al.* [1977].
Dose Alclofenac has been given in doses of 1.5 to 3 g daily.

Brogden RN *et al.* (1977). Alclofenac: a review of its pharmacological properties and therapeutic efficacy in rheumatoid arthritis and allied rheumatic disorders. *Drugs* 14: 241–259.

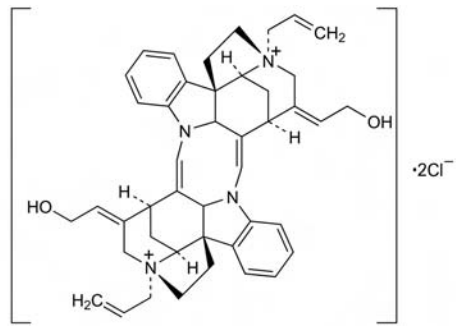
Alcuronium Chloride

Muscle Relaxant

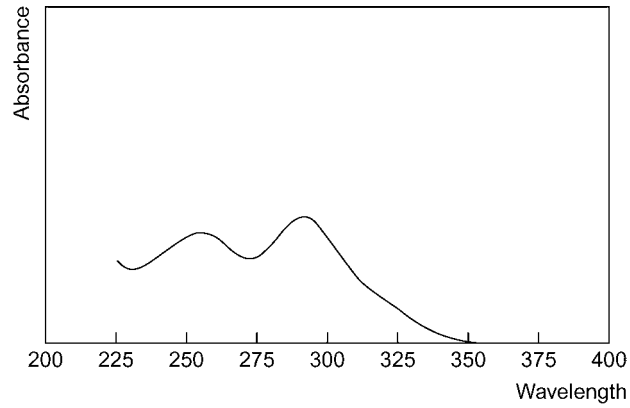
$C_{44}H_{50}Cl_2N_4O_2,5H_2O = 827.9$

CAS—23214-96-2 (alcuronium); 15180-03-7 (chloride)

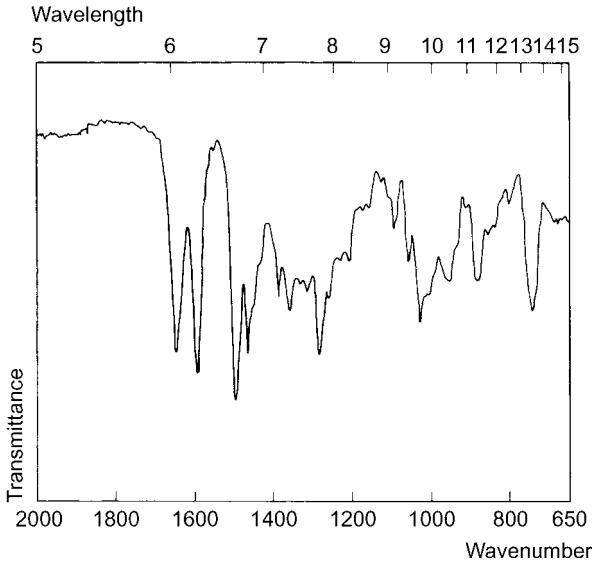
Synonyms Allnortoxiferin chloride; diallylnortoxiferine dichloride; diallyltoxiferine chloride; 4,4′-didemethyl-4,4′-di-2-propenyltoxiferine dichloride.
Proprietary Name *Alloferin*



Chemical Properties A colourless crystalline powder. Mp 220°. Soluble in water and ethanol; soluble 1 in 5 of methanol.
Colour Tests Mandelin's test—blue-violet; Marquis test—green-brown.
Thin-layer Chromatography System TA—R_f 0.01; system TB—R_f 0.00 (alcuronium); system TE—R_f 0.00; system TAE—R_f 0.00 (acidified potassium permanganate solution, positive).
High Performance Liquid Chromatography System HX—RI 354.
Ultraviolet Spectrum Aqueous acid—255, 291 nm (A^1_1=185b).



Infrared Spectrum Principal peaks at wavenumbers 1495, 1592, 1283, 1650, 1030, 757 cm^{-1} (KBr disk).



Quantification

Plasma **HPLC** Column: Spherisorb 5-CN (250 × 4 mm). Mobile phase: acetonitrile: aqueous solution of 60 mmol/L Na_2SO_4 and 5 mmol/L H_2SO_4 (46:54), flow rate 1 mL/min. Internal standard (IS): laudanosine. UV detection (λ=294 nm). Retention time: 3.2 min for IS; 5.4 min for alcuronium. Limit of detection, 25 µg/L [Kunzer *et al.* 1994]. Electrochemical detection. Limit of detection, 100 µg/L [Tovey *et al.* 1983].

Spectrofluorimetry [Walker *et al.* 1980].

Urine **HPLC** See Plasma [Kunzer *et al.* 1994].

Disposition in the Body After i.v. administration it is widely distributed throughout the tissues. About 80 to 85% of a dose is excreted in the urine as unchanged drug and about 10 to 15% is secreted in the bile and eliminated in the faeces.

Therapeutic Concentration

Following i.v. administration of 0.25 mg/kg to 17 subjects, plasma concentrations of 0.74 to 2.25 mg/L (mean 1.4 mg/L) were reported after 3 to 30 min [Walker *et al.* 1980].

Half-life Plasma half-life, about 3 h; increased in subjects with renal failure.

Volume of Distribution About 0.4 L/kg.

Clearance Plasma clearance, about 1.3 mL/min/kg.

Protein Binding About 40%.

Note For a review of the pharmacokinetics of alcuronium chloride and other muscle relaxants, see Ramzan *et al.* [1981].

Dose Initially 200 to 300 µg/kg intravenously.

Kunzer T *et al.* (1994). Simple and rapid high-performance liquid chromatography method for the determination of alcuronium in human plasma and urine. *J Chromatogr B, Biomed Appl* 653(1): 63–68.

Aldesleukin

Antineoplastic, Immunomodulator, Biological Response Modifier

$C_{690}H_{1115}N_{177}O_{203}S_6$ = 15330.7

CAS—110942-02-4

Synonyms DRG-0021; recombinant human interleukin-2; rIL-2; r-serHuIL-2; serine-125 human interleukin-2.

Proprietary Name *Proleukin*

Chemical Properties A human recombinant interleukin-2 product, approximate molecular weight 15 300 daltons.

Quantification

Serum **Immunobioassay** Limit of quantification, 0.1 µg/L [Nadeau *et al.* 1989].

Disposition in the Body The pharmacokinetics of aldesleukin show considerable inter- and intra-subject variation. Following IV administration it undergoes rapid distribution into the extravascular space. Distribution may be related to the method of administration and may therefore affect its efficacy. It is eliminated by the kidneys by both glomerular filtration and peritubular secretion.

Therapeutic Concentration

Twelve patients with either metastatic renal cell carcinoma or melanoma were administered with aldesleukin at a dose of 1.1 mg/m^2 daily (18×10^6 IU/m^2 daily) as a continuous IV infusion for 5 days. The maximum serum concentration was 2.2 ± 1.1 µg/L (40 IU/L) after 24 or 48 h. After that time, the serum concentrations decreased to 0.59 ± 0.43 µg/L (10.6 IU/L) by the end of the 5-day treatment [Fish *et al.* 1991].

Toxicity Capillary leak syndrome leading to pulmonary oedema and hypertension is a major adverse effect.

Half-life Plasma, 85 min to 4 h (IV bolus); 12 h (1-h infusion).

Volume of Distribution 6.3 to 7.9 L (following IV bolus or 2-h infusion) which increases with repeated doses.

Clearance Plasma, 140 to 300 mL/min (mean clearance 268 mL/min); 8.4 to 18 L/h.

Note For a review of aldesleukin, see Whittington and Faulds [1993].

Dose 600 000 units/kg every 8 h by IV infusion over 15 min for a maximum of 14 doses repeated after 9 days. Alternatively, a dose of up to 18 million international units may be given subcutaneously.

Fish *et al.* (1991). *Br J Cancer* 64 (Suppl.15)4.

Aldicarb

Acaricide, Carbamate, Insecticide, Nematocide

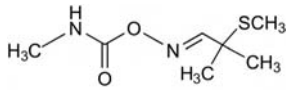
$C_7H_{14}N_2O_2S$ = 190.3

CAS—116-06-3

IUPAC Name [(*E*)-(2-Methyl-2-methylsulfanylpropylidene)amino] *N*-methyl carbamate

Synonyms Aldicarbe; carbanolate; ENT 27093; 2-methyl-2-(methylthio)propanal-*O*-[methylamino(carbonyl)]oxime; NCI-CO8640; OMS 771; UC 21149.

Proprietary Names *Sentry*; *Temic*; *Temik*.



Chemical Properties A white crystalline powder. Mp 90° to 100°. It is soluble in water (0.1–1.0 mg/mL at 22°), DMSO (>100 mg/mL at 21°), 95% ethanol (>100 mg/mL at 21°), acetone (>100 mg/mL at 21°), chloroform, isopropane, toluene and most organic solvents; insoluble in heptane and mineral oils. Log *P* (octanol/water), 1.13 (25°). Aldicarb and its metabolites are not stable in beef or chicken liver when stored at −4° with 100% depletion of fortified samples occurring at 3–6 months [Ali *et al.* 1993].

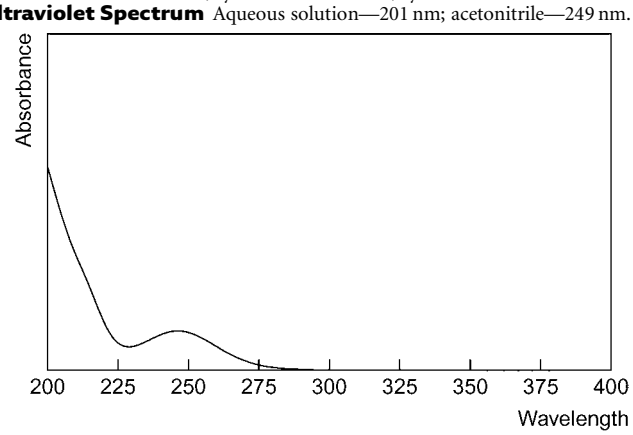
Thin-layer Chromatography System TX—R_f 0.18; system TY—R_f 0.12; system TZ—R_f 0.65; system TAA—R_f 0.12; system TAB—R_f 0.04; system TAC—R_f 0.03.

Plate: silica gel G. Mobile phase: *n*-hexane : acetone (4 : 1). Developed with zinc chloride–diphenylamine spray reagent (110° for 10 min). R_f 0.4 [Sevalkar *et al.* 1991].

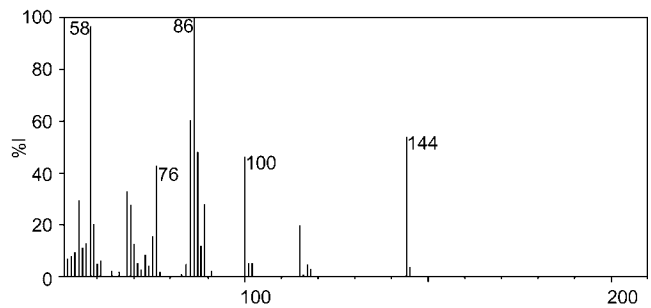
Gas Chromatography System GA—RI 1320; system GKA—RI 866; system GKB—RI 966; system GKC—RI 1088.

High Performance Liquid Chromatography System HZ—RT 3.6 min; system HAA—RT 15.1 min; system HAO—*k* 7.63; system HAP—*k* 0.69.

Ultraviolet Spectrum Aqueous solution—201 nm; acetonitrile—249 nm.



Mass Spectrum Principal peaks at *m/z* 86, 58, 144, 84, 100, 76.



A

Quantification

Blood **HPLC** Column: Waters C_{18} (150 × 3.9 mm i.d., 4 µm). Mobile phase: water : methanol : acetonitrile, flow rate 1.5 mL/min. Fluorescence detection (λ_{ex} = 339 nm, λ_{em} = 445 nm). Limit of detection, 1 µg/L [Proença *et al.* 2004].

Serum **HPLC** Column: Alltima RP-C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : water (35 : 65), flow rate 1.5 mL/min. DAD (λ = 210 nm). Retention time: 7.2 min. Limit of detection, 0.05 mg/L [Covaci *et al.* 1999].

Urine **GC** Column: 3% polyethylene glycol 20M–GasChrom Q (2.1 m × 2.7 mm i.d.). Temperature: 160°. FPD. Limit of detection, 2.4 µg/L [Lian *et al.* 1991].

HPLC Column: Hypersil C_{18} (100 × 3.0 mm i.d., 5 µm). Mobile phase: acetonitrile : water (15 : 85 to 100 : 0 at 6 min for 3 min to 15 : 85 at 14 min), flow rate 1 mL/min. UV detection (λ = 210 nm). Limit of quantification, 1 µg/L for aldicarb, 3 µg/L for the metabolites, limit of detection, 0.3 µg/L for aldicarb and 1 µg/L for the metabolites [Parilla Vázquez *et al.* 2000]. Column: Hypersil C_{18} (100 × 3 mm i.d., 5 µm). Mobile phase: water : acetonitrile : methanol (90 : 10 : 0 for 4 min to 90 : 5 : 5 at 4.01 min for 2 min to 0 : 100 : 0 in 4 min), flow rate 1.0 mL/min. UV detection (λ = 210 nm). Limit of detection, 4 µg/L for aldicarb and 10 µg/L for metabolites [Martínez Fernández *et al.* 2000]. See Serum [Covaci *et al.* 1999].

LC-MS Column: Hypersil C_{18} (100 × 3 mm i.d., 5 µm). Mobile phase: water : acetonitrile (80 : 20 for 3 min to 0 : 100 at 7 min for 2 min), flow rate 0.8 mL/min. ESI, positive ion mode, SIM acquisition mode. Limit of detection, 0.1 µg/L for aldicarb and aldicarb sulfoxide, 0.5 µg/L for aldicarb sulfone [Martínez Fernández *et al.* 2000].

Other **HPLC** Food. Column: Waters (150 × 3.9 mm i.d., 4 µm). Mobile phase: water : methanol : acetonitrile. Fluorescence detection (λ_{ex} = 339 nm, λ_{em} = 445 nm). Limit of quantification, 0.7, 0.9 and 0.07 µg/kg for aldicarb, aldicarbsulfoxide and aldicarbsulfone, respectively [Borkovcová *et al.* 2004]. Environmental Water. Column: Varian octadecylsilica (150 × 4.6 mm i.d., 5 µm). Mobile phase: methanol : water (18 : 82 to 19 : 81 at 11 min to 20 : 80 at 13 min to 27 : 73 at 15 min to 49 : 51 at 25 min to 70 : 30 at 35 min to 80 : 20 at 45 min to 100 : 0 at 46 min), flow rate 1 mL/min. Fluorescence detection (λ_{ex} = 330 nm, λ_{em} = 465 nm). Limit of detection, 3–4 µg/L [García de Llasera, Bernal-González 2001]. Drinking Water. Column: Phenomenex ODS (250 × 4.6 mm i.d., 5 µm). Mobile phase: water : acetonitrile (70 : 30), flow rate 1.0 mL/min. Fluorescence detection (λ_{ex} = 330 nm, λ_{em} = 465 nm). Retention time: 11.9 min. Limit of detection, <0.1 µg/L [Morrica *et al.* 2005]. Air. Column: Nova-Pak C_{18} (300 × 3.9 mm i.d.). Mobile phase: propan-1-ol–TEA phosphate buffer 0.02 mol/L (pH 7.0; 2 : 98): propan-1-ol-acetonitrile (2 : 98; 97 : 3 to 5 : 95 at 30 min for 5 min), flow rate 1.0 mL/min. DAD (λ = 200 nm). Limit of quantification, 2.42 µg/sample [Kennedy *et al.* 1997]. Tobacco. Column: Hypersil C_{18} (200 × 4.6 mm i.d.). Mobile phase: 0.1% triethanolamine in acetonitrile-water (20 : 80) : 0.1% triethanolamine in water (10 : 90 for 4 min to 30 : 70 in 7 min to 90 : 10 over 5 min for 10 min), flow rate 1 mL/min. Fluorescence detection (λ_{ex} = 330 nm, λ_{em} = 465 nm). Limit of detection not reported [Yang, Smetena 1994]. Drinking Water. Column: Nucleosil 100 C_{18} (150 × 4.6 mm i.d., 5 µm). Mobile phase: 0.01 mol/L phosphate buffer (pH 3.0) : acetonitrile-water (90 : 10; 95 : 5 to 0 : 100 at 25 min for 5 min), flow rate 1 mL/min. DAD (λ = 215 nm) or fluorescence detection (λ_{ex} = 330 nm, λ_{em} = 460 nm). Limit of quantification, 0.1 µg/L for DAD, 0.01 µg/L for fluorescence; limit of detection, 0.1 µg/L for DAD, 0.005 µg/L for fluorescence [Patsias, Papadopoulou-Mourkidou 1999]. Column: Supersphere 60 RP-8 (250 × 4.6 mm i.d., 4 µm). Mobile phase: acetonitrile : methanol : water (40 : 40 : 20) : acetonitrile : water (10 : 90; 5 : 95 to 20 : 80 at 15 min to 30 : 70 in 20 min to 65 : 35 in 20 min to 100 : 0 in 7 min), flow rate 0.8 mL/min. UV detection (λ = 220 nm). Limit of detection, 0.03 µg/L for aldicarb, 5 µg/L for aldicarb sulfone and aldicarb sulfoxide (lower limits with post-column fluorescence derivatisation) [Chiron, Barcelo 1993]. Column: Beckman Ultrasphere ODS (250 × 4.6 mm i.d., 5 µm). Mobile phase: methanol : water (15 : 85 to 100 : 0 in 32 min), flow rate 1.0 mL/min. Fluorescence detection (λ_{ex} = 230 nm, λ_{em} = 418 nm). Limit of detection, 1.0 µg/L for aldicarb, 2.0 µg/L for aldicarb sulfone and aldicarb sulfoxide [Edgell *et al.* 1991].

LC-MS Apples. Column: Atlantis dC_{18} (100 × 2.1 mm i.d., 3 µm). Mobile phase: acetonitrile: 0.1 mol/L ammonium acetate in acetonitrile : water (20 : 80): water (8 : 10 : 82 to 90 : 10 : 0 at 7 min to 90 : 10 : 0 at 25 min to 100 : 0 : 0 at 28 min to 8 : 10 : 82 at 34 min), flow rate 0.2 mL/min for 25 min to 0.3 mL/min until 33 min to 0.2 mL/min for 1 min. ESI, positive ion mode, MRM acquisition mode. Limit of detection, 0.6 µg/kg [Wang, Wotherspoon 2007]. Soy-based Infant Formulas. Column: YMC ODS-AQ S-3 (50 × 2 mm). Mobile phase: acetonitrile : 0.1 mol/L ammonium acetate with 20% acetonitrile in water : water (80 : 20 : 0 to 90 : 10 : 0 over 9 min for 4 min to 100 : 0 : 0 for 2 min to 8 : 10 : 82 for 5 min), flow rate 0.2 mL/min for 13 min to 0.3 mL/min for 6 min to 0.2 mL/min for 1 min. ESI, positive ion mode, MRM acquisition mode. Retention time: 8.46 min. Limit of detection, 0.6 µg/kg [Wang, Cheung 2006]. Apple-based Infant Food. Column: YMC ODS-AQ S-3 (50 × 2 mm i.d.). Mobile phase: acetonitrile : 0.1 mol/L ammonium acetate in 20% acetonitrile : water (8 : 10 : 82 to 90 : 10 : 0 at 9 min for 4 min to 100 : 0 : 0 for 2 min to 8 : 10 : 82 for 5 min), flow rate 0.2 mL/min for 13 min to 0.3 mL/min for 6 min to 0.2 mL/min for 1 min. ESI, positive ion mode, MRM acquisition mode. Limit of detection, 0.2, 0.1 and 0.09 µg/kg for aldicarb, aldicarb sulfoxide and aldicarb sylfone, respectively [Wang *et al.* 2005]. Fruit and Vegetables. Column: Zorbax Eclipse XDB C_{18} (150 × 3 mm i.d., 5 µm). Mobile phase: methanol : 10 mmol/L ammonium acetate (30 : 70 to 100 : 0 at 15 min), flow rate 500 µL/min. APCI, positive ion mode, SIM acquisition mode. Limit of detection, 0.5–5.0 µg/L [Takino *et al.* 2004]. Natural Waters. Column: Hypersil reversed phase C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: methanol : water (20 : 80 to 100 : 0 in 35 min), flow rate 1.0 mL/min. ESI, positive and negative ion modes. Limit of detection, 0.6 ng/L [Di Corcia *et al.* 2000]. Fruit and Vegetables. Column: Zorbax C_{18} (150 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : 0.05 mol/L ammonium formate (5 : 95 to 30 : 70 at 10 min to 5 : 95 for 20 min), flow rate 1.0 mL/min. APCI, SIM acquisition mode. Limit of detection, 0.5 ng [Nunes *et al.* 2000].

CE Groundwater. Capillary: fused silica (57/50 cm total/effective length, 75 µm i.d.). Buffer: sodium borate : 20 mmol/L hydrochloric acid (pH 8). DAD (λ = 210 nm). Limit of quantification, 24.9 µg/L, limit of detection, 7.47 µg/L [Arráez-Román *et al.* 2004]. Drinking Water. Capillary: untreated fused silica (52/40 cm total/effective length, 50 µm i.d.). Buffer: 50 mmol/L SDS-10 mmol/L borate buffer-15 mmol/L β-cyclodextrin : acetonitrile (78 : 22). UV detection (λ = 202 nm). Limit of detection, 0.46 µg/L [Fung, Mak 2001].

CE-MS Spiked Tap Water. Capillary: bare fused silica (60/67 cm total/effective length, 50 µm i.d.). Buffer: 5 mmol/L ammonium acetate in water : 5 mmol/L ammonium acetate in methanol (50 : 50), flow rate 4 µL/min. ESI, SIM acquisition mode. Limit of detection, 0.01 mg/L [Van Biesen, Bottaro 2006].

Disposition in the Body Aldicarb is efficiently absorbed from the gastrointestinal tract and to a lesser extent through the skin. It is distributed to all tissues, but it does not significantly cross the blood–brain barrier. It is metabolised to aldicarb sulfoxide and aldicarb sulfone, both of which are toxic. Both metabolites can be detoxified by hydrolysis to oximes and nitriles. The drug and metabolites are excreted primarily in urine but a small amount is also excreted through biliary elimination. Aldicarb does not accumulate in the body during long-term exposure.

Toxicity Aldicarb features prominently in accidental pesticide poisonings because of the way it is misused. Aldicarb exposure may be fatal and may occur by ingestion, inhalation or when absorbed through the skin. Very high doses may result in paralysis of the respiratory system and the nervous system. Toxicity can occur between 15 min and 3 h postexposure but effects can disappear quite quickly within 4–12 h. The allowed daily intake is 0.005 mg/kg body weight.

A 24-year-old man was found unconscious, frothing at the mouth. He was dead on arrival at hospital. Postmortem aldicarb concentrations were 6.2 mg/L (blood), 48.9 mg/kg (stomach), 0.80 mg/kg (liver), 8.10 mg/kg (kidney), 6.70 mg/kg (heart), and 17.5 mg/L (urine) [Proença *et al.* 2004].

A 65-year-old man and a 63-year-old woman were admitted to hospital with signs of cholinergic crisis. Their serum and urine aldicarb concentrations were as follows:

Concentration (mg/L)	*Male*	*Female*
Serum		
Day 1 (19 : 30)	0.90	0.85
Urine		
Day 1 (20 : 00)	1.00	0.61
Day 1 (24 : 00)	0.28	0.25
Day 2	—	—

[Covaci *et al.* 1999].

A 40-year-old woman was found unconscious and later pronounced dead. It was believed that she had ingested a black granular substance known as Temic. Postmortem analysis revealed the following aldicarb levels: blood concentration 11 mg/L, total stomach contents 213 mg and liver >1 mg/kg [Hoai Ngo 1991].

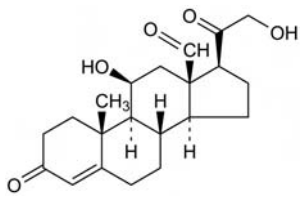
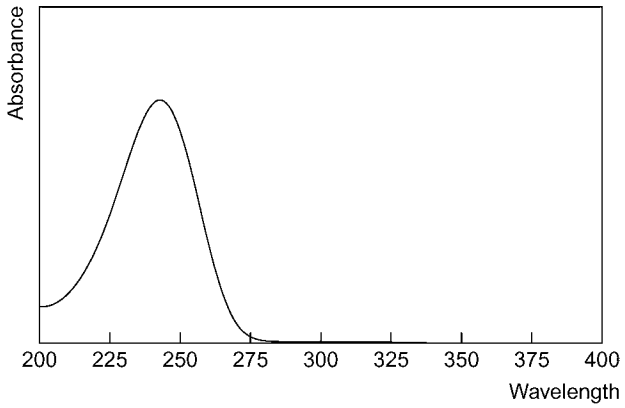
Aldosterone

Corticosteroid
$C_{21}H_{28}O_5$ = 360.4
CAS—52-39-1

IUPAC Name (8*S*,9*S*,10*R*,11*S*,13*R*,14*S*, 17*S*)-11-Hydroxy-17-(2-hydroxyacetyl)-10-methyl-3-oxo-1,2,6,7,8,9,11,12,14,15,16,17-dodecahydrocyclopenta[a]phenanthrene-13-carbaldehyde
Synonyms (11β)-11,21-Dihydroxy-3,20-dioxopregn-4-en-18-al; electrocortin.
Proprietary Name *Aldocorten*



Chemical Properties Mp 164°.
Ultraviolet Spectrum Methanol—241 nm (A^{1}_{1}=437b).



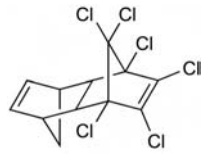
Infrared Spectrum Principal peaks at wavenumbers 1650, 986, 1020, 999, 1062, 1075 cm^{-1} (KBr disk).
Quantification
Plasma **LC-MS** (*m/z* 359.2 to 331.2). APCI Limit of quantification, 15 ng/L, limit of detection, 10 ng/L [Fredline *et al.* 1997].
Serum **HPLC** MS detection (*m/z* 359.2 to 331.2). See Plasma [Fredline *et al.* 1997].
Dose Aldosterone has been given in doses of 500 µg intravenously, repeated several times a day.

Fredline VF *et al.* (1997). A reference method for the analysis of aldosterone in blood by high-performance liquid chromatography-atmospheric pressure chemical ionization-tandem mass spectrometry. *Anal Biochem* 252: 308–313.

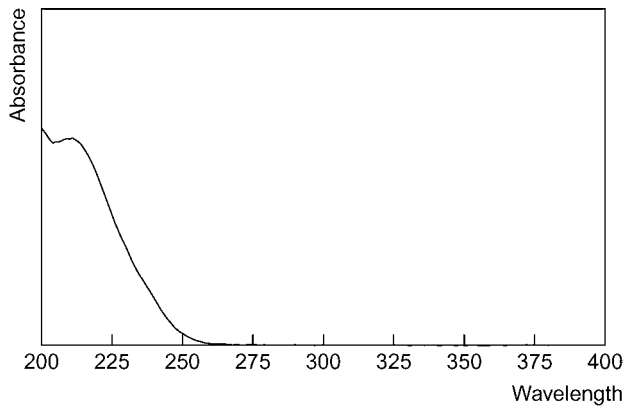
Aldrin

Insecticide
$C_{12}H_8Cl_6$ = 364.9
CAS—309-00-2

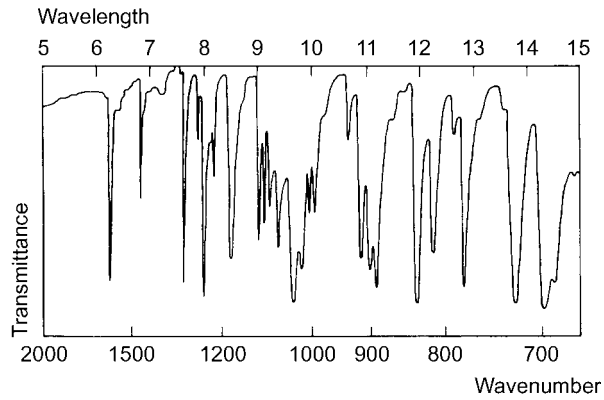
Synonyms Compd 118; HHDN.
Proprietary Names *Alderstan*; *Aldrex*; *Octalene*.



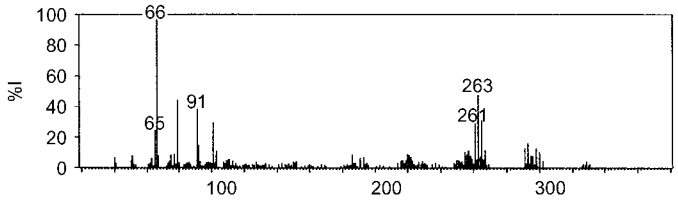
Note Aldrin usually contains 95% w/w of 1,2,3,4,10,10-hexachloro-1,4,4a,5,8,8a-hexahydro-1,4:5,8-dimethanonaphthalene (HHDN) together with 5% w/w of active related compounds.
Chemical Properties White crystals. When heated to decomposition it evolves highly toxic fumes of phosgene and hydrogen chloride. The technical grade is a tan to dark brown solid containing 85% or more of HHDN. Mp 104° (pure grade), 49° to 60° (technical grade). Practically insoluble in water; soluble 1 in 20 of ethanol, 1 in 1 of acetone, 1 in 0.55 of benzene, and 1 in 0.33 of carbon tetrachloride; soluble in ether. Log *P* (octanol), 3.0.
Colour Tests Nitric–sulfuric acid (Erdman's reagent)—pink; sulfuric acid–fuming sulfuric acid—red (slow).
Thin-layer Chromatography System TX—aldrin R_f 0.89, dieldrin R_f 0.65; system TY—aldrin R_f 0.98, dieldrin R_f 0.87; system TAB—aldrin R_f 0.67, dieldrin R_f 0.51; system TAC—aldrin R_f 0.52, dieldrin R_f 0.27.
Gas Chromatography System GA—aldrin RI 1943, dieldrin RI 2110; system GK—aldrin retention time 0.88, dieldrin retention time 1.13 (both relative to caffeine); system GKA—aldrin RI 2008, dieldrin RI 2170; system GKB—aldrin RI 2096, dieldrin RI 2304; system GKC—aldrin RI 2226, dieldrin RI 2528.
High Performance Liquid Chromatography System HAO—*k* 0.00; system HAP—*k* 33.86.
Ultraviolet Spectrum No significant absorption, 230 to 360 nm.



Infrared Spectrum Principal peaks at wavenumbers 696, 1036, 835, 723, 1255, 893 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 66, 91, 79, 263, 65, 101, 261, 265; dieldrin 79, 82, 81, 263, 77, 108, 265, 80.



Quantification

Blood **GC** ECD. Limit of detection, 0.1 µg/L [Rosell *et al.* 1993].

GC-MS Column: fused silica capillary (30 m x 0.25 mm i.d., 0.25 µm). Temperature: 250°. Carrier gas: He. IS: endosulfan-I-d_4. Retention time: aldrin, 21.9 min; dieldrin, 31.4 min [Liu, Pleil 2002]. Limit of quantification, 25–50 pg (*m/z* 263, 378) [Liu, Pleil 2002].

Disposition in the Body Poorly absorbed after oral ingestion but when dissolved in oils or other lipids it is readily absorbed by the skin and gastrointestinal tract. It is rapidly metabolised in the body by epoxidation to dieldrin; dieldrin is stored in the body fat and persists for several weeks after the cessation of exposure. It is slowly eliminated in the faeces, mainly as unknown hydrophilic metabolites; a small amount is excreted in the urine as metabolites.

Blood Concentration Blood concentrations of dieldrin averaging 1 µg/L have been reported in 10 subjects with no occupational exposure to insecticides. Serum concentrations in subjects with low to high occupational exposure averaged 1 to 2 µg/L for aldrin and 9 to 27 µg/L for dieldrin.

Toxicity Severe symptoms may follow absorption of 1 to 3 g; the estimated minimum lethal dose is 5 g. The maximum permissible atmospheric concentration is 0.25 mg/m^3 and the maximum permissible concentration in food is 0.1 ppm.

The body fat of a 23-year-old man poisoned by aldrin, while working in a formulating plant, contained 60 µg/g of dieldrin 15 days after the last exposure; a blood concentration of 0.1 mg/L was reported 4 months later. The blood concentrations of two men exposed to aldrin in the same plant and showing symptoms of poisoning were 0.28 and 0.13 mg/L of dieldrin 1 month after the last exposure. In 2 further cases of poisoning, the concentrations of dieldrin in the body fat 3 and 5 weeks after exposure were 149 and 44 µg/g respectively; the corresponding blood concentrations were 0.53 and 0.13 mg/L [Kazantzis *et al.* 1964].

Half-life Blood half-life, dieldrin 50 to 170 days (mean 97).

Distribution in Blood Plasma : whole blood ratio, dieldrin about 1.5.

Kazantzis G *et al.* (1964). Poisoning in industrial workers by the insecticide aldrin. *Br J Ind Med* 21: 46–51.

Liu S, Pleil JD (2002). Human blood and environmental media screening method for pesticides and polychlorinated biphenyl compounds using liquid extraction and gas chromatography-mass spectrometry analysis. *J Chromatogr B Analyt Technol Biomed Life Sci* 769: 155–167.

Alefacept

Antipsoriatic, Immunosuppressant, Protein, T-Cell Activation Inhibitor

CAS—222535-22-0

IUPAC Name Dimer of 1-92 antigen LFA-3 (human) fusion protein with human immunoglobulin G1 (hinge-C_H2-C_H3 γ1-chain)

Synonyms BG-9273; BG9712; LFA3TIP; recombinant human LFA-3-IgG1 fusion protein.

Proprietary Name *Amevive*

Disposition in the Body Following IM injection, serum concentrations of alefacept are detectable ≈6 h later, with peak concentrations achieved between 24 and 192 h.

Therapeutic Concentration

Twelve young healthy male volunteers were administered 0.15 mg/kg of alefacept by IV bolus. The mean peak serum concentration was 3.1 mg/L at 0.4 h. In another study, two groups of eight young healthy volunteers were administered 0.04 mg/kg alefacept either as an IV infusion or IM injection. Peak serum concentrations for the IV and IM groups were 0.96 mg/L and 0.36 mg/L, respectively, and attained at 2.8 h and 86 h, respectively [Vaishnaw, TenHoor 2002].

Bioavailability Approximately 70% following IM injection.

Half-life Serum, ≈12 days.

Volume of Distribution 0.09 to 0.13 L/kg.

Clearance 0.18 to 0.34 mL/h/kg.

Dose Given in a dose of 7.5 mg once weekly by IV injection, or 15 mg once weekly by IM injection, for 12 weeks.

Vaishnaw AK, TenHoor CN (2002). Pharmacokinetics, biologic activity, and tolerability of alefacept by intravenous and intramuscular administration. *J Pharmacokinet Pharmacodyn* 29: 415–426.

Alendronic Acid

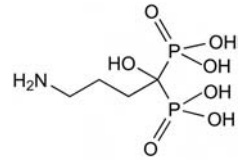
Bone Modulator

$C_4H_{13}NO_7P_2$ = 249.1

CAS—66376-36-1

IUPAC Name (4-Amino-1-hydroxy-1-phosphonobutyl)phosphonic acid

Synonyms Alendronate; (4-amino-1-hydroxybutylidene)bisphosphonic acid; aminohydroxybutylidene diphosphonic acid.



Chemical Properties A fine white powder. Mp 233° to 235°, with decomposition. pK_a (25°) 2.7, 8.7, 10.5, 11.6. Log *P* (octanol/water), −1.30.

Alendronate Sodium

$C_4H_{12}NNaO_7P_2,3H_2O$ = 325.1

CAS—121268-17-5

Proprietary Names *Adronat*; *Alendros*; *Dronal*; *Fosamax*.

Chemical Properties A white crystalline non-hygroscopic powder. It is soluble in water; very slightly soluble in ethanol; practically insoluble in chloroform.

Quantification

Plasma **HPLC** Electrochemical detection. Limit of quantification, 5 µg/L [Kline, Matuszewski 1992].

Urine **HPLC** Electrochemical detection. Limit of quantification, 1 µg/L. Fluorescence detection, 2.5 µg/L [Kline, Matuszewski 1992]. Fluorescence detection. Limit of quantification, 5 µg/L [Kline *et al.* 1990].

Disposition in the Body Alendronate is poorly absorbed after oral administration and absorption is decreased by food, especially products containing calcium or other polyvalent cations. The drug is rapidly cleared from plasma and about half of the absorbed dose is excreted in urine with the remainder being sequestered to bone for a prolonged period. It does not appear to be metabolised and is slowly released from skeletal deposits. Approximately 45% is excreted in urine in the first 8 h after an IV dose and then 5% is excreted much more slowly between 8 and 72 h. The drug is probably bound to the mineral phase of the skeleton and of that retained, approximately one-third is excreted over the first 6 months.

Half-life 10.5 years.

Volume of Distribution Steady state (estimated), greater than 28 L.

Clearance Systemic clearance (estimated), no more than 11.94 L/h.

Protein Binding 78%.

Dose For Paget's disease of bone the equivalent of 40 mg of alendronic acid daily; for treatment of postmenopausal osteoporosis 10 mg daily.

Kline WF *et al.* (1990). Determination of 4-amino-1-hydroxybutane-1,1-bisphosphonic acid in urine by automated pre-column derivatization with 2,3-naphthalene dicarboxyaldehyde and high-performance liquid chromatography with fluorescence detection. *J Chromatogr* 534: 139–149.

Kline WF, Matuszewski BK (1992). Improved determination of the bisphosphonate alendronate in human plasma and urine by automated precolumn derivatization and high-performance liquid chromatography with fluorescence and electrochemical detection. *J Chromatogr* 583: 183–193.

Aletamine

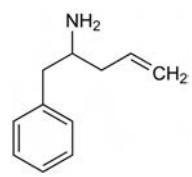
Analgesic

$C_{11}H_{15}N$ = 161.2

CAS—4255-23-6

IUPAC Name 1-Phenylpent-4-en-2-amine

Synonyms Alfetamine; α-allylphenethylamine.



Aletamine Hydrochloride

$C_{11}H_{15}N,HCl$ = 197.7

CAS—4255-24-7

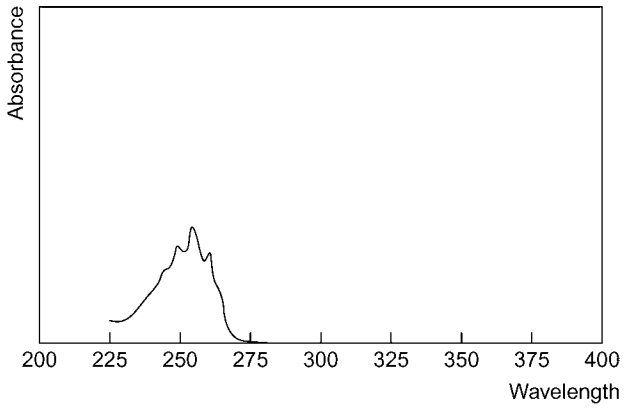
Chemical Properties White crystals. Soluble in water.

Colour Tests Liebermann's reagent—orange; Marquis test—orange.

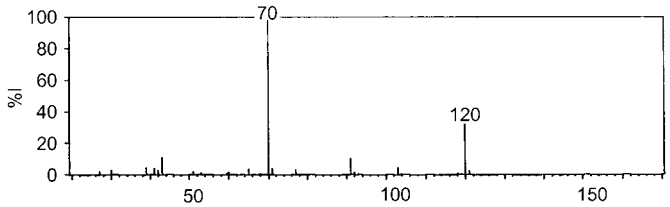
Thin-layer Chromatography System TA—R_f 0.59; system TB—R_f 0.37; system TC—R_f 0.40; system TL—R_f 0.42 (acidified iodoplatinate solution, positive; acidified potassium permanganate solution, positive).

Gas Chromatography System GA—RI 1293.

Ultraviolet Spectrum Aqueous acid—251, 257 (A^1_1=10b), 263 nm.



Mass Spectrum Principal ions at *m/z* 70, 120, 43, 91, 39, 103, 71, 65.



Dose Aletamine hydrochloride has been given in doses of 375 to 750 mg daily.

Alfacalcidol

Vitamin

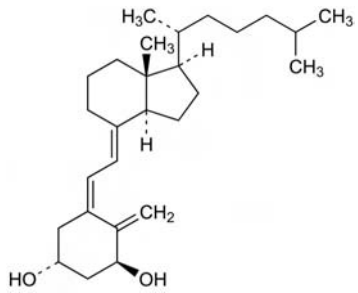
$C_{27}H_{44}O_2 = 400.6$

CAS—41294-56-8

IUPAC Name (1*R*,3*S*,5*Z*)-5-[(2E)-2-[(1*R*,3a*S*,7a*R*)-7a-Methyl-1-[(2*R*)-6-methylheptan-2-yl]-2,3,3a,5,6,7-hexahydro-1H-inden-4-ylidene]ethylidene]-4-methylidenecyclohexane-1, 3-diol

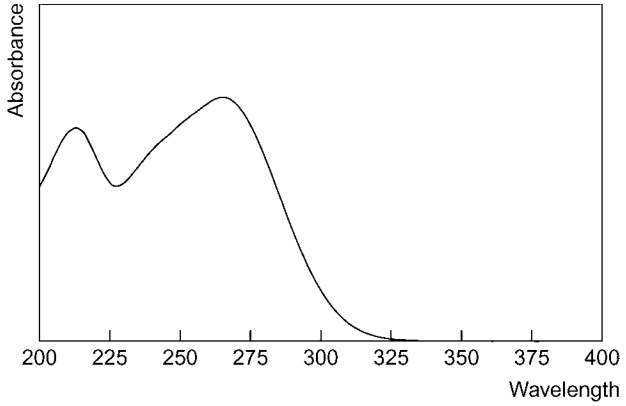
Synonyms 1α-Hydroxycholecalciferol; 1α-hydroxyvitamin D_3; (5*Z*,7*E*)-9,10-secocholesta-5,7,10(19)-triene-1α,3β-diol.

Proprietary Names *Alfa D*; *AlfaD*; *Alfadelta*; *Alfarol*; *Bondiol*; *Dediol*; *Diseon*; *Doss*; *EinsAlpha*; *Etalpha*; *One-Alpha*; *Un-Alfa*.



Chemical Properties White or almost white crystals that are sensitive to air, heat and light. Mp 134° to 136°. It is practically insoluble in water; freely soluble in ethanol; soluble in fatty oils. Reversible isomerisation to pre-alfacalcidol may take place in solution. Log *P* (octanol/water), 9.11.

Ultraviolet Spectrum Principal peaks at 214, 267 nm.



Disposition in the Body Alfacalcidol is well absorbed after oral administration. Bile is essential for intestinal absorption. It is converted rapidly in the liver to calcitriol and eliminated via bile and kidneys.

Therapeutic Concentration Peak serum concentrations occur about 12 h after a single dose.

Half-life Plasma, calcitriol 3 to 6 h.

Protein Binding Bound to specific α-globulins for transport.

Dose Initially 1 µg daily, usual maintenance 0.25 to 1 µg daily.

Alfadolone

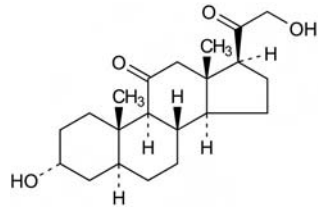
Anaesthetic (General)

$C_{21}H_{32}O_4 = 348.5$

CAS—14107-37-0

IUPAC Name (3*R*,5*S*,9*S*,14*S*)-3-Hydroxy-17-(2-hydroxyacetyl)-10,13-dimethyl-1,2,3,4,5,6,7,8,9,12,14,15,16,17-tetradecahydrocyclopenta[a]phenanthren-11-one

Synonyms Alphadolone; 3α,21-dihydroxy-5α-pregnane-11,20-dione.



Chemical Properties Mp 167° to 170°.

Alfadolone Acetate

$C_{23}H_{34}O_5 = 390.5$

CAS—23930-37-2

Synonym It is an ingredient of alphadione (with alfaxalone)

Proprietary Names It is an ingredient of *Alfatesin(e)*, *Alfathesin*, *Althesin* and *Saffan* (vet.).

Chemical Properties A white to creamy-white powder. Mp 175° to 177°. Practically insoluble in water; soluble 1 in 15 of ethanol and 1 in 2 of chloroform. Log *P* (octanol/water), 2.67.

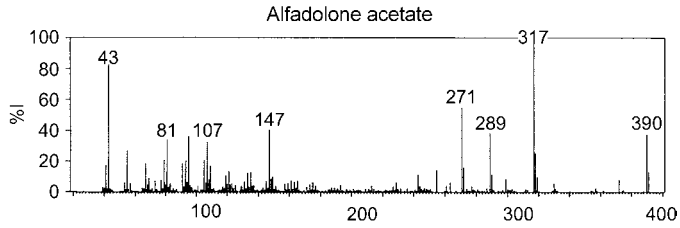
Colour Tests Antimony pentachloride—yellow; naphthol–sulfuric acid—orange-brown/orange; sulfuric acid—yellow.

Thin-layer Chromatography Alfadolone acetate: system TD—R_f 0.35; system TE—R_f 0.71; system TF—R_f 0.40; system TP—R_f 0.59; system TQ—R_f 0.22; system TR—R_f 0.80; system TS—R_f 0.45, streaking may occur; system TAD—R_f 0.62 (*p*-toluenesulfonic acid solution, positive).

Ultraviolet Spectrum Alfadolone acetate: methanol—290 nm (A^1_1=about 2).

Infrared Spectrum Principal peaks at wavenumbers 1228, 1758, 1710, 1278, 1010, 1043 cm^{-1} (alfadolone acetate, KBr disk).

Mass Spectrum Principal ions at *m/z* 317, 43, 271, 147, 289, 390, 95, 81 (alfadolone acetate).



Quantification

Plasma **GC-MS** ECD. Limit of detection, 10 µg/L [Pateman 1981].

Biological material **GC** [Heusler 1985].

Disposition in the Body Rapidly and widely distributed after injection. Alfadolone acetate is metabolised in the liver to alfadolone and alfadolone glucuronide which are excreted in the urine. Alfadolone is considered to be about 50% as potent an anaesthetic as alfaxalone.

Protein Binding 20 to 40%.

Dose See under Alfaxalone.

Heusler H (1985). Quantitative analysis of common anaesthetic agents. *J Chromatogr* 340: 273–319.

Pateman AJ (1981). Sensitive gas chromatographic method for the determination of alphadolone in plasma. *J Chromatogr* 226(15): 213–218.

Alfaxalone

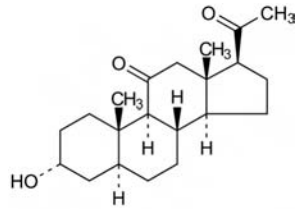
Anaesthetic (General)

$C_{21}H_{32}O_3 = 332.5$

CAS—23930-19-0

A

IUPAC Name (3*R*,5*S*,8*S*,9*S*,10*S*,13*S*,14*S*,17*S*)-17-Acetyl-3-hydroxy-10,13-dimethyl-1,2,3, 4,5,6,7,8,9,12,14,15,16,17-tetradecahydrocyclopenta[a]phenanthren-11-one
Synonyms Alphaxalone; (3α,5α)-3-hydroxypregnane-11,20-dione.
Proprietary Names It is an ingredient of *Alfatesin(e)*, *Alfathesin*, *Althesin* and *Saffan* (vet.).



Chemical Properties A white to creamy-white powder. Mp 165° to 171°. Practically insoluble in water; soluble 1 in 10 of ethanol and 1 in 2 of chloroform.
Thin-layer Chromatography System TP—R_f 0.60; system TQ—R_f 0.22; system TR—R_f 0.90; system TS—R_f 0.72, streaking may occur (*p*-toluenesulfonic acid solution, positive).
Ultraviolet Spectrum Methanol—290 nm (A^1_1=about 2).
Infrared Spectrum Principal peaks at wavenumbers 1695, 1148, 1220, 1267, 1000, 1252 cm^{-1} (KBr disk).
Quantification
***Plasma* GC** AFID. Limit of detection, 10 µg/L [Sear *et al.* 1980].
Disposition in the Body Alfaxalone is rapidly and widely distributed following injection. It undergoes almost 100% first-pass metabolism by reduction of the 20-oxo group and conjugation with glucuronic acid, and is excreted in the urine. About 60% of a dose is excreted in the urine in 24 h and 80% in 5 days.
Therapeutic Concentration
During constant IV infusion of 18, 52 and 90 µg/min/kg to 22 subjects, mean steady-state plasma concentrations of 1.9, 2.9 and 3.9 mg/L, respectively, were reported. [Sear, Prys-Roberts 1979].
Half-life Plasma half-life, about 0.5 h.
Volume of Distribution About 0.8 L/kg.
Clearance Plasma clearance, about 20 mL/min/kg.
Protein Binding 20 to 50%.
Note For a review of the pharmacokinetics of IV anaesthetic agents, see Duvaldestin [1981].
Dose A solution containing alfaxalone 9 mg and alfadolone acetate 3 mg/mL has been administered intravenously; doses of 0.05 to 0.075 mL/kg and 10 to 20 mL/h have been given to induce and maintain anaesthesia, respectively.

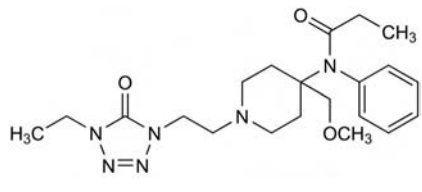
Alfentanil

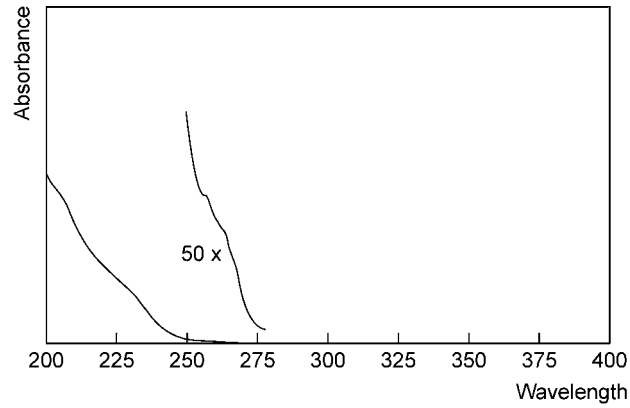
Narcotic Analgesic
$C_{21}H_{32}N_6O_3$ = 416.5
CAS—71195-58-9
IUPAC Name *N*-[1-[2-(4-Ethyl-4,5-dihydro-5-oxo-1*H*-tetrazol-1-yl)ethyl]-4-{methoxymethyl)-4-piperidinyl]-*N*-phenylpropanamide



Chemical Properties pK_a 6.5. Extraction yield (chlorobutane), 1 [Demme *et al.* 2005].

Alfentanil Hydrochloride

$C_{21}H_{32}N_6O_3$,HCl, H_2O = 471.0
CAS—69049-06-5 (anhydrous); 70879-28-6 (monohydrate)
Proprietary Names *Alfenta*; *R-39209*; *Rapifen*.
Chemical Properties A white powder. Mp 135° to 140°. Readily soluble in water; soluble 1 in 5 of ethanol, 1 in <2 of chloroform, and 1 in <2 of methanol; practically insoluble in ether.
Thin-layer Chromatography System TB—R_f 0.16; system TE—R_f 0.72; system TF—R_f 0.08; system TAE—R_f 0.78.
Gas Chromatography System GA—RI 2970; system GB—RI 3108; system GM—not eluted.
High Performance Liquid Chromatography System HX—RI 378.
Ultraviolet Spectrum Isopropyl alcohol—258 (A^1_1=6.3b), 264 (A^1_1=4.5b), 268 nm (A^1_1=3.1b).



Infrared Spectrum Principal peaks at wavenumbers 1722, 1654, 1252, 1109, 715, 967 cm^{-1} (alfentanil hydrochloride, KBr disk).
Quantification
***Plasma* GC** Column: 3% OV-17 on 80/100 mesh Supelcoport (1 m × 3 mm i.d.). Carrier gas: N_2, 35 mL/min. Temperature: 290°. AFID. Retention time: 2.7 min. Limit of detection, 1 µg/L [Woestenborghs *et al.* 1981].
GC-MS Column: DB-5MS (15 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 14 kPa. Temperature programme: 40° for 1 min to 120° at 40°/min to 290° at 30°/min. EI ionisation at 70 eV, SIM acquisition mode. Limit of quantification, 5 µg/L [Mautz *et al.* 1994].
HPLC Column: Econosphere CN (250 × 4.6 mm i.d., 5 µm). Mobile phase: 0.01 mol/L potassium dihydrogen phosphate (pH 2.8) : acetonitrile (65 : 35), flow rate 1.4 mL/min. IS: papaverine. UV detection (λ= 195 nm). Retention time: IS, 4.8 min; alfentanil, 5.3 min. Limit of quantification 2 µg/L, limit of detection, 0.25 µg/L [Kumar *et al.* 1996].
***Urine* GC-MS** Column: DB5-MS (30 m × 0.25 mm i.d., 0.15 µm). Carrier gas: He, 2.5 mL/min. Temperature programme: 70° to 280° at 60°/min. EI ionisation at 70 eV, SIM acquisition mode. Limit of detection, 7.5 ng/L [Van Nimmen *et al.* 2004]. Column: 5% cross-linked phenylmethylsiloxane HP-5 (15 m × 0.2 mm i.d., 0.33 µm). Temperature programme: 85° for 0.75 min to 315° at 22.5°/min for 0.75 min. EI ionisation at 70 eV. Limit of detection, 300 ng/L for norsufentanil [Valaer *et al.* 1997].
LC-MS Column: Macherey-Nagel Pyramid C_{18} (70 × 4 mm i.d., 5 µm). Mobile phase: 5 mmol/L ammonium acetate with 0.1% acetic acid : acetonitrile (100 : 0 for 1 min to 0 : 100 within 7 min for 1 min to 100 : 0 for 2.7 min), flow rate 800 µL/min. CID, MRM acquisition mode. Limit of detection, 0.5 µg/L [Thevis *et al.* 2005].
Disposition in the Body
Therapeutic Concentration
Eight patients undergoing lower abdominal surgery were anaesthetised and 1 mg alfentanil was administered epidurally before induction of the general anaesthesia. The mean peak plasma concentration was 9.7 µg/L, observed between 30 and 120 min [Haak-van der Lely *et al.* 1994].
Following an IV injection of 50 µg/kg to 2 subjects, a mean plasma concentration of 0.54 mg/L was reported at 1 min, decreasing to 0.038 mg/L at 1 h [Michiels *et al.* 1983].
Half-life Plasma half-life, ~1.5 h.
Volume of Distribution ~0.5–1.0 L/kg.
Clearance Plasma clearance, ~3–8 mL/min/kg.
Distribution in Blood Plasma : whole blood ratio, 1.6.
Protein Binding Approximately 90% (concentration dependent; decreases at plasma concentrations >0.1 µg/mL).
Note For a review of alfentanil see Mather [1983].
Dose Initially the equivalent of up to 500 µg alfentanil IV, followed by supplementary doses of 250 µg. With assisted ventilation, an initial dose of 30 to 50 µg/kg IV may be given.

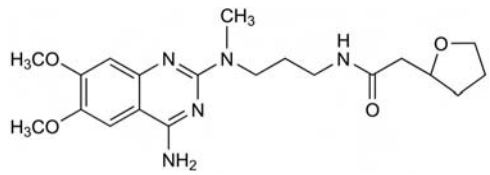
Alfuzosin

α_1-Adrenoceptor Antagonist
$C_{19}H_{27}N_5O_4 = 389.5$
CAS—81403-80-7

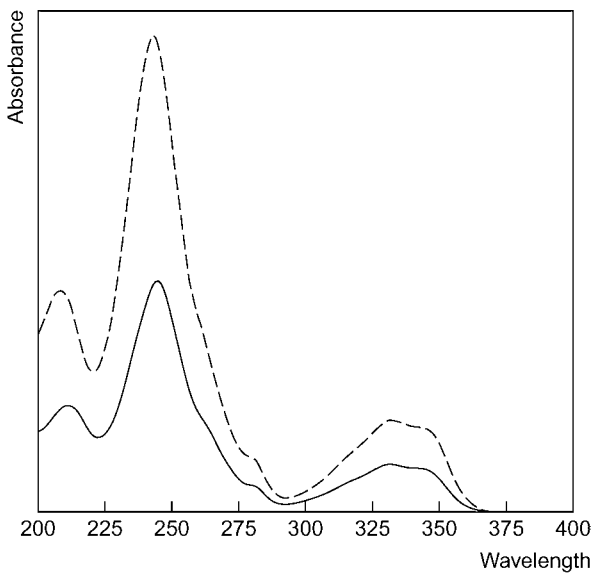
IUPAC Name *N*-[3-[(4-Amino-6, 7-dimethoxyquinazolin-2-yl)-methylamino] propyl]oxolane-2-carboxamide
Synonyms *N*-[(3-[(4-Amino-6,7-dimethoxy-2-quinazolinyl)(methylamino] propyl]tetrahydro-2-furancarboxamide; SL-77.499.



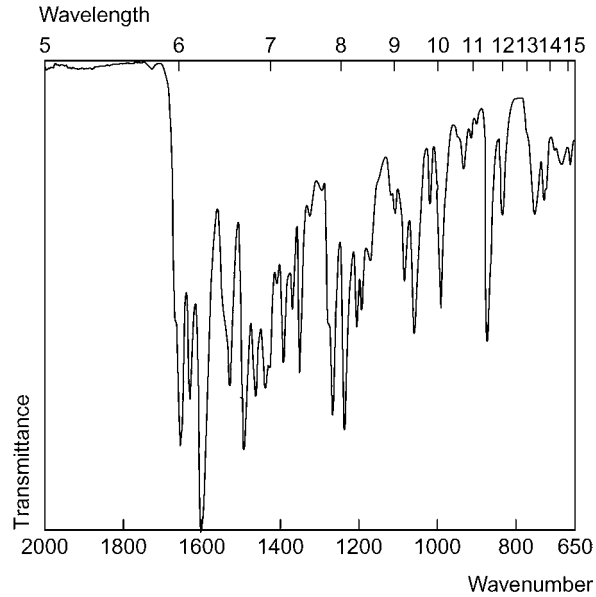
Chemical Properties pK_a 8.1.

Alfuzosin Hydrochloride
$C_{19}H_{27}N_5O_4,HCl = 425.9$
CAS—81403-68-1
Synonym SL-77.499-10
Proprietary Names *Alfoten*; *Benestan*; *Dalfaz*; *Mittoval*; *Urion*; *UroXatral*; *Xatral.*
Chemical Properties A white or almost white slightly hygroscopic crystalline powder. Mp 225°, also reported as 235°. It is freely soluble in water; sparingly soluble in ethanol; practically insoluble in dichloromethane.

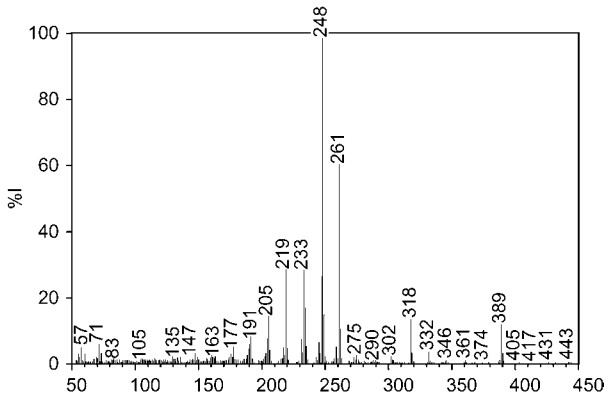
High Performance Liquid Chromatography System HZ—retention time 2.4 min; system HAA—retention time 10.4 min.
Ultraviolet Spectrum Neutral (water)—245, 210, 331 nm (hydrochloride).



Infrared Spectrum Principal peaks at wavenumber 1598, 1492, 1238, 3366, 873 cm^{-1} (hydrochloride).



Mass Spectrum Principal ions at *m/z* 248, 261, 219, 233, 247, 205, 318, 389.



Quantification
Blood **HPLC** Fluorescence detection [Guinebault *et al.* 1986].
Plasma **HPLC** Limit of detection, 1 µg/L for each enantiomer [Rouchouse *et al.* 1990]. See Blood. Limit of detection, 0.5 to 1.0 µg/L [Guinebault *et al.* 1986].
Urine **HPLC** See Blood [Guinebault *et al.* 1986].
Disposition in the Body Alfuzosin is readily absorbed after oral administration. Peak plasma concentrations occur about 0.5 to 3 h after a dose. It is extensively metabolised in the liver to inactive metabolites and excreted primarily in faeces via bile. About 11% of a dose is excreted unchanged in urine.
Therapeutic Concentration
Following oral administration of 1, 2.5, 5 and 10 mg twice daily for 3 days to 6 subjects and 10 mg twice daily to 3 subjects, peak plasma concentrations measured after a dose on the fourth day were 4.1, 11.8, 20.8 and 46.0 µg/L, respectively. These concentrations were observed after 1.8, 1.3, 1.0 and 2.0 h for the doses 1, 2.5, 5 and 10 mg, respectively. All subjects were healthy males, aged between 21 and 32 years with a mean of 23.8 years [Scott *et al.* 1989].
Bioavailability About 64%.
Half-life Plasma, 3 to 5 h.
Protein Binding 90%.
Dose Up to 10 mg daily.

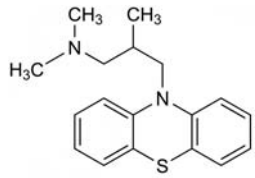
Alimemazine

Antihistamine, Phenothiazine, Sedative
$C_{18}H_{22}N_2S = 298.4$
CAS—84-96-8

A

IUPAC Name *N,N*,β-Trimethyl-10*H*-phenothiazine-10-propanamine
Synonym Trimeprazine



Chemical Properties Crystals. Mp 68°. Solubility in water is 0.9415 mg/L at 25°. Log *P* (buffer/hexane), 1.5 to 129.4 (see table). Extraction yield (chlorobutane), 1 [Demme *et al.* 2005]. Dissolved in mobile phase, the drug was stable for 6 months when stored at –20° and 3–5 months at 60°. In whole blood, the drug was stable for at least 24 h at 4° and for at least 1 h at 25° and at 37° [Hu *et al.* 1986].

pH	*Log P*
4.82	1.5
6.00	4.53
7.00	7.53
8.2	8.58
9.3	16.28
10.54	129.4

[Hu *et al.* 1986].

Standard solutions were stable for at least 2 months when stored at 4° [Shinmen *et al.* 2008].

Alimemazine Tartrate

$(C_{18}H_{22}N_2S)_2,C_4H_6O_6 = 747.0$
CAS—4330-99-8
Proprietary Names *Nedeltran*; *Panectyl*; *Repeltin*; *Theralen(e)*; *Vallergan*; *Variargil*.
Chemical Properties White or slightly cream-coloured crystalline powder that darkens in colour on exposure to light. Mp 159° to 163°. Soluble 1 in 4 of water, 1 in 30 of ethanol, and 1 in 5 of chloroform; very slightly soluble in ether. Log *P* (octanol/pH 7.4), 2.9; log *P* (octanol/water), 4.71.

Colour Tests Formaldehyde–sulfuric acid—red-violet; Forrest reagent—brown-red; FPN reagent—brown-red; Mandelin's test—violet; Marquis test—violet.
Thin-layer Chromatography System TA—R_f 0.58; system TB—R_f 0.54; system TC—R_f 0.39; system TE—R_f 0.77; system TL—R_f 0.31; system TAE—R_f 0.32; system TAF—R_f 0.46 (Dragendorff spray, positive; FPN reagent, pink; acidified iodoplatinate solution, positive; Marquis reagent, pink; ninhydrin spray, positive).

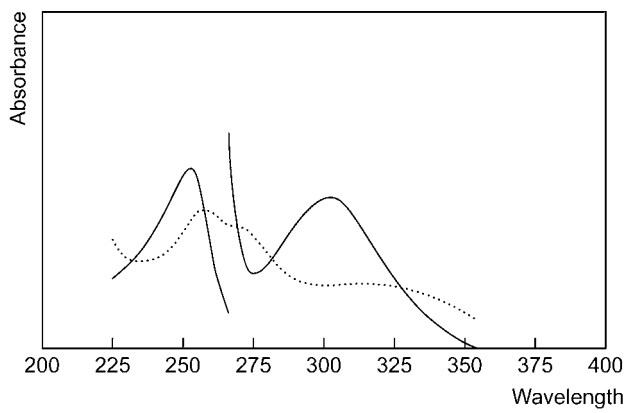
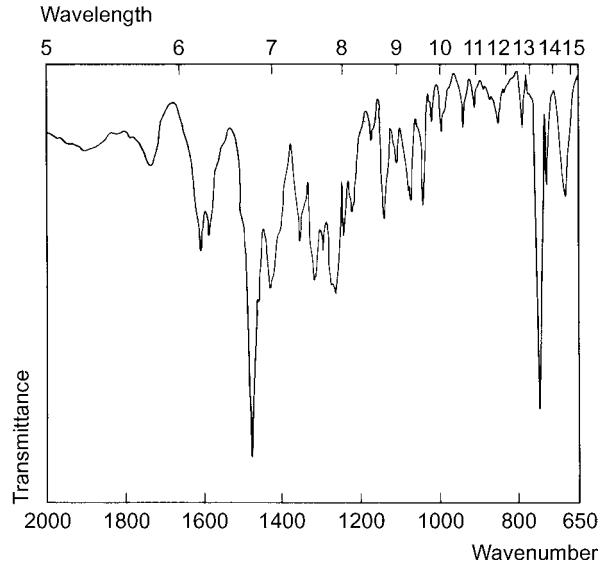
High Performance Liquid Chromatography System HA—*k* 3.1; system HX—RI 420; system HAX—RT 14.9 min; system HAY—RT 7.1 min.

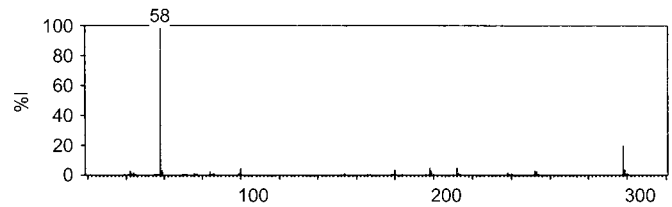
Column: Discovery C_{18} (150 × 4.6 mm i.d., 5 µm). Mobile phase: 575 mg ammonium formate with 1.3 mL formic acid in 500 mL water: acetonitrile (60 : 40 for 3 min to 20 : 80 at 11 min to 0 : 100 at 12 min to 60 : 40 at 13 min for 2 min), flow rate 1.0 mL/min. Fluorescence detection ($\lambda_{ex} = 378$ $\lambda_{em} = 502$ at 0.01 min to $\lambda_{ex} = 344$ nm $\lambda_{em} = 380$ nm at 4.75 min to $\lambda_{ex} = 351$ nm, $\lambda_{em} = 436$ nm at 8.35 min to $\lambda_{ex} = 344$ nm, $\lambda_{em} = 389$ nm at 10 min; $\lambda_{ex} = 344$ nm, $\lambda_{em} = 379$ nm). Limit of detection, 4 nmol/L [Diehl, Karst 2000].
Ultraviolet Spectrum Aqueous acid—251 nm ($A_1^1 = 926$a), 300 nm; aqueous alkali—256, 310 nm.



Infrared Spectrum Principal peaks at wavenumbers 748, 1248, 1260, 1305, 1590, 1275 cm^{-1} (alimemazine tartrate, KBr disk).



Mass Spectrum Principal ions at *m/z* 58, 298, 212, 198, 100, 299, 252, 199.



Quantification

Blood **GC** Column: Equity-5 (30 m × 0.32 mm i.d., 0.25 µm). Carrier gas: He, 3.0 mL/min. Temperature programme: 140° for 1 min to 300° at 15°/min. NPD. Limit of detection, 0.6 µg/L [Shinmen *et al.* 2008]. Column: DB-1 (30 m × 0.32 mm i.d., 0.25 µm). Carrier gas: He, 22 cm/s. Temperature programme: 120° to 280° at 6°/min. SID. Retention time: 19.3 min. Limit of detection, 250–500 ng/L [Hattori *et al.* 1992].

HPLC Column: Spherisorb CN (250 × 3.2 mm i.d., 5 µm). Mobile phase: acetonitrile : 0.015 mol/L sodium acetate-acetic acid (pH 6.5, 95 : 5), flow rate 1.0 mL/min. UV detection (λ = 254 nm). Limit of detection, 20 µg/L [Kintz *et al.* 1995]. Column: Micropak CN (10 µm). Mobile phase: acetonitrile : 0.1 mol/L ammonium acetate (90 : 10), flow rate 2.0 mL/min. Electrochemical detection. Retention time: 4.4 min. Limit of detection not reported [Hu *et al.* 1986].

Plasma **GC** See Blood. Limit of detection, 0.8 µg/L [Shinmen *et al.* 2008].

HPLC Column: Zorbax CN (250 × 4.6 mm i.d., 5 µm). Mobile phase: 0.1 mol/L ammonium acetate buffer in acetonitrile (10 : 90), flow rate 4.0 mL/min. Electrochemical detection. Retention time: 2.74 min. Limit of quantification, 0.25 µg/L, limit of detection, 0.125 µg/L [McKay *et al.* 1982]. Column: Spherisorb (15 cm × 4.6 mm i.d., 5 µm). Mobile phase: 0.1 mol/L aqueous dipotassium hydrogen phosphate (pH 6.5) : methanol : acetonitrile (11 : 4 : 6). Electrochemical detection. Limit of detection, 0.1 µg/L [Holt *et al.* 1983].

HPLC Fluorescence detection. Limit of detection, 0.004 µg/L [Diehl, Karst 2000].

Urine **GC** See Blood [Kintz *et al.* 1995]. See Blood [Hattori *et al.* 1992].

Bile **GC** See Blood [Kintz *et al.* 1995].

Gastric Contents **GC** See Blood [Kintz *et al.* 1995].

Brain **GC** See Blood [Kintz *et al.* 1995].

Hair **LC-MS** Column: XTerra MS C_{18} (100 × 2.1 mm i.d., 3.5 µm). Mobile phase: acetonitrile : formate buffer (pH 3.0, 5 : 95 to 80 : 20 at 10 min), flow rate 0.2 mL/min. ESI, positive ion mode, MRM acquisition mode. Limit of detection, 2 pg/mg [Kintz *et al.* 2006].

Heart **GC** See Blood [Kintz *et al.* 1995].

Kidney **GC** See Blood [Kintz *et al.* 1995].

Liver **GC** See Blood [Kintz *et al.* 1995].

Muscle **GC** See Blood [Kintz *et al.* 1995].

Disposition in the Body Readily absorbed after oral administration and widely distributed throughout the body. About 70% of an oral dose is excreted in the urine in 48 h, mostly as sulfoxides and glucuronides.

Therapeutic Concentration

Following single oral doses of 5 mg to 2 subjects, peak plasma concentrations of 0.8 and 1.8 µg/L were reported at 4 h [McKay *et al.* 1982].

Six healthy males, aged 20–40 years, were administered 5 mg alimemazine as a syrup and in tablet form after an overnight fast. The mean peak blood concentrations after the syrup were 2.34 µg/L and 0.95 µg/L with the tablet. These concentrations were observed at 3.5 and 4.5 h, respectively [Hu *et al.* 1986].

Six children aged 1.5–9.5 years were orally administered 3 mg/kg body weight for 30–85 min (median, 65 min). The mean peak blood alimemazine concentration was 0.357 µmol/L (range, 0.27–0.51) observed at 55–105 min [Sponheim *et al.* 1990].

Toxicity

A 50-year-old male was found dead at his home with a suicide note. Toxicological analysis showed that he had an alimemazine concentration of 1.91 mg/L in his blood and 25.05 mg/L in his urine. Noralimemazine was detected in his urine at 13.59 mg/L and alimemazine sulfoxide at 7.84 mg/L. In this case, the blood alimemazine concentration was 1000-times greater than reported therapeutic concentrations [Kintz, Mangin 1995] (last accessed on 18 October 2010, http://www.tiaft.org/tmembers/cnrarchive/25_3_5.php

A 58-year-old male with a history of clinical depression was found dead at his home. Several empty containers of alimemazine were found near his bed. Alimemazine was detected in his femoral blood at a concentration of 6.52 mg/L; in urine at 6.22 mg/L; bile, 4.44 mg/L; gastric contents, 80.19 mg/L; brain, 19.9 µg/g (major site of drug disposition); liver, 18.69 µg/g; kidney, 19.13 µg/g; heart, 16.62 µg/g and in muscle at a concentration of 1.43 µg/g. The postmortem blood concentration was 10,000-times that observed at therapeutic levels [Kintz *et al.* 1995].

Half-life Mean, 6.8 h (children).

Clearance Blood, 3.7 L/kg/h (children).

Blood Distribution Plasma : red blood cell ratio, 1.17.

Dose Usually 10 to 40 mg of alimemazine tartrate daily; up to 100 mg daily has been given. Elderly, 10 to 20 mg daily. Children >2 years' old, 2.5 to 5 mg three or four times daily.

Allantoin

Urea Derivative, Vulnerary

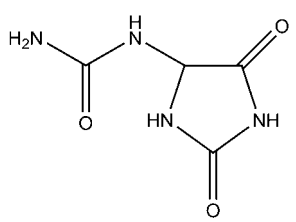
$C_4H_6N_4O_3$ = 158.1

CAS—97-59-6

IUPAC Name (2,5-Dioxo-4-imidazolidinyl)urea

Synonyms Alyoxyldiureide; cordianine; 2,5-dioxoimidazolidin-4-ylurea; glyoxyldiureide; 5-ureidohydantoin; 5-ureidoimidazolidine-2,4-dione.

Proprietary Names *Alantan*; *Masse*. It is also an ingredient in *Actinac*; *Alasulf*; *Alphosyl HC*; *Anbesol Cold-Sore Therapy*; *Anodesyn*; *Atopiclair*; *Blistex*; *Blistex Lip Balm*; *Cicatryl*; *Contractubex*; *Deltavac*; *DIT1-2*; *Dr Dermi-Heal*; *Lonax Astringent*; *Orabase Lip*; *Tanac*; *Tanac Dual Core*; *Vesagex Heelbalm*. For further information see Sweetman [2009].



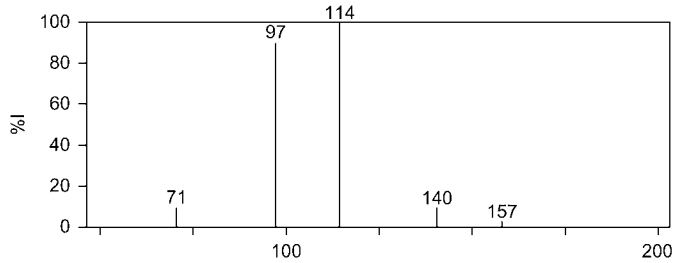
Chemical Properties Monoclinic plates or prisms from water. Mp 238°. Slightly soluble in water (5.26 g/L), very slightly soluble in alcohol (2 g/L), more soluble in hot water and hot ethanol; almost insoluble in ether [O'Neil *et al.* 2006]. Log *P* (octanol/water) −3.14 [Meylan, Howard 1995]. Urine samples spiked with allantoin were stable for at least 24 h, and also after 3 freeze–thaw cycles; post-process samples stored in injection vials at room temperature were stable for up to 72 h [Berthemy *et al.* 1999].

Colour Test Treat a solution with concentrated furfuraldehyde solution to which a little hydrochloric acid is added—violet.

Ultraviolet Spectrum Aqueous alkali (pH 9.4)—224 nm.

Infrared Spectrum Principal peaks at wavenumbers 1710, 1652, 1530 cm^{-1} (KBr disc).

Mass Spectrum Principal ions at *m/z* 114, 97, 71, 140, 157.



Quantification

Plasma **HPLC** Column: C_{18} (150 × 4.0 mm i.d., 5 µm). Mobile phase: 5% acetonitrile in 8.3 mmol/L phosphate buffer (pH 6.1): 50% acetonitrile in 8.3 mmol/L phosphate buffer (pH 6.1; 95 : 5 to 40 : 60 over 20 min to 0 : 100 over 2 min for 13 min), flow rate 0.5 mL/min. UV detection (λ = 360 nm). Retention times: *syn*-isomer 14.8 min, *anti*-isomer 20.8 min (glyoxylate-2,4-dinitrophenylhydrazine derivatives). Limit of quantification not reported [Kand'ar *et al.* 2006]. Column: C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: 0.01 mol/L potassium phosphate (pH 5.5) : methanol (100 : 0 to 90 : 10 over 10 min to 80 : 20 over 10 min), flow rate 1.0 mL/min. UV detection (λ = 220 nm). Retention time: 3.3 min. Limit of quantification, 0.2 µmol/L [Terzuoli *et al.* 1999]. Column: C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: 5 mmol/L potassium dihydrogen phosphate with 5 mmol/L 1-heptanesulfonic acid (pH 3.1), flow rate 1.0 mL/min. UV detection (λ = 210 nm). Retention time: 3.0 min. Limit of detection, 5 µmol/L [Benzie *et al.* 1999].

CE Column: uncoated silica capillary (total/effective length: 57/50 cm, 75 µm i.d.). Buffer: 20 mmol/L borate buffer (pH 10.1). UV detection (λ = 214 nm). Migration time: 13.7 min. Limit of quantification not reported [Terzuoli *et al.* 1999].

Serum **GC-MS** Column: HP-1 (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1.0 mL/min. Temperature programme: 150° to 270° at 20°/min. EI ionisation at 70 eV, SIM acquisition mode. Limit of quantification, 0.111 µmol/L for methyl-(tert-butyldimethylsilyl)trifluoroacetamide derivative [Pavitt *et al.* 2002].

Urine **HPLC** Column: C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: 10 mmol/L potassium dihydrogen phosphate (pH 4.7), flow rate 1.0 mL/min. UV detection (λ = 220 nm). Retention time: 4.4 min. Limit of quantification not reported [George *et al.* 2006]. Column: C_2 (250 × 4.6 mm i.d., 5 µm). Mobile phase: 0.05 mol/L potassium dihydrogen phosphate with 0.005 mol/L sodium 1-pentane sulfonate monohydrate, flow rate 1.0 mL/min. UV detection (λ = 225 and 286 nm). Retention time: 3.4 min. Limit of quantification, 34.5 µg/L, limit of detection, 10.4 µg/L [Carlson, Thompson 2001].

LC-MS Column: DVB polyamine (250 × 4.6 mm i.d., 5 µm). Mobile phase: water : acetonitrile (0 : 100 to 8 : 92 over 5 min to 10 : 90 over 2 min for 8 min), flow rate 1.5 mL/min for 5 min to 1.0 mL/min over 0.1 min for 10 min. ESI, negative ion mode, SRM acquisition mode. Retention time: ≈10 min. Limit of quantification, 14.6 mg/L [Berthemy *et al.* 1999].

CE Column: fused silica capillary (total/effective length: 44/37 cm, 75 µm i.d.). Buffer: 30 mmol/L sodium tetraborate (pH 10) for CZE, with the addition of 75 mmol/L sodium dodecyl sulfate for MECC. UV detection (λ = 195 nm). Migration time: 5.4 min. Limit of detection, 5 µmol/L [Alfazema *et al.* 1998].

Note For a TLC determination of allantoin in urine, see Thrasher and Hansen [1980].

Other **HPLC** Microdialysate Samples. Column: C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: 5 mmol/L ortophosphoric acid (pH 2.4) with 1.5 mmol/L tetrabutylammonium hydrogen sulfate, flow rate 0.8 mL/min. UV detection (λ = 205 nm). Limit of quantification, 0.25 mmol/L [Marklund *et al.* 2000].

LC-MS Herbal Tablets (Liuwei Dihuang). Column: C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: methanol : acetonitrile : formic acid in water (pH 3.3; 2 : 0 : 98 for 3 min to 0 : 2 : 98 over 1 min to 0 : 6 : 94 over 8 min to 0 : 20 : 80 over 14 min for 4 min to 0 : 30 : 70 over 10 min), flow rate 1.0 mL/min. ESI, positive ion mode. Retention time: 6 min. Limit of quantification not reported [Zhao *et al.* 2007]. Carotid Artery Plaque. Column: Supelcosil LC-ABZ (250 × 4.6 mm i.d., 5 µm). Mobile phase: 10 mmol/L ammonium acetate solution (pH 4.8) : methanol (100 : 0 for 10 min to 25 : 75 over 20 min to 0 : 100 over 20 min), flow rate 1.0 mL/min. ESI, positive ion mode, MRM acquisition mode. Retention time: 2.8 min. Limit of quantification not reported [Catinella *et al.* 2001].

CE Carotid Artery Plaque. Column: uncoated silica capillary (total/effective length: 57/50 cm, 75 µm i.d.). Buffer: 20 mmol/L borate buffer (pH 10.1). UV detection (λ = 214 nm). Migration time: 13.7 min. Limit of quantification not reported [Terzuoli *et al.* 1999].

Dose It is present in multi-ingredient preparations intended for various skin disorders. It is also used for its astringent properties in preparations for the treatment of haemorrhoids and other anorectal disorders.

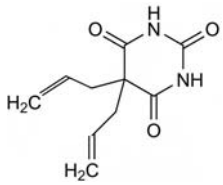
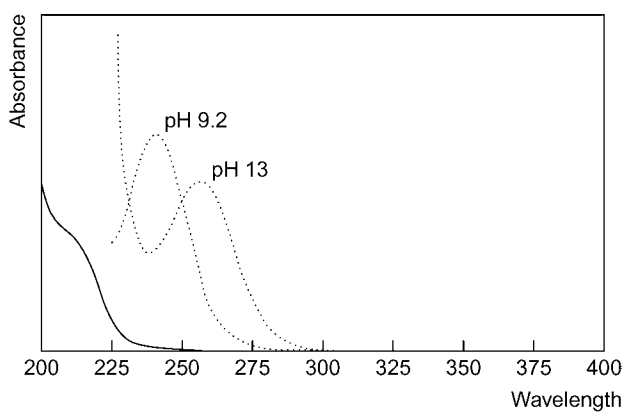
Allobarbital

Sedative, Barbiturate
$C_{10}H_{12}N_2O_3 = 208.2$
CAS—52-43-7

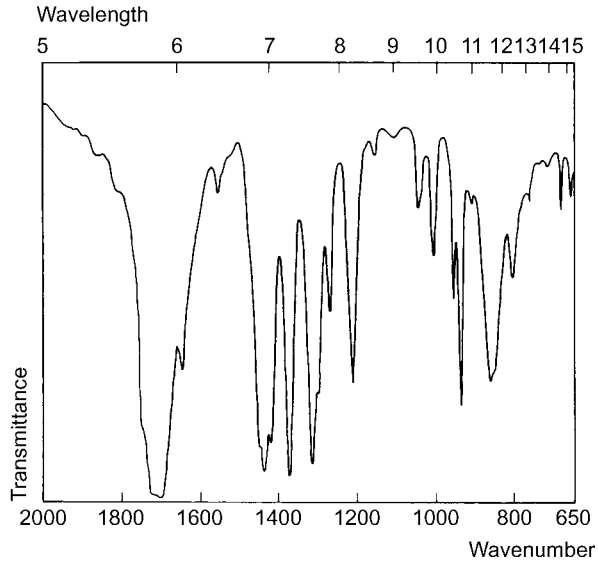
IUPAC Name 5,5-Bis(prop-2-enyl)-1,3-diazinane-2,4,6-trione
Synonyms Allobarbitone; diallylbarbitone; diallylmalonylurea; diallymalum; 5,5-di-2-propenyl-2,4,6(1*H*,3*H*,5*H*)pyrimidinetrione.
Proprietary Name It is an ingredient of *Dialog*.



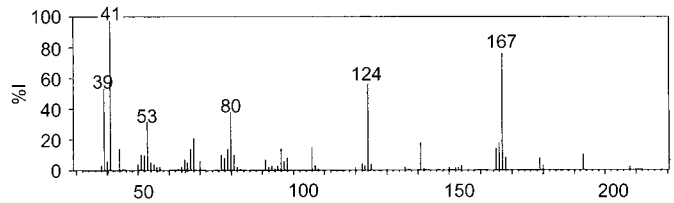
Chemical Properties A white crystalline powder. Mp about 173°. Soluble 1 in 700 of water, 1 in 15 of ethanol and 1 in 20 of ether; soluble in solutions of alkalis. pK_a 7.8 (25°).
Colour Tests Koppanyi-Zwikker test—violet; mercurous nitrate—black; vanillin reagent—brown-orange/violet (transient).
Thin-layer Chromatography System TD—R_f 0.50; system TE—R_f 0.34; system TF—R_f 0.66; system TH—R_f 0.53; system TAD—R_f 0.56; system TAE—R_f 0.87 (mercurous nitrate spray, black; acidified potassium permanganate solution, yellow-brown).
Gas Chromatography System GA—allobarbital RI 1600, allobarbital-Me_2 RI 1636; system GB—allobarbital-Me_2 RI 1505; system GF—allobarbital RI 2340.
High Performance Liquid Chromatography System HG—*k* 2.46; system HH—*k* 1.33; system HX—RI 346; system HZ—retention time 2.7 min.
Ultraviolet Spectrum Borax buffer 0.05 mol/L (pH 9.2)—241 (A_1^1=460a); 1 mol/L sodium hydroxide (pH 13)—256 nm (A_1^1=356b).



Infrared Spectrum Principal peaks at wavenumbers 1687, 1315, 925, 1219, 847, 1640 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 41, 167, 124, 39, 80, 53, 68, 141.



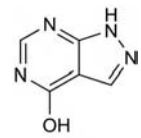
Quantification
Blood **HPLC** Column: (1) C_{18} RP TSK gel Super-ODS (100 × 4.6 mm i.d., 2 µm); (2) C_{18} RP Hypersil ODS-C_{18} (100 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : 8 mmol/L KH_2PO_4 (30:70), flow rate 0.4 mL/min. Internal standard: 5-(4-methylphenyl)-5-phenylhydantoin. UV detection (λ=215 nm). Retention time: (1) 5.1 min; (2) 5.7 min [Tanaka *et al.* 1997]. Limit of quantification, 50 µg/L [Tanaka *et al.* 1997].
Urine **HPLC** See Blood [Tanaka *et al.* 1997].
Brain **HPLC** See Blood [Tanaka *et al.* 1997].
Liver **HPLC** See Blood [Tanaka *et al.* 1997].
See under Amobarbital.
Disposition in the Body Allobarbital is absorbed after oral administration. It may persist unchanged in the body for up to one week; about 10 to 35% of a dose is slowly excreted unchanged in the urine.
Therapeutic Concentration In plasma, usually in the range 15 to 40 mg/L.
Toxicity The estimated minimum lethal dose is 2 g. Plasma concentrations of 50 mg/L or more are usually toxic.
Dose Allobarbital has been given in doses of 90 to 200 mg daily.

Tanaka E *et al.* (1997). Forensic analysis of 10 barbiturates in human biological samples using a new reversed-phase chromatographic column packed with 2-micrometre porous microspherical silica-gel. *Forens Sci Int* 85: 73–82.

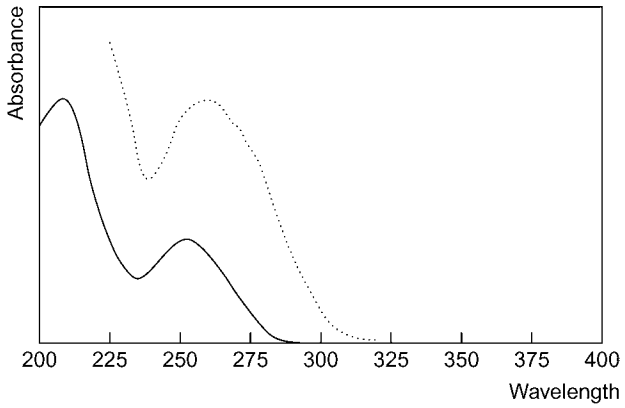
Allopurinol

Xanthine Oxidase Inhibitor
$C_5H_4N_4O = 136.1$
CAS—315-30-0

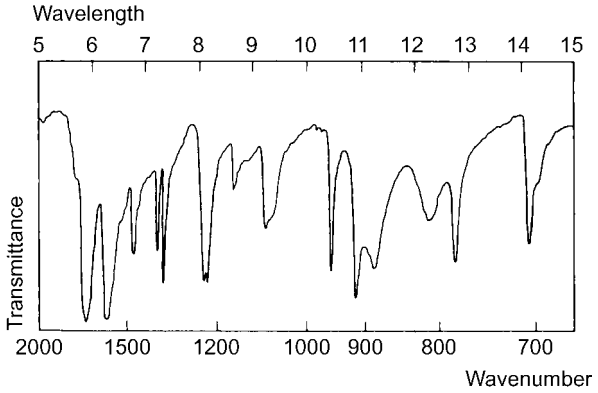
IUPAC Name 1,2-Dihydropyrazolo[3,4-d]pyrimidin-4-one
Synonyms 1,5-Dihydro-4*H*-pyrazolo[3,4-*d*]pyrimidin-4-one; HPP; isopurinol; BW-56158.
Proprietary Names *Adenock*; *Alloprin*; *Allopur*; *Aloral*; *Alositol*; *Aluline*; *Anoprolin*; *Blemimol*; *Bloxanth*; *Caplenal*; *Cosuric*; *Dabroson*; *Embarin*; *Epidropal*; *Foligan*; *Gichtex*; *Hexanurat*; *Ledopor*; *Lysuron*; *Miniplanor*; *Monarch*; *Progout*; *Remin*; *Sigapural*; *Takanarumin*; *Uriscel*; *Urobenyl*; *Urtias*; *Xanturat*; *Zyloprim*; *Zyloric*.



Chemical Properties A white microcrystalline powder. No characteristic melting point; it is unchanged up to 300°, after which it begins to darken and at an indefinite high temperature it chars and decomposes. Very slightly soluble in water and ethanol; practically insoluble in chloroform and ether; soluble in dimethylformamide and in dilute solutions of alkali hydroxides. pK_a 9.4.
Colour Test Folin-Ciocalteu reagent—grey-blue.
Thin-layer Chromatography System TE—R_f 0.21; system TAE—R_f 0.75.
Gas Chromatography System GA—RI 882.
High Performance Liquid Chromatography System HY—RI 128; system HZ—retention time 1.55 min.
Ultraviolet Spectrum Aqueous acid (prepared by dissolving in alkali and diluting with acid)—250 (A^1_1=563a); aqueous alkali—257 nm (A^1_1=523a).



Infrared Spectrum Principal peaks at wavenumbers 1692, 1587, 916, 1224, 1235, 956 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 136, 135, 52, 28, 137, 109, 29, 18.
Quantification
Plasma **HPLC** UV detection. Limit of detection, 0.1 mg/L [de Vries *et al.* 1993]. UV detection. Limit of detection, 100 µg/L for allopurinol and oxipurinol [Breithaupt, Goebel 1981].
Serum **GC-MS** Limit of detection, 25 µg/L [Lartigue-Mattei *et al.* 1982].
Urine **GC-MS** See Serum [Lartigue-Mattei *et al.* 1982].
HPLC See Plasma. Limit of detection, 0.2 mg/L [de Vries *et al.* 1993]. See Plasma [Breithaupt, Goebel 1981].
Disposition in the Body Allopurinol is rapidly absorbed after oral administration. The major metabolite, oxipurinol (alloxanthine), is active but less potent than allopurinol. Subjects with a genetic deficiency of xanthine oxidase are unable to metabolise allopurinol to oxipurinol. The excretion of unchanged drug appears to vary with acute or chronic administration, <10% of a single dose being excreted unchanged in the urine whereas about 30% is excreted in the urine as unchanged drug after chronic administration. Most of the remainder of a dose is slowly excreted in the urine as oxipurinol; about 20% of a dose is eliminated in the faeces in 72 h.
Therapeutic Concentration Oxipurinol accumulates during chronic administration and may contribute significantly to the therapeutic effect.

Ten elderly patients with bronchitis, angina and degenerative bone/joint disease (mean age 76.5 years; range 71 to 93 years) and 9 young volunteers (30.3; 24 to 35 years) were administered 200 mg allopurinol orally and 200 mg intravenously after a standard breakfast. The peak allopurinol concentrations were 1.24 mg/L at 0.8 h and 0.64 mg/L at 1.2 h for the young and elderly subjects, respectively. The peak oxipurinol concentrations were 3.75 mg/L at 4.2 h and 5.63 mg/L at 4.5 h, respectively [de Vries *et al.* 1993].

Eighteen healthy volunteers, aged 22 to 27 years, were administered a single dose of 2 different tablet formulations of allopurinol with an interval of 2 weeks. The mean peak concentrations were 1.91 and 1.93 mg/L for allopurinol at 1.17 and 1.53 h, respectively, and for the metabolite, oxipurinol, 4.59 and 4.78 mg/L at 5.22 and 4.94 h, respectively [Barthel *et al.* 1999].

Following a single oral dose of 300 mg given to 6 subjects, peak plasma concentrations of 1.4 to 2.6 mg/L (mean 2) of allopurinol and 4.4 to 7.8 mg/L (mean 6.3) of oxipurinol were attained in about 0.5 to 2 h and 2 to 5 h, respectively [Breithaupt, Tittel 1982].

Following daily oral administration of 300 mg to 7 subjects, steady-state serum concentrations of oxipurinol, determined immediately prior to a dose, were reported to range from 3.4 to 19.4 mg/L (mean 9.7) [Rodnan *et al.* 1975].

Bioavailability About 90%.
Half-life Plasma half-life, allopurinol about 0.5 to 2 h, oxipurinol 12 to 40 h.
Volume of Distribution About 0.6 L/kg.
Clearance Plasma clearance, about 11 mL/min/kg.
Protein Binding Allopurinol < 5%, oxipurinol about 17%.
Dose 100 to 600 mg daily.

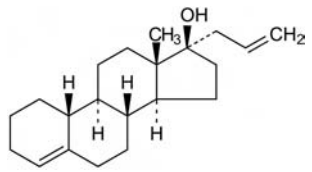
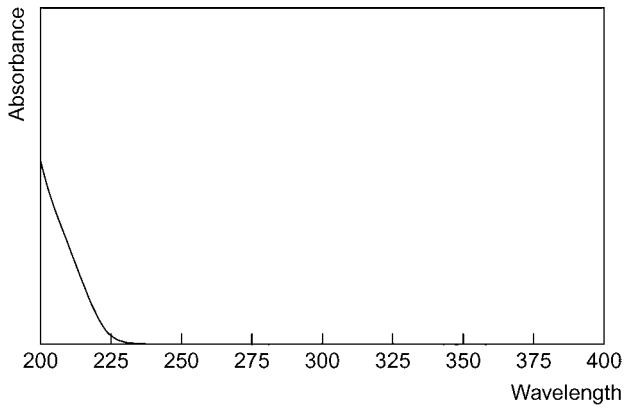
Allylestrenol

Progestogen
$C_{21}H_{32}O$ = 300.5
CAS—432-60-0

IUPAC Name (8*R*,9*S*,10*R*,13*S*,14*S*,17*R*)-13-Methyl-17-prop-2-enyl-2,3,6,7,8,9,10,11,12,14,15,16-dodecahydro-1H-cyclopenta[a]phenanthren-17-ol
Synonym Allyloestrenol; (17β)-17-(2-propenyl)-estr-4-en-17-ol.
Proprietary Names *Gestanin*; *Gestanon*; *Gestanyn*; *Orageston*; *Turinal*.



Chemical Properties Crystals. Mp 80°. Practically insoluble in water; soluble in ethanol, chloroform and ether.
Ultraviolet Spectrum No significant absorption, 230 to 360 nm.

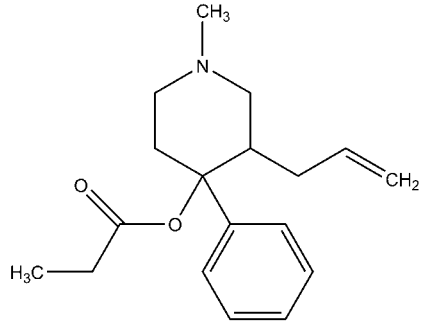


Infrared Spectrum Principal peaks at wavenumbers 905, 1008, 999, 1020, 1101, 985 cm^{-1} (Nujol mull).
Dose Allylestrenol has been given in doses of 5 to 20 mg daily.

Allylprodine

Narcotic Analgesic
$C_{18}H_{25}NO_2$ = 287.4
CAS—25384-17-2

IUPAC Name 1-Methyl-4-phenyl-3-(2-propenyl)-4-piperidinol propanoate
Synonyms NIH-7440; Ro-2-7113.



Chemical Properties Very slightly soluble in water (430 mg/L). Log *P* (octanol/water) 2.97 [Biobyte].

Allylprodine Hydrochloride

$C_{18}H_{25}NO_2$,HCl = 323.9

Chemical Properties Crystals from acetone + methanol. Mp 186° to 187° [O'Neil *et al.* 2006].

Colour Tests Ammonium molybdate test—grey→green; ammonium vanadate test—grey-olive; sulfuric acid-formaldehyde test—blue-black (limit of detection 0.1 µg); Vitali's test—grey-purple→brown.

Ultraviolet Spectrum Aqueous acid (0.1 N sulfuric acid)—252, 258, 264 nm.

Biobyte, Biobyte Inc. *Allylprodine.* www.biobyte.com/blqsar/index.html. (accessed 5 February 2008).

Alminoprofen

Antiinflammatory, Antirheumatic, COX-2 Inhibitor, NSAID, Phenylpropionic Acid

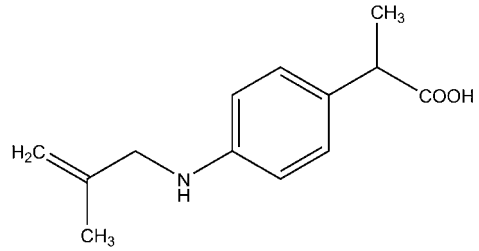
$C_{13}H_{17}NO_2$ = 219.3

CAS—39718-89-3

IUPAC Name 2-[4-(2-Methylprop-2-enylamino)phenyl]propanoic acid

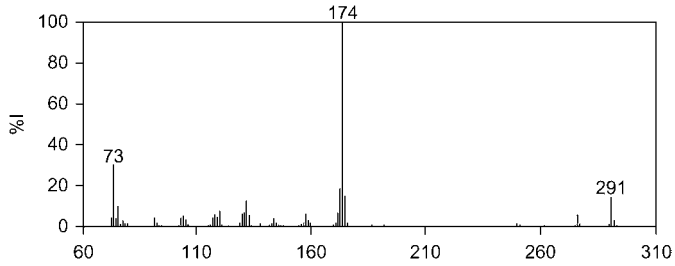
Synonyms EB-382; 4-[(2-methylallyl)amino]hydratropic acid; α-methyl-4-[(2-methyl-2-propenyl)amino]benzeneacetic acid.

Proprietary Name *Minalfene*



Chemical Properties Mp 107°. Soluble in water (307 mg/L). Log *P* (octanol/water), 2.87 [Meylan, Howard 1995].

Mass Spectrum Principal ions at *m/z* 174, 73, 291(TMS TFA derivative) [Premel-Cabic *et al.* 1980].



Quantification

Plasma **GC** Column: 3% OV1 on Gaschrom Q 80-100 mesh (2 m × 3.0 mm i.d.). Carrier gas: N_2, 30 mL/min. Temperature: 200°. FID and EI ionisation at 70 eV. Retention time: ~5 min. Limit of detection, 1 mg/L [Premel-Cabic *et al.* 1980].

HPLC Column: µBondapak C_{18} (300 × 4.6 mm i.d., 10 µm). Mobile phase: methanol : water (50 : 50) with 1% glacial acetic acid, flow rate 0.85 mL/min. UV detection (λ = 235 nm). Retention time: approx. 8 min. Limit of quantification, 4 mg/L, limit of detection, 1 mg/L [Paillet *et al.* 1985].

Urine **HPLC** Column: Nucleosil C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: methanol : water : acetic acid : dimethyl sulfoxide (50 : 46 : 0.8 : 3), flow rate 1 mL/min. UV detection (λ = 251 nm). Retention time: 8.1 min. Limit of quantification, 2 mg/L [Tod *et al.* 1995].

GC Column: 3% OV1 Gas-chrom Q 80-100 mesh (2 m × 3.0 mm i.d.). Carrier gas: N_2, 30 mL/min. Temperature: 200°. FID. Retention time: ~5 min. Limit of detection, 0.5 mg/L [Premel-Cabic *et al.* 1980].

Synovial Fluid **HPLC** Column: Nucleosil C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: methanol : water : acetic acid : dimethyl sulfoxide (50 : 46 : 0.8 : 3), flow rate 1 mL/min. UV detection (λ = 251 nm). Retention time: 8.1 min. Limit of quantification, 2 mg/L [Tod *et al.* 1995].

Disposition in the Body Readily absorbed following ingestion. Eliminated mainly by the renal route, conjugated as glucuronide.

Therapeutic Concentration

Four patients were administered 300 mg alminoprofen orally ≈0.5 h before breakfast. Peak plasma concentrations were 36.2 to 41.5 mg/L, reached between 0.5 and 1.5 h. In another study, 7 patients were administered 300 mg alminoprofen orally 3 times daily during meals for a period of 5 days. On day 5, the mean morning plasma alminoprofen concentration was 3.1 mg/L and in the evening it was 28.5 mg/L [Premel-Cabic *et al.* 1980].

A group of healthy subjects was administered a single 300 mg oral dose of alminoprofen at either 8 am (group A) or 6 pm (group B). In Group A, a mean peak plasma concentration of 34.4 g/L was reached after 1.5 h. Bioavailability seemed slightly decreased when the drug was given in the evening. The pharmacokinetics were not significantly different in group B, although bioavailability was slightly decreased [Paillet *et al.* 1985].

A group of 45 patients with knee effusion was administered 300 mg alminoprofen orally 3 times daily for 4 days. Plasma and synovial fluid concentrations were measured over 12 h post-ingestion of the final dose and were reported as:

Time (h)	*Plasma (mg/L)*	*Synovial fluid (mg/L)*
1	24.2	4.7
2	19.0	9.3
4	15.8	7.2
6	8.6	5.6
8	4.0	4.7
12	2.1	2.3

[Tod *et al.* 1995].

Half-life Approximately 3 h.

Volume of Distribution Apparent, 7.8 L.

Clearance Approximately 43 mL/min.

Dose Up to 900 mg daily by mouth in inflammatory and rheumatic disorders.

Meylan WM, Howard P (1995). Atom/fragment contribution method for estimating octanol–water partition coefficients. *J Pharm Sci* 84: 83–92.
Paillet M *et al.* (1985). Rapid determination of alminoprofen in plasma by high-performance liquid chromatography. *J Chromatogr* 343: 455–459.

Tod M *et al.* (1995). A population pharmacokinetic study of alminoprofen penetration into synovial fluid. *Biopharm Drug Dispos* 16: 627–634.

Almotriptan

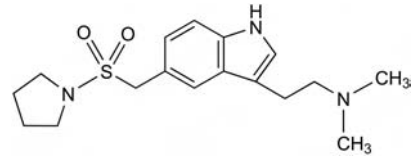
Antimigraine

$C_{17}H_{25}N_3O_2S$ = 335.5

CAS—154323-57-6

IUPAC Name *N*, *N*-Dimethyl-2-[5-(pyrrolidin-1-ylsulfonylmethyl)-1H-indol-3-yl]ethanamine

Synonyms 1-[[[3-[2-(Dimethylamino)ethyl-1H-indol-5-yl]methyl]sulfonyl] pyrrolidine; LAS-31416.



Almotriptan Maleate

$C_{19}H_{25}N_3O_2S,C_4H_6O_5$ = 469.6

CAS—181183-52-8

Synonym PNU-180638E

Proprietary Names *Almogran*; *Axert*.

Quantification

Plasma **LC-MS** Limit of quantification, 0.5 µg/L [Fleishaker *et al.* 2001a,b].

Urine **LC-MS** Limit of quantification, 50 µg/L [Fleishaker *et al.* 2001a,b].

Disposition in the Body Almotriptan is well absorbed after oral administration and metabolised in the liver by monoamine oxidase and cytochrome P450 isoenzymes (CYP3A4 and CYP2D6). Metabolites are inactive. It is eliminated by a number of pathways and 40 to 50% of a dose is recovered unchanged in urine.

Therapeutic Concentration

Twelve healthy male and female volunteers aged 18 to 51 years (mean, 31 years) were treated with 12.5 mg almotriptan with 1 week wash-out periods in-between. The peak plasma concentration was 39.6 µg/L at 2.67 h [Fleishaker *et al.* 2000].

Eleven healthy women and 3 men, aged 18 to 55 years (mean, 35.3 years), were administered with a single 12.5 mg dose of almotriptan after a 10 h fast. The same dose was also administered on day 8 of treatment after 20 mg 3 times daily of fluoxetine for days 1 to 8. The peak plasma concentration of almotriptan was 44.3 µg/L for the single dose and 52.5 µg/L for the dose administered with fluoxetine. The time to reach these concentrations was 2.46 and 1.86 h, respectively [Fleishaker *et al.* 2001b].

Bioavailability 69 to 80%.
Half-life 3.1 to 3.6 h.
Volume of Distribution 249 L.
Clearance 26.6 L/h.
Dose 12.5 mg repeated after 2 h if migraine recurs with a maximum of 25 mg in 24 h.

Fleishaker JC *et al.* (2000). Pharmacokinetic interaction between verapamil and almotriptan in healthy volunteers. *Clin Pharmacol Ther* 67(5): 498–503.

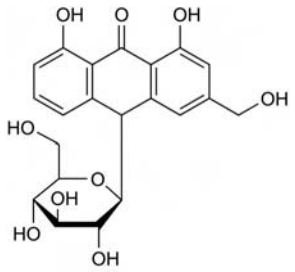
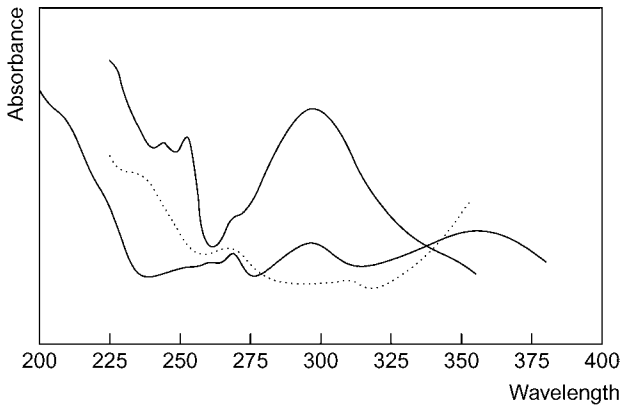
Aloin

Purgative
$C_{21}H_{22}O_9$ = 418.4
CAS—8015-61-0 (aloin); 1415-73-2 (barbaloin)

IUPAC Name (10R)-1,8-Dihydroxy-3-(hydroxymethyl)-10-[(2*S*,3*R*,4*R*,5*S*,6*R*)-3,4, 5-trihydroxy-6-(hydroxymethyl)oxan-2-yl]-10*H*-anthracen-9-one
Synonyms Barbaloin; 10-glucopyranosyl-1,8-dihydroxy-3-(hydroxymethyl)-9 (10*H*)-anthracenone.



Chemical Properties A crystalline substance extracted from aloes and consisting almost entirely of barbaloin. A pale or dull yellow crystalline powder. It darkens on exposure to light. Mp 148° to 80°. Almost completely soluble 1 in 130 of water; soluble 1 in 20 of ethanol; soluble in acetone; very slightly soluble in chloroform and ether.
Colour Tests Ferric chloride—brown; Folin-Ciocalteu reagent—blue; Liebermann's reagent—black; Millon's reagent—pink→red.
Ultraviolet Spectrum Aqueous acid—245, 253, 300 nm; aqueous alkali—268 nm.



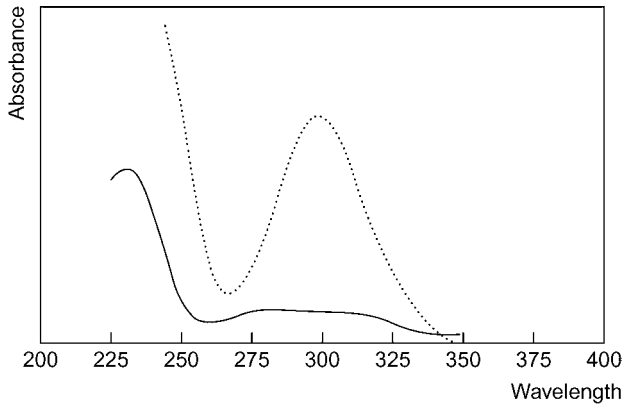
Thin-layer Chromatography Plate: silica gel (Merck). Mobile phase: methylisobutylketone : m-xylene : hexane : glacial acetic acid (60:20:12:0.5). Detection: sprayed with 3 mol/L potassium hydroxide and examined at 254 nm (yellow/red) and 366 nm (orange/red). R_f 0.75 [Perkins, Livesey 1993].
Dose Aloin has been given in doses of 13 to 60 mg.

Perkins SL, Livesey JF (1993). A rapid high-performance thin-layer chromatographic urine screen for laxative abuse. *Clin Biochem* 26(3): 179–181.

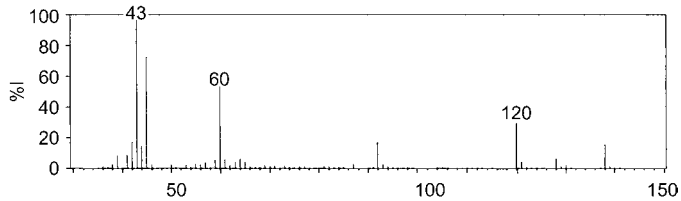
Aloxiprin

Analgesic
CAS—9014-67-9

Note A polymeric condensation product of aluminium oxide and aspirin which contains about 83% of total salicylates. Approx. formula: $Al_3O_2[C_6H_4(OOCCH_3)COO]_5$
Proprietary Names *Lyman*; *Palaprin Forte*; *Rumatral*.
Chemical Properties A fine white or slightly pink powder. Practically insoluble in water, ethanol and ether; soluble 1 in 200 of chloroform.
Thin-layer Chromatography System TD—R_f 0.04; system TE—R_f 0.09; system TF—R_f 0.10; system TAD—R_f 0.22.
Ultraviolet Spectrum Aqueous acid—231 nm; aqueous alkali—298 nm.



Infrared Spectrum Principal peaks at wavenumbers 1597, 1198, 1562, 1220, 1745, 760 cm^{-1} (KBr disk).
Mass Spectrum Principal ions at *m/z* 43, 45, 60, 120, 42, 92, 138, 44.

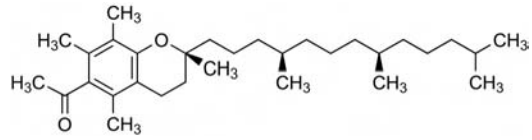


Disposition in the Body Aloxiprin is hydrolysed to aspirin in the gastrointestinal tract.
Dose Up to 100 mg/kg daily, orally.

Alpha Tocoferil Acetate

Vitamin E Activity
$C_{31}H_{52}O_3$ = 472.8
CAS—52225-20-4

IUPAC Name [(2*R*)-2,5,7,8-Tetramethyl-2-[(4*R*,8*R*)-4,8,12-trimethyltridecyl]-3, 4-dihydrochromen-6-yl] acetate
Synonyms α-Tocopherol acetate; (±)-α-tocopheryl acetate; *dl*-α-tocopherol acetate; α-tocoferil acetate; vitamin E acetate.
Proprietary Names *Aquasol E*; *Ephynal*; *Evion*; *Tocomine*; *Tokols (d=+)*; *Vita-E (d=+)*; *Detulin*; *Eusovit*.



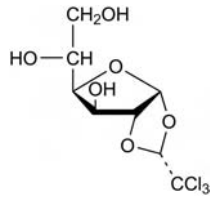
Chemical Properties A clear, slightly greenish-yellow, viscous, oily liquid. Relative density 0.952 to 0.966. Practically insoluble in water; soluble in ethanol; freely soluble in dehydrated alcohol, chloroform, and ether.
Ultraviolet Spectrum Methanol—284 nm (A_1^1=43a).
Infrared Spectrum Principal peaks at wavenumbers 1210, 1755, 1075, 1105, 1160, 1250 cm^{-1} (thin film).

A

Alphachloralose

Rodenticide
$C_8H_{11}Cl_3O_6$ = 309.5
CAS—15879-93-3

IUPAC Name (1*R*)-1-[(2*R*,3a*R*,5*R*,6*S*,6a*R*)-6-Hydroxy-2-(trichloromethyl)-3a,5,6, 6a-tetrahydrofuro[2,3-d][1,3]dioxol-5-yl]ethane-1,2-diol
Synonyms α-Chloralosane; chloralose; glucochloral; glucochloralose; (*R*)-1,2-*O*-(2,2,2-trichloroethylidene)-α-D-glucofuranose.
Proprietary Names *Alfamat*; *Alphabird*; *Alphakil*; *Alphamouse*; *Aphosal*; *Dulcidor*; *Murex*; *Somi*.



Chemical Properties Mp 182° to 184°. It is soluble in water 4.44 g/L at 15°. Log *P* (octanol/water), 1.02.
Quantification
Blood **GC-MS** Limit of detection, 0.5 mg/L (mg/kg) [Kintz *et al.* 1999].
Bile **GC-MS** See Blood [Kintz *et al.* 1999].
Tissue **GC-MS** See Blood [Kintz *et al.* 1999].
Disposition in the Body Alphachloralose is detected in urine as the parent compound and also as the β-isomer.
Toxicity The toxic dose of alphachloralose is approximately 1 g in adults and 20 mg/kg in infants.

An 18-year-old man was found dead at home with 3 bags, which had contained 5 g 100% alphachloralose. Postmortem toxicological analysis showed that the man had a peripheral blood alphachloralose concentration of 175.7 mg/L, cardiac blood concentration of 282.2 mg/L, and bile concentration of 279.6 mg/L. No other drugs or ethanol was detected [Kintz *et al.* 1999].

Kintz P *et al.* (1999). Testing for alpha-chloralose by headspace-GC/MS. A case report. *Forens Sci Int* 104: 59–63.

Alphameprodine

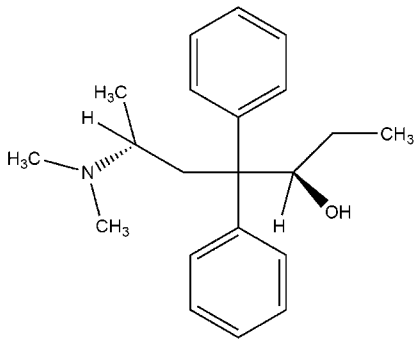
Narcotic Analgesic
$C_{17}H_{25}NO_2$ = 275.4
IUPAC Name [(3*S*,4*R*)-3-Ethyl-1-methyl-4-phenylpiperidin-4-yl] propanoate

Alphameprodine Hydrochloride
Chemical Properties White crystals. Soluble in water.

Colour Tests Ammonium molybdate test—blue-grey→green with blue rim (limit of detection 0.5 μg); ammonium vanadate test—grey (limit of detection 0.5 μg); sulfuric acid-formaldehyde test—brownish-red (limit of detection 0.25 μg).
Thin-Layer Chromatography System TA—R_f 50, streaking (location reagent acidified iodoplatinate spray, positive reaction).
Gas Chromatography System G2/225—RRT 1.00 (relative to diphenhydramine); system G4—RRT 0.48 (relative to diphenhydramine).
Ultraviolet Spectrum Aqueous acid (0.1 N sulfuric acid)—247, 252, 263 nm.

Alphamethadol

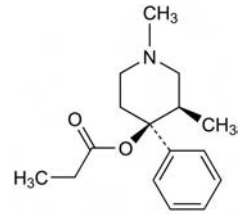
Narcotic Analgesic
$C_{21}H_{29}NO$ = 311.5
IUPAC Name 6-Dimethylamino-4,4-di(phenyl)heptan-3-ol
Synonym α-6-Dimethylamino-4,4-diphenylheptan-3-ol



Chemical Properties A white crystalline solid.
Colour Test Sulfuric acid-formaldehyde test—purple-brown→grey-green (limit of detection, 0.25 μg); ammonium molybdate test—brown-purple→green (limit of detection, 0.25 μg); ammonium vandate test—grey-green (limit of detection, 0.25 μg).
Thin-layer Chromatography System T1—R_f 57 (acidified iodoplatinate-spray—positive reaction).
Gas Chromatography System G2/225—RRT 2.55 (relative to diphenhydramine); system G4—RRT 2.44 (relative to diphenhydramine); system G5—RRT 0.69 (relative to barbital).
UV Spectrum Aqueous acid (0.05 mol/L sulfuric acid)—maximum at 253.5 nm (A^{1}_{1} 17.5) and 259 nm (A^{1}_{1} 20.2).

Alphaprodine

Narcotic Analgesic
$C_{16}H_{23}NO_2$ = 261.4
CAS—77-20-3; 15867-21-7 (± alphaprodine)
IUPAC Name [(3*S*,4*R*)-1,3-Dimethyl-4-phenylpiperidin-4-yl] propanoate
Synonyms (*cis*)-1,3-Dimethyl-4-phenyl-4-piperidinol propanoate; prisilidene; (±)-α-prodine.

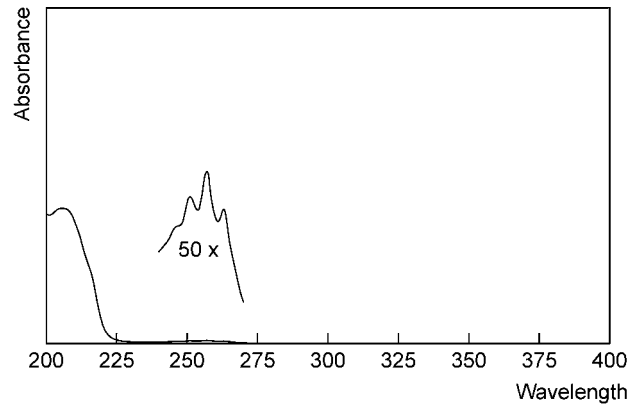


(+)-form

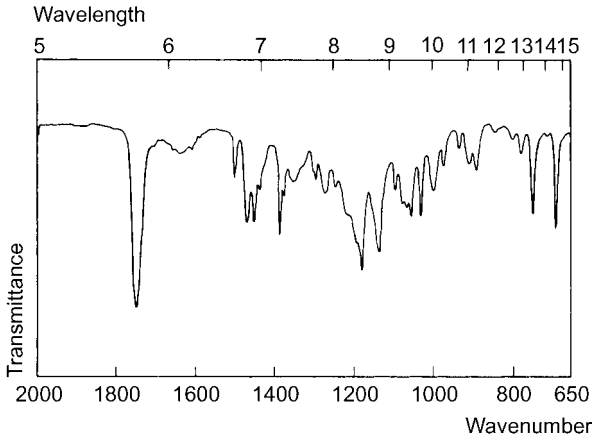
Chemical Properties Practically insoluble in water; soluble in chloroform. pK_a 8.7 (20°).

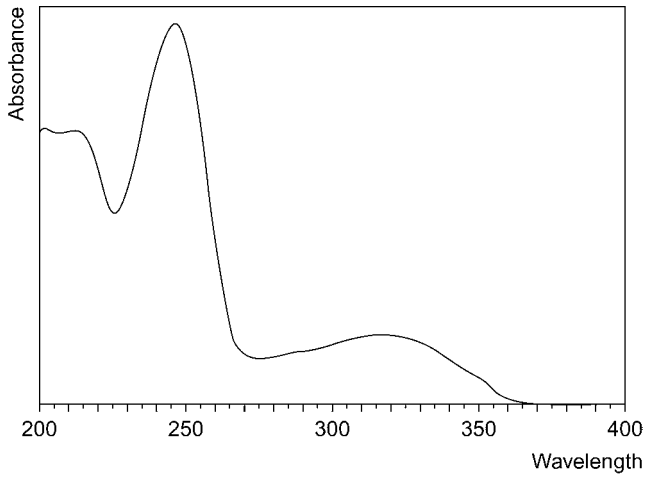
Alphaprodine Hydrochloride
$C_{16}H_{23}NO_2$,HCl = 297.8
CAS—561-78-4 (± alphaprodine hydrochloride)
Proprietary Name *Nisentil*
Chemical Properties A white crystalline powder. Mp 218° to 220°. Soluble 1 in 2 of water, 1 in 7 of ethanol, 1 in 47 of acetone and 1 in 3 of chloroform; very slightly soluble in ether.

Colour Tests Mandelin's test—blue-grey; Marquis test—brown-red.
Thin-layer Chromatography System TA—R_f 0.50; system TB—R_f 0.30; system TC—R_f 0.35; system TE—R_f 0.62; system TF—R_f 0.01; system TL—R_f 0.11; system TAE—R_f 0.28; system TAJ—R_f 0.23; system TAK—R_f 0.05; system TAL—R_f 0.60 (dragendorff spray, positive; Acidified iodoplatinate solution, positive; Marquis reagent, red-brown).
Gas Chromatography System GA—RI 1792; system GB—RI 1862.
High Performance Liquid Chromatography System HA—*k* 2.8 (tailing peak); system HX—RI 363; system HY—RI 317.
Ultraviolet Spectrum Aqueous acid—251, 257 (A^{1}_{1}=9a), 263 nm. No alkaline shift.



Infrared Spectrum Principal peaks at wavenumbers 1740, 1178, 1134, 694, 1030, 1055 cm^{-1} (KBr disk).





Mass Spectrum Principal ions at *m/z* 172, 187, 84, 57, 42, 188, 44, 43.

Quantification

Plasma **GC** FID. Limit of detection, 30 µg/L [Fung *et al.* 1980].

Disposition in the Body Alphaprodine is a homologue of pethidine but its action is more rapid in onset and of shorter duration.

Therapeutic Concentration

After a rapid IV injection of 0.5 mg/kg to 6 subjects, plasma concentrations of about 0.8 mg/L were measured after 5 min, declining to 0.07 mg/L at 5 h [Fung *et al.* 1980].

Toxicity The estimated minimum lethal dose is 0.1 g. Prolonged use of alphaprodine is liable to produce dependence of the morphine type.

The following postmortem tissue concentrations were reported in an accidental fatality caused by the IV administration of 40 mg of alphaprodine: blood 0.62 mg/L, liver 0.97 µg/g, urine 0.30 mg/L; a blood-alcohol concentration of 1.7 mg/L was also reported [Griesemer, Nakamura 1973].

Half-life Plasma half-life, about 2 h.

Volume of Distribution About 2 L/kg.

Clearance Plasma clearance, about 10 mL/min/kg.

Dose 20 to 60 mg of alphaprodine hydrochloride by subcutaneous injection, or 10 to 30 mg intravenously.

Fung DL *et al.* (1980). A comparison of alphaprodine and meperidine pharmacokinetics. *J Clin Pharmacol* 20: 37–41.

Griesemer E, Nakamura GR (1973). *TIAFT Bull* 9(1–2)5.

Alpidem

Anxiolytic, Imidazopyridine

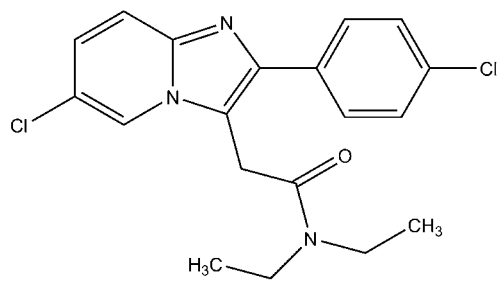
$C_{21}H_{23}Cl_2N_3O = 404.3$

CAS—82626-01-5

IUPAC Name 2-[6-Chloro-2-(4-chlorophenyl)imidazo[3,2-a]pyridin-3-yl]-*N*,*N*-dipropylacetamide

Synonyms 6-Chloro-2-(4-chlorophenyl)-*N*,*N*-dipropylimidazo[1,2-a]pyridine-3-acetamide; SL-80.0342-00.

Proprietary Name *Ananxyl*



Chemical Properties White, fluffy, microcrystalline powder. Mp 140° to 141°. Sparingly soluble in water (20 mg/L). pK_a 4.25, Log *P* (octanol/water), 4.4. [Durand *et al.* 1992].

Ultraviolet Spectrum

Principal peak at 249 nm.

Quantification

Plasma **GC** Column: 5% phenylmethylsilicone (25 m × 0.32 mm i.d., 0.52 µm). Carrier gas: He, 2.1 mL/min. Temperature programme: 210° to 285° at 2.5°/min. NPD. Retention time: 1.77 (relative to prazepam). Limit of quantification not reported [Gaillard *et al.* 1993].

HPLC Column: C_8 (150 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : methanol : 0.025 mol/L phosphate buffer (pH 4.5, 40 : 15 : 45), flow rate 1.5 mL/min. Fluorescence detection ($\lambda_{ex} = 255$ nm, $\lambda_{em} = 423$ nm). Retention time: 14 min. Limit of quantification, 2.5 µg/L for alpidem; 1.5 µg/L for metabolites [Flaminio *et al.* 1994]. Column: C_{18} (300 × 3.9 mm i.d., 4 µm). Mobile phase: methanol : tetrahydrofuran : phosphate buffer (pH 2.6, 65 : 5 : 30), flow rate 0.8 mL/min. DAD. Retention time: 11 min. Limit of quantification, not reported [Tracqui *et al.* 1993]. Column: C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : methanol : 0.025 mol/L potassium dihydrogen phosphate (pH 4.8; 45 : 10 : 45), flow rate 1.5 mL/min. Fluorescence detection ($\lambda_{ex} = 255$ nm, $\lambda_{em} = 423$ nm). Retention time: 24 min. Limit of detection, 1 µg/L [Ascalone *et al.* 1987].

Disposition in the Body Alpidem undergoes first-pass metabolism, being metabolised to several active products via *N*-alkylation or oxidation (or a combination of both processes) of the propyl side chain and aromatic oxidation reactions. Elimination is mainly via the faeces and less than 0.1% of a dose is found in urine.

Therapeutic Concentration

A group of 21 healthy man volunteers was administered single oral doses of 25, 50, 100 or 200 mg alpidem. Mean peak plasma concentrations for the four doses were 39, 128, 237 and 270 µg/L, respectively, attained at 8, 3, 4, and 3 h, respectively [Jonkman *et al.* 1991].

A group of 10 healthy volunteers was administered single oral doses of 25, 50, or 100 mg alpidem. Mean peak plasma concentrations for the three doses were 24.7, 78.1 and 119.3 µg/L, respectively, reached after 2.2, 2.6 and 1.9 h [Saletu *et al.* 1986].

Toxicity Alpidem was withdrawn from the market following reports of hepatic dysfunction.

Bioavailability Approximately 32%.

Half-life Approximately 18 h (range 7 to 44 h); increases to 23 h in elderly subjects.

Volume of Distribution 8.7 L/kg.

Clearance 0.86 L/h/kg.

Protein Binding 99.1%.

Alprazolam

Anxiolytic, Benzodiazepine

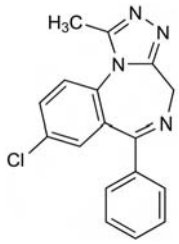
$C_{17}H_{13}ClN_4 = 308.8$

CAS—28981-97-7

IUPAC Name 8-Chloro-1-methyl-6-phenyl-4*H*-[1,2,4]-triazolo[4,3-*a*][1,4]-benzodiazepine

A

Proprietary Names *Alpralid*; *Alpraz*; *Alprox*; *Alzam*; *Anxirid*; *Apo-Alpraz*; *Apox*; *Azor*; *Calmax*; *Cassadan*; *Drimpam*; *Esparon*; *Gerax*; *Kalmor*; *Mialin*; *Novo-Alprazol*; *Nu-Alpraz*; *Panix*; *Ralozam*; *Valeans*; *Xanagis*; *Xanax*; *Xanolam*; *Xanor*; *Zopax*.



Chemical Properties A white crystalline powder. Mp 228° to 228.5°. Practically insoluble in water; sparingly soluble in alcohol and in acetone; freely soluble in chloroform and dichloromethane. pK_a 2.4. Log *P* 2.12. Extraction yield (chlorobutane), 0.95 [Demme *et al.* 2005].

Thin-layer Chromatography System TA—R_f 0.67; system TB—R_f 0.01; system TC—R_f 0.57; system TD—R_f 0.07; system TE—R_f 0.47; system TF—R_f 0.02; system TL—R_f 0.14; system TAD—R_f 0.40; system TAE—R_f 0.67; system TAF—R_f 0.66.

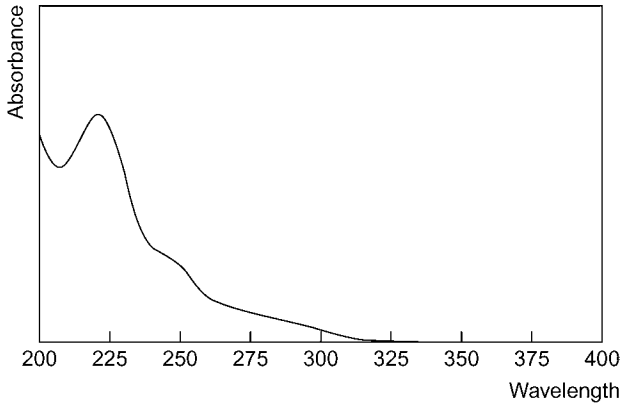
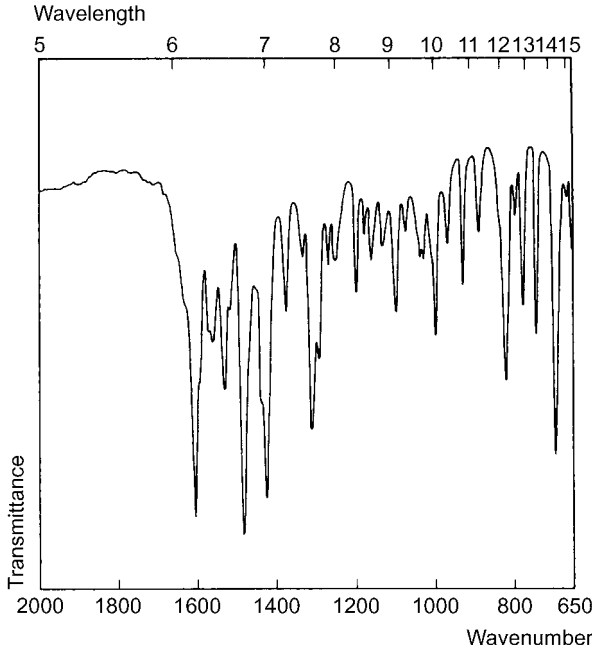
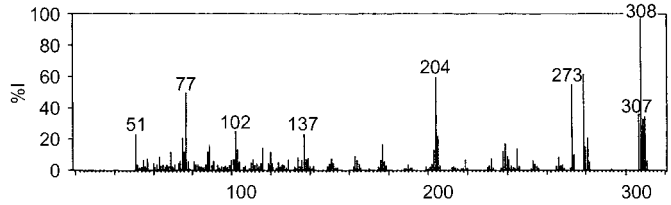
Ultraviolet Spectrum Aqueous acid—260 nm.



Infrared Spectrum Principal peaks at wavenumbers 1490, 1610, 697, 1316, 1540, 827 cm^{-1} (KBr disk). Three polymorphic forms may occur.



Mass Spectrum Principal ions at *m/z* 308, 279, 204, 273, 77, 307, 310, 309.



Quantification

Blood **GC** Column: SE-54 5% phenyl methyl silicone (25 m × 0.31 mm i.d., 0.17 μm). Carrier gas: He, 2–3 mL/min. Temperature programme: 200° for 1 min to 290° at 10°/min. NPD or ECD. Limit of detection not reported [Lillsunde, Seppälä 1990].

GC-MS Column: HP-1 methylsilicone (12.5 m × 0.2 mm i.d.). Carrier gas: He, 1.0 mL/min. Temperature programme: 70° to 280° at 20°/min. Retention time: 6.6 min. Limit of quantification, 18 μg/L [Hall *et al.* 1995]. Column: Ultra-2 (25 m × 0.2 mm i.d., 0.33 μm). Carrier gas: He, 40 cm/s. Temperature programme: 150° for 1 min to 280° at 30°/min for 12 min. NICI. Limit of quantification, 4 μg/L [Cairns *et al.* 1994].

HPLC Column: Acquity BEH Phenyl (100 × 2.1 mm i.d., 1.7 μm). Mobile phase: 0.1% formic acid in water : 0.1% formic acid in acetonitrile (80 : 20 for 0.25 min to 65 : 35 over 2.25 min for 2.5 min to 20 : 80 over 1 min to 80 : 20 over 0.01 min for 1.4 min), flow rate 0.5 mL/min. ESI, MRM acquisition mode. Limit of detection not reported [Gunn *et al.* 2010]. Column: Restek Allure C_{18} (150 × 3.2 mm i.d., 5 μm). Mobile phase: 5 mmol/L ammonium acetate : acetonitrile : methanol (90 : 5 : 5), flow rate 0.45 mL/min. DAD. Limit of quantification, 2 μg/L [Dussy *et al.* 2006].

Plasma **GC** Column: CPSIL 8 CB (25 × 0.25 mm i.d., 0.25 μm). Carrier gas: He, 1 mL/min. Temperature programme: 150° to 230° at 40°/min for 2 min to 250° at 5°/min for 1 min to 300° at 15°/min for 3 min. NPD. Limit of detection, 0.01–0.48 μmol/L [Reubsaet *et al.* 1998]. Column: C_8 Ultra-2 (25 m × 0.32 mm i.d., 0.52 m). Carrier gas: He, 2.1 mL/min. Temperature programme: 210° to 285° at 2.5°/min. NPD and ECD. Relative retention time: 1.48. Limit of quantification, 2 μg/L [Gaillard *et al.* 1993]. See Blood [Lillsunde, Seppälä 1990].

GC-MS Column: Restek-200 capillary (15 m × 0.25 mm i.d., 0.25 μm). Carrier gas: H_2, 7 psi. Temperature programme: 190° for 1 min to 320° at 20°/min for 2 min. NCI. Limit of quantification, 1 μg/L [Höld *et al.* 1996].

HPLC Column: C_{18} (250 × 4.6 mm). Mobile phase: methanol : water (65 : 35), flow rate 1.0 mL/min. UV detection (λ = 230 nm) [Liang *et al.* 2009]. Column: Kromasil C_8 (250 × 5 mm i.d., 5 μm). Mobile phase: methanol : acetonitrile : 0.05 mol/L ammonium acetate. DAD (λ = 240 nm). Limit of quantification, 0.07–1.57 mg/L, limit of detection, 0.02–0.47 mg/L [Uddin *et al.* 2008]. Column: Inertsil C_8 (250 × 4 mm i.d., 5 μm). Mobile phase: ammonium acetate : 0.05 mol/L methanol : acetonitrile (33 : 57 : 10). Limit of detection, 3.3–10.2 ng [Samanidou *et al.* 2007]. Column: reversed phase C_{18}. Mobile phase: methanol : water (60 : 40) containing 0.1% formic acid, flow rate 250 μL/min. Limit of detection, 0.05 μg/L [Crouch *et al.* 1999]. Column: C_{18} ODS (150 × 4.6 mm i.d., 5 μm) at 30°. Mobile phase: methanol : water with 1% diethylamine (pH 6, 60 : 40), flow rate, 1.5 mL/min. UV detection (λ = 240 nm). Limit of detection, 200 μg/L [Jenkins *et al.* 1997].

See also Akerman *et al.* [1996], and Rieck, Platt [1992].

LC-MS Column: XTerra MS C_{18} (150 × 2.1 mm i.d., 3.5 μm). Mobile phase: acetonitrile : water : 100 mmol/L ammonium formate (pH 3.0, 55 : 40 : 5), flow rate 0.125 mL/min. ESI, MRM acquisition mode. Retention time: 4.93 min. Limit of quantification, 20 μg/L, limit of detection, 10 μg/L [Marin *et al.* 2008; Marin, McMillin 2010].

Serum **HPLC** See Blood [Dussy *et al.* 2006; Gunn *et al.* 2010]. See Plasma [Akerman *et al.* 1996]. Column: LiChrosorb RP 18 (100 × 4.6 mm i.d., 5 μm). Mobile phase: methanol : water (65 : 35), flow rate 1.2 mL/min. UV detection (λ = 230 nm). Retention time: 3.1 min. Limit of detection, 10 mg/L [Goldnik *et al.* 1994]. Column: Supelco C_{18} (150 × 4.6 mm i.d., 5 μm). Mobile phase: methanol : 0.001 mol/L phosphate buffer with 0.003 mol/L heptyltriethylammonium phosphate in water (pH 7.4, 40 : 60), flow rate 2 mL/min. Limit of detection, 1 μg/L [Schmith *et al.* 1991].

LC-MS See Plasma [Marin, McMillin 2010]. Unison UK-C_{18} RP ODS (150 × 2 mm i.d., 3 μm). Mobile phase: 10 mmol/L aqueous ammonium formate containing 0.1% formic acid : methanol containing 0.1% formic acid (70 : 30 over 20 min to 20 : 80 over 5 min), flow rate 0.25 mL/min. MRM acquisition mode. Limit of detection, 0.3–11.4 μg/L [Nakamura *et al.* 2009]. See Plasma [Marin *et al.* 2008].

Urine **GC** See Plasma [Reubsaet *et al.* 1998].

GC-MS Column: Column: BP1 polydimethylsiloxane (30 m × 0.25 mm i.d., 0.25 μm). Carrier gas: He, 1.2 mL/min. Temperature programme: 65° for 1 min to 250° at 15°/min, for 8 min, to 300° at 10°/min for 2 min. SIM acquisition mode. Retention time: 21.49 min. Limit of detection, 1.0–1.7 μg/L (SIM) and 13–30 μg/L (scan mode) for alprazolam and other benzodiazepines [Borrey *et al.* 2001a; Borrey *et al.* 2001b]. Column: 5% phenylmethylsiloxane (25 m × 0.2 mm i.d., 0.33 μm). Carrier gas: He, 0.5 mL/min. Temperature programme: 240° to 260° at 25°/min to 300° at 30°/min. SIM acquisition mode. Limit of detection, 0.1 mg/L [Black *et al.* 1994]. Column: DB-5 bonded-phase (30 m × 0.25 mm i.d., 0.25 μm). Carrier gas: He, 0.9 mL/min. Temperature programme: 130° for 1 min to 270° at 30°/min for 5 min to 300° at 40°/min for 6 min. EI ionisation, SIM acquisition mode. Limit of quantification, 16.5 μg/L, limit of detection, 6.8 μg/L [Joern 1992].

HPLC See Plasma [Uddin *et al.* 2008]. Column: Inertsil C_8 (250 × 4 mm i.d., 5 µm). Mobile phase: ammonium acetate : 0.05 mol/L methanol : acetonitrile (33 : 57 : 10). Limit of detection, 2.6–12.6 ng [Samanidou *et al.* 2007]. Column: Hypersil C_{18} (100 × 4.6 mm i.d., 3 µm). Mobile phase: acetonitrile : 0.04 mol/L phosphate buffer (pH 4.5; 35 : 65), flow rate, 1 mL/min. UV detection: DAD at 240 nm. Retention time: 3.48 min for α-hydroxyalprazolam and 4.98 min for alprazolam. Limit of detection, 9.2 µg/L [Segura *et al.* 2001].

LC-MS See Plasma [Marin *et al.* 2008; Marin, McMillin 2010]. Column: Symmetry C_{18} (100 × 2.1 mm i.d., 3.5 µm). Mobile phase: acetonitrile : 5 mmol/L ammonium acetate (pH 5.0, 10 : 90 to 30 : 70 at 5 min to 80 : 20 at 9.0 min to 10 : 90 at 9.1 min), flow rate 0.3 mL/min. Limit of quantification, 0.002 µmol/L [Hegstad *et al.* 2006].

Meconium **LC-MS** See Plasma [Marin *et al.* 2008; Marin, McMillin 2010].

Oral Fluid **HPLC** See Plasma [Uddin *et al.* 2008].

LC-MS Column: Atlantis dC_{18} (50 × 2.1 mm i.d., 3.5 µm). Mobile phase: acetonitrile : 5 mmol/L aqueous ammonium acetate (pH 5, 10 : 90 to 40 : 60 at 4 min to 90 : 10 at 4.1 min until 8 min to 10 : 90 at 8.1 min), flow rate 0.3 mL/min. ESI, MRM acquisition mode. Limit of quantification, 0.093 µg/L [øiestad *et al.* 2007].

Liver **GC-MS** See Blood [Cairns *et al.* 1994].

Disposition in the Body Alprazolam is readily absorbed after oral administration and undergoes extensive metabolism. The major metabolites are α-hydroxyalprazolam, 4-hydroxyalprazolam (both active) and a benzophenone derivative of alprazolam. Approximately 80% of a dose is excreted in the urine in 72 h, of which 11% is unchanged drug, 15% is α-hydroxyalprazolam and 9% is the benzophenone metabolite. Small amounts of desmethylalprazolam and 4-hydroxyalprazolam are also excreted in the urine. Approximately 7% of a dose is eliminated in the faeces.

Therapeutic Concentration The serum therapeutic concentration range is 0.005–0.05 mg/L; it has also been reported as 0.025–0.102 mg/L.

After a single oral dose of 1 mg alprazolam given to 10 subjects, peak plasma concentrations of 0.011–0.020 mg/L (mean, 0.015) were attained in ~1.75 h. Following daily oral doses of 0.5 mg 3 times a day to the same subjects, minimum steady-state plasma concentrations of 0.006–0.017 mg/L (mean, 0.011) and a mean maximum steady-state plasma concentration of 0.018 mg/L were reported [Smith *et al.* 1983].

In 227 patients treated for panic disorder with alprazolam (dosage titrated up to 6 mg daily), after 3 weeks of treatment, alprazolam plasma concentrations were significantly correlated with daily dosage: 70% of those with levels greater than 0.02 mg/L achieved complete remission of attacks compared with 30% of those with levels below 0.02 mg/L. At week 8, plasma alprazolam levels no longer correlated with efficacy [Greenblatt *et al.* 1993a].

Toxicity The serum toxic concentration range is 0.1–0.4 mg/L.

In a fatality attributed to acute alprazolam toxicity, the following postmortem tissue concentrations were reported for alprazolam and α-hydroxyalprazolam, respectively: heart blood 2.1 mg/L and not detected, subclavian blood 2.3 and 0.12 mg/L, urine 1.0 and 1.4 mg/L, bile 2.8 and 1.3 mg/L, vitreous humour 0.58 mg/L and not detected, liver 9.2 and 0.83 µg/g, kidney 3.8 µg/g and not detected, stomach contents 13 mg in 110 mL and not detected; the alprazolam concentration in the heart blood (2.1 mg/L) was the highest reported so far in the literature [Jenkins *et al.* 1997].

The following postmortem concentrations were reported in a 30-year-old female who ingested an unknown quantity of alprazolam and tramadol: alprazolam, α-hydroxyalprazolam and tramadol, respectively, in peripheral blood 0.21, not detected and 38.3 mg/L; bile 0.27, 0.12 and 44.0 mg/L, liver 0.23, <0.005 and 27.6 µg/g, and gastric contents (100 mL) 2.73, not detected and 130 mg [Michaud *et al.* 1999].

Half-life Plasma half-life, 11–15 h (mean, 12).

Volume of Distribution ~0.7 L/kg.

Distribution in Blood Plasma : whole blood ratio, 1.35

Clearance Plasma clearance, ~0.7 mL/min/kg.

Protein Binding ~70–80%.

Note For a review of alprazolam, see Dawson *et al.* [1984]; for its pharmacokinetics, see Greenblatt, Wright [1993] and Greenblatt *et al.* [1993b].

Dose 1 to 3 mg daily; up to 10 mg in the treatment of panic attacks.

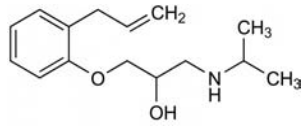
Alprenolol

β-*Adrenoceptor Antagonist*

$C_{15}H_{23}NO_2$ = 249.4

CAS—13655-52-2; 23846-70-0 (±)

IUPAC Name 1-(Propan-2-ylamino)-3-(2-prop-2-enylphenoxy)propan-2-ol



Chemical Properties Mp 57° to 59.° pK_a 9.5 (20°). Log *P* (octanol/water pH 7.0), 0.5. Extraction yield (chlorobutane), 1 [Demme *et al.* 2005].

Alprenolol Hydrochloride

$C_{15}H_{23}NO_2$,HCl = 285.8

CAS—13707-88-5; 13678-97-2 (±)

Proprietary Names *Apllobal*; *Aptin(e)*; *Betacard*; *Duriles*; *Gubernal*; *Regletin*; *Yobir*.

Chemical Properties Colourless crystals or a white crystalline powder. Mp 108° to 111°. Soluble 1 in <1 of water, 1 in 2 of ethanol, and 1 in 3 of chloroform; soluble in acetone and dilute acetic acid; practically insoluble in ether.

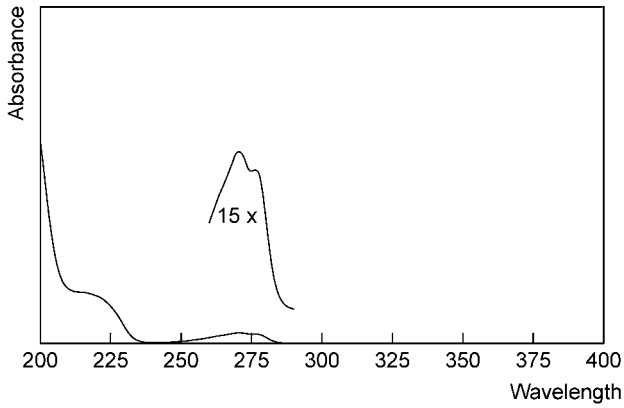
Colour Tests Liebermann's reagent—red; Mandelin's test—brown-violet; Marquis test—red; sulfuric acid—orange.

Thin-layer Chromatography System TA—R_f 0.52; system TB—R_f 0.11; system TC—R_f 0.12; system TE—R_f 0.49; system TAE—R_f 0.22; system TAG—R_f 0.11 (acidified iodoplatinate solution—positive).

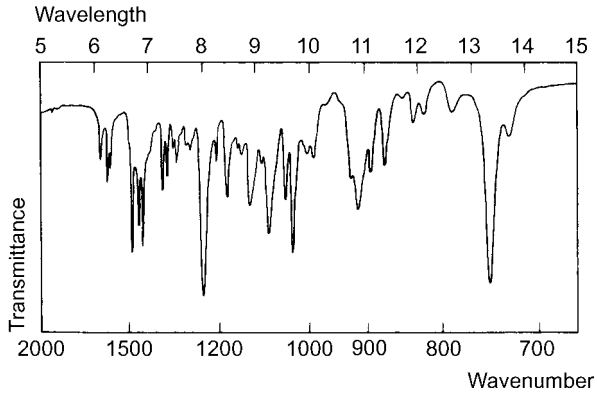
Gas Chromatography System GA—RI 1820.

High Performance Liquid Chromatography System HA—*k* 1.2; system HY—RI 323; system HZ—RT 3.87 min.

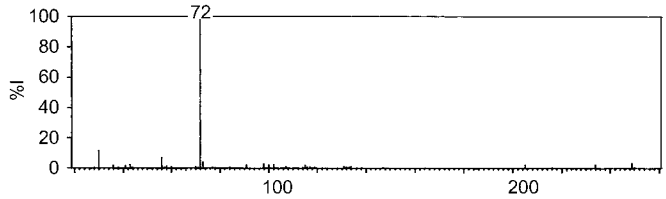
Ultraviolet Spectrum Aqueous acid—270 (A_1^1 = 69b), 276 nm. No alkaline shift.



Infrared Spectrum Principal peaks at wavenumbers 1242, 746, 1031, 1492, 1079, 916 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 72, 30, 56, 73, 249, 98, 234, 102.



Quantification

***Plasma* GC** Column: 3% OV-17 on Gas-Chrom Q 100/120 mesh (1.5 m × 0.2 cm i.d.). Carrier gas: N_2, 40 mL/min. Temperature: 235°. FID. Limit of detection, 2.5 µg/L [Poole *et al.* 1980].

LC-MS Column: Chiral-CBH (100 × 3.0 mm i.d., 5 µm). Mobile phase: 10 mmol/L ammonium acetate and 0.02% acetic acid (pH 5.0) : acetonitrile (65 : 35), flow rate 0.9 mL/min. TIS, MRM acquisition mode. Limit of quantification, 0.5 µg/L [Jiang *et al.* 2008]. Column: LiChroCART (125 × 2 mm i.d.). Mobile phase: 5 mmol/L aqueous ammonium formate (pH 3.0) : acetonitrile (80 : 20 for 2.2 min to 60 : 40 at 2.21 min until 5.5 min to 10 : 90 at 5.51 min until 8 min to 80 : 20 at 8.01 min until 10 min), flow rate 0.4 mL/min for 5.5 min to 0.7 mL/min at 5.51 mL/min to 6.5 mL/min at 8.01 min to 0.4 mL/min at 9.51 min. APCI, positive ion mode, SIM acquisition mode. Limit of detection, 0.01 mg/L [Maurer *et al.* 2004].

***Serum* GC** Column: OV-101 (25 m × 0.25 mm i.d., 0.3 µm). Carrier gas: N_2, 16 cm/s. Temperature: 205°. ECD. Relative retention time: 6 min. Limit of detection, 2 pg [Debruyne *et al.* 1979].

***Urine* HPLC** Column: µBondapak C_{18} (300 × 3.9 mm i.d., 10 µm); Mobile phase: acetonitrile : water (40 : 60) containing 5 µmol/L potassium dihydrogen phosphate/dipotassium hydrogen phosphate (pH 6.5), flow rate 1.3 mL/min. Electrochemical detection. Retention time: 11.42 min (k 4.71). Limit of quantification, 500 µg/L [Maguregui *et al.* 1995].

Disposition in the Body Alprenolol is rapidly and almost completely absorbed after oral administration but undergoes extensive first-pass metabolism; bioavailability ~5–10%. Approximately 90% of an oral dose is excreted in the urine in 24 h, with ~40% as the glucuronide conjugate of the active metabolite 4-hydroxyalprenolol, 5% as free 4-hydroxyalprenolol, 20–30% as alprenolol glucuronide, 1% as desisopropylalprenolol, and <1% as unchanged drug; unknown metabolites account for the remainder of the dose.

Therapeutic Concentration There is considerable intersubject variation in plasma concentrations and in the ratio of 4-hydroxyalprenolol to alprenolol.

After oral administration of 200 mg to 2 subjects, peak plasma alprenolol concentrations of 0.07 and 0.22 mg/L were reported; peak plasma concentrations of the 4-hydroxy metabolite were 0.04 and 0.06 mg/L [Alvan *et al.* 1977].

Following oral administration of 200 mg three times a day to 16 subjects, average steady-state plasma alprenolol concentrations of 0.01–0.14 mg/L (mean, 0.04) were reported [Collste *et al.* 1976].

Toxicity

In 2 fatalities, caused by the ingestion of ~4 g and 20 g, respectively, the following postmortem tissue alprenolol concentrations were reported: blood 40 and 43 mg/L, liver 72 and 91 µg/g [Dickson *et al.* 1978].

Half-life Plasma half-life, alprenolol and 4-hydroxyalprenolol ~2–3 h.

Volume of Distribution ~3 L/kg.

Clearance Plasma clearance, ~15 mL/min/kg.

Distribution in Blood Plasma : whole blood ratio, ~1.6.

Protein Binding 80–90%.

Dose 200 to 800 mg of alprenolol hydrochloride daily.

Alprostadil

Prostaglandin, Vasodilator

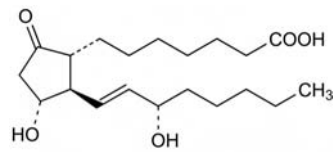
$C_{20}H_{34}O_5$ = 354.5

CAS—745-65-3

IUPAC Name 7-[(1*R*,3*R*)-3-Hydroxy-2-[(E, 3*S*)-3-hydroxyoct-1-enyl]-5-oxocyclopentyl]heptanoic acid

Synonyms (*E*)-(8*R*,11*R*,12*R*,15*S*)-11,15-Dihydroxy-9-oxoprost-13-en-1-oic acid; prostaglandin E_1; PGE_1.

Proprietary Names *Alprostar (alprostadil alfadex)*; *Caverject*; *Edex*; *Liple*; *Minprog*; *Muse*; *Prostandin (alprostadil alfadex)*; *Prostavasin (alprostadil alfadex)*; *Prostin VR*; *Prostine VR*; *Prostivas*; *Sugiran (alprostadil alfadex)*; *Viridal (alprostadil alfadex)*.



Chemical Properties A white to off-white crystalline powder. Mp about 110°. It is soluble in water and in acetone; freely soluble in ethanol; very slightly soluble in chloroform and in ether; slightly soluble in ethyl acetate. pK_a 4.85. Log *P* (octanol/water), 3.20.

Thin-layer Chromatography Plate: silica LK6D (5 × 20 cm). Mobile phase: ethyl acetate: acetic acid (99.5:0.5). PGE_0, R_f 0.50; PGE_2 R_f 0.31 [Schweer *et al.* 1994].

Quantification

***Plasma* GC-MS** Limit of quantification, 1 ng/L for alprostadil and 5 ng/L for its metabolite [Schweer *et al.* 1994].

Disposition in the Body Alprostadil is rapidly distributed throughout the body (except in the CNS) following IV administration. Between 60 and 90% (depending on dose) is rapidly metabolised by oxidation during passage through pulmonary circulation. It is also metabolised by the liver and kidneys to prostaglandin E_0 (PGE_0) and 15-hydroxy-PGE_0. The drug is excreted principally in urine (88% of a dose) as metabolites and a small amount is excreted in faeces via bile (12%).

Therapeutic Concentration

Following IV infusion of 20 µg over 30 min in 24 subjects, mean peak plasma concentrations of 8.2 ng/L were observed. Following intracavernous injection of 20 µg, mean peak plasma concentrations of 17.6 ng/L were reached after a mean of 4.8 min [Cawello *et al.* 1997].

Mean peak plasma concentrations of 4.8 (range, 3.4 to 6.3), 7.7 (6.7 to 10.8) and 12.9 (10.2 to 14.6) ng/L were measured in 12 healthy male subjects (aged between 20 and 35 years) after IV infusion over 2 h of 30, 60 and 120 µg, respectively. These levels were observed by the end of the infusion. The mean

peak plasma PGE_0 concentrations were 8.3, 15.1 and 29.2 ng/L for the 30, 60 and 120 µg doses and the 15-hydroxy-PGE_0 metabolite, 108.6, 203.6 and 395.6 ng/L, respectively [Cawello *et al.* 1995].

Bioavailability 15%.

Half-life Plasma, 0.2 to 8 min (after single dose).

Volume of Distribution 0.8 L/kg.

Clearance Plasma, 115 L/min; also reported as 20 mL/min/kg.

Protein Binding 81 to 93% (to albumin).

Note For a review of the pharmacokinetics of alprostadil see Kirsten *et al.* [1998].

Dose Usually, 5 to 20 µg by intracavernous injection; 250 µg by transurethral delivery (initial dose); 50 to 100 ng/kg/min by IV infusion (reduced to lowest dose).

Cawello W *et al.* (1995). Dose proportional pharmacokinetics of alprostadil (prostaglandin E1) in healthy volunteers following intravenous infusion. *Br J Clin Pharmacol* 40: 273–276.

Alteplase

Antithrombotic

$C_{2569}H_{3894}N_{746}O_{781}S_{40}$ = 59007.6

CAS—105857-23-6

Synonyms G-11044; G-11021; recombinant tissue-type plasminogen activator; rt-PA.

Proprietary Names *Actilyse*; *Actiplas*; *Activase*; *Besospartin*; *Lysatec-rt-PA*.

Chemical Properties A white to off-white powder.

Quantification

Note For an ELISA for the quantification of alteplase see Matsuo *et al.* [1983].

Disposition in the Body Alteplase is rapidly cleared from plasma and metabolised mainly in the liver to low molecular weight compounds and amino acids. After IV infusion, 50% of the dose is cleared from plasma within 5 min and 80% within 10 min. 80% of a dose of alteplase is excreted within 18 h, via the kidneys.

Therapeutic Concentration

Six healthy volunteers were administered with a 0.25 mg/kg dose of alteplase and 6 with 0.5 mg/kg. Peak plasma concentrations of 0.96 mg/L and 1.83 mg/L, respectively, were reached by the end of infusion [Tanswell *et al.* 1989]. Patients with acute myocardial infarction show increased peak plasma concentrations with similar doses.

Toxicity Acute overdosing (over 150 mg) can lead to internal bleeding, including intracranial, gastrointestinal and peripheral and ocular haemorrhaging.

Half-life Plasma half-life is 4 to 5 min (α-phase), ~40 min (β-phase).

Volume of Distribution Initial volume of distribution approximates plasma volume, 2–5 L.

Clearance Plasma clearance, 550 to 650 L/min.

Dose Adult: dose ranges between 0.02 to 0.04 mg/kg body weight and 1.5 mg/kg body weight, depending on symptoms. Maximum dose of 100 mg. Children: 0.01 to 0.05 mg/kg body weight.

Matsuo O *et al.* (1983). Determination of tissue plasminogen activator by an enzyme-immunoassay method. *Anal Biochem* 135: 58–63.

Altretamine

Antineoplastic

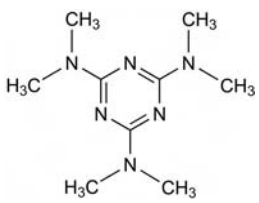
$C_9H_{18}N_6$ = 210.3

CAS—645-05-6

IUPAC Name 2-*N*,2-*N*,4-*N*,4-*N*,6-*N*,6-*N*-Hexamethyl-1,3,5-triazine-2,4,6-triamine

Synonyms ENT-50852; hexamethylmelamine; HMM; NSC-13875; 2,4,6-tris (dimethylamino)-1,3,5-triazine.

Proprietary Names *Hexalen*; *Hexastat*; *Hexinawas*.



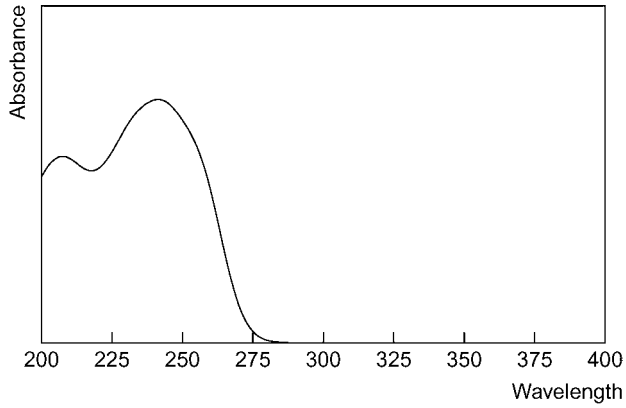
Chemical Properties A white crystalline powder. Mp about 172°. It is practically insoluble in water and physiological solvents; soluble in chloroform, DMSO, ethanol and acetone. Log *P* (octanol/water), 2.73.

Note Altretamine is an irritant; avoid contact with skin and mucous membranes.

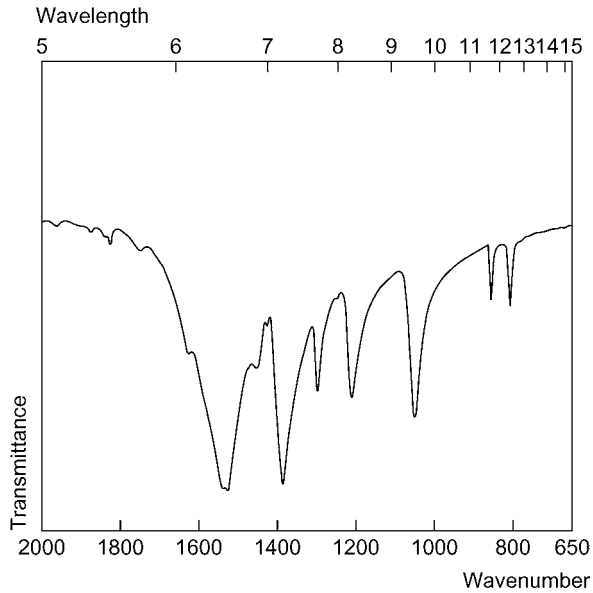
High Performance Liquid Chromatography System HAA—retention time 17.8 min.

Column: ODS Hypersil (100 × 4.6 mm i.d., 5 µm). Mobile phase: methanol, flow rate 0.5 mL/min. DAD. Retention time: 3.2 min [Mills, Roberson 1993].

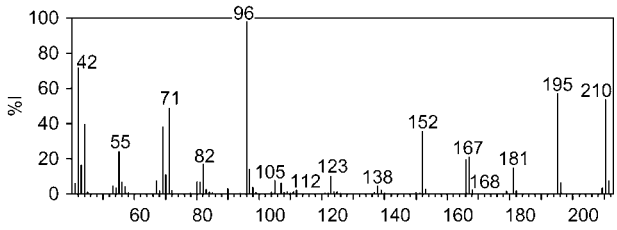
Ultraviolet Spectrum Aqueous acid (0.2 mol/L NH_2SO_4)—240 nm; Ethanol—226 nm; basic—241 nm.



Infrared Spectrum Principal peaks at wavenumber 1527, 1387, 1051 cm^{-1} (KBr pellet).



Mass Spectrum Principal ions at *m/z* 96, 42, 195, 210, 71, 69, 44, 152.



Quantification

Plasma **GC** AFID. Limit of detection, 0.005 mg/L [Hulshoff *et al.* 1980]. AFID. Limit of detection, 0.2 mg/L for altretamine and 0.025 mg/L for pentamethylmelamine [Ames, Powis 1979].

HPLC UV detection. Limit of quantification, 0.15 mg/L [Barker *et al.* 1994].

Serum **GC** See Plasma [Hulshoff *et al.* 1980].

Urine **GC** See Plasma [Ames, Powis 1979].

Disposition in the Body Altretamine is rapidly and well absorbed after oral administration and quickly distributed to tissues with a high lipid component. It is rapidly demethylated in the liver to pentamethylmelamine and other metabolites that are excreted in urine. Formaldehyde is also produced which is subsequently oxidised to carbon dioxide and expired. Other metabolites include dimethylmelamine, monomethylmelamine, trimethylmelamine and melamine, and these have been detected in urine. No parent drug has been detected in urine. Metabolism is

A

catalysed by cytochrome P450 enzymes. Accumulation in plasma has not been observed with multiple dosing.

Therapeutic Concentration

Twenty patients with gynaecological malignancies were administered with 200 to 300 mg/m^2 doses and peak plasma concentrations of 0.32 to 4.28 mg/L were observed after 0.5 to 3 h. 12 patients administered with a 200 mg dose reached peak concentrations of 0.3 to 0.9 mg/L at ~1 h. Peak plasma concentrations vary widely among patients because of the rapid hepatic metabolism [Damia, D'Incalci 1995].

Half-life Plasma, 4 to 13 h.

Protein Binding Altretamine 94%; pentamethylmelamine 75%.

Dose 260 mg/m^2 daily for 14 consecutive days in a 28-day cycle.

Ames MM, Powis G (1979). Determination of pentamethylmelamine and hexamethylmelamine in plasma and urine by nitrogen-phosphorus gas-liquid chromatography. *J Chromatogr* 174: 245–249.

Aluminium

Metal

Al = 26.98

CAS—7429-90-5

Synonyms Aluminum; aluminium bronze; aluminium dehydrated; alumina fibre; aluminium flake; aluminium powder; metana.

Proprietary Names *Aluminum-27*; *JISC 3108/3110*; *Metana*; *Noral Aluminum*; *Pap-1*.

Chemical Properties Malleable, ductile tin-white with bluish tint metal, also exists as a crystalline solid. Mp 660°. Bp 2467°. Insoluble in water, soluble in alkalis and acids. Flammable solid if finely divided and is easily ignited. Valency Al (0) and Al (+3). Occurrence: owing to its high reactivity, it is never found as the free metal in nature. It is found combined with other elements (oxygen, silicone, and fluorine). The metal is usually obtained from the mineral bauxite. Uses include as an alloy for food and drink packaging, construction materials, bodies and mechanical parts of transportation vehicles, electrical applications, and cooking utensils. It is used for the absorption of occluded gases in the manufacture of steel; testing for gold, arsenic, and mercury; precipitating copper; in explosives; and in flashes for photography. Aluminium powder is used in paints, protective coatings, and fireworks. Naturally occurring aluminium-containing minerals such as bentonite and zeolite are used in water purification, sugar refining and in the brewing and paper industries.

Aluminium Chloride

$AlCl_3$ = 133.3

CAS—7446-70-0

Synonyms Aluminum chloride; aluminium chloride (1 : 3); aluminium trichloride; trichloroaluminium.

Proprietary Name *Pearsall*

Chemical Properties White or yellowish crystals with a strong odour of hydrochloric acid. Mp 190° at 2.5 atm, also reported to volatilise without melting. Bp 182.7°. Freely soluble in benzophenone, benzene, nitrobenzene, carbon tetrachloride, trichloromethane; soluble in alcohol and ether; reacts explosively with water, evolving HCl gas. Used as an acid catalyst in Friedel–Crafts-type reactions, in the cracking of petroleum in the manufacture of rubbers and lubricants. In cosmetics, it is used as a topical astringent; it is also used in refining crude oil, dyeing fabrics, and manufacturing parchment paper. The hexahydrate form is used in preserving wood, as a disinfectant, and in deodorants and antiperspirants.

Aluminium Chlorhydrate

$AlClH_5O_5$ = 147.5 (other formulae have been suggested, including $Al_2(OH)_5Cl{,}2H_2O$ or $Al_6(OH)_{15}C_{13}$ or $[Al_2(OH)_5Cl]_x$)

CAS—1327-41-9; 11097-68-0; 84861-98-3

Synonyms Aluminium chloride, basic; aluminium chloride hydroxide; aluminium chlorohydroxide; aluminium hydroxychloride; polyaluminium chloride.

Proprietary Names *Astringen*; *Chlorhydrol*; *Locron*.

Chemical Properties Glassy solid. Soluble in water, forming turbid colloidal suspensions. Used as an active ingredient in many antiperspirants and deodorants.

Aluminium Hydroxide

$Al(OH)_3$ = 78.0

CAS—21645-51-2

Synonyms α-Alumina trihydrate; aluminium (III) hydroxide; aluminium oxide hydrate; hydrated alumina.

Proprietary Names *Alcoa331*; *Alugel*; *Alumigel*; *British Aluminum AF260*; *Calmogastrin*; *Higilite H 31S*; *Hychol 705*; *Hydrafil*; *Hydral 705*; *Martinal A*; *Reheis F1000*.

Chemical Properties White, bulky amorphous powder. Mp 300°. Practically insoluble in water, forming gels on prolonged contact; soluble in alkaline aqueous solutions or in hydrochloric and sulfuric acids. Used in stomach antacids, as a desiccant powder, in antiperspirants and dentifrices, in packaging materials, as a soft abrasive for brass and plastics, as a glass additive, in ceramics, and as a filler in plastics, rubber, cosmetics, and paper. It is also used to lower plasma phosphorus levels in patients with renal failure.

Aluminium Nitrate

AlN_3O_9 = 213.0 (also as hydrated form, $AlN_3O_9{,}9H_2O$ = 375.1)

CAS—13473-90-0

Synonyms Aluminium (III) nitrate (1 : 3); aluminium trinitrate; nitric acid, aluminium salt.

Chemical Properties Odourless white nonahydrate deliquescent crystals. Mp 73°, decomposes at 135°. Very soluble in water; very slightly soluble in acetone; almost insoluble in ethyl acetate and pyridine. Used in antiperspirants, for tanning leather, as a corrosion inhibitor, in the preparation of insulating papers, in transformer core laminates, in incandescent filaments, and in cathode ray tube heating elements.

Aluminium Oxide

Al_2O_3 = 101.9

CAS—1344-28-1

Synonyms Activated aluminium oxide; alumina; β-aluminium oxide; aluminium sesquioxide; aluminium trioxide.

Proprietary Names *Almite*; *Alon*; *Aloxite*; *Alumite*; *Alundum*; *Campalox*; *Dispol Alumina*; *Exolon XW 60*; *Faserton*; *Hypalox II*; *Ludox CL*; *Martoxin*; *Microgrit WCA*; *Poraminar*.

Chemical Properties White crystalline powder. Mp 2000°. Bp 3000°. Practically insoluble in water; slowly soluble in aqueous alkaline solutions; practically insoluble in non-polar organic solvents. Used in the production of aluminium; manufacture of abrasives, ceramics, refractories, electrical insulators, catalyst and catalyst supports, paper, spark plugs, crucibles, and laboratory works; adsorbent for gases and water vapours; in chromatographic analysis, fluxes, light bulbs, artificial gems; heat-resistant fibres; food additive; in fibre membrane units in water desalination, industrial ultrafiltration, haemodialysis; as dosimeter for measuring personnel radiation exposure.

Aluminium Phosphate

$AlPO_4$ = 122.0

CAS—7784-30-7

Synonyms Aluminium orthophosphate; aluminium phosphate tribasic; phosphoric acid, aluminium salt (1 : 1).

Proprietary Names It is an ingredient in *Alaphos*; *Phosphaljel*; *Phosphalugel*; *Phosphalutab*; *Ukocid*.

Chemical Properties White crystals. Mp>1460°. Insoluble in water; very slightly soluble in concentrated hydrochloric acid and nitric acid. Used in OTC stomach antacids.

Aluminium Phosphide

AlP = 58.0

CAS—20859-73-8

Synonym Aluminium monophosphide

Proprietary Names *Celphos*; *Delicia*; *Delicia Gastoxin*; *Detia GAS EX-B/EX-T*; *Detia phospine pellets*; *Phostoxin*; *Quick-Phos*; *Quick-Fume*.

Chemical Properties Dark grey or dark yellow crystals with a garlic odour. Does not melt or decompose thermally at temperatures up to 1000°. Decomposes in water to give phosphine gas. Used as insecticidal grain fumigant.

Aluminium Sulfate

$Al_2(SO_4)_3$ = 342.1

CAS—10043-01-3

Synonyms Alum; aluminium sulphate (2 : 3); cake alum; dialuminium sulphate; filter alum; papermakers' alum; patent alum; peral alum; pickle alum.

Proprietary Names *Cake Alum*; *Patent Alum*.

Chemical Properties Odourless white lustrous crystals (also pieces, granules or powder). Decomposes at 770°. Soluble in water and dilute acids; practically insoluble in alcohol. Used primarily for water purification systems and sewage treatment systems as a flocculent; in the paper and pulp industry; in fireproofing and waterproofing cloth; in clarifying oils and fats; in waterproofing concrete; in antiperspirants; in tanning leather; as a mordant in dyeing; in agricultural pesticides; as a soil conditioner to increase acidity for plants; and in cosmetics and soaps. Solutions containing 5–10% have been used as local applications to ulcers and to stop discharges from mucous surfaces.

Colour Test Addition of sodium hydroxide to aluminium ions—forms a white precipitate that dissolves in excess sodium hydroxide.

Quantification

Specimen Collection Blood/serum/plasma—5 mL, plain or lithium heparin tube; urine—20 mL plastic universal container; dialysis fluid—20 mL plastic universal container.

Note Aluminium is the most abundant element on earth and contamination from needles, syringes, collection tubes, glassware, analytical reagents, and equipments is a major problem. It is always advisable to analyse a sample of aluminium-free water alongside the test samples.

Blood **DPV** Buffer: 0.5 mol/L ammonium acetate plus 0.5 mol/L ammonia with 13.3% 2 mol/L sodium chloride and dopamine. Scan rate: 20 mV/s. Pulse

amplitude: 50 mV. Pulse width: 60 ms. Limit of detection, 19 nmol/L [Zhang *et al.* 2002]. Buffer: 0.08 mol/L ammonium acetate : ammonia (pH 8.5). Limit of detection, 76 nmol/L [Zhang *et al.* 2000].

ETAAS Dry cycle: 110° at 10 s for 5 s to 150° in 60 s for 15 s (to 400° at 1 s for 15 s in blood with a haematocrit of >0.5 L/L). Char cycle: 1400° at 40 s for 20 s (ramp time extended to 100 s in blood with a haematocrit of >0.5 L/L. Atomisation cycle: 260° for 8 s. Gas: N_2, 100 mL/min. Limit of detection, 2.3 µg/L [van der Voet *et al.* 1985]. Dry cycle: 120° at 15 s for 15 s, 300 mL/min. Char cycle: 300° in 5 s for 5 s to 1530° in 25 s for 10 s, 300 mL/min. Atomisation cycle: 2700° in 1 s for 13 s, 20 mL/min for first 6 s to 300 mL/min for last 7 s. Limit of detection, 20 pg [D'Haese *et al.* 1985].

ICP-AES Limit of detection, 0.1 mg/kg [Dinya *et al.* 2005]. Plasma gas: Ar, 12 L/min. Nebuliser gas: Ar, 0.5 L/min. Nebuliser pressure: 2.3 bar (λ = 396.2 nm). Limit of detection, 0.12 µmol/L [Chappuis *et al.* 1992].

ICP-MS Plasma gas: 15 L/min. Auxiliary gas: 1.13 L/min. Nebuliser gas: 1.0 mL/min. Limit of detection not reported [Rainska *et al.* 2007]. Plasma gas: Ar, 14.8 L/min. Auxiliary gas: Ar, 0.9 L/min. Carrier gas: 1.1 L/min. Babington nebuliser (*m/z* 27). Limit of detection not reported [Botta *et al.* 2006]. Limit of detection, 0.1 µg/L [Nagaoka, Maitani 2005]. Plasma gas: 16 L/min. Auxiliary gas: 1 L/min. Nebuliser gas: 1.15 or 1.33 mL/min. Limit of detection, 40 µg/L [De Boer *et al.* 2004]. Limit of detection, 171 ng/L [Liao *et al.* 2004]. Outer gas: Ar, 15 L/min. Intermediate gas: 0.85 L/min. Carrier gas: 0.91 L/min. Limit of detection not reported [Nagaoka, Maitani 2001].

Plasma **ETAAS** Dry cycle: 120° at 1 s for 20 s to 160° in 10 s for 10 s. Char cycle: 1000° in 10 s for 20 s. Atomisation cycle: 2600° for 5 s to 2650° in 1 s for 7 s. Gas: Ar (λ = 309 nm). Limit of detection not reported [Progar *et al.* 1996]. Dry cycle: 110° at 10 s for 5 s to 150° in 60 s for 15 s. Char cycle: 1400° in 40 s for 20 s. Atomisation cycle: 260° for 8 s. Gas: N_2, 100 mL/min. Limit of detection, 1.8 µg/L [van der Voet *et al.* 1985]. See Blood. Dry cycle: 100° at 15 s for 15 s to 120° in 10 s for 10 s, 300 mL/min. Char cycle: 700° in 2 s for 1 s to 1580° in 120 s for 10 s, 300 mL/min [D'Haese *et al.* 1985].

ICP-AES Plasma gas: Ar, 0.01 L/min. Auxiliary gas: Ar, 10 L/min. Nebuliser gas: Ar, 0.8 L/min. McPherson 216 or Minuteman 310-SMP spectrometer (λ = 308 nm). Limit of detection not reported [Progar *et al.* 1996].

Serum **ETAAS** See Blood. Limit of detection, 1.9 µg/L [van der Voet *et al.* 1985]. Dry cycle: 350° for 60 s. Char cycle: 1500° for 60 s. Atomisation cycle: 2600° for 12 s. Aluminium hollow cathode lamp (λ = 309 nm). Limit of detection not reported [Gorsky, Dietz 1978].

ICP-AES Plasma gas: Ar, 12 L/min. Meinhard nebuliser (λ = 167 nm). Limit of quantification, 0.97 µg/L; limit of detection, 0.5 µg/L [Bianchi *et al.* 2007]. External gas: 14.0 L/min. Indirect gas: 0.5 L/min. Bearing gas: 1.0 L/min. Meinhard nebuliser (λ = 165–460 nm). Limit of detection not reported [Olszewski *et al.* 2006]. See Blood [Chappuis *et al.* 1992].

ICP-MS Outer gas: 15.0 L/min. Carrier gas: 0.8 L/min. Make-up gas: 0.17 L/min. Limit of detection, 5 µg/L [Murko *et al.* 2007].

FPLC-ICP-MS Column: Mono-Q HR 5/5 FPLC (50 × 5 mm i.d., 10 µm). Mobile phase: 0.05 mol/L TRIS hydrochloride : 0.05 mol/L TRIS hydrochloride with 0.25 mol/L ammonium acetate (100 : 0 to 0 : 100 at 15 min), flow rate 1 mL/min. UV-vis detection (proteins, λ = 295 nm). Carrier gas: 1.1 or 1.15 L/min. Intermediate gas: 1.0 or 0.9 L/min. Outer gas: 15.0 or 14.5 L/min for quadrupole and double-focusing ICP-MS, respectively. Limit of detection, <5 µg/L [Soldado Cabezuelo *et al.* 1997, 1998].

CSF **DPV** See Blood [Zhang *et al.* 2002].

ETAAS Palladium-triton modifier (λ = 396.2 nm). Limit of detection, 2 ppb [Gane *et al.* 1996].

Urine **CE** Capillary: Uncoated. Limit of detection, 2 ppb [Blanco-Gonzalez *et al.* 1998].

DPV See Blood [Zhang *et al.* 2000, 2002].

ETAAS Dry cycle: 110° at 1 s for 20 s to 130° in 15 s for 20 s. Char cycle: 1250° in 30 s for 15 s, change gas from Ar to 5% H_2 in Ar for 5 s. Atomisation cycle: 2300° for 5 s. Normal gas: Ar, 250 mL/min. Purge gas: 5% H_2 in Ar, 250 mL/min. Hollow cathode lamp (λ = 309.3 nm). Limit of detection, 0.06 µg/L [Lin, Huang 2001]. Perkin-Elmer 5100. Limit of detection, 0.25 µg/L [White 1999]. See Plasma. Limit of detection, 26 pg [D'Haese *et al.* 1985]. Dry cycle: 100 for 60 s. See Serum [Gorsky, Dietz 1978].

ICP-MS See Blood [Botta *et al.* 2006; Rainska *et al.* 2007]. Limit of detection, 15 µg/L [De Boer *et al.* 2004], 4.92 µg/L [Liao *et al.* 2004]. Perkin-Elmer Sciex Elan 5000. Nebuliser gas: 1.0 mL/min. Limit of detection, 35 ng/L [White 1999].

Milk **ICP-MS** Plasma gas: 12–13 L/min. Auxiliary gas: 0.9 to 1.0 L/min. Sample gas: 1.0 –1.2 L/min. Limit of detection, 39 µg/L [Krachler *et al.* 2000].

Ascitic Fluid **DPV** See Blood [Zhang *et al.* 2002].

ETAAS Dry cycle: 60° to 90° in 15 s for 5 s to 100° in 10 s for 5 s to 110° in 15 s for 5 s to 140° for 5 s, 200 mL/min. Char cycle: 140° to 1000° in 10 s for 20 s, 100 mL/min. Atomisation cycle: 2700° for 4 s. Lamp current: 10.0 mA (λ = 309.3 nm). Limit of detection, 1.0 µg/L [Milacic, Benedik 1999; Scancar *et al.* 1999].

Brain **ICP-AES** Sample flow rate: 2.0 mL/min. Plasma gas: 15 L/min. Auxiliary gas: 0.5 L/min. Aerosol gas: 0.8 L/min. UV detection (λ = 167 to 395 nm). Limit of quantification, 1 mg/kg [Andrasi *et al.* 2005]. Plasma gas: Ar, 16 L/min. Auxiliary gas: 0 L/min. Nebuliser gas: 0.8 L/min. Limit of detection not reported [Carpenter 1985].

ETAAS Hollow cathode lamp (λ = 309.3 nm). Limit of detection, 5.0 µg/kg [van Ginkel *et al.* 1990]. Dry cycle: 110° for 20 s to 250° for 5 s. Char cycle: 1100° for 20 s. Atomisation cycle: 2600° for 13 s. Aluminium hollow cathode lamp (λ = 309.3 nm). Gasflow: Ar. Limit of detection, 1.9 µg/L [Bouman *et al.* 1986].

Hair **DPV** See Blood [Zhang *et al.* 2000].

Note For a study following the trace element hair analysis of 1 man over 2 decades, see Klevay *et al.* [2004].

Heart **ETAAS** See Brain [Bouman *et al.* 1986].

ICP-AES Plasma gas: Ar, 1.2 L/min. Cooling gas: 14 L/min. Shimadzu ICP-1000III (λ = 396 nm). Limit of detection, 50 µg/L [Minami *et al.* 1996].

Iliac Crest **ETAAS** Dry cycle: 60° to 90° in 10 s for 5 s to 100° in 10 s for 5 s to 150° in 10 s, 200 mL/min. Char cycle: 150° to 1000° in 10 s for 20 s, 100 mL/min. Atomisation cycle: 2700° for 4 s. Lamp current: 10.0 mA (λ = 309.3 nm). Limit of detection, 1.0 µg/L [Scancar *et al.* 2000].

Kidney **ETAAS** See Brain [Bouman *et al.* 1986].

Liver **ICP-AES** See Brain [Carpenter 1985].

ETAAS See CSF [Gane *et al.* 1996]. See Blood. Dry cycle: 100° at 10 s for 10 s, 300 mL/min. Char cycle: 700° in 10 s for 10 s to 1500° in 30 s for 10 s, 300 mL/min. Limit of detection, 50 µg/kg [D'Haese *et al.* 1985].

Rib Bone **ICP-AES** See Brain [Carpenter 1985].

Skeletal Muscle **ICP-AES** See Brain [Carpenter 1985].

Spinal Cord **ETAAS** See Brain [Bouman *et al.* 1986].

Other **HPLC** Environmental and Biological Samples. Column: Spherisorb ODS 2 (150 × 4.6 mm i.d., 5 mm). Mobile phase: methanol : water (pH 1.0, 30 : 70), flow rate 1.0 mL/min. Diode array and fluorometric detection (λ_{ex} = 418 nm, λ_{em} = 490 nm). Limit of detection, 2 nmol/L for Al–morin complex [Lian *et al.* 2003].

DPV Drinking Water, Hydrothorax, Sodium Chloride Injections, Sucrafate, and Synthetic Renal Dialysate. See Blood [Zhang *et al.* 2000].

ETAAS Cocaine Samples. Char cycle: 1400°. Atomisation cycle: 2300° (λ = 309.3 nm). Limit of detection not reported [Bermejo-Barrera *et al.* 1999]. Infusion Solutions and Solutions for Nutritional Support. Char cycle: 1400°. Atomisation cycle: 2500°. Graphite tube pyrolytically coated with L'vov platform (λ = 396 nm). Limit of detection, 0.6 µg/L [Recknagel *et al.* 1994]. Aqueous Solutions. See Blood. Limit of detection, 1.3 µg/L [van der Voet *et al.* 1985].

ICP-AES Argentine Wine. Outer gas: 8.5 L/min. Auxiliary gas: 1.0 L/min. Nebuliser gas: 1.0 L/min (λ = 308.1 nm). Limit of detection, 0.3 µg/L [Lara *et al.* 2005]. Infusion solutions and solutions for nutritional support. Outer gas: Ar, 12 L/min. Auxiliary gas: Ar, 0.3 L/min. Nebuliser gas, 0.8 L/min. Meinhard nebuliser (λ = 167 nm). Limit of detection, 2.5 µg/L [Recknagel *et al.* 1994]. Infant Formulae. Plasma gas: Ar, 18 L/min. Coating gas: Ar, 0.9 L/min. Carrier gas: Ar, 0.1 L/min. Meinhard nebuliser (λ= 237 nm). Limit of quantification, 15 µg/L, limit of detection, 4.5 µg/L [Coni *et al.* 1993]. Infant Milk Formulae. Nebuliser gas: Ar, 0.8 L/min (λ = 308 nm). Limit of detection, 50 µg/L [Bloodworth *et al.* 1991].

ICP-MS Meals from Catering Establishments. Plasma gas: 15 L/min. Auxiliary gas: 0.9 L/min. Nebuliser gas: 0.73 L/min. Limit of quantification, 0.12 mg/kg [Noel *et al.* 2003]. Infant Formulae. See Milk [Krachler *et al.* 2000].

Note For a review of detection methods to evaluate the speciation of metals for toxicity assessment and the difficulties in measuring aluminium, see Caruso *et al.* [2006]. For a comparison of 6 catechols as electroactive ligands in the speciation analysis of aluminium, see Liu *et al.* [2002]. For the detection of aluminium fluoride in natural waters by ICP-MS, see Bayon *et al.* [1999]. For a review of the measurement of aluminium in clinical samples, see Taylor and Walker [1992]. For a DC plasma emission spectrometry method for the measurement of aluminium in serum, see Roberts and Williams [1988].

Disposition in the Body In living organisms, aluminium exists as the free ion, low-molecular-weight complexes, physically bound macromolar complexes (e.g. transferrin), and as covalently bound macromolecular complexes. The complexes are active metabolites, particularly the non-polar ones.

Inhalation exposure Occupational exposure to fumes, dust and flakes results in increased serum, tissue and urinary concentrations of aluminium. It has been suggested that the fractional absorption of aluminium from lung to blood is higher in individuals exposed to fumes as opposed to dust. Studies have also shown that aluminium may directly enter the brain via the olfactory tract. However, it has also been demonstrated that exposure to aluminium oxide or chlorhydrate does not necessarily result in significant increases in tissue or serum levels which would indicate lung retention rather than absorption is taking place. This is supported further by the fact that lungs have the highest aluminium concentration when compared with other organs and that the pulmonary concentration of aluminium increases with age.

Oral exposure As little as 0.1 to 0.3% of aluminium ingested in the diet and drinking water is absorbed. More bioavailable forms, particularly complexes with carboxylic acids (e.g. citrate), can reach 1%. In antacid therapy, where patients may consume several grams of aluminium per day, approx. 99% of the ingested aluminium is recovered in the faeces, with blood concentrations rarely rising more than 50% above the pre-antacid level. Aluminium bioavailability is mainly related to the form in which it is ingested and the presence of dietary constituents with which the metal cation can complex. For example, presence of citric acid greatly increases the bioavailability of the cation.

Dermal exposure Aluminium cholrohydrate salts are commonly used in underarm antiperspirants, which are thought to act as an obstructive plug of aluminium hydroxide within the sweat duct. Studies in animals have demonstrated that aluminium can be directly absorbed through the skin.

Excretion Aluminium is excreted by the kidneys and no accumulation occurs in subjects with normal renal function. Uraemic patients are susceptible to aluminium

A

toxicity owing to accumulation in the bone and tissues either from dosage with phosphate binders or exposure to parenteral intake from dialysis fluid.

Normal Concentrations Serum—1–4 μg/L (0.04–0.16 μmol/L); urine—<15 μg/L (0.5 μmol/L). Guideline concentration for potable water—50 μg/L (1.9 μmol/L). Recommended upper limit for dialysis fluid—30 μg/L (1.1 μmol/L). Minimum risk level: 2 mg/kg/day oral.

A study of aluminium in tobacco and cannabis using ETAAS found the following concentrations [Exley *et al.* 2006]:

Brand/type of tobacco/cannabis	*Al content (mg/g product)*
Bangladeshi tobacco	2.3–3.7
Rothmans	0.6–1.5
Natural tobacco	1.2–2.0
Medium tobacco	0.8–1.4
Cannabis (2 types)	0.1–0.4
Cannabinoid extract (THC)	0.1–0.4

Toxicity Uraemic patients undergoing dialysis with fluid prepared from aluminium-rich tap water may develop an encephalopathy, dialysis dementia, which can be fatal. The same illness may ensue in uraemic patients receiving large quantities of phosphate-binding aluminium salts. Aluminum phosphide, which releases phosphine when ingested, is highly toxic, with a fatal dose as low as 1.5 g.

Twenty-seven patients with end-stage renal disease received chronic intermittent haemodialysis with dialysate contaminated with both calcium and aluminium. Ten of the patients died following convulsions, sepsis, and coma. Antemortem serum concentrations of aluminium were 808 μg/L, with concentrations of 255 μg/L found in the serum of the survivors. Postmortem toxicological analysis was performed on four of the patients and the following concentrations were found [De Wolff *et al.* 2002]:

Patient	*Serum (μg/L)*	*Liver (μg/g)*	*Bone (μg/g)*[a]	*Cerebral cortex (μg/g)*[b]
1	517	43.0	21.9	1.09
2	696	32.7	88.7	1.40
3	1275	51.7	7.54	1.12
4	894	4.7	77.0	1.78
Reference values	<10	<2	<2	0.14–0.22

[a]Collected from the femoral shaft.
[b]Collected from the gyrus temporalis inferior and superior.

Serum aluminium concentrations were measured in patients undergoing haemodialysis. Concentrations were 44.5 ± 29.0 μg/L compared with 10.8 ± 2.5 μg/L in controls [Neiva *et al.* 2002].

One hundred patients undergoing chronic haemodialysis had blood and serum concentrations, respectively, of 79 and 77 μg/L, compared with 12.1 and 2.0 μg/L in controls [D'Haese *et al.* 1985].

Serum aluminium levels have also been measured in blood donors, exposed (directly and indirectly) and non-exposed workers. Concentrations were as follows [Ruangyuttikarn *et al.* 2002]:

	N	*Al (μg/L)*
Blood donors	500	8.8 ± 5.7
Directly exposed	62	13.6 ± 4.5
Indirectly exposed	130	9.4 ± 5.3
Not exposed	207	7.9 ± 6.5

Aluminium has been implicated in Alzheimer's disease (AD). Brain samples from 3 control patients (aged 55 to 71 years) and 3 patients with AD (aged 72 to 80 years) were tested for their aluminium, magnesium, and phosphorus content. The concentration of aluminium was consistently higher in AD specimens than in controls. The mean aluminium concentration in brain regions ranged from 1.4 to 2.5 mg/kg in control samples and from 3.5 to 10.2 mg/kg in AD samples [Andrasi *et al.* 2005]:

Brain region	*Control patients*			*AD patients*		
	Al	*Mg*	*P*	*Al*	*Mg*	*P*
Ammon's horn	1.4 ± 0.6	680 ± 100	13190 ± 960	4.9 ± 3.0	557 ± 82	11000 ± 480
Cortex entorhinalis	1.5 ± 0.9	666 ± 106	12560 ± 900	10.2 ± 9.0	540 ± 55	10700 ± 500
Cortex frontalis parasagittalis	1.8 ± 0.6	606 ± 89	12040 ± 850	6.8 ± 4.3	625 ± 35	10860 ± 550
Cortex frontalis basalis	2.5 ± 0.7	673 ± 48	12500 ± 940	6.4 ± 2.9	623 ± 53	10650 ± 730
Globus pallidus	1.8 ± 0.7	628 ± 80	13000 ± 1000	3.5 ± 0.4	552 ± 48	10850 ± 860

In another study of postmortem hippocampal (dentate gyrus) tissue from 12 patients with AD (aged 65 to 93 years), the concentration of aluminium was 0.3 ± 0.08 μg/g in AD compared with 0.12 ± 0.07 μg/g in controls (aged 63 to 89 years) [Corrigan *et al.* 1993].

The parietal cortex of patients with AD has also been found to have higher concentrations of aluminium when compared with controls [Srivastava and Jain 2002].

Aluminium concentrations in 4 brain regions from 6 patients with pathologically verified amyloid lateral sclerosis (ALS) were significantly higher than in controls [Yasui *et al.* 1991]:

Motor area	*ALS*			*Controls (5)*
	Case 1	*Case 2*	*Other 4 cases*	
Precentral gyrus	213.0	169.2	33.8 ± 8.0	22.3 ± 1.5
Internal capsule	69.5	40.5	18.6 ± 2.7	18.0 ± 1.5
Crus cerebri	102.4	–	26.1 ± 1.8	19.4 ± 2.8
Spinal cord	517.8	88.2	33.5 ± 4.2	22.1 ± 1.2

A 39-year-old man committed suicide by ingesting aluminium phosphide. He was discovered 10 days after the event. Postmortem concentrations were reported as follows [Anger *et al.* 2000]:

Biological media	*Phosphorus found (mg/L or mg/g)*	*Usual values*	*Aluminium found (μg/L or μg/g)*	*Usual values*
Blood	76.3	25–45	1537.5	9–15
Urine	564	681–1300	<0.1	<0.1
Brain	4.3	2.36–0.5	36	2 ± 1
Heart	1.37	1.27–0.3	4.6	<1
Surrenal	4.52	—	44	—
Liver	8.22	200–0.05	75	3 ± 1
Kidney	2.05	1.75–0.05	3	3 ± 1

A 24-year-old pregnant woman accidentally exposed to aluminium phosphide visited her physician with tachycardia (218 bpm). She vomited but remained lucid. Clear frothy sputum began emanating from her mouth and nostrils. She was transferred to hospital but shortly after arrival suffered a cardiac arrest and died. Her blood aluminium concentration was 713 μg/L (normal range, 2 to 42 μg/L) [Garry *et al.* 1993].

Note For a review of aluminium phosphide poisoning cases, see Gupta and Ahlawat [1995]; for an investigation of toxic trace elements in the hair of children with autism, see Fido and Al Saad [2005]. For an evaluation of metal levels in welders, see Iarmarcovai *et al.* [2005]. For a comparison of trace metal profiles in hair samples from children in urban or rural areas, see Hasan *et al.* [2004] and for a study on the environmental influences on the trace element content of teeth, see Brown *et al.* [2004]. Rahil-Khazen *et al.* [2002] have studied trace element levels in the autopsy tissue of 30 Norwegians. For a review of aluminium and neurotoxicity, see Yokel [2000]. For a study of serum aluminium concentrations in dialysis patients, see van Landeghem *et al.* [1998]; for concentrations in the urine of glass-manufacturing workers, see Apostoli *et al.* [1998].

Bioavailability Dependent on the route of exposure, see Yokel and McNamara [2001].
Half-life From blood or urine, very short. Because of this, the use of human biomonitoring to estimate aluminium exposure in environmental medicine is not recommended [Wilhelm *et al.* 2004].
Distribution in Blood Blood : plasma ratio approx. 0.95. For a study on the distribution of aluminium between plasma and erythrocytes, see van der Voet and De Wolff [1985].
Protein Binding Approximately 90%, mainly to transferrin and influenced by the concentration of iron [Nagaoka, Maitani 2001; van Landeghem *et al.* 1997].

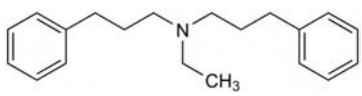
Alverine

Antispasmodic
$C_{20}H_{27}N = 281.4$
CAS—150-59-4

Synonyms Dipropyline; *N*-ethyl-*N*-(3-phenylpropyl)-benzenepropanamine; phenpropamine.



Alverine Citrate

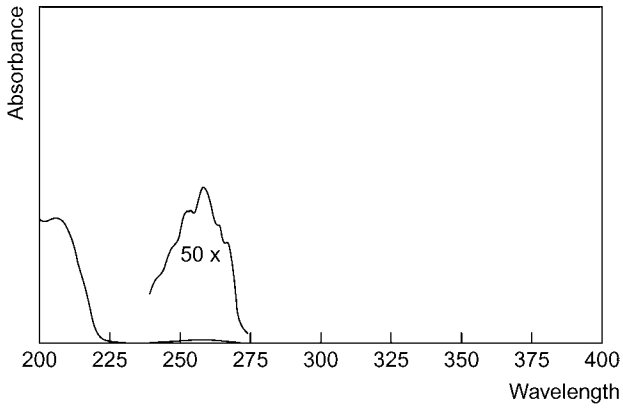
$C_{20}H_{27}N,C_6H_8O_7 = 473.6$
CAS—5560-59-8

Proprietary Names *Profenil*; *Spasmavérine*; *Spasmonal*.
Chemical Properties A white powder. Mp 100° to 103°. Slightly soluble in water and chloroform; sparingly soluble in ethanol; very slightly soluble in ether.

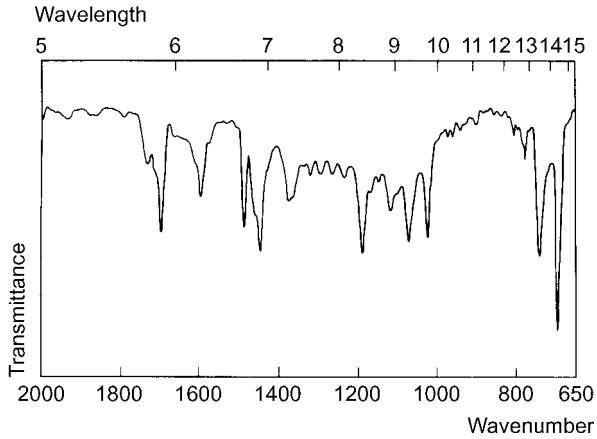
Colour Tests Liebermann's reagent—orange; Mandelin's test—grey–green; Marquis test—orange–red.
Thin-layer Chromatography System TA—R_f 0.66; system TB—R_f 0.65; system TC—R_f 0.39; system TL—R_f 0.38 (acidified potassium permanganate solution, positive).
Gas Chromatography System GA—RI 2142.
High Performance Liquid Chromatography System HA—*k* 1.8.

A

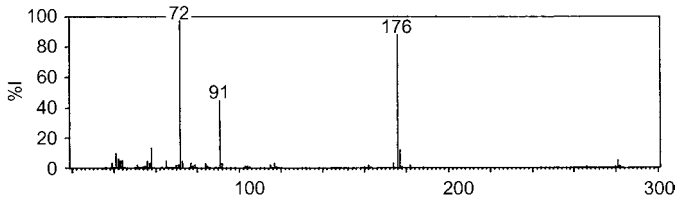
Ultraviolet Spectrum Aqueous acid—253, 259 (A_1^1=14.4 b), 264, 268 nm.



Infrared Spectrum Principal peaks at wavenumbers 694, 1190, 740, 1075, 1020, 1694 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 72, 176, 91, 58, 177, 41, 42, 30.



Dose The equivalent of 40 to 240 mg of alverine daily.

Amantadine

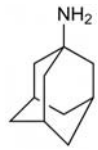
Antiviral, Antiparkinsonian

$C_{10}H_{17}N$ = 151.3

CAS—768-94-5

IUPAC Name Adamantan-1-amine

Synonym 1-Adamantanamine



Chemical Properties Crystals. Mp 160° to 190°, also reported as 180 to 192°. Sparingly soluble in water; soluble in chloroform. pK_a 10.1. Extraction yield (chlorobutane), 0.5 [Demme *et al.* 2005].

Amantadine Hydrochloride

$C_{10}H_{17}N,HCl$ = 187.7

CAS—665-66-7

Synonyms EXP-105-1; NSC-83653.

Proprietary Names *Amazolon*; *Antadine*; *Mantadine*; *Mantadix*; *Mantandan*; *Symmetrel*; *Virofral*.

Chemical Properties A white crystalline powder. Mp 360° with decomposition. Soluble 1 in 2.5 of water, 1 in ~5 of ethanol and 1 in 18 of chloroform; practically insoluble in ether.

Amantadine Sulfate

$C_{10}H_{17}N,^1/_2H_2SO_4$ = 200.3

CAS—31377-23-8

Proprietary Names *Contenton*; *PK-Merz*; *Trivaline*.

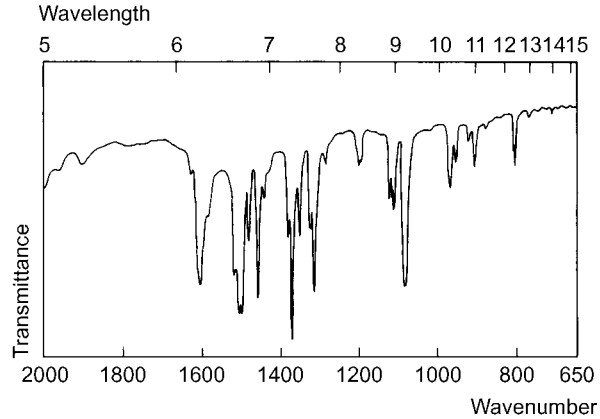
Colour Test Ninhydrin—pink-violet

Thin-layer Chromatography System TA—R_f 0.23; system TB—R_f 0.19; system TC—R_f 0.07; system TE—R_f 0.35; system TL—R_f 0.04; system TAE—R_f 0.07; system TAF—R_f 0.77 (acidified iodoplatinate solution—positive).

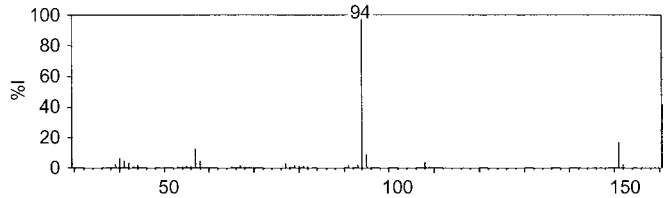
Gas Chromatography System GA—amantadine RI 1240, amantadine-AC RI 1640.

Ultraviolet Spectrum No significant absorption, 230–360 nm.

Infrared Spectrum Principal peaks at wavenumbers 1503, 1497, 1316, 1603, 1089, 1517 cm^{-1} (amantadine hydrochloride, KBr disk).



Mass Spectrum Principal peaks at *m/z* 94, 151, 57, 95, 40, 41, 58, 108.



Quantification

Plasma **GC** Column: HP-1 capillary (10 m × 0.53 mm i.d., 2.65 µm). Carrier gas: He, 20 mL/min. Temperature: 180°. ECD. Limit of quantification, 2.3 µg/L [Rakestraw 1993]. FID. Limit of detection, 100 µg/L [Bélanger, Grech-Belanger 1982]. Column: 5% SE-30 on Chromosorb W HP 80/100 mesh (2 m × 3 mm i.d.). Carrier gas: 40 mL/min. Temperature: 200°. ECD. Limit of detection, 10 µg/L [Sioufi, Pommier 1980].

HPLC Column: stainless steel (27 × 2.1 mm i.d.). Mobile phase: acetonitrile : water (55 : 45 for 1.5 min to 85 : 15 at 5.5 min for 5 min to 55 : 45 at 11.5 min until 13.47 min), flow rate 1.5 mL/min. Fluorescence detection (λ_{ex}= 254 nm, λ_{em}= 305–395 nm). Limit of detection, 0.79 ng [Zhou *et al.* 1993].

LC-MS Column: Agilent Zorbax SB-CN (150 × 2.1 mm i.d., 5 µm). Mobile phase: methanol : 0.5% formic acid (20 : 80), flow rate 0.2 mL/min. ESI, SRM acquisition mode. Limit of quantification, 20 µg/L [Feng *et al.* 2009]. Column: Hypersil-HypurityC_{18} reversed-phase (150 × 2.1 mm i.d., 5 µm). Mobile phase: methanol : acetonitrile : 20 µmol/L ammonium acetate (pH 4.0, 45 : 10 : 45) containing 1% acetic acid. Limit of quantification, 3.9 µg/L [Wang *et al.* 2007].

Serum **HPLC** Column: Phenomenex Luna C_8(2) (100 × 2.0 mm i.d., 3 µm). Mobile phase: water : acetonitrile (60 : 40) with 5 g/L formic acid, flow rate 0.2 mL/min. Limit of detection, 20 mg/L [Arndt *et al.* 2005].

Urine **GC** See Plasma. Limit of detection, 4 µg/L [Bélanger, Grech-Belanger 1982]. See Plasma [Sioufi, Pommier 1980].

HPLC Column: TSK gel ODS-80TM (250 × 4.6 mm i.d.). Mobile phase: methanol : water (10 : 1). Fluorescence detection (λ_{ex}= 355 nm, λ_{em}= 405 nm). Limit of detection, 2 mg/L [Fujino *et al.* 1993]. See Plasma [Zhou *et al.* 1993]. Column: Hypersil ODS (150 × 3 mm i.d., 5 µm). Mobile phase: acetonitrile : 10 mmol/L citrate buffer (pH 2.5, 75 : 25), containing 20 mmol/L tetramethylammonium. UV detection (λ= 350 nm). Limit of detection, 75 µg/L [van der Horst *et al.* 1990].

Disposition in the Body Amantadine is slowly but almost completely absorbed after oral administration. It is mainly excreted unchanged in the urine (~56% of a dose being excreted unchanged in 24 h and ~86% in 4 days) although small amounts of metabolites have also been detected. The major metabolic pathway is *N*-acetylation but several unusual routes (*N*-methylation, formation of Schiff bases and *N*-formiates) have also been observed. Amantadine crosses the placenta and the blood–brain barrier. It is also distributed into breast milk.

Therapeutic Concentration

Following a single oral dose of 150 mg given to 6 subjects, peak plasma concentrations of 0.32–0.56 µg/mL (mean, 0.4) were attained in ~3–4 h [Aoki *et al.* 1979].

After oral administration of 100 mg twice daily, steady-state plasma concentrations of 0.1–1.1 μg/mL (mean, 0.5) were observed in 22 patients [Greenblatt *et al.* 1977].

Toxicity

An adolescent who ingested 1.3 g amantadine developed complex ventricular arrhythmias and altered mental status. The arrhythmias were completely suppressed with IV lidocaine [Pimentel, Hughes 1991].

In a fatality involving the ingestion of amantadine, the following postmortem tissue concentrations were reported: blood 21 μg/mL, bile 418.6 μg/mL, liver 135.4 μg/g, urine 1330 μg/mL [Reynolds, van Meter 1984].

Half-life Plasma half-life, 10 to 15 h in patients with normal renal function but significantly prolonged in the elderly and in patients with renal impairment.

Protein Binding ~67%.

Note For studies on the use of amantadine as a medication for cocaine dependence, see Shoptaw *et al.* [2002].

Dose Usually 100 to 200 mg of amantadine hydrochloride daily. Doses up to 400 mg daily have occasionally been used, but this dose should not be exceeded.

Amatoxins

Protein Synthesis Inhibitor, Toxin

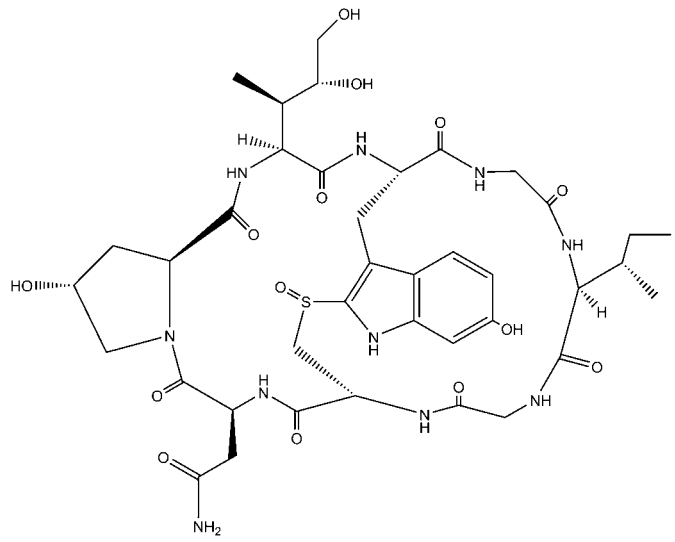
CAS—11030-71-0

Amatoxins are group 1 mushroom toxins from *Amanita, Galerina* and *Lepita* species of fungi, comprising α- β- and γ-amanitin and amanin. α-Amanitin is 10 to 20 times more toxic than phalloidin. Amatoxins are bicyclic octapeptides.

α-Amanitin

$C_{39}H_{54}N_{10}O_{14}S = 919$

CAS—23109-05-9



Chemical Properties Needles from methanol. Mp 254° to 255°. pK_a 9.72 [Morris *et al.* 1978]. Log *P* (octanol/water), −9.28 [Meylan, Howard 1995].

β-Amanitin

$C_{39}H_{53}N_9O_{15}S = 920$

CAS—21150-22-1

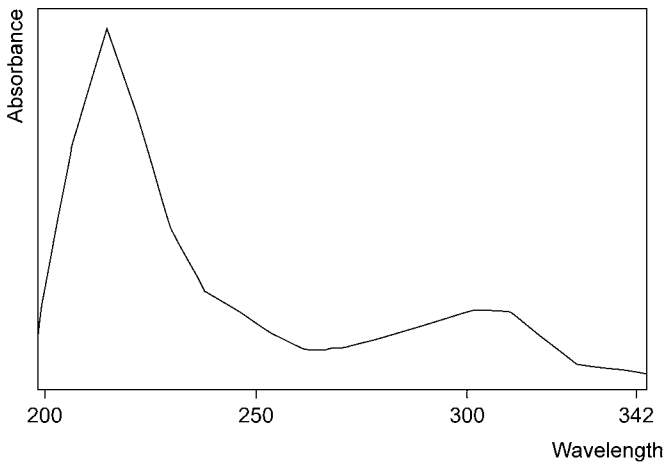
Chemical Properties Needles from methanol. Mp 300°. Soluble in water, methanol, ethanol and aqueous butanol.

Thin Layer Chromatography Plates: silica gel G. Solvent system: methyl ethyl ketone : methanol (1 : 1). Cinnamaldehyde spray (1% in methanol) followed by exposure to hydrochloric acid vapours. R_f 0.20, 0.38 and 0.51 for β- α- and γ-amanitin, respectively. Limit of detection not reported [Benedict *et al.* 1966].

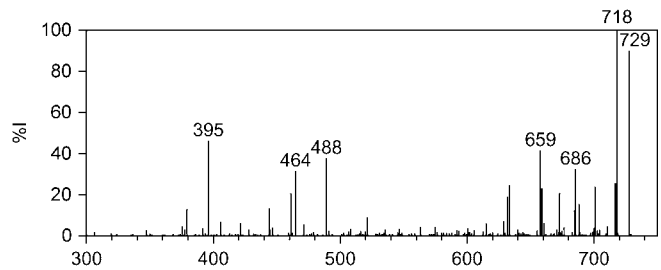
High Performance Liquid Chromatography Column: Spherisorb (25 cm × 4.6 mm i.d., 5 μm). Mobile phase: acetonitrile : water 915 : 85), flow rate 1 mL/min. UV detection (λ= 302 nm). Limit of detection, 0.5 mg/L [Pastorello *et al.* 1982].

Capillary Electrophoresis Capillary: fused silica (84 cm length). Running buffer: aqueous solution of 20 mmol/L ammonium formate (pH 10.8). ESI, negative ion mode, SIM acquisition mode. Limit of detection, 27, 42 and 87 nmol/L for α-, β- and γ-amanitin, respectively [Rittgen *et al.* 2008].

Ultraviolet Spectrum Principal peak at 302 nm.



Mass Spectrum



Quantification

Plasma **HPLC** Column: PLRP-S 100 Å (150 × 4.6 mm i.d.). Mobile phase: 0.05 mol/L phosphate buffer : acetonitrile (pH 9.5; 91 : 9), flow rate 0.5 mL/min. Electrochemical detection. Limit of detection, 2 μg/L [Tagliaro *et al.* 1991].

Serum **HPLC** Column: Develosil RP AQUEOUS. Mobile phase: acetonitrile containing 0.01 mol/L ammonium acetate (pH 5.0). UV detection (λ= 295, 302 and 230 nm). Limit of detection, 0.2 mg/L [Nishizawa, Yamaura 2003]. Column: Ultrasphere ODS C_{18} silica (250 × 4.6 mm i.d., 5 μm). Mobile phase: 0.02 mol/L aqueous ammonium acetate : acetonitrile (88 : 12), flow rate 1 mL/min. UV detection (λ= 280 nm). Retention time 12.1 and 7.4 min for α- and β-amanitin, respectively. Limit of detection, 10 μg/L for α- and β-amanitin [Jehl *et al.* 1985]. Column: Lichrosorb RP-18 (125 × 4 mm i.d., 5 μm). Mobile phase: acetonitrile : 0.01 mol/L acetic acid–ammonium acetate buffer (pH 5.0; 7 : 93 for 7 min to 25 : 75 at 30 min), flow rate 1 mL/min. UV detection (λ= 302 nm). Retention time: β-amanitin 9.1 min; α-amanitin 14.9 min. Limit of detection, 10 ng on column [Caccialanza *et al.* 1985].

LC-MS Column: Synergi RP-Polar (100 × 4.6 mm i.d.). Mobile phase: 0.01 mol/L ammonium acetate in 0.1% aqueous formic acid : 0.01 mol/L ammonium acetate in 0.1% aqueous methanolic formic acid (40 : 60 for 5 min to 10 : 90 for 2 min to 40 : 60 for 8 min), flow rate 0.5 mL/min. ESI, full scan mode. Retention time: α-amanitin 4.5 min. Limit of detection, 0.26 μg/kg [Filigenzi *et al.* 2007].

Urine **HPLC** Column: Inertsil ODS-3 (150 × 4.6 mm i.d.). Mobile phase: 0.01 mol/L ammonium acetate buffer (pH 5.0) : chloroform (84 : 16), flow rate 1.0 mL/min. DAD. Limit of detection not reported [Gonmori, Yoshioka 2003]. Column: HP ODS Hypersil RP_{18} (100 × 2.1 mm i.d., 3 μm). Mobile phase: methanol-ammonium acetate (pH 5.0; 10 : 90) : methanol-ammonium acetate (pH 5.0; 70 : 30; 0 : 100 for 6 min to 100 : 0 for 5.5 min), flow rate 350 μL/min for 3 min to 50 μL/min for 2 min to 150 μL/min for 1 min to 460 μL/min for 3.5 min to 350 μL/min. UV detection (λ= 302 nm). Limit of quantification, 5 μg/L, limit of detection,

A

2.5 μg/L [Maurer *et al.* 2000]. Column: Supelcosil LC_{18} (250 × 4.6 mm i.d.). Mobile phase: 5 mmol/L bisodic phosphate aqueous solution (pH 7.2) : acetonitrile (90 : 10), flow rate 1 mL/min. Electrochemical detection. Limit of quantification, 10 μg/L [Defendenti *et al.* 1998]. Column: Ultrasphere ODS C_{18} silica (250 × 4.6 mm i.d., 5 μm). Mobile phase: 0.02 mol/L aqueous ammonium acetate : acetonitrile (88 : 12), flow rate 1 mL/min. UV detection (λ = 280 nm). Retention time: 12.1 and 7.4 min for α- and β-amanitin, respectively. Limit of detection, 10 μg/L for α- and β-amanitin [Jehl *et al.* 1985]. Column: Lichrosorb RP-18 (125 × 4 mm i.d., 5 μm). Mobile phase: acetonitrile: 0.01 mol/L acetic acid-ammonium acetate buffer (pH 5.0; 7 : 93 for 7 min to 25 : 75 at 30 min), flow rate 1 mL/min. UV detection (λ = 302 nm). Retention time: β-amanitin 9.1 min, α-amanitin 14.9 min. Limit of detection, 10 ng on column [Caccialanza *et al.* 1985].

LC-MS Column: Chromcart CC Kromasil RP_{18} (125 × 2 m i.d., 5 μm). Mobile phase: methanol : 0.02 mol/L ammonium acetate (pH 5; 22 : 78), flow rate 75 μL/min. API, ESI, SIM acquisition mode. Limit of detection, 10 μg/L for α- and β-amanitin [Maurer *et al.* 1997a, b].

Gastric Contents **HPLC** Column: Ultrasphere ODS C_{18} silica (250 × 4.6 mm i.d., 5 μm). Mobile phase: 0.02 mol/L aqueous ammonium acetate : acetonitrile (88 : 12), flow rate 1 mL/min. UV detection (λ = 280 nm). Retention times 12.1 and 7.4 min for α- and β-amanitin, respectively. Limit of detection, 10 μg/L for α- and β-amanitin [Jehl *et al.* 1985].

Liver **LC-MS** Column: Synergi RP-Polar (100 × 4.6 mm i.d.). Mobile phase: 0.01 mol/L ammonium acetate in 0.1% aqueous formic acid : 0.01 mol/L ammonium acetate in 0.1% aqueous methanolic formic acid (40 : 60 for 5 min to 10 : 90 for 2 min to 40 : 60 for 8 min), flow rate 0.5 mL/min. ESI, full scan mode. Retention time: α-amanitin 4.5 min. Limit of detection, 0.50 μg/kg [Filigenzi *et al.* 2007].

Other **TLC** *Amanita verna* Bull. Plates: Silica gel 60 (10 × 10 cm). Solvent system: chloroform : methanol : acetic acid : water (75 : 33 : 5 : 7.5). Densitometric detection. Limit of detection not reported [Seeger, Stijve 1979]. *Amanita phalloides* and *Galerina marginata.* Plates: Silica gel G (8 × 8 in [20 × 20 cm]). Solvent system: methanol : methyl ethyl ketone (1 : 1). Visualised using 1% cinnamaldehyde in methanol and exposure to hydrochloric acid vapour. R_f 0.46 and 0.23 for α- and β-amanitin, respectively. Limit of detection not reported [Sullivan *et al.* 1965].

HPTLC *Amanita phalloides*. Plates: Silicagel 60 for nano-TLC (10 × 10 cm). Solvent system: chloroform : methanol : acetic acid : water (75 : 33 : 5 : 7.5) or 2-butanol : ethylacetate : water (56 : 48 : 20). Visualisation with 1 mL cinnamaldehyde in 100 mL methanol in a tank of fuming hydrochloric acid. Limit of detection, 50 ng [Stijve, Seeger 1979].

HPLC *Amanita exitialis*. Column: YWG C_{18} reversed phase (300 × 4 mm i.d., 10 μm). Mobile phase: 0.02 mol/L aqueous ammonium acetate-acetonitrile (90 : 10) : 0.02 mol/L aqueous ammonium acetate-acetonitrile (76 : 24; 100 : 0 to 95 : 5 at 15 min to 20 : 40 at 40 min to 0 : 100 at 50 min to 100 : 0 at 60 min), flow rate 1.0 mL/min. UV detection (λ = 295 nm). Retention times: 13.86 and 8.41 min for α- and β-amanitin, respectively. Limit of detection not reported [Zhang *et al.* 2005]. Rat Urine. Column: NH2 Dynamax (250 × 4.6 mm i.d., 8 μm). Mobile phase: water : acetonitrile (90 : 10 for 10 min to 70 : 30 at 11 min for 19 min), flow rate 1.0 mL/min. UV detection (λ = 305 nm). Limit of detection, 5 μg/L for α-amanitin [Lee *et al.* 2001]. *Galerina fasciculate* and *Galerina helvoliceps*. Column: μBondasphere C_{18} 100 Å (5 μm). Mobile phase: 20 mmol/L ammonium acetate containing 5% methanol (pH 5.0) : 20 mmol/L ammonium acetate containing 80% methanol (pH 5.85; 80 : 20 for 15 min to 1 : 99 at 30 min for 10 min), flow rate 10 mL/min. DAD (λ = 210–550 nm). Retention times 16.5, 18.5 and 25.2 min for β-, α- and γ-amanitin, respectively. Limit of detection not reported [Muraoka *et al.* 1999]. *A. phalloides.* Column: Ultrasphere ODS reversed phase (250 × 4.6 mm i.d., 5 μm). Mobile phase: 0.02 mol/L aqueous ammonium acetate-acetonitrile (pH 5.0, 90 : 10) : 0.02 mol/L aqueous ammonium acetate-acetonitrile (pH 5.0, 76 : 24; 100 : 0 for 4 min to 43 : 57 for 16 min to 0 : 100 for 10 min to 100 : 0), flow rate 1 mL/min. UV detection (λ = 214 and 295 nm). Limit of detection, 10 μg/L [Enjalbert *et al.* 1992].

LC-MS Dog Liver. Column: Polar-RP (150 × 4.6 mm i.d.). Ion trap MS. Limit of detection, 0.5 μg/L [Puschner *et al.* 2007].

Note For a study of the distribution of amatoxins and phallotoxins in *A. phalloides,* see Enjalbert *et al.* [1999]; in various other mushrooms, see Faulstich *et al.* [1974]. For a fluorescence method for the detection of amanitins, see Vlaskin *et al.* [2006].

Disposition in the Body Kinetics studies of amanitins in human poisoning have shown that they are present in plasma at low concentrations 24–48 h after ingestion; they are present in urine at high concentrations, and large amounts may be eliminated 3–4 days following ingestion. High concentrations are found in the gastrointestinal aspiration fluid from 48–110 h and large amounts may be eliminated in the faeces [Jaeger *et al.* 1993].

Toxicity People eating *A. phalloides* present with gastrointestinal problems such as vomiting and diarrhoea within 8 to 14 h of ingestion. Amatoxins are taken up into hepatocytes where they inhibit RNA polymerase II, ultimately resulting in a severe acute hepatitis that is indistinguishable from acute viral hepatitis [Lampe, McCann 1987]. If untreated, mortality is as high as 80%. Treatment includes supportive measures, inactivation of the toxin, and, in cases of liver failure, liver transplantation [Yildiz *et al.* 2008]. The lethal dose in humans is 0.1 mg/kg and the toxicity of α-amanitin is increased by lysine-orotate [Halacheva *et al.* 1988].

A 56-year-old man was admitted to hospital 42 h after mushroom ingestion. His main complaints of nausea and vomiting had begun 12 h after the ingestion. His laboratory findings were normal apart from the renal, liver and cardiac function markers, which were all elevated. The patient was treated with activated charcoal, high-dose IV penicillin G, and IV silibinin (5 mg/kg bolus and 20 mg/kg/24 h continuous infusion for 3 days). Because of the elevated cardiac enzymes, he was also given acetylsalicylic acid and metoprolol. After 480 h, the majority of the patient's biochemical parameters had returned to normal. The patient was discharged but with a haemodialysis schedule owing to chronic renal failure [Unverir *et al.* 2007].

Forty-five patients were admitted to hospital in France after accidental intoxication with *A. phalloides*. Amanitin analysis was performed on plasma (43 cases), urine (35 cases), gastroduodenal fluid (12 cases), faeces (12 cases), and tissues (4 cases). The concentration ranges were as follows:

	α-Amanitin	*β-Amanitin*
Plasma (μg/L)	8–190	15.9–162
Urine (mg)	0.02–3.29	0.04–5.21
Gastric fluid	ND	ND
Faeces (μg/L)	28–6986	42–14 900
Liver (μg/kg)	0–19	0–3298
Kidney (μg/kg)	122–1719	1017–1391

ND, not detectable [Jaeger *et al.* 1993].

A middle aged Finnish-born engineer was admitted to hospital in upstate New York 30 h after ingesting ~30 tiny fruiting bodies of *Lepiota josserandii* Bon and Boif, which he had mistakenly identified as *Lepiota excoriate*. His respiratory rate was 40 breaths/min; his systolic blood pressure was 60 mmHg, his abdomen was soft, and his liver was markedly enlarged and diffusely tender. His distal extremities were cold and cyanotic. Initial laboratory findings were as follows:

	Result (normal range)
Haematocrit (%)	60 (40–49)
Sodium (mEq/L)	120 (135–145)
Potassium (mEq/L)	6.7 (3.5–5.2)
Bicarbonate (mEq/L)	7.5 (21–30)
Glucose (mg/L)	390 (650–1150)
Urea nitrogen (mg/L)	820 (100–200)
Arterial pH	7.16 (7.37–7.45)
Platelet count (μL)	30 000 (130 000–350 000)

The prothrombin time and activated partial thromboplastin time were elevated beyond routine measurement capabilities. These findings suggested severe metabolic acidosis, haemoconcentration, coagulopathy, and renal and hepatic failure. Despite invasive haemodynamic monitoring, ventilatory support, and large amounts of IV fluids, the patient became comatose 100 h after ingestion and died 10 h later. Postmortem examination revealed hepatic necrosis consistent with amatoxin mushroom poisoning [Haines *et al.* 1986]

Note For a report on acetylcysteine as a life-saving antidote in *A. phalloides* poisoning, see Montanini *et al.* [1999], although there is some evidence that it is ineffective against α-amanitin [Schneider *et al.* 1992]. For a report of amanita toxicosis in a dog, see Puschner *et al.* [2007]. For a review of the clinical characteristics of amanita and non-amanita mushroom poisoning in Turkish children, see Erguven *et al.* [2007]; in Turkish adults, see Yilmaz *et al.* [2006]. For a review investigating the geographical distribution of mushroom poisoning in Japan, see Gonmori and Yoshioka [2003].

Half-life 32.2 ± 51.9 and 80.2 ± 94.6 μg/h for α- and β-amanitin, respectively.

Protein Binding Amanitin does not bind to plasma proteins.

Ambazone

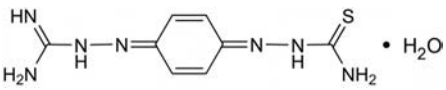
Bacteriostat

$C_8H_{11}N_7S,H_2O = 255.3$

CAS—6011-12-7 (monohydrate); 539-21-9 (anhydrous)

Synonym 2-[4-[(Aminoiminomethyl)hydrazono]-2,5-cyclohexadien-1-ylidene]-hydrazinecarbothioamide monohydrate

Proprietary Names *Bridal*; *Iversal*; *Primal(s)*.

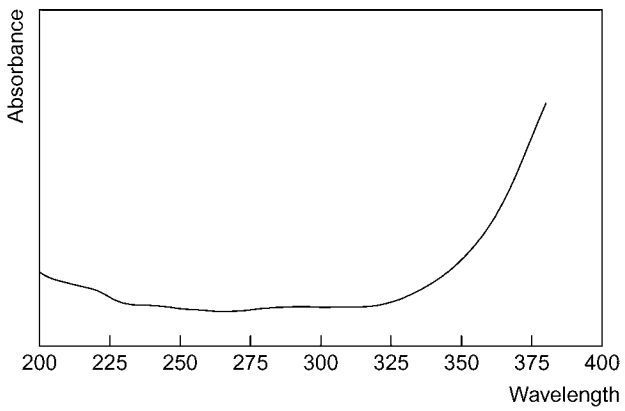


Chemical Properties A brown microcrystalline powder. Mp 192° to 194°, with decomposition. Practically insoluble in water; very slightly soluble in ethanol; soluble in DMF and in solutions of acids and of alkali hydroxides.

Colour Test Palladium chloride—brown.

Thin-layer Chromatography System TA—R_f 0.55; system TB—R_f 0.00; system TC—R_f 0.04; system TE—R_f 0.38; system TL—R_f 0.08; system TAD—R_f 0.00; system TAE—R_f 0.70 (acidified potassium permanganate solution, positive).

Ultraviolet Spectrum No significant absorption, 230 to 360 nm.



Infrared Spectrum Principal peaks at wavenumbers 1130, 1515, 1587, 1612, 1639, 1315 cm^{-1}.

Note For the chemical and analytical characterisation of ambazone, see Miosga *et al.* [1988].

Dose Ambazone is given as 10-mg lozenges in doses of 30 to 50 mg daily.

Miosga N *et al.* (1988). Chemical-analytical characterization of dihydroambazone. *Pharmazie* 43: 541–543.

Ambenonium Chloride

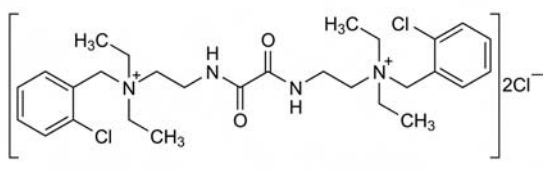
Anticholinesterase

$C_{28}H_{42}Cl_4N_4O_2 = 608.5$

CAS—7648-98-8 (ambenonium); 115-79-7 (chloride, anhydrous); 52022-31-8 (chloride, tetrahydrate)

Synonyms Ambestigmini chloridum; *N,N′*-[(1,2-dioxo-1,2-ethanediyl)bis(imino-2,1-ethanediyl)]bis[2-chloro-*N,N*-diethylbezenemethanaminium] dichloride; oxazyl.

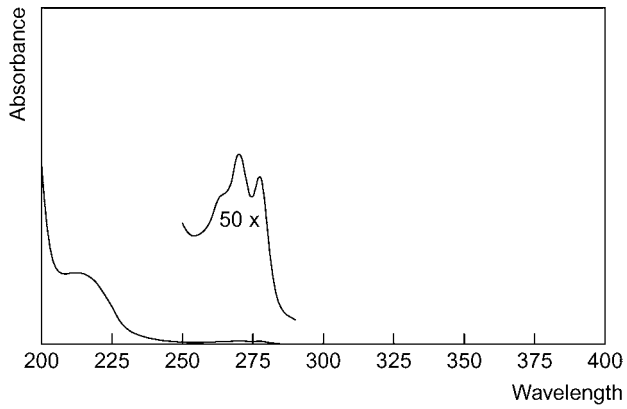
Proprietary Names *Mysuran*; *Mytelase*.



Chemical Properties A white powder. Mp about 200°. Soluble 1 in 5 of water and 1 in 20 of ethanol; slightly soluble in chloroform; practically insoluble in acetone and ether.

Thin-layer Chromatography System TA—R_f 0.02 (acidified iodoplatinate solution, positive).

Ultraviolet Spectrum Aqueous acid—271 (A^1_1=30c), 277 nm (A^1_1=29c). No alkaline shift.



Infrared Spectrum Principal peaks at wavenumbers 1675, 1505, 767, 806, 1136, 1190 cm^{-1} (KBr disk).

Therapeutic Concentration

Six patients with myasthenia gravis with mean age 47.8 years (34 to 56 years) were administered 10 mg ambenonium chloride (group A) and 7 patients with mean age 48.1 years (25 to 68 years) administered 5 mg (group B) after an overnight fast of 12 h or 30 min after a standard meal. The mean peak concentrations were 9.12 µg/L observed at 85 min for group A when fasting and 2.50 µg/L at 120 min after a meal. For group B, mean concentrations were 5.61 µg/L at 55.7 min when fasting and 1.29 µg/L at 72.9 min after a meal [Ohtsubo *et al.* 1992].

Dose 15 to 100 mg daily; doses of over 200 mg daily have been given.

Ohtsubo K *et al.* (1992). Influence of food on serum ambenonium concentration in patients with myasthenia gravis. *Eur J Clin Pharmacol* 42(4): 371–374.

Ambucetamide

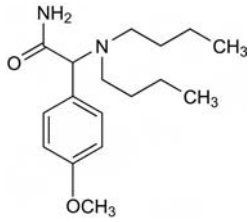
Antispasmodic

$C_{17}H_{28}N_2O_2 = 292.4$

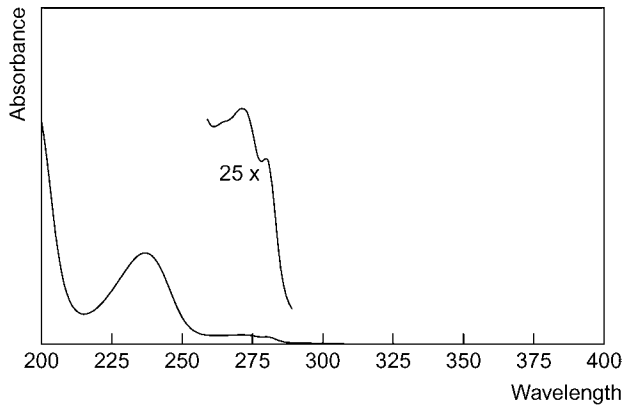
CAS—519-88-0

Synonym 2-Dibutylamino-2-(4-methoxyphenyl)acetamide

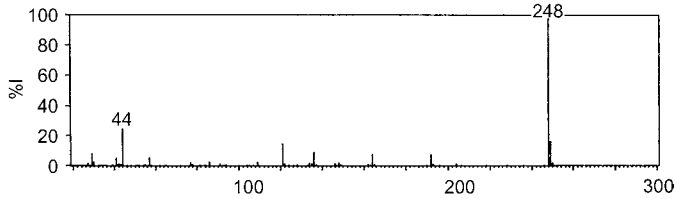
Proprietary Name It is an ingredient of *Femerital*.



Chemical Properties A white crystalline powder. Mp 134°. Practically insoluble in water; soluble in ethanol, chloroform, glacial acetic acid and isopropyl alcohol.
Thin-layer Chromatography System TA—R_f 0.73; system TB—R_f 0.05; system TC—R_f 0.68; system TE—R_f 0.76; system TL—R_f 0.61; system TAE—R_f 0.76; system TAF—R_f 0.88 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—RI 2330.
Ultraviolet Spectrum Aqueous acid—235 nm; aqueous alkali—279, 286 nm.



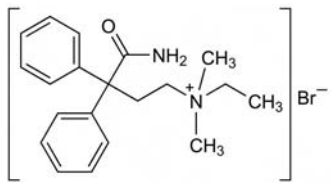
Infrared Spectrum Principal peaks at wavenumbers 1656, 1513, 1176, 1250, 1026, 820 cm^{-1} (KBr disk).
Mass Spectrum Principal peaks at *m/z* 248, 44, 249, 121, 136, 29, 164, 192.



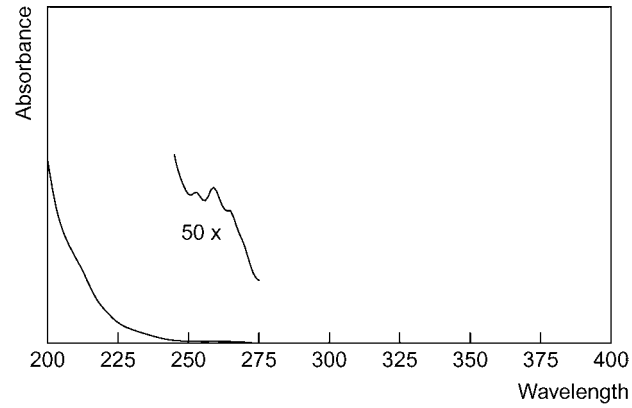
Dose 300 to 600 mg daily.

Ambutonium Bromide

Anticholinergic
$C_{20}H_{27}BrN_2O$ = 391.4
CAS—14007-49-9 (ambutonium); 115-51-5 (bromide)
Synonym γ-(Aminocarbonyl)-*N*-ethyl-*N*,*N*-dimethyl-γ-phenylbenzenepropanaminium bromide
Proprietary Name It is an ingredient of *Aludrox SA* and *Praxiten SP*.



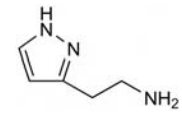
Chemical Properties White crystals. Mp 228° to 229°, with decomposition. Soluble 1 in 1.4 of water, 1 in 27 of ethanol, 1 in 500 of acetone and 1 in 3.5 of chloroform.
Colour Test Liebermann's reagent—brown-orange.
Thin-layer Chromatography System TA—R_f 0.03 (acidified iodoplatinate solution, positive).
Ultraviolet Spectrum Aqueous acid—253, 259 (A^1_1=11.5b), 265 nm.



Infrared Spectrum Principal peaks at wavenumbers 700, 1664, 764, 1590, 1315, 979 cm^{-1}.
Dose 7.5 to 20 mg daily.

Ametazole

Diagnostic Agent (Gastric Secretion)
$C_5H_9N_3$ = 111.1
CAS—105-20-4
IUPAC Name 2-(1*H*-Pyrazol-5-yl)ethanamine
Synonyms Betazole; gastramine; 1*H*-pyrazole-3-ethanamine.

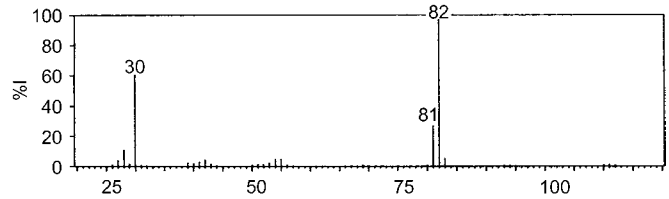


Chemical Properties A viscous liquid. Bp 118° to 123°. pK_a 2.2, 9.6 (20°).

Ametazole Hydrochloride

$C_5H_9N_3$,2HCl = 184.1
CAS—138-92-1
Proprietary Names *Betazol*; *Histalog*.
Chemical Properties A white, hygroscopic, crystalline powder. Mp about 240°. Soluble 1 in 3 of water and 1 in 50 of ethanol; practically insoluble in chloroform; very slightly soluble in ether.

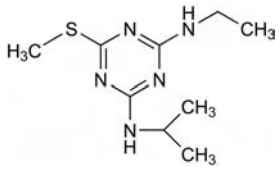
Thin-layer Chromatography System TA—R_f 0.26; system TB—R_f 0.11; system TC—R_f 0.00 (Dragendorff spray, positive; acidified iodoplatinate solution, positive; Marquis reagent, brown; ninhydrin spray, positive; acidified potassium permanganate solution, positive).
Gas Chromatography System GA—RI 1390.
Ultraviolet Spectrum No significant absorption, 230 to 360 nm.
Infrared Spectrum Principal peaks at wavenumbers 1563, 1316, 1647, 775, 928, 1044 cm^{-1}.
Mass Spectrum Principal ions at *m/z* 82, 30, 81, 83, 55, 54, 42, 27.



Dose 500 µg/kg of ametazole hydrochloride by subcutaneous or intramuscular injection.

Ametryne

Herbicide
$C_9H_{17}N_5S$ = 227.3
CAS—834-12-8
IUPAC Name 4-*N*-Ethyl-6-methylsulfanyl-2-*N*-propan-2-yl-1,3,5-triazine-2,4-diamine
Synonyms Ametryn; *N*-ethyl-*N*′-(1-methylethyl)-6-(methylthio)-1,3,5-triazine-2,4-diamine.
Proprietary Names *Ametrex*; *Evik*; *Gesapax*; *G-34162*.

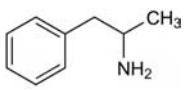


Chemical Properties Colourless crystals. Mp 84° to 86°. Very slightly soluble in water; soluble in chloroform and methanol.
Thin-layer Chromatography System TA—R_f 0.76; system TX—R_f 0.26; system TY—R_f 0.23 (dragendorff spray, positive).
Gas Chromatography System GA—RI 1879.
Infrared Spectrum Principal peaks at wavenumbers 1515, 1595, 1294, 1166, 806, 1140 cm^{-1} (KBr disk).

Amfetamine

Phenethylamine, Stimulant (Central), Sympathomimetic
$C_9H_{13}N = 135.2$
CAS—300-62-9

IUPAC Name 1-Phenylpropan-2-amine
Synonyms Amphetamine; desoxynorephedrine.
Proprietary Names *Elastonon*; *Fenopromin*; *Mydrial*; *Phenamine*. It is an ingredient of *Biphetmaine* and *Durophet*.



Chemical Properties A colourless, mobile, slowly volatile liquid. It absorbs carbon dioxide from the air forming a violent carbonate. Bp 200° to 203°. Soluble 1 in 50 of water; soluble in ethanol and ether; readily soluble in acids. pK_a 9.9 [Baselt 2008]. Log *P* (octanol/water), 1.8 [Baselt 2008]. Extraction yield (chlorobutane), 0.5 [Demme *et al.* 2005].

Amfetamine Hydrochloride

$C_9H_{13}N,HCl = 141.7$
IUPAC Name 1-Phenylpropan-2-amine hydrochloride

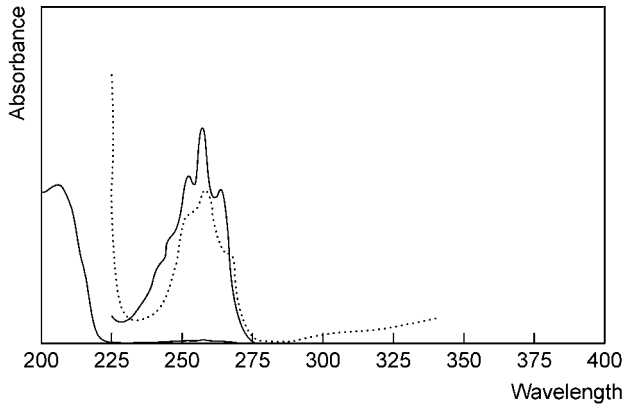
Amfetamine Phosphate

$C_9H_{13}N,H_3PO_4 = 233.2$
CAS—139-10-6
IUPAC Name 1-Phenylpropan-2-amine; phosphoric acid
Synonyms Amphetamine phosphate; monobasic racemic amphetamine phosphate.
Proprietary Names *Dynaphenil*; *Monophos*; *Profetamine*.
Chemical Properties A white crystalline powder with no characteristic melting point; it sinters at ~150° and decomposes at ~300°. Freely soluble in water; slightly soluble in ethanol; practically insoluble in benzene, chloroform and ether.

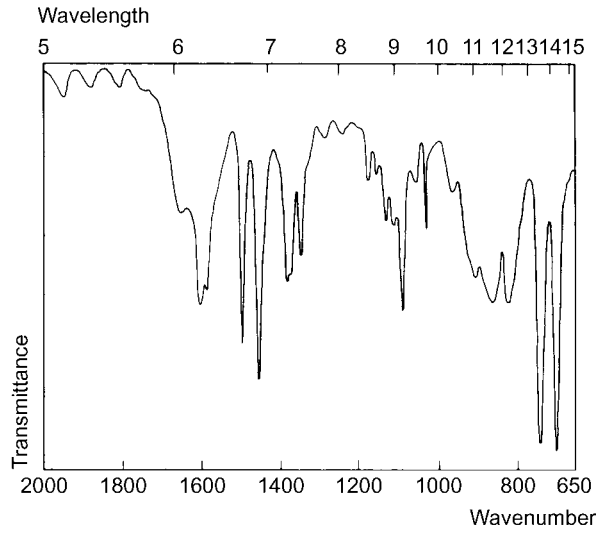
Amfetamine Sulfate

$(C_9H_{13}N)_2,H_2SO_4 = 368.5$
CAS—60-13-9
IUPAC Name 1-Phenylpropan-2-amine sulfuric acid
Synonym Amphetamine sulfate
Proprietary Names *Benzedrine*; *Benzpropamine*; *Centramina*; *Fabedrine*; *Fenamin*; *Phenaminum*; *Phenopromin*; *Sympamine*. It is an ingredient of *Adderall*, *Epipropane* and *Ortenal*.
Chemical Properties A white crystalline powder. Mp above 300°, with decomposition. Soluble 1 in 9 of water and 1 in 515 of ethanol; practically insoluble in chloroform and ether.

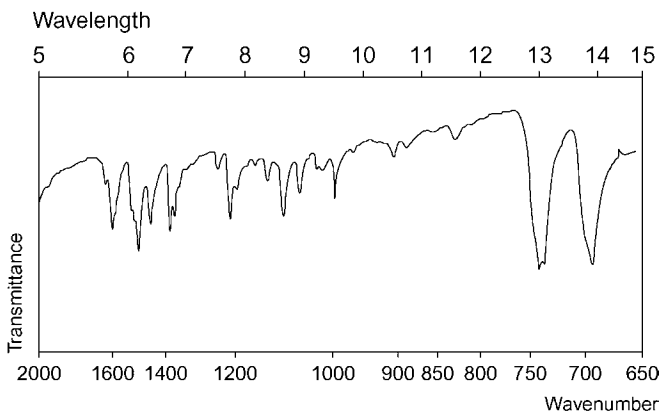
Colour Test Liebermann's reagent—red-orange; Marquis test—orange→brown; ninhydrin—pink-orange.
Thin-layer Chromatography System TA—R_f 0.43; system TB—R_f 0.20; system TC—R_f 0.09; system TE—R_f 0.43; system TL—R_f 0.18; system TAE—R_f 0.12; system TAF—R_f 0.75 (acidified iodoplatinate solution—positive; acidified potassium permanganate solution—positive; Dragendorff spray—positive; FPN reagent— pink; Marquis test—brown; ninhydrin—positive).
Gas Chromatography System GA—RI 1125, amfetamine-trifluroacetic acid RI 1095, amfetamine-PFP RI 1330, amfetamine-TMS RI 1190, amfetamine-AC RI 1501, art (formyl) RI 1100, M (3-OH-)-PFP_2 RI 1520, M (3-OH-)-TMS_2 RI 1850, M (3-OH-)-AC_2 RI 1930, M (4-OH-) RI 1480, M (4-OH-)-AC_2 RI 1900, M (3,4-di-OH-)-AC_3 RI 2150, M (OH-methoxy-) RI 1465, M (OH-methoxy-)-AC_2 RI 2065, M (desamino-oxo-OH-)-AC RI 1520, M (desamino-oxo-OH-methoxy-) RI 1510, M (desamino-oxo-OH-methoxy-)-AC RI 1600, M (desamino-oxo-di-OH-)-AC_2 RI 1735; system GB—RI 1150art (formyl) RI 1142; system GC—RI 1536; system GF—RI 1315; system GAD—RT 7.5 min; system GAK—RT 4.9 min.
High Performance Liquid Chromatography System HA—*k* 0.9; system HB—*k* 8.48; system HC—*k* 0.98; system HX—RI 244; system HAA—RT 3.7 min; system HBC—RT 2.1 min; system HBD—RT 3.7 min.
Ultraviolet Spectrum Aqueous acid—251 nm, ($A\frac{1}{1}$ = 14a), 257 nm, 263 nm.



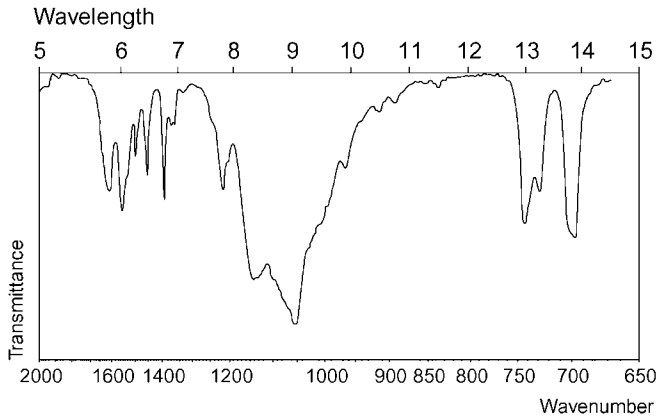
Infrared Spectrum Principal peaks at wave numbers 700, 740, 1495, 1090, 1605, 825 cm^{-1} (thin film, see below).



D-Amfetamine Hydrochloride

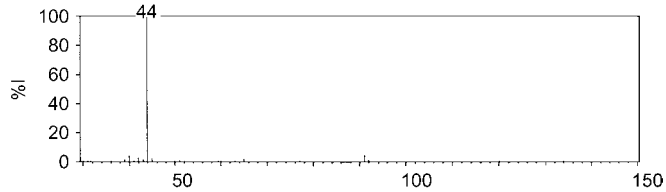


DL-Amfetamine Sulfate



A

Mass Spectrum Principal ions at *m/z* (amfetamine) 44, 91, 40, 42, 65, 45, 39, 43; (phenylacetone) 43, 91, 134, 92, 65, 39, 63, 135.



Quantification

Blood **GC-MS** Column: HP-5 MS (15 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He. Temperature programme: 60° for 1 min, to 220° at 20°/min. EI ionisation, SIM acquisition mode. Retention time: 4.66 min for amfetamine, 5.3 min for metamfetamine, 7.14 min for 3,4-methylenedioxymethamfetamine (MDMA) [Gunn *et al.* 2010]. Column: Supelco, PTE-5 (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 0.4 mL/min. Temperature programme: 60° for 3 min to 280° at 20°/min. EI ionisation, SIM acquisition mode. Limit of quantification, 0.5 ng/g for amfetamines and metamfetamine [Okajima *et al.* 2001]. Column: Supelco PTE-5 (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 60 kPa. Temperature programme: 60° for 3 min, to 280° at 20°/min. EI ionisation, SIM acquisition mode. Limit of detection, 10 ng/g [Namera *et al.* 2000]. Column: HP-5 MS capillary (30 m × 0.32 mm i.d.). El ionisation, SIM acquisition mode. Limit of quantification, 10 µg/L, limit of detection 0.5–8 µg/L [Marquet *et al.* 1997]. Column: fused silica (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 8 psi. Temperature programme: 45° for 3.5 min to 270° at 25°/min. EI ionisation, SIM acquisition mode. Limit of detection, 0.01 µg/g for amfetamine and metamfetamine [Nagasawa *et al.* 1996].

LC-MS Column: Varian Pursuit 3 C_{18} (100 × 3 mm i.d., 3 µm). Mobile phase: 2 mmol/L ammonium formate buffer: acetonitrile (pH 5.3, 92 : 8): methanol (97 : 3 for 3 min, to 80 : 20 over 4 min for 4 min to 70 : 30 over 6 min, to 10 : 90 over 13 min), flow rate 0.3 mL/min. MRM acquisition mode. Limit of quantification, 0.010 mg/g, limit of detection, 0.0008 mg/g [Bjork *et al.* 2010]. Column: Sphinx RP. Mobile phase: 10 mmol/L ammonium formate buffer : acetonitrile. Limit of quantification, 2.5 µg/L, limit of detection, 0.05–0.5 µg/L [Fernandez *et al.* 2009]. Column: Uptisphere ODB C_{18} (150 × 2.1 mm i.d., 5 µm). Mobile phase: acetonitrile : 2 mmol/L formate buffer (pH 3.0, 20 : 80 for 8 min to 90 : 10 over 5 min to 20 : 80 over 7 min), flow rate 250 µL/min. ESI, positive ion mode, MRM acquisition mode. Limit of quantification, 0.1 µg/L [Chèze *et al.* 2007]. Column: BEH C_{18} (50 × 2.1 mm). Mobile phase: aqueous pyrrolidine : methanol (52 : 48), flow rate 0.4 mL/min. Retention time: 1.32 min [Apollonio *et al.* 2006]. Column: Hypersil BDS-C_{18} (100 × 2.1 mm i.d., 3 µm). Mobile phase: acetonitrile : 0.001% formic acid (6 : 94 for 5 min to 50 : 50 over 10 min to 6 : 94 over 5 min for 15 min), flow rate 0.3 mL/min. Sonic spray ionisation. Limit of detection, 5 µg/L [Mortier *et al.* 2002].

Plasma **GC** Column: HP (25 m × 0.3 mm i.d., 1.05 µm). Carrier gas: He, 2 mL/min. Temperature programme: 105° for 0.50 min to 300° at 5°/min for 15 min. ECD. Limit of detection, <1 µg/L [Asghar *et al.* 2001]. Column: HP-5 (25 m × 0.32 mm i.d., 0.52 µm). NPD. Limit of quantification, 1 µg/L, limit of detection, 1 µg/L [Cheung *et al.* 1997].

GC-MS See Blood [Gunn *et al.* 2010]. Column: HP-5 MS (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1.0 mL/min. Temperature programme: 80° to 280° at 20°/min for 1.5 min. EI ionisation, SIM acquisition mode. Limit of detection not reported [Kronstrand *et al.* 2003]. Column: SGE-BPX5 (15 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1.5 mL/min. Temperature programme: 100° for 1 min to 180° at 40°/min to 195° at 5°/min to 310° at 40°/min for 2 min. NICI, SIM acquisition mode. Limit of quantification, 0.049 µg/L for (*R*)-(−)-amfetamine and 0.195 µg/L for (*S*)-(+)-amfetamine [Leis *et al.* 2003]. Column: HP-5 MS (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 0.6 mL/min. Temperature programme: 100° to 250° at 10°/min to 310° at 30°/min for 1 min. EI ionisation, SIM acquisition mode. Limit of quantification, 5 µg/L [Peters *et al.* 2003a]. Column: HP-5 MS (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1.0 mL/min. Temperature programme: 100° to 180° at 30°/min to 230° at 5°/min to 310° at 30°/min. NICI, SIM acquisition mode. Limit of detection not reported [Peters *et al.* 2003b].

HPLC Fluorescence detection. Limit of detection, 0.87 µg/L for amfetamine and metamfetamine [Nakashima *et al.* 2003]. Column: MetaSil Basic (100 × 2 mm i.d., 3 µm). Mobile phase: 0.1% formic acid: methanol (73 : 27), flow rate 0.25 mL/min. APCI, positive ion mode, MRM acquisition mode. Limit of quantification, 0.2 µg/L [Slawson *et al.* 2002]. Column: ODS. Mobile phase: acetonitrile : citrate buffer (55 : 45). UV detection. Limit of detection, 20 µg/L [Farrell, Jefferies 1983].

LC-MS Column: Alltima RP C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : 5 mmol/L formic acid (10 : 90 for 2 min to 25 : 75 in 16 min to 30 : 70 in 0.1 min to 100 : 0 over 12 min), flow rate 1.0 mL/min. Positive ion mode, MRM acquisition mode. Limit of quantification, 1.0 µg/L, limit of detection, 0.6 µg/L [Sergi *et al.* 2009]. Column: Atlantis dC_{18} (100 × 2.1 mm i.d., 3 µm). Mobile phase: acetonitrile : ammonium formate buffer (5 : 95 for 1 min, to 50 : 50 in 10 min for 1 min, to 5 : 95 in 1 min for 4 min), flow rate 0.2 mL/min. ESI, SIM acquisition mode. Limit of quantification, 2 µg/L, limit of detection, 0.5–1 µg/L [Concheiro *et al.* 2006]. Column: Hypersil BDS-C_{18} (100 × 2.1 mm i.d., 3 µm). Mobile phase: 10 mmol/L ammonium acetate : acetonitrile. ESI, positive ion mode, MRM acquisition mode. Limit of quantification, 0.5 µg/L, limit of detection, 0.5 µg/L [Wood *et al.* 2003].

Serum **GC-MS** See Blood [Gunn *et al.* 2010]. Column: DB-5 MS (30 m × 0.32 mm i.d., 1.0 µm). Carrier gas: He. Temperature programme: 130° for 2 min, to 320° at 15°/min for 3 min. SIM acquisition mode. Limit of detection not reported [Kankaanpää *et al.* 2004]. Column: DB-5 MS (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1 mL/min. Temperature programme: 60° to 120° at 30°/min to 180° at 20°/min to 250° at 30°/min for 0.5 min. SIM acquisition mode. Limit of detection, 0.6 µg/L [Lee *et al.* 2000]. Column: DB-5 MS (30 m × 0.25 mm i.d., 0.25 µm). Temperature programme: 80° for 1 min to 200° at 20°/min to 240° at 5°/min to 310° at 30°/min for 6 min. SIM acquisition mode. Limit of quantification, 4.9 µg/L, limit of detection, 1.5 µg/L [Weinmann *et al.* 2000].

HPLC Superspher 100 RP C_{18} (125 × 3 mm i.d., 4 µm). Mobile phase: acetonitrile : 50 mmol/L ammonium formate buffer (25 : 75), flow rate 0.3 mL/min. APCI, SIM acquisition mode. Limit of detection, 2 µg/L [Bogusz *et al.* 2000]. Column: Superspher Select B (125 × 3 mm i.d.). Mobile phase: 50 mmol/L ammonium formate buffer (pH 3.0) : acetonitrile (60 : 40), flow rate 0.8 mL/min. UV detection (λ= 250 nm). Limit of detection, 30 µg/L [Bogusz *et al.* 1997]. Column: Superspher Select B (125 × 3 mm i.d.). Mobile phase: 50 mmol/L ammonium formate buffer (pH 3.0) : acetonitrile (60 : 40), flow rate 0.8 mL/min. DAD. Limit of detection, 100 µg/L [Bogusz *et al.* 1997].

Urine **GC** Column: HP-5 (300 × 32 mm i.d., 0.25 µm). Carrier gas: He, 1.5 mL/min. Temperature programme: 140° to 300° at 20°/min. PDHID. Limit of detection, 0.5 mg/L [Casari, Andrews 2001]. See Plasma. Limit of quantification, 20 µg/L, limit of detection, 1 µg/L [Cheung *et al.* 1997]. NPD. Limit of quantification, 0.05 mg/L [Jonsson *et al.* 1996]. Column: DB-5 MS (150 × 2.5 mm i.d.). Carrier gas: He, 1 mL/min. Temperature programme: 70° to 200° at 15°/min. FTIR. Limit of quantification, 20 µg/L, limit of detection, 10 µg/L [Kalasinsky *et al.* 1993]. ECD. Limit of detection, 10 µg/L [Terada *et al.* 1982]. See also Ugland *et al.* [1999], Ugland *et al.* [1997] and Van Bocxlaer *et al.* [1997].

GC-MS Column: DB-5 MS (5 m × 100 µm i.d., 0.1 µm). Carrier gas: He, 0.6 mL/min. Temperature programme: 85° to 115° at 62°/min for 0.8 min to 300° at 65°/min for 0.52 min. SIM acquisition mode. Limit of detection, 6.25 µg/L [Marais, Laurens 2009]. Column: HP-5 MS (150 mm). Temperature programme: 100° for 1.8 min to 200° at 15 to 30°/min. SIM acquisition mode. Limit of detection, 62.5 µg/L [Stout *et al.* 2002]. See Serum. Limit of quantification, 200 µg/L [Kankaanpää *et al.* 2004]. Column: HP-5 MS (300 × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 0.8 mL/min. Temperature programme: 100° for 1 min to 300° at 10°/min for 3 min. EI ionisation, SIM acquisition mode. Limit of detection, 5 µg/L [Nishida *et al.* 2003]. Column: HP-5 MS (300 × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1 mL/min. Temperature programme: 90° for 3 min to 280° at 20°/min for 3 min. SIM acquisition mode. Limit of quantification, 1.0 µg/L, limit of detection, 0.3 µg/L [Huang *et al.* 2002]. See also Centini *et al.* [1996], Dallakian *et al.* [1996], Dasgupta, Spies [1998], Hensley, Cody [1999], Jurado *et al.* [2000], Karacic, Skender [2000], McCambly *et al.* [1997], Myung *et al.* [1998], Namera *et al.* [2002], Pellegrini *et al.* [2002], Valentine *et al.* [1995], Wang *et al.* [2001] and Yashiki *et al.* [1995].

HPLC Column: Supelcosil LC-CN (33 × 4.6 mm i.d., 3 µm). Mobile phase: acetonitrile : 50 mmol/L ammonium acetate (15 : 85), flow rate 0.4 mL/min. ESI, SIM acquisition mode. Limit of quantification, 13 µg/L [Wu *et al.* 2001]. Column: RP C_{18} ODS (250 × 4 mm i.d.). Mobile phase: tetrahydrofuran : acetonitrile : 0.1% TEA (15 : 15 : 70). UV detection (λ= 260 nm). Limit of detection, 10 µg [Veress 2000]. Column: ODS. Mobile phase: 0.1 mol/L Tris-hydrochloride buffer (pH 7.0) : acetonitrile (45 : 55), flow rate 0.2 mL/min. Fluorescence detection [[Al-Dirbashi *et al.* 2000a]. UV detection. Limit of quantification, 47 µg/L, limit of detection, 14 µg/L [Fisher, Bourque 1993]. See Plasma. Limit of detection, 4 µg/L [Farrell, Jefferies 1983]. See also Campins-Falcó [1995], Campins-Falcó *et al.* [1996], Al-Dirbashi *et al.* [1997], Al-Dirbashi *et al.* [1998], Katagi *et al.* [1996] and Molins Legua *et al.* [1995].

LC-MS See Blood. Limit of quantification, 25 µg/L, limit of detection, 0.25–2.5 µg/L [Fernandez *et al.* 2009]. Column: CAPCELL PAK C_{18} MG-II (150 × 2.0 mm i.d., 5 µm). Mobile phase: 5 mmol/L ammonium formate : acetonitrile (95 : 5 to 20 : 80 in 8 min for 1 min), flow rate 0.23 mL/min. ESI, MRM acquisition mode. Limit of quantification, 5.0 µg/L, limit of detection, 0.87 µg/L [Kim *et al.* 2008]. See Blood [Chèze *et al.* 2007]. Column: Symmetry Shield RP C_{18} (150 × 2.1 mm i.d., 5 µm). Mobile phase: acetronitrile : 0.05% trifluoroacetic acid (10 : 90), flow rate 0.2 mL/min. MRM acquisition mode. Limit of quantification, 5 µg/L, limit of detection, 1 µg/L [Fuh *et al.* 2006]. Column: Symmetry Shield RP C_{18} (50 × 2.1 mm i.d., 3.5 µm). MRM acquisition mode. Limit of quantification, 9.1 µg/L, limit of detection, 2.8 µg/L [Wu, Fuh 2005].

Bile **GC-MS** See Vitreous Humour [Kiely *et al.* 2009].

LC-MS Column: Shiseido CAPCELL PAK SCX80 (250 × 1.5 mm i.d.). Mobile phase: 25 mmol/L ammonium acetate (pH 4.0) : acetonitrile (3 : 7), flow rate 0.2 mL/min. ESI, SRM acquisition mode. Limit of detection not reported [Kuwayama *et al.* 2008].

CSF **GC-MS** SIM acquisition mode [Narasimhachari *et al.* 1979].

Meconium **GC-MS** Column: HP-5 MS (15 m × 0.25 mm i.d., 0.25 µm). Temperature programme: 120° for 5 min, to 260° at 35°/min for 0.5 min. EI ionisation, SIM acquisition mode. Limit of quantification, 75 ng/g, limit of detection, 30 ng/g [Gunn *et al.* 2008]. DB-1 (10 m × 0.18 mm i.d., 0.4 µm). Temperature programme: 120° for 1 min to 150° at 5°/min. Limit of quantification, 100 ng/g, limit of detection, 50 ng/g [Elsohly *et al.* 1999].

LC-MS Column: Synergi Hydro RP (150 × 2 mm i.d., 4 µm). Mobile phase: 1 mmol/L ammonium formate, (pH 3.4) : acetonitrile and 5% 1 mmol/L ammonium formate (100 : 0 to 70 : 30 over 8 min, to 65 : 35 over 2 min for 1 min, to

100 : 0 over 2.5 min), flow rate 0.250 mL/min. MRM acquisition mode. Limit of quantification, 5 ng/g, limit of detection, 1 ng/g [Gray *et al.* 2009]. Column: Phenomenex Synergi Hydro RP (50 × 2.0 mm i.d., 2.0 µm). Mobile phase: 10 mmol/L ammonium acetate with 0.1% formic acid : acetonitrile with 0.1% formic acid (88 : 12), flow rate 0.6 mL/min. Limit of quantification, 0.6 ng/g, limit of detection, 0.2 ng/g [Jones *et al.* 2009]. Column: Synergi Polar RP (150 × 2.0 mm i.d., 4 µm). Mobile phase: 10 mmol/L ammonium acetate containing 0.01% formic acid : acetonitrile (90 : 10 for 1 min to 50 : 50 over 13 min for 2 min to 10 : 90 over 2 min for 2 min to 90 : 10 over 2 min), flow rate 200 µL/min. MRM acquisition mode. Limit of quantification, 12.5 ng/g, limit of detection, 4 ng/g [Kelly *et al.* 2008]. Column: C_{18}. Mobile phase: 10 mmol/L ammonium bicarbonate : methanol. SIM acquisition mode. Limit of quantification, 0.005 µg/g [Pichini *et al.* 2004].

HPLC Column: Supelcosil LC-18 DB C_{18} (150 × 4.6 mm i.d., 5 µm). Mobile phase: potassium dihyrogen phosphate : methanol : acetonitrile : tetrahydrofuran : TEA (600 : 100 : 25 : 7 : 1 : 5), flow rate 1 mL/min. DAD (λ = 204 nm). Limit of quantification, 0.5 µg/g [Franssen *et al.* 1994]

Milk **HPLC** Phenomenex Aqua C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : 45 mmol/L phosphate buffer (12 : 88), flow rate 1.2 mL/min. UV detection (λ = 200 nm). Limit of quantification, 3 mg/L [Bartu *et al.* 2009].

Oral Fluid **GC-MS** Column: DB-5 (30 × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1.0 mL/min. Temperature programme: 100° for 1 min to 230° at 10°/min for 10 min. SIM acquisition mode. Limit of detection, 100 µg/L [Meng, Wang 2010]. Column: Varian (15 m × 0.25 mm i.d.). Limit of quantification, 3 µg/L [Cone *et al.* 2007]. Column: HP-5 MS (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1 mL/min. Temperature programme: 100° to 190° at 30°/min, to 230° at 5°/min to 245° at 30°/min to 260° at 5°/min to 310° at 30°/min. NICI mode, SIM acquisition mode. Limit of detection not reported [Peters *et al.* 2007]. Column: HP-5 MS (30 m × 0.32 mm i.d., 0.25 µm). Carrier gas: He, 1.5 mL/min. Temperature programme: 70° to 170° at 25°/min for 2 min to 195° at 5°/min for 0.5 min to 300° at 30°/min for 1 min. EI ionisation, SIM acquisition mode. Limit of quantification, 5.0 µg/L, limit of detection, 2.5 µg/L [Scheidweiler, Huestis 2006]. See Serum. Limit of quantification, 5 µg/L [Kankaanpää *et al.* 2004].

LC-MS ESI. Limit of quantification, 0.4–5 µg/L [Fritch *et al.* 2009]. See Plasma. Limit of quantification, 1.5 µg/L, limit of detection, 0.5 µg/L [Sergi *et al.* 2009]. Column: Pinnacle II C_{18} (50 × 4.6 mm i.d., 5 µm). Mobile phase: 5 mmol/L ammonium acetate : methanol containing 0.1% formic acid, flow rate 1.2 mL/min. MRM acquisition mode. Limit of quantification, 10 µg/L, limit of detection, 10 µg/L [Kala *et al.* 2008]. Column: Atlantis dC_{18} (100 × 2.1 mm i.d., 3 µm). Mobile phase: acetonitrile : ammonium formate buffer (pH 3.0, 5 : 95 for 1 min to 50 : 50 in 10 min for 1 min to 5 : 95 in 1 min), flow rate 0.2 mL/min. ESI, SIM acquisition mode. Limit of quantification, 1 µg/L, limit of detection, 0.5 µg/L [Concheiro *et al.* 2007]. See Plasma [Wood *et al.* 2003].

Stomach Contents **GC-MS** See Vitreous Humour [Kiely *et al.* 2009]. Column: DB-5 (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 0.9 mL/min. Limit of detection not reported [Takekawa *et al.* 2007]. Column: DB-5 fused silica (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 0.8 mL/min. Temperature programme: 70° for 1 min, to 100° at 30°/min to 270° at 10°/min. Limit of detection not reported [Meyer *et al.* 1997].

Vitreous Humour **GC-MS** Column: DB-5 MS (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1.0 mL/min. Temperature programme: 80° to 120° at 40°/min to 240° at 10°/min for 5 min. Limit of detection not reported [Kiely *et al.* 2009].

HPLC Column: Hypersil BDS-C_{18} (100 × 2.1 mm i.d., 3 µm). Fluorescence detection (λ_{ex} = 288 nm, λ_{em} = 324 nm). Limit of quantification, 2.0 µg/L, limit of detection, 0.8 µg/L [Clauwaert *et al.* 2000].

LC-MS Column: Hypersil BDS-C_{18} (100 × 2.1 mm i.d., 3 µm). Limit of quantification, 2.0 µg/L, limit of detection, 0.8 µg/L [Clauwaert *et al.* 2000].

Bone and Bone Marrow **GC-MS** [Sato *et al.* 2000].

Brain **GC-MS** See Vitreous Humour [Kiely *et al.* 2009]. Column: HP-1 MS (3 m × 0.32 mm i.d., 0.25 µm). Carrier gas: He, 1.1 mL/min. Temperature programme: 70° for 1 min to 175° at 30°/min to 250° at 23°/min to 310° at 18°/min for 5 min. SIM acquisition mode. Limit of quantification, 50 ng/g, limit of detection, 50 ng/g [Lowe *et al.* 2006]. See Stomach Contents [Meyer *et al.* 1997].

Hair **GC** Column: CBJ-17. NPD. Limit of detection, 0.1 µg/g for amfetamine and and 0.4 µg/g for metamfetamine [Koide *et al.* 1998].

GC-MS Column: DB-5 MS (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1.1 mL/min. Temperature programme: 90° for 0.5 min to 150° at 25°/min for 1.5 min to 230° at 15°/min for 1 min to 300° at 40°/min for 1.3 min. EI ionisation, SIM acquisition mode. Limit of quantification, 0.1 µg/g, limit of detection, 0.027 µg/g [Kim *et al.* 2010a]. G&W Scientific Agilent Technologies 5% phenyl-MS (17 m × 0.2 mm i.d., 0.33 µm). Carrier gas: He, 20 psi. Temperature programme: 100° for 1 min to 140° at 8°/min to 310° at 30°/min for 2 min. Limit of quantification, 0.2 µg/g for (*R*)-(−) and (*S*)-(+)-enantiomers, limit of detection, 0.1 µg/g for (*R*)-(−) and (*S*)-(+)-enantiomers [Strano-Rossi *et al.* 2009]. Column: HP-5 MS (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1.0 mL/min. Temperature programme: 100° for 1 min to 300° at 10°/min for 3 min. Limit of detection, 1.6 µg/g [Nishida *et al.* 2006a]. See Plasma [Kronstrand *et al.* 2003]. See Urine. Limit of detection, 0.25 µg/g [Nishida *et al.* 2003]. See also Cirimele *et al.* [1995], Kintz *et al.* [1995], Liu *et al.* [2001], Musshoff *et al.* [2002], Rohrich, Kauert [1997] and Skender *et al.* [2002].

HPLC Column: SP-120-5-ODS-BP (250 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : methanol : water (30 : 40 : 30), flow rate 1.0 mL/min. Fluorescence detection (λ_{ex} = 325 nm, λ_{em} = 430 nm). Limit of detection, 11 ng/g [Kaddoumi *et al.* 2004]. See Plasma. Mobile phase: acetonitrile : methanol : citrate buffer (45 : 20 : 37.5). Limit of detection, 0.12 ng/g for amfetamine and metamfetamine [Nakashima *et al.* 2003]. See Urine. Limit of quantification, 0.06 µg/g [Wu *et al.* 2001]. Column: Chiralcel OD-RH (150 × 2 mm i.d.). Mobile phase: phosphate-citrate buffer (pH 4.0) containing sodium hexafluorophosphate : acetonitrile (43 : 57), flow rate 0.1 mL/min. Fluorescence detection (λ_{ex} = 330 nm, λ_{em} = 440 nm). Limit of detection, 54.0 ng/g [Al-Dirbashi *et al.* 2000b].

LC-MS See Blood. Limit of quantification, 14.7 ng/g [Chèze *et al.* 2007]. Column: Chiral DRUG (150 × 2 mm i.d.). Mobile phase: 2 mmol/L ammonium formate buffer (pH 5) in methanol : 2 mmol/L ammonium formate buffer (pH 5.0, 40 : 60 for 20 min to 95 : 5 over 55 min), flow rate 0.1 mL/min. ESI, SIM acquisition mode. Limit of detection, 0.05 µg/g for (*R*)-(−) and (*S*)-(+)-enantiomers [Nishida *et al.* 2006b]. Column: Betasil C_8. Mobile phase: water : acetonitrile containing 0.1% formic acid (80 : 20). MRM acquisition mode. Limit of quantification, 25 ng/g, limit of detection, 25 ng/g [Cairns *et al.* 2004]. Column: LiChroCART Purospher 60 RP C_{18} (125 × 4 mm i.d., 5 µm). Mobile phase: acetonitrile : water (100 : 0 to 60 : 40 at 15 min to 100 : 0 at 15.2 min for 5 min), flow rate 1 mL/min. APCI, SIM acquisition mode. Limit of detection, 0.10 µg/g [Stanaszek, Piekoszewski 2004]. Column: CAPCELL PAK SCX UG 80 (150 × 1.5 mm i.d., 5 µm). Mobile phase: 12.5 mmol/L ammonium acetate containing formic acid : acetonitrile (40 : 60), flow rate 0.15 mL/min. Positive ion mode, SIM acquisition mode. Limit of detection, 0.02 µg/g [Miki *et al.* 2003].

Kidney **GC-MS** See Stomach Contents [Meyer *et al.* 1997].

Liver **GC-MS** See Vitreous Humour [Kiely *et al.* 2009]. See StomachContents [Meyer *et al.* 1997].

Lung **GC-MS** [Sato *et al.* 2000]

Muscle **GC-MS** [Sato *et al.* 2000]. XTI-5 (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1.7 mL/min. Temperature programme: 60° for 1 min to 290° at 20°/min. SIM acquisition mode. Limit of detection not reported [Hara *et al.* 1997].

Nail Clippings **GC-MS** Column: DB-5 MS (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1 mL/min. Temperature programme: 90° for 3 min to 170° at 15°/min for 2 min to 210° at 25°/min for 1.5 min to 230° at 20°/min for 0.5 min, to 300° at 40°/min for 0.3 min. EI ionisation, SIM acquisition mode. Limit of quantification, 0.063 µg/g, limit of detection, 0.019 µg/g [Kim *et al.* 2010b]. Column: DB-5 MS (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1.1–1.4 mL/min. Temperature programme: 100° for 1 min to 150° at 20°/min for 1.5 min to 285° at 30°/min for 0.5 min to 300° at 30°/min for 2.5 min. EI ionisation, SIM acquisition mode. Limit of quantification, 0.1 µg/g, limit of detection, 0.016 µg/g [Kim *et al.* 2008]. HP-1 MS (30 m × 0.25 mm i.d., 0.25 µm). Temperature programme: 60° for 1 min to 300° at 20°/min for 1 min. Limit of detection, 0.2 µg/g [Lin *et al.* 2004]. See Hair. Limit of detection, 12.0 µg/g [Cirimele *et al.* 1995].

Placenta **GC-MS** Column: ZB-5 (15 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 0.8 mL/min. Temperature programme: 70° for 2 min, to 160° at 30°/min to 170° at 5°/min to 200° at 20°/min to 210° at 10°/min to 300° at 30°/min for 3 min. EI ionisation. Limit of quantification, 3.4 µg/L, limit of detection, 1.1 µg/L [Joya *et al.* 2010].

Disposition in the Body

Amfetamine is readily absorbed after oral or rectal administration. It is rapidly distributed extravascularly and taken up, to some extent, by red blood cells. The main metabolic reaction is oxidative deamination to form phenylacetone, which is then oxidised to benzoic acid and conjugated with glycine to form hippuric acid; minor reactions include aromatic hydroxylation to form 4-hydroxyamfetamine (an active metabolite), β-hydroxylation, which is stereoselective for the (+)-isomer of amfetamine, to form norephedrine (phenylpropanolamine), and *N*-oxidation to form a hydroxylamine derivative. The products of aromatic hydroxylation and *N*-oxidation may be conjugated with sulfate or glucuronic acid.

Excretion of amfetamine is markedly dependent on urinary pH, being greatly increased in acid urine. After large doses, amfetamine may be detected in urine for several days. Under uncontrolled urinary pH conditions, ~30% of the dose is excreted unchanged in the urine in 24 h and a total of ~90% of the dose is excreted in 3–4 days. The amount excreted unchanged in 24 h may increase to 74% of the dose in acid urine and decrease to 1 to 4% in alkaline urine; under alkaline conditions, hippuric acid and benzoic acid account for ~50% of the urinary material. Under normal conditions, 16–28% is excreted as hippuric acid, ~4% as benzoylglucuronide, 2–4% as 4-hydroxyamfetamine and ~2% as norephedrine in 24 h; small amounts of conjugated 4-hydroxynorephedrine and phenylacetone are also excreted. No elimination in the faeces has been detected.

Amfetamine is a metabolite of benzfetamine, metamfetamine and selegiline.

Therapeutic Concentration After normal therapeutic doses the plasma concentration is usually <0.1 mg/L. However, continued use of amfetamine may cause addiction, and ingestion of 10 times the usual therapeutic dose is common among addicts; in such cases the plasma concentration may be up to 3 mg/L.

The IV administration of 160 mg amfetamine to a regular user resulted in a plasma concentration of 0.59 mg/L after 1 h [Anggård *et al.* 1970].

After a single oral dose containing 10 mg amfetamine to 4 subjects, peak plasma concentrations of ~0.02 mg/L were attained [Wan *et al.* 1978].

Toxicity The estimated minimum lethal dose in non-addicted adults is 200 mg. Toxic effects may be produced with blood concentrations of 0.2–3 mg/L, and fatalities with concentrations greater than 0.5 mg/L. Death from overdosage are comparatively rare.

In a fatality caused by IV administration of amfetamine, the following postmortem tissue concentrations were reported: blood 41 mg/L, liver 23 µg/g and urine 39 mg/L [Adjutantis *et al.* 1975].

A

Urine concentrations of >0.5–320 mg/L (mean, 76) were reported in 11 fatalities caused by amfetamine [Holmgren, Lindquist 1975].

In a 22-year-old man who died of cardiorespiratory arrest following amfetamine ingestion, the following postmortem tissue concentrations were reported for racemic, (*R*)- and (*S*)-amfetamine, respectively: blood 2.44, 1.26 and 1.18 mg/L; urine 33.4, 16.7 and 16.7 mg/L; liver 11.7, 6.07 and 5.64 µg/g; kidney 3.85, 2.00 and 1.85 µg/g; and brain 5.50, 2.95 and 2.55 µg/g [Meyer *et al.* 1997].

Half-life Plasma half-life, 4 to 8 h when the urine is acidic and approx. 12 h in subjects whose urinary pH values are uncontrolled.

Volume of Distribution ≈3–4 L/kg.

Distribution in Blood Plasma : whole blood, 1.0

Protein Binding 15–40%.

Saliva Plasma : saliva ratio, ~0.35

Dose 20 to 100 mg of amfetamine sulfate daily has been used in the treatment of narcolepsy.

Note For a review of the toxicokinetics of amfetamines, see Kraemer, Maurer [2002]; for a study of the pharmacokinetic and pharmacodynamic drug interactions in the treatment of attention-deficit hyperactivity disorder, see Markowitz, Patrick [2001].

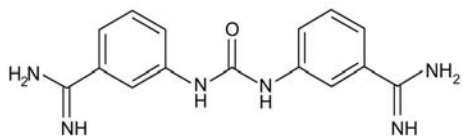
Amicarbalide

Antiprotozoal (Veterinary)
$C_{15}H_{16}N_6O$ = 296.3
CAS—3459-96-9

IUPAC Name 1,3-Bis(3-carbamimidoylphenyl)urea
3,3′-(Carbonyldiimino)bisbenzenecarboximidamide



Amicarbalide Isetionate

$C_{19}H_{28}N_6O_9S_2$ = 548.6
CAS—3671-72-5
Synonym M&B 5062A
Proprietary Name *Diampron*
Chemical Properties A white or slightly cream-coloured powder. Mp 200° to 204°. Soluble 1 in less than 1 of water and 1 in 250 of ethanol; practically insoluble in chloroform and ether.

Colour Tests Aromaticity (method 2)—yellow/orange; Liebermann's test (100°)—yellow.
Thin-layer Chromatography System TA—R_f 0.05, streaking (acidified iodoplatinate solution, positive).
Ultraviolet Spectrum Aqueous acid—231 nm (A^1_1=1236a), inflexion at 256 nm.
Infrared Spectrum Principal peaks at wavenumbers 1195, 1590, 1672, 1250, 1562, 1052 cm^{-1} (KBr disk).

A

Amidefrine

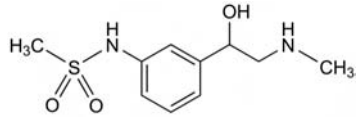
Sympathomimetic

$C_{10}H_{16}N_2O_3S = 244.3$

CAS—3354-67-4

IUPAC Name *N*-[3-[1-Hydroxy-2-(methylamino)ethyl]phenyl]methanesulfonamide

Synonyms Amidephrine; MJ-1996.



Chemical Properties Crystals. Mp 159° to 161°. pK_a 9.1.

Amidefrine Mesilate

$C_{10}H_{16}N_2O_3S,CH_3SO_3H = 340.4$

CAS—1421-68-7

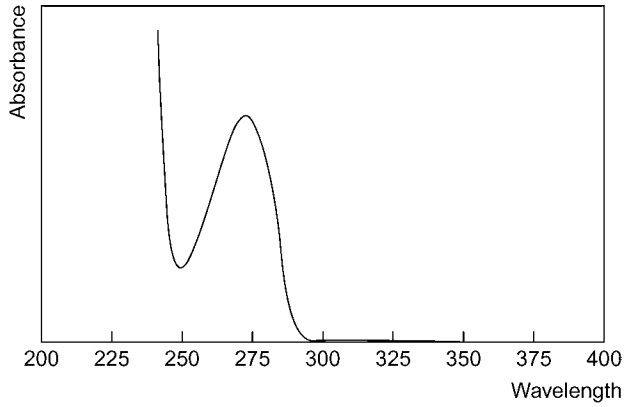
Chemical Properties A white crystalline solid. Mp 207° to 209°. Soluble 1 in about 5 of water; very slightly soluble in chloroform.

Colour Test Mandelin's test—violet.

Thin-layer Chromatography System TA—R_f 0.15; system TB—R_f 0.00; system TC—R_f 0.01; system TE—R_f 0.00; system TL—R_f 0.02; system TAE—R_f 0.01 (acidified potassium permanganate solution, positive).

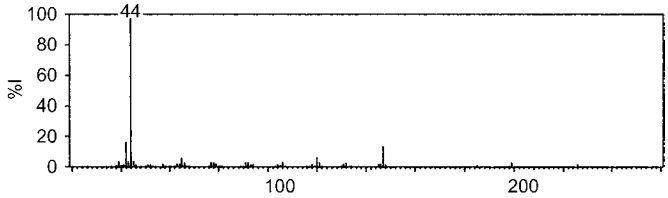
Gas Chromatography System GA—not eluted.

Ultraviolet Spectrum Aqueous acid—272 nm (A^1_1=22a).



Infrared Spectrum Principal peaks at wavenumbers 1101, 1153, 1270, 799, 1207, 1316 cm^{-1}.

Mass Spectrum Principal ions at *m/z* 44, 42, 147, 120, 65, 43, 45, 39.



Use A 0.1% solution of amidefrine mesilate has been used as a nasal decongestant.

Amifostine

Cytoprotective

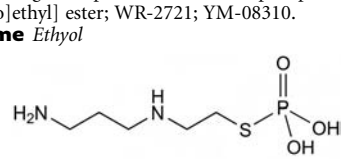
$C_5H_{15}N_2O_3PS = 214.2$

CAS—20537-88-6

IUPAC Name 2-(3-Aminopropylamino)ethylsulfanylphosphonic acid

Synonyms Ethiofos; gammaphos; NSC-296961; phosphorothioic acid *S*-[2-[(3-aminopropyl)amino]ethyl] ester; WR-2721; YM-08310.

Proprietary Name *Ethyol*



Chemical Properties A white to off-white crystalline powder. Mp 160°. It is freely soluble in water, >9 g/100 mL. pK_a(water), 10.14, 7.26. Log *P* (octanol/water), −1.07.

Thin-layer Chromatography (All systems are for the *S*-2-(3-aminopropylamino)-ethanethiol, WR-1065, metabolite.)

Plate 1: silica 60 (0.25 mm). Mobile phase: 0.50 mol/L sodium acetate buffer (pH 5.5): methanol (50 to 90%). R_f 0.03. Plate 2: alumina 60 (0.25 mm). Mobile phase 1: 0.50 mol/L sodium acetate buffer (pH 5.5): methanol (50 to 90%). R_f 0.70 (50% methanol), R_f 0.45 (60%) and R_f 0.03 (70 to 90%). Mobile phase 2: 0.1 mol/L phosphate buffer (pH 5.5): methanol (50 to 90%). R_f 0.03 [Mank *et al.* 1995].

Quantification

Blood **HPLC** Column: LC-ABZ Supelcosil (15 cm × 4.6 mm i.d., 5 µm). Mobile phase: methanol: 10 mmol/L ethylamine in 0.1 mol/L monochloroacetic acid (pH 2.8) (10:90), flow rate 1.0 mL/min. Fluorescence detection (λ_{ex}=385 nm, λ_{em}=515 nm). Retention time: 4.0 min for amifostine metabolite, WR-1065. Limit of detection, 0.25 mg/L [Bonner, Shaw 2000].

Disposition in the Body Amifostine is rapidly cleared from plasma with <10% remaining in plasma 6 min after administration. It is metabolised in the liver by alkaline phosphatase to the active free thiol metabolite, *S*-2-(3-aminopropylamino)-ethanethiol, WR-1065, and the inactive WR-33278 metabolite. <4% of the parent drug and metabolites are excreted in urine, WR-1065 is found in bone marrow.

Therapeutic Concentration

Five cancer patients were administered a 740 mg/m^2 dose of amifostine and 7 patients with 910 mg/m^2. Peak plasma levels of 0.10 and 0.24 nmol/L were reached [Shaw *et al.* 1994].

Toxicity Hypotension is the main toxic effect.

Half-life Elimination half-life is ~9 min.

Volume of Distribution Steady state between 3.5 and 7 L.

Clearance Plasma clearance 2.17 L/min.

Protein Binding Approximately 4%

Dose Usual dose given is 910 mg/m^2 body surface but can be reduced to 740 mg/m^2, if necessary.

Bonner HS, Shaw LM (2000). Measurement of both protein-bound and total S-2-(3-aminopropylamino)ethanethiol (WR-1065) in blood by high-performance liquid chromatography. *J Chromatogr Biomed Sci Appl* 739: 357–362.

Mank AJ *et al.* (1995). Determination of the anticancer drug metabolite WR1065 using pre-column derivatization and diode laser induced fluorescence detection. *J Pharm Biomed Anal* 13(3): 255–263.

Shaw L *et al.* (1994). *Proc Am Soc Cancer Res* 13144.

Amikacin

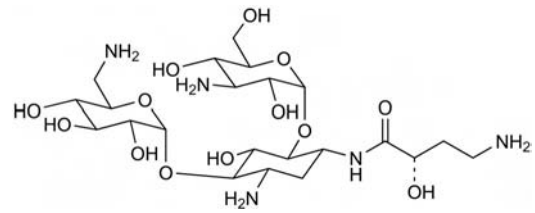
Antibacterial

$C_{22}H_{43}N_5O_{13} = 585.6$

CAS—37517-28-5

IUPAC Name (2S)-4-Amino-N-[(1R,2S,3S,4R,5S)-5-amino-2-[(2S,3R,4S,5S,6R)-4-amino-3,5-dihydroxy-6-(hydroxymethyl)oxan-2-yl]oxy-4-[(2R,3R,4S,5S,6R)-6-(aminomethyl)-3,4,5-trihydroxyoxan-2-yl]oxy-3-hydroxycyclohexyl]-2-hydroxybutanamide

Synonym *O*-3-Amino-3-deoxy-α-D-glucopyranosyl-(1→6)-*O*-[6-amino-6-deoxy-α-D-glucopyranosyl-(1→4)]-N^1-[(2*S*)-4-amino-2-hydroxy-1-oxobutyl]-2-deoxy-D-streptamine



Chemical Properties A white crystalline powder. Mp 201° to 204°, with decomposition. Sparingly soluble in water.

Amikacin Sulfate

$C_{22}H_{43}N_5O_{13},2H_2SO_4 = 781.8$

CAS—39831-55-5

Proprietary Names *Amiglyde-V*; *Amikin*; *BB-K8*; *Biklin*; *Lukadin*; *Mikavir*; *Novamin*; *Pierami*.

Chemical Properties Freely soluble in water.

Thin-layer Chromatography System TAE—R_f 0.00.

Ultraviolet Spectrum No significant absorption, 230 to 360 nm.

Infrared Spectrum Principal peaks at wavenumbers 1050, 1630, 1120, 1145, 1545, 940 cm^{-1} (KBr disk).

Quantification

Plasma **HPLC** Column: C_{18} µBondapak (300 × 3.9 mm, 10 µm). Mobile phase: acetonitrile: 2-methoxyethanol: tetrahydrofuran: glacial acetic acid: tris(hydroxymethyl): aminoethane (1% aqueous solution) (41:4:52:4:0.21:50). Flow rate 1.0 mL/min for 8.5 min; 0.5 mL/min to 19 min; 3.0 mL/min to 25 min; 1.0 mL/min for 5 min. Internal standard (IS): Cefepine. UV detection. Retention time(s): 16.5 min. Limit of quantification, 0.5 mg/L [Papp *et al.* 1992]. Fluorescence detection (λ_{ex}=340 nm; λ_{em}=418 nm). Limit of quantification, 25 µg/L [Wichert *et al.* 1991].

Serum **GC-MS** ECD. Limit of detection, amikacin, gentamicin and tobramycin, 600 µg/L [Mayhew, Gorbach 1978].

HPLC Fluorescence detection. Limit of detection 1 mg/L for amikacin, gentamicin and tobramycin [Anhalt, Brown 1978].

Urine **HPLC** See Plasma. Limit of quantification, 0.5 mg/L [Papp *et al.* 1992].
Note For a fluoroimmunoassay for amikacin, see Thompson and Burd [1980]. For a bioassay for aminoglycoside antibiotics, see Broughall [1978]. For a review of methods for the determination of aminoglycoside antibiotics, see Maitra *et al.* [1979].
Disposition in the Body Poorly absorbed after oral administration but rapidly absorbed after i.m. injection. About 90% of a dose is excreted in the urine unchanged in 24 h.
Therapeutic Concentration During treatment, the serum concentration should be in the range 15 to 25 mg/L and should be monitored regularly, especially in patients who have renal insufficiency. During multiple dosing, the trough concentration immediately preceding a dose should not exceed 10 mg/L.

A male patient aged 36 years with multi-drug resistant tuberculosis was administered 750 mg amikacin intravenously for 5 days. The mean peak concentration was 39.3 mg/L observed between 0.5 and 1.5 h. [Yew *et al.* 1999].

Eighteen patients with cystic fibrosis, aged 1.7 to 22.2 years, were administered a daily IV dose of 35 mg/kg amikacin over 30 min. The mean peak serum concentration was 121.4 mg/L (range 42.7 to 176 mg/L) after the 30 min and the trough concentration was 0.88 (0.2 to 1.9) mg/L. The peak concentration in sputum was 10.95 mg/L observed at 2 h which decreased slowly to a mean concentration of 2.14 mg/L just before the next infusion [Canis *et al.* 1997].

A patient received 300 mg of amikacin intravenously on its own over a 30-min infusion or in combination with 2000 mg cefepime. The mean plasma amikacin concentration was 27.4 mg/L when the drug was administered alone and 24.6 mg/L when in combination with cefepime. The peak concentrations were observed at the end of the infusion [Papp *et al.* 1992].

A single IM dose of 500 mg given to 6 subjects, produced a mean peak serum concentration of 20 mg/L in 1.5 h [Yates *et al.* 1978].

Toxicity Toxic effects may be produced at serum concentrations of 30 mg/L or more or, during chronic treatment, if the trough serum concentration exceeds 10 mg/L.

The following postmortem tissue concentrations were reported in a patient who died 5 days after discontinuation of amikacin treatment: serum 2.2 mg/L, heart 20 µg/g, kidney 794 µg/g, liver 30 µg/g, lungs 48 µg/g, muscle 11 µg/g [French *et al.* 1981].

Half-life Plasma half-life, 2 to 3 h.
Volume of Distribution About 0.2 L/kg.
Clearance Plasma clearance, about 1 mL/min/kg.
Protein Binding <10%.
Note For a review of the pharmacokinetics of amikacin, see Andrews [1977].
Dose The equivalent of 15 mg of amikacin/kg daily, given parenterally; maximum of 1.5 g daily. The total dose should not exceed 15 g.

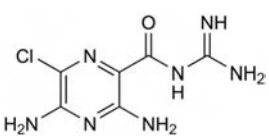
Amiloride

Diuretic
$C_6H_8ClN_7O$ = 229.6
CAS—2609-46-3

IUPAC Name 3,5-Diamino-6-chloro-*N*-(diaminomethylidene)pyrazine-2-carboxamide
Synonyms Amipramidin; amipramizide; 3,5-diamino-*N*-(aminoiminomethyl)-6-chloropyrazinecarboxamide; guanamprazine.

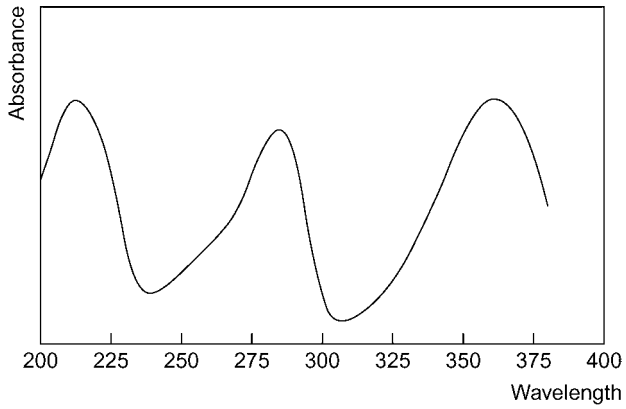


Chemical Properties Mp 240° to 242°. pK_a 8.7.

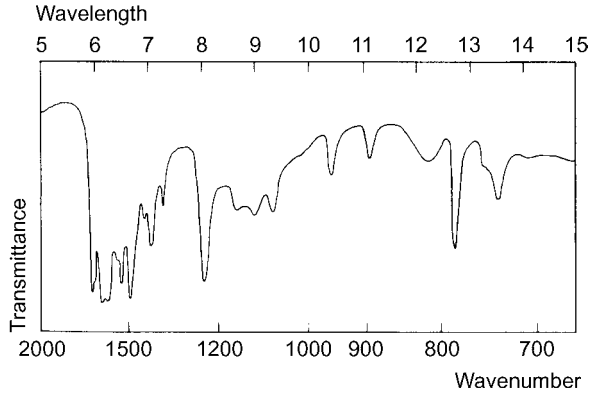
Amiloride Hydrochloride

$C_6H_8ClN_7O,HCl,\ 2H_2O$ = 302.1
CAS—2016-88-8 (anhydrous)
Synonym Amipramizide
Proprietary Names *Arumil*; *Midamor*; *Modamide*. It is an ingredient of *Amilco*, *Frumil*, *Moducren* and *Moduretic*.
Chemical Properties A pale yellow to greenish-yellow powder. Mp 285° to 288°, with decomposition. Soluble in water and ethyl acetate; soluble 1 in 350 of ethanol; practically insoluble in chloroform and ether.

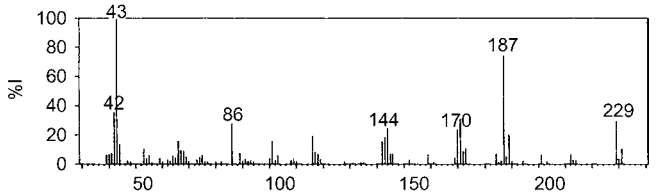
Colour Tests Marquis test—yellow; sulfuric acid—yellow.
Thin-layer Chromatography System TA—R_f 0.24; system TB—R_f 0.00; system TC—R_f 0.01; system TE—R_f 0.24; system TL—R_f 0.02; system TAD—R_f 0.00; system TAE—R_f 0.06; system TAF—R_f 0.74; system TAJ—R_f 0.00; system TAK—R_f 0.00; system TAL—R_f 0.29 (acidified iodoplatinate solution, strong reaction).
High Performance Liquid Chromatography System HY—RI 190; system HX—RI 257; system HAA—retention time 3.6 min.
Ultraviolet Spectrum Aqueous acid—285 (A^1_1=731a), 361 nm (A^1_1=802a).



Infrared Spectrum Principal peaks at wavenumbers 1634, 1602, 1504, 1686, 1238, 1538 cm^{-1} (amiloride hydrochloride, KBr disk).



Mass Spectrum Principal ions at *m/z* 43, 187, 42, 171, 229, 86, 144, 170.



Quantification
Plasma **TLC** See Reuter *et al.* [1982].

HPLC Fluorescence detection (λ_{ex}=360 nm; λ_{em}=413 nm). Limit of detection, 0.03 µg/L [Reeuwijk *et al.* 1992]. Fluorescence detection (λ_{ex}=286 nm; λ_{em}=418 nm). Limit of detection, 0.5 µg/L [Xu *et al.* 1991].

Spectrofluorimetry See Baer *et al.* [1967].
Serum **Spectrofluorimetry** See Plasma [Baer *et al.* 1967].
Urine **GC-MS** Limit of detection, 4 mg/L [Bi *et al.* 1992].

HPLC UV detection (λ=363, 213 and 285 nm). Limit of detection, 0.12 mg/L [Bi *et al.* 1992]. Fluorescence detection (λ_{ex}=286 nm; λ_{em}=418 nm). Limit of detection, 0.5 µg/L [Xu *et al.* 1991]. DAD. Limit of detection, 1.0 mg/L [Park *et al.* 1990].

Spectrofluorimetry See Plasma Baer *et al.* [1967].
Disposition in the Body Incompletely absorbed after oral administration; it does not appear to be metabolised. About 50% of an oral dose is excreted unchanged in the urine and 40% is eliminated in the faeces in 72 h.

A

Therapeutic Concentration

Eight healthy subjects aged 22 to 33 years (mean 25 years) inhaled 1 mg/mL (a volume of 4.5 mL in container) amiloride for 12 min. The mean volume aerolised was 3.5 mL in the 12 min. The peak plasma concentrations of amiloride were 3.36 µg/L after 30 min [Noone *et al.* 1997].

Six adult subjects were administered 10 mg amiloride as a Chinese formulation and an imported formulation. After 4 h, the peak plasma amiloride concentration was 27.76 µg/L for the Chinese and 23.17 µg/L for the imported formulations, respectively. After 24 h, the plasma concentrations had decreased to 5.76 µg/L and 3.57 µg/L, respectively [Xu *et al.* 1991].

After a single oral dose of 20 mg to 6 subjects, peak serum concentrations of about 0.05 mg/L were attained in 4 h [Smith, Smith 1973].

Half-life Plasma half-life, 6 to 10 h.

Volume of Distribution About 5 L/kg.

Protein Binding Not significantly bound.

Dose 5 to 20 mg of amiloride hydrochloride daily.

Baer JE *et al.* (1967). The potassium-sparing and natriuretic activity of N-amidino-3,5-diamino-6-chloropyrazinecarboxamide hydrochloride dihydrate (amiloride hydrochloride). *J Pharmacol Exp Ther* 157: 472–485.

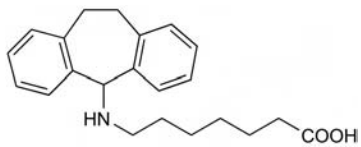
Amineptine

CNS Stimulant, Dopamine Reuptake Inhibitor, Tricyclic Antidepressant

$C_{22}H_{27}NO_2 = 337.5$

CAS—57574-09-1

Synonym 7-[10,11-Dihydro-5*H*-dibenzo[*a*,*d*]-cyclohepten-5-ylamino]heptanoic acid



Chemical Properties Log P (octanol/water), 2.66 [Meylan, Howard 1995].

Amineptine Hydrochloride

$C_{22}H_{28}ClNO_2 = 373.9$

CAS—30272-08-3

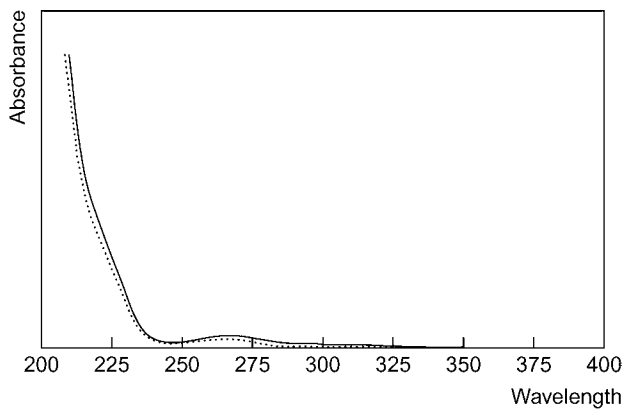
Synonyms S-1694

Proprietary Names *Maneon*; *Survector*.

Chemical Properties Crystals from distilled water. Mp 226° to 230°.

High Performance Liquid Chromatography System HAA—RT 14.0 min.

Ultraviolet Spectrum Aqueous acid—266 nm.



Mass Spectrum Principal peaks at *m/z* 191, 192, 207, 208, 209.

Quantification

Blood **HPLC** Column: Polygosil C_{18} (250 × 4.6 mm i.d., 10 µm). Mobile phase: M/400 TEA–trifluoroacetic acid (pH 2.0) : acetonitrile (100 : 0 to 20 : 80), flow rate 1 mL/min. DAD. Limit of detection not reported [Grislain *et al.* 1990].

Plasma **GC-MS** Column: fused silica capillary OV-1 (25 m × 0.35 mm i.d., 0.20 µm). Carrier gas: N_2, 20 mL/min. EI ionisation at 35 eV. Limit of detection not reported [Tsaconas *et al.* 1989].

HPLC Column: µBondapak C_{18} (300 × 3.9 mm i.d., 10 µm). Mobile phase: acetonitrile : 0.025 mol/L potassium dihydrogen phosphate (45 : 55), flow rate 0.8 mL/min UV detection (λ = 210 nm). *k*: amineptine 1.47, metabolite 0.93. Limit of detection, <0.05 mg/L [Rop *et al.* 1990]. Column: Nucleosil C_{18} (150 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : water (38 : 62). UV detection (λ = 220 nm). Limit of detection, ≥0.01 mg/L [Lachatre *et al.* 1989]. Column: Nucleosil C_{18} (150 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : water (38 : 62). UV detection (λ = 220 nm). Limit of detection, 10 µg/L [Nicot *et al.* 1984].

Disposition in the Body Amineptine is rapidly absorbed and metabolised to produce 7 metabolites. Metabolism is mainly via β-oxidation of the heptanoic side-chain, resulting in pentanoic and propanoic side-chain metabolites, and hydroxylation of the dibenzocycloheptyl ring to produce 2 diestereoisomers. *N*-Dealkylation of the lateral alkyl chain can also occur to produce dibenzosuberamine (DBZ), which is only found as a trace. Elimination is mainly (70–75%) via urine and complete within ~12 h [Grislain *et al.* 1990].

Therapeutic Concentration

Six healthy males and 6 females, aged between 23 and 46 years, were administered a single dose of 100 mg amineptine hydrochloride. Mean peak plasma concentrations of 0.28–2.22 mg/L amineptine were reached within 0.36–1.40 h. Peak plasma concentrations of the metabolites reached 0.14–1.07 mg/L within 0.44–2.32 h. No significant differences were observed between males and females [Lachatre *et al.* 1989].

Ten healthy volunteers were administered a single oral dose of 200 mg amineptine. Peak plasma concentrations were reached within 1 h, and blood concentrations had fallen below the limit of quantification after 4 h. The amineptine metabolite appeared ~30 min after administration of amineptine and the peak concentration occurred after ~1 h. The concentrations of the metabolite decreased more slowly than the parent compound and could still be found in the blood 10 h after administration [Riché *et al.* 1989].

Six healthy volunteers (5 men, 1 woman) were administered 200 mg amineptine in capsule form. Peak blood concentrations were reached within an hour and decreased and were no longer detectable 240 min after administration. Three of the same volunteers took 300 mg as 3 × 100–mg tablets three times daily for 10 days. Elimination half-lives were 106 ± 10 min for the capsule and 90 ± 7 min for the tablet [Sbarra *et al.* 1981].

Toxicity Severe acne-type lesions are associated with chronic self-administration of high doses (200–1000 mg) [Grimalt *et al.* 1999; Vexiau *et al.* 1988; Vexiau *et al.* 1990]. Amineptine-induced acne, like other iatrogenic acne, is dose dependent and usually appears in adulthood [Bettoli *et al.* 1998]. Lesions occur mainly on the face, back and thorax but also on the extremities and in the perineal region [Farella *et al.* 1996]. Inflammatory lesions are usually absent or scarce [De Gálvez Aranda *et al.* 2001]. Amineptine produces toxic hepatitis after therapeutic doses [Lazaros *et al.* 1996; Ricca Rosellini *et al.* 1990; Sebastián Domingo *et al.* 1994], which can be linked to genetic polymorphism [Larrey *et al.* 1989].

Note For 2 cases of amineptine addiction, see Biondi *et al.* [1990]; for a review of the pharmacology of amineptine, see Garattini [1997].

Half-life 0.5–1.2 h.

Volume of Distribution Apparent, 0.8–4.0 L/kg.

Clearance Plasma clearance, 124.8 L/h.

Dose A usual dose of 100 to 200 mg is administered daily.

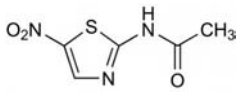
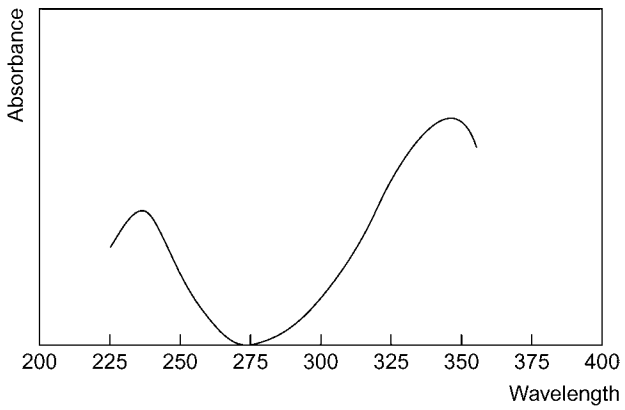
Aminitrozole

Antiprotozoal
$C_5H_5N_3O_3S$ = 187.2
CAS—140-40-9

IUPAC Name N-(5-Nitro-1,3-thiazol-2-yl)acetamide
Synonyms Acinitrazole; nithiamide; *N*-(5-nitro-2-thiazolyl)acetamide.
Proprietary Names *Enheptin-A*; *Trichorad*; *Tricosil*; *Trigamma*; *Tritheon*.



Chemical Properties A buff or yellowish-buff powder. Mp 264° to 265°; slight decomposition may occur. Very slightly soluble in water; soluble 1 in 300 of ethanol and 1 in 900 of chloroform; slightly soluble in ether; soluble in aqueous solutions of sodium hydroxide and ammonia.
Colour Test Methanolic potassium hydroxide—orange.
Thin-layer Chromatography System TA—R_f 0.80 (acidified potassium permanganate solution, positive).
Ultraviolet Spectrum Aqueous acid—237, 345 nm (A^1_1=435b).

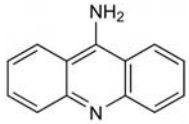


Infrared Spectrum Principal peaks at wavenumbers 1314, 1176, 1709, 1215, 818, 740 cm^{-1}.
Dose Aminitrozole has been given in doses of 200 to 400 mg daily.

Aminoacridine

Antiseptic
$C_{13}H_{10}N_2$ = 194.2
CAS—90-45-9

IUPAC Name Acridin-9-amine
Synonym 9-Acridinamine; aminacrine.



Chemical Properties Yellow needles. Mp 241°. Freely soluble in ethanol; soluble in acetone; slightly soluble in chloroform. pK_a 9.5 (25°).

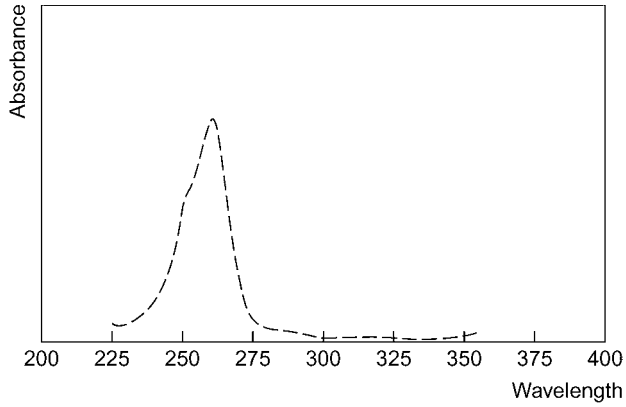
Aminoacridine Hexylresorcinate

$C_{13}H_{10}N_2,C_{12}H_{18}O_2$ = 388.5
CAS—7527-91-5
Synonyms Acrisorcin; aminoacridine 4-hexylresorcinate.
Chemical Properties A yellow crystalline powder. Slightly soluble in water and ethanol.

Aminoacridine Hydrochloride

$C_{13}H_{10}N_2$,HCl, H_2O = 248.7
CAS—134-50-9 (anhydrous)
Synonym Acramine Yellow
Proprietary Names *Aminopt*; *Monacrin*.
Chemical Properties A yellow crystalline powder. Mp about 235°. Soluble 1 in 300 of water; a saturated solution in water is pale yellow with a greenish-blue fluorescence, becoming blue when freely diluted. Soluble 1 in 150 of ethanol; practically insoluble in chloroform and ether.

Colour Tests Aromaticity (method 2)—yellow/red; Liebermann's reagent (100°)—red. Cold nitric acid gives a red colour in 15 s.
Thin-layer Chromatography System TA—R_f 0.54; system TB—R_f 0.00; system TE—R_f 0.57; system TAE—R_f 0.09 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—RI 2240.
High Performance Liquid Chromatography System HX—RI 320.
Ultraviolet Spectrum Aqueous acid—260 (A^1_1=4442a), 313 (A^1_1=74b), 326 nm (A^1_1=81b); methanol—260 (A^1_1=4480b), 311, 325 nm.

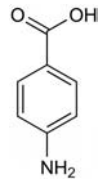


Infrared Spectrum Principal peaks at wavenumbers 760, 1556, 1645, 1655, 750, 1612 cm^{-1} (KBr disk).

Aminobenzoic Acid

Sunscreen Agent
$C_7H_7NO_2$ = 137.1
CAS—150-13-0

IUPAC Name 4-Aminobenzoic acid
Synonyms Amben; PAB; PABA; pabacidum; para-aminobenzoic acid; vitamin H′.
Proprietary Names *Hill-Shade*; *Pabagel*; *Pabanol*; *Paraminan*; *Presun 8*; *RVPaba*.

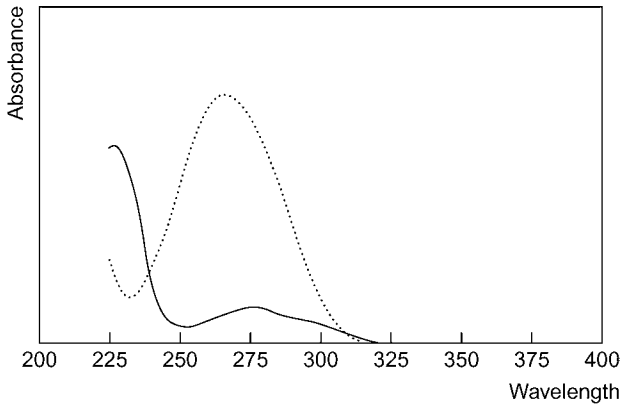


Chemical Properties White or slightly yellow crystals or crystalline powder. It gradually darkens on exposure to air and light. Mp 186° to 189°. Soluble 1 in 200 of water, 1 in 10 of boiling water, 1 in 8 of ethanol, and 1 in 50 of ether; slightly soluble in chloroform; freely soluble in solutions of alkali hydroxides and carbonates. pK_a 2.4, 4.9 (25°).

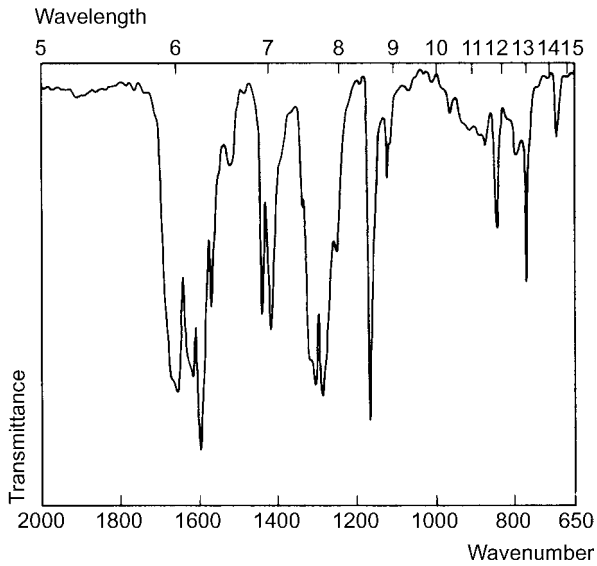
Potassium Aminobenzoate

$C_7H_6KNO_2$ = 175.2
CAS—138-84-1
Proprietary Name *Potaba*
Chemical Properties A crystalline powder. Very soluble in water; less soluble in ethanol; practically insoluble in ether.

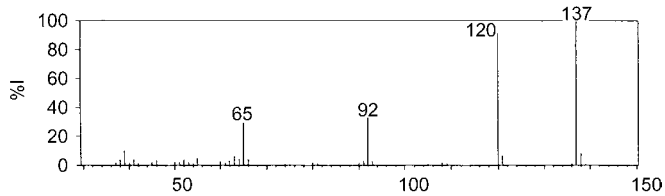
Colour Tests Coniferyl alcohol—orange; diazotisation—red.
Thin-layer Chromatography System TA—R_f 0.58; system TD—R_f 0.19; system TE—R_f 0.01; system TF—R_f 0.43; system TAD—R_f 0.31; system TAJ—R_f 0.44; system TAK—R_f 0.44; system TAL—R_f 0.83 (*p*-aminobenzoic acid) (acidified potassium permanganate solution, positive; Van Urk reagent, yellow).
Gas Chromatography System GA—RI 1547.
High Performance Liquid Chromatography System HY—RI 66 (*m*-aminobenzoic acid), RI 235 (*o*-aminobenzoic acid), RI 212 (*p*-aminobenzoic acid).
Ultraviolet Spectrum Aqueous acid—270 nm (A^1_1=95b); aqueous alkali—265 nm (A^1_1=1063a).



Infrared Spectrum Principal peaks at wavenumbers 1597, 1168, 1290, 1665, 1305, 1625 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 137, 120, 92, 65, 39, 138, 121, 63.



Quantification
Serum **HPLC** UV detection. Aminobenzoic acid and metabolites [Brown, Michalski 1976].
Urine **HPLC** Column: C_{18} Separon-6 RP (150 × 3.2 mm i.d., 5 µm). Mobile phase: methanol: 0.02 mol/L ammonium acetate (20:80 pH 4), flow rate 0.5 mL/min. UV detection (λ=280 nm). *k* value: *p*-aminobenzoic acid, 1.86; *m*-hydroxybenzoic acid, 2.74; *N*-acetyl-*p*-aminobenzoic acid, 3.89. Limit of detection, 12.5 mg/L [Kastel *et al.* 1994]. See Serum [Brown, Michalski 1976].
Disposition in the Body Aminobenzoic acid is readily absorbed after oral administration. It is conjugated with aminoacetic acid to form *p*-aminohippuric acid which is excreted in the urine together with a small amount of *p*-aminobenzoyl glucuronide, *p*-acetamidobenzoyl glucuronide, and traces of *p*-acetamidohippuric acid, *p*-acetamidobenzoic acid and unchanged aminobenzoic acid.

Aminobenzoic acid may be detected in the urine as a metabolite of tetracaine, benzocaine and procaine.
Toxicity Toxic effects are infrequent and are usually associated with plasma concentrations greater than about 600 mg/L.
Uses Aminobenzoic acid is used topically as a 5% solution; potassium aminobenzoate has been given orally, in doses of 12 g daily.

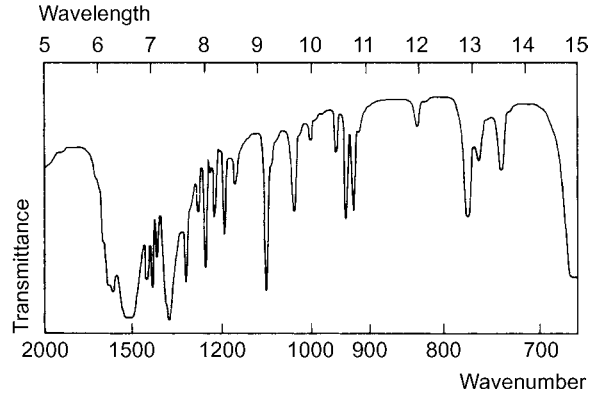
Brown ND, Michalski EJ (1976). An improved high-performance liquid chromatographic method for quantifying p-aminobenzoic acid and some of its metabolites. *J Chromatogr* 121: 76–78.
Kastel R *et al.* (1994). Simultaneous determination of p-aminobenzoic acid and its metabolites in urine by high performance liquid chromatography. *Biomed Chromatogr* 8: 294–296.

Aminocaproic Acid

Haemostatic
$C_6H_{13}NO_2$ = 131.2
CAS—60-32-2

IUPAC Name 6-Aminohexanoic acid
Synonyms CY-116; EACA; epsilcapramin; epsilon aminocaproic acid.
Proprietary Names *Amicar*; *Capracid*; *Capralense*; *Capramol*; *Ekaprol*; *Epsikapron*; *Hemocaprol*; *Ipsilon*.

Chemical Properties Colourless crystals or white crystalline powder. Mp about 204°, with decomposition. Soluble 1 in 1.5 of water; slightly soluble in ethanol; practically insoluble in chloroform and ether; freely soluble in solutions of acids and alkalis. pK_a 4.4, 10.8 (25°).
Thin-layer Chromatography System TAJ—R_f 0.01; system TAL—R_f 0.45.
Infrared Spectrum Principal peaks at wavenumbers 1538, 1613, 1098, 1319, 1258, 1203 cm^{-1} (KBr disk).



Quantification
Plasma **HPLC** Fluorescence detection. Limit of detection, 50 µg/L [Lam 1990].
Serum **HPLC** Fluorescence detection. Limit of detection, 0.01 ng [Farid 1979]. UV detection. Limit of detection 3 ng [Farid 1979].
Urine **HPLC** See Plasma [Lam 1990].
Disposition in the Body Aminocaproic acid is readily absorbed after oral administration and widely distributed throughout the body fluids. About 70 to 80% of a dose is excreted in the urine unchanged in 12 h.
Therapeutic Concentration In plasma, usually in the range 100 to 400 mg/L.
Half-life Plasma half-life, about 2 to 5 h.
Volume of Distribution About 0.4 L/kg.
Note For a review of aminocaproic acid, see Anon [1981].
Dose 3 to 6 g may be given 4 to 6 times daily.

(1981). Profile on Epsilon aminocaproic acid. *Aust J Pharm* 62: 403–407.

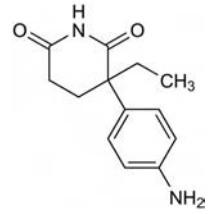
Lam S (1990). High performance liquid chromatographic assay of Amicar, epsilon-aminocaproic acid, in plasma and urine after pre-column derivatization with o-phthalaldehyde for fluorescence detection. *Biomed Chromatogr* 4(4): 175–177.

Aminoglutethimide

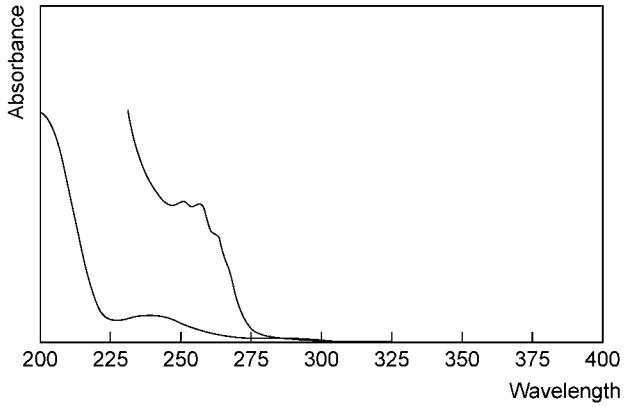
Antineoplastic
$C_{13}H_{16}N_2O_2$ = 232.3
CAS—125-84-8

IUPAC Name 3-(4-Aminophenyl)-3-ethylpiperidine-2,6-dione
Synonym 3-(4-Aminophenyl)-3-ethyl-2,6-piperidinedione
Proprietary Names *Cytadren*; *Elipten*; *Orimeten*.

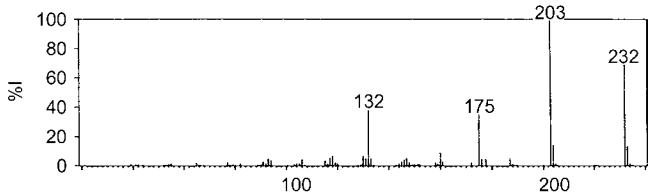


Chemical Properties A white crystalline powder. Mp about 151°. Very slightly soluble in water; freely soluble in organic solvents.
Colour Tests Coniferyl alcohol—yellow; Koppanyi-Zwikker test—violet; mercurous nitrate—black.

Thin-layer Chromatography System TD—R_f 0.32; system TE—R_f 0.65; system TF—R_f 0.47; system TAD—R_f 0.53.
Gas Chromatography System GA—RI 2227.
High Performance Liquid Chromatography System HZ—retention time 2.5 min.
Ultraviolet Spectrum Aqueous acid—251 (A^1_1=18b), 257 nm (A^1_1=18b).



Infrared Spectrum Principal peaks at wavenumbers 1695, 1185, 1200, 1515, 1623, 1267 cm^{-1} (KCl disk).
Mass Spectrum Principal ions at *m/z* 203, 232, 132, 175, 204, 233, 160, 118.



Quantification
Plasma **HPLC** Column: Chiralcel OD cellulose tris(3,5-dimethylphenyl carbamate). Mobile phase: hexane: methanol: isopropyl alcohol (65:17.5:17.5), flow rate 0.7 mL/min. UV detection. Retention time: *R*-*N*-acetylaminoglutethimide 17.7 min (*k* 1.2); *S*-*N*-acetylaminoglutethimide 21.5 min (*k* 1.5); (*R*-aminoglutethimide) 32.7 min (*k* 2.6); (*S*-aminoglutethimide) 37.7 min (*k* 3.3). Limit of detection, 0.24 mg/L for *N*-acetylaminoglutethimide and 0.32 mg/L for aminoglutethimide [Alshowaier *et al.* 1995]. UV detection. Limit of detection, <230 µg/L [Robinson, Cornell 1983].
Urine **HPLC** See Plasma [Alshowaier *et al.* 1995].
Saliva **HPLC** See Plasma [Alshowaier *et al.* 1995].
Disposition in the Body Aminoglutethimide is readily absorbed after oral administration. About 10% of an oral dose is excreted in the urine as unchanged drug in 48 h; acetamidoglutethimide has been identified as a metabolite. Aminoglutethimide appears to induce its own metabolism.
Therapeutic Concentration

Postmenopausal women with advanced metastatic breast carcinoma, mean age 53 years, were administered 500 mg aminoglutethimide after an overnight fast. The mean peak concentration of *R*-aminoglutethimide was 3.8 (range 2.5 to 4.3) g/L observed at 1.4 (0.5 to 2.0) h and for *S*-aminoglutethimide 3.3 (2.4 to 4.3) g/L at 1.3 (1 to 2) h [Alshowaier *et al.* 1999].

After a single oral dose of 500 mg given to 6 subjects, peak plasma concentrations of 5.8 to 6.3 (mean 5.9) mg/L were attained in 1.3 h [Thompson *et al.* 1981].

Steady-state serum concentrations of 4.7 to 32.4 (mean 11.5) mg/L were reported in 7 subjects receiving chronic treatment with oral doses of 1 g daily [Murray *et al.* 1979].

Toxicity The estimated minimum lethal dose is 5 g.
Half-life Plasma half-life about 13 h following a single dose but appears to decrease during chronic treatment.
Volume of Distribution About 1.4 L/kg.
Clearance Plasma clearance about 1.3 mL/min/kg.
Distribution in Blood Plasma:whole blood ratio, about 0.7.
Protein Binding About 25%.
Dose 0.5 to 1 g daily.

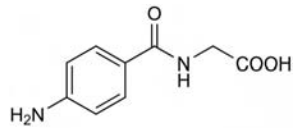
Aminohippuric Acid

Diagnostic Agent (Renal Function)
$C_9H_{10}N_2O_3$ = 194.2
CAS—61-78-9
IUPAC Name 2-[(4-Aminobenzoyl)amino]acetic acid
Synonyms *N*-(4-Aminobenzoyl)glycine; *p*-aminobenzoylglycine; PAHA; para-aminohippuric acid.



Chemical Properties A white crystalline powder, which discolours on exposure to light. Mp about 195°, with decomposition. Soluble 1 in 45 of water, 1 in 50 of ethanol and 1 in 5 of dilute hydrochloric acid; very slightly soluble in carbon tetrachloride, chloroform and ether; freely soluble, with decomposition, in solutions of alkali hydroxides and carbonates. pK_a 3.6.

Sodium Aminohippurate

$C_9H_9N_2NaO_3$ = 216.2
CAS—94-16-6
Proprietary Name *Nephrotest*
Chemical Properties Soluble in water.

Colour Test Diazotisation—red.
Thin-layer Chromatography System TA—R_f 0.55 (Van Urk reagent, yellow).
Ultraviolet Spectrum Methanol—280 nm (A^1_1=880b).
Quantification
Plasma **HPLC** Column: Ultracarb ODS 30 (150 × 4.6 mm i.d., 5 µm). Mobile phase: 7 mmol/L 1-decanesulfonic acid (pH 3.7) : acetonitrile (82:18), flow rate 1.0 mL/min. Internal standard (IS): *p*-aminobenzoic acid. UV detection (λ=280 nm). Retention time: 2.4 min. Limit of detection, 1 mg/L [Pastore *et al.* 2001]. UV detection (λ=285 nm). Limit of quantification, 6.25 mg/L [Dowling *et al.* 1999]. UV detection. Limit of detection, 1 mg/L [Prueksaritanont *et al.* 1984].
Serum **HPLC** UV detection (λ=275 nm). Limit of detection, 0.18 mg/L [Marsilio *et al.* 1997].
Urine **HPLC** See Plasma [Pastore *et al.* 2001]. See Plasma [Dowling *et al.* 1999]. See Serum [Marsilio *et al.* 1997]. See Plasma [Prueksaritanont *et al.* 1984].
Disposition in the Body Aminohippuric acid is a major metabolite of aminobenzoic acid. After IV administration it is rapidly excreted in the urine in subjects with normal renal function.
Half-life Biological half-life, about 0.2 h.
Dose 2 to 30 g of sodium aminohippurate intravenously, to measure renal function.

Marsilio R *et al.* (1997). Rapid determination of p-aminohippuric acid in serum and urine by high-performance liquid chromatography. *J Chromatogr B Biomed Sci Appl* 704: 359–364.

Aminometradine

Pyrimidinedione, Diuretic
$C_9H_{13}N_3O_2$ = 195.2
CAS—642-44-4
IUPAC Name 6-Amino-3-ethyl-1-(2-propenyl)-2,4(1*H*,3*H*)-pyrimidinedione
Synonyms Aminometramide; SC 3497.
Proprietary Names *Mictine*; *Mincard*.
Chemical Properties White crystals from water. Mp 75° to 115° (monohydrate), Mp 143° to 144° (anhydrous) [O'Neil *et al.* 2006]. Soluble 1 in 50 of water, 1 in 2.5 of ethanol and 1 in 8 of chloroform. Log *P* (octanol/water), 0.08 [Meylan, Howard 1995].
Ultraviolet Spectrum Ethanol—267 nm.
Infrared Spectrum Principal peaks at wavenumbers 1608, 1642, 1508 cm^{-1} (KBr disc).
Dose Up to 800 mg daily.

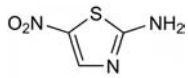
Meylan WM, Howard PH (1995). Atom/fragment contribution method for estimating octanol-water partition coefficients. *J Pharm Sci* 84: 83–92.
O'Neil MJ *et al.* (2006). *The Merck Index: An encyclopedia of chemicals, drugs and biologicals,* 14 edn. Whitehouse Station, NJ: Merck & Co., Inc.

Aminonitrothiazole

Antiprotozoal (Veterinary)
$C_3H_3N_3O_2S$ = 145.1
CAS—1320-42-9
IUPAC Name 4-Nitro-1,3-thiazol-2-amine

A

Synonym 5-Nitro-2-thiazolamine

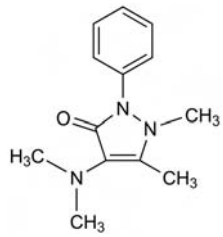


Chemical Properties A greenish-yellow to orange-yellow light powder. Mp 200°, with decomposition. Slightly soluble in water; soluble 1 in 250 of ethanol and ether; practically insoluble in chloroform; soluble in dilute mineral acids and propylene glycol.
Colour Test Diazotisation—violet.
Thin-layer Chromatography System TA—R_f 0.75 (visible yellow spot; acidified iodoplatinate solution, strong reaction).
Gas Chromatography System GA—not eluted.
Ultraviolet Spectrum Water—386 nm (A_1^1=1060a).
Infrared Spectrum Principal peaks at wavenumbers 1200, 1623, 1176, 1504, 1515, 1252 cm^{-1} (KBr disk).

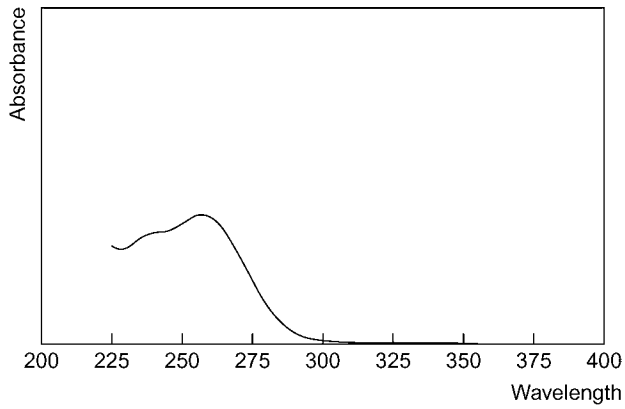
Aminophenazone

Analgesic
$C_{13}H_{17}N_3O$ = 231.3
CAS—58-15-1

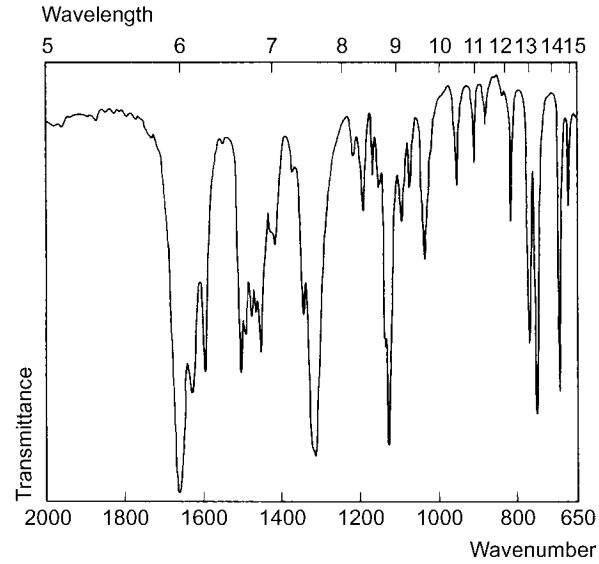
IUPAC Name (1*R*)-1-[(2*R*,3a*R*,5*R*,6*S*,6a*R*)-6-Hydroxy-2-(trichloromethyl)-3a,5,6,6a-tetrahydrofuro[2,3-d][1,3]dioxol-5-yl]ethane-1,2-diol
Synonyms Amidazofen; amidopyrine; amidopyrine-pyramidon; aminopyrine; dimethylaminoantipyrine; 4-(dimethylamino)-1,2-dihydro-1,5-dimethyl-2-phenyl-3*H*-pyrazol-3-one; dimethylaminophenazone.
Proprietary Names It is an ingredient of *Gineburno*; *Thermocutan*; *Virdex*.



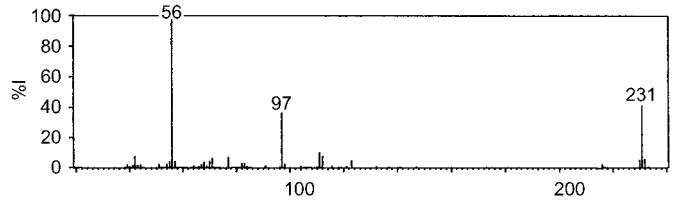
Chemical Properties Small colourless crystals or white crystalline powder. Mp 107° to 109°. Soluble 1 in 18 of water, 1 in 12 of benzene, 1 in 1.5 of ethanol, 1 in 1 of chloroform, and 1 in 13 of ether. pK_a 5.0 (20°). Log *P* (octanol/water), 1.0. A number of salts of aminophenazone have been used, including the ascorbate, gentisate, hydroxyisophthalate and salicylate.
Colour Tests Ferric chloride—blue-violet; Liebermann's reagent (100°)—blue; nitrous acid—violet (transient).
Thin-layer Chromatography System TA—R_f 0.66; system TB—R_f 0.21; system TD—R_f 0.25; system TE—R_f 0.62; system TF—R_f 0.10; system TAD—R_f 0.58; system TAE—R_f 0.70; system TAF—R_f 0.68; system TAJ—R_f 0.53; system TAK—R_f 0.00; system TAL—R_f 0.76 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—aminophenazone RI 1895, M(nor-) RI 1980, M(bis-nor-) RI 1955, M(desamino-OH-) RI 1855; system GB—RI 1992; system GC—RI 2370; system GF—RI 2265.
High Performance Liquid Chromatography System HA—*k* 0.3; system HD—*k* 0.2; system HW—*k* 0.32; system HX—RI 262; system HY—RI 204; system HZ—retention time 2.1 min.
Ultraviolet Spectrum Aqueous acid—257 nm (A_1^1=443c); aqueous alkali—264 nm (A_1^1=353b).



Infrared Spectrum Principal peaks at wavenumbers 1660, 1315, 1126, 750, 700, 1620 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 56, 231, 97, 111, 112, 42, 77, 71.



Quantification
Plasma **GC** FID. Limit of detection, 100 µg/L [Sioufi, Colussi 1978].
Urine **HPLC** Column: Spherisorb ODS (250 × 4.6 mm i.d., 5 µm). Mobile phase: water : methanol : triethylamine : acetic acid (70.9:27.7:0.9:0.5), flow rate 1 mL/min. UV detection (λ=254 nm). Retention time 29 min [Agundez *et al.* 1994]. UV detection. Limit of quantification, 1 mg/L for aminophenazone. Limit of detection, 0.10 mg/L for aminophenazone, and dipyrone and metabolites [Agundez *et al.* 1994]. UV detection [Shimada, Nagase 1980].
Disposition in the Body Absorbed after oral administration. It is rapidly and extensively metabolised. About 30 to 50% of a dose is excreted in the urine in 3 days as 4-aminophenazone and its acetyl derivative 4-acetamidophenazone which is the major urinary metabolite; other metabolites found in the urine include two red pigments, rubazonic acid and methylrubazonic acid; dimethylnitrosamine may be formed in the stomach. <5% of a dose is excreted in the urine unchanged.
Toxicity The use of aminophenazone is discouraged due to the risk of fatal agranulocytosis. The estimated minimum lethal dose is 5 g.
Half-life Plasma half-life about 2 to 3 h.
Protein Binding In plasma 25 to 30%.
Dose Aminophenazone was formerly given in doses of up to 1.5 g in 24 h.

Agundez JA *et al.* (1994). Determination of aminopyrine, dipyrone and its metabolites in urine by high-performance liquid chromatography. *Ther Drug Monit* 16: 316–322.
Shimada K, Nagase Y (1980). Quantitative high-performance liquid chromatographic determinations of aminopyrine and its metabolites in man. *J Chromatogr* 181(7): 51–57.

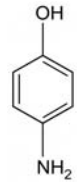
4-Aminophenol

Phenol
C_6H_7NO = 109.1
CAS—123-30-8

IUPAC Name 4–Aminophenol
Synonyms *p*-Aminophenol; *p*-hydroxyaniline.



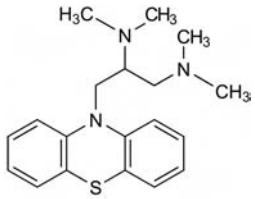
Chemical Properties Crystals. Mp about 190°. The commercial product is usually pink; Mp 186°. Slightly soluble in water; soluble in dehydrated alcohol; practically insoluble in chloroform.
Colour Test Liebermann's reagent—black.
Thin-layer Chromatography System TB—R_f 0.03; system TD—R_f 0.21; system TE—R_f 0.59; system TF—R_f 0.40; system TAD—R_f 0.30; system TAE—R_f 0.75 (ferric chloride solution, violet; acidified potassium permanganate solution, positive; Van Urk reagent, yellow).
Gas Chromatography System GA—4-aminophenol RI 1253, 4-aminophenol-AC_2 RI 1765, 4-aminophenol-AC_3 RI 2085, 4-aminophenol-Me RI 1100; system GB—4-aminophenol RI 1280.
Ultraviolet Spectrum Aqueous acid—271 nm (A^1_1=133b); aqueous alkali—266 nm (broad) (A^1_1=731b); methanol—233 nm (A^1_1=587b), 303 nm (A^1_1=177b).
Mass Spectrum Principal ions at *m/z* 109, 80, 53, 81, 108, 52, 54, 110.
Quantification
Urine **HPLC** UV detection (λ=215 nm). Limit of detection, 1 mg/L [Brega *et al.* 1990].
Disposition in the Body 4-Aminophenol is a metabolite of aniline, nitrobenzene, paracetamol and phenazopyridine.
Toxicity

Following paracetamol overdose, 3 patients were observed to have urine discoloration. Investigation by chromatographic and colorimetric methods revealed the presence of 4-aminophenol, responsible for the dark brown discoloration [Clark *et al.* 1986].

Brega A *et al.* (1990). Determination of phenol, m-, o- and p-cresol, p-aminophenol and p-nitrophenol in urine by high-performance liquid chromatography. *J Chromatogr* 535: 311–316.
Clark PM *et al.* (1986). Urine discoloration after acetaminophen overdose. *Clin Chem* 32: 1777–1778.

Aminopromazine

Antispasmodic (Veterinary)
$C_{19}H_{25}N_3S$ = 327.5
CAS—58-37-7
IUPAC Name 1-*N*,1-*N*,2-*N*,2-*N*-Tetramethyl-3-phenothiazin-10-ylpropane-1,2-diamine
Synonyms Proquamezine; tetrameprozine; *N*,*N*,*N*′,*N*′-tetramethyl-3-(10*H*-phenothiazin-10-yl)-1,2-propanediamine.



Chemical Properties pK_a 9.8. Log *P* (octanol/water), 4.8.

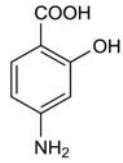
Aminopromazine Fumarate

$(C_{19}H_{25}N_3S)_2,C_4H_4O_4$ = 771.1
CAS—3688-62-8
Synonym Proquamezine fumarate
Proprietary Names *Lispamol*; *Sedofarmolo*.
Chemical Properties White powder. Mp about 166° to 170°, with decomposition. Soluble 1 in 11 of water, 1 in 200 of ethanol, and 1 in 20 of methanol; practically insoluble in ether.

Colour Tests Forrest reagent—violet→red→orange; FPN reagent—violet-red→red→orange; Mandelin's test—orange→violet; Marquis test—violet.
Thin-layer Chromatography System TA—R_f 0.50; system TAE—R_f 0.12; system TAG—R_f 0.08; system TB—R_f 0.42; system TC—R_f 0.19; system TE—R_f 0.60 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—RI 2434.
High Performance Liquid Chromatography System HX—RI 427.
Ultraviolet Spectrum Aqueous acid—248 (A^1_1 = 965a), 297 nm (broad) (A^1_1 = 106a)
Infrared Spectrum Principal peaks at wavenumbers 1584, 745, 660, 1278, 1190, 765 cm^{-1} (aminopromazine fumarate, KBr disk).
Mass Spectrum Principal ions at *m/z* 198, 58, 115, 70, 269, 199, 72, 71.

Aminosalicylic Acid

Antituberculosis
$C_7H_7NO_3$ = 153.1
CAS—65-49-6
IUPAC Name 4-Amino-2-hydroxybenzoic acid
Synonyms Aminosalylum; para-aminosalicylic acid; PAS; pasalicylum.
Proprietary Names *Nemasol*; *Parasal*; *Rezipas*; *Teebacin Acid*.



Chemical Properties A white bulky powder, which darkens on exposure to air and light. Aqueous solutions are unstable. Mp 150° to 151°, with effervescence. Soluble 1 in about 600 of water, 1 in about 20 of ethanol, 1 in 6 of acetone, 1 in 4000 of chloroform, and 1 in 50 of ether. pK_a 1.8 (-NH_2), 3.6 (-COOH). Log *P* (octanol/water), 0.87.

Calcium Aminosalicylate

$(C_7H_6NO_3)_2Ca,3H_2O$ = 398.4
CAS—133-15-3 (anhydrous)
Synonym Aminosalicylate calcium
Chemical Properties A white or slightly yellow, hygroscopic, crystalline powder. Aqueous solutions are unstable and darken in colour. Soluble 1 in 7 to 1 in 10 of water; slightly soluble in ethanol.

Phenyl Aminosalicylate

$C_{13}H_{11}NO_3$ = 229.2
CAS—133-11-9
Synonym Fenamisal
Chemical Properties A white crystalline solid. Mp 153°. Practically insoluble in water.

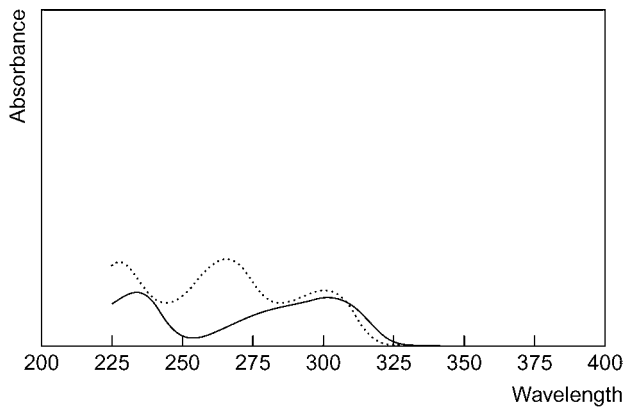
Potassium Aminosalicylate

$C_7H_6KNO_3$ = 191.2
CAS—133-09-5
Synonym Aminosalicylate potassium
Proprietary Name *Teebacin Kalium*
Chemical Properties A white to cream-coloured crystalline powder. Aqueous solutions are unstable. Freely soluble in water; sparingly soluble in ethanol; very slightly soluble in chloroform and ether.

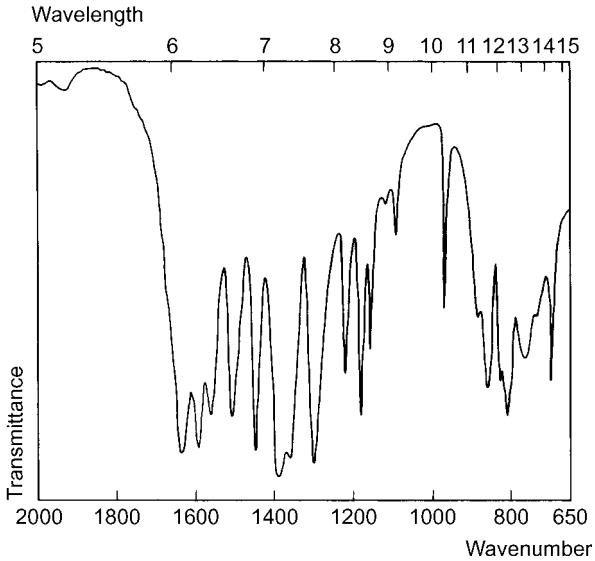
Sodium Aminosalicylate

$C_7H_6NNaO_3,2H_2O$ = 211.1
CAS—133-10-8 (anhydrous); 6018-19-5 (dihydrate)
Synonyms Aminosalicylate sodium; pasalicylum solubile.
Proprietary Names *Eupasal Sodico*; *Italpas Sodico*; *Parasal Sodium*; *Pasalba*; *Teebacin*.
Chemical Properties White or cream-coloured crystals or crystalline powder. Aqueous solutions are unstable. Soluble 1 in 2 of water; sparingly soluble in ethanol; practically insoluble in chloroform and ether.

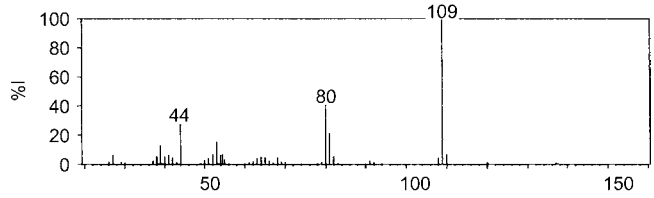
Colour Tests Coniferyl alcohol—orange; Ferric chloride—violet; Folin-Ciocalteu reagent—blue; McNally's test—brown precipitate.
Thin-layer Chromatography System TA—R_f 0.70; system TD—R_f 0.05; system TE—R_f 0.07; system TF—R_f 0.24; system TAD—R_f 0.15 (location under UV light, blue fluorescence; ferric chloride solution, violet; acidified potassium permanganate solution, positive; Van Urk reagent, yellow).
Gas Chromatography System GA—RI 1309.
High Performance Liquid Chromatography System HZ—retention time 1.5 min.
Ultraviolet Spectrum Aqueous acid—234 (A^1_1=496a), 300 nm (A^1_1=330a); aqueous alkali—265 (A^1_1=846a), 300 nm (A^1_1=532a).



Infrared Spectrum Principal peaks at wavenumbers 1301, 1638, 1595, 1510, 805, 1180 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 109, 80, 44, 81, 53, 39, 52, 54.



Quantification

Plasma **HPLC** Column: LiChrospher 60 RP-select B (250 × 4.6 mm i.d., 5 µm). Mobile phase: water (pH 3): methanol: acetonitrile (60:20:20), flow rate 1.2 mL/min. Internal standard (IS): *N*-acetyl-anthranilic acid. Fluorescence detection (λ_{ex}=311 nm; λ_{em}=449 nm). Retention time: 4 min for acetyl-5-aminosalicylic acid. Limit of quantification, 100 µg/L and limit of detection, 20 µg/L [Bystrowska *et al.* 2000]. Fluorescence detection. Limit of detection, 0.5 ng [Honigberg *et al.* 1980]. Fluorescence detection. Limit of detection, 500 µg/L for aminosalicylic acid and *p*-acetamidosalicylic acid [Stoll *et al.* 1972].

Urine **HPLC** See Plasma [Bystrowska *et al.* 2000]. See Plasma [Stoll *et al.* 1972].

Intestinal Biopsy Samples **HPLC** Column: C_{18} Erbasil S (250 × 4.6 mm i.d., 10 µm). Mobile phase: 0.01 mol/L Na_2HPO_4 containing 0.1 mmol/L EDTA, 0.1 mol/L citric acid and 0.1 mmol/L heptanesulfonic acid: methanol (85:15), pH 3, flow rate 1.0 mL/min. IS: 3,4-dihydroxybenzylamine. Electrochemical detection. Retention time: 3.2 min for 5-aminosalicylic acid; 8.3 min for acetyl-5-aminosalicylic acid; 6.5 min for 2,5-dihydroxybenzoic acid [Palumbo *et al.* 1995].

Disposition in the Body Aminosalicylic acid is readily absorbed after oral administration and widely distributed throughout the body, with high concentrations in the kidneys, lungs and liver. It is metabolised by acetylation to *p*-acetamidosalicylic acid and by conjugation with glycine, producing *p*-aminosalicyluric acid; both metabolites are inactive. More than 80% of a dose is excreted in the urine in 24 h with about 50% of the dose consisting of *p*-acetamidosalicylic acid; up to 25% of the dose may be excreted as free and acetylated *p*-aminosalicyluric acid, and the remainder is mostly unchanged drug with small amounts of 2,4-dihydroxybenzoic acid.

Therapeutic Concentration

Following a single oral dose of 4 g of aminosalicylic acid to 12 subjects, a mean peak plasma concentration of 50 mg/L was attained in 3.5 h; after oral administration of 4 g of sodium aminosalicylate to the same subjects, a mean peak plasma concentration of 155 mg/L was attained in about 0.8 h [Wan *et al.* 1974].

Toxicity Prolonged administration may give rise to toxic symptoms characteristic of the salicylates.

Half-life Plasma half-life, aminosalicylic acid about 0.5 to 1 h, *p*-acetamidosalicylic acid about 1.5 h.

Protein Binding 60 to 70%.

Dose 12 g of sodium aminosalicylate daily; up to 20 g daily has been given.

Bystrowska B *et al.* (2000). Validation of a LC method for the determination of 5-aminosalicylic acid and its metabolite in plasma and urine. *J Pharm Biomed Anal* 22: 341–347.

Aminotriazole

Herbicide

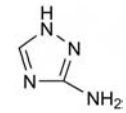
$C_2H_4N_4$ = 84.1

CAS—61-82-5

IUPAC Name 1*H*-1,2,4-Triazol-5-amine

Synonyms Amitrole; ATA; ENT-25445.

Proprietary Names *Amizol*; *Cytrol*; *Weedazol*. It is an ingredient of a number of weed-killers.



Chemical Properties A white crystalline powder. Mp 159°. Soluble 1 in 3.5 of water and 1 in 4 of ethanol; practically insoluble in acetone, ether, and non-polar solvents; sparingly soluble in ethyl acetate.

Colour Test Add sodium hypobromite solution to the sample—orange-red.

Thin-layer Chromatography System TA—R_f 0.68 (acidified iodoplatinate solution, positive).

Gas Chromatography System GA—aminotriazole RI 1312, aminotriazole-Me_2 RI 1050, aminotriazole-AC RI 1010; system GK—not eluted.

Ultraviolet Spectrum No significant absorption, 230 to 360 nm.

Infrared Spectrum Principal peaks at wavenumbers 1639, 1047, 1534, 1595, 1211, 971 cm^{-1} (KBr disk).

Mass Spectrum Principal ions at *m/z* 84, 58, 43, 44, 42, 53, 55, 86.

Toxicity

A 54-year-old man was hospitalised following poisoning with *Radoxone TL*, a weed-killer containing ammonium thiocyanate and aminotriazole. The patient was in a coma with myoclonic jerks and vascular collapse. Thiocyanate and aminotriazole blood levels were 750 mg/L and 138 mg/L, respectively, >12 h after ingestion. The patient died 48 h later of potanoxic coma [Legras *et al.* 1996].

Legras A *et al.* (1996). Herbicide: fatal ammonium thiocyanate and aminotriazole poisoning. *J Toxicol Clin Toxicol* 34: 441–446.

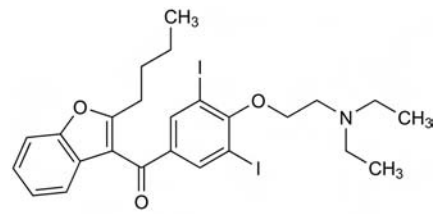
Amiodarone

Antiarrhythmic

$C_{25}H_{29}I_2NO_3$ = 645.3

CAS—1951-25-3

IUPAC Name (2-Butyl-1-benzofuran-3-yl)[4-(2-diethylaminoethoxy)-3,5-diiodophenyl]methanone



Chemical Properties pK_a 5.6. Extraction yield (chlorobutane), 0.95 [Demme *et al.* 2005].

Amiodarone Hydrochloride

$C_{25}H_{29}I_2NO_3$,HCl = 681.8

CAS—19774-82-4

Proprietary Names *Amiodar*; *Ancaron*; *Cordarex*; *Cordarone*; *Cordarone X*; *Ortacrone*; *Tachydaron*; *Trangorex*.

Chemical Properties A white crystalline powder. Mp about 161°. Very slightly soluble in water; soluble in ethanol; freely soluble in chloroform.

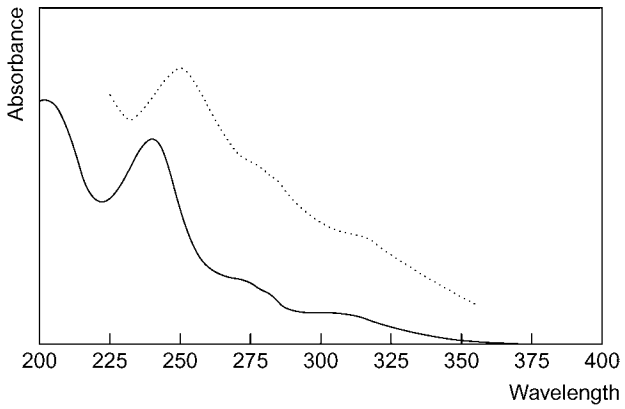
Colour Tests Iodine test (omitting MnO_2)—positive; Liebermann's reagent—brown-yellow; sulfuric acid—yellow.

Thin-layer Chromatography System TA—R_f 0.72; system TB—R_f 0.62; system TC—R_f 0.68; system TE—R_f 0.82; system TL—R_f 0.55; system TAE—R_f 0.54; system TAF—R_f 0.64 (dragendorff spray, positive; acidified iodoplatinate solution, positive; Marquis reagent, yellow).

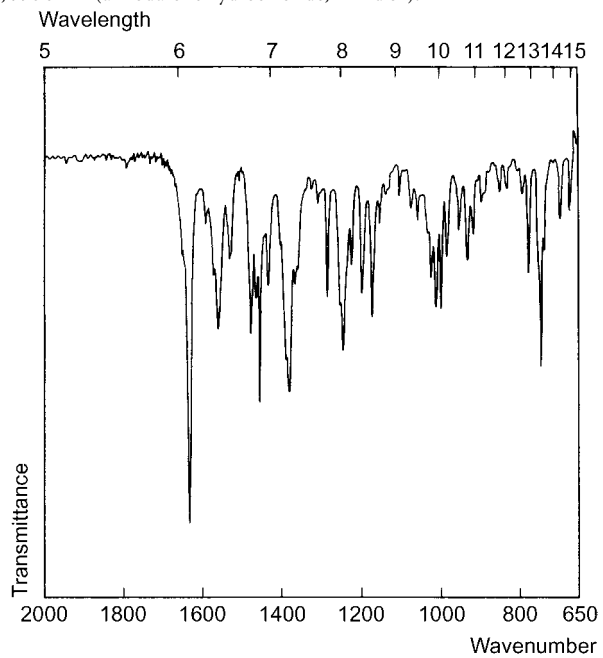
Gas Chromatography System GA—RI 3335amiodarone; RI 2800O-desalkylamiodarone (art).

High Performance Liquid Chromatography System HA—amiodarone *k* 2.4, monodesethylamiodarone *k* 1.8; system HX—RI 683; system HY—RI 476; system HZ—retention time 90.4 min.

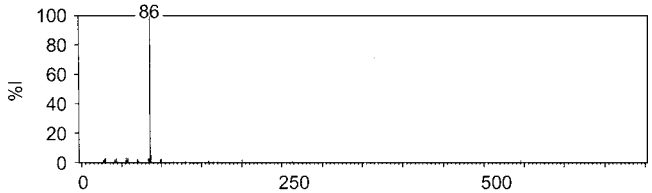
Ultraviolet Spectrum Aqueous acid—241 nm; aqueous alkali—251 nm.



Infrared Spectrum Principal peaks at wavenumbers 1630, 748, 1245, 1558, 1170, 998 cm^{-1} (amiodarone hydrochloride, KBr disk).



Mass Spectrum Principal ions at *m/z* 86, 36, 87, 84, 58, 56, 44, 38.



Quantification

Plasma **HPLC** Limit of quantification, 50 µg/L for drug and metabolite. UV detection. Limit of detection, 1 µg/L for amiodarone and 0.5 µg/L for desethylamiodarone [Kollroser, Schober 2002]. UV detection. Limit of detection, 25 µg/L for amiodarone and monodesethylamiodarone [Plomp *et al.* 1983]. UV detection. Limit of detection, 100 µg/L for amiodarone and monodesethylamiodarone [Storey *et al.* 1982].

Urine **HPLC** See Plasma [Plomp *et al.* 1983].

Tissues **HPLC** See Plasma [Plomp *et al.* 1983].

Disposition in the Body Amiodarone is slowly and incompletely absorbed after oral administration; it is distributed to the tissues where it is strongly bound. It is metabolised by *N*-dealkylation to monodesethylamiodarone which is the major plasma metabolite during chronic dosing. High concentrations of amiodarone and monodesethylamiodarone are found in the liver, lungs and adipose tissue. Enterohepatic circulation may occur. Only a small amount is excreted in the urine as unchanged drug.

Therapeutic Concentration Accumulates on chronic administration; steady state plasma concentrations are attained in about 1 month.

Fifteen patients were administered 400 mg amiodarone 3 times daily and peak plasma concentrations of the drug were 1.478 to 1.983 mg/L. Peak plasma concentrations of the metabolite, desethylamiodarone, were 0.522 to 1.008 mg/L [Kollroser, Schober 2002].

Following oral administration of 400 mg to 7 subjects, peak plasma concentrations of about 0.5 to 1 mg/L were attained in about 7 h. After administration of 200 mg 8-hourly to 6 subjects for 1 month, plasma concentrations determined immediately before the morning dose ranged from 0.75 to 2.8 mg/L (mean 1.5 mg/L) [Andreasen *et al.* 1981].

During chronic treatment with 400 mg daily to 33 subjects, mean steady-state plasma concentrations of 2.2 mg/L of amiodarone and 2.0 mg/L of monodesethylamiodarone were reported. [Flanagan *et al.* 1982].

Half-life Plasma half-life during chronic dosing, 14 to 107 days (mean 50).

Distribution in Blood Plasma:whole blood ratio, 1.3.

Protein Binding Extensively bound.

Note For a review of the pharmacokinetics of amiodarone, see Latini *et al.* [1984].

Dose Initially 600 mg of amiodarone hydrochloride daily; maintenance, 200 to 400 mg daily.

Amiphenazole

Narcotic Antagonist, Respiratory Stimulant

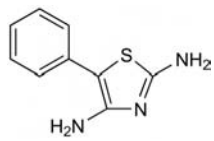
$C_9H_9N_3S$ = 191.3

CAS—490-55-1

IUPAC Name 5-Phenyl-1,3-thiazole-2,4-diamine

Synonyms DAPT; phenamizole; 5-phenyl-2,4-thiazolediamine.

Proprietary Names *Daptazile*; *Daptazole*; *Dizol*; *Fenamizol*.



Chemical Properties Flakes which turn brown on exposure to light and air. Mp 163° to 164°, with decomposition.

Amiphenazole Hydrochloride

$C_9H_9N_3S,HCl$ = 227.7

CAS—942-31-4

Synonym Amiphenazole chloride

Proprietary Names *Daptazile*; *Daptazole*.

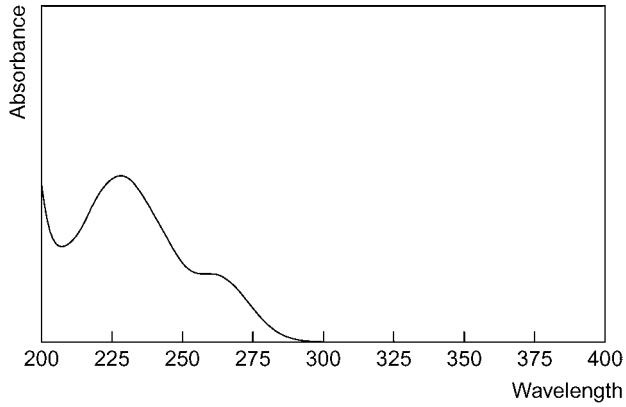
Chemical Properties A white, fine crystalline or granular, mobile powder. Aqueous solutions hydrolyse slowly. Mp 236°. Soluble 1 in 16 of water and 1 in 50 of ethanol; slightly soluble in acetone, chloroform and ether.

Colour Test Liebermann's reagent (100°)—green-blue.

Thin-layer Chromatography System TA—R_f 0.61; system TB—R_f 0.02; system TC—R_f 0.33; system TE—R_f 0.62; system TL—R_f 0.57 (acidified iodoplatinate solution, positive).

Gas Chromatography System GB—RI 1150; system GC—RI 2563.

Ultraviolet Spectrum Aqueous acid—230 (A^1_1=998a), 261 nm.



Infrared Spectrum Principal peaks at wavenumbers 1495, 1637, 688, 750, 1665, 1050 cm^{-1} (KBr disk).

Mass Spectrum Principal ions at *m/z* 191, 121, 77, 104, 122, 43, 51, 192.

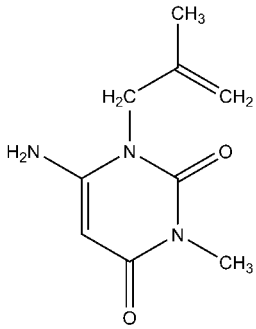
Dose Amiphenazole hydrochloride has been given parenterally in doses of 100 to 150 mg.

A

Amisometradine

Pyrimidine, Diuretic
$C_9H_{13}N_3O_2$ = 195.2
CAS—550-28-7

IUPAC Name 6-Amino-1,2,3,4-tetrahydro-3-methyl-1-methyl-allyl-2,4-dioxo-pyrimidine
Synonym Aminoisometradine
Proprietary Name *Rolicton*



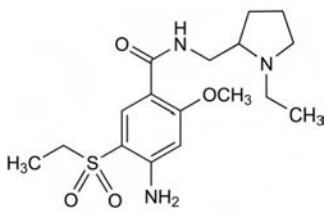
Chemical Properties White crystalline powder. Mp 175°. Slightly soluble in cold water, the solubility increasing rapidly on heating; freely soluble in ethanol and acetone; insoluble in ether. It is extracted by organic solvents from aqueous acid or alkaline solutions. Amisometradine is an isomer of aminometradine. Log *P* (octanol/water) 0.13 [Meylan, Howard 1995].
Thin-Layer Chromatography System T1—R_f 0.68 (location reagent potassium permanganate spray, positive reaction).
Ultraviolet Spectrum Aqueous acid (0.1 N sulfuric acid)—268.5 nm; methanol—267 nm.
Infrared Spectrum Principal peaks at wavenumbers 1639, 1492 or 1604, 1680 cm^{-1} (KBr disk).
Disposition in the Body
Toxicity LD_{50} (oral) in mice: 610 mg/kg.
Dose Up to 1.6 g daily.

Meylan WM, Howard PH (1995). Atom/fragment contribution method for estimating octanol-water partition coefficients. *J Pharm Sci* 84: 83–92.

Amisulpride

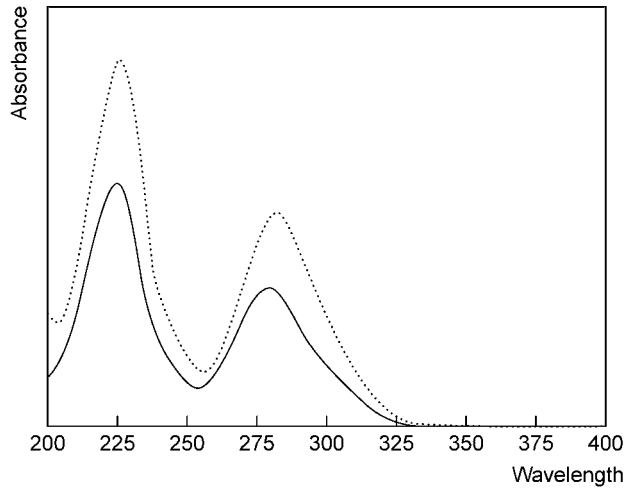
Antipsychotic
$C_{17}H_{27}N_3O_4S$ = 369.5
CAS—71675-85-9

IUPAC Name 4-Amino-*N*-[(1-ethylpyrrolidin-2-yl)methyl]-5-ethylsulfonyl-2-methoxybenzamide
Synonyms Aminosultopride; 4-amino-*N*-[(1-ethyl-2-pyrrolidinyl)methyl]-5-(ethylsulfonyl)-2-methoxybenzamide; DAN-2163.
Proprietary Names *Deniban*; *Solian*; *Sulamid*.

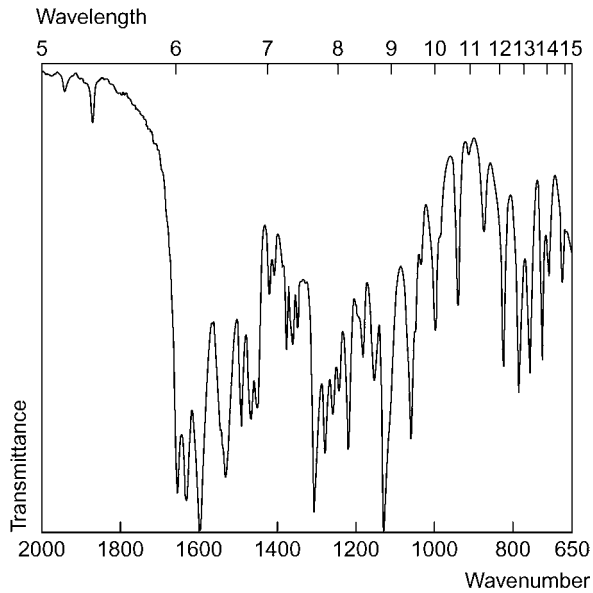


Chemical Properties Crystals from acetone. Mp 126° to 127°. pK_a 9.37. Log *P* (octanol/water), 1.10. Extraction yield (chlorobutane), 0.6 [Demme *et al.* 2005]. Stock solutions were stable for at least 1 month stored at 0–5°. Amisulpride is stable in human plasma for at least 24 h either at room temperature or at 37° [Malavasi *et al.* 1996]. Stability of amisulpride in methanol and human plasma was satisfactory at room temperature and at 37°. It was also satisfactory in human plasma following 2 freeze-thaw cycles and in human plasma diluted with borate buffer (pH 9.0) [Ascalone *et al.* 1996].
High Performance Liquid Chromatography System HAA—amisulpride RT 8.9 min, M1 RT 7.1 min, M2 RT 10.9 min.

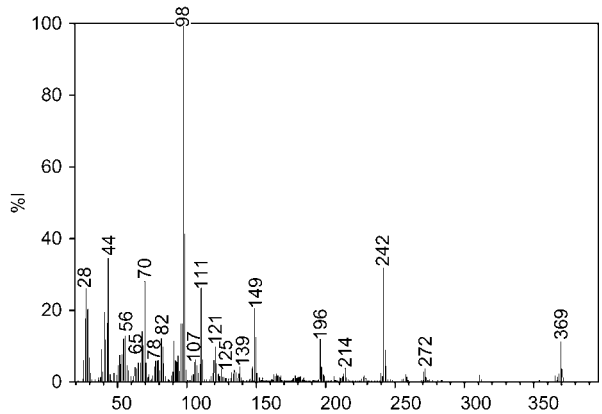
Column: Hypersil C_{18} BDS (150 × 4.6 mm i.d., 5 µm). Mobile phase: water-TEA-1 mol/L potassium dihydrogen phosphate (pH 3.0, 974 : 1 : 25) : acetonitrile (850 : 150), flow rate 1 mL/min. Fluorescence detection (λ_{ex} = 280 nm, λ_{em} = 370 nm). Retention time: 4 min [Malavasi *et al.* 1996].
Ultraviolet Spectrum Aqueous acid—230, 285 nm.



Infrared Spectrum



Mass Spectrum Principal ions at *m/z* 98, 44, 242, 70, 28, 111, 149, 369.



Quantification
Blood **HPLC** Column: Nova-Pak C_{18} (300 × 3.9 mm i.d., 4 µm). Mobile phase: methanol : tetrahydrofuran : potassium dihydrogen phosphate (pH 2.6, 65 : 5 : 30). DAD. Retention time: 5.67 min. Limit of detection, 49 µg/L [Tracqui *et al.* 1995].
Plasma **HPLC** Column: Chiralpak AS (250 × 4.6 mm i.d.). Mobile phase: *n*-hexane: ethanol (67 : 33) containing 0.2% diethylamine, flow rate 0.5 mL/min. UV (λ = 280 nm) or fluorescence (λ_{ex} = 280 nm, λ_{em} = 370 nm) detection. Limit of quantification, 2.5 µg/L for both enantiomers [Ascalone *et al.* 1996]. Column: Hypersil C_{18} (150 × 4.6 mm i.d., 5 µm). Mobile phase: 850 mL 1 mol/L potassium dihydrogen phosphate (25 mL in 950 mL water with 1 mL TEA, pH 3.0 to 1 L with

water) to 1 L with acetonitrile, flow rate 1.0 mL/min. Fluorescence detection (λ_{ex} = 280 nm, λ_{em} = 370 nm). Limit of quantification, 0.5 µg/L [Malavasi *et al.* 1996]. Column: RP-18 (250 × 4.6 mm i.d., 5 µm). Mobile phase: methanol : water : diethylamine (532 : 468 : 0.8), flow rate 1 mL/min. UV detection (λ = 226 nm). Retention time: 10.3 min. Limit of detection, 5 µg/L [Bohbot *et al.* 1987].

Serum **LC-MS** Column: C_{18} (50 × 4.6 mm i.d., 5 µm). Mobile phase: methanol : 5 mmol/L acetic acid (pH 3.9, 20 : 80 to 70 : 30 over 4 min for 1 min), flow rate 1.0 mL/min. ESI, positive ion mode, MRM acquisition mode. Retention time: 1.5 min. Limit of quantification, 28.3 µg/L [Kirchherr, Kühn-Velten 2006].

Urine **HPLC** See Plasma. Limit of quantification, 50 µg/L for both enantiomers [Ascalone *et al.* 1996]. See Plasma. Limit of quantification, 100 µg/L [Malavasi *et al.* 1996].

Disposition in the Body Following oral administration, amisulpride is readily absorbed, with 2 absorption peaks observed, the first after ~1 h and the second between 3 and 4 h after administration. It is only weakly metabolised; metabolites account for only ~4% of the dose and are inactive. It is excreted largely unchanged in urine (70%) and a small amount in faeces as the unchanged drug. Amisulpride is widely distributed throughout the body and is only very weakly dialysed.

Therapeutic Concentration

Following administration of a single oral dose of 50 mg amisulpride to 18 healthy subjects the mean plasma concentrations were 18.8, 17.9 and 17.2 µg/L at 2, 4 and 6.5 h, respectively. Following administration of a single 200 mg dose, the plasma concentrations were 76.2, 83.0, and 92.1 µg/L at 2, 4 and 6.5 h, respectively [Mattila *et al.* 1996].

Toxicity

In a non-fatal overdose, a 30-year-old Caucasian woman who had taken ~3 g amisulpride and an unknown amount of dosulepin had a blood amisulpride concentration of 9.63 mg/L. Her gastric fluid concentration was 14.3 mg/L. The patient experienced generalised convulsions, which resolved spontaneously, followed by coma, motor restlessness, tachycardia and slight prolongation of the QT interval. The subject was treated with gastric lavage and recovered within 48 h. The drug blood concentration was 10–50 times higher than that observed at therapeutic levels. A second subject who had been found dead had a blood amisulpride concentration of 41.7 mg/L. This is 40–200 times the observed therapeutic concentration [Tracqui *et al.* 1995].

Half-life Plasma, 12 h.

Volume of Distribution 5.8 L/kg.

Clearance 20 L/h

Protein Binding 16%.

Dose Up to 1200 mg daily orally; up to 400 mg daily has been given IM.

Amitriptyline

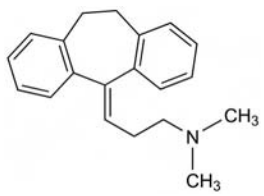
Tricyclic Antidepressant

$C_{20}H_{23}N$ = 277.4

CAS—50-48-6

IUPAC Name 3-(10,11-Dihydro-5*H*-dibenzo[*a,d*]cyclohepten-5-ylidene)-*N,N*-dimethyl-1-propanamine

Synonym 10,11-Dihydro-*N,N*-dimethyl-5*H*-dibenzo[*a,d*]cycloheptene-Δ5,γ-propylamine



Chemical Properties A colourless oil, which becomes yellow on standing through oxidation to a ketonic product. pK_a 9.4 [Sangster 1997]. Log *P* (octanol/water), 4.92 [Hansch *et al.* 1995], 4.94. Extraction yield (chlorobutane), 1 [Demme *et al.* 2005].

Amitriptyline Embonate

$(C_{20}H_{23}N)_2,C_{23}H_{16}O_6$ = 943.2

CAS—17086-03-2

Proprietary Name *Tryptizol* (syrup).

Chemical Properties A pale yellow to brownish-yellow powder. Mp ~140°. Practically insoluble in water; soluble 1 in 120 of ethanol, 1 in 6 of acetone, and 1 in 8 of chloroform.

Amitriptyline Hydrochloride

$C_{20}H_{23}N,HCl$ = 313.9

CAS—549-18-8

Proprietary Names *Adepril*; *Amavil*; *Amiline*; *Amineurin*; *Amioxid*; *Amitid*; *Amitril*; *Amitrip*; *Amitrol*; *Domical*; *Elatrol*; *Elavil*; *Endep*; *Equilibrin*; *Klotriptyl*; *Laroxyl*; *Lentizol*; *Levate*; *Meravil*; *Novoprotect*; *Novotriptyn*; *Redomex*; *Saroten*; *Sarotex*; *Syneudon*; *Triptyl*; *Tryptanol*; *Tryptil*; *Tryptizol*. It is an ingredient of *Etrafon*; *Limbatril*; *Limbitrol*; *Triavil*; *Triptafen*.

Chemical Properties Colourless crystals or white powder. Mp 196° to 197°. Soluble 1 in 1 of water, 1 in 1.5 of ethanol, 1 in 56 of acetone, 1 in 1.2 of chloroform, and 1 in 1 of methanol; practically insoluble in ether. pK_a 9.4 (25°). Log *P* (octanol/water), 2.18 [Meylan, Howard 1995].

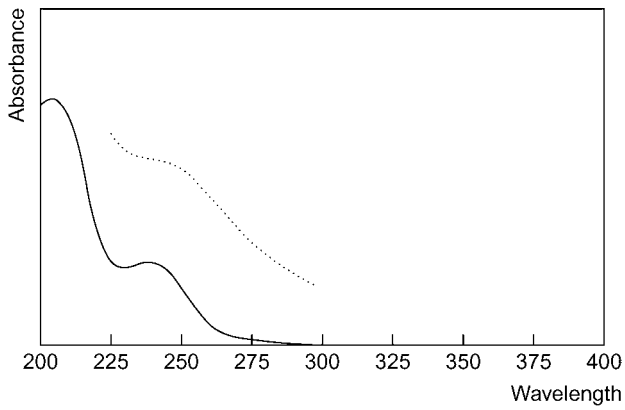
Colour Tests Mandelin's test—brown→green; Marquis test—brown-orange; sulfuric acid—orange.

Thin-layer Chromatography System TA—R_f 0.51; system TB—R_f 0.50; system TC—R_f 0.32; system TE—R_f 0.69; system TL—R_f 0.15; system TAE—R_f 0.27; system TAF—R_f 0.51; system TAJ—R_f 0.13; system TAK—R_f 0.05; system TAL—R_f 0.56 (Dragendorff spray, positive; acidified iodoplatinate solution, positive; Marquis test, brown).

Gas Chromatography System GA—amitriptyline RI 2194, M (*cis*-10-OH-) RI 2348, M (*trans*-10-OH-) RI 2348, M (*N*-oxide) RI 1975, M (nortriptyline) RI 2215, M (cyclobenzaprine) RI 2235, M (OH-) RI 2380, M (nor-OH-) RI 2390; system GB—amitriptyline RI 2284, M (*cis*-10-OH-) RI 2454, M (*cis*-10-OH-*N*-oxide) RI 2215, M (*trans*-10-OH-) RI 2466, M (*trans*-10-OH-*N*-oxide) RI 2239, M (cyclobenzaprine) RI 2330, M (*N*-oxide) RI 2051; system GF—amitriptyline RI 2510, M (10-OH-) RI 2830 or 2880 (stereoisomers); system GM—amitriptyline RRT 0.723, M (*cis*-10-OH-) RRT 1.149, M (*trans*-10-OH-) RRT 1.168, M (cyclobenzaprine) RRT 0.850 (all relative to iprindole); system GS—RT 16.1 min.

High Performance Liquid Chromatography System HA—amitriptyline *k* 3.3, M (10-OH-) *k* 2.9, M (nor-10-OH-) *k* 1.8, M (nortriptyline) *k* 2.0; system HF—amitriptyline *k* 5.42, M (nortriptyline) *k* 4.58; system HX—RI 440; system HY—RI 375; system HZ—RT 7.5 min; system HAA—RT 15.9 min; system HAX—RT 15.8 min; system HAY—RT 7.3 min; system HAZ—amitriptyline *k* 1.76, M (nortriptyline) k 1.71 [Aymard *et al.* 1997].

Ultraviolet Spectrum Aqueous acid—239 nm (A^1_1 = 504a).



Infrared Spectrum Principal peaks at wavenumbers 756, 770, 746, 969, 1014, 1258 cm^{-1} (amitriptyline hydrochloride, KBr disk).

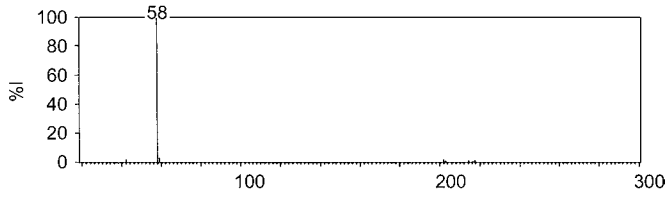
Mass Spectrum Principal ions at *m/z* 58, 59, 202, 42, 203, 214, 217; 10-OH-amitriptyline 58, 42, 69, 41, 30, 215, 202, 59; 10-OH-nortriptyline 44, 45, 26, 218, 215, 203, 202, 42; nortriptyline 44, 202, 45, 220, 218, 215, 91.



Quantification

Blood **GC** Carrier gas: He, 4 mL/min. Temperature programme: 100° for 1 min to 300° at 15°/min. FID. Limit of detection, 32 µg/L [Lee *et al.* 1997].

GC-MS Column: AT-5MS (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 20 cm/s. Temperature programme: 70° for 5 min to 310° at 20°/min for 10 min. EI ionisation at 70 eV, SIM acquisition mode. Retention time: 18.4 min. Limit of detection, 0.12 mg/L [Stiakakis *et al.* 2009]. Ultra 2 capillary 5% phenylmethylsiloxane (12 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1 mL/min. Temperature programme: 150° for 2 min to 200° at 15°/min for 2 min to 270° at 30°/min for 7 min. EI ionisation, SIM acquisition mode. Limit of quantification, 100 µg/L, limit of detection, 9 µg/L [Margalho *et al.* 2007]. Column: DB-5 cross-linked 5% phenylmethylsiloxane (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1 mL/min. Temperature programme: 50° for 2 min to 180° at 30°/min to 280° at 5°/min for 19 min. Full scan mode. Retention time: 17.8 min. Limit of quantification, 0.05 mg/L [Paterson *et al.* 2004].

HPLC Column: Spheri-5 RP-18 (100 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : 0.1 mol/L sodium dihydrogen phosphate : diethylamine (40 : 57.5 : 2.5), flow rate 2.0 mL/min. UV detection (λ = 220 and 254 nm). Limit of detection, 0.05 mg/L [McIntyre *et al.* 1993].

LC-MS Column: Xterra RP-18. Mobile phase: acetonitrile : 4 mmol/L ammonium formate buffer (pH 3.2). ESI, MRM acquisition mode. Limit of quantification, 2 µg/L [Titier *et al.* 2007].

Plasma **GC** Column: 5% phenylmethylsilicone (12 m × 0.2 mm i.d., 0.33 µm). Carrier gas: He, 0.8 mL/min. Temperature programme: 150° to 300° at 10°/min. NPD. Limit of quantification, 19.3 µg/L, limit of detection, 5.8 µg/L [de la Torre *et al.* 1998]. NPD. Limit of quantification, 125 µg/L [Ulrich, Martens 1997; Vandel *et al.* 1992]. Column: 3% SP-2250 on Supelcoport 80/100 mesh (2 m × 2 mm i.d.). Carrier gas: Ar, 3×10^5 N/m^2. Temperature: 250°. AFID. Retention time: 3.5 min. Limit of detection, 10 µg/L [Dawling, Braithwaite 1978].

GC-MS Column: DB-5MS (30 m × 0.32 mm i.d., 0.25 µm). Carrier gas: He, 2.0 mL/min. Temperature programme: 100° for 1 min to 300° at 20°/min. EI ionisation, positive ion mode, SIM acquisition mode. Limit of quantification, 2 µg/L, limit of detection, 0.5 µg/L [Lee *et al.* 2008]. PBMS. Limit of detection, 2 ng/g for amitriptyline and 5 ng/g for nortriptyline [Kudo *et al.* 1997].

HPLC Column: µBondapak C_{18} (250 × 3.9 mm i.d.). Mobile phase: phosphate buffer : acetonitrile : TEA (65 : 35 : 0.1, pH 5.1). UV detection (λ = 239 nm). Limit of detection, 5 µg/L [Zarghi *et al.* 2001]. Column: Supelcosil LC-PCN cyanopropyl (150 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : methanol : 0.005 mol/L ammonium phosphate buffer (pH 7.0, 70 : 15 : 15), flow rate 1.5 mL/min. UV detection (λ = 254 nm). Limit of detection, 29 nmol/L [Johansen, Rasmussen 1998]. Column: Nova-Pak RP C_{18} (150 × 4.6 mm i.d., 4 µm). Mobile phase: 5 mmol/L potassium dihydrogen phosphate : acetonitrile : diethylamine (pH 8, 500 : 500 : 2), flow rate, 0.9 mL/min. UV detection (λ = 242 nm). Retention time: 17 min. Limit of detection, 60 nmol/L [Theurillat, Thormann 1998]. Column: Symmetry RP C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: 0.067 mol/L potassium dihydrogen phosphate (pH 3, 65 : 35); flow rate, 1.2 mL/min. DAD (λ = 200 nm or 450 nm). Retention time: 11.3 min. Limit of detection, 5 µg/L [Aymard *et al.* 1997]. Column: silica. Mobile phase: acetonitrile : 0.1 mol/L ammonium acetate (94 : 6). UV detection. Limit of detection, 5 ng/g for amitriptyline and 10 ng/g for nortriptyline [Kudo *et al.* 1997]. Column: Nova-Pak C_{18} (5 µm). Mobile phase: water : acetonitrile (70 : 30) containing 1% TEA (pH 3.0), flow rate 2.0 mL/min. UV detection (λ = 240 nm). Retention time: 10.5 min. Limit of detection, 2 µg/L [Ghahramani, Lennard 1996].

See also Härtter, Hiemke [1992] and Queiroz *et al.* [1995].

LC-MS Column: Symmetry C_{18} (150 × 3.0 mm i.d., 5 µm). Mobile phase : acetonitrile: 0.1% formic acid (28 : 72 for 4 min to 70 : 30 in 1 min for 3 min to 28 : 72 in 0.7 min). APCI, positive ion mode, full scan mode. Limit of quantification, 10 µg/L, limit of detection, 5 µg/L [Kollroser, Schober 2002]. Column: C_{18} (15 × 2.1 mm i.d.). Mobile phase: 3 mmol/L ammonium acetate (pH 3.3) : acetonitrile (66 : 34), flow rate 1.4 mL/min. API, TIS. Limit of quantification, 1–2 µg/L, limit of detection, 5 µg/L [Zhang *et al.* 2000].

Note For a fluorescence polarisation immunoassay for amitriptyline and other tricyclic antidepressants and its comparison with HPLC see Hackett *et al.* [1998].

Serum **GC** Column: HP-5 (25 m × 0.2 mm i.d., 0.33 µm). Carrier gas: N_2, 0.7 mL/min. Temperature programme: 120° to 240° at 30°/min for 20 min. NPD. Limit of detection, 1.5 ng/mL [Ulrich *et al.* 1996].

GC-MS Column: HP-5 MS (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1 mL/min. Temperature programme: 60° for 1 min to 280° at 10°/min for 20 min. EI ionisation at 70 eV. Retention time: 22.5 min. Limit of quantification, 0.025 mg/L, limit of detection, <0.025 mg/L [Maresova *et al.* 2008].

HPLC See Plasma [Theurillat, Thormann 1998]. Column: Separon SGX CN (150 × 3 mm i.d., 7 µm). Mobile phase: 0.05 mol/L phosphoric acid with 0.05 mol/L ammonium phosphate containing 28 mmol/L diethylamine (pH 2.55) : acetonitrile (74 : 26), UV detection (λ = 210 nm). Limit of detection, 20–25 µg/L [Dolezalova 1992]. Column: Nucleosil 100 CN cyanopropyl (250 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : methanol: 0.01 mol/L phosphate buffer (pH 6.8, 578 : 188 : 235), flow rate 1.5 mL/min. UV detection (λ = 214 nm). Retention time: 8.54 min. Limit of quantification, ~5 µg/L, limit of detection, 5–10 µg/L [Härtter, Hiemke 1992]. Column: reversed phase C_8 (150 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : phosphate buffer (pH 3.0, 50 : 50), flow rate 1.0 mL/min. UV detection (λ = 254 nm). *k'*: 3.333. Limit of detection, 10 µg/L [Segatti *et al.* 1991].

LC-MS Column: Xterra MS C_{18} (50 × 2.1 mm i.d., 5 µm). ESI, positive ion mode, MRM acquisition mode. Limit of detection, 10 µg/L [Sauvage *et al.* 2006].

Note For an immunoassay for the detection of amitriptyline see Rao *et al.* [1994].

Urine **HPLC** DAD [Li *et al.* 1994]. Column: Nucleosil C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: 10 mmol/L perchloric acid (pH 2.5) : acetonitrile (60 : 40), flow rate 1.2 mL/min. UV detection (λ = 254 nm). Retention time: 13.0 min [Fischer, Breyer-Pfaff 1995].

Bile **GC-MS** See Blood [Stiakakis *et al.* 2009].

Ocular Fluid **GC-MS** See Blood [Stiakakis *et al.* 2009].

Brain **GC-MS** See Blood [Stiakakis *et al.* 2009].

Hair **GC-MS** Column: BP-5 (12.5 m × 0.22 mm i.d.). Carrier gas: He, 3.2 mL/min. Temperature programme: 60° for 1 min to 280° at 30°/min for 5 min. EI ionisation at 70 eV. Limit of detection not reported [Couper *et al.* 1995; Tracqui *et al.* 1992].

Kidney **GC-MS** See Blood [Stiakakis *et al.* 2009].

Liver **GC-MS** See Blood [Stiakakis *et al.* 2009].

HPLC See Blood [McIntyre *et al.* 1993].

Liver Microsomes **HPLC** Column: RP C_{18} ODS (150 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : 12 mmol/L tetramethylethylene diamine (pH 5.5, 40 : 60), flow rate, 1.5 mL/min. UV detection (λ = 242 nm). Retention time: 8.9 min. Limit of detection, 10 µg/L [Shu *et al.* 1998]. See Plasma [Ghahramani, Lennard 1996].

Other **HPLC** Biological Samples. UV detection [Tanaka *et al.* 1997].

Note For a review of analytical methods see Scoggins *et al.* [1980].

Disposition in the Body Amitriptyline is readily absorbed after oral administration and rapidly taken up by the tissues. The main metabolic reaction, demethylation to form the major active metabolite nortriptyline, is catalysed by CYP2C19 and CYP3A4 isoforms. Hydroxylation is catalysed by CYP2D6; *N*-oxidation and conjugation also occur; other metabolites include didesmethylamitriptyline, 10-hydroxy-derivatives, conjugates and amitriptyline *N*-oxide; the 10-hydroxy metabolites may also have some activity. It is mainly excreted in the urine as free and conjugated metabolites, up to ~35% of a single dose being excreted in 24 h. Approximately 50% of the excreted material is 10-hydroxynortriptyline and its glucuronide conjugate; up to 27% is 10-hydroxyamitriptyline (mainly conjugated); unchanged drug and nortriptyline each account for <5% of the excreted material. Approximately 8% of a dose may be eliminated in the faeces as unchanged drug. There appears to be polymorphic variation in the metabolite pattern. Amitriptyline and nortriptyline are widely distributed; they cross the placenta and are excreted in breast milk

Therapeutic Concentration In plasma, usually in the range 0.1–0.2 mg/L (combined amitriptyline and nortriptyline).

After a single oral dose of 50 mg to 3 subjects, peak plasma concentrations for amitriptyline of 0.02–0.04 mg/L (mean 0.025) and for nortriptyline of ~0.01 mg/L were attained in 2–4 h [Garland 1977].

Following daily oral doses of 150 mg to 14 subjects for 3 weeks, steady-state serum concentrations of 0.05–0.24 mg/L (mean 0.13) amitriptyline, 0.04–0.26 mg/L (mean 0.11) nortriptyline, 0.05–0.25 mg/L (mean 0.13) (*E*)-10-hydroxynortriptyline, and 0.005–0.04 mg/L (mean 0.02) 10-hydroxyamitriptyline were reported [Edelbroek *et al.* 1984].

Toxicity Moderate intoxication is associated with plasma concentrations of 0.05–0.43 mg/L (mean: 0.17) and severe toxic symptoms with concentrations >0.3 mg/L. The fatal blood concentration range is 0.55–16.1 mg/L (mean 3.3). Corresponding toxic doses are >1 g (moderate intoxication) and >2 g (severe or fatal).

In 3 deaths attributed to amitriptyline overdose, postmortem tissue concentrations were:

	Amitriptyline	*Nortriptyline*
Blood (mg/L)	6, 18, 3	5, –, 2
Liver (µg/g)	72, 66, 58	98, 24, 60
Urine (mg/L)	6, 28, 7	10, 12, 7

[Munksgaard 1969]

In 7 deaths attributed to amitriptyline overdose, postmortem concentrations (mean), were:

	Amitriptyline	*Nortriptyline*
Blood (mg/L)	0.43–8.30 (3.4)	0.29–6.50 (1.6)
Liver (μg/g)	10.4–243 (92)	4.2–456 (94)

[Bailey, Shaw 1980]

In a fatality involving the suicidal ingestion of amitriptyline, 10 blood samples taken 21 h after discovery of the body and ~28.5 h after the ingestion revealed concentrations of 2.5–12 mg/L amitriptyline, 0.7–3.1 mg/L nortriptyline, and 81–244 salicylate; a further 10 h later, the concentrations were 1–39 mg/L, 0.6–7.0 mg/L, and 86–310 mg/L, respectively. Of tissue samples, drug concentrations were highest in the liver (amitriptyline 301 μg/g, salicylates 670 μg/g) [Pounder *et al.* 1994].

A 44-year-old female was found dead in bed. Postmortem blood amitriptyline concentration was 85.9 mg/L [Margalho *et al.* 2007].

A 37-year-old female was found dead in her apartment. Amitriptyline and nortriptyline were quantified in her blood at concentrations of 7.0 and 7.4 mg/L, respectively [Stiakakis *et al.* 2009].

Bioavailability 30–60%.
Half-life Plasma half-life, 9–36 h, increased in overdosage.
Volume of Distribution ≈15 L/kg.
Clearance Plasma clearance, 11.5 mL/min/kg.
Distribution in Blood Plasma : whole blood ratio, 1.2.
Saliva Saliva : plasma ratio, 3.
Protein Binding 91–97%.
Note For a review of the pharmacokinetics of tricyclic antidepressants see Molnar, Gupta [1980].
Dose For depression, 50 to 150 mg amitriptyline hydrochloride daily; up to 300 mg daily has been given.

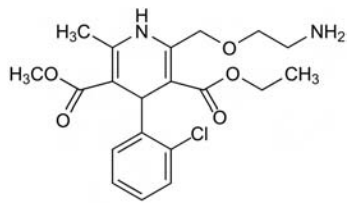
Amlodipine

Calcium Channel Blocker
$C_{20}H_{25}ClN_2O_5$ = 408.9
CAS—88150-42-9

IUPAC Name 3-*O*-Ethyl 5-*O*-methyl 2-(2-aminoethoxymethyl)-4-(2-chlorophenyl)-6-methyl-1, 4-dihydropyridine-3,5-dicarboxylate
Synonyms 2-[(2-Aminoethoxy)methyl]-4-(2-chlorophenyl)-1,4-dihydro-6-methyl-3,5-pyridinedicarboxylic acid 3-ethyl 5-methyl ester; UK-48340.



Chemical Properties pK_a 8.6. Log *P* (octanol/water), 3.00. Extraction yield (chlorobutane), 1 [Demme *et al.* 2005].

Amlodipine Maleate
$C_{20}H_{25}ClN_2O_5,C_4H_4O_4$ = 525.0
CAS—88150-47-4
Synonym UK-48340-11
Chemical Properties A white crystalline powder. Mp 178° to 179°.

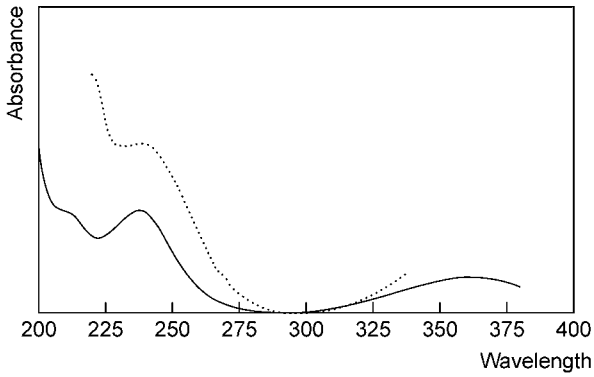
Amlodipine Besilate
$C_{20}H_{25}ClN_2O_5,C_6H_5SO_3H$ = 567.1
CAS—111470-99-6
Synonyms Amlodipine besylate; amlodipine monobenzenesulfonate.
Proprietary Names *Amlodin*; *Amlor*; *Antacal*; *Astudal*; *Istin*; *Monopina*; *Norvas*; *Norvasc*.
Chemical Properties A white crystalline powder. It is slightly soluble in water; sparingly soluble in ethanol.

A

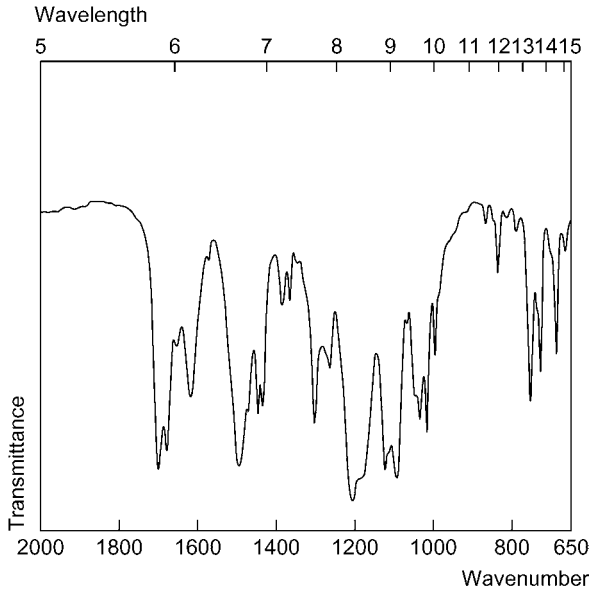
Thin-layer Chromatography System TE—R_f 0.36; system TB—R_f 0.02; system TAE—R_f 0.11.
Gas Chromatography System GB—RI 2982; system GP—M (dehydro-2-$HOOC^-$)-ME-, RI 2430, M (dehydro-desamino-$HOOC^-$)-ME-, RI 2635.
High Performance Liquid Chromatography System HX—RI 428; system HZ—retention time 4.9 min; system HAA—retention time 15.1 min.

Column: ODS Cosmosil 5 C_{18}-P (150 × 4.6 mm, 5 µm). Mobile phase: 0.05 mol/L phosphate buffer solution (pH 3.1) : acetonitrile (65:35) containing 0.005 mol/L sodium octane sulfonate and 5 mg/L EDTA, flow rate 1 mL/min. Electrochemical detection. Retention time: 10.1 min [Shimooka *et al.* 1989].

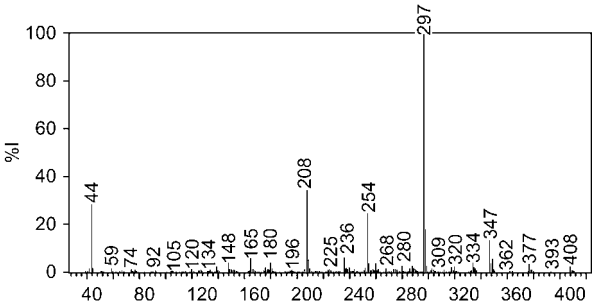
Ultraviolet Spectrum Aqueous acid (0.2 mol/L NH_2SO_4)—239 nm; basic—238 nm (besilate).



Infrared Spectrum Principal peaks at wavenumber 1208, 1182, 1094 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 297, 208, 44, 254, 298, 347, 236, 165.



Quantification

Plasma **GC** Column: DB1 (40 m × 0.25 mm i.d. × 0.25 mm); Temperature: 250°. Carrier gas: H_2, 32 cm/s. Detection: NPD. Retention time: 9.9 min [Monkman *et al.* 1996]. Limit of detection, 0.5 µg/L [Monkman *et al.* 1996]. ECD. Limit of detection, 0.02 µg/L for each enantiomer [Scharpf *et al.* 1994]. ECD. Limit of detection, 0.2 µg/L [Beresford *et al.* 1987]. Column: fused silica coated with cross-linked 5% phenylmethyl silicone (25 m × 0.31 mm i.d., 0.17 µm). Temperature programme: 280° to 320° at 20°/min, for 9 min. Carrier gas: N_2, flow rate 1 mL/min. ECD. Retention time: 4.4 min [Faulkner *et al.* 1986]. Limit of detection, 0.2 µg/L [Faulkner *et al.* 1986].

HPLC Electrochemical detection. Limit of detection, about 0.2 µg/L for each enantiomer [Josefsson, Norlander 1996].

Serum **HPLC** Electrochemical detection. Limit of detection, 0.1 µg/L [Shimooka *et al.* 1989].

Gingival Crevicular Fluid **GC-MS** ECD. Limit of detection, 0.5 µg/L [Monkman *et al.* 1996].

Tissue **GC-MS** ECD. Limit of detection, 0.5 ng/g for each enantiomer [Scharpf *et al.* 1994].

Note For GC-MS method see Beresford *et al.* [1988].

Disposition in the Body Amlodipine is slowly and almost completely absorbed after oral administration; peak plasma concentrations occur after 6 to 12 h. Absorption is not affected by food. It undergoes minimal presystemic metabolism; bioavailability is about 60 to 65% and it undergoes extensive but slow metabolism in the liver. Metabolites lack significant pharmacological activity and are excreted predominantly in urine (about 60% of a dose); <10% of a dose is excreted as the unchanged drug. About 20 to 25% of a dose is eliminated via bile. It is not removed by haemodialysis.

Therapeutic Concentration

The mean peak plasma concentration 7.6 h after administration of a 10 mg single oral dose in 12 healthy male subjects (with a mean age of 25.8 years) was 5.9 µg/L. The drug was administered after an overnight fast. Following oral administration of 15 mg daily for 14 days in 56 subjects mean peak plasma concentration was 18.1 µg/L after 8.7 h [Faulkner *et al.* 1986].

Toxicity

A 42-year-old female ingested 50 to 100 mg of amlodipine besylate together with alcohol in a suicide attempt. Symptoms included hypotension and sinus tachycardia. Serum-amlodipine concentration measured 2.5 h after ingestion was 88 µg/L; this had reduced to 79 µg/L 37.5 h after ingestion. Treatment included activated charcoal, whole bowel irrigation and intravenous sodium chloride 0.9%; the woman was discharged on day 2 [Stanek *et al.* 1997].

Bioavailability 60 to 65%.

Half-life Plasma, 35 to 50 h; 65 h in elderly subjects; 56 h in patients with hepatic impairment.

Volume of Distribution 21 L/kg.

Clearance Plasma, 18.5 L/h (elderly); 24.6 L/h (young); also, stated as 7 mL/min/kg.

Protein Binding 95 to 98%.

Dose Up to 10 mg (of the base) daily.

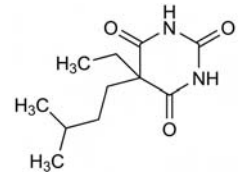
Amobarbital

Barbiturate
$C_{11}H_{18}N_2O_3$ = 226.3
CAS—57-43-2

IUPAC Name 5-Ethyl-5-(3-methylbutyl)-2,4,6-(1*H*,3*H*,5*H*)-pyrimidinetrione
Synonyms Amylobarbital; amylobarbitone; pentymalum.
Proprietary Names *Amal*; *Amytal*; *Eunoctal*; *Neur-Amyl*; *Stadadorm*.



Chemical Properties A white crystalline powder. Mp 156° to 158°. Soluble 1 in 1300 of water, 1 in 5 of ethanol, 1 in 17 of chloroform and 1 in 6 of ether; freely soluble in benzene; soluble in aqueous solutions of alkali hydroxides and carbonates; insoluble in petroleum ether and aliphatic hydrocarbons. pK_a 7.9 (25°). Log *P* (octanol/pH 7.4), 1.6.

Amobarbital Sodium

$C_{11}H_{17}N_2NaO_3$ = 248.3
CAS—64-43-7
Synonyms Amylobarbitone sodium; barbamylum; soluble amylobarbital.

Proprietary Names *Amylbarb Sodium*; *Amylobeta*; *Neur-Amyl Sodium*; *Sodium Amytal*. It is an ingredient of *Tuinal*.

Chemical Properties A white, hygroscopic, granular powder. Mp about 156°. Soluble 1 in <1 of water and 1 in 1 of ethanol; practically insoluble in chloroform and ether. Solutions in water decompose on standing.

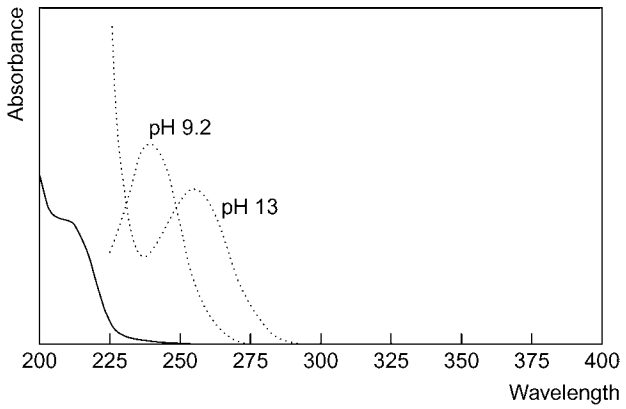
Colour Tests Koppanyi–Zwikker test—violet; mercurous nitrate—black.

Thin-layer Chromatography System TD—R_f 0.52; system TE—R_f 0.44; system TF—R_f 0.66; system TH—R_f 0.74; system TAD—R_f 0.58; system TAE—R_f 0.88. (Mercuric chloride–diphenylcarbazone reagent, positive; mercurous nitrate spray, black; Zwikker's reagent, pink.)

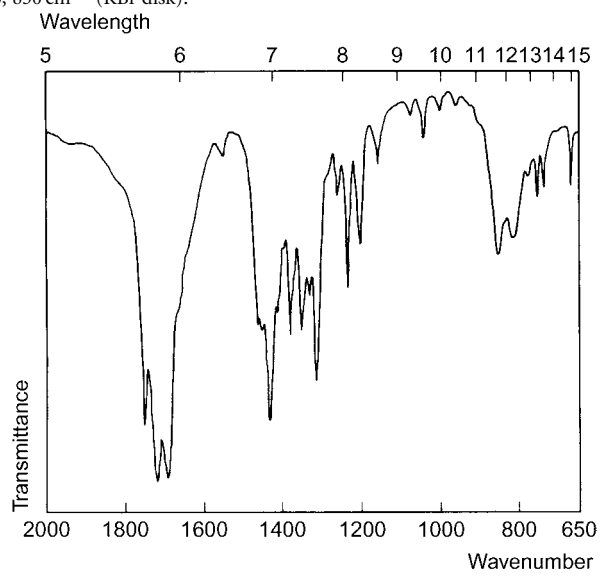
Gas Chromatography System GA—amobarbital RI 1710; amobarbital-Me_2 RI 1593, M (3-OH-) RI 1915, M (3-OH-)-Me_2- RI 1750, M (COOH-) RI 1960; system GB—amobarbital RI 1742; M (3-OH-) RI 2015; system GF—RI 2430; system GAJ—amobarbital RRT 0.794, M (3-OH-) RRT 1.138, M (COOH-) RRT 0.775 (relative to methylphenobarbital).

High Performance Liquid Chromatography System HG—*k* 10.91; system HH—*k* 7.05; system HX—RI 424; system HY—RI 374; system HZ—retention time 4.0 min; system HAA—retention time 16.6 min.

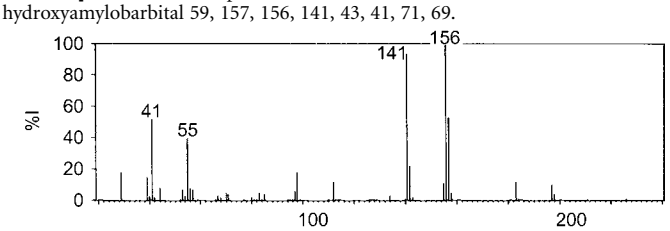
Ultraviolet Spectrum Borax buffer 0.05 mol/L (pH 9.2)—240 nm (A^1_1=445a); 1 mol/L sodium hydroxide (pH 13)—255 nm (A^1_1=364b).



Infrared Spectrum Principal peaks at wavenumbers 1725, 1696, 1758, 1317, 1240, 850 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 156, 141, 157, 41, 55, 142, 98, 39; 3′-hydroxyamylobarbital 59, 157, 156, 141, 43, 41, 71, 69.



Quantification The following are general methods for most barbiturates.

Blood **HPLC** UV detection. Limit of detection, <1 mg/L [Gill *et al.* 1981].

Plasma **GC** AFID. Limit of detection, <500 ng/L [Villén, Petters 1983]. AFID. Limit of detection, <500 µg/L [Turcant *et al.*].

Immunoassay FPIA on COBAS INTEGRA. For comparison with GC–MS, see Cannon *et al.* [1999].

Serum **GC** NPD. Limit of detection, 500 µg/L [Soo *et al.* 1986].

Immunoassay FPIA on COBAS INTEGRA. For comparison with EMIT and GC–MS, see Schwenzer *et al.* [2000]. FPIA on COBAS INTEGRA. For comparison with GC–MS, see Cannon *et al.* [1999]].

Urine **GC** AFID. Limit of detection, <500 ng/L [Villén, Petters 1983].

GC–MS Limit of detection, about 20 µg/L [Liu *et al.* 1994].

HPLC UV detection. For amobarbital *N*-glycosides, see Nandi, Soine [1997].

Immunoassay For comparison with EMIT and GC–MS, see Schwenzer *et al.* [2000]. EMIT. Limit of detection, 2 mg/L for quinalbarbital [Law, Moffat 1981]. RIA. Limit of detection, 10 µg/L for quinalbarbital [Law, Moffat 1981].

Saliva **HPLC** UV detection. Limits of detection, 0.5 to 2.5 ng [Haginaka, Wakai 1987].

Note For a review of gas chromatographic methods, see Pillai, Dilli [1981].

Disposition in the Body Readily and almost completely absorbed after oral administration. It is metabolised by hydroxylation to give the major metabolite 3′-hydroxyamobarbital, which has about one-third of the activity of the parent substance. About 80 to 90% of a dose is excreted in the urine in 6 days, of which 30 to 50% is 3′-hydroxyamobarbital, up to 30% is *N*-β-D-glucopyranosylamobarbital and about 1% is unchanged drug. The metabolite pattern appears to be genetically determined. 5-(3′-Carboxybutyl)-5-ethylbarbituric acid has also been identified as a metabolite in urine. About 5% of a dose is eliminated in the faeces in 6 days.

Therapeutic Concentration In plasma, usually in the range 2 to 12 mg/L.

Toxicity The estimated minimum lethal dose is 1.5 g. Toxic effects are associated with plasma concentrations greater than 9 mg/L and fatalities with postmortem blood concentrations of 9 to 26 to 72 mg/L.

In a review of 55 cases of fatal overdosage, postmortem blood concentrations were in the range 13 to 96 mg/L [Gupta, Kofed 1966].

In 3 fatalities attributed to amobarbital overdose, the following postmortem tissue concentrations, mg/L or µg/g, were reported:

	Amobarbital	*3′-Hydroxyamobarbital*
Blood	36, 35, 25	2, –, 2
Bile	198, 178, –	6, –, –
Kidney	32, 59, 87	–, 2, 4
Liver	71, 79, 224	1, 2, 2
Lung	43, 40, 84	–, 2, 4
Spleen	77, 63, 104	–, 1, –
Urine	12, 12, –	9, –, –

[Robinson, McDowall 1979].

Bioavailability About 95%

Half-life Plasma half-life, 8 to 40 h (mean 24).

Volume of Distribution About 1 L/kg.

Clearance Plasma clearance, about 0.5 mL/min/kg.

Saliva Plasma : saliva ratio, about 2.8.

Protein Binding 40 to 60%.

Note For a review of the clinical pharmacokinetics of barbiturates, see Breimer [1977].

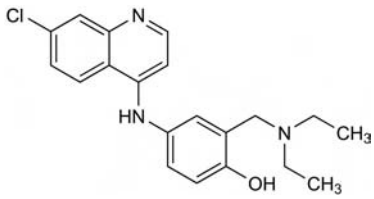
Antimalarial
$C_{20}H_{22}ClN_3O = 355.9$
CAS—86-42-0

IUPAC Name 4-[(7-Chloroquinolin-4-yl)amino]-2-(diethylaminomethyl) phenol
Synonym Amodiachin
Proprietary Name *Basoquin*

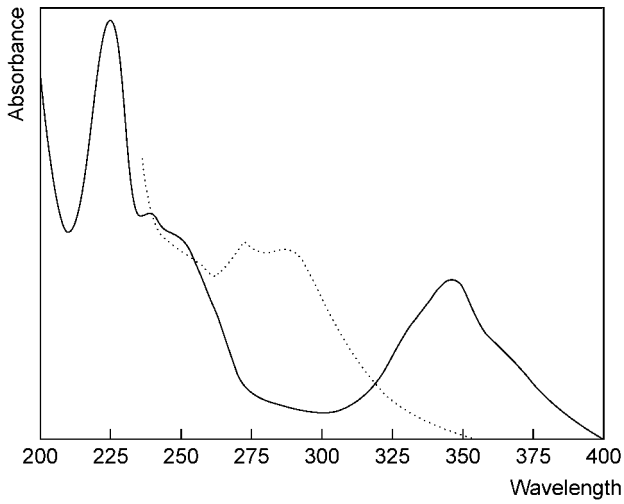


Chemical Properties White crystals. Mp 208°.

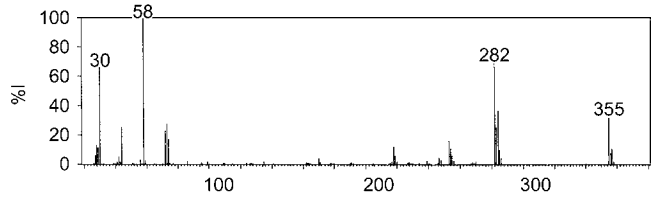
Amodiaquine Hydrochloride

$C_{20}H_{22}ClN_3O,2HCl, 2H_2O = 464.8$
CAS—69-44-3 (anhydrous); 6398-98-7 (dihydrate)
Proprietary Names *Camoquin*; *Flavoquine*.
Chemical Properties A yellow crystalline powder. Mp about 158°. Soluble 1 in about 22 of water and 1 in about 70 of ethanol; practically insoluble in chloroform and ether.

Colour Tests Folin-Ciocalteu reagent—blue; Liebermann's reagent—black; Millon's reagent—orange.
Thin-layer Chromatography System TA—R_f 0.62; system TB—R_f 0.08; system TC—R_f 0.40; system TE—R_f 0.74; system TL—R_f 0.37; system TAE—R_f 0.38; system TAJ—R_f 0.15; system TAK—R_f 0.00; system TAL—R_f 0.09 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—not eluted.
Ultraviolet Spectrum Aqueous acid—237 (A^{1}_{1}=600b), 343 nm; aqueous alkali—273, 287 nm.



Infrared Spectrum Principal peaks at wavenumbers 1565, 815, 1535, 1255, 869, 847 cm^{-1} (KBr disk).
Mass Spectrum Principal ions at *m/z* 58, 282, 30, 284, 355, 73, 283, 44.



Quantification

Note For a spectrofluorimetry method for the measurement of amodiaquine see Trenholme *et al* [1974].
Disposition in the Body Amodiaquine is readily absorbed after oral administration and widely distributed throughout the tissues. After absorption it is slowly released into the blood and excreted in the urine for at least 7 days after a single dose; the rate of excretion is increased in acid urine.

Therapeutic Concentration

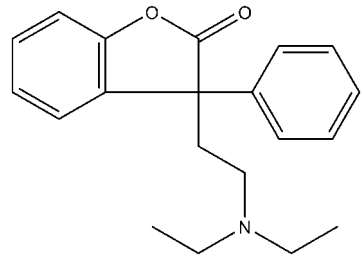
Following a single oral dose of 10 mg/kg to 5 subjects, serum concentrations of 0.30 to 0.68 (mean 0.5) mg/L were reported after 4 h; the ratio of erythrocyte to serum concentration varied with time and between individuals, but erythrocyte concentrations were generally higher than serum concentrations after 48 h [Trenholme *et al.* 1974].

Dose For an acute attack, the equivalent of 1.5 g of amodiaquine in 48 h (1.2 g in the first 24 h); for suppression, the equivalent of 300 to 600 mg every 7 days.

Trenholme GM *et al.* (1974). A method for the determination of amodiaquine. *Bull WHO* 51: 431–434.

Amolanone

Butyrolactone, Anaesthetic (Local)
$C_{20}H_{23}NO_2 = 309.4$
IUPAC Name 3-(2-Diethylaminoethyl)-3-phenyl-1-benzofuran-2-one
Synonyms AP 43; γ-diethylamino-α-o-hydroxyphenyl-α-phenylbutyrolactone.



Chemical Properties White crystals. Mp 43° to 44°. Bp 192° to 194°. Extracted by organic solvents from aqueous alkaline solutions.

Amolanone Hydrochloride

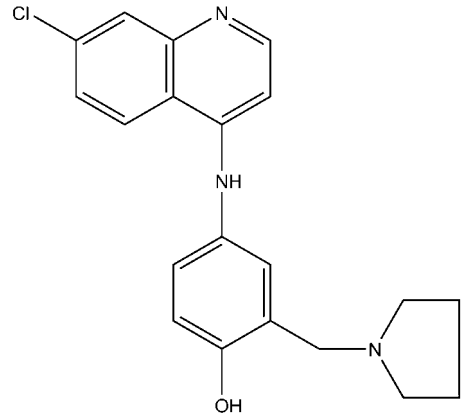
$C_{20}H_{23}NO_2,HCl = 345.9$
Proprietary Name *Amethone Hydrochloride*
Chemical Properties White crystals. Mp 152° to 153°. Soluble in water.

Colour Test Vitali's test—pale-brown/yellow (limit of detection, 0.25 μg).
Thin-layer Chromatography System T1—R_f 0.71 (location reagent acidified iodoplatinate spray positive reaction).
Gas Chromatography System G2/225—retention time 0.66 relative to codeine; system G4—retention time 0.43 relative to codeine.
Ultraviolet Spectrum Aqueous acid (0.1 N sulfuric acid)—265, 269, 276.5 nm.
Infrared Spectrum Principal peaks at wavenumbers 1795, 1025, 750, 1455 cm^{-1} (KBr disk).
Dose Used for local anaesthesia of the lower urinary tract; a 0.33% solution is instilled intra-urethrally. The maximum safe amount for topical use is 30 mL of a 0.33% solution.

Amopyroquine

Aminoquinoline, Antimalarial
$C_{20}H_{20}ClN_3O = 353.9$
CAS—550-81-2

IUPAC Name 4-(7-Chloro-4-quinolylamino)-2-(pyrrolidin-1-ylmethyl)phenol
Synonyms CI-356; PAM-780; WR-4835.



Chemical Properties Extracted by organic solvents from aqueous alkaline solutions.

Amopyroquine Hydrochloride

$C_{20}H_{20}ClN_3O,2HCl = 426.8$
CAS—10350-81-9
Proprietary Name *Propoquin*
Chemical Properties Yellow crystalline powder.

Colour Tests Ammonium molybdate—(yellow) blue-black→green (limit of detection, 0.1 µg); Vitali's test—(yellow) orange/yellow/brown (limit of detection, 0.1 µg).
Thin-Layer Chromatography System T1—R_f 0.45 (location reagent acidified iodoplatinate spray, strong reaction).
Ultraviolet Spectrum Aqueous acid (0.1 N sulfuric acid)—224, 238, 342 nm.
Infrared Spectrum Principal peaks at wavenumbers 1563, 1490, 1252 cm^{-1} (KBr disk).
Quantification
***Other* HPLC** Rabbit plasma and red blood cells. Column: C_{18} Nucleosil (100 × 4.6 mm i.d., 3 µm). Mobile phase: acetonitrile : 45 mmol/L potassium dihydrogenphosphate (pH 3.0; 15 : 85), flow rate 1.0 mL/min. UV detection (λ = 340 nm). Retention time: 3.5 min. Limit of detection, 7.1 µg/L in both media [Pussard *et al.* 1987]. Rat Plasma and Urine. Column: phenyl (100 × 8.0 mm i.d., 10 µm). Mobile phase: water : acetonitrile : methanol (90 : 8 : 2) containing triethylamine to pH 2.55 with orthophosphoric acid, flow rate 4.0 mL/min. UV detection (λ = 254 nm). Retention time: 4.0 min. Limit of detection, 5 to 10 µg/L in plasma [Coleman *et al.* 1987].
Disposition in the Body Rapidly absorbed following IM administration with peak plasma concentrations reached within 0.25 h. A primary amine metabolite is present in blood and plasma but in very low concentrations, with unchanged amopyroquine being the major circulating compound. The rapid absorption phase is followed by a tri-phasic decline with plasma concentrations representing only 9.5, 4.5 and 2.5% of the peak concentration after 3, 24 and 48 h, respectively. Unchanged amopyroquine and its amine metabolite are detectable in urine 48 h post-administration (1.2 and 0.2% of the administered dose, respectively).
Therapeutic Concentration

Ten healthy volunteers (mean age 27 years) were administered a single IM dose of amopyroquine base (2 mg/kg). The mean peak plasma concentration was 536 nmol/L after 0.25 h (range 296 to 883 nmol/L). In another study, 3 groups of patients diagnosed with *Plasmodium falciparum* malaria were administered different doses of IM amopyroquine. Patients in Group A were given a single 3 mg/kg injection; Group B 6 mg/kg; and Group C 6 mg/kg followed by 3 mg/kg after a 24-h interval. Whole blood concentrations in Group A ranged from 62 to 123 nmol/L at 48 h; Group B from 131 to 237 nmol/L at 24 h; and Group C from 106 to 236 nmol/L at 48 h [Verdier *et al.* 1989].

Twelve healthy male Caucasians (mean age 24 years) were administered 2 IM doses of amopyroquine base (6 mg/kg) with a 24-h interval. Peak blood and plasma concentrations for amopyroquine and its amine metabolite were reported as follows:

	Amopyroquine		*Amine metabolite*	
	C_{max} *(nmol/L)*	*Time (h)*	C_{max} *(nmol/L)*	*Time (h)*
Blood	2100	0.8	35	3.3
Plasma	800	0.6	10	2.7

An unidentified metabolite was also detected in blood and plasma at 3.3 h and 2.7 h, respectively [Pussard *et al.* 1994].
Volume of Distribution Apparent, 238 L/kg.
Clearance Systemic, approximately 2.06 L/min; renal 119 mL/min.
Distribution in Blood Blood : plasma ratio, 4.8.
Note For a review of the pharmacokinetics of amopyroquine and other 4-aminoquinoline antimalarials, see Pussard and Verdier [1994].
Dose Up to 9 mg/kg of the hydrochloride IM.

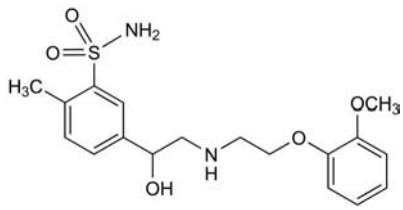
Amosulalol

Antihypertensive
$C_{18}H_{24}N_2O_5S = 380.5$
CAS—85320-68-9
IUPAC Name 5-[1-Hydroxy-2-[2-(2-methoxyphenoxy)ethylamino]ethyl]-2-methylbenzenesulfonamide



Chemical Properties pK_a 7.72; 10.04. Log *D* (octanol/pH 7.5), 0.82.

Amosulalol Monohydrochloride

$C_{18}H_{25}ClN_2O_5S = 416.9$
CAS—70958-86-0; 93633-92-2
Synonym YM-09538
Proprietary Name *Lowgan*
Chemical Properties Colourless crystals. Mp 158° to 160°.

Ultraviolet Spectrum Aqueous acid—272 nm; aqueous alkali—272 nm.
Infrared Spectrum Principal peaks at wavenumber 1330, 1260, 1165, 755 cm^{-1}.
Mass Spectrum Principal ions at *m/z* (5-hydroxyl-) 196, 239, 208, 200, 225, 397, 396, 257.
Quantification
***Plasma* HPLC** Column: LiChrosorb RP-18 (15 cm × 4 mm i.d., 5 µm), stainless steel. Mobile phase: acetonitrile: methanol: 0.6 mol/L acetic acid : 0.02 mol/L ammonium acetate (20:5:30:50). UV detection (λ=271 nm). Retention time: amosulalol, 7.2 min; 5-hydroxylated amosulalol, 3.3 min [Kamimura *et al.* 1985]. Limit of detection, 0.02 mg/L [Kamimura *et al.* 1981].
***Urine* GC** Limit of detection, 0.2 mg/L [Kamimura *et al.* 1983].
Disposition in the Body Amosulalol is metabolised to at least 6 metabolites (free and conjugated forms), the main metabolite in humans being the sulfate conjugate of 5-hydroxyl amosulalol. 25 to 35% of an administered dose is excreted in urine unchanged within the first 6 h.
Therapeutic Concentration

Twenty five healthy men, aged between 24 and 45 years, were administered with single oral doses of 12.5, 25, 50, 100 and 150 mg amosulalol after a fast. Mean peak plasma concentrations of 0.2, 0.49, 1.11, 1.87 and 4.09 mg/L were reached within 2.5 to 4 h respectively [Nakashima *et al.* 1984].

Toxicity Toxic by subcutaneous and IV routes.
Bioavailability Approximately 100%.
Half-life Approximately, 2.8 h (IV administration) or 5.7 h (oral).
Volume of Distribution 0.75 L/kg.
Clearance Approximately 8.09 L/h (IV); 7.28 L/h (oral).
Protein Binding 97 to 98%.
Dose Starting oral dose of 10 mg twice daily, up to a maximum daily dose of 60 mg.

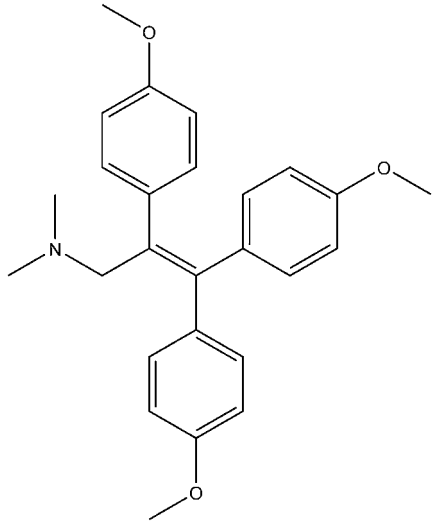
Amotriphene

Vasodilator, Antiarrhythmic (Coronary)
$C_{26}H_{29}NO_3 = 403.5$
CAS—5585-64-8
IUPAC Name 2,3,3-Tris(4-methoxyphenyl)-*N*,*N*-dimethyl-prop-2-en-1-amine
Synonyms Aminoxitrifeno; aminoxytriphen; aminoxytriphenum; 2,3,3-tris(*p*-methoxyphenyl)-*N*,*N*-dimethylallylamin; 2,3,3-tris(*p*-methoxyphenyl)-*N*,*N*-dimethylallylamine.



Amotriphene Hydrochloride

$C_{26}H_{29}NO_3$,HCl = 439.9

CAS—568-69-4

IUPAC Name 2,3,3-Tris(4-methoxyphenyl)-*N*,*N*-dimethyl-prop-2-en-1-amine hydrochloride

Synonyms Aminooxytriphene hydrochloride; 3-dimethylamino-1,1,2-tris(4-methoxyphenyl)-1-propene hydrochloride; Win 5494.

Proprietary Name *Myordil*

Disposition in the Body

Therapeutic Concentration

Amotriphene hydrochloride (100 mg) was administered to 40 angina patients. This dose caused gastric irritation in a moderate number of patients, so the dose was reduced to 50 mg for the last 8 months of the study. Two patients stopped drug therapy due to nausea, 1 patient was classified as a failure, and 2 died. Of the remaining 35 patients, 50% remained free of anginal pain whereas the remaining 17 were put onto their original therapy with concomitant therapy with amotriphene [Day 1961].

In another study, a dose of 25 to 50 mg was orally administered 3 times daily to 75 patients: 36 had coronary artery disease, 6 had acute myocardial infarction, and 33 had various cardiac arrhythmias. The drug improved the status and wellbeing of patients, and reduced the incidence of ventricular premature contractions [Harris 1961].

Day HW (1961). Angina pectoris: a clinical note in the use of Myordil (Win 5494). *J Kans Med Soc* 62: 143.

Harris R (1961). Clinical observations of amotriphene hydrochloride. *NY State J Med* 61: 4009–4014.

Amoxapine

Dibenzoxazepine, Tricyclic Antidepressant

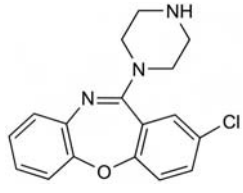
$C_{17}H_{16}ClN_3O$ = 313.8

CAS—14028-44-5

IUPAC Name 8-Chloro-6-piperazin-1-ylbenzo[*b*][1,5]benzoxazepine

Synonyms 2-Chloro-11-(1-piperazinyl)dibenz[b,f]oxazepine; CL-67772.

Proprietary Names *Asendin*; *Asendis*; *Defanyl*; *Demolox*; *Moxadil*.

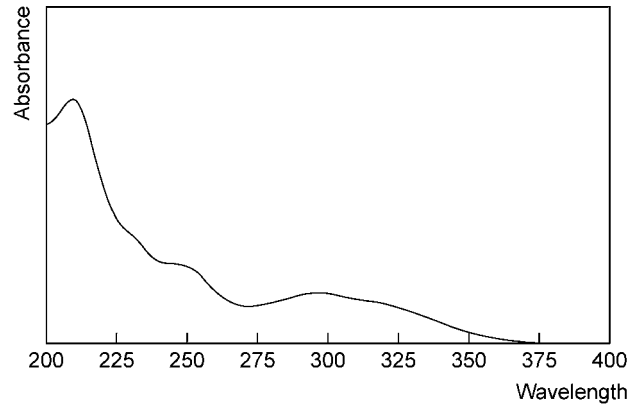


Chemical Properties Crystals. Mp 175° to 176°. Log *P* (octanol/water) 3.38 [Meylan, Howard 1995].

Gas Chromatography System GA—amoxapine RI 2638, M (7-OH-) RI 2951, M (8-OH-) RI 2959; system GB—amoxapine RI 2746, M (7-OH-) RI 3525, M (8-OH-) RI 3546, system GM—amoxapine RRT 2.831 (relative to iprindole).

High Performance Liquid Chromatography System HX—RI 398; system HAA—RT 14.19 min.

Ultraviolet Spectrum Aqueous acid—252 (A_1^1=362 a), 293 (A_1^1=315 a); aqueous alkali—250, 299 nm.



Infrared Spectrum Principal peaks at wavenumbers 1604, 1592, 752, 1181, 1246, 1107 cm^{-1}.

Mass Spectrum Principal ions at *m*/*z* 245, 257, 247, 193, 56, 246, 228, 259.

Quantification

Blood **GC** Column: Cross-linked methyl silicone fused silica capillary (25 m × 0.20 mm i.d., 0.11 µm). Carrier gas: He, 195 kPa. Temperature programme: 180° for 1 min to 300° at 10°/min for 3 min. NPD. Limit of quantification, 140–204 µg/L; limit of detection, 42–62 µg/L depending on the Bond-Elut column used for extraction [Martinez *et al.* 2002]. Column; Rtx-50 (30 m × 0.32 mm i.d., 0.25 µm). Temperature programme: 130° for 3 min to 270° at 10°/min for 10 min to 295° at 10°/min for 5 min. Retention time: 1.22 min. Limit of quantification, 0.05 mg/L [Mazzola *et al.* 2000]. Column: 3% GasChrom Q 100/120 mesh (90 cm [3 ft]). Temperature programme: 200° for 8 min to 260° at 8°/min for 16 min. FID. Limit of detection not reported [Rohrig, Backer 1986]. Column: 3% OV-17 on Chromosorb WHP 100/120 mesh (1.83 m × 6.3 mm o.d.). Carrier gas: He, 32 mL/min. Temperature programme: 190° for 1 min to 300° at 16°/min for 19 min. Retention time: 10.0 min. Limit of detection, 0.5 mg/L [Winek *et al.* 1984]. Column: 3% OV-17 Gas-Chrom Q, 100/120 mesh (1.2 m × 3 mm i.d.). Carrier gas: N_2, 30 mL/min. Temperature: 220°. FID. Limit of detection, 0.25 mg/L [Taylor *et al.* 1982].

GC-MS Column: 5% OV-225 Chromosorb-WHP, 80/100 mesh (1.2 m × 2 mm i.d.). Carrier gas: He, 20 mL/min. Temperature: 240°. EI ionisation at 70 eV. Limit of detection, 0.5 mg/L [Wu Chen *et al.* 1983].

HPLC Column: (1) C_8 RP TSK gel Super-Octyl (100 × 4.6 mm i.d., 2 µm); (2) Hypersil MOS-C_8 (100 × 4.6 mm, 5 µm). Mobile phase: methanol : 20 mmol/L potassium dihydrogen phosphate (pH 7, 60 : 40), flow rate 0.6 mL/min. Retention time: 5.6 min for column 1, 7.8 min for column 2. Column: C_8 reversed phase (100 × 4.6 mm i.d., 2 µm). Mobile phase: methanol : 20 mmol/L potassium dihydrogen phosphate (pH 7.0, 60 : 40), flow rate 0.6 mL/min. UV detection (λ = 254 nm). Retention time: 5.6 min. Limit of quantification, 0.5 mg/L [Tanaka *et al.* 1997].

LC-MS Column: Xterra RP_{18} (100 × 2.1 mm i.d.). Mobile phase: acetonitrile : 4 mmol/L ammonium formate buffer (pH 3.2, 5 : 95 for 2 min to 20 : 80 over 2 min to 30 : 70 over 12 min for 2 min), flow rate 0.3 mL/min. ESI, positive ion mode, MRM acquisition mode. Limit of quantification, 2 µg/L [Titier *et al.* 2007].

Plasma **GC-MS** Column: DB-5MS fused silica capillary (30 m × 0.32 mm i.d., 0.25 µm). Carrier gas: He, 2.0 mL/min. Temperature programme: 100° for 1 min to 300° at 20°/min. EI ionisation at 70 eV, SIM acquisition mode. Limit of quantification, 5 µg/L, limit of detection, 1.0 µg/L [Lee *et al.* 2008].

HPLC Column: Reversed phase CN (250 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : 0.5 N acetic acid (30 : 70) containing 0.05% hexylamine, flow rate 0.8 mL/min. UV detection (λ = 310 nm). Limit of detection, 5.9 µg/L [Hüe *et al.* 1998]. Column: Spherisorb C_6 (150 × 4.6 mm i.d., 5 µm). Mobile phase: 5 mmol/L potassium dihydrogen phosphate containing 14 mmol/L orthophosphoric acid : acetonitrile containing 105 µmol/L nonylamine (77 : 23), flow rate 2.2 mL/min. UV detection (λ = 210 nm). Limit of detection, 2 µg/L [Cheung *et al.* 1991]. Column: ODS-2 Spherisorb (150 × 4.6 mm i.d., 5 µm). Mobile phase: 0.15% TEA (pH 3.0) : acetonitrile (1 : 1), flow rate 1.5 mL/min. UV detection (λ = 212 nm). Limit of quantification, 2.0 µg/L [Selinger *et al.* 1989]. Column: Supelco LC-1 TMS-bonded silica (250 × 4.6 mm i.d., 5 µm). Mobile phase: 0.05 mol/L potassium dihydrogen phosphate : acetonitrile (75 : 25) containing 1.2 mL/L *n*-butylamine, 1.0 mL/L orthophosphoric acid and 0.005 mol/L heptanesulfonic acid, flow rate 1.8 mL/min. Electrochemical detection. Limit of detection, 5 µg/L [Suckow, Cooper 1985]. Column: Cyanopropylsilane (250 × 4.6 mm i.d.). Mobile phase: 0.03 mol/L sodium acetate (pH 6.0) : acetonitrile (35 : 65), flow rate 3.0 mL/min. UV detection (λ = 250 nm). Limit of detection, 25 µg/L for amoxapine and metabolites [Johnson *et al.* 1984]. See also Yufu *et al.* [1984] and Kimball, Lampert [1982].

LC-MS Column: Inertsil C_8 (150 × 2.0 mm i.d., 5 µm). Mobile phase: methanol : 10 mmol/L ammonium acetate (pH 5.0) : acetonitrile (70 : 20 : 10), flow rate 1.0 mL/min. Positive ion mode, full scan mode. Retention time: 6.5 min. Limit of quantification, 0.2 mg/L, limit of detection, 0.16 mg/L [Shinozuka *et al.* 2006].

Serum **GC** Column: 3% SP 2100 on 100/120 mesh (1.8 or 2 m × 4 mm i.d.). Temperature: 255°. Carrier gas: Ar : CH_4. ECD. Limit of detection not reported [Cooper, Kelly 1979].

HPLC See Blood. Limit of quantification, 0.05 mg/L [Tanaka *et al.* 1997]. Column: TSkgel ODS-80TM (150 × 4.0 mm i.d.). Mobile phase: acetonitrile : 100 mmol/L potassium phosphate buffer (pH 2.7) containing sodium 1-heptanesulfonate (22.5 : 77.5 to 30 : 70 at 10 min). UV detection (λ = 210 nm). Limit of detection, 10 µg/L [Matsumoto *et al.* 1989]. Column: Cosmosil C_{18} reversed phase (150 × 4.6 mm i.d., 5 µm). Mobile phase: 1% TEA (pH 3.0) : methanol : tetrahydrofuran (70 : 20 : 10), flow rate 1 mL/min. UV detection (λ = 254 nm). Limit of detection, 10 µg/L [Kobayashi *et al.* 1985]. Column: µBondapak C_{18}. Mobile phase: acetonitrile-water (85 : 15) with 5 mL 10 mol/L Tris buffer (pH 9), flow rate 4.0 mL/min. UV detection (λ = 254 nm). Limit of detection, 50 µg/L for amoxapine and 8-hydroxyamoxapine [Tasset, Pesce 1984]. Column: Zorbax cyanopropyl (250 × 4.6 mm i.d., 5–6 µm). Mobile phase: 0.5 mol/L acetic acid: acetonitrile : *n*-butylamine (59 : 41 : 0.024), flow rate 1.5 mL/min). UV detection (λ = 254 nm). Limit of detection, 8–10 µg/L [Lensmeyer, Evenson 1984]. See also Beierle, Hubbard [1983], Ketchum *et al.* [1983], and Tasset, Hassan [1982].

LC-MS Column: Xterra MS C_{18} (50 × 2.1 mm i.d., 5 µm). ESI, positive ion mode, MRM acquisition mode. Retention time: 4.9 min. Limit of detection, 10 µg/L [Sauvage *et al.* 2006].

Urine **GC** See Blood [Winek *et al.* 1984]. Column: 3% OV-17 Gas-Chrom Q 100/120 mesh (1.2 m × 3 mm i.d.). Carrier gas: N_2, 30 mL/min. Temperature: 220°. FID. Limit of detection, 0.25 mg/L [Taylor *et al.* 1982]. Column: 3% SP 2100 on 100/120 mesh (1.8 or 2 m × 4 mm i.d.). Temperature: 255°. Carrier gas: He. FID. Limit of detection not reported [Cooper, Kelly 1979].

HPLC See Blood [Tanaka *et al.* 1997].

Disposition in the Body Amoxapine is rapidly and almost completely absorbed following oral administration, reaching a peak after ~90 min [Kimball, Lampert 1982]. It is metabolised by hydroxylation to 7-hydroxyamoxapine and 8-hydroxyamoxapine, which are both active. The hydroxylated metabolites are excreted in the urine as glucuronide conjugates and are also eliminated in the faeces in the unconjugated form. <5% of a dose is excreted in the urine as unchanged drug. Amoxapine is the *N*-demethylated metabolite of the antipsychotic agent loxapine.

Therapeutic Concentration

After a single oral dose of 50 mg to 26 subjects, a mean peak serum amoxapine concentration of 0.03 mg/L was attained in 1–2 h; the peak concentration of 8-hydroxyamoxapine was of a similar order [Cooper, Kelly 1979].

Following oral administration of 300 mg amoxapine daily in divided doses to 10 subjects, steady-state serum concentrations of 0.02–0.09 mg/L of amoxapine and 0.16–0.51 mg/L of 8-hydroxyamoxapine were reported [Boutelle 1980].

Six healthy male volunteers were administered a single dose of 150 mg amoxapine. A mean peak plasma concentration of 78 µg/L was reached at 1.64 h [Selinger *et al.* 1989].

Toxicity

A 69-year-old woman was found dead with a green, powdery substance on her lips. She was in possession of a prescription for loxapine. The concentration of amoxapine in her heart blood and bile at postmortem were 0.6 and 4.7 mg/L, respectively [Mazzola *et al.* 2000].

A 46-year-old female committed suicide with aspirin, diphenhydramine and amoxapine. Amoxapine and its metabolite concentrations at postmortem were as follows:

	Amoxapine	*N-acetylated amoxapine*
Premortem		
Blood (mg/L)	0.4	0.7
Postmortem		
Blood (mg/L)		
16 : 10	0.3	0.4
22 : 00	0.8	0.6
Liver (mg/kg)	27.6	3.7
Brain (mg/kg)	12.9	2.4
Stomach (mg)	123	1978
Small bowel (mg/kg)	2.1	16.8

[Osiewicz, Middleberg 1989].

Two fatal cases of amoxapine overdose (a 48-year-old white female and a 41-year-old white male) had blood amoxapine concentrations of 5.7 and 3.2 mg/L, respectively. The metabolites were not detected [Rohrig, Backer 1986].

The following postmortem concentrations were reported in 3 fatalities caused by amoxapine overdose: blood 11.5, 2.8 and 0.89 mg/L; bile 1264.5, 69.1 and 14.3 mg/L; and liver 112.2, 40.1 and 16.8 µg/g; in the first case brain and urine concentrations of 2.5 µg/g and 28.3 mg/L, respectively, were also reported [Winek *et al.* 1984].

Five patients with amoxapine overdose achieved maximum serum concentrations ranging from 308–2900 and 405–1480 µg/L for amoxapine and 8-hydroxyamoxapine, respectively [Tasset, Pesce 1984].

In a review of 33 cases of amoxapine overdose, 3 subjects had no toxic symptoms, 10 suffered mild toxic reactions, 15 developed severe toxicity and 5 died. Postmortem blood concentrations of 0.26–6.70 mg/L (mean, 2.8) of amoxapine plus 8-hydroxyamoxapine were reported in 4 of the 5 fatalities [Litovitz, Troutman 1983].

The following postmortem tissue concentrations were reported in death following ingestion of 2 g amoxapine: blood 7.2 mg/L, bile 823 mg/L, liver 36 µg/g; a blood-alcohol concentration of 280 mg/L was also reported. In a further 2 cases where amoxapine was a contributory cause of death, postmortem concentrations were blood 1.66 and 2.95 mg/L, bile 75 mg/L, liver 23.2 µg/g and urine 22 mg/L [Wu Chen *et al.* 1983].

In 5 fatal overdoses in which the subjects had ingested between 2000 and 8500 mg amoxapine, postmortem blood concentratins ranged from 261–6700 µg/L [Litovitz, Troutman 1983].

A 53-year-old male (A) and a 21-year-old female (B) died following the ingestion of amoxapine and the following concentrations were measured at postmortem:

Sample	*Case A*	*Case B*
Liver (mg/kg)	150 ± 13	ND
Gastric contents (mg/L)	110 ± 12	ND
Bile (mg/L)	61 ± 11	ND
Blood (mg/L)	18 ± 2.2	6.7 ± 0.9
Urine (mg/L)	13 ± 2.3	11 ± 0.8

ND, not determined
[Taylor *et al.* 1982].

In a non-fatal case of overdose in a 36-year-old woman, the following serum amoxapine and metabolite concentrations (µg/L) were measured at various time points after her admission to hospital:

Time after admission (h)	*Amoxapine*	*7-OH-Amoxapine*	*8-OH-Amoxapine*
0	2300	110	820
3	1150	60	860
8	700	<50	630

[Bock *et al.* 1982].
For a case of recovery from amoxepine overdose, see Miller *et al.* [1990].

Half-life Plasma half-life: amoxapine ~8 h, 7-hydroxyamoxapine ~6 h, 8-hydroxyamoxapine ~33 h.

Protein Binding ~90%.

Note For a review of the pharmacokinetics of amoxapine, see Jue *et al.* [1982] or Calvo *et al.* [1985].

Amoxicillin

Antibacterial

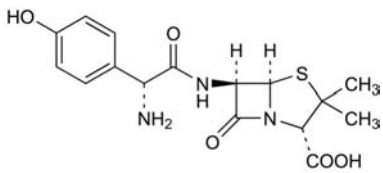
$C_{16}H_{19}N_3O_5S = 365.4$

CAS—26787-78-0

IUPAC Name (2*S*,5*R*,6*R*)-6-[[(2*R*)-2-Amino(4-hydroxyphenyl)acetyl]amino]-3,3-dimethyl-7-oxo-4-thia-1-azabicyclo[3.2.0]heptane-2-carboxylic acid

Synonyms D(−)-α-Amino-*p*-hydroxybenzylpenicillin; Amoxycillin; Amoxicilline.

Proprietary Names *AMPC*; *Amolin*; *Amopenixin*; *Helvamox*; *Moxal*; *Pasetocin*; *Penimox*; *Zamocilline*.



Chemical Properties pK_a 2.4, 7.4, 9.6. Log *P* (octanol/water), 0.87.

Amoxicillin Sodium

$C_{16}H_{18}N_3NaO_5S = 387.4$

CAS—34642-77-8

Proprietary Names *Amoxil (injection)*; *Clamoxyl (injection)*.

Chemical Properties A white powder. Soluble 1 in less than 1 of water.

Amoxicillin Trihydrate

$C_{16}H_{19}N_3O_5S,3H_2O = 419.4$

CAS—61336-70-7

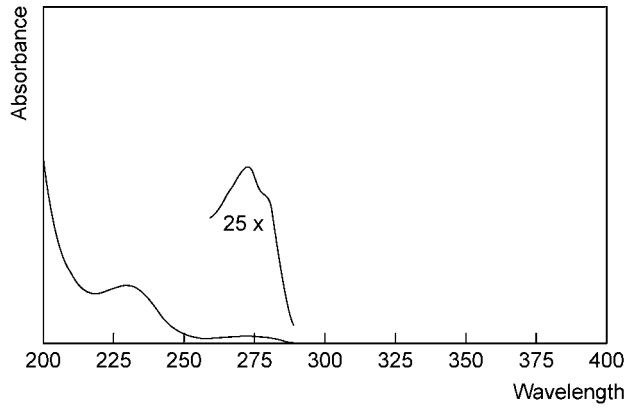
Synonym Amoxicillin

Proprietary Names *Amoxican*; *Amoxil*; *Amoxypen*; *Clamoxyl*; *Imacillin*; *Larotid*; *Moxacin*; *Moxilean*; *Novamoxin*; *Penamox*; *Polymox*; *Robamox*; *Trimox*; *Utimox*; *Wymox*. It is an ingredient of *Augmentin*.

Chemical Properties A white crystalline powder. Soluble 1 in 400 of water, 1 in 1000 of ethanol, and 1 in 200 of methanol; practically insoluble in chloroform and ether.

High Performance Liquid Chromatography System HY—RI 226; system HAA—retention time 3.1 min.

Ultraviolet Spectrum Amoxicillin trihydrate, aqueous acid—230 (A_1^1=225a), 272 (A_1^1=26a); aqueous alkali—247 nm (A_1^1=286b), 291 nm (A_1^1=62a).



Infrared Spectrum Principal peaks at wavenumbers 1775, 1583, 1684, 1248, 1613, 1313 cm^{-1} (amoxicillin trihydrate, KBr disk).

Quantification

Blood **HPLC** UV detection (λ=210 nm). Limit of quantification, 1.0 mg/L [Yuan *et al.* 1997].

Plasma **HPLC** DAD. Limit of quantification, 1.0 mg/L [Menelaou *et al.* 1999]. Fluorescence detection (λ_{ex}=395 nm; λ_{em}=485 nm). Limit of quantification, 0.1 mg/L [Mascher, Kikuta 1998]. UV detection (λ=210 nm). Limit of quantification, 0.25 mg/L [Yuan *et al.* 1997]. UV detection. Limit of detection, 500 µg/L [Lee, Brooks 1984].

Serum **HPLC** See Plasma [Mascher, Kikuta 1998].

Urine **HPLC** Fluorescence detection. Limit of detection, 2.5 mg/L for amoxicillin and penicilloic acid [Lee 1979].

Ear Fluid **HPLC** See Plasma [Yuan *et al.* 1997].

Disposition in the Body Amoxicillin is rapidly absorbed after oral administration. About 60% of an oral dose is excreted in the urine as unchanged drug in 6 h and 20% as the inactive metabolite, penicilloic acid, in the same period. After parenteral administration, up to 75% of a dose is excreted in the urine unchanged in 6 h.

Therapeutic Concentration

Twelve healthy male and female subjects with a mean age of 33.7 years (range 18 to 47 years) were fasted overnight and after administration of 1 g standard reference formulation amoxicillin (A), dispersible tablet (B) and 1 g dispersible tablet in suspension (C) the mean peak serum concentrations observed were 14.1 mg/L at 2.3 h for A, 15.1 mg/L at 2.0 h for B and 15.1 mg/L at 1.5 h for C [Prevot *et al.* 1997].

Following an oral dose of 500 mg to 8 subjects, peak plasma concentrations of 6.0 to 15.3 (mean 10) mg/L were attained in 1 to 2 h [Arancibia *et al.* 1980].

Half-life Plasma half-life, about 1 h, increased in renal failure.

Volume of Distribution About 0.2 to 0.4 L/kg.

Clearance Plasma clearance, 3 to 5 mL/min/kg.

Protein Binding About 20%.

Note For reviews of the pharmacokinetics of amoxicillin, see Brogden *et al.* [1975, 1979].

Dose The equivalent of 0.75 to 1.5 g of amoxicillin daily. One-day courses of 3 to 6 g are also given.

Amphotericin B

Antifungal

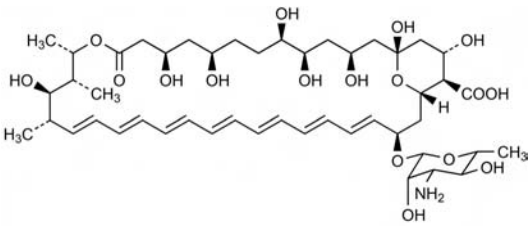
$C_{47}H_{73}NO_{17}$ = 924.1

CAS—1397-89-3

IUPAC Name (1*R*,3*S*,5*R*,6*R*,9*R*,11*R*,15*S*,16*R*,17*R*,18*S*,19*E*,21*E*,23*E*,25*E*,27*E*,29*E*,31*E*,33*R*,35*S*, 36*R*,37*S*)-33-[(2*R*,3*S*,4*S*,5*S*,6*R*)-4-Amino-3,5-dihydroxy-6-methyloxan-2-yl]oxy-1,3,5,6,9,11,17,37-octahydroxy-15,16,18-trimethyl-13-oxo-14,39-dioxabicyclo[33.3.1]nonatriaconta-19,21,23,25,27,29,31-heptaene-36-carboxylic acid.

Synonyms Amphotericin; anfotericina B.

Proprietary Names *Ampho-Moronal*; *Fungilin*; *Fungizone*. It is an ingredient of *Mysteclin (syrup)*.



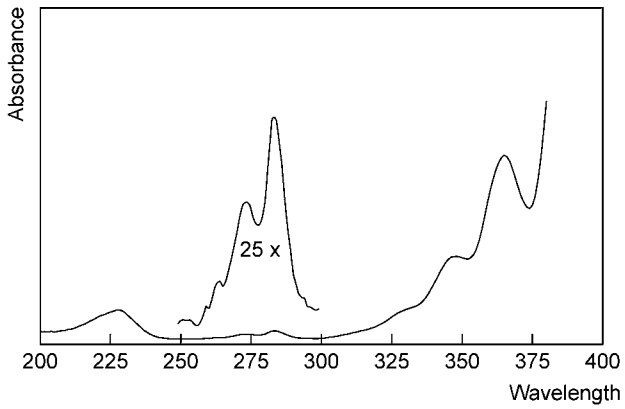
Chemical Properties A yellow to orange powder. It gradually decomposes above 170°. Practically insoluble in water, ethanol, chloroform and ether; soluble 1 in 200 of dimethylformamide and 1 in 20 of dimethylsulfoxide; soluble in propylene glycol. pK_a 5.5, 10.0.

Note A mixture of antifungal polyenes produced by the growth of certain strains of *Streptomyces nodosus* or by any other means.

High Performance Liquid Chromatography System HAA—retention time 15.7 min.

Column: RP-C_{18} μBondapak (300 × 3.9 mm i.d., 10 μm). Mobile phase: acetonitrile: 10 mmol/L acetate buffer , pH 4 (37:63 v/v). Flow rate: 1 mL/min for first 6 min and 2 mL/min until completion. Internal standard (IS): natamycin. UV detection (λ=383 nm). Retention time: 15 min [Lambros *et al.* 1996].

Ultraviolet Spectrum



Infrared Spectrum Principal peaks at wavenumbers 1010, 1065, 1038, 1103, 1183, 1126 cm^{-1} (KBr disk).

Quantification

Plasma **HPLC** Column: RP-C_{18} μBondapak (300 × 4.6 mm i.d., 5 μm). Mobile phase: acetonitrile: 20 mmol/L disodium edetate , pH 5 (45:55), flow rate 1 mL/min. IS: 1-amino-4-nitronaphthalene. UV detection (λ=407 nm). Retention time: 6.3 min [Eldem, Arica-Cellat 2001]. Limit of detection, 5 μg/L [Eldem, Arica-Cellat 2001].

LC-MS detection. Limit of quantification, 2 mg/L [Lee *et al.* 2001].

Serum **HPLC** UV detection. Limit of quantification, 0.05 mg/L [Alak *et al.* 1996]. UV detection (λ=383 nm). Limit of detection, 0.1 mg/L [Lambros *et al.* 1996]. UV detection. Limit of detection, 20 μg/L [Nilsson-Ehle *et al.* 1977].

Cerebrospinal Fluid **HPLC** See Serum [Nilsson-Ehle *et al.* 1977].

Urine **LC-MS** See Plasma. Limit of quantification, 0.05 mg/L [Lee *et al.* 2001].

Liver **HPLC** See Serum [Lambros*et al.* 1996].

Lung **HPLC** See Plasma [Lambros*et al.* 1996].

Faeces **LC-MS** See Plasma. Limit of quantification, 0.4 mg/L [Lee *et al.* 2001].

Note For an immunoassay for the quantification of amphotericin see Machard *et al.* [2000].

Disposition in the Body Amphotericin B is poorly absorbed after oral, i.m. or s.c. administration. It is slowly excreted in the urine, less than 10% of a dose being excreted unchanged in 24 h; up to 40% of a dose is excreted in the urine in 7 days and traces are still detectable in urine 2 months after cessation of treatment.

Therapeutic Concentration

Ten critically ill patients, aged 20 to 67 years, were administered liposomal amphotericin B IV at a dose of 1.2 to 4.2 mg/kg over 1 h, and 6 male and female patients, aged 49 to 76 years, were administered amphotericin B deoxycholate at a standard dose of 1.0 mg/kg over 1 h. The median peak concentration of amphotericin B was 14.4 (range 6.4 to 89.0) mg/L after the infusion and for amphotericin B deoxycholate, 1.7 (1.5 to 2.1) mg/L [Heinemann *et al.* 1997].

Adult patients, children (aged 1 to 12 years) and neonates (aged 14 to 30 days) all with invasive fungal infection were administered 1.0 mg/kg liposomal amphotericin B as a 60-min infusion. Mean peak plasma concentrations of 1.02 mg/L were detected at 0.83 to 1.22 h on day 1 which increased to 1.66 mg/L on day 28 for the adults. In the children, the peak concentrations were 0.63 mg/L at 0.36 to 0.95 h on day 1 and 1.1 mg/L on day 28. For the neonates, the peak plasma concentration was 0.54 mg/L at 0.34 to 1.0 h on day 1 and 0.73 mg/L on day 28 [Kotwani *et al.* 2002].

A mean serum concentration of 1.2 mg/L was reported in 20 subjects 1 h after an intravenous infusion of 50 mg [Fields *et al.* 1970].

Half-life Plasma half-life, about 24 to 48 h; a longer terminal elimination phase of about 15 days has also been reported.

Volume of Distribution About 4 L/kg.

Clearance Plasma clearance, about 0.4 mL/min/kg.

Protein Binding 90 to 97%.

Note For a review of amphotericin B, see Daneshead and Warnock [1983].

Dose Up to 800 mg daily by mouth. Doses of 0.25 to 1 mg/kg daily are given intravenously.

Ampicillin

Antibiotic

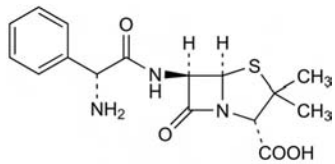
$C_{16}H_{19}N_3O_4S$ = 349.4

CAS—69-53-4

IUPAC Name (2*S*,5*R*,6*R*)-6-[[(2*R*)-2-Amino-2-phenylacetyl]amino]-3,3-dimethyl-7-oxo-4-thia-1-azabicyclo[3.2.0]heptane-2-carboxylic acid

Synonyms AY-6108; BRL-1341; P-50; aminobenzylpenicillin; anhydrous ampicillin.

Proprietary Names *A-Cillin*; *Albipen*; *Alpen*; *Amblosin*; *Amcill*; *Amfipen*; *Amipenix*; *Ampipenin*; *Amperil*; *Ampilar*; *Ampilean*; *Ampitab*; *Binotal*; *Biosan*; *Bonapicillin*; *Britacil*; *Britcin*; *D-Amp*; *Doktacillin*; *Domicillin*; *Dumopen*; *Grampenil*; *Nuvapen*; *Omnipen*; *Pen A*; *Penbritin(e)*; *Penicicline*; *Pensyn*; *Pentrexyl*; *Polycillin*; *Principen*; *Robamox*; *Supen*; *Tokiocillin*; *Totacillin*; *Vidopen*.



Chemical Properties A white crystalline powder. Mp about 200°. Soluble 1 in 170 of water; practically insoluble in ethanol, acetone, carbon tetrachloride, chloroform and ether. pK_a 2.5 (-COOH), 7.3 (-NH_2) (25°).

Ampicillin Sodium

$C_{16}H_{18}N_3NaO_4S$ = 371.4

CAS—69-52-3

Chemical Properties A white, hygroscopic, crystalline or amorphous powder. Aqueous solutions containing 10% or more deteriorate rapidly on storage. Mp about 205°, with decomposition. Soluble 1 in 2 of water and 1 in 50 of acetone; slightly soluble in chloroform; practically insoluble in ether. With ethanol, ampicillin sodium forms a colloidal dispersion which gels on standing.

Ampicillin Trihydrate

$C_{16}H_{19}N_3O_4S,3H_2O$ = 403.4

CAS—7177-48-2

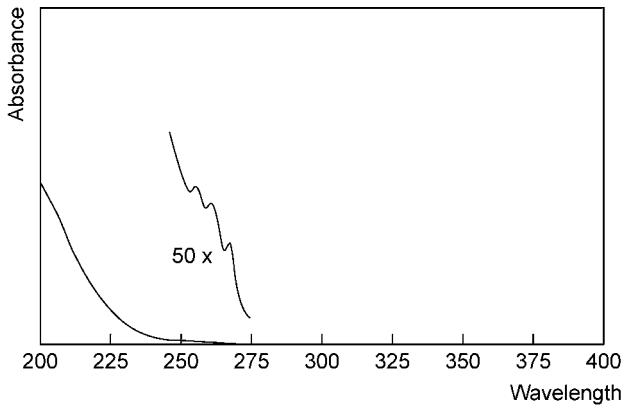
Chemical Properties A white crystalline powder. Soluble 1 in 150 of water; practically insoluble in ethanol, acetone, carbon tetrachloride, chloroform and ether.

A

Colour Tests Liebermann's reagent—orange. Suspend 10 mg in 1 mL of water and add 2 mL of a mixture of 2 mL of potassium cupritartrate solution and 6 mL of water—red-violet.

High Performance Liquid Chromatography System HY—RI 250; system HAA—retention time 3.8 min.

Ultraviolet Spectrum Aqueous acid—257 (A_1^1=9.2a), 262, 268 nm.



Infrared Spectrum Principal peaks at wavenumbers 1775, 1693, 1526, 1308, 1497, 1583 cm^{-1} (KBr disk).

Quantification

Plasma **HPLC** UV detection. Limit of detection, 500 µg/L [Vree *et al.* 1978].

Serum **HPLC** Fluorescence detection (λ_{ex}=364 nm; λ_{em}=422 nm). Limit of detection, 2 µg/L [Lal *et al.* 1994].

Spectrofluorimetry Limit of detection, 50 µg/L [Keshavan *et al.* 1979].

Oral fluid **HPLC** See Plasma [Vree *et al.* 1978].

Urine **HPLC** See Plasma [Vree *et al.* 1978].

Note For a Polarography method for the detection of ampicillin, see Vree *et al.* [1978].

Disposition in the Body Ampicillin is readily but incompletely absorbed after oral administration. About 30% of an oral dose is excreted in the urine in 6 h as unchanged drug and about 10% as penicilloic acid; after parenteral administration about 75% is excreted unchanged in 6 h. High concentrations of ampicillin are attained in the bile.

Therapeutic Concentration

After an oral dose of 500 mg given to 6 young subjects, peak plasma concentrations of 2.65 to 4.0 (mean 3.4) mg/L were attained in about 2 h; higher concentrations were reported when a similar dose was given to 6 elderly subjects [Triggs *et al.* 1980].

Half-life Plasma half-life, about 1 to 2 h.

Volume of Distribution About 0.2 to 0.5 L/kg.

Clearance Plasma clearance, about 3 to 4 mL/min/kg.

Distribution in Blood Plasma:whole blood ratio, 1.8.

Protein Binding About 20%.

Note For a review of the pharmacokinetics of penicillins see Barza, Weinstein [1976].

Dose 1 to 8 g daily.

Amprenavir

Antiviral

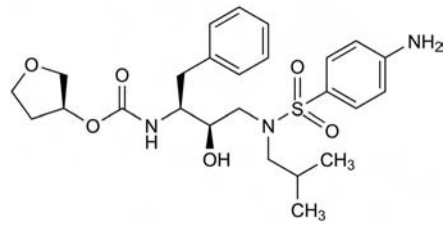
$C_{25}H_{35}N_3O_6S$ = 505.6

CAS—161814-49-9

IUPAC Name [(3*S*)-Oxolan-3-yl] *N*-[(2*S*, 3*R*)-4-[(4-aminophenyl)sulfonyl-(2-methylpropyl)amino]-3-hydroxy-1-phenylbutan-2-yl]carbamate

Synonyms [(1*S*,2*R*)-3-[[(4-Aminophenyl)sulfonyl]-(2-methylpropyl)amino]-2-hydroxy-1-(phenylmethyl)propyl]carbamic acid (3*S*)-tetrahydro-3-furanyl ester; KVX-478; VX-478; 141-W94.

Proprietary Names *Agenerase*; *Vertex*.



Chemical Properties A white to cream coloured solid with a solubility of 0.04 g/L in water, 86 g/L in alcohol (25°). pK_a 1.97 (25°).

High Performance Liquid Chromatography System HAB—Retention time 4.0 min; system HAC—*k* 2.5; system HAE—retention time 9.40 min.

Column: C_{18} AB Nucleosil 100 (5 µm). Mobile phase: acetonitrile : phosphate buffer, (pH 5.15) containing 0.02% sodium heptanesulfonate 15:85 to 30:70 at 2 min, to 32:68 at 8 min, to 42:58 at 18 min, to 46:54 at 34 min. UV detection (λ=201 nm). Retention time: 16.3 min [Marzolini *et al.* 2000].

Ultraviolet Spectrum Aqueous alkali—265 nm.

Quantification

Plasma **HPLC** UV detection (λ=261 nm). Limit of quantification, 25 µg/L [Aymard *et al.* 2000]. Column: C_{18} Novapak (150 × 2.1 mm i.d., 4 µm). Mobile phase: 0.5%, 5.8 mol/L orthophosphoric acid, 0.02% triethylamine (pH 5.0): acetonitrile: methanol. (40:35 for 10 min, to 25:75 for 15 min), flow rate 0.4 mL/min . UV detection (λ=265 nm). Retention time: 3.1 min [Poirier *et al.* 2000]. Limit of quantification, 5 µg/L [Poirier *et al.* 2000]. UV detection (λ=260 nm). Limit of quantification, 50 µg/L [Proust *et al.* 2000]. Limit of quantification, 1 µg/L [Sparidans *et al.* 2000]. Limit of quantification, 10 µg/L [Veronese *et al.* 2000].

Semen **HPLC** Limit of quantification, 1 µg/L [Sparidans *et al.* 2000].

Disposition in the Body Amprenavir is rapidly absorbed and metabolised in the liver to 2 major metabolites by oxidation, and minor metabolites which are glucuronide conjugates of these oxidised metabolites. In total there are 24 detected metabolites. <2% of the drug is recovered unchanged with the majority as metabolites in urine (14%) and faeces (75%).

Therapeutic Concentration

Ten healthy volunteers, 10 patients with moderate cirrhosis and 10 with severe cirrhosis, male and female, aged between 18 and 65 years, were administered with a 600 mg dose of amprenavir. Peak plasma concentrations of 4.9, 6.5 and 9.4 mg/L were observed for 3 groups, respectively. These levels were reached within 1 h [Veronese *et al.* 2000].

Twelve HIV infected patients, 18 to 55 years old, were administered with single oral doses of 150, 300, 600, 900 and 1200 mg. Peak plasma concentrations reached 2.00, 3.51, 6.27, 7.76 and 9.11 mg/L, respectively, within 1 to 2 h [Sadler *et al.* 1999].

Toxicity A severe or life-threatening rash including Stevens–Johnson syndrome has been observed.

Half-life Approximately, 8 h (range, 5.6 to 10.6 h).

Volume of Distribution 430 L.

Clearance 946 mL/min (healthy volunteers); 564 mL/min (patients with moderate cirrhosis); 295 mL/min (severe cirrhosis).

Distribution in Blood Partitioning into erythrocytes is low.

Protein Binding 90%.

Note For a review of the pharmacokinetics of amprenavir see Veronese *et al.* [2000] and Sadler *et al.* [1999].

Dose The usual dose administered is 1200 mg twice daily. Children aged between 4 and 12 years or those weighing below 50 kg: 40 to 45 mg/kg body weight is administered. The maximum dose is 2400 mg daily. The dose is reduced in patients with hepatic impairment.

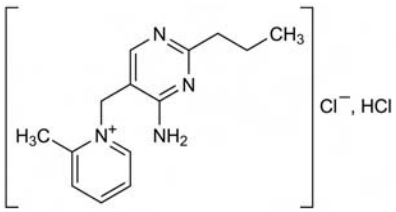
Sparidans RW *et al.* (2000). Sensitive liquid chromatographic assay for amprenavir, a human immunodeficiency virus protease inhibitor, in human plasma, cerebrospinal fluid and semen. *J Chromatogr Biomed Sci Appl* 742: 185–192.

Veronese L *et al.* (2000). Single-dose pharmacokinetics of amprenavir, a human immunodeficiency virus type 1 protease inhibitor, in subjects with normal or impaired hepatic function. *Antimicrob Agents Chemother* 44: 821–826.

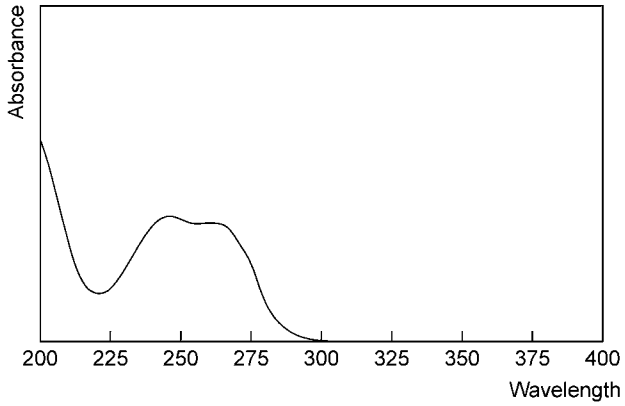
Amprolium Hydrochloride

Coccidiostat (Veterinary)
$C_{14}H_{19}ClN_4,HCl = 315.2$
CAS—121-25-5 (amprolium); 137-88-2 (hydrochloride)

IUPAC Name 5-[(2-Methylpyridin-1-ium-1-yl)methyl]-2-propylpyrimidin-4-amine chloride hydrochloride
Synonym 1-[(4-Amino-2-propyl-5-pyrimidinyl)methyl]-2-methylpyridinium chloride hydrochloride
Proprietary Names It is an ingredient of *Amprolmix-UK*, *Amprol-Plus*, *Pancoxin* and *Supacox*.



Chemical Properties A white powder. Mp 247°, with decomposition. Soluble 1 in 2 of water and 1 in 170 of ethanol; practically insoluble in chloroform; very slightly soluble in ether.
Colour Test Aromaticity (method 2)—colourless/yellow.
Thin-layer Chromatography System TA—R_f 0.02 (acidified iodoplatinate solution, positive).
Ultraviolet Spectrum Aqueous acid—246 (A^1_1=420b), 262 nm.

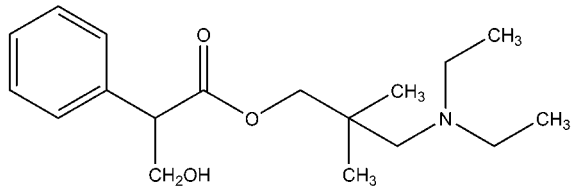


Infrared Spectrum Principal peaks at wavenumbers 1638, 1522, 1593, 787, 1562, 1149 cm^{-1}, (Amprolium, KBr disk).

Amprotropine

Atropine Derivative, Parasympatholytic
$C_{18}H_{29}NO_3 = 307.4$
CAS—148-32-3

IUPAC Name 3-Diethylamino-2,2-dimethylpropyl(±)tropate



Chemical Properties Extracted by organic solvents from aqueous alkaline solutions.

Amprotropine Phosphate

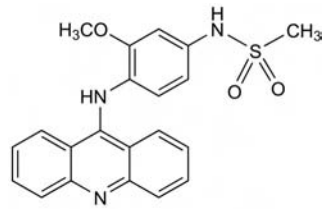
CAS—134-53-2
Proprietary Name *Syntropan*
Chemical Properties White crystalline powder. Mp 142° to 145°. Soluble in water; slightly soluble in ethanol; insoluble in ether and chloroform.

Colour Test Ammonium molybdate—blue (limit of detection 0.1 µg).
Thin-Layer Chromatography System T1—R_f 0.71 (location reagent acidified iodoplatinate spray, positive reaction).
Gas Chromatography System G2/225—retention time 1.70 relative to diphenhydramine; system G4—retention time 2.40 relative to diphenhydramine.
Infrared Spectrum Principal peaks at wavenumbers 1730, 1162, 1060, 1195, 1378 cm^{-1} (KBr disk).
Dose Up to 400 mg daily.

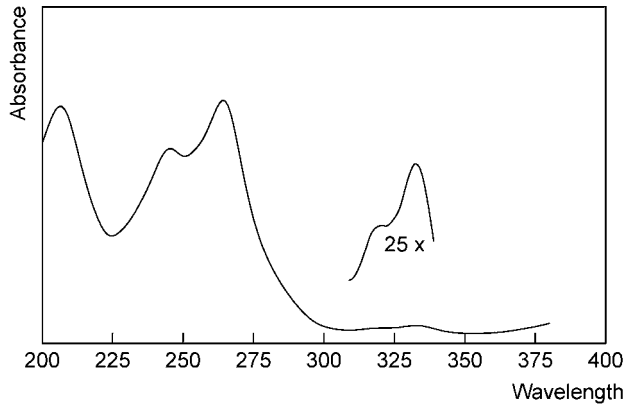
Amsacrine

Antineoplastic
$C_{21}H_{19}N_3O_3S = 393.5$
CAS—51264-14-3

IUPAC Name *N*-[4-(9-Acridinylamino)-3-methoxyphenyl]methanesulfonamide
Synonyms Acridinyl anisidide; *m*-AMSA; CI-880; NSC-249992; SN-11841
Proprietary Names *Amekrin*; *Amsa P-D*; *Amsidine*; *Amsidyl*.



Chemical Properties Log *P* (octanol/water), 3.89.
Ultraviolet Spectrum



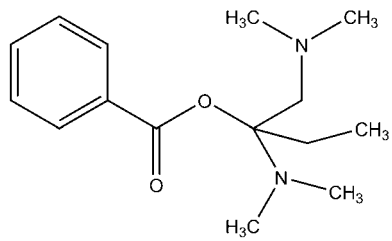
Mass Spectrum Principal ions at *m/z* 314, 315, 393, 270, 283, 79, 271, 394.
Quantification
Plasma **GC** FID. Limit of detection, 0.125 mg/L [Eksborg, Ehrsson 1985]. NPD. Limit of detection, 0.05 mg/L [Eksborg, Ehrsson 1985].
HPLC UV detection (λ=254 nm). Limit of detection, 50 nmol/L [Jurlina, Paxton 1983].
Disposition in the Body Amsacrine is poorly absorbed after oral administration. Following intravenous administration it is well distributed, except to the brain and CSF (cerebrospinal fluid). It is metabolised in the liver mostly as amasacrine–glutathione metabolites. It is excreted primarily in the bile by an active transport mechanism. >20% of the drug is recovered unchanged in urine.
Therapeutic Concentration The trough serum therapeutic concentration is 0.03 mg/L and the peak, 0.15 to 5.5 mg/L.
Half-life Plasma, 7 h.
Volume of Distribution 1.67 L/kg; 87.1 L/m^2.
Clearance 150 $mL/min/m^2$.
Protein Binding 98%.
Dose For induction therapy up to 120 mg/m^2 intravenously daily for 5 to 8 days.

Eksborg S, Ehrsson H (1985). Drug level monitoring: cytostatics. *J Chromatogr* 340: 31–72.
Jurlina JL, Paxton JW (1983). High-performance liquid-chromatographic method for the determination of 4′-(9-acridinylamino)methanesulfon-m-anisidide in plasma. *J Chromatogr* 276: 367–374.

Amydricaine

Benzoic Acid Ester, Anaesthetic (Local)
$C_{16}H_{26}N_2O_2 = 278.4$

IUPAC Name 1,1-Di(dimethylaminomethyl)propyl benzoate



A

Chemical Properties Extracted by organic solvents from aqueous alkaline solutions.

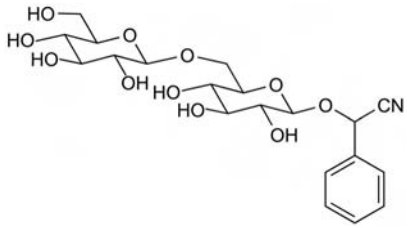
Amydricaine Hydrochloride

$C_{16}H_{26}N_2O_2$,HCl = 314.9
Proprietary Name *Alypin Hydrochloride*
Chemical Properties White hygroscopic crystalline powder. Mp ≈169°. Soluble 1 in 1 of water and 1 in 4 of ethanol; soluble in chloroform; insoluble in ether.

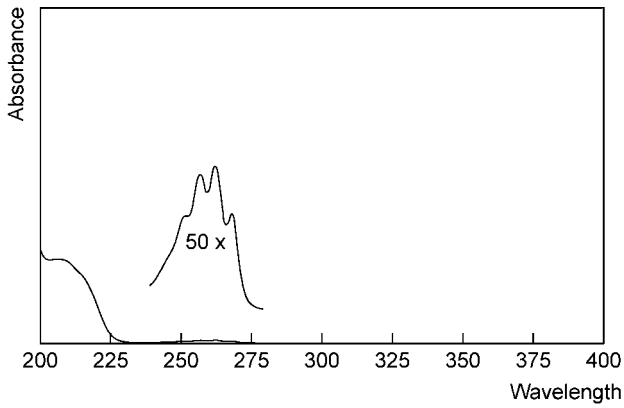
Thin-Layer Chromatography System T1—R_f 0.41 (location reagent acidified iodoplatinate spray, positive reaction).
Ultraviolet Spectrum Aqueous acid (0.1 N sulfuric acid)—237, 277 nm (base); water—234 nm (hydrochloride).
Infrared Spectrum Principal peaks at wavenumbers 1282, 1715, 710 cm^{-1} (KBr disk).
Toxicity Amydricaine is as toxic as cocaine. The minimum SC lethal dose is 70 mg/kg in dogs and 200 to 430 mg/kg in rats.

Amygdalin

Cyanogenic Glycoside
$C_{20}H_{27}NO_{11}$ = 457.4
CAS—29883-15-6
IUPAC Name [(6-*O*-β-D-Glucopyranosyl-β-D-glucopyranosyl)oxy]benzeneacetonitrile
Synonym Amygdaloside



Note The name 'laetrile' is frequently used to describe amygdalin but it has also been used to describe L-mandelonitrile-β-glucuronide, a substance that may be derived from amygdalin.
Chemical Properties A colourless, crystalline, cyanogenic glycoside present in bitter almond seeds (*Prunus amygdalus* var. *amara*) apricot kernels and other seeds of the Rosaceae. Mp about 220°; after solidifying the substance 125° to 130°. Soluble 1 in 12 of water and 1 in 900 of ethanol; almost insoluble in ether. Log *P* (octanol/water), −4.3.
Thin-layer Chromatography System TA—R_f 0.87; system TE—R_f 0.56; system TAJ—R_f 0.54; system TAK—R_f 0.62; system TAL—R_f 0.92.
Infrared Spectrum Principal peaks at wavenumbers 1065, 1025, 695, 758, 1272, 890 cm^{-1} (KCl disk).



Mass Spectrum Principal ions at *m/z* 43, 31, 57, 73, 60, 29, 55, 44.
Quantification
Plasma **GC** FID. Limit of detection, 2 mg/L [Stobaugh 1978].
HPLC UV detection. Limit of detection, 1 mg/L for amygdalin and prunasin [Rauws *et al.* 1982].
Urine **HPLC** UV detection. Limit of detection, 1 mg/L for amygdalin and prunasin [Rauws *et al.* 1982].
Note For review of methods in body fluids or tissues, including GC–MS, HPLC or TLC, see Balkon [1982].
Disposition in the Body Poorly absorbed after ingestion and slowly hydrolysed in the gastro-intestinal tract to mandelonitrile-β-glucoside (prunasin), mandelonitrile and glucose, and finally to benzaldehyde and hydrogen cyanide. After ingestion, about 8 to 32% of a dose is excreted unchanged in the urine; after parenteral administration, only small amounts are hydrolysed and most of a dose is excreted unchanged in the urine. Urinary cyanide and thiocyanate concentrations are not significantly elevated after oral or intravenous administration.

Blood Concentration
In 6 subjects ingesting 500 mg of amygdalin three times a day, peak plasma concentrations of <1 mg/L of amygdalin were attained in 30 to 60 min; peak plasma-cyanide concentrations of 0.4 to 2.1 mg/L (mean 1.0) were reported 1.5 to 2 h after a dose on the second day; plasma-thiocyanate concentrations accumulated on repeated administration of amygdalin to about 25 mg/L on the last day of ingestion [Moertel *et al.* 1981].
Following an intramuscular injection of 6 g to 1 subject, a peak plasma concentration of 180 mg/L was attained in 1.25 h [Ames *et al.* 1978].
Toxicity Several reports of cyanide poisoning following administration of amygdalin have been recorded, mostly involving the ingestion of apricot or other fruit kernels. Cyanide release from amygdalin is known to occur in the presence of β-glucosidase enzymes that are present in some raw fruits and vegetables. Toxic effects or fatalities have been associated with blood-cyanide concentrations greater than 2 mg/L.
A blood-cyanide concentration of 10 mg/L was reported in one subject with toxic effects following daily ingestion of 1500 mg of amygdalin [Smith *et al.* 1977].
In a fatality involving amygdalin ingestion, a postmortem blood-cyanide concentration of 2.18 mg/L was reported [Vogel *et al.* 1981].
Note For a review of the literature on amygdalin, see Chandler *et al.* [1984].

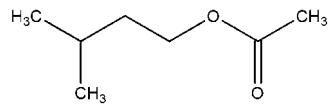
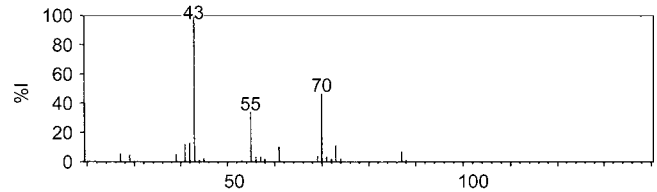
Amyl Acetate

Solvent
$C_7H_{14}O_2$ = 130.2
CAS—123-92-2 (iso); 53496-15-4 (sec); 628-63-7 (*n*)
IUPAC Name 3-Methylbutyl acetate
Synonyms Amyl acetic ester; banana oil; pear oil; pentyl acetate.



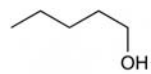
Chemical Properties A colourless, mobile, inflammable liquid. Bp ~140°. Refractive index 1.1400. Slightly soluble in water; miscible with ethanol and ether. Log *P* (octanol/water), 2.3. A mixture of isomers, principally isoamyl acetate (3-methylbutyl acetate), *sec*-amyl acetate (2-methylbutyl acetate) and *n*-amyl acetate.
Mass Spectrum Principal ions at *m/z* 43, 70, 55, 42, 41, 73, 61, 7.



Toxicity The estimated minimum lethal dose is 50 g and the maximum permissible atmospheric concentration is 100 ppm for isoamyl acetate or *n*-amyl acetate and 125 ppm for *sec*-amyl acetate.

Amyl Alcohol

Solvent
$C_5H_{12}O$ = 88.15
CAS—123-51-3 (3-methyl-1-butanol); 137-32-6 (2-methyl-1-butanol).
IUPAC Name Pentan-1-ol
Synonyms Butylcarbinol; 1-pentanol; pentyl alcohol.

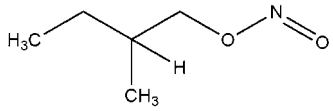


Chemical Properties A colourless liquid obtained by purifying fusel oil. Bp 128° to 132°. Refractive index 1.4075. Slightly soluble in water; miscible with ethanol, chloroform and ether. Log *P* (octanol/water), 1.2 (3-methyl-1-butanol), 1.3 (2-methyl-1-butanol). A mixture of mainly 3-methyl-1-butanol (primary isoamyl alcohol; $(CH_3)_2CHCH_2CH_2OH$) with some 2-methyl-1-butanol (primary amyl alcohol; $CH_3CH_2CH(CH_3)CH_2OH$).

Mass Spectrum Principal ions at *m/z* 55, 41, 42, 43, 70, 57, 29, 1.
Disposition in the Body
Toxicity Amyl alcohol is toxic after ingestion. The estimated minimum lethal dose is 30 g and the maximum permissible atmospheric concentration is 100 ppm.

Amyl Nitrite

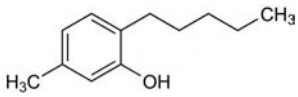
Antianginal Vasodilator
$C_5H_{11}NO_2$ = 117.1
CAS—8017-89-8; 110-46-3
IUPAC Name 3-Methylbutyl nitrite
Synonyms Amilnitrite; isoamyl nitrite; isopentyl nitrite.



Chemical Properties A clear, yellow, volatile, inflammable liquid with a fragrant odour. Incompatible with ethanol. Store in a cool place in airtight containers; protect from light. Bp 96°. Refractive index 1.3871. Practically insoluble in water; miscible with ethanol, chloroform and ether. Log *P* (octanol/water), 2.8. It consists of the nitrites of 3-methylbutan-1-ol [$(CH_3)_2CHCH_2CH_2OH$] and 2-methylbutan-1-ol [$CH_3CH_2CH(CH_3)CH_2OH$], with other nitrites of the homologous series.
Colour Tests To 0.2 mL add 2 mL of a 2% ferrous sulfate solution and 5 mL of dilute hydrochloric acid—green-brown; to 0.2 mL add 0.5 mL of aniline and 5 mL of acetic acid—orange-red.
Gas Chromatography System GA—RI >1000; system GI—RT 20.3 min.
Mass Spectrum Principal ions at *m/z* 70, 43, 55, 41, 57, 42, 71, –.
Disposition in the Body Absorbed from the mucous membranes after inhalation but rapidly inactivated by hydrolysis. Inactive after ingestion owing to hydrolysis in the gastrointestinal tract.
Toxicity Recovery has occurred after the ingestion of 12 mL.
Dose 0.12 to 0.3 mL, by inhalation.
Caution Amyl nitrite forms an explosive mixture with air or oxygen. It is very inflammable and must not be used where it may be ignited.

Amylmetacresol

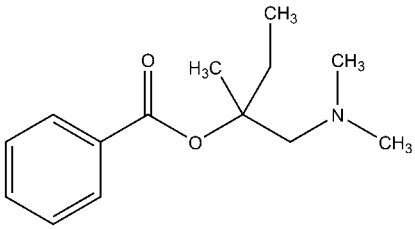
Antiseptic
$C_{12}H_{18}O$ = 178.3
CAS—1300-94-3; 53043-14-4
IUPAC Name 5-Methyl-2-pentylphenol
Synonym 6-Pentyl-*m*-cresol
Proprietary Name It is an ingredient of *Strepsils*.



Chemical Properties A colourless or slightly yellow, clear liquid or solid crystalline mass, which darkens on keeping. Mp 24°. Practically insoluble in water; soluble in ethanol and ether. Log *P* (octanol/water), 4.6.
Ultraviolet Spectrum Acidified dehydrated alcohol—278 nm (A^1_1=132a), 286 nm.
Infrared Spectrum Principal peaks at wavenumbers 1120, 1225, 1272, 805, 1584, 938 cm^{-1} (thin film).

Amylocaine

Anaesthetic (Local)
$C_{14}H_{21}NO_2$ = 235.3
CAS—644-26-8
IUPAC Name [1-(Dimethylamino)-2-methylbutan-2-yl] benzoate
Synonym 1-Dimethylaminomethyl-1-methylpropyl benzoate
Chemical Properties Log *P* (octanol/water), 2.89 [Meylan, Howard 1995].



Amylocaine Hydrochloride

$C_{14}H_{21}NO_2$,HCl = 271.8
CAS—532-59-2
IUPAC Name Methylethyldimethylamino-methylcarbinol benzoyl ester hydrochloride
Synonyms Amyleine hydrochloride; 1-(dimethyylamino)-2-methyl-2-butanol benzoate hydrochloride.
Proprietary Name *Stovaine*

Chemical Properties Crystals. Freely soluble in water and ethanol, practically insoluble in ether. pK_a 7.96 [Polasek *et al.* 1992]. Log *P* (octanol/water), 0.12 [Meylan, Howard 1995].
Thin-layer Chromatography System T1—R_f 0.66; system TA—R_f 0.73; System TB—R_f 0.60; System TC—R_f 0.67; System TL—R_f 0.63.
Atomic Absorption Spectrometry Coil: (700 × 0.5 mm i.d.). Carrier: 0.1% Reinecke's salt (ammonium tetrathiocyanoammonochromate) solution (pH 5.0). Limit of detection, 2.1 mg/L [Eisman *et al.* 1993].
Ultraviolet Spectrum Peaks at 234 and 275 nm.
Infrared Spectrum Principal peaks at 1275, 1710, 710 and 1110 cm^{-1} (KBr disk).
Disposition in the Body
Toxicity When investigated in cultured human conjunctival and other cells, the order of toxicity was procaine < lidocaine < piperocaine < amylocaine < amethocaine < cinchocaine [Dawson, Mustafa 1985]. A temperature of 45° was optimum for the sporicidal activity of amylocaine versus *Aspergillus niger*, while a temperature of 84° was optimum against *Bacillus subtilis* [Abdelaziz, el Nakeeb 1988].

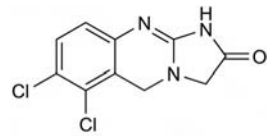
Anagrelide

Antithrombotic
$C_{10}H_7Cl_2N_3O$ = 256.1
CAS—68475-42-3
IUPAC Name 6,7-Dichloro-1,5-dihydroimidazo-[2,1-*b*]quinazolin-2-(3*H*)-one



Anagrelide Hydrochloride

$C_{10}H_8Cl_3N_3O$ = 292.5
CAS—58579-51-4
Synonyms BL-4162A; BMY-26538-01.
Proprietary Names *Agrelin*; *Agrylin*.
Chemical Properties It is an off-white powder. Mp >280°. It is very slightly soluble in water; sparingly soluble in dimethylsulfoxide and dimethylformamide.

High Performance Liquid Chromatography Column: phenyl μBondapak (300 × 3.9 mm i.d.). Mobile phases: (A) acetonitrile : 0.01 mol/L sodium acetate (pH 4) (25:75), flow rate 2.5 mL/min for first 10 min; (B) dimethylsulfoxide, flow rate 2.5 mL/min, reduced to 1 mL/min at 13 min. Mobile phase A reused at minute 18, flow rate 2.5 mL/min. UV detection (λ=254 nm). Retention time: 6 to 8 min [Gaver *et al.* 1981].
Quantification
Plasma **HPLC** UV detection (λ=254 nm). Limit of detection, 5 μg/L [Gaver *et al.* 1981].
Disposition in the Body Anagrelide is rapidly absorbed after oral administration (minimum 75%) and is extensively metabolised. A minimum of four metabolites have been identified, none of which are glucuronide or sulfate conjugates. It is excreted mainly in urine (70 to 75% over 5 days) and in faeces (10%). <1% of the dose is excreted unchanged. It is extensively distributed.
Therapeutic Concentration
Five healthy men, aged 19 to 26 years, were administered with a 1.2 mg anagrelide hydrochloride (1 mg free base) dose after an overnight fast. Mean peak plasma concentrations were 4.5 ± 0.9 μg/L and reached within 0.9 ± 0.4 h, rapidly declining in the first 6 to 8 h [Gaver *et al.* 1981].
Toxicity Cardiac and CNS toxicity can be expected with overdose. It may also cause fetotoxicity and renal failure. Doses greater than 5 mg daily can lead to hypotension.
Bioavailability 13.8% after administration with food.
Half-life 1.3 h (fasting state); 1.8 h (dose administered with food).
Volume of Distribution 12 L/kg.
Clearance 9 L/h.

Dose An initial dose of 2 mg daily is administered which can be increased to a maximum of 10 mg daily.

Gaver RC *et al.* (1981). Disposition of anagrelide, an inhibitor of platelet aggregation. *Clin Pharmacol Ther* 29(3): 381–386.

Anastrozole

Antineoplastic

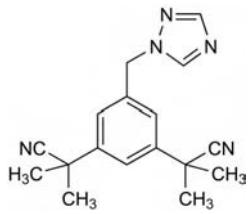
$C_{17}H_{19}N_5 = 293.4$

CAS—120511-73-1

IUPAC Name α,α,α′,α′-Tetramethyl-5-(1*H*-1,2,4-triazol-1-ylmethyl)-1,3-benzenediacetonitrile

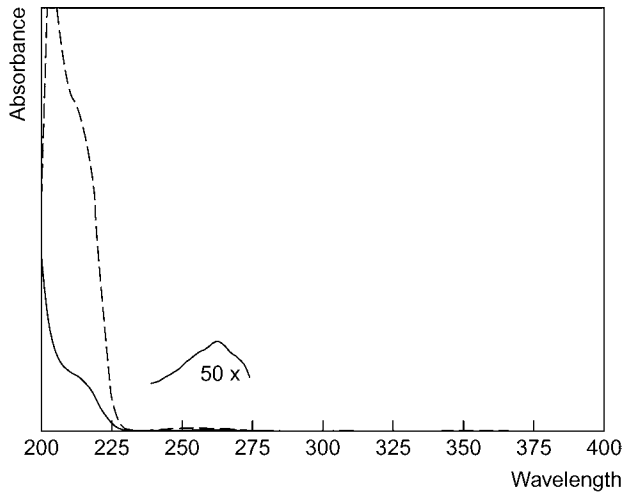
Synonyms ZD1033; ICI-D-1033.

Proprietary Name *Arimidex*

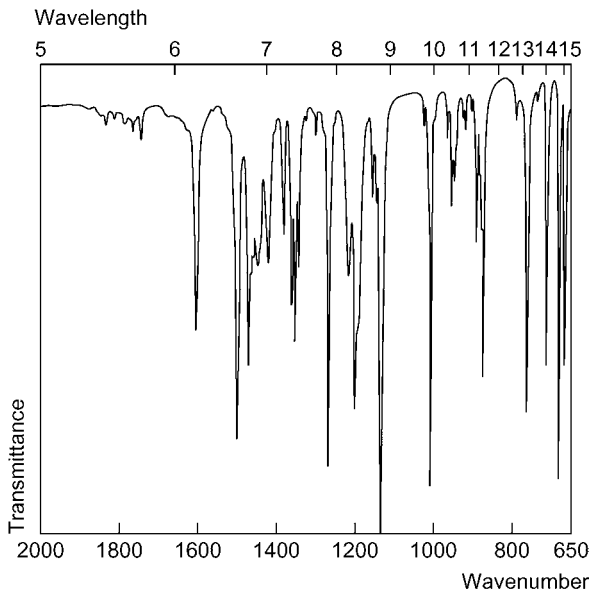


Chemical Properties An off-white powder. Mp 81° to 82°. It is soluble in water 0.5 mg/mL at 25°; freely soluble in acetone, ethanol, methanol and tetrahydrofuran; very soluble in acetonitrile.

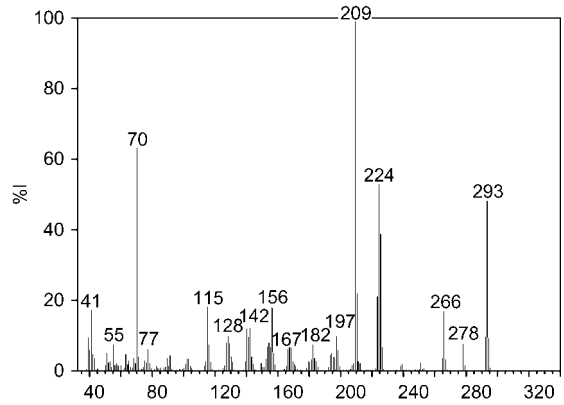
Ultraviolet Spectrum



Infrared Spectrum



Mass Spectrum Principal ions at *m/z* 209, 70, 224, 293, 115, 41, 156, 266.



Quantification

Plasma **GC** ECD. Limit of quantification, 3 µg/L, limit of detection, 0.5 µg/L [Bock *et al.* 1997].

Disposition in the Body Anastrozole is rapidly and almost completely absorbed after oral administration; peak plasma concentrations occur within about 2 h. The drug undergoes metabolism in the liver by *N*-dealkylation, hydroxylation and glucuronidation. The main inactive metabolite is triazole. The metabolites are excreted mainly in urine; less than 11% is excreted unchanged. It is removed by dialysis.

Half-life Plasma, 50 h.

Protein Binding 40%.

Dose 1 mg daily.

Bock MJ *et al.* (1997). Validated assay for the quantification of anastrozole in human plasma by capillary gas chromatography-63Ni electron capture detection. *J Chromatogr B Biomed Sci Appl* 700: 131–138.

Androstanediol

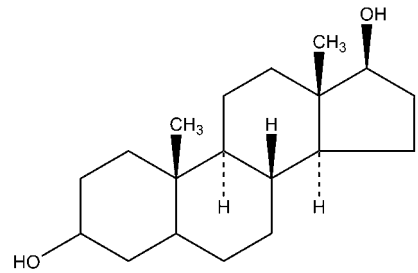
Anabolic Steroid

$C_{19}H_{32}O_2 = 292.5$

CAS—25126-76-5

IUPAC Name 10,13-Dimethyl-2,3,4,5,6,7,8,9,11,12,14,15,16,17-tetradecahydro-1*H*-cyclopenta[*a*]phenanthrene-3,17-diol

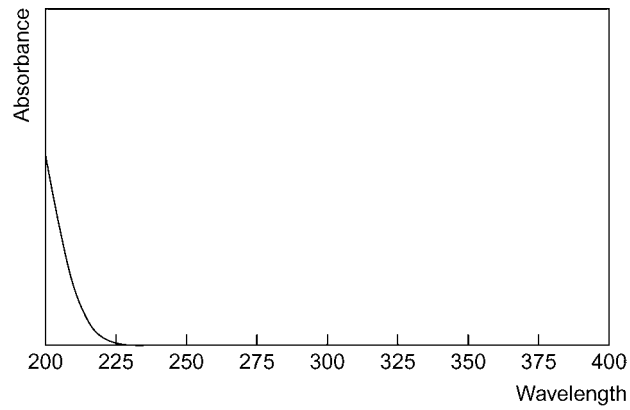
Synonym Androstane-3,17-diol



Chemical Properties Yellow-white crystalline powder. Mp 227° to 228°.

Thin-layer Chromatography Plates: silica gel 60F 254 (20 × 20 cm) with concentrating zone (4 × 20 cm) precoated (2.0 mm). System I: dichloromethane : diethyl ether (90 : 10). System IIa: toluene : ethyl acetate (50 : 50). System IIb: toluene : ethyl acetate (70 : 30). Biological samples: (1) Double run, *y* direction, system I at 4° (up to 10 spots per plate); (2) double run, *y* direction, system I at 4° followed by double run, *x* direction system IIa (single spot) or system IIb (two tracks or more). Limit of detection, 100 dpm [Vingler *et al.* 1991].

Ultraviolet Spectrum



Mass Spectrum Principal ion at *m/z* 470.

Quantification

Plasma **HPLC** Column: Rainin Hibar RT Lichrosorb (250 × 4.0 mm i.d., 5.0 µm). Mobile phase: 12.5% ethanol in heptane: heptane (5 : 95 to 95 : 5 over 180 min), flow rate 1.5 mL/min. UV detection (λ= 220 nm). Limit of detection not reported [Rao *et al.* 1987].

Urine **GC-MS** Column: Fused silica CP Sil 5CB (25 m × 0.2 mm i.d.). Carrier gas: He, 0.8 mL/min. Temperature programme: 204° for 20 min to 240° at 4°/min. EI ionisation at 70 eV, SIM acquisition mode. Limit of detection not reported [Vierhapper *et al.* 1988].

GC-MS Column: HP cross-linked 50% phenylmethysiloxane fused silica capillary (30 m × 0.25 mm i.d., 0.15 µm). Temperature programme: 80° for 1 min to 270° at 15°/min to 300° at 35°/min for 3 min. Limit of quantification not reported, limit of detection not reported [Maitre *et al.* 2004].

LC-MS Column: Spherisorb ODS 2 (250 × 4 mm i.d., 5 µm). Mobile phase: acetonitrile : water (10 : 90 to 100 : 0 at 25 min), flow rate 1 mL/min. Column: BPX35 (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He. Temperature programme: 100° to 260° at 2.4°/min. FID. Limit of detection not reported [Minut *et al.* 1999].

Amniotic Fluid **GC-MS** Column: Macherey-Nagel OV-1 fused silica (25 m × 0.2 mm, 0.1 µm). SIM acquisition mode. Limit of detection not reported although highly sensitive for androstanediol [Wudy *et al.* 1999].

Other **LC-MS** Rat Plasma. Column: Synergy Max-RP (50 × 2 mm i.d., 5.0 µm). Mobile phase: 0.05% acetic acid in water : 0.05% acetic acid in methanol (50 : 50 for 0.3 min to 0 : 100 at 5.7 min to 50 : 50 at 6 min), flow rate 150 µL/min. APCI, positive ion mode. Limit of quantification, 10 µg/L, limit of detection, 2 µg/L [Reddy *et al.* 2005].

Disposition in the Body

Therapeutic Concentration

Six healthy men (20 to 27 years) and 5 healthy women (24 to 30 years, in the follicular phase of the menstrual cycle) were given infusions of [^{13}C] testosterone. The doses administered were 20 mg in 500 mL for men and 5 mg in 500 mL for women, at a rate of 125 mL/h over 4 h. Urine was collected before (−10 to 0 h), during (0 to 4 h) and after (4 to 6 h, 8 to 10 h, and 10 to 24 h) the infusion and analysed by GC-MS. Cumulative excretion rates were expressed in µg/24 h and as the percentage of the infused amount of [^{13}C]testosterone [Vierhapper 1990].

	Testosterone	*3α-Androstanediol*
Men	15.6 ± 9.60 µg/24 h 0.08 ± 0.05%	67.7 ± 19.9 µg/24 h 0.30 ± 0.10%
Women	1.14 ± 1.55 µg/24 h 0.02 ± 0.03%	9.98 ± 5.95 µg/24 h 0.20 ± 0.12%

The mean urinary excretion rates for the male subjects were as follows [Vierhapper *et al.* 1988].

Time (h)	*^{12}C (µg/h)*	*^{13}C (µg/h)*
−10 to 0	2.40 ± 0.82	—
0–4	1.70 ± 1.35	4.70 ± 3.82
4–6	1.07 ± 0.59	5.36 ± 2.78
6–8	1.89 ± 1.05	6.23 ± 4.28
8–10	1.86 ± 1.54	3.98 ± 3.92
10- 24	1.81 ± 1.63	1.77 ± 1.61

Young (21 to 49 years) and elderly (62 to 77 years) men undergoing cardiac catheterisation were given infusions of [^{14}C]testosterone and [^{3}H] androstanediol. The plasma concentration of androstanediol was 180 ± 20 and 150 ± 40 ng/L in the young and elderly groups, respectively [Morimoto *et al.* 1981].

Androstanolone

Anabolic Steroid

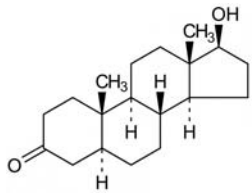
$C_{19}H_{30}O_2$ = 290.4

CAS—521-18-6

IUPAC Name (5*S*,8*R*,9*S*,10*S*,13*S*,14*S*,17*S*)-17-Hydroxy-10,13-dimethyl-1,2,4,5,6,7,8,9,11,12,14,15,16,17-tetradecahydrocyclopenta[*a*]phenanthren-3-one

Synonyms Dihydrotestosterone; (5α,17β)-17-hydroxyandrostan-3-one; stanolone.

Proprietary Names *Anabolex*; *Andractim*; *Androlone*.



Chemical Properties White crystalline powder. Mp 181°. Practically insoluble in water; soluble 1 in 20 of ethanol and 1 in 70 of ether; soluble in acetone. Log *P* (octanol/water), 3.6.

Thin-layer Chromatography System TP—R_f 0.78; system TQ—R_f 0.11; system TR—R_f 0.90; system TS—R_f 0.72.

Gas Chromatography System GA—dihydrotestosterone RI 2510; dihydrotestosterone-AC RI 2630; dihydrotestosterone-TMS RI 2485; dihydrotestosterone enol-TMS_2 RI 2450; system GAI—urinary metabolite:5α-dihydrotestosterone RRT 0.95 (relative to 17α-methyl-5α-androstan-3β,17β-diol.

Infrared Spectrum Principal peaks at wavenumbers 1698, 1046, 1277, 1027, 1064, 1079 cm^{-1} (KBr disk).

Quantification

Hair **GC-MS** Column: CP-Sil 5 CB (15 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1.0 mL/min. Temperature programme: 100° for 1 min to 300° at 20°/min for 5 min. EI ionisation at 70 eV, SIM acquisition mode. Retention time: 10.3 min. Limit of quantification, 0.05 ng/mg, limit of detection, 0.01 ng/mg [Deng *et al.* 1999].

Dose Androstanolone has been given sublingually or sublabially in doses of 50 to 75 mg daily.

Deng XS *et al.* (1999). Detection of anabolic steroids in head hair. *J Forensic Sci* 44: 343–346.

Androstenedione

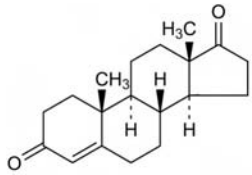
Anabolic Steroid

$C_{19}H_{26}O_2$ = 286.4

CAS—63-05-8

IUPAC Name Androst-4-ene-3,17-dione

Proprietary Name *Androtex*

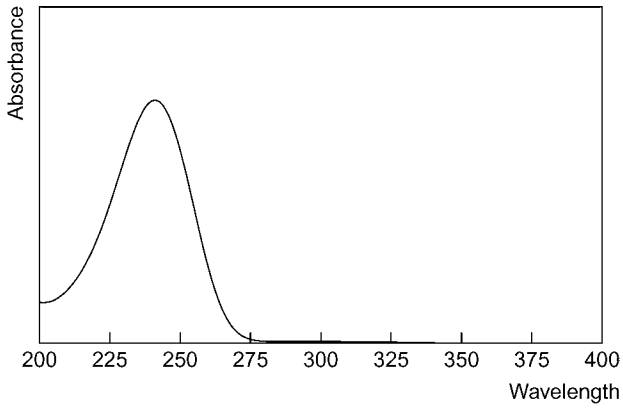


Chemical Properties Appears as needles or crystals. Mp 158°. Soluble in water (57.82 mg/L at 25°). Log *P* (octanol/water), 2.75.

Gas Chromatography System GA—RI 2600.

Column: 5% phenyl, methyl silicone HP Ultra-2 (25 m × 0.2 mm i.d., 0.33 µm). Temperature programme: 100° for 1 min, 16°/min to 220°, 3.8°/min to 300°, for 10 min. Carrier gas: He, flow rate 0.6 to 0.8 mL/min. IS: 5α-androstane-17-one. MS detection (EI, SIM). Retention time: androstenediol 24 min; androstenedione 24.5 min [Masse *et al.* 1989].

Ultraviolet Spectrum Water—235 nm.



Mass Spectrum Principal ions at *m/z* 286, 124, 244, 148, 109, 107, 287, 147.
Quantification
Plasma **HPLC** Limit of detection, 5 pg [Walker *et al.* 1996].
Serum **HPLC** Limit of detection, 5 pg [Walker *et al.* 1996].
Disposition in the Body After oral administration, androstenedione is metabolised in the liver to testosterone. Blood testosterone levels increase ~15 min after oral administration and remain elevated for up to 3 h. Blood testosterone peaks at ~1 to 1.5 h after ingestion.
Therapeutic Concentration In young males, a single oral dose of 100 mg can increase endogenous androstenedione serum concentrations by 175% within the first 60 min after administration and 325 to 350% between 90 and 270 min after administration.
Dose The recommended dosage is between 50 and 300 mg daily.

Masse R *et al.* (1989). Studies on anabolic steroids. I. Integrated methodological approach to the gas chromatographic-mass spectrometric analysis of anabolic steroid metabolites in urine. *J Chromatogr B Biomed Sci Appl* 489: 23–50.

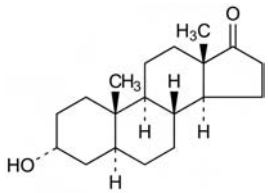
Androsterone

Androgen
$C_{19}H_{30}O_2$ = 290.4
CAS—53-41-8
IUPAC Name (3α,5α)-3-Hydroxyandrostan-17-one

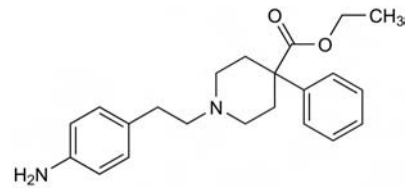


Chemical Properties A white crystalline powder. Mp about 185°. Practically insoluble in water; soluble in ethanol, ether and most organic solvents. Log *P* (octanol/water), 3.7.
Colour Tests Antimony pentachloride—yellow→brown; naphthol-sulfuric acid—orange-brown/orange; sulfuric acid—yellow.
Thin-layer Chromatography System TB—R_f 0.16; system TE—R_f 0.72; system TF—R_f 0.52; system TAE—R_f 0.90.
Gas Chromatography System GA—androsterone RI 2475, androsterone-AC RI 2580, androsterone enol-TMS_2 RI 2500; system GAR—retention time 11.9 min.
Ultraviolet Spectrum No significant absorption, 230 to 360 nm.
Infrared Spectrum Principal peaks at wavenumbers 1724, 1000, 1031, 1062, 1242, 1282 cm^{-1} (Nujol mull).
Mass Spectrum Principal ions at *m/z* 290, 67, 108, 107, 79, 55, 41, 93.
Quantification
Urine **GC–MS** Limits of detection, 15 to 20 pg for androsterone glucuronide and other androgen glucuronides [Choi *et al.* 2000].
Disposition in the Body Androsterone is a naturally occurring androgen which may be isolated from male urine. It is a major metabolite of testosterone.

Choi MH *et al.* (2000). Simultaneous determination of urinary androgen glucuronides by high temperature gas chromatography-mass spectrometry with selected ion monitoring. *Steroids* 65: 54–59.

Anileridine

Narcotic Analgesic
$C_{22}H_{28}N_2O_2$ = 352.5
CAS—144-14-9
IUPAC Name Ethyl-1-[2-(4-aminophenyl)ethyl]-4-phenyl-4-piperidinecarboxylate



Chemical Properties A white to yellowish-white crystalline powder. When exposed to light and air it oxidises and darkens in colour. There are 2 crystalline forms which melt at about 80° and about 89°. Very slightly soluble in water; soluble 1 in 2 of ethanol and 1 in 1 of chloroform; soluble in ether but solutions may be turbid. pK_a 3.7, 7.5. Log *P* (octanol/water), 4.1.

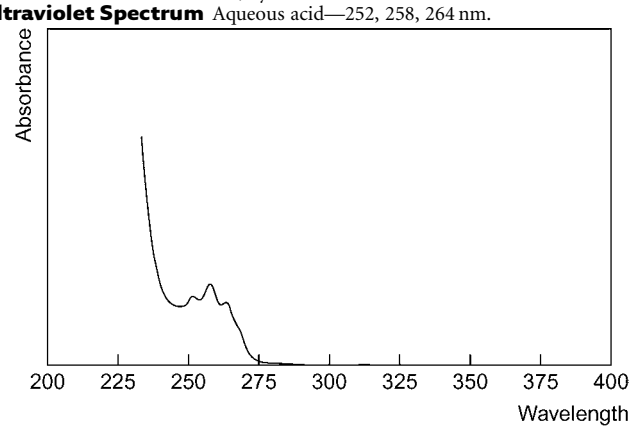
Anileridine Hydrochloride

$C_{22}H_{28}N_2O_2,2HCl$ = 425.4
CAS—126-12-5
Proprietary Name *Leritine* (tablets)
Chemical Properties A white crystalline powder. Mp about 270°, with decomposition. Soluble 1 in 5 of water and 1 in 80 of ethanol; practically insoluble in chloroform and ether.

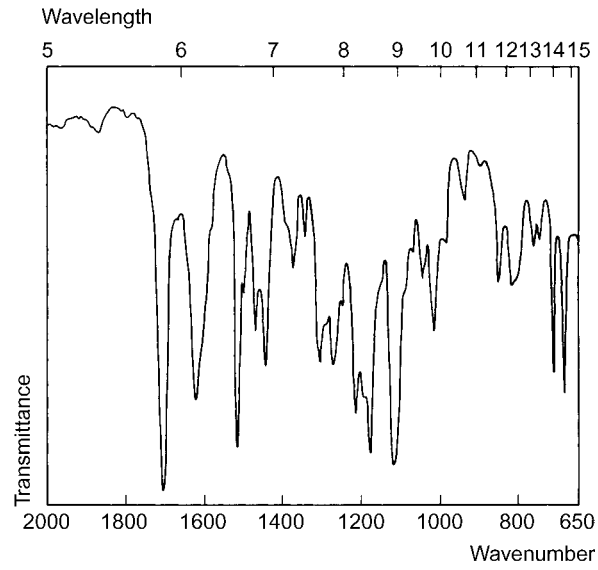
Anileridine Phosphate

$C_{22}H_{28}N_2O_2,H_3PO_4$ = 450.5
CAS—4268-37-5
Proprietary Name *Leritine* (injection)
Chemical Properties A white crystalline powder. Very soluble in water. Solutions are unstable above pH 4.

Colour Tests Diazotisation—red; Marquis test—orange (slow).
Thin-layer Chromatography System TA—R_f 0.73; system TB—R_f 0.12; system TC—R_f 0.56; system TE—R_f 0.79; system TL—R_f 0.51; system TAE—R_f 0.60; system TAF—R_f 0.66; system TAJ—R_f 0.20; system TAK—R_f 0.00; system TAL—R_f 0.68 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—RI 2850; system GC—RI 3469.
High Performance Liquid Chromatography System HA—*k* 1.1; System HAX—retention time 11.7 min; System HAY—retention time 5.9 min.
Ultraviolet Spectrum Aqueous acid—252, 258, 264 nm.



Infrared Spectrum Principal peaks at wavenumbers 1700, 1120, 1179, 1512, 1219, 1620 cm^{-1} (KCl disk).



Mass Spectrum Principal ions at *m/z* 246, 247, 42, 120, 218, 172, 106, 91.

Disposition in the Body Readily absorbed after oral administration. Metabolised by hydrolysis to anileridinic acid followed by acetylation to acetylanileridinic acid; conjugation with acetic acid followed by partial de-esterification to acetylanileridinic acid also occurs. After oral administration, 5% of the dose is excreted in the urine as unchanged drug, with 7 to 14% as free anileridinic acid, 1 to 2% as acetylanileridinic acid, 0.5 to 2% as acetylanileridine, and 15 to 35% as diazotisable metabolites, tentatively identified as *p*-acetylaminophenylacetic acid; norpethidine has also been detected in urine.

Toxicity The estimated minimum lethal dose is 0.5 g but it may be up to 5 g in addicts.

The following postmortem concentrations were reported in a fatality attributed to oral overdosage of anileridine: blood 0.9 mg/L, bile 2.4 mg/L, urine 11.4 mg/L, vitreous humour 0.07 mg/L; diazepam was also detected [Peat, Kopjak 1979].

Dose Up to the equivalent of 200 mg of anileridine daily.

Peat MA, Kopjak L (1979). *Bull Int Assoc Forensic Toxicol* 14(3): 19.

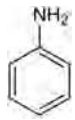
Aniline

Dye

$C_6H_5NH_2 = 93.1$

CAS—62-53-3

Synonym Phenylamine



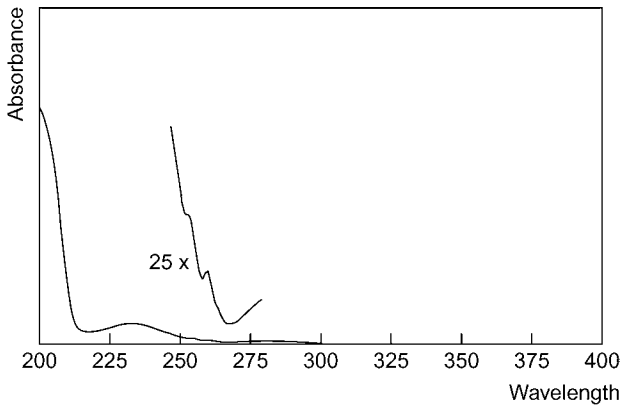
Chemical Properties A colourless or pale yellow oily liquid, with a characteristic odour. It readily darkens to brown on exposure to air and light. Fp −6°. Bp about 183°. Refractive index 1.5863. Soluble 1 in about 29 of water; miscible with ethanol, benzene, chloroform and ether. pK_a 4.6 (25°). Log *P* (octanol/water), 0.9.

Colour Tests Coniferyl Alcohol—orange; Diazotisation—red; Liebermann's Reagent—red-orange; Potassium Dichromate—blue-green (2 min).

Thin-layer Chromatography System TA—R_f 0.72; system TE—R_f 0.00; system TAJ—R_f 0.64; system TAK—R_f 0.00; system TAL—R_f 0.96 (acidified potassium permanganate solution, positive; van Urk reagent, bright yellow).

Gas Chromatography System GA—aniline RI 1158, 4-aminophenol RI 1253.

Ultraviolet Spectrum Aqueous acid—229 nm (A^1_1=13b), 255 nm (A^1_1=16b), 261 nm (A^1_1=12.5b); ethanol—235 nm (A^1_1=1007b), 286 nm (A^1_1=179b).



Mass Spectrum Principal ions at *m/z* 4-aminophenol 109, 80, 53, 81, 108, 52, 54, 110.

Quantification

Serum **GC–MS** Limit of detection, 0.1 mg/L [Dasgupta 1998; Dasgupta, Jagannath 1999].

Urine **GC–MS** Limits of detection, 0.05 to 2 µg/L for aniline and other aromatic amines and aromatic nitro metabolites [Weiss, Angerer 2002].

Tissues **GC** AFID. See Oliver and Williams [1974].

Disposition in the Body Readily absorbed from the skin and mucous membranes. Metabolised to 4-aminophenol and 4-acetamidophenol which are excreted in the urine as glucuronide and sulfate conjugates. *N*-Phenylsulfamic acid (aniline *N*-sulfate) is also a metabolite. The main toxic effect of aniline, the formation of methaemoglobin, is thought to be due to an oxidation product of aniline, phenylhydroxylamine.

Aniline is a metabolite of phenazopyridine.

Toxicity The minimum lethal dose may be as low as 1 g although recovery has followed the ingestion of 30 g. Serious toxic effects may occur after exposure for about 1 h to atmospheric concentrations of 100 to 160 ppm. The maximum permissible atmospheric concentration is 2 ppm. Urinary concentrations of >10 mg/L of 4-aminophenol may indicate toxic exposure to aniline.

The following postmortem tissue concentrations were reported in a fatality attributed to ingestion of an aniline-based ink: blood 6.3 mg/L, liver 20 µg/g, urine 40 mg/L [Oliver, Williams 1974].

Dasgupta A (1998). Gas chromatographic-mass spectrometric identification and quantification of aniline after extraction from serum and derivatization with 2,2,2-trichloroethyl chloroformate, a novel derivative. *J Chromatogr B Biomed Sci Appl* 716: 354–358.

Aniracetam

Cognition Enhancer, Nootropic

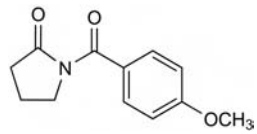
$C_{12}H_{13}NO_3 = 219.2$

CAS—72432-10-1

IUPAC Name 1-(4-Methoxybenzoyl)-2-pyrrolidinone; 1-*p*-Anisoyl-2-pyrrolidinone

Synonym Aniracetamum

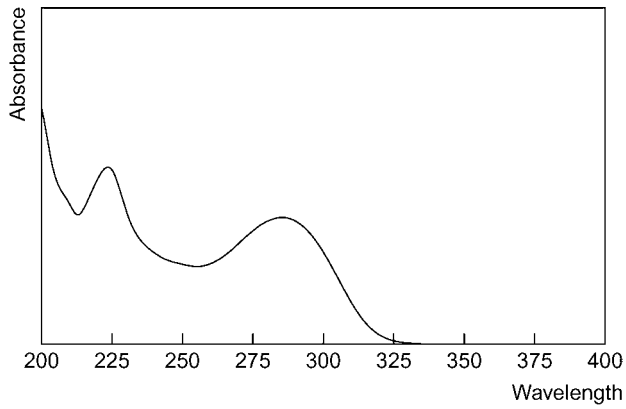
Proprietary Names *Ampamet*; *Draganon*; *Reset*; *Sarpul*.



Chemical Properties Odourless and colourless crystals. Mp 121° to 122°. It has limited aqueous solubility (approximately, 1.5 g/L) which is not affected by pH (1.47 g/L at pH 1.2 and 1.38 g/L at pH 7.5). Log *P* (octanol/buffer pH 7.4), 10 (22°). It is essentially a neutral molecule with moderate lipophilicity.

High Performance Liquid Chromatography Column: ODS-silica Hypersil ODS (60 × 4.0 mm i.d., 3 µm). Mobile phase : water : methanol : acetonitrile (70:30:10), flow rate 1.0 mL/min. UV detection (λ=282 nm). Retention time: 4.3 min.

Ultraviolet Spectrum Principal peaks at 224, 288 nm.



Quantification

Plasma **HPLC** Column: C_{18} µBondapak (300 × 3.9 mm i.d., 10 µm). Mobile phase: methanol : triethylamine : 0.1 mol/L phosphate buffer (pH 3.0; 530 : 0.05 : 470), flow rate 1.0 mL/min. DAD. Retention time: *N*-anisoyl-GABA, 5.3 min [Guenzi, Zanetti 1990]. Limit of quantification, 5 µg/L and 50 µg/L for aniracetam and *N*-anisoyl-GABA, respectively, limit of detection, 2 µg/L and 5 µg/L, respectively [Guenzi, Zanetti 1990].

Disposition in the Body Aniracetam is rapidly absorbed from the gastrointestinal tract and essentially absorption is complete. Aniracetam undergoes extensive biodegradation and therefore bioavailability is very low at ~0.2% (only 0.2% reaches the systemic circulation as the parent drug). Aniracetam is metabolised in the body and the main metabolite produced is *N*-anisoyl-GABA (~70%) but 2-pyrrolidinone, 5-hydroxy-2-pyrrolidinone and anisic acid are also produced. Rapid and complete elimination occurs via urine (84%), faeces (0.8%) and expired air (11%) as CO_2. Elimination is biphasic. *N*-Anisoyl-GABA and anisic acid are secreted in breast milk. All can traverse the placenta from blood and/or metabolites formed before reaching fetus.

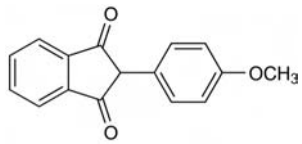
A

Therapeutic Concentration
After oral administration, 1000 mg, peak plasma concentrations varied greatly between 42 and 246 μg/L for 6 subjects and were detected at 5 min. Peak plasma concentrations for a 2 g dose varied between 55 and 116 μg/L, and between 42 and 1087 μg/L for a 4 g dose Roncari *et al* 1984.
Toxicity Toxicity testing in several animal species, including mouse, rat, rabbit and dog shows that aniracetam has extremely low toxicity.
Half-life For the parent drug, aniracetam, the half-life is 30 min and for its metabolites, 12.8 to 15.7 h.
Volume of Distribution Steady state, 2.5 L/kg (ranging between 1.9 and 4.1 L/kg).
Clearance Total clearance, ~9.9 L/min (range between 6.4 and 14.9 L/min).
Distribution in Blood Aniracetam is equally distributed between red blood cells and plasma (blood : plasma concentration ratio range 0.92 to 0.95). Distribution outside the vascular space and probable binding with tissue components also occurs.
Protein Binding 66%.
Dose Recommended dose of 1500 mg daily orally, either as a single dose (as sugar-free sachets) or as 750 mg doses in the form of a tablet.

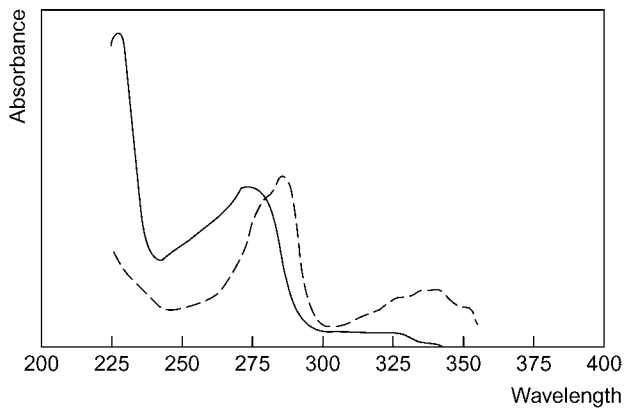
Guenzi A, Zanetti M (1990). Determination of aniracetam and its main metabolite, N-anisoyl-GABA, in human plasma by high-performance liquid chromatography. *J Chromatogr* 530: 397–406.
Roncari *et al.*, 1984, F. Hoffman-La Roche data on file B-104′488

Anisindione

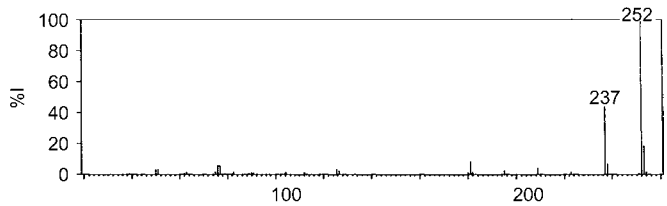
Anticoagulant
$C_{16}H_{12}O_3$ = 252.3
CAS—117-37-3
IUPAC Name 2-(4-Methoxyphenyl)-1*H*-indene-1,3(2*H*)-dione
Proprietary Names *Miradon*; *Unidone*.



Chemical Properties A white or creamy-white powder. Mp 152° to 158°. Practically insoluble in water; soluble in ether and methanol. pK_a 4.1. Log *P* (octanol/water), 2.9.
Thin-layer Chromatography System TA—R_f 0.98; system TE—R_f 0.15; system TAJ—R_f 0.82; system TAK—R_f 0.70; system TAL—R_f 0.95.
Gas Chromatography System GA—RI 2273.
Ultraviolet Spectrum Aqueous acid—273 nm; ethanol—286 nm (A^{1}_{1}=1400b), 340 nm.



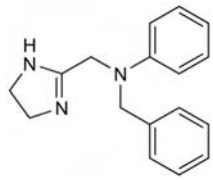
Mass Spectrum Principal ions at *m/z* 252, 237, 253, 181, 238, 77, 76, 209.



Dose Maintenance, 25 to 250 mg daily.

Antazoline

Antihistamine
$C_{17}H_{19}N_3$ = 265.4
CAS—91-75-8
IUPAC Name 4,5-Dihydro-*N*-phenyl-*N*-(phenylmethyl)-1*H*-imidazole-2-methanamine
Synonyms Imidamine; phenazoline.



Chemical Properties Crystals. Mp 120° to 122°. pK_a 2.5, 10.1 (25°). Log *P* (octanol/water), 3.4.

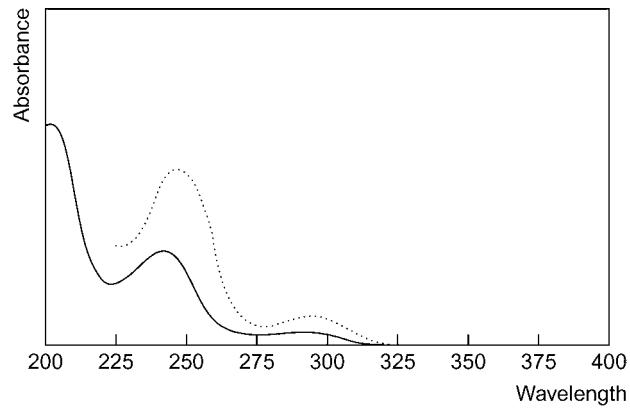
Antazoline Hydrochloride
$C_{17}H_{19}N_3$,HCl = 301.8
CAS—2508-72-7
Synonyms Imidamine hydrochloride; phenazolinum.
Proprietary Names *Wasp-Eze* (ointment). It is an ingredient of *Modantis* and *RBC*.
Chemical Properties A white crystalline powder. Mp 237° to 241°. Soluble 1 in 40 of water and 1 in 25 of ethanol; practically insoluble in ether, benzene and chloroform.

Antazoline Mesilate
$C_{17}H_{19}N_3$,CH_3SO_3H = 361.5
CAS—3131-32-6
Synonyms Antazoline mesylate; antazoline methanesulphonate; imidamine mesilate.
Chemical Properties A white, slightly hygroscopic powder. Mp 165° to 168°. Soluble 1 in 6 of water, 1 in 7 of ethanol and 1 in 12 of chloroform; practically insoluble in ether.

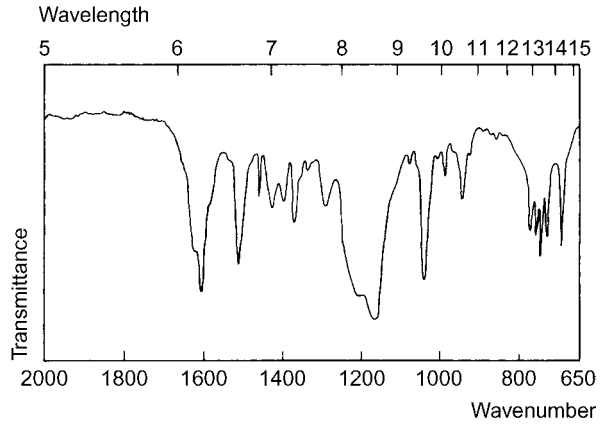
Antazoline Phosphate
$C_{17}H_{19}N_3$,H_3PO_4 = 363.4
CAS—154-68-7
Synonym Imidamine phosphate
Proprietary Names It is an ingredient of *Albalon-A*, *Antazoline-V*and *Vasocon A*.
Chemical Properties A white crystalline powder. Mp 194° to 198°. Soluble in water; sparingly soluble in methanol; practically insoluble in benzene and ether.

Antazoline Sulfate
$(C_{17}H_{19}N_3)_2$,H_2SO_4, $2H_2O$ = 664.8
CAS—24359-81-7 (anhydrous)
Synonym Imidamine sulphate
Proprietary Names It is an ingredient of *Antistin(e)-Privin(e)* and *Otrivine-Antistin*.

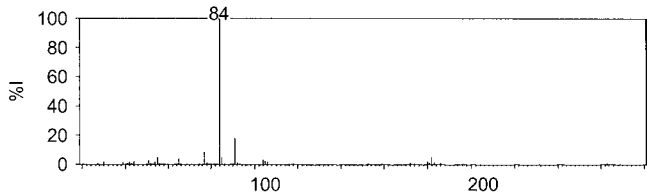
Colour Tests Liebermann's reagent—red; Mandelin's test—red-violet.
Thin-layer Chromatography System TA—R_f 0.31; system TB—R_f 0.06; system TC—R_f 0.07; system TE—R_f 0.47; system TL—R_f 0.03; system TAE—R_f 0.05; system TAF—R_f 0.66; system TAJ—R_f 0.00; system TAK—R_f 0.00; system TAL—R_f 0.15 (Dragendorff spray, positive; FPN reagent, pink; acidified iodoplatinate solution, positive).
Gas Chromatography System GA—RI 2318; system GB—RI 2421; system GC—RI 2749.
High Performance Liquid Chromatography System HA—*k* 1.8; system HX—RI 383; system HY—RI 294.
Ultraviolet Spectrum Aqueous acid—241 nm (A^{1}_{1}=578a), 291 nm; aqueous alkali—247, 295 nm.



Infrared Spectrum Principal peaks at wavenumbers 1164, 1599, 1042, 1508, 750, 700 cm^{-1} (antazoline mesilate, KBr disk).



Mass Spectrum Principal ions at *m/z* 84, 91, 77, 55, 182, 85, 65, 104.



Quantification

Urine **Colorimetry** See Wahba *et al.* [1974].

Disposition in the Body Readily absorbed after oral or parenteral administration. About 2% of an oral dose is excreted unchanged in the urine in 24 h.

Dose Antazoline hydrochloride has been given in doses of 100 to 600 mg daily.

Wahba N *et al.* (1974). Colorimetric determination of antazoline excreted in urine. *Pharmazie* 29: 790–791.

Antimony

Antiprotozoal, Metal

Sb = 121.8

CAS—7440-36-0

Synonyms Antimony black; antimony regulus; stibium.

Chemical Properties Silvery white solid. Mp 630.5°. Bp 1750°. Insoluble in water. Valencies: Sb (−3), Sb(0), Sb (+3) and Sb (+5). Metallic antimony is the only allotropic form of antimony that is stable under normal conditions and is occasionally found uncombined in nature. Antimony has two stable isotopes, ^{121}Sb and ^{123}Sb. One radioactive isotope, ^{125}Sb, is a fission product released in nuclear explosions or nuclear fuel reprocessing plants. Used in alloys, solder, sheet and pipe, bearings, castings and type metal, ammunition, and cable sheathing. High-purity antimony is used as a dopant in semi-conductors and in devices such as infrared detectors and diodes.

Antimony Pentasulfide

Sb_2S_5 = 403.8

CAS—1315-04-4

Synonyms Antimony persulfide; antimony red; antimonial saffron; antimonic sulfide; golden antimony sulfide.

Chemical Properties Odourless yellow solid. Mp 75° with decomposition. Insoluble in water and alcohol.

Antimony Pentoxide

Sb_2O_5 = 323.5

CAS—1314-60-9

Synonyms Antimonic acid; antimonic anhydride; antimonic oxide; antimony pentaoxide; diantimony pentoxide; stibic anhydride.

Chemical Properties Yellow solid. Mp 380° with decomposition. Very slightly soluble in water.

Antimony Potassium Tartrate

$Sb_2C_8H_4K_2O_{12},3H_2O$ = 333.9

CAS—28300-74-5

Synonyms Antimonyl potassium tartrate; tartar emetic; tartox; tartrated antimony.

Chemical Properties Odourless, colourless solid. Mp 100°. Soluble in water and glycerine. Insoluble in alcohol. Used in the treatement of schistosomiasis.

Antimony Trichloride

$SbCl_3$ = 228.1

CAS—10025-91-9

Synonyms Antimonous chloride; antimony butter; antimony (III) chloride; chloride antimony; trichlorostibine.

Chemical Properties Colourless solid with a sharp, unpleasant odour. Mp 73.4°. Bp 283°. Very soluble in water; soluble in alcohol, tartaric acid, methylene chloride, benzene and acetone.

Antimony Trioxide

Sb_2O_3 = 291.5

CAS—1309-64-4

Synonyms Antimonious oxide; antimony peroxide; antimony sesquioxide; antimony white; diantimony trioxide; exitelite; flowers of antimony; senarmontite; timothox; valentinite.

Proprietary Names *Fire Shield H*; *H Grade*; *HP*; *KR-LTS*; *LP*; *KR*; *Montana Brand*; *Thermoguard S*; *White Star*.

Chemical Properties Senarmontite is a white solid; valentinite is a colourless solid. Mp 656°. Bp 1550°. Very slightly soluble in water; soluble in tartaric acid, acetic acid and hydrochloric acid. Used as a fire retardant.

Antimony Trisulfide

Sb_2S_3 = 339.7

CAS—1345-04-6

Synonyms Antimonous sulphide; antimony crimson; antimony glance; antimony needles; antimony orange; antimony sesquisulfide; antimony sulphide; antimony vermilion; stibite.

Chemical Properties Black solid. Mp 550°. Bp 1150°. Slightly soluble in water; insoluble in acetic acid.

Stibine

SbH_3 = 124.8

CAS—7803-52-3

Synonyms Antimony hydride; antimony trihydride; hydrogen antimonide.

Chemical Properties Colourless gas with hydrogen sulfide-type odour. Mp −88°. Bp −17°. Soluble in carbon disulfide and ethanol.

Colour Tests

Reinsch test. Applicable to urine, gastric contents, scene residues. Clean a 5 × 10 mm square of copper foil (2–3 cm copper wire) with aqueous nitric acid (500 mL/L) until shiny. Rinse the copper with purified water and add 10 mL of concentrated hydrochloric acid and 20 mL of test sample in a 100 mL conical flask. Heat in a boiling water bath in a fume cupboard for 1 h. Cool and gently wash the copper with purified water.—Antimony imparts a black stain to the copper (arsenic, bismuth, selenium and tellurium also give black deposits).

Confirmatory test. Place the stained copper in 100 g/L potassium cyanide solution and leave for 10 min. Wash any undissolved stain with purified water and add 1 mL of freshly prepared sodium sulfite solution (50 g/L) and 1 mL of 3 mol/L nitric acid. Agitate frequently for 5 min and add 1 mL of purified water and 1 mL of a mixture of quinine/potassium iodide reagent (prepared by dissolving 1 g of quinine sulfate in 100 mL of purified water containing 0.5 mL of concentrated nitric acid and adding 2 g of potassium iodide when the quinine has dissolved).—Stains caused by arsenic dissolve in potassium cyanide solution; stains caused by antimony and bismuth do not. Bismuth slowly forms an orange/brown suspension with quinine/potassium iodide reagent.

Quantification

Specimen Collection Blood—10 mL K-EDTA tube; urine—20 mL plastic universal container.

Blood **FAAS** Flame: air–acetylene. Carrier gas: N_2, 105 mL/min. Hollow cathode lamp (λ = 217.6 nm). Limit of detection not reported [Le *et al.* 1992].

ETAAS Limit of detection, 0.5 µg/L [Gebel *et al.* 1998a]. Dry cycle: 120° in 10 s for 20 s, Ar, 300 mL/min. Char cycle: 1000° in 10 s for 20 s; Ar, 300 mL/min. Atomisation cycle: 2050° for 3 s (gas stop). Electrodeless discharge lamp (λ = 217 nm). Limit of detection, 2.6 µg/L [Subramanian *et al.* 1997]. Dry cycle: 90° at 15 s for 4 s to 130° in 30 s for 10 s. Char cycle: 700° in 60 s for 30 s to 1100° in 30 s for 16 s. Atomisation cycle: 2500° in 1 s for 4 s. Limit of detection, 25 µg/L following digestion [Costantini *et al.* 1985a].

ICP-MS Plasma gas: 15 L/min. Auxillary gas: 0 L/min. Carrier gas: 0.86 L/min. Glass expansion micromist nebuliser. Limit of detection, 0.03 µg/L [Bazzi *et al.* 2005]. Plasma gas: 16 L/min. Auxiliary gas: 1 L/min. Nebuliser gas: 1.15 or 1.33 mL/min. Limit of detection, 0.2 µg/L [De Boer *et al.* 2004]. ELAN 5000A. Limit of detection, 8 ng/L [Miekeley *et al.* 2002]. Limit of detection, 142 ng/L [Liao *et al.* 2004]. Nebuliser gas: Ar, 1.0 L/min. Auxillary gas: Ar, 0.95 L/min. Coolant gas: Ar, 15.0 L/min. Limit of quantification, 0.01 µg/L [Delves *et al.* 1997].

Plasma **ICP-MS** See Blood [Miekeley *et al.* 2002].

Serum **ETAAS** See Blood [Subramanian *et al.* 1997].

ICP-MS See Blood [Delves *et al.* 1997].

Urine **FAAS** See Blood [Le *et al.* 1992].

ETAAS Limit of detection, 0.5 µg/L [Gebel *et al.* 1998a, 1998b]. Dry cycle: 140° at 30 s for 20 s. Char cycle: 800° in 30 s for 45 s; Ar 300 mL/min. Atomisation cycle: 2000° for 4 s (gas stop). Limit of detection, 0.69 µg/L [Smith *et al.* 1995]. See Blood [Costantini *et al.* 1985b]. Dry cycle: 110° for 20 s. Char cycle: 700° for 20 s. Atomisation cycle: 2200° for 2 s. Carbon furnace mode (λ = 217.6 nm). Limit of detection, not reported [Smith, Griffiths 1982].

ICP-AES Plasma gas: 0.8 L/min. Coolant gas: 16 L/min. Carrier gas: 0.4 L/min. Limit of detection, 0.09 µg/L for trivalent antimony [Li *et al.* 2006].

GC-ICP-MS Limit of detection, 2 to 12 pg/L [Kresimon *et al.* 2001].

ICP-MS Plasma gas: Ar, 15 L/min. Auxillary gas: Ar, 1.3 L/min. Sample gas: 1.0 L/min. Meinhard nebuliser. Limit of detection, 0.43 ng/L [Alimonti *et al.* 2005]. See Blood. Limit of detection, 0.15 µg/L [De Boer *et al.* 2004]. Limit of detection, 3 ng/L [Liao *et al.* 2004]. See Blood [Delves *et al.* 1997; Miekeley *et al.* 2002]. Plasma gas:

15 L/min. Nebulizer gas: 0.825 L/min. Auxillary gas: 0.8 L/min. Limit of detection, 0.03 μg/L [Schramel *et al.* 1997]. See also Dezateux *et al.* [1997].

Note For a candoluminescence spectrometry method for the determination of antimony in urine, see Clark and Patel [1986]. For a colorimetric method for the determination of antimony in urine (limit of quantification, 20 μg/L), see Kneip *et al.* [1976].

Hair **ETAAS** Limit of detection, 5 μg/kg [Gebel *et al.* 1998a; Gebel *et al.* 1998b].

Note For an instrumental neutron activation analysis of antimony in hair, see Dorea *et al.* [1987].

Liver **ICP-MS** Nebuliser gas: Ar, 1.04 L/min. Limit of detection, 23 ng/L [Patriarca *et al.* 1999]. Nebuliser gas: Ar, 1.0 L/min. Auxillary gas: Ar, 0.95 L/min. Coolant gas: Ar, 15.0 L/min. Limit of quantification, 0.7 μg/kg [Delves *et al.* 1997].

Lung **ICP-MS** See Blood. Limit of quantification, 0.8 μg/kg [Delves *et al.* 1997].

Synovial Fluid **ICP-MS** Coolant gas: Ar, 15.0 L/min. Auxiliary gas: 0.99 L/min. Nebuliser gas: 1.0 L/min. Limit of detection, low ng/L [Krachler *et al.* 2000].

Other **AAS** Fresh and Freeze-dried Plant Samples. Carrier gas: Ar, 50 mL/min. Atomisation cycle: 770°. Hollow cathode lamp ($\lambda = 217.6$ nm). Limit of detection not reported [Krachler, Emons 2000]. Bovine liver and porcine kidney. Carrier gas: Ar, 50 mL/min. Atomisation cycle: 770° ($\lambda = 217$ nm). Limit of quantification, 23 ng/kg, limit of detection, 7 ng/kg [Krachler *et al.* 1999].

ETAAS River Water and Seawater. Dry cycle: 100° at 10 s for 10 s. Char cycle: 1000° in 5 s for 10 s, Ar 250 mL/min. Atomisation cycle: 2200° for 3 s (gas stop). Antimony hollow cathode lamp ($\lambda = 217$ nm). Limit of detection, 8.0 ng/L for Sb (III) and 9.2 ng/L for Sb [Fan 2007]. Waste. Dry cycle: 120° in 1 s for 20 s to 130° in 3 s for 35 s. Char cycle: 1300° at 8 s for 25 s; Ar, 250 mL/min. Atomisation cycle: 1900° for 5 s (gas stop). Antimony hollow cathode lamp ($\lambda = 217$ nm). Limit of detection, 0.3 μg/L [Bosch Ojeda *et al.* 2005]. Naphtha. Dry cycle: 50° for 10 s to 90° in 25 s to 120° in 10 s; Ar, 200 mL/min. Atomisation cycle: 2500° for 8 s (gas stop; $\lambda = 217.6$ nm). Limit of detection, 2.5 μg/L [Cassella *et al.* 2004].

ICP-AES Pharmaceutical Formulations. Plasma gas: Ar, 15 L/min. Nebuliser gas: Ar, 0.48 L/min. Meinhard nebuliser. Limit of quantification, 21.7 ng/L [Cabral *et al.* 2008]. Bullet wounds. Plasma gas: Ar, 1.2 L/min. Cooling gas: 14 L/min. Carrier gas: 1.0 L/min. ICPS-7510 ($\lambda = 207$ nm). Limit of detection not reported [Wunnapuk *et al.* 2007].

ICP-MS Lymph Node Biopsy Microwave Digests. Plasma gas: 15 L/min. Carrier gas: 1.05 L/min. Limit of detection, 0.048 μg/L [Beavis *et al.* 2008]. Solid and liquid food samples. Limit of quantification, 3 μg/kg and 0.3 μg/L for solid and liquid samples, respectively; limit of detection, 1 μg/kg and 0.1 μg/L for solid and liquid samples, respectively [Cheung Chung *et al.* 2008]. Well Water. Method 200.8 of the EPA. Limit of detection, 1 μg/L [McCarty *et al.* 2004]. Plasma gas: 15 L/min. Nebuliser gas: 0.95 L/min. Auxillary gas: 0.8 L/min. Limit of detection, 0.044 μg/L [Dawson *et al.* 2003]. Meals from Catering Establishments. Plasma gas: 15 L/min. Auxiliary gas: 0.9 L/min. Nebuliser gas: 0.73 L/min. Limit of quantification, 2 μg/kg [Noel *et al.* 2003]. GSR. Coolant gas: 15 L/min. Auxiliary gas: 1.1 L/min. Sample gas: 0.97 L/min. Limit of detection, 0.045 μg/L [Reis *et al.* 2003].

Note For a review of analytical methods for the detection of antimony in waters, see Shotyk *et al.* [2005]. For a study of antimony in airborne particulate matter collected in Tokyo between 1995 and 2004, see Furuta *et al.* [2005]. For a study of antimony in soils, plants, water, and sediments in Korea, see Jung *et al.* [2002]. For the polarographic analysis of antimony compounds in antibilharzial preparations, see Gawargious *et al.* [1987].

Disposition in the Body Soluble forms of trivalent and pentavalent antimony administered by inhalation or parenteral injection are rapidly absorbed and eliminated, mainly via the kidneys, with greater than 50% in the urine 6 h following injection. Orally ingested soluble forms are slowly absorbed and urinary elimination is prolonged. Highest concentrations of antimony are found in the liver after therapeutic administration of antimonials, and the liver can reduce the pentavalent form to the trivalent form. Trivalent antimony is predominantly excreted in the faeces and not as rapidly excreted in the urine as the pentavalent form (25% excreted in the urine 24 h post injection).

Normal Concentrations Blood—<1 μg/L (8 nmol/L); urine—<1 μg/L (8 nmol/L); kidney—0.01 mg/kg; liver—0.02 mg/kg; lung—0.3 mg/kg.

Note For studies on antimony concentrations in infants, see Cullen *et al.* [1998] and Dezateux *et al.* [1997].

Therapeutic Concentration

Twenty-nine male patients with cutaneous leishmaniasis were administered sodium stibogluconate IM equivalent to 600 mg antimony per day for 10 days. The mean peak plasma concentration was 8.77 mg/L at 1.34 h [Jaser *et al.* 1995].

Five patients with visceral leishmaniasis were treated with sodium stibogluconate (2 patients) or meglumine antimonite (3 patients) given IM equivalent to antimony 10 mg/kg bodyweight. Treatment lasted 30 days. Mean peak blood concentrations of 9 to 12 mg/L occurred at 2 h [Chulay *et al.* 1988].

Toxicity Occupational inhalation of antimony compounds such as the oxide or trichloride from dust or fumes damages the upper respiratory tract, and prolonged exposure leads to gastrointestinal symptoms similar to those seen in arsenic poisoning. Symptoms of acute antimony poisoning resemble those of acute arsenic poisoning.

Urine antimony concentrations up to 150 μg/L (1.2 μmol/L) developed in a group of occupationally exposed workers [Smith *et al.* 1995].

A 32-year-old man suffering from AIDS was admitted to hospital for treatment of visceral leishmaniasis. He was also inadvertently treated with 10 times the prescribed dose of sodium stibogluconate (6500 mg instead of 650 mg). The concentration of antimony was ≈11 μmol/L at 20 h with biexponential elimination [Reymond, Desmeules 1998].

A 27-year-old woman acquired cutaneous leishmaniasis in Central America. She was inadvertently treated with 10 times the intended daily dose of the antimonial compound sodium stibogluconate (Pentostam), 8500 mg (143 mg/kg) instead of 850 mg. Concentrations of antimony in her serum and urine were as follows:

	Time	*Sb (mg/L)*
Serum		
Day 1	11.00 pm	210
Day 2	2.30 am	27.5
Day 2	7.15 am	4.6
Day 3	7.00 am	<2
Urine		
Day 1–2	24 h	579
Day 4	10.45 am	4.6

[Herwaldt *et al.* 1992].

Four adults were admitted to the emergency department with severe abdominal cramps, nausea, continuous vomiting and watery diarrhoea. Three of the patients survived with no sequelae but one, a 93-year-old man, had marked cyanosis and haematemesis. He subsequently died. The cause of the poisoning was the use of 'tartar emetic' in the place of 'cream of tartar' in baking. Antimony concentrations in the deceased were as follows:

	Antimony (μg/L)
Bile	471
Colon	53
Gallbladder	459
Heart	6
Kidney	103
Liver	491
Lung	32
Muscle (upper arm)	3
Nails	176
Skin/hair	6
Small bowel	224
Stomach	114
Vertebra	10

[Lauwers *et al.* 1990].

A 44-year-old white male doctor dosed himself with wine made of *Cephaelis ipecacuanha* and requested his apothecary to administer James' powder, a mixture of antimony oxide and potassium tartrate. A severe bout of vomiting and diarrhoea lasting more than 18 h followed and despite physician intervention the patient died [Miller 1982].

A woman ingested antimony trichloride solution and died 48 h later. She had tissue concentrations of 4.6 mg/L (blood), 6 mg/kg (brain), 6 mg/kg (lung), 45 mg/L (liver), 404 mg/L (bile) and 32 mg/kg (kidney) [Baselt 2005].

Note For an investigation of toxic trace elements in the hair of children with autism, see Fido and Al Saad [2005]. For a study of postmortem concentrations in deceased smelter workers, see Gerhardsson *et al.* [1982]. For concentrations in the urine of glass-manufacturing workers, see Apostoli *et al.* [1998], Arai *et al.* [1994] and Ludersdorf *et al.* [1987].

Volume of Distribution Apparent, ~0.22 L/kg.

Half-life Elimination half-life 38 days after IV injection. Following IM injection, biphasic, 2.02 and 76 h.

Distribution in Blood Trivalent antimony is bound predominantly to erythrocytes. Pentavalent antimony is predominantly found in serum.

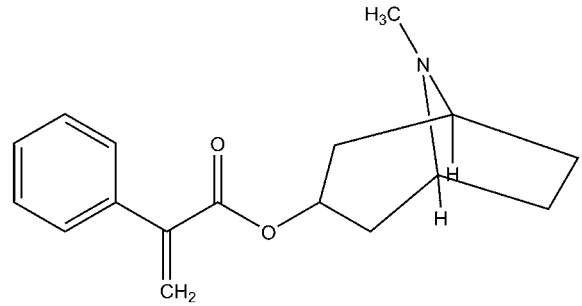
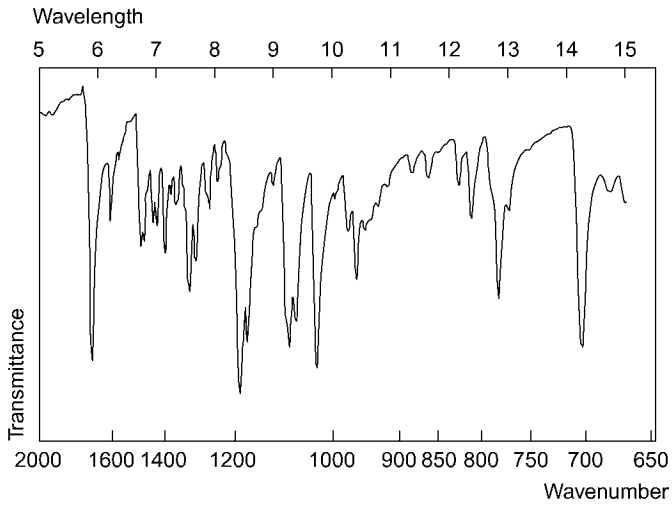
Apoatropine

Tropane, Alkaloid
$C_{17}H_{21}NO_2 = 271.4$
CAS—500-55-0

IUPAC Name Tropyl atropate
Synonyms Atropamine; atropoyltropeine.



Chemical Properties Obtained from the root of *Atropa belladonna*, *Latua pubiflora* (Solanaceae) and other plants of the genera *Datura* and *Scopolia*. Apoatropine is formed during the racemisation of hyoscyamine to atropine. Prisms from chloroform. Mp 60° to 62°. Almost insoluble in water; freely soluble in ethanol, ether, and chloroform; soluble in dilute acetic acid. Extracted by organic solvents from aqueous alkaline solutions. Log *P* (octanol/water) 3.37 [Meylan, Howard 1995].
Colour Test Vitali's test—purple (limit of detection, 0.1 μg).
Thin-layer Chromatography System T1—R_f 0.18 (location reagent acidified iodoplatinate spray, positive reaction).
Gas Chromatography System G2/225—RRT 1.75 (relative to diphenhydramine); system G4—RRT 0.43 (relative to diphenhydramine).
High Performance Liquid Chromatography Column: Lichrosorb Diol (250 × 4.0 mm i.d., 7 μm). Mobile phase: 0.0125 mol/L sodium phosphate buffer (pH 7.2) : acetonitrile (80 : 20), flow rate 1.0 mL/min. UV detection (λ = 220 nm). Retention time: apoatropine 6.3 min, atropine 4.7 min, scopolamine 3.6 min. Limit of quantification not reported [Leroy, Nicolas 1987].
Infrared Spectrum Principal peaks at wavenumbers 1190, 1710, 1025 cm^{-1} (KBr disk).



Mass Spectrum See Wada *et al* [1994].
Quantification
***Other* TLC** Plant Material (*Scopolia tangutica*). Plates: silica gel G (10 × 15 cm). Solvent system: chloroform : methanol : 25% ammonium hydroxide (85 : 15 : 0.7). Location reagent: modified Dragendorff reagent. R_f values: apoatropine 0.77, tropine 0.04, cuscohygrine 0.12, (–)–6β-hydroxyhyoscyamine 0.23, hyoscyamine 0.34, daturamine 0.85, scopolamine 0.92. Limit of quantification not reported [Peigen, Liyi 1982].

GC-MS Plant Material (*Latua pubiflora*). Column: DB-1 fused silica capillary (30 m × 0.25 mm i.d., 0.25 μm). Carrier gas: He, 34.0 cm/s. Temperature

A

programme: 90° for 1 min to 300° at 6°/min for 4 min. EI ionisation at 70 eV (SIR). Retention time: apoatropine 21.2 min, 3α-cinnamoyloxytropane, hyoscyamine 24.8 min, scopolamine 26.3 min. Limit of quantification not reported [Munoz, Casale 2003]. Guinea Pig Tissue. Column: 2% OV-17 on Chromosorb W (AW-DMCS) (1.1 m × 3.2 mm i.d.). Carrier gas: He, 30 mL/min. Temperature: 220°. EI ionisation at 70 eV. Retention time: 2.5 min. Limit of quantification not reported [Wada *et al.* 1994].

HPLC Plant Material (*Datura innoxia* and *Atropa belladonna*). Column: C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: 30 mmol/L potassium dihydrogen phosphate-dipotassium hydrogen phosphate (815 : 185 g/g, pH 6.0) : methanol : acetonitrile (80.1 : 7.9 : 12), flow rate 1.0 mL/min. DAD. Retention times: apoatropine 9.2 min, (–)–6β-hydroxyhyoscyamine 10.6 min, scopolamine 15.7 min, hyoscyamine 18.6 min. Limit of quantification, 4 mg/L [Kursinszki *et al.* 2005]. Belladonna Preparations (tincture and powder). Column: Lichrosorb Diol (250 × 4.0 mm i.d., 7 µm). Mobile phase: 0.0125 mol/L sodium phosphate buffer (pH 7.2) : acetonitrile (80 : 20), flow rate 1.0 mL/min. UV detection (λ= 220 nm). Retention times: apoatropine 6.3 min, atropine 4.7 min, scopolamine 3.6 min. Limit of quantification not reported [Leroy, Nicolas 1987].

Note For a study on the characterisation of alkaloids in hairy root cultures of *Datura stramonium*, see Berkov *et al.* [2003].

Toxicity Similar to atropine. LD_{50} (oral) in mice: 160 mg/kg.

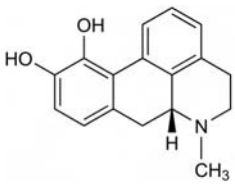
Apomorphine

Antiparkinsonian, Emetic

$C_{17}H_{17}NO_2$ = 267.3

CAS—58-00-4

IUPAC Name (6a*R*)-5,6,6a,7-Tetrahydro-6-methyl-4*H*-dibenzo[*de,g*]quinoline-10,11-diol



Chemical Properties Crystals. Mp about 195°, with decomposition. The crystals and aqueous solutions oxidise rapidly in light and air, turning green. Slightly soluble in water, benzene, ether and petroleum ether; soluble in ethanol and chloroform. pK_a 7.2, 8.9 (15°). Log *P* (octanol/water), 2.3. Extraction yield (chlorobutane), 0.8 [Demme *et al.* 2005].

Apomorphine Hydrochloride

$C_{17}H_{17}NO_2$,HCl, $^1/_2H_2O$ = 312.8

CAS—314-19-2 (anhydrous); 41372-20-7 (hemihydrate)

Proprietary Names *Apofin*; *APO-go*; *Apokinon*; *Apomine*; *Britaject*; *Uprima*.

Chemical Properties White or greyish-white glistening crystals or microcrystalline powder. Decomposes between 225° and 236°. Soluble 1 in 50 of water and 1 in 17 of water at 80°; soluble 1 in 50 of ethanol; very slightly soluble in chloroform and ether.

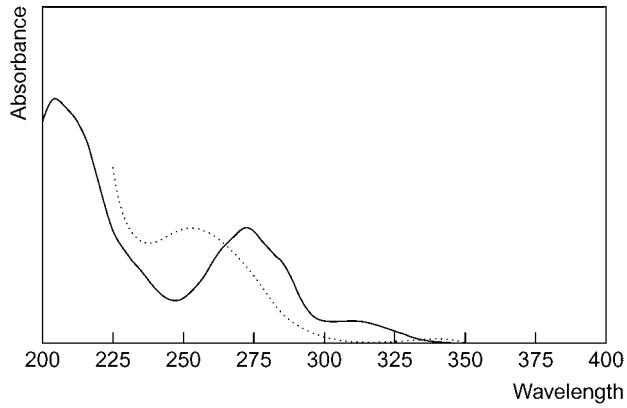
Colour Tests Ferric chloride—blue; Liebermann's reagent—black; Marquis test—violet→black; methanolic potassium hydroxide—green→red; Nessler's reagent—black.

Thin-layer Chromatography System TA—R_f 0.83; system TB—R_f 0.00; system TC—R_f 0.21; system TE—R_f 0.58; system TL—R_f 0.27; system TAE—R_f 0.54; system TAJ—R_f 0.06; system TAK—R_f 0.00; system TAL—R_f 0.22 (acidified iodoplatinate solution, positive).

Gas Chromatography System GA—apomorphine RI 2530; apomorphine-AC_2 RI 2830.

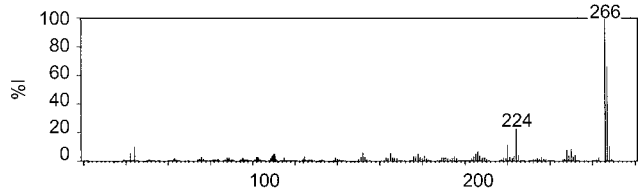
High Performance Liquid Chromatography System HA—*k* 3.7 (tailing peak); system HX—RI 348; system HY—RI 256; system HAA—retention time 9.0 min.

Ultraviolet Spectrum Aqueous acid—272 nm (A^1_1=626a); aqueous alkali—253 nm.



Infrared Spectrum Principal peaks at wavenumbers 1265, 1298, 1204, 752, 985, 790 cm^{-1} (KBr disk).

Mass Spectrum Principal ions at *m/z* 266, 267, 224, 220, 268, 44, 250, 248.



Quantification

Plasma **GC** FID. Limit of detection, 1 mg/L [Baaske *et al.* 1977].

HPLC Electrochemical detection. Limit of detection, 20 pg [Bolner *et al.* 1997]. Electrochemical detection. For *R*- and *S*-apomorphine, apocodeine, isoapocodeine and conjugated metabolites. Limits of detection, 0.3 µg/L and 0.6 µg/L for *R*- and *S*-apomorphine, respectively [van der Geest *et al.* 1997]. Fluorescence detection, see Priston, Sewell [1996]. Electrochemical detection, see Sam *et al.* [1994]. Electrochemical detection, limit of detection, 0.5 µg/L [Essink *et al.* 1991]. Fluorescence detection, limit of detection, 100 µg/L [Smith, De Moreno 1983].

Urine **HPLC** See Plasma [van der Geest *et al.* 1997].

Disposition in the Body

Therapeutic Concentration

Apomorphine was administered by IV infusion (the rate was increased by 10 µg/kg every 20 min up to 100 µg/kg/h or until adverse effects occurred) to 10 subjects with parkinsonism, 8 of whom responded. Clinical efficacy occurred at a minimum concentration of 1.4 to 10.7 µg/L (mean 4.7) and dyskinesia occurred at 2.7 to 20 µg/L (mean 8.5); the minimal toxic concentration was 6.5 to24.5 µg/L (mean 16.7) [van Laar *et al.* 1998].

After a single sublingual dose of apomorphine 0.21 to 0.91 mg/kg to 5 patients (2 received 18 mg, 3 received 39 mg), peak plasma concentrations of 11.3 to 144.0 µg/L were attained at 45 to 90 min [Durif *et al.* 1991].

Dose 100 µg/kg of apomorphine hydrochloride subcutaneously, as a single dose.

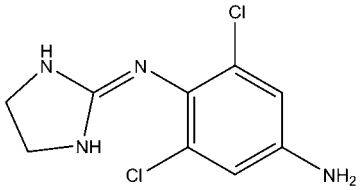
Apraclonidine

α_2-Adrenoceptor Agonist, Antiglaucoma

$C_9H_{10}Cl_2N_4$ = 245.1

CAS—66711-21-5

IUPAC Name 2,6-Dichloro-N^1-(4,5-dihydro-1*H*-imidazol-2-yl) benzene-1,4-diamine
Synonyms *p*-Aminoclonidine; aplonidine.



Chemical Properties Solid. Mp >230°. Log *P* (octanol/water), 1.53 [Wishart 2006].

Apraclonidine Hydrochloride

$C_9H_{10}C_{l2}N_4$,HCl = 281.6
CAS—73218-79-8
Synonyms ALO-2145; p-aminoclonidine Hydrochloride; aplonidine hydrochloride; NC-14.
Proprietary Names *Iopidine*; *Alcon*.
Chemical Properties A white to off-white, odourless to practically odourless powder. Soluble in methyl alcohol, sparingly soluble in water and alcohol, and insoluble in chloroform, ethyl acetate and hexanes.

Apraclonidine Dihydrochloride

$C_9H_{10}C_{l2}N_4$,2HCl = 318.1
CAS—73217-88-6

Ultraviolet Spectrum Peaks at 215, 252 and 300 nm.
Quantification
Plasma **GC-MS** Column: capillary. ECD. Limit of detection, 0.2 µg/L [Coleman *et al.* 1990; Robin, Coleman 1990].
Disposition in the Body
Therapeutic Concentration A 0.5% apraclonidine solution has been shown to be effective in reducing intra-ocular pressure in short and longer-term situations [Gross *et al.* 1997]. A 0.5% solution is as effective as a 1% solution in preventing intra-ocular pressure elevation after trabeculoplasty, iridotomy or capsulotomy [Rosenberg *et al.* 1995]. Plasma levels were not reported in either study.

Twenty healthy female volunteers (aged 21 to 47 years) were administered 2 drops of either 0.25% or 0.5% apraclonidine hydrochloride into both eyes or 0.5% apraclonidine into one eye and placebo into the other, with a 1 h break between each drop. Median plasma concentrations were as follows:

	Concentration (µg/L)		
Time (h)	Apraclonidine HCl 0.25%	Apraclonidine 0.5%	Unilateral 0.5% apraclonidine
2	ND	0.45	0.60
5	0.30	0.55	0.65
8	0.20	0.60	0.20

ND: not detectable (<0.2 µg/L) [Coleman *et al.* 1990; Robin, Coleman 1990].

Toxicity Systemic absorption of apraclonidine can occur following use of apraclonidine eye drops and cardiovascular effects have been reported. The drops should not be used concomitantly with monoamine oxidase inhibitors, tricyclic antidepressants, or systemic sympathomimetics. Ocular intolerance can occur with regular use.

A 56-year-old woman who underwent laser capsulotomy for cataract removal was prescribed apraclonidine hydrochloride ophthalmic solution. She was admitted to the emergency department with hypotension (BP 80/60 mmHg), drowsiness (Glasgow Coma Score 13) and bradycardia (heart rate 40 bpm). After a bolus of normal saline and IV atropine (1 mg), her blood pressure and heart rate returned to normal. A detailed history revealed that she had used the entire 5 mL apraclonidine solution within 12 h of the operation [Pekdemir *et al.* 2005]

Half-life Approximately 8 h.
Protein Binding Approximately 99%.
Dose To control postoperative increase in intra-ocular pressure, one drop of a 1% solution is instilled before and following laser eye surgery. One or two drops of a 0.5% solution is instilled three times a day for control of raised intra-ocular pressure (short-term use only).

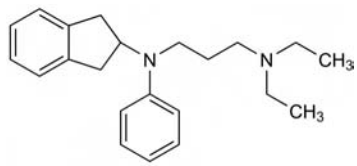
A

Aprindine

Antiarrhythmic
$C_{22}H_{30}N_2$ = 322.5
CAS—37640-71-4
IUPAC Name *N*-(2,3-Dihydro-1*H*-inden-2-yl)-*N*′,*N*′-diethyl-*N*-phenyl-1,3-propanediamine

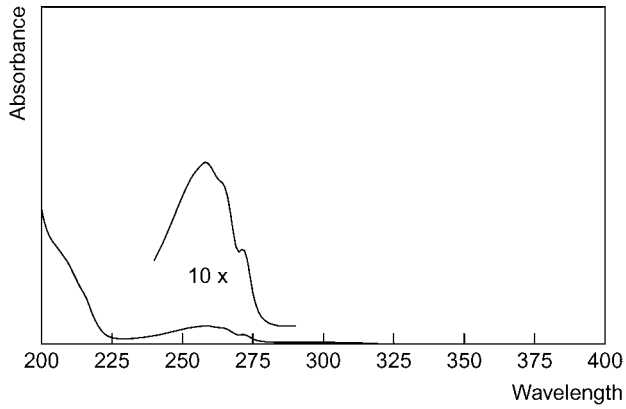


Chemical Properties pK_a 10.1. Log *P* (octanol/water), 4.9. Extraction yield (chlorobutane), 0.95 [Demme *et al.* 2005].

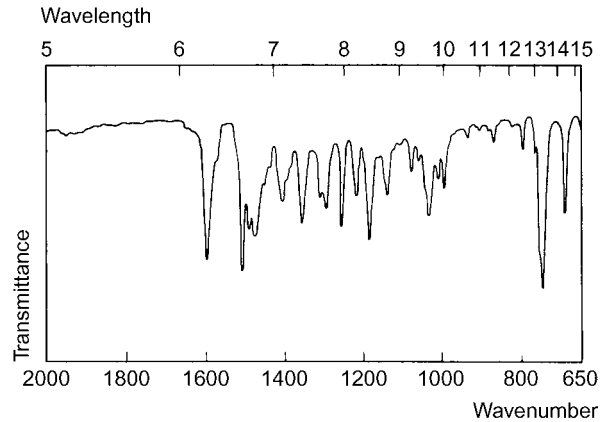
Aprindine Hydrochloride

$C_{22}H_{30}N_2$,HCl = 359.0
CAS—33237-74-0
Proprietary Names *Amidonal*; *Fiboran*.
Chemical Properties A white to yellowish-white microcrystalline powder. Mp 127° to 130°. Very soluble in water; freely soluble in ethanol and chloroform; practically insoluble in ether.

Thin-layer Chromatography System TB—R_f 0.63; system TE—R_f 0.76; system TAE—R_f 0.20.
Gas Chromatography System GA—aprindine RI 2462; M (*N*-desalkyl-) RI 1920, M (*p*-aminophenol-) RI 1253, M (OH-)-AC- RI 2850, M (OH-methoxy-)-AC- RI 2995, M (desindane)-AC- RI 1880, M (desphenyl-)-AC- RI 2300.
High Performance Liquid Chromatography System HX—RI 433; system HAA—retention time 17.0 min.
Ultraviolet Spectrum Aqueous acid—260, 266 nm (A_1^1=38a), 272 nm; ethanol—258 nm (A_1^1=389a), 296 nm (A_1^1=47a).



Infrared Spectrum Principal peaks at wavenumbers 745, 1510, 1602, 1187, 1258, 1035 cm^{-1} (aprindine hydrochloride, KBr disk).



Mass Spectrum Principal ions at *m/z* 113, 86, 116, 98, 117, 115, 58, 84; M (*N*-desalkyl-)aprindine *m/z* 104, 209, 77, 116, 115, 94.
Quantification
Plasma **GC** AFID. Limit of detection, 20 µg/L [Nash, Carmichael 1980].

A

HPLC UV detection, see Misztal and Przyborowski [1995]. UV or fluorescence detection. For aprindine and other antiarrhythmic drugs, see Verbesselt *et al.* [1991]. UV detection. Limits of detection, 20 µg/L and 50 µg/L for aprindine and monodesethylaprindine, respectively [Kobari *et al.* 1983].

***Serum* GC** Surface ionization detection. Limit of detection, 16 pg [Kawano *et al.* 1989].

Disposition in the Body Almost completely absorbed after oral administration. Extensively metabolised by aromatic hydroxylation and *N*-dealkylation followed by glucuronic acid conjugation; the monodesethyl metabolite, which can be detected in plasma after chronic administration, is active. <1% of a dose is excreted in the urine as unchanged drug and about 40 to 65% as conjugated metabolites; 35 to 60% of the dose is eliminated in the faeces over a period of 5 days.

Therapeutic Concentration In plasma, usually in the range 0.7 to 2 mg/L.

After a single oral dose of 200 mg to 12 subjects, peak plasma concentrations of 0.6 to 2 mg/L (mean 0.9) were attained in 2 h [Fasola, Carmichael [1974]].

Following daily oral doses of 100 to 150 mg, plasma concentrations in 28 patients ranged from 0.73 to 2.55 mg/L [Van Durme *et al.* 1974].

In 38 patients given a single oral dose of 100 to 150 mg aprindine hydrochloride, mean peak plasma concentrations of 0.33 to 1.40 mg/L (mean 0.77) were achieved in 1.5 to 4.0 h (mean 2.9). With repeated administration of 10 or 20 mg doses every 8 h, steady-state plasma concentrations of 0.155 to 0.455 mg/L and 0.39 to 1.53 mg/L, respectively, were attained in 7 to 19 days [Yokota *et al.* 1987].

Toxicity Toxic effects are usually associated with plasma concentrations greater than 2 mg/L.

Toxic effects were found in 9 patients whose plasma concentrations ranged from 1.2 to 4.9 mg/L (mean 2.6) [Van Durme *et al.* 1974].

Bioavailability About 75%.

Half-life Plasma half-life, 12 to 66 h (mean 30) in normal subjects but the half-life is apparently longer in patients with chronic ventricular arrhythmias and myocardial infarction (average, about 50 h).

Volume of Distribution About 4 L/kg.

Clearance Plasma clearance, about 2.5 mL/min/kg in normal subjects; decreased to about 1 mL/min/kg in patients with cardiac disease.

Protein Binding >95% at therapeutic concentrations, decreasing at higher concentrations.

Note For a review of the pharmacokinetics of antiarrhythmic agents, see Ronfeld [1980].

Dose 50 to 100 mg of aprindine hydrochloride daily; initial doses of up to 200 mg daily may be given.

Aprobarbital

Sedative, Barbiturate

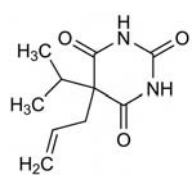
$C_{10}H_{14}N_2O_3$ = 210.2

CAS—77-02-1

IUPAC Name 5-(1-Methylethyl)-5-(2-propenyl)-2,4,6(1*H*,3*H*,5*H*)-pyrimidinetrione

Synonyms Allylisopropylmalonylurea; allypropymal; aprobarbitone.

Proprietary Name *Alurate*



Chemical Properties A white crystalline powder. Mp 140° to 141.5°. Soluble 1 in 350 of water, 1 in 30 of boiling water, 1 in 2.5 of ethanol, 1 in 40 of chloroform, and 1 in 5 of ether; soluble in acetone, glacial acetic acid and aqueous solutions of alkali hydroxides and carbonates; almost insoluble in petroleum ether and aliphatic hydrocarbons. pK_a 8.0 (25°). Log *P* (octanol/water), 1.2.

Aprobarbital Sodium

$C_{10}H_{13}N_2NaO_3$ = 232.2

CAS—125-88-2

Synonym Aprobarbitone sodium

Chemical Properties A white, hygroscopic, microcrystalline powder. Very soluble in water; slightly soluble in ethanol; practically insoluble in ether.

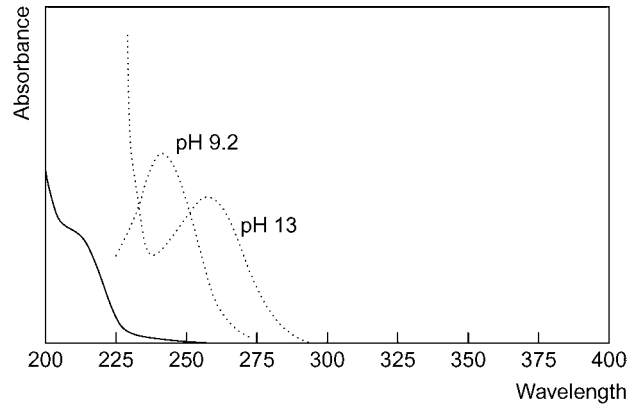
Colour Test Koppanyi-Zwikker test—violet.

Thin-layer Chromatography System TD—R_f 0.48; system TE—R_f 0.40; system TF—R_f 0.65; system TH—R_f 0.66; system TAD—R_f 0.57; system TAE—R_f 0.86 (mercurous nitrate spray, black; acidified potassium permanganate solution, yellow-brown; Zwikker's reagent, pink).

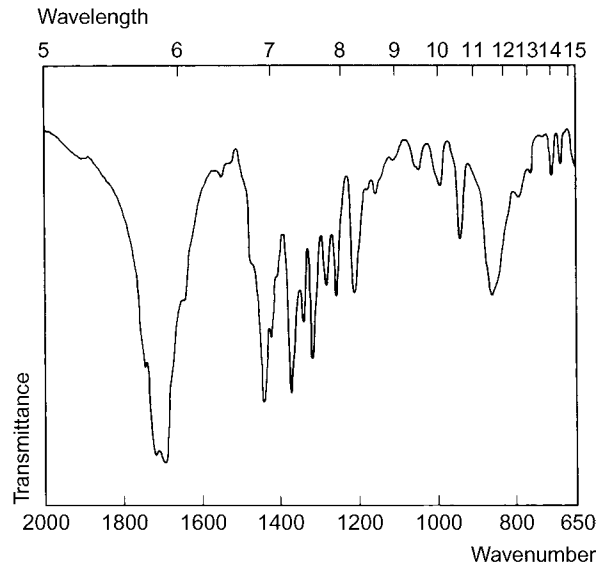
Gas Chromatography System GA—aprobarbital RI 1618, M (OH-) RI 1815, aprobarbital-Me_2 RI 1540.

High Performance Liquid Chromatography System HG—*k* 3.42; system HH—*k* 2.22; system HX—RI 357; system HY—RI 319; system HZ—retention time 2.8 min; system HAL—retention time 2.0 min.

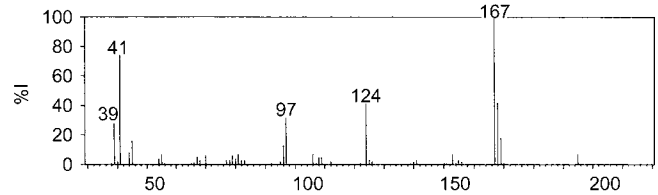
Ultraviolet Spectrum Borax buffer 0.05 mol/L (pH 9.2)—241 nm (A^1_1=451a); 1 mol/L sodium hydroxide (pH 13)—257 nm (A^1_1=331b).



Infrared Spectrum Principal peaks at wavenumbers 1693, 1720, 1745, 1316, 1255, 860 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 167, 41, 124, 168, 97, 39, 169, 45; *N*-hydroxyaprobarbital 41, 43, 183, 167, 140, 184, 124, 109.



Quantification See also under Amobarbital.

***Urine* GC–MS** For aprobarbital, *N*-hydroxyaprobarbital and aprobarbital diol, see Gilbert *et al.* [1978].

Disposition in the Body Absorbed after oral administration and slowly excreted in the urine, mainly as metabolites, <3% of a dose being excreted as

unchanged drug in 24 h. About 12% of a dose is excreted in the urine as the diol derivative and 4% as *N*-hydroxyaprobarbital in 3 days, together with 9% as unchanged drug.

Therapeutic Concentration In plasma, usually in the range 10 to 40 mg/L.

Toxicity The estimated minimum lethal dose is 2 g. Plasma concentrations greater than 40 mg/L are usually associated with toxic effects; concentrations greater than 50 mg/L may be fatal.

In 4 cases of death attributed to overdoses ranging from 2.5 to 7.7 g, antemortem serum concentrations ranged from 120 to 150 mg/L. In 44 cases of overdose in which the patients subsequently recovered, the serum concentrations 24 h after ingestion were in the range 40 to 130 mg/L [Lous 1954].

In a number of fatalities attributed to aprobarbital, a mean postmortem blood concentration of 50 mg/L in 9 cases and a mean postmortem liver concentration of 83 μg/g in 12 cases were reported [Bonnichsen *et al.* 1961].

Half-life Plasma half-life, 0.5 to 1.5 days.

Protein Binding 55 to 70%.

Dose 40 to 160 mg daily.

Bonnichsen R *et al.* (1961). Barbiturate analysis: method and statistical survey.. *J Forensic Sci* 6: 411–443.

Gilbert JN *et al.* (1978). The synthesis and urinary estimation of N-hydroxyaprobarbitone. *J Pharm Pharmacol* 30: 173–175.

Apronal

Hypnotic, Sedative

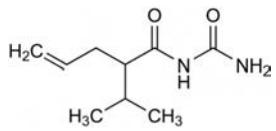
$C_9H_{16}N_2O_2$ = 184.2

CAS—528-92-7

IUPAC Name *N*-(Aminocarbonyl)-2-(1-methylethyl)-4-pentenamide

Synonyms Allylisopropylacetylurea; apronalide.

Proprietary Name *Sedormid*



Chemical Properties Colourless crystals or white crystalline powder. Mp 194°. Soluble 1 in 3000 of cold water, 1 in 210 of boiling water, 1 in 10 of ethanol, 1 in 45 of chloroform, and 1 in 75 of ether. Log *P* (octanol/water), 1.7.

Thin-layer Chromatography System TD—R_f 0.33; system TE—R_f 0.67; system TF—R_f 0.52 (acidified potassium permanganate solution, positive).

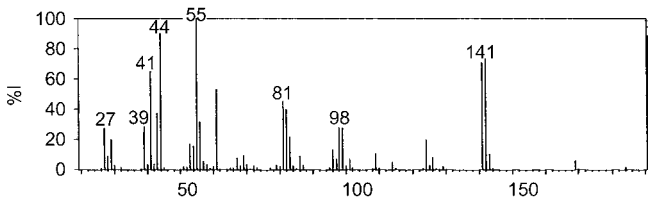
Gas Chromatography System GA—RI 1331.

High Performance Liquid Chromatography System HX—RI 396.

Ultraviolet Spectrum No significant absorption, 230 to 360 nm.

Infrared Spectrum Principal peaks at wavenumbers 1676, 1704, 1092, 1620, 1185, 750 cm^{-1} (KBr disk).

Mass Spectrum Principal ions at *m/z* 55, 44, 142, 141, 41, 61, 81, 82.



Dose Apronal was formerly given in doses of 250 to 750 mg daily.

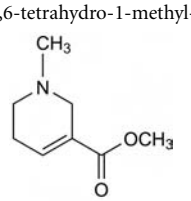
Arecoline

Purgative

$C_8H_{13}NO_2$ = 155.2

CAS—63-75-2

IUPAC Name Methyl-1,2,5,6-tetrahydro-1-methyl-3-pyridinecarboxylate



Chemical Properties Arecoline is an alkaloid which is obtained from the seeds of *Areca catechu* (Palmae). An oily liquid which is a strong base. Bp 209°. Miscible with water, ethanol and ether; soluble in chloroform. pK_a 7.4 (20°). Log *P* (octanol/water), 0.4.

Arecoline Hydrobromide

$C_8H_{13}NO_2$,HBr = 236.1

CAS—300-08-3

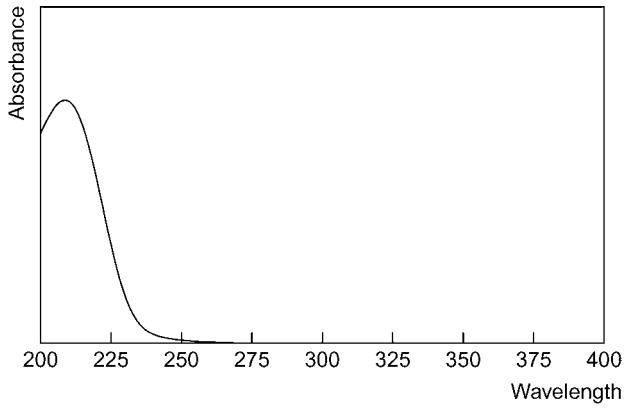
Chemical Properties A white crystalline powder. Unstable in light. Mp 169° to 171°. Soluble 1 in 1 of water and 1 in 10 of ethanol; slightly soluble in chloroform and ether.

Thin-layer Chromatography System TA—R_f 0.53; system TB—R_f 0.39; system TE—R_f 0.59; system TAE—R_f 0.41; system TAJ—R_f 0.28; system TAK—R_f 0.00; system TAL—R_f 0.28 (acidified potassium permanganate solution, positive).

Gas Chromatography System GA—RI 1195.

High Performance Liquid Chromatography System HX—RI 79; system HAA—retention time 3.1 min.

Ultraviolet Spectrum No significant absorption, 230 to 360 nm.



Infrared Spectrum Principal peaks at wavenumbers 1712, 1262, 1135, 1282, 1020, 1650 cm^{-1} (KCl disk).

Mass Spectrum Principal ions at *m/z* 155, 96, 140, 43, 42, 81, 94, 53.

Quantification

Plasma **GC–MS** Limit of detection, <1 μg/L [Hayes *et al.* 1989].

Biological Tissue **GC–MS** Limit of detection, <25 pmol for arecoline, acetylcholine and choline [Patterson, Kosh 1992].

Argatroban

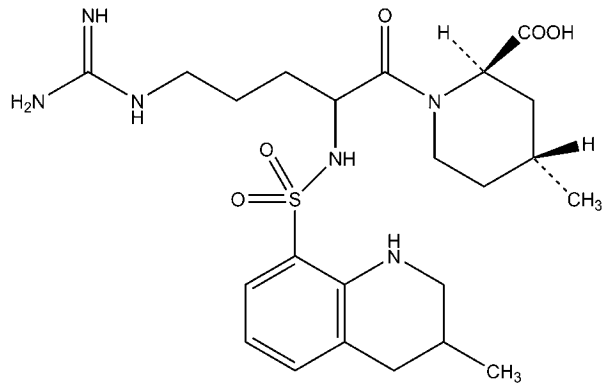
Antithrombotic

$C_{23}H_{36}N_6O_5S$ = 508.6

CAS—74863-84-6 (anhydrous)

IUPAC Name (2*R*,4*R*)-1-[(2*S*)-5-(Diaminomethylideneamino)-2-[(3-methyl-1,2,3,4-tetrahydroquinolin-8-yl)sulfonylamino]pentanoyl]-4-methylpiperidine-2-carboxylic acid hydrate

Synonyms (2*R*,4*R*)-1-[(2*S*)-5-[(Aminoiminomethyl)amino]-1-oxo-2-[[(1,2,3,4-tetrahydro-3-methyl-8-quinolinyl)sulfonyl]amino]pentyl]-4-methyl-2-piperidinecarboxylic acid; argipidine; 1-[5-guanidino-2-[(3-methyl-1,2,3,4-tetrahydroquinolin-8-yl)sulfonylamino]pentanoyl]-4-methyl-piperidine-2-carboxylic acid; MQPA.



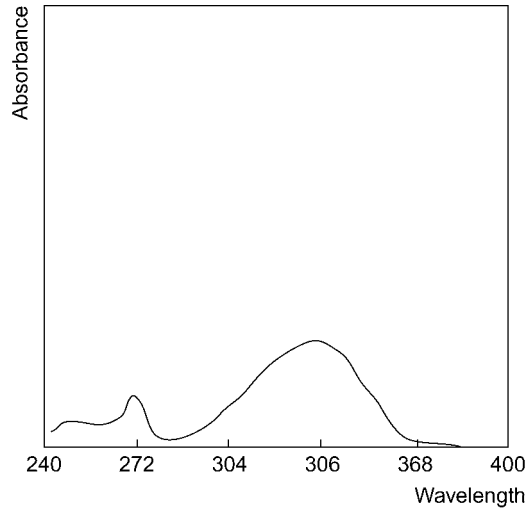
Chemical Properties Crystals. Mp 188° to 191°. Log *P* (octanol/water), 0.749 [Wishart 2006].

A

Argatroban Monohydrate

$C_{23}H_{36}N_6O_5S,H_2O = 526.7$
CAS—141396-28-3
Synonyms DK-7419; GN-1600; MCI-9038; MD-805; OM-805.
Proprietary Names *Novastan*; *Slonnon*.
Chemical Properties Crystals. Mp 176° to 180°.

Ultraviolet Spectrum Normal saline—333 nm.



Quantification

Plasma **HPLC** Column: Reversed phase C_{18}. Mobile phase: 1% TEA in water (pH 7.5 with 85% phosphoric acid) : acetonitrile (70 : 30), flow rate 1.0 mL/min. UV detection ($\lambda = 320$ nm). Limit of quantification, 0.4 mg/L [Ahmad *et al.* 1999].

Note For the enantiomeric separation of argatroban, see Rawson *et al.* [1993].

Disposition in the Body Extensively metabolised in the liver, mainly by hydroxylation and aromatisation of the 3-methyltetrahydroquinolone ring, to at least 4 metabolites. It appears to be metabolised by CYP3A4/5. The antithrombin potency of the major metabolite is about 30% that of the parent compound. It is excreted primarily in the faeces, via the bile as metabolites and as unchanged drug. Approximately 16% of a dose is excreted unchanged in the urine and 14% unchanged in faeces.

Therapeutic Concentration

A bolus dose of 125 µg/kg argatroban over 1 min followed by a 4 h continuous infusion of 2.5 µg/kg/min was administered to 20 young and 20 elderly volunteers. Mean steady-state argatroban plasma concentrations were as follows:

	Young		*Elderly*	
	Men	**Women**	**Men**	**Women**
Steady state concentration (µg/L)	541	473	657	511

In a separate study, 12 healthy adults were administered 2.5 µg/kg/min argatroban over 4 h and 12 patients with moderate hepatic impairment were administered 1.25 µg/kg/min over the same period. Mean steady-state plasma concentrations were 0.539 mg/L for the first group and 1.05 mg/L for the second [Swan, Hursting 2000].

Half-life In the range 40 to 50 min.
Volume of Distribution Steady state, approx. 0.2 L/kg.
Clearance Approximately 0.3 L/h/kg.
Protein Binding Approximately 54%.

Dose In the management of heparin-induced thrombocytopenia, 2 to 10 µg/kg/min argatroban hydrochloride solution IV. In percutaneous coronary interventions in patients at risk of heparin-induced thrombocytopenia, 25 to 350 µg/kg/min IV over 3 to 5 min.

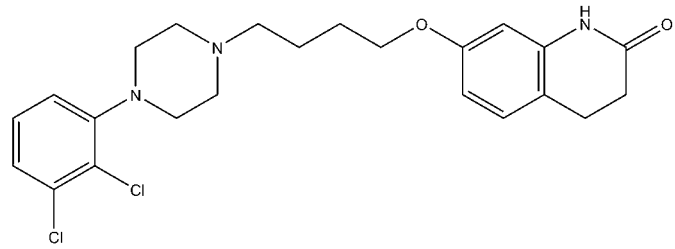
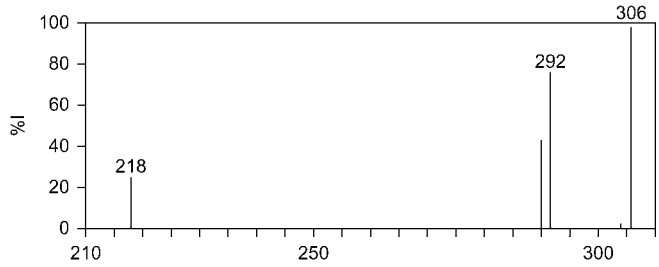
Aripiprazole

5-HT_{2A} Receptor Antagonist, 5-HT_1 Receptor Agonist, Dopamine D_2 Agonist, Antipsychotic, Dehydroquinoline
$C_{23}H_{27}Cl_2N_3O_2 = 448.4$
CAS—129722-12-9

IUPAC Name 7-[4-[4-(2,3-Dichlorophenyl)piperazin-1-yl]butoxy]-3,4-dihydro-1*H*-quinolin-2-one
Synonyms Aripiprazol; 7-[4-[4-(2,3-dichlorophenyl)-1-piperazinyl]butoxy]-3,4-dihydrocarbostyril; 7-{4-[4-(2,3-dichlorophenyl)-1-piperazinyl]butoxy}-3,4-dihydro-2(1*H*)-quinolinone; OPC-14597; OPC-31.
Proprietary Names *Abilify*; *Arlemide*; *Azymol*; *Groven*; *Irazem*; *Real One*; *Siblix*; *Viza*.



Chemical Properties Colourless flake crystals. Mp 139° to 139.5° [O'Neil *et al.* 2006]. Insoluble in water.
Mass Spectrum Principal ions at *m/z* 306, 292, 280, 218 (TMS derivative).



Quantification

Plasma **GC-MS** Column: 5% phenyl polysilphenylene-siloxane (25 m × 0.22 mm i.d., 0.25 µm). Carrier gas: He, 0.6 mL/min. Temperature programme: 90° to 240° at 15°/min to 300° at 10°/min for 15 min. EI ionisation at 70 eV, scan acquisition mode. Retention time: aripiprazole 9.7 min, dehydroaripiprazole 9.8 min (both as TMS derivatives). Limit of quantification, 14.4 µg/L for aripiprazole, 6.9 µg/L for dehydroaripiprazole; limit of detection, 4.8 µg/L for aripiprazole, 2.3 µg/L for dehydroaripiprazole [Huang *et al.* 2007].

LC-MS Column: ODS-W (150 × 2.1 mm i.d., 5 µm). Mobile phase: 0.1% acetic acid in water : acetonitrile (65 : 35), flow rate 0.2 mL/min. ESI, positive ion mode, SRM acquisition mode. Limit of quantification, 0.1 µg/L [Kubo *et al.* 2005].

Serum **HPLC** Column: LiChrospher CN (250 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : 1.825 g/L dipotassium phosphate trihydrate (pH 6.4; 50 : 50), flow rate 1.2 mL/min. UV detection ($\lambda = 210$ nm). Retention time: approx. 17.8 min. Limit of quantification, 50 µg/L [Kirschbaum *et al.* 2005].

LC-MS Column: C_{18} (50 × 4.6 mm i.d., 5 µm). Mobile phase: methanol : 5 mmol/L acetic acid (pH 3.9, 20 : 80 to 70 : 30 over 4 min for 1 min), flow rate 1.0 mL/min. ESI, positive ion mode, MRM acquisition mode. Retention time: 4.0 min. Limit of quantification, 0.8 µg/L [Kirchherr, Kuhn-Velten 2006].

Other **HPLC** Rat Brain. Column: NovaPak phenyl (150 × 3.9 mm i.d., 4 µm). Mobile phase: acetonitrile : methanol : 20 mmol/L sodium sulfate : acetic acid (27 : 25 : 48 : 1), flow rate 1.0 mL/min. UV detection ($\lambda = 254$ nm). Limit of quantification, 30 ng/g [Shimokawa *et al.* 2005]. Rat plasma. Column: NovaPak phenyl (150 × 3.9 mm i.d., 4 µm). Mobile phase: acetonitrile : methanol : 20 mmol/L sodium sulfate : acetic acid (27 : 25 : 48 : 1), flow rate 1.0 mL/min. UV detection ($\lambda = 254$ nm). Limit of quantification, 10 µg/L [Shimokawa *et al.* 2005].

LC-MS *In vitro* Samples. Column: C_{18} (100 × 2.1 mm i.d., 1.7 µm). Mobile phase: acetonitrile : 30 mmol/L ammonium acetate (62 : 38), flow rate 0.3 mL/min. ESI, positive ion mode, MRM acquisition mode. Limit of quantification, 50 ng/L; limit of detection, 5 ng/L [Li *et al.* 2007].

Disposition in the Body Aripiprazole is rapidly absorbed following oral administration, with peak plasma concentrations reached within 3 to 5 h. Steady-state plasma concentrations are achieved by day 14, with evidence of accumulation (mean AUC values of 10 or 15 mg/day are 4-fold greater on day 14 than on day 1). Aripiprazole has extensive extravascular distribution. It is extensively metabolised by CYP3A4 and CYP2D6 via *N*-dealkylation, hydroxylation or dehydrogenation pathways, with the formation of dehydroaripiprazole as the main systemic metabolite. At steady state, ≈40% of the plasma aripiprazole concentration is represented by the major metabolite, although it is unclear if dehydroaripiprazole is pharmacologically active. Aripiprazole is excreted via the kidney and liver, with 25% of the dose being recovered in urine (<1% unchanged) and 55% in the faeces (18% unchanged). Aripiprazole is distributed into breast milk.

Therapeutic Concentration

In a dose-ranging study of aripiprazole, groups of healthy volunteers were administered daily oral doses of either 5, 10, 15 or 20 mg in tablet form. Peak plasma concentrations were reported as follows:

Day	Parameter	Aripiprazole dose (mg/day)			
		5	10	15	20
1	C_{max} (μg/L)	27.3	38.9	70.8	65.6
	Time (h)	3.4	5.0	3.5	6.8
8	C_{max} (μg/L)	76.7	149	218	302
	Time (h)	3.5	3.5	4.7	4.6
14	C_{max} (μg/L)	98.2	163	242	393
	Time (h)	3.3	2.8	3.0	3.8

[Mallikaarjun *et al.* 2004].

In a study investigating the effects of concomitant administration of carbamazepine to an aripiprazole regimen, a group of chronically ill patients with schizophrenia or schizoaffective disorder were given 30 mg/day aripiprazole therapy for 14 days. Co-administration with carbamazepine was then started at 200 mg once daily for 3 days and then increased to 400 mg daily for 1 week. Plasma concentrations for both aripiprazole and its metabolite were reported as follows:

Parameter	Aripiprazole		Dehydroaripiprazole	
	Monotherapy	With carbamazepine	Monotherapy	With carbamazepine
C_{max} (μg/L)	519	176	118	39
Time (h)	3	3	3.5	5

[Citrome *et al.* 2007].

A 30-year-old lactating woman was administered 10 mg aripiprazole daily, which was increased to 15 mg on day 4. Aripiprazole concentrations in plasma and milk on day 15 were 71 and 13 μg/L, respectively [Schlotterbeck *et al.* 2007].

Note For a study on the effects of several types of co-medication on the serum levels of aripiprazole, see Castberg and Spigset [2007].

Toxicity As aripiprazole is a substrate for CYP3A4 and CYP2D6, it has potential for drug interactions, for example with fluoxetine, paroxetine and carbamazepine. It has also been reported that poor metabolisers of CYP2D6 substrates undergo an ~80% increase in aripiprazole plasma concentrations and a 30% decrease in dehydroaripiprazole plasma concentrations [Bristol-Myers Squibb, Otsuka America Pharmaceuticals 2007].

A 2.5-year-old girl ingested 13 tablets of aripiprazole 15 mg (17 mg/kg). Ten hours post-ingestion, the serum concentration of aripiprazole was 1.42 mg/L and of dehydroaripiprazole 0.45 mg/L. At 57.25 h post-ingestion, the concentrations were 0.34 and 0.30 mg/L, respectively. The child was discharged 7 days later with no apparent sequelae [Seifert *et al.* 2005].

A 3-year-old boy ingested one half of a 15 mg tablet of aripiprazole. The serum aripiprazole concentration 87 h post-ingestion was 63 μg/L. The peak serum concentration was estimated at 136 μg/L [Schonberger *et al.* 2004].

A 27-year-old suicidal woman ingested 22 tablets of aripiprazole 15 mg, one tablet of cyclobenzaprine 10 mg, and one tablet of quetiapine 25 mg. Approximately 3.5 h post-ingestion, the serum concentrations of aripiprazole and dehydroaripiprazole were 0.60 and 0.12 mg/L, respectively [Carstairs, Williams 2005].

Bioavailability Approximately 87%.

Half-life Reported as between 47 to 68 h and also 75 to 146 h (depending on CYP2D6 phenotype).

Volume of Distribution Approximately 4.9 L/kg.

Clearance Oral, 3.3 to 4.0 L/h.

Protein Binding 88 to 99%, primarily to albumin.

Note For more information on the pharmacokinetic variability of aripiprazole, see Molden *et al.* [2006].

Dose For the treatment of schizophrenia, given by mouth in an initial dose of 10 or 15 mg once daily. The usual maintenance dose is 15 mg once daily although the dose may be adjusted at intervals of not less than 2 weeks up to a maximum of 30 mg daily. In the USA, aripiprazole is also used for the treatment of mania associated with bipolar disorder; it is given orally in an initial dose of 30 mg once daily, this may subsequently be decreased to 15 mg once daily according to tolerance.

Arsenic

Metal

As = 74.9

CAS—7440-38-2

Synonyms Arsenic black; colloidal arsenic; grey arsenic.

Chemical Properties Odourless grey solid. Mp 817° (at 28 atm). Bp 613°. Insoluble in water, soluble in nitric acid. Urine samples stored at room temperature had low (58 to 75%) recoveries of As^3, dimethylarsinic acid (DMA), and As^5. When stored at 4° or -20° the species were better recovered (87 to 100%) with the urine samples stored at -20° having a better recovery of As^3 (98.9%) compared with those stored at 4° (87%) [Morton, Mason 2006]. Valency: As (−3), As (0), As (+3) and As (+5). As(0) occurs as two allotropic forms, yellow and metallic grey. The metallic grey form is the stable form under ordinary conditions. It occurs most often as the sulfide in a variety of complex minerals containing copper, lead iron, nickel, cobalt, and other metals. It is widely distributed in the biosphere and is present in soil, water, and food. Non-toxic organic arsenic compounds are present in fish and shellfish. Human poisoning from contaminated well-water supplies is widespread in parts of India, Bangladesh and Vietnam.

Uses include the production of non-ferrous alloys, principally lead alloys used in lead–acid batteries. It may be added to alloys for bearing, type metal, lead ammunition, and automotive body solder. It can be added to brasses to improve corrosion resistance. High-purity arsenic is used in the manufacture of gallium arsenide and other intermetallic compounds used in semiconductors.

Arsenic Acid

AsH_3O_4 = 151

CAS—7778-39-4

Synonym Orthoarsenic acid

Proprietary Names *Desican L-10*; *Scorch*.

Chemical Properties White solid. Mp 35.5°, loses water at 160°. Soluble in water and alcohol. Used in herbicides, as a defoliant in cotton plants.

Arsenic Pentoxide

As_2O_5 = 229.8

CAS—1303-28-2

Synonyms Arsenic acid anhydride; arsenic (V) oxide; diarsenic pentoxide.

Chemical Properties White solid. Mp 315° with decomposition. Soluble in water, alcohol and acid. Used as a wood preservative.

Arsenic Trioxide

As_2O_3 = 197.8

CAS—1327-53-3

Synonyms Arsenic oxide; arsenious acid; arsenious oxide; white arsenic.

Proprietary Names *Arsenolite*; *Claudelite*; *Trisenox*.

Chemical Properties Odourless white solid. Mp 312.3°. Bp 465°. Soluble in water, hydrogen chloride, slightly soluble in alcohol. Used as a antineoplastic; wood preservative.

Calcium Arsenate

$Ca_3(AsO_4)_2$ = 398.1

CAS—7778-44-1

Synonyms Arsenic acid calcium salt; calcium orthoarsenate.

Proprietary Names *Pencal*; *Spra-cal*.

A

Chemical Properties Odourless, colourless solid. Slightly soluble in water, soluble in acids, insoluble in organic solvents. Formerly used in pesticides and herbicides.

Gallium Arsenide
GaAs = 144.6
CAS—1303-00-0
Synonym Gallium monoarsenide
Chemical Properties Dark grey solid. Mp 1238°. Used in semiconductor applications including solar cells; light-emitting diodes; lasers and integrated circuits.

Sodium Arsenate
Na_2HAsO_4 = 185.9
CAS—7778-43-0
Synonyms Disodium arsenate; disodium hydrogen arsenate.
Chemical Properties Odourless solid. Soluble in water and glycerol; slightly soluble in alcohol. Used in pesticides.

Sodium Arsenite
$NaAsO_2$ = 129.9
CAS—7784-46-5
Synonyms Arsenious acid, sodium salt; sodium metaarsenite.
Proprietary Names *Atlas A*; *Chem Sen*; *Kill-All*.
Chemical Properties Grey-white solid. Very soluble in water; slightly soluble in alcohol. Formerly used in herbicides and to debark trees.

Arsanilic Acid
$(C_6H_4NH_2)H_2AsO_3$ = 217.1
CAS—98-50-0
Synonyms 4-(Aminophenyl)arsenic acid; atoxylic acid.
Proprietary Names *Premix*; *Pro Gen*.
Chemical Properties Practically ordourless white solid. Mp 232°. Very soluble in hot water, soluble in alcohol, insoluble in ether, slightly soluble in acetic acid. Used in the manufacture of medicinal arsenicals; veterinary medicine: as a growth promoter, to improve feed efficiency, and to control swine dysentery.

Arsenobetaine
$(CH_3)_3As^+CH_2CO_2^-$ = 178.1
CAS—64436-13-1
Synonym Fish arsenic
Chemical Properties Solid. Mp 204 to 210°. Soluble in alcohol.

Dimethylarsinic Acid
$(CH_3)_2As(O)OH$ = 138.0
CAS—75-60-5
Synonyms Cacodylic acid; DMA; DMAA; hydroxydimethylarsine oxide.
Proprietary Names *Ansar*; *Arsan*; *Silvisar*; *Phytar*.
Chemical Properties Odourless. Colourless solid. Mp 195° to 196°. Very soluble in water, alcohol and acetic acid. pK_{a1} 1.3, pK_{a2} 6.2 [Sur, Dunemann 2004]. Used as a dermatologic agent; tonic (vet.).

Disodium Methanearsonate
$CH_3Na_2AsO_3$ = 183.9
CAS—144-21-8
Synonyms Disodium monomethane arsonate; DSMA.
Proprietary Names *Ansar 8100*; *Arrhenal*; *Arsinyl*; *Clout*; *Crab-E-Rad*; *Dal-E-Rad*; *Metar*; *Sodar*.
Chemical Properties Colourless solid. Mp >355°. Very soluble in water, slightly soluble in alcohol. Used as a herbicide.

Methanearsonic Acid
$CH_3H_2AsO_3$ = 134.0
CAS—124-58-3
Synonyms Arsonic acid, methyl-; MA; MMA; monomethylarsonic acid.
Chemical Properties White solid. Pleasant acid taste. Mp 161°. Soluble in water and alcohol. pK_{a1} 3.6, pK_{a2} 8.2 [Sur, Dunemann 2004]. Used as a herbicide.

Roxarsone
$C_6H_6AsNO_6$ = 263.1
CAS—121-19-7
Synonyms 4-Hydroxy-3-nitrophenylarsonic acid; NSC-2101; nitrophenolarsonic acid.
Proprietary Name *Ren-o-sal*
Chemical Properties Pale yellow solid. Puffs up and deflagrates on heating. Slightly soluble in cold water; soluble in approx. 30 parts boiling water; freely soluble in methanol, ethanol, acetic acid, acetone and alkalis; sparingly soluble in dilute mineral acids. Insoluble in ether, ethyl acetate. Used as an antibacterial.

Sodium Arsanilate
$C_6H_7AsNNaO_3$ = 239.1
CAS—127-85-5
Synonyms Arsanilic acid sodium salt; sodium aminarsonate; sodium anilarsonate.
Proprietary Names *(4-Aminophenyl)-arsonic acid sodium salt*; *Arsamin*; *Atoxyl*; *Nuarsol*; *Protoxyl*; *Soamin*; *Sonate*; *Piglet Pro-Gen V*; *Trypoxyl*.
Chemical Properties The tetrahydrate is a white odourless crystalline powder. Soluble in water and alcohol. Formerly used as an antisyphilitic.

Sodium Cacodylate
$C_2H_6AsNaO_2$ = 160.0
CAS—124-65-2
Synonyms [(Dimethylarsino)oxy]sodium As-oxide; sodium dimethylarsonate.
Proprietary Names *Arsecodile*; *Arsicodile*; *Arsycodile*; *Rad-e-cate*; *Silvisar*.
Chemical Properties The trihydrate is a granular solid with a slight odour. Liquifies at approx. 60° becoming anhydrous at 120°. Burns with a bluish flame, emitting an odour similar to garlic. Soluble in water and alcohol. Used as a herbicide; in treatment of chronic anaemia, eczema, and as a tonic (vet.).

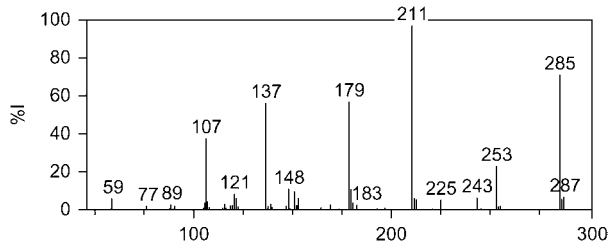
Sodium Methanearsonate
$CH_3NaHAsO_3$ = 162.0
CAS—2163-80-6
Synonyms Monosodium methanearsenate; MSMA.
Proprietary Names *Bueno*; *Daconate*; *Phybane*.
Chemical Properties Solid. Mp 115° to 119°. Used as a herbicide.

Colour Test Reinsch test (applicable to urine, gastric contents, scene residues)—arsenic imparts black stain to copper (antimony, bismuth, selenium and tellurium also give black deposits).

Clean a 5 × 10 mm square of copper foil (2–3 cm copper wire) with aqueous nitric acid (500 mL/L) until shiny. Rinse the copper with purified water, add 10 mL of concentrated hydrochloric acid and 20 mL of test sample in a 100 mL conical flask. Heat on a boiling water bath in a fume cupboard for 1 h. Cool and gently wash the copper with purified water. Confirmatory Test: place the stained copper in 100 g/L potassium cyanide solution and leave for 10 min. Arsenic stains dissolve in the cyanide solution (stains due to antimony or bismuth remain). Limit of detection, 5 mg/L.

Note For reference values for arsenic in the German population, see Wilhelm *et al.* [2004].

Mass Spectrum Principal ions at *m/z* 75; 211, 285, 179, 137, 107, 253 (thioglycolic acid methyl ester derivative of As^3).



Quantification Specimen collection: Blood—10 mL, K-EDTA tube; urine—20 mL plastic universal container.

Blood **AAS** Perkin-Elmer 3300. Arsenic hollow cathode lamp (λ = 193.7 nm). Limit of detection, 1.0–2.0 µg/L [Alauddin *et al.* 2003]. Limit of detection, 1.95 ng [Concha *et al.* 1998]. GBC hollow cathode lamp (λ = 193.7 nm). Carrier gas: N_2, 200 mL/min. Limit of detection, 0.02 µg/L [Tripathi *et al.* 1997]. Perkin-Elmer 5000 (λ = 193.7). Arsenic hollow cathode lamp. Limit of detection, 0.5 µg/L [Foà *et al.* 1984].

FAAS Flame: air-acetylene. Carrier gas: N_2, 90 mL/min. Hollow cathode lamp (λ = 193.7 nm). Limit of detection not reported [Le *et al.* 1992].

ETAAS Carrier gas: Ar. Dry cycle: 200° at 35 s for 30 s. Char cycle: 1600° at 20 s for 15 s. Atomisation cycle: 2500° for 4 s, gas stop. Limit of detection, 2 µg/L [Campillo *et al.* 2000].

HPLC-AAS Column: Phenomenex Bondclone (300 × 3.9 mm i.d., 10 µm). Arsenic hollow cathode lamp (λ = 193.7 nm). Limit of detection, 10 µg/L for arsenobetaine, DMA, and arsenite; 15 µg/L for MMA; and 20 µg/L for arsenate [Le *et al.* 1994].

HPLC-ICP-MS Column: Inertsil AS (150 × 2.1 mm i.d., 3.0 mm). Mobile phase: 10 mmol/L sodium butanesulfate : 4 mmol/L tetramethyl ammonium hydroxide : 4 mmol/L malonic acid : 0.05% methanol (pH 3.0), flow rate 0.2 mL/min. Limit of quantification, 0.1 µg/L for As^3, As^5 and the methylated metabolites [Fujisawa *et al.* 2007]. Column: Phenomenex Bondclone (300 × 3.9 mm i.d., 10 µm). Mobile phase: 50 mmol/L phosphate or carbonate buffer (pH 7.5, 9.0, or 10.3), flow rate 1.0 mL/min. Outer gas: 13.8 L/min. Auxiliary gas: 0.70 L/min. Nebuliser gas: 0.96 L/min. Meinhard nebuliser. Limit of detection not reported [Le *et al.* 1994].

ICP-MS Limit of detection, 0.97 µg/L [Liao *et al.* 2004]. Coolant gas: 16 L/min. Auxiliary gas: 1.4 L/min. Nebuliser gas: 0.7 L/min. Limit of quantification, 5 µg/L for DMA, arsenocholine, and As^5; 4 µg/L for arsenobetaine; 0.8 µg/L for As^3; and 0.6 µg/L for MMA. Limit of detection, 2 µg/L for DMA and As^5, 1 µg/L for arsenobetaine and arsenocholine, and 0.2 µg/L for As^3 and MMA [Milstein *et al.* 2003]. Plasma gas: 15 L/min. Auxiliary gas: 1.0 L/min. Method of detection, 30, 45, 27, and 61 ng/L for AsB, DMA, MMA, and As^5, respectively [Wei *et al.* 2000]. Plasma gas: Ar, 16 L/min. Auxiliary gas: 1.4 L/min. Carrier gas: 0.5 L/min. Limit of detection not reported [Tanaka *et al.* 1996].

Note For spectrophotometric methods for the detection of arsenic in blood, see Pillai *et al.* [2000] and Lakso *et al.* [1979].

Serum **ETAAS** See Blood [Campillo *et al.* 2000].

ICP-MS Column: Inertsil AS (150 × 2.1 mm i.d., 3 µm). Mobile phase: 10 mmol/L butane sulfonic sodium : 4 mmol/L malonic acid: 4 mmol/L tetramethylammonium hydroxide (pH 3.0), flow rate 0.2 mL/min. Plasma gas: Ar, 18 L/min. Limit of detection,not reported [Fukai *et al.* 2006].

Urine **LC-MS** Column: weak anion exchange. Mobile phase: methanol ammonium dihydrogen phosphate : ammonium acetate : glacial acetic acid. Limit of

detection, 0.5 µg/L for As^3 and As^5, 2.0 µg/L for MMA, 1.5 µg/L for DMA, and 1.0 µg/L for arsenobetaine [Apostoli *et al.* 1999].

AAS Perkin-Elmer MHS-20. Varian AA 1275. Limit of detection, 1 µg/L (approx. 1 ng) [Heilier *et al.* 2005]. Phillips AAS-PU-9100 ($\lambda = 193.7$ nm). Arsenic hollow cathode lamp. Limit of detection, 0.5 µg/L [Dang *et al.* 1999]. Limit of detection, 1.95 ng [Concha *et al.* 1998]. Carrier gas: Ar, 200 mL/min. Dry cycle: 50° to 80° for 10 s to 120° for 10 s. Char cycle: 120° to 400° for 20 s. Atomisation cycle: 2600° for 5 s, gas stop. Limit of detection not reported [Das *et al.* 1995]. See Blood [Foà *et al.* 1984].

HPLC-AFS Column: Hamilton PRP-X100 anion exchange (250 × 4.1 mm i.d., 10 µm). Mobile phase: 10 mmol/L ammonium dihydrogen phosphate (pH 5.8) : 60 mmol/L ammonium dihydrogen phosphate (pH 5.8, 100 : 0 for 2 min to 0 : 100 at 2 min for 4 min to 100 : 0 for 6 min), flow rate 1.0 mL/min. Retention time: 2.6, 3.6, 6.4 and 8.8 min for As^3, DMA, MA, and As^5, respectively. Arsenic-boosted discharge hollow cathode super lamp ($\lambda = 197.3$, 193.7 and 189.0 nm). Carrier gas: Ar, 0.25 L/min. Drying gas: N_2, 2.5 L/min. Limit of quantification, 10, 11, 6, and 6 µg/L for As^3, DMA, MMA, and As^5, respectively. Limit of detection, 3, 4, 2, and 2 µg/L for As^3, DMA, MMA, and As^5, respectively [Lindberg *et al.* 2007].

FAAS See Blood [Le *et al.* 1992].

ETAAS Dry cycle: 130° at 20 s for 10 s. Char cycle: 1400° in 5 s for 30 s. Atomisation cycle: 2500° for 5 s. Limit of detection, 0.03 µg/L [Horng *et al.* 2002]. See Blood [Campillo *et al.* 2000]. Limit of detection, 0.5 µg/L [Gebel *et al.* 1998].

ICP-MS See Serum [Fukai *et al.* 2006]. Limit of quantification, 0.18 µg/L; limit of detection, 0.05 µg/L [Brima *et al.* 2006], 9.98 µg/L [Liao *et al.* 2004]. Coolant gas: 16 L/min. Auxiliary gas: 1.4 L/min. Nebuliser gas: 0.7 L/min. Limit of quantification, 5 µg/L for DMA, arsenocholine and As^5; 4 µg/L for arsenobetaine; 0.8 µg/L for As^3; 0.6 µg/L for MMA. Limit of detection, 2 µg/L for DMA and As^5; 1 µg/L for arsenobetaine and arsenocholine; 0.2 µg/L for As^3 and MMA [Milstein *et al.* 2003]. Plasma gas: 15 L/min. Auxiliary gas: 1.0 L/min. Limit of detection, 30, 45, 27 and 61 ppt for AsB, DMA, MMA, and As^5, respectively [Wei *et al.* 2000]. See also Apostoli *et al.* [1999], Amarasiriwardena *et al.* [1998] and Alves *et al.* [1993].

GC-ICP-MS Limit of detection, 2–12 pg/L [Kresimon *et al.* 2001].

HPLC-ICP-MS Column: Inertsil AS (150 × 2.1 mm i.d., 3.0 mm). Mobile phase: 10 mmol/L sodium butanesulfate : 4 mmol/L tetramethyl ammonium hydroxide : 4 mmol/L malonic acid : 0.05% methanol (pH 3.0), flow rate 0.2 mL/min. Limit of quantification, 0.1 ppb for As^3, As^5, and the methylated metabolites [Fujisawa *et al.* 2007]. Column: Hamilton PRP-X100 (250 × 4.1 mm i.d., 10 µm). Mobile phase: 10 mmol/L ammonium carbonate in 2% methanol (pH 9.0) : 50 mmol/L ammonium carbonate in 2% methanol (pH 9.0; 100 : 0 for 0.5 min to 0 : 100 at 0.5 min for 12.5 min), flow rate 1.0 mL/min. Plasma gas: 15 L/min. Auxiliary gas: 1.1 L/min. Nebuliser gas: 1.0 L/min. Limit of detection, 0.003, 0.01, 0.004, 0.003 and 0.002 µg/L for arsenobetaine, As^3, DMA, MMA and As^5, respectively [Wang *et al.* 2007]. Column: Shodex RSpak NN-614 cation exchange (150 × 4.6 mm i.d.) Mobile phase: 5 mmol/L nitric acid : 6 mmol/L ammonium nitrate : 1.5 mmol/L 2, 6-pyridinedicarboxylic acid, flow rate 1.0 mL/min. Limit of detection, 0.1 µg/L [Hata *et al.* 2007]. Column: Hamilton PRPX100 spherical poly(styrene-divinyl-benzene) trimethylammonium exchanger (250 × 4.1 mm i.d.). Mobile phase: 10 mmol/L ammonium carbonate : 20 mmol/L ammonium carbonate (100 : 0 for 5 min to 0 : 100 at 6 min for 16 min to 100 : 0 at 23 min for 4 min), flow rate 1 mL/min. Nebuliser gas: 0.85 L/min. Limit of detection, 0.8 µg/L [Morton, Mason 2006]. Limit of detection, 0.3 µg/L for As^3, MMA, and DMA; 0.4 µg/L for As^5 [Christian *et al.* 2006]. See also Chowdhury *et al.* [2003]; Kavanagh *et al.* [1998]; Lai *et al.* [2004]; Le *et al.* [1994]; Mandal *et al.* [2003]; Meza *et al.* [2004]; Sur, Dunemann [2004]; Zheng *et al.* [1999].

Note For spectrophotometric methods for the detection of arsenic in urine, see Lakso *et al.* [1979] and Kneip *et al.* [1977].

Hair **AAS** See Urine [Das *et al.* 1995]. Perkin-Elmer 403 ($\lambda = 193.7$ nm). Carrier gas: Ar. Fuel: H_2. Oxidant: Air. Limit of detection, 0.02 µg [Curatola *et al.* 1978].

ETAAS Dry cycle: 80° to 120° in 10 s. Char cycle: 300° to 400° at 10 s. Atomisation cycle: 2700° to 2800° in 5 s. Carrier gas: 200 mL/min. Hitachi model 180-50, S.N.5721-2 ($\lambda = 193.8$ nm). Limit of detection not reported [Kazi *et al.* 2006]. See Urine. Limit of detection, 5 µg/kg [Gebel *et al.* 1998]. Dry cycle: 140° at 5 s for 15 s. Char cycle: 1300° in 15 s for 30 s. Atomisation cycle: 2700° for 5 s. Perkin-Elmer 5000 ($\lambda = 193.7$ nm). Limit of detection, 10 pg [Koons and Peters 1994].

ICP-MS Plasma gas: Ar, 13 L/min. Auxiliary gas: Ar, 0.9 L/min. Nebuliser gas: Ar, 0.95 L/min. Limit of quantification, 0.036 µg/kg [Kintz *et al.* 2007]. Limit of detection, 0.13 mg/kg [Nadal *et al.* 2005]. Plasma gas: 15 L/min. Auxiliary gas: 0.8 L/min. Nebuliser gas: 0.8 L/min. Limit of detection not reported [Samanta *et al.* 2004].

HPLC-ICP-MS Column: RP-C_{18} (100 × 4.6 mm i.d.). Mobile phase: 0.35 mmol/L tetrabutylammonium hydrogen sulfate (pH 5.75), flow rate 1 mL/min. Carrier gas: Ar, 0.75 L/min. Plasma gas: 16 L/min. Auxiliary gas: 1 L/min. Limit of detection not reported [Yáñez *et al.* 2005]. Column: Shodex Asahipak ES-502N 7C (100 × 7.6 mm i.d.). Mobile phase: 15 mmol/L citric acid monohydrate (pH 2.0), flow rate 1.0 mL/min. Plasma gas: 15 L/min. Auxiliary gas: 1.2 L/min. Limit of detection not reported [Mandal *et al.* 2003].

Liver **AAS** See Urine [Das *et al.* 1995].

Nail **AAS** See Urine [Das *et al.* 1995].

ICP-MS See Hair [Samanta *et al.* 2004]. Perkin-Elmer Sciex ELAN 5000. Plasma gas: Ar. Limit of detection, 0.07 µg/L [Chen *et al.* 1999].

HPLC-ICP-MS Column: Shodex Asahipak ES-502N 7C (100 × 7.6 mm i.d.). Mobile phase: 15 mmol/L citric acid monohydrate (pH 2.0), flow rate 1.0 mL/min. Plasma gas: 15 L/min. Auxiliary gas: 1.2 L/min. Limit of detection not reported [Mandal *et al.* 2003].

Milk **AAS** See Urine [Concha *et al.* 1998].

ICP-MS Plasma gas: 12 to 13 L/min. Auxiliary gas: 0.9 to 1.0 L/min. Sample gas: 1.0 to 1.2 L/min. Limit of detection, 0.2 µg/L [Krachler *et al.* 2000].

Other **GC-MS** Water. Column: HP-5MS (30 m × 0.25 mm i.d., 0.25 µm). Temperature programme: 75° for 0.5 min to 280° at 30°/min for 1 min. Carrier gas: He, 0.75 mL/min. EI ionisation at 70 eV. Limit of detection, 0.1 µg/L for DMA and MMA, 3 µg/L for total inorganic arsenic [Claussen 1997].

AAS Fresh and Freeze-dried Plant Ssamples. Carrier gas: Ar, 50 mL/min. Atomisation cycle: 770°. Hollow cathode lamp ($\lambda = 193.7$ nm). Limit of detection not reported [Krachler, Emons 2000]. Seafood Products. Perkin-Elmer 5000. Limit of detection, 0.7 µg/kg [Muñoz *et al.* 1999]. Water. See Urine [Das *et al.* 1995].

ETAAS Naphtha. Dry cycle: 50° for 10 s to 90° in 25 s to 120° in 10 s, Ar, 200 mL/min. Atomisation cycle: 2500° for 8 s (gas stop; $\lambda = 193.7$ nm). Limit of detection, 2.7 µg/L [Cassella *et al.* 2004].

ICP-MS Seafood. Perkin-Elmer Elan 6000. Limit of detection, 0.05 mg/kg [Falcó *et al.* 2006]. Infant Food Products. Coolant gas: Ar, 12 L/min. Auxiliary gas: Ar, 1.0 L/min. Nebuliser gas: 0.8 L/min. Limit of detection, 5 µg/kg for As^3, MMA and DMA; 10 µg/kg for As^5 [Vela, Heitkemper 2004]. Food. Varian-Vista with an ultrasonic nebuliser. Limit of detection, 0.06 mg/kg [Llobet *et al.* 2003]. Meals from a Catering Establishments. Plasma gas: 15 L/min. Auxiliary gas: 0.9 L/min. Nebuliser gas: 0.73 L/min. Limit of quantification, 16 µg/kg [Noel *et al.* 2003]. Vegetables. Limit of detection, 0.04 µg/L [Alam *et al.* 2003]. Well Water. Limit of detection, 3 µg/L [Rahman *et al.* 2001]. Beverages. Limit of detection, 0.3 µg/kg [MacIntosh *et al.* 2000]. Method 200.8 of the EPA. Limit of detection, 1 µg/L [McCarty *et al.* 2004].

HPLC-ICP-MS Rice. Column: CAPCELL PAK C_{18}MG (250 × 4.6 mm i.d.). Mobile phase: 10 mmol/L sodium 1-butanesulfonate : 4 mmol/L tetramethylammonium hydroxide : 4 mmol/L malonic acid : 0.05% methanol (pH 3.0), flow rate 0.75 mL/min. Plasma gas: 15 L/min. Carrier gas: 0.70 L/min. Auxiliary gas: 0.9 L/min. Makeup gas: 0.43 L/min. Limit of quantification, 7.9 µg/kg; limit of detection, 2.4 µg/kg [Hamano-Nagaoka *et al.* 2008]. Drinking Water. Column: Agilent (250 × 4.6 mm i.d., 5 µm). Mobile phase: 2.0 mmol/L sodium dihydrogen phosphate : 0.2 mmol/L EDTA (pH 6.0), flow rate 1.0 mL/min. Plasma gas: Ar, 15 L/min. Auxiliary gas: 1.0 L/min. Carrier gas: 1.0 L/min. Limit of detection, 67, 74, 35 and 89 ng/L for As^3, DMA, MMA and As^5, respectively [Day *et al.* 2002].

Note For colourimetric assays for arsenic, see George *et al.* [1973] and Crawford and Tavares [1974]. For a study of arsenic in soils, plants, water and sediments in Korea, see [Jung *et al.* [2002].

Disposition in the Body

Absorption **Inhalation exposure** Arsenic absorption via the lungs is a two-step process: deposition of the particles on to the lung surface, and absorption of arsenic from the deposited material. In patients with lung cancer exposed to arsenic in cigarette smoke, deposition was estimated to be approx. 40% and absorption 75 to 85%. Thus, overall absorption was approx. 30 to 34%. In workers exposed to arsenic trioxide dusts in smelters, the amount excreted in the urine was approx. 40 to 60% of the inhaled dose.

Oral exposure Arsenates and arsenites are well absorbed from the gastrointestinal tract. In one study where faecal excretion was measured in humans given oral doses of arsenite, less than 5% was recovered. This indicates absorption was at least 95%. This is supported in studies where urinary excretion in humans was found to account for 55 to 80% of daily oral intakes of arsenate or arsenite. However, gastrointestinal absorption may be lower if highly insoluble forms or arsenic are ingested.

Dermal exposure Studies investigating percutaneous absoption of ^{73}As as arsenic acid alone and mixed with soil has been measured in skin from cadavers. Labelled arsenic was applied to skin in diffusion cells and transit through the skin into receptor fluid measured. After 24 h, 0.93% of the dose passed through the skin and 0.98% remained in the skin after washing. Absorption was lower with ^{73}As mixed with soil.

Arsenates and arsenites are well absorbed following both oral and inhalation exposure. Data on distribution are limited but it appears arsenic is transported to nearly all tissues with the highest concentrations found in muscle. Metabolism involves mainly reduction-oxidation reactions that interconvert $As^{+5}$and As^{+3}; and methylation of As^{+3} to form MA and DMA. Most arsenic is rapidly excreted in urine as a mixture of inorganic arsenics, MA and DMA, although some may remain bound in tissues (especially skin, hair and fingernails). The capacity of the body to methylate inorganic arsenic is very important in terms of detoxification. Limited data suggest that the methylation system might begin to become saturated at intakes of approx. 0.2 to 1 mg per day. Urinary excretion is complete within 6 days and accounts for approx. 90% of the dose. Trivalent arsenic salts are excreted as DMA (50%), MA (14%), As(+5) (8%), and As(+3) (8%). Organo-arsenic compounds (e.g. arsenobetaine, arsenochlorine), which are present in various types of seafood, are excreted unchanged.

Normal Concentrations Blood—<10 µg/L (0.1 µmol/L); urine—<10 µg/L (0.1 µmol/L); hair—<1 µg/g (0.01 µmol/L).

Therapeutic Concentration

A group of 12 Japanese patients with relapsed or refractory acute promyelocytic leukaemia (APL) were treated with arsenic trioxide at a daily dose of 15 mg/kg. As^3 and As^5 reached mean peak plasma concentrations of

A

12.4 ± 8.4 and 10.2 ± 3.9 µg/L, respectively, attained at 1.9 ± 0.7 and 1.8 ± 0.9 h, respectively [Fujisawa *et al.* 2007].

A 72-year-old Japanese male with APL was treated with arsenic trioxide IV at a daily dose of 0.08 mg/kg. Concentrations of As^3, MMA and DMA in serum ranged from 18 to 41 µg/L during 24 h on day 4. The concentration of total arsenic in urine on day 4 was 4.46 mg [Fukai *et al.* 2006].

Toxicity Chronic arsenic poisoning is linked to lung and skin cancers, neurological disturbances, and cardiovascular abnormalities. Urine arsenic concentrations of 78 to 220 µg/L have been associated with chronic toxicity (equivalent to exposure to 50 µg/m^3) in workers [Apostoli *et al.* 1999]. Hair arsenic concentrations in chronically poisoned subjects range from 1 to 5 µg/g and can be as high as 47 µg/g [Hindmarsh *et al.* 1977], but there are difficulties in distinguishing between endogenous arsenic and external contamination [Hindmarsh 2002]. Trivalent salts of arsenic, such as sodium arsenate ($NaAsO_2$), cause serious toxicity and death after ingestion of as little as 200 mg. Lethal acute doses lead to convulsions, coma and death from respiratory failure. More moderate acute doses cause symptoms of gastro-enteritis with vomiting and bloody diarrhoea. Exposure to arsine gas (AsH_3) can result in massive haemolysis and renal failure.

A 22-month-old boy ingested an insecticide ant bait gel containing arsenic trioxide. His serum arsenic concentration was 1.7 mg/L 5 h post ingestion. Urinary concentrations at a number of times post ingestion were as follows:

Time post-ingestion (h)	*Urinary As (µg/L)*	*Cumulative As excreted (µg)*	*Urine volume (L)*
6.7	2085	876	0.42
12	583	2028	1.98
36	308	2762	2.38
60	229	3495	3.2
88	372	4027	1.43
110	201	4397	1.84
131	83	4499	1.23
162	46	ND	ND

ND, not determined [Stephanopoulos *et al.* 2002].

A 26-year-old man was admitted to hospital with multiple organ dysfunction. A screen for heavy metals on day 4 revealed a urine arsenic concentration of 867 µg/L. It was estimated that the patient's wife had administered a dose of 10 g As_2O_3 over the course of the 2 weeks prior to admission [Hantson *et al.* 2003].

A 41-year-old woman ingested 5 g of trivalent arsenic. Upon admission to hospital (approx. 4 h post-ingestion) the concentration of arsenic in her urine was 3.7 mg/L. The following day the urine arsenic concentration was 11.3 mg/24 h. The concentration of arsenic was measured in each 2 L of gastric effluent. Two days following intoxication, the arsenic concentration was 2.51 mg/L in the first 2 L collection of gastric effluent. Thereafter, there was an exponential decrease in the arsenic content [Michaux *et al.* 2000].

A 28-year-old man died following the ingestion of approx. 8 g of arsenic trioxide. Concentrations of total arsenic and arsenic species in his organs and blood were as follows:

Organ	*Total arsenic and arsenic species (mg/kg dry weight)*				
	As^3	*DMA*	*MMA*	*As^5*	*Total*
Brain	4.41	1.10	2.65	<LoQ	8.33
Cerebellum	5.15	1.60	3.76	<LoQ	11.0
Haemolysed blood	0.224	0.0539	0.135	0.009	0.422
Heart	9.05	0.64	1.61	<LoQ	11.8
Kidneys	20.0	1.60	4.52	0.53	26.6
Liver	122.0	5.91	14.7	2.94	147
Lung	9.46	0.45	1.11	<LoQ	11.1
Muscle	9.17	0.73	1.96	<LoQ	12.3
Pancreas	9.18	0.45	1.34	<LoQ	11.2
Skin	1.62	0.34	0.91	<LoQ	2.9
Spleen	9.50	0.598	1.65	<LoQ	11.7

[Benramdane *et al.* 1999].

A man who survived swallowing approx. 1 g of arsenic trioxide had arsenic concentrations of 0.415 µg/L (blood) and 51.4 mg/L (urine) 20 h after ingestion [Kamijo *et al.* 1998].

A 22-month-old girl ingested approx. 1 oz (27 g) of 2.27% sodium arsenate contained in an ant killer. Her 24 h urinary arsenic levels were as follows:

Day	*Concentration (µg/L)*
1	4880
3	1355
4	682
5	650
8	—
9	139
12	96

[Cullen *et al.* 1995]

A 35-year-old man experienced bouts of sudden extreme malaise after the introduction of a new detergent cleanser in the workplace. At first, his serum arsenic concentration was normal (10 ng/L), but 2 months later a 24 h urine collection revealed arsenic excretion of 11.3 mg/24 h, 450 times the normal level. A repeat urine sample showed arsenic excretion of 0.95 mg/24 h. His hair arsenic concentration was 0.9 g/kg, 1000 times the normal level, attesting to protracted exposure [Risk, Fuortes 1991].

A 29-year-old man injected unknown amounts of potassium cyanide and sodium arsenite IV. The initial urine sample was negative for arsenic but the 12 h collection started on admission contained 10 065 µg. On his third hospital day his blood concentration was 70 µg/L and the 24 h urine contained 19500 µg. [DiNapoli *et al.* 1989].

A 51-year-old man injected barbital IV and ingested arsenic orally. Antemortem blood and postmortem concentrations of arsenic were as follows:

Specimen	*Concentration (mg/L or mg/kg)*
Antemortem blood (serum)	0.3
Postmortem blood	1.3
Injection site	Trace
Urine	Present
Kidney	35
Liver	14
Spleen	11
Syringe	Absent

[Graham *et al.* 1983]

A person ingested an unknown quantity of wood-preserving solution containing large amounts of copper sulfate and sodium dichromate with a smaller but still substantial arsenic compound. Concentrations of arsenic in various tissues were reported as follows:

Tissue	*Concentration (µg/kg)*
Blood	2.0
Brain	2.7
Heart	7.7
Kidney	17.5
Liver	13.9
Lung	7.7
Spleen	7.4
Stomach	21.1

[Cross *et al.* 1979]

In 2 men who died after being exposed to arsine gas, arsenic concentrations were as follows:

Tissue	*Case 1*	*Case 2*
Bile (mg/kg)	139	104
Blood (mg/L)	58	11
Brain (mg/kg)	76	49
Kidney (mg/kg)	282	18
Liver (mg/kg)	401	136
Lungs (mg/kg)	35	—
Spleen (mg/kg)	342	66
Urine (mg/L)	12	35

[Pothel, Brosseau 1976]

Note For an investigation of toxic trace elements in the hair of children with autism, see Fido and Al Saad [2005]. For 5 cases of acute oral intoxication by trivalent arsenic, see Mahieu *et al.* [1981]. For concentrations in the urine of glass-manufacturing workers, see Apostoli *et al.* [1998].
Half-life In blood approximately 7 h.
Volume of Distribution 0.2 L/kg.
Distribution in Blood Blood : plasma ratio 1.

Arsenic Trioxide

Antineoplastic
As_2O_3 = 197.8
CAS—1327-53-3

IUPAC Name Arsenic (3+); oxygen(2−)
Synonyms Arsenic oxide; arsenic (III) oxide; arsenious acid; arsenious acid anhydride; arsenious oxide; arsenite; arsenous acid; arsenous acid anhydride; arsenous oxide; arsenic sesquioxide; white arsenic.
Proprietary Name *Trisenox*
Chemical Properties White or transparent, glassy, amorphous lumps or crystalline powder. Two crystalline modifications: claudetite, mp 313°, and arsenolite, mp 275°. Bp 465°. It is intensely poisonous. It is sparingly and extremely slowly soluble in cold water; soluble in boiling water, dilute hydrochloric acid, alkali hydroxide and carbonate solutions; practically insoluble in alcohol, chloroform and ether.
Quantification
Blood **LC-ICP-MS** Column: PRP X100 (100 × 4.1 mm i.d.). Mobile phase: 20 mmol/L ammonium dihydrogen phosphate (pH 5.0) in methanol, flow rate 1.5 mL/min. Limit of detection, ng/g range [Slejkovec *et al.* 2008].
Plasma **GC** Column: 3% OV-17 (2 m). Carrier gas: N_2, 45 mL/min. Limit of detection, 0.15 nmol [Ni *et al.* 1998].
Urine **GC** See Plasma [Ni *et al.* 1998].
AAS λ= 193.7 nm. Limit of detection, 1 μg/L [Heinrich-Ramm *et al.* 2003].

Disposition in the Body The extent of arsenic trioxide absorption depends on the physical form of the compound; for example, a coarse powder may be eliminated in faeces before significant dissolution and absorption can occur. Arsenic trioxide is partly methylated (detoxification) to monomethylarsonic acid (MMA) and dimethylarsinic acid (DMA) in the liver. Both of these metabolites are relatively non-toxic and are excreted mostly in urine along with other inorganic arsenic compounds. During treatment with arsenic trioxide, the arsenic content of urine over a 24 h period accounted for 1–8% of the administered daily dose. Smaller amounts of arsenic are also excreted in faeces and sweat and via the lungs and skin. It has also been detected in breast milk and is known to cross the placenta. After ingestion of large doses, arsenic is widely distributed throughout the body to all organs, with the highest concentrations in liver and kidneys, with 10-fold and 3-fold higher concentrations, respectively.
Therapeutic Concentration
Arsenic trioxide was administered at a dose of 10 mg daily to 4 male patients with acute promyelocytic leukaemia. The relative proportions of arsenic (III), arsenic (V), MMA and DMA in 24 h urine samples were 27.6, 2.8, 22.8, and 43.7%, respectively [Wang *et al.* 2004].
Arsenic trioxide was administered at a dose of 10 mg daily to 8 patients with relapsed acute promyelocytic leukaemia. The peak plasma concentration reached 0.94 mg/L at 4 h after dosing. [Ni *et al.* 1998]
Toxicity The major toxic effect in severe arsenic poisoning is haemorrhagic gastroenteritis, which may lead to severe dehydration, collapse, shock and even death. Cardiac arrhythmias and convulsions have also been reported. A dose of 70–300 mg arsenic trioxide has been associated with fatalities depending on the physical form of the compound and the extent of its absorption. In the absence of adequate treatment, death may occur within 1 h but can be prolonged to 12–48 h.
A 21-year-old man ingested approximately 0.6 g arsenic trioxide. After 11 h, his arsenic trioxide concentration was 95096 μg/L [Heinrich-Ramm *et al.* 2003].
A 28-year-old man committed suicide by ingesting ~8 g of arsenic trioxide; he died 3 days after ingestion. Major intoxication symptoms observed were hepatic and renal failure and cardiovascular and neurological effects. After toxicological analysis of his organs, the highest arsenic concentrations were found in the liver (147 μg/g) and kidneys (26.6 μg/g). Other organs contained lower but very similar concentrations: muscle, 12.3 μg/g; heart, 11.75 μg/g; spleen, 11.72 μg/g; pancreas, 11.2 μg/g; lungs, 11.13 μg/g; cerebellum, 10.95 μg/g; and brain, 8.33 μg/g. Skin had the lowest concentration, at 2.9 μg/g. These concentrations were made up of arsenic (III) and the 2 metabolites MMA and DMA [Benramdane *et al.* 1999].
Half-life Plasma half-life, 12 h.
Clearance Systemic, 1.43 L/h.

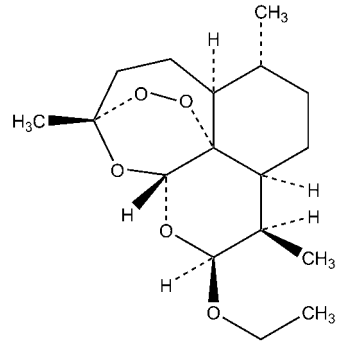
Arteether

Antimalarial
$C_{17}H_{28}O_5$ = 312.4
CAS—75887-54-6

Synonyms α/β-Arteether; artemotil; dihydroartemisinin ethyl ether; (3*R*,5a*S*,6*R*,8a*S*,9*R*,10*S*,12*R*,12a*R*)-10-ethoxydecahydro-3,6,9-trimethyl-3,12-epoxy-12*H*-pyrano[4,3-j]-1,2-benzodioxepin; SM-227.
Proprietary Names *Rapither AB*; *EMAL*.



Chemical Properties White crystalline solid. Mp 80° to 82°. Log *P* (octanol/water), 3.89 [Ramu, Baker 1995]. Biosamples were stable at –50° for over 60 days. Analytes were stable after 3 freeze–thaw cycles [Sabarinath *et al.* 2003, 2005, 2006]. Analytes were stable after reconstitution for at least 24 h at 4° [Rajanikanth *et al.* 2003]. Storage in plasma in plastic containers results in a considerable loss of drug, even over a 24 h period [Idowu *et al.* 1989].
Thin-layer Chromatography Plate: Reversed phase C_{18}. Solvent system: acetonitrile : water (50 : 25). Derivatised with 4-methoxybenzaldehyde in methanol : water. Limit of quantification, 0.5 μg [Gabriels, Plaizier-Vercammen 2004]. Plate: Silica gel. Solvent system: chloroform. Visualisation in 4-methoxybenzaldehyde reagent of 1% acidic solution of sulfuric acid (98%) and acetic acid (96 to 98%, 2% and 10% in alcohol : water 60 : 30). Limit of quantification, 0.5 μg [Gabriels, Plaizier-Vercammen 2003].
Mass Spectrum Principal ions at *m/z* 267, 284, 330, 221, 253 and 239.
Quantification
Blood **LC-MS** Column: Spheri-5 C_{18} reversed phase (100 × 4.6 mm i.d.). Mobile phase: methyl alcohol : 10 mmol/L ammonium acetate buffer (pH 4.0, 93 : 7), flow rate 0.65 mL/min. ESI, positive ion mode, MRM acquisition mode. Limit of quantification, 0.5 μg/L [Sabarinath *et al.* 2005].
Plasma **LC-MS** See Blood. Limit of quantification, 0.39 μg/L [Sabarinath *et al.* 2005].
Urine **LC-MS** See Plasma [Sabarinath *et al.* 2005].
Other **HPLC** Tablets. Column: Macherey-Nagel Nucleosil 120-4 C_{18} (125 × 4 mm i.d., 5 μm). Mobile phase: acetonitrile : water : 0.05 mol/L potassium hydrogen phosphate (pH 5; 500 : 100 : 320), flow rate 1.0 mL/min. UV detection (λ = 215 nm). Limit of detection not reported [Atemnkeng *et al.* 2007]. Rat Plasma. Column: Beckman Ultrasphere-ODS C_{18} reversed phase (150 × 4.6 mm i.d., 5 μm). Mobile phase: acetonitrile : water (60 : 40), flow rate 0.75 mL/min. UV detection (λ = 253 nm). Limit of detection not reported [Idowu *et al.* 1989].
LC-MS Rat Plasma. Column: Ultracarb Phenomenex C_{18} (30 × 4.6 mm i.d., 5 μm). Mobile phase: methanol : 10 mmol/L ammonium acetate (pH 4; 90 : 10), flow rate 0.4 mL/min. ESI, positive ion mode, MRM acquisition mode. Limit of quantification, 0.78 μg/L [Sabarinath *et al.* 2006]. Monkey Plasma. Column: Spheri-10 RP_{18} (100 × 4.6 mm i.d., 5 μm). Mobile phase: methanol : ammonium acetate buffer (pH 4, 92 : 8), flow rate 0.65 mL/min. ESI, positive ion mode, MRM acquisition mode. Limit of quantification, 0.78 μg/L; limit of detection, 0.39 μg/L [Sabarinath *et al.* 2003]. Rat Plasma. Column: Spheri-10 RP_{18} (100 × 4.6 mm i.d.,

5 μm). Mobile phase: methanol : potassium phosphate buffer (pH 4; 73 : 27 to 100 : 0 at 3 min for 5 min), flow rate 1.0 mL/min. ESI, positive ion mode. Limit of quantification, 4.38 and 10 μg/L for the α- and β-isomers, respectively; limit of detection, 2.5 μg/L [Rajanikanth *et al.* 2003]. Rat Plasma. Column: Whatman Partisil P/5 ODS 3 C_{18} reversed phase (235 × 4.7 mm i.d., 5 μm). Mobile phase: methanol : water (60;40 for 5 min to 82 : 18 over 10 min, maintaining 0.1 mol/L ammonium acetate throughout), flow rate 1.0 mL/min. Positive ion mode, SIM acquisition mode. Limit of detection, 2 μg/L [Chi *et al.* 1991].

Disposition in the Body Arteether is converted to artenimol, primarily by CYP3A4 with a secondary contribution by CYP2B6, which is extensively eliminated via biliary excretion.

Therapeutic Concentration

Thirteen healthy male volunteers (aged 25 to 50 years) were administered a single IM injection of 150 mg arteether containing both α- and β-isomers in the ratio 30 : 70. Maximum plasma concentrations of 60.7 and 49.8 μg/L were reached at 4.77 ± 1.21 h and 6.96 ± 1.62 h for the α- and β-isomers, respectively [Sabarinath *et al.* 2005].

Fifty-six Thai patients with *Plasmodium falciparum* malaria were administered β-arteether according to one of the following regimens. A dose of 3.2 mg/kg on day 0 followed by 1.6 mg/kg on days 1 to 4 or a dose of 4.8 mg/kg followed by 1.6 mg/kg 6 h later and 1.6 mg/kg on days 1 to 4. Mean peak plasma concentrations of 63.7 μg/L at 6.1 h and 140.8 μg/L at 5.7 h were reached in the low- and high-dose groups, respectively [Li *et al.* 2004].

Toxicity In rats, dogs and primates, IM injections of arteether have produced selective damage to brain stem centres involved in auditory processing and vestibular reflexes [Nontprasert *et al.* 1998].

Bioavailability 34% following IM injection [Navaratnam *et al.* 2000].

Half-life 13.2 ± 1.08 and 30.2 ± 2.44 h for the α- and β-isomers, respectively.

Volume of Distribution 12 ± 1.37 and 36.2 ± 4.78 for the α- and β-isomers, respectively.

Clearance 1.41 ± 0.49 and 1.36 ± 0.23 mL/h for the α- and β-isomers, respectively.

Distribution in Blood Partition ratios between whole blood and plasma: 1.8 and 1.91 for α- and β-arteether, respectively.

Protein Binding 78.7 ± 2.1%, binding to α_1-acid glycoprotein is 20-fold greater than to albumin [Wanwimolruk *et al.* 1992].

Artemether

Antimalarial

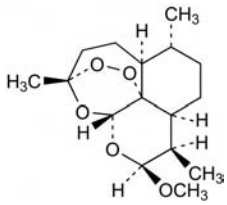
$C_{16}H_{26}O_5$ = 298.4

CAS—71963-77-4

IUPAC Name (3*R*,5a*S*,6*R*,8a*S*,9*R*,10*S*,12*R*,12a*R*)-Decahydro-10-methoxy-3,6,9-trimethyl-3,12-epoxy-12*H*-pyrano[4,3-j]-1,2-benzodioxepin

Synonyms Dihydroartemisinin methyl ether; dihydroqinghaosu methyl ether; *o*-methyl-dihydroartemisinin; SM-224.

Proprietary Names *Artemos*; *Qing Hao*.



Chemical Properties White crystalline powder. Mp 86° to 88°.

Quantification

Plasma **GC–MS** Limit of quantification, 5 μg/L [Mohamed *et al.* 1999].

HPLC Electrochemical detection. Limit of quantification, 26 μg/L for artemether and metabolite, dihydroartemisinin (DHA) [Teja-Isavadharm *et al.* 1996].

Note For a bioassay, limit of quantification 60 μg/L for DHA, see Teja-Isavadharm *et al.* [1996].

Disposition in the Body Artemether is rapidly but incompletely absorbed after oral administration and is metabolised in the liver to the demethylated derivative DHA. It is rapidly eliminated. Oral bioavailability, after IM injection, is ~43%.

Therapeutic Concentration

Six healthy Malaysian males were administered with a single oral dose of 200 mg artemether. Peak plasma concentrations of 310 ± 153 μg/L were reached within 1.88 ± 0.21 h. The peak concentration of the metabolite, DHA, was 273 ± 64 μg/L which was reached within 1.92 ± 0.13 h [Mordi *et al.* 1997].

Six patients with severe falciparum malaria and acute renal failure and 11 patients without renal failure were intramuscularly administered with a total dose of 640 mg (over 7 days) artemether. Patients with renal failure had a slightly higher peak plasma concentration compared with those without failure (1.89 to 3.95 μg/L/mg dose versus 1.05 to 3.38 μg/L/mg dose) [Karbwang *et al.* 1998].

Toxicity Neurotoxicity.

Half-life Elimination half-life for artemether is 1.5 to 3.5 h and for DHA is 1.4 to 2.4 h.

Volume of Distribution Apparent volume of distribution is 3.2 to 6.9 L/kg for patients with acute renal failure and 4.2 to 12.3 L/kg for those without.

Clearance Plasma clearance is 5.4 to 13.8 mL/min/kg for patients with acute renal failure and 8.5 to 25.1 mL/min/kg for those without.

Protein Binding About 50%.

Dose An IM dose of 3.2 mg/kg is administered initially followed by 1.6 mg/kg daily for a maximum of 7 days, then changed to oral administration. Capsule formulation: 160 mg on the first day followed by 80 mg daily for the next 4 days.

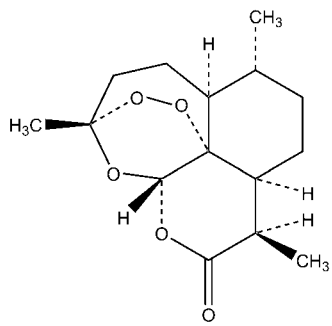
Artemisinin

Antimalarial

$C_{15}H_{22}O_5$ = 282.3

CAS—63968-64-9

Synonyms Arteannuin; artemisine; huanghuahaosu; (3*R*,5a*S*,6*R*,8a*S*,9*R*,12*S*,12a*R*)-octahydro-3,6,9-trimethyl-3,12-epoxy-12*H*-pyrano-[4,3-j]-1,2-benzodioxepin-10(3*H*)-one; QHS; qinghaosu; qing hau sau.



Chemical Properties Isolated from the traditional Chinese medicinal herb *Artemisia annua* L., Compositae. Needles. Mp 156° to 157°. Soluble in methanol,

A

100% ethanol, dimethyl formamide, DMSO, chloroform and acetone. Almost insoluble in water. Log *P* (octanol/water), 2.9 [Avery *et al.* 1995]. Stability established after storage in plasma at room temperature for 4 h. Processed samples were stable for up to 24 h in the autosampler, at –20° for at least 4 weeks and over at least 3 freeze–thaw cycles [Xing *et al.* 2006].

Dihydroartemisinin

$C_{15}H_{24}O_5$ = 284.3
CAS—71939-50-9
Synonym Dihydroqinghaosu

Thin-layer Chromatography Plate: Reversed phase C_{18}. Solvent system: acetonitrile : water (50 : 25). Derivatised with 4-methoxybenzaldehyde in methanol : water. Limit of quantification, 0.5 µg [Gabriels, Plaizier-Vercammen 2004].

Quantification

Blood **SCFC** Column: Deltabond cyano (200 × 1 mm i.d., 5 µm). ECD. Limit of detection, 20 µg/L [Mount *et al.* 1995].

Plasma **HPLC** Column: ADS-C_{18} reversed phase (100 × 4.6 mm i.d., 3 µm). Mobile phase: acetonitrile : water (2 : 98), flow rate 1.2 to 3.0 mL/min. UV detection (λ = 289 nm). Limit of quantification, 10 µg/L [Gordi *et al.* 2000]. Column: Versapak cyanopropyl (300 × 4.6 mm, 10 µm). Mobile phase: 100 mmol/L acetate buffer : acetonitrile (pH 5.0; 60 : 40), flow rate 1.5 mL/min. Electrochemical detection. Limit of quantification, 5 µg/L [van Agtmael *et al.* 1998].

Serum **HPLC** Column: Supelco discovery HS C_{18} (250 × 4.6 mm i.d.). Mobile phase: 20 mmol/L imidazole–nitric acid buffer (pH 8.5) : acetonitrile (30 : 70), flow rate 0.5 mL/min. Chemiluminescence detection. Limit of detection, 17.5 µg/L [Amponsaa-Karikari *et al.* 2006]. Column: Ultrasphere ODS bonded silica (150 × 2.0 mm i.d., 5 µm). Mobile phase: acetonitrile : water (50 : 50), flow rate 0.3 mL/min. Chemiluminescence detection. Limit of quantification, 25 µg/L [Green *et al.* 1995].

Oral Fluid **HPLC** See Plasma. Limit of quantification, 2 µg/L [Gordi *et al.* 2000].

Other **LC-MS** Rat Urine. Column: Luna ODS C_{18} (150 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : 10 mmol/L ammonium acetate containing 0.1% formic acid (85 : 15), flow rate 0.8 mL/min. ESI, positive ion mode, MRM acquisition mode. Limit of quantification, 1.0 µg/L [Xing *et al.* 2006].

Disposition in the Body The metabolism of artemisinin is primarily mediated by CYP2B6, with a secondary contribution of CYP3A4. Urinary metabolites include deoxyarteminisin, deoxydihydroarteminisin, and 9,10-dihydrodeoxyarteminisin. The amount of unchanged drug excreted in human urine or faeces is negligible.

Therapeutic Concentration

Eight male volunteers given 10 mg/kg of artemisinin orally as an aqueous suspension had a mean peak plasma concentration of 0.58 mg/L at 2.5 h after dosing [Chan *et al.* 1997].

After administration of 400 mg artemisinin as an aqueous oral suspension to healthy subjects, a mean peak plasma concentration of 0.26 mg/L was attained after 1 h. The elimination half-life of 1.9 h was prolonged to 7.4 h by IM administration of the same dose [Titulaer *et al.* 1990].

Fourteen healthy male volunteers received 1 L of tea prepared from 9 g of *A. annua* L. leaves. This corresponded to a dose of 94.5 mg artemisinin. The mean peak plasma concentration was 0.24 mg/L after 0.6 h [Rath *et al.* 2004].

Bioavailability Between 19 and 35%.

Half-life Between 0.7 and 2.4 h for oral administration.

Volume of Distribution 16 L/kg.

Protein Binding Approximately 64%.

Note For a study investigating protein binding of dihydroartemisinin *in vivo*, see Batty *et al.* [2004] and for pharmacokinetic values, see Teja-Isavadharm *et al.* [2001].

Dose For the treatment of malaria in areas of multidrug resistance, artemisinin may be given orally as a 3-day course: 25 mg/kg bodyweight on the first day with 12.5 mg/kg on the second and third days.

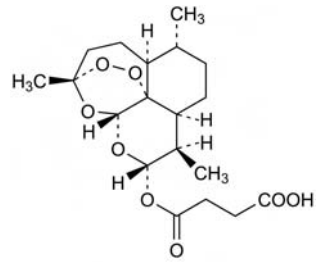
Artesunate

Antimalarial
$C_{19}H_{28}O_8$ = 384.4
CAS—88495-63-0

IUPAC Name Butanedioic acid mono[(3*R*,5a*S*,6*R*,8a*S*,9*R*,10*R*,12*R*,12a*R*)-decahydro-3,6,9-trimethyl-3,12-epoxy-12*H*-pyrano[4,3-*j*]-1,2-benzodioxepin-10-yl] ester

Synonyms Artesunic acid; dihydroartemisinin hemisuccinate; dihydroqinghaosu hemisuccinate.



Chemical Properties A fine white crystalline powder.

Artesunate Sodium

$C_{19}H_{27}NaO_8$ = 406.4
Synonyms Dihydroartemisinin hemisuccinate sodium; dihydroqinghaosu hemisuccinate sodium; SM-804.
Proprietary Name *Arsumex*
Chemical Properties Poor stability in aqueous solutions.

Mass Spectrum Principal ions at *m/z* (cyclohexane pyrolysis product of DQHS) 43, 55, 69, 81, 152, 210, 95, 180.

Quantification

Blood **GC–MS** Column: 3% OV-3 on 100-120 Supelcocort (silanised glass, 2 m × 2 mm i.d.). Temperature programme: 160° to 24° at 10°/min. Carrier gas: methane, flow rate 20 mL/min. MS detection (EI, SIM at *m/z* 221). Internal standard: cedrol. Retention time: dihydroqinghaosu (DQHS) (cyclohexane pyrolysis product) 5.5 min. Limit of detection, 2 µg/L for DQHS [Theoharides *et al.* 1988].

Plasma **HPLC** Column: C_{18} Nova-Pak (150 × 3.9 mm i.d., 5 µm), column and detector oven set at 20°. Mobile phase (kept at 35°): acetonitrile : 0.1 mol/L dilute acetic acid (pH 4.80) (45:55). Flow rate 1.5 mL/min. Electrochemical detection. Retention time: α-dihydroartemisinin (DHA), 2.9 min; β-DHA, 4.2 min; artesunate, 4.5 min. Limit of quantification, 5 µg/L for artesunate, 3 µg/L for DHA [Na-Bangchang *et al.* 1998]. Column: C_8 Econosil (250 × 4.6 mm, 10 µm). Mobile phase: acetonitrile : 0.05 mol/L acetic acid (42:58), (pH 5.0), flow rate 1.5 mL/min . Electrochemical detection. Retention time: artesunate, 6.6 min; DHA, 8.7 min. Limit of detection, 4.0 µg/L for artesunate and the metabolite, DHA [Navaratnam *et al.* 1997].

Disposition in the Body Artesunate is rapidly metabolised to its active metabolite dihydroartemisinin (DHA) (dihydroqinghaosu, DQHS). After oral administration, bioavailability of DHA is 82%.

Therapeutic Concentration

Twenty six Vietnamese patients with falciparum malaria were administered with either a 120 mg IV dose or 100 mg oral dose of artesunate. With the IV dose, peak plasma concentrations of 11 mg/L artesunate and 2.64 mg/L DHA were reached. With the oral dose of artesunate, peak concentrations of 0.74 mg/L DHA were observed [Batty *et al.* 1998].

Eleven Thai patients, aged between 15 and 37 years, with acute uncomplicated falciparum malaria were administered with an initial, oral dose of 200 mg, followed by 100 mg daily (total of 700 mg). After the initial dose, peak plasma concentrations of artesunate at 0.5 to 1.9 µg/L were reached within 0.5 to 1 h and 1.2 to 4.1 µg/L for the metabolite, DHA (1.5 to 2.5 h). After the first 100 mg dose, peak concentrations reached 0.62 to 2.9 µg/L and 1.3 to 4.2 µg/L, respectively, within 2 h [Karbwang *et al.* 1998].

Bioavailability Bioavailability of DHA is 82%.

Half-life Elimination half-life of artesunate is 2.7 min and 40 min for DHA (IV administration) and 21.6 and 38.4 min, respectively, for oral administration.

Volume of Distribution Artesunate, 0.14 L/kg; DHA, 0.76 L/kg (IV administration). Oral administration, 6.8 L/kg for artesunate and DHA.

Clearance Clearance of artesunate is 2.33 L/h/kg and of DHA is 0.75 L/kg/h (intravenous administration). Oral administration, 0.005 and 0.003 L/kg/h for artesunate and DHA, respectively.

Distribution in Blood Blood cells : plasma concentration ratio 5:5.
Note Refer to Karbwang *et al.* [1998] and Batty *et al.* [1998] for a review of the pharmacokinetics.
Dose A dose of 10 mg/kg body weight daily (intravenously) is administered for a minimum of 5 days (3 days if in combination). Lowest dose of 2 mg/kg body weight daily. Total oral dose of 600 mg over 5 days.

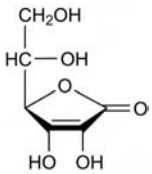
Ascorbic Acid

Vitamin
$C_6H_8O_6 = 176.1$
CAS—50-81-7

IUPAC Name (2R)-2-[(1S)-1,2-Dihydroxyethyl]-4,5-dihydroxyfuran-3-one
Synonyms L-Ascorbic acid; cevitamic acid; 3-oxo-L-gulofuranolactone (enolic form); vitamin C.
Proprietary Names *Alba CE*; *Ascorbicap*; *Ascorbicin*; *Ascorvit*; *Buffered C*; *Cantan*; *Cebid*; *Cebion*; *Cecon*; *Celaskon*; *Celin*; *Cenolate*; *Cetebe*; *Cevi-Bid*; *Cevilan*; *Ce-Vi-Sol*; *Cevitan*; *Cewin*; *Dull-C*; *Favorcee*; *Haliborange Halibonbons*; *Hybrin*; *N'ice Vitamin C*; *RedoxonVitacin*; *Vitascorbol*.

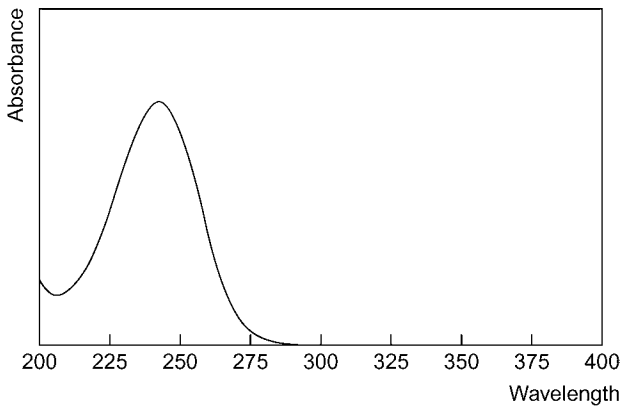


Chemical Properties Ascorbic acid and ascorbates are ingredients of many proprietary preparations. Colourless crystals or white or very pale yellow crystalline powder. Solutions, especially when made alkaline, deteriorate rapidly in air. Mp 190° to 192°, with some decomposition. Soluble 1 in about 3 of water, 1 in 30 of ethanol, 1 in 10 of methanol and 1 in 20 of propylene glycol; soluble in acetone; insoluble in benzene, chloroform, ether, petroleum ether, oils, fats and fat solvents. pK_a 4.2, 11.6 (25°). Log *P* (octanol/water), −1.8.

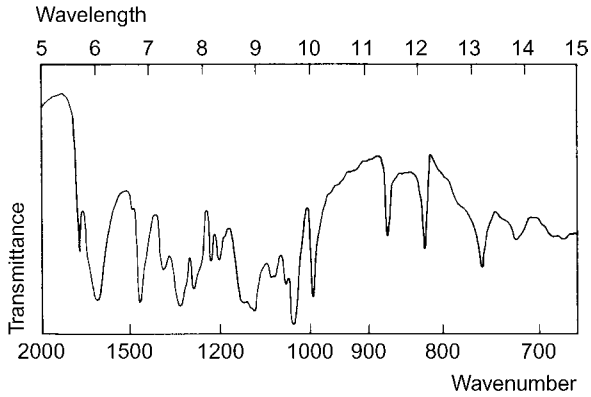
Sodium Ascorbate

$C_6H_7NaO_6 = 198.1$
CAS—134-03-2
Chemical Properties White or very faintly yellow crystals or crystalline powder. It gradually darkens on exposure to light. Mp 218° with decomposition. Soluble 1 in 1.3 of water; very slightly soluble in ethanol; practically insoluble in chloroform and ether.

Colour Tests Ammoniacal silver nitrate—black; Benedict's reagent—red; Nessler's reagent—black; palladium chloride—black.
Gas Chromatography System GA—RI 2120, ascorbic acid-AC RI 2065, ascorbic acid (methylated) RI 1700.
High Performance Liquid Chromatography System HY—RI 52; system HZ—retention time 1.5 min (ascorbate).
Ultraviolet Spectrum Aqueous acid—243 nm (A_1^1=556a).



Infrared Spectrum Principal peaks at wavenumbers 1026, 1111, 1312, 1136, 1653, 990 cm^{-1} (Nujol mull).



Mass Spectrum Principal ions at *m/z* 29, 41, 39, 42, 69, 116, 167, 168.
Quantification
Plasma **GC–MS** For ascorbic and dehydroascorbic acids, see Deutsch and Kolhouse [1993].

HPLC Fluorescence detection. For ascorbic and dehydroascorbic acids, see Kall and Andersen [1999]. UV detection. See Rumelin *et al.* [1999]. UV detection. Postmortem Tissues **HPLC** UV detection. See Allender [1982].
Note For review of analysis methods in biological samples, pharmaceuticals and food, see Pachla *et al.* [1985].
Disposition in the Body Readily absorbed after oral administration; the proportion of a dose absorbed tends to decrease with increasing dose; it is widely distributed in the body tissues. The concentration of ascorbic acid is higher in leucocytes and platelets than in erythrocytes and plasma. Ascorbic acid is metabolised to dehydroascorbic acid, 2,3-diketogulonic acid, oxalate and carbon dioxide; some conjugation with sulfate occurs to form ascorbate-3-sulfate. Ascorbic acid in excess of the body's requirements is rapidly eliminated in the urine. About 85% of an IV dose, given to subjects previously saturated with the vitamin, is excreted in the urine in 24 h, with about 70% of the dose excreted unchanged and 15% as dehydroascorbic acid and diketogulonic acid. The amount normally present in the body is in excess of 1.5 g.
Blood Concentration Concentrations in plasma and in leucocytes are normally about 5 to 12 mg/L and 25 to 30 µg/10^8 cells respectively; these concentrations exhibit circadian and seasonal rhythms.
Protein Binding About 25%.
Dose 0.2 to 3 g daily.

Asparaginase

Antineoplastic
CAS—9015-68-3

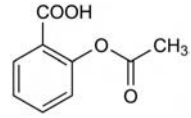
Synonyms L-Asnase; L-asparaginase; L-asparagine amidohydrolase; colaspase; E. C.3.5.1.1; Mk-965; NSC-109229.
Proprietary Names *Crasnitin*; *Crasnitine*; *Elspar*; *Erwinase (Crisantaspase-recombinant)*; *Kidrolase*; *Laspar*; *Leucogen*; *Leunase*; *Oncaspar (Pegaspargase-recombinant)*; *Paronal*.
Chemical Properties Commonly obtained from *E. coli* and *Erwinia* sp. Asparaginase from *E.coli* has a molecular weight of about 136000. A white crystalline powder. It is freely soluble in water where it appears to be global in shape; practically insoluble in methanol, in acetone and in chloroform.
Quantification
***Serum* TLC** Reaction with ^{14}C-asparagine and detection with scintillation counter. Limit of detection, 0.05 U/mL [Clausen, Christensen 1986].
Disposition in the Body It is sequestered slowly by the reticulo-endothelial system. It is found in the lymph at about 20% of the concentration in plasma. There is virtually no diffusion into the CSF. Little is excreted in the urine. Preparations derived from *E. coli* and *Erwinia* differ in their pharmacokinetic and pharmacodynamic properties.
Toxicity Allergic reactions are frequent and can lead to death.
Half-life Plasma, 8 to 30 h (IV administration); up to 49 h (intramuscular administration).
Protein Binding 30%.
Dose Up to 1000 units/kg intravenously daily for 10 days.

Clausen N, Christensen E (1986). Determination of L-asparaginase activity in serum by thin-layer chromatography: application to the treatment of acute lymphoblastic leukemia. *Clin Chim Acta* 161: 111–116.

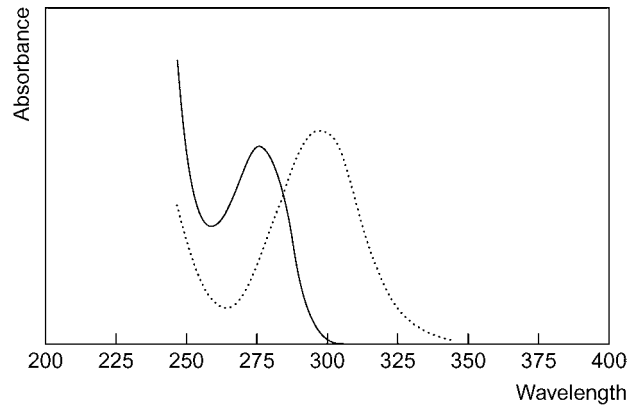
Aspirin

Analgesic, Antiplatelet, Antipyretic, NSAID
$C_9H_8O_4$ = 180.2
CAS—50-78-2

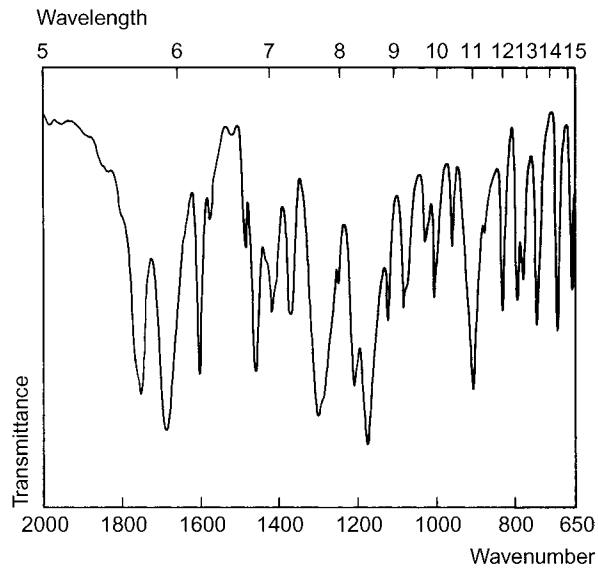
IUPAC Name 2-Acetyloxybenzoic acid
Synonyms 2-Acetoxybenzoic acid; acetylsalicylic acid; salicylic acid acetate.
Proprietary Names *Adprin-B*; *Angettes*; *Ascriptin*; *Aspergum*; *Asprimox*; *Aspro*; *Asatard*; *Beechams Lemon Tablets*; *Bufferin*; *Buffex*; *Caprin*; *Cardiprin*; *Cemerit*; *Claragine*; *Disprin*; *Easprin*; *Ecotrin*; *Empirin*; *Encaprin*; *Enprin*; *Gencardia*; *Genprin*; *Halfprin*; *Micropirin*; *Magnaprin*; *Nu-Seals*; *Platet*; *PostMI*; *Rhonal*; *Solprin*; *ZORprin*. Aspirin is an ingredient of many proprietary preparations [Sweetman 2007].



Chemical Properties Colourless or white crystals or white crystalline powder or granules. It is stable in dry air but gradually hydrolyses in contact with moisture to acetic and salicylic acids. Mp 135°. Soluble 1 in 300 of water, 1 in 5 of ethanol, 1 in 17 of chloroform, and 1 in 10 to 15 of ether; soluble in solutions of acetates and citrates and, with decomposition, in solutions of alkali hydroxides and carbonates. pK_a 3.5 (25°). Log *P* (octanol/pH 7.4), −1.1.
Colour Test McNally's test—red (after hydrolysis).
Thin-layer Chromatography System TA—R_f 0.90; system TD—aspirin R_f 0.18, salicylic acid R_f 0.07, salicyluric acid R_f 0.00; system TE—aspirin R_f 0.09, salicylic acid R_f 0.10, salicyluric acid R_f 0.00; system TF—aspirinR_f 0.30, salicylic acid R_f 0.01, salicyluric acid R_f 0.00; system TAD—aspirin R_f 0.31, salicylic acid R_f 0.24; system TAE—aspirin R_f 0.78, salicylic acid R_f 0.86; system TAJ—R_f 0.40; system TAK—R_f 0.65; system TAL—R_f 0.90.
Gas Chromatography System GA—aspirin RI 1545, M (aspirin-Me) RI 1394, salicylic acid RI 1307, M (salicylic acid-Me) RI 1195; system GB—salicylic acid RI 1340, M (salicylic acid-Me) RI 1228.
High Performance Liquid Chromatography System HD—aspirin *k* 0.5, salicylic acid *k* 0.7; system HW—aspirin *k* 2.70, salicylic acid *k* 4.60; system HX—aspirin RI 350; system HY—aspirin RI 318; system HZ—aspirin RT 2.7 min; system HAX—salicylic acid RT 5.2 min; system HAY—salicylic acid RT 4.4 min.
Ultraviolet Spectrum Aqueous acid—230 (A^1_1 = 466a), 278 nm (A^1_1 = 68a); aqueous alkali—231 (A^1_1 = 409b), 298 nm (A^1_1 = 190b).



Infrared Spectrum Principal peaks at wavenumbers 1183, 1688, 1305, 1755, 925, 1219 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 120, 43, 138, 92, 121, 39, 64, 63 (aspirin); 120, 92, 138, 64, 39, 63, 121, 65 (salicylic acid); 121, 120, 69, 92, 195, 39, 93, 45 (salicyluric acid).

Quantification

Plasma **GC** Column: 5% OV-17 on CQ 80/100 mesh (1.8 m × 4 mm i.d.). Carrier gas: N_2, 50 mL/min. Temperature programme: 160° to 200° at 2°/min. FID. Limit of detection, 200–500 μg/L for aspirin, salicylic acid and salicylamide [Rance *et al.* 1975].

GC-MS Column: reversed phase Luna C_{18} (50 × 2.0 mm i.d., 3 μm). Mobile phase: acetonitrile and water containing 0.1% formic acid (8 : 2), flow rate 0.2 mL/min. MRM acquisition mode, negative ion mode. Limit of quantification, 5 μg/L for aspirin and 50 μg/L for salicylic acid [Bae *et al.* 2008]. Column: Column: DB-1701 (15 m × 0.25 mm i.d., 0.25 μm). Carrier gas: He, 25 kPa. Temperature programme: 100° for 2 min to 300° at 25°/min. NICI or EI ionisation. Limit of quantification, 200 ng/L [Tsikas *et al.* 1998].

HPLC Column: MC-SAX (10 × 4 mm i.d., 50 μm). Mobile phase: water-acetonitrile (1000 : 10) containing 0.2% trifluroacetic acid : water-acetonitrile (100 : 900) containing 0.1% trifluroacetic acid (100 : 0 to 70 : 30 for 18 min for 2 min), flow rate 1.0 mL/min. UV detection (λ = 235 nm). Limit of quantification, 60 μg/L for aspirin and salicylic acid [Yamamoto *et al.* 2007]. Column: C_8 Nucleosil (250 × 4.6 mm i.d., 5 μm). Mobile phase: water : methanol : acetonitrile : orthophosphoric acid (650 : 200 : 150 : 1), flow rate 1 mL/min. UV detection (λ = 225 nm). Limit of quantification, 0.1 mg/L, limit of detection, 0.04 mg/L for aspirin and salicylic acid [McMahon, Kelly 1998]. Column: LiChrospher 100 RP-18. Mobile phase: water : phosphate buffer (pH 2.5) : acetonitrile (35 : 40 : 25), flow rate 1 mL/min. Limit of detection, 0.1 mg/L for aspirin and salicylic acid [Pirola *et al.* 1998]. Column: Alltech ODS (150 × 4.6 mm i.d., 5 μm). Mobile phase: 30 mmol/L sodium citrate : 30 mmol/L sodium acetate (pH 4.8), flow rate, 1.0 mL/min. UV detection (λ = 305 nm). Limit of detection, <5 μmol/L for salicylic acid [Coudray *et al.* 1996]. Column: Nova-Pak C_{18} (150 × 4 mm i.d., 4 μm). Mobile phase: water : 85% orthophosphoric acid : acetonitrile (740 : 0.9 : 180). UV detection (λ = 237 nm). Limit of quantification, 100 μg/L for aspirin and salicylic acid [Kees *et al.* 1996]. See Urine [Krivosiková *et al.* 1996]. See Oral Fluid [Legaz *et al.* 1992]. See also Buskin *et al.* [1982], Gaspari, Locatelli [1987], Owen *et al.* [1987] and Rumble *et al.* [1981].

Serum **HPLC** Column: ACE C_{18} (150 × 4.6 mm i.d., 5 μm). Mobile phase: acetonitrile : 0.1% aqueous orthophosphoric acid (40 : 60 to 45 : 55 at 3.5 min to 70 : 30 at 5.5 min until 8 min to 40 : 60 at 9 min for 1 min), flow rate 1 mL/min for 3.5 min to 2 mL/min at 5.5 min to 3 mL/min at 7 min. Fluorescence detection (λ_{ex} = 290 nm, λ_{em} = 445 nm). Limit of detection, <0.05 pmol for aspirin, salicylic acid, piroxicam and mefanamic acid [Ibrahim *et al.* 2007]. Column: ODS. Mobile phase: methanol : 0.7 mmol/L phosphoric acid (pH 2.5, 50 : 50). UV detection. Limit of detection, 114 μg/L for aspirin and 38 μg/L for salicylic acid [Ohwaki *et al.* 2007].

Urine **HPLC** Column: LiChroCART (250 × 4 mm i.d., 5 μm). Mobile phase: acetonitrile : methanol : 0.05% trifluoroacetic acid in water (96 : 3 : 1 to 70 : 29 : 1 at 30 min to 50 : 49 : 1 at 60 min), flow rate 1.0 mL/min to 1.2 mL/min at 30 min to 1.4 mL/min at 60 min. DAD (λ = 200–450 nm). Limit of quantification, 0.46 mg/L, limit of detection, 0.14 mg/L [Baranowska *et al.* 2009]. Column: Separon SGX C_{18} (150 × 3.3 mm i.d.). Mobile phase: water : 85% phosphoric acid : butanol : tetrabutylammonium hydroxide : methanol (134 : 1 : 1 : 1 : 63), flow rate, 0.9 mL/min. UV detection (λ = 305 nm). Limit of detection, 0.2 μmol/L salicylic acid and salicyluric acid [Krivosiková *et al.* 1996]. Column: μBondapak Phenyl (300 × 4.6 mm i.d., 10 μm). Mobile phase: methanol : acetonitrile : TEA : 10 mmol/L potassium dihydrogen phosphate (18 : 110 : 1 : 871, pH 2.8), flow rate 1.0 mL/min. UV detection (λ = 237 nm). Limit of detection, 2 mg/L for salicyl acyl glucuronide, salicyl phenolic acid glucuronide and salicyluric phenolic glucuronide; 1 mg/L for gentisic acid; and 0.5 mg/L for salicylic acid and salicyluric acid [Shen *et al.* 1991].

Oral Fluid **HPLC** Column: Spherisorb ODS-2 (200 × 4.6 mm i.d., 5 μm). Mobile phase: methanol : water : acetic acid (400 : 98 : 2), flow rate 1.0 mL/min. UV detection (λ = 237 nm). Limit of detection, 100 g/L [Legaz *et al.* 1992].

Skin **HPLC** See Plasma. Limit of detection, 0.1 μg/cm^2 for aspirin and salicylic acid [Pirola *et al.* 1998].

Note For a review of the analysis of salicylates, see Hori *et al.* [2003].

Disposition in the Body

Aspirin is readily absorbed after oral administration and rapidly hydrolysed to salicylic acid, which is the active agent. Salicylic acid is conjugated with glucuronic acid and glycine to form acyl and ether glucuronides and salicyluric acid; some hydroxylation also occurs to give dihydroxy and trihydroxy derivatives of salicylic acid. Aspirin is excreted almost entirely in the urine with ~50–80% of a dose as salicyluric acid, 10–30% as salicyl *O*-glucuronide, 5% as salicyl ester glucuronide, and 5–10% as free salicylic acid, together with small amounts of gentisic acid, gentisuric acid, and unchanged drug; salicylates are reabsorbed by the renal tubules from acid urine and thus alkaline diuresis increases the rate of salicylate elimination; ~85% of a dose is excreted as free salicylic acid if the urine is made alkaline.

Aspirin is a metabolite of aloxiprin and benorilate.

Therapeutic Concentration In plasma, salicylic acid is usually in the range 20–100 mg/L for analgesia and 150–300 mg/L for anti-inflammatory effect.

After a single oral dose of 900 mg given to 5 subjects, peak plasma aspirin concentrations of 16–50 mg/L (mean, 37) were attained in ~14 min, and peak plasma salicylic acid concentrations of 47–113 mg/L (mean, 78) were reported at 0.5–1 h [Cham *et al.* 1980].

Following daily oral doses of 3.9 g to 8 subjects for 8 days, steady-state plasma salicylic acid concentrations of 105–227 mg/L (mean, 173) were reported; by the 36th day of treatment, the steady-state plasma concentrations had declined to 45–208 mg/L (mean, 129) [Rumble *et al.* 1980].

Toxicity The estimated minimum lethal dose is 15 g. Plasma concentrations of salicylic acid greater than 300 mg/L are likely to produce toxic reactions and concentrations greater than 500 mg/L are associated with moderate to severe intoxication. The maximum permissible atmospheric concentration is 5 mg/m^3.

In a review of 62 fatalities attributed to salicylate poisoning, the following postmortem tissue concentrations were reported: blood 61–7320 mg/L (mean, 661; 52 cases), brain 22–700 μg/g (mean, 218; 20 cases), kidney 19–1200 μg/g (mean, 408; 21 cases), liver 13–1000 μg/g (mean, 437; 24 cases), spleen 103–1230 μg/g (mean, 421; 16 cases), urine 180–1350 mg/L (mean, 593; 15 cases) [Rehling 1967].

A 43-year-old female attempted suicide by self-administration, in the form of an enema, of ~700 aspirin tablets dissolved in water. The initial salicylate concentration in the serum was 590 mg/L and rose to 900 mg/L 12 h later; after haemodialysis, serum salicylate concentration fell to 160 mg/L but the patient remained in a coma for more than a year. The patient's poor outcome was attributed to retention of aspirin products in the rectal vault plus poor recognition of the delayed absorption properties of rectally administered aspirin [Watson, Tagupa 1994].

In 3 cases of severe salicylate poisoning, haemofiltration treatment reduced serum salicylate from 8.5–3.5 mmol/L after 3 h in 1 patient and in another patient from 6.2–4 mmol/L after 4 h and to 1.4 mmol/L after a further 7 h. The third patient who had persistent salicylism (serum level of 3 mmol/L), serum salicylate levels were decreased with haemofiltration [Wrathall *et al.* 2001]

An 86-year-old woman who took an overdose of tablets each containing 300 mg aspirin had respiratory alkalosis and a blood salicylate concentration of 850 mg/L. As the patient was elderly and frail, she was treated with urinary alkalinisation and she showed rapid clinical improvement [Basavarajaiah *et al.* 2004].

A 14-year-old girl who had ingested 120 tablets each containing 81 mg aspirin had a salicylate level of 10 mg/L 4 h after ingestion and she denied having any adverse symptoms. She was given one dose of activated charcoal. At 35 h she had dizziness, tinnitus and epigastric discomfort and a salicylate level of 460 mg/L. The delayed salicylate toxicity was treated with a second dose of activated charcoal and IV bicarbonate and potassium [Rivera *et al.* 2004].

A 52-year-old woman who died after ingesting ~300 tablets each containing 325 mg aspirin had the following post-mortem salicylate levels: 1.1 g/L (heart blood), 1.3 g/L (femoral blood), 0.3–0.4 mg/g (brain), 0.9–1.4 mg/g (lung), 0.6–0.8 mg/g (liver) and 0.9 g/L (kidney) [Ihama *et al.* 2007].

A 41-year-old man died after ingesting ~200 aspirin tablets (65 g asprin). Blood levels of salicylate ~12 h after ingestion were 475 to 557 mg/L. Postmorten levels were 762 mg/L (heart blood) and 215 mg/L (femoral blood). Lethal levels were also found in all tested organs (e.g. 503 mg/L (liver) and 251 mg/L (brain) [Wollersen *et al.* 2007].

A 74-year-old patient admitted to intensive care because of impaired consciousness developed irreversible asystole ~6 h later and was found to have a plasma salicylate concentration of 876 mg/L [Galbois *et al.* 2009].

A 35-year-old man admitted to hospital 7.5 h after ingesting 400 tablets each containing 325 mg aspirin was treated with activated charcoal and IV hydration with sodium bicarbonate. 2 h after admission his salicylate concentration was 916 mg/L. He was treated with haemodialysis and 22 h after presentation, the salicylate level was 884 mg/L and he died 40 h after the overdose [Minns *et al.* 2010].

Half-life Plasma half-life, aspirin ~17 min, salicylic acid dose dependent (2–4 h after doses of less than 3 g, increasing to ~19 h after large doses).

Volume of Distribution Aspirin ~0.15 L/kg, salicylic acid ~0.1–0.2 L/kg (dose dependent).

Protein Binding Salicylic acid ~90% at concentrations below 100 μg/mL, decreasing to 50% at concentrations above 400 μg/mL.

Note For reviews of the pharmacokinetics of salicylates, see Levy [1978] and Mandelli, Tognoni [1980]. For reviews of salicylate poisoning, see Pearlman, Gambhir [2009] and Reingardiene, Lazauskas [2006].

Dose

Usually 1.2 to 4 g daily; doses of up to 8 g daily are given in acute rheumatic disorders. Low-dose aspirin for antiplatelet effects; initially 300 mg then 75 to 150 mg daily.

Astemizole

Antihistamine

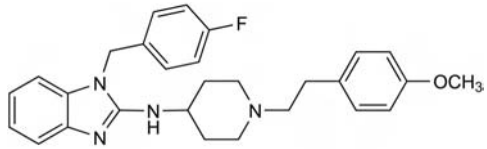
$C_{28}H_{31}FN_4O$ = 458.6

CAS—68844-77-9

IUPAC Name 1-[(4-Fluorophenyl)methyl]-*N*-[1-[2-(4-methoxyphenyl)ethyl] piperidin-4-yl]-benzimidazol-2-amine

Synonym R-43512

Proprietary Names *Alermizol*; *Esmacen*; *Hismacap*; *Hismanal*; *Histamen*; *Histaminos*; *Hubermizol*; *Laridal*; *Paralergin*; *Pollon-eze*; *Pollonis*; *Retolen*; *Rifedot*; *Rimbol*; *Romadin*; *Simprox*; *Urdrim*.



Chemical Properties A white or almost white powder. Mp 175° to 178°. Also described as white, odourless crystals. Mp 149.1°. Practically insoluble in water; soluble in ethanol; freely soluble in dichloromethane, methanol and other organic solvents. Log *P* (octanol/water), 6.43.

Thin-layer Chromatography System TAE—astemizoleR_f 0.56, M (nor) R_f 0.55; system TB—astemizole R_f 0.01, M (nor) R_f 0.00; system TE—astemizole R_f 0.64, M (nor) R_f 0.51.

Plates: silica gel 60 F_{254}. Solvent system: *n*-butanol : acetic acid : water (12 : 5 : 2). UV detection (λ= 280 nm). R_f 0.45 [Mangalan *et al.* 1991].

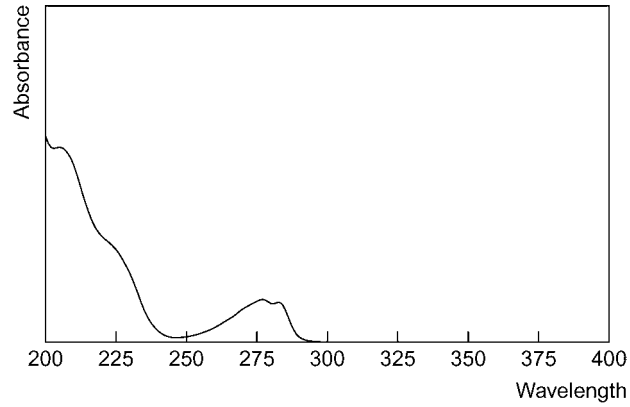
Plates: silica gel 60 F_{254} (20 × 20 cm, 0.25 mm). Solvent system: chloroform : methanol (85 : 15). UV detection (λ= 254 nm). R_f 0.67 (astemizole); 0.36 (demethylated derivative). R_f 1.86 relative to its metabolite [al Deeb *et al.* 1992].

Gas Chromatography System GA—astemizole RI 3150, M (*N*-desalkyl) RI 2470.

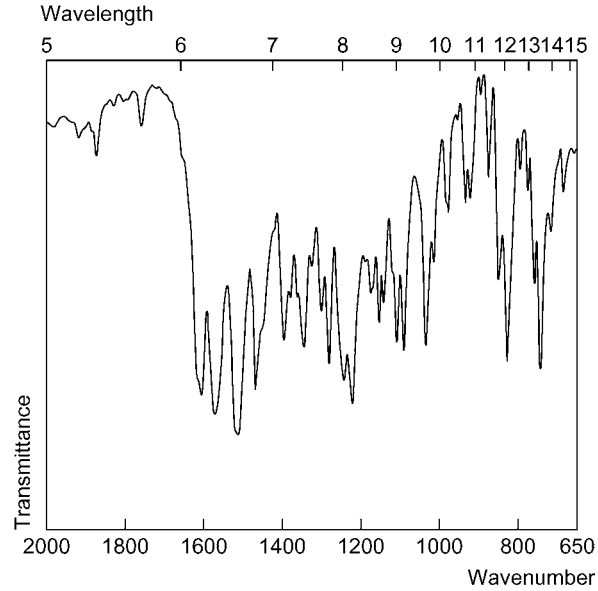
High Performance Liquid Chromatography System HX—astemizole RI 383, M (nor) RI 361; system HY—RI 286; system HZ—RT 3.9 min; system HAA—RT 13.2 min.

Column: ODS Hypersil (100 × 4.6 mm i.d., 5 µm). Mobile phase: methanol : aqueous 0.01 mol/L dihydrogen potassium phosphate buffer (pH 3.5, 70 : 30), flow rate 1 mL/min. DAD. Retention time: 3.2 min [Mills, Roberson 1993].

Ultraviolet Spectrum Aqueous acid (ethanol)—219, 249, 286 (A^1_1= 306.5) nm; 0.1 mol/L hydrochloric acid—209, 277 nm.



Infrared Spectrum Principal peaks at wavenumber 1506, 1217, 738 cm^{-1} (KBr pellets).



Mass Spectrum Principal peaks at *m/z* 96, 109, 97, 294, 95, 135, 121, 242 (astemizole); 109, 241, 132, 83, 242, 111 M (*N*-desalkyl).

Quantification

***Other* HPLC** Animal Plasma and Tissue. Column: RSIL C_{18} HL reversed phase (150 × 2.1 mm i.d., 5 µm). Mobile phase: acetonitrile : water (50 : 50), flow rate 0.6 mL/min. UV detection (λ= 254 nm). Limit of detection, 1 µg/L in plasma, 5 ng/g in tissue [Woestenborghs *et al.* 1983].

Note For a spectrophotometric method for the determination of astemizole in pharmaceutical preparations, see Güngör, Onur [2001].

Disposition in the Body Astemizole is rapidly absorbed after oral administration. It is widely distributed although does not cross the blood–brain barrier to a significant extent. It is distributed into breast milk. The drug undergoes extensive first-pass metabolism mediated by the cytochrome P450 enzyme system (mainly by isoenzyme CYP3A4 and to a lesser extent by CYP2D6 and CYP2A6) [Matsumoto *et al.* 2002]. Desmethylastemizole is the major metabolite and has histamine H_1-blocking activity. Other metabolites include norastemizole and 6-hydroxydesmethylastemizole. The metabolites are slowly excreted, primarily in faeces via bile and undergo enterohepatic recycling. No unchanged drug has been detected and it is not known to accumulate once steady state levels have been reached.

Therapeutic Concentration Peak plasma concentrations are reached within 1–2 h. At steady state, the average peak plasma concentration of astemizole plus desmethylastemizole is 3–5 µg/L.

Toxicity Elevated plasma astemizole concentrations are associated with QT interval prolongation and serious cardiotoxicity. Arrhythmias, including torsade de pointes, have occurred rarely at doses as low as 20–30 mg daily.

A 4-year-old boy who ingested 1.7 mg/kg astemizole became lethargic 4 h later. The serum astemizole concentration measured 4.5 h after ingestion was 14 μg/L. Four other children aged 1.5–11 years who had ingested 2.2–12.2 mg/kg all had prolonged QT intervals on ECG recordings, which took 1–3 days to resolve [Wiley *et al.* 1992].

Plasma astemizole concentrations following accidental overdose in a 28-month-old child who had taken 16.7 mg/kg and in a 24-month old child who had taken 2.5 to 3.3 mg/kg were 250 and 15.9 μg/L, respectively (time after ingestion not stated). The child who had ingested 16.7 mg/kg developed ventricular fibrillation requiring DC cardioversion 46 h after ingestion. Both children made a full recovery [Hoppu *et al.* 1991].

A 14-year-old girl took an overdose of 200 mg astemizole. The peak plasma concentration was ~10 times greater than that seen after a single 20 mg dose. The apparent plasma half-life was 31 h [Kingswood *et al.* 1986].

A 16-year-old girl who had taken an overdose of 200 mg astemizole became unconscious with no cardiac output 7 h later. After another hour she developed ventricular tachyarrhythmia requiring DC cardioversion [Craft 1986].

Half-life Plasma half-life: astemizole 1–2 days, desmethylastemizole 9–13 days. The half-life of the drug and metabolites may increase to 18–20 days after long-term administration.

Volume of Distribution 250 L/kg.

Clearance Plasma, 11 mL/min/kg.

Protein Binding 96%.

Note For reviews of astemizole, see Richards *et al.* [1984] and Paton, Webster [1985].

Atenolol

β-*Adrenoceptor Antagonist*

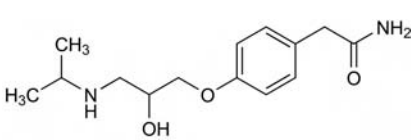
$C_{14}H_{22}N_2O_3 = 266.3$

CAS—29122-68-7

IUPAC Name 2-[4-[2-Hydroxy-3-(propan-2-ylamino)propoxy]phenyl]acetamide

Synonyms 2-{*p*-[2-Hydroxy-3-(isopropylamino)propoxy]phenyl}acetamide; 4-[2-hydroxy-3-[(1-methylethyl)amino]propoxy]benzeneacetamide; ICI-66082.

Proprietary Names *Anselol*; *Antipressan*; *Ate*; *Atebeta*; *Atehexal*; *Atendol*; *Atenix*; *Ateno*; *Atenol*; *Betatop*; *Blocotenol*; *Cuxanorm*; *Duratenol*; *Evitocor*; *Falitonsin*; *Jenatenol*; *Juvental*; *Myocord*; *Noten*; *Prenormine*; *Tenoblock*; *Tenlol*; *Teno*; *Tenormin(e)*; *Tensig*; *Tonoprotect*; *Totamol*; *Uniloc*; *Xaten*. It is an ingredient of *AtenixCo*; *Beta-Adalat*; *Kalten*; *Tenben*; *Tenchlor*; *Tenif*; *Tenoret(ic)*; *Totaretic*.



Chemical Properties Crystals. Mp 146° to 148°. Slightly soluble in water and isopropanol; freely soluble in methanol; soluble in acetic acid and dimethylsulfoxide; very slightly soluble in acetone and dioxane; practically insoluble in acetonitrile, ethylacetate and chloroform. pK_a 9.6 (24°). Log *P* (octanol), 0.23. Extraction yield (chlorobutane), 0 [Demme *et al.* 2005].

Colour Tests Liebermann's reagent—black; Nessler's reagent—yellow-brown (slow).

Thin-layer Chromatography System TA—R_f 0.45; system TB—R_f 0.00; system TC—R_f 0.02; system TE—R_f 0.22; system TL—R_f 0.02; system TAE—R_f 0.14.

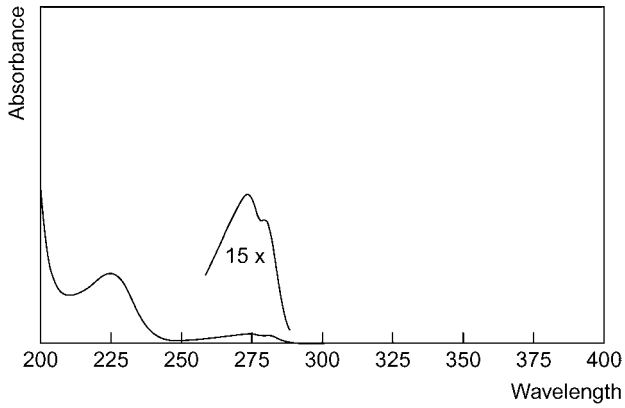
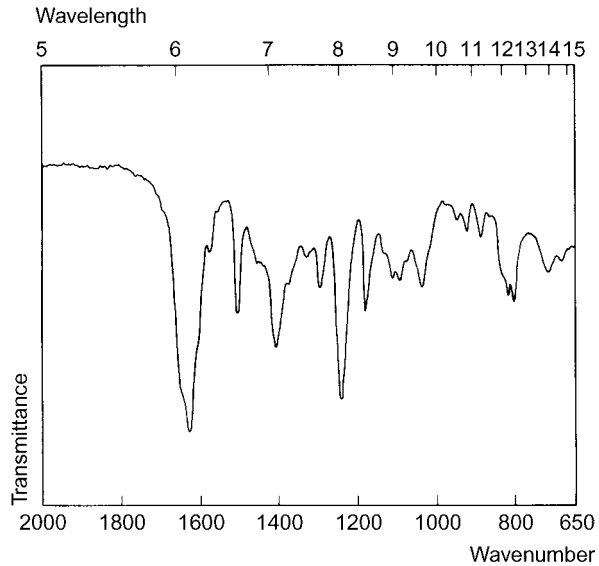
High Performance Liquid Chromatography System HA—*k* 1.3; system HX—RI 243; system HY—RI 194; system HZ—RT 1.7 min; system HAA—RT 3.6 min.

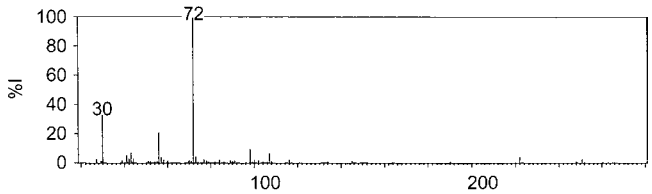
Ultraviolet Spectrum Aqueous acid—274 nm ($A_1^1 = 48$b), 280 nm. No alkaline shift.



Infrared Spectrum Principal peaks at wavenumbers 1633, 1245, 1510, 1184, 805, 820 cm^{-1}.



Mass Spectrum Principal ions at *m/z* 72, 30, 56, 98, 43, 107, 41, 73.



Quantification

Blood **GC-MS** Column: HP-ULTRA-1 cross-linked 100% methylsiloxane capillary (12 m × 0.2 mm i.d., 0.33 μm). Carrier gas: He, 1.0 mL/min. Temperature programme: 70° to 290° at 30°/min for 2.67 min. SIM acquisition mode, full scan mode. Retention time: 5.74 min. Limit of detection not reported [Angier *et al.* 2005].

HPLC Column: Nucleosil C_{18} (150 × 4.6 mm i.d., 5 μm). Mobile phase: acetonitrile : methanol : 0.05 mol/L phosphate triethylamine buffer (pH 3.3, 2 : 8 : 90), flow rate 1.2 mL/min. Fluorescence detection (λ_{ex} = 230 nm, λ_{em} = 300 nm). Retention time: 4.4 min. Limit of quantification, 20 μg/L, limit of detection, 10 μg/L [Miller 1991]. Column: Varian Micro-Pak MCH-10 C_{18} (250 × 2.0 mm i.d.). Mobile phase: 0.01 mol/L heptanesulfonic acid in water : 0.01 mol/L heptanesulfonic acid in methanol (28 : 72), flow rate 40 mL/h. Fluorescence detection

A

(λ_{ex}= 212 nm, λ_{em}= 326.5 nm). Retention time: 10.8 min. Limit of detection, 1 μg/L [Yee *et al.* 1979].

LC-MS Column: Atlantis dC_{18} (150 × 2.1 mm i.d., 3.0 μm). Mobile phase: 10 mmol/L ammonium formate (pH 3.1) : acetonitrile (90 : 10 to 10 : 90 over 10 min for 3 min to 90 : 10 over 5 min. ESI, positive ion mode, SIM acquisition mode. Limit of quantification, 0.03 μmol/L [Kristoffersen *et al.* 2007].

Plasma **TLC** Fluorescence detection. Limit of detection, 5 μg/L [Schäfer, Mutschler 1979].

GC Column: 3% OV-1 on Gas-Chrom Q 100/120 mesh (2 m × 2 mm i.d.). Carrier gas: Ar : CH_4 (95 : 5), 30 mL/min. Temperature: 300°. ECD. Limit of detection, 5 μg/L [Ervik *et al.* 1980].

HPLC Column: C_{18} Shim Pack (150 × 4.6 mm i.d., 4 μm). Mobile phase: 0.05 mol/L phosphate buffer (pH 5.5) : methanol (80 : 20), flow rate 0.7 mL/min. Fluorescence detection (λ_{ex}= 235 nm, λ_{em}= 290 nm). Retention time: 12.7 min. Limit of quantification, 8 μg/L, limit of detection, 4 μg/L [Leite Fda *et al.* 2006]. Column: ThermoHypersil Hypurity C_{18} (250 × 4.6 mm i.d., 5 μm). Mobile phase: acetonitrile : phosphate buffer (pH 3.8), flow rate 1.0 mL/min. UV detection (λ= 220 nm). Limit of detection, 5–10 μg/L for atenolol and other β-blockers [Delamoye *et al.* 2004]. Fluorescence detection (λ_{ex}= 258 nm; λ_{em}= 300 nm) [de Abreu *et al.* 2003]. Column: Chiracel OD-H. Mobile phase: hexane : ethanol (85 : 15) plus 0.1% diethylamine. Limit of quantification, 10 μg/L for atenolol enantiomers [Iha *et al.* 2002]. Column ODS. Mobile phase: 0.05 mol/L SDS in phosphate buffer (pH 5.8) : propan-1-ol (95 : 5), flow rate 1.3 mL/min. Fluorimetric detection. Limit of detection, 10 μg/L [Giachetti *et al.* 1997]. Column: Alltech Spherisorb ODS-2 (250 × 4.6 mm i.d., 5 μm). Mobile phase: methanol : 0.5% TEA (pH 3.5, 18 : 72), flow rate 1.0 mL/min. Fluorescence detection (λ_{ex}= 229 nm, λ_{em}= 298 nm). Retention time: 4.5 min. Limit of detection, 1 μg/L [Chiu *et al.* 1997]. See also Egginger *et al.* [1993a] and He *et al.* [1993]. See Urine [Bühring, Garbe 1986]; Enquist, Hermansson 1989; [Mehvar 1989; Morris *et al.* 1991]. See Milk [Bhamra *et al.* 1983]. See Blood [Yee *et al.* 1979].

LC-MS Column: Capcell Pak C_{18} (50 × 2 mm i.d., 5 μm). Mobile phase: acetonitrile and water, both containing 0.02% formic acid, flow rate 0.3 mL/min. ESI, MRM acquisition mode. Atenolol and other antiarrhythmic drugs [Li *et al.* 2007]. Column: Chromsep SS (30 × 3.0 mm i.d.). Mobile phase: 5% methanol in 10 mmol/L formic acid and 10 mmol/L heptanfluorobutyric acid : 50% methanol in 10 mmol/L formic acid and 10 mmol/L heptanfluorobutyric acid (95 : 5 to 15 : 85 at 8 min for 1 min to 95 : 5 at 10 min for 6 min). ESI, SIM acquisitin mode. Limit of quantification, 25 μg/L [Ho *et al.* 2005]. Column: Hypersil (50 × 4.6 mm). Mobile phase: acetonitrile : water : acetic acid : trifluoroacetic acid (85 : 15 : 0.5 : 0.04), flow rate 2.0 mL/min. ESI mode [Li *et al.* 2005]. APCI, SIM acquisition mode. Atenolol and other β-blockers [Maurer *et al.* 2004].

Serum **HPLC** Fluorescence detection [Alebic-Kolbah *et al.* 1989].

Urine **TLC** See Plasma. Limit of detection, 500 μg/L [Schäfer, Mutschler 1979].

GC See Plasma [Ervik *et al.* 1980].

GC-MS See Blood [Angier *et al.* 2005].

HPLC Column: ADS-LiChrospher RP-18 (25 × 4 mm i.d., 25 μm). Mobile phase: acetonitrile : methanol : acetic acid : triethylamine (55 : 45 : 0.3 : 0.3). Fluorescence detection (λ_{ex}= 230 nm, λ_{em}= 310 nm). Limit of detection, 15 μg/L [Lamprecht *et al.* 2000]. Column: RP-18 (3.00 × 4.6 mm i.d., 5 μm). Mobile phase: methanol : glacial acetic acid : water (30 : 1 : 69), flow rate 1.5 mL/min. Fluorescence detection (λ_{ex}= 222 nm, λ_{em}= 300 nm). Limit of detection, 0.5 μg/L [Morris *et al.* 1991]. Column: Chiral α1-AGP (100 × 4.0 mm i.d., 5 μm). Mobile phase: 0.01 mol/L phosphate buffer (pH 7.1) containing 0.25% acetonitrile, flow rate 0.9 mL/min. Limit of detection, <6 μg/L for atenolol enantiomers [Enquist, Hermansson 1989]. Column: C_{18} (100 × 4.6 mm i.d., 5 μm). Mobile phase: water : acetonitrile : methanol (43 : 35 : 22), flow rate 1.2 mL/min. Fluorescence detection (λ_{ex}= 195 nm, no emission filter). Limit of detection not reported [Mehvar 1989]. Column: LiChrosorb Si-60 (125 × 4 mm i.d., 7 μm). Mobile phase: 1 mol/L ammonium phosphate buffer (pH 4) : water : acetonitrile (5 : 92 : 3), flow rate 1.8 mL/min. Fluorimetric detection (λ_{ex}= 225 nm, λ_{em}= 300 nm). Limit of detection, 50 μg/L (5 μg/L in plasma) [Bühring, Garbe 1986]. See Plasma [Chiu *et al.* 1997; Iha *et al.* 2002]. See Milk [Bhamra *et al.* 1983].

LC-MS Column: Uptisphere HDD C_{18} (100 × 2 mm i.d., 3 μm). Mobile phase: 10 mmol/L ammonium formate buffer (pH 3.9) : methanol (83 : 17 to 60 : 40 in 22 min to 0 : 100 in 8 min to 83 : 17 for 15 min), flow rate 0.3 mL/min. ESI. Limit of quantification, 0.69 μg/L [Pujos *et al.* 2009]. Column: fused silica capillary (75 μm; Nano-LC), packed with chiral modified silica particles (5 μm). Mobile phase: 500 mmol/L ammonium acetate (pH 4.5) : methanol: acetonitrile (1 : 60 : 39), flow rate 900 nL/min. ESI. Limit of quantification, 400 μg/L, limit of detection, 50 μg/L, for atenolol enantiomers [D'Orazio, Fanali 2006].

Biological Samples **HPLC** Enantiomers of atenolol and other β-blockers [Egginger *et al.* 1993b].

LC-MS Column: Supelcosil LC_{18} (150 × 4.6 mm i.d., 3 μm). Mobile phase: aqueous mixture : methanol (90 : 10 to 10 : 90 at 5 min to 90 : 10 at 7 min for 3 min), flow rate 1.0 mL/min. APCI, PCI. Limit of quantification, 1.6 μg/L, limit of detection, 0.78 μg/L [Johnson, Lewis 2006].

Milk **HPLC** Column: Microparticulate silica (5 μm). Mobile phase: methanol containing 1 mmol/L *d*-10-camphorsulfonic acid monohydrate. Fluorescence detection (λ_{ex}= 195 nm). Limit of quantification, 20 μg/L [Bhamra *et al.* 1983].

Heart **GC-MS** See Blood [Angier *et al.* 2005].

Kidney **GC-MS** See Blood [Angier *et al.* 2005].

Liver **GC-MS** See Blood [Angier *et al.* 2005].

Disposition in the Body Atenolol is rapidly but incompletely absorbed after oral administration; bioavailability is ~50%. It is excreted almost entirely as unchanged drug, 35–50% of an oral dose being excreted in the urine and 30–50% in the faeces in 24 h; small amounts of 2-hydroxyatenolol and atenolol glucuronide are excreted in the urine.

Therapeutic Concentration

After a single oral dose of 100 mg given to 12 subjects, peak plasma concentrations of 0.41–0.87 mg/L (mean, 0.6) were attained in ~3 h [Mcainsh *et al.* 1980].

Following daily oral doses of 25, 50 and 100 mg to 7, 7 and 6 subjects, respectively, mean maximum steady-state plasma concentrations of 0.12, 0.22 and 0.39 mg/L, respectively, were reported 4 h after a dose; the corresponding mean trough concentrations were 0.02, 0.04 and 0.07 mg/L [Ishizaki *et al.* 1983].

Toxicity Atenolol is relatively non-toxic; there is one case report of ingestion of 1.2 g with subsequent recovery.

A 44-year-old obese female survived after ingesting 200 mg diazepam and 1000 mg atenolol in a suicide attempt. Upon admission to hospital 24 h later, she was in deep coma with a blood atenolol level of 250 mg/L [Hagemann 1986].

A man survived after ingesting a massive overdose of atenolol and diltiazem despite having an atenolol level of 35 mg/L [Snook *et al.* 2000].

A 28-year-old patient with end-stage renal failure suffered cardiac arrest and cardiogenic shock after receiving an overdose of atenolol. During haemodialysis with charcoal haemoperfusion (four dialyses carried out over 72 h), plasma atenolol levels declined from 7.4–2.1 mg/L [Salhanick, Wax 2000].

A woman in her twenties had fatal cardiac arrhythmias after an overdose of atenolol and pilsicainide. Blood levels were 4.94 mg/L and 7.83 mg/L, respectively [Hikiji *et al.* 2008].

A 45-year-old woman with liver cirrhosis who took a massive overdose of atenolol and nifedipine (blood levels of 69.6 mg/L and 63 μg/L, respectively), survived after treatment with continuous veno-venous haemo-diafiltration [Pfaender *et al.* 2008].

Half-life Plasma half-life, 4–14 h (mean, 7).

Volume of Distribution ~0.5–1.5 L/kg.

Clearance Plasma clearance, ~2 mL/min/kg.

Distribution in Blood Plasma : whole blood ratio, ~0.8–0.9.

Protein Binding <5%.

Note For reviews of the pharmacokinetics of atenolol, see Heel *et al.* [1979] and Kirch, Gorg [1982]. For a discussion of the pharmacokinetics, toxicology and management of β-blocker overdose, see O'Grady *et al.* [2001].

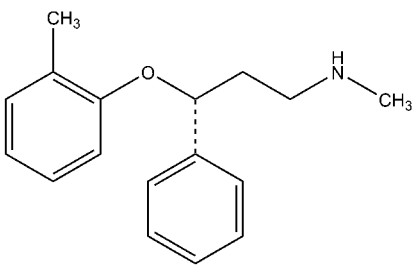
Atomoxetine

SSNRI, Treatment of ADHD
$C_{17}H_{21}NO$ = 255.4
CAS—83015-26-3

IUPAC Name (3*R*)-*N*-Methyl-3-(2-methylphenoxy)-3-phenylpropan-1-amine
Synonyms LY-135252; LY-139602; LY-139603; (γ*R*)-*N*-methyl-γ-(2-methylphenoxy)-benzenepropanamine; (—)-*N*-methyl-3-(*o*-tolyloxy)-3-phenylpropylamine; tomoxetine.



Chemical Properties Log *P* (octanol/water), 4.66 [Wishart 2006].

Atomoxetine Hydrochloride

$C_{17}H_{21}NO,HCl$ = 291.8
CAS—82248-59-7
IUPAC Name (3*R*)-*N*-Methyl-3-(2-methylphenoxy)-3-phenylpropan-1-amine hydrochloride
Proprietary Name *Strattera*
Chemical Properties Crystals or white solid. Mp 166° to 168° or 162° to 164°. Soluble in water. Provided in the pure *R*(−)-isomer form. pK_a 10.1. Stability was demonstrated for stock solutions as well as in plasma and urine [Mullen *et al.* 2005].

Mass Spectrum Principal ions at *m/z* 44, 148, 255 [Garside *et al.* 2006].

Quantification

Blood **GC** Column: DB-5 capillary (15 m × 0.53 mm i.d., 1.5 µm). Carrier gas: He, 6.7 mL/min. Temperature programme: 120° to 300° at 15°/min for 3 min. NPD. Limit of quantification, 0.1 mg/L; limit of detection, 0.05 mg/L [Garside *et al.* 2006].

Plasma **HPLC** Column: Intersil ODS-3 C_{18} (150 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : phosphate buffer (pH 6.6; 39 : 61), flow rate 1.0 mL/min. UV detection (λ = 210 nm). Limit of detection, 2.5 µg/L [Guo *et al.* 2007]. Column: Agilent SB-C_{18} (150 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : 5 mmol/L heptane sulfonic acid buffer with 1% triethylamine (pH 4.8; 40 : 60), flow rate 1 mL/min. UV detection (λ = 272 nm). Limit of quantification, 50 µg/L [Patel *et al.* 2007]. Column: Luna C_{18} (2) reversed phase (250 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : water (75 : 25), flow rate 1.0 mL/min. Fluorescence detection (λ_{ex} = 318 nm, λ_{em} = 448 nm). Limit of detection, 0.3 µg/L [Zhu *et al.* 2007].

LC-MS Column: Brownlee Spheri-5 C_{18} polyfunctional (100 × 4.6 mm i.d., 5 µm). Mobile phase: water : 5 mmol/L ammonium acetate-47.2 mmol/L formic acid-4 mmol/L trifluoroacetic acid in acetonitrile-water (85 : 15; 25 : 75 until 0.8 min to 0 : 100 at 1 min until 2.5 min to 25 : 70 at 3 min), flow rate 1.0 mL/min. APCI , positive ion mode. SRM acquisition mode. Limit of detection not reported [Mullen *et al.* 2005].

Urine **GC** See Blood [Garside *et al.* 2006].

LC-MS Column: Spheri-5 C_{18} polyfunctional (100 × 4.6 mm i.d., 5 µm). Mobile phase: water : 5 mmol/L ammonium acetate-47.2 mmol/L formic acid-4 mmol/L trifluoroacetic acid in acetonitrile-water (85 : 15; 25 : 75 until 0.8 min to 0 : 100 at 1 min until 2.5 min to 25 : 70 at 3 min), flow rate 1.0 mL/min. APCI , positive ion modeSRM acquisition mode. Limit of detection not reported [Mullen *et al.* 2005].

Vitreous Humour **GC** See Blood [Garside *et al.* 2006].

Bile **GC** See Blood [Garside *et al.* 2006].

Liver **GC** See Blood [Garside *et al.* 2006].

Disposition in the Body Rapidly absorbed after oral administration and eliminated primarily through oxidative metabolism by CYP2D6 and subsequent glucuronidation. The major oxidative metabolite is 4-hydroxyatomoxetine-*O*-glucuronide, which is mainly excreted in urine (80% of the administered dose) and <17% in faeces. A second metabolite, *N*-desmethylatomoxetine, is formed by the action of CYP2C19. Less than 3% is excreted as the unchanged drug. Peak plasma concentrations occur 1 to 2 h after dosing. Administration of the drug with a high fat meal decreases the rate of absorption and peak plasma concentrations. The drug is primarily distributed into total body water.

Therapeutic Concentration Therapeutic plasma concentrations after 40 mg a day for 5 days are 0.036 to 0.116 mg/L for extensive metabolisers and 0.500 to 0.915 mg/L for poor metabolisers [Garside *et al.* 2006].

A single-dose, open label dose titration study with 21 children who were CYP2D6 extensive metabolisers showed that atomoxetine was rapidly absorbed, with peak plasma concentrations occurring 1 to 2 h after dosing. Half-life averaged 3.12 and 3.28 h after a single dose and at steady state, respectively [Witcher *et al.* 2003].

Toxicity CYP2D6 inhibitors, such as paroxetine, fluoxetine and quinidine, may increase plasma concentrations of atomoxetine in extensive, but not poor, metabolisers. For a case report of acute atomoxetine and oxcarbazepine overdose with quetiapine, see Barker *et al.* [2004][No levels reported]. Garside *et al.* [2006] have provided 3 case reports:

Case 1. An 11-year-old Caucasian female collapsed during a ball game at school. She had been diagnosed with attention-deficit hyperactivity disorder (ADHD) for which she was originally prescribed dextroamfetamine. Several weeks prior to her death, she was started on atomoxetine while continuing treatment with dextroamfetamine. The death was ruled to be unrelated to atomoxetine [Garside *et al.* 2006].

Case 2. A 19-year-old Caucasian female with a 3-year history of depression and previous suicide attempts was found at home with poor respiration. A suicide note was found at the scene with several empty pill bottles. She was pronounced dead 2 h later. The deceased had been prescribed venlafaxine, ziprasidone, clonazepam, and atomoxetine [Garside *et al.* 2006].

Case 3. A 24-year-old Hispanic male with a history of ADHD was found dead on the floor of his home. He had been prescribed atomoxetine 20 mg twice a day. The death was ruled to be unrelated to atomoxetine [Garside *et al.* 2006].

Postmortem fluid and tissue distribution of atomoxetine were measured by GC-MS for all three cases:

	Atomoxetine (mg/L or mg/kg)						
	Aorta blood	*Femoral blood*	*Vitreous*	*Bile*	*Urine*	*Liver*	*Gastric (mg total)*
Case 1	0.65	0.33	0.1	1	NA	3.9	0.0097
Case 2	8.3	5.4	0.96	33	NA	29	16.8
Case 3	<0.1	<0.1	N/A	NA	<0.1	<0.44	NA

NA, not available [Garside *et al.* 2006].

Bioavailability Approximately 63% for extensive metabolisers and 94% for poor metabolisers.

Half-life Approximately 5.2 h for adult extensive metabolisers and 21.6 h for poor metabolisers.

Volume of Distribution Steady state, 0.85 L/kg.

Clearance Plasma, 0.35 L/h/kg for extensive metabolisers and 0.03 L/h/kg for poor metabolisers

Protein Binding Approximately 98%.

A

Dose Children and adults <70 kg bodyweight: 0.5 mg/kg atomoxetine hydrochloride daily, increased to 1.2 mg/kg bodyweight daily after 3 days. Patients >70 kg bodyweight: 40 mg daily increased to 80 mg after 3 days and up to 100 mg after 2 to 4 weeks.

Atorvastatin

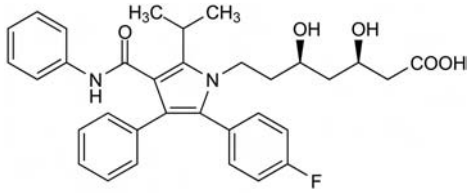
HMG-CoA Reductase Inhibitor

$C_{33}H_{35}FN_2O_5$ = 558.7

CAS—134523-00-5

IUPAC Name [*R*-(*R**,*R**)]-2-(4-Fluorophenyl)-β,δ-dihydroxy-5-(1-methylethyl)-3-phenyl-4-[(phenylamino)carbonyl]-1*H*-pyrrole-1-heptanoic acid

Synonym CI-981



Chemical Properties pK_a 4.46. Log *P* (octanol/water), 6.36.

Atorvastatin Calcium

$C_{66}H_{68}CaF_2N_4O_{10},3H_2O$ = 1209.4

CAS—134523-03-8

Proprietary Names *Lipitor*; *Sortis*; *Torvast*; *Totalip*; *Xarator*.

Chemical Properties A white to off-white crystalline powder, which is insoluble in aqueous solutions with pH≤4.0. It is very slightly soluble in distilled water, phosphate buffer (pH 7.4) and acetonitrile; slightly soluble in ethanol; freely soluble in methanol.

Atorvastatin Lactone

$C_{33}H_{33}FN_2O_4$ = 540.6

Chemical Properties Mp 159.2° to 160.7°. Solubility, 1.34 ± 0.53 mg/L (pH 2.3 to 7.7 at 30°).

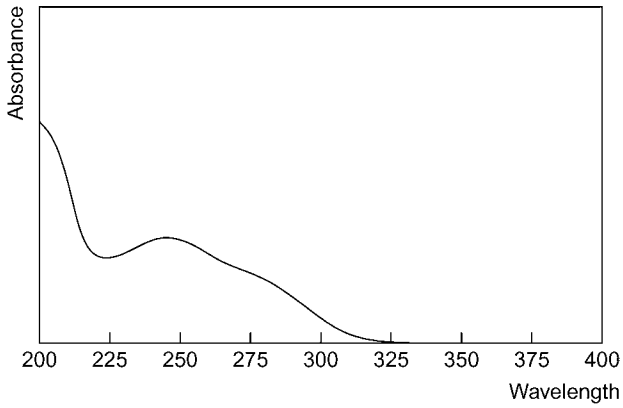
Atorvastatin Sodium

$C_{33}H_{34}FN_2NaO_5$ = 580.6

Chemical Properties Soluble in water at 30°, with a solubility of 20.4 mg/L at pH 2.1 and 1.23 g/L at pH 6.0.

High Performance Liquid Chromatography Column: ODS Ultrasphere (250 × 4.6 mm, 5 µm). Mobile phase: acetonitrile : sodium acetate in water (pH 4.0), flow rate 1.0 mL/min. UV detection (λ=246 nm). Retention time: atorvastatin sodium, 4 min; atorvastatin lactone, 7 min [Kearney *et al.* 1993].

Ultraviolet Spectrum



Quantification

***Plasma* HPLC** Column: C_{18} YMC J'Sphere H80 (150 × 2 mm i.d., 4 µm). Mobile phase: acetonitrile : acetic acid (0.1%) (70:30). Flow rate 0.2 mL/min. MS–MS detection. Retention time: para-hydroxyatorvastatin, 2.27 min; ortho-hydroxyatorvastatin, 3.36 min; atorvastatin, 4.12 min. Limit of quantification, 0.25 µg/L [Bullen *et al.* 1999].

Bioassay Limit of quantification, 0.36 µg/L [Shum *et al.* 1998]. Limit of quantification, 0.3 µg/L [Gibson *et al.* 1996].

***Serum* HPLC** Column: YMC basic (2 × 50 mm, 5 µm) (at 40°). Mobile phases: (gradient elution) (A) water: methanol : formic acid (88%) (950 mL : 50 mL : 43 µL), (B) acetonitrile : methanol: formic acid (950 mL : 50 mL : 43 µL). 70% A and 30% B to 45% A and 55% B, 0 to 1 min; hold 0.5 min; to 70% A and 30% B, 0.1 min; hold, flow rate 0.3 mL/min. MS–MS detection. Retention time: atorvastatin, 2.78 min; 2-hydroxyatorvastatin, 2.69 min; 4-hydroxyatorvastatin, 2.31 min. Limit of quantification, 0.5 µg/L [Jemal *et al.* 1999].

Disposition in the Body Atorvastatin is rapidly absorbed after oral administration, which increases in proportion to the dose administered. Absolute bioavailability is ~12% due to presystemic clearance in the gastrointestinal mucosa and metabolism by cytochrome P450 3A4 in the liver. A number of metabolites have been identified, all with inhibitory activity, including 2- and 4-hydroxyatorvastatin, *ortho*- and *para*-hydroxylated derivatives and various β-oxidation products. Atorvastatin is excreted as metabolites, primarily in bile, with <2% of the dose present in urine.

Therapeutic Concentration

Sixteen young, healthy men and women, aged between 19 and 35 years, and 16 healthy, elderly men and women, 66 to 92 years old, were administered with a 20-mg dose of atorvastatin, after fasting for 8 h. Maximum plasma concentrations for the young volunteers reached 12.7 µg/L within 1 to 2 h and 18.1 µg/L for the elderly. Differences were also observed between the men and women with 14.2 µg/L (within 2.3 h) and 16.7 µg/L (1.4 h), respectively [Gibson *et al.* 1996].

Toxicity

A 73-year-old, moderately obese woman with type II diabetes and hypertension was admitted to hospital. She had been receiving a number of medications with no other problems and was prescribed a 10 mg daily dose of atorvastatin. 4 days later, she developed a red, itchy, painful rash (potentially life-threatening dermatosis). Treatment with atorvastatin was stopped but she still developed severe stomatitis, diffuse erythema, oedema of face, trunk and extremities, and other symptoms. Supportive care including intravenous fluids, morphine, corticosteroids and a liquid diet were required. She eventually recovered after being seriously ill for 4 months [Pfeiffer *et al.* 1998].

Half-life Elimination half-life, approximately 14 h.

Volume of Distribution Mean, approximately 565 L.

Distribution in Blood Blood cells : plasma, 0.25.

Protein Binding 98%

Dose An initial dose of 10 mg daily is administered with a maximum of 80 mg daily.

Atovaquone

Antiprotozoal

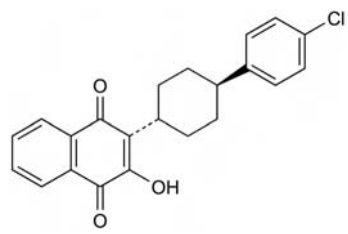
$C_{22}H_{19}O_3Cl$ = 366.8

CAS—95233-18-4

IUPAC Name *trans*-2-[4-(4-Chlorophenyl)cyclohexyl]-3-hydroxy-1,4-naphthalenedione

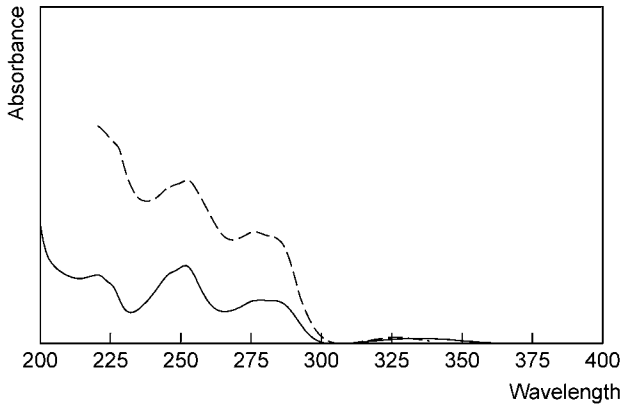
Synonyms 566C80; BW-566C; BW-566C-80.

Proprietary Names *Acuvel*; *Mepron*; *Wellvone*.

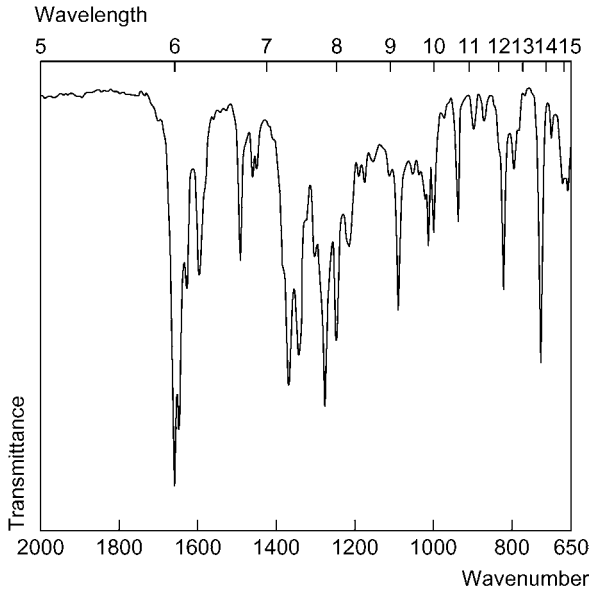


Chemical Properties A yellow crystalline solid. Also, reported as crystals from acetonitrile. Mp 216° to 219°. It is practically insoluble in water (>0.2 mg/L); poorly soluble in a variety of organic solvents.

Ultraviolet Spectrum Basic—252, 276 nm.



Infrared Spectrum Principal peaks at wavenumbers 1659, 1278, 1370 cm^{-1} (KBr pellet).



Mass Spectrum Principal ions at *m/z* 202, 366, 115, 77, 368, 125, 105, 213.

Quantification

Plasma **GC** ECD. Sensitivity, 0.01 mg/L [Rolan *et al.* 1994].

HPLC UV detection (λ=254 nm). Limit of quantification, 0.1 mg/L [Hannan *et al.* 1996]. Column: C_6 Spherisorb (250 × 4.6 mm i.d., 5 µm). Mobile phase: methanol : 10 mmol/L triethylamine in 0.2% aqueous trifluoroacetic acid, pH 2 (76:24), flow rate 1 mL/min. Retention time: 8.8 min. UV detection. Limit of detection, 0.5 mg/L [Hansson *et al.* 1996]. UV detection. Limit of detection, 0.25 mg/L [Studenberg *et al.* 1995]. UV detection (λ=254 nm). Limit of quantification, 0.25 mg/L [DeAngelis *et al.* 1994]. UV detection. Limit of detection, 0.05 mg/L [Rolan *et al.* 1994].

Disposition in the Body Atovaquone is rapidly but poorly absorbed after oral administration; bioavailability shows considerable inter-individual variation and is increased by concomitant administration with food, especially food with high fat content. The drug is excreted almost entirely in faeces (94% of an administered dose over 21 days) as the unchanged drug, with little present in urine. There is no evidence that atovaquone is metabolised in the body. It may undergo enterohepatic recycling. Plasma concentrations do not increase proportionally with dose.

Therapeutic Concentration

Six male individuals, HIV-sero-positive, with CD4 counts >200 cells/mm^3 were administered with single 500, 1000 and 1500 mg doses after an overnight fast. Peak plasma concentrations reached 2.7, 5.6 and 4.3 mg/L, respectively, between 1.5 and 2.5 h. Following administration of 1000 mg daily with a high-fat meal and 1000 mg twice daily with or without a high-fat meal, for 14 days, the mean concentrations were 24.2, 41.3 and 34.4 mg/L, respectively. These levels were detected at 9.1, 3.7 and 2.1 h [Dixon *et al.* 1996].

The mean peak plasma concentration occurring 6 h after administration of 750 mg three times a day for 5 days followed by 750 mg twice a day for 16 days, with a standard breakfast, was 51 mg/L in 4 male subjects, aged over 18 years, with CD4 counts ≥250 cells/mm^3. Single doses of 100, 250, 750, 1500 and 3000 mg administered to the same group produced peak concentrations of 4.5, 14.3, 37.9, 33.4 and 39.0 mg/L, respectively, observed between 4 and 8 h [Hughes *et al.* 1991].

Toxicity It is safe to give doses of up to 3000 mg daily.

Half-life Plasma, between 60 and 70 h.

Volume of Distribution 0.6 L/kg.

Clearance Plasma, 0.15 mL/min/kg; also, reported as 1.56 L/h.

Protein Binding >99%.

Note For reviews of atovaquone see Haile, Flaherty [1993] and Spencer, Goa [1995].

Dose 750 mg as an oral suspension twice a day or 750 mg as tablets three times a day.

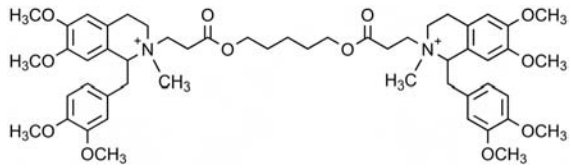
Atracurium

Skeletal Muscle Relaxant

$C_{53}H_{72}N_2O_{12}$ = 929.2

CAS—64228-79-1

IUPAC Name 2,2′-[1,5-Pentanediylbis[oxy(3-oxo-3,1-propanediyl)]]bis[1-[(3,4-dimethoxyphenyl)-methyl]-1,2,3,4-tetrahydro-6,7-dimethoxy-2-methylisoquinolinium]



Atracurium Besilate

$C_{53}H_{72}N_2O_{12}.2C_6H_5O_3S$ = 1243.5

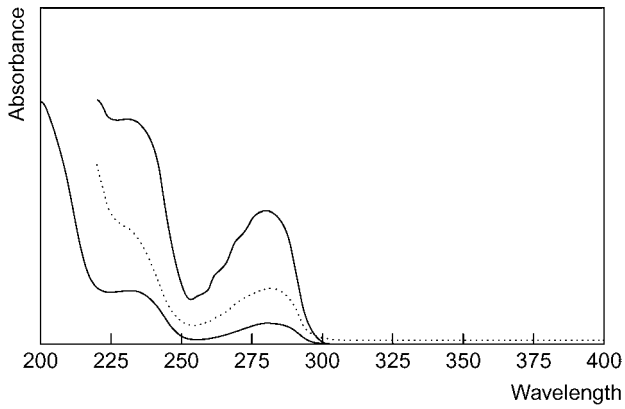
CAS—64228-81-5

Synonyms Atracurium besylate; BW-33A.

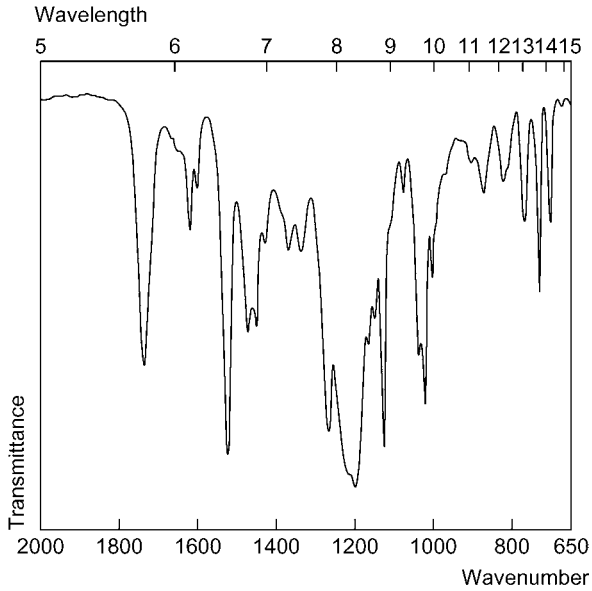
Proprietary Name *Tracrium*

Chemical Properties An off-white powder. Mp 85° to 90°. Softens at 60°.

Ultraviolet Spectrum Ethanol—231, 280 nm; basic—281 nm.



Infrared Spectrum Principal peaks at wavenumber 1725, 1513, 1189 cm^{-1} (KBr pellets).



Quantification

Plasma **HPLC** Column: μPorasil (150 × 3.9 mm i.d.). Mobile phase: acetonitrile : 0.002 mol/L sulfuric acid (50:50), flow rate 2 mL/min. UV detection (λ=210 nm). Retention time: 3.5 min. Limit of detection, 0.025 mg/L for atracurium and laudanosine [Bjorksten *et al.* 1990]. Column: Spherisorb C_8 (100 × 4.9 mm, 5 μm). Mobile phase: (A) acetonitrile : methanol : 0.03 mol/L dibasic potassium phosphate buffer (37.5:5:57.5); (B) acetonitrile : methanol : 0.1 mol/L dibasic potassium phosphate buffer (37.5:15:47.5), final pH 5. Elution programme: 0 to 100% (B) over 8 min, flow rate 1.7 mL/min. Fluorescence detection (λ_{ex}=240 nm, λ_{em}=320 nm). Retention time: 6.2 min. Limit of detection, 0.02 mg/L for atracurium, 0.01 mg/L for laudanosine [Varin *et al.* 1990]. Fluorescence detection. Limit of detection, about 0.01 mg/L for atracurium, 0.005 mg/L for laudanosine [Simmonds 1985].

Disposition in the Body After IV administration, it is inactivated in plasma by Hofmann elimination, a non-enzymatic breakdown process occurring at physiological pH and temperature, to produce laudanosine and other metabolites. It also undergoes ester hydrolysis by non-specific plasma esterases. The metabolites have no neuromuscular blocking activity although laudanosine may have some stimulatory action on the CNS. Excreted in urine and bile, mostly as metabolites. It crosses the placenta.

Therapeutic Concentration The serum therapeutic concentration range is 0.1 to 1.0 mg/L.

A study in 20 male and female subjects undergoing major surgery, with a mean age of 59.4 years, found that 90% paralysis was maintained by a mean infusion rate of 4.25 μg/kg/min of atracurium (mean plasma concentration 1.13 mg/L) [Beemer *et al.* 1990].

A study in 20 subjects on mechanical ventilation receiving atracurium infusion found that stable neuromuscular blockade was associated with a plasma-atracurium concentration of 1.5 mg/L, but this had increased to 5.3 mg/L at 38 h. Plasma-laudanosine concentrations were measured in 6 of the subjects and the maximum concentrations measured ranged from 1.9 to 5.1 mg/L [Yate *et al.* 1987].

An atracurium infusion was given for 71 days to a 35-year-old IV drug abuser who contracted tetanus. The mean rate of infusion over the period was 1.3 mg/kg/h. There was no evidence of accumulation of laudanosine as plasma concentration at the end of the infusion was 0.985 mg/L. The plasma-atracurium concentration was 1.5 mg/L [Peat *et al.* 1988].

Toxicity

A 59-day-old infant weighing 2.75 kg received 37 mg of atracurium over 75 min when the syringe driver was set up incorrectly. The infant made a full recovery by 135 min after the infusion was stopped. It was estimated that the plasma-laudanosine concentration at the time neuromuscular function recovered was about 19 mg/L. No atracurium was detectable in the plasma sample taken [Charlton *et al.* 1989].

A 3-week-old ventilated neonate weighing 3.9 kg received a bolus overdose of atracurium of 5.1 mg/kg in error. Intense bronchospasm occurred, systolic blood pressure fell to 28 mmHg and pulse rate increased from 140/min to 180/min. The neonate recovered within 3 h following treatment with adrenaline and ventilatory support [Durcan, Carter 1986].

Half-life Plasma, atracurium 20 min; laudanosine 3 h.

Volume of Distribution 0.16 L/kg.

Clearance Plasma, 4.4 to 6.5 mL/min/kg.

Protein Binding 80%

Dose Initially 300 to 600 μg/kg of atracurium besilate intravenously with subsequent doses of 100 to 200 μg/kg as necessary; 5 to 10 μg/kg/min has been given as a continuous IV infusion.

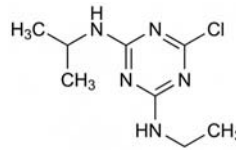
Atrazine

Herbicide

$C_8H_{14}ClN_5$ = 215.7

CAS—1912-24-9

IUPAC Name 6-Chloro-*N*-ethyl-*N*′-(1-methylethyl)-1,3,5-triazine-2,4-diamine



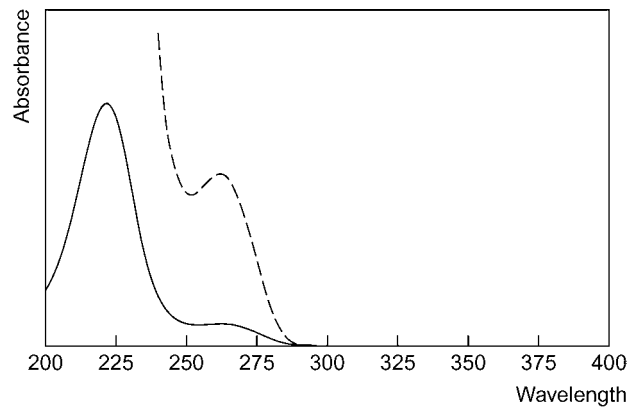
Chemical Properties Colourless crystals. Mp 171° to 174°. Practically insoluble in water; soluble 1 in 20 of chloroform, 1 in 80 of ether and 1 in 55 of methanol. pK_a 1.7. Log *P* (octanol/water), 2.6.

Thin-layer Chromatography System TA—R_f 0.77; system TAB—R_f 0.04; system TAC—R_f 0.08.

Gas Chromatography System GA—atrazine RI 1714, M (desethyl-) RI 1680, M (desethyl-deschloro-methoxy-) RI 1670; system GK—RRT 0.79(relative to caffeine).

High Performance Liquid Chromatography System HY—RI 401; system HAA—retention time 18.2 min; system HAO—*k* 10.75; system HAP—*k* 1.24.

Ultraviolet Spectrum Ethanol—263 nm (A^1_1=195b).



Infrared Spectrum Principal peaks at wavenumbers 1539, 1612, 1295, 804, 1161, 1121 cm^{-1} (KBr disk).

Mass Spectrum Principal ions at *m/z* 43, 58, 44, 200, 68, 215, 41, 42.

Quantification

Urine **HPLC** Limits of detection, 0.2 to 0.5 μg/L for atrazine and other pesticide metabolites [Baker *et al.* 2000]. Limit of detection, 0.5 μg/L for atrazine metabolites [Beeson *et al.* 1999]. For atrazine metabolites, see Buchholz *et al.* [1999].

Note For an ELISA for the quantification of atrazine and its major metabolites, see Lucas *et al.* [1993].

Disposition in the Body

Toxicity

In a fatality involving the ingestion of 500 mL of a herbicide mix containing atrazine (100 g), aminotriazole (25 g), ethylene glycol (25 g), and formaldehyde (0.15 g), the postmortem tissue concentrations of atrazine were reported to be: liver 32.04 μg/g, pancreas 30.99 μg/g, small intestine μg/g, kidney 97.62 μg/g, lung 79.53 μg/g, heart 15.27 μg/g, muscle 19.93 μg/g. At the time of death, about 3 days after ingestion, the plasma atrazine concentration was 1.49 mg/L [Pommery *et al.* 1993].

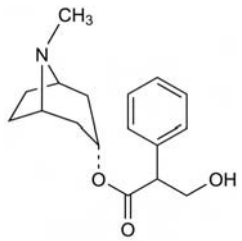
Atropine

Anticholinergic
$C_{17}H_{23}NO_3$ = 289.4
CAS—51-55-8

IUPAC Name [(1*R*,5*S*)8-Methyl-8-azabicyclo[3.2.1]octan-3-yl] 3-hydroxy-2-phenylpropanoate
Synonyms (±)-Hyoscyamine; (3-endo)-8-methyl-8-azabicyclo[3.2.1]oct-3-yl-α-(hydroxymethyl)benzene acetate; (1*R*,3*R*,5*S*,8*R*)-tropan-3-yl (*RS*)-tropate.
Proprietary Name *Atropinol*. Atropine and its salts are ingredients in and also used as adjuncts in many proprietary preparations [Sweetman 2007].



Chemical Properties An alkaloid obtained from *Duboisia* spp. and other solanaceous plants, or prepared by synthesis. Colourless crystals or white crystalline powder. Mp 114° to 118°. Soluble 1 in 455 of water, 1 in 50 of boiling water, 1 in 2 of ethanol, 1 in 1 of chloroform, 1 in 25 of ether and 1 in 27 of glycerol. pK_a 9.9 (20°). Log *P* (octanol), 1.8. Extraction yield (chlorobutane), 0.6 [Demme *et al.* 2005].

Atropine Sulfate

$(C_{17}H_{23}NO_3)_2,H_2SO_4,H_2O$ = 694.8
CAS—55-48-1 (anhydrous); CAS—5908-99-6 (monohydrate).
Proprietary Names *AtroPen*; *Atropisol*; *Atropocil*; *Atropt*; *Atrospan*; *Liotropina*; *Ocu-Tropine*; *Sal-Tropine*.
Chemical Properties Colourless crystals or white crystalline powder. It effloresces in dry air. Mp ≈190°, with decomposition, after drying at 135° for 15 min. Soluble 1 in 0.4 of water and 1 in 5 of ethanol; practically insoluble in chloroform and ether.

Colour Test Liebermann's reagent—red-orange.
Thin-layer Chromatography System TA—R_f 0.18; system TB—R_f 0.05; system TC—R_f 0.03; system TE—R_f 0.24; system TL—R_f 0.01; system TAE—R_f 0.05; system TAF—R_f 0.28 (acidified iodoplatinate solution—positive; Dragendorff spray—positive; Marquis test—pink).

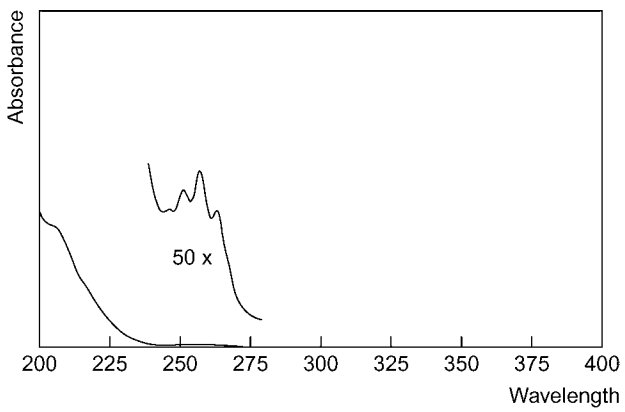
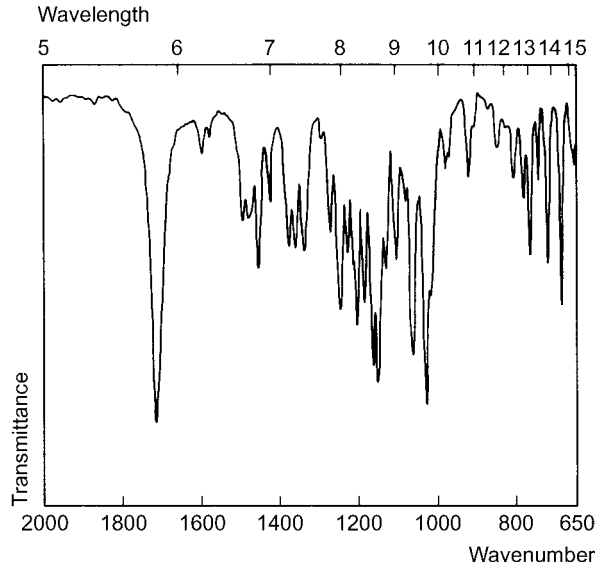
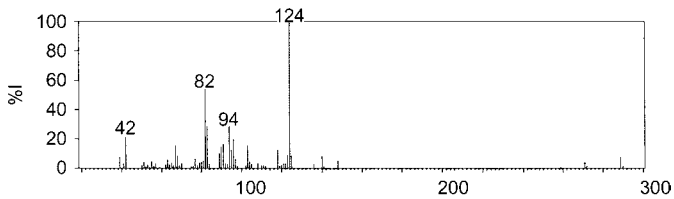
High Performance Liquid Chromatography System HA—*k* 3.9 (tailing peak); system HX—RI 306; system HY—RI 251; system HZ—RT 2.2 min; system HAA—RT 10.4 min.
Ultraviolet Spectrum Aqueous acid—252, 258 (A^1_1= 6.3 c), 264 nm. No alkaline shift.



Infrared Spectrum Principal peaks at wavenumbers 1720, 1035, 1153, 1163, 1063, 1204 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 124, 82, 94, 83, 42, 96, 103, 67.



Quantification

Blood **GC-MS** Column: cross-linked methyl silicone capillary (25 m × 0.2 mm i.d., 0.33 µm). Temperature programme: 100° to 240° at 20°/min. EI ionisation, SIM acquisition mode. Retention time: 1.7 min. Limit of quantification, 10 µg/L [Saady, Poklis 1989].

LC-MS Column: LiChroCART LiChrospher 60 RP-select B. Mobile phase: 0.1% formic acid in water and in acetonitrile. APCI. Atropine, fentanyl and scopolamine. Limit of quantification, 0.9 µg/L, limit of detection, 0.6–0.7 µg/L [Skulska *et al.* 2007].

CE Capillary: 50 cm. Buffer: borate-phosphate (pH 9.2) with 50 mol/L SDS. Limit of quantification, 0.2 µg/L, limit of detection, 0.06 µg/L for atropine (in presence of strychnine and tetracaine [Plaut, Staub 1998].

Plasma **HPLC** Column: ODS. Mobile phase: acetonitrile : 50 mmol/L potassium phosphate buffer (pH 3.0) containing 2 mmol/L sodium heptane sulfonate (16 : 84). UV detection (λ= 220 nm). Limit of quantification, 1 mg/L [Rbeida *et al.* 2005].

LC-MS Column: Atlantis T3 C_{18} (150 × 4.6 mm i.d., 5 µm). Mobile phase: 0.1% formic acid : acetonitrile-water and 0.1% formic acid (80 : 20, 77 : 23 to 62 : 38 at 5 min to 20 : 80 at 6 min for 1 min to 77 : 23 at 7.5 min for 1 min), flow rate 1.0 mL/min. ESI, positive ion mode, MRM acquisition mode. Limit of quantification, 0.05 µg/L, limit of detection, 0.01 µg/L [John *et al.* 2010]. Column: XTerraMS C_8 (100 × 2.1 mm i.d., 3.5 µm). Mobile phase: 2 mmol/L formate buffer (pH 3) : acetonitrile (99 : 1 for 2 min to 98 : 2 at 3 min to 5 : 95 at 3.1 min for 7.5 min to 99 : 1 at 8 min until 11 min), flow rate 0.2 mL/min. ESI, positive ion mode, MRM acquisition mode. Limit of quantification, 0.25 µg/L, limit of detection, 0.075 µg/L [Abbara *et al.* 2008]. Column: C_8 Superspher 60 RP select B (125 × 2 mm i.d.). Mobile phase: 50 mmol/L ammonium formate (pH 3.5) : acetonitrile (90 : 10 for 2 min to 20 : 80 at 5 min for 2 min to 90 : 10 at 7.01 min until 10 min), flow rate 0.4 mL/min for 2 min to 0.6 mL/min at 2.01 min to 0.4 mL/min at 7.01 min. APCI or ESI. Limit of quantification, 5 µg/L (APCI) and 0.1 µg/L (ESI) [Beyer *et al.* 2007].

Radioimmunoassay Limit of detection, 2.5 µg/L for atropine and hyoscyamine [Virtanen *et al.* 1980].

Serum **GC-MS** Column: HP-5MS (30 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 0.8 mL/min. Temperature programme: 50° for 1 min to 300° at 20°/min for 5 min. EI ionisation at 70 eV, SIM acquisition mode. Limit of detection, 5 µg/L for tropane alkaloids [Namera *et al.* 2002].

LC-MS Column: Hypurity C_{18} (50 × 2.1 mm i.d., 5 µm). Mobile phase: aqueous buffer (10 g/L ammonium acetate, 15 mL/L acetic acid and 2 mL/L trifluoroacetic anhydride) : water : acetonitrile (5 : 95 : 0 for 1 min to 5 : 0 : 95 at 5 min to 5 : 95 : 0 at 5.5 min), flow rate 0.2 mL/min. ESI, positive ion mode, SRM acquisition mode. Limit of quantification, 5 µg/L [Boermans *et al.* 2006].

Radioimmunoassay See Plasma [Virtanen *et al.* 1980].

Urine **GC-MS** See Serum [Namera *et al.* 2002].

LC-MS See Blood [Skulska *et al.* 2007]. See Serum [Boermans *et al.* 2006].

Stomach Contents **CE** See Blood [Plaut, Staub 1998].

A

Biological Specimens **HPLC** Column: TSK gel ODS-120A (250 × 4.6 mm i.d., 5 μm). Mobile phase: acetonitrile : water (2 : 8) containing 6 mmol/L phosphoric acid (pH 2.7), flow rate 1.0 mL/min. UV detection (λ = 215 nm). Limit of detection, 8.5 μg/L [Okuda *et al.* 1991].

Disposition in the Body Atropine is readily absorbed from mucous membranes, skin and the gastrointestinal tract but not from the stomach. Approximately 80–90% of a dose is excreted in the urine in 24 h, 50% of the dose as unchanged drug, <2% as tropic acid and tropine, and ~30% as unknown metabolites. Traces of the dose are eliminated in the faeces.

Therapeutic Concentration

Following an IV dose of 1 mg atropine to 6 subjects, plasma concentrations of ~0.25 mg/L were observed at 2 min, decreasing to 0.005 mg/L at 20 min; following an IM dose of 1 mg to 4 subjects, peak plasma concentrations of ~0.003 mg/L were attained in 30 min [Berghem *et al.* 1980].

Toxicity The amount of a toxic dose appears to vary considerably with individuals. Fatalities are reported to have occurred with doses of 50–100 mg, but recovery has occurred after administration of 1 g; doses of 10 mg or less may be lethal in children or in susceptible individuals.

A man was found dead after having ingested an unknown amount of atropine sulfate tablets. Blood contained 0.2 mg/L atropine and urine 1.5 mg/L [Corbett *et al.* 1978].

Of 240 children accidentally injected with automatic atropine injectors, which had been distributed in Israel during the Persian Gulf Crisis as an antidote to chemical warfare agents, 20 (8%) showed signs of severe atropinization; no fatalities occurred. High serum atropine levels of 0.0062 to 0.061 mg/L were noted approximately 1 h after injection in six of the children [Amitai *et al.* 1992].

A 58-year-old man who ingested 500 mg atropine sulfate became unconscious within 1 h and was admitted to hospital. Although he was only prescribed 0.5 mg atropine sulfate orally he was inadvertently given 500 mg dispensed by the pharmacy. At 4 h after ingestion, his serum atropine concentration was 244 μg/L. He recovered after treatment with IV fluids, sedation and ventilator control [Otani *et al.* 2004].

A patient who became restless and excitable after eating boiled jimson weed (*Datura stramonium*) had serum levels of 31.3 μg/L atropine and 30.6 μg/L scopolamine, which decreased to 6.7 and 8.5 μg/L, respectively, after 2 h. The patient was treated with gastric lavage, activated charcoal and neostigmine [Matsuda *et al.* 2006].

A 17-year-old man who ingested *D. stramonium* had a blood concentration of 1.7 μg/L atropine at 12 h; a 17-year-old woman who had also ingested *D. stramonium* had urine levels of 114 μg/L atropine at day 1 [Marc *et al.* 2007].

A 46-year-old man who had ingested three handfuls of *Atropa belladonna* showed symptoms of toxicity (disorientation, aggressiveness, tachycardia) within 6 h; he was treated with diazepam, physostigmine and activated charcoal. After an initial improvement, his condition deteriorated, requiring sedation and continuous physostigmine, before complete recovery within 2 days. Muscarinic receptor total binding equivalent to binding of 130 μg/L atropine was found in the early phase of hospitalisation [Bogan *et al.* 2009].

Seven cases of the anticholinergic syndrome associated with ingestion of cooked vegetables containing *Datura innoxia* have been reported. Atropine and scopolamine were detected in urine and vegetable samples but not in plasma (possibly because of delay in sample collection). Atropine concentrations in urine ranged from 67.1–691.7 μg/L and the cooked vegetables contained 0.8 μg/g [Papoutsis *et al.* 2010].

Half-life Plasma half-life, ~2–4 h; a longer terminal phase of 13–38 h has also been reported.

Volume of Distribution ~2–3 L/kg.

Clearance Plasma clearance, ~8 mL/min/kg.

Protein Binding ~50%.

Note For the symptoms of atropine and other toxic alkaloid poisoning and a review of methods of their detection in biological fluids, see Beyer *et al.* [2009].

Dose Usually 0.25 to 2 mg atropine sulfate daily.

Atropine Methobromide

Anticholinergic

$C_{18}H_{26}BrNO_3$ = 384.3

CAS—2870-71-5

Synonyms Atropine methylbromide; methylatropine bromide; mydriasine.

Chemical Properties Colourless crystals or a white crystalline powder. Mp 222° to 223°. Soluble 1 in 1 of water and 1 in 20 of ethanol; very slightly soluble in dehydrated alcohol; almost insoluble in chloroform and ether. Log *P* (octanol/water), −1.6.

Colour Tests Aromaticity (method 2)—colourless/yellow; Liebermann's reagent—orange.

Atropine Methonitrate

Anticholinergic

$C_{18}H_{26}N_2O_6$ = 366.4

CAS—52-88-0

Synonym Methylatropine nitrate

Chemical Properties Colourless crystals or a white crystalline powder. Mp 163°. Soluble 1 in less than 1 of water and 1 in 13 of ethanol; very slightly soluble in chloroform and ether. Log *P* (octanol/water), −2.2. Aqueous solutions are unstable.

Colour Tests Aromaticity (method 2)—colourless/violet (transient); Liebermann's reagent—orange.

Thin-layer Chromatography System TA—R_f 0.02; system TB—R_f 0.00; system TE—R_f 0.00; system TN—R_f 0.95; system TO—R_f 0.35; system TAE—R_f 0.00 (acidified iodoplatinate solution, positive).

High Performance Liquid Chromatography System HX—RI 299.

Ultraviolet Spectrum Aqueous acid—252 nm (A^1_1=about 5), 258 nm (A^1_1=about 5), 264 nm (A^1_1=about 4).

Infrared Spectrum Principal peaks at wavenumbers 1159, 1045, 1718, 1176, 700, 1212 cm^{-1} (Nujol mull).

Atropine Oxide

Anticholinergic

$C_{17}H_{23}NO_4$ = 305.4

CAS—4438-22-6

IUPAC Name (3-*endo*)-8-Methyl-8-azabicyclo[3.2.1]oct-3-yl-α-(hydroxymethyl)-benzeneacetate *N*-oxide

Synonyms Aminoxytropine tropate; atropine aminoxide; atropine *N*-oxide.

Chemical Properties A very hygroscopic, crystalline powder. Mp 127° to 128°; it decomposes at 135°. Soluble in ethanol and chloroform; practically insoluble in ether.

Atropine Oxide Hydrochloride

$C_{17}H_{23}NO_4$,HCl = 341.8

CAS—4574-60-1

Proprietary Name *Génatropine*

Chemical Properties Crystals. Mp 192° to 193°.

Thin-layer Chromatography System TA—R_f 0.21 (acidified iodoplatinate solution, positive).

Infrared Spectrum Principal peaks at wavenumbers 1164, 1730, 1118, 1026, 1056, 1195 cm^{-1}.

Aviptadil

Hormone, Muscle Relaxant
$C_{147}H_{238}N_{44}O_{42}S$ = 3325.8
CAS—40077-57-4

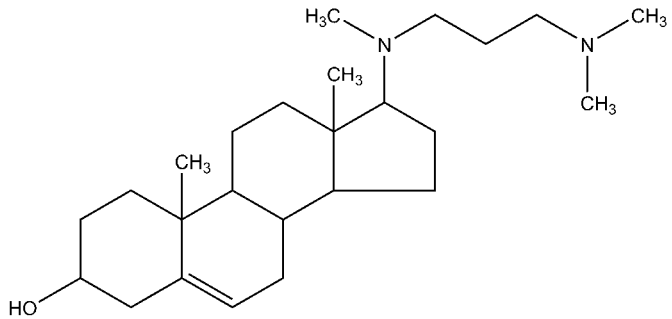
Synonym Vasoactive intestinal octacosapeptide (swine)
Proprietary Name *Invicorp*
Disposition in the Body Vasoactive intestinal peptide acts as a hormone and neurotransmitter in various parts of the body; it is a potent relaxant of smooth muscle and has vasodilator and bronchodilator properties as well as stimulating the gastrointestinal tract to increased secretion.
Dose Has been used in different doses in the management of acute oesophageal food impaction, and for the treatment of acute respiratory distress syndrome, pulmonary arterial hypertension, acute lung injury, and chronic thromboembolic pulmonary hypertension. It has also been used as a combination product with phentolamine for erectile dysfunction.
Note For a review of the clinical trials of aviptadil, see Keijzers [2001].

Keijzers GB (2001). Aviptadil (Senatek). *Curr Opin Investig Drugs* 2: 545–549.

Azacosterol

Anticholesteraemic, Contraceptive (Veterinary)
$C_{25}H_{44}N_2O$ = 388.6
CAS—1249-84-9

IUPAC Name 17β-{[3-(Dimethylamino)propyl]methylamino}androst-5-en-3β-ol
Synonyms 20,25-Diazacholesterol; SC-12937.



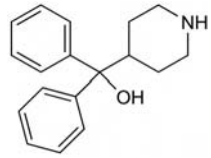
Chemical Properties Slightly soluble in water (7.05 mg/L). Log *P* (octanol/water), 4.35 [Meylan, Howard 1995]. Extracted by organic solvents from aqueous alkaline solutions.
Colour Tests Ammonium molybdate test—dull orange→green (limit of detection 0.1 µg); Ammonium vanadate test—orange→blue (limit of detection 0.1 µg); sulfuric acid-formaldehyde test—brown-orange (limit of detection 0.1 µg).
Infrared Spectrum Principal peaks at wavenumbers 1065, 1455, 1345 cm^{-1} (KBr disk).
Quantification
Note For a HPLC method for the analysis of azacosterol in quail feed or serum, see Johnston *et al.* [2001].

Johnston JJ *et al.* (2001). Determination of DiazaCon in quail feed and quail serum by ion pair reversed-phase chromatography. *J AOAC Int* 84: 634–639.
Meylan WM, Howard PH (1995). Atom/fragment contribution method for estimating octanol-water partition coefficients. *J Pharm Sci* 84: 83–92.

Azacyclonol

Tranquilliser
$C_{18}H_{21}NO$ = 267.4
CAS—115-46-8

IUPAC Name α,α-Diphenyl-4-piperidinemethanol



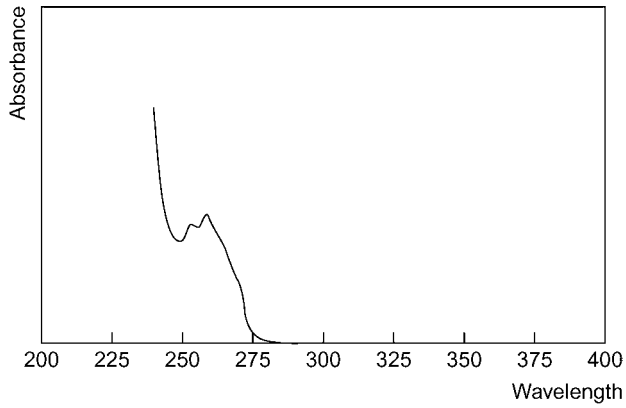
Chemical Properties Crystals. Mp 160° to 161°. Log *P* (octanol/water), 3.4.

Azacyclonol Hydrochloride

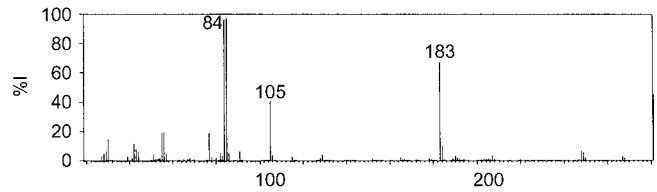
$C_{18}H_{21}NO,HCl$ = 303.8
CAS—1798-50-1
Synonym Azacyclonolium chloride
Proprietary Names *Frenoton*; *Frenquel.*

Chemical Properties Small white crystals or crystalline powder. Mp 270° to 281°. Soluble 1 in 200 of water and 1 in 1000 of ethanol; practically insoluble in acetone, chloroform, ether and light petroleum.

Colour Tests Liebermann's reagent—brown; Mandelin's test—red; Marquis test—yellow.
Thin-layer Chromatography System TA—R_f 0.10; system TB—R_f 0.00; system TC—R_f 0.03; system TE—R_f 0.14; system TL—R_f 0.01; system TAE—R_f 0.03; system TAL—R_f 0.40 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—RI 2243; system GB—RI 2361.
High Performance Liquid Chromatography System HA—*k* 1.2; system HAX—retention time 8.7 min; system HAY—retention time 4.5 min.
Ultraviolet Spectrum Aqueous acid—253, 259 nm (A^1_1=17.4a).



Infrared Spectrum Principal peaks at wavenumbers 702, 745, 1316, 1063, 971, 1155 cm^{-1} (KBr disk).
Mass Spectrum Principal ions at *m/z* 85, 84, 183, 105, 56, 77, 55, 30.

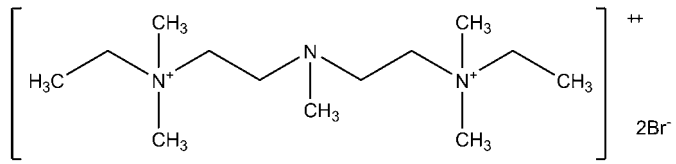


Dose Azacyclonol hydrochloride has been given in doses of 100 to 800 mg daily.

Azamethonium Bromide

Quaternary Ammonium, Ganglion Blocker, Antihypertensive
$C_{13}H_{33}Br_2N_3$ = 391.3
CAS—306-53-6; 60-30-0 (azamethonium)

IUPAC Name 2,2′-Methyliminobis(diethyldimethylammonium) dibromide
Synonyms Ciba 9295; pentamethazene bromide; pentamin.
Proprietary Name *Pendiomide*



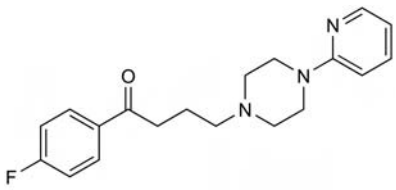
Chemical Properties White hygroscopic crystalline powder. Mp 212° to 215°. Soluble in water and ethanol; almost insoluble in ether.
Colour Test Vitali's test—pale brown/yellow (limit of detection 0.25 µg).
Thin-layer Chromatography System T1—R_f 0.00 (location reagent acidified iodoplatinate spray, positive reaction).
Infrared Spectrum Principal peaks at wavenumbers 1477, 1014, 968 or 1620 cm^{-1} (KBr disk).
Disposition in the Body
Toxicity LD_{50} (oral) in mice: 2.5 g/kg.

Azaperone

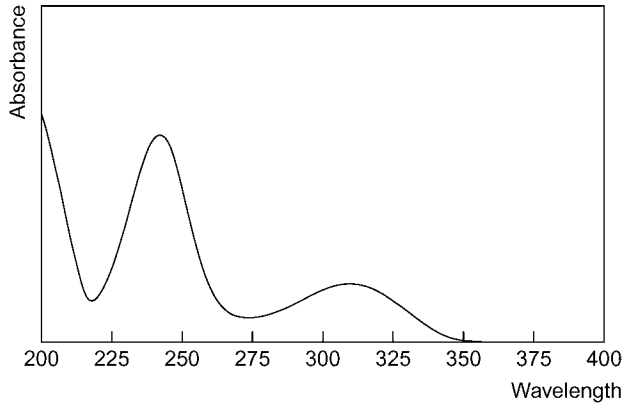
Tranquilliser (Veterinary)
$C_{19}H_{22}FN_3O$ = 327.4
CAS—1649-18-9

A

IUPAC Name 1-(4-Fluorophenyl)-4-[4-(2-pyridinyl)-1-piperazinyl]-1-butanone
Proprietary Names *Stresnil*; *Suicalm*. It is an ingredient of *Fentazin*. (All veterinary.)



Chemical Properties A white to yellowish-white microcrystalline powder. Mp 73° to 75°. Practically insoluble in water; soluble 1 in 29 of ethanol, 1 in 4 of chloroform and 1 in 31 of ether; soluble in dilute organic acids. Log *P* (octanol/water), 3.3.
Colour Tests Cyanogen bromide—orange; Mandelin's test—yellow.
Thin-layer Chromatography System TA—R_f 0.66; system TB—R_f 0.30; system TE—R_f 0.72; system TL—R_f 0.09; system TAE—R_f 0.65; system TAJ—R_f 0.54; system TAK—R_f 0.00; system TAL—R_f 0.67 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—RI 2705; system GV—retention time 19.0 min.
High Performance Liquid Chromatography System HX—RI 319.
Ultraviolet Spectrum Aqueous acid—242 nm (A^1_1=800a), 312 nm; methanol—247 nm (A^1_1=1260b), 300 nm (A^1_1=200b).



Infrared Spectrum Principal peaks at wavenumbers 1587, 1669, 775, 1236, 1222, 1152 cm^{-1} (KBr disk).
Mass Spectrum Principal ions at *m/z* 107, 165, 123, 95, 121.
Quantification
Urine **GC–MS** Animal urine (azaperone and other tranquillisers). Limit of detection, 5 µg/L for azaperone [Olmos-Carmona, Hernandez-Carrasquilla 1999].
Kidney **GC–MS** For azaperone, azaperol, and carazolol in swine kidney, see Fluchard *et al.* [2000].
Muscle **GC–MS** See Kidney Fluchard *et al.* [2000].

Fluchard D *et al.* (2000). Determination of a method for detecting and quantifying azaperone, azaperol and carazolol in pig tissues by liquid chromatography-tandem mass spectrometry. *J Chromatogr B Biomed Sci Appl* 744: 139–147.

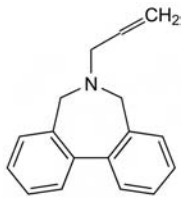
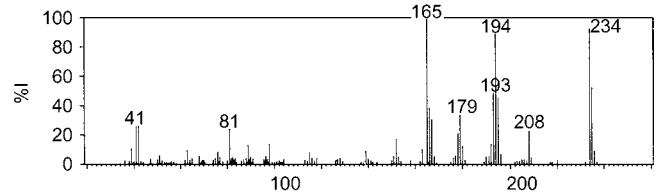
Azapetine

Vasodilator
$C_{17}H_{17}N$ = 235.3
CAS—146-36-1
IUPAC Name 6-Allyl-6,7-dihydro-5*H*-dibenz[*c*,*E*]azepine
Synonym Azepine



Azapetine Phosphate

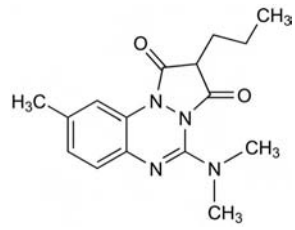
$C_{17}H_{17}N,H_3PO_4$ = 333.3
CAS—130-83-6
Chemical Properties Crystals. Mp 211° to 215°, with decomposition. Soluble at least 1 in 100 of water.
Colour Test Mandelin's test—brown.
Thin-layer Chromatography System TA—R_f 0.70; system TB—R_f 0.57; system TC—R_f 0.67; system TE—R_f 0.78; system TL—R_f 0.56; system TAE—R_f 0.14; system TAJ—R_f 0.59; system TAK—R_f 0.26; system TAL—R_f 0.90 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—RI 1939.
Ultraviolet Spectrum Aqueous acid—248 nm.
Infrared Spectrum Principal peaks at wavenumbers 748, 918, 1063, 990, 1111, 1639 cm^{-1} (KBr disk).
Mass Spectrum Principal ions at *m/z* 165, 234, 194, 235, 193, 196, 166, 179.



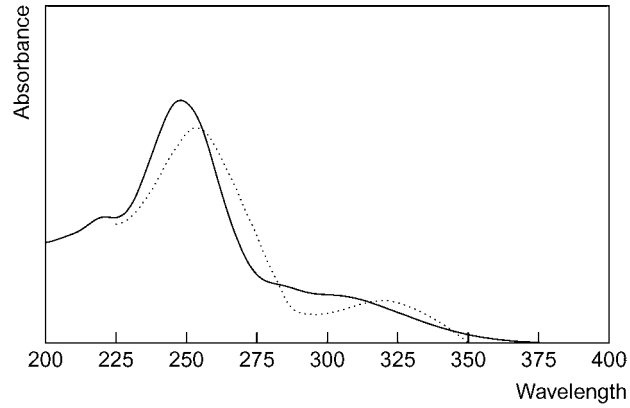
Dose The equivalent of 75 to 225 mg of azapetine has been given daily.

Azapropazone

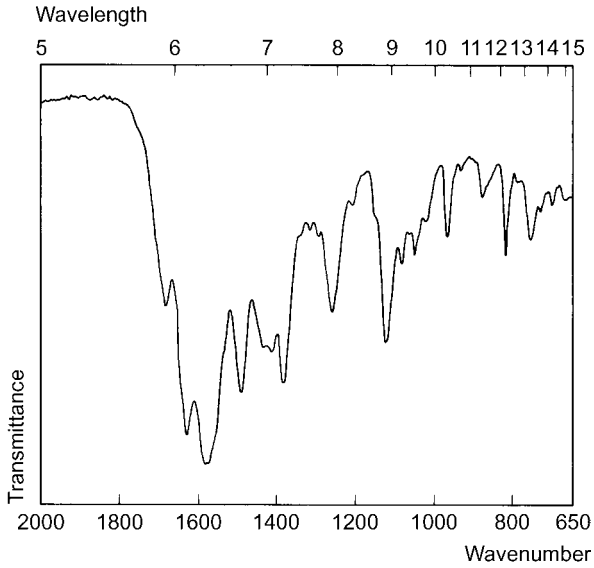
Analgesic
$C_{16}H_{20}N_4O_2,2H_2O$ = 336.4
CAS—13539-59-8 (anhydrous)
IUPAC Name 5-(Dimethylamino)-9-methyl-2-propyl-1*H*-pyrazolo[1,2-*a*][1,2,4]-benzotriazine-1,3(2*H*)-dione dihydrate
Synonym Apazone
Proprietary Names *Prolixan(a)*; *Rheumox*; *Tolyprin*.



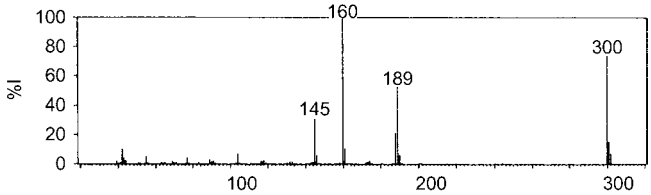
Chemical Properties Almost colourless crystals. Mp 228°; 247° to 248° (dihydrate). Log *P* (octanol/pH 7.4), 1.0.
Colour Tests Liebermann's reagent—grey-green; Mandelin's test—grey-green.
Thin-layer Chromatography System TA—R_f 0.68; system TB—R_f 0.53; system TC—R_f 0.05; system TE—R_f 0.08; system TL—R_f 0.67; system TAE—R_f 0.88; system TAJ—R_f 0.11; system TAK—R_f 0.06; system TAL—R_f 0.61.
Gas Chromatography System GA—RI 2461; system GF—RI 3010.
High Performance Liquid Chromatography System HZ—retention time 2.0 min.
Ultraviolet Spectrum Azapropazone dihydrate: aqueous acid—250 nm (A^1_1=1040b); aqueous alkali—255 nm (A^1_1=1080b), 325 nm.



Infrared Spectrum Principal peaks at wavenumbers 1590, 1640, 1500, 1133, 1270, 1695 cm^{-1}.



Mass Spectrum Principal ions at *m/z* 160, 300, 189, 145, 188, 301, 161, 42.



Quantification
Plasma **HPLC** UV detection. Limit of detection, 400 µg/L for azapropazone, 1.5 to 3 mg/L for 6-hydroxyazapropazone [Kline *et al.* 1983].

Ultraviolet spectrophotometry For comparison with gas chromatographic and colorimetric methods, see Leach [1976].
Serum **Colorimetry** Limit of detection, 10 mg/L [Farrier 1974].
Urine **HPLC** See Plasma [Kline *et al.* 1983].
Disposition in the Body Readily absorbed after oral administration. About 95% of a dose is excreted in the urine, of which about 60% is unchanged drug and about 20% is the inactive metabolite, 6-hydroxyazapropazone.
Therapeutic Concentration

After a single oral dose of 600 mg, administered to 6 subjects, plasma concentrations of 34 to 54 mg/L (mean 43) were attained in 4 h [Ritch *et al.* 1982].

Steady-state plasma concentrations of 32 to 89 mg/L (mean 57) were reported during the daily administration of 800 mg to 10 subjects [Thune 1976].

Half-life Plasma half-life, 8 to 24 h (mean 15), increased in elderly subjects and in subjects with impaired renal or liver function.
Volume of Distribution About 0.2 L/kg.
Clearance Plasma clearance, 0.1 to 0.2 mL/min/kg.
Protein Binding About 99%.
Dose 0.6 to 1.2 g daily.

Farrier DS (1974). Spectroscopic methods for the determination of azapropazone in serum developed and evaluated using radio-isotopic techniques. *Arzneimittelforschung* 24: 747–751.

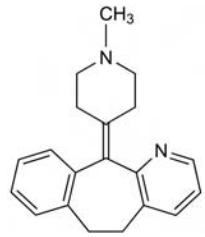
Azatadine

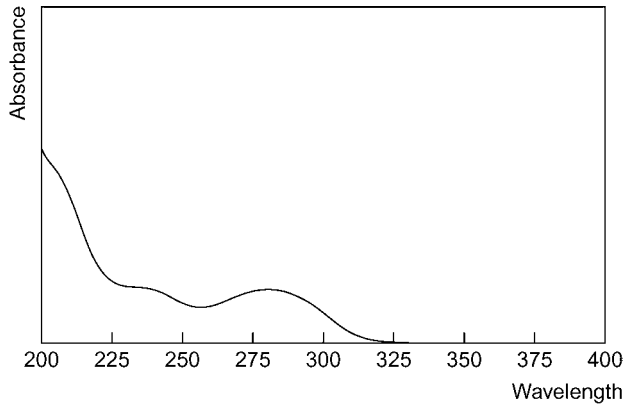
Antihistamine
$C_{20}H_{22}N_2 = 290.4$
CAS—3964-81-6
IUPAC Name 6,11-Dihydro-11-(1-methyl-4-piperidinylidene)-5*H*-benzo[5,6]cyclohepta-[1,2-*b*]pyridine



Chemical Properties Log *P* (octanol/water), 3.6.

Azatadine Maleate
$C_{20}H_{22}N_2,2C_4H_4O_4 = 522.6$
CAS—3978-86-7
Proprietary Names *Idulamine*; *Idulian*; *Lergocil*; *Optimine*; *Zadine*.
Chemical Properties A white crystalline powder. Mp 145° to 154°. Soluble in water, ethanol, chloroform, dimethylformamide and methanol; practically insoluble in ether.

Colour Tests Cyanogen bromide—pink; Marquis test—violet.
Thin-layer Chromatography System TA—R_f 0.39 (acidified potassium permanganate solution, strong reaction).
Gas Chromatography System GA—azatadine RI 2377, M (OH-alkyl-)-H_2O- RI 2410, M (OH-alkyl-)-AC- RI 2520, M (OH-aryl-)-AC- RI 2540, M (nor-)-AC- RI 2720; system GB—azatadine RI 2499.
High Performance Liquid Chromatography System HAX—retention time 10.7 min; System HAY—retention time 4.6 min.
Ultraviolet Spectrum Aqueous acid—283 nm (A_1^1=330b).

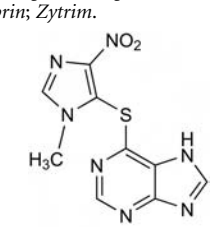


Infrared Spectrum Principal peaks at wavenumbers 752, 1271, 1124, 803, 984, 795 cm^{-1} (KBr disk).
Quantification
Urine **HPLC** For UV detection, see Alton *et al.* [1987].
Dose 2 to 4 mg of azatadine maleate daily.

Alton KB *et al.* (1987). High-performance liquid chromatographic assay for azatadine in human urine. *J Chromatogr* 385: 249–259.

Azathioprine

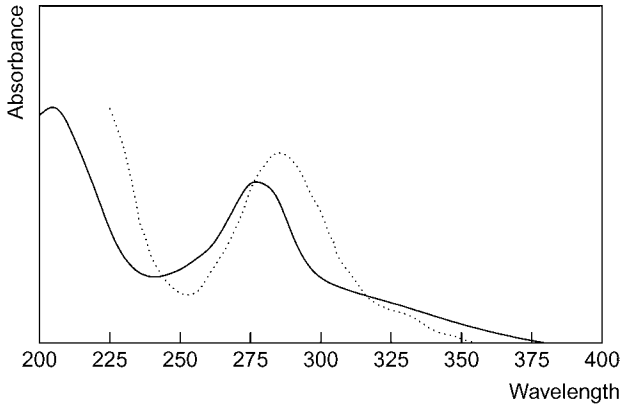
Immunosuppressant
$C_9H_7N_7O_2S = 277.3$
CAS—446-86-6
IUPAC Name 6-[(1-Methyl-4-nitro-1*H*-imidazol-5-yl)thio]-1*H*-purine
Proprietary Names *Aseroprim*; *Azahexal*; *Azamun(e)*; *Azatrilem*; *Azopi*; *Azopine*; *Berkaprine*; *Immunoprin*; *Imuprin*; *Imuran*; *Imurek*; *Imurel*; *Oprisine*; *Satedon*; *Thioprine*; *Tiosalprin*; *Zytrim*.



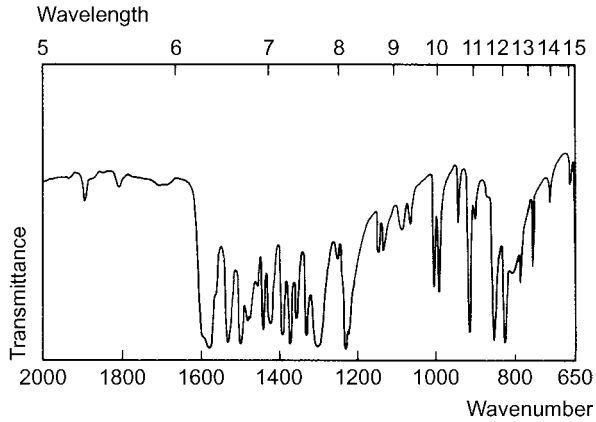
Chemical Properties A pale yellow powder. Mp about 238°, with decomposition. Practically insoluble in water; very slightly soluble in ethanol and chloroform; sparingly soluble in dilute mineral acids; soluble in dilute solutions of alkali hydroxides but decomposes in stronger solutions. pK_a 8.2 (25°). Log *P* (octanol/water), 0.1. Extraction yield (chlorobutane), 0 [Demme *et al.* 2005].

A

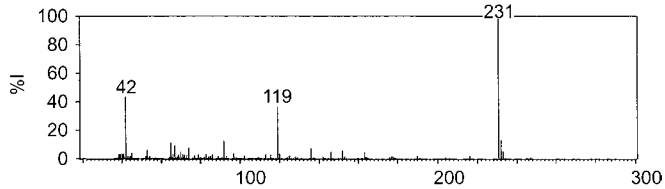
Thin-layer Chromatography System TA—R_f 0.53; system TB—R_f 0.03; system TC—R_f 0.08; system TE—R_f 0.06; system TL—R_f 0.04; system TAD—R_f 0.71; system TAE—R_f 0.80.
High Performance Liquid Chromatography System HX—RI 323.
Ultraviolet Spectrum Aqueous acid—280 nm (A^{1}_{1}=600a); aqueous alkali—285 nm.



Infrared Spectrum Principal peaks at wavenumbers 1237, 1306, 1580, 832, 1500, 1531 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 231, 42, 119, 232, 92, 65, 67, 74.



Quantification
Blood **HPLC** For azathioprine metabolites, see Dervieux and Boulieu [1998]. For azathioprine metabolites, see Weller *et al.* [1995].
Plasma **HPLC** Azathioprine and 6-mercaptopurine. Limit of detection, <5 µg/L for azathioprine [Van Os *et al.* 1996]. Azathioprine metabolites. Limit of detection, 5 µg/L [Weller *et al.* 1995]. UV detection. Limit of detection, 40 µg/L for azathioprine, 5 µg/L for mercaptopurine [Ding, Benet 1979].

Spectrofluorimetry Azathioprine and mercaptopurine. Limit of detection, 10 µg/L [Maddocks 1979].
Serum **HPLC** UV detection. Limit of detection, <2.5 ng [Binscheck *et al.* 1996].
Urine **HPLC** For azathioprine metabolites, see Weller *et al.* [1995].
Biological Fluids **HPLC** For thiopurine metabolites of azathioprine, see Boulieu *et al.* [1993].
Disposition in the Body Absorbed after oral administration and distributed throughout the body. It is readily metabolised to mercaptopurine, which is the major active metabolite, and to 1-methyl-4-nitro-5-(*S*-glutathionyl)-imidazole; other metabolites include 1-methyl-4-nitroimidazole, 1-methyl-4-nitro-5-thioimidazole and 6-thiouric acid; mercaptopurine is further metabolised to its ribonucleotide, thioinosinic acid, which is the active moiety. About 50% of a dose is excreted in the urine in 24 h, mainly as thiouric acid and other metabolites, with about 10% consisting of unchanged drug; about 12% of a dose is eliminated in the faeces in 48 h.
Therapeutic Concentration
After daily oral doses of 50 to 100 mg to 3 renal transplant patients, peak steady-state plasma concentrations of 0.05 to 0.08 mg/L of mercaptopurine were reported 1 h after a dose [Ding, Benet 1979].

Half-life Plasma half-life, azathioprine about 3 h, mercaptopurine about 0.5 to 1.5 h.
Protein Binding About 30%.
Dose 1 to 5 mg/kg daily, orally.

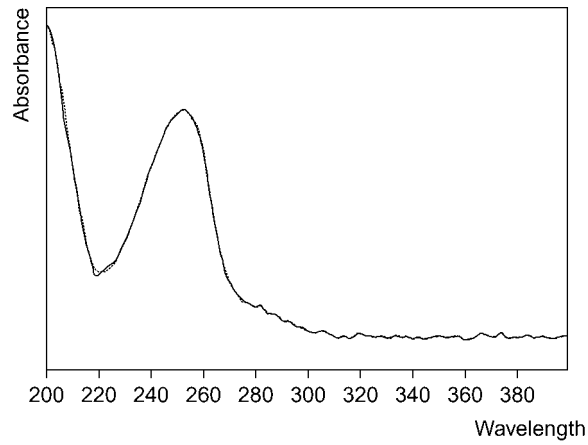
Azide

Anion
HN_3 = 22

Synonym Hydrazoic acid
Chemical Properties Characteristic pungent odour. Bp 37°. pK_a 4.7 [Baselt 2008].

Sodium Azide
N_3Na = 65.01
CAS—26628-22-8
Synonym Smite
Chemical Properties Colourless hexagonal crystals. Very soluble in water; soluble in liquid ammonia; slightly soluble in alcohol; insoluble in ether. Used in the preparation of hydrazoic acid, lead azide, pure sodium; as preservative for laboratory reagents and urine specimens; as a propellant for inflating automotive safety bags; as an agricultural nematocide, herbicide; in fruit rot control.

Colour Test Add 400 µL of test solution to 400 µL of $CuCl_2$ (0.4 g of hydrated cupric chloride in 20 mL dH_2O). Centrifuge. Add 500 µL 0.5 mol/L NaOH. Centrifuge—Sodium azide initially results in a bright green solution with a dark brown precipitate (if present). Following NaOH, there is a green flash followed by a milky blue solution. After centrifugation, the pellet is grey-blue with a clear supernatant [Fleming, Nixon 1986]. Limit of detection, 19 mmol/L.
Ultraviolet Spectrum Principal peaks at 252 nm (benzoyl derivative) [Marquet *et al.* 1996].



Quantification
Blood **GC** Column: HP-5 fused silica capillary (15 m × 0.53 mm i.d., 1.5 µm). Temperature programme: 80° to 230° at 10°/min. Carrier gas: He, 6.0 mL/min. NPD. Limit of detection, 5 µg/L [Kikuchi *et al.* 2001].

GC-MS Column: HP-5 fused silica capillary (20 m × 0.25 mm i.d., 0.25 µm). Temperature programme: 40° for 1 min to 90° at 30°/min to 130° at 10°/min to 300° at 30°/min. Carrier gas: He, 1 mL/min. EI ionisation at 70 eV, full scan mode. Limit of detection, 100 µg/L [Kikuchi *et al.* 2001]. Column: DB-225 fused silica capillary (30 m × 0.32 mm i.d., 0.25 µm). Temperature programme: 50° for 3 min to 220° at 10°/min. Carrier gas: He, 2 mL/min. EI ionisation at 70 eV, positive and negative ion mode, full scan mode. Limit of detection, approx. 0.5 µmol/L [Kage *et al.* 2000].

HPLC Column: Ultrasphere ODS (150 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : water (1 : 1), flow rate 1 mL/min. DAD (λ= 240–254 nm). Limit of detection, 80 µg/L [Lambert *et al.* 1995a]. Column: Novapak C_{18} (150 × 4.6 mm i.d., 5 µm). Mobile phase: 0.05 mol/L potassium dihydrogen phosphate Tris buffer

(pH 4.6) : acetonitrile (55 : 45), flow rate 1.1 mL/min. DAD (λ = 200–400 nm). Limit of detection, 200 µg/L [Marquet *et al.* 1996].

Note For an ion chromatography method for the determination of sodium azide in blood, see Kruszyna *et al.* [1998].

Urine **GC** Column: HP-5 fused silica capillary (15 m × 0.53 mm i.d., 1.5 µm). Temperature programme: 80° to 230° at 10°/min. Carrier gas: He, 6.0 mL/min. NPD. Limit of detection, 0.5 µg/L [Kikuchi *et al.* 2001].

GC-MS See Blood. Limit of detection, 10 µg/L [Kikuchi *et al.* 2001]. See Blood [Kage *et al.* 2000].

Disposition in the Body Little is known of the fate of azide in the body. It is converted to nitric oxide by erythrocytes; cyanide, which is produced *in vitro* by incubation in whole blood, is thought to be a metabolite. For a review of azide pharmacokinetics in animals, see Reinhardt and Brittelli [1981].

Toxicity Azide is similar to cyanide in that it exerts the majority of its toxic effects by inhibiting cytochrome oxidase. Acute poisoning following inhalation of the vapour or ingestion of the salts is characterised by tachycardia, metabolic acidosis, severe hypotension, respiratory depression, and convulsions. There is some evidence from mouse experiments that the formation of an azide–methaemoglobin complex may afford some protection against toxicity [Abbanat, Smith 1964].

A 47-year-old male ingested approx. 9 g of sodium azide. Postmortem sodium azide concentrations in his gastric contents, bile, brain and lung were 1036, 21.4, 2.7 and 17.6 mg/kg, respectively. Concentrations were 7.4 and 8.3 mg/L in his thoracic and suprahepatic blood, respectively [Marquet *et al.* 1996].

A 25-year-old female was found with no signs of life. She had a lethal concentration of cyanide in her blood (9 mg/L) together with a high azide concentration (262 mg/L). Concentrations of azide in her stomach contents, liver, kidney and bile were 754, 14, 205 and 1283 mg/L, respectively [Lambert *et al.* 1995a, b].

A woman who was administered 800 mg of sodium azide accidentally by mouth died 3.5 days later. She had a urine azide concentration of 0.14 mg/L [Howard *et al.* 1990].

A 52-year-old man ingested between 1.2 and 2 g of sodium azide. On arrival at hospital (approx. 3 h after ingestion) he had a plasma cyanide concentration of 1.6 mg/L. At 12, 18 and 24 h later his cyanide concentrations were 1.7, 0.6 and 0.1 mg/L [Klein-Schwartz *et al.* 1989].

A 20-year-old man ingested a white unknown powder and died 40 min later. The amount of sodium azide found by volumetric analysis was 86.7 mg% in the stomach wall and 42.9 mg% in the small intestine. There was no sodium azide found in the liver [Kozlicka-Gajdzinska, Brzyski 1966].

Note For cases of fatal sodium azide ingestion, see Abrams *et al.* [1987]; Albertson *et al.* [1986]; Emmett and Ricking [1975]; Judge and Ward [1989].

Azinphos-(Et)

Acaricide, Insecticide

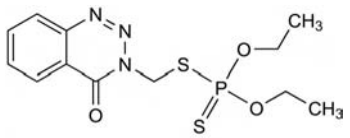
$C_{12}H_{16}N_3O_3PS_2$ = 345.4

CAS—2642-71-9

IUPAC Name Phosphorodithioic acid *O,O*-diethyl *S*-[(4-oxo-1,2,3-benzotriazin-3(4*H*)-yl)methyl] ester

Synonyms Bayer 16259; ENT-22014; ethyl guthion; gusathion A; R-1513.

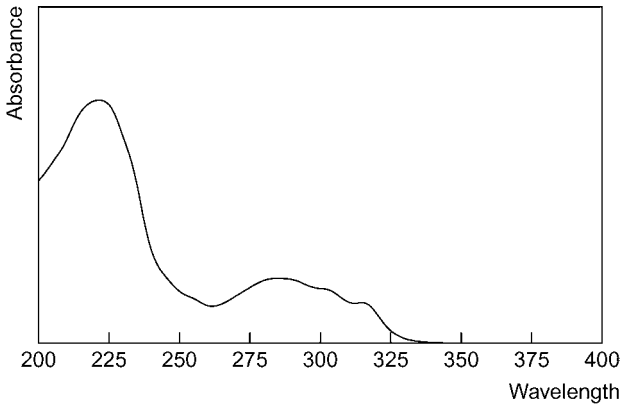
Proprietary Names *Azinos*; *Azinugec E*; *Bionex*; *Contrion-Ethyl*; *Gutex*; *Sepizin L*; *Triazotion*.



Chemical Properties Colourless crystals. Mp 53°. Bp 111°. It is soluble in water (4 to 5 mg/L at 20°); readily soluble in most organic solvents except aliphatic hydrocarbons. Log *P* (octanol/water), 3.40. Extraction yield (chlorobutane), 1 [Demme *et al.* 2005].

Thin-layer Chromatography System TX—R_f 0.24; system TY—R_f 0.48; system TAE—R_f 0.81.

Gas Chromatography System GA—RI 2560.



Mass Spectrum Principal ions at *m/z* 132, 77, 160, 105, 29, 65, 76, 97.

Quantification

Blood **GC** FPD. Limit of detection, 1 µg/L [Marques 1990].

Plasma **GC** Column: 3% OV-1 on 100 to 120 mesh Gas-Chrom Q (1.8 m × 0.25 mm i.d.). Temperature: 245°. Detector temperature: 300°. Carrier gas: 5% methane in argon, flow rate 50 mL/min. Detection: electron capture ^{63}Ni. Retention time: azinphos-ethyl, 1.5 min. Limit of detection, 1 µg/L [Stein, Pittman 1976].

Disposition in the Body Azinphos is rapidly absorbed from the gastro-intestinal tract after ingestion. It is excreted in urine.

Toxicity

In a series of azinphos-ethyl poisoning cases, fatal cases were found to have blood levels of 1.112 mg/L and above, serious cases of intoxication with levels of 494 µg/L and above, and less serious cases with levels above 57 µg/L. Serious intoxication was always observed with concentrations above 370 µg/L [Marques 1990].

Azinphos-(Me)

Acaricide, Insecticide

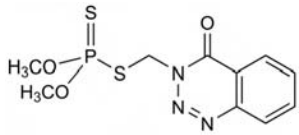
$C_{10}H_{12}N_3O_3PS_2$ = 317.3

CAS—86-50-0

IUPAC Name Phosphorodithioic acid *O,O*-dimethyl-*S*-[(4-Oxo-1,2,3-benzotriazin-3(4*H*)-yl)methyl] ester

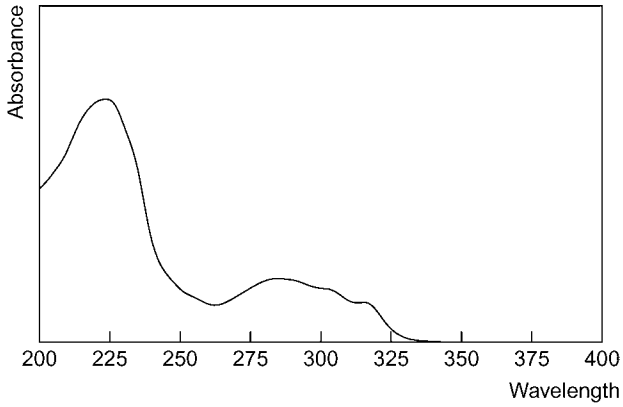
Synonym DBD

Proprietary Names *Gusathion M*; *Guthion*.



A

Chemical Properties Colourless crystals. It is rapidly hydrolysed in alkaline or acid media. Mp 73° to 74°. Soluble 1 in 30 000 of water; soluble in ethanol, methanol and propylene glycol. Log *P* (octanol/water), 2.8. Extraction yield (chlorobutane), 1 [Demme *et al.* 2005].
Colour Tests Palladium chloride—brown; phosphorus test—yellow.
Thin-layer Chromatography System TA—R_f 0.84; system TB—R_f 0.40; system TC—R_f 0.99; system TD—R_f 0.91; system TE—R_f 0.99; system TF—R_f 0.93; system TL—R_f 0.99; system TW—R_f 0.68; system TX—R_f 0.20; system TY—R_f 0.42; system TAD—R_f 0.94; system TAE—R_f 0.81; system TAF—R_f 0.87.
Gas Chromatography System GA—RI 2473; system GK—RRT 1.60 (relative to caffeine).
High Performance Liquid Chromatography System HY—RI 513.
Ultraviolet Spectrum Hexane—285 nm ($A_1^{\downarrow}$=280b), 302, 315 nm.



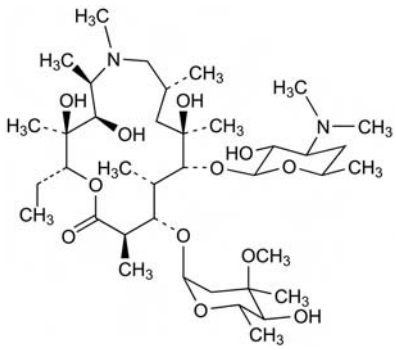
Infrared Spectrum Principal peaks at wavenumbers 1000, 1666, 833, 781, 1041, 775 cm^{-1}.
Mass Spectrum Principal ions at *m/z* 77, 160, 132, 44, 105, 104, 93, 76.
Disposition in the Body
Toxicity Azinphos-methyl is less toxic than mevinphos or parathion. The maximum permissible atmospheric concentration is 0.2 mg/m^3.

Demme U *et al.* (2005). Systematic evaluation of 1-chlorobutane for liquid-liquid extraction of drugs. *Proceedings of the 12th TIAFT*, Seoul: 481–486.

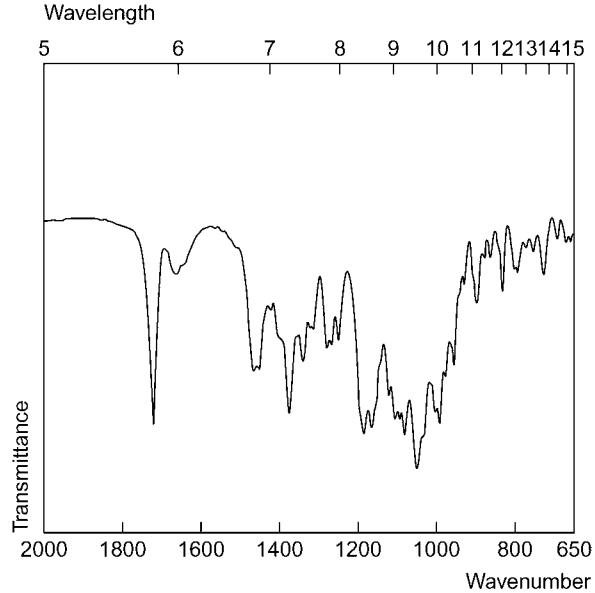
Azithromycin

Antibacterial
$C_{38}H_{72}N_2O_{12}$ = 749.0
CAS—83905-01-5 (anhydrous); 117772-70-0 (dihydrate)

IUPAC Name [2*R*-(2*R**,3*S**,4*R**,5*R**,8*R**,10*R**,11*R**,12*S**,13*S**,14*R**)]-13-[2,6-Dideoxy-3-*C*-methyl-3*O*-methyl-α-L-*ribo*-hexopyranosyl)oxy]-2-ethyl-3,4,10-trihydroxy-3,5,6,8,10,12,14-heptamethyl-11-[[3,4,6-trideoxy-3-(dimethylamino)-β-D-*xylo*-hexopyranosyl]oxy]-1-oxa-6-azacyclopentadecan-15-one
Synonyms 9-Deoxo-9a-aza-9a-methyl-9a-homoerythromycin A; CP-62993; XZ-450.
Proprietary Names *Azitrocin*; *Azitromax*; *Goxil*; *Ribotrex*; *Sumamed*; *Toraseptol*; *Trozocina*; *Vinzam*; *Zentavion*; *Zithromax*; *Zitromax*.



Chemical Properties Mp 113° to 115°. pK_a 8.1 and 8.8. Log *P* (octanol/water), 4.02.
High Performance Liquid Chromatography System HBA—retention time 20.7 min; system HBB—retention time 9.6 min.
Infrared Spectrum Principal peaks at wavenumbers 1721, 1188, 1052 cm^{-1} (KBr pellet).



Quantification
Plasma **HPLC** Electrochemical detection. Limit of quantification, 0.03 mg/L [Taninaka *et al.* 2000].
Serum **HPLC** Fluorescence detection (λ_{ex}=255 nm, λ_{em}=315 nm). Limit of detection, 0.09 mg/L [Sastre Toraño, Guchelaar 1998]. Electrochemical detection. Limit of detection, 0.01 mg/L [Shepard *et al.* 1991].
Tissue **HPLC** Electrochemical detection. Limit of detection, 100 mg/g [Shepard *et al.* 1991].
Note For a comparison of microbiological assay and high performance liquid chromatography methods for the determination of azithromycin, see Riedel *et al.* [1992].
Disposition in the Body Azithromycin is rapidly absorbed after oral administration with a bioavailability of about 40%. Absorption from the capsule formulation, but not the tablet formulation, is reduced by food. It is extensively distributed to the tissues; tissue concentrations are much higher than those in blood and high concentrations are taken up into white blood cells. There is little diffusion into CSF unless meninges are inflamed. Some demethylation of the drug occurs in the liver and it is excreted in bile as the unchanged drug and its metabolites (~10 with no microbial activity); more than 50% of a dose is excreted in faeces as the unchanged drug. About 12% of an oral dose is excreted in urine over the course of about a week.
Therapeutic Concentration
Peak plasma concentrations of 0.165 to 0.623 mg/L (mean, 0.383 mg/L) were reported following oral administration of 10 mg/kg on day 1 followed by 5 mg/kg on days 2 to 5 in 14 children aged 6 to 15 years, both boys and girls. Peak concentrations were reached after 1 to 4 h (mean 2.4 h) [Nahata *et al.* 1993].
Following administration of a 1-g oral dose to 14 male subjects, mean peak serum concentrations at 1.7 h were 0.82 mg/L and mean peak lymph concentrations after 3.1 h were 0.22 mg/L [Bergan *et al*].
Bioavailability 37%.
Half-life Plasma half-life, 14 to >40 h.
Volume of Distribution 23 to 31 L/kg.
Clearance Plasma clearance, 630 mL/min.
Protein Binding Decreasing from 51% at 0.02 to 0.05 mg/L to 7% at 1 mg/L.
Note For reviews of azithromycin, see Hopkins [1991], Peters *et al.* [1992] and Lalak, Morris [1993].
Dose Usually 500 mg daily.

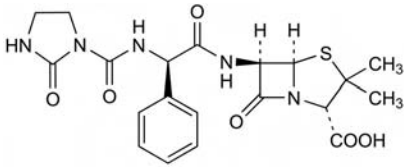
Azlocillin

Antibacterial
$C_{20}H_{23}N_5O_6S = 461.5$
CAS—37091-66-0

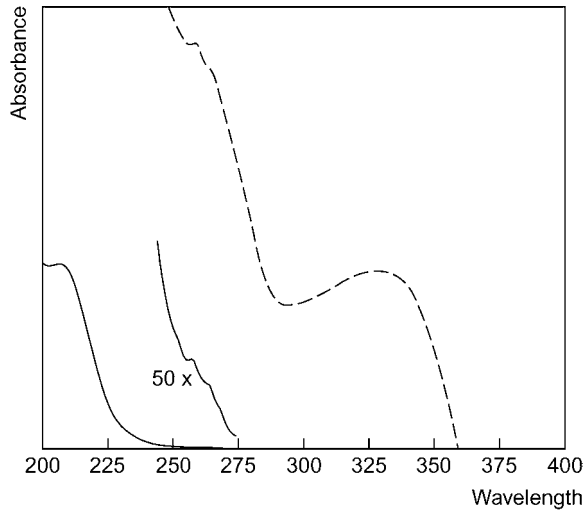
IUPAC Name (6*R*)-6-[D-2-(2-Oxoimidazolidine-1-carboxamido)-2-phenylacetamido]penicillin
Synonym Bay e 6905



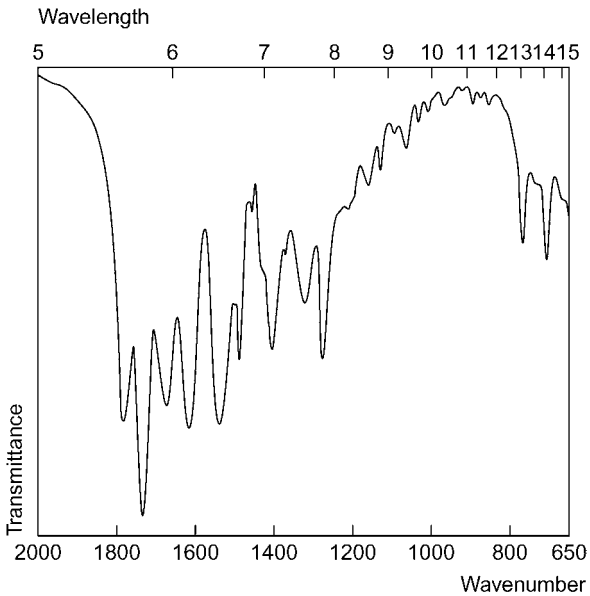
Azlocillin Sodium

$C_{20}H_{22}N_5NaO_6S = 483.5$
CAS—37091-65-9
Proprietary Names *Azlin*; *Securopen*.
Chemical Properties A white to pale yellow hygroscopic powder. It is freely soluble in water; soluble in dimethyl formamide and methanol; slightly soluble in ethanol and isopropanol; practically insoluble in acetone, chloroform and ether.

Ultraviolet Spectrum Water—257, 320 nm (sodium salt).



Infrared Spectrum Principal peaks at wavenumber 1722, 1606, 1532, 1772, 1272, 3295 cm^{-1} (sodium salt) (KBr disk).



Quantification
Plasma **HPLC** UV detection (λ=220 nm). Limit of detection, 0.1 mg/L [Knöller *et al.* 1988]. UV detection (λ=220 nm). Limit of quantification, 5 µg/mL, limit of detection, 1.3 µg/mL [Hildebrandt, Gundert-Remy 1982]. UV detection. Limit of detection, 0.7 mg/L [Gundert-Remy and De Vries 1979].
Serum **HPLC** See Plasma [Knöller *et al.* 1988]. UV detection (λ=214 nm). Limit of detection, 0.1 mg/L [Jehl *et al.* 1987]. UV detection. Limit of detection, 0.4 mg/L [Weber *et al.* 1983].
Urine **HPLC** See Plasma [Knöller *et al.* 1988]. See Serum [Jehl *et al.* 1987]. UV detection. Limit of detection, 1 to 2 mg/L, azlocillin, 5 to 7 mg/L penicilloic acid metabolite [Gau, Horster 1979].
Bile **HPLC** See Serum [Jehl *et al.* 1987].
Tissues **HPLC** See Plasma [Knöller *et al.* 1988].
Disposition in the Body Azlocillin is poorly absorbed from the gastro-intestinal tract but is widely distributed following IV administration in body tissues and fluids. It crosses the placenta and small amounts are distributed into breast milk. There is little diffusion into CSF unless meninges are inflamed. It is metabolised to a limited extent and about 50 to 70% of a dose is excreted unchanged in the urine by glomerular filtration and tubular secretion. This occurs within 24 h of administration, therefore, producing high urinary concentrations. It is partly excreted in bile. Concomitant administration of probenecid increases plasma concentrations. It can be removed by haemodialysis.
Therapeutic Concentration
Following administration of 4 g as an IV infusion over 20 min to 12 healthy male and female subjects, the mean peak plasma concentration was 451 mg/L. This decreased to 223 mg/L after 30 min and 33 mg/L 4 h from the beginning of infusion [Colaizzi *et al.* 1986].
Half-life Plasma half-life, 1 h; 2 to 6 h in renal impairment.
Volume of Distribution 0.22 L/kg.
Clearance Serum clearance, 153 mL/min/1.73 m^2.
Protein Binding Between 20 and 46%.
Note For a review of the pharmacokinetics of azlocillin, see Bergan [1983].
Dose Up to 5 g (of the base) intravenously every 8 h; reduced in patients with renal dysfunction.

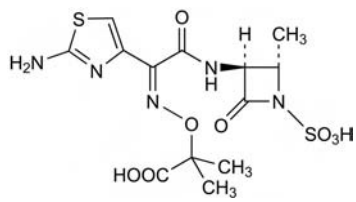
Aztreonam

Antibacterial
$C_{13}H_{17}N_5O_8S_2 = 435.4$
CAS—78110-38-0

IUPAC Name [2*S*-[2α,3β(*Z*)]]-2-[[[1-(2-Amino-4-thiazolyl)-2-[(2-methyl-4-oxo-1-sulfo-3-azetidinyl)amino]-2-oxoethylidene]amino]oxy]-2-methylpropanoic acid
Synonyms Azthreonam; SQ-26776.
Proprietary Names *Azactam*; *Azonam*; *Aztreon*; *Nebactam*; *Primbactam*; *Urobactam*.



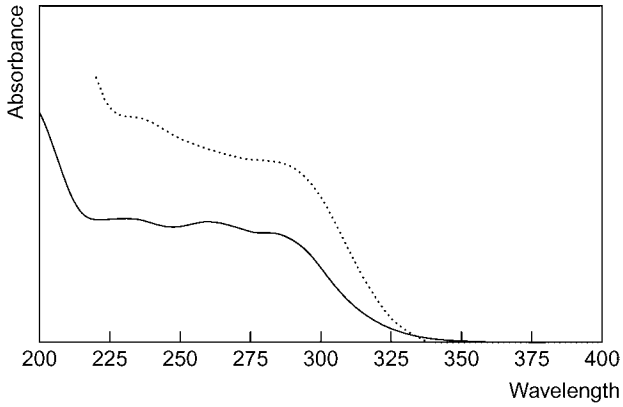
Chemical Properties A white crystalline odourless powder. Decomposes at 227°. It is very slightly soluble in dehydrated alcohol; slightly soluble in methanol; soluble in dimethylformamide and dimethylsulfoxide; practically insoluble in chloroform, ethyl acetate and toluene. pK_a, less than 2.0.

Aztreonam Disodium

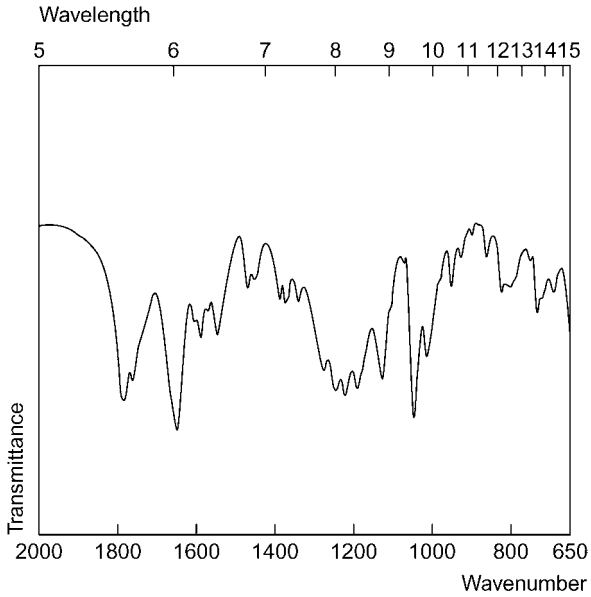
$C_{13}H_{15}N_5Na_2O_8S_2 = 479.4$

A

Ultraviolet Spectrum Aqueous acid (ethanol)—268, 281 nm; basic—289 nm.



Infrared Spectrum Principal peaks at wavenumber 1640, 1041, 633 cm^{-1} (KBr disk).



Quantification

Serum **HPLC** UV detection. Limit of detection, 0.5 mg/L [Jehl *et al.* 1987]. UV detection. Limit of detection, 1 mg/L [Mihindu *et al.* 1983]. UV detection (λ=293 nm). Limit of detection, 1 mg/L [Pilkiewicz *et al.* 1983]. UV detection. Limit of detection, 1 mg/L [Swabb *et al.* 1981].

Bile **HPLC** See Serum [Jehl *et al.* 1987].

Faeces **HPLC** UV detection. Limit of detection, about 2 μg/g [Ehret *et al.* 1987].

Bioassay Limit of detection, 0.03 mg/L [Ehret *et al.* 1987].

Disposition in the Body Aztreonam is completely absorbed after IM administration, with peak concentrations reached within 1 h. It takes 1 to 3 h for equilibrium to be reached between tissues and plasma. It is widely distributed in body tissues and fluids, including bile, but diffusion into CSF is poor unless meninges are inflamed. It crosses the placenta and small amounts are distributed into breast milk. Only about 6 to 16% is metabolised to inactive metabolites by hydrolysis. The drug is excreted predominantly in urine by renal tubular secretion and glomerular filtration; about 60 to 75% of a dose appears within 8 h as the unchanged drug with only small quantities of metabolites. Only small amounts of the unchanged drug and metabolites are excreted in faeces. It is removed by haemodialysis and to a lesser extent by peritoneal dialysis.

Therapeutic Concentration The trough serum therapeutic concentration range is 1 to 10 mg/L and the peak, 50 to 250 mg/L.

Twenty-four male volunteers were divided into 4 groups according to the degree of creatinine clearance. Group 1 (mean age, 27 years): creatinine clearance, ≥80 mL/min, group 2 (mean age, 43): 30 to 79 mL/min, group 3 (mean age, 44): 10 to 29 mL/min, group 4 (mean, 40 years old): <10 mL/min. Each group was administered with an IV dose of 1 g aztreonam over 2 min, after an overnight fast followed by a 2-h fast after administration. The mean peak serum concentrations for the groups were 78, 98, 98 and 145 mg/L, respectively, observed after 10 min [Mihindu *et al.* 1983].

Half-life Plasma half-life, 1.4 to 2.2 h; prolonged to 4.7 to 6 h in renal impairment and to some extent in hepatic impairment.

Volume of Distribution 0.11 to 0.21 L/kg; increased in neonates and paediatric patients (from 1 week to 12 years) to 0.3 to 1 L/kg.

Clearance Plasma clearance, 93 mL/min; reduced in neonates.

Protein Binding About 56%.

Note For reviews of aztreonam, see Brogden, Heel [1986] and Neu [1990].

For reviews of the pharmacokinetics of aztreonam, see Mattie [1988] and Mattie [1994].

Dose Up to 8 g daily by intravenous or intramuscular injection. Dose may need to be reduced in patients with severe renal impairment.

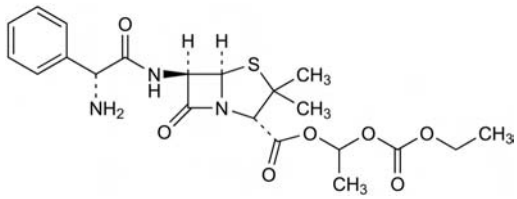
Bacampicillin

Antibacterial
$C_{21}H_{27}N_3O_7S = 465.5$
CAS—50972-17-3

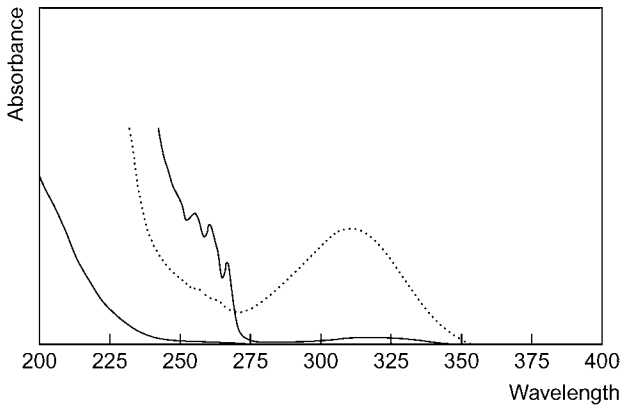
IUPAC Name (2*S*,5*R*,6*R*)-6-[[(2*R*)-Aminophenylacetyl]amino]-3,3-dimethyl-7-oxo-4-thia-1-azabicyclo[3.2.0]heptane-2-carboxylic acid 1-[(ethoxycarbonyl) oxy]ethyl ester
Synonym Carampicillin



Bacampicillin Hydrochloride

$C_{21}H_{27}N_3O_7S,HCl = 502.0$
CAS—37661-08-8
Proprietary Names *Ambaxin*; *Penglobe*; *Spectrobid*.
Chemical Properties A white crystalline powder. Mp 171°. Soluble 1 in 15 of water, 1 in 7 of ethanol, and 1 in 10 of chloroform; practically insoluble in ether.

High Performance Liquid Chromatography System HAA—retention time 14.7 min.
Ultraviolet Spectrum Water—258, 263 (A_1^1=13b), 269 nm; aqueous alkali—310 nm.

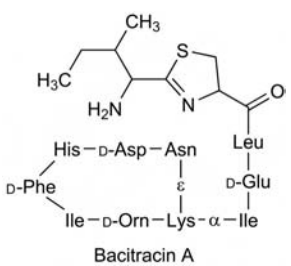


Infrared Spectrum Principal peaks at wavenumbers 1770, 1075, 1788, 1263, 1687, 1744 cm^{-1} (bacampicillin hydrochloride, KBr disk).
Dose 0.8 to 2.4 g of bacampicillin hydrochloride daily.

Bacitracin

Antibacterial
CAS—92528-87-5

IUPAC Name 4-[[2-[[2-(1-Amino-2-methylbutyl)-4,5-dihydro-1, 3-thiazole-4-carbonyl]amino]-4-methylpentanoyl]amino]-5-[[1-[[19-(2- amino-2-oxoethyl)-4-(3-aminopropyl)-10-benzyl-7-butan-2-yl-16- (carboxymethyl)-13-(4H-imidazol-4-ylmethyl)-2,5,8,11,14,17, 20-heptaoxo-3,6,9,12,15,18, 21-heptazacyclopentacos-1-yl]amino]-3-methyl-1-oxopentan-2-yl]amino]-5- oxopentanoic acid; zinc
Synonym Bacitracin is a polypeptide produced by the growth of an organism of the licheniformis group of *Bacillus subtilis*.
Proprietary Names *Baciguent*; *Bacitin*. It is an ingredient of *Ototrips* and *Polybactrin Soluble GU*.



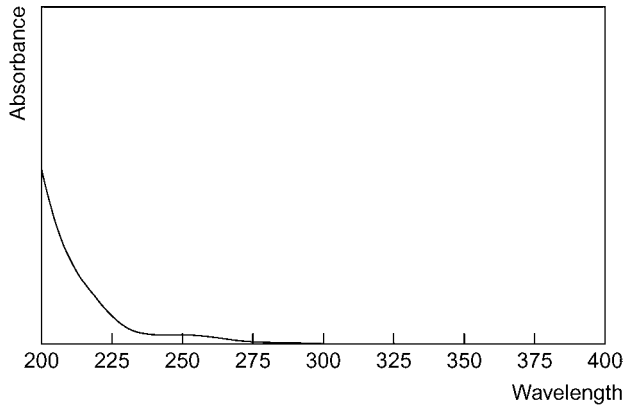
Bacitracin A

Chemical Properties A white to pale buff hygroscopic powder. Freely soluble in water; soluble in ethanol; practically insoluble in acetone, chloroform and ether.

Bacitracin Zinc

CAS—1405-89-6
Synonyms Bacitracins zinc complex; zinc bacitracin.
Proprietary Names It is an ingredient of *Cicatrene*, *Cicatrex*, *Cicatrin*, *Dispray Antibiotic*, *Polyfax*, and *Tribiotic*.
Chemical Properties A white, pale buff or tan, hygroscopic powder. Soluble 1 in 900 of water and 1 in 500 of ethanol; very slightly soluble in ether; practically insoluble in chloroform.

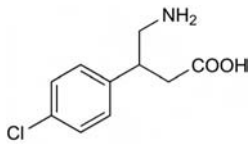
Ultraviolet Spectrum Bacitracin zinc: aqueous acid—252 nm (A_1^1=18b).



Baclofen

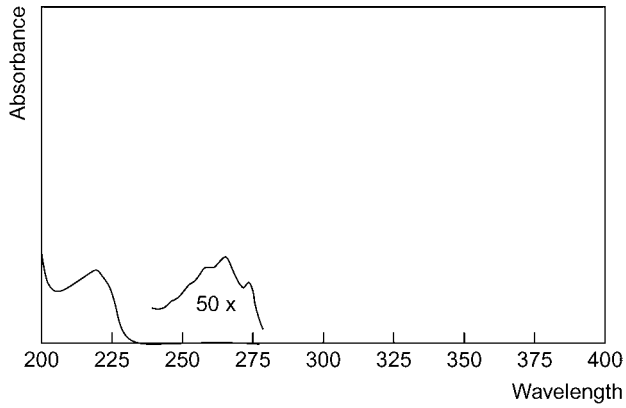
Muscle Relaxant
$C_{10}H_{12}ClNO_2 = 213.7$
CAS—1134-47-0

IUPAC Name β-(Aminomethyl)-4-chlorobenzenepropanoic acid
Synonym Aminomethyl chlorohydrocinnamic acid
Proprietary Name *Lioresal*

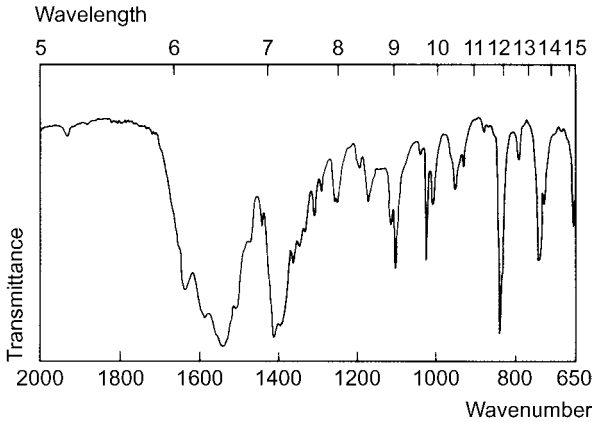


Chemical Properties A white crystalline solid. Mp about 207°. Slightly soluble in water; poorly soluble in organic solvents. pK_a 3.9, 9.6. Log *P* (octanol/water), −1.0.
Colour Test Liebermann's reagent—orange.
Thin-layer Chromatography System TD—R_f 0.01; system TE—R_f 0.00; system TF—R_f 0.00; system TAD—R_f 0.00.
Gas Chromatography System GA—RI 2010.
High Performance Liquid Chromatography System HZ—retention time 2.0 min.

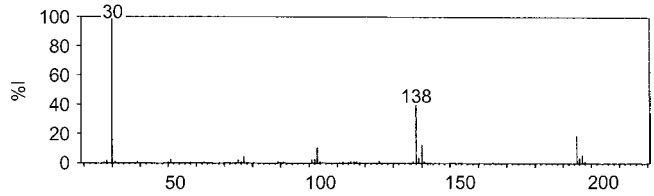
Column: C_{18} Bondapak (300 × 3.9 mm i.d., 10 µm). Mobile phase: methanol : water (45:55), flow rate 0.4 mL/min. Fluorescence detection (λ_{ex}=463 nm; λ_{em}=524 nm). Retention time: 4.0 min [Tosunoglu, Ersoy 1995].
Ultraviolet Spectrum Aqueous acid—259, 266 (A_1^1=11.3a), 274 nm. No alkaline shift.



Infrared Spectrum Principal peaks at wavenumbers 1527, 835, 1574, 1495, 1624, 1095 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 30, 138, 195, 140, 103, 197, 77, 196.



Quantification

Plasma **GC** ECD. Limit of detection, 50 µg/L [Degen, Riess 1976].

HPLC Electrochemical detection. Limit of quantification, 10 µg/L, limit of detection, 2.5 µg/L [Millerioux *et al.* 1996].

Serum **GC–MS** Limit of detection, 5 µg/L [Swahn *et al.* 1979].

Urine **GC** See Plasma [Degen, Riess 1976].

Cerebrospinal Fluid **GC–MS** See Serum [Swahn *et al.* 1979].

Disposition in the Body Baclofen is rapidly absorbed after oral administration. About 80% of a dose is excreted in the urine in 24 h, mostly as unchanged drug. About 15% of a dose is metabolised, mainly to the deaminated derivative; about 20% of a dose may be eliminated in the faeces as unchanged drug and metabolites.

Therapeutic Concentration

A 45-year-old, healthy, woman administered 20 mg baclofen orally produced a peak plasma concentration of 270 µg/L after 2.5 h [Tosunoglu, Ersoy 1995].

After an oral dose of 40 mg to 1 subject, a peak plasma concentration of unchanged drug of about 0.6 mg/L was attained in 2 h; a peak concentration of metabolites of about 0.1 mg/L was attained in about 4 h [Faigle, Keberle 1972].

Toxicity Recovery has occurred after the ingestion of 1.5 g.

A fatality occurred after ingestion of baclofen. Baclofen was detected in serum at a concentration of 17 mg/L and in urine at 760 mg/L which was collected 12 h after ingestion of the drug [Fraser *et al.* 1991].

Coma, respiratory failure and severe seizures occurred in a 39-year-old female subject after ingestion of 450 mg of baclofen; following treatment, the patient regained consciousness within 36 h, at which time a plasma concentration of 0.2 mg/L was reported; the plasma half-life was found to be 35 h [Ghose *et al.* 1980].

Half-life Plasma half-life, about 2 to 4 h.

Protein Binding About 30%.

Dose 15 to 60 mg daily; maximum of 100 mg daily.

Degen PH, Riess W (1976). The determination of gamma-amino-beta-(p-chlorophenyl)butyric acid (baclofen) in biological material by gas-liquid chromatography. *J Chromatogr* 117: 399–405.

Balsalazide

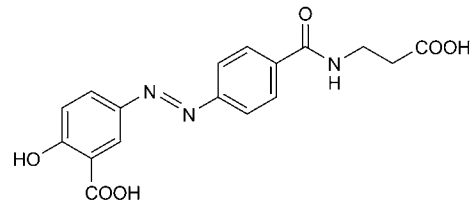
Mesalamine, Antiinflammatory

$C_{17}H_{15}N_3O_6 = 357.3$

CAS—80573-04-2

IUPAC Name (3*Z*)-3-[[4-(2-Carboxyethylcarbamoyl)phenyl]hydrazinylidene]-6-oxocyclohexa-1,4-diene-1-carboxylic acid

Synonyms 5-[(1*E*)-[4-[[2-Carboxyethyl)amino]carbonyl]phenyl]azo]-2-hydroxybenzoic acid; 5-[4-(2-carboxyethylcarbamoyl)phenylazo]salicylic acid; (*E*)-5-[[*p*-[2-carboxyethyl)carbamoyl]phenyl]azo]-2-salicylic acid.



Chemical Properties Crystals from hot ethanol. Mp 254° to 255°.

Balsalazide Disodium Dihydrate

$C_{17}H_{17}N_3Na_2O_8,2H_2O = 437.3$

CAS—150399-21-6; 82101-18-6 (anhydrous)

Synonyms Balsalazide sodium; BX-661A.

Proprietary Names *Colazal*; *Colazide*.

Chemical Properties Orange-to-yellow microcrystalline powder. Mp >350°. Non-hygroscopic. Freely soluble in water and isotonic saline; sparingly soluble in methanol and ethanol; practically insoluble in organic solvents.

Disposition in the Body Balsalazide is metabolised in the colon by bacterial azoreductases to 5-aminosalicyclic acid (5-ASA). 5-ASA is responsible for the antiinflammatory action, and 4-aminobenzoyl-β-alanine (4-ABA) is an inert carrier. Twenty-five percent of the released 5-ASA is inactivated in the colonic mucosa and liver to the *N*-acetylated metabolite NASA. 4-ABA is also converted to its *N*-acetylated metabolite NABA. Only NASA and NABA are detected in urine; the parent drug is excreted mainly in the faeces.

Therapeutic Concentration

Twenty healthy male and female volunteers were administered 2.25 g balsalazide (equivalent to 800 mg 5-ASA). A mean peak plasma 5-ASA concentration of 348 µg/L was reached at 9.1 h [Sandborn *et al.* 2004].

Fifty-four adult patients with ulcerative colitis (in remission) were administered with 3 to 6 g daily for at least 1 year. Peak plasma concentrations of 0.324 mg/L were reached within 2 h. [Green *et al.* 1998].

Peak plasma concentrations of the metabolite 4-ABA were <0.096 mg/L within 9 to 10 h after administration of a 2.25-g dose of balsalazide [Riddell *et al.* 1998].

Toxicity

Co-administration of balsalazide with azathioprine or 6-mercaptopurine in patients with Crohn's disease may result in leucopaenia [Lowry *et al.* 2001].

Hypersensitivity reaction: a 59-year-old woman was administered 2.25 g balsalazide 3 times a day. After 8 days, she was admitted into hospital with central chest pain, shortness of breath, and back pain which worsened over the next 3 days. Upon examination, she was apyrexial, with splinter haemorrhages in her fingernails, raised jugular venous pressure, a loud pericardial rub, and a soft, tender liver. Balsalazide treatment was stopped and all symptoms resolved within 1 month. [Adhiyaman *et al.* 2000].

Half-life Elimination half-life of NASA is 6 to 9 h, and for 5-ASA is ≈1 h.

Clearance 4.5 L/h.

Protein Binding 5-ASA ≈40% and NASA 80%.

Dose An initial dose of 2.25 g three times a day is administered for up to 12 weeks. Maintenance dose of 1.5 g twice daily with a maximum of 6 g daily.

Adhiyaman V *et al.* (2000). Hypersensitivity reaction to balsalazide. *BMJ* 320: 613.

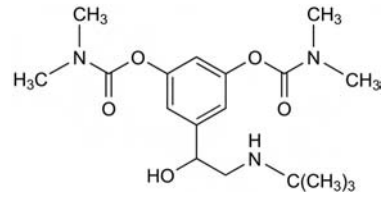
Bambuterol

Bronchodilator, β_2-Adrenoceptor Agonist

$C_{18}H_{29}N_3O_5 = 367.5$

CAS—81732-65-2

IUPAC Name Dimethylcarbamic acid 5-[2-[(1,1-dimethylethyl)amino]-1-hydroxyethyl]-1,3-phenylene ester

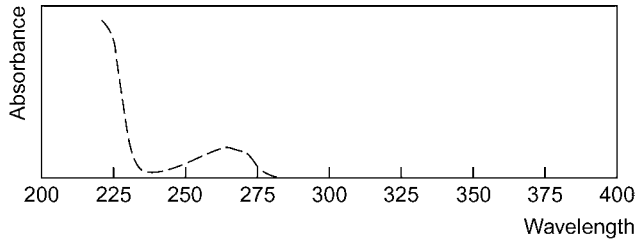


Bambuterol Hydrochloride

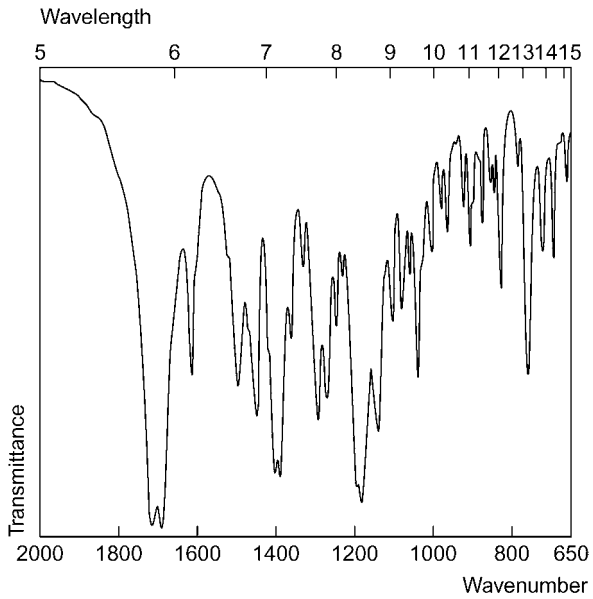
$C_{18}H_{29}N_3O_5$,HCl = 403.9
CAS—81732-46-9
Synonym KWD-2183
Proprietary Name *Bambec*
Chemical Properties A white or almost white crystalline powder. Exhibits polymorphism. It is freely soluble in water; soluble in ethanol.

Thin-layer Chromatography System TB—R_f 0.02 (bambuterol), R_f 00 (bambuterol monocarbamate); system TE—R_f 0.37 (bambuterol), R_f 0.21 (bambuterol monocarbamate); system TAE—R_f 0.18 (bambuterol); R_f 0.19 (bambuterol monocarbamate).
High Performance Liquid Chromatography System HX—RI 353 (bambuterol), RI 304 (bambuterol monocarbamate).

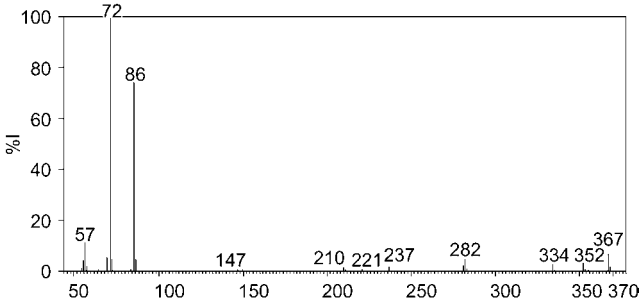
Column: LC-18-DB Supelcosil (150 × 4.6 mm i.d., 5 µm). Mobile phase: 6.0 mmol/L sodium octane sulfonate and methanol : acetonitrile : 50 mmol/L phosphate buffer pH 3.0 (34:11:55), flow rate 1.0 mL/min. UV detection (λ=214 nm). Retention time: 10 min [Wannerberg, Persson 1988].
Ultraviolet Spectrum Water—264 nm.



Infrared Spectrum Principal peaks at wavenumber 1695, 1720, 1190, 1200, 1390, 1350 cm^{-1}.



Mass Spectrum Principal ions at *m/z* 72, 86, 57, 70, 367, 282, 352, 334.



Quantification
Plasma **GC–MS** Limit of quantification, 0.2 µg/L [Lindberg *et al.* 1990].
Urine **GC–MS** Limit of quantification, 1.5 µg/L [Lindberg *et al.* 1990].
Disposition in the Body About 20% of a dose is absorbed after oral administration. It concentrates in lung tissue where it is hydrolysed primarily by a plasma cholinesterase to its active metabolite terbutaline (β_2 adrenergic receptor agonist). It is also metabolised by oxidative enzymes in the liver. Approximately one-third of an IV dose is converted to terbutaline. It also undergoes oxidative metabolism to products that are then metabolised to terbutaline. Very little bambuterol is excreted unchanged in urine.

Therapeutic Concentration

Twelve healthy volunteers, male and female, aged between 23 and 62 years, were administered with IV doses of 30 g/kg over 5 min and oral doses of 7 g/kg as an aqueous solution. Peak plasma concentrations after the IV dose ranged between 72.5 and 184 nmol/L with a mean of 129 nmol/L. The mean peak plasma concentration, after a single oral dose, was 6.9 nmol/L (2.3 to 24.3 nmol/L) and was reached within 2.3 h (ranging between 1 and 4 h). [Nyberg *et al.* 1998].

Twenty-three healthy Caucasian volunteers (12 women), aged between 20 and 56 years, were administered with oral tablets: 10, 20 and 30 mg, and a 20 mg solution as an open, crossover, random study. After the first dose, the mean peak plasma concentration was 3.69 nmol/L (1.0 to 8.8 nmol/L) for the 10 mg tablet, 8.56 nmol/L (ranging between 3.5 and 16.9 nmol/L) for the 20 mg tablet, 14.23 nmol/L (range, 5.3 to 30.4 nmol/L) for 30 mg and 6.13 nmol/L (1.7 to 13.6 nmol/L) for the 20 mg solution. The mean time to the peak concentration was 1.4 to 1.8 h [Rosenborg *et al.* 2000].

Bioavailability <15%.
Half-life Plasma, 12 h (oral administration); 2.6 h (IV administration).
Volume of Distribution Women, between 1.6 and 2.1 L/kg; men, 1.2 to 1.4 L/kg.
Clearance Plasma, 1250 mL/min.
Protein Binding 40 to 50%.
Distribution in Blood Distributes extensively outside the plasma component.
Note For a review of the pharmacokinetics of bambuterol, see Sitar [1996].
Dose Usually 20 mg daily.

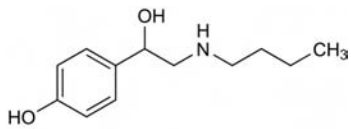
Bamethan

Vasodilator
$C_{12}H_{19}NO_2$ = 209.3
CAS—3703-79-5
IUPAC Name α-[(Butylamino)methyl]-4-hydroxybenzenemethanol

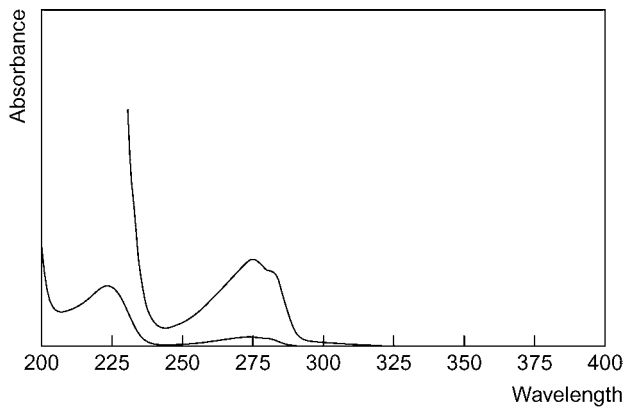


Chemical Properties Crystals. Mp 123.5° to 125°. pK_a 9.0, 10.2 (25°). Log *P* (octanol/water), 1.3.

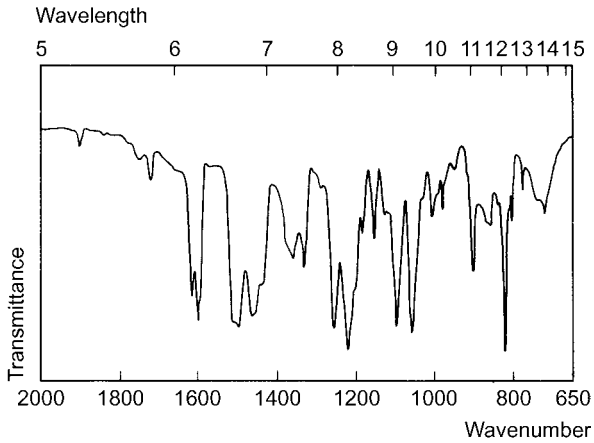
Bamethan Sulfate

$(C_{12}H_{19}NO_2)_2,H_2SO_4$ = 516.7
CAS—5716-20-1
Proprietary Names *Vasculat*; *Vasculit*.
Chemical Properties Soluble in water.

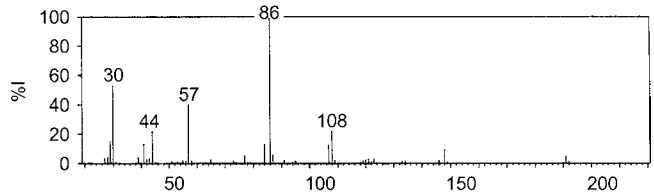
Colour Tests Folin-Ciocalteu reagent—blue; Liebermann's reagent—violet-brown; Mandelin's test—blue→green.
Thin-layer Chromatography System TA—R_f 0.55; system TB—R_f 0.04; system TC—R_f 0.06; system TL—R_f 0.00; system TAE—R_f 0.23 (acidified potassium permanganate solution, positive).
Gas Chromatography System GA—RI 1920.
High Performance Liquid Chromatography System HA—*k* 0.9; system HX—RI 250; system HAA—retention time 5.9 min.
Ultraviolet Spectrum Aqueous acid—275 nm (A^{1}_{1}=64a); aqueous alkali—242, 290 nm.



Infrared Spectrum Principal peaks at wavenumbers 832, 1228, 1066, 1264, 1494, 1108 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 86, 30, 57, 108, 44, 29, 84, 41.



Disposition in the Body Bamethan is rapidly absorbed after oral administration. About 80% of a dose is excreted in the urine in 24 h, with about 30% of the dose as unchanged drug.

Therapeutic Concentration

After a single oral dose of 25 mg given to 5 subjects, peak serum concentrations of 0.04 to 0.11 mg/L (mean 0.07) were attained in 0.5 to 1 h [Hengstmann, Steinkamp 1981].

Half-life Plasma half-life, about 2.5 h.

Volume of Distribution 2.5 to 5 L/kg (mean 3.7).

Clearance Plasma clearance, 12 to 20 (mean 16) mL/min/kg.

Dose 100 mg of bamethan sulfate daily.

Hengstmann JH, Steinkamp B (1981). [Pharmacokinetics of 3H-bamethan in humans]. *Arzneimittelforschung* 31: 843–848.

Bamifylline

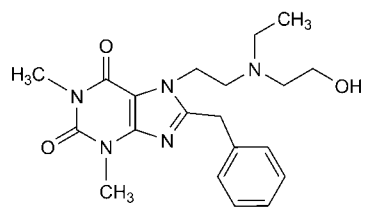
Adenosine A1 Antagonist, Bronchodilator

$C_{20}H_{27}N_5O_3 = 385.5$

CAS—2016-63-9

IUPAC Name 7-[2-(Ethyl-(2-hydroxyethyl)amino)ethyl]-1,3-dimethyl-8-(phenylmethyl)purine-2,6-dione

Synonyms Bamifyllin; benzetamophylline; 7-[2-[Ethyl(2-hydroxyethyl)amino] ethyl]-3,7-dihydro-1,3-dimethyl-8-(phenylmethyl)-1*H*-purine-2,6-dione.



Chemical Properties Crystals. Mp 80° to 80.5°.

Bamifylline Hydrochloride

$C_{20}H_{27}N_5O_3,HCl = 421.9$

CAS—20684-06-4

IUPAC Name 8-Benzyl-7-[2-(ethyl-(2-hydroxyethyl)amino)ethyl]-1,3-dimethylpurine-2,6-dione hydrochloride

Proprietary Names *Pulmac*; *Trentadil*.

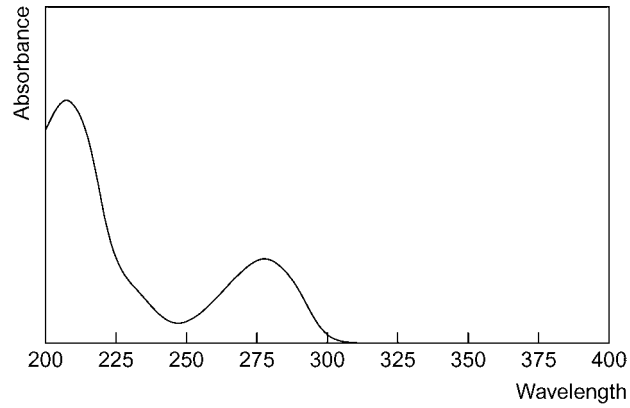
Chemical Properties Crystalline solid. Mp 185° to 186°. Soluble in water. Log *P* (octanol/water) 1.6 [Meylan, Howard 1995].

Colour Test Amalic acid test—orange/violet.

Thin-layer Chromatography System TA—R_f 0.65; system TAE—R_f 0.71; system TAG—R_f 0.34; system TB—R_f 0.00; system TC—R_f 0.54 (acidified iodoplatinate solution, positive).

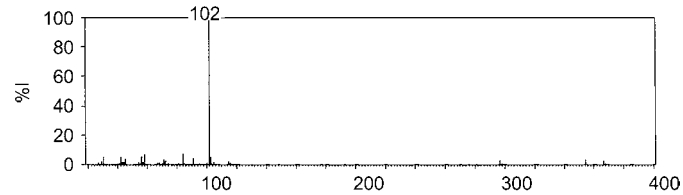
High Performance Liquid Chromatography System HAA—RT 10.3 min.

Ultraviolet Spectrum Aqueous acid—278 nm ($A^1_1 = 310$a); methanol—277 nm ($A^1_1 = 280$b).



Infrared Spectrum Principal peaks at wavenumbers 1650, 1698, 1538, 729, 1041, 1205 cm^{-1} (KBr disk).

Mass Spectrum Principal ions at *m/z* 102, 84, 58, 56, 42, 30, 103, 91.



Quantification

Blood **GC-MS** Column: OV 101 fused silica capillary (15 m, 0.1 μm). Temperature programme: 120° for 1 min to 280° at 10°/min for 1 min. Limit of detection not reported [Offidani *et al.* 1993].

Plasma **HPLC** UV detection (λ = 280 nm). Limit of detection, 20 μg/L [Segre *et al.* 1990]. Column: Ultrasphere IP (250 × 4.6 mm i.d., 5 μm). Mobile phase: acetonitrile : 0.1 mol/L potassium dihydrogen phosphate containing 10 g tetrabutylammonium hydrogen sulphate/L (5 : 95). UV detection (λ = 276 nm). Limit of detection, 0.1 mg/L [Gerlo, Maes 1988]. Column: Hypersil ODS (5 μm). Mobile phase: 1.5 g heptanesulfonate and 3 g potassium chloride/L (pH 3.0) : acetonitrile (78 : 22), flow rate 1.3 mL/min. UV detection (λ = 275 nm). Limit of detection, 10 μg/L for bamifylline and desalkyl metabolites [Nicot *et al.* 1983].

Other **HPLC** Bulk Materials and Pharmaceutical Forms. Column: Column: Erbasil ODS (250 × 4.6 mm i.d., 5 μm). Mobile phase: methanol : tetrahydrofuran : 0.01 mol/L potassium dihydrogen phosphate (pH 7.5; 60 : 4 : 40), flow rate 1.0 mL/min. UV detection (λ = 278 nm). Limit of detection, 10 μg/L [Carlucci *et al.* 1990].

Disposition in the Body

Therapeutic Concentration

Six male and female healthy subjects, mean age 33.3 years, were administered 600 mg bamifylline every 12 h for 7 days. The mean peak plasma concentration after the first dose was 1165 μg/L (range, 463 to 1708 μg/L) observed 1 h after dosing and 1038 (777 to 1238) μg/L for the last dose administered [Segre *et al.* 1990].

Toxicity

A 21-year-old woman who suffered from asthma was found dead. She had a blood bamifylline concentration of 205 mg/L [Offidani *et al.* 1993].

Dose Bamifylline hydrochloride has been given in doses of 0.9 to 1.8 g daily.

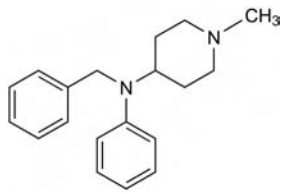
Bamipine

Antihistamine
$C_{19}H_{24}N_2$ = 280.4
CAS—4945-47-5
IUPAC Name 1-Methyl-*N*-phenyl-*N*-(phenylmethyl)-4-piperidinamine

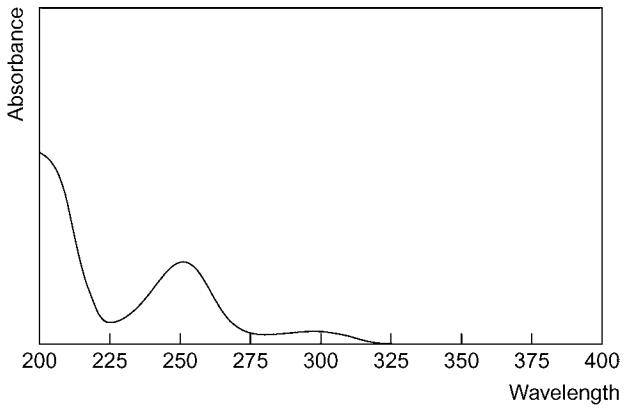


Chemical Properties Crystals. Mp about 115°. Soluble 1 in 75 of water. Log *P* (octanol), 4.1.

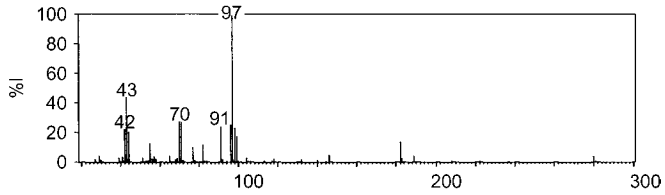
Bamipine Hydrochloride

$C_{19}H_{24}N_2$,HCl = 316.9
CAS—1229-69-2
Proprietary Names *Soventol*; *Taumidrine*.

Colour Tests Liebermann's reagent—red-orange; Mandelin's test—brown.
Thin-layer Chromatography System TA—R_f 0.49; system TB—R_f 0.40; system TC—R_f 0.43; system TL—R_f 0.13; system TAE—R_f 0.24 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—RI 2250, RI 2580 M (OH^-)-.
High Performance Liquid Chromatography System HX—RI 468.
Ultraviolet Spectrum Aqueous acid—251, 298 nm; methanol—251 (A_1^1=439b), 298 nm (A_1^1=62b).



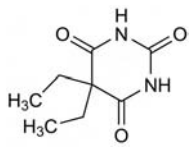
Infrared Spectrum Principal peaks at wavenumbers 745, 1593, 725, 1495, 690, 1275 cm^{-1} (KBr disk).
Mass Spectrum Principal ions at *m/z* 97, 43, 71, 70, 96, 91, 98, 42.



Dose Bamipine hydrochloride has been given in doses of 75 to 400 mg daily.

Barbital

Sedative, Barbiturate
$C_8H_{12}N_2O_3$ = 184.2
CAS—57-44-3
IUPAC Name 5,5-Diethyl-2,4,6(1*H*,3*H*,5*H*)-pyrimidinetrione
Synonyms Barb; barbitalum; barbitone; diemalum; diethylmalonylurea; malonal.

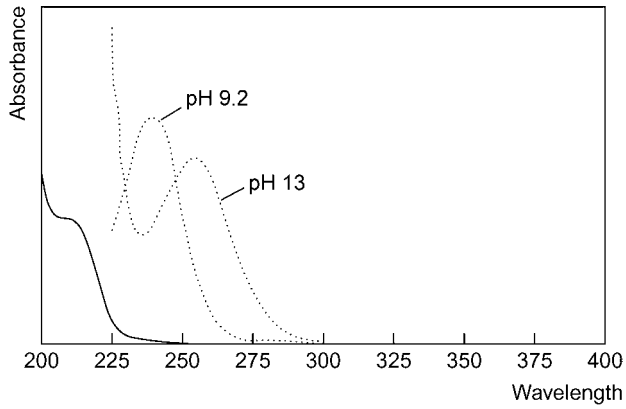


Chemical Properties Colourless crystals or white crystalline powder. Mp 188° to 192°. Soluble 1 in about 130 of water, 1 in 13 of boiling water, 1 in 14 of ethanol, 1 in 75 of chloroform and 1 in 35 of ether; soluble in acetone, ethyl acetate, petroleum ether, acetic acid, amyl alcohol, pyridine, aniline and nitrobenzene, and in solutions of alkalis. pK_a 8.0 (25°). Log *P* (octanol/water), 0.7.

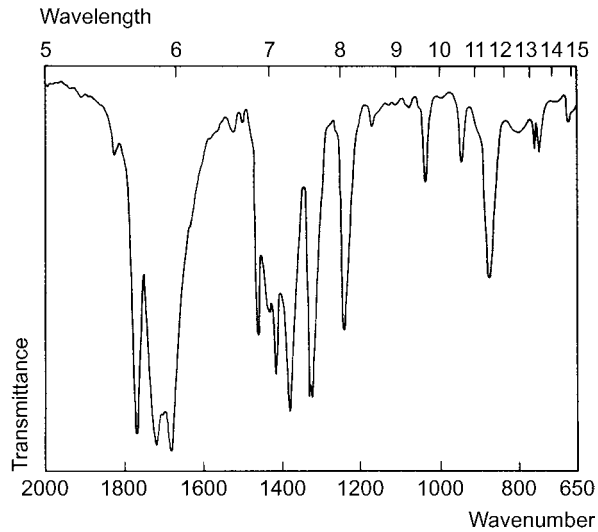
Barbital Sodium

$C_8H_{11}N_2NaO_3$ = 206.2
CAS—144-02-5
Synonyms Barbitalum natricum; barbitone sodium; diemalnatrium; soluble barbitone.
Proprietary Name *Neurinase*
Chemical Properties A white crystalline powder. A solution in water slowly decomposes. Mp about 190°. Soluble 1 in 5 of water (1 in 2.5 of boiling water) and 1 in 400 of ethanol; practically insoluble in chloroform and ether.

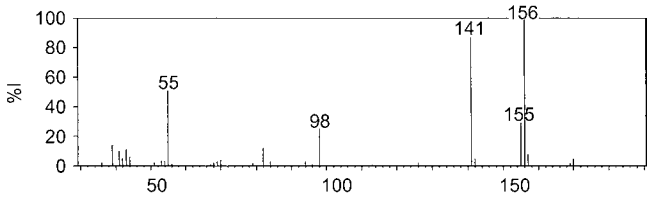
Colour Tests Koppanyi-Zwikker test—violet; mercurous nitrate—black.
Thin-layer Chromatography System TD—R_f 0.41; system TE—R_f 0.32; system TF—R_f 0.61; system TH—R_f 0.51; system TAD—R_f 0.57; system TAE—R_f 0.84 (mercuric chloride–diphenylcarbazone reagent, positive; mercurous nitrate spray, black; Zwikker's reagent, pink).
Gas Chromatography System GA—barbital RI 1489, barbital-Me_2 RI 1420, barbital-Me (metharbital) RI 1470, barbituric acid-Me_3 RI 1645; system GF—RI 2230; system GAJ—RRT 0.612 (relative to methylphenobarbital).
High Performance Liquid Chromatography System HG—*k* 1.11; system HH—*k* 0.63; system HX—RI 308; system HY—RI 258; system HZ—retention time 2.2 min; system HAA—retention time 10.4 min; system HAL—retention time 1.4 min.
Ultraviolet Spectrum Borax buffer 0.05 mol/L (pH 9.2)—239 nm (A_1^1=549a); 1 mol/L sodium hydroxide (pH 13)—254 nm (A_1^1=427b).



Infrared Spectrum Principal peaks at wavenumbers 1680, 1720, 1767, 1320, 1245, 875 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 156, 141, 55, 155, 98, 39, 82, 43.



Quantification See also under Amobarbital.
Plasma **GC–MS** Limit of detection, 0.5 mg/L [Varin *et al.* 1980].
Disposition in the Body Readily absorbed after oral administration. It is excreted slowly in the urine almost entirely as unchanged drug; about 2% of a dose is excreted in 8 h, about 16% in 32 h, and detectable amounts may still be present in the urine after 16 days. Barbital is a metabolite of metharbital.
Therapeutic Concentration In plasma, usually in the range 5 to 30 mg/L.
Toxicity The estimated minimum lethal dose is 2 g. Toxic effects may be produced with blood concentrations of about 20 mg/L or more, and concentrations greater than 90 mg/L may be lethal.

In 6 cases of acute poisoning, the amounts ingested ranged from 5 to about 25 g. In 2 cases, death ensued after 150 and 160 h when the serum concentrations were about 100 and 170 mg/L respectively. In the other 4 cases, the serum concentrations on awakening from coma were 70 to 150 µg/L. [Lous 1954a, 1954b].

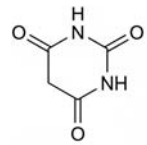
Half-life Plasma half-life, about 2 days.
Volume of Distribution About 0.5 L/kg.
Saliva Plasma : saliva ratio, about 1.
Protein Binding <20%.
Dose Barbital has been given in a dose of 300 to 600 mg.

Lous P (1954a). Plasma levels and urinary excretion of three barbituric acids after oral administration to man. *Acta Pharmacol Toxicol (Copenh)* 10: 147–165.
Lous P (1954b). Barbituric acid concentration in serum from patients with severe acute poisoning. *Acta Pharmacol Toxicol (Copenh)* 10: 261–280.
Varin F *et al.* (1980). GLC-mass spectrometric procedure with selected-ion monitoring for determination of plasma concentrations of unlabeled and labeled barbital following simultaneous oral and intravenous administration. *J Pharm Sci* 69(6): 640–643.

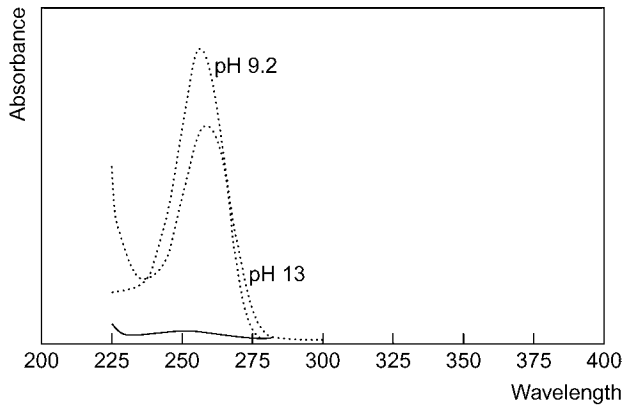
Barbituric Acid

Barbiturate
$C_4H_4N_2O_3$ = 128.1
CAS—67-52-7

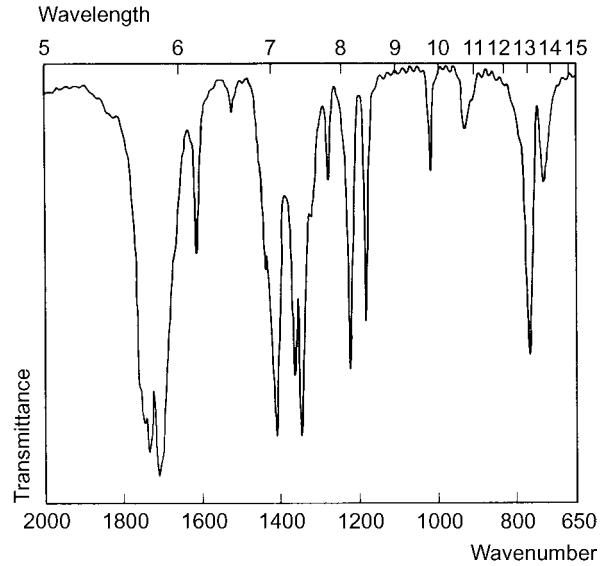
IUPAC Name 2,4,6-(1*H*,3*H*,5*H*)-pyrimidinetrione
Synonym Malonylurea



Chemical Properties Crystals. Mp about 248°, with some decomposition. pK_a 4.0 (25°). Log *P* (octanol/water), −1.5.
Thin-layer Chromatography System TD—R_f 0.00; system TE—R_f 0.00; system TF—R_f 0.00; system TH—R_f 0.03; system TAD—R_f 0.00; system TAE—R_f 0.84.
Ultraviolet Spectrum Borax buffer 0.05 mol/L (pH 9.2)—257 nm; 1 mol/L sodium hydroxide (pH 13)—259 nm.



Infrared Spectrum Principal peaks at wavenumbers 1710, 1734, 1750, 1225, 775, 1190 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 42, 128, 85, 43, 44, 41, 70, 69.

Barium

Potassium Channel Antagonist, Diagnostic Aid (Radiopaque Medium)
Ba^{2+} = 137.3
CAS—7440-39-3

Synonyms Barium, alloys non-pyrophoric; barium, alloys, pyrophoric; barium ion; barium, metal, non-pyrophoric; elemental barium.
Chemical Properties Silver-white malleable metal. Mp 710°. Bp 1600°. Soluble in benzene. Used as a gas absorbent.

Barium Acetate

$Ba(CH_3CO_2)_2$ = 255.5
CAS—543-80-6
Synonyms Acetic acid, barium salt; barium acetate monohydrate; barium diacetate.
Chemical Properties White crystals. Mp 41° (monohydrous). Very soluble in water, soluble in alcohol. Used as a mordant for printing fabrics; in lubricants; as catalyst in organic reactions.

Barium Carbonate

$BaCO_3$ = 197.3
CAS—513-77-9
Synonyms Carbonic acid, barium salt; witherite.
Proprietary Names *C. I. Pigment White 10*; *C. I. 77099*.
Chemical Properties White heavy powder. Decomposes at 1300° into BaO and CO_2. Almost insoluble in water; slightly soluble in CO_2–water; soluble in dilute hydrochloric acid, nitric acid or acetic acid; soluble in ammonium chloride and ammonium nitrate. Used as rat poison; in ceramics, paints, enamels; as a marble substitute; in the manufacture of paper, barium salts, electrodes, optical glass; as an analytical agent.

Barium Chloride

$BaCl_2$ = 208.2
CAS—10361-37-2
Synonyms Barium chloride dihydrate; barium dichloride.
Proprietary Name *SBA-0108E*
Chemical Properties The dihydrate occurs as crystals, granules or powder with a bitter salty taste. Mp 963°. Very soluble in water; soluble in methanol; practically insoluble in ethanol, acetone and ethyl acetate. Used in the manufacture of pigments, glass; in aluminium refining; as a pesticide; in tanning and finishing leather; as a boiler compound for softening water; formerly used as purgative in horses and as ruminatoric in cattle.

Barium Cyanide

$Ba(CN)_2$ = 189.4
CAS—542-62-1
Synonym Barium dicyanide
Chemical Properties Crystals; slowly decomposes in air. Very soluble in water, soluble in alcohol. Used in electroplating processes, metallurgy.

Barium Hydroxide

$Ba(OH)_2$ = 171.3
CAS—17194-00-2
Synonyms Barium dihydroxide; barium hydrate; barium hydroxide lime; barium hydroxide monohydrate; barium hydroxide octahydrate.
Proprietary Name *Caustic baryta*

Chemical Properties The monohydrate is a white powder. Slightly soluble in water; soluble in dilute acids. The octahydrate occurs as transparent crystals or white masses. Freely soluble in water, methanol; slightly soluble in ethanol; practically insoluble in acetone. Used in the manufacture of alkali, glass; in synthetic rubber vulcanisation; in corrosion inhibitors, drilling fluids, lubricants, pesticides, sugar industry, boiler scale remedy; refining animal and vegetable oils; softening water; fresco painting.

Barium Oxide

BaO = 153.3

CAS—1304-28-5

Synonyms Barium monoxide; barium protoxide.

Chemical Properties White to yellowish-white powder or lumps. Mp 1200°. Soluble in water, dilute acids, methanol and ethanol. Used for drying gases and solvents; in the manufacture of lubricating oil detergents.

Barium Sulfate

$BaSO_4$ = 233.4

Synonyms Artificial heavy spar; artificial barite; barites; blanc fixe.

Proprietary Names *Baridol*; *C.I. 77120*; *C.I. Pigment White 21*; *Citobaryum*; *Enamel White*; *E-Z-Paque*; *Solbar*; *Steripaque*.

Chemical Properties Fine heavy, odourless powder or polymorphous crystals. Mp 1600° with decomposition. Practically insoluble in water, dilute acids, alcohol. Soluble in hot concentrated sulfuric acid. Used in the manufacture of photographic papers, artificial ivory, cellophane; as a filler for rubber, linoleum, oil cloth, polymeric fibres and resins, paper, lithographic inks; as a water-colour pigment for coloured paper; in wallpaper; in heavy concrete for radiation shield.

Colour Tests

Qualitative Test (Applicable to gastric contents and scene residues.) Dip one end of a platinum wire into concentrated hydrochloric acid. Dip the moistened end into the test material. Insert the material into the hot region of a microburner and observe the colour of the flame—Barium imparts a yellow green colour to the flame (copper and thallium salts also produce a green flame). Limit of detection, 50 mg/L.

Confirmatory Test Mix 2 mL of lead acetate solution (100 g/L) with 2 mL of 1 mol/L sulfuric acid and add sufficient aqueous acetic acid (50 mL/L) to dissolve the lead sulfate precipitate. Add 0.1 mL of dilute acetic acid to 1 mL of sample, add 1 mL of the lead sulfoacetate solution (from step 1) and vortex mix for 5 s. Centrifuge for 2 min and examine the tube against a black background—The presence of barium is indicated by a white turbidity or a white precipitate (calcium and strontium interfere). Limit of detection, 100 mg/L.

Quantification

Specimen Collection Blood—5 mL K-EDTA tube; urine—20 mL plastic universal container.

Blood **ICP-AES** Limit of detection, 2 µg/kg [Dinya *et al.* 2005].

ICP-MS Plasma gas: 16 L/min. Auxiliary gas: 1 L/min. Nebuliser gas: 1.15 or 1.33 mL/min. Limit of detection, 10 µg/L [De Boer *et al.* 2004].

Serum **ICP-AES** Outer gas: 16.0 L/min. Nebulizer gas: 0.9 L/min. RCA 1P28 photomultiplier ($\lambda = 455$ nm). Limit of quantification, 11 µg/L, limit of detection, 0.22 µg/L [Mianzhi, Barnes 1985].

Urine **CE** Capillary: Polyimide-coated fused silica (total/effective length 81/60 cm, 100 µm). UV detection ($\lambda = 255$ nm). Limit of detection not reported [Xu *et al.* 1994]. Capillary: AccuSep fused silica (52 cm effective length, 75 µm). UV detection ($\lambda = 214$ nm). Limit of detection not reported [Buchberger *et al.* 1994].

ICP-MS See Blood. Limit of detection, 5 µg/L [De Boer *et al.* 2004].

Oral Fluid **ICP-MS** Plasma gas: 13 L/min. Auxillary gas: 0.55 L/min. Nebulizer gas: 0.1 L/min. Limit of detection, 0.11 µg/L [Menegario *et al.* 2001].

Synovial Fluid **ICP-MS** Coolant gas: Ar, 15.0 L/min. Auxiliary gas: 0.99 L/min. Nebuliser gas: 1.0 L/min. Limit of detection, a few nanograms per litre [Krachler *et al.* 2000].

Other **ICP-MS**. GSR. Coolant gas: 15 L/min. Auxiliary gas: 1.1 L/min. Sample gas: 0.97 L/min. Limit of detection, 0.507 µg/L [Reis *et al.* 2003].

Disposition in the Body

Approximately 90% of the total body burden of barium is found in the bone and teeth, with trace amounts present in all other human tissues. It is estimated that the gastrointestinal absorption of barium is <5%. Barium is not metabolised in the body but may be metabolically transported or incorporated into complexes or tissues. Only a fraction of an ingested dose is excreted in the urine (less than 3%), with the main route of elimination being via the faeces.

Note For a pharmacokinetic model of the transfer of alkaline earth elements to the fetus, see Fell *et al.* [2001] and for data on whole-body retention of injected ^{133}Ba, see Newton *et al.* [2001].

Normal Concentrations Plasma—<1 µg/L (<7 nmol/L); urine—< 20 µg/24h (<0.15 nmol/24 h); bone—2000 µg/kg; brain—4 µg/kg; heart—9 µg/kg; kidney—16 µg/kg; liver—3 µg/kg; lung—160 µg/kg.

Toxicity Insoluble barium salts (e.g. barium sulfate) are relatively innocuous by oral ingestion, although inhalation of barium dusts can produce a benign pneumoconiosis (baritosis) in mine workers. Soluble barium salts (e.g. the carbonate and chloride) are very toxic after oral or pulmonary ingestion and induce abdominal pain, diarrhoea, vomiting and muscular paralysis. This can be accompanied by a severe hypokalaemia, which causes disturbances in the cardiac rhythm. Doses as low as 0.5 g of a soluble barium salt can be lethal in an adult.

A 42-year-old man presented with marked lethargy and fever. He had ingested approx. 50 mL of an industrial chemical solution approx. 1 h prior to admission. His serum barium concentration was 34.1 µg/L [Hung, Chung 2004].

A 52-year-old woman attempted suicide by ingesting 70 mg amlodipine, 280 mg fluoxetine, and an unknown amount of an unidentified white powder. Barium carbonate intoxication was suspected so continuous venovenous haemodiafiltration (CVVHDF) was initiated. A total of 125 mg of barium was eliminated 14 h after initiation of CVVHDF and 152 mg after 42 h, at discontinuation of CVVHDF. Average barium concentrations in the 24 h urine collections on days 2 and 3 were 18.7 and 69.7 mg/L, respectively. Urinary barium excretion on days 2 and 3 was 69.7 and 101 mg, respectively [Koch *et al.* 2003].

A 61-year-old woman was hospitalised for the treatment of suspected acute pancreatitis. Following the administration of barium contrast material on day 27, the patient presented with severe abdominal bloating and prostration. The patient's condition continued to deteriorate and she died on day 41. The serum barium concentration was 370 µg/L on day 39 and 150 µg/L on day 41. The concentration of barium in the CSF was 440 µg/L [Pelissier-Alicot *et al.* 1999].

A study of welders using consumable electrodes with high barium content for 4 h each day showed high concentrations of barium in the urine, but they suffered no discernable health effects [Zschiesche *et al.* 1992].

A 22-year-old man swallowed approximately 5 to 10 g barium carbonate in an attempt to commit suicide. On admission, his plasma barium concentration was approx. 250 µg/L. Following haemodialysis, his plasma barium concentration had decreased to approx. 18 µg/L, with a half-life of 1.9 h. After haemodialysis, the plasma barium concentration increased transiently (redistribution) and then steadily decreased with a half-life of 18 h [Schorn *et al.* 1991].

An adult who died several hours after ingesting a depilatory containing barium sulfide had barium concentrations of 1.9 mg/L (blood), 0.4 mg/kg (brain), 1.6 mg/kg (liver), 6.1 mg/kg (bile), 5.9 mg/kg (spleen), 7.5 mg/kg (kidney), and 0.5 mg/L (vitreous) [Baselt 2005].

In 2 cases of non-fatal barium poisoning, serum barium concentrations of 3.4 and 7.8 mg/L were measured [Boehnert *et al.* 1985; Phelan *et al.* 1984].

A 62-year-old man sustained a barium burn when his jackhammer penetrated a pocket of molten barium chloride. Approximately 2 h after the burn, the plasma barium concentration was 12.4 mg/L. At 4, 8, 12 and 18 h postburn the barium concentrations were 10.3, 8.2, 8.9 and 4.0 mg/L, respectively. After several successful skin grafts, the patient was discharged [Stewart, Hummel 1984].

Two individuals who died 14 and 31 h after ingesting barium sulfide were found to have barium concentrations of 132 and 14 mg/kg in liver and 160 and 162 mg/kg in kidney, respectively [Baisane *et al.* 1978].

Note For a report of 2 cases of acute dyspnoea following aspiration of large amounts of barium sulfate, see Tamm and Kortsik [1999]; for a study on the environmental influences on the trace element content of teeth, see Brown *et al.* [2004]. Rahil-Khazen *et al.* [2002] have studied trace element levels in the autopsy tissue of 30 Norwegians.

Half-life 10–18 h [Baselt 2008].

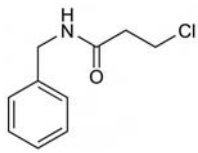
B

Beclamide

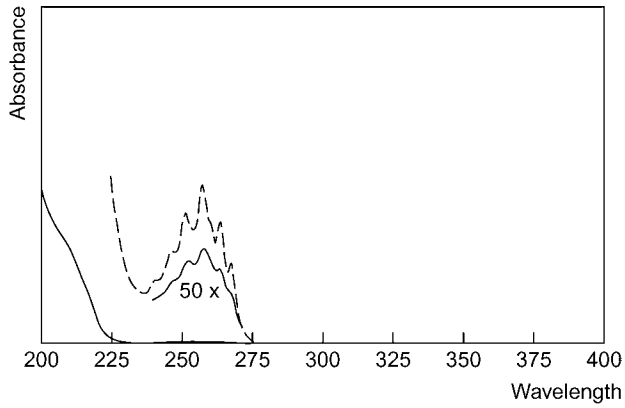
Anticonvulsant
$C_{10}H_{12}ClNO$ = 197.7
CAS—501-68-8

IUPAC Name 3-Chloro-*N*-(phenylmethyl)propanamide
Synonyms Benzchlorpropamide; chloroethylphenamide.
Proprietary Names *Neuracen*; *Nydrane*; *Posedrine*.

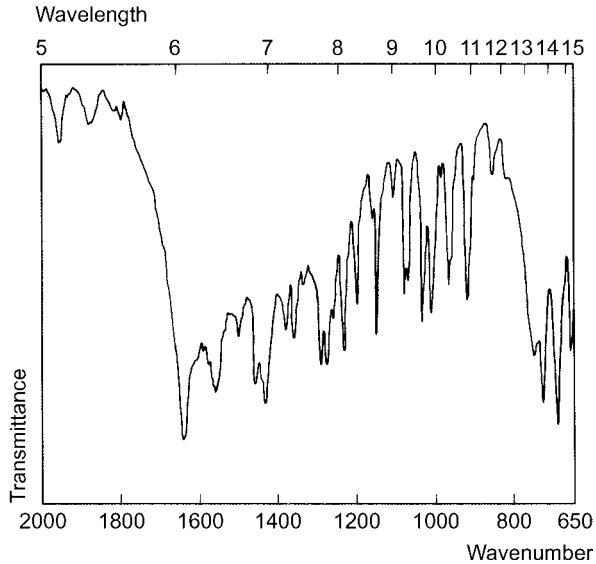


Chemical Properties Colourless crystals. Mp 91° to 94°. Slightly soluble in water; soluble 1 in 14 of ethanol, 1 in 5 of chloroform, and 1 in less than 100 of ether. Log *P* (octanol/water), 1.8.

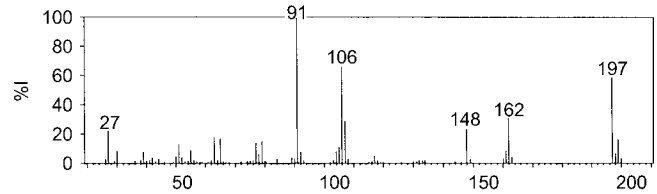
Colour Test Liebermann's reagent—red-orange.
Thin-layer Chromatography System TA—R_f 0.65; system TB—R_f 0.08; system TC—R_f 0.65; system TL—R_f 0.64; system TAE—R_f 0.90 (acidified potassium permanganate solution, positive, developing slowly).
Gas Chromatography System GA—beclamide RI 1720, beclamide-Art RI 1680; system GB—beclamide RI 1778, beclamide-Art RI 1539.
Ultraviolet Spectrum Aqueous acid—252, 258, 264 nm; methanol—252, 258 nm (A^1_1=9.6b), 264, 268 nm.



Infrared Spectrum Principal peaks at wavenumbers 1640, 696, 736, 1558, 1275, 1290 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 91, 106, 197, 162, 107, 148, 27, 63.



Quantification
***Plasma* GC** FID. Limit of detection, 200 µg/L [Jones *et al.* 1975].
***Urine* HPLC** Column: Apex ODS (250 × 4.5 mm i.d., 5 µm). Mobile phase: acetonitrile : water (22.5:77.5): potassium dihydrogen phosphate (1.4 g/L), flow rate 2 mL/min. Internal standard: hexobarbital. UV detection (λ=215 nm). Retention time: beclamide 8.8 min; 4-hydroxybeclamide 3.0 min; 3-hydroxybeclamide 3.5 min. Limit of detection, 0.2 mg/L for beclamide and metabolites [Ahmadi *et al.* 1995].
Disposition in the Body Beclamide is absorbed after oral administration. <0.5% of a dose is excreted in the urine as unchanged drug in 24 h; a metabolite, tentatively identified as an *N*-hydroxybenzyl-3-chloropropionamide, has been detected in the urine as a glucuronide conjugate. Its 3-hydroxyphenyl (7% excreted over 24 h) and 4-hydroxyphenyl (24% over 24 h) metabolites are detected as both glucuronide (majority) and sulfate conjugates in urine. Approximately 22% of an administered dose is excreted as hippuric acid.
Therapeutic Concentration
Following a single oral dose of 1 g to 6 subjects, peak plasma concentrations of 8.7 to 18.9 (mean 13) mg/L were attained in 1 to 4 h [Leach *et al.* 1975].
Dose 1.5 to 4 g daily.

Ahmadi M *et al.* (1995). Metabolism of beclamide after a single oral dose in man: quantitative studies. *J Pharm Pharmacol* 47: 876–878.
Jones OP *et al.* (1975). A simple method for the determination of beclamide in plasma by gas chromatography. *Br J Clin Pharmacol* 2: 364–365.

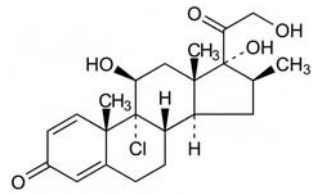
Beclometasone

Corticosteroid
$C_{22}H_{29}ClO_5$ = 408.9
CAS—4419-39-0

IUPAC Name (11β,16β)-9-Chloro-11,17,21-trihydroxy-16-methylpregna-1,4-diene-3,20-dione
Synonyms Beclomethasone; 9α-chloro-16β-methylprednisolone.



Chemical Properties Log *P* (octanol/water), 2.0.

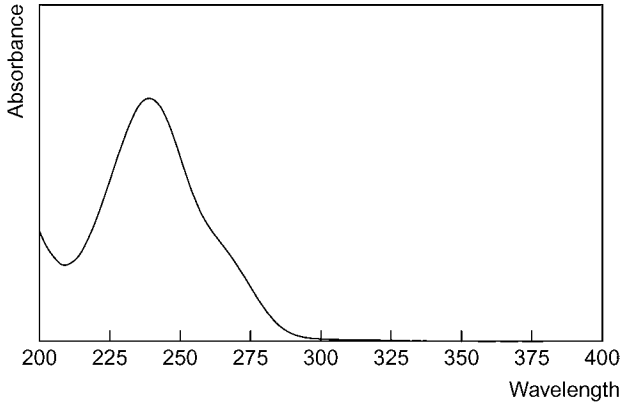
Beclometasone Dipropionate

$C_{28}H_{37}ClO_7$ = 521.0
CAS—5534-09-8
Proprietary Names *Aldecin*; *Becloforte*; *Beclovent*; *Beconase*; *Becotide*; *Clenil*; *Propaderm*; *Sanasthmyl*; *Turbinal*; *Vancenase*; *Vanceril*; *Viarox*. It is an ingredient of *Ventide*.
Chemical Properties A white to creamy-white powder. Mp about 212°, with decomposition. Practically insoluble in water; soluble 1 in 60 of ethanol and 1 in 8 of chloroform; freely soluble in acetone.

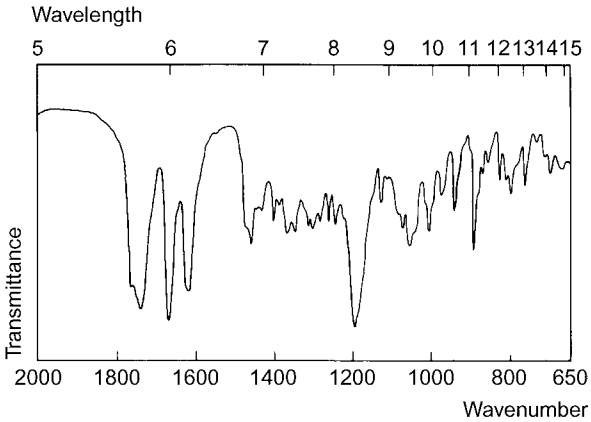
Colour Tests Naphthol–sulfuric acid—green/brown-yellow; sulfuric acid—orange (slow).
Thin-layer Chromatography Beclometasone dipropionate: system TP—R_f 0.75; system TQ—R_f 0.38; system TR—R_f 0.89; system TS—R_f 0.42, streaking may occur (*p*-Toluenesulfonic acid solution, positive).
High Performance Liquid Chromatography System HT—*k* 4.2; system HX—RI 444; system HY—RI 711 (dipropionate).
Column: C_{18} Alltima (250 × 4.6 mm i.d.). Mobile phase: methanol : water : acetonitrile : glacial acetic acid (650:262:88:1.75), flow rate 1.3 mL/min. Internal standard (IS): dexamethasone-21-acetate. UV detection (λ=242 nm). Retention time: beclometasone, 3.9 min; beclometasone propionate, 15.4 min [Foe *et al.* 1998a].
Column: (1) C_{18} Alltima 16% carbon load (250 × 4.6 mm i.d., 5 µm); (2) C_{18} Econosphere 10% carbon load (250 × 4.6 mm i.d., 5 µm); (3) C_8 Ultrasphere (150 × 4.6 mm i.d., 5 µm). Mobile phase: (1) methanol : water : acetonitrile : acetic acid (309:146:44:1), flow rate 1.3 mL/min; (2) (250:205:44:1), 1.2 mL/min; (3) (275:180:44:1), 1.3 mL/min. UV detection (λ=242 nm). Retention time:

beclometasone, (1) 4.9 min, (2) 5.5 min, (3) 3.3 min; beclometasone propionate, (1) 23.0 min, (2) 25.9 min, (3) 17.6 min [Foe *et al.* 1998b].

Ultraviolet Spectrum Beclometasone dipropionate: dehydrated alcohol—239 nm (A^{1}_{1}=292a).



Infrared Spectrum Principal peaks at wavenumbers 1190, 1658, 1730, 1608, 890, 1053 cm^{-1} (beclometasone dipropionate, KBr disk).



Quantification

Hair **HPLC–MS** MS detection (*m/z* 411). Limit of detection, 0.17 ng/g [Cirimele *et al.* 2000].

Disposition in the Body Beclometasone dipropionate is rapidly converted to the metabolite beclometasone-17-monopropionate.

Therapeutic Concentration

Twelve healthy males, aged 22 to 39 years, were administered a single IV dose of 1.0 mg over a 10-min infusion, a single intranasal dose of 1.344 mg, a single inhaled dose of 1.0 mg and a single oral dose of 4.0 mg as an aqueous solution. Subjects were fasted 12 h before dosing and for 2 h afterwards. The median peak plasma beclometasone dipropionate concentrations for the above doses were 35.356 µg/L (range 20.2 to 61.7 µg/L) observed at 0.2 to 0.3 h, 0.31 (0.256 to 0.375) µg/L at 4 to 8 h, 0.319 (0.184 to 0.553) µg/L at 0.2 to 0.5 h and 0.703 (0.563 to 0.879) µg/L at 1.5 to 6.0 h, respectively [Daley-Yates *et al.* 2001].

Half-life Beclometasone dipropionate, 0.3 to 0.7 h; beclometasone 17-monopropionate, 1.3 to 5.3 h.

Volume of Distribution Beclometasone dipropionate, median, 20 L (range 10.6 to 39.4); beclometasone 17-monopropionate, 424 (362 to 496) L.

Clearance Plasma, beclometasone dipropionate, median, 150 (98.8 to 228) L/h; beclometasone 17-monopropionate, 120 (104 to 139) L/h.

Dose Usually 300 to 400 µg of beclometasone dipropionate daily, by aerosol inhalation; maximum of 2 mg daily.

Bemegride

CNS Stimulant, Antidote (Barbiturate Poisoning)

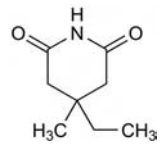
$C_8H_{13}NO_2$ = 155.2

CAS—64-65-3

IUPAC Name 4-Ethyl-4-methyl-2,6-piperidinedione

Synonym Methetharimide

Proprietary Names *Eukraton*; *Megimide*.



Chemical Properties White flakes or crystalline powder. Mp 126° to 128°. Soluble 1 in 170 of water, 1 in 30 of ethanol, 1 in 12 of acetone, 1 in 4 of chloroform and 1 in 100 of ether; soluble in aqueous solutions of alkali hydroxides. pK_a 11.6. Log *P* (octanol/water), 0.5.

Bemegride Sodium

$C_8H_{12}NNaO_2$ = 177.2

CAS—25334-00-3

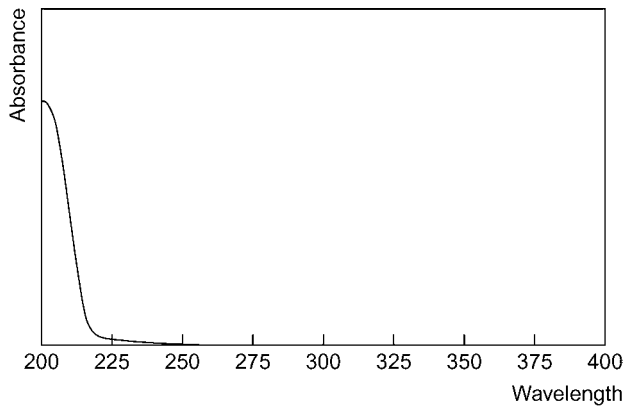
Chemical Properties A fine white powder. Soluble 1 in 11 of water and 1 in 20 of ethanol; practically insoluble in acetone and ether.

Colour Tests Koppanyi-Zwikker test—violet; mercurous nitrate—black.

Thin-layer Chromatography System TD—R_f 0.52; system TE—R_f 0.68; system TF—R_f 0.53; system TAD—R_f 0.64; system TAF—R_f 0.88 (mercuric chloride–diphenylcarbazone reagent, positive; mercurous nitrate spray, black).

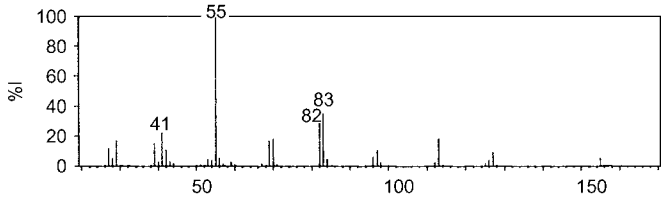
Gas Chromatography System GA—RI 1373; system GC—RI 1253.

Ultraviolet Spectrum No significant absorption, 230 to 360 nm.



Infrared Spectrum Principal peaks at wavenumbers 1680, 1277, 1730, 860, 1160, 1145 cm^{-1} (KBr disk).

Mass Spectrum Principal ions at *m/z* 55, 83, 82, 41, 113, 70, 29, 69.



Disposition in the Body Metabolised by hydroxylation of the ethyl side-chain and excreted in the urine as unchanged drug and as the hydroxy metabolite.

Dose Bemegride has been given in doses of 25 to 50 mg intravenously, repeated as necessary.

Bemiparin

Anticoagulant, Heparin, Anti-Factor Xa Activity

CAS—9041-08-1

Synonyms Bemiparin sodium; RO-11.

Proprietary Names *Hibor*; *Ivor*; *Zibor*.

Chemical Properties Prepared by alkaline degradation of heparin obtained from the intestinal mucosa of pigs. The majority of the components have a 2-*O*-sulfo-4-enepyranosuronic acid structure at the non-reducing end and a 2-*N*,6-*O*-disulfo-D-glucosamine structure at the reducing end of their chain. The average molecular weight is approx. 3600 (3000 to 4200). The degree of sulfation is approx. 2 per disaccharide unit.

Disposition in the Body Rapidly absorbed after SC injection, with peak plasma activity reached in about 2 to 4 h, depending on the dose. Peak plasma

activity following IV administration is approx. 3 times that following SC administration of the same dose. Data concerning the metabolism of bemiparin are not available, although it is suggested that elimination occurs via the renal route.

Therapeutic Concentration

Twelve healthy young male volunteers were administered three SC injections of bemiparin: 7500 IU anti-FXa (90 mg), 9000 IU anti-FXa (120 mg), and 12 500 IU anti-FXa (150 mg), leaving a washout period of 1 week between treatments. Tissue factor pathway inhibitor (TFPI, total and free) plasma levels were reported as follows:

Bemiparin anti-FXa (IU)	*Plasma TFPI (μg/L)*
Total TFPI	
7 500	112.8
9 000	133.0
12 500	139.2
Free TFPI	
7 500	43.5
9 000	53.2
12 500	61.7

These were reached within 2 to 6 h but returned to baseline levels 10 to 12 h after injection [Falkon *et al.* 1998].

In 2 dose-ranging studies, healthy volunteers were administered SC injections of bemiparin: 2500, 5000, 7500, 9000, and 12 500 IU anti-FXa. Maximum anti-Xa activity (E_{Max}) was reported as follows:

Regimen (anti-Xa IU)	*E_{max} (IU/mL)*	*t_{max} (h)*
2 500	0.34	2 to 3
5 000	0.54	3 to 4
7 500	1.22	3 to 6
9 000	1.42	3 to 6
12 500	2.03	2 to 6

Another set of subjects was administered an IV injection of 5000 IU anti-Fxa; the E_{max} was reported as 1.30 IU/mL [Falkon *et al.* 1995, 1997].

Twelve healthy volunteers were administered SC injections of bemiparin 3500 IU anti-XFa. The maximum anti-Xa activity was reported as 0.34 IU/mL after 2.5 h [Depasse *et al.* 2003].

Bioavailability Approximately 96%.

Half-life Approximately 5 to 6 h.

Volume of Distribution Approximately 5.1 L.

Clearance 0.90 L/h.

Dose In the prophylaxis of venous thromboembolism during general surgery with moderate risk, bemiparin sodium is given SC in a dose of 2500 IU once daily, with the first dose given 2 h before or 6 h after surgery; in patients undergoing orthopaedic surgery with high risk of thromboembolism, the dose should be 3500 IU initially and then once daily. Treatment should be continued for at least 7 to 10 days and until the patient is fully ambulant. For treatment of thromboembolism, a dose of 115 IU/kg is given SC once daily. For the prevention of clotting in the extracorporeal circulation during haemodialysis, bemiparin sodium is administered into the arterial side of the dialyser in a single dose of 2500 IU for patients weighing less than 60 kg and 3500 IU for patients weighing more than 60 kg.

Depasse F *et al.* (2003). Comparative study of the pharmacokinetic profiles of two LMWHs – bemiparin (3500 IU, anti-Xa) and tinzaparin (4500 IU, anti-Xa) – administered subcutaneously to healthy male volunteers. *Thromb Res* 109: 109–117.

Falkon L *et al.* (1995). Bioavailability and pharmacokinetics of a new low-molecular-weight heparin (RO-11): a three way cross-over study in healthy volunteers. *Thromb Res* 78: 77–86.

Falkon L *et al.* (1998). Tissue factor pathway inhibitor and anti-FXa kinetic profiles of a new low-molecular-mass heparin, bemiparin, at therapeutic subcutaneous doses. *Blood Coagul Fibrinolysis* 9: 137–141.

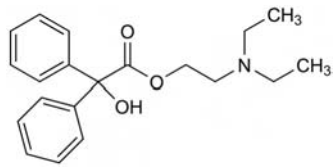
Benactyzine

Antispasmodic

$C_{20}H_{25}NO_3$ = 327.4

CAS—302-40-9

IUPAC Name α-Hydroxy-α-phenylbenzeneacetic acid 2-(diethylamino)ethyl ester



Chemical Properties Crystals. Mp 51°. pK_a 6.6. Log *P* (octanol/water), 2.9.

Benactyzine Hydrochloride

$C_{20}H_{25}NO_3$,HCl = 363.9

CAS—57-37-4

Proprietary Name It is an ingredient of *Deprol*.

Chemical Properties A white crystalline powder. Mp 177° to 181°. Soluble 1 in 14 of water and 1 in 22 of ethanol; very slightly soluble in ether.

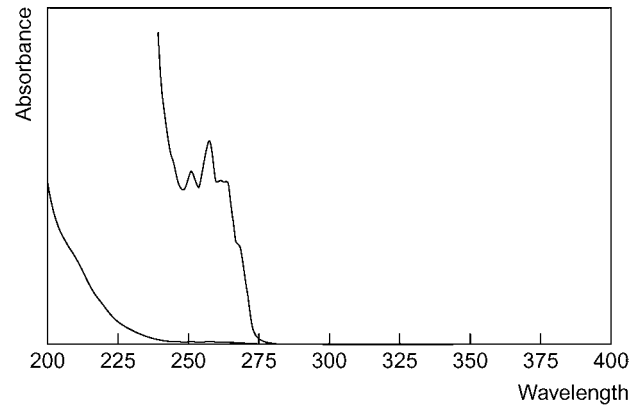
Colour Tests Liebermann's reagent—orange→brown; Marquis test—orange→green→blue; sulfuric acid—orange.

Thin-layer Chromatography System TA—R_f 0.66; system TB—R_f 0.40; system TC—R_f 0.53; system TL—R_f 0.53; system TAE—R_f 0.52; system TAF—R_f 0.57; system TAJ—R_f 0.34; system TAK—R_f 0.03; system TAL—R_f 0.48 (acidified iodoplatinate solution, positive).

Gas Chromatography System GA—RI 2255.

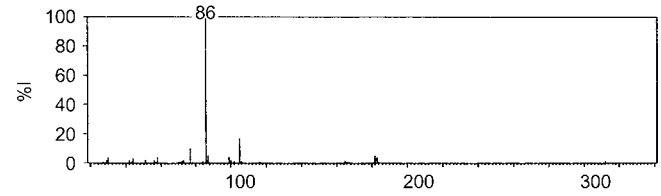
High Performance Liquid Chromatography System HA—*k* 1.7; system HX—RI 382.

Ultraviolet Spectrum Aqueous acid—252, 258 (A_1^1=14a), 262, 264 nm.



Infrared Spectrum Principal peaks at wavenumbers 695, 1723, 1231, 1054, 1162, 751 cm^{-1} (KBr disk).

Mass Spectrum Principal ions at *m/z* 86, 105, 77, 87, 182, 99, 183, 58.



Disposition in the Body Rapidly metabolised and excreted.

Dose 3 to 9 mg of benactyzine hydrochloride daily.

Benaprizine

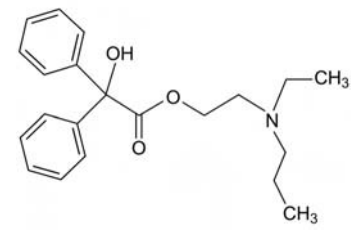
Anticholinergic

$C_{21}H_{27}NO_3$ = 341.4

CAS—22487-42-9

IUPAC Name 2-(*N*-Ethylpropylamino)ethyl benzilate

Synonym Benapryzine



Benaprizine Hydrochloride

$C_{21}H_{27}NO_3$,HCl = 377.9

CAS—32702-55-9

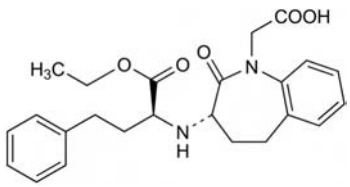
Chemical Properties A white crystalline powder. Mp about 166°. Soluble 1 in 35 of water, 1 in 56 of dehydrated alcohol, 1 in 120 of acetone and 1 in 8 of chloroform.

Thin-layer Chromatography System TAJ—R_f 0.48; system TAK—R_f 0.05; system TAL—R_f 0.58.
Ultraviolet Spectrum Aqueous acid—251, 257, 261, 264 nm.
Infrared Spectrum Principal peaks at wavenumbers 1753, 1215, 700, 690, 1180, 1020 cm^{-1} (benaprizine hydrochloride, KCl disk).
Dose 150 to 200 mg of benaprizine hydrochloride daily.

Benazepril

ACE Inhibitor, Antihypertensive
$C_{24}H_{28}N_2O_5$ = 424.5
CAS—86541-75-5

IUPAC Name 2-[(3*S*)-3-[[(2*S*)-1-Ethoxy-1-oxo-4-phenylbutan-2-yl]amino]-2-oxo-4,5-dihydro-3*H*-1-benzazepin-1-yl]acetic acid
Synonym [*S*-(*R**, *R**)]-3-[[1-(Ethoxycarbonyl)-3-phenylpropyl]amino]-2,3,4,5-tetrahydro-oxo-1*H*-1-benzazepine-1-acetic acid



Chemical Properties Mp 148.5°. Log *P* (octanol/water), 3.50.

Benazepril Hydrochloride

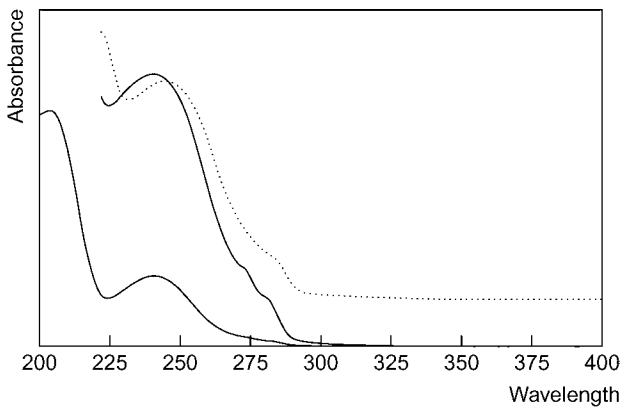
$C_{24}H_{28}N_2O_5$,HCl = 461.0
CAS—86541-74-4
Synonym CGS 14824A
Proprietary Names *Briem*; *Cibace*; *Cibacen*; *Cibacene*; *Fortekor*; *Labopal*; *Lotensin*; *Tensanil*; *Zinandril*.
Chemical Properties A white to off-white crystalline powder. It is soluble in water, ethanol and methanol.

Gas Chromatography System GP—methyl ester (-ME) derivative RI 3030, M (-ME_3) RI 2985.
High Performance Liquid Chromatography System HAA—RT 17.0 min.

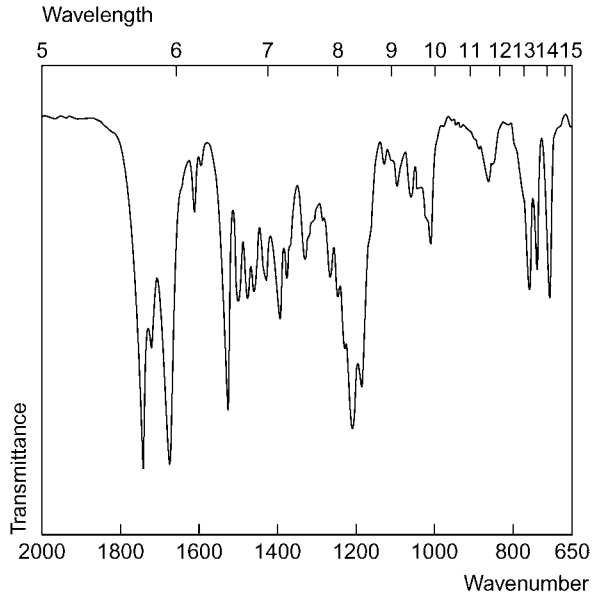
Column: RP-BDS C_{18} (250 × 3 mm i.d., 5 µm). Mobile phase: 0.025 mol/L sodium dihydrogen phosphate (pH 4.8) : acetonitrile (55 : 45), flow rate 0.4 mL/min. UV detection (λ = 250 nm). Retention time: benazepril hydrochloride, 4.95 min. [Panderi, Parissi-Poulou 1999].

Column: Hypersil ODS (250 × 4.5 mm i.d., 5 µm). Mobile phase: 20 mmol/L sodium heptane sulfonate (pH 2.5) : acetonitrile (5% THF; 52 : 48), flow rate 1.0 mL/min. UV detection (λ = 215 nm). Retention time: 15 min [Bonazzi *et al.* 1997].

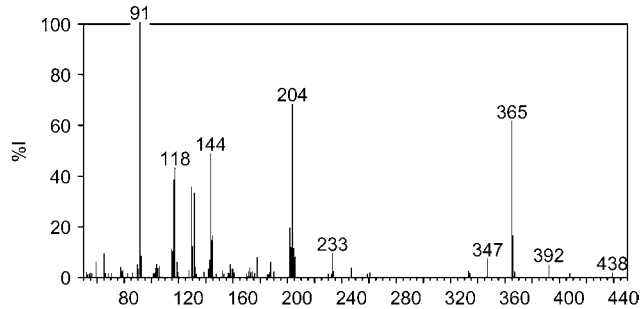
Ultraviolet Spectrum Aqueous acid (0.2 mol/L sulfuric acid)—237 nm; basic—241 nm; aqueous acid (0.1 mol/L hydrochloric acid)—237.2 nm (hydrochloride salt).



Infrared Spectrum Principal peaks at wavenumber 1739, 1674, 1211 cm^{-1} (KBr pellet).



Mass Spectrum Principal peaks at *m/z* 365, 204, 91, 366, 392, 347 (benazepril methyl ester derivative); 379, 204, 380, 91, 144, 438 (benzaprilat).



Quantification

Plasma **GC-MS** Column: Resteck Rtx-1 (15 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 50 mL/min. Temperature programme: 190° for 0.5 min to 290° at 30°/min. MSD. Limit of quantification, 2.5 µg/L [Pommier *et al.* 2003]; Column: cross-linked methyl silicone (12.5 m × 0.2 mm i.d.). Carrier gas: He, 55 kPa. Temperature programme: 210° for 0.5 min to 290° at 50°/min. MSD. Limit of quantification, 5.4 nmol/L [Sioufi *et al.* 1988]. Column: 3% OV-101 on Gaschrom Q, 80/100 mesh (1.5 m × 2 mm i.d.). Temperature: 275°. Carrier gas: He, 30 mL/min. EI ionisation at 70 eV, SIM acquisition mode. Retention times: benazepril (ME derivative) 2.55 min, benazeprilat 2.3 min. Limit of quantification, 26 µg/L for benazepril and 23 µg/L for benazeprilat, limit of detection, 3.4 µg/L for benazepril and 2.3 µg/L for benazeprilat [Kaiser *et al.* 1987].

HPLC Column: Hypersil BDS-C_{18} (300 × 4.6 mm i.d., 5 µm). Mobile phase: 10 mmol/L phosphate buffer (pH 2.6) : acetonitrile 70 : 30 for 6 min to 50 : 50 at 15 min for 1 min to 70 : 30 at 20 min for 3 min), flow rate 1.0 mL/min. UV detection (λ = 237 nm). Limit of quantification, 20 µg/L, limit of detection, 10 µg/L for benazepril and benazeprilat [Wang *et al.* 2007].

LC-MS Column: reversed-phase porous graphitised carbon (125 × 2.1 mm i.d., 5 µm). Mobile phase: 55% acetonitrile : 0.3% formic acid (55 : 45), flow rate 0.15 mL/min. SIM acquisition mode. Limit of quantification, 5 µg/L for benazepril, benazeprilat and hydrochlorothiazide [Vonaparti *et al.* 2006]. Column: Spherigel C_{18} (250 × 4.6 mm i.d., 5 µm). Mobile phase: acetonitrile : 0.1% aqueous formic acid (35 : 65 for 5 min to 65 : 35 at 5.5 min until 12 min to 35 : 65 at 12.5 min until 15 min), flow rate 0.8 mL/min. ESI, positive ion mode, SIM acquisition mode. Limit of quantification, 6.67 µg/L, limit of detection, 2.5 µg/L [Xiao *et al.* 2005].

Bioassay Limit of detection, 8.5 µg/L [Graf *et al.* 1988].

Urine **GC-MS** See Plasma. Limit of quantification, 11 nmol/L [Sioufi *et al.* 1988]. SIM acquisition mode. Limit of quantification, 34 µg/L for benazepril and 64.5 µg/L for benazeprilat, limit of detection, 6.4 µg/L for benazepril and 7.6 µg/L for benazeprilat [Kaiser *et al.* 1987].

Bioassay Limit of detection, 4.25 µg/L [Graf *et al.* 1988].

Other **HPLC** Tablets. Column: BDS C_{18} (250 × 3.0 mm i.d., 5 µm). Mobile phase: 0.025 mol/L sodium dihydrogen phosphate (pH 4.8) : acetonitrile (55 : 45), flow rate 0.4 mL/min. UV detection (λ = 250 nm). Limit of quantification, 2.92 mg/L, limit of detection, 0.88 mg/L [Panderi, Parissi-Poulou 1999].

Disposition in the Body A minimum of 37% of an oral dose of benazepril is absorbed (fasting) and is rapidly converted to its active carboxylic metabolite benazeprilat by enzymatic hydrolysis in the liver. Benazepril is cleared mainly by

metabolic transformation, with <1% being excreted unchanged in urine along with its acyl glucuronide metabolite. Approximately 18% of an oral dose is recovered in urine as the diacid benazeprilat. Peak plasma concentrations of benazeprilat occur 1–2 h after administration if fasting, and 2–4 h in the non-fasting state. The majority of benazeprilat is excreted in urine, with 11–12% excreted in bile. Elimination is slow in renal impairment. Very small amounts of benazepril and benazeprilat are secreted into breast milk.

Therapeutic Concentration

A daily (oral) dose of 10 mg benazepril was administered to 9 young subjects (male; 21–39 years) and 9 elderly subjects (6 male, 3 female; between 66 and 76 years), over 8 consecutive days. After repeated administration, benazeprilat was detected in plasma immediately before the last dose with mean values of 0.015 µg/L for the young subjects and 0.037 µg/L for the elderly. These values, and those obtained 24 h later, are consistent with steady-state disposition of benazeprilat. Time to peak concentrations was 1.5 h for both groups, after acute and chronic administration [Macdonald *et al.* 1993].

Toxicity Severe hypotension with acute overdose.

Half-life Apparent elimination half-life for benazepril is 0.6 h and it is eliminated from plasma completely within 4 h. Benazeprilat is eliminated in a biphasic manner with an initial half-life of 3 h and a terminal half-life of 17 h.

Volume of Distribution Steady state, ~0.7 L/kg (metabolite).

Distribution in Blood Benazeprilat is not extensively distributed into extravascular sites with minimum passage across the blood–brain barrier.

Protein Binding Benazepril and benazeprilat both bind serum proteins, ~94% and 93%, respectively.

Note For a study on the pharmacokinetics and pharmacodynamics of benazepril, see Shionoiri *et al.* [1992].

Dose For hypertension, an initial dose of 10 mg once daily is recommended in patients with creatinine clearance of 30 mL/min or greater and in those not receiving diuretics. For those with a creatinine clearance <30 mL/min or receiving diuretics, an initial daily dose of 5 mg is recommended. For heart failure, an initial daily dose of 2.5 mg is recommended. A usual daily dose is between 20 and 40 mg with a maximum of 80 mg (lower in heart failure and renal impairment).

Bendroflumethiazide

Diuretic

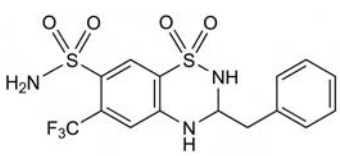
$C_{15}H_{14}F_3N_3O_4S_2 = 421.4$

CAS—73-48-3

IUPAC Name 3,4-Dihydro-3-(phenylmethyl)-6-(trifluoromethyl)-2*H*-1,2,4-benzothiadiazine-7-sulfonamide 1,1-dioxide

Synonyms Bendrofluazide; benzydroflumethiazide.

Proprietary Names *Aprinox*; *Berkozide*; *Centyl*; *Naturetin*; *Neo-NaClex*; *Pluryl*; *Polidiuril*; *Salural*; *Sinesalin*; *Uriside*. It is an ingredient of *Abicol*, *Corgaretic*, *Inderetic*, *Inderex*, *Prestim*, *Rauzide* and *Tenavoid*.



Chemical Properties A white or cream-coloured crystalline powder. Mp about 220°, with decomposition. Practically insoluble in water and chloroform; soluble 1 in 17 of ethanol, 1 in 1.5 of acetone and 1 in 500 of ether. pK_a 8.5 (25°). Log *P* (octanol/water), 1.9.

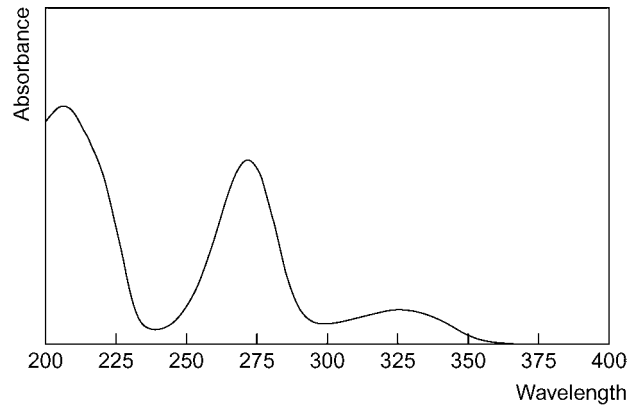
Colour Tests Koppanyi-Zwikker test—violet; Liebermann's reagent—blue; sulfuric acid—violet.

Thin-layer Chromatography System TD—R_f 0.25; system TE—R_f 0.52; system TF—R_f 0.71; system TAD—R_f 0.30; system TAJ—R_f 0.38; system TAK—R_f 0.11; system TAL—R_f 0.72 (location under UV light, violet fluorescence).

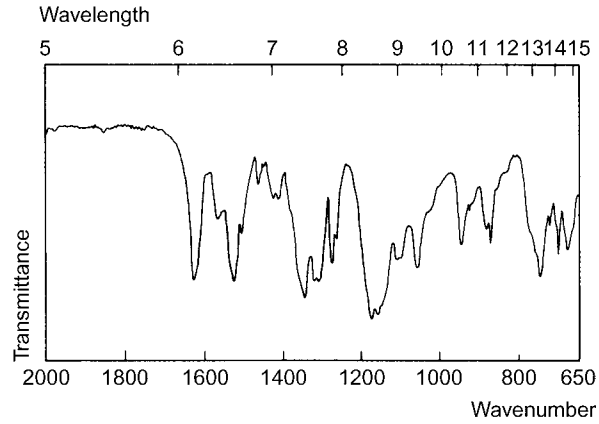
Gas Chromatography System GX—retention time 10.7 min, bendrofluazide-ME4; system GY—retention time 5.6 min, bendrofluazide-ME4.

High Performance Liquid Chromatography System HN—*k* 15.35; system HX—RI 508; system HAA—retention time 18.6 min.

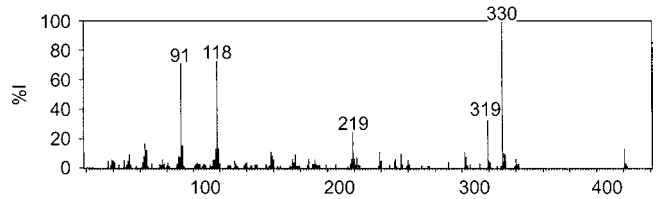
Ultraviolet Spectrum Aqueous acid—207, 273 (A^1_1=585a), 325 nm; aqueous alkali—273 (A^1_1=410a), 330 nm.



Infrared Spectrum Principal peaks at wavenumbers 1170, 1155, 1306, 1518, 1621, 750 cm^{-1} (KBr disk). There are 2 polymorphic forms.



Mass Spectrum Principal ions at *m/z* 330, 118, 91, 319, 219, 64, 92, 421.



Quantification

Plasma **GC** ECD. Limit of detection, 5 µg/L [Beermann *et al.* 1976].

Disposition in the Body Readily and almost completely absorbed after oral administration. Up to about 30% of a dose is excreted unchanged in the urine in 48 h; the remainder is excreted as unidentified metabolites.

Therapeutic Concentration

A single oral dose of 10 mg given to 9 subjects, produced peak plasma concentrations of 0.07 to 0.10 mg/L in 1.6 to 2.4 h [Beermann *et al.* 1977].

Peak plasma concentrations of 0.04 to 0.06 (mean 0.05) mg/L were reported 2 h after a dose, following administration of 5 mg daily to 8 hypertensive patients [Beermann *et al.* 1978].

Half-life Plasma half-life, about 9 h.

Volume of Distribution About 1.5 L/kg.

Protein Binding About 94%.
Note For a review of the clinical pharmacokinetics of diuretics, see Beermann, Groschinsky-Grind [1980].
Dose 2.5 to 10 mg daily.

Beermann B *et al.* (1976). A GLC assay for bendroflumethiazide. Preliminary data about its plasma level in man. *Eur J Clin Pharmacol* 10: 293–295.

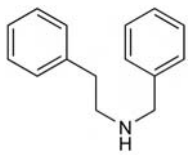
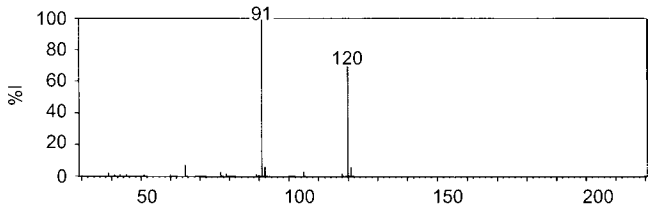
Benethamine

Pharmaceutical Adjuvant
$C_{15}H_{17}N = 211.3$
IUPAC Name *N*-Benzylphenethylamine

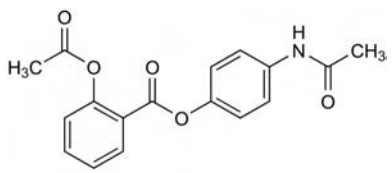


Chemical Properties Soluble in chloroform.
Colour Tests Liebermann's reagent—red-orange; Marquis test—orange-brown→brown.
Thin-layer Chromatography System TA—R_f 0.64; system TB—R_f 0.48; system TC—R_f 0.59; system TL—R_f 0.43 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—RI 1798.
Ultraviolet Spectrum Water—258 nm (A_1^1=12b).
Infrared Spectrum Principal peaks at wavenumbers 696, 745, 1111, 1022, 1592, 1067 cm^{-1} (KBr disk).
Mass Spectrum Principal ions at *m/z* 91, 120, 65, 121, 92, 105, 77, 118.

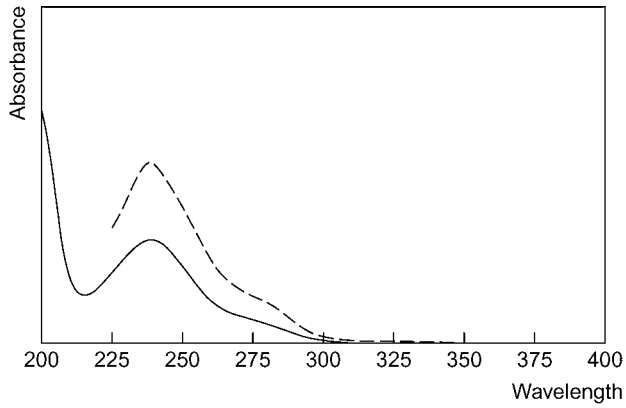


Benorilate

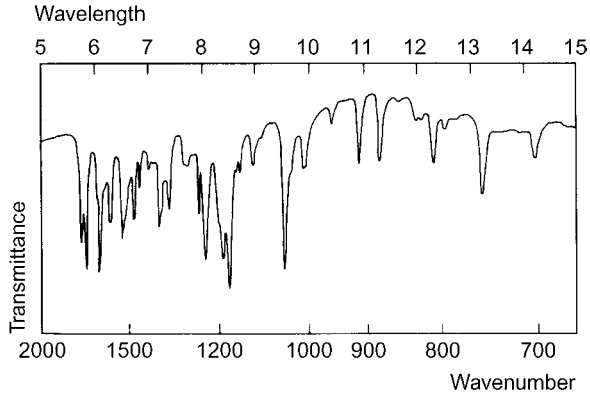
Analgesic
$C_{17}H_{15}NO_5 = 313.3$
CAS—5003-48-5
IUPAC Name 2-(Acetyloxy)benzoic acid 4-(acetylamino)phenyl ester
Synonyms Benorylate; fenasprate.
Proprietary Names *Benoral*; *Benortan*; *Salipran*.



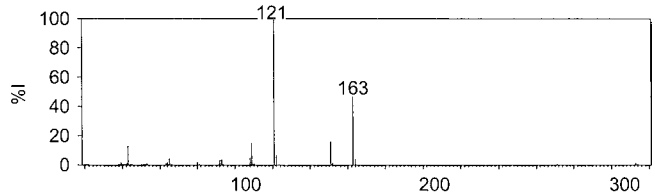
Chemical Properties A white crystalline powder. Mp 178° to 181°. Practically insoluble in water; soluble 1 in 88 of ethanol, 1 in 22 of acetone, 1 in 18 of chloroform and 1 in 900 of ether. Log *P* (octanol/water), 2.2.
Colour Tests Liebermann's reagent—black; Mandelin's test—green; Marquis test—violet.
Thin-layer Chromatography System TA—R_f 0.67; system TB—R_f 0.00; system TC—R_f 0.51; system TL—R_f 0.62; system TAE—R_f 0.86 (marquis reagent, positive).
Gas Chromatography System GA—benorilate RI 1840, aspirin RI 1309, paracetamol RI 1687.
High Performance Liquid Chromatography System HD—benorilate *k* 0.7, aspirin *k* 0.5, paracetamol *k* 0.1; system HW—benorilate *k* 22.4, aspirin *k* 2.7, paracetamol *k* 0.32.
Ultraviolet Spectrum Dehydrated alcohol—240 nm (A_1^1=740a).



Infrared Spectrum Principal peaks at wavenumbers 1182, 1050, 1661, 1730, 1248, 1194 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 121, 163, 151, 109, 43, 122, 108, 65; aspirin 120, 43, 138, 92, 121, 39, 64, 63; paracetamol 109, 151, 43, 80, 108, 81, 53, 52.

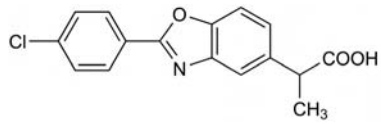


Quantification See also under Aspirin and Paracetamol.
Plasma **GC** FID. Aspirin and salicylic acid. Limit of detection, 2 mg/L for aspirin [Cailleux *et al.* 1979].
HPLC UV detection. Limit of detection, 200 µg/L for benorilate, 400 µg/L for paracetamol [Cailleux *et al.* 1979].
Disposition in the Body Benorilate is readily absorbed after oral administration. It is hydrolysed in the blood to aspirin and paracetamol, and about 85% of a dose is excreted in the urine in 72 h by the normal metabolic routes for these substances. About 15% of a dose is eliminated in the faeces.
Therapeutic Concentration
Following oral administration of 4 g as a suspension to 20 subjects, mean peak plasma concentrations of 2.2 mg/L of benorilate and about 120 mg/L of salicylate were attained in 0.5 and 3 h, respectively [Aylward *et al.* 1975].
Half-life Plasma half-life, about 1 h.
Dose 4.5 to 8 g daily.

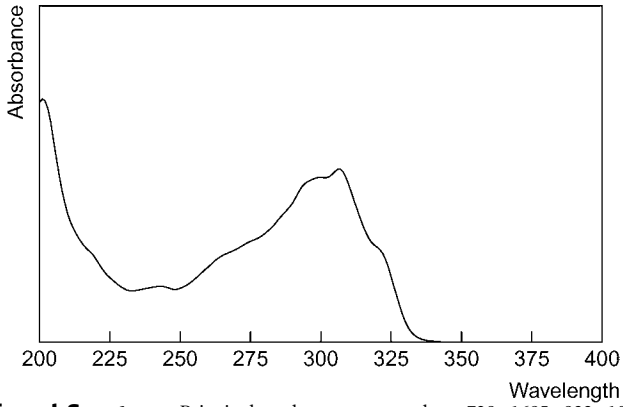
Aylward M *et al.* (1975). Simultaneous pharmacokinetics of benorylate in plasma and synovial fluid of patients with rheumatoid arthritis. *Scand J Rheumatol* Suppl. 13: 9–12.
Cailleux A *et al.* (1979). [Analysis of benorylate and its metabolites in blood by high performance liquid chromatography and gas chromatography]. *Therapie* 34: 73–79.

Benoxaprofen

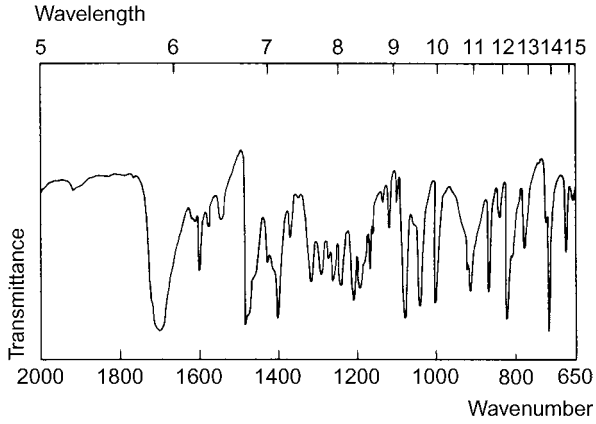
Analgesic
$C_{16}H_{12}ClNO_3 = 301.7$
CAS—67434-14-4
IUPAC Name 2-(4-Chlorophenyl)-α-methyl-5-benzoxazoleacetic acid
Proprietary Names *Opren*; *Oraflex*.



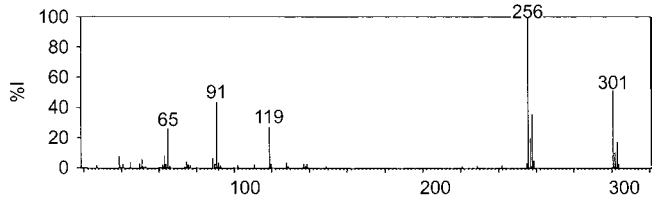
Chemical Properties A cream-coloured solid. Mp 189° to 190°. pK_a 3.5. Log *P* (octanol/water), 3.2.
Thin-layer Chromatography System TG—R_f 0.14; system TAJ—R_f 0.56; system TAK—R_f 0.80; system TAL—R_f 0.99 (Ludy Tenger reagent, orange).
Gas Chromatography System GA—RI 2550, RI 2485benoxaprofen-ME; system GB—not eluted; system GD—RRT 1.98 methyl derivative to *n*-$C_{16}H_{34}$.
High Performance Liquid Chromatography System HD—*k* 11.3; system HV—RRT 0.98 to meclofenamic acid.
Ultraviolet Spectrum Aqueous alkali—244 (A_1^1=295b), 309 nm (A_1^1=900b).



Infrared Spectrum Principal peaks at wavenumbers 728, 1695, 833, 1086, 1050, 1010 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 256, 301, 91, 258, 119, 65, 257, 303.



Quantification
Plasma **GC** ECD. Limit of detection, 10 µg/L [Chatfield, Woodage 1978].
HPLC UV detection. Limit of detection, 25 µg/L [Ekman *et al.* 1980].
Urine **GC** See Plasma [Chatfield, Woodage 1978].
HPLC See Plasma [Ekman *et al.* 1980].
Disposition in the Body Benoxaprofen is readily absorbed after oral administration. About 15% of a dose is excreted in the urine in 24 h, mainly as the glucuronic acid conjugate, together with small amounts of unchanged drug. In 5 days about 60% of a dose is excreted in the urine and 40% is eliminated in the faeces.
Therapeutic Concentration
After a single oral dose of 400 mg, administered to 4 subjects, a mean peak plasma concentration of 45 mg/L was attained in 2 to 4 h [Smith *et al.* 1977].
Toxicity Because of reports of adverse reactions and fatalities, benoxaprofen was withdrawn worldwide in 1982.
Half-life Plasma half-life, about 30 to 35 h; increased in renal impairment.
Protein Binding >99%.

Dose Benoxaprofen has been given in doses of 600 mg daily.

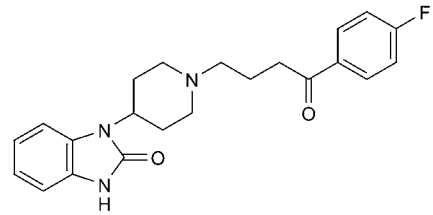
Benperidol

Butyrophenone, Antipsychotic
$C_{22}H_{24}FN_3O_2$ = 381.4
CAS—2062-84-2

IUPAC Name 3-[1-[4-(4-Fluorophenyl)-4-oxobutyl]piperidin-4-yl]-1*H*-benzimidazol-2-one
Synonyms Benzperidol; 1-[1-[3-(*p*-fluorobenzoyl)propyl]-4-piperidyl]-2-benzimidazolinone; 1-[1-[4-(*p*-fluorophenyl)-4-oxybutyl]piperidin-4-yl]-2-benzimidazolinone; 1-[1-[4-(4-fluorophenyl)-4-oxobutyl]-4-piperidinyl]-1,3-dihydro-2*H*-benzimidazol-2-one; McN-JR-4854; R-4584.
Proprietary Names *Anquil*; *Frénactil*; *Glianimon*.

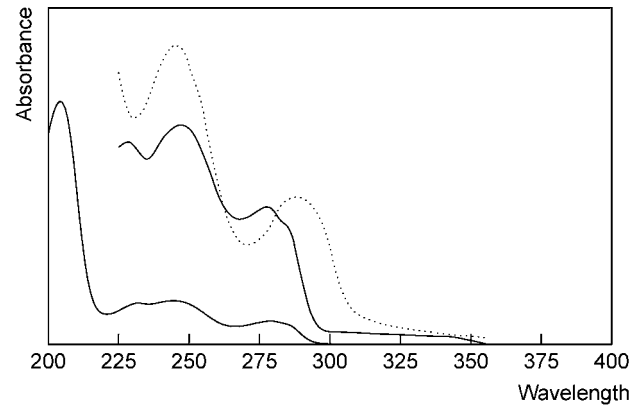


Chemical Properties An off-white amorphous powder or crystals. It darkens slowly on exposure to light. Mp 170° to 171.8°. Practically insoluble in water; soluble 1 in 1000 of ethanol, 1 in 4 of chloroform, and 1 in 625 of ether; sparingly soluble in dilute mineral acids. pK_a 7.9 [Seiler *et al.* 1994]. Log *P* (octanol/water) 3.9 [Hansch *et al.* 1995]. Extraction yield (chlorobutane), 1 [Demme *et al.* 2005].

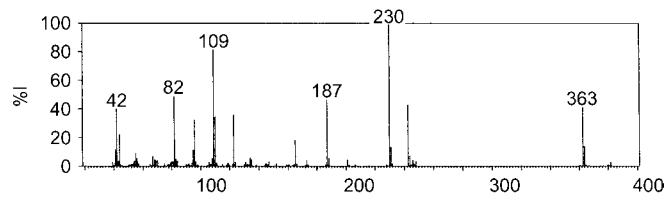
Benperidol Hydrochloride

$C_{22}H_{24}FN_3O_2$,HCl = 417.9
Chemical Properties Solid. Mp 134° to 142°.

Colour Tests Koppanyi–Zwikker test—violet; Mandelin's test—violet; mercurous nitrate—black.
Thin-layer Chromatography System TAE—R_f 0.62; system TAF—R_f 0.69; system TAG—R_f 0.32; system TF—R_f 0.03.
Gas Chromatography System GA—RI 3433, RI 2415 M (*N*-desalkyl-); system GB—RI 3667.
High Performance Liquid Chromatography System HA—*k* 1.1; system HX—RI 393; system HY—RI 324; system HZ—RT 3.6 min.
Ultraviolet Spectrum Aqueous acid—231, 249 (A_1^1 = 348b), 279 nm; aqueous alkali—248 (A_1^1 = 445b), 288 nm.



Infrared Spectrum Principal peaks at wavenumbers 1694, 757, 1587, 1162, 1204, 1219 cm^{-1}.
Mass Spectrum Principal ions at *m/z* 230, 109, 82, 187, 243, 363, 42, 123.



Quantification

Plasma **GC** Column: 2% OV3 or 3% Dexil 300 on HP Chrom W AW DMCS 80/100 mesh (1 m × 2 mm i.d.). Carrier gas: N_2, 35 mL/min. Temperature programme: 230° to 285° at 2°/min to 290° at 3°/min. FID. Limit of detection, 30 µg/L [Quaglio *et al.* 1982].

HPLC Column: CPS (3 µm). Mobile phase: 0.15 mol/L acetate buffer (pH 4.7) : acetonitrile (75 : 25). Electrochemical detection. Limit of quantification, 2.4 µg/L; limit of detection, 0.8 µg/L [Seiler *et al.* 1994]. Column: Hypersil-CPS (250 × 4.6 mm i.d., 5 µm). Mobile phase: 0.15 mol/L acetate buffer (pH 4.7) : acetonitrile (75 : 25), flow rate 1.5 mL/min. Electrochemical detection. Limit of detection 0.5 µg/L [Suss *et al.* 1991]. Column: C_{18} Nucleosil (250 × 4 mm i.d., 5 µm). Mobile phase: acetonitrile : 0.05 mol/L potassium dihydrogen phosphate (pH 2.8; 32 : 68), flow rate 1.0 mL/min. UV detection (λ = 254 nm). Retention time: 5.9 min. Limit of detection, 0.5–1 µg/L [Kruger *et al.* 1984].

Serum **HPLC** Column: C_8 (250 cm × 2.6 mm i.d., 10 µm). Mobile phase: 0.12 mol/L acetate buffer (pH 4.2) : acetonitrile (60 : 40), flow rate 1 mL/min. Electrochemical detection. Limit of detection, 0.2 µg/L [Furlanut *et al.* 1987].

LC-MS Column: Chromolith Speed ROD C_{18} (50 × 4.6 mm i.d., 5 µm). Mobile phase: methanol : 5 mmol/L acetic acid (pH 3.9) in ammonia (20 : 80 to 70 : 30 at 4 min for 1 min to 20 : 80), flow rate 1.0 mL/min. ESI, positive ion mode, MRM acquisition mode. Limit of quantification, 0.17 µg/L [Kirchherr, Kühn-Velten 2006].

Disposition in the Body

Therapeutic Concentration

Thirteen schizophrenic patients were orally administered 6 mg benperidol as liquid and 6 mg as tablets. The mean peak plasma concentration was 10.2 µg/L at 1.0 h for the liquid and 7.3 µg/L at 2.7 h for the tablet formulation [Seiler *et al.* 1994].

Dose 0.25 to 1.5 mg daily.

Benserazide

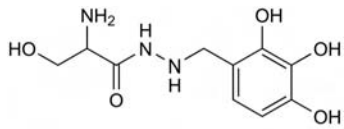
Dopa-Decarboxylase Inhibitor, Antiparkinsonian

$C_{10}H_{15}N_3O_5$ = 257.2

CAS—322-35-0

IUPAC Name DL-Serine 2-[(2,3,4-trihydroxyphenyl)methyl] hydrazide

Synonym Serazide



Chemical Properties Extraction yield (chlorobutane), 0 [Demme *et al.* 2005].

Benserazide Hydrochloride

$C_{10}H_{15}N_3O_5$,HCl = 293.7

CAS—14919-77-8; 14046-64-1

Proprietary Names It is an ingredient of *Madopar* and *Prolopa*.

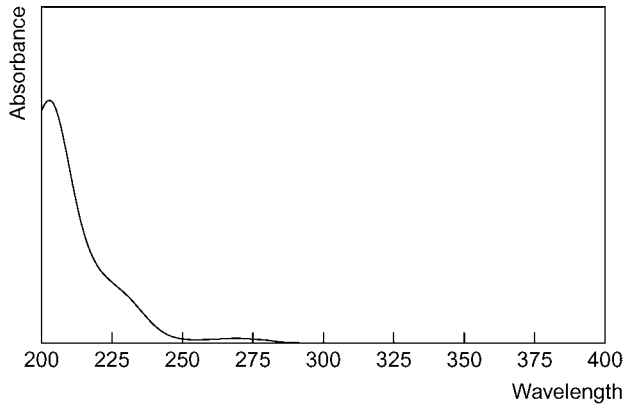
Chemical Properties An off-white crystalline powder. Mp 146° to 148°. Soluble 1 in 3 of water, 1 in 118 of ethanol, 1 in 66 of acetone, 1 in 180 of chloroform and 1 in 455 of ether.

Colour Tests Ammoniacal silver nitrate—black; *p*-dimethyl-aminobenzaldehyde—red/-; ferric chloride—green-brown; Folin-Ciocalteu reagent—blue; methanolic potassium hydroxide—red; Millon's reagent—red-orange; Nessler's reagent—black; palladium chloride—orange→brown; potassium dichromate—brown.

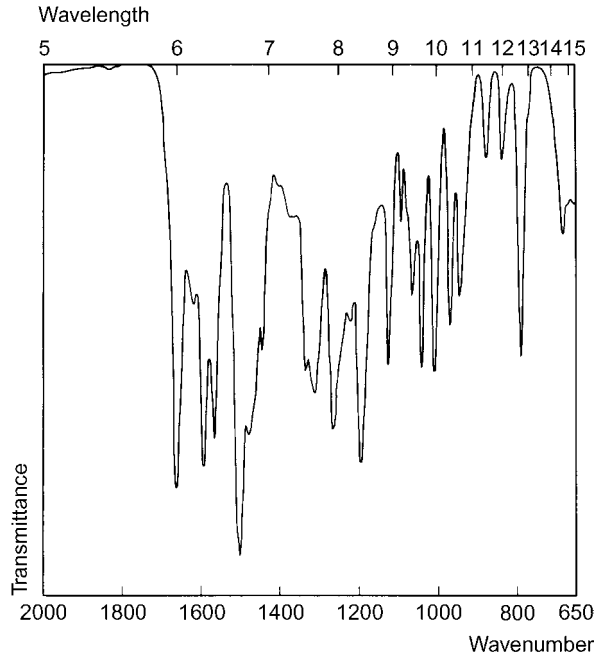
Thin-layer Chromatography System TA—R_f 0.01; system TB—R_f 0.00; system TC—R_f 0.01; system TL—R_f 0.03; system TAE—R_f 0.07.

High Performance Liquid Chromatography System HX—RI 35.

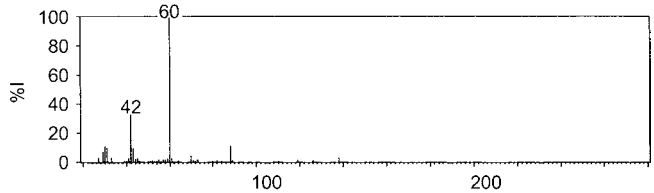
Ultraviolet Spectrum Aqueous acid—203, 269 nm.



Infrared Spectrum Principal peaks at wavenumbers 1500, 1665, 1593, 1195, 1570, 1265 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 60, 42, 88, 30, 31, 43, 29, 70.



Disposition in the Body Rapidly absorbed after oral administration and appears to be rapidly metabolised. About 50 to 60% of an oral dose and 80% of an IV dose is excreted in the urine in 24 h, and about 30% and 10% of the respective doses are eliminated in the faeces in 7 days.

Therapeutic Concentration

After an oral dose of 50 mg of ^{14}C-benserazide hydrochloride, peak plasma concentrations of about 1 mg/L were attained in 1 h [Schwartz *et al.* 1974].

Dose Usually the equivalent of 50 mg of benserazide daily, increasing to 100 to 250 mg daily (given in combination with levodopa in the treatment of parkinsonism).

Demme U *et al.* (2005). Systematic evaluation of 1-chlorobutane for liquid-liquid extraction of drugs. *Proceedings of the 12th TIAFT*, Seoul: 481–486.

Schwartz DE *et al.* (1974). Pharmacokinetics of the decarboxylase inhibitor benserazide in man; its tissue distribution in the rat. *Eur J Clin Pharmacol* 7: 39–45.

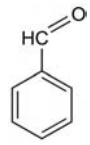
Benzaldehyde

Flavouring Agent

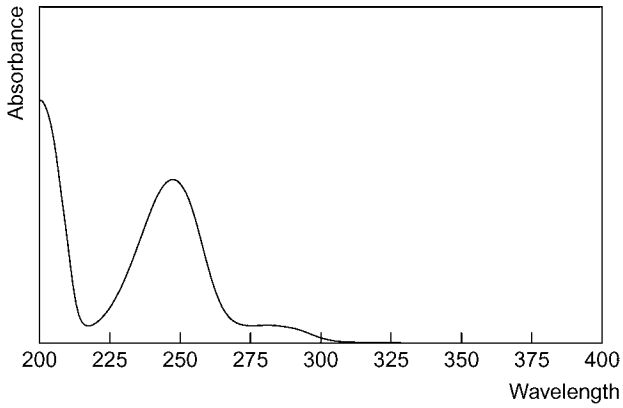
C_6H_5CHO = 106.1

CAS—100-52-7

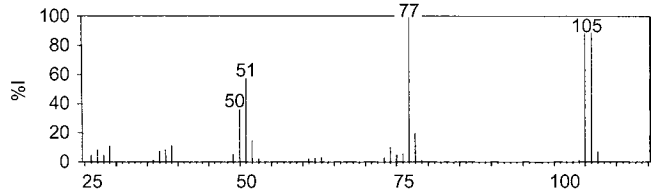
Synonym Artificial essential oil of almond



Chemical Properties A clear, colourless, strongly refractive liquid, with a characteristic odour of bitter almonds. It becomes yellowish on storage and oxidises in air to benzoic acid. Bp about 179°. Refractive index, at 20°, 1.544 to 1.5465. Soluble 1 in 350 of water; miscible with ethanol and ether. Log *P* (octanol/water), 1.5.
Gas Chromatography System GA—RI 947; system GI—retention time 34.2 min.
Ultraviolet Spectrum Ethanol—245 (A^1_1=1294b), 279 (A^1_1=126b), 289 nm (A^1_1=105b).



Infrared Spectrum Principal peaks at wavenumbers 1700, 1210, 1601, 1175, 1318, 753 cm^{-1} (thin film).
Mass Spectrum Principal ions at *m/z* 77, 106, 105, 51, 50, 78, 52, 39.



Quantification
Blood **GC** For detection and identification of volatile compounds using head-space analysis and FID, see Ramsey and Flanagan [1982].
Serum **GC–MS** For head-space analysis, see Zlatkis *et al.* [1974].

Benzalkonium Bromide

Quaternary Ammonium, Antiseptic
CAS—8001-54-5

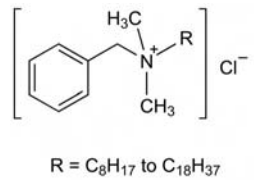
Proprietary Name *Morpan BB*
Chemical Properties A mixture of alkylbenzyldimethylammonium bromides of the general formula $[C_6H_5CH_2N(CH_3)_2R]Br$ in which R represents a mixture of the alkyls from C_8H_{17} to $C_{18}H_{37}$. An aqueous solution containing the equivalent of 50% of $[C_6H_5CH_2N(CH_3)_2C_{13}H_{27}]Br$ is a colourless or pale-yellow syrupy liquid, which is miscible with water, ethanol, and acetone.
Note See Benzalkonium Chloride.

Benzalkonium Chloride

Cationic Disinfectant, Antiseptic
CAS—8001-54-5

Note A mixture of alkylbenzyldimethylammonium chlorides of the general formula $[C_6H_5{\cdot}CH_2{\cdot}N(CH_3)_2{\cdot}R]Cl$, in which R represents a mixture of the alkyls from C_8H_{17} to $C_{18}H_{37}$.

Proprietary Names *Benzalchlor-50*; *Cetal Conc. A and B*; *Empigen BAC*; *Hyamine 3500*; *Laudamonium*; *Morpan BC*; *Ovules Pharmatex*; *Quartamon*; *Roccal*; *Sabol*; *Silquat B10*; *Silquat B50*; *Vantoc CL*; *Zephiran*. It is an ingredient of *Polycide*, *Stomosol* and *Timodine*.



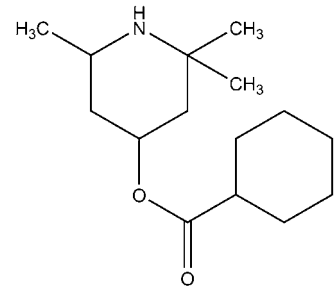
R = C_8H_{17} to $C_{18}H_{37}$

Chemical Properties A white or yellowish-white amorphous powder, thick gel or gelatinous pieces. A solution in water gives a clear, colourless or pale yellow, syrupy liquid, which foams strongly when shaken. Very soluble in water, ethanol and acetone; practically insoluble in ether.
Thin-layer Chromatography System TL—R_f 0.00; system TAE—R_f 0.04; system TAF—R_f 0.66.
Ultraviolet Spectrum Water—256 (A^1_1=4.9b), 262 (A^1_1=5.8b), 268 nm (A^1_1=4.6b).
Infrared Spectrum Principal peaks at wavenumbers 702, 726, 780, 875, 1618, 1211 cm^{-1} (thin film).

Benzamine

Piperidine, Anaesthetic (Local)
$C_{15}H_{21}NO_2$ = 247.3
CAS—500-34-5

IUPAC Name 4-Benzoyloxy-2,2,6-trimethylpiperidine
Synonyms Betacaine; racemic benzamine.



Chemical Properties Extracted by organic solvents from aqueous alkaline solutions. Log *P* (octanol/water) 2.95 [Meylan, Howard 1995].

Benzamine Hydrochloride

Synonyms Beta-eucaine hydrochloride; eucaine hydrochloride.
Chemical Properties White crystalline powder. Mp 274°, with decomposition. Soluble 1 in 30 of water, 1 in 35 of ethanol and 1 in 30 of chloroform.

Benzamine Lactate

Chemical Properties White crystalline powder. Mp 152°. Soluble 1 in 5 of water and 1 in 8 of ethanol.

Thin-layer Chromatography System T1—R_f 0.57 (location reagent acidified iodoplatinate spray, positive reaction).
Ultraviolet Spectrum Aqueous acid (0.1 N sulfuric acid)—233, 274 nm.
Infrared Spectrum Principal peaks at wavenumbers 1714, 1276, 711 or 1108 cm^{-1} (KBr disk).
Toxicity The minimum IV lethal dose in rats is 15 to 25 mg/kg.
Dose Up to 30 mg.

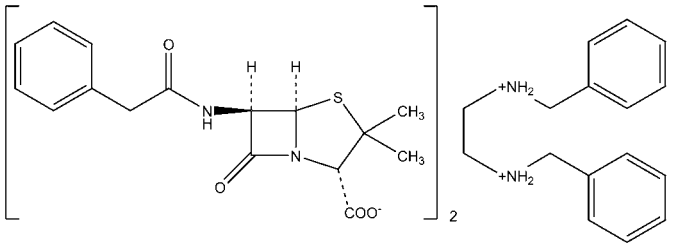
Meylan WM, Howard PH (1995). Atom/fragment contribution method for estimating octanol-water partition coefficients. *J Pharm Sci* 84: 83–92.

Benzathine Benzylpenicillin

Natural Penicillin, Antibiotic
$C_{16}H_{20}N_2(C_{16}H_{18}N_2O_4S)_2$ = 909.1
CAS—1538-09-6 (anhydrous benzathine benzylpenicillin); 5928-83-6 (benzathine benzylpenicillin monohydrate); 41372-02-5 (benzathine benzylpenicillin tetrahydrate)

IUPAC Name *N*, *N*′-Dibenzylethylenediammonium bis[(6*R*)-6-(2-phenylacetamido)penicillanate]

Synonyms Benzathine benzylpenicillin; benzathine penicillin G; benzethacil; dibenzylamine penicillin G; penzaethinum G.
Proprietary Names *Benzatron*; *Benzetacil*; *Bepeben*; *Bicillin*; *Dibencil*; *Extencilline*; *Galtamicina*; *Longacilin*; *Neolin*; *Penadur*; *Pen di Ben*; *Penditan*; *Pendysin*; *Penadur*; *Penidural*; *Permapen*; *Retarpen*. It is also an ingredient in *Bicillin C-R*; *Pecivax*; *Tardocillin*.



Chemical Properties White powder. Mp 129° to 133° with decomposition. Soluble 1 in 6000 of water and 1 in 1000 of ethanol; freely soluble in dimethylformamide and in formamide; almost insoluble in ether and chloroform. The tetrahydrate is a white, odourless, crystalline powder. Soluble 1 in 5000 of water and 1 in 65 of alcohol. Dissolve 50 mg of dehydrate alcohol in 50 mL of water, the pH will be between 4.0 and 6.5.
High Performance Liquid Chromatography Column: Hypersil C_{18} (100 × 4.6 mm i.d., 5 µm). Mobile phase: phosphate buffer (4.32 g/L potassium hydrogen phosphate; 6.30 g/L sodium heptane-1-sulfonate) : acetonitrile (pH 3.17; 71.5 : 28.5), flow rate 1.0 mL/min. UV detection (λ = 258 nm). Retention times: penicillin G ≈4 min, benzathine ≈8 min. Limit of quantification not reported [Irwin *et al.* 1984].
Ultraviolet Spectrum Methanol—251, 257, 263, 266, 320 nm.
Disposition in the Body Relatively stable in the presence of gastric juice or serum, and penicillin is slowly released after PO or IM administration. When benzathine benzylpenicillin is given by mouth, the maximum concentration of penicillin in the blood is obtained less rapidly than after a comparable dose of a soluble salt of penicillin by injection, but the level is maintained for a longer period; doses of 225 mg usually give effective blood levels for 6 h. When given by IM injection, benzathine benzylpenicillin forms a depot from which penicillin is released over several days. After a single dose of 450 mg, an effective concentration in the blood may be maintained for ≥1 week. Distribution into the CSF is reported to be poor. Due to the slow absorption from the injection site, benzylpenicillin has been detected in the urine for up to 12 weeks after a single dose.

Therapeutic Concentration

In a group of 193 patients receiving a 4-weekly dose of IM benzathine benzylpenicillin (1 200 000 units) for the prevention of secondary rheumatic fever, mean serum concentrations at days 1, 3, 10, 21 and 28 were reported as being ≈0.17, 0.11, 0.04, 0.03 and 0.02 mg/L, respectively [Kaplan *et al.* 1989].

Twenty-five healthy pregnant volunteers at 38–39 weeks' gestation scheduled for elective caesarean delivery were administered benzathine benzylpenicillin (2400000 units) IM preoperatively. Ten women delivered 1 day after injection, 5 delivered 2–3 days after and 10 delivered 7 days after. Penicillin concentrations (mg/L) in compartments of the maternal-placental-fetal unit were reported as follows:

Sample	*Day 1*	*Days 2–3*	*Day 7*
Maternal serum	0.14	0.14	0.08
Maternal CSF	0.005	0.005	0.005
Cord serum	0.12	0.04	0.04
Amniotic fluid	0.16	0.04	0.03
Maternal/cord serum	4.03	19.2	5.8

[Nathan *et al.* 1993]

Toxicity Allergic reactions may occur. It should not be injected IV because ischaemic reactions may occur.
Dose Benzathine benzylpenicillin has the same antimicrobial action as benzylpenicillin, to which it is hydrolysed gradually after deep IM injection. This results in a prolonged effect but, because of the relatively low blood concentrations of benzylpenicillin produced, its use should be restricted to micro-organisms that are highly susceptible to benzylpenicillin. In acute infections (and if bacteraemia is present), the initial treatment should be with benzylpenicillin by injection. Usually up to 900 mg daily by mouth or up to 1.8 g IM as a single dose.

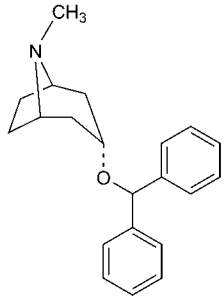
B

Benzatropine

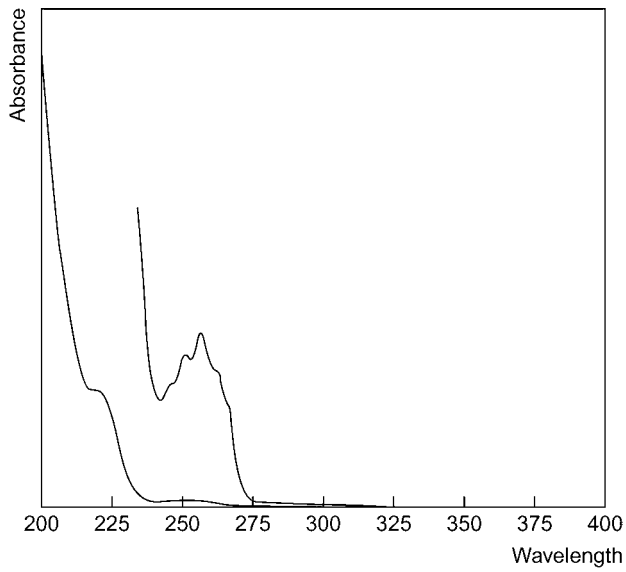
Dopamine Uptake Inhibitor, Anticholinergic
$C_{21}H_{25}NO$ = 307.4
CAS—86-13-5
IUPAC Name (1*R*,5*R*)-3-[Di(phenyl)methoxy]-8-methyl-8-azabicyclo[3.2.1] octane
Synonyms Benztropine; 3-(diphenylmethoxy)-8-methyl-8-azabicyclo[3.2.1] octane.



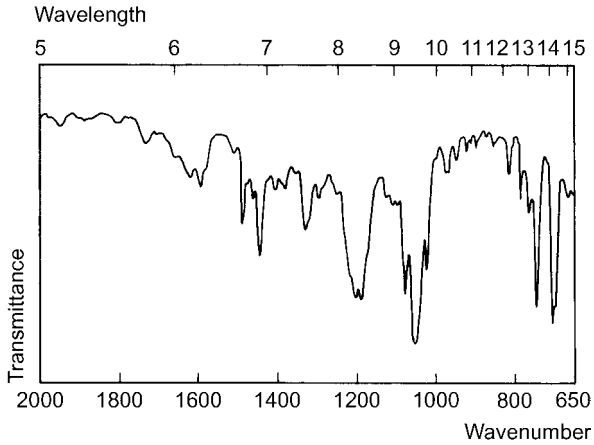
Chemical Properties Soluble in chloroform. Log *P* (octanol/water) 4.28 [Meylan, Howard 1995]. Extraction yield (chlorobutane), 1 [Demme *et al.* 2005].

Benzatropine Mesilate

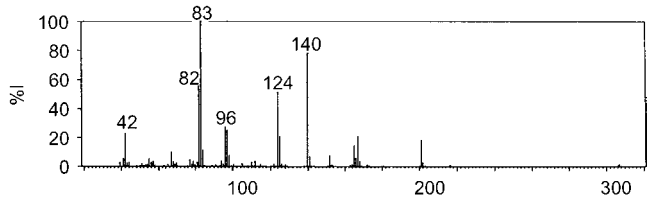
$C_{21}H_{25}NO,CH_4O_3S$ = 403.5
CAS—132-17-2
IUPAC Name (1*R*,5*R*)-3-Benzhydryloxy-8-methyl-8-azabicyclo[3.2.1]octane methanesulfonic acid
Synonyms Benzatropine methanesulfonate; tropine diphenylmethyl ether.
Proprietary Names *Bensylate*; *Cogentin*.
Chemical Properties A white, slightly hygroscopic, crystalline powder. Mp 141° to 145°. Soluble 1 in 0.7 of water, 1 in 1.5 of ethanol, and 1 in 2 of chloroform; practically insoluble in ether. pK_a 10.0 (20°). Log *P* (octanol/water) 3.91 [Meylan, Howard 1995], (heptane) 0.4.
Colour Tests Mandelin's test—yellow; Marquis test—yellow.
Thin-layer Chromatography System TA—R_f 0.13; system TAE—R_f 0.06; system TAG—R_f 0.02; system TB—R_f 0.26; system TC—R_f 0.06 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—RI 2302; system GB—RI 2423.
High Performance Liquid Chromatography System HA—*k* 3.7 (tailing peak).
Ultraviolet Spectrum Aqueous acid—253, 259 nm (A_1^1 = 14.5a).



Infrared Spectrum Principal peaks at wavenumbers 1054, 700, 742, 1191, 1204, 1075 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 83, 140, 82, 124, 96, 97, 42, 125.



Quantification

Blood **GC-MS** Column: DB-5MS 5% phenyl-methylpolysiloxane capillary (15 m × 0.25 mm i.d., 0.25 µm). Carrier gas: He, 1 mL/min. Temperature programme: 125° to 290° at 20°/min for 5 min. EI ionisation. Limit of detection not reported [Rosano *et al.* 1994].

Plasma **GC-MS** Column: Silanised glass with 5% dimethyldichlorosilane in toluene packed with 1.5% OV-17 on 100/200 mesh gas chrom Q (2 mm i.d.). Carrier gas: He, 20.0 mL/min. Temperature: 220°. EI ionisation at 70 eV, full scan mode. Limit of detection, 2 µg/L [Jindal *et al.* 1981].

HPLC Column: C_8 Spherisorb (150 × 3.9 mm i.d., 5 µm). Mobile phase: 0.15% triethylamine (pH 3) : acetonitrile (40 : 60), flow rate 1.5 mL/min. UV detection (λ = 199 nm). Retention time: 7.0 min. Limit of quantification, 0.25 µg/L [Selinger *et al.* 1989].

Serum **GC-MS** See Blood [Rosano *et al.* 1994].

Urine **GC-MS** See Blood [Rosano *et al.* 1994]. See Plasma [Jindal *et al.* 1981].

Disposition in the Body Absorbed after oral administration.

Toxicity

In a fatality attributed to the ingestion of an unknown quantity of benzatropine tablets, the following postmortem concentrations were reported: blood 0.7 mg/L, liver 1.6 µg/g, and urine 0.8 mg/L. In a second case, a liver concentration of 2.3 µg/g was found [del Villar, Liddy 1976].

A 41-year-old male with a history of schizophrenia and drug abuse was found dead. Benzatropine at a concentration of 0.183 mg/L in his blood and 7.12 mg/L in his urine was found [Rosano *et al.* 1994].

Dose 0.5 to 6 mg of benzatropine mesilate daily.

Benzbromarone

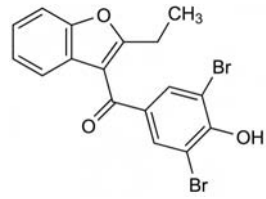
Uricosuric

$C_{17}H_{12}Br_2O_3$ = 424.1

CAS—3562-84-3

IUPAC Name (3,5-Dibromo-4-hydroxyphenyl)(2-ethyl-3-benzofuranyl) methanone

Proprietary Names *Desuric*; *Narcaricin*; *Normurat*; *Uricovac M*.

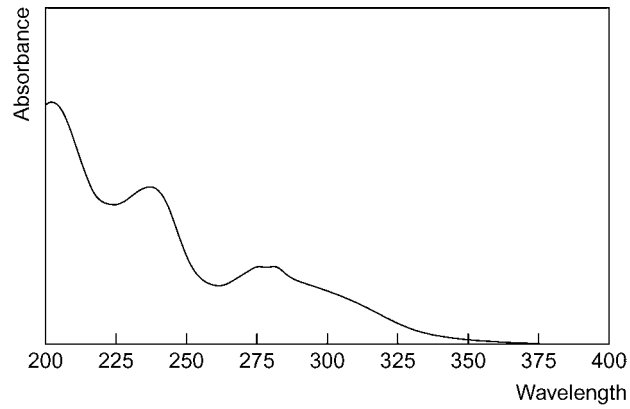


Chemical Properties Yellowish crystals. Mp 151°. Log *P* (octanol/water), 6.0.

Thin-layer Chromatography System TF—R_f 0.49; system TAE—R_f 0.94.

High Performance Liquid Chromatography System HX—RI 860; system HAA—retention time 26.1 min.

Ultraviolet Spectrum Methanolic acid—237 (A^1_1=666b), 274 (inflexion), 281 (A^1_1=314b); aqueous alkali—240 nm (A^1_1=440b), 281 (inflexion), 355 nm (A^1_1=513b).



Quantification

Plasma **HPLC** UV detection. Limit of detection, 0.01 mg/L for benzarone [de Vries *et al.* 1986].

Serum **HPLC** UV detection. Limit of detection, 140 µg/L for benzbromarone, 90 µg/L for benzarone [Vergin, Bishop 1980].

Urine **HPLC** See Plasma [de Vries *et al.* 1986].

Disposition in the Body Benzbromarone is incompletely absorbed after oral administration. It is metabolised by debromination to bromobenzarone and benzarone which are both active metabolites. About 50% of a dose is excreted in the bile as free and conjugated (glucuronide) metabolites and less than 10% of a dose is excreted in the urine.

Therapeutic Concentration

Following a single oral dose of 100 mg to 7 subjects, peak plasma concentrations of 1.4 to 2.9 (mean 2.2) mg/L of benzbromarone and 0.6 to 1.2 (mean 0.8) mg/L of benzarone were attained in about 3 and 6 h, respectively [Ferber *et al.* 1981].

Half-life Plasma half-life, benzbromarone about 3 h, benzarone about 13 h.

Note For a review of benzbromarone, see Heel *et al.* [1977].

Dose Usually 100 mg daily; up to 300 mg daily has been given.

de Vries JX *et al.* (1986). Determination of benzarone in human plasma and urine by high-performance liquid chromatography and gas chromatography-mass spectrometry. Identification of the conjugates. *J Chromatogr* 382: 167–174.

Benzene

Solvent

C_6H_6 = 78.11

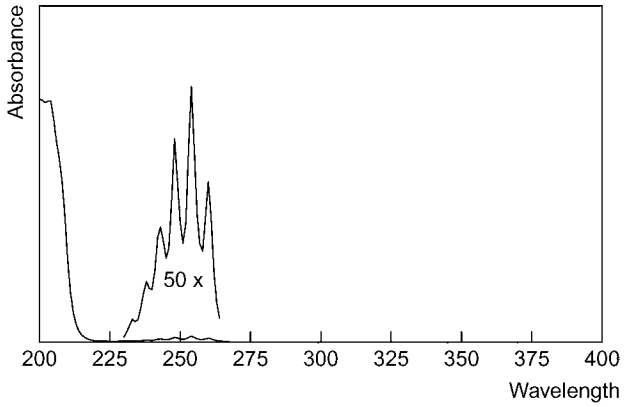
CAS—71-43-2

Synonyms Cyclohexatriene; phenyl hydride.

Chemical Properties A clear, colourless, mobile, inflammable liquid, with a characteristic aromatic odour, which burns with a smoky flame. Bp 80.1°. It solidifies when cooled to 0°. Practically immiscible with water; miscible with dehydrated alcohol, acetone, chloroform, ether and glacial acetic acid. Log *P* (octanol/water), 2.1.

Gas Chromatography System GA—RI 1000; system GI—retention time 14.8 min.

High Performance Liquid Chromatography System HAA—retention time 19.5 min.
Ultraviolet Spectrum Ethanol—255 nm (A_1^1=28b).



Mass Spectrum Principal ions at *m/z* 78, 77, 52, 51, 50, 39, 79, 74.
Quantification
Blood **GC** FID. For head-space analysis, see Collom, Winek [1970].
Urine **GC** FID. Limit of quantification, 23 µg/L, limit of detection, 7 µg/L [Ljungkvist *et al.* 2001]. FID. Limit of detection, 10 µg/L for phenol [Rick *et al.* 1982].

HPLC Fluorescence detection (λ_{ex}=395 nm; λ_{em}=470 nm). Limit of detection, 1 µg/L [Einig, Dehnen 1995]. SIM acquisition mode. Limit of detection, 0.01 mg/L for *trans, trans*-muconic acid (metabolite) [Ruppert *et al.* 1995]. UV detection (λ = 265 nm). Limit of detection, 125 ng [Lee *et al.* 1993].
Tissue **GC** See Snyder *et al.* [1977]. See Blood Collom, Winek [1970].
Disposition in the Body Benzene is absorbed from the gastrointestinal tract, through the skin and from the lungs. About 50% of inhaled benzene is retained in the body; eventually up to 50% of the retained benzene may be eliminated via the lungs, only very small amounts (~0.1%) appearing unchanged in the urine. The remainder of the retained benzene is excreted in the urine, mainly as phenol together with small amounts of catechol and quinol. The excretion of phenol is highest in the first 24 h and is complete within 48 h of exposure. The phenolic metabolites are excreted mainly in the conjugated form as ethereal sulfates and glucuronides.
Toxicity The maximum permissible atmospheric concentration is 10 ppm or 30 mg/m^3. The maximum exposure limit is 1 ppm. Chronic poisoning may result from exposure to low concentrations over a period of time; 1500 ppm for an hour causes marked depression of the CNS and 7500 ppm for half an hour or 20 000 ppm for a few minutes may cause death; chronic inhalation of as little as 100 ppm is likely to cause severe bone marrow depression. The ingestion of 10 mL has caused death.

In a death attributed to inhalation of benzene vapours (glue sniffing), the postmortem concentration of benzene in the blood was 0.94 mg/L and in the kidney 5.5 µg/g [Collom, Winek 1970].

The following postmortem tissue concentrations were reported in a fatality due to the ingestion of benzene: blood 38 mg/L, brain 253 µg/g, kidney 21 µg/g, liver 105 µg/g, urine 20 mg/L [Alha *et al.* 1975].

A 3-year-old child drank some benzene and died 2 h later; postmortem concentrations were: brain 250 µg/g, kidney 20 µg/g, liver 800 µg/g [Heyndrickx *et al.* 1966].

Half-life Plasma half-life, 9 to 24 h.
Note For a review of the effects on health of benzene inhalation, see Haley [1977].

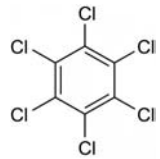
Benzene Hexachloride

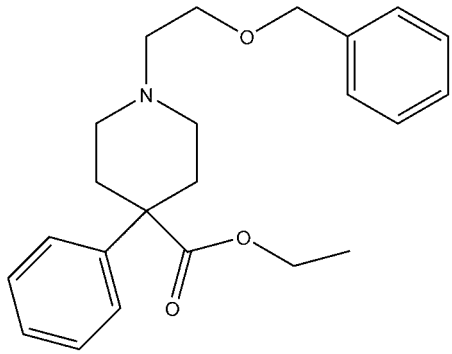
Insecticide
$C_6H_6Cl_6$ = 290.8
CAS—319-84-6 (α-isomer); 319-85-7 (β-isomer); 58-89-9 (γ-isomer); 319-86-8 (δ-isomer); 6108-10-7 (ε-isomer)
Synonyms BHC; HCH; hexachlorocyclohexane; technical benzene hexachloride.



Chemical Properties A mixture of the several isomers of 1,2,3,4,5,6-hexachlorocyclohexane; it contains not less than 12% of the gamma isomer. Benzene hexachloride has 5 known isomers designated alpha, beta, gamma, delta and epsilon; of these only the gamma isomer (see Lindane) is outstandingly active as an insecticide. White to light brown granules, flakes or powder, with a characteristic musty odour. Mp 159°. Practically insoluble in water; its solubility in organic solvents depends on the proportions of the various isomers present.
Gas Chromatography System GA—α-isomer RI 1690, β-isomer RI 1710, δ-isomer RI 1755, γ-isomer RI 1745.
Infrared Spectrum Principal peaks at wavenumbers 688, 855, 704, 781, 917, 957 cm^{-1} (Nujol mull).
Quantification See under Lindane.
Disposition in the Body Absorbed after ingestion, inhalation or through the skin. It is stored in the body fat and adrenal glands. The β-isomer accumulates on chronic exposure (see under Lindane).
Toxicity Benzene hexachloride has a greater chronic toxicity than lindane. Ingestion of 20 to 30 g may produce serious toxic effects but death is unlikely unless it is dissolved in an organic solvent.

Benzethidine

Narcotic Analgesic
$C_{23}H_{29}NO_3$ = 367.5
CAS—3691-78-9
IUPAC Name Ethyl-1-(2-benzyloxyethyl)-4-phenylpiperidine-4-carboxylate
Synonyms Benzyloxyethylnorpethidine; TA-28.

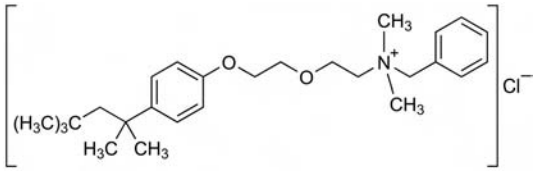


Chemical Properties Extracted by organic solvents from aqueous alkaline solutions. Log *P* (octanol/water) 4.46 [Meylan, Howard 1995].
Colour Tests Ammonium molybdate test—orange-brown (limit of detection 0.5 µg); sulfuric acid-formaldehyde test—dull orange (limit of detection 0.5 µg).
Thin-layer Chromatography System T1—R_f 0.74 (location reagent acidified iodoplatinate spray, positive reaction).
Gas Chromatography System G2/225—retention time 2.53 relative to codeine; system G4—retention time 1.70 relative to codeine.
Ultraviolet Spectrum Aqueous acid (0.1 N sulfuric acid)—252, 258, 264 nm and an inflexion at 267 nm.

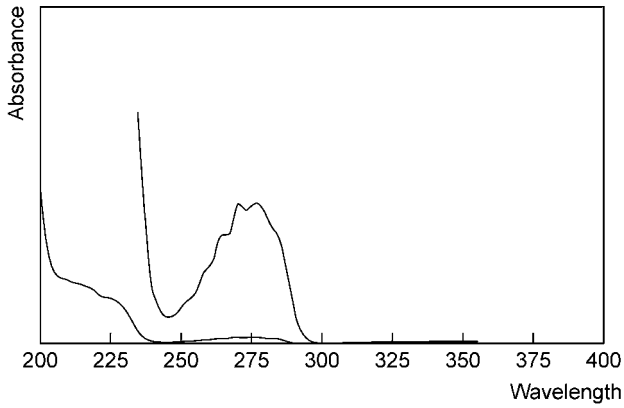
Meylan WM, Howard PH (1995). Atom/fragment contribution method for estimating octanol-water partition coefficients. *J Pharm Sci* 84: 83–92.

Benzethonium Chloride

Cationic Disinfectant, Antiseptic
$C_{27}H_{42}ClNO_2$ = 448.1
CAS—121-54-0
IUPAC Name *N,N*-Dimethyl-*N*-[2-[2-[4-(1,1,3,3-tetramethylbutyl)phenoxy] ethoxy]-ethyl]-benzenemethanaminium chloride
Proprietary Names *Hyamine 1622*; *Phemerol Chloride*.



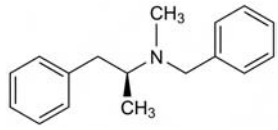
Chemical Properties White crystals. A solution in water foams strongly when shaken. Mp 160° to 165°. Soluble 1 in 0.6 of water, 1 in 0.6 of ethanol and 1 in 1 of chloroform; slightly soluble in ether; practically insoluble in light petroleum. Log *P* (octanol/water), 4.0.
Colour Test Marquis test—orange.
Thin-layer Chromatography System TA—R_f 0.03 (acidified iodoplatinate solution, positive).
Ultraviolet Spectrum Aqueous acid—263, 269 (A^1_1=29c), 274 nm (A^1_1=28c). No alkaline shift.



Infrared Spectrum Principal peaks at wavenumbers 1240, 1505, 1120, 826, 1063, 769 cm^{-1} (KBr disk).
Use Used as 0.1 to 0.2% solutions.

Benzfetamine

Anorectic
$C_{17}H_{21}N$ = 239.4
CAS—156-08-1
IUPAC Name (α*S*)-*N*,α-Dimethyl-*N*-(phenylmethyl)benzeneethanamine
Synonym Benzphetamine
Proprietary Name *Didrex*



Chemical Properties A liquid. Bp 127°. Practically insoluble in water; soluble in methanol, ethanol, chloroform, acetone, benzene and ether. pK_a 6.6. Log *P* (octanol/water), 4.1.

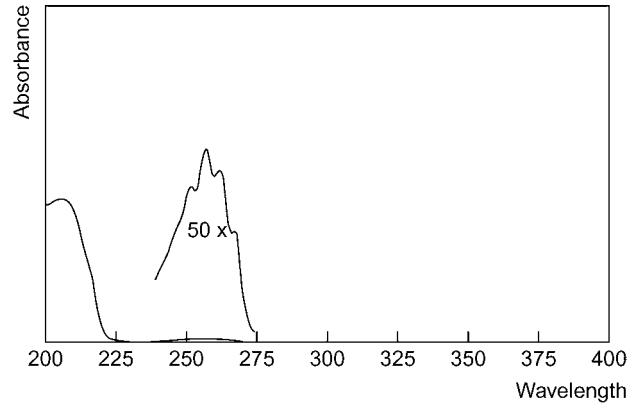
Benzfetamine Hydrochloride

$C_{17}H_{21}N,HCl$ = 275.8
CAS—5411-22-3
Proprietary Names *Didrex*; *Inapetyl*.
Chemical Properties A white crystalline powder. Mp about 131°. Freely soluble in water, ethanol and chloroform; slightly soluble in ether.

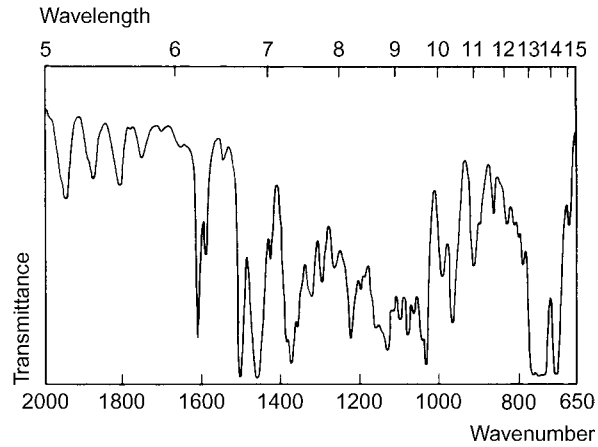
Colour Test Marquis test—orange
Thin-layer Chromatography System TA—R_f 0.73; system TB—R_f 0.67; system TC—R_f 0.70; system TE—R_f 0.87; system TL—R_f 0.70; system TAE—R_f 0.60 (dragendorff spray, positive; acidified iodoplatinate solution, positive; Marquis reagent, brown).
Gas Chromatography System GA—benzfetamine RI 1855, amfetamine RI 1125, metamfetamine RI 1175; system GB—benzfetamine RI 1899, amfetamine RI 1150, metamfetamine RI 1200; system GC—benzfetamine RI 2172, amfetamine RI 1536, metamfetamine RI 1722; system GF—benzfetamine RI 2050, amfetamine RI 1315, metamfetamine RI 1335.

Column: TC-1 cross-linked methylsilicone (20 m × 0.25 mm i.d., 0.25 µm). Temperature programme: 60° for 0.5 min, to 280° at 20°/min. Carrier gas: He, flow rate 1 mL/min. SIM acquisition mode. Retention time: amfetamine, 4.6 min; metamfetamine, 5.4 min; benzfetamine, 8.2 min [Kikura, Nakahara 1995].
High Performance Liquid Chromatography System HA—benzfetamine *k* 1.2, amfetamine *k* 0.9, metamfetamine *k* 2.0; system HC—benzfetamine *k* 0.15, amfetamine *k* 0.98, metamfetamine *k* 2.07.

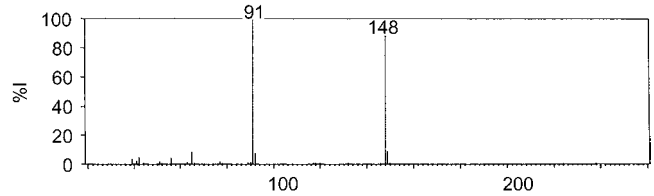
Ultraviolet Spectrum Aqueous acid—252, 258 nm (A^1_1=19c), 262, 268 nm.



Infrared Spectrum Principal peaks at wavenumbers 1497, 740, 698, 1028, 1125, 1220 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 91, 148, 149, 65, 92, 42, 56, 39.



Quantification

***Urine* GC-MS** Column: HP-1 (12 m × 0.2 mm i.d., 0.33 µm). Temperature programme: 80° for 1 min, to 210° at 20°/min for 2 min. Carrier gas: He, flow rate 1 mL/min. Retention time: amfetamine, 4.2 min; metamfetamine, 5.1 min; benzfetamine, 8.2 min. Limit of detection, 5 µg/L for amfetamine and metamfetamine, 2 µg/L for benzfetamine [Cody, Valtier 1998].

HPLC Benzfetamine metabolites Fujinami *et al.* [1998].

***Hair* GC-MS**. Limit of detection, 0.5 ng/mg [Nakahara 1995].

Disposition in the Body Readily absorbed after oral administration and mainly excreted in the urine as amfetamine and metamfetamine; the metabolism of benzfetamine to desmethylbenzfetamine may be a major pathway in its metabolism. It is also excreted in the urine as conjugated metabolites, *p*-hydroxy-*N*-benzylamfetamine glucuronide and *p*-hydroxybenzfetamine glucuronide; very little is excreted as unchanged drug.

Therapeutic Concentration

Urinary concentrations of *p*-hydroxy-*N*-benzylamfetamine glucuronide (pHBAG) and *p*-hydroxybenzfetamine glucuronide (pHBZG) were determined in 2 healthy volunteers after the administration of 10 mg benzfetamine hydrochloride. After 6 h, pHBAG concentrations were 450 nM (subject 1) and 800 nM (subject 2), and pHBZG 800 nM (subject 1) and 1900 nM (subject 2). After 24 h, pHBAG levels dropped to 50 nM for both subjects and pHBZG concentrations were negligible [Fujinami *et al.* 1998].

Toxicity

A 16-year-old male was found dead with several medicine bottles in the room. Postmortem examination and toxicological analysis revealed the following benzfetamine concentrations: blood 13.9 mg/L, urine 8.0 mg/L, liver 106.3 mg/kg, brain 30.5 mg/kg, and gastric contents (total) 53.1 mg [Brooks *et al.* 1982].

Dose 25 to 150 mg of benzfetamine hydrochloride daily.

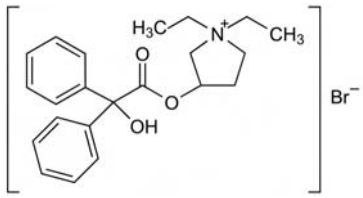
Benzilonium Bromide

Anticholinergic
$C_{22}H_{28}BrNO_3 = 434.4$
CAS—1050-48-2

IUPAC Name 1,1-Diethyl-3-[(hydroxydiphenylacetyl)oxy]pyrrolidinium bromide

Proprietary Names *Portyn*; *Ulcoban*.

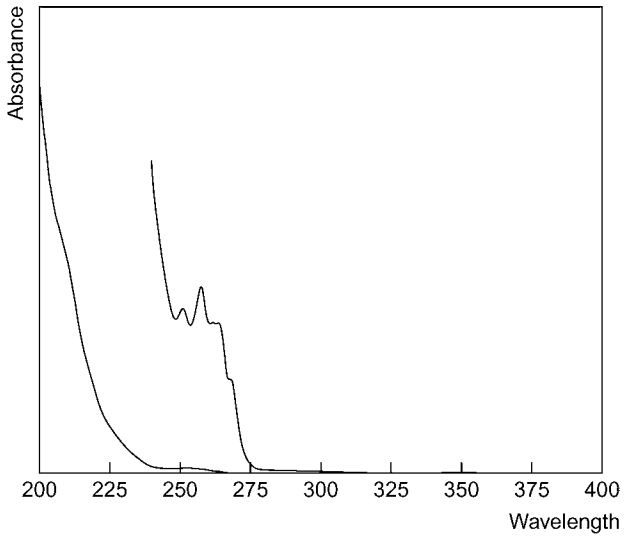


Chemical Properties A white crystalline powder. Mp 203° to 204°. Soluble in water. Log *P* (octanol/water), −0.3.

Colour Tests The following tests are performed on benzilonium nitrate: Liebermann's reagent—brown; Marquis test—orange→green→blue; sulfuric acid—orange.

Thin-layer Chromatography System TA—R_f 0.03; system TAJ—R_f 0.00; system TAK—R_f 0.00; system TAL—R_f 0.05 (acidified iodoplatinate solution, positive).

Ultraviolet Spectrum Aqueous acid—252, 258 (A^{1}_{1}=11a), 264 nm.



Infrared Spectrum Principal peaks at wavenumbers 1728, 1220, 1190, 1162, 690, 1052 cm^{-1} (KBr disk).

Quantification
Plasma **GC–MS** Limit of detection, 5 µg/L [Dahlström *et al.* 1980].

Dose 30 to 70 mg daily.

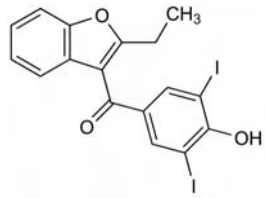
Dahlström H *et al.* (1980). Quantitative determination of benzilonium bromide in plasma by gas chromatography-mass spectrometry after oxidation to benzophenone. *J Chromatogr* 183: 511–513.

Benziodarone

Uricosuric, Vasodilator
$C_{17}H_{12}I_2O_3 = 518.1$
CAS—68-90-6

IUPAC Name 2-Ethyl-3-benzofuranyl 4-hydroxy-3,5-diiodophenyl methanone

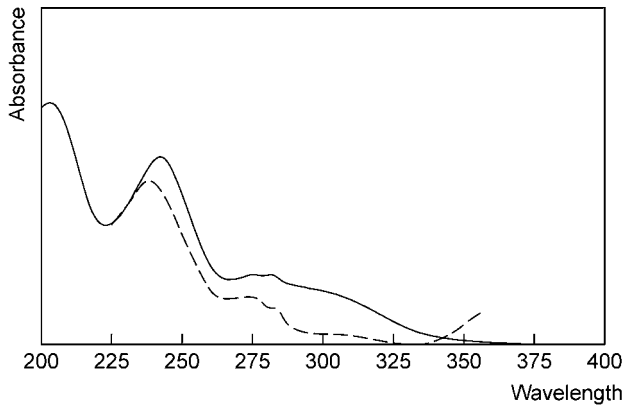
Proprietary Name *Amplivix*



Chemical Properties A yellowish powder. Mp 167°. Soluble 1 in about 500 of water at 25° and 1 in about 100 of water at 45°; soluble in acetone and chloroform. Log *P* (octanol/water) 6.6.

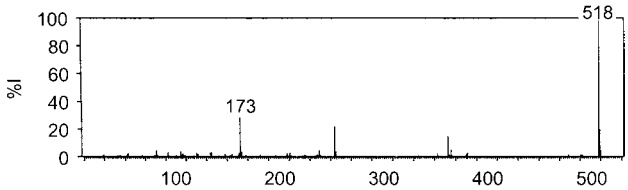
Thin-layer Chromatography System TD—R_f 0.62; system TE—R_f 0.23; system TF—R_f 0.58; system TAD—R_f 0.65.

Ultraviolet Spectrum Methanol—240 nm (A^{1}_{1}=1280b), 275, 357 nm.



Infrared Spectrum Principal peaks at wavenumbers 1618, 756, 1577, 1135, 1293, 1176 cm^{-1} (Nujol mull).

Mass Spectrum Principal ions at *m/z* 518, 173, 264, 519, 373, 376, 520, 249.



Dose Benziodarone has been given in initial doses of 600 mg daily and maintenance doses of 300 to 400 mg daily.

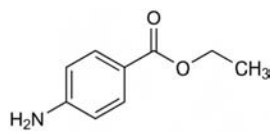
Benzocaine

Anaesthetic (Local)
$C_9H_{11}NO_2 = 165.2$
CAS—94-09-7

IUPAC Name 4-Aminobenzoic acid ethyl ester

Synonyms Anaesthesinum; anesthamine; éthoforme; ethyl aminobenzoate.

Proprietary Names *Americaine*; *Anaesthesin*; *Flavamed*; *Subcutin*. It is an ingredient of *AAA*, *Audicort*, *Auralgan*, *Auralgicin*, *Auraltone*, *Merocaine*, *Transvasin*, *Tyrosolven* and *Tyrozets*.



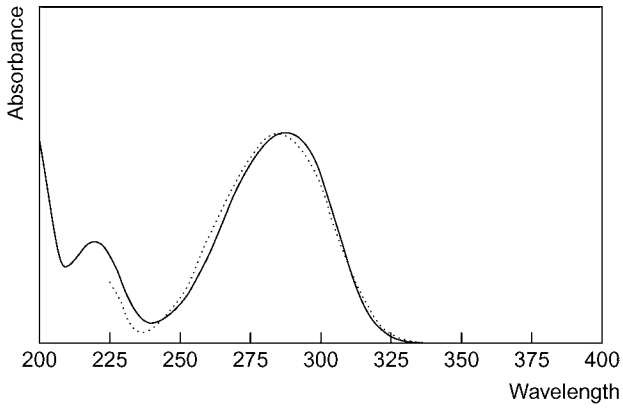
Chemical Properties Colourless crystals or white crystalline powder. Mp 88° to 92°. Soluble 1 in 2500 of water, 1 in 8 of ethanol, 1 in 2 of chloroform and 1 in 4 of ether; soluble in dilute acids. pK_a 2.5 (25°). Log *P* (octanol/water), 1.9.

Colour Test Diazotisation—red.

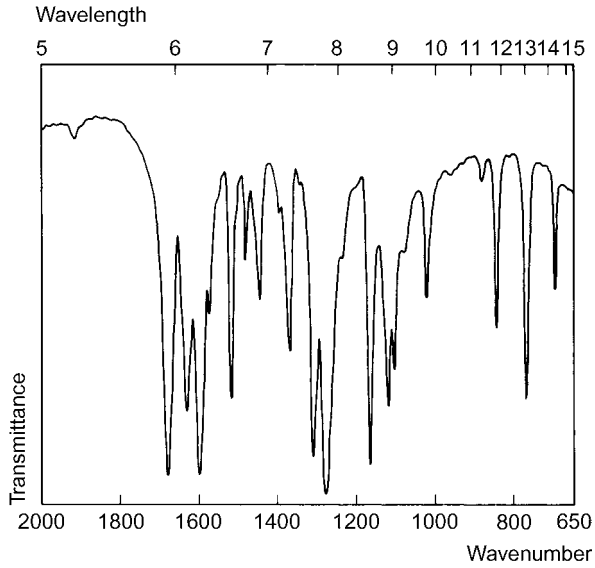
Thin-layer Chromatography System TA—R_f 0.67; system TB—R_f 0.06; system TC—R_f 0.57; system TD—R_f 0.56; system TE—R_f 0.77; system TF—R_f 0.62; system TL—R_f 0.66; system TAD—R_f 0.63; system TAE—R_f 0.84; system TAF—R_f 0.87 (ninhydrin spray, positive; acidified potassium permanganate solution, positive; Van Urk reagent, bright yellow).

Gas Chromatography System GA—benzocaine RI 1555, 4-aminobenzoic acid RI 1547; system GF—RI 2100.

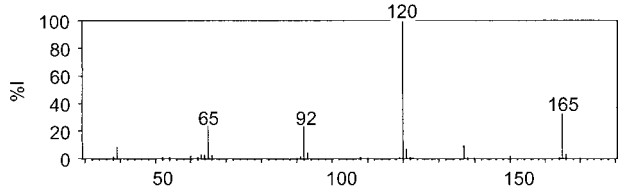
High Performance Liquid Chromatography System HA—*k* 0.1; system HQ—*k* 20.06; system HR—*k* 1.61; system HX—RI 404; system HY—RI 358; system HZ—retention time 4.3 min.
Ultraviolet Spectrum Aqueous acid—272 (A^1_1=90c), 278 nm; aqueous alkali—285 nm (A^1_1=930a); ethanol—293 nm (A^1_1=1238a).



Infrared Spectrum Principal peaks at wavenumbers 1280, 1680, 1598, 1170, 1315, 1634 cm^{-1} (KBr disk).



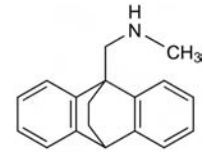
Mass Spectrum Principal ions at *m/z* 120, 165, 92, 65, 137, 39, 121, 93; 4-aminobenzoic acid 137, 120, 92, 65, 39, 138, 121, 63.



Disposition in the Body Benzocaine is metabolised by hydrolysis to 4-aminobenzoic acid. At the concentrations normally used (2 to 10%) it is comparatively non-irritant and non-toxic, having only about one-tenth the toxicity of cocaine. The maximum safe amount for topical use is 5000 mg (25 mL of a 20% solution).

Benzoctamine

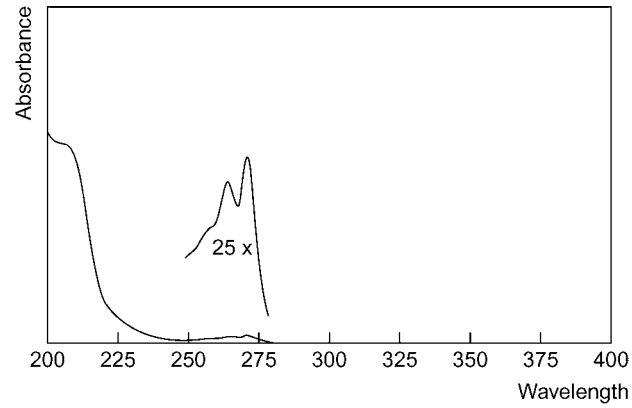
Tranquilliser
$C_{18}H_{19}N$ = 249.4
CAS—17243-39-9
IUPAC Name *N*-Methyl-9,10-ethanoanthracene-9(10*H*)-methenamine



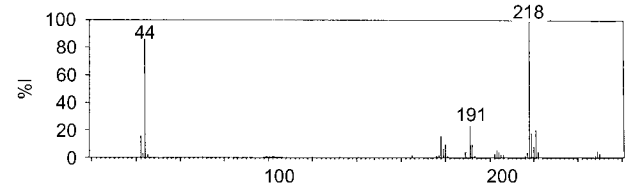
Chemical Properties pK_a 7.6. Log *P* (octanol/water), 3.5.

Benzoctamine Hydrochloride
$C_{18}H_{19}N,HCl$ = 285.8
CAS—10085-81-1
Synonym Ba-30803
Proprietary Name *Tacitin(e)*
Chemical Properties A white crystalline powder. Mp 320° to 322°. Soluble in water, ethanol and chloroform; sparingly soluble in acetone and ether.

Colour Tests Mandelin's test—blue-green; Marquis test—red-violet.
Thin-layer Chromatography System TA—R_f 0.59; system TB—R_f 0.57; system TC—R_f 0.52; system TL—R_f 0.43; system TAE—R_f 0.38; system TAJ—R_f 0.31; system TAK—R_f 0.14; system TAL—R_f 0.65 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—RI 2078; system GB—RI 2172; system GF—RI 2445.
High Performance Liquid Chromatography System HA—*k* 1.7; system HX—RI 380; system HY—RI 322.
Ultraviolet Spectrum Aqueous acid—264, 271 nm (A^1_1=57a).



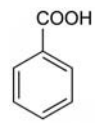
Infrared Spectrum Principal peaks at wavenumbers 757, 743, 732, 1134, 1060, 1020 cm^{-1} (KBr disk).
Mass Spectrum Principal ions at *m/z* 218, 44, 191, 221, 219, 178, 42, 180.



Dose 30 to 60 mg of benzoctamine hydrochloride daily.

Benzoic Acid

Preservative
$C_7H_6O_2$ = 122.1
CAS—65-85-0
Synonyms Benzenecarboxylic acid; phenylformic acid.
Proprietary Names It is an ingredient of *Aserbine* and *Malatex*.

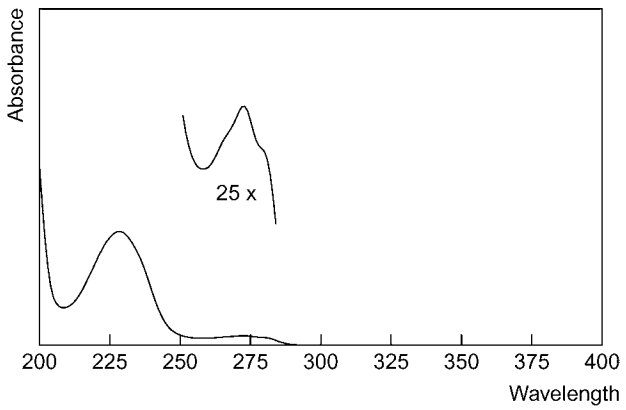


Chemical Properties Colourless, light feathery crystals or white scales or powder. Mp 122.4°. It sublimes on heating. Soluble 1 in about 350 of water, 1 in 20 of boiling water, 1 in 3 of ethanol, 1 in 5 of chloroform and 1 in 3 of ether; freely soluble in acetone. pK_a 4.2 (25°). Log *P* (octanol/water), 1.9.

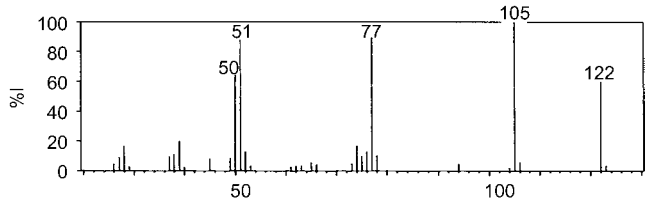
Sodium Benzoate
$C_7H_5O_2Na$ = 144.1
CAS—532-32-1

Chemical Properties A white, amorphous, granular, flaky, or crystalline powder. Soluble 1 in 2 of water and 1 in 90 of ethanol.

Thin-layer Chromatography System TD—R_f 0.26; system TE—R_f 0.07; system TF—R_f 0.28; system TAD—R_f 0.35; system TAJ—R_f 0.55; system TAK—R_f 0.81; system TAL—R_f 0.92.
Gas Chromatography System GA—RI 1180.
High Performance Liquid Chromatography System HX—RI 360; system HY—RI 327; system HZ—retention time 3.0 min (benzoate).
Ultraviolet Spectrum Aqueous acid—230 (A^1_1=923a), 273 nm (A^1_1=85a); methanol—227 (A^1_1=895a), 272 (A^1_1=73a), 280 nm (A^1_1=61b).



Infrared Spectrum Principal peaks at wavenumbers 709, 1689, 1296, 667, 935, 685 cm^{-1} (KBr disk).
Mass Spectrum Principal ions at *m/z* 105, 77, 51, 122, 50, 39, 74, 76; hippuric acid 105, 135, 51, 134, 77, 106, 50, 78.



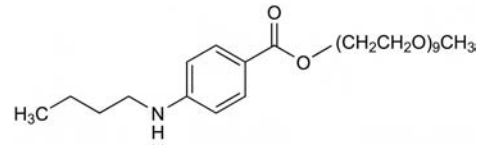
Quantification
Plasma **GC** FID. Limit of detection, 0.1 mg/L [Li, Zhao 2001]. ECD. Limit of detection, 10 µg/L [Sioufi, Pommier 1980].
HPLC UV detection (λ=283 nm). Limit of quantification, 0.05 mg/L [Nomeir *et al.* 1994].
Urine **GC** FID. Limit of detection, 0.2 mg/L [Li, Zhao 2001]. ECD. Limit of detection, 0.5 µg/L [Aprea *et al.* 1997]. See Plasma [Sioufi, Pommier 1980].
Disposition in the Body Benzoic acid is metabolised in the liver by conjugation with glycine and is rapidly and completely excreted in the urine as hippuric acid. Normal urinary excretion of hippuric acid is 1 to 2.5 g daily, equivalent to 0.7 to 1.7 g of benzoic acid. When taken in large doses, a proportion may be excreted as benzoylglucuronic acid. Benzoic acid may be found in the urine as a metabolite of benzaldehyde, and is also a metabolite of numerous other compounds.
Uses Benzoic acid is used as a preservative in a concentration of 0.1%. Sodium benzoate is given by mouth in a dose of 6 g to test liver function.

Aprea C *et al.* (1997). Analytical method for the determination of urinary 3-phenoxybenzoic acid in subjects occupationally exposed to pyrethroid insecticides. *J Chromatogr B Biomed Sci Appl* 695 (2): 227–236.
Li AQ, Zhao XL (2001). Determination and pharmacokinetic study of 1-p-(3.3-dimethyl-1-triazeno) benzoic acid in cancer patients by capillary gas chromatography. *Biomed Chromatogr* 15 (2): 75–78.
Nomeir AA *et al.* (1994). Liquid chromatographic analysis, stability and protein binding studies of the anti-HIV agent benzoic acid, 2-chloro-5[[(1-methylethoxy)thioxomethyl]amino]-,1-methylethyl ester. *J Pharm Biomed Anal* 12(5): 693–698.
Sioufi A, Pommier F (1980). Gas chromatographic determination of low concentrations of benzoic acid in human plasma and urine. *J Chromatogr* 181(7); B Biomed. Appl.: 161–168.

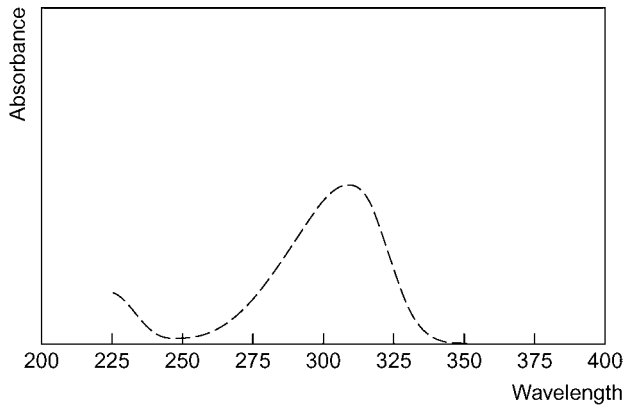
Benzonatate

Cough Suppressant
$C_{30}H_{53}NO_{17}$ = 603.7
CAS—104-31-4
IUPAC Name 4-(Butylamino)benzoic acid 3,6,9,12,15,18,21,24,27-nonaoxaoctacos-1-yl ester
Synonyms Benzonatine; benzononatine.

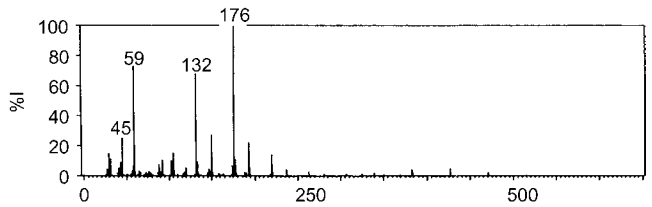
Proprietary Name *Tessalon*



Chemical Properties A clear, pale yellow, viscous liquid. Miscible with water, ethanol, chloroform and ether. Log *P* (octanol/water), 2.4.
Colour Tests Aromaticity (method 2)—yellow/red; Liebermann's test (at 100°)—blue.
Thin-layer Chromatography System TA—R_f 0.61; system TAJ—R_f 0.56; system TAK—R_f 0.23; system TAL—R_f 0.90 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—not eluted.
Ultraviolet Spectrum Ethanol—308 nm (A^1_1=473c).



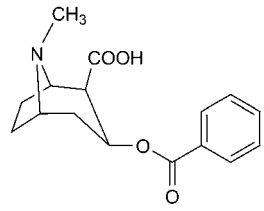
Infrared Spectrum Principal peaks at wavenumbers 1095, 1605, 1266, 1172, 1698, 1527 cm^{-1} (KBr disk).
Mass Spectrum Principal ions at *m/z* 176, 59, 132, 150, 45, 193, 105, 29.



Dose 300 to 600 mg daily.

Benzoylecgonine

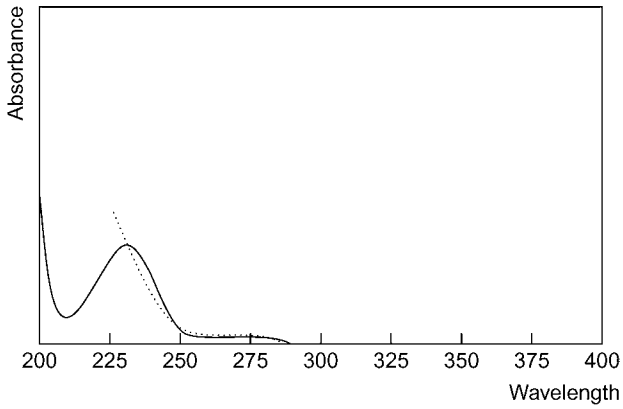
Alkaloid
$C_{16}H_{19}NO_4$ = 289.3
CAS—519-09-5
IUPAC Name 3-(Benzoyloxy)-8-methyl-8-azabicyclo[3.2.1]octane-2-carboxylic acid
Synonym Ecgonine benzoate



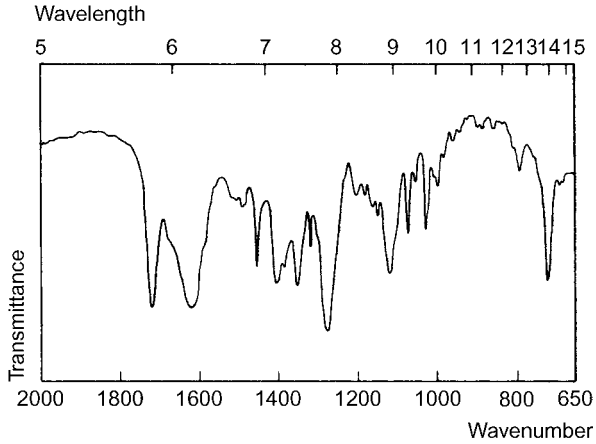
Chemical Properties An alkaloid obtained from coca leaves, *Erythroxylum coca* (Erythroxylaceae) and its varieties. The hydrated form occurs as crystals. Mp 86° to 92° (anhydrous) 195° (with decomposition). Very soluble in hot water; soluble in ethanol; practically insoluble in ether; soluble in dilute acids and alkalis. Log *P* (octanol/water) −1.3. Extraction yield (chlorobutane), 0 [Demme *et al.* 2005].
Thin-layer Chromatography System TA—R_f 0.21; system TB—R_f 0.00; system TC—R_f 0.01 (acidified iodoplatinate solution, positive).
Plate: silica 60 F_{254} (10 × 10 cm). Mobile phase: hexane : toluene : diethylamine (65 : 20 : 5). UV detection. R_f 0.02 [Antonilli *et al.* 2001].
Gas Chromatography System GA—benzoylecgonine RI 2570; cocaine RI 2187; system GB—benzoylecgonine RI 2663, cocaine RI 2289.

High Performance Liquid Chromatography System HA—*k* 0.9 (tailing peak); system HQ—*k* 5.68; system HY—RI 236; system HZ—RT 1.7 min; system HAA—RT 9.7 min.

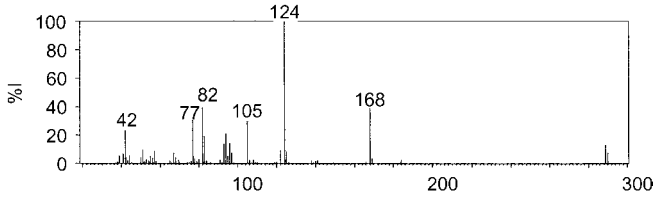
Ultraviolet Spectrum Aqueous acid—234 ($A_1^1 = 376a$), 274 nm.



Infrared Spectrum Principal peaks at wavenumbers 1275, 1720, 1618, 717, 1116, 1316 cm^{-1}.



Mass Spectrum Principal ions at *m/z* 124, 82, 168, 77, 105, 42, 94, 83.



Quantification See also under Cocaine.

Blood **LC-MS** CI. Limit of detection, 2 µg/L [Sosnoff *et al.* 1996].

Plasma **GC-MS** SIM acquisition mode (*m/z* 404, 140 and 298). Limit of detection, 5 µg/L [Wang *et al.* 1994].

Urine **GC-MS** SIM acquisition mode (*m/z* 318, 439). Limit of detection, 1 µg/L [de la Torre *et al.* 1995]. See Plasma [Wang *et al.* 1994].

HPLC Column: LiChrocart-LiCrospher 100 RP-18 (250 × 4 mm i.d., 5 µm). Mobile phase: 0.045 mol/L ammonium acetate-methanol-acetonitrile (80 : 10 : 10) : 0.045 mol/L ammonium acetate-methanol-acetonitrile (20 : 40 : 40; 100 : 0 to 47.2 : 52.8 in 20 min), flow rate 1 mL/min. UV detection (λ = 235 nm). Retention time: 8.48 min. Limit of quantification, 200 µg/L, limit of detection, 25 µg/L [Antonilli *et al.* 2001

LC-MS Column: Allure Basix (30 × 2.1 mm, 5 µm). Mobile phase: 50 mmol/L formic acid-100 mmol/L ammonium formate-acetonitrile : acetone (60 : 40). Tandem MS detection (*m/z* 290 to 168 transition). Retention time: 1.5 min. Limit of detection, 0.5 µg/L [Jeanville *et al.* 2001].

Oral Fluid See Plasma [Wang *et al.* 1994].

Hair **GC-MS** SIM acquisition mode (*m/z* 240 and 361). Limit of detection, 0.2 µg/g using a 30 mg sample [Kintz, Mangin 1995]. See Plasma. Limit of detection, 0.5 µg/g [Wang *et al.* 1994].

Disposition in the Body Benzoylecgonine is the first hydrolysis product formed in the metabolism of cocaine; it is then further hydrolysed to ecgonine.

Antonilli L *et al.* (2001). Analysis of cocaethylene, benzoylecgonine and cocaine in human urine by high-performance thin-layer chromatography with ultraviolet detection: a comparison with high-performance liquid chromatography. *J Chromatogr B Biomed Sci Appl* 751: 19–27.

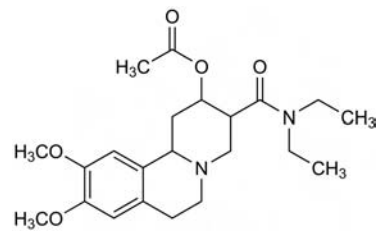
Benzquinamide

Antiemetic

$C_{22}H_{32}N_2O_5 = 404.5$

CAS—63-12-7

IUPAC Name 2-(Acetyloxy)-*N*,*N*-diethyl-1,3,4,6,7,11b-hexahydro-9,10-dimethoxy-2*H*-benzo[*a*]-quinolizine-3-carboxamide



Chemical Properties A yellowish crystalline powder. Mp 130° to 131.5°. Soluble in dilute acetic acid. pK_a 5.9. Log *P* (octanol/water), 1.9.

Benzquinamide Hydrochloride

$C_{22}H_{32}N_2O_5,HCl = 441.0$

CAS—113-69-9

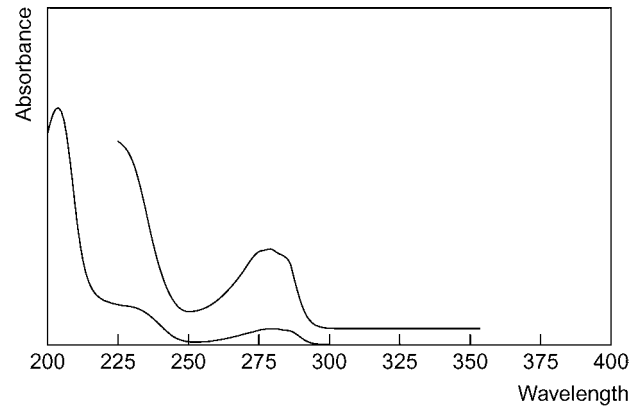
Proprietary Name *Emete-con*

Colour Tests Liebermann's reagent—black; Marquis test—yellow; sulfuric acid—orange.

Thin-layer Chromatography System TA—R_f 0.65; system TB—R_f 0.07; system TC—R_f 0.69; system TL—R_f 0.36; system TAJ—R_f 0.53; system TAK—R_f 0.06; system TAL—R_f 0.91 (acidified iodoplatinate solution, positive).

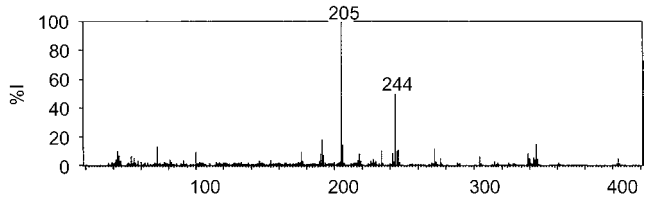
High Performance Liquid Chromatography System HA—*k* 0.3.

Ultraviolet Spectrum Aqueous acid—282 nm (A_1^1=95b). No alkaline shift.



Infrared Spectrum Principal peaks at wavenumbers 1244, 1733, 1633, 1204, 1515, 1123 cm^{-1} (KBr disk).

Mass Spectrum Principal ions at *m/z* 205, 244, 191, 345, 206, 72, 272, 246.



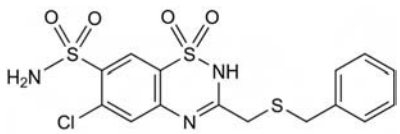
Quantification
Plasma **GC–MS** Limit of detection, 10 µg/L [Hobbs, Connolly 1978].
Disposition in the Body Readily absorbed after oral administration; bioavailability about 35%. Metabolised by *O*-demethylation, deacetylation and *N*-dealkylation. After an oral dose, up to about 7% is excreted unchanged in the urine in 24 h.
Therapeutic Concentration
Following oral administration of 200 mg to 20 subjects, a mean peak plasma concentration of 0.6 mg/L was attained in 1.2 h. Following intramuscular injection of 50 mg to 20 subjects, a mean peak plasma concentration of 0.7 mg/L was attained in 0.26 h [Hobbs, Connolly 1978].
Half-life Plasma half-life, about 1 h.
Volume of Distribution About 1 L/kg.
Dose The equivalent of 50 mg of benzquinamide by intramuscular injection, repeated as necessary.

Hobbs DC, Connolly AG (1978). Pharmacokinetics of benzquinamide in man. *J Pharmacokinet Biopharm* 6: 477–485.

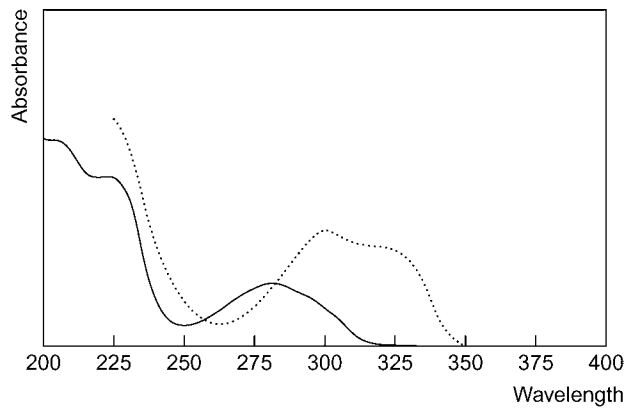
Benzthiazide

Diuretic, Antihypertensive
$C_{15}H_{14}ClN_3O_4S_3 = 431.9$
CAS—91-33-8

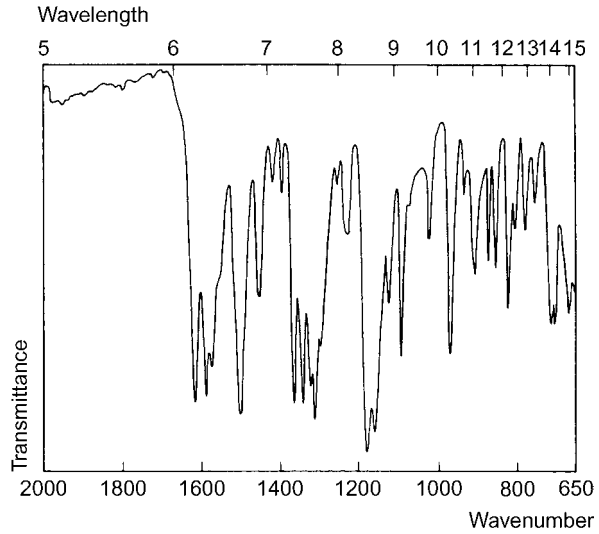
IUPAC Name 6-Chloro-3-[[(phenylmethyl)thio]methyl]-2*H*-1,2,4-benzothiadiazine-7-sulfonamide 1,1-dioxide
Proprietary Names *Aquatag*; *Exna*; *Hydrex*. It is an ingredient of *Decaserpyl Plus* and *Dytide*.



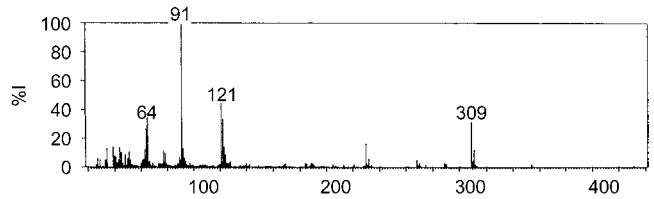
Chemical Properties A white crystalline powder. Mp 231° to 232°. Practically insoluble in water, chloroform and ether; slightly soluble in ethanol; soluble 1 in 100 of acetone; freely soluble in dimethylformamide and in solutions of alkalis. pK_a 6.0. Log *P* (octanol/water), 1.7.
Colour Tests Koppanyi-Zwikker test—violet; Liebermann's reagent—red-brown; sulfuric acid—yellow.
Thin-layer Chromatography System TD—R_f 0.14; system TE—R_f 0.09; system TF—R_f 0.51; system TAD—R_f 0.30; system TAJ—R_f 0.31; system TAK—R_f 0.06; system TAL—R_f 0.71.
Gas Chromatography System GA—RI 2680.
High Performance Liquid Chromatography System HN—*k* 9.32; system HY—RI 415.
Ultraviolet Spectrum Aqueous acid—283 nm (A^1_1=292a); aqueous alkali—297 nm (A^1_1=310b).



Infrared Spectrum Principal peaks at wavenumbers 1180, 1160, 1310, 1502, 1620, 1590 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 91, 121, 65, 122, 309, 64, 230, 123.



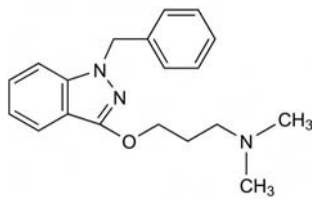
Quantification
Plasma **HPLC** Column: reversed phase. UV detection (λ=280 nm). Limit of detection, 10 µg/L [Meyer *et al.* 1982].
Urine **HPLC** See Plasma [Meyer *et al.* 1982].
Faeces **HPLC** See Plasma [Meyer *et al.* 1982].
Disposition in the Body Poorly absorbed after oral administration. Less than 10% of a dose is excreted in the urine as unchanged drug in 48 h, and about 80% of a dose is eliminated in the faeces.
Therapeutic Concentration
Following an oral dose of 50 mg to 4 subjects, peak plasma concentrations of about 0.008 and 0.02 mg/L were attained in 3 h in 2 subjects; in the remaining 2 subjects benzthiazide was not detectable in the plasma [Meyer *et al.* 1982].
Half-life Derived from urinary excretion data, about 10 to 15 h.
Dose 50 to 200 mg daily.

Meyer MC *et al.* (1982). HPLC determination of benzthiazide in biologic material. *Biopharm Drug Dispos* 3: 1–9.

Benzydamine

Analgesic
$C_{19}H_{23}N_3O = 309.4$
CAS—642-72-8

IUPAC Name *N*,*N*-Dimethyl-3-[[1-(phenylmethyl)-1*H*-indazol-3-yl]oxy]-1-propanamine
Synonym Benzindamine

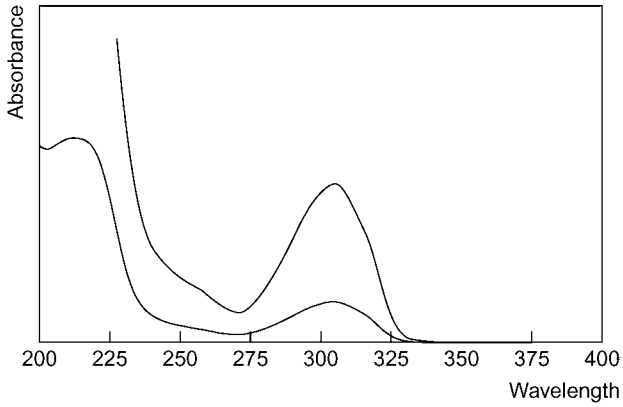


Chemical Properties Bp 160°. Log *P* (octanol/water), 4.2.

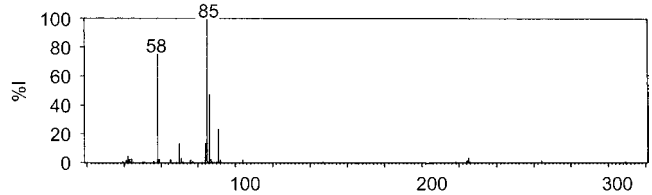
Benzydamine Hydrochloride
$C_{19}H_{23}N_3O,HCl = 345.9$
CAS—132-69-4
Proprietary Names *Afloben*; *A-Termadol*; *Difflam*; *Imotryl*; *Multum*; *Tantum*; *Verax*.

Chemical Properties A white crystalline powder. Mp 160°. Soluble 1 in 1 of water, 1 in 8 of ethanol and 1 in 4 of chloroform; practically insoluble in ether.

Colour Test Mandelin's test—brown-green.
Thin-layer Chromatography System TA—R_f 0.44; system TB—R_f 0.36; system TC—R_f 0.22; system TL—R_f 0.09; system TAE—R_f 0.16 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—RI 2380.
High Performance Liquid Chromatography System HAA—retention time 15.0 min.
Ultraviolet Spectrum Aqueous acid—307 nm (A^1_1=144c). No alkaline shift.



Infrared Spectrum Principal peaks at wavenumbers 1529, 740, 1491, 1613, 1182, 1141 cm^{-1} (KBr disk).
Mass Spectrum Principal ions at *m/z* 85, 58, 86, 91, 84, 70, 42, 225.



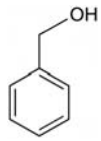
Quantification
Plasma **HPLC** Limit of quantification, 0.5 µg/L [Baldock *et al.* 1990].
Urine **HPLC** Limit of quantification, 1.0 µg/L [Baldock *et al.* 1990].
Disposition in the Body Absorbed after oral administration. About 50% of a dose is excreted unchanged in the urine.
Therapeutic Concentration
An oral dose of 1 mg/kg produced a blood concentration of about 0.8 mg/L within 2 h and a significant concentration was maintained for several hours [Catanese *et al.* 1966].
Protein Binding A fraction of benzydamine is bound to proteins in the blood.
Dose 150 to 200 mg of benzydamine hydrochloride daily.

Baldock GA *et al.* (1990). Determination of benzydamine and its N-oxide in biological fluids by high-performance liquid chromatography. *J Chromatogr* 529(1): 113–123.
Catanese B *et al.* (1966). Studies on the absorption and elimination of benzydamine in the mouse, rat, dog, and man. *Arzneimittelforschung* 16: 1354–1357.

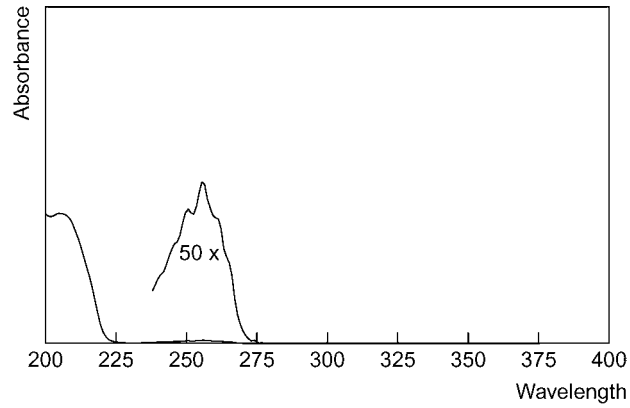
Benzyl Alcohol

Anaesthetic (Local), Disinfectant
C_7H_8O = 108.1
CAS—100-51-6

Synonyms Phenylcarbinol; phenylmethanol.



Chemical Properties A colourless liquid with a faint aromatic odour. Mass per mL 1.043 to 1.046 g. Bp 203° to 208°. Soluble 1 in 25 of water; miscible with ethanol, chloroform and ether. pK_a 15.4. Log *P* (octanol/water), 1.1.
Thin-layer Chromatography System TAE—R_f 0.86.
Gas Chromatography System GA—RI 1040.
Ultraviolet Spectrum Methanol—252 (A^1_1=14b), 258 (A^1_1=17b), 264 nm (A^1_1=13b).



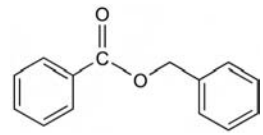
Mass Spectrum Principal ions at *m/z* 79, 77, 108, 101, 51, 50, 39, 40.
Quantification
Blood **GC–MS** Limit of detection, 1 mg/L [Dasgupta, Steinagel 1997].
Plasma **HPLC** Column: C_{18}. Mobile phase: water : acetonitrile : glacial acetic acid. UV detection (λ=254 nm). Limit of detection, 10 ng [Tan *et al.* 1991].
Serum **GC–MS** SIM (*m/z* 69, 77, 91, 105, 121, 504 and 518). Limit of detection, 0.1 mg/L [Dasgupta, Humphrey 1998]. See Blood [Dasgupta, Steinagel 1997].
Use Topically in concentrations of up to 10%.

Dasgupta A, Steinagel G (1997). Gas chromatographic-mass spectrometric identification and quantitation of benzyl alcohol from human serum and postmortem blood after derivatization with 4-carbethoxy hexafluorobutyryl chloride: a novel derivative. *J Forensic Sci* 42(4): 697–700.
Dasgupta A, Humphrey PE (1998). Gas chromatographic-mass spectrometric identification and quantitation of benzyl alcohol in serum after derivatization with perfluorooctanoyl chloride: a new derivative. *J Chromatogr B Biomed Sci Appl* 708(1–2): 299–303.
Tan HS *et al.* (1991). Determination of benzyl alcohol and its metabolite in plasma by reversed-phase high-performance liquid chromatography. *J Chromatogr* 568(1): 145–155.

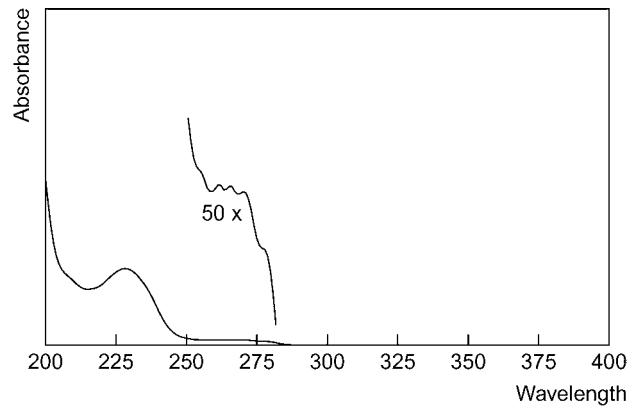
Benzyl Benzoate

Acaricide
$C_{14}H_{12}O_2$ = 212.2
CAS—120-51-4

Proprietary Names *Antiscabiosum Mago*; *Ascabiol*; *Benzemul*; *Scabanca*.



Chemical Properties Colourless crystals or a clear, colourless, oily liquid. Bp 323° to 324°. Practically insoluble in water; miscible with ethanol, acetone, carbon disulfide, chloroform and ether. Log *P* (octanol/water), 4.0.
Thin-layer Chromatography System TF—R_f 0.73; system TAD—R_f 0.09.
Gas Chromatography System GA—RI 1738.
Ultraviolet Spectrum Ethanol—230 nm (A^1_1=843b).

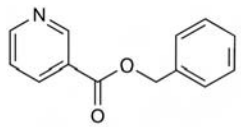


Infrared Spectrum Principal peaks at wavenumbers 1263, 1706, 1106, 713, 698, 1067 cm^{-1} (thin film).
Mass Spectrum Principal ions at *m/z* 77, 105, 91, 51, 65, 212, 50, 78.
Disposition in the Body Rapidly hydrolysed to benzoic acid and benzyl alcohol; benzyl alcohol then undergoes further oxidation to benzoic acid followed by conjugation with glycine to form hippuric acid. Excreted in the urine mainly as hippuric acid.
Uses Topically as a 25% application; a 5% solution is used as an insect repellent.

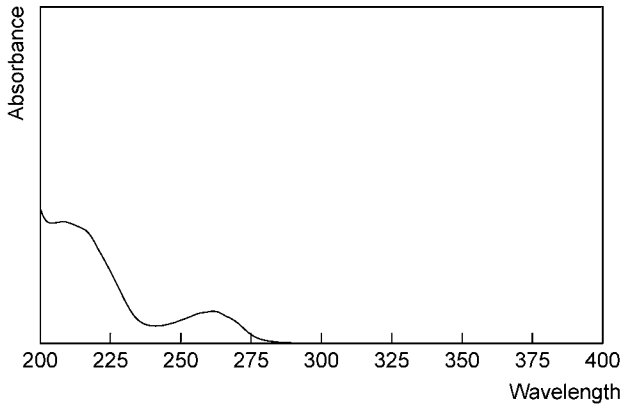
Benzyl Nicotinate

Rubefacient (Topical)
$C_{13}H_{11}NO_2$ = 213.2
CAS—94-44-0

Proprietary Names *Rubriment*. It is an ingredient of *Bayolin*.



Chemical Properties A liquid. Log *P* (octanol/water), 2.4.
Colour Tests Cyanogen bromide—red-orange; Liebermann's reagent—brown; sulfuric acid—orange.
Thin-layer Chromatography System TA—R_f 0.63; system TB—R_f 0.42; system TC—R_f 0.71; system TL—R_f 0.60 (acidified potassium permanganate solution, positive).
Ultraviolet Spectrum Methanol—262 nm (A^1_1=152b).

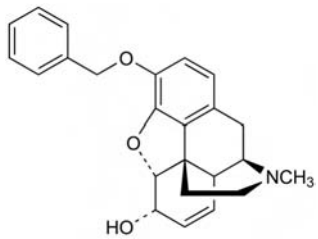


Infrared Spectrum Principal peaks at wavenumbers 1278, 1724, 1108, 740, 699, 1587 cm^{-1} (KCl disk).
Use Topically in a concentration of 2.5%.

Benzylmorphine

Narcotic Analgesic
$C_{24}H_{25}NO_3$ = 375.5
CAS—14297-87-1

IUPAC Name 7,8-Didehydro-4,5-epoxy-17-methyl-3-(phenylmethoxy)morphinan-6-ol



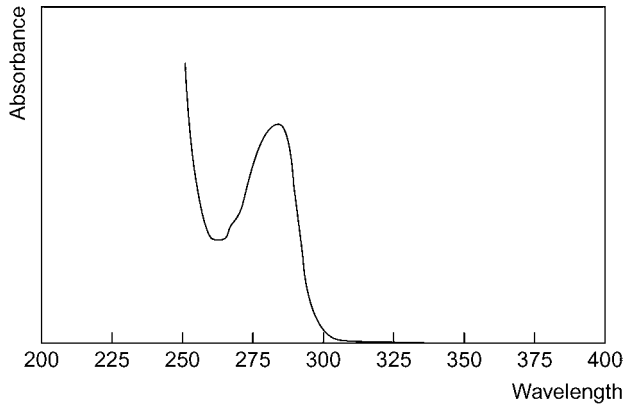
Chemical Properties A colourless crystalline powder. Mp 132°. Soluble 1 in 2500 of cold water; 1.6 parts dissolves in 100 parts ether; readily soluble in 50% ethanol and in benzene. pK_a 8.1 (20°). Log *P* (octanol/water), 3.0.

Benzylmorphine Hydrochloride

$C_{24}H_{25}NO_3$,HCl = 411.9
CAS—630-86-4

Proprietary Name *Peronine*
Chemical Properties A colourless microcrystalline powder. Soluble 1 in 200 of water and 1 in 160 of ethanol; practically insoluble in chloroform and ether.

Colour Test Marquis test—red→violet.
Thin-layer Chromatography System TA—R_f 0.41; system TB—R_f 0.06; system TC—R_f 0.23; system TL—R_f 0.08; system TAE—R_f 0.20; system TAF—R_f 0.23 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—RI 3015.
High Performance Liquid Chromatography System HA—*k* 4.4 (tailing peak); system HC—*k* 1.03.
Ultraviolet Spectrum Aqueous acid—284 nm (A^1_1=48b).

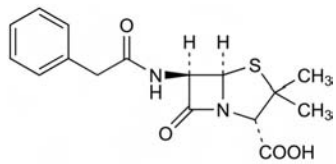


Infrared Spectrum Principal peaks at wavenumbers 1274, 1040, 1502, 1017, 763, 1056 cm^{-1}.
Mass Spectrum Principal ions at *m/z* 284, 91, 375, 81, 42, 36, 285, 175.
Dose Benzylmorphine hydrochloride was formerly given in doses of 8 to 30 mg.

Benzylpenicillin

Antibiotic
$C_{16}H_{18}N_2O_4S$ = 334.4
CAS—61-33-6

IUPAC Name (2*S*,5*R*,6*R*)-3,3-Dimethyl-7-oxo-6-[(phenylacetyl)amino]-4-thia-1-azabicyclo[3.2.0]heptane-2-carboxylic acid
Synonyms Crystalline penicillin G; penicillin; penicillin G; penicillin II.



Note The name 'benzylpenicillin' and its synonyms are commonly used to describe either benzylpenicillin potassium or benzylpenicillin sodium.
Chemical Properties An antimicrobial acid produced by the growth of certain strains of *Penicillium notatum*. pK_a 2.8 (25°). Log *P* (octanol/water), 1.8.

Benzylpenicillin Potassium

$C_{16}H_{17}KN_2O_4S$ = 372.5
CAS—113-98-4

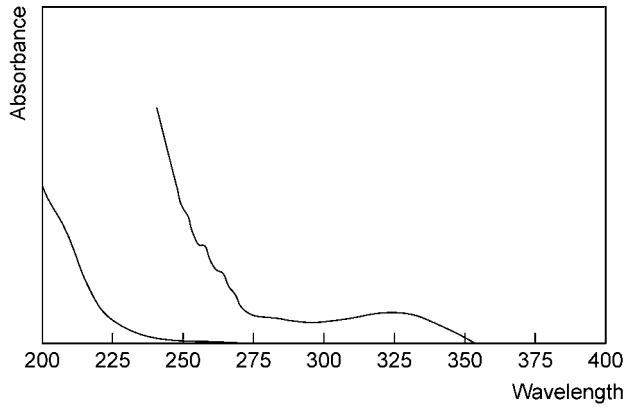
Proprietary Names *Abbocillin-G*; *Crystapen G*; *Falapen*; *Hyasorb*; *M-Cillin B*; *Megacillin*; *Novopen*; *P-50*; *Paclin G*; *Pentids*; *Pfizerpen*; *Sugracillin*.
Note *Megacillin* is also used as a proprietary name for clemizole penicillin, phenoxymethylpenicillin and procaine penicillin (procaine benzylpenicillin).
Chemical Properties A white, finely crystalline powder. Mp 214° to 217°, with decomposition. Very soluble in water; soluble in ethanol; practically insoluble in chloroform and ether.

Benzylpenicillin Sodium

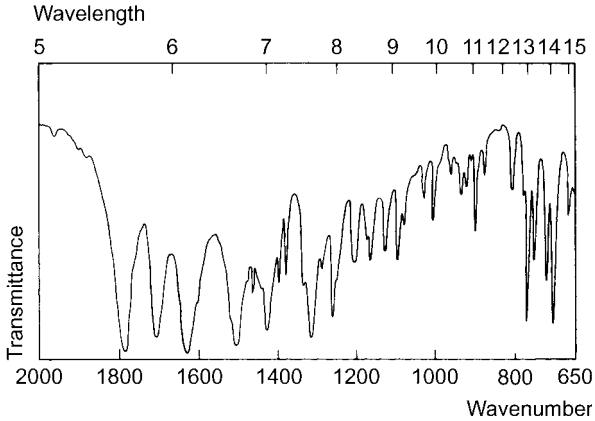
$C_{16}H_{17}N_2NaO_4S$ = 356.4
CAS—69-57-8

Proprietary Names *Crystapen*; *Gonopen*; *Spécilline G*. It is an ingredient of *Bicillin* and *Triplopen*.
Note *Bicillin* is also used as a proprietary name for benzathine benzylpenicillin.
Chemical Properties A white to slightly yellow, finely crystalline powder. Very soluble in water; soluble in ethanol; practically insoluble in chloroform and ether.

High Performance Liquid Chromatography System HY—RI 376.
Ultraviolet Spectrum Benzylpenicillin sodium: water—257 (A^1_1=7b), 264, 325 nm.



Infrared Spectrum Principal peaks at wavenumbers 1620, 1777, 1500, 1310, 1700, 703 cm^{-1} (benzylpenicillin sodium, KBr disk).



Quantification

Serum **HPLC** UV detection (λ=208 nm). Limit of quantification, 0.5 to 50 mg/L [Mendez-Alvarez *et al.* 1991].

Disposition in the Body About 30% of an oral dose is absorbed, the remainder being inactivated by gastric acid; maximum concentrations are attained about 1 h after oral administration. After IM injection it is rapidly absorbed, peak concentrations being attained in 15 to 30 min. About 60 to 90% of an IM dose is excreted in the urine, mainly in the first few hours; the urinary material consists of unchanged drug and penicilloic acid (about 20% of the dose). Biliary excretion also occurs.

Therapeutic Concentration In plasma, minimum inhibitory concentration 0.006 to 2 mg/L.

Half-life Plasma half-life, about 0.5 to 1 h; increased in infants and elderly subjects, and in renal impairment.

Distribution in Blood Plasma : whole blood ratio, 1.6.

Protein Binding 45 to 65%.

Note For a review of the pharmacokinetics of penicillin antibiotics, see Barza, Weinstein [1976]. For a review of clinical pharmacology and therapeutic use of penicillins, see Nathwani, Wood [1993].

Dose 0.6 to 2.4 g daily, given parenterally; up to 24 g daily in severe infections.

Barza M, Weinstein L (1976). Pharmacokinetics of the penicillins in man. *Clin Pharmacokinet* 1: 297–308.

Mendez-Alvarez E *et al.* (1991). A reversed phase liquid chromatographic method for the simultaneous determination of several common penicillins in human serum. *Biomed Chromatogr* 5(2): 78–82.

Nathwani D, Wood MJ (1993). Penicillins. A current review of their clinical pharmacology and therapeutic use. *Drugs* 45: 866–894.

N-Benzylpiperazine

Stimulant

$C_{11}H_{16}N_2$ = 176.3

CAS—2759-28-6

IUPAC Name 1-(Phenylmethyl)piperazine

Synonyms 1-Benzyl-1,4-diazacyclohexane; 1-benzylpiperazine; BZP.

Street Names A2; Bliss; Charge; Frenzy; Herbal ecstasy; Legal E; Legal X.

Chemical Properties Pale yellow viscous liquid. Mp 17° to 20°. pK_a 9.59 [Bishop *et al.* 2005]. Log *P* (octanol/water), 1.36 [Meylan, Howard 1995]. Human urine samples were stable for up to 3 months at –20° [Nordgren, Beck 2004]. There was no indication of instability of processed samples over a time period of 30 h. Freeze–thaw stability was established [Peters *et al.* 2003].

N-Benzylpiperazine Hydrochloride

$C_{11}H_{16}N_2$,HCl = 212.8

CAS—72878-35-4

Chemical Properties White solid.

N-Benzylpiperazine Dihydrochloride

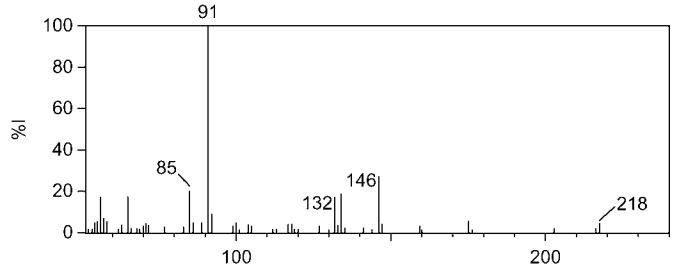
$C_{11}H_{16}N_2$,2HCl = 249.3

CAS—5321-63-1

Chemical Properties White solid. Mp 287° to 292°.

Ultraviolet Spectrum Neutral—211 nm.

Mass Spectrum Principal ions at *m/z* 91, 134, 56, 176, 120, 118, 119, 77, 91, 146, 134, 132, 85, 56, 218, 175 (AC derivative), Staack *et al.* [2002]; 91, 272, 181, 56, 69, 175, 146, 196 (TFAA derivative), Wikstrom *et al.* [2004]; 91, 281, 372, 175, 295 (HFBA derivative).



Quantification

Blood **GC-MS** Column: HP-5MS 5% phenylmethylsilicone (30 m × 0.25 mm i.d., 0.25 μm). Carrier gas: He, 0.9 mL/min. EI ionisation, SIM acquisition mode. Limit of quantification, 0.02 μg/g [Wikstrom *et al.* 2004].

Plasma **GC-MS** Column: HP-5MS capillary 5% phenylmethylsiloxane (30 m × 0.25 mm i.d., 250 nm). Carrier gas: He, 0.6 mL/min. Temperature programme: 100° to 250° at 10°/min to 310° at 30°/min for 1 min. EI ionisation at 70 eV, SIM acquisition mode. Limit of quantification, 5 μg/L; limit of detection, approx. 1 μg/L [Peters *et al.* 2003]. Column: HP-5MS (19 m × 0.25 mm i.d., 0.25 μm). Carrier gas: He, 1 mL/min. Temperature programme: 90° for 1 min to 300° at 15°/min for 5 min. EI ionisation at 70 eV. Limit of quantification not reported [de Boer *et al.* 2001].

Urine **GC-MS** Column: Fused silica capillary (30 m × 0.25 mm i.d., 0.25 μm). Carrier gas: He, 1 mL/min. Temperature programme: 80° for 1 min to 250° at 10°/min. EI ionisation at 70 eV. Limit of detection, 20 μg/L for BZP and 500 μg/L for 3-hydroxy-BZP and 4-hydroxy-BZP [Tsutsumi *et al.* 2005].

LC-MS Direct injection, positive ion mode, MRM acquisition mode. Limit of detection, 8.8 μg/L (screening), 0.9 μg/L (confirmation) [Nordgren *et al.* 2005]. Column: SCX (150 × 0.2 mm i.d.). Mobile phase: acetonitrile : 40 mmol/L ammonium acetate (pH 4; 75 : 25), flow rate 0.15 mL/min. ESI, positive ion mode, SIM acquisition mode. Limit of detection, 0.2 μg/L for BZP and 0.4 μg/L for 3-hydroxy-BZP and 4-hydroxy-BZP [Tsutsumi *et al.* 2005]. Column: HyPURITY Advance (30 × 2.1 mm i.d., 3 μm). Mobile phase: 10 mmol/L ammonium acetate : methanol (95 : 5 at 0.1 min to 20 : 80 at 1 min to 95 : 5 for 5 min), flow rate 400 μL/min. APCI, positive ion mode. Retention time: 1.44 min. Limit of detection, 0.9 μg/L [Nordgren, Beck 2004].

Other **GC-MS** Rat Urine. Column: Fused silica capillary DB-5MS (30 m × 0.25 mm i.d., 0.25 μm). Carrier gas: He, 1 mL/min. Temperature programme: 80° for 1 min to 250° at 10°/min. EI ionisation at 70 eV. Limit of detection not reported [Tsutsumi *et al.* 2006].

LC-MS Rat Urine Column: SCX (150 × 0.2 mm i.d.). Mobile phase: acetonitrile : 40 mmol/L ammonium acetate (pH 4; 75 : 25), flow rate 0.15 mL/min. ESI, positive ion mode. Limit of detection not reported [Tsutsumi *et al.* 2006].

Disposition in the Body Metabolised by CYP2D6 to form 4-hydroxy-BZP, 3-hydroxy-BZP, 4-hydroxy-3-methoxy-BZP, piperazine, benzylamine and *N*-benzylethylenediamine. The 4-hydroxy-BZP and 4-hydroxy-methoxy-BZP metabolites are also excreted as glucuronic and/or sulfuric acid conjugates in urine.

BZP has been measured in 13 non-fatal (0.02 to 1.2 μg/g blood) and 1 fatal instance of ingestion (1.7 μg/g blood) [Wikstrom *et al.* 2004].

Note For further reading on the metabolism of BZP, see Staack *et al.* [2002]. BZP is a metabolite of the antidepressant drug piberaline [Olajos, Sztaniszlav 1986].

Toxicity There have been few published cases of fatal BZP toxicity. It stimulates the release of dopamine and noradrenaline and also inhibits dopamine, noradrenaline and serotonin uptake. It acts as a CNS stimulant, producing effects comparable to amfetamine [Maurer *et al.* 2004; Wikstrom *et al.* 2004].

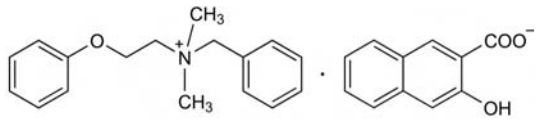
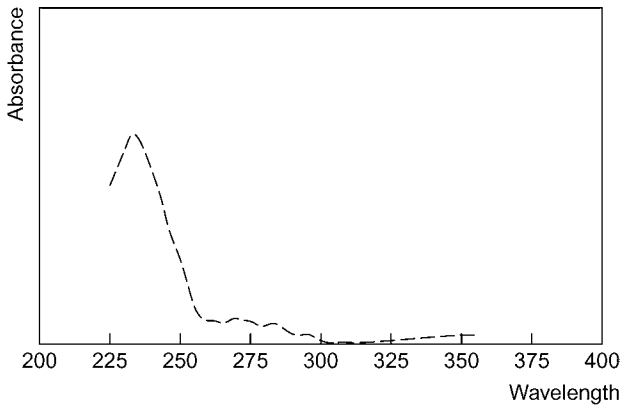
Bephenium Hydroxynaphthoate

Anthelmintic
$C_{28}H_{29}NO_4$ = 443.5
CAS—7181-73-9 (bephenium); 3818-50-6 (hydroxynaphthoate)

IUPAC Name *N*,*N*-Dimethyl-*N*-(2-phenoxyethyl)benzenemethanaminium 3-hydroxy-2-naphthoate
Synonym Naphthammonum
Proprietary Name *Alcopar(a)*



Chemical Properties A yellow to greenish-yellow crystalline powder, which gives a green fluorescence when examined under ultraviolet light. Mp 170° to 171°. Practically insoluble in water; soluble 1 in 50 of ethanol. Log *P* (octanol/water), 0.5.
Colour Tests Mandelin's test—green; Marquis test—red-violet.
Thin-layer Chromatography System TA—R_f 0.77 (acidified potassium permanganate solution, positive).
Ultraviolet Spectrum Methanol—234 (A^{1}_{1}=1300b), 263, 270, 283, 295, 352 nm.



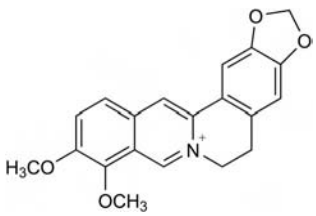
Infrared Spectrum Principal peaks at wavenumbers 1233, 768, 1653, 1590, 858, 726 cm^{-1} (KBr disk).
Quantification
Urine **Colorimetry** See Rogers [1958].
Disposition in the Body Bephenium hydroxynaphthoate is poorly absorbed after oral administration; less than 1% of a dose is excreted in the urine in 24 h.
Dose The equivalent of 2.5 g of bephenium, as a single dose.

Rogers EW (1958). Excretion of bephenium salts in urine of human volunteers. *BMJ* 2: 1576–1577.

Berberine

Alkaloid
$[C_{20}H_{18}NO_4]^+$ = 336.4
CAS—2086-83-1 ($C_{20}H_{18}NO^+_4$); 117-74-8 ($C_{20}H_{18}NO_4$·OH)

IUPAC Name 5,6-Dihydro-9,10-dimethoxybenzo[*g*]-1,3-benzodioxolo[5,6-*a*] quinolizinium



Chemical Properties A quaternary alkaloid present in *Hydrastis*, in various species of *Berberis*, and in many other plants. Yellow crystals. Mp 145°. Soluble 1 in 4.5 of water and 1 in 100 of ethanol; very slightly soluble in ether. Log *P* (octanol/water), 2.1.

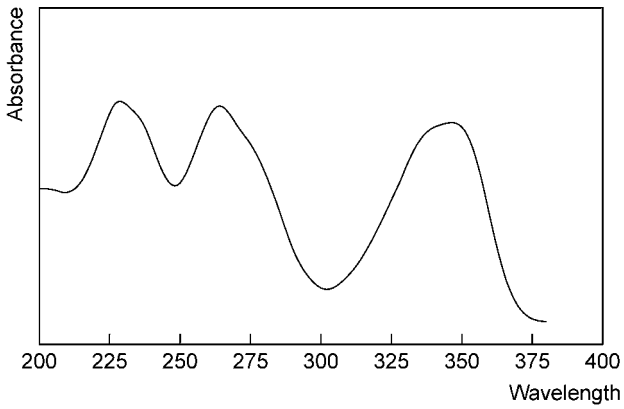
Berberine Hydrochloride

$C_{20}H_{18}ClNO_4,2H_2O$ = 407.8
CAS—633-65-8 (anhydrous); 5956-60-5 (dihydrate)
Synonym Berberine chloride
Chemical Properties Bright yellow acicular crystals or powder. Soluble 1 in 400 of water; freely soluble in boiling water; soluble in ethanol; practically insoluble in chloroform and ether.

Berberine Sulfate

$C_{20}H_{18}NO_4,HSO_4$ = 433.4
CAS—633-66-9
Synonyms Berberine acid sulfate; berberine bisulfate.
Chemical Properties Bright yellow acicular crystals or dark yellow powder. Soluble 1 in about 100 of water; slightly soluble in ethanol.

Colour Tests Mandelin's test—blue-green→brown; Marquis test—green.
Thin-layer Chromatography System TA—R_f 0.07; system TL—R_f 0.00; system TAE—R_f 0.04; system TAF—R_f 0.56; system TAJ—R_f 0.00; system TAK—R_f 0.00; system TAL—R_f 0.20 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—RI 2070.
High Performance Liquid Chromatography System HY—RI 327.
Ultraviolet Spectrum Aqueous acid—264 (A^{1}_{1}=554b), 345 nm.



Infrared Spectrum Principal peaks at wavenumbers 1505, 1271, 1234, 1030, 1587, 1098 cm^{-1} (KBr disk).
Mass Spectrum Principal ions at *m/z* 321, 278, 320, 292, 306, 191, 322, 304.
Quantification
Plasma **HPLC** UV detection (λ=346 nm). Limit of detection, 0.4 ng [Zeng 1999]. Limit of detection, 18.1 µg/L [Chen, Chang 1995].
Urine **GC–MS** Limit of detection, 1 µg/L [Miyazaki *et al.* 1978].
HPLC Limit of detection, 2.3 µg/L [Chen, Chang 1995].
Bile **HPLC** Limit of detection, 90.4 µg/L [Chen, Chang 1995].
Disposition in the Body After oral administration, <0.1% of a dose is excreted in the urine unchanged in 24 h.
Dose Berberine sulfate has been given in doses of 150 mg daily.

Beryllium

Metal
Be = 9.01
CAS—7440-41-7

Synonyms Beryllium-9; beryllium metallic; glucinium; glucinum.
Chemical Properties Grey solid. Mp 1287° to 1292°. Bp 2970°. Insoluble in water; soluble in dilute acid and alkali. Valencies: Be(0) and Be(+2). Naturally occurring element found in surface rocks at levels of <1 to 15 mg/kg. It is not found as the free metal because of its high reactivity. There are approx. 45 mineralised forms of beryllium, but the most important are beryl and bertrandite. Beryl is known as the gemstones: emerald, aquamarine and beryl. Used in aircraft disc brakes, X-ray transmission windows, space vehicle optics, aircraft/satellite structures, missile guidance systems, nuclear reactor neutron reflectors, nuclear warhead triggering devices, fuel containers, precision instruments, rocket propellants, navigational systems, heat shields, mirrors, computers.

Beryllium Chloride

$BeCl_2$ = 79.92
CAS—7787-47-5
Synonym Beryllium dichloride
Chemical Properties Colourless needles. Mp 405°. Bp 520°. Very soluble in water, alcohol, ether, pyridine; slightly soluble in benzene and chloroform. Used in the manufacture of beryllium and as an acid catalyst in organic reactions.

Beryllium Fluoride

BeF_2 = 47.01
CAS—7787-49-7
Synonym Beryllium difluoride

Chemical Properties Colourless glassy hygroscopic mass. Mp 555°. Bp 1175°. Very soluble in water; slightly soluble in alcohol. Used in the manufacture of beryllium, in beryllium alloys and glass, in nuclear reactors.

Beryllium Hydroxide

$Be(OH)_2 = 43.03$
CAS—13327-32-7
Synonyms Beryllium dihydroxide; beryllium hydrate.
Chemical Properties White amorphous powder or crystalline solid. Decomposes in water. Very slightly soluble in water; soluble in hot concentrated acid and alkali. Used in the manufacture of beryllium and beryllium oxide.

Beryllium Oxide

BeO = 25.01
CAS—1304-56-9
Synonyms Beryllia; beryllium monoxide.
Chemical Properties White light amorphous powder. Mp 2508° to 2547°. Bp 3787°. Very sparingly soluble in water; soluble in concentrated acids. Used in the manufacture of beryllium oxide ceramics and glass, in nuclear reactor fuels and moderators, as a catalyst for organic reactions.

Beryllium Nitrate

$Be(NO_3)_2 = 133.0$
CAS—13597-99-4 (anhydrous); 13510-48-0 (tetrahydrate)
Synonym Nitric acid, beryllium salt
Chemical Properties White crystals. Mp 60.5°. Bp 142° with decomposition. Very soluble in water, ethanol. Used in stiffening mantles in gas and acetylene lamps.

Quantification

Specimen collection Blood—10 mL, K-EDTA tube; urine—20 mL, plastic universal container; lung—for post-mortem examination of beryllium-related deaths.
Blood **ICP-MS** Plasma gas: 16 L/min. Auxiliary gas: 1 L/min. Nebuliser gas: 1.15 or 1.33 mL/min. Limit of detection, 0.3 µg/L [De Boer *et al.* 2004].
Urine **ETAAS** Dry cycle: 130° at 20 s for 10 s. Char cycle: 1400° in 5 s for 30 s. Atomisation cycle: 2500° for 5 s. Limit of detection, 0.02 µg/L [Horng *et al.* 2002]. Dry cycle: 80° to 120° for 30 s. Char cycle: 600° to 1200° for 45 s. Atomisation cycle: 288° for 4 s. Limit of detection, 0.37 µg/L [Wang *et al.* 2001].

FAAS Dry cycle: 180° at 5 s for 30 s. Char cycle: 1400° in 5 s for 5 s. Atomisation cycle: 2400° for 4 s. Limit of detection, 1.7 pg [Paschal, Bailey 1986]. Dry cycle: 100° for 50 s. Char cycle: 1000° for 60 s. Atomisation cycle: 2600° for 10 s. Ar, 50 mL/min ($\lambda = 235$ nm). Limit of quantification, 10 ng/L [Hurlbut 1978].

ICP-MS See Blood. Limit of detection, 0.2 µg/L [De Boer *et al.* 2004]. Limit of quantification, 0.03 µg/L [Apostoli, Schaller 2001].

ICP-MS-ETV Outer gas: 15 L/min. Intermediate gas: 0.9 L/min. Nebulizer gas: 0.7 L/min. Carrier gas: 0.4 L/min. Dry cycle: 60° in 4 s for 4 s. Vaporisation cycle: 900° for 4 s. Limit of detection, 0.072 ng/L [Xia *et al.* 2004].
Hair **ETAAS** Dry cycle: 80° to 120° for 30 s; Ar, 200 mL/min. Char cycle: 600° to 1400° for 30 s; Ar, 200 mL/min. Atomisation cycle: 2900° for 5 s (gas stop). Limit of detection, 2 µg/kg [Li, Kuo 2002].

FAAS Dry cycle: 100° for 50 s. Char cycle: 1000° for 60 s. Atomisation cycle: 2600° for 10 s. Ar, 50 mL/min ($\lambda = 235$ nm). Limit of quantification, <1 µg/kg [Hurlbut 1978].

ICP-MS Limit of detection, 0.13 mg/kg [Nadal *et al.* 2005].

ICP-MS-ETV Outer gas: 15 L/min. Intermediate gas: 0.9 L/min. Nebuliser gas: 0.7 L/min. Carrier gas: 0.4 L/min. Dry cycle: 60° in 4 s for 4 s. Vaporisation cycle: 900° for 4 s. Limit of detection, 0.072 ng/L [Xia *et al.* 2004].
Note For a spectroflurometric method for the determination of beryllium in mineral water and hair, see Jiang and He [2003].
Synovial Fluid **ICP-MS** Coolant gas: Ar, 15.0 L/min. Auxiliary gas: 0.99 L/min. Nebuliser gas: 1.0 L/min. Limit of detection, low ng/L [Krachler *et al.* 2000].
Faeces **FAAS** See Hair. Limit of quantification, 1 µg/L [Hurlbut 1978].
Other **FAAS** Industrial Dust. Limit of detection, 30 µmol/L [Rouleau *et al.* 2005].

ICP-MS Industrial Dust. Limit of detection, 5 nmol/L [Rouleau *et al.* 2005].
Note For an overview of the beryllium content of food and water, see Vaessen and Szteke [2000].
Disposition in the Body Approximately 90% of an ingested dose of beryllium is excreted via the kidneys over a period of 3 to 5 days and the remainder is deposited, mainly in the liver and bones. The metal or its insoluble salts, when inhaled, are deposited in the lungs and are only slowly absorbed and excreted. Workers exposed in this way may continue to excrete beryllium in the urine 10 years later. The biological half-life of beryllium is inversely proportional to the dose.
Normal Concentrations Blood—<1 µg/L (0.1 µmol/L); urine—<1 µg/L (0.1 µmol/L).
Toxicity Contact dermatitis has been reported after beryllium exposure. Inhalation can cause bronchitis and severe pneumonitis. Chronic exposure by inhalation leads to pulmonary granulomatous (berylliosis) with fatigue, weight loss, and increased risk of lung cancer [Aller 1990]. Beryllium levels >20 µg/kg in dried lung tissue indicate significant exposure [Sprince *et al.* 1976]. Beryllium concentrations in urine samples from 65 exposed workers ranged from 0.12 to 0.15 µg/L (13 to 17 nmol/L) compared with <0.063 µg/L (7 nmol/L) in control subjects [Apostoli, Schaller 2001].

A 27-year-old white woman worked as a dental technician for 3 years. She was referred to hospital with shortness of breath, weakness, nausea, vomiting, diarrhoea and weight loss. She was referred and sent home but 6 months later she was referred back. This time her chest radiograph showed an increased interstitial pattern with hilar lymphadenopathy. Her beryllium lymphocyte transformation test revealed values of 5.90 and 2.54 on the stimulation index at 10^{-4} mol/L (1 mmol/L) and 10^{-5} mol/L (0.1 mmol/L) of $BeSO_4$, respectively (normal values SI <1.7) [Fireman *et al.* 2001].

Concentrations of 0.9 ± 0.5 µg/kg were found in 20 people with no professional contact with beryllium. High concentrations of 2 µg/kg were measured in the urine of smokers of filterless cigarettes, the cigarettes themselves containing 120 ng [Stiefel *et al.* 1980].

Note For an investigation of toxic trace elements in the hair of children with autism, see Fido and Al Saad [2005]. For a thermodynamic model predicting the chemistry of beryllium in simulated biological fluids, see Sutton and Burastero [2003]. For biological monitoring of beryllium in workers in hazardous-waste incineration, see Schuhmacher *et al.* [2002] and Domingo *et al.* [2001]; in steel production workers, see Horng *et al.* [2002]. For a study on the suitability of urinary beryllium for assessing occupational exposure, see Apostoli and Schaller [2001]. For a mortality study of workers at a beryllium plant, see Ward *et al.* [1992].
Distribution in Blood 60–70% bound to serum proteins prealbumins and gammaglobulins.

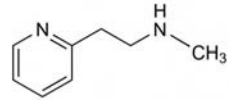
Betahistine

Vasodilator
$C_8H_{12}N_2 = 136.2$
CAS—5638-76-6
IUPAC Name *N*-Methyl-2-pyridine-ethanamine



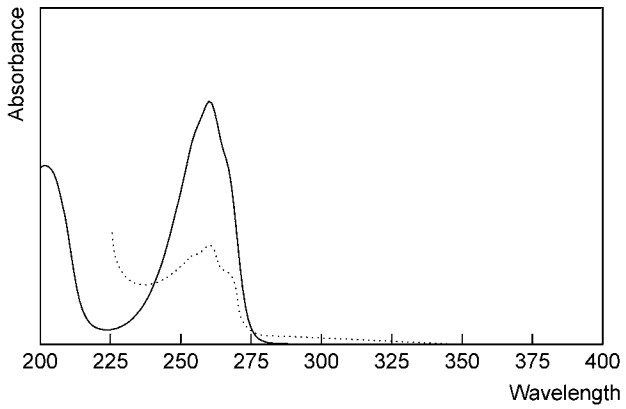
Chemical Properties A liquid. Bp 113° to 114°. Miscible with water, ethanol, chloroform and ether. pK_a 3.5, 9.7. Log *P* (octanol/water), 0.7.

Betahistine Hydrochloride

$C_8H_{12}N_2,2HCl = 209.1$
CAS—5579-84-0
Proprietary Names *Betaserc*; *Microser*; *Serc*; *Vasomotal*.
Chemical Properties A white or creamy-white, hygroscopic, crystalline powder. Mp about 152°. Freely soluble in water; soluble in ethanol and methanol; practically insoluble in carbon tetrachloride, chloroform and ether.

Thin-layer Chromatography System TA—R_f 0.10 (acidified iodoplatinate solution, strong reaction).

Gas Chromatography System GA—RI 1235.
High Performance Liquid Chromatography System HA—*k* 3.1; system HAA—retention time 3.2 min.
Ultraviolet Spectrum Aqueous acid—261 nm (A_1^1=358b).

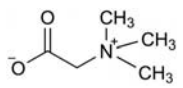


Infrared Spectrum Principal peaks at wavenumbers 1585, 1560, 1290, 762, 1238, 1145 cm^{-1} (KBr disk).
Mass Spectrum Principal ions at *m/z* 79, 105, 104, 51, 78, 52, 50, 77.
Quantification
Serum **GC** FID. Limit of detection, 600 µg/L [Douglas, Hohing 1978].
Disposition in the Body Betahistine is readily absorbed after oral administration; peak plasma concentrations of the metabolites are attained in 3 to 5 h. Most of a dose is excreted in the urine as metabolites.
Dose 24 to 48 mg of betahistine hydrochloride daily.

Douglas JF, Hohing TL (1978). GLC determination of betahistine in serum. *Experientia* 34: 499–500.

Betaine

Treatment of Hypochlorhydria
$C_5H_{11}NO_2$ = 117.2
CAS—107-43-7
IUPAC Name 1-Carboxy-*N*,*N*,*N*-trimethylmethanaminium inner salt
Synonyms Glycine betaine; glycocoll betaine; lycine; oxyneurine; trimethylglycine.



Chemical Properties Deliquescent crystals. Mp about 310°, with decomposition. Soluble 1 in 0.6 of water and 1 in 11 of ethanol; sparingly soluble in ether; soluble 1 in 2 of methanol. pK_a 1.8 (25°). Log *P* (octanol/water), −4.9.

Betaine Hydrochloride

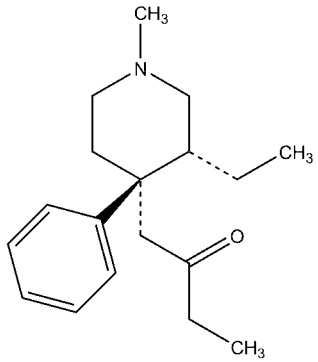
$C_5H_{11}NO_2$,HCl = 153.6
CAS—590-46-5
Proprietary Names It is an ingredient of *Acidol-Pepsin* and *Kloref*.
Chemical Properties Colourless crystals or white crystalline powder. When dissolved in water betaine hydrochloride hydrolyses and almost 25% of its weight of hydrochloric acid is formed. Mp about 230°, with decomposition. Soluble 1 in 2 of water and 1 in 20 of ethanol (90%); practically insoluble in chloroform and ether.

Colour Test To an aqueous solution add iodine solution—red precipitate.
Thin-layer Chromatography System TA—R_f 0.23; system TAE—R_f 0.16; system TAF—R_f 0.11 (acidified iodoplatinate solution, positive).
Gas Chromatography System GA—not eluted.
Ultraviolet Spectrum No significant absorption, 230 to 360 nm.
Infrared Spectrum Principal peaks at wavenumbers 1731, 1206, 885, 994, 902, 1250 cm^{-1} (KBr disk).
Quantification
Blood **HPLC** UV detection (λ=254 nm). Limit of detection, 5 µmol/L (=0.6 mg/L) [Laryea *et al.* 1998].
Urine **HPLC** See Blood [Laryea *et al.* 1998]. UV detection. Limit of detection, 0.9 µg [Laryea *et al.* 1994].
Dose 0.18 to 3.5 g of betaine hydrochloride daily.

Laryea MD *et al.* (1994). Simultaneous determination of betaine and N,N-dimethylglycine in urine. *Clin Chim Acta* 230(2): 169–175.
Laryea MD *et al.* (1998). Simple method for the routine determination of betaine and N,N-dimethylglycine in blood and urine. *Clin Chem* 44(9): 1937–1941.

Betameprodine

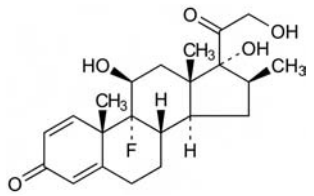
Narcotic
$C_{17}H_{25}NO_2$ = 275.4
CAS—468-51-9
IUPAC Name β-3-Ethyl-1-methyl-4-phenyl-4-propionyloxypiperidine
Synonym β-Meprodine



Chemical Properties Extracted by organic solvents from aqueous alkaline solutions.
Colour Tests Ammonium molybdate test—blue-grey→green (limit of detection 0.5 µg); ammonium vanadate test—blue-grey (limit of detection 0.5 µg); sulphuric acid-formaldehyde test—reddish-purple (limit of detection 0.25 µg).
Thin-layer Chromatography System T1—R_f 0.64 (location reagent acidified iodoplatinate spray, positive reaction).
Gas Chromatography System G2/225—retention time 0.92 relative to diphenhydramine; system G4—retention time 0.40 relative to diphenhydramine.

Betamethasone

Corticosteroid
$C_{22}H_{29}FO_5$ = 392.5
CAS—378-44-9
IUPAC Name (8*S*,9*R*,10*S*,11*S*,13*S*,14*S*,16*S*,17*R*)-9-Fluoro-11,17-dihydroxy-17-(2-hydroxyacetyl)-10,13,16-trimethyl-6,7,8,11,12,14,15,16-octahydrocyclopenta[*a*]phenanthren-3-one
Synonyms Flubenisolonum; 9α-fluoro-16β-methylprednis-olone; (11β,16β)-9-fluoro-11,17,21-trihydroxy-16-methylpregna-1,4-diene-3,20-dione; NSC-39470; Sch-4831.
Proprietary Names *Betnelan*; *Betnesol*; *Celeston(e)*; *Desacort-Beta*; *Minisone*; *No-Reumar*; *Pertene*.



Chemical Properties Betamethasone is a synthetic glucocorticoid and an isomer of dexamethasone. A white to creamy-white crystalline powder. Mp ≈240°, with decomposition. A solution in dioxan is dextrorotatory. Practically insoluble in water; soluble 1 in 65 of ethanol, 1 in 15 of warm ethanol, and 1 in 325 of chloroform; very slightly soluble in ether; sparingly soluble in acetone and methanol. Log *P* (octanol), 1.9. Stable at ambient temperature for 5 h, in the autosampler for at least 24 h, after 3 freeze-thaw cycles and plasma samples were stable at −70° for 2 weeks [Zou *et al.* 2008].

Betamethasone Acetate

$C_{24}H_{31}FO_6$ = 434.5
CAS—987-24-6
Proprietary Name It is an ingredient of *Celestone Suluspan*.
Chemical Properties A white to creamy-white powder. Mp ≈165° and, with decomposition, 200° to 205–8°. Practically insoluble in water; soluble 1 in 9 of ethanol and 1 in 16 of chloroform; freely soluble in acetone.

Betamethasone Benzoate

$C_{29}H_{33}FO_6$ = 496.6
CAS—22298-29-9
Proprietary Names *Beben*; *Benisone*; *Uticort*.
Chemical Properties A white powder. Mp ≈225° to 228°, with decomposition. Practically insoluble in water; soluble in ethanol, chloroform, and methanol.

Betamethasone Dipropionate

$C_{28}H_{37}FO_7$ = 504.6
CAS—5593-20-4

Proprietary Names *Alphatrex*; *Diprolene*; *Diprosone*; *Maxivate*; *Psorion*; *Teladar.*
Chemical Properties A white or creamy-white powder. Mp 170° to: 179°, with decomposition. Practically insoluble in water; sparingly soluble in ethanol; freely soluble in acetone and chloroform.

B

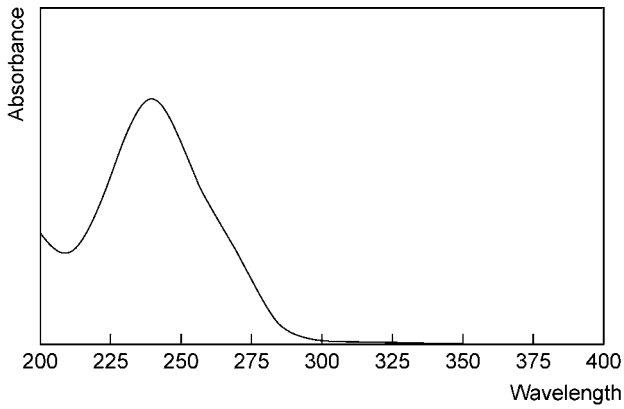
Betamethasone Sodium Phosphate

$C_{22}H_{28}FNa_2O_8P = 516.4$
CAS—151-73-5
Synonym Betamethasone disodium phosphate.
Proprietary Names *Bentelan*; *Betameson*; *Betnesol*; *B-S-P*; *Celeston(e)*; *Cel-U-Jec*; *Emilan*; *Paucisone*; *Selestoject*; *Vista-Methasone.*
Chemical Properties A white hygroscopic powder. Soluble 1 in 2 of water and 1 in 470 of dehydrated alcohol; freely soluble in methanol; practically insoluble in acetone, chloroform and ether.

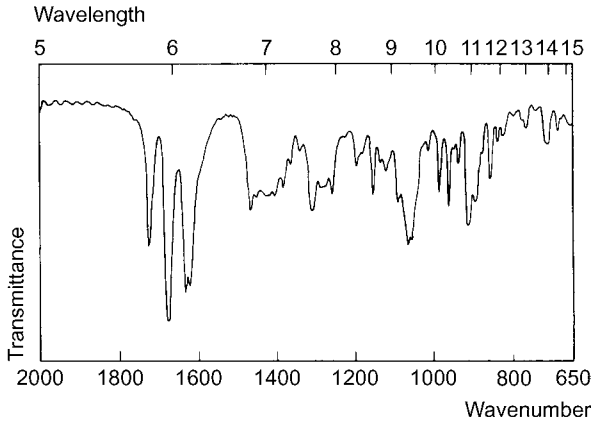
Betamethasone Valerate

$C_{27}H_{37}FO_6 = 476.6$
CAS—2152-44-5
Synonym 9α-Fluoro-16β-methylprednisolone 17-valerate.
Proprietary Names *Bedermin*; *Betacap*; *Betacort*; *Betaderm*; *Betatrex*; *Beta-Val*; *Betnelan-V*; *Betnesol-V*; *Betneval*; *Betnovat(e)*; *Bettamousse*; *Bextasol*; *Celestoderm (-V)*; *Celestone-V*; *Dermovaleas*; *Ecoval*; *Luxiq*; *Valisone.*
Chemical Properties A white to creamy-white powder. Mp ≈183° to 184°, with decomposition. Practically insoluble in water; soluble 1 in 12 to 1 in 16 of ethanol, 1 in <10 of chloroform, and 1 in 50 of isopropyl alcohol; freely soluble in acetone; slightly soluble in ether.
Note In alkaline media, betamethasone 17-valerate undergoes a rearrangement to betamethasone 21-valerate.

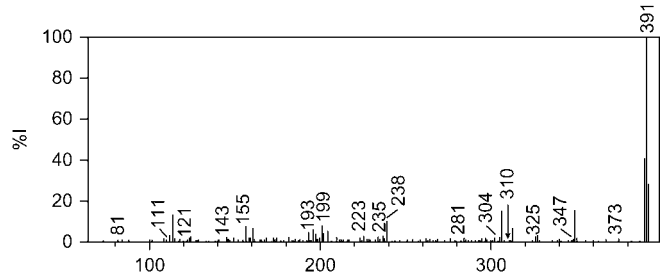
Colour Tests Antimony pentachloride—green→brown; naphthol–sulfuric acid—green-brown/orange-brown; sulfuric acid—pink-orange.
Thin-layer Chromatography System TP—betamethasone R_f 0.30, betamethasone valerate R_f 0.58; system TQ—betamethasone R_f 0.00, betamethasone valerate R_f 0.27; system TR—betamethasone R_f 0.00, betamethasone valerate R_f 0.20; system TS—betamethasone R_f 0.00, betamethasone valerate R_f 0.02, streaking may occur (DPST solution). Betamethasone sodium phosphate remains on the baseline in all systems.
High Performance Liquid Chromatography System HAA—RT 13.3 min; system HY—betamethasone valerate RI 584; system HZ—RT 14.2 min.
Ultraviolet Spectrum Betamethasone: ethanol—240 nm ($A^1_1 = 390a$). Betamethasone sodium phosphate: water—241 nm ($A^1_1 = 296a$).



Infrared Spectrum Principal peaks at wavenumbers 1660, 1617, 1606, 1710, 1056, 907 cm^{-1} (KBr disk).



Mass Spectrum Principal ions at *m/z* 121, 43, 122, 223, 147, 91, 41, 135.



Quantification

Plasma **LC-MS** Column: Venusil XBP-C_8 (200 × 3.9 mm i.d., 5 µm). Mobile phase: methanol : ammonium formate (80 : 20), flow rate 0.4 mL/min. ESI, positive ion mode. Limit of quantification, 0.5 µg/L [Qu *et al.* 2008]. Column: Hanbon Lichrospher C_{18} (150 × 4.6 mm i.d., 5 µm). Mobile phase methanol : water (85 : 15), flow rate 0.7 mL/min. ESI. Limit of quantification, 0.1 µg/L for betamethasone and 0.05 µg/L for betamethasone 17-monopropionate [Zou *et al.* 2008]. Column: C_{18} Genesis (100 × 2.1 mm i.d., 4 µm). Mobile phase: acetonitrile : 10 mmol/L ammonium formate (80 : 20), flow rate 350 µL/min. APPI, negative ion mode, MRM acquisition mode. Limit of quantification, 50 ng/L [Pereira Ados *et al.* 2005].
Serum **HPLC** Column: Kromasil C_{18} (150 × 4.0 mm i.d., 5 µm). Mobile phase: methanol : water (70 : 30) with 0.1% hydrochloric acid, flow rate 0.9 mL/min. UV-vis detection (λ = 240 nm). Limit of detection, 20–50 µg/L [Quintana *et al.* 2004].
LC-MS Column: SYNERGI MAX-RP (50 × 4.6 mm i.d., 4 µm). Mobile phase: acetonitrile : 0.1 mmol/L ammonium acetate (29 : 71 for 9.5 min to 65 : 35 for 4 min to 29 : 71 for 0.5 min), flow rate 750 µL/min. TIS, positive ion mode, MRM acquisition mode. Limit of detection, 0.6–1.6 nmol/L for betamethasone and other corticosteroids [Taylor *et al.* 2004].
Urine **LC-MS** See Serum [Taylor *et al.* 2004]. Column: Chrompack microspher C_{18} (50 × 4.6 mm i.d., 3 µm). Mobile phase: methanol : water (50 : 50) containing 0.1 mol/L ammonium acetate or acetonitrile : water (37 : 63) containing 0.15 mol/L ammonium acetate or 0.05 mol/L ammonium acetate, flow rate 1.3 mL/min. SIM acquisition mode. Limit of quantification, 1 µg/L LC-LC-MS(-MS), limit of detection, 10 µg/L LC-MS(-MS) or LC-LC(-MS) , 0.2 µg/L LC-LC-MS(-MS) [Polettini *et al.* 1998].
Note For a comparison of ELISA, GC-MS and LC-MS for the analysis of corticosteroids, see Pujos *et al.* [2005].

Disposition in the Body

Therapeutic Concentration

Five healthy volunteers were administered 0.6 mg betamethasone orally and betamethasone 17-valerate as a topical application prepared as a suspension and applied to a 100 cm^2 area on the back for 28 h. The mean peak plasma concentrations were 5.0 and 0.24 mg/L, respectively [Kubota *et al.* 1994].
Dose 0.5 to 5 mg daily.

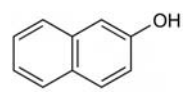
Betanaphthol

Parasiticide
$C_{10}H_8O = 144.2$
CAS—135-19-3
IUPAC Name 2-Naphthalenol
Synonyms β-Naftol; naphthol.



Chemical Properties White crystalline leaflets or powder; stable in air but darkens on exposure to light. Mp 121° to 123°. Bp 285° to 286°. Soluble 1 in 1000 of

cold water, 1 in 80 of boiling water, 1 in 0.8 of ethanol and 1 in 1.3 of ether; soluble in chloroform and in solutions of alkali hydroxides. pK_a 9.5 (25°). Log *P* (octanol/water), 2.7.

Colour Tests Ferric chloride—green; Liebermann's reagent—green. To 200 mg add 2 mL of an 8% sodium hydroxide solution and 1 drop of chloroform, then warm—blue.

Ultraviolet Spectrum Ethanol—274 (A_1^1=326b), 285 (A_1^1=230b), 322 (A_1^1=120b), 330 nm (A_1^1=140b).

Disposition in the Body Rapidly absorbed from the gastrointestinal tract and may be absorbed through intact skin. It is excreted mainly as the glucuronide and gives a reddish tint to the urine.

Toxicity The estimated minimum lethal dose is 2 g. Severe nephritis and fatalities have occurred following its absorption through intact skin.

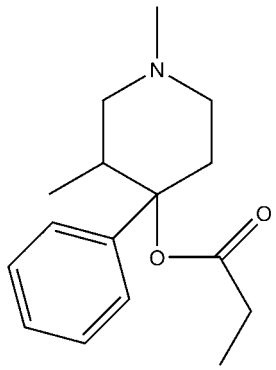
Betaprodine

Narcotic, Piperidine

$C_{16}H_{23}NO_2$ = 261.4

CAS—468-59-7

IUPAC Name β-1,3-Dimethyl-4-phenyl-4-propionyloxypiperidine



Chemical Properties Extracted by organic solvents from aqueous alkaline solutions. Log *P* (octanol/water) 3.45 [Meylan, Howard 1995].

Betaprodine Hydrochloride

Synonym NU-1779

Chemical Properties Crystals from acetone : methanol. Mp 190° to 192°.

Colour Tests Ammonium molybdate test—blue-green→green with blue rim (limit of detection 0.5 µg); ammonium vanadate test—blue-grey (limit of detection 0.5 µg); sulphuric acid-formaldehyde test—reddish-purple (limit of detection 0.25 µg).

Thin-layer Chromatography System T1—R_f 0.61 (location reagent acidified iodoplatinate spray, positive reaction).

Gas Chromatography System G2/225—retention time 0.84 relative to diphenhydramine; system G4—retention time 0.41 relative to diphenhydramine.

Ultraviolet Spectrum Aqueous acid (0.1 N sulfuric acid)—248, 253, 258, 264, 268 nm.

Meylan WM, Howard PH (1995). Atom/fragment contribution method for estimating octanol-water partition coefficients. *J Pharm Sci* 84: 83–92.

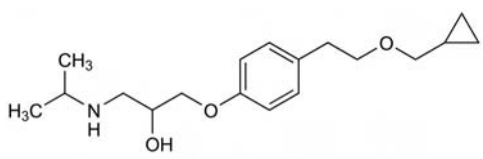
Betaxolol

β-*Blocker*

$C_{18}H_{29}NO_3$ = 307.4

CAS—63659-18-7

IUPAC Name 1-[4-[2-(Cyclopropylmethoxy)ethyl]phenoxy]-3-[(1-methylethyl) amino]-2-propanol



Chemical Properties Crystals from petroleum ether. Mp 70° to 72°. pK_a 9.4. Log *P* (octanol/water), 2.81. Extraction yield (chlorobutane), 1 [Demme *et al.* 2005].

Betaxolol Hydrochloride

$C_{18}H_{29}NO_3$,HCl = 343.9

CAS—63659-19-8

Synonyms SLD-212; SL-75.212.

Proprietary Names *Betoptic*; *Betoptima*; *Betoquin*; *Kerlon*; *Kerlone*; *Oxodal*.

Chemical Properties A white or almost white crystalline powder. Mp 113° to 117°. It is very soluble to freely soluble in water; freely soluble in chloroform, ethanol and methanol; soluble in dichloromethane; practically insoluble in ether.

Thin-layer Chromatography System TB—R_f 0.11; system TE—R_f 0.51; system TF—R_f 0.00; system TAE—R_f 0.22.

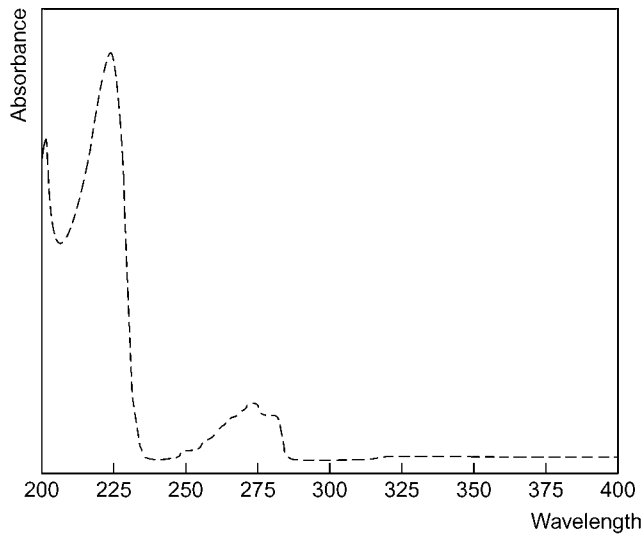
Gas Chromatography System GA—RI 2370 (betaxolol), RI 2410 (Art), RI 2400 (Art-H_2O); system GB—RI 2420 (betaxolol), RI 2508 (Art), RI 2519 (Art-H_2O).

Column: 5% phenyl-methyl silicone RTx-5 fused-silica capillary (30 m × 0.25 mm i.d.). Temperature programme: 110°, held for 1 min; increased to 170° at 20°/min; increased to 225° at 7°/min; 290° at 24°/min, held 10 min. Carrier gas: He. MS detection. Retention time (relative to isoproteronol, internal standard): 1:32. [Branum *et al.* 1998].

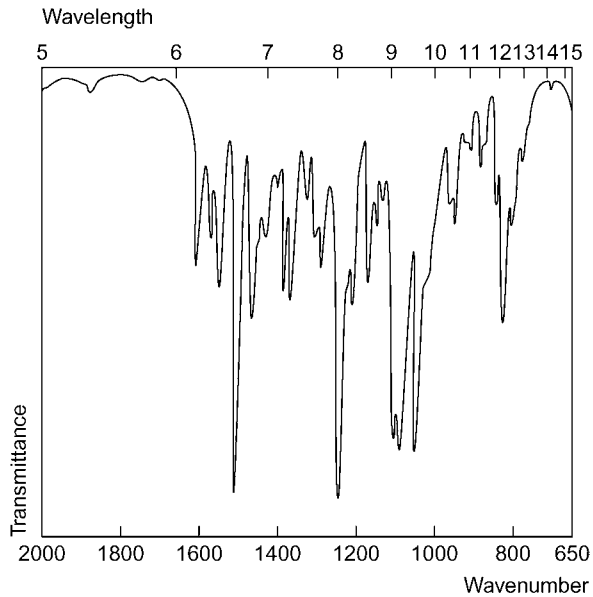
High Performance Liquid Chromatography System HX—RI 386; system HY—RI 301; system HZ—retention time 3.8 min; system HAA—retention time 13.4 min.

Column: C_{18} Ultrasphere (75 × 4.5 mm i.d., 3 µm). Mobile phase: acetonitrile : 0.05 mol/L DMOA (pH 3) : water (8:10:82), 1 mL/min. Fluorescence detection (λ_{ex}=200 nm). Retention time: betaxolol, 9.9 min; α-hydroxybetaxolol, 2.3 min.

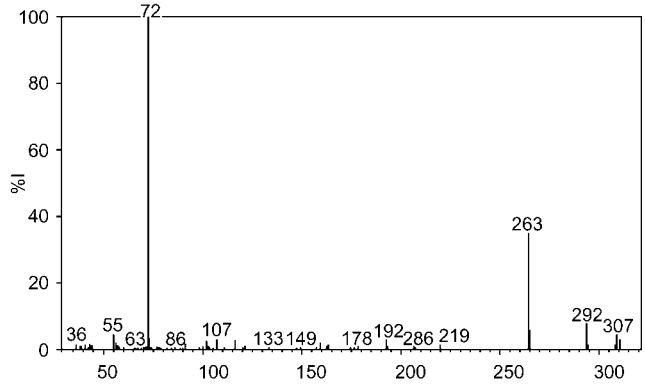
Ultraviolet Spectrum Ethanol—224, 280 nm.



Infrared Spectrum Principal peaks at wavenumbers 1515, 1249, 1091, 1053, 3250, 830 cm^{-1}.



Mass Spectrum Principal ions at *m/z* 72, 263, 292, 307, 55, 107, 192, 219 (betaxolol); *m/z* 55, 91, 316, 140, 125, 98, 43, 331 (betaxolol methaneboronate).



Quantification

Blood **GC** Limit of detection, 0.5 µg/L [Ganansia *et al.* 1983].

HPLC Column: C_{18} Nova-Pak (150 × 3.9 mm, 5 µm). Mobile phase: acetonitrile : glacial acetic acid : distilled water (29:1:70), 0.9 mL/min flow rate. Fluorescence detection (λ_{ex}=200 nm). Retention time: acid metabolites, 7.4 min. Limit of detection, 1 to 5 µg/L betaxolol, 5 to 20 µg/L betaxolol metabolites [Wong, Ludden 1990]. Fluorescence detection. Limit of detection 0.5 µg/L (separate enantiomers) [Darmon, Thenot 1986]. Fluorescence detection (λ_{ex}=275 nm, λ_{em}=305 nm). Limit of detection, 5 µg/L [Caqueret, Bianchetti 1984].

Plasma **HPLC** Fluorescence detection. Limit of detection, 5 µg/L [Bhamra *et al.* 1987]. Fluorescence detection (λ_{ex}=270 nm, λ_{em}=320 nm). Limit of detection, 4 µg/L [Canal, Flouvat 1985].

Serum **HPLC** See Plasma [Bhamra *et al.* 1987].

Urine **GC** See Blood [Ganansia *et al.* 1983].

HPLC See Blood [Wong, Ludden 1990]. See Blood [Caqueret, Bianchetti 1984].

Tissues **GC** See Blood [Ganansia *et al.* 1983].
