EDITOR BIOGRAPHIES

Editor-In-Chief

Zaheer-Ud-Din Babar

Zaheer-Ud-Din Babar is Professor in Medicines and Healthcare and the Director of Centre of Pharmaceutical Policy and Practice Research at the University of Huddersfield, United Kingdom. He has worked as an academic in Pakistan, Malaysia, New Zealand, and in the United Kingdom, and understands the health systems and pharmacy globally. He is known for his work in pharmaceutical policy and practice, including quality use of medicines, clinical pharmacy practice, access to medicines, and issues related to pharmacoeconomics. Previously, he was the Head of Pharmacy Practice at the University of Auckland and received Vice Chancellor's Research Excellence Award from the University. He has published in high impact journals, such as *PLoS Medicine* and *Lancet* and has acted as a consultant for World Health Organization, Royal Pharmaceutical Society, Health Action International, International Union Against Tuberculosis and Lung Disease, World Bank, International Pharmaceutical Federation (FIP), and for the Pharmaceutical Management Agency of New Zealand.

His other work includes *Economic Evaluation of Pharmacy Services*, *Pharmaceutical Prices in the 21st Century*, *Pharmaceutical Policies in Countries With Developing Healthcare Systems*, and *Pharmacy Practice Research Methods*. Published by Elsevier and Adis/Springer, the books are used in curriculum design, policy development, and for referral all around the globe. Professor Babar is also the Editor-in-Chief of *BMC Journal of Pharmaceutical Policy and Practice* and can be contacted at z.babar@hud.ac.uk.

Section Editors

Zubin Austin

Zubin Austin BScPhm MBA MISc PhD FCAHS is Professor and Koffler Chair in Management at the Leslie Dan Faculty of Pharmacy and the Institute for Health Policy, Management, and Evaluation—Faculty of Medicine at the University of Toronto. His research focuses on the professional and personal development of the health workforce. He has published over 160 peer-reviewed manuscripts and authored four reference texts. In 2017, he was installed as a Fellow of the Canadian Academy of the Health Sciences, the highest award for health services researchers in Canada. He is the only faculty member of University of Toronto to have ever received both the President's Teaching Award for excellence in education and the President's Research Impact Award for the societal significance of his work. He has also been named undergraduate Professor of the Year by students on 18 separate occasions.

Ahmed Awaisu

Dr. Ahmed Awaisu is an Associate Professor of Clinical Pharmacy and Practice in the College of Pharmacy at Qatar University. He received his Bachelor of Pharmacy degree from Ahmadu Bello University Zaria, Nigeria in 1999, his masters and PhD degrees in Clinical Pharmacy from Universiti Sains Malaysia (USM) in 2004 and 2009, respectively. He is also a licensed pharmacist and has practiced in the hospital setting since 1999. Dr. Awaisu has a unique privilege of past academic experiences in international pharmacy degree programs. He has made substantial and tremendous contributions that impact teaching and learning, research, curriculum design, as well as professional development of students and healthcare practitioners in Qatar and other countries. He received the Qatar University Merit Award for Outstanding Faculty for 2016–17 Academic Year. He is a member of the American College of Clinical Pharmacy (ACCP), and the International Society for Pharmacoeconomics and Outcomes Research (ISPOR), among others.

Professor Awaisu has extensive experience in the conduct of pharmacy practice and clinical research involving various types of study designs including case-control and cohort studies, quantitative surveys, mixed-methods designs, randomized control trials, and systematic reviews mostly on diabetes, cardiovascular diseases, tobacco dependence, and other chronic diseases. He has published over 100 peer-reviewed articles in internationally reputable pharmacy and healthcare journals and 10 book chapters related to the field of pharmacy. He has successfully supervised several postgraduate and undergraduate research projects, including MSc and PhD.

His research interest includes pharmacy practice especially pharmacists' expanded scope of practice, outcome-based research, pharmacoepidemiology and medication safety, and health promotion. Dr. Ahmed Awaisu has conducted training sessions and workshops on research methodology and biostatistics, drugs in sports, developing cognitive pharmacy services, and responding to symptoms in pharmacy practice. He presents regularly at continuing professional development programs for healthcare professionals in Qatar and other countries.

Timothy Chen

Professor Timothy Chen is a registered pharmacist and Professor of Medication Management, School of Pharmacy, The University of Sydney, Australia. Tim is nationally and internationally renowned for his research in medication management review and strategies to reduce medication related harm. Tim's research directly informed the Australian Government funded Home Medicines Review programme (MBS Item 903). Tim is an experienced educator and health services researcher, with experience in both community pharmacy and hospital pharmacy practice. Tim leads a productive research team (>160 peer-reviewed papers) and has completed main supervision of 15 PhDs, amongst other postgraduates. Tim has delivered >70 invited presentations at conferences and meetings across the globe. Tim has received university and national awards (Australian Government) for teaching, is an International Pharmaceutical Federation (FIP) Fellow (2016), and is President of the Social and Administrative Pharmacy Section, FIP.

Louise Curley

Louise Curley is a pharmacist and Senior Lecturer in Pharmacy practice at the School of Pharmacy. Louise's area of research focuses on the effects of recreational drug use in humans. She began her research as an undergraduate by investigating the subjective and electrophysiological effects of the Party Pill drugs using electroencephalography (EEG) and graduated with a PhD in pharmacy in 2012. Her thesis investigated the effects of the main constituents of "Party Pills" benzylpiperazine (BZP) and trifluromethylphenylpiperazine (TFMPP) on executive functioning and reward using functional magnetic resonance imaging (fMRI). Currently, her focus is developing new fMRI paradigms to investigate different aspects of risk, specifically by comparing populations of dependent versus non-dependent participants. Louise also has an interest in pharmacy practice research including innovative methods of teaching undergraduate students using different technologies and evaluating the effects of these innovations. She has recently been awarded the Butland Teaching Award: Innovation in Teaching.

Danijela Gnjidic

Dr. Danijela Gnjidic (BSc PhD MPH) is an NHMRC Dementia Leadership Fellow and Senior Lecturer at the School of Pharmacy, Faculty of Medicine and Health, University of Sydney. Her research expertise is in clinical and geriatric pharmacology, clinical studies on polypharmacy, high risk prescribing, and deprescribing in older people, pharmacoepidemiology, and the quality use of medicines. Danijela's academic track record includes 115 publications, 3-book chapters, with over 2500 citations on Scopus and $4M in research funding. Danijela was awarded the Australasian Society of Clinical and Experimental Pharmacologists and Toxicologists (ASCEPT) Denis Wade Johnson & Johnson New Investigator Award in 2012. Internationally, Danijela's contribution to the filed was recognized with the 2018 American Society of Clinical Pharmacology and Therapeutics William B. Abrams award in Geriatric Clinical Pharmacology. Danijela is an Associate Editor of the *Journal of Alzheimer's Disease* and Academic Editor of the *PloS One Journal*.

Arijana Meštrović

Dr. sc Arijana Meštrović, MPharm, FFIP has been working as a community pharmacist and she was responsible for education, services, and competency development in the biggest pharmacy chain in Croatia. She is now independent consultant and educator in Pharma Expert international agency, providing lectures and workshops in CPD programs for pharmacists, pharmacy technicians, medical representatives, implementing new services in pharmacy chains, and teaching Social Pharmacy and Pharmaceutical Care at universities in Croatia and Cyprus as Assistant Professor. Her Doctor's degree is in biomedical sciences—competency development in pharmacy. Arijana serves as member of the International Services Program Advisory Group the Accreditation Council for Pharmacy Education (ACPE, USA), member of PCNE (Pharmaceutical Care Network of Europe), ExCo member of FIP (Pharmaceutical International Federation) Academic section, and WHO international expert consultant in Pharmaceutical care field. She used to serve as Co-Chair of the FIP World Congress Programme Committee, Expert Member of the Board of Pharmacy Practice at FIP. In Croatia, she is a leader in Croatian Pharmaceutical Society and Croatian Chamber of Pharmacist as a Lecturer and Co-author of New services model in community pharmacy practice. Arijana is dedicated to promoting competency-based education in CPD cycle, so her teaching usually addresses all components of competencies—knowledge, experience, and motivation. In collaboration with ACPE International Services, she has founded and implemented SMART Pharmacy CPD model for pharmacists in more than 12 countries all over the world. She was invited speaker and consultant in more than 40 countries.

Kath Ryan

Kath is Professor of Social Pharmacy at the University of Reading, and Visiting Professor at Bournemouth University, United Kingdom. She has 45 years of experience as a pharmacist in the pharmaceutical industry, community practice, and academia. She has held posts at the University of Otago, New Zealand; Bournemouth University, United Kingdom; La Trobe University, Melbourne, Australia; and the University of Reading, United Kingdom. She also has experience in academic nursing and midwifery. Her research interests include extended roles for pharmacists, especially in general practice; application of the behavioral sciences to pharmacy practice; personal experiences of health and illness; and public and patient involvement, engagement and participation in research, and the education of health professionals. She has expertise in quantitative, qualitative, and mixed methods research. She also has an interest in infant feeding,

particularly breastfeeding research, promotion and support, from lay, professional, and academic perspectives. She has been a health advisor to La Leche League International and La Leche League New Zealand. Kath has been on Scientific Committees for the International Social Pharmacy Workshops and the Australasian Pharmaceutical Sciences Association. She has consulted for the National Institutes of Health, USA; Canadian Forces; Health Technology Assessment, NHS UK; and the NZ Ministry of Health.

Kath has over 100 publications in peer-reviewed journals and several book chapters and reports. She produced two multimedia, online resources for Health Talk: women's experiences of breastfeeding in the United Kingdom, and people's experiences of ageing in Australia. She was a Founding Co-Director of Health Talk Australia.

FOREWORD

This first edition of the Encyclopedia of Pharmacy Practice and Clinical Pharmacy is one-of-a-kind and the most comprehensive amalgamation of an inclusive range of topics relevant to the pharmacy profession brought together to ensure safe and effective provision of pharmaceutical care across the world. Professor Zaheer Babar is a Professor in Medicines and Healthcare at the University of Huddersfield and also a global expert in pharmacy practice and pharmaceutical policy. He has united over hundreds of researchers and practitioners from across the world in a collaborative endeavor to provide a unique insight into current best practice and strategies for the future for the profession of pharmacy and its practice.

As patient care becomes more complex with advances in medicines and new developments in practice, including pharmacogenomics and pharmacoeconomics, there is an ever-evolving demand for practice and policy to keep pace. This encyclopedia contains 180 chapters, from all fields of pharmacy practice and clinical pharmacy, providing an in-depth coverage of modern approaches to the practice of pharmacy and highlighting the directions that will enable advancement to continue.

This encyclopedia includes definitions, concepts, theories, and applications of clinical pharmacy and pharmacy practice, providing background knowledge of the area that will provide valuable information for students of pharmacy practice. By providing relevant and topical summaries on a broad range of subjects, this book is also an excellent resource for those seeking information beyond their specific areas of expertise. In addition, the information contained in this book and its communication is of importance to a range of stakeholders, such as physicians and other healthcare professionals, health regulatory authorities, and the pharmaceutical and health industry, in addition to patients and their caregivers.

This encyclopedia also provides an excellent insight into pharmacy practice research and methods, as well as pharmacovigilance, pharmacoeconomics, social and administrative pharmacy, public health pharmacy, pharmaceutical systems research, the future of pharmacy, and new interventional models of pharmaceutical care. In addition, new treatments, algorithms, standard treatment guidelines, and pharmacotherapies regarding diseases and disorders are also covered.

The six key strands around which this encyclopedia is arranged pay testament to the complex and broad nature of the topic and are key topics of interest in pharmacy today and drivers of change for the future, for the benefit of public health across the world.

1. Pharmacy practice
2. Pharmacy practice research methods
3. Clinical pharmacy education, professional standards, and workforce
4. Clinical pharmacy and pharmacotherapy
5. Pharmacoepidemiology and pharmacovigilance
6. Socio-behavioral and administrative pharmacy

Topics range from the education and training of pharmacists, technicians and assistants to counterfeit medicines, pharmaceutical pricing policies, and implementation of change. As pharmacy practice evolves to meet the ever-more-complex health and medicines needs of patients, practitioners need an understanding of the social, political, and economic contexts across the world, noting particular highlights and challenges in developing countries to reach high standards. While it is acknowledged that there are differences between countries in terms of legislation, regulations, and guidelines (as detailed in individual chapters), the vision for the profession must be for a world in which everyone can access safe, effective, and affordable medicines and pharmaceutical care. The chapters include many examples of innovation and best practice in delivering health

services for the future, embracing additional roles beyond the supply of medicines in a robust manner underpinned by scientific and evidenced practice. Quantitative, qualitative, and mixed methods of pharmacy practice research are presented alongside expanded and evolving roles for pharmacists and where technology may take us. More quality research and coordinating efforts will bring a range of theoretical concepts and an evidence-based practice to the forefront of our activities, to focus a global workforce to meet the challenges of this exciting new era for pharmacy practice. This timely volume exemplifies the willingness and ability of the profession to work collaboratively on global issues, representing an unprecedented opportunity to shape the future of pharmacy practice.

With ever-increasing demands on healthcare systems, alongside growing financial pressures, it is essential that we work collaboratively with other pharmacists and the wider public health workforce who have the expertise, opportunity, and capacity to support and inform development.

In this context, this encyclopedia is an important resource with far-reaching impact on global healthcare community, and I hope this will be well liked by students, researchers, and academics.

Professor Barbara Conway
Department of Pharmacy, University of Huddersfield, Queensgate, Huddersfield, United Kingdom

March 2019

PREFACE

Encyclopedia of Pharmacy Practice and Clinical Pharmacy

This encyclopedia has 180 chapters in total and it covers all domains of pharmacy practice and clinical pharmacy, including pharmacy practice research, socio-administrative and behavioral pharmacy, pharmacy education, pharmacoepidemiology, and the pharmacotherapy. One main question being asked is the need for this work. *What encyclopedia of pharmacy practice and clinical pharmacy adds to the current body of literature and what it means for global pharmacy community?* The answer to that is, though there were a number of books available on pharmacotherapy, however, current landscape lacks material comprehensively covering aspects, such as pharmacy practice, pharmacy practice research, social pharmacy, pharmacoepidemiology, pharmacy education, and the linking of clinical pharmacy with the health system. This encyclopedia aims to provide a collection of chapters on the above-mentioned areas. It also developed, synthesized knowledge, and provided policy guidance in the areas where there were gaps in the literature. For example, filling the gaps and including chapters on health systems, pharmaceutical policy, evidence and impact in pharmacy practice research, and on pharmacy education.

Here is a brief summary of what is being covered in its three volumes: Volume 1, 2, and 3.

Volume 1 includes chapters on pharmacy practice and pharmacy practice research. The pharmacy practice section starts with the historical evolution of pharmacy practice, medicines management, expanded roles of pharmacists, cognitive pharmacy services, community, and ambulatory pharmacy practice, ethics and regulation, and the new models of pharmaceutical care. There are also chapters on prescribing standards, practices, and competencies, interpersonal communication, evidence-based medicine, models on patient counseling, innovative pharmacy services, technology in pharmacy practice, and the pharmacist's role in substance misuse. The case studies chapters include pharmacy practice in high, low, and middle-income countries; United Kingdom, Western Europe, Australia, New Zealand, China, India, Gulf States, Philippines, and Portugal.

It is vital to understand and discuss the quality of evidence in pharmacy practice research, for example, how the evidence is produced and how it could impact on health outcomes. This is a niche section in the encyclopedia covering chapters on quantitative and qualitative methods in pharmacy practice research, quality of qualitative research, philosophical perspective and theories applied in pharmacy practice research, meta-synthesis, mixed methods research, discrete choice experiments, and the use of network meta-analysis in pharmacy practice. There are also chapters on evolution and definition of practice research, evidence, impact, and gaps in pharmacy practice research in low- and middle- and high-income countries.

Volume 2 covers pharmacovigilance, pharmacoepidemiology, and the socio-behavioral and administrative aspects of pharmacy and medicines use. The knowledge regarding pharmacoepidemiology and pharmacovigilance significantly impacts on medicines safety. The chapters included are on definitions, principles, and application of pharmacoepidemiology, descriptive and drug utilization studies, case-control and cohort studies, methodological challenges in epidemiological studies, data sources, and the issues related to medicines safety and comparative effectiveness research.

The socio-administrative and behavioral pharmacy section covers two broad aspects, namely, social pharmacy and pharmacy administration. Social pharmacy section covers concepts, development, and theories related to social pharmacy, public and patient engagement, sociology for pharmacists, implementation of change in pharmacy practice, and the social perspectives in addiction. There are also chapters on medicines adherence, compliance, and concordance, medication narratives, investigating medicines use among elderly

from a sociological perspective, changing nature of pharmacy as a profession, the impact of culture and religion on medicine use, and the issues related to disease mongering.

The understanding of health system is vital when promoting access and the use of medicines, hence in this context understanding administrative aspects of pharmacy are crucial. This section explores the dynamics between public policy, pharmaceutical policy, pharmacy practice, health systems, and patient-health outcomes. It covers a range of pharmaceutical policy and health system issues including access to biosimilars, access to high-cost medicines, counterfeit medicines, factors influencing pharmaceutical policy implementation, funding mechanisms for community pharmacy services, generic drug policies, national medicine policies, essential medicines list, pharmaceutical company sponsored medication assistance programs, and the pharmaceutical pricing policies.

Volume 3 covers clinical pharmacy education and pharmacotherapy. Pharmacy education training and the workforce have a great impact on global health. There are 25 chapters or more on pharmacists' training, and certification exploring the relationship between education, regulation, and practice. This is one of the largest collection of chapters covering pharmacy education and regulation at the global level. This includes chapters on pharmacist workforce, competency standards for clinical pharmacists, quality assurance in the pharmacy education, developing and evaluating clinical skills, continuing professional development, experiential education, inter-professional learning, leadership in pharmacy education, and the needs-based education. There are also case studies chapters on clinical pharmacy professional standards in the United States of America, Canada, the European Union, and in the low- and middle-income countries.

The pharmacotherapy section covers over 70 chapters discussing standard treatment guidelines, pharmacist's role in the central nervous system, infectious diseases, cardiovascular disorders, skin and endocrine disorders, musculoskeletal disorders, neurology, gastrointestinal disorders, and the respiratory disorders. The other key chapters include clinical pharmacy concepts, history, and development, clinical governance principles, pharmacokinetics, therapeutic guidelines, end of life care, palliative care, long-term care, fundamentals of pharmaceutical care planning, health outcomes and quality of life, the role of the pharmacist in the military and prisons, and the pharmacotherapy and deprescribing.

It has been a challenging task to complete this encyclopedia within a short span of 2 years. However, I am very thankful to the support of my section editors, reviewers, and hundreds of authors from all over of the world to come together and to contribute to this exciting project.

I hope you will like this effort and it will serve its purpose.

Pharmacy Practice and Its Research: Evolution and Definitions

Syed Shahzad Hasan[*,†], **Kaeshaelya Thiruchelvam**[†,‡], **Therese Kairuz**[†], **Nasir Abbas**[*], **Zaheer-Ud-Din Babar**[*], [*]University of Huddersfield, Huddersfield, West Yorkshire, United Kingdom; [†]University of Newcastle, Callaghan, NSW, Australia; [‡]International Medical University, Kuala Lumpur, Malaysia

The Development of Pharmacy Practice Research

Pharmacy has traditionally been portrayed as a profession responsible for formulating and dispensing medicines. In the early 1900s, pharmacists were experts in apothecary, *secundum artem*, i.e. the art for empirical or medicinal use. As clinical pharmacy emerged as a speciality discipline, its development was influenced by the introduction of hospital pharmacy in the 1920s (Gregory, 2013). In the 1960s, clinical pharmacy started evolving and this aspect of the profession became patient-oriented rather than product-based. The significance and recognition of clinical pharmacy services were first documented in the 1970s and 1980s, respectively (International Pharmaceutical Federation, 2019; World Health Organization, 2006). This marked the beginning of the professional integration of pharmacists' roles and enhanced interactions with medical practitioners and other healthcare professionals such as nurses, physiotherapists, and dieticians (Pearson, 2007; Zermansky et al., 2006).

In 1991, Hepler proposed the concept of program evaluation for clinical pharmacy services and made useful suggestions to improve research designs (Hepler, 1991). In 1992, Ascione et al. made recommendations and provided insightful information on improving research in pharmaceutical care (Ascione et al., 1992). As pharmacy practice research continued to mature at its own pace, there was a paucity of literature in pharmaceutical care research. In 1998, Kennie et al. published a critical analysis of 12 pharmaceutical care research studies conducted between 1992 and 1998 (Kennie et al., 1998), and recommended that there was scope for improvement in study design, reporting of outcomes, and the associated relationships with structure and process, as defined by the Economic, Clinical and Humanistic Outcomes (ECHO) model (Strand et al., 1990).

The Nuffield Foundation was the first organization to advocate pharmaceutical sociology in 1986 (Deb, 1986). A few years later in 1994, Nick Mays explained that the sociological theory should be utilized to explain pharmacy practice research (Mays, 1994); however, it was not until 2001 that Bissell, Traulsen, and Haugbolle formally introduced the concepts of sociology and its importance in pharmacy practice research (Bissell et al., 2001). Morrall (2001) defined the discipline of sociology as one that reveals the nature of health and illness (Morrall, 2001). Health and illness have been identified as social phenomena and thus are susceptible to sociological analysis; for example, mortality and morbidity vary depending on the social differences such as age, gender, and ethnicity. There seems to be a social pattern associated with all forms of illness, and the analysis and elaboration of such patterns signify the importance of sociology in pharmacy practice research (Bissell et al., 2001).

Part of being diagnosed with an illness may involve taking medicines and there are many social aspects to the use and beliefs about medicines. Practice of pharmacists, use of medicines by patients, interactions between pharmacists and their patients, and the organizational and institutional structure of pharmacy services have the potential for an analysis through sociological theories (Bissell et al., 2001). Bissell et al. (2001) strongly believed that these theories directly contribute to strength, diversity, and dynamism of pharmacy practice research (Bissell et al., 2001).

Evolution of Pharmacy Practice Research and Its Literature

Pharmacy practice research continued to evolve after 2000s, particularly in the United Kingdom, the United States, Australia, Canada, and Scandinavia. In 2002, Felicity Smith published a book entitled *Research Methods in Pharmacy Practice* outlining how to conduct a practice project (Smith, 2002). These research interests also shifted from pharmacotherapy to pharmaceutical services involving education and medication advice (Fish et al., 2002). In 2015, Zaheer Babar edited *Pharmacy Practice Research Methods, an edition* that discusses theories, methodologies, models, and techniques (Babar, 2015).

In 2019, Austin and Sutton published *Research Methods in Pharmacy Practice Methods and Applications Made Easy*. This book explains basic concepts, as well as case studies outlining practice (Austin and Sutton, 2019). The current encyclopedia of pharmacy

practice and clinical pharmacy is comprehensive and has sections on pharmacy practice, covering qualitative, quantitative techniques, mixed methods approaches, meta synthesis, as well as the chapters on evidence and impact.

Definition and Evolution of Pharmacy Practice

The definition of pharmacy practice varies; in the context of this chapter, it is imperative to understand what activities or practices constitute pharmacy practice. In order to bridge this gap, a methodical and structured review of literature was performed. A summary of definitions of pharmacy practice and pharmacy practice research are presented in Table 1 and Table 2 respectively. In the process of searching for a clear and universal definition of pharmacy practice, we have identified 11 documents describing pharmacy practice published. These were all published between 1990 and 2019. The seven definitions (7/13) defined pharmacy practice as a discipline within pharmacy that involves health or pharmacy services delivery. The reason for incorporating health services provision in the definition of pharmacy practice could be increasing number of services provided by the pharmacists in both hospital and community settings.

Table 1 Summary of pharmacy practice definitions

Reference	*Relevance/ Context*	*Term used*	*Definition*	*Reference type*
Collett and Aulton (1990)	United Kingdom	Pharmaceutical practice	Pharmaceutical practice embraces the techniques of preparation and presentation of medicines, a knowledge of the biological fate of drugs and medicines, the symptomatic treatment of minor ailments, and the abilities to relate to and communicate with the patient, the prescriber, and other members of the healthcare team	Book (*Pharmaceutical Practice*)
World Health Organization (1996)	Global	Good Pharmacy Practice (GPP)	GPP is the practice of pharmacy that responds to the needs of the people who use the pharmacists' services to provide optimal, evidence-based care. The potential contribution of pharmacists extends to all levels of planning and provision of services. The mission of pharmacy practice is to provide medications and other healthcare products and services and to help people and society to make the best use of them (Pharmaceutical Care [PC] and GPP are largely identical, where GPP could be the way to implement PC)	WHO Report
RPSGB (1997a)	United Kingdom	Pharmaceutical service/ pharmacy practice	Five main areas in which pharmacy makes major contributions to health outcomes are management of prescribed medicines, management of chronic conditions, management of common ailments, promotion and support of healthy lifestyles, and advice and support for other healthcare professionals	RPSGB Report
Horne (2001)	United Kingdom	Pharmacy practice	Pharmacy practice serves to facilitate the appropriate use of medicines	Book (*Pharmacy Practice*)
Taylor and Harding (2001)	United Kingdom	Effective pharmacy practice	Effective pharmacy practice requires an understanding of the social context within which pharmacy is practiced, recognizing the particular needs and circumstances of the users of pharmaceutical services, and of pharmacy's place within health service provision	Book (*Pharmacy Practice*)
FIP/WHO (2011)	Global	Pharmacy practice	WHO described the mission of pharmacy practice as being "to provide medicines and other healthcare products and services and to help people and society to make the best use of them"	WHO Technical Report (Joint WHO/FIP Guidelines on GPP)

Table 1 Summary of pharmacy practice definitions (*cont.*)

Reference	*Relevance/ Context*	*Term used*	*Definition*	*Reference type*
American Pharmacy Association Academy of Pharmaceutical Research and Science (1998)	United States	Pharmacy practice activity	The PPAC is focused primarily on activities of licensed, practicing pharmacists across the continuum of healthcare settings. The classification captures a range of activities from traditional dispensing to direct patient care services. These include ensuring appropriate therapy and outcomes, dispensing medication and devices, health promotion and disease prevention, and health systems management	Pharmacy Practice Activity Classification (PPAC, 2019) Project
Whalley (2008)	United Kingdom	Pharmacy practice	Pharmacy practice is a discipline within pharmacy that involves developing the professional roles of the pharmacist. The critical parts of the discipline are understanding healthcare systems and public health	Book (*Foundation in Pharmacy Practice*)
Council on Credentialing in Pharmacy (2009) and National Association of Boards of Pharmacy (NABP) (2019)	United States	Pharmacy practice	NABP defines the pharmacy practice as the interpretation, evaluation, and implementation of Medical Orders; the Dispensing of Prescription Drug Orders; participation in Drug and Device selection; Drug Administration; Drug Regimen Review; the Practice of Telepharmacy within and across state lines; Drug or Drug-related research; the provision of Patient Counseling; the provision of those acts or services necessary to provide Pharmacist Care in all areas of patient care, including Primary Care and Collaborative Pharmacy Practice; and the responsibility for Compounding and Labeling of Drugs and Devices, proper and safe storage of Drugs and Devices, and maintenance of required records. The practice of pharmacy also includes continually optimizing patient safety and quality of services through effective use of emerging technologies and competency-based training	Reports (Council on Credentialing in Pharmacy, 2009; National Association of Boards of Pharmacy, 2019)
Moullin et al. (2013)	Australia	Pharmacy service/ pharmacy practice	A professional pharmacy service is defined as "an action or set of actions undertaken in or organized by a pharmacy, delivered by a pharmacist or other health practitioner, who applies their specialized health knowledge personally or via an intermediary, with a patient/client, population, or other health professional to optimize the process of care, with the aim to improve health outcomes and the value of healthcare"	Journal article
Almarsdottir et al. (2014)	Europe	Pharmacy practice	Pharmacy practice and social pharmacy are two important contemporary research areas within the field of pharmaceutical sciences, studying the role of medicines, patients, and pharmacists within the healthcare sector and society at large	Journal article
Fathelrahman et al. (2016)	Developing countries	Pharmacy practice	It is a description of what pharmacists normally do while acting in a professional context and it represents also the essential components and basic requirements for performing every job or action related to pharmacy, including where and how pharmacists do it	Book (*Pharmacy Practice in Developing Countries*)
Scahill and Babar (2017)	Global	Pharmaceutical Practice	Pharmaceutical practice encompasses everything, which is related to availability of medicines, access, and use at the individual and the population levels. This term encapsulates the research, development, formulation, distribution, access, and clinical use of medicines. It incorporates the human capital required to deliver pharmacy services and the impact on end users of pharmaceutical products and services	Journal article

Table 2 Summary of pharmacy practice research definitions

Reference	*Relevance*	*Term used*	*Definition*	*Reference Type*
Royal Pharmaceutical Society/King's Fund (RPSGB, 1997b)	United Kingdom	Pharmacy practice research	A useful definition of pharmacy practice research has been provided by the King's Fund (1997), which describes it as "research which attempts to inform and understand pharmacy and the way in which it is practiced, in order to support the objectives of pharmacy practice and to ensure that pharmacists' knowledge and skills are used to best effect in solving the problems of the health service and meeting the health needs of the population"	RPSGB Report
Smith (2010)	Global	Pharmacy practice research	Pharmacy practice research is used as an umbrella term for research into pharmacy services, medicines use, professional practice, and education. Research into the practice of pharmacy and the use of medicines is viewed as a branch of health services research	Book (*Conducting your Pharmacy Practice Research Project*)
Koster et al. (2014)/The Utrecht Pharmacy Practice network for Education and Research (2014)	Europe	Pharmacy practice research	Pharmacy practice research is necessary to generate evidence for further development of pharmacy services Pharmacy practice research can be divided in two main themes: (1) research related to the pharmacy as data source (e.g., studies regarding prescribing behavior or medication use) or (2) research related to the pharmacy as object of research (e.g., studies regarding internal pharmacy procedures, guideline adherence or quality of patient counseling)	Pharmacy Practice network for Education and Research Report
Almarsdottir et al. (2014)	Europe	Pharmacy practice research	Research within the field of pharmaceutical sciences, combining natural sciences with social and humanistic research to study the role of medicines, patients, and pharmacists within the healthcare sector and society at large	Journal article
Awaisu and Alsalimy (2015)	Global	Pharmacy practice research	"Pharmacy practice research" to be any research activity that pertains pharmacy practice or patient care, including, but not limited to, clinical and outcome research, health services research, and comparative effectiveness research	Journal article
Bond (2015)	Global	Pharmacy practice research	Pharmacy practice research, a sub-speciality within health services research, focuses on exploring how and why people access pharmacy services, the costs of pharmacy services, and the outcomes for patients as a result of these services, and comparison of these costs and outcomes compared to the same or similar services delivered by other providers	Book (*Pharmacy Practice Research Methods*)
Almarsdottir and Babar (2016)	Global	Pharmacy practice research	Many pharmacy practice researchers define their work as part of drug utilization research (DUR), clinical pharmacy, social pharmacy, pharmaceutical policy, health services research, or health economics	Journal article
Dolovich and Tsuyuki (2016)/Canadian Pharmacists Association/ Canadian Pharmacy Practice Research Group (2016)	Canada	Pharmacy practice research	Pharmacy practice research is defined as a component of health services research that focuses on the assessment and evaluation of pharmacy practice. It includes studies that evaluate pharmacists' roles in a variety of capacities. These studies include systems research, patient-centered research, and community-based research that encompasses a variety of determinants of health and their influence on patient outcomes and population health	Journal article and professional group
FIP Pharmacy Practice Research Special Interest Group (2019)	Global	Pharmacy practice research	Pharmacy practice research looks at the impact of the practice of pharmacy on healthcare systems, medicines use, and patient care. Its scope has expanded over the past 50 years to encompass aspects such as the clinical, behavioral, economic, and humanistic implications of the pharmacy practice, as well as change management and implementation	Special interest group

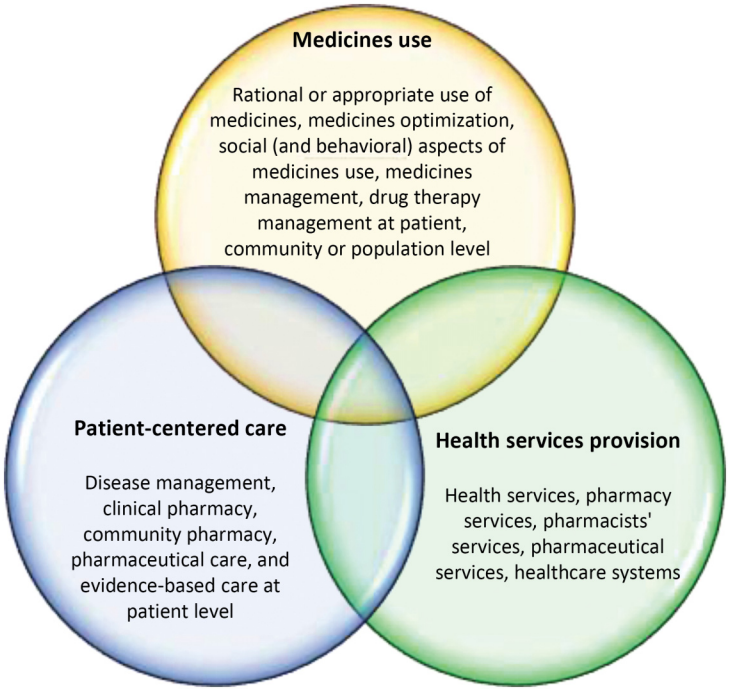

Figure 1 Diagrammatic representation of the different facets of pharmacy practice and its research.

The majority of the authors have used the term "pharmacy practice" except for a few (Collett and Aulton, 1990; Scahill and Babar, 2017) who used the term "pharmaceutical practice". The major difference between the two terms is the incorporation of pharmaceutical sciences in the definition of pharmaceutical practice.

The pharmacy practice definitions also vary according to who defines it and how they are being defined in a healthcare system. For example, in the United States, clinical pharmacy seems to be more a popular term or practice and is defined by the American College of Clinical Pharmacy as "*a health science discipline in which pharmacists provide patient care that optimizes medication therapy and promotes health, wellness, and disease prevention*" (American College of Clinical Pharmacy, 2008). In the United Kingdom, 'health services delivery' and 'medicines optimization' are more commonly used. Health services and medicines management were adopted and are widely promoted by the World Health Organization. Fig. 1 presents the three major elements (themes) which contribute to pharmacy practice and pharmacy practice research, namely medicines use, patient-centered care and health services provision.

Conclusion

It is commendable that pharmacy practice research has gained recognition in the international arena. Moving forward, pharmacy practice research should be performed in a manner which captures quality evidence on the use of medicines, patient-centered care, and provision of health services. These goals provide all the more reason to collaborate with other healthcare professionals and initiate new health services, with input from stakeholders and supported by research evidence.

List of Abbreviations

ECHO	Economic, Clinical and Humanistic Outcomes
FIP	International Pharmaceutical Federation
GPP	Good Pharmacy Practice
NABP	National Association of Boards of Pharmacy
PC	Pharmaceutical Care
RPSGB	Royal Pharmaceutical Society of Great Britain

Research Designs and Methodologies Related to Pharmacy Practice

Ahmed Awaisu, Banan Mukhalalati, Mohamed Izham Mohamed Ibrahim, Qatar University, Doha, Qatar

Learning Objectives

- Discuss the value of pharmacy practice research to evidence-based practice and policy.
- Describe the classifications and types of study designs commonly used in pharmacy practice research.
- Discuss the concepts and structure of common study designs used in pharmacy practice research including experimental, quasi-experimental, observational, qualitative, and mixed method designs.
- Discuss the important considerations for conducting pharmacy practice research in terms of study design, data collection, data analyses, and ethical considerations.

Introduction to Research Methodologies Used in Pharmacy Practice

The mission of pharmacy profession and the role of pharmacists in healthcare have evolved toward patient-centered care in the last few decades. Pharmacists with their expertise in drug therapy and accessibility to the public have unprecedented opportunities to assume increasing responsibility for direct patient care (Bond, 2006). New cognitive pharmaceutical services and new roles for pharmacists continue to emerge.

In the era of evidence-based practice and health services, it is not just adequate to propose those new pharmacy services or new roles without evidence of their benefit (Awaisu and Alsalimy, 2015; Bond, 2006). New pharmacy services and new roles must be proven to be feasible, acceptable, cost-effective, and increase health outcomes. Pharmacy practice research provides such evidence and can confirm the value of a new service, inform policy, and result in practice changes (Bond, 2006; Chen and Hughes, 2016). Research evidence should be used to identify new areas for improved health service delivery and rigorously

evaluate new services. The research used to generate such evidence should be grounded in robust and rigorous methodologies (Chen and Hughes, 2016). Traditionally, common quantitative and qualitative methods such as randomized controlled trials, cohort study, case control study, questionnaire-based surveys, and phenomenology using qualitative interviews have been used in pharmacy. However, in recent years, novel and more complex methods are being developed and utilized. Pharmacy practice researchers need to know how these old and new methodological approaches should be selected, applied, and interpreted in addressing research problems.

Various study designs, including, but not limited to experimental, quasi-experimental, observational, qualitative, and mixed method designs, have been used in pharmacy practice research. Furthermore, different classification systems (e.g., quantitative vs. qualitative, experimental vs. observational, descriptive vs. analytical study designs) have been used in the literature. The choice of a study design to answer a research question in pharmacy practice research is driven by several factors, including the type of the research question or the research hypothesis, expertise of the investigator, availability of data, and funding opportunities. Pharmacy practice researchers need to be competent in the selection, design, application, and interpretation of these methodological and analytical approaches. Today, many of the research methods used in pharmacy practice research have been adapted from fields such as sociology, anthropology, psychology, economics, and other disciplines. This paradigm shift has led to a greater emphasis on the appropriate choice of a specific research design or method to answer a specific research question (Chen and Hughes, 2016). Consequently, pharmacy practice researchers should place an emphasis on the reliability of the methods selected, the correct interpretation of their findings, the testing of a specific hypothesis, and the internal validity of their data, among other considerations. Novice and early career researchers should be familiar and have sound foundation in a variety of methods applied in pharmacy practice research, which will be covered in this chapter and other chapters in this Encyclopedia. We do believe that more experienced researchers should focus on certain methods in order to advance research in our discipline.

Core Quantitative and Qualitative Approaches Used in Pharmacy Practice Research

Traditionally, core quantitative approaches used in pharmacy practice research include nonexperiments, quasi-experimental designs, and true experimental designs such as prospective randomized controlled intervention trials. Nonexperiments also include observational study designs that are often described as pharmacoepidemiologic study designs such as case–control study, cohort study, nested case–control study, and cross-sectional study (Etminan, 2004; Etminan and Samii, 2004). In recent years, conventional qualitative approaches and their philosophical paradigms are increasingly been used in pharmacy. These include the five qualitative approaches to inquiry: narrative research, phenomenology, grounded theory, ethnography, and case study. These qualitative methods are often difficult for pharmacy practice researchers to comprehend, and researchers tend to describe the methods of data collection such as individual interviews and focus group discussions as qualitative methods of inquiry. These data collection methods are briefly described later in this chapter, among others. Furthermore, there is an increasing importance on the appropriate selection and use of mixed method approach (Hadi et al., 2013; Hadi and Closs, 2016a, 2016b), which are often designed and applied wrongly. Finally, it is worthwhile to be familiar with novel research methodologies such as discrete choice experiments, Delphi techniques, simulated client technique, and nominal group techniques, which fall between quantitative and qualitative approaches, often with no clear differentiation on where they belong. Although called "novel" in the context of this chapter, these methods are not new in other relevant disciplines, but new and not commonly used in pharmacy practice research.

Research Question and Selection of Study Design

Pharmacy practice researchers begin by conception of a research idea or identifying a research question and defining a hypothesis based on the question. The researcher then selects a study design that will be suitable to answer the research question. The study design should be appropriately selected prior to initiation of any research investigation. Selecting an inappropriate study design may potentially undermine the validity of a study in its entirety. Investigators are encouraged to critically think about the possible study designs to ensure that the research question is adequately addressed and should be able to adequately justify their choice. These study designs have been variously classified and one common classification system is quantitative vs. qualitative study designs. Study designs play a major role in determining the scientific value of research studies. Inappropriate choice of a study design is impossible to correct after completion of the study. Therefore, thorough planning is required to avoid unconvincing results and invalid conclusions. Good understanding of basic study design concepts will aid researchers in conducting robust and rigorous practice-based research. This chapter introduces the structure and the fundamentals of common study designs used in pharmacy practice research and discusses the important considerations for conducting pharmacy practice research in terms of study design, data collection, data analyses, and ethical considerations.

Classification of Research Methodologies Used in Pharmacy Practice

Various classifications for research designs and methods used in pharmacy practice have been used in the literature. The following are some of the approaches for the classification of research designs:

1. Classification based on time orientation: Retrospective vs. prospective designs

a. Retrospective design—A retrospective study design observes what has happened in the past. It begins and ends in the present. This design involves a major limitation as it looks to collect information about events that occurred in the past. An example of this design is retrospective case-control study.
Case example: Investigators were looking for the association between acute myocardial infarction and smoking status, type of tobacco, amount of smoke, etc. (Teo et al., 2006). Another example of a case–control study from published literature is the study investigating the association between the use of phenylpropanolamine and the risk of hemorrhagic stroke (Kernan et al., 2000).
b. Prospective design—A prospective study design begins in the present and progresses forward, collecting data from subjects whose outcomes lie in the future. An example of this design is prospective cohort study.
Case example: Investigators were interested to determine the long-term effectiveness of influenza vaccines in elderly people; they recruited cohorts of vaccinated and unvaccinated community-dwelling elderly (Nichol et al., 2007).

2. Classification based on study purpose: Descriptive vs. analytical designs

a. Descriptive design—A descriptive study describes a population/sample in terms of distribution of the variables, and frequency of outcomes of interest. Unlike analytical studies that include control (comparison) group, descriptive studies do not include a comparison group. Descriptive studies include case reports, case series reports, cross-sectional studies, surveillance studies, and ecological studies.
Case example: A case report was written by a physician who contracted Severe Acute Respiratory Syndrome (SARS) during an outbreak in Hong Kong (Wu and Sung, 2003). Another example is an ecological study examining diet and sunlight as risks for prostate cancer mortality (Colli and Colli, 2006). Chim et al. conducted a large population-based survey in Australia to determine what community members think about the factors that do and should influence government spending on prescribed medicines (Chim et al., 2017).
b. Analytical design—An analytical study identifies risk factors, associated factors, mediating factors, etc. Analytical studies are either experimental or observational. Case–control and cohort studies are types of observational studies.
Case example: A group of investigators carried out a study to establish an association between the use of traditional eye medicines (TEM) and corneal ulcers. In this case, both case–control and cohort study designs are applicable. In an example of a case control study, Archibugi et al. aimed to investigate the association between aspirin and statin exclusive and combined and pancreatic ductal adenocarcinoma occurrence (Archibugi et al., 2017). Another example of a cohort study is a study carried out by Wei et al. in which they investigated whether or not acid-suppression medicines increased the risk of bacterial gastroenteritis (Wei et al., 2017).

3. Classification based on investigator orientation: Experimental vs. quasi-experimental vs. observational designs

a. Experimental design—In experimental design (also known as interventional design), the investigator performs an intervention and evaluates cause and effect relationships.
Case examples: Investigators conducted a study about the newer versus older antihypertensive agents in African hypertensive patients (NOAAH) trial (nct01030458) to compare the efficacy of single-pill combinations of newer versus older antihypertensive agents (i.e., a single-pill combination of newer drugs, not involving a diuretic, with a combination of older drugs including a diuretic) (Odili et al., 2012). In a crossover design, a group of investigators evaluated the effect of spironolactone on nonresolving central serous chorioretinopathy (Bousquet et al., 2015).
b. Quasi-experimental design—The quasi-experimental design is very similar to the true experimental design described above and it involves an intervention. The design has been employed when randomization is inappropriate or impossible, especially when implementing complex interventions.
Case examples: Prashanth et al. aimed to understand if (and how) a package of interventions targeting primary health centers and community participation platforms affect utilization and access to generic medicines for people with noncommunicable diseases using quasi-experimental design approach (Prashanth et al., 2016).
c. Observational design—It involves only observation of natural phenomena and does not involve investigator intervention. Typically, this study design investigates associations and not causation. Examples include cohort study and case–control study. These studies can explore an association between a pharmacologic agent and a disease of interest. Case examples: Please see previous examples of these.

4. Classification based on question orientation: Quantitative vs. qualitative vs. mixed method designs

a. Quantitative design—This is based on measurement of quantity and it is applicable to phenomenon that can be quantified (i.e., expressed in terms of numbers).
Case examples: Please see experimental studies, and case–control and cohort study designs.
b. Qualitative design—Qualitative research is concerned with qualitative phenomenon (i.e., a phenomenon relating to or involving quality).
Case examples: Investigators in Canada explored the lived experiences of youth who are prescribed antipsychotics by conducting interpretative phenomenology study (Murphy et al., 2015).

c. Mixed method designs—Mixed method design brings together qualitative and quantitative methodologies within a single study to answer or understand a research problem (Hadi et al., 2013).
Case examples: Shiyanbola et al. combined focus group discussion with a survey tool to investigate patients' perceived value and use of quality measures in evaluating and choosing community pharmacies (Shiyanbola and Mort, 2015).

5. Classification of pharmacoepidemiologic study designs
Below is a brief description of traditional and novel pharmacoepidemiologic study designs. Several examples of pharmacoepidemiologic study designs are provided above. Some descriptive studies including case reports, case series, and ecological studies will not be described in this chapter.

a. Case–control studies—In this design, patients (those who develop the disease or outcome of interest) are identified and control patients (those who do not develop the disease or outcome of interest) are sampled at random from the original cohort that gives rise to the cases (Etminan and Samii, 2004; Newman et al., 2013). The distribution of exposure to certain risk factors between the cases and the controls is then explored, and an odds ratio (OR) is calculated.
b. Cohort studies—This can be described as a study in which a group of exposed subjects and a group of unexposed subjects are followed over time and the incidence of the disease or outcome of interest in the exposed group is compared with that in the unexposed group (Etminan and Samii, 2004; Hulley et al., 2013).
c. Case-crossover studies—The case-crossover may be considered comparable to a crossover randomized controlled trial in which the patients act as their own control (Etminan and Samii, 2004). Pattern of exposure among the cases is compared between event time and control time. The between-patient confounding that occurs in a classic case-control study is circumvented in this design. Tubiana et al. evaluated the role of antibiotic prophylaxis and assessed the relation between invasive dental procedures and oral streptococcal infective endocarditis, using a nationwide population-based cohort and a case-crossover study design (Tubiana et al., 2017).
d. Case–time control studies—This design is an extension of the case-crossover design, but includes a control group (Etminan and Samii, 2004). A group of researchers assessed medication-related hospitalization. They used the case–time control study design to investigate the associations between 12 high risk medication categories (e.g., antidiabetic agents, diuretics, benzodiazepine hypnotics) and unplanned hospitalizations (Lin et al., 2017).
e. Nested case–control studies—In this design, a cohort of individuals is followed during certain time periods until a certain outcome is reached and the analysis is conducted as a case–control study in which cases are matched to only a sample of control subjects (Etminan, 2004). de Jong et al. examined the association between interferon-β (IFN-β) and potential adverse events using population-based health administrative data in Canada (De Jong et al., 2017).
f. Cross-sectional studies—In this type of study, the investigator measures the outcome of interest and the exposures among the study participants at the same time (Hulley et al., 2013; Setia, 2016b). It provides a snapshot of a situation for a particular period.

Quantitative Research Designs in Pharmacy Practice

A wide range of quantitative methods are commonly applied in pharmacy practice research. These methods are widely used in published pharmacy practice literature to explore appropriateness of medicines use, appropriateness and quality of prescribing, and medication safety, through analyzing existing datasets, direct observation, or self-report (Green and Norris, 2015). Pharmacy practice research questions also seek to determine the knowledge, behaviors, attitudes, and practices of pharmacists, other healthcare providers, patients, policy-makers, regulators, and the general public. Quantitative methods are also used in evaluating the effect of new pharmacy services and interventions to improve medicines use. These practice research projects provide valuable insights about how medicines are used, and how to maximize their benefits and minimize their harmful effects. In the context of this chapter, quantitative study designs will be broadly classified into three: (1) observational, (2) experimental and quasi experimental, and (3) other designs.

Observational Study Designs

Pharmacoepidemiology is a "relatively new science that explores drug efficacy or toxicity using large observational study designs" (Etminan, 2004; Etminan and Samii, 2004). These study designs explore drug use studies that usually cannot be answered using randomized controlled trials or other experimental designs. In several instances, experimental study designs may not be suitable or feasible; in such circumstances, observational study designs are applied (Cummings et al., 2013). As the name implies, observational studies involve merely observing the subjects in a noncontrolled setting, without investigator intervention or manipulating other aspects of the study. Therefore, observational studies are nonexperimental. The observation of the variables of interest can be prospective, retrospective, or current depending on the type of the observational study.

In pharmacoepidemiology and other areas of pharmacy practice, researchers are often interested in measuring the relationships between exposure to a drug and its efficacy, toxicity, or other outcomes of interest using observational study designs. It is worthwhile to note that observational study designs investigate association, but, in most cases, not causation. Here, we provide descriptions of some commonly used study designs in pharmacoepidemiology and pharmacy practice research in general.

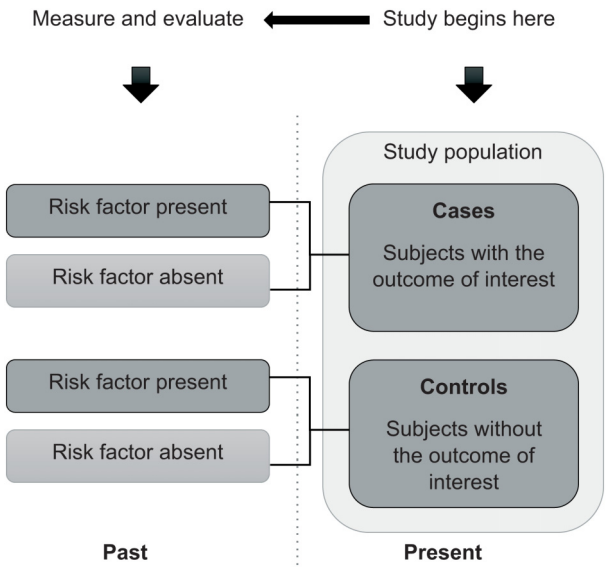

Figure 1 Case–control study design.

Case–Control Studies

Case–control study design is used to determine association between risk factors or exposures and outcomes. It is a useful design to study exposures in rare diseases or diseases that take long time to develop (Newman et al., 2013). It investigates exposures in individuals with and those without the outcome of interest. Nevertheless, case–control studies can help to identify harmful or beneficial exposures. Furthermore, the outcome of interest can be undesirable (e.g., mortality) or desirable (e.g., microbiological cure). As the name suggests, in a case–control study design, there are two groups of subjects: (1) cases (individuals with the outcome of interest) and (2) controls (individuals without the outcome of interest) (Newman et al., 2013). Cases are randomly selected based on prespecified eligibility criteria from a population of interest. Appropriate representative controls for the cases selected are then identified. The researchers then retrospectively investigate possible exposures to the risk factor. **Fig. 1** represents a schematic diagram of a case–control study.

Case–control studies are relatively inexpensive, less time-consuming to conduct, allow investigation of several possible exposures or associations, and are suitable for rare diseases. Selection of the control group is a critical component of case–control studies. Case–control studies have several drawbacks: confounding must be controlled, subject to recall, observation, and selection biases.

OR is the measure of association used for the analysis of case–control studies. This is defined as the odds of exposure to a factor in those with a condition or disease compared with those who do not have the condition or disease.

Cohort Studies

Similar to case–control studies, cohort studies determine an association between exposures/factors and development of an outcome of interest. As previously described, a cohort study is a study in which a group of exposed subjects and a group of unexposed subjects are followed over time to measure and compare the rate of a disease or an outcome of interest in both groups (Etminan and Samii, 2004; Hulley et al., 2013). A cohort study can be prospective (most common) or retrospective. While a case–control study begins with patients with and those without the outcome of interest (e.g., diseased and nondiseased patients), a cohort study begins with exposed and unexposed patients (e.g., patients with and those without certain risk factor) (Hulley et al., 2013; Setia, 2016a). In a cohort study, both the exposed and the unexposed subjects are members of a larger cohort in which subjects may enter and exit the cohort at different periods in time (Etminan and Samii, 2004; Hulley et al., 2013).

Typically, a cohort study should have a defined time zero, which is defined as the time of entry into the cohort (Etminan and Samii, 2004). The cohort (a group of exposed and unexposed subjects, who are free of the outcome at time zero) is followed for a certain period until the outcome of interest occurs. In addition, information or data related to all potential confounders or covariates should also be collected as failure to account for these can bias the results and over- or underestimates the risk estimate. There are two types of cohort studies: retrospective cohort and prospective cohort studies.

Retrospective cohort study, also known as historical cohort study, begins and ends in the present, while looking backward to collect information about exposure that occurred in the past (**Fig. 2**). Historical cohort studies are relatively less time-consuming and less expensive than prospective cohort studies (Etminan and Samii, 2004; Hulley et al., 2013; Setia, 2016a). In addition, there is no loss to follow-up and researchers can investigate issues not amenable to intervention study designs. However, these studies are only as good as the data available, the investigator has limited control of confounding variables, and it is prone to recall bias.

On the other hand, prospective cohort study, also known as longitudinal cohort study, begins in the present and progresses forward, collecting data from enrolled subjects whose outcomes fall in the future (Etminan and Samii, 2004; Hulley et al., 2013;

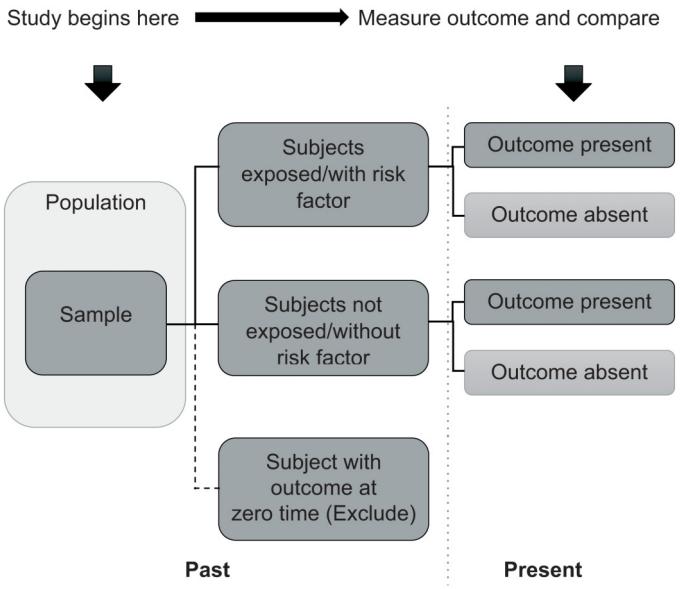

Figure 2 Retrospective (historical) cohort study design.

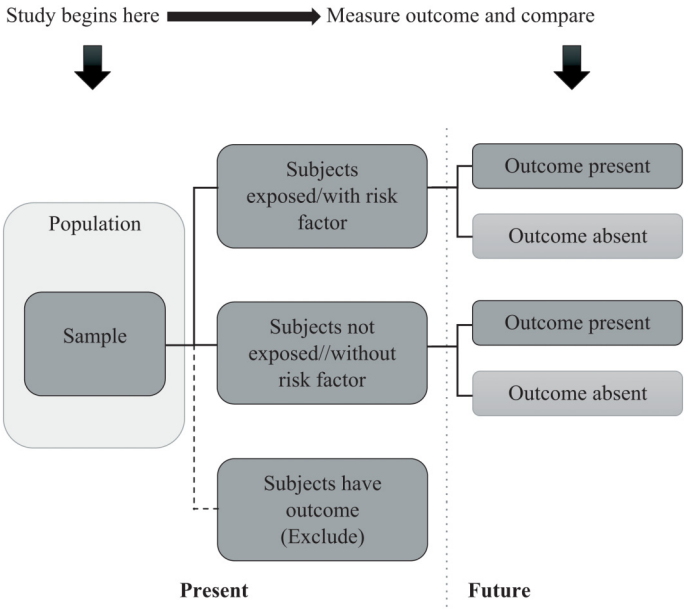

Figure 3 Prospective (longitudinal) cohort study design.

Setia, 2016a) (**Fig. 3**). Prospective cohort studies are easier to plan for data collection, have low recall bias, and the researcher has a better control of confounding factors. On the other hand, it is difficult to study rare conditions; they are more prone to selection bias, more time-consuming, expensive, and loss of subjects to follow-up is common.

Relative risk (RR) is the measure of association used for the analysis of a cohort study. This is defined as the risk of an event or development of an event relative to exposure (i.e., the risk of subjects developing a condition when exposed to a risk factor compared with subjects who have not been exposed to the risk factor).

Case-Crossover Studies

This is a relatively new design in the field of epidemiology in which the patients act as their own controls (Maclure, 1991). In this design, there is a case and a control element both of which come from the same subject. In other words, each case serves as its own control. It can be considered equivalent to a crossover RCT with a washout period (Etminan and Samii, 2004). Pattern of exposure to the risk factor is compared between the event time and the control time (Etminan and Samii, 2004). Case-crossover study design is useful to investigate triggers within an individual. For instance, it is applicable when studying a transient exposure or risk factor.

However, determination of the period of the control and case components is a crucial and challenging aspect of a case-crossover study design. Since the patients serve as their own controls, the interindividual variability that is inherent in classic case–control studies is eliminated. This is important in studies involving progressive disease states in which disease severity may differ between patients such as multiple sclerosis. OR is estimated using techniques such as Mantel–Haenszel statistics and logistic regression.

Cross-Sectional Studies

Cross-sectional studies also known as prevalence studies identify the prevalence or characteristics of a condition in a group of individuals. This design provides a snapshot of the prevalence or the characteristics of the study subjects in a single time point. The study investigator measures the outcomes and the exposures in the study subjects simultaneously (Etminan and Samii, 2004; Hulley et al., 2013; Setia, 2016b). Hence, cross-sectional studies do not follow up patients to observe outcomes or exposures of interest. Data are often collected through surveys. Cross-sectional design cannot provide cause and effect relationships between certain exposures and outcomes of interest.

Experimental and Quasi-Experimental Study Designs

In a typical experimental study design, the investigator assigns subjects to the intervention and control/comparison groups in an effort to determine the effects of the intervention (Cummings et al., 2013). Since the investigator has the opportunity to control various aspects of the experiment, this allows the researcher to determine the causal link between exposure to the intervention and outcome of interest. The researcher either randomly or conveniently assigns the subjects to an experimental group and a control group. When the investigator performs randomization, the study is considered a true experiment (see Fig. 4). On the other hand, if subjects are assigned into groups without randomization, the study is considered a quasi-experiment (refer to Fig. 5). As with experimental designs, quasi-experimental designs also attempt to demonstrate a causal link between the intervention and the outcome of interest. Due to the challenges of conducting a true experimental design, the quasi-experimental study designs have been consistently used in pharmacist intervention research.

RCTs are considered the gold standard of experimental study designs in pharmacy practice and evidence-based research (Cummings et al., 2013). The investigator randomly assigns a representative sample of the study population into an experimental group and a control group (Fig. 4). Randomization in RCT is to minimize confounding and selection bias; it enables attainment of similar experimental and control groups, thereby isolating the effect of the intervention. The experimental group receives the treatment or intervention (e.g., a new drug or pharmaceutical care for treatment of a certain disease), while the control group receives a placebo treatment, no treatment, or usual care treatment depending on the objective of the study (Cummings et al., 2013). These groups are then followed prospectively over time to observe the outcomes of interest that are hypothesized to be affected by the treatment or intervention. The result of the study is considered to have high internal validity if significant changes on the outcome variable occur in the experimental group, but not the control group. The investigator can infer that the treatment or intervention is the most probable cause of the changes observed in the intervention group. The unit of randomization in RCTs is usually the patient, but can sometimes be clusters to circumvent the drawbacks of contamination.

RCTs are very challenging to undertake and pharmacy practice researchers should ensure design of robust experiments, while considering all essential elements and adhering to best practices. For instance, to determine the impact of a cognitive pharmaceutical service, the selection of a representative sample of the population is a prime consideration in an RCT. Moreover, RCTs are expensive, labor-intensive, and highly prone to attrition bias or loss to follow-up.

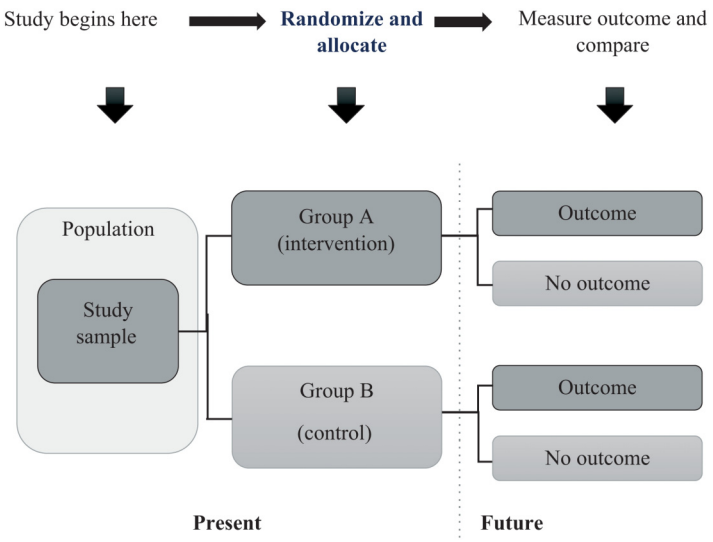

Figure 4 True experimental study design.

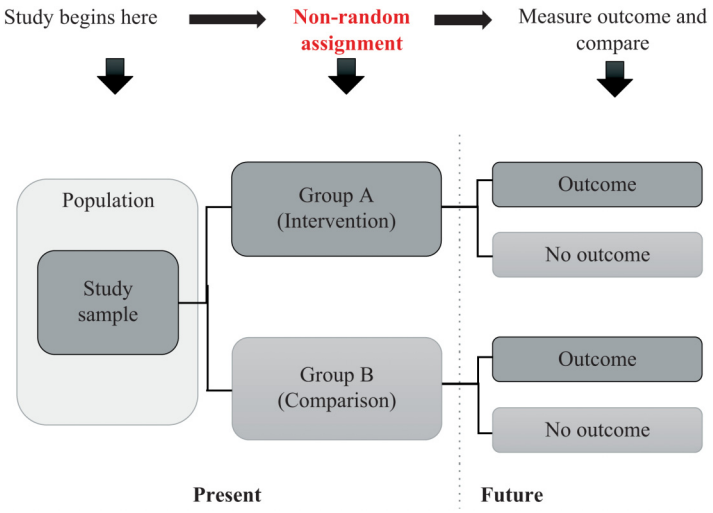

Figure 5 Quasi experimental study design.

In pharmacy practice research, it is often difficult to comply with the stringent requirements of true experimental designs such as RCTs, due to logistic reasons and/or ethical considerations (Grady et al., 2013; Krass, 2016). Whenever true experimental models are not feasible to be applied in pharmacy practice research, the researcher should endeavor to use a more robust quasi-experimental design. For instance, when randomization is not feasible, the researcher can choose from a range of quasi-experimental designs that are non-randomized and often noncontrolled (Grady et al., 2013; Krass, 2016). Quasi-experimental studies used in pharmacy literature may be classified into five major categories: (1) quasi-experimental design without control groups (i.e., one group pre–posttest design); (2) quasi-experimental design that use control groups with no pretest; (3) quasi-experimental design that use control groups and pretests (i.e., nonequivalent control group design with dependent pretests and posttests) (see **Fig. 5**); (4) interrupted time series and; (5) stepped wedge designs (Brown and Lilford, 2006; Grady et al., 2013; Harris et al., 2006).

The one group pretest posttest design and the nonequivalent control group design (**Fig. 5**) are the most commonly applied quasi-experimental designs in practice-based research literature. These designs have been commonly used to evaluate the effect of pharmacist interventions in medications management in general and specific disease states management. The lack of randomization and/or the lack of control group is a major weakness and a threat to internal validity in quasi-experimental designs (Grady et al., 2013). The observed changes could be due to some effects other than the treatment.

Other Quantitative Study Designs

In addition to the common observational, experimental, and quasi-experimental designs described above, there are other designs that are used in pharmacy. These research methods include, but are not limited to, simulated client technique, discrete choice experiments, and Delphi techniques. These methods, which are considered relatively new to pharmacy, are now commonly used in pharmacy practice research. In this chapter, we briefly describe these methods and their application in pharmacy. However, a more detailed description of their components and the nitty gritty of their application in pharmacy practice are available elsewhere within this textbook.

Simulated Client Method

The use of simulated client or simulated patient (mystery shopper) method to assess practices or behaviors in pharmacy practice has received much attention in recent times (Watson et al., 2004, 2006). "A simulated patient is an individual who is trained to visit a pharmacy (or drug store) to enact a scenario that tests a specific behavior of the pharmacist or pharmacy staff" (Watson et al., 2006). A review by Watson et al. demonstrated the versatility and applicability of this method to pharmacy practice research in both developing and developed countries (Watson et al., 2006). The investigators also identified some important characteristics that should be taken into consideration in designing studies that use this technique.

This method can be used to assess wide range of cognitive pharmacy services including counseling and advice provision, treatment of minor ailments, provision of nonprescription medicines, and public health pharmacy, among other things. This method can be a robust and rigorous method of assessing pharmacy practice if used appropriately (Watson et al., 2006; Xu et al., 2012). More recent developments have documented that the simulated patient methods have been used to provide formative feedback in addition to assessing practice behavior of pharmacists and their staff (Xu et al., 2012).

In a case example, a group of investigators evaluated Qatari pharmacists' prescribing, labeling, dispensing, and counseling practices in response to acute community-acquired gastroenteritis (Ibrahim et al., 2016). In another example, the investigators documented the state of insomnia management at community pharmacies in Pakistan (Hussain et al., 2013).

Discrete Choice Experiments

Evidence in healthcare suggests that understanding consumers' preferences can help policy-makers to design services to match their views and preferences (Ryan, 2004). Traditionally, studies to understand patients' and consumers' preferences for pharmaceutical services used opinion or satisfaction survey instruments. Nevertheless, such satisfaction surveys lack the ability to identify the drivers of satisfaction or the relative importance of the different characteristics of the service (Vass et al., 2016). Discrete choice experiments are a novel survey-based method in pharmacy that are predicated on economic theories that allow systematic quantification of preferences to help identify which attributes of a good or service consumers like, the relative value of each attribute, and the balance between the different attributes (Naik Panvelkar et al., 2010; Ryan, 2004; Vass et al., 2016). In-depth description of this method and its essential elements are described in another chapter in the Encyclopedia.

Qualitative Research Designs in Pharmacy Practice

Qualitative research methodology is applied to investigate a problem that has unmeasurable variables, to get a comprehensive understanding of the topic, through discussing it with the involved individuals, and to recognize the natural context in which the investigated issue takes place (Creswell, 2013). The use of qualitative research methodology is becoming increasingly common across diverse health-related disciplines, including pharmacy practice. This is because of its ability to describe social processes and behaviors associated with patients or healthcare professionals, which strengthen the research impact (McLaughlin et al., 2016). Therefore, pharmacy researchers and practitioners need to be better oriented to qualitative research methods (Behar-Horenstein et al., 2018).

In the following section, interpretative frameworks and philosophical orientations, methodologies, data collection and analysis methods, approaches to ensure rigor, and ethical considerations in qualitative research are briefly discussed (Cohen et al., 2013; Creswell, 2013).

Interpretative Framework and Philosophical Assumptions of Qualitative Research

Interpretative Frameworks

Interpretative frameworks are the conceptual structures for comprehension, which form researcher's reasoning and views of truth and knowledge (Babbie, 2015). Different scholars have categorized qualitative research paradigms or interpretative frameworks differently. The following are examples of interpretative framework categories that are used in health science research based on the categorization of Creswell (2013): (1) social constructivism (interpretivism) framework; (2) post-positivism framework; (3) transformative, feminist, critical frameworks and disabilities theories; (4) postmodern frameworks; (5) pragmatism frameworks.

Philosophical Assumptions

Philosophical assumptions are theories and perspectives about ontology, epistemology, axiology, and methodology, which underpin the interpretative frameworks selected by qualitative researchers (Cohen et al., 2013). As with interpretative framework, there are numerous means to categorize the philosophical assumptions that are folded within interpretative framework. The following are explanations of philosophical assumptions based on the categorization of Creswell (2013):

1. Ontological assumptions, which define the nature of reality
2. Epistemological assumptions, which clarify means for knowing reality
3. Axiological assumptions, which explain the role and influence of researcher values
4. Methodological assumptions, which identify approaches to inquiry

It is important that a qualitative researcher understands how interpretative frameworks (e.g., social constructivism, post-positivism, and pragmatic interpretative frameworks) are differentiated because of their underpinning philosophical assumptions (i.e., ontological, epistemological, axiological, and methodological assumptions).

Approaches to Inquiry (Methodology)

It is important that qualitative researchers understand the differences between the characteristics of the five qualitative approaches to inquiry, in order to select an approach to inquiry and attain methodological congruence (Creswell, 2013). The five approaches to qualitative research inquiry are:

a. Narrative research: Describes participants' written and spoken stories about their experiences with a phenomenon being investigated, while considering the chronological connection of the phenomenon's series of events (Anderson and Kirkpatrick, 2016; Creswell, 2013; Czarniawska, 2004).
b. Phenomenological research: Describes the essence of participants' common experiences of a phenomenon, so that the description is a general essence rather than an individual experience (Creswell, 2013; Giorgi, 1997; Moustakas, 1994).

c. Grounded theory research: Aims to generate a theory grounded in participants' data that conceptually explain a social phenomenon, which could involve social processes, or actions or interactions (Creswell, 2013; Strauss and Corbin, 1990; Woods et al., 2016).
d. Ethnographic research: Involves describing the shared patterns of values, behaviors, and beliefs of culture-sharing participants (Creswell, 2013; Harris, 1968; Rosenfeld et al., 2017).
e. Case study research: Provides an in-depth examination of a real-life contemporary phenomenon that researchers cannot change over time, to illustrate the significance of another general topic (Baker, 2011; Creswell, 2013; de León-Castañeda et al., 2018; Mukhalalati, 2016; Yin, 2014).

Data Collection and Analysis Methods in Qualitative Research

1. Data collection methods
   Data collection tools in qualitative research can be categorized into the following fundamental categories (Creswell, 2013):
   a. Observation
   b. Documents
   c. Individual semi-structured interviews
   d. Focus groups (FGs)
   e. Audio-visual materials
   f. Emails chat rooms, weblogs, social media, and instant messaging.
2. Common elements and steps in conducting individual interviews and focus groups
   a. Topic guides: Topic guides guide the discussions in focus groups and individual interviews, and contain open-ended questions and probes, to enable the researcher to understand the complete picture, based on participant views and experiences. They are developed based on the literature review, aim and objectives, research questions, and propositions (Kleiber, 2004).
   b. Audio recording of FGs and interviews: Audio recording of discussions that take place in interviews and FGs is essential for managing and analyzing data, and for increasing the accuracy of data collection and analysis, and ultimately enhancing the dependability and credibility of the research (Rosenthal, 2016; Tuckett, 2005).
   c. Transcription of FGs and interviews recording: Verbatim transcription refers to the word-for-word conversion of oral words from an audio-recorded format into a scripted text format. Transcribing data is considered as the first data reduction step because it generates texts that can be examined and rechecked (Miles et al., 2014; Grossoehme, 2014).
3. Data analysis
   Data analysis comprises several fundamental steps, including reading the transcribed text, arranging data, coding data deductively based on prefigured themes or inductively to produce emergent themes, and then summarizing the codes into themes, and finally presenting the analyzed data as results (Cohen et al., 2013; Crabtree and Miller, 1999; Pope et al., 2000).
   The most commonly used data analysis methods in health science research are:
   a. Thematic analysis
      Thematic analysis is characterized by identifying, analyzing, and reporting themes that are available in the data (Braun and Clarke, 2006; Castleberry and Nolen, 2018).
   b. Content analysis
      Content analysis comprises systematic coding followed by quantification of the analyzed data in a logical and unbiased way (Berelson, 1952; Vaismoradi et al., 2013).
   c. Discourse analysis
      Discourse analysis emphasizes the core format and the structure of texts to examine the assumptions and concealed aspirations behind discourses (Brown and Yule, 1983; Gee, 2004).

Quality Perspectives in Qualitative Research

Qualitative research validation involves ensuring the rigor of the utilized data collection, management, and analysis methods, by utilizing approaches to ensure the quality. In pharmacy practice research, Hadi and Closs (2016a, 2016b) argued that quality in qualitative research topic has not been discussed widely in the literature, and therefore Hadi and Closs (2016a, 2016b) suggested using several trustworthiness criteria to ensure the rigor of qualitative study. The trustworthiness criteria for ensuring quality in qualitative research (Lincoln and Guba, 1985) are:

1. The trustworthiness criteria
   a. Credibility
      This criterion aims to ensure that the results are true and increases the possibility that the conclusions are credible (Cohen and Crabtree, 2008).

b. Dependability
This criterion aims to indicate that the research results are repeatable and consistent, in order to support the conclusions of the research (Cohen and Crabtree, 2008).
c. Confirmability
This criterion aims to confirm the neutrality in interpretation by ensuring that the perspectives of participants, not the bias of researchers, influence the results (Krefting, 1991).
d. Transferability
This criterion involves identifying the contexts to which the study results can be generalized, and indicating if the study conclusions can be applied in similar setting (Yin, 2014).

2. Reflexivity in qualitative research
Reflexivity implies revealing and evaluating the effect and biases that researchers can possibly bring to research process, by explaining the researcher's opinion, feelings, and experience with the phenomenon in question, and explaining the influence of this experience on research methods, findings, and write-ups (Creswell, 2013; Krefting, 1991; Lincoln and Guba, 1985).

Ethical Considerations

Obtaining an ethical approval from the Institutional Review Board (IRB) is required before conducting the qualitative research (Creswell, 2013). The key ethical issues that need to be considered are:

a. Informed consent and participant information leaflet
Informed consent refers to the decision taken by a competent individual to voluntarily participate in a research, after adequately understanding the research. Participant information leaflet is usually distributed to participants before they consent to participate in the research to clarify them the voluntary nature of research participation, the aim and objectives of the research, the rights of the respondents and the potential risks and harms, the data collection, management and storage conditions, and the right of participants to withdraw from the research (Jefford and Moore, 2008).
b. Anonymity and confidentiality
The anonymity is usually ensured by not disclosing names of participants and by utilizing a code system to identify them during data collection, management, analysis, and in the writing up of the research. The confidentiality of participants and data is ensured by using a code system to identify participants, and by storing all data in a locked cabinet and a password-protected computer for a specified period of time (Creswell, 2013).
c. Power relations in qualitative research settings
Power imbalance is caused by the fact that participants have the experience about the investigated phenomenon, and researchers need to obtain information about these experiences. The power imbalance is usually associated with interaction between the researcher and participants during recruitment stage, and during data collection, analysis, interpretation, and validation stages. Hence, researchers should take suitable measures at each stage to decrease the influence of possible power imbalance, and should enhance trust with participants (Karnieli-Miller et al., 2009; Yardley, 2000).

Mixed Methods in Pharmacy Practice Research

Research studies in pharmacy practice usually utilize single-method research designs. However, often these report numerous limitations and may not adequately answer the research question. Therefore, the combination of more than one research method to answer certain research questions has become increasingly common in pharmacy practice research (Ryan et al., 2015). Mixed methods research design is now a popular and widely used research paradigm in pharmacy practice research fields (Hadi et al., 2013, 2014; Hadi and Closs, 2016a, 2016b; Ryan et al., 2015). Mixed methods research allows the expansion of the scope of research to offset the weaknesses of using either quantitative or qualitative approach alone (Creswell et al., 2004; Hadi et al., 2013; Hadi and Closs, 2016a, 2016b; Pluye and Hong, 2014). Typically, qualitative and quantitative data are collected concurrently or sequentially in order to increase the validity and the comprehensiveness of the study findings (Creswell et al., 2004; Hadi et al., 2013; Hadi and Closs, 2016a, 2016b; Pluye and Hong, 2014; Ryan et al., 2015). The mixed method approach provides an expanded understanding of phenomenon under investigation through the comparison between qualitative and quantitative data (Hadi et al., 2013; Hadi and Closs, 2016a, 2016b; Pluye and Hong, 2014).

This section provides an overview and application of mixed method research in pharmacy practice. However, considerations in selecting, designing, and analyzing mixed methods research studies as well as the various typologies of mixed methods research are discussed elsewhere. Johnson et al. (2007) proposed the following definition for mixed methods research: "The type of research in which a researcher or team of researchers combines elements of qualitative and quantitative research approaches (e.g., use of qualitative and quantitative viewpoints, data collection, analysis, inference techniques) for the broad purpose of breadth and depth of understanding and corroboration."

Mixed methods design allows the viewpoints of participants to be reflected, enables methodological flexibility, and promotes multidisciplinary teamwork (Ryan et al., 2015). Furthermore, the approach allows a more holistic understanding of the research

question. However, its major limitations include: need for wide range of research expertise across the research team members, highly labor-intensive, and the complexity of data integration.

Scholars believe that it is challenging to provide researchers with a step-by-step guide on how to undertake a mixed methods study and that this is driven by the specific research question (Ryan et al., 2015). Nevertheless, the investigator should precisely determine the type of qualitative and quantitative methods to be employed, the order of data collection to be undertaken, the data collection instruments to be used, and the method of data analysis (Ryan et al., 2015). This approach encompasses a synthesis of findings from both quantitative and qualitative components, which is achieved through integration of the findings from each approach (Hadi et al., 2013; Hadi and Closs, 2016a, 2016b; Pluye and Hong, 2014).

Different models or typologies for mixed methods research have been described in the literature. The most common typologies used in pharmacy practice and health services research include: concurrent or convergent parallel design, exploratory sequential design, explanatory sequential design, and the embedded design (Hadi et al., 2013; Pluye and Hong, 2014). Scholars believe that there are several factors to consider when selecting the typology or model of mixed methods research to use. These factors include: the order of qualitative and quantitative data collection (concurrent vs. sequential); priority of data (i.e., which type of data has priority between quantitative and qualitative data); purpose of integration of the data (e.g., triangulation); and number of data strands (Hadi et al., 2013; Pluye and Hong, 2014). In mixed methods research, integration of qualitative and quantitative findings is critical, and this research approach does not simply involve the collection of these data (Ryan et al., 2015).

Summary and Take-Home Messages

- In the era of evidence-based practice, it is not sufficient to propose new pharmacy services or roles without evidence of their benefit.
- New pharmacy services and new roles must be proven to be feasible, acceptable, beneficial, and cost-effective.
- Practice-based research provides such evidence and can inform policy, confirm the value of the new service, and change practice.
- Various study designs, including, but not limited to experimental, quasi-experimental, observational, qualitative, and mixed-methods designs, have been used in pharmacy practice research.
- Pharmacy practice researchers need to be competent in the selection, design, application, and interpretation of these methodological and analytical approaches.
- The choice of any study design in pharmacy practice research is driven by the expertise of the investigator, type of research question or hypothesis, data availability, time orientation, ethical issues, and availability of funding.

Conclusion

There is a great demand for innovation and quality in pharmacy practice. These can be achieved partly through robust and well-designed pharmacy practice research. Pharmacy students, practitioners, educators, and policy-makers are exposed to a variety of research designs and methods. We need to have the best evidence (e.g., in policy, regulation, practice) for making decisions about the optimal research design that ensures delivering an ultimate pharmacy practice and a quality patient care.

Glossary

Pharmacy practice research The Canadian Pharmacists Association defines pharmacy practice research as a component of health services research that focuses on the assessment and evaluation of pharmacy practice (Koshman and Blais, 2011).
Quantitative research Is simply defined as "a research in which things are counted." These things might be people, medicines, opinions, behaviors, etc. "While qualitative research is very useful for describing phenomena in depth (particularly motivations, feelings, understandings), quantitative research can tell us how common and widespread the phenomena are" (Green and Norris, 2015).
Qualitative research Qualitative research within the health sciences has developed as a means to gather an in-depth understanding of human behavior, as well as to find the underlying reasons, attitudes, and motivations that govern such behavior (Kaae and Traulsen, 2015).
Mixed methods research A mixed methods research typically involves both the components of qualitative and quantitative research approaches embedded within a single study or research program for the broad purpose of breadth and depth of understanding and corroboration (Creswell et al., 2004; Johnson et al., 2007; Tashakkori and Creswell, 2007).
Observational studies Observational studies involve merely observing the study subjects in a noncontrolled setting, without investigator intervention or manipulating other aspects of the study in order to determine an association between an exposure and an outcome of interest.

Experimental studies In experimental design (also known as interventional design), the investigator performs an intervention and evaluates cause and effect relationships between exposure to the intervention and an outcome of interest (Cummings et al., 2013). Subjects are typically randomly assigned into experimental and control groups.

Quasi-experimental studies Quasi-experimental designs are studies that aim to evaluate interventions, but that do not use randomization and at times noncontrolled (Harris et al., 2006; Krass, 2016). Similar to true experimental studies, quasi-experiments aim to determine causality between an intervention and an outcome of interest.

Quantitative Methods in Pharmacy Practice Research

Rabia Hussain*, **Mohamed Azmi Hassali***, **Zaheer-Ud-Din Babar**†, *School of Pharmaceutical Sciences, Universiti Sains Malaysia, Penang, Malaysia; †Department of Pharmacy, University of Huddersfield, Queensgate, Huddersfield, United Kingdom

Background

Research methods are specific procedures, techniques, and strategies that can be employed to analyze and interpret data (Merriam, 2002; Bodgan and Biklen, 2007). The three research methods, that is, quantitative, qualitative, and mixed methods serve to a different set of epistemological and ontological perspectives (Morrison, 2000; Creswell and Creswell, 2017). The selection of a particular research method is based on its capability to provide answers to a specific research problem (Polit and Beck, 2008; LoBiondo-Wood et al., 2013). In quantitative research methods, a researcher designs a research framework, analyzes, and quantifies the relationship between the variables (Polit and Beck, 2004; Creswell and Clark, 2007).

Pharmacy and Research Methods

Pharmacy profession has experienced a significant progress in terms of health-care delivery. To play the role effectively, a pharmacist has to be well equipped with the knowledge and skills to evaluate quality and outcome of treatment; however, this can only be done by considering both qualitative and quantitative research techniques (Azhar et al., 2009).

But looking into the long history of quantitative methods, researchers, especially the pharmacists, are more familiar with the quantitative research than the qualitative research (Smith, 2010b). Quantitative research deals with the findings that can be observed and quantified by involving subject of interests. This also includes people and events to establish a relationship between variables by applying statistical techniques (Leedy, 1993; Couchman and Dawson, 1995).

In this paper, we will elaborate various quantitative methods that can be employed in pharmacy practice research.

Types of Quantitative Research Methods

Quantitative research methods employed in pharmacy practice include nonexperimental research and experimental research methods (Austin and Sutton, 2018) (**Fig. 1**).

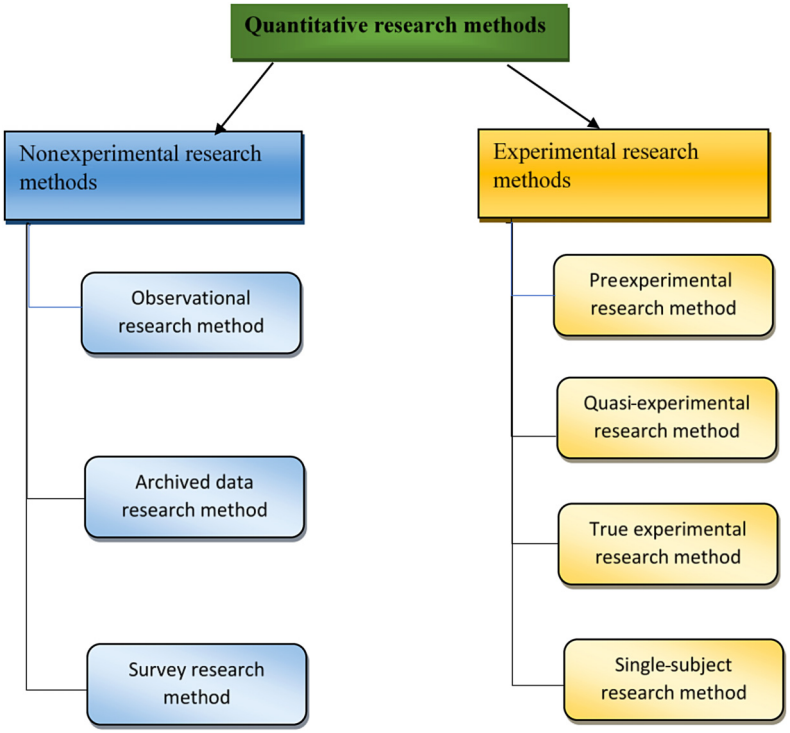

Figure 1 Quantitative research methods.

Nonexperimental Research Methods

Nonexperimental research or descriptive research method involves methodology that measures the variables in their true form without changing the study variables (Belli, 2009).

It is meant to describe a single or multivariables and a possible link between them. In this research method, researchers collect data to generate a hypothesis rather than other methods where a hypothesis is first generated and then tested. Nonexperimental research or descriptive research method selects subjects on the basis of the characteristics that meet the criteria to be included in a research study, for example, knowledge, attitudes, or health status (Dulock, 1993).

Nonexperimental research methods can be classified into the following three main categories (**Fig. 1**):

1. Observational research method
2. Archived data research method
3. Survey research method

Observational Research Method

In observational research method, a researcher observes subjects as samples and collects data for a certain period of time, but this is done without interacting with the environment they are living or working in; neither the researcher initiates any situation nor does the researcher manipulate any behavior (Smith, 1998; Austin and Sutton, 2018). In some cases, a researcher directly observes behaviors, attitude, practices, and events instead of depending upon the information provided by the participants, known as nonparticipant observation.

The researcher then analyzes the information to get numeric frequencies to establish a relationship between the observed data.

Sometimes, a researcher may visit a community pharmacy and act as a patient, observing and recording information for further analysis (Green and Norris, 2015). Madden et al. (1997) named these subjects as surrogate patients, mystery shoppers, or undercover care-seekers. In this scenario, the researcher directly observes and interprets findings, and relates and applies these to pharmacy practice setting.

Observational research method in pharmacy practice research also relies on the reported behavior and attitudes of people involved in a particular study setting (Green and Norris, 2015). Observational research methods are based on either nonparticipant observation or participant observation. However, for quantitative studies, we rely more on nonparticipant observation method where the researcher selects the site of the study and then designs a data collection tool. This method is used to explore, for instance,

services at a particular pharmacy by vising it to observe patient experience or visiting an outpatient clinic without involving the patients or healthcare providers. This technique may help in finding out more about experiences in a healthcare setting (Green et al., 2013; Austin and Sutton, 2018).

Limitations of Observational Research Method

In observational research, there is a little or no involvement from the participants, and things happen naturally in a flow, making the study more reliable.

Availability of resources can be a limitation in observation methods, as the researcher or an observer needs to travel and be present at the site of data collection. In this context, the study population and the study site could be an area of concern, especially in the settings when there are limited resources. The identity of study participants should be kept confidential in observational research, because otherwise, it may raise serious concern for the validity of the observational study (Smith, 1998).

Archived Data Research Method

Another nonexperimental method to collect data is by analyzing previously available datasets. This enables the researchers to analyze and interpret relationship between the variables of interest. Analysis of dataset is a popular method to look for possible research answers related to the use of medicines, medication safety, and rational prescribing (Green and Norris, 2015).

The following categories are described later.

Collecting Data from Administrative Datasets

Administrative datasets include information on prescribing or funding (Green and Norris, 2015). These can be available in the form of surveys, health insurance claims, electronic financial transactions for health insurance claims, computer-based patient records (CPRs), and disease registries (Lohr and Donaldson, 1994). Datasets also help in the prediction of trends. Sushmita et al. (2015) used machine learning algorithms to predict the cost of health care from data based on the public surveys and found a significant relationship between these variables.

Some administrative databases may have data on prescription medicine use, but normally they do not have data for nonprescription or over-the-counter medicines, as this happened in the case of over-the-counter sale of statins in the United Kingdom (Stewart et al., 2007).

In Canada medicines are funded on the basis of State policy; Ontario is the only state where elderly patients are fully covered by this scheme. Thus, most medicine use data and research outputs from Ontario are related to elderly population (Foster et al., 2013; Piszczek et al., 2014). This shows that the results based on a particular dataset or only on prescription medicine use may be biased, and thus it will be difficult to generalize the findings (Green and Norris, 2015).

Secondary Analysis of Primary Data

The already available data can be reanalyzed as some datasets may remain underanalyzed. Systematic reviews and meta-analysis are some examples of reanalysis of published and unpublished data, and this may help in finding the trends over rational medicine prescribing and medicine use (Green and Norris, 2015).

Survey Research Method

Survey research methods are widely used in health services research, and they employ standardized questionnaires to systematically collect data about a certain population regarding their attitudes, behaviors, and practices (Austin and Sutton, 2018). Survey research helps to describe the characteristics of a specific population and to present their opinion, attitudes, and practices (Creswell, 2005).

In pharmacy practice, these can be related to the assessment of beliefs, knowledge, attitudes, and experiences about medicine use, adherence, or other health-related topics both from patients and practitioners perspective (Green and Norris, 2015). To assess the perceptions of the general practitioners on access to medicines issues in New Zealand, Babar et al. (2015) conducted a questionnaire-based survey. The findings suggested that the GPs have the opinion that the medicines are sufficiently available to treat the conditions they saw in their daily practice. However, the majority of the GPs felt that New Zealand is slower to fund new medicines (Babar et al., 2015). Surveys are also used to assess services at the community pharmacies as shown in a survey-based study in Jordan (El-Dahiyat et al., 2019).

Survey is an excellent tool for the measurement of a wide-ranging population datasets, including traits, preferences, beliefs, and other information (Jones et al., 2013). This method is convenient and cost-effective as compared to experimental research or the case study research method (Mertler, 2016).

There are two main types of surveys: cross-sectional and longitudinal surveys.

A cross-sectional survey gives the evaluation of similar characteristics and differences among several samples of a population, and this is done at one point in time (Christensen et al., 2014c). Longitudinal survey involves the consideration of a single population during different times. This requires the administration of surveys at several points in time describing change, stability, or trends over a specified period of time (Dulock, 1993; Christensen et al., 2014c).

Method of Data Collection for Surveys

The use of questionnaire in data collection is a very useful tool. However, the results from the questionnaires can only be valid if they are constructed precisely and are consistent and clear. The method is cheap and quick, but the risk of bias cannot be ruled out in this method (Mathers et al., 2007; Austin and Sutton, 2018).

In postal surveys, the questionnaires are sent in hard copy to the targeted individuals requesting them to return the mail before a specified date. The process can be expensive, but the researcher gains access to a wider range of population. However, this also has some disadvantages, including the lack of encouragement in the absence of a face-to-face interaction resulting in a lower response rate (Christensen et al., 2014c; Austin and Sutton, 2018).

Telephone surveys are more expensive as they require individual administration to the participants. In these surveys, each survey question needs to be read by the researcher or the other supporting staff, requiring more time and resources (Christensen et al., 2014c; Austin and Sutton, 2018).

The technological advancement has led to the development of electronic surveys that are time- and cost-efficient (Mertler, 2002). Such surveys are delivered to the potential participants by sending them email messages or a link to the survey web page (Christensen et al., 2014c; Austin and Sutton, 2018).

Mentioned hereunder are the links for several websites that can be helpful in developing these surveys:

Kwik Surveys (www.kwiksurveys.com) (Kwik Surveys, 2019)
Question Pro (www.questionpro.com) (Question Pro, 2019)
So Go Survey (www.sogosurvey.com) (So Go Survey, 2019)
SurveyMonkey (www.surveymonkey.com) (Survey Monkey, 2019)

The limitations of this method include: filling the online survey, inactive email address of the participants, and failure to deliver email to multiple participants (Carbonaro and Bainbridge, 2000; Mertler, 2002).

Bias in Survey

There are several factors that contribute to bias in a survey methodology. The types of biases that can have an impact on the outcomes of the survey are discussed below (Bhattacherjee, 2012).

Sampling bias

Sampling bias is rampant in telephone surveys, where the respondents are selected and contacted from a random sample of publicly available telephone numbers. This systematically excludes people who do not have a mobile phone, landline numbers, or are unable to take the call when the survey is conducted. This also leads to disproportionate representation in the survey sample of—respondents with listed phone numbers; people who stay at home; elderly, disabled, or unemployed. Similarly, young people and students have more chances to be contacted through online surveys as they use technology and Internet more than other groups of population, thus systematically excluding people with no access to Internet.

In questionnaire surveys, there is a tendency to exclude uneducated and children as they are unable to read and write. Such bias in sampling compromises the generalizability of the results (Bhattacherjee, 2012).

Recall bias

Willingness to respond to a survey question is influenced by memory and motivation of the respondents as many survey questions draw from the past experiences (Green and Norris, 2015). It means that if a respondent cannot recall the information, the response would not be accurate. The problem of recall bias can be overcome by asking the respondents about the incidents rather than asking them about their emotions or behaviors (Bhattacherjee, 2012).

Social desirability bias

This bias arises when the respondents are asked about their views on negative opinions about their surroundings, thus making them uncomfortable to answer in a truthful manner. Many participants try to avoid responding to negative opinions or a question regarding their workplace, family, or friends.

In such situation, they usually try to spin the truth with not-so-true response as, otherwise, it may disturb their social desirability (Green and Norris, 2015).

These biases in a survey disturb the validity of the survey outcomes. The problem can be tackled by opting for an in-depth interview, as this can identify inconsistency in the answers (Bhattacherjee, 2012).

Experimental Research Methods

In experimental research methods, the researcher establishes different situations or treatments as variables and studies their effects on the participants (Hopkins, 2008). Researcher can control and manipulate variables and can study the cause and effect relationship for each variable (Christensen et al., 2014b). These are also known as intervention-based studies as they involve more than just observing the phenomenon (Hopkins, 2008).

The general requirements for the experimental research studies are as follows:

- A randomly selected or a randomly assigned group of participants to be included in a comparison group (which can either be an experimental group or a control group) except quasi-experimental design where the randomization of sample is not possible.
- An independent variable (a treatment, a cause, or an experiment variable) applied to the experimental group.
- A dependent variable commonly known as criterion variable (also known as posttest or effect variable) is identically measured in all groups in a study (Mertler, 2016).

Random selection of the study population and random assignment of these individuals to both experimental and control group are mandatory requirements for an experimental research method. This ultimately helps to maintain the equivalence between two groups, and also helps to control the factors that may interfere with the results of the study (Smith, 2010b).

Experimental research methods can be further categorized into the following four categories (Mertler, 2016) (**Fig. 1**):

1. Pre-experimental research method
2. Quasi-experimental research method
3. True experimental research method
4. Single-subject research method

Experimental methods can also be categorized into two main groups: single variable design and factorial design. Single variable design involves manipulation of one independent variable, whereas factorial design is comprised of two or more variables, in which at least one independent variable is manipulated (Mertler, 2016).

Pre-experimental Research Method

The method is called one-shot case study, and it is used to get the preliminary data regarding a problem. Preexperimental research method involves the inclusion of a single group of population that undergoes treatment and is also posttested. This research method does not control extraneous or unrelated variables; hence, it is not a preferred choice for a study research (Christensen et al., 2014b).

There is another type of preexperimental research method that is posttest only, that is, no pretest is done before exposure of treatment. Another method is pretest–posttest design, which is similar to the single group posttest design, but prior to the exposure of treatment, a pretest is done (Gay et al., 2009; Smith, 2010b). Pretest and posttest scores are evaluated to see if there is any change in the response. In this case, the researcher will be able to find out the difference in the response and its possible explanation (Smith, 2010b; Leedy and Ormrod, 2013).

Limitations

The method does not have any control over unrelated variables, hence making researcher unable to conclude definitive cause and effect relationship between variables (Leedy and Ormrod, 2013; Christensen et al., 2014b).

Quasi-experimental Research Method

Quasi-experimental research methods are considered as the closest form of true experiments, but they do not involve the random selection of the participants, and this ultimately weakens the ability to control extraneous factors (Christensen et al., 2014a). However, like other experimental research methods, quasi-experimental research seeks a causal relationship between an intervention and its outcome, and ultimately they provide further rationale for more exploratory trial involving robust research system (Krass, 2016).

Thus, in pharmacy practice, quasi-experimental method helps in the assessment of an intervention over a certain period of time. In a study at the University of Michigan Medical Center, it was observed that the medication-related discrepancies were resolved by the involvement of pharmacist in a hospital discharge program (Walker et al., 2009). Another pharmacist-led intervention study in six hospitals in Hawaii showed a significant reduction in the cost of hospitalization of elderly patients (Pellegrin et al., 2017).

Quasi-experimental research is a preferred choice in the cases where it is not feasible to randomize participants to a treatment or intervention group due to logistical or ethical reasons (Krass, 2016).

Limitations

The design is very useful in cases where random assignments of participants are not possible (Christensen et al., 2014a). However, the design lacks the random assignment of participants to the treatment groups. This ultimately results in an increased risk of bias in the study (Thompson and Panacek, 2006).

True Experimental Research Method

The method involves the random selection of participants to the assigned treatment conditions (Gay et al., 2009). In such design, participants are randomly assigned to the control and experimental group, and the study design is commonly known as randomized controlled trial. Such research design is a preferred choice in pharmacy practice research, and it helps in evaluating the impact of new health-care service or intervention (Smith, 2010b).

In control group, no active treatment is given or sometimes a standard value is used that does not affect the value of the independent variable. But, in an experimental group or a treatment group, participants receive a treatment or an intervention that can alter the value of an independent variable resulting in an impact or an effect (Christensen et al., 2014b). The involvement of at least one comparison group is an important feature in this study design (Mertler, 2016).

In a research method, where the participants are not aware of the identity of treatment or intervention is known as single blind controlled trial. In a double blind controlled trial, both researchers and participants have no information regarding who is receiving a treatment or an intervention (Hopkins, 2008; Christensen et al., 2014b). The randomization of participants helps to control the risk factors, which may emerge as a threat to the validity of data (Fraenkel et al., 2011).

Limitations

The major strength of a truly experimental research method is its ability to clearly draw a cause and effect relationship in a study. However, true experimental methods require stringent requirements to not risk the validity of the data (Mertler, 2016).

Single-Subject Research Method

Most of the experimental studies require group of participants, whereas in single-subject research design, the studies can be conducted on an individual case basis (Smith, 2010a). Single-subject research design is preferably used to study the time course, effect of a treatment, or an intervention on a single patient, and is mostly employed in primary care research-based studies (Janosky, 2005).

In the single-subject case studies, the outcome from dependent variables is measured and recorded for individual participants during different times and at different levels of intervention (Lobo et al., 2017). The performance of a subject is evaluated both in a nontreatment and treatment phase (Gay et al., 2009). The nontreatment phase can be regarded as phase A, while the treatment phase can be marked as phase B (Janosky, 2005). There are various types of single-subject design, one of which is called the A-B design. In single-subject research, initial measurement of variables (A) is taken, and then a treatment (B) is given to the subject and a change is observed to see the treatment effect (Janosky, 2005).

Another design is reverse design or commonly known as A-B-A (measurement-treatment-measurement). This design is comprised of baseline measurements (first phase) followed by treatment (second phase) and finally the removal or withdrawal of treatment (third phase). However, it is required that the researcher should accurately measure the behavior change before and after applying the treatment. This can be repeated many times (Hopkins, 2008). On the removal of the treatment, if condition reverses, it means that the treatment has some positive effect on the subject (Price et al., 2015). A study by Freeman et al. (2010) employed an A-B-A research method to determine the core stability training in eight patients with multiple sclerosis. The researcher maintained the baseline level for 4 weeks, followed by 8 weeks of intervention then was a withdrawal after 4 weeks resulting into patient's improved walking (Freeman et al., 2010).

Limitations

A major limitation of single-subject research method is that some interventions cannot be withdrawn or reversed (Mertler, 2016; Lobo et al., 2017). Also, this research design lacks the generalizability in terms of its outcome and is only focused to study the effectiveness of treatment on a single participant. This is effective to measure an impact and study behavior modifications in one single individual. However, a possibility of an alternative explanation for a certain behavior in an individual cannot be ruled out (Janosky, 2005; Mertler, 2016).

Validation of a Research Method

Validity of a research method refers to the value, truth, and originality one can place on the study findings. Validity of research is the degree to which one can say that the research outcomes are accurate and generalizable. Factors affecting internal and external validity should be controlled; otherwise, it may jeopardize the reliability of results and the conclusion of the study (Green and Norris, 2015; Mertler, 2016).

In order to measure the external validity of the quantitative research methods, it is important that the accurate data from the appropriate subjects must be collected in the right setting. The specifications of a target population must be clearly described, and the selected subjects must represent the population under study (Smith, 2010a; Austin and Sutton, 2018). The instruments used (equipment, questionnaires, or interviews that measure physiological or psychosocial variables) should be standardized. Before employing newly developed instruments into a research study, the same should be pilot tested (Dulock, 1993).

Conclusion

There are many different quantitative approaches, which give the freedom to the researcher to choose the appropriate methodology. However, it is important to understand that every design has it's own set of limitation, and this is vital to consider when choosing a research method in the pharmacy practice research.

Qualitative Methods in Pharmacy Practice Research

Helena Herrera, School of Pharmacy and Biomedical Sciences, University of Portsmouth, Portsmouth, UK

Introduction

Until recently, much of the health and pharmacy practice research undertaken focused on what were considered good rigorous practices, based on the measurement and collection of numerical data that would be able to quantify phenomena or test hypotheses (Smith, 2002). This was the result of the widespread acceptance of the scientific method as the cornerstone of science and the way by which reality could be appropriately researched (Crotty, 2003). The scientific method was built on the belief that measurement was at the center of discovery, and that the designing and execution of the right experiments or observations would lead to the advancement of knowledge (Popper, 1959/2002). This view of what would constitute good research has been increasingly challenged in recent times due to its limitations in arriving at understanding of many aspects of healthcare and the provision of services. This would be the case in studies involving human participants, who could be patients, professionals, students, educators, or other stakeholders, which need to deal with the subjectivity which is associated with human behavior (Bowling, 2014). As a result of this, it is now accepted that the world and society may not operate according to general laws, and therefore measurement may not always be possible, with the testing of hypotheses or the quantifying of variables being unable to provide complete answers to certain research questions (Robson and McCartan, 2015).

Qualitative research has presented itself as a practical solution to this problem, providing a whole new range of approaches to data analysis and methodologies for data collection that can enable the investigation of issues that could not be explored in such depth before (Patton, 2015). It has particularly succeeded on studying the perceptions of those involved in healthcare, also looking at experiences and the way that individuals and groups communicate and relate to the world, being also very useful in educational research (Austin and Sutton, 2018). This shift from focusing in measurement and prediction, to exploration and understanding can be considered to constitute a paradigm shift, affecting the way science is understood, with this no longer seen as objective and invariable (Kuhn, 1970). This is a very important point to consider for those engaging in qualitative research, which need to embrace that they will be managing more than one possible interpretation of reality, and questions which may be answered in more than one way (Denzin and Lincoln, 2017).

A range of research traditions within the qualitative paradigm have been proposed to exist in order to guide those navigating through all the possibilities that these approaches and methodologies can offer (Poth and Creswell, 2013). These have been named and categorized by authors in different ways, and can appear at times artificial and confusing (Tesh, 1990). In the following sections, key aspects to consider when undertaking and understanding this type of work have been presented without focusing on these

research traditions. This is with the purpose of avoiding confusion and helping investigators and practitioners gain the knowledge they would need to undertake, report, and critique these studies. For this reason, building on accepted terminology and classifications, this chapter would aim to prepare for *real world research* (Robson and McCartan, 2015), and for solving relevant problems in a way which is methodologically sound. On these lines it must be noted that it will focus on using qualitative data in ways which are consistent with the principles of qualitative research. Some of the approaches can be thought to be part of the quantitative rather than the qualitative paradigm, or sit in between, and they have been covered in this chapter as the results that they can arrive to can be very useful in qualitative pharmacy practice studies. It must be remembered that qualitative data is something different than nominal data; qualitative data involves information provided through the use of language on a phenomenon, while nominal data can be a value or variable which is expressed in words (Denzin and Lincoln, 2017).

There are many options to choose from when using qualitative methods in pharmacy practice research (Austin and Sutton, 2018). It is advisable to read this chapter in its entirety before using its content to inform any choices, as the subtle differences in these approaches and methodologies can sometimes only become apparent when comparing one another. The degree of interpretation and depth of analysis required by a specific study can be particularly difficult to judge by individuals with more limited experience in this field. It is therefore encouraged that familiarity with the whole qualitative paradigm is achieved before engaging in data collection and analysis, as this will ensure that rigorous practices continue to guide researchers in this area. For this purpose, understanding the different approaches to finding meanings in the data is essential, and should be achieved prior to making decisions with regard to how this data should be collected and handled.

Choosing an Appropriate Qualitative Method

The most important aspect of qualitative research and managing qualitative data is the central role which language plays to convey messages and provide meanings, which are shared by human participants, and after analysis will lead to answers to the research questions under investigation (Smith et al., 2009). The approach selected to finding meanings will therefore determine the results which will be obtained, and it is useful to consider analysis prior to making decisions about how the data will be collected (Silverman, 2016). For example, if further understanding was required on how patients make sense of being diagnosed with a terminal illness, meanings sought would be of greater depth than those involved in finding out what service users thought of having to pay car park charges when visiting a hospital. The following sections outline what aspects of the different approaches to finding meanings in the data need to be considered before choosing one based on the depth of analysis, degree of interpretation required, and the main implications of using these.

The first consideration to make when engaging on finding meanings in qualitative data would be whether descriptive or latent meanings are sought (Smith et al., 2009). This is the fundamental distinction between finding meanings by analyzing concepts and finding meanings by analyzing themes. A concept would represent an idea which is defined and described by the terminology used to relate to it, having a near literal meaning. In contrast, a theme would relate to a latent meaning found in the data after a process of interpretation, where language does not explicitly present an idea (Braun and Clarke, 2008). For example, when researching community pharmacists' role satisfaction, it could be possible to come across the following a statement from a participant in a group discussion: "Oh, yes, I like admin work." This data could include the concept "admin work," as it is explicitly quoted, and also the theme "dislike of admin work," depending on what was meant by the participant when making this statement.

The following sections explain this in more detail, providing an overview of the different approaches for finding meanings by analyzing concepts and themes, defining what these approaches are, when they would be most useful, and providing examples to illustrate how they can be applied.

Finding Meanings by Analyzing Concepts

As it has been explained before, approaches to finding meanings by analyzing concepts are not based on interpretation (Smith et al., 2009). However, it would be very difficult to argue that they do not involve some degree of subjectivity (Robson and McCartan, 2015). They aim to arrive at categorizations where there is no overlap, and in some cases, there is even a degree of quantifying taking place. When investigators aim to find meanings by analyzing concepts, the purpose is to arrive at results that could be accepted as some definitive answer to the research question (Hsiu-Fang and Shannon, 2005).

These approaches do not entirely belong within the qualitative paradigm, and are included in this chapter because they rely on qualitative data (Poth and Creswell, 2013). For some of these there are prescriptive ways of undertaking analysis, with others embedding a number of different practices (Poth and Creswell, 2013). Analyzing concepts enables researchers in pharmacy practice to ascertain, and sometimes quantify, key meanings, which is often done to inform policy and to make judgments with regard to health interventions (Smith, 2002). They can be very useful in providing specific answers to general problems, where there are larger amounts of data and limited depth in the analysis is required (Robson and McCartan, 2015).

When finding meanings by analyzing concepts, the process can be deductive or inductive, by which specific meaning are searched for in the data, or in contrast, emerge from it and are not anticipated (Silverman, 2016). For example, in a deductive approach to investigating factors that influence the choice of community pharmacy, the data may be searched for the presence of specific concepts which have been chosen prior to starting analysis (often by reviewing the literature or because these have been judged as important). These could be convenience, waiting times, services offered, and friendliness of the staff, with the analysis

focusing on whether these are present in the data and what importance participants attributed to them. In contrast, in an inductive approach, the process would involve to look for factors which emerge from the data, without any preconceptions on what these would be (Ritchie et al., 2013). As such, it could emerge that availability of parking spaces, allowing to pre-order prescriptions on-line or having a members of staff which speak additional languages are the factors present in a specific dataset. In this way, finding meanings by analyzing concepts would be useful to check interpretations, to some extent quantify and explain phenomena, and sometimes proposing hypothesis or theories for further testing (Austin and Sutton, 2018). While the more limited degree of interpretation that they require and the set steps prescribed for some of them may make them appear as more accessible and easier to use (Hsiu-Fang and Shannon, 2005), they require an amount of skills and experience which can be as large as those needed to effectively find meanings in the data by analyzing themes. They should therefore only be chosen when they would be best suited to answer the research question under investigation.

Content Analysis

Content analysis would be the most basic way of manipulating qualitative data, and is often concerned with how frequently a concept, or single unit of meaning (which could include more than one word), is present in the data. In content analysis, concepts are identified, categorized, and often counted (Hsiu-Fang and Shannon, 2005). For example, "teamwork" would be a concept often sought when undertaking analysis of job applications in order to identify, for the purpose of recruitment, what could suitable candidates for a role which involves working with others. Content analysis can be undertaken in any way which ensures that concepts are identified and grouped consistently under pertinent categories (Ritchie and Spencer, 1994). As per the example given, it can provide quicker answers to specific questions, but it is of limited used within pharmacy practice research, as there are other approaches which can deal with the greater complexities which are often present in this type of work (Smith, 2002). Sometimes authors have used the term content analysis to refer to thematic analysis (Braun and Clarke, 2008), and care must be exercised when accessing the literature, as both are very different approaches, which may be suitable in very different situations.

Framework Analysis

Framework analysis is a defined approach to finding meanings by analyzing concepts, which is carried out following set steps proposed by the authors (Ritchie and Spencer, 1994). In this approach, meanings are sought in order to construct a framework which provides an overall description of a phenomenon, dealing with a greater degree of complexity than content analysis, while looking at key concepts present in the data and how they relate to each other (Ritchie et al., 2013). For example, framework analysis could be very useful to study barriers and drivers affecting the success of a childhood obesity intervention implemented across a number of schools. Using framework analysis, concepts within the dataset can be indexed, and presented in a simple but effective model (Ritchie and Spencer, 1994). While it may not enable to investigate aspects in great deal of detail, or including additional meanings to those which are in the majority, it can be useful when answers are needed to specific questions within large datasets. Framework analysis is successfully used in policy making and larger scale studies involving qualitative data (Gale et al., 2013).

Delphi Technique

The Delphi technique involves a process by which the views of a group of individuals on a specific subject are gathered with the purpose of establishing what issues are important and determine a hierarchy of how these would relate to each other (Keeney and McKenna, 2010). This is done following steps which aim to arrive at consensus among the individuals in the group on the degree of importance of these different issues. It is a structured approach to arrive at which concepts are more pertinent to the research question under investigation. By arriving at those which are more representative, it would be expected that predictions could be made (Salkin, 2010). Delphi technique often involves a face-to-face data collection event where there are two rounds of questions, for which answers are provided, with these being ordered by the group and a hierarchy arrived at. All suggestions are then passed unedited and unattributed to all group members, who are asked to re-rank suggestions, drawing up a priority list from members' rankings (Skulmoski et al., 2007).

The Delphi technique can be useful when agreement is sought from a group of informants or experts on an aspect for which there is little or no evidence, there would be a variety of factors to consider, and it is necessary to narrow these down to those which would be most important (Skulmoski et al., 2007). For example, in order to identify which would be the attributes which define professionalism in practicing pharmacists in order to inform the development of a suitable education and training initiative, this could be a useful approach.

Grounded Theory

Grounded theory is a well-defined and prescriptive approach to finding meanings in qualitative data where a theory is constructed at the end of the process (Poth and Creswell, 2013). Grounded theory can be useful in large datasets when the purpose is to arrive at a model which would aim to describe and explain relationships within the phenomenon under investigation (Bowling, 2014). This approach could sit well within the quantitative paradigm if it were not based on the analysis of qualitative data. It follows a set of defined steps with the purpose of standardizing the analysis and avoiding the need for interpretation. The two main approaches to undertaking grounded theory (Glaser and Strauss, 1967; Strauss and Corbin, 1997) are covered in a different chapter of this book.

Finding Meanings by Analyzing Themes

In contrast to those included in the previous sections, approaches for finding meanings by analyzing themes are based on varying degrees of interpretation (Braun and Clarke, 2008). Their way of manipulating data leads to categories that overlap, and no quantifying takes place, nor becomes necessary. In these, interpretation is aimed for and put at the center of analysis (Smith et al., 2009). These approaches enable qualitative data to be fully understood and analyzed following the fundamental principles which guide the qualitative paradigm. When finding meanings by analyzing themes, there is no single prescribed way of how analysis should happen, with authors making suggesting rather than proposing set methodologies or steps (Robson and McCartan, 2015). Analyzing themes enables researchers in pharmacy practice to ascertain, sometimes unveil, but never quantify, meanings within the data which can often be hidden. These are used to understand how individuals perceive service provision or a certain aspect of reality (Smith, 2002). They can be very powerful in providing insights and answers to research questions which involve personal views and accounts, experiences, and how these are felt by those being researched (Crotty, 2003).

Approaches to finding meanings by analyzing themes are language centered, but they are also concerned with the context in which the language frames meanings (Polgar and Thomas, 2013). They see this as a tool for communication, not merely for the transmission of information, and these approaches are built on the assumption that how things are talked about matters, in addition to what it is said (Smith et al., 2009). Researchers must be careful therefore when using these approaches to avoiding fragmenting the phenomena being study, and ensure that there is clarity with regard to how themes have been developed to ensure transparency and rigor of the practices followed. When finding meanings by analyzing themes, the approach should always be inductive, by which themes emerge from the data, rather than investigators looking for the presence or frequencies of certain themes (Patton, 2015). In this way, these approaches would be useful for studies which aim to build interpretations, explain phenomena, and sometimes propose hypothesis for further testing (Smith, 2012).

Thematic Analysis

Thematic analysis would be a versatile approach to finding meanings in qualitative data for pharmacy practice and health research in general (Bowling, 2014). This is due to its flexibility, lack of assumptions on what constitutes knowledge, and its ability to provide ways to find meanings which allow a degree of interpretation that can be adapted to the nature of the research question and the aims of the study. It focuses on finding patterns of commonality, which are not always obvious in the data, and for which clear practical ways have been proposed (Braun and Clarke, 2008). Thematic analysis is undertaken by facilitating that themes emerge from the data, rather than being imposed by looking for specific concepts. In order for this to happen, research questions are left deliberately loose, and a process of induction and iteration, by which researchers go through a dataset many times, is used until meanings are found (Patton, 2015).

Thematic analysis would be best suited for real life problems which require an investigation which does not need to be entirely focused at the outset, is able to deal with complexities and individuality on how a situation is perceived, while aiming to gather common themes that can illustrate key aspects of a phenomenon (Braun and Clarke, 2008). For example, it can be very useful at assessing views on services or educational interventions, where there is limited knowledge about what are the perceptions of the relevant stakeholders.

Discourse Analysis

Discourse analysis is concerned with looking at the ways that things are talked about. It aims to reveal socio-psychological aspects that intentionally or accidentally are hidden in language (Robson and McCartan, 2015). It is similar to thematic analysis, but can be considered to have added layers of interpretation. This is because discourse analysis builds on the assumption that individuals talk about things choosing certain language which on itself frames reality and would add to the meaning of the message that it gives. It aims to reveal characteristics beyond looking at a text structure and meaning (Hodges et al., 2008).

Discourse analysis can be useful to gather meanings on aspects where the choice of language is as important as the choice of content, and when there are potential relationships of power between stakeholders and non-explicit agendas guiding communication (Ritchie et al., 2013). For example, it could be useful to study the nature of discussions between pharmacists and patients about their non-adherence to prescribed medication.

Interpretive Phenomenological Analysis

Interpretive phenomenological analysis (IPA) is a very in-depth approach to finding meanings by analyzing themes, where data analysis is centered on aspects of a *lived experience*. It has been relatively recently introduced in the social sciences (Smith et al., 2009), and is being used in patient-centered healthcare research due to its powerful ways of helping to understand how an individual perceive and make sense of health and care. IPA studies involve a very close examination of the accounts of a small number of participants. This is so in order to obtain the richest meanings in the data through a thorough and complex analysis. More advanced IPA study designs may include participants which provide different perspectives of the same lived experience as a result of belonging to different groups (for example, patients and people who care for these) or they may follow these for some length of time (Brocki and Wearden, 2006).

IPA requires an insightful and skillful interpretation through a process of reflection, where researchers must make sense of how participants make sense of the lived experience under research in a process of double hermeneutic analysis (Smith, Flowers and Larkin, 2009). It would therefore be suitable for studies for which very little is known, which need to deal with the complex aspects of

interpreting human nature and human experience (Silverman, 2016). For example, it would be very useful in order to understand the experience of caring for a terminally ill patient at home, or processes such as how transgender patients' experiences in their journey through care.

Collecting Qualitative Data and Reporting Results

The previous section has described how to find meanings in qualitative data in order to provide answers to research questions which are relevant to pharmacy practice. It is necessary to understand how analysis is going to take place within an investigation in order to make decisions about how to collect and manage the data (King and Horrocks, 2010). This section provides guidance on how to do so, covering sampling and recruitment, and including specific aspects to consider with regard to ethical issues and reporting results in these types of studies.

While some of the approaches for finding meanings would be incompatible with some of the methods for gathering data, for example, Delphi technique would be incompatible with reflective diaries, when the practicalities enable the collection of the data needed to be done by a specific method, investigators can decide how to pair the approach to analysis with the method for data collection (Polgar and Thomas, 2013). There will be occasions where data can be obtained using more than one method, but in others there may be one which is more adequate to arrive at meanings of type sought (Austin and Sutton, 2018). The aim at all times should be to obtain data which is of the most possible quality, as any compromises made here will have an impact on the study; analyzing data which has not been collected well is much more difficult to do, as its focus can easily deviate from what was the original research question set for investigation (Bowling, 2014).

Sampling and Recruitment of Participants

Sampling of participants in qualitative research is different than that in other types of enquiry, as it allows the intentional selection of specific individuals by virtue of the investigators deciding that they present a specific characteristic or characteristics which makes their inclusion in the study adequate. This is generally done through purposive sampling, where the sample frame includes potential participants which are chosen for a reason, rather than these being selected at random (Patton, 2015). For example, in a study looking at the transition into higher education of pharmacy students which have undertaken their previous education in a country other than where they register to complete their pharmacy degree, the selection of students within a course at random would not be appropriate. Those individuals which are suitable can be identified as having the characteristics sought after and subsequently invited to take part in the study. In those occasions where the characteristic which is sought in individuals to be included in the study is rare, or there is no sampling frame available, snowball sampling can be of used (Salkin, 2010). In this, potential participants and those taking part in the investigation are asked to identify further participants, which can subsequently be invited. The use of purposive or snowball sampling should not be seen as a limitation of the study, as if this is done well, it will increase richness in the data being collected and lead to more meaningful and complete results (Denzin and Lincoln, 2017).

In terms of recruitment for studies which involve the collection of qualitative data, this is often driven by the practicalities of sampling participants. It could be the case that the entirety of a group available with the specific feature or involvement in the phenomenon under research is invited, for example, having being subject to an intervention or experience an innovative service or educational program (Smith, 2002). When there are potentially large numbers of individuals for which this may be the case, accessing previous literature can be very useful to identify how purposive sampling could better take place (Austin and Sutton, 2018). Alternatively, additional practicalities for accessing participants can be used to inform recruitment strategies, always remembering that gathering quality data rather than convenience should be guiding sampling and recruitment. It must be noted that, particularly in approaches to finding meanings by analyzing concepts, sometimes sampling and recruitment of participants is not necessary, as there may be suitable secondary data already available for analysis (Ando et al., 2014).

Gathering and Preparing Qualitative Data

As in any investigation, the process of gathering and preparing data is central to qualitative research. However, unlike in other designs, in this case data collection is often an iterative process which is informed by data analysis, with results obtained feeding into how further data collection is undertaken (Braun and Clarke, 2008). This process can be flexible and allows to aim for investigating issues which may have not been anticipated but rather emerge from the data. As a result of this, piloting data collection tools is not undertaken in the same way as it would be if following a quantitative design, as it is possible to refocus how the data is collected as part of the process of gathering it (Ando et al., 2014). For example, when researching patients' health choices within individuals of a certain ethnicity, there may be a specific aspect which features as more important to some participants, which is in tension with which the literature shows to be the case for other groups, and therefore worth investigating. Once this is identified, subsequent participants can be asked widely about their choices, but also more specifically about this emerging theme. When sampling and recruiting participants to a study, it is important to consider any ethical issues that can be encountered, as there may be instances where sensitive or confidential information is involved in an investigation, or data which relates to patients and their care (Wingfield and Badcott, 2007). Ethical issues are covered in a further section of this chapter, where their implications and how to avoid key issues are explained.

Generally, qualitative research data in pharmacy practice will be obtained from documents, observations, or discussions, by being written, observed, or shared (Smith, 2002). Irrespectively of how this data is gathered, it will generally be presented or prepared as a written text which will subsequently be analyzed, either by finding concepts or themes which are present. This is not to say that data could not be accessed in other prepared formats, such as audio-recordings or pictures, which although much less common, may suit certain investigations (Austin and Sutton, 2018). The following sections will outline key practical considerations when gathering and preparing qualitative data depending on how this is obtained, in order to ensure that key aspects are not overlooked.

Collecting Data Which Is Observed

The collection of data which is observed, or participant observation, is a method widely used in other disciplines, such as psychology, in order to research behavior (Patton, 2015). In pharmacy practice it can be useful to explore how processes are undertaken and in which ways these could become more efficient, to identify learning needs and to investigate aspects of service provision which are overlooked by those involved with it. Participant observation can encounter challenges in ensuring that it is carried out with the consent of all of those which would be involved and in a way that is still able to capture real practices and behaviors, not influenced by the presence of the investigators (DeWalt, 2001). This method has great potential of growth within pharmacy practice, although currently it still encounters barriers as a result of the need to deal with issues of confidentiality, rigor of the observation and any bias introduced by the presence of the investigators (Bryman, 2015).

Data which is observed is generally collected through field notes, data collection forms or audit tools aiming to capture the aspects of reality that are being investigated (Polgar and Thomas, 2013). In any case, researchers need to be vigilant to identify conducts and trends relevant to the research question. Unlike the gathering of data by other means, participant observation often relies on collecting data in a process as it happens in real time, with no opportunity to go back to the phenomenon to check or expand on incomplete information. There may be situations where it could be possible to video-record the process which is being investigated, although when this is the case, the potential for more complete data which can be revisited at a later data may be over outweighed by the introduction of additional bias as a result of participants changing their behavior due to not only being observed, but also recorded (DeWalt, 2001).

Participant observation can be very useful in educational research, when the aim is to look at how students learn or apply some learning (Austin and Sutton, 2018). For example, it would be a good choice in order to collect data to look at inter-professional working involving students of different disciplines, and how they relate to each other when undertaking practical work.

Collecting Data Which Is Written

As mentioned earlier in this section, most of the qualitative research undertaken in pharmacy practice leads to a dataset which is converted into a written text (Smith, 2002). This section will cover the collection of data which is originated in a written format, rather than gathered in a different way to then be prepared as a written text. Written texts of any type can be subject to qualitative data analysis, and what types of texts may be suitable, if at all, to answer a research question will depend on what the question is and what meanings are sought in the data (Bryman, 2015). As explained in the previous sections, the information that could be found in written texts could be explicit, and often documents are used in this way to find meanings by analyzing concepts (Hsiu-Fang and Shannon, 2005). In some cases, investigators may be looking for information within the data of certain texts which is not explicit, in which case it would be useful to look for meanings by analyzing themes (Ryan and Bernard, 2003). For example, discourse analysis could be undertaken on written information provided to the general public on a certain aspect of healthcare, looking at how language constructs aim to influence healthcare behaviors as part of the promotion of public health.

There are two types of texts which can be particularly useful in health research: documents and reflective journals (Bowling, 2014). Documents which can be subject to analysis would include written processes, policies, lay literature, and medical documents. Reflective diaries offer an additional and powerful tool for collecting data which is written, and unlike documents constructed for a different purpose, reflective diaries are often designed and set up for gathering data to describe a specific experience (Robson and McCartan, 2015). They can be very useful to enable participants to develop a view on a particular aspect over time, or make sense of a change of identity, and they can be paper based or undertaken on-line. Reflective diaries require participants to be able to articulate their thoughts and reflections in writing, and are well suited for educational research (Polgar and Thomas, 2013).

Collecting Data Which Is Shared

The collection of data which is shared by participants can be considered the most common way of gathering qualitative data for pharmacy practice research. This is the case as this enables a focused investigation, where researchers remain in some control over participants' contributions, while allowing the necessary flexibility to follow ideas which were not anticipated but are relevant to the research question (Austin and Sutton, 2018). There are two main ways of collecting data which is shared by participants: one-to-one and group interviews, with the latter also being called focus groups (Bloor et al., 2000).

One-to-one interviews are very popular in qualitative research in general, as they would suit most investigations to some extent, the practicalities involved in carrying these out being less than those involved in other ways of collecting data, and they also perceived as being less intrusive than other methods such as participant observation (King and Horrocks, 2010). They enable the gathering of relevant data in great deal of depth, considering individualities and issues which are important for the specific participant from which the data is gathered (Robson and McCartan, 2015). In pharmacy practice research, one-to-one interviews

will generally be semi-structured, following an interview guide with set open questions which may also include scenarios or pictures to facilitate discussion (Smith, 2002). This interview schedule is designed to be used flexibly, and the questions that it contains often become more focused as the interview progresses in order to gather more general thoughts first, to then narrow these down to those aspects which are more closely related to the investigation (Austin and Sutton, 2018). In some cases, one-to-one interviews can go into more depth looking at life stories and including un-structured descriptions and accounts of life events (Smith et al., 2009). These are less used within pharmacy practice research, although they can lead to very powerful interpretations of specific aspects that can be presented as case studies. One-to-one interviews as always better carried out face-to-face, and this way of communication would almost inevitably lead to richer data. However, it would sometimes be adequate or necessary to undertake one-to-one interviews by telephone or video-conference, in which case practical aspects such as privacy and ensuring matters discussed are sufficiently covered should be considered to minimize any potential impact of the lack of face-to-face contact (Robson and McCartan, 2015).

Group interviews, or focus groups, are another way of collecting data which is shared by participants and are increasingly popular in pharmacy practice and healthcare research (Barbour, 2018). Group interviews generally involve 6–8 participants discussing a topic following an interview schedule with the direction of a moderator. While they do not provide the opportunity to arrive at the depth of exploration that one-to-one interviews may do, they allow for issues to be discussed as a group, and the different perspectives of the different people to be explored and developed (Polgar and Thomas, 2013). Group interviews can include individuals with similar or different backgrounds and a variety of stakeholders that can be similarly or differently affected by the issue under investigation, depending on the focus of the study. They can be very useful in research questions that look at processes or services which involve different stakeholders, and discussions where a range of perspectives can be beneficial (Smith, 2002). As many services and educational experiences are provided in this way, the use of group discussions would be very suitable to research these, as they would enable inclusion of different types of individuals that would be affected by the experience or phenomenon being researched. While group discussions are generally guided by a semi-structured interview schedule, they can also be based around the discussion of scenarios in the same way as one-to-one interviews (Krueger and Casey, 2014).

Both in the case of one-to-one and group interviews, the content of these discussions is generally audio recorded with permission from the participants (King and Horrocks, 2010). These recordings are transcribed verbatim to arrive at a written account which contains the narrative produced on the discussion. The process of transcribing the content of one-to-one or group interviews is very time consuming, but facilitates data analysis enormously as it enables easy access to the entirety of the dataset, assisting in the complex process of finding meanings (Barbour, 2018).

Ethical Issues

Qualitative research in pharmacy practice will inevitable involve human participants or data which relates to some aspect of human behavior. Even in situations where there are no specific individuals associated with information or data, for example, in some forms of documentary analysis, how the research may impact on research participants, researchers and society, is very important (Wiles, 2012). The two key aspects to consider to ensure that qualitative research is undertaken ethically mirror those involved in professional practice. These are confidentiality and consent (Wingfield and Badcott, 2007), which are very closely linked to each other. They are particularly relevant as this type of research can easily involve sensitive issues, vulnerable participants, and data which have been shared under certain assumptions (Austin and Sutton, 2018).

Qualitative research data is generally anonymized very early on in the analysis, if it included any participants' details, and while information can sometimes be held that can lead to linking specific meanings to a named person, this is not normally accessed and can be easily kept secure (King and Horrocks, 2010). Research participants may have agreed for the data they have provided and the information that enable linking it to individuals to be kept for a lengthy period of time, and even to be re-analyzed or contrasted with data from future studies (Wiles, 2012). However, there are two specific circumstances where care must be exercised. Firstly, when reporting this data, as while specific meanings may not be attributed to individual participants, it would be impossible to ensure that, due to its context or other details provided, a participant could not ultimately be identified (Smith, 2002). Another instance which can compromise anonymity is the collection of data through group discussions, where despite that it could be requested that all the participants keep the contents of any discussion private, there is no way to warrantee that this will be the case (Bowling, 2014).

An additional consideration would particularly apply to approaches for finding meanings by analyzing themes. In the more interpretive forms of this, there could be very powerful processes where individuals are making sense of reality, with meanings emerging during the research process which were not anticipated by investigators or participants (Smith et al., 2009). While constructing and sharing these meanings, participants may become aware of interpretations of their own reality which they did not have before (Crotty, 2003). This may mean that, for example, that an interview on a topic which could present itself as being relatively safe to discuss, can bring up unanticipated and sensitive issues. At the same time, investigators may find that very personal views and experiences are shared with them, which could have an effect on how they relate to the person being researched. It is therefore important that participants and investigators understand completely what is involved in a study, have time to reflect and understand this information, and in the case of those being researched, feel that they can withdraw participation at any time (Wiles, 2012). Provided that all the aspects described here with regard to confidentiality are adequately explained to participants, consent needs to extend as well to ensure that they understand practicalities, who is undertaking the study, how is funded, and ensuring that participants do not feel pressured to take part (Salkin, 2010).

Reporting and Writing up Results

Qualitative research in pharmacy practice can be undertaken for a variety of purposes, and while its design and results will have to be reported, this may be done differently depending on the nature of the research question, the approach to analysis and the type of data collected in the project (Silverman, 2016). Studies that aim to find meanings by analyzing concepts may follow prescriptive ways for presenting results provided by the authors, or arrive at a specific output at the end of the research process such as a framework or a theory (Glaser and Strauss, 1967; Ritchie and Spencer, 1994). Those where meanings are found by analyzing themes often combine results and discussion, to construct a narrative which tells a story and describes, explains and illustrates with relevant quotes from the participants, the given interpretation of the phenomenon under research (Smith, 2002). This section would focus on the reporting of these types of studies.

In the more interpretive types of research, where meanings are found by analyzing themes, difficulties can be encountered in constructing the narrative which will present the results and in making judgments with regard to how the story that this narrative provides should be told (Patton, 2015); researchers may unnecessarily be trying to arrive at a final interpretation, when this is conceptually unnecessary (Smith et al., 2009). The narrative presenting the results, and the quotes which are chosen to illustrate these, should be driven by the research question and what it is trying to answer, rather than how frequently a theme appears in the data and other similar measures which belong to the quantitative paradigm (Braun and Clarke, 2008). In this way, it is arriving at a useful and informative story what researchers should strive to do. While quotes can be perceived to provide validity checks of the researcher interpretation, they should instead enrich and illustrate this, building on the assumption that, if the analysis has been performed well, this interpretation truly describes aspects of the phenomenon under investigation (Robson and McCartan, 2015). When providing the quotes, these can be introduced with the participant number, transcript number, or similar, so there is an element of context provided within this story.

Any report from a pharmacy practice study involving qualitative data, as with any type of research, should contain an overview of previous literature (Smith, 2002). This will include not only that which is relevant to provide an introduction to what is being investigated, but also some background which relates to how this was researched and the characteristics of what was studied that led to the use of the selected approach to finding meanings and method for gathering data (Ritchie et al., 2013). For example, in a study looking at organizational factors affecting pharmacists' role satisfaction within a big pharmacy chain, previous literature would show that the phenomenon can be complex enough to need meanings to be sought by analyzing themes. The fact that pharmacists often work in isolation from each other, staff members work under their supervision and most organizational factors are under the control of their line managers need to be provided as a context to show that the investigation would better involve one-to-one rather than group interviews. After providing a clear account of what previous literature exists on the subject and any relevant context that informs the reader of background to the methods selected, the methodology followed to undertake the study will have to be reported with great deal of clarity, to demonstrate that this has been rigorous and the gathering, preparation, and analysis of the data are robust and trustworthy (Robson and McCartan, 2015). While in some types of studies it would not be appropriate to claim that there is a unique interpretation of what is being researched, it is always necessary to be transparent on how the given interpretation has been arrived at (Braun and Clarke, 2008). Otherwise the research runs the risk of being considered under-developed and with limited credibility on the results that it has arrived at. Particular attention will have to be paid to report how the meanings have been found, and if a tradition has been followed, whether any modifications to the way that is described by the authors has taken place, referencing these appropriately (Robson and McCartan, 2015).

Writing up a study involving qualitative research data can be a much lengthier process than initially anticipated, as further refining of the results arrived at can take place as part of the writing process. Researchers involved in reporting these type of studies are encouraged to start writing up results at the nearest opportunity, as this can take as long as the very time consuming process of finding meanings in the data (Salkin, 2010).

Final Considerations and Steps to Go Further

Investigators have been concerned with obtaining knowledge and what is its nature since research began to shape the way that we find out more about the world (Bowling, 2014). As explained at the beginning of this chapter, in the scientific method, which underpins quantitative research, knowledge can be considered to be factual, unique, and accessible (Popper, 1959/2002). In contrast, the qualitative paradigm is built on the assumption that knowledge is socially constructed, and only real as beliefs in individuals, with a changing nature and no longer valid by the time is identified (Patton, 2015). These two paradigms do not have to be in tension, nor the approaches described here or the traditions defined by other authors (Poth and Creswell, 2013). Researchers need to make methodological choices that suit the investigations they are undertaking and to be responsive to what it is being researched. A pluralistic approach, where barriers are limited and enquiry is led by the need to provide practical solutions to real world problems, rather than underlying assumptions about the world and knowledge could be favored (Frost et al., 2010). More experienced researchers can even go further to undertake dual analysis, looking at the same data from different perspectives, finding meanings by analyzing concepts, themes or both in different ways in order to maximize what it can tell about what it is investigated (Ryan and Bernard, 2003). The webpages included in the list of relevant websites at the end of this chapter provide more in-depth explanations, examples, and aspects to reflect on which can guide researchers wanting to further their expertise on this field. For this purpose, it can also be useful to revisit previous sections of this chapter that can

provide additional useful information on a second read, once further development of understanding of these approaches and techniques has taken place.

In the same way that early generations of researchers pushed the boundaries of accepted practices by using innovative techniques (Paley and Lilford, 2011), those starting to look at questions for which no easy methodological choices exist should continue to make this field to evolve. In this respect, some terms such as data saturation, triangulation, and mixed-methods are in decreased use, as a result of further understanding of what these methodologies are about (Teddlie and Tashakkori, 2008). Research in pharmacy practice should be guided by the needs of patients, practitioners, and service provision, and change to ensure it is able to provide answers to questions to better meet these needs.

Glossary

Analysis: Process by which research data is manipulated in order to present it in a way that makes the results more accessible to the reader.
Concept: A unit of meaning which contains an idea which is defined and described by the terminology used to relate to it, having a near literal meaning.
Data saturation: The arrival at a point in the research process where the collection of additional qualitative data to answer a specific research question is thought to no longer arrive at finding additional meanings.
Deduction: Process by which pre-specified meanings are sought in research data.
Epistemology: The branch of philosophy which studies the nature of knowledge.
Framework: An ordered presentation of results which has some structure. It aims to provide some explanation of a phenomenon but is less developed than a theory.
Hermeneutics: Method for understanding aspects of a phenomenon based on interpreting how these are perceived by individuals who relate to them closely, generally by having experienced them.
Induction: Process by which meanings emerge from research data, without being pre-specified or anticipated.
Iteration: The recurrent process of looking at meanings to frame understanding of a phenomenon, which will then determine the way by which further meanings continue to be sought.
Meanings: In the context of this chapter, meanings are concepts and themes, both of which are understood as aspects of a phenomenon.
Nominal data: Data which relates to properties, which can provide a measure of an attribute without including any numerical values.
Paradigm: A model, which could be based on beliefs about the world and what is knowledge, which underpins explanations about reality, and how this can be studied.
Phenomenon: An occurrence that can be observed and researched. This is often what a research question in qualitative research aims to describe.
Phenomenology: The philosophical study of the structures of experience and consciousness.
Philosophy: The study of the fundamental problems concerning existence, knowledge, values, reason, mind, and language.
Research tradition: An accepted overarching and distinct set of assumptions about the world and knowledge, and how this would be best understood and researched.
Scientific method: An approach to investigation based on measurement and the collection of data to test pre-formulated hypotheses and build theories.
Theme: An idea which has been extracted from a latent meaning found in data after a process of interpretation, and which has not been explicitly shared by research participants.
Theory: An ordered and structured presentation of results which aims to explain phenomena. A theory would be further developed than a framework.
Triangulation: The use of one or more methods of data collection with the purpose of corroborating or arriving to a more complete description of a phenomenon.

Meta-Synthesis of Qualitative Research in Pharmacy Practice

Fatima Tauqeer*, Zikria Saleem†, Zaheer-Ud-Din Babar‡, *Institute of Health and Society, University of Oslo, Oslo, Norway; †University College of Pharmacy, University of the Punjab, Lahore, Pakistan; ‡University of Huddersfield, Huddersfield, United Kingdom

Introduction

Qualitative research in health care is a relatively new phenomenon and has gained a lot of attention in the past two decades (Shuval et al., 2011). It intends to synthesize views, experiences, behaviors, and opinions of a wide variety of pharmacy-oriented stakeholders, which may include pharmacists, patients, and other health-care providers (Tonna and Edwards, 2013). It provides a valuable snapshot on why people do what they do and focuses on extracting underlying reasons, factors, and attitudes in doing so (Austin and Sutton, 2014; Yin, 2016). A variety of methods to conduct a qualitative study in pharmacy practice have been adopted such as interviews, focus group discussions, participant observations, contextual inquiry, and document analysis (Kaae and Traulsen, 2015; Tonna and Edwards, 2013). The study sample is chosen in such a way as to bring out distinctive experiences and opinions, which may or may not include a general pattern or theme (Yin, 2016). The syntheses of a number of qualitative studies generate new evidence-based knowledge for potential use in pharmacy practice and health-related policy formation (Tong et al., 2012).

What Is Meta-Synthesis of Qualitative Research?

Much like a systematic review, a systematic approach to identify, sum up, and synthesise novel knowledge from multiple qualitative studies on a chosen topic of interest is called meta-synthesis (Barnett-Page and Thomas, 2009). According to Walsh and Down, it is a process that assembles findings from a collection of different yet interconnected qualitative studies with an "interpretive, rather than aggregating, intent" (Walsh and Downe, 2005) and as Margarete Sandelowski describes, "are more than the sum of parts, in that they offer novel interpretations of findings" (Thorne et al., 2004). The process uses a systematic style to infer readily accessible and understandable themes from studies about the topic of inquiry, to enable knowledge development (Barnett-Page and Thomas, 2009; Thorne et al., 2004).

The process of meta-synthesis goes one step ahead of systematic literature review and traditional narrative review (Britten et al., 2002). It involves translation and comparison of interpretations gathered from the selected studies into one another to synthesise new knowledge and possibly to introduce "conceptual innovation." This conceptual development through systematic charting of the concepts extracted from the available data distinguishes meta-synthesis from other methods of literature review (Britten et al., 2002). It enhances the power of available qualitative data by generating theories that can be further explored and investigated (Britten et al., 2002; Sandelowski, 2007). However, the analysis and interpretations, otherwise known as third-order interpretations, depends mainly on the "judgment and insights of the reviewers" (Noblit and Hare, 1988; Thomas and Harden, 2008). Hence, an interdisciplinary team can further improve the quality of a meta-synthesis (Lachal et al., 2017).

Several scholars have illustrated the process of meta-synthesis. Thorne explains meta-synthesis as a process that,

> "demands exploitation of variations and complexities within the data set toward an integrative conclusion that extends beyond the scope of what would have been achievable within the temporal, spatial, or epistemological confines of individual studies or programs of research" (Thorne, 2008).

Barroso explains it as a method that "refers to both an interpretive product and the analytic processes, by which the findings of studies are aggregated, integrated, summarized, or otherwise put together" (Julie et al., 2003). Meta-synthesis is an umbrella term and has been used interchangeably with meta-ethnography and qualitative meta-analysis many times (Finfgeld, 2003).

A classic explanation of meta-synthesis by Schreiber states,

> "it is the bringing together and breaking down of findings, examining them, discovering the essential features, and, in some way, combining phenomena into a transformed whole" (Schreiber et al., 1997).

Types of Meta-Synthesis

There is no definite rule to perform meta-synthesis. It can be done in a number of different ways, and each technique has a name as proposed by Schreiber (Schreiber et al., 1997) and explained by Finfgeld (Finfgeld, 2003). These approaches overlap in many instances and can go hand in hand (Finfgeld-Connett, 2010). A brief description of the types of meta-synthesis is as follows:

1. Theory building, for example, grounded formal theory or meta-study
2. Theory explication
3. Descriptive meta-synthesis or meta-summary
4. Meta-ethnography

Theory building is the approach of meta-synthesis that involves building either a formal theory using "Grounded formal theory" or creating a new theoretical interpretation using "meta-study" method based on findings found from the qualitative studies included in the process (Finfgeld, 2003). Theory explication reconceptualizes an original concept. It involves a deconstruction, followed by a reconstruction and finally synthesis of the findings around a single concept. In descriptive meta-synthesis, original findings are evaluated comprehensively (Finfgeld, 2003).

Meta-Synthesis of Qualitative Research in Pharmacy Practice

The aim of meta-synthesis in pharmacy practice qualitative research is to combine, understand, and synthesize findings from the present pool of empirical qualitative studies around a phenomenon and then to generate a comprehensive understanding of that phenomenon (Sandelowski, 2007). It has been applied expansively in health-related research and has branched out into the field of pharmacy practice. A well-executed qualitative pharmacy practice meta-synthesis has the potential to develop new knowledge and understandings. This also has the capability to help make evidence-informed policy decisions and value-added clinical choices (Finfgeld-Connett, 2010; Mohammed et al., 2016b).

The approach of meta-synthesis is in its infancy in pharmacy practice qualitative research and here are a few examples of qualitative meta-synthesis.

Examples of Meta-Synthesis in Pharmacy Practice

Illustrated examples of meta-synthesis in pharmacy practice research (2005 till 2018)

Categories	*Examples*	*Synthesis*
Pharmacy services	Qualitative meta-synthesis of barriers and facilitators that influence the implementation of community pharmacy services: perspectives of patients, nurses, and general medical practitioners (Hossain et al., 2017)	Three-stage method for thematic synthesis described by Thomas and Harden (2008)
Meaning of medications for patients	Understanding the meaning of medications for patients: The medication experience (Shoemaker and Ramalho de Oliveira, 2008)	Analytic technique, "free imaginative variation" to determine the essential, structural themes
Perceptions and experiences of taking oral medicines	Perceptions and experiences of taking oral medications for the treatment of Type 2 diabetes mellitus: a systematic review and meta-synthesis of qualitative studies (McSharry et al., 2016)	Meta-ethnography model described by Noblit and Hare (1988)
Accessibility and affordability of medicines	Trans-Pacific Partnership Agreement and Its Impact on Accessibility and Affordability of Medicines—a meta-synthesis (Yap et al., 2017)	Meta-synthesis—thematic analysis
Migraine patients' perspectives regarding migraine treatment	Meta-synthesis on migraine management (Minen et al., 2018)	Meta-synthesis—thematic analysis
Medication-related burden and patients' lived experience with medicines	Medication-related burden and patients' lived experience with medicine: a systematic review and meta-synthesis of qualitative studies (Mohammed et al., 2016a)	Meta-ethnography methods and a comparative thematic analysis
Patients' experiences and perceptions of receiving benzodiazepines and Z-drugs	A systematic review and meta-synthesis of patients' experiences and perceptions of seeking and using benzodiazepines and Z-Drugs: toward safer prescribing (Sirdifield et al., 2017)	Thematic synthesis

Step-by-Step Guide to Meta-Synthesize Qualitative Literature in Pharmacy Practice

There are a number of recommended guidelines to synthesize new and overarching knowledge from the existing qualitative studies (Lachal et al., 2017; Noblit and Hare, 1988; Tong et al., 2012; Walsh and Downe, 2005). These guidelines coincide in many respects and have differences as well; however, none are binding or all-encompassing. Based on our literature review, some of these guidelines assume an "aggregate" approach toward meta-synthesis, while most incline toward "interpretative" style. A multidisciplinary meta-synthesizing team is deemed important "to assess rigor and develop richer and more complex understandings" of the data (Lachal et al., 2017). The team can choose one author's guidelines or may combine two or more depending on the nature of their review and the intended approach.

The earliest work on meta-synthesis is done by Noblit and Hare, who recommended seven steps to perform a meta-ethnographic synthesis: *getting started:* the initial stage where the meta-synthesizers build an interest in their research topic; *deciding what is relevant to the initial interest:* the stage where relevant qualitative studies are sought and included; *reading the studies*: to read the included studies in-depth; *determining how the studies are related*: creating a list of relevant concepts and chunks from all the studies and establishing a relationship among them; *translating the studies into one another*: the stage in which all the extracted concepts and chunks are compared and contrasted; *synthesising translations*: bringing together all the concepts and chunks in one new piece; and *expressing the synthesis*: as a written paper or in the form of a video (Noblit and Hare, 1988). Later, Walsh and Down illustrated five stages of meta-synthesis, which include framing the scope of the meta-synthesis, locating relevant papers, framing the inclusion criteria, appraising the studies, and finally analyzing and synthesizing (Walsh and Downe, 2005).

Tong advanced the concept of standardizing the process of qualitative synthesis as a whole by composing the ENTREQ (The Enhancing transparency in reporting the synthesis of qualitative research) checklist, which provides an all-encompassing framework to report the key steps in qualitative syntheses (Tong et al., 2012). This 21-item checklist gives a very broad sense of planning and executing a synthesis and covers five general domains: introduction, methods and methodology, literature search and selection, appraisal, and synthesis of findings (Tong et al., 2012).

After reviewing a set of seminal academic work on meta-synthesis, the following step-by-step guide provides comprehensive information for reviewers who intend to design and conduct a meta-synthesis.

Step 1 Frame a Clear Research Question/Objective

A clear and focused research question or objective should be established before diving into the process of meta-synthesis. One rational approach to frame the research objective is to have a preliminary review of the available qualitative literature. Therefore, a preliminary literature search on the topic of interest is required to ensure that enough data are available to meet the merit of a meta-synthesis. The team aiming to write a meta-synthesis should be clear about "What" and "Why" of their research objective.

In one example, the research question in a qualitative meta-synthesis was to pinpoint barriers and facilitators to implement community pharmacy services in Australia from the available literature (Hossain et al., 2017). Just like a systematic review of primary studies, they conducted a systematic search in three databases, namely, PubMed, Scopus, and Informit, to find studies that explored patients', general practitioners', and nurses', perceptions about community pharmacy services in Australia.

Step 2 Strategize the Search

The next step is to establish a strategy to systematically search for the required literature. However, there is no clear consensus on the need to follow some sort of methodical search strategy, and this is one way where a meta-synthesis differs from systematic review (Britten et al., 2002; Tong et al., 2012). Furthermore, for a meta-synthesis, there is no set requirement on the number of studies to include (Thomas and Harden, 2008). The process of data inclusion can terminate once saturation is achieved.

The search strategy includes a set of rules to find and select studies starting off by identifying the databases that are relevant to the research objective. Commonly used databases include PubMed, EMBASE, Web of Science, CINAHL, COCHRANE, SCOPUS, and ProQuest. Search terms or queries are developed based on the target topic. These search terms or queries can be developed using a number of search tools such as PICO, PICOS, and SPIDER (Alison et al., 2012; Curtin University, 2018).

PICOS and SPIDER are intended for qualitative and mixed methods evidence synthesis. Whatever search tool or concept is preferred, it results in a list of relevant key words or search terms. The PICO tool (Curtin University, 2018) is the most comprehensive one and focuses on the *Population, Intervention, Comparison and Outcomes*. It is intended for quantitative evidence synthesis but has been descrambled to suit qualitative setting as *Population, Interest and Context* (Curtin University, 2018). The PICOS tool focuses on the *Population, Intervention, Comparison, Outcomes and the Study design* of an article. The SPIDER tool, developed by Cooke et al. focuses on *Sample, Phenomenon of Interest, Design, Evaluation and Research type* (Alison et al., 2012). It narrows down the initial number of articles due to its high specificity (Methley et al., 2014). Methley recommends SPIDER for researchers achieving systematic narrative reviews of qualitative literature but finds it less effective than PICO (Methley et al., 2014). To translate the research topic more effectively into search queries, Boolean operators OR, AND, and NOT can be used with the search terms.

The search strategy may also include the following filters:

1. Original qualitative studies: Would you include only qualitative studies or mixed-methods too?
2. Language: Would you include studies published in English only?
3. Time span: What would be the time span, e.g., from 2000 to 2018, to search studies?

One way of reporting the search strategy clearly is by using the PRISMA tool. Although meant for systematic reviews and meta-analyses, it is a comprehensive tool to enhance the quality of search strategy (Moher et al., 2009).

The search strategy of a meta-synthesis on women's experiences of their pregnancy and postpartum image used PICO tool—Population (pregnan* OR postnatal OR postpartum OR prenatal OR antenatal OR *gravida* OR *parou) and Outcome (appearance OR body image OR body dissatisfaction). In addition, the researchers observed PRISMA guidelines to report their methods (Hodgkinson et al., 2014).

Step 3 Define and Refine an Inclusion Criterion

Once an initial list of studies has been finalized, the meta-synthesis panel will review all the studies to filter the ones that meet the inclusion criteria. In general, a study may be included based on the following information:

1. Relevance to the research objective
2. Relevance to the design methodology predefined by the meta-synthesis panel
3. Published in a peer-reviewed journal

At first, the screening process includes reading the titles and abstracts of all articles to evaluate if they align with the research objectives. Later, the preferred literature is refined by reading full text articles. Another recommended manual practice is to adopt the "pearl-growing" technique, which is to hand-search the reference lists and selectively choose additional research articles from the included literature (Schlosser et al., 2006). This way citations are thoroughly screened to assess their eligibility to be included in the meta-synthesis.

An optional yet valuable step is to do a quality appraisal of included studies. Most researchers have found it useful (Atkins et al., 2008; Tong et al., 2012; Uhrenfeldt et al., 2013). It could be performed by using any quality assessment tool from a plethora of options such as Critical appraisal skills program (2017), The Joanna Briggs Institute Reviewers' Manual (2015), checklist designed by Atkins et al. (2008), etc. An assessment of the quality of the selected studies can make a difference in the overall quality of the meta-synthesis. Before selecting a study for review, the reviewers can check its trustworthiness and rigor, i.e., Are the findings credible? or How valid is the data? (Sullivan and Sargeant, 2011).

Levack and his team explored the use of meta-synthesis to inform discussion on the selection of outcome measures for evaluation of services provided to adults with traumatic brain injury using several databases. They included studies comprising adult participants between 1965 and 30 June 2009. The search strategy was based on text–words and Medical Subject Headings terms intended to detect studies that talked about the key components of topic (Levack et al., 2010):

1. patients with TBI—search terms "exp Craniocerebral trauma/," "exp Cerebrovascular Trauma/," "brain injury," as a text–word, etc.,
2. study methodology of interest—search terms such as "exp Qualitative Research/," "qualitative" as a text–word, "grounded theory" as a text–word, etc., and
3. phenomena of interest, e.g., text–words concerning the concepts of experience, outcome and recovery

Step 4 Synthesize New Knowledge

This phase is the essence of a meta-synthesis. After finalizing the studies to be included, the meta-synthesis team can read the studies together with extracting relevant codes and themes. Later, all the codes and themes are organized together to look for similarities and differences and can be grouped under major themes or concepts. These themes are then further discussed and refined.

1. **Reading and analyzing to generate analytical themes**
   The reading phase is the nucleus as all the subsequent steps are dependent on this step. Effective reading might involve: R = recording, E = extracting, A = appraising, D = describing (Lachal et al., 2017). Careful reading of each study is essential to familiarize oneself with the original content and with the prominent findings across all the studies (Noblit and Hare, 1988). These findings are in the form of either interpreted data, original quotes, documents, or notes. In addition, formal details about each study, which may include study context, location, methodology and data analysis, should be recorded and presented in the final report (Lachal et al., 2017). During and after this phase, each member of the panel should start extracting codes and themes they find relevant to their research objective or theoretical framework. For the management of qualitative data, NVivo, a computer software, is a recommended tool (Mohammed et al., 2016b). Data extraction and management could be done by other ways too, for instance, using a methodological framework that entails categorizing extracted data in a tabular form or in groups or in the form of a grid (Britten et al., 2002) and then codifying that data for themes and concepts related to the topic under study (Graneheim and Lundman, 2004).

In principle, data analysis, that is, coding and/or thematizing, can be performed simultaneouly on both forms of the data, that is, informant quotes (findings/results) and authors' interpretations (dicussion). At this stage, initial extracted themes or concepts should be clustered in one place, be it NVivo or a simple Excel sheet, to have an idea about the available data. This would help in translating the studies into one another. One way of doing the analysis is using Noblit and Hare's ethnographic approach to begin with identifying the first-order constructs. These are key findings or codes identified by the reviewers from the original quotations in the studies. This should be followed by identifying the second-order constructs, which are extracted key findings or codes from the interpretations done by the authors in the discussion section of the studies (Noblit and Hare, 1988). The reviewers generate their third-order constructs, which are the final product of a meta-ethnography, based on the first- and second-order constructs (Thomas and Harden, 2008) translated across all the studies. These synthesized third-order constructs open on to the synthesis of new knowledge that might take the form of a succinct conceptual "line of argument" that goes "beyond the content of the original studies" (Thomas and Harden, 2008), and/or a new model or theory (Atkins et al., 2008; Lachal et al., 2017).

Data analysis can also be performed by following the six phases of thematic analysis described by Braun and Clarke: (1) familiarization with the data; (2) coding; (3) searching for themes; (4) reviewing themes; (5) defining and naming themes, and; (6) writing up (Braun and Clarke, 2006). In addition, Thomas and Harden describe thematic synthesis in three steps (Thomas and Harden, 2008). The first step is coding of findings of studies "line-by-line" and to group the codes based on similarities and differences between them. This step complements Noblit and Hare's recommendation to translate studies into one another, that is, themes from one study are compared with themes from another, through a repetitive comparison of similarities and differences across studies. The second step is the development of "descriptive themes" to describe the cluster of codes and/or concepts. Third, the generation of "analytical themes" where comprehensions of the reviewers are included that act to a specific review question and/or a theoretical framework. (Thomas and Harden, 2008). The analytical process in meta-synthesis works by an initial deconstruction of "what is known" and "how it is known" (Paterson et al., 2001). It includes extracting, aggregating, interpreting, and finally synthesizing the analytical themes from primary qualitative studies (Sandelowski, 2007).

Conceptually, analytical themes seem very much like third-order interpretations; however, according to Thomas and Harden, they differ based on the types of review questions. Analytical themes are constructed by comparing and contrasting the descriptive themes with a specific review question. In contrast, third-order interpretations build on the data to attend to a comprehensive or emerging review question (Thomas and Harden, 2008).

At this stage, the meta-synthesis team has developed key overall concepts or translations across studies, which are synthesized to grow into overall new interpretations or understandings (Britten et al., 2002; Noblit and Hare, 1988). The SAGE encyclopaedia of Qualitative Research Methods elaborates on this step as:

> "the meta-synthesist's task is not simply to determine a best fit, but rather to transform the data set that exists, with all of its inherent strengths and limitations, into a new conceptualization with the capacity of integrating the entire body of qualitatively derived knowledge about the phenomenon" (Given, 2008).

In one example, the reviewers adopted thematic synthesis to synthesize new insights about suicidal youths' care in the field of psychiatry. They developed their third-order interpretations to recommend a more conceptual line-of-argument or conclusion stating that "the violence of the message of a suicidal act and the fears associated with death lead to incomprehension and interfere with the capacity for empathy of both family members and professionals" (Lachal et al., 2017).

2. **Going back and forth to confirm analytical themes**

With codes, core themes as structured data sets or constructs, and analytical themes in place, clarification is done next through in-depth examination and analysis. Both Braun and Clarke and Thomas (Braun and Clarke, 2006; Thomas and Harden, 2008) emphasize that thematic analysis is an iterative process—moving back and forth between the stages is recommended as part of reconsidering original data. The analytical themes now require team work to redetermine the analysis with frequent discussions on the extracted common themes and on the emerging themes or concepts by recurrent returns to the original data.

A meta-synthesis on perceptions and experiences of taking oral medications for the treatment of Type 2 diabetes mellitus by McSharry et al. translated the included studies by identifying one paper and adding it to the first row of the translation table. Subsequent papers were added to this translation table in chronological order of publication. Later, they assessed the relationships, variances, and contradictions across studies to develop twelve overall translations. Three third-order constructs, such as (1) medication for diabetes: a necessary evil, (2) the passive patient as active experimenter, and (3) taking oral medication for Type 2 diabetes: a unique context, were established (McSharry et al., 2016).

3. **Framing the syntheses output**

After interpreting, reinterpreting, and analyzing the formulated theories and concepts across the studies, the final meta-synthesis report should generate a synthesis of new knowledge, understandings, and interpretations that go beyond a compilation of the primary studies. This new knowledge could be a new model of evidence, a critical framework, or a new theoretical insight (Tong et al., 2012). **Fig. 1** illustrates the process of meta-synthesis.

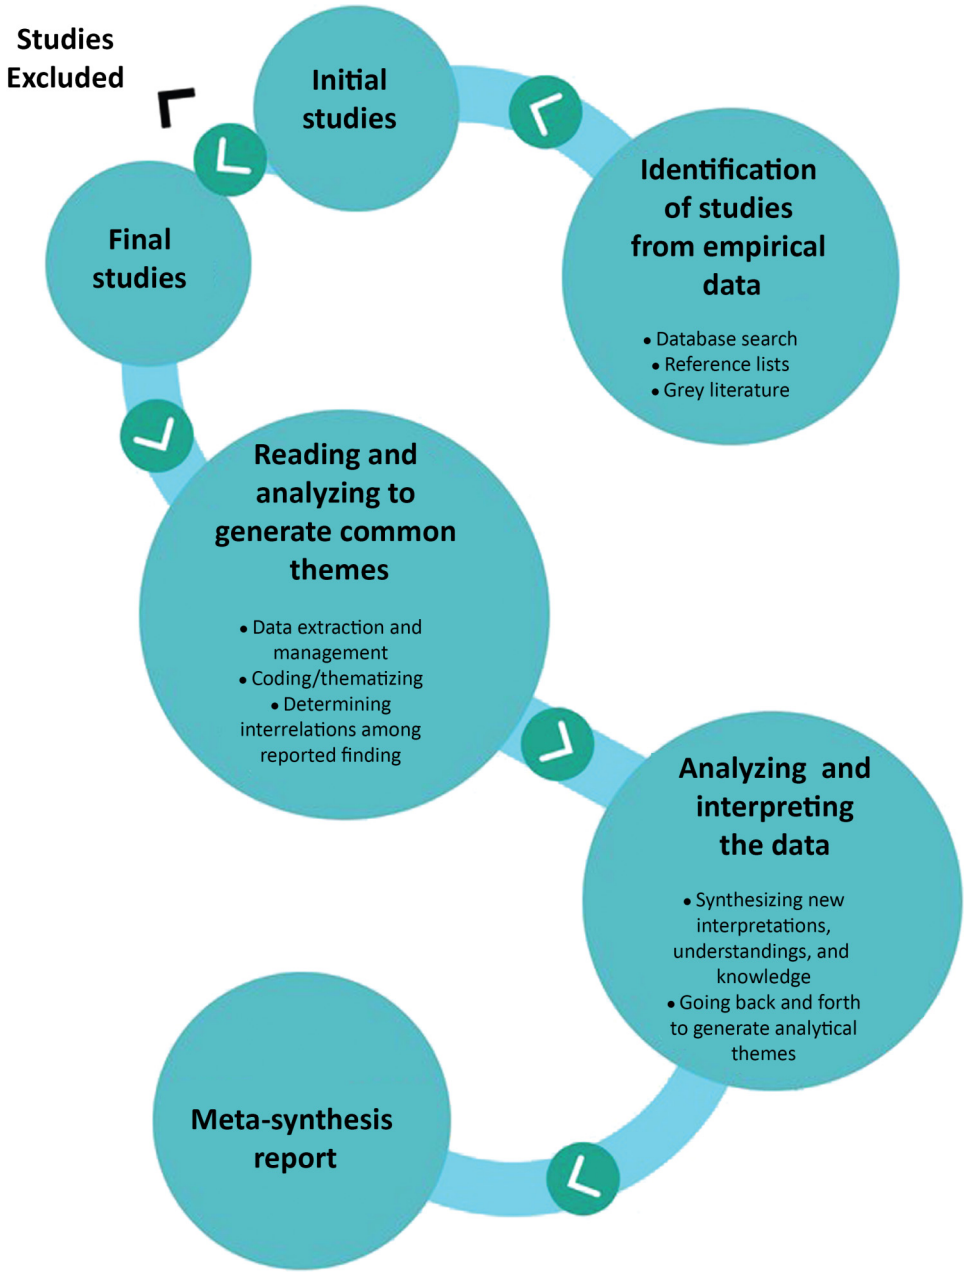

Figure 1 The step-by-step process to prepare a meta-synthesis report.

Conclusion

This chapter summarizes the key stages to conduct a meta-synthesis illustrating examples from the qualitative literature. Meta-synthesis is an important approach in qualitative research, and this aims to aggregate, interpret, and present previous findings to synthesise new knowledge for a wide range of health-related stakeholders. It is a rigorous way of fusing several qualitative findings to generate new knowledge for potential application in pharmacy and clinical practice, and to inform policy.

Acknowledgment

We would like to offer our special thanks to Kirsten Myhr (MSciPharm, MPH) for her comments and language editing on an earlier version of the manuscript.

Mixed Methods Research in Pharmacy Practice: Basics and Beyond

Sara Ramzan*, Muhammad Abdul Hadi†, Zaheer-Ud-Din Babar*, *University of Huddersfield, Huddersfield, United Kingdom; †University of Birmingham, Birmingham, United Kingdom

Introduction

The role of pharmacists has become more patient oriented in the past couple of decades. Pharmacists are now involved in direct patient care and play a crucial role in ensuring safe and effective use of medicines in both community and hospital settings (Dhanani et al., 2017). In this context, pharmacy practice research is critically important to generate evidence to support and identify weaknesses, if any, for improvement of pharmacy services within health care systems (Bissell and Traulsen, 2005). Although, mixed methods is not a new methodology, it has become more popular in the last decade as it brings together strengths of both qualitative and quantitative approaches (Creswell and Plano Clark, 2018; Johnson et al., 2007; Pelto, 2015). Mixed methods research offers an alternative methodology to researchers who seek to answer complex research questions requiring both qualitative and quantitative approaches within a single study (Creswell and Plano Clark, 2018). Furthermore, it allows researcher to choose and mix methods from both qualitative and quantitative methodologies best suited to answer the research question.

In this chapter a range of topics related to mixed methods methodology have been discussed including typologies of mixed methods methodology, methods of integration of qualitative and quantitative strands within a mixed methods study, challenges in undertaking these studies, how to evaluate quality of these studies and examples of research questions that can be answered by mixed methods studies. These examples have been taken from the recent pharmacy practice literature.

What is Mixed Methods Research?

Mixed methods is often referred to as the *third methodological movement* (Teddlie and Tashakkori, 2009; Venkatesh et al., 2013). Although, mixed methods studies have both qualitative and quantitative components but how and when these strands should be combined is still a hotly debated area among methodologists (Tashakorri, 2007). Various terminologies have been used in the literature to describe mixed methods research including "integrated," "hybrid," "mixed research," "mixed methodology," "mixed methodology research," "combined," "multimethod," and "methodological triangulation" (Bryman, 2007; Driscoll et al., 2007; Johnson et al., 2007; Morse, 1991). Johnson et al. (2007) analyzed definitions of mixed methods provided by a number of "leaders" in the field. After analyzing these definitions, they defined mixed methods research as a type of research *"in which a researcher or team of researchers combines elements of qualitative and quantitative research approaches (e.g., use of qualitative and quantitative viewpoints, data collection, analysis, inference techniques) for the broad purposes of breadth and depth of understanding and corroboration."* (p. 123).

This definition was extended with a definition of the research type:

> "A mixed methods study would involve mixing within a single study; a mixed method program would involve mixing within a program of research and the mixing might occur across a closely related set of studies" (p. 123).

Figure 1 Knowledge cycle illustrating phases in the planning of mixed methods research design in pharmacy practice.
Source: Adapted from Creswell and Plano Clark (2018).

Tashakkori and Creswell's (2007) defined mixed methods research in the first editorial of *Journal of Mixed Methods Research* as *"research in which the investigator collects and analyses data, integrates the findings, and draws inferences using both qualitative and quantitative approaches or methods in a single study or program of inquiry"* (p. 4).

The key message from these definitions is that the mixed methods designs should be not used as a "tool" to collect two different datasets but there should be purposeful integration between qualitative and quantitative datasets to comprehensively answer the research question.

Planning of Mixed Methods Research

Several frameworks have been developed to guide on how to conduct and evaluate mixed methods research (Creswell et al., 2011; Tashakkori and Teddlie, 2010; Wisdom et al., 2012). In this chapter, we have adapted and modified framework developed by Creswell and colleagues (Creswell and Plano Clark, 2018) to illustrate the planning of a mixed methods research design (**Fig. 1**). In the first phase, the researcher would be driven by their curiosity regarding a theme or issue within the health-care setting. According to King et al. (1994), intellectual stimuli are the "purest" drive for conducting research (King et al., 1994). If the researchers decide to pursue this curiosity, they will have to formulate objectives and research questions which require a mixed methods approach. The rationale for using a mixed methods research design should always be justified and should result in more valuable and comprehensive findings than using a single method (Creswell and Plano Clark, 2018).

After formulating a strong research question/objective, a suitable methodological approach must be considered. The selection of appropriate mixed methods research study design in pharmacy practice must always be guided by the research question (Hadi et al., 2013a). There are a few questions which researchers need to ask themselves to establish if a mixed method approach is suitable for the planned study; Do the posed questions have quantitative and qualitative elements? How will the quantitative and qualitative methods be prioritized? In which sequence will they be conducted? And how and when will the integration of data take place? (Creswell and Plano Clark, 2018; Liamputtong, 2013). The sample size, data collection, data analysis must be planned for both qualitative and quantitative phases, and ethical approval should be obtained, if necessary. It is also critically important to consider and plan the integration and interpretation of the data. All these steps should be clearly and transparently reported in a manner that other researchers can replicate the methods. Authors must reflect on the findings of the study and explain how the use of mixed methods has helped to answer the original research question.

Mixed Methods Research Designs: How to Use Them?

Choosing between mixed methods designs is challenging (Creswell and Plano Clark, 2018; Leech and Onwuegbuzie, 2009). It is recommended for new researchers to familiarize themselves with established mixed methods research designs and choose a suitable

mixed methods design based on the research question (Bryman, 2007; Driscoll et al., 2007). Although, mixed methods research is a flexible methodology, it is important that the study design is justifiable and the pros and cons of all available study designs are weighed carefully (Creswell and Plano Clark, 2018).

Several typologies and classifications of mixed methods research exist in the literature (Greene et al., 1989; Leech and Onwuegbuzie, 2009; Teddlie and Tashakkori, 2009). We need to consider how each component will be integrated when the data have been collected. The following four guiding questions can help researcher to choose best mixed methods design for their research study (Creswell and Plano Clark, 2018):

- First, the researcher should decide the level of interaction between qualitative and quantitative strands. Will the qualitative and quantitative strands be kept independent or interactive?
- Secondly, the researcher must decide on the timing of data collection of both qualitative and quantitative strands. Quantitative and qualitative data can be collected sequentially or concurrently.
- Thirdly, the researcher needs to consider weighing of each component in mixed-methods design. Will the quantitative or qualitative component be given priority in answering the research question, or will they be weighed equally?
- Lastly, the researcher must decide the timing of integration of two datasets, as this can happen at different phases of the research (i.e., during data collection, data interpretation, etc.).

The four commonly used typologies used in mixed methods research are described below together with an example of their application from published pharmacy practice literature.

The Exploratory Sequential Design

In this design, the research is conducted in two sequential phases. This qualitative component is conducted first and is given more weighing in answering the research question. The quantitative component is used to generate generalizable data from the qualitative phase (Hadi et al., 2013a; Morse, 1991; Teddlie and Tashakkori, 2009; Wittenberg, 2000).

Fisher et al. (2018) conducted a mixed methods study to gain understanding of pharmacist independent prescribers' knowledge, perception and beliefs about departmental infrastructure, pharmacy and multidisciplinary team support, attitudes and behavioral determinants associated with prescribing. The study was conducted across 14 health care boards in Scotland. The qualitative data, gathered through focus groups and semistructured interviews of pharmacist independent prescribers, informed the design of a structured questionnaire (online cross-sectional survey) used to assess knowledge, perception, attitudes, and beliefs toward prescribing. Using mixed methods as methodological approach in this study allowed not only generalizable results but also provided broader insight to which organizational culture changes are required to influence prescribing.

The Explanatory Sequential Design

This design also consists of two phases. The quantitative component is conducted first and is given preference in answering the research question. In the first phase, quantitative data are collected and analyzed. In the second phase qualitative data are collected. This method is suitable when the qualitative component is needed to explain and clarify findings from the quantitative component (Hadi et al., 2013a; Morse, 1991; Teddlie and Tashakkori, 2009; Wittenberg, 2000).

Stewart et al. (2018) used an explanatory mixed methods research design to explore behavioral determinants related to error reporting among health care professionals. In the first phase behavioral determinants were identified through a cross-sectional survey. The authors reported that medication error reporting was associated with issues related to emotions and belief of consequences. Although, all health care professionals included in the sample had these issues, however, these were more common among younger health care professionals. In the second phase of the study, focus group interviews were conducted to develop an in-depth understanding of the survey findings. The data from the two components were triangulated at the completion of study to get a broader understanding of medication error reporting.

The Convergent Parallel Design

In convergent parallel design, the quantitative and qualitative components are undertaken at the same time. Each component is carried out independently but at the same time (i.e., each dataset is collected, analyzed and then findings are integrated during the interpretation phase). The study design allows to triangulate findings from the two components in order to understand the research question. For this reason, the study design is also referred to as "current triangulation," "simultaneous triangulation," and "parallel study design" (Hadi et al., 2013a; Morse, 1991; Teddlie and Tashakkori, 2009; Wittenberg, 2000).

El-Jardali et al. (2017) used a convergent parallel mixed methods research design to investigate the attitudes of community pharmacists and their practices in relation to the implementation of the generic drug substitution policy in Lebanon. The two components in the study were given equal priority. The quantitative component (self-administered questionnaires) was followed by the qualitative component (semistructured interviews). The aim of both components was to document experiences while implementing this new policy. In the quantitative phase, respondent's attitudes toward generic substitution and outcomes of the new generic drug substitution policy were measured. The semistructured interviews supplemented the quantitative findings by

expanding on the participants' experiences by exploring perceived barriers and facilitators. The data collection was carried out separately, but the findings were interpreted and reported together.

The Embedded Design

In the embedded design, one component act as a principal method and the other component is used as a "supportive method." Depending on the study objectives, both qualitative and quantitative components can act as the principal method. The data can either be collected concurrently or sequentially. The research design is suited when the researcher intends to use different methodologies for different research questions within the same study (Hadi et al., 2013a; Morse, 1991; Teddlie and Tashakkori, 2009; Wittenberg, 2000).

Hadi et al. (2013b, 2016a,b) conducted a mixed methods study to evaluate nurse pharmacist managed pain clinic. The quantitative component evaluated the impact of clinic on patient reported outcomes (e.g., pain intensity, physical functioning, and quality of life) and qualitative component explored patients' experiences of the clinic. This research design allowed the authors to answer different research question within a single study by using different methods. Quantitative method was given priority in answering the research question and the qualitative component (semistructured interviews) were used as supportive method which generated data associated with the quality and effectiveness of the service and interaction with the nurse and pharmacist.

Literature Review: Mixed Methods Studies in Pharmacy Practice

To develop a broader picture of how mixed methods research designs have been used in recent pharmacy practice literature, a scoping literature review was undertaken. We searched PubMed for studies describing or evaluating the roles of pharmacist and pharmacy interventions using mixed methods design in the past five years (1 June 2013–31 May 2018). During our search we used the keywords: "Pharmacy practice," "pharmacy," "pharmacist," "mixed methods," "pharmacy interventions," "public health pharmacy," "health system pharmacy," "health pharmacist," "medicine use," and "Health care." The search was restricted to only include full-text research articles only published in English language. Fifty-three articles were identified for full-text review. The final sample included 35 relevant articles after duplicates were removed (date of search; 8 August 2018). The included studies were conducted in UK (15)), USA (3), Qatar (2), Uganda (1), Guatemala (1), Ghana (1), Iraq (1), Australia (2), Korea (1), India (2), Lebanon (1), Thailand (1), Canada (1), Brazil (1), Netherlands (1), and Switzerland (1). This highlights that mixed methods approach has gained popularity among pharmacy practice researchers across the world. The studies were conducted in community pharmacies, primary care settings, hospitals and clinics. Mixed methods studies investigated pharmacy services, physicians' attitudes and perception, medicine use, and education and knowledge of patients.

In the literature review, all the studies were labeled as mixed methods studies, however only one-fourth of the studies described and justified the application of the mixed methods design.

There were few examples of multimethods research inappropriately labeled as mixed methods. As mixed methods has evolved over time, we believe that the mixing of quantitative and qualitative methods should only be labeled as mixed methods research. Labeling multiple methods of collecting qualitative or quantitative data only as mixed methods research design is inappropriate and should be discouraged.

The quantitative component in included studies mostly consisted of surveys. There were more variations in the use of the qualitative component which included interviews, focus groups, observations, and document analysis. Only four of the included studies described how the quality of the collected data was assessed. The description of the integration between quantitative and qualitative components was found to be very shallow in most studies. Scarce details and unclear reporting of a study does not only make it hard for the reader to understand the intend of the study but also makes it low quality research.

Approaches of Integration of Findings in Mixed Methods Research

As previously mentioned, mixed methods research does not only involve mere collection quantitative and qualitative data. Without meaningful integration, the true purpose of undertaking mixed methods study would not be fulfilled. The integration of data starts as early as at the planning stage of the research (e.g., study design and methodological approach). In the early days of mixed methods research, Jick and colleagues acknowledged the method's ability to draw on the strengths of individual qualitative and quantitative methods used in the study (Jick, 1979).

Hammersley (1996) proposed the following three methods for integration of qualitative and quantitative data: triangulation, facilitation, and complementarity. There must be a clear reflection from the beginning of the study on how one approach will be supporting the other (Venkatesh et al., 2013). The literature describes triangulation as a method to study a research question using multiple methods (Fetters et al., 2013; O'Cathain et al., 2010). The literature classifies triangulation into four categories: methodological triangulation, theory triangulation, data triangulation, and investigator triangulation (Denzin, 2009). There are limitations with regard to a step-by-step guidance on how to perform triangulation of results in health care studies (Jick, 1979; Östlund et al., 2011). Farmer and colleagues have developed a triangulation protocol which can help increase transparency in the conducted research regardless of the used typology (Farmer et al., 2006). In terms of triangulation the researcher must consider three aspects of

the research methods: First, explore the research process itself (e.g., did the applied methods answer the posed research question). Second, look for incongruity in the used method; are the findings the same or do they contradict each other? Finally, look at how the methods complement each other; which results are gained from each method (Farmer et al., 2006)? O'Cathain et al. emphasizes the importance of making an informed decision about the weighing of the used dataset (O'Cathain et al., 2010). Currently, these decisions are likely to be subjectively assessed. If there is no consensus approach on how to order triangulated datasets, these decisions are left to the researcher. Farmer et al. (2006) described that these decisions should be based on the contribution each method brings toward answering the research question (Farmer et al., 2006). One method can be used to validate the findings from the other method. Quantitative data can, for example, be used to explain findings from qualitative data (Fetters et al., 2013).

Quality in Mixed Methods Research

It is commonly agreed that health services research should be reported transparently (Creswell and Tashakkori, 2007; O'Cathain et al., 2008b; Wisdom et al., 2012). The literature reports on various methods for evaluating the quality of quantitative and qualitative methods on their own. During our review of pharmacy practice literature, we found that there is a lack of definition of the mixed methods research. There are currently several definitions of "mixed methods" (Creswell et al., 2004; Johnson et al., 2007) and it is important to justify and describe the adapted definitions, so the reader can make an informed judgment of the quality of the study.

There is a lack of consensus in the description of quality of a mixed method study. This is also being observed in other areas of health serviced research (Hadi and Closs, 2016b; O'Cathain et al., 2008b). One reason for this trend could be that there is a lack of consensus guidelines on how to evaluate mixed methods research designs. Currently there are no rules on how to evaluate mixed methods research. However, there are several mixed methods guidelines and frameworks proposed in the literature (Hadi et al., 2014a; Leech and Onwuegbuzie, 2010; NIH, 2018). The mentioned guidelines and frameworks have a common goal to improve reporting quality. The key elements in the guidelines are to: justify the used methods approach, describe the mixed methods design (priority, purpose, sequencing, and stage of integration), describe the used methods (sample size, data collection, and analysis), describe how, when, and where integration has occurred and identify limitations related to the applied research design. Adhering to these guidelines and frameworks as well as to individual standards for the quantitative and qualitative components is recommended. In terms of integration of data and how will disagreements between two components be dealt with. It is important to emphasize that it should be described how these disagreements will be resolved to allow the reader to asses quality of the study (Curry et al., 2013; O'Cathain et al., 2010).

To summaries, different disciplines uses different typologies within mixed methods research design (Tashakkori and Teddlie, 2010). There are no rigorous rules on how to validate mixed methods research designs, and hence it is up to the individual researcher to choose an appropriate method to evaluate their study design.

What are the Challenges in Using Mixed Methods Research

Mixed methods is as challenging as any other method, expertise in multiple areas is required due to the use of quantitative and qualitative methods in the same study.

Conducting mixed methods research is time consuming and expensive, hence the researcher must consider if they have the necessary time and resources to carry out mixed methods research (Ivankova et al., 2006). The researcher also needs to consider, whether one has the necessary skills to conduct mixed methods research. In the past, the tendency has been toward studies being carried out by researchers who either possess quantitative or qualitative skills. This trend has changed toward research projects being carried out in research teams utilizing the individual researcher's strengths across disciplines (Hadi et al., 2014a,b; O'Cathain et al., 2008a). A lead investigator with research experience with quantitative and qualitative methodologies can act as in an important bridge in the mixed methods research team. There is currently no standard systematic way to conduct a mixed methods study. A well-considered rationale for the approach may help ease this process (Hadi et al., 2014a). Bryman suggests that it is not easy to make sense of one's findings the mixed methods research designs may need to be reconsidered (Bryman, 2007). Lastly, there is the question of reaching a wider audience. Policymakers and practitioners need multiple forms of evidence to document and inform a research problem. Pioneers in the application of mixed methods in pharmacy practice have reported that it has been challenging to report on mixed methods without compromising on the transparency of the design due to the journals word limit of original articles (Hadi et al., 2014a,b; Wisdom et al., 2012).

Application of Mixed Methods Methodology in a Program of Inquiry

Until now, the focus of this chapter has been on the use and application of mixed methods research within a single study (fixed mixed methods designs), however, mixed methods approaches (emergent mixed methods designs) can be used within a program of enquiry. Emergent mixed methods arise to resolve quires and address issues that develop during the process of conducting research (Creswell, 2018). To illustrate this we will use an example of health services evaluation of a chronic pain service. As part of these

services the pharmacist conducted medication reviews and offered medication related advice to ensure safe and effective use of medicines. The nurse educated patients about pain, clarified misconceptions, managed treatment expectations, and promoted self-management of chronic pain. The original focus of the research at the beginning of protocol development was to evaluate a community-based nurse-pharmacist managed pain clinic using a mixed methods design (Hadi et al., 2013b, 2016a). However, during extensive literature review and the course of the study, following additional questions arose:

1. Is pharmacist-led medication review effective in the management of chronic pain in adult patients?
2. What is the magnitude and extent of the impact of chronic pain on patients' quality of life in relation to other long-term conditions?
3. What are the barriers to effective pain management encountered by patients with chronic pain in primary care?

Subsequently, a pragmatic approach was adopted to answer these questions. For the first question, a systematic review and metaanalysis was conducted to evaluate the effectiveness of pharmacist-led medication review in chronic pain management (Hadi et al., 2013b, 2014b). The metaanalysis found that patients in pharmacist-led medication review group had significant reduction in pain intensity, improvement in physical functioning and patient satisfaction compared to the control group. For the second and third questions, the qualitative interview guide was expanded and additional questions were asked to explore the impact of chronic pain on patients' lives and barriers to effective management of chronic pain in primary care, in addition to originally proposed questions aiming to explore patients' experiences of nurse-pharmacist managed pain clinic. In order to truly understand the impact of chronic pain of patients' lives, a mixed methods approach was adopted (convergent parallel design) (Hadi et al., 2018). Published data on quality of life from two different datasets, the Third Oxford and Lifestyles Survey and Welsh Health Survey, were also extracted and a secondary analysis was undertaken to allow comparison of QoL of chronic pain patients with that of the general population and patients with long-term conditions. The authors found that patients with chronic pain had significantly poorer quality of life compared to patients with other long-term conditions (Hadi et al., 2018). Qualitative themes emerged from data analysis reflected the diversity in the nature of impact of chronic pain on patients' lives. For the third question, qualitative-only approach was used and qualitative data were analyzed with an aim to develop themes based on the barriers encountered by patients with chronic pain in primary care (Hadi et al., 2017). This example demonstrates the use of emergent mixed methods design in pharmaceutical health services research. It should be noted here that the selection of choosing an appropriate method was guided by research question. Quantitative-only and qualitative-only and mixed methods approaches were used as appropriate during the program of enquiry. The emergent mixed methods design gave authors the flexibility to choose the best method to answer the research question.

Conclusion

A mixed methods approach is suitable when the use of two methods is likely to enhance our understanding enhance the knowledge in a specific research question as compared to using a monomethod approach. It is essential to choose an appropriate typology for the mixed methods research approach and this should be guided by the individual research question. Rigor in mixed methods research should be ensured by adhering to quality principles of the quantitative and qualitative components as well as mixed methods research guidelines and frameworks. Both humanist and financial resources should be carefully considered before embarking on a mixed methods study. New mixed methods researchers should choose fixed mixed methods approach and should consider collaborating with an experienced researcher early during the designing phase of the study.

Publication Bias

Rabia Hussain*, Mohamed Azmi Hassali*, Mahendra Patel†, Zaheer-Ud-Din Babar†, *Universiti Sains Malaysia, Penang, Malaysia; †University of Huddersfield, Huddersfield, United Kingdom

Background

The "dictionary of epidemiology" defines publication bias as "an editorial predilection for publishing particular findings, e.g., positive results, which leads to the failure of authors to submit negative findings for publication (Last et al., 2001)." The term "Publication Bias" was first defined by Begg in 1985 as studies in which the observed efficacy of the treatment is much more likely to be reported than those in which the observed efficacy is average or poor (Begg, 1985). Publication bias is the biased projection of researchers, reviewers, and editors to submit and publish studies based on usually positive findings (Dickersin, 1990). Publication

bias also occurs when the chance of getting publishing a paper depends on the outcome of the findings (Brown et al., 2017). It means that the statistically insignificant results, studies of small magnitude or findings contradicting prior theories or findings from other studies will be less likely to be published (Harrison et al., 2017; Dickersin and Min, 1993).

Publication bias can also be explained as results having statistical significance, have a likelihood to be published faster, multiple times, publishing in high impact journals and to be cited more often. In this regard, the evidence based on "non-significant results" in systematic reviews cannot be ignored and hence it is as much important as the evidence contributed by significant results (Rodrigues, 2013).

Role of Publication Bias in Evidence-Based Clinical Decision Making

Publication bias has not only influenced the education and psychology related research, but it has also greatly affected the medical literature too. The main consequence of this bias would be exaggerated claims of treatment effects or presence of risk-factors related to published work. These could be misleading in many ways including management of patients or health related policy making (Easterbrook et al., 1991). Meta-analysis and systematic review-based syntheses of published research is in high demand to support the evidence-based decision making policy. But, research with unfavorable results is less likely to be published and hence contributes to bias in the selection of the studies for meta-analyses or systematic reviews (Dickersin, 1990; Dickersin and Min, 1993; Easterbrook et al., 1991). As unpublished studies and studies are marked as grey literature and they are not easily accessible (Mueller et al., 2013). So, the effect estimates on the basis of such publications might be overestimating the effect size than what actually exists (Song et al., 2000; Easterbrook et al., 1991). It also compromises the quality of the systematic reviews and meta-analysis, which are only based on published literature (Easterbrook et al., 1991). Systematic reviews and meta-analyses are considered as the most powerful analytical tool, thus claimed to have an impact on the current and future research trends (Easterbrook et al., 1991; Crawford et al., 2010).

Easterbrook et al. performed a literature search for 1982–89 and found that two-thirds of meta-analyses are based on the studies, which were more biased prone especially more toward publication bias. The study further suggested that non-randomized trials with small sample size should be used cautiously, specifically when to be included in a systematic review or meta-analysis or otherwise (Easterbrook et al., 1991). This can be further explained as the field of medicine relies on multiple studies based on small sample size (Ioannidis, 2005). So, if the effects of a medicine are demonstrated as combination of both positive and negative outcomes, so, only the studies with positive results will be published. In this context, the researcher and practitioner will think that the medicine or a treatment is beneficial, while this is not the case in actual sense (Paulson et al., 2011). Paulson et al. evaluated abstracts submitted at the 2006 Center for International Blood and Marrow Transplant Research (CIBMTR)/American Society for Blood and Marrow Transplantation (ASBMT) "tandem" meeting. They found that only 43% of the abstracts were later published as complete papers. Another interesting finding came out from the study that the results with the positive findings were published in high impact journals, while unstated or negative studies were published in low impact factor journals (Paulson et al., 2011).

Similarly clinical trials-based medical decisions are based on the public reporting of such clinical trials (Craig et al., 2001; Hagdrup et al., 1998).

Due to the failure of an intervention, the results of a clinical trial remain unpublished especially if the intervention is found to be harmful, so chances are that considering these studies may have greater harm to the patients (Parekh-Bhurke et al., 2011). Therefore, selective publication of clinical trials and their associated outcome can mislead due to unrealistic estimation of drug effect (Kyzas et al., 2005; Whittington et al., 2004). In this regard, Turner et al. conducted a systematic review of literature on 12 antidepressants agents and compared them with the reviews from Food and Drug Administration involving 12564 patients in trials (Turner et al., 2008). They compared the trials' outcomes and effect size of the treatment from published data and the data obtained from the FDA. The published literature showed that 94% of the conducted trials were positive comparable to the 51% derived from the FDA (Turner et al., 2008). Thus, a non-representative selection of the data in a systematic review may decrease the validity and usefulness of practice and policy based on such studies, hence it is important for clinicians, health policy makers, and researchers to understand the concept of publication bias before considering such evidence (Parekh-Bhurke et al., 2011).

History of Publication Bias

The decision of what should be or what should not be published is solely a personal decision and to some extent influenced by the trends, however, science does not dictate any formal guidelines on what should be included in a publication (Dickersin, 1990). Robert Boyle was the first scientist to bring the necessary details of the experiments into the publication. This initiative of sharing research findings with peers led to a new type of reporting that described the errors and difficulties, one can encounter doing the experiment. Thus, between 1600 and 1800s, the scientific reporting not only presented the "positive" but also the "negative" results. In 1661, Boyle being concerned about the publication practices in the field of science expressed his concerns over this issue and said that the scientists are being compelled not to publish the experiments but to bring out something "big" (Dickersin, 1990).

Awareness of publication bias began in 1956 when the editor of the *Journal of Abnormal Social Psychology* indicated that negative studies were less likely to be published in his journal (Thornton and Lee, 2000). In 1959, it was found that very few negative results were reported in four psychological journals, a finding strongly suggesting publication bias (Sterling, 1959). Since 1979, the number

of references relevant to publication bias has increased (Boisen, 1979). In 1979 Rosenthal used another term "file-drawer problem" to describe the lack of publication of completed studies (Song et al., 2013).

Types

Publication bias does not only include the urge to publish positive results, but it also includes various other reasons which can be listed as different types of bias influencing the publication.

Here are different types of publication bias:

Multiple Publication Bias

Depending upon the nature and outcome of the study, studies that get chance to publish in more than one place might get more weightage for readership and more likely to be included in a meta-analysis (Egger and Smith, 1998; Higgins and Green, 2011).

Time Lag Bias

Time lag bias indicates that some studies take long time to get published especially those with the undesired or no positive outcome. Contrary to this, studies with positive results or attention drawing findings are published much faster (Hopewell et al., 2007). For example, one study assessing efficacy trials of HIV treatments concluded that the time from study enrollment to publication was significantly longer for negative trials than that for positive trials (Ioannidis, 1998).

Location Bias

It is related to the publication of research findings in journals, which are indexed in different databases and then perhaps comparing them with the outcomes of the study (Pittler et al., 2000; Vickers et al., 1998).

Citation Bias

Citation bias is based on the selection of the study that a researcher wants to cite from other studies or sources (Christensen-Szalanski and Beach, 1984).

Language Bias

The choice of publication in a particular language, ignoring those studies which are not in your native language (Egger et al., 1997).

Outcome Reporting Bias

It is based upon the publication of selective research findings depicting positive outcome of the study (Chan et al., 2004).

Confirmatory Bias

When one's beliefs and experiences are supported by some studies and they emphasize certain studies to build a support and ignore others though relevant, this type of bias is known as confirmatory bias and it is most evident in clinical research (Mahoney, 1977).

Funding Bias

Sometimes the funders may withhold the results with negative outcomes and do not disclose them to the public. It has been observed that independent studies have less significant or favorable results than the funded studies (Lexchin, 2012).

Factors Contributing Toward Publication Bias

Several factors contributing toward publication bias are described as below:

Design and Implementation of Study

The role of design or execution of single studies is a factor contributing toward publication bias as sample size and method of data reporting greatly influences the phenomenon (Thornton and Lee, 2000). Besides, the belief and expectation of the investigator also play an important role in publication bias (Angell, 1989). A small sample size lacks the power thus fails to prove the statistical

importance of an effect under study and hence fails to get published (Thornton and Lee, 2000). Contrary to this, large studies have a good chance to answer many questions as the author has to dig in the information deeply to obtain positive results even if the data is showing negative outcomes. This means that the chances to get significant results will increase with the detailed analysis of further subgroups (Angell, 1989; Thornton and Lee, 2000). Publication bias also arises if the data recording is inadequate. Although the difference between data produced and published is rare, but some researchers may tamper the data and this data tempering remains unnoticed during peer-review and even during the replication (Engler et al., 1987; Felson, 1992)

Publication Bias due to Unpublished Studies

Sometimes findings from a study do not seem to impart much for the promotion of a certain theory or a policy, for which the study was meant for. Certain results seem less interesting to be published and less appraised by the editors and reviewers. Due to these reasons, researchers find it inconvenient to publish certain research findings (Brown et al., 2017).

Publication bias may also occur when researcher has a lack of interest in publication or want to submit the research to a specific journal for the publication. For instance, if a study is based on a large sample size, researchers are keen to publish their research, regardless of the outcome of the study (Thornton and Lee, 2000).

Publication Bias due to Rejection of Journals

The *British Medical Journal* states that "negative results have never made riveting reading" (Dickersin, 1990). Some readers and editors strongly discourage negative outcome-based studies as thinking that only positive outcome studies improve the clinical practice. While negative studies are not published, however in some cases it has been found that even the studies with negative outcomes are better planned and conducted than positive outcome studies (Dickersin, 1990).

A study explored process of peer review by assigning manuscripts with positive, negative, no and mixed results to 75 journal reviewers. Reviewers gave minor revisions on studies with positive outcomes and gave major revisions and rejections to the negative studies (Mahoney, 1977).

Sponsorship

Sponsorship is another important factor which cannot be ignored while evaluating factors of publication bias. Sometimes funders decide whether a study would be published or otherwise, considering that, if a pharmaceutical product shows null effects, the manufacturers usually discourage the publication of the results (Thornton and Lee, 2000; Lexchin, 2012). A study revealed that up to 89% of studies funded by the pharmaceutical industry ended up in favoring a new therapy, while only 61% favored the therapy, if the studies are funded by other sources (Begg and Berlin, 1988).

Methods of Detecting and Correcting for Publication Bias

To address problem of publication bias, is as crucial as to promote good scientific knowledge (Brown et al., 2017). Hence, several methods have been developed to identify and minimize such bias (Song et al., 2010).

A Health Technology Assessment (HTA) report published in 2000, highlighted the issues in publication bias. The report included 193 systematic reviews published in 1996 (Song et al., 2000). It was found in the report that not only the literature search was inadequate in some reviews, but also the publication bias was not taken into account while conducting those reviews (Landis and Koch, 1977). Another shortcoming of this review was the lack of representation of the sample studies (Landis and Koch, 1977). Besides, it was found in HTA report that the issue of publication bias was largely being overlooked, as a small number of reviews actually used any methods to identify, avoid, or counter publication bias (Song et al., 2000).

To evaluate whether the practices have changed an assessment of systematic reviews published in 2006 was compared to the systematic review done in 1996. It has been observed that there has been a remarkable increase in the consideration of measures to identify and decrease publication bias in a decade (Parekh-Bhurke et al., 2011).

To detect publication bias in a systematic review or a meta-analysis, several measures have been suggested (Song et al., 2010) as below:

Unpublished Data and Publication Bias

If relevant studies are missed or are available as gray literature or in languages other than English, risk of bias is present. Hence, to overcome the issue an in-depth literature search should be done while conducting a systematic review and multiple electronic databases should be searched, as many journals are not listed in certain databases. These strategies help to avoid chances of bias (McDonald et al., 1999). An in-depth literature search related to non-bibliographical sources will also help to overcome publication bias. This include searching for conference abstracts, scientific reports from companies, reports from government and regulatory bodies, study registries, scientific data from personal research group, which are otherwise not available in standard databases (Lefebvre et al., 2009).

Graphical and Statistical Methods

To assess the publication bias different methods are used including both graphical and statistical methods. Graphical assessment includes funnel plots which were first used in the educational research (Richard et al., 1984). To detect publication bias in systematic reviews, most common methods employed were, Begg's test, Egger's test, and funnel plots. Similarly, in 1996, the Fail-N safe method was used in some reviews, however it is being much less likely to be used in recent reviews (7% vs. 1%, respectively) (Song et al., 2010).

Funnel Plot

Funnel plot is the simplest and easiest method to detect publication bias. A funnel graph is a simple graph between sample size of the component studies and summary outcome measures or effect size, assuming that all studies will assume the similar effect (Richard et al., 1984). It is plotted by taking effect size on *X* axis and variance or sample size on *Y* axis (Borenstein et al., 2009).

To do so, the point estimate from studies under consideration is plotted against the standard error or the sample size. The studies having highest precise values usually appear high on the *y* axis in a cluster fashion (Borenstein et al., 2009). Plot of studies having little or no publication bias appears more like an inverted funnel. Small studies appear arranged in a symmetrical manner on both sides of the larger studies which are located at the apex of the funnel plot (Torgerson, 2006).

However, in case of publication bias, usually one side (mostly the left side) of the funnel is missing indicating negative or null studies (Borenstein et al., 2009). On the other side, it can also be recognized as deterioration of the central part of funnel, suggesting that publications with statistically significant results are published while those without significant results are not. Therefore, it is necessary to consider the funnel plots before and during finalizing the systematic review (Torgerson, 2006).

Funnel plot asymmetry may not always reflect accurate publication bias, and there may be other factors contributing toward asymmetry, therefore, if the results from funnel plots are interpreted inappropriately, it could lead to misleading conclusions (Lau et al., 2006; Ioannidis and Trikalinos, 2007; Sterne et al., 2008). In some cases, due to small and methodologically weak studies, an irregular funnel plot appears, producing biased estimates of effect and this appear as positive. In reality, however this should appear as null or negative result otherwise (Torgerson, 2006).

Sterne et al. has listed four reasons that may possibly contribute toward an asymmetry in funnel plots. These include bias in publication, poor study design, irregularity in data, and heterogeneity (Sterne et al., 2000).

Fail-Safe N Test

To check whether a systematic review has a publication bias, one can use Fail-safe N test to detect publication bias (Rosenthal, 1979).

This test determines the number of missing studies averaging a *z* value of zero to make the combined effect size of zero (Rosenthal, 1979). This would reduce the summary effect to non-significance or would show the overall probability of Type 1 error to a stated level of significance, such as $P = 0.05$ (Rosenthal, 1978, 1979). Rosenthal (1979) suggested that to make *P*-value insignificant, it is important to know that how many missing studies would be needed to retrieve and to be added in the analysis, considering the mean effect of the missing studies as zero. In case, if only a few studies such as five or ten are required, to cancel the effect, then the true effect will be zero, while, in case if a large number of studies are needed to cancel the effect, such as 20,000 studies, hence it will be safe to assume that there is no publication bias in this case (Rosenthal, 1979). Rosenthal (1979) also identified the presumed location of missing studies as File drawer and Harris Cooper (Begg and Mazumdar, 1994) suggested that to nullify the effect, the number of missing studies to be incorporated to an analysis should be called the Fail-safe N (Begg and Mazumdar, 1994).

Fail-safe N test has certain limitations, that it does not emphasize on the substantive significance (real world relevance), rather its more oriented toward the statistical significance (Miller, 2008; Borenstein et al., 2009). For instance, it focuses on questions such as how many hidden studies should be added to make the effect statistically insignificant instead of looking into the answer that how many hidden studies are required to reduce the effect where it no more remains of substantive importance (Borenstein et al., 2009). This test relies on the *P*-values based test of significance, but with recent development in statistics, first the summary effect is calculated and then the *P*-value for this effect is computed. As the *P*-values are computed by using different approaches, testing different null hypotheses means that *P*-vales are not the same. Hence, the approach is not recommended in cases where effect size is priority (Borenstein et al., 2009).

Orwin's Fail-Safe N

Orwin (1983) developed a variant to Rosenthal's method, as the later allowed to determine that how many missing studies could bring the overall effect to a specified level, rather to bring it to a zero value (Orwin, 1983). Thus allowing the researcher to select the value with smallest effect is important as one can calculate that how many studies will be needed to bring the summary effect below the specified point (Borenstein et al., 2009). This method also helps the researcher to label the mean effect in missing studies as non-zero value and allow to compute a model for a series of other distributions and missing studies (Begg and Mazumdar, 1994).

Duval and Tweedie's Trim and Fill

The Trim and Fill method is used to estimate the number of studies missing from a meta-analysis that may result from the suppression of the most extreme results on one side of the funnel plot. The method does not validate the outcome or the overall effect but it helps in the determination of particular form of publication bias (Duval and Tweedie, 2000b, 2000a).

Trim and Fill method re-computes the effect size by removing the extremely small studies from the positive side of the funnel plot, thus making the funnel plot, more like a symmetric as of the new effect size. This trimming yield adjusts effect size, reduces the variance effect, and produces a confidence interval of too narrow value. Hence, the algorithm adds back the studies to the analysis and produces a mirror image for each, making the variance correct but no impact on point estimate (Borenstein et al., 2009; Duval and Tweedie, 2000a, 2000b).

The advantage of the above-mentioned approach is that it helps in the estimation of unbiased effect size. Besides, the computer programs based on Trim and Fill method are able to create a funnel plot comprised of both the observed and the imputed studies (to replace the missing data) (Borenstein et al., 2009). Hence, one can easily observe that how the effect size shifts when studies are added to the plot (Borenstein et al., 2009).

Limitations of this method includes that Trim and Fill method largely depends on the assumptions that why studies are missing. Also, the algorithm for detecting an asymmetry can be influenced if one or two studies are not-uniform (Borenstein et al., 2009).

Comparison of Published and Unpublished Data

Another method to detect publication bias is to compare the results from both published and unpublished studies evaluating the same research question. If a single meta-analysis includes both published and unpublished studies, the difference in results can indicate the presence and extent of publication bias.

In an example, published results of selective serotonin reuptake inhibitors showed favorable risk benefit profile for childhood depression, however the unpublished data on citalopram, paroxetine, and sertraline clearly indicate the associated risk of these medicines and their impact on children and youngsters (Whittington et al., 2004). However, the true estimates of unpublished results are difficult to predict, as to obtain data from such unpublished studies is a big challenge for the researchers (Song et al., 2013).

Analyzing Larger Studies Only

Another strategy to deal with publication bias is limiting the analysis to only larger studies (Borenstein et al., 2009). If it is assumed that the publication bias is majorly associated with smaller studies, then considering only larger studies would overcome the problem in theory. A strategy is to illustrate all possible thresholds by drawing a cumulative meta-analysis. This is developed by running one study at a time, then perhaps adding a second study, third, and so on (Borenstein et al., 2009).

Similar to this is a cumulative forest plot. In the forest plot the first row shows the effect expressed by one study, the second rows show effect based on two studies, and so on.

A potentially useful strategy is to illustrate all possible thresholds by drawing a cumulative meta-analysis (Borenstein et al., 2009). In order to examine the effect of different threshold for study size, the studies are arranged in the sequence of largest to smallest or being most precise to least precise.

Then a cumulative meta-analysis is performed with the addition of each study. If the point estimate has no effect upon the addition of smaller studies and if it has stabilized with the addition of larger studies, it can be assumed that smaller studies are not contributing toward any bias. Contrary to this if point estimate upon the addition of smaller studies shows a shift then there is a definite need to find out the reason for this shift (Borenstein et al., 2009).

Technological Aids in the Detection of Publication Bias

A number of computer-based programs are available to help in the detection of publication bias in meta-analysis. These include Comprehensive Meta Analysis (CMA), RevMan Analyses, Stata, and MetaWin (Borenstein, 2005).

Comprehensive Meta Analysis (Version 2.0)

Comprehensive Meta Analysis (CMA) is considered as the unique program for carrying out meta-analysis. The software was developed with the collaboration of experts from medicine, social sciences, and epidemiology (Meta-analysis.com, 2006). The program has an ability to execute all tests for the detection of publication bias including funnel plot, forest plot, rank correlation test, Trim and Fill, Egger's test, and other related tests (Borenstein et al., 2005). CMA accepts data in around 100 formats, the most utilized of which are number of events occurring in a single group and sample size. It can also execute the data if data input is in the format of means and standard deviations, correlations, point estimates, and confidence intervals (Borenstein, 2005).

Review Manager (Version 4.2)

Review Manager is a special software provided to researchers by the Cochrane Collaboration, meant for the reviews to be included in Cochrane library (Cochrane, 2014). The statistical procedure of the software is based on a module called RevMan Analyses, previously known as MetaView (Borenstein, 2005). RevMan will only execute data in the format of point estimate and standard error. It also accepts data in the form of number of events and sample size in each group, means and standard deviation (Borenstein, 2005).

Stata (Version 8.2)

Stata is a general software based on statistical package, which is not routinely used for meta-analysis (Stata.com, 2018). However, with some modifications in the running of this program (by using certain macros), Stata can create funnel plot, forest plot, compute

Egger's test, Trim and Fill test, rank correlation test (Sterne et al., 2009). It will accept data in the format of point estimate and standard error, point estimate and confidence interval, number of events and sample size, and means and standard deviations in each group (Borenstein, 2005).

MetaWin (Version 2.0)

MetaWin is another program for meta-analysis. It is mostly utilized in the field of ecology but due to its generalizability, it can be used in many other fields. It is capable to create funnel plot, forest plot, to compute the fail-safe N test, rank correlation, and other tests (Borenstein, 2005). MetaWin will only process the data if it is available in the format of number of events and sample size, means and standard deviation, correlations. It will also analyze the data if data is formatted as point estimate and variance (Rosenburg et al., 2000).

Tackling Publication Bias

There are many strategies which can help minimizing publication bias:

Trial Registries

If the researcher add registries in their search strategies and the results are accessible, this can help in the reduction of publication bias (Parekh-Bhurke et al., 2011). Because once the trial is registered, regardless of the outcome whether negative or positive or insignificant, the trial needs to be published (Parekh-Bhurke et al., 2011).

In 2004, an initiative was taken by the International Committee of Medical Journal Editors, which made it mandatory to register the trial and it needs to be available to the public at no cost (De Angelis et al., 2005). In 2005, the World Health Organization has initiated efforts to set International standards for clinical trial registration (Gülmezoglu et al., 2005). The British Medical Journal has also asked for trial registration and devised a modified-criteria for the registration of trials (Abbasi, 2004). These policies have resulted in the numbers of trial registration and been effective in reducing the risk of publication bias (Laine et al., 2007).

Data Availability

Sharing of the data and making it public would reduce the chances of publication bias. However, the availability of data and issues related to its privacy are challenging. A number of data repositories are available, where data can be saved with no or minimal cost. In addition to this, challenges related to data privacy and its transparency can be overcome by arranging the data in such a way that the data linking with participants cannot be possible (Brown et al., 2017).

Mandating Publication

Another approach to tackle the publication bias is to have the mandatory publication of research studies (Carroll et al., 2017). Some institution has made it mandatory to publish the research funded through them and one such initiative is Wellcome Open Research (2018). Another option is to publish in the journals, where authors can upload the paper even before the peer review, for instance F1000 research open platform, where authors upload the manuscript before the actual review of the study (F1000 Research, 2018).

Open Access Journals

Sometimes scientifically valid results remain unpublished due to limited readership, editors' decision making and due to limited space in journals. Therefore online, open access journals improve the readability and reduce publication bias. Therefore the studies which might get delay in publication due to being less attractive to the high impact print based journals can be published in online, open access journals, without wasting too much time on the process of rejection and submission (Brown et al., 2017). The electronic publishing has more advantages as compared to conventional publishing as electronic publish is not bound to follow the limits as the traditional printed journal has to do (Berlin, 1992)

Peer Review Process and Publication Bias

Peer review serves as the source to improve quality checks to published articles, but delay in publication or preference of a reviewer or even journal's choice to publish a certain study result in publication bias (Brown et al., 2017). Thus, change in the traditional review process may decrease the chance of publication bias.

Some journals have the policy that the editor of the original journal, which has originally rejected the article may suggest an alternative journal, thus decreasing time between submissions and peer-review process. Another option is "registered reports"; this is a two tier process, in which the outcome is independent of the review process (Chambers, 2013). An article is published based on the proposed hypotheses, methodology and predesigned analysis and it is published once the data is collected, interpreted and results

are finalized. Thus publication in such journals is based on the methodology and perhaps not on the outcome of the results (Brown et al., 2017).

Editorial Policy

An editorial policy can also be helpful to eliminate the publication bias (Thornton and Lee, 2000). This can be done only if the journal editors and reviewers could focus on reviewing high standards in conducting research, as well as excluding key factors influencing publication bias. They can look or may ask for the proof of registration of a trial, confirmation of randomization or any other factor that may contribute toward publication bias (Begg and Berlin, 1988; Chalmers et al., 1990).

Conclusion

The publication bias has significantly influenced the scientific research. It can be in various forms; however, it deteriorates the quality of published research thus resulting in the waste of resources and leading to poor patient health outcomes. There is a need to employ data quality assurance techniques before publishing scientific results as this may undermine the quality of evidence-based decision making in health research.

Discrete Choice Experiment

Dalia M. Dawoud, Cairo University, Giza, Egypt

Introduction

Methods for eliciting people's preferences for choosing products and services have evolved over the time. Opinion polls and traditional satisfaction surveys have been the most commonly used methods. However, more rigorous methods used in marketing and psychology research started to attract considerable attention from the pharmacy practice research community.

Preferences, in general, can be either "revealed" in the choices people make in real-life situations or "stated" by the individual when asked about them in surveys. Revealed preferences are considered the most informative for understanding the real decisions made by individuals. However, there are methodological problems that hinder the feasibility of measuring revealed preferences, particularly in the context of preferences for pharmaceutical products and services that are still in development and not currently available in the market. Hence, measuring stated preferences is more widely used in this context and is generally considered an acceptable alternative (Quaife et al., 2018).

Stated preference methods, on the other hand, involve asking people to state how they would behave, or what they would prefer, based on a hypothetical scenario (Louviere et al., 2000). Several methods exist for assessing stated preferences. These can be classified into either choice-based; where individuals are asked to make choices between alternatives with different attributes (i.e., characteristics), or nonchoice-based methods; where only one option is given and the respondent is asked to rate her/his preference for this option (Carson and Louviere, 2011). **Fig. 1** provides a taxonomy of stated preference elicitation techniques.

Choice-based methods are, generally, preferred for eliciting stated preferences as these can give more granular information regarding the trade-offs that people are willing to make between different attributes of a product or service (e.g., people may be willing to accept higher risk in return for improved outcomes and/or reduced costs). They also reflect real-life situations, where people are faced by choices and trade-offs to make in their everyday life. The most widely used of these choice-based methods is the conjoint analysis, best-worst scaling, and discrete choice experiments (DCEs) (Elliott and Payne, 2005). In this chapter, we discuss DCE as a promising methodology that has many applications in pharmacy practice research.

Discrete Choice Experiment

Definition

DCE is a survey-based quantitative technique for eliciting individuals' preferences. The method involves asking individuals to choose between alternatives, where each is described by a number of attributes and their levels (Mangham et al., 2009). These attributes are the characteristics of the intervention of interest and can relate to its outcomes (e.g., the probability of conceiving for a fertility treatment) or the processes involved in delivering the intervention (e.g., waiting time for or the location of a service).

The choices are usually presented to respondents in the form of choice sets. Respondents are asked to indicate their preference between a discrete set of two (or more) alternatives; using the attributes and levels to describe these alternatives (Amaya-Amaya et al., 2008). The responses are used to determine the attributes that significantly influence individual preferences as well as their relative importance (Mangham et al., 2009).

Fig. 2 presents a hypothetical example of a choice set from a DCE illustrating its basic elements.

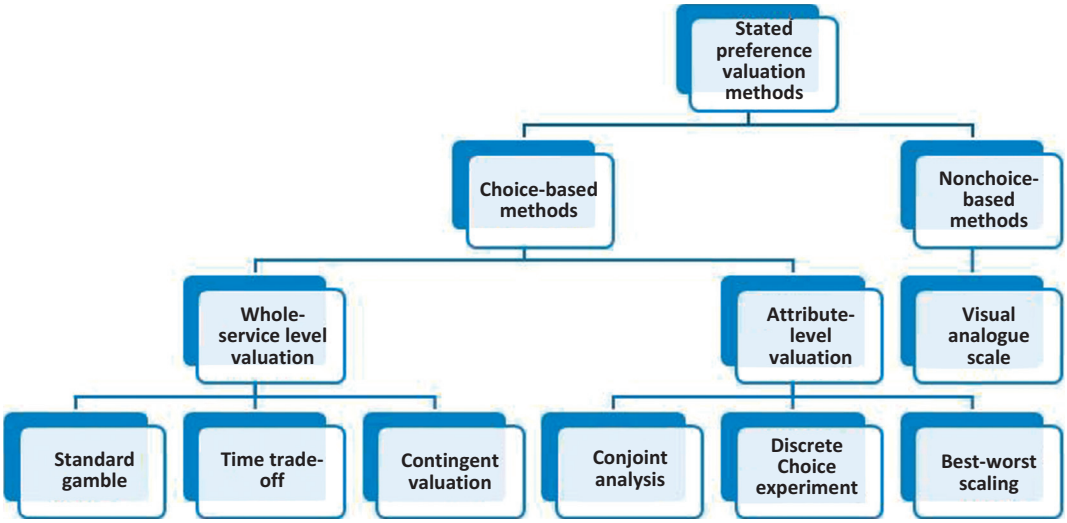

Figure 1 Stated preference valuation methods.

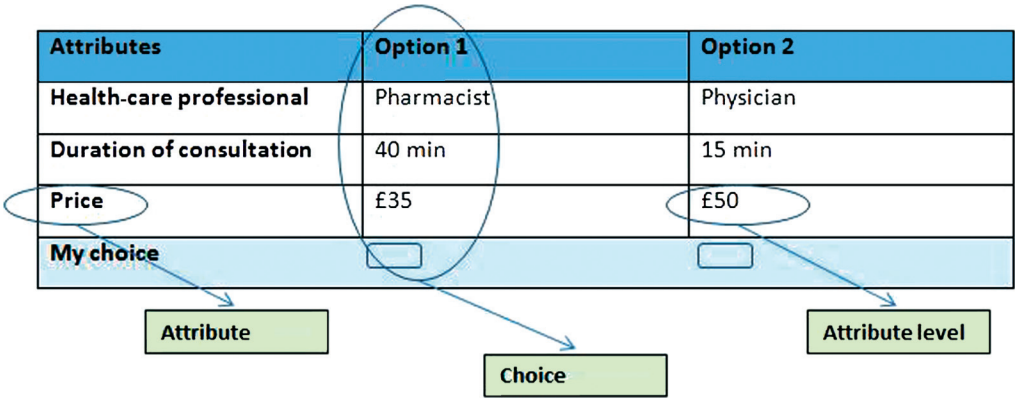

Figure 2 A hypothetical example of DCE choice set with illustration of its elements.

The DCE technique is particularly useful in the absence of revealed preference data; for example:

- if the product or service in question is still under development,
- if there is no variation in the available product or service, and
- if there is value for individuals who are not currently using the product or service in question (e.g., if the individual would have preference for a service to be available for potential use in the future).

Theoretical Foundation of Discrete Choice Experiments

DCE has its foundations in economic theories, namely, random utility theory (Hall et al., 2004b) and Lancaster's theory (Lancaster, 1966). The former is based on two main assumptions: "economic rationality" and "utility maximization." These refer to assuming that individuals make rational choices (economic rationality), and in doing so, they choose the alternative that yields the highest individual benefit (utility) for them (utility maximization). Lancaster's theory argues that utility generated for the individual by an alternative is assumed to depend on the utilities associated with its composing attributes and attribute levels (Lancaster, 1966).

As Mangham et al. (2009) explain:

If $\boldsymbol{Y_{iq}}$ is the utility of individual q for the ith alternative, then

$$Y_{iq} = X_i\beta_i + \varepsilon_{iq}$$

where

$\boldsymbol{X_i}$ is a vector of attributes for the ith alternative, $\boldsymbol{\beta_i}$ is a set of weights that establish the relative contribution of each attribute to the utility associated with the ith alternative, $\boldsymbol{\varepsilon_{iq}}$ is the residual capturing the unobserved variation in the characteristics of different options and any measurement errors.

Design and Administration of Discrete Choice Experiments

As an experimental technique, undertaking a DCE involves a number of steps. It starts with design, followed by data collection, analysis, and interpretation. The ultimate aim of the experiment is to examine the effect of the intervention's attributes at their different levels on respondents' preferences for/valuation of the intervention. Thus, the attributes are considered as the independent variables, which can take two or more values (levels) each and the preference for/valuation of the intervention as the dependent variable.

However, before embarking on undertaking a DCE, it is important to make a decision about the target population. This means deciding whose preferences should be elicited. Eliciting the preferences of current service users is usually the main aim of a DCE, but it is also important to consider the views of future users to inform service/product development. Furthermore, in health care, eliciting the views of the service providers such as doctors, nurses, and pharmacists would be important to allow comparisons with the views and preferences of the service/product users.

The following are the main steps involved in undertaking a DCE.

1. *Choosing the attributes*

   The first step in designing a DCE is the choice of the attributes that can be used to describe the product or service of interest. These attributes can be qualitative (e.g., who delivers an immunization service) or quantitative (e.g., the number of follow-up visits required) (Hensher et al., 2005; Ryan et al., 2001). Mangham et al. (2009) consider reviewing the published and gray literature, such as policy documents, to be the best starting point for identifying relevant attributes (Mangham et al., 2009). However, they argue that primary data collection might still be needed to improve the face validity of the DCE by ensuring that it reflects the study setting. This usually takes a qualitative research approach (e.g., face-to-face interviews or focus groups) and requires input from stakeholders and decision makers who will be using the results of the DCE in informing the design and/or delivery of the product/intervention.

   It is also important to ensure that there is no overlap between the attributes, which is referred to as inter-attribute correlation, as this makes it difficult to establish the effect of each attribute in isolation. The chosen attributes should also represent both the benefits and risks of the product or intervention in question in order to give a comprehensive description and ensure that the respondent is aware of both aspects when making a choice (Ryan et al., 2001). This is particularly important when a trade-off is required between benefits and harms, for example, where increased efficacy through using higher doses of a drug means more side effects. Including both risks and benefits of pharmaceutical products allows the estimation of benefit–risk assessment (BRA) models and calculating the maximum acceptable risk (MAR) that respondents are willing to take (Seston et al., 2007a).

   Including a cost attribute has an added benefit, as it allows estimating the monetary value placed by the respondents on each of the attributes included in the DCE (Morris et al., 2007). When a cost attribute is included; the willingness to pay (WTP) for a favorable change in the level of each of the other attributes can also be calculated. This is presented as the marginal rate of substitution (MRS), which is a measure of the trade-offs that the respondent (consumer, patient, or health-care professional) is willing to make, and is calculated by dividing the coefficient for this attribute by the coefficient for the cost attribute (i.e., $\beta_{\text{attribute}}/\beta_{\text{cost}}$) (Morris et al., 2007). This trade-off vs cost can, alternatively, be represented as the willingness to accept (WTA), which is the amount of money respondents believe compensates for an unfavorable change in the attribute. A drawback of including a cost attribute arises in health systems where the intervention will be free at the point of service, where the respondents may not provide credible answers (Guttmann et al., 2009). More detailed discussion of the applications of WTP calculations in pharmacoeconomic evaluations using cost–benefit analyses can be found elsewhere (Drummond et al., 1987).

   It has to be noted that it is not possible to include every single attribute or characteristic of the service/product in question in the DCE. This is why deciding the number of attributes to include in a DCE is another important aspect of its design. In practice, most DCEs will include fewer than 10 attributes so that all of them can be considered by the respondents when making their choice; with some arguing that a maximum of 7 should be considered (DeShazo and Fermo, 2002). The rationale behind this is that the more the attributes, the greater the cognitive burden of completing the DCE. So, to avoid the risk of low response rate, it is advisable to limit the number of attributes to a recommended maximum of 7–10 (DeShazo and Fermo, 2002).

2. *Assigning levels to the chosen attributes*

   The nature of the attribute, qualitative or quantitative, will dictate the nature of the levels to be used. For example, an attribute may be related to who delivers the service in question, and in this case, the levels listed will be those professionals that are likely to provide the service (e.g., for an immunization service, this could include pharmacist, nurse, or doctor). Quantitative attributes, such as the frequency of administration of a new drug and cost, will be given numerical levels.

   The chosen levels should reflect the range that the respondents might experience or expect to experience if the product or service is a new one (e.g., a new treatment being developed), so that a comprehensive description of the intervention in question is given (Lancsar and Louviere, 2008). Additionally, the chosen levels for the quantitative variables should be evenly spaced and cover a wide range to avoid respondents' not making a choice because of the similarity of the levels. This also allows more accurate estimation of the effect of these quantitative attributes (Lancsar and Louviere, 2008).

   A specific issue relating to defining levels for risk attributes (e.g., percentage probability of side effects) is the difficulty that some respondents may have in understanding probabilities. Hence, effort should be made to ensure that the descriptions are clear and communicated in a way easy to understand (Peters et al., 2006).

Similar to the number of attributes, the number of levels should be kept to a minimum to avoid cognitive overload and difficulty making choices for the respondent. Piloting can then show whether a change to the chosen attributes and levels is required (Mangham et al., 2009).

3. *Designing the choice sets*

   Each DCE consists of a number of choices made of the same number of attributes. The total possible number of choices in the experiment will be based on the total number of attributes and levels in a full factorial design. Considering a DCE that includes 5 attributes, each with 3 levels, then, the total number of possible choices is 243 (3^5). However, this is likely to result in an unmanageable number of choices to be presented to the respondents. As a general rule, it has been reported that respondents can manage between 9 and 16 pairwise choices before they get tired or bored of the experiment (Hanley et al., 2007).

   Hence, approaches have been developed to allow reducing the number of choice sets in a DCE. These include linear and nonlinear methods. The classical linear method uses fractional factorial design and orthogonal arrays to create the choice set, while nonlinear methods utilize Bayesian optimal designs.

   The linear fractional factorial design uses a principle of maintaining orthogonality. This means that each attribute independently affects the overall preference for the service and its utility. The task of reducing the number of choice sets is facilitated by the use of programs such as SPSS Statistics Software (IBM®). These can provide scenarios that describe the level to assign to each of the attributes. However, the full and fractional factorial designs may result in DCE parameters that do not fit the linear models.

   A Bayesian design, on the other hand, maximizes precision of estimated parameters for a given number of choice questions by incorporating *a priori* information about the sign and value of parameters (Reed Johnson et al., 2013). The *a priori* information can be obtained by undertaking pilot studies (Hifinger et al., 2017b). Bayesian optimal designs can be generated algorithmically by using JMP statistical software (SAS Institute Inc.).

   Creating the choice sets then follows, by combining the scenarios in sets of two or more. Two methods are usually quoted as the most commonly used approaches to undertake this task: constant comparison and random pairing (Phillips et al., 2002). In the former, one scenario is kept constant and paired against the remaining scenarios to create the choice sets. This is usually a scenario that describes the status-quo or the existing service. In the latter, the scenarios are randomly paired to create the required number of choice sets.

   Additionally, decisions concerning various presentation options, including whether and how to include the opt-out option and how to frame and depict the attribute levels should be made. The inclusion of a nonchoice option is considered to represent the real-world context. However, these nonchoice responses do not provide any information on how individuals trade-off the attribute levels presented to them. Labeling the choices, e.g., by mentioning the product name, is not generally preferred as it usually introduces selection bias and reduces respondents' attention to the attribute levels (de Bekker-Grob et al., 2010).

   Checks can be incorporated to assess internal validity by examining whether the respondents understand what is required. Two approaches are reported in the literature to do this, namely, dominance and consistency (Janssen et al., 2017). Dominance works by including a choice that includes a dominant scenario, which is better than the alternative in all attributes. If the respondent understands the task, then he/she should be choosing the dominant option. On the other hand, consistency works by repeating a choice set to check if the respondent will have consistency in his/her choice by choosing the same scenario in both instances (Janssen et al., 2017).

4. *Designing the DCE questionnaire*

   Designing the DCE questionnaire is a very important step that affects its validity and usefulness. The choice sets created form the basis of the DCE questionnaire. However, it is important to provide enough context to the task, and this is why the questionnaire usually starts by a detailed introduction to the task and what is required.

   Taking into account the level of respondents' understanding and ensuring they know what is required and how to complete the task will ensure collecting useful data. This is usually achieved by providing enough explanation and examples. Thus, it might be essential to provide the questionnaire in more than one language and more than one format (Mangham et al., 2009).

   Additionally, in populations with lower levels of literacy, the use of diagrams and pictures can be particularly useful. Another design decision that has to be made is about the order of presenting the choice sets, which can affect the choices respondents make. It is good practice to collect data on socioeconomic indicators as this allows analysis of the impact of individual characteristics on the choices made (Mangham et al., 2009).

   Sample size calculation is an important consideration at the stage of designing the DCE. Formal calculations of sample size need to take into account the heterogeneity in preferences and any planned subgroup analysis (de Bekker-Grob et al., 2015). A commonly used method for calculating sample size in DCEs is the Rule of Thumb calculation described by Orme (Orme, 1998, 2010). It has been reported that the precision of DCEs rapidly decreases at sample sizes less than 150 (Reed Johnson et al., 2013).

5. *Pretesting/piloting*

   Piloting is an essential step before the administration of the DCE. The pilot exercise should be used primarily to ensure that respondents properly understand the questions and the tasks they are asked to complete. For example, respondents can be asked to mark every question or answer category that they did not understand and provide suggestions for improvement. This is particularly relevant when working with different languages and or/cultures (Hall et al., 2004a).

   During piloting, it is also possible to check whether respondents consider the range of attributes and levels included in the DCE to be appropriate and to invite them to suggest changes to existing attributes or their levels, addition of new attributes or levels or omission of attributes or levels. This can be done in different formats, including the use of face-to-face interviews or focus groups.

It can also take the form of a ranking exercise in which the respondents are asked to rank the attributes according to their importance (Mangham et al., 2009).

If a sufficiently large sample is included in the pilot DCE, it is possible to quantitatively analyze the data to get some information about the significance of the included attributes and any interaction between them. This information is very valuable in informing the analysis of the final DCE. Additionally, the quantitative information from the analysis of pilot DCE data can be used to finalize the decisions regarding the appropriate attributes and levels that can be included in the analysis of the final DCE. Piloting also ensures that the range of socio-economic and other information requested from respondents in the final DCE are appropriate. Moreover, sample size calculations can be based on the pilot data to ensure that significant differences for each attribute can be detected (Bliemer and Rose, 2009).

6. *Administration*

Once the design of the DCE is finalized, based on the outcomes of the piloting stage, and the sampling frame is agreed; administration and data collection for the main study can be initiated. The DCE can either be self- or interviewer administered. Self-administered questionnaires can be administered by post, phone, or online, while Interviewer-administered DCEs are usually completed face-to-face or over the phone (Ryan, 2004).

Postal and online surveys may not always be feasible particularly in settings with lower levels of literacy. Additionally, they usually have low response rates. Thus, having trained interviewers administering the DCE is usually the preferred method as it can ensure that respondents will be given the required directions to facilitate completing the task. However, this is usually more costly.

Analysis and Interpretation

Analysis of DCE data is based on the use of statistical regression models, which have a categorical dependent variable that is either dichotomous or polychotomous (Hauber et al., 2016). These models include probit, logit, and multinominal logit. Panel data estimation techniques are usually required in the analysis of DCE data as respondents are asked to consider multiple choice pairs, which means independence of the error terms cannot be assumed (Hauber et al., 2016).

In DCEs where two choices without an opt-out option are presented to a respondent, either random effects logit or random effects probit are usually considered most appropriate. On the other hand, if the respondent is asked to choose from more than two options, or two options plus an opt-out, then the data can usually be analyzed using multinomial models (Hauber et al., 2016).

Generally, a positive significant coefficient, β, means that the respective attribute levels significantly increase overall preference (utility). This is usually expected for favorable attributes such as treatment efficacy. A negative significant coefficient, β, in contrast means that the respective attribute level decreases the overall preference. This is expected to be seen for attributes representing side effects or costs of services or treatments.

The analysis of DCE data also involves the quantification of the trade-offs made by the respondents. For example, in benefit–risk assessment studies of pharmaceutical products, MAR for each risk attribute is usually presented. MAR is defined as the maximum level of each risk criterion, which participants are willing to accept in order to increase 1 unit level of efficacy. It is equal to the ratios between benefit and risk coefficients (i.e., $\beta_{\text{benefit}}/\beta_{\text{risk}}$) (Vass and Payne, 2017). Similarly, as explained earlier, it is possible to calculate the WTP and the WTA in DCE studies that include a cost attribute, which represent the monetary trade-offs that participants are willing to make.(Drummond et al., 1987).

DCE is also useful in understanding the estimation of differences between subgroups and identifying the individual characteristics that have significant effect on individual preferences. This is usually done by including interaction terms into the analysis model with a priori determined variables of interest (Hauber et al., 2016).

Applications in Pharmacy Practice Research

DCE is a relatively new research method when it comes to its use in pharmacy practice research. However, its use in healthcare research in general predates its use in pharmacy research. A scoping search of the literature conducted in MEDLINE in May 2018, using the free text terms Discrete Choice Experiment* AND Pharm* to identify some examples of applications of DCE in pharmacy research, returned 61 records. Of these, 41 primary research studies, (Albada and Triemstra, 2009; Ashcroft et al., 2006; Bansback et al., 2016; Boonen et al., 2011; Boonen et al., 2009; Byun et al., 2016a; Byun et al., 2016b; Cheung et al., 2018; Cristina et al., 2002; de Vries et al., 2015; Diaby et al., 2011; Feehan et al., 2017; Gerard et al., 2012; Grindrod et al., 2010; Haac et al., 2017; Hifinger et al., 2017a; Hifinger et al., 2017b; Hong et al., 2011; Kawaguchi et al., 2014; Laba et al., 2013; Laba et al., 2012; Mantovani et al., 2005; Munger et al., 2017; Naik-Panvelkar et al., 2012a; Naik-Panvelkar et al., 2012b; Ngorsuraches et al., 2015; Ngorsuraches and Thongkeaw, 2015; Park et al., 2012; Porteous et al., 2016; Porteous et al., 2006; Rennie et al., 2012; Rockers et al., 2012; Scalone et al., 2009; Scott et al., 2007; Seston et al., 2007a, 2007b; Tinelli et al., 2009; Wang et al., 2011; Wanishayakorn et al., 2016; Wellman and Vidican, 2008; Whitty et al., 2015) and 3 systematic reviews (Katherine and Rachel, 2005; Pradnya et al., 2013; Vass et al., 2017) were considered relevant.

The identified systematic reviews (n = 3) were all focused on studies of pharmaceutical services (Katherine and Rachel, 2005; Pradnya et al., 2013; Vass et al., 2016). The primary research studies dated back to 2002, with the number published annually up to 2017 ranging from 1 to 7.

Most of the primary research studies focused on examining aspects of pharmaceutical services (n = 23), while the remainder focused on pharmaceutical products (n = 18). The studies were either conducted in a single country (n = 39) or were multinational (n = 2). The single country studies were conducted in the United Kingdom (n = 8), the United States (n = 7), the Netherlands (n = 6), Australia (n = 5), Korea (n = 3), Thailand (n = 3), Italy (n = 2), and one each in Canada, Cote d'Ivoire, Japan, New Zealand, and Uganda. Of the two multinational studies, one was conducted in the United Kingdom, Hungary, and Romania, and the second was conducted across 12 European countries.

Studies of Pharmaceutical Services

The most recent systematic review of DCEs in pharmacy has included 17 studies (Vass et al., 2016). These covered studies published up to 2012. Since then, six more studies were identified that were considered to be good examples of using DCEs to assess preferences to pharmaceutical services, taking the total to 23 studies (Albada and Triemstra, 2009; Boonen et al., 2011; Boonen et al., 2009; Cristina et al., 2002; Feehan et al., 2017; Gerard et al., 2012; Grindrod et al., 2010; Hong et al., 2011; Kawaguchi et al., 2014; Munger et al., 2017; Naik-Panvelkar et al., 2012a; Naik-Panvelkar et al., 2012b; Porteous et al., 2016; Porteous et al., 2006; Rennie et al., 2012; Rockers et al., 2012; Scalone et al., 2009; Scott et al., 2007; Seston et al., 2007b; Tinelli et al., 2009; Wang et al., 2011; Wellman and Vidican, 2008; Whitty et al., 2015).

The main interventions/services assessed in these studies included pharmacist prescribing, medicines management and other specialist services, electronic prescribing, pharmacist counseling, community pharmacy service models, community pharmacy-based services for chronic conditions, and management of minor ailments.

The sampling frames in these studies included single, mainly patients or health-care professionals, or multiple populations. The number of respondents ranged from 80 to 9252; with response rates ranging from 10% to 99%. Similar to studies of pharmaceutical products; studies that used face-to-face and online administration seemed to achieve higher response rates. In the majority of the studies, mailed survey was the method used for the administration of the DCEs, followed by online/web administration, which was used in the most recent studies.

The approaches used for choosing the attributes and levels were primarily literature reviews with expert input. Few studies reported the use of some form of formal qualitative research methods and, where used, reporting quality was generally low. The number of attributes included in the scenarios ranged from 3 to 11, with the majority including 6 or more attributes. The number of levels for each attribute ranged from 2 to 7. This is likely to be due to the complex nature of the pharmaceutical services interventions compared to pharmaceutical products, which necessitates the use of large number of attributes to allow accurate description of the intervention. The attributes were generally study specific. Examples include who delivers the service, length of consultations, waiting time, the cost or copayments, and workload.

Similar to studies of pharmaceutical products, the most commonly used DCE design was the fractional factorial design, though Bayesian approaches featured in a few studies. The analysis approach used in the majority of the studies utilized the multinomial logit model.

Studies of Pharmaceutical Products

Studies of pharmaceutical products (n = 18) focused on assessing patients' and/or health-care professionals' preferences for the characteristics of these drug products (e.g., timing, frequency, and route of administration), the benefit–risk trade-offs they make, their WTP for and adherence to these products) (Ashcroft et al., 2006; Bansback et al., 2016; Byun et al., 2016a; Byun et al., 2016b; Cheung et al., 2018; de Vries et al., 2015; Haac et al., 2017; Laba et al., 2013; Laba et al., 2012; Mantovani et al., 2005; Park et al., 2012; Seston et al., 2007a; Wanishayakorn et al., 2016; Diaby et al., 2011; Hifinger et al., 2017a; Hifinger et al., 2017b; Ngorsuraches et al., 2015; Ngorsuraches and Thongkeaw, 2015). These studies are useful in informing the development of pharmaceutical products and ensuring their acceptability to the consumer/patient and prescriber.

The pharmaceutical products covered in these studies included drugs for psoriasis, hemophilia, osteoarthritis, rheumatoid arthritis, renal cell carcinoma, breast cancer, diabetes, venous thromboembolism (VTE) prophylaxis, insomnia, and hypercholesterolemia, as well as human papilloma virus (HPV) vaccination. Two studies focused on examining the public's preferences for the characteristics of prescribed medications; in general, to assess their impact on adherence (Laba et al., 2012, 2013) while another study examined prescribers' preferences for these characteristics to assess their impact on formulary inclusion and reimbursement decisions (Diaby et al., 2011).

The sampling frames in these studies included patients, carers, consumers/general public, health-care professionals (physicians, nurses, and pharmacists). Some studies included both patients/consumers and health-care professionals to compare between the preferences of these groups (Mantovani, 2005; Park, 2012; Byun, 2016; Wanishayakorn, 2016). The number of respondents in the included studies ranged from 126 to 2663, with a response rate ranging from 10% to 100%. The majority of the DCEs were administered using postal or online surveys. Face-to-face interviews were used mainly with patients. The higher response rate appeared to be associated with face-to-face administration of the DCE.

The most common approach used for choosing the attributes and levels was using literature reviews and expert input, with only one study reporting the use of formal qualitative research methods (Wanishayakorn et al., 2016). The number of attributes included in the scenarios ranged from 4 to 8. These were primarily related to treatment efficacy, side-effect, route, and frequency of administration and cost. The cost attributes were included in 9 studies and facilitated the calculation of WTP for favorable

changes in the included attributes. The number of levels ranged from 2 to 4 and included combination of qualitative and quantitative descriptors.

The most commonly used DCE design was the fractional factorial design, although other design approaches including Bayesian design were also utilized. The analysis approach used in the majority of the studies was the multinomial conditional logit modeling.

An example of a DCE study is provided in Box 1.

Box 1

Example

Study:
Haac et al. (2017)

Title
Patient preferences for venous thromboembolism (VTE) prophylaxis after injury: a discrete choice experiment

Objective
To elicit patient preferences towards route of administration, complications, and costs of prophylaxis options for VTE after injury

Country
USA

Population
Adult orthopedic trauma patients who have survived a VTE event

DCE design:

1. *Choosing the attributes:*
   Seven attributes were chosen based on literature review, patient interviews, expert consultation, and retrospective review of patient outcomes
   The attributes are route of administration, cost, possible side effects, risk of major bleeding, risk of VTE requiring therapeutic anticoagulation for 6 months, risk of requiring reoperation, and risk of death due to pulmonary embolism (PE).
2. *Assigning levels to the chosen attributes:*
   Two attributes were qualitative: Route of administration (oral tablet, subcutaneous injection) and possible side effects (none, bruising on leg, stomach pain). Five attributes were quantitative. Risk attributes were presented as *n* per 1000.
3. *Designing the choice sets*
   Forty choice sets were developed, using Bayesian D-optimal optimal design with using JMP statistical soft-ware (SAS Institute Inc.) and randomly divided into 4 groups of 10 choice sets each. Two hypothetical medications were compared in each choice set.
4. *Designing the DCE*
   The questionnaire included questions covering the respondents' demographics including age, sex, race, type of injury, income, health insurance, and days on prophylaxis. Sample size calculation was completed using the Rule of Thumb calculation (Orme, 1998).
5. *Pretesting/piloting*
   No piloting or retesting was reported.
6. *Administration*
   The survey was self-administered face-to-face in the presence of a member of the research team. Demographic data were also collected in the survey.

Analysis:

- A multinomial logit model with effect coding was used in the analysis to calculate the marginal utility, willingness to pay (WTP), and acceptable trade-off estimates for 1% reduction in VTE complication or side effects. Preference heterogeneity based on respondent characteristics was also assessed by adding interaction terms.

Results:

- Reducing the risk of death due to PE was the most strongly preferred attribute, with a marginal utility of 4.57 ($P < 0.0001$) followed by preference for reducing the risk of VTE requiring therapeutic anticoagulation (0.25; $P < 0.0001$).
- Oral administration was also preferred (marginal utility 0.16; $P < 0.0001$); however; possible medication side effects such as stomach pain or bruising were not a significant attribute ($P > 0.1$).
- The highest WTP was for 1% absolute risk reduction in PE was $1686.9. Respondents also were willing to pay $117.45 to receive prophylaxis via the oral route.
- To change preference from oral to subcutaneous route, an absolute reduction in the risk of death due to PE of only 0.07% is required, while the absolute VTE risk reduction required for this change was 1.27%.
- Subgroup analysis assessing the heterogeneity of respondents' preferences showed that some covariates significantly affected preference for the oral route. These were being female, white, or having lower extremity injury.

Conclusion
The study demonstrated that orthopedic trauma patients preferred the oral route for VTE prophylaxis administration, when all other attributes were equal. However, reducing the risk of death due to PE was the most influential factor when making a decision about medication choice.

Summary

From this quick snapshot of the literature, it was possible to see that the use of DCE in pharmacy practice research has been growing steadily. Many topics have been suitable areas for this new research method. Studies that used DCE assessed preferences of different populations groups (patients, carers, general public, health-care professionals, and decision makers) to a range of interventions (pharmaceutical products and services) with the results directly impacting on policy making, clinical practice, and product development. This goes to show the potential for this technique to exponentially grow as a research method in pharmacy practice research over the coming years. It is important for pharmacy practice researchers to equip themselves with the knowledge of the basics and applications of this research method in order to make the best use of DCE to advance pharmacy practice and science.

Glossary

Attributes Characteristics of the intervention of interest. These could be quantitative or qualitative and are described using levels.
Best-worst scaling A survey-based method for assessing stated preferences where respondents are asked to select their most preferred and least preferred option out of a number of options.
Conjoint analysis A survey-based method used in market research that helps determine how people value different attributes of a product or service.
Discrete choice experiment A survey-based method underpinned by economic theory that allows the systematic quantification of respondents' preferences for the different characteristics (attributes) of a good or service, the balance between these different attributes and the relative value of each attribute.
Levels The values that the attributes describing a good or service can take.
Stated preferences The preferred options for individuals as stated by them when asked to choose their preferred option from a series of hypothetical scenarios.

Quality of Qualitative Research

Muhammad Abdul Hadi*, Theo Ansong†, Josie Solomon†, *School of Pharmacy, Institute of Clinical Sciences, University of Birmingham, Birmingham, United Kingdom; †Leicester School of Pharmacy, University of Lincoln, Lincoln, United Kingdom

Chapter Overview

This chapter focuses on, perhaps, the most debated issue among research methodologists-quality assurance of qualitative research. Unlike existing literature, which either focuses on the process-oriented approach or the output-oriented approach, this chapter provides a comprehensive review of both approaches. This chapter begins with an introduction section, which provides an overview of the issue of quality in qualitative research. The first half of the chapter focuses on process-oriented approach and various strategies/tools that can be used to ensure quality. The second half focuses on output-oriented approach and highlights advantages and disadvantages of the two most commonly used checklists developed to improve quality of reporting of qualitative research. The chapter has been divided in various subsections to improve the readability and flow.

Introduction

Like any other research methodology, quality is of critical importance in qualitative research and this is to ensure that the qualitative research is credible and dependable. The reasons that make issue of quality in qualitative research complicated are multifaceted. These include: the diversity in research methods available under the umbrella term of qualitative research methodology; multiplicity of viewpoints available in literature on the issue of "quality" and lack of clear and explicit guidance in simple language understandable to health-care researchers undertaking qualitative research, and the very nature of health-care researchers-who are fundamentally trained with "quantitative" mindset, often find it difficult to transit to "qualitative" mindset and truly embrace the philosophy of qualitative research. Furthermore, health-care researchers have "borrowed" qualitative research methods from social science disciplines, and therefore, the understanding of what constitutes a good qualitative research may vary across these disciplines.

Reynolds et al. (2011) reviewed literature debating various issues related to quality assurance of qualitative research and found two dominant, yet contrasting, approaches to quality assurance in qualitative research, process-oriented approach and

output-oriented approach. The process-oriented approach, epistemologically linked to interpretive/constructionist approach, is based on the internal set of values or principles of "best practices" inherent to qualitative research. The authors identified six principles of process-oriented approach: reflexivity in terms of researcher's epistemological position, assumptions, and practice; detailed description of decisions made, and assumptions supported; comprehensiveness of approach to research question; responsibility toward decision making throughout the research process; adherence to good ethical practices; and a methodical approach in designing and conducting the study (Reynolds et al., 2011). On the other hand, output-oriented approach is drawn from positivist or post-positivist paradigm. It advocates the use of certain techniques, often in the form checklists, and demonstrating their use is considered an indicator of quality.

In this chapter, we will discuss the issue of quality in qualitative research based on these two narratives proposed by Reynolds et al. (2011).

Process-Oriented Approach: Practices to Ensure Rigour and Trustworthiness

Given the theoretical and philosophical differences between qualitative and quantitative methodologies, applying the same quality criteria of validity and reliability across both research methodologies is unjustified. Therefore, instead of using quantitative terms such as reliability, internal validity, objectivity, and generalizability; the use of alternative qualitative equivalent terminologies such as dependability, credibility, conformability, and transferability, respectively, is advocated to describe rigor and trustworthiness in qualitative research (Lincoln and Guba, 1985; Noble and Smith, 2015).

Methodologists have developed several strategies to ensure trustworthiness of qualitative research. It is not expected that the researcher would engage with all these strategies in a single study as it will not be always either practical or possible to engage with of all them. However, it has been recommended that at least two of these strategies should be used in a particular qualitative study (Creswell, 2006). A brief description of commonly used strategies is given below.

Triangulation

Triangulation aims to reduce bias typically associated with single data source and/or method by using at least two different but related data sources, data collection methods, or researchers. It is frequently used to ensure credibility and conformability of qualitative studies (Creswell, 2006) as it helps researchers to ascertain the validity of the interpretations derived from different data sources. For example, a researcher who is interested to understand barriers to medication adherence among patients with long-term conditions may consider interviewing both patients and their health-care providers. The researcher then draws themes after analyzing and integrating data from both datasets.

Self-Description/Reflexivity

Self-description also referred as self-reflection is perhaps the most important tool not only to acknowledge but also to reduce researcher bias. Self-description allows qualitative researchers to explain their epistemological position, personal beliefs in relation to the research topic, field experiences, and previous research and/or professional training and how these things might have influenced the research findings (Hammersley and Atkinson, 1995; Long and Johnson, 2000). To recognize and disclose any personal bias, it has been suggested that the qualitative researchers should make field notes and maintain a reflective journal (Long and Johnson, 2000). Self-reflection ensures credibility and conformability of research findings.

Member Checking

Member checking, also known as respondent validation, is considered in the literature as the single most important method to ensure a study's credibility (Lincoln and Guba, 1985). Member checking involves checking of various, but not all, steps of data collection, analysis, and interpretation by the study participants from whom the data were originally collected (Long and Johnson, 2000). For example, a researcher using member checking technique may take themes emerged from the analysis of focus group interviews back to the participants of a particular focus group and discuss if the themes resonate their experiences/views. Member checking can ensure dependability and credibility of qualitative research. However, member checks should not be used as a verification strategy to judge the "truth" in data analysis. Researchers should also be very careful in accommodating respondent's views as this method can alter researcher's interpretation and may make findings descriptive.

Prolonged Engagement

Given the nature of qualitative research, establishing rapport with respondents and gaining their trust are critical to obtain in-depth information from the respondents. Prolonged engagement with respondents and community aims to do that and will help researcher to study the research topic more comprehensively (Creswell, 2006). Prolonged engagement may promote the credibility of a qualitative study. Typically used in ethnography, prolonged engagement involves spending sufficient time in the field observing different social, political, and economic constructs of a culture/society, engaging with diverse group of people, and developing

relationships with members of the culture with an aim to understand and appreciate the culture, social setting, or phenomenon of interest beyond personal preconceptions (Creswell, 2006).

Audit Trail

Audit tail involves providing detailed description of all the steps (data collection, analysis, and interpretation) and decisions made during the course of the study. This will facilitate readers to make their own personal judgments about the rigor, trustworthiness, and worth of a study (Sandelowski, 1986).

Peer Debriefing

Peer debriefing is another commonly used technique in qualitative research. In peer-debriefings, the researcher holds regular meetings with a peer throughout the research process and discusses the research methodology, data analysis, and interpretations (Lincoln and Guba, 1985). Ideally, a typical peer is someone who is not directly involved in the research and is an experienced qualitative researcher who can not only stimulate critical thinking but also can ask questions about the researcher's interpretations. Research supervisors/mentors can act as "peers" for their research students. Presenting research findings to interested groups and at conferences can also provide alternative forms of peer debriefing. Peer debriefing is also known as "analytic triangulation" (Nguyen, 2008).

Thick Description

Thick description refers to providing detailed description about settings, inclusion/exclusion criteria, sample characteristics, and data collection and analysis methods. This will enable the readers to evaluate the extent to which authors' conclusions are transferable to other external settings and different populations. Thick description is the most important tool to ensure external validity (transferability) of qualitative research (Long and Johnson, 2000). It also promotes study credibility as well.

Output-Oriented Approach: Quality of Reporting of Qualitative Research

Increasing numbers of qualitative research are being published by journals as a contribution to understanding of decisions and behaviors not only of patients but also of the health-care professionals involved in their care (Morse, 2015). The increased acceptance and publication of qualitative research is a reflection of the wide variety of qualitative methodologies and the maturity of the associated methods (Sidhu et al., 2017). In spite of this expansion, qualitative research is still viewed negatively by some journal editors as it was noted in an editors' meeting of the *British Medical* Journal. The editors argued in favor to effectively restrict publication of research aligned to the qualitative research philosophy (Greenhalgh et al., 2016; Loder et al., 2016).

Sidhu et al. (2017) argued that the current negative views about qualitative research may be overcome by ensuring that authors adhere to acceptable reporting standards. In particular, they mentioned that in addition to appropriately framing the research question in relation to existing evidence base, it is also important to make due consideration to the contribution of the research to clinical practice through the research process and the completeness and clarity of how this is being reported within the criteria imposed by relevant medical journals (Sidhu et al., 2017).

Significance of Quality of Reporting to Stakeholders

It has been highlighted that incomplete or unclear write-up reporting of qualitative research can largely contribute to rejection of papers. This, in turn, leads to the lack of dissemination of new knowledge and insights that could influence practice (Blignault and Ritchie, 2009). In addition, poorly designed studies make it difficult for users to assess the research findings and may lead to adoption and incorrect changes to health-care practice (Tong et al., 2007). It is important for authors to present clear and transparent research so that the readers can understand the process of research and how credible the findings are for adoption. Moher et al. (2014a,b) asserted that researchers have an ethical responsibility to provide a clear and accurate report of their research.

Appropriate and clear reporting of the research process and its outcome contributes to the establishment of rigor and credibility of qualitative research through demonstration of transparency (Malterud, 2001). Transparency of the research process and its findings is necessary to help stakeholders make appropriate judgments about how to identify and use the new knowledge.

Reporting Guidelines

The problem of incomplete reporting of qualitative research has led to the development of criteria, which guide authors while preparing and submitting qualitative papers. Simera et al. (2010) while writing about Enhancing the Quality and Transparency of Health Research Network (EQUATOR) described reporting guidelines as minimum set of required items (in the form of a checklist or flow diagram). These items provide advice on how to report research methods, results, and issues, which may contribute to bias in research.

The development of appropriate and relevant reporting guidelines is important for several reasons:

1. Availability of reporting guidelines enable authors to provide the necessary information required by journal editors.
2. Knowledge of established guidelines enables these to be taken account during the planning and execution of the research study.
3. Reviewers have the benefit of a uniform set of standards for comparability of submitted manuscripts.
4. There is improved appraisal of qualitative evidence synthesis due to the enhanced quality of reports available.
5. The guidelines can help peer reviewers to assess manuscripts for suitability and quality.
6. Editors can refer to existing reporting standards or develop specific guidelines, which contributes to accuracy, clarity, and transparency in the reporting of the qualitative research.
7. Meeting reporting standards will provide confidence to users of research such as health-care professionals, and it will enable them to adopt these findings into practice.
8. Stringent reporting standards provide the research community with assurance that qualitative research has appropriate scientific rigor.

Reporting Guidelines: Do They Improve Quality?

The development and promotion of reporting guidelines by editors and researchers is widely advocated. This may be a recognition that reporting guidelines are proving effective in improving the transparency and rigour in the way the design and procedures of research are communicated. A Cochrane review of the impact of the CONSORT statement indicates that the adoption of reporting guidelines contributed modestly to improvement in transparency of reporting (Turner et al., 2012). Many believe that the development and promotion of reporting guidelines for qualitative research will follow a similar pattern (The Equator Network).

Altman and Moher (2014) described a growing recognition that the adoption of reporting guidelines is effective in communication of research methods and findings. It is therefore important that researchers are encouraged to adopt reporting guidelines appropriate to their type of study as it would help improve transparency in research. In this regard, editors have an important role to play by demanding full and transparent reporting (Altman and Simera, 2010).

Concerns about the existence of checklists for reporting guidelines have been raised in that they may appear overly prescriptive thereby promoting overuse. There is a risk that without a broader understanding of the qualitative research design and data analysis, the unique contribution of qualitative research to health services research may be compromised (Barbour, 2001).

Mcleroy et al. (2016) make it clear that the primary purpose of reporting guidelines is to help readers to understand the published research by enhancing transparency. They are not intended to define how the research itself is conducted, nor are they meant to be used to evaluate the quality of the study per se. Smith et al. (2018) also states that the most appropriate reporting guidelines must be selected based on the relevant qualitative methodology guiding the study.

Common Reporting Guidelines for Qualitative Research

Guidelines for conduct and reporting of quantitative research have long existed to improve quality and allow understanding of various aspects of the respective research types. In recent years, there has been a proliferation of reporting different kinds of guidelines for qualitative research studies. However, the Consolidated Criteria for Reporting Qualitative Research (COREQ) developed by Tong et al. (2007) and Standards for Reporting Qualitative Research (SRQR) (O'Brien et al., 2014) are two key guidelines widely adopted for evaluating the quality of reporting of qualitative research. Consolidated Criteria for Reporting Qualitative Research (COREQ) is a set of reporting guidelines consisting of 30 items, which is meant to enhance comprehensiveness of reporting of interviews and focus group studies. SRQR, on the other hand, is a 21-item framework, which was developed through the input of international experts to act as standards for accurate reporting of a variety of qualitative studies.

Another widely used reporting guideline is the Enhancing Transparency in Reporting the Synthesis of Qualitative Research (ENTREQ) (Tong et al., 2012). The ENTREQ statement (framework) consists of 21 items grouped into five domains (Introduction, Methods and Methodology, Literature Search and Selection, Appraisal, and Synthesis of Findings). ENTREQ is useful to students and researchers on how to conduct and assess the synthesis of multiple qualitative health research studies (Tong et al., 2012). Notably, the framework has not undergone a Delphi exercise, a fundamental step in guideline development. This means that it has only fulfilled the first criterion for guideline development (Flemming et al., 2018). Users are advised to be mindful of this limitation.

There are other reporting guidelines for qualitative research studies that have been developed for specific health-care areas and other forms of interventions. The Enhancing the Quality and Transparency of Health Research (Equator) Network is an international initiative that seeks to promote accurate reporting of research through wider use of reporting guidelines thereby enhancing the value of research (*The Equator Network*). The EQUATOR website has a compilation of reporting guidelines for qualitative and other types and forms of research. In addition, it disseminates regular online newsletters highlighting new reporting guidelines and organizes workshops and courses to support the adoption and use of the resources listed on its website (Simera et al., 2010).

In addition to the above, specific guidelines have been developed by respective journals to ensure standardization of qualitative research manuscripts for peer review and publication. For example, The American Pharmaceutical Education journal (Anderson, 2010) has developed criteria to be used by authors for reporting their research. On the other hand, some journals and publications such as Biomed Central, BMJ, and Journal of Advanced Nursing advised authors to follow acceptable reporting guidelines for the respective type of study (e.g., COREQ, SRQR) as recommended by repositories such as the EQUATOR network.

Consolidated Criteria for Reporting Qualitative Research

COREQ is a 32-item checklist developed by Tong et al. (2007) for evaluating the comprehensiveness of reporting of qualitative studies. It does not purport to set standards for conducting qualitative research and it is mainly focussed on studies reporting focus groups and interviews. The development of COREQ is based on a systematic literature review and identifying items published within other tools and checklists for qualitative research studies.

Development of the COREQ Checklist

The authors searched electronic databases (CINAHL, MEDLINE), Cochrane, and Campbell protocols, including author and reviewer guidelines of major medical journals and reference lists of relevant publications for guidelines and checklists used to evaluate qualitative studies. After excluding duplicate checklists, criteria for assessing and reporting qualitative studies from each of the studies were extracted to give a comprehensive list of 72 items from 22 checklists (Tong et al., 2007). The items were grouped into three domains with duplicates removed and a descriptor was attached to each item to promote clarity (**Table 1**). Two new items: "identifying the authors who conducted the interviews or focus group" and "presence of nonparticipants" were considered relevant for reporting qualitative research by consensus and therefore included to make a final list of 32 items.

Uses and Benefits of COREQ

COREQ offers the following benefits:

1. COREQ can be used by editors and reviewers in the assessment of qualitative research manuscripts prior to publication.
2. It can be used to evaluate the validity and transferability of the findings from qualitative research reports.
3. It can be used as a form of standardization for researchers undertaking qualitative evidence synthesis and systematic reviews.
4. The popular application of COREQ as indicated by recommendations of journal editors and other members of the research community despite the absence of specific empirical validation gives an indication that it serves as a useful tool for comprehensive and accurate reporting of qualitative studies. Subsequently, there has been an increase in number of papers published in the BMJ and BioMed Central group journals by adhering to these guidelines.
5. The authors of COREQ suggest that although it was developed based on interviews and focus groups, it may still be used for other qualitative research methods.

Limitations of COREQ

1. The development of COREQ was based on interviews and focus groups, and therefore, its value may be more limited when used for other qualitative methodologies.
2. The absence of Delphi studies or consensus meetings in the development of COREQ appears to have limited its rate of adoption and acceptability.
3. The tool has not been validated to provide an empirical confirmation that it is likely to improve the quality of reporting of qualitative studies. However, the authors contend that the effect is likely to be similar to when other guidelines such as CONSORT was introduced and has subsequently been found to have improved the quality of reporting of the specific study type (Moher et al., 2001).
4. The slow development of extensions to the COREQ tool may arise from the absence of empirical validation and a lack of international consensus on uniform criteria for qualitative research.

Standards for Reporting Qualitative Research

SRQR is a 21-item checklist (**Table 2**) of clear reporting standards which is aimed at improving the transparency of all aspects of qualitative research (O'Brien et al., 2014). It was formulated through a systematic approach of rigorous synthesis of previously published guidelines followed by expert recommendations. Key elements of each item are defined and explained by the authors including providing examples from published articles (O'Brien et al., 2014).

Development of the Standards

The authors of SRQR identified previously proposed recommendations by systematically reviewing PubMed, Web of Science, and Google and by reviewing the reference list of the retrieved sources. A comprehensive list of items that were potentially important in reporting qualitative research was initially generated, which was then refined to a shorter list by identifying core concepts and combining related items.

The shorter list was then compared with the original sources to check for missing concepts and then appropriate explanatory definitions were included. The resulting prefinal list was reviewed by five experienced qualitative researchers for omitted or redundant items and to suggest improvement in clarity and relevance. Following the expert review, a final set of reporting standards was created by consolidating some items and making amendments to the wording of some labels and definitions (O'Brien et al., 2014).

Table 1 Domains and items in the COREQ list

	Details of item	*Guide questions/Descriptions*
Domain 1—research team and reflexivity		
Personal characteristics		
1.	Interviewer/Facilitator	Which author(s) conducted the interview or focus group?
2.	Credentials	What were the researcher's credentials? For example, PhD, MD.
3.	Occupation	What was their occupation at the time of the study?
4.	Gender	Was the researcher male or female?
5.	Experience and training	What experience or training did the researcher have?
Relationship with Participants		
6.	Relationship established	Was a relationship established prior to study commencement?
7.	Participant knowledge of the interviewer	What did the participants know about the researcher? For example, personal goals, reason for doing the research.
8.	Interviewer characteristics	What characteristics were reported about the interviewer/facilitator? For example, bias, assumptions, reasons, and interests in the research.
Domain 2—study design		
Theoretical framework		
9.	Methodological orientation and theory	What methodological orientation was stated to underpin the study? For example, grounded theory, discourse analysis, ethnography, phenomenology, content analysis.
Participant selection		
10.	Sampling	How were participants selected? For example, purposive, convenience, consecutive, snowball.
11.	Method of approach	How were participants approached? For example, face to face, telephone, mail, email.
12.	Sample size	How many participants were in the study?
13.	Nonparticipation	How many people refused to participate or dropped out? Reasons?
Setting		
14.	Setting of data collection	Where was the data collected? For example, home, clinic, workplace.
15.	Presence of nonparticipants	Was anyone else present beside the participants and researchers?
16.	Description of sample	What are the important characteristics of the sample? For example, demographic data, date.
Data collection		
17.	Interview guide	Were questions, prompts, guides provided by the authors? Was it pilot tested?
18.	Repeat interviews	Were repeat interviews carried out? If yes, how many?
19.	Audio/visual recording	Did the research use audio or visual recording to collect the data?
20.	Field notes	Were field notes made during and/or after the interview or focus group?
21.	Duration	What was the duration of the interviews or focus group?
22.	Data saturation	Was data saturation discussed?
23.	Transcripts returned	Were transcripts returned to participants for comments or corrections?
Domain 3—analysis and findings		
Data analysis		
24.	Number of data coders	How many data coders coded the data?
25.	Description of the coding tree	Did authors provide a description of the coding tree?
26.	Derivation of themes	Were themes identified in advance or derived from the data?
27.	Software	What software, if applicable, was used to manage the data?
28.	Participant checking	Did participants provide feedback on the findings?
Reporting		
29.	Quotations presented	Were participant quotations presented to illustrate the themes/findings? Was each quotation identified? For example, participant number.
30.	Data and findings consistent	Was there consistency between the data presented and the findings?
31.	Clarity of major themes	Were major themes clearly presented in the findings?
32.	Clarity of minor themes	Is there a description of diverse cases or discussion of minor themes?

Source: Adapted from Tong, A., Sainsbury, P., Craig, J., 2007. Consolidated criteria for reporting qualitative research (COREQ): a 32-item checklist for interviews and focus groups. Int. J. Qual. Health Care, 19 (6), 349-357.

Table 2 Standards for reporting qualitative research (SRQR)[a]

	Topic	*Item*
Title and abstract		
S1	Title	Concise description of the nature and topic of the study, identifying the study as qualitative or indicating the approach (e.g., ethnography, grounded theory), or data collection methods (e.g., interview, focus group) are recommended.
S2	Abstract	Summary of key elements of the study using the abstract format of the intended publication; typically includes background, purpose, methods, results, and conclusions
Introduction		
S3	Problem formulation	Description and significance of the problem/phenomenon studied; review of relevant theory and empirical work; problem statement
S4	Purpose or research question	Purpose of the study and specific objectives or questions
Methods		
S5	Qualitative approach and research paradigm	Qualitative approach (e.g., ethnography, grounded theory, case study, phenomenology, narrative research) and guiding theory if appropriate; identifying the research paradigm (e.g., postpositivist, constructivist/ interpretivist) is also recommended; rationale[b]
S6	Researcher characteristics and reflexivity	Researchers' characteristics that may influence the research, including personal attributes, qualifications/ experience, relationship with participants, assumptions, and/or presuppositions; potential or actual interaction between researchers' characteristics and the research questions, approach, methods, results, and/or transferability
S7	Context	Setting/site and salient contextual factors; rationale[b]
S8	Sampling strategy	How and why research participants, documents, or events were selected; criteria for deciding when no further sampling was necessary (e.g., sampling saturation); rationale[b]
S9	Ethical issues pertaining to human subjects	Documentation of approval by an appropriate ethics review board and participant consent, or explanation for lack thereof; other confidentiality and data security issues
S10	Data collection methods	Types of data collected; details of data collection procedures including (as appropriate) start and stop dates of data collection and analysis, iterative process, triangulation of sources/methods, and modification of procedures in response to evolving study findings; rationale[b]
S11	Data collection instruments and technologies	Description of instruments (e.g., interview guides, questionnaires) and devices (e.g., audio recorders) used for data collection; if/how the instrument(s) changed over the course of the study
S12	Units of study	Number and relevant characteristics of participants, documents, or events included in the study; level of participation (could be reported in results)
S13	Data processing	Methods for processing data prior to and during analysis, including transcription, data entry, data management and security, verification of data integrity, data coding, and anonymization/deidentification of excerpts
S14	Data analysis	Process by which inferences, themes, etc., was identified and developed, including the researchers involved in data analysis; usually references a specific paradigm or approach; rationale[b]
S15	Techniques to enhance trustworthiness	Techniques to enhance trustworthiness and credibility of data analysis (e.g., member checking, audit trail, triangulation); rationale[b]
Results/findings		
S16	Synthesis and interpretation	Main findings (e.g., interpretations, inferences, and themes) might include development of a theory or model or integration with prior research or theory
S17	Links to empirical data	Evidence (e.g., quotes, field notes, text excerpts, photographs) to substantiate analytic findings
Discussion		
S18	Integration with prior work, implications, transferability, and contribution(s) to the field	Short summary of main findings; explanation of how findings and conclusions connect to, support, elaborate on, or challenge conclusions of earlier scholarship; discussion of scope of application/generalizability; identification of unique contribution(s) to scholarship in a discipline or field
S19	Limitations	Trustworthiness and limitations of findings
Other		
S20	Conflicts of interest	Potential sources of influence or perceived influence on study conduct and conclusions; how these were managed
S21	Funding	Sources of funding and other support; role of funders in data collection, interpretation, and reporting

[a]The authors created the SRQR by searching the literature to identify guidelines, reporting standards, and critical appraisal criteria for qualitative research; reviewing the reference lists of retrieved sources; and contacting experts to gain feedback. The SRQR aims to improve the transparency of all aspects of qualitative research by providing clear standards for reporting qualitative research.

[b]The rationale should briefly discuss the justification for choosing that theory, approach, method, or technique rather than other options available; the assumptions and limitations implicit in those choices; and how those choices influence study conclusions and transferability. As appropriate, the rationale for several items might be discussed together.

Source: Adapted from O'Brien, B., et al., 2014. Standards for Reporting Qualitative Research: A Synthesis of Recommendations. Acad. Med. 89 (9), 1245-1251.

Uses and Benefits of SRQR

1. The twenty one standards provide users with a framework and recommendations for comprehensive reporting of qualitative studies.
2. The standards can assist users during preparation of their manuscripts to meet requirements of editors and other reviewers for complete reporting of qualitative research.
3. Journal editors, funding organizations, and other members of the research community may find SRQR useful in relation to standardization of clarity and completeness of reporting of qualitative research studies.
4. The authors identified items with broad relevance in an attempt to cover the wide range of qualitative approaches and methodologies.
5. The framework is robust because it is based on previously published criteria, critical review by experts, and wide-ranging experience and perspectives among its authors.
6. Descriptions and examples of how the framework can be used have been supplied by the authors to enable researchers to use these standards.
7. A checklist for reporting standards such as SRQR can help advance qualitative research methodologies by enhancing transparency in the research process and its findings.

Limitations of SRQR

1. The authors of SRQR advise that it may be inappropriate to use the framework to assess the quality of research methods and findings. This follows from the deliberate avoidance of recommendations that define methodological rigour during the development of the framework.
2. The diverse range of qualitative research approaches may lead some users to be critical of the suitability of a consolidated framework for evaluating different types of qualitative studies. This could limit its usefulness among a section of the research community.

Conclusion

In conclusion, both process- and output-oriented approaches should be considered while designing, conducting, and reporting qualitative research. For novice researchers, engaging with literature of appropriate quality, getting formal training in undertaking qualitative research, and working with a senior qualitative researcher can facilitate good quality qualitative research. No single checklist is applicable to all forms of qualitative research. Checklist gives reporting so transparency in order to enable the quality of the research, but a high score intensified does not necessarily indicate high quality research, nor would getting a lower score necessarily indicate poor quality research. Engagement with reporting checklists in early stages of designing qualitative studies can help researchers ensure quality in qualitative work.

Clinical Pharmacists as Principal Investigators in Clinical Trials

Sheraz Ali[*,§], **Dimitrios Karakitsos**[†,‡], [*]Institute of Biomedicine, University of Eastern Finland, Kuopio, Finland; [†]University of Southern California, Los Angeles, CA, United States; [‡]King Saud Medical City, Ministry of Health, Riyadh, Kingdom of Saudi Arabia; [§]Ministry of Health, Riyadh, Kingdom of Saudi Arabia

Introduction

Clinical research is a multidisciplinary endeavor that follows a collaborative approach to promote advances in health care (VanWormer et al., 2012). The extent to which clinical trials are conducted is a reflection of the level of advancement that exists within a health care system. Clinical trials are conducted on human volunteers in a prospective manner to ascertain the effectiveness and safety of investigational products, such as drugs and devices; clinical trials data eventually serve to optimize patient care. Clinical trials are typically conducted in four phases [**Table 1**] (U.S. National Library of Medicine, 2018). Randomized controlled trials are the gold standard in the spectrum of clinical research; they ascertain the effects of interventions and possess a higher place in the hierarchy of evidence (Burns et al., 2011). Clinical trials are usually conducted by collaborative efforts of the principal investigator (PI) or investigator, subinvestigator, pharmacist, physician/dentist, research nurse, clinical research coordinator and clinical research associate or monitor. The International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use Good Clinical Practice Guidelines (ICH-GCP) defined an investigator as "a person responsible for the conduct of the clinical trial at a trial site." If a trial involves several individuals at a study site, one individual is designated as a PI and will therefore be the responsible team leader (ICH, 2016).

It is imperative for the research team to maintain the credibility of clinical trials by protecting the rights, safety and well-being of the study volunteers (ICH, 2016). After the adoption of the Kefauver Harris Amendment in 1962 by US Food and Drug Administration (US FDA), pharmaceutical sponsors are required to submit both efficacy and safety data of drugs to obtain regulatory approvals (Kay et al., 2018). This major development was a result of human tragedy that occurred due to the use of thalidomide in pregnant women, which, in turn, prompted the US FDA to amend the Federal Food, Drug, and Cosmetic Act. The American Society of Health-System Pharmacists (ASHP) highlights the role of pharmacists in the management of investigations and approving drugs in a clinical trial and/or a routine clinical care setting. Moreover, their presence in a clinical research team is crucial for executing successful research projects (ASHP, 2016; Kay et al., 2018).

The ICH-GCP, the American College of Clinical Pharmacy (ACCP), and the research guidelines issued by the ASHP uphold the participation of trained and experienced pharmacists as PIs in clinical trials. The provision of educational sessions and monitoring of investigational drugs are deemed core components of drug trials, whereas pharmacists are also best suited to perform these functions (ASHP, 2016; Kay et al., 2018).

The credit of conducting the first ever controlled clinical trial of the modern era is given to physician Dr. James Lind. This clinical trial was conducted in 1747 to ascertain the cure of scurvy (Bhatt, 2010).

Ethics in Clinical Trials

There have been several cases of unethical practices when patients' rights, safety and well-being were not taken into consideration by physicians, eventually resulting in the reporting of fatalities. For example, the Tuskegee syphilis study (1932–72), Nazi medical experiments (1939–45), and the thalidomide tragedy (1960s) are well-known historical events in clinical research. In addition, the

Table 1 Phases of clinical trials

Phase	*Objective*	*Questions*	*Typical number of subjects*
I (or first-in-man studies)	Safety	Evaluated parameters: Dose, frequency, route, pharmacokinetics and pharmacodynamics	20–100
II	Efficacy and safety	To assess efficacy and define therapeutic dose range and dosing regimen. Further information on safety, pharmacokinetics and pharmacodynamics	50–300
III	Confirmation of efficacy and safety	To assess treatment outcomes and compare investigational drug with an approved treatment or placebo	100–1000
IV	Post marketing surveillance, effectiveness of drug, and impact on quality of life	To evaluate long-term effects of drugs (efficacy, safety, and side effects) in a large number of population and explore new indications	1000

aforementioned incidents prompted the emergence of ethical principles that were included in the Nuremberg Code, the Belmont Report, and the Declaration of Helsinki.

The ICH-GCP remains a vital document for conducting clinical trials. Several regulatory authorities, including the European Medicines Agency and the FDA, endorse the GCP as a unified document for conducting ethically and scientifically sound clinical trials. These guidelines are followed for designing, conducting, recording and reporting clinical trials involving human volunteers. The first version of the ICH harmonized guideline, E6 (R1), was released in 1996, and its amended version, E6 (R2), was recently released in November 2016 (ICH, 2016). Sponsors have a mandate to select the study investigators by assessing the statement of investigators, Form FDA 1572, which is utilized to acquire qualification and experience details. Form FDA 1572 is only required for studying investigational new drugs; this form is not employed for investigational device studies where a signed investigator agreement is collected (FDA, 2010). Investigators are permitted to initiate clinical trials (phases I–IV) after the submission of Form FDA 1572, and approval is at the discretion of the study sponsors. However, the requirement of this form is specifically for studies that are conducted under the US Investigational New Drug Application (IND); this form is also mandatory when an IND study is conducted outside the territory of the US, while foreign clinical studies are typically not conducted under an IND. Furthermore, postmarketing and observational studies are exempted from the requirement of Form FDA 1572. Investigators comply with the GCP and other requirements of regulatory authorities that are crucial for promoting the subject's safety and successful execution of clinical trials. The selection of a clinical pharmacist as a PI is subject to the inclusion of a doctor (or dentist, when appropriate) as a subinvestigator (FDA, 2010).

Health care professionals should familiarize themselves with principles and guidelines such as the ICH-GCP, the Nuremberg Code, the Belmont Report, and the Declaration of Helsinki. These ethical considerations are of paramount importance in clinical trials to develop safe and effective medications. As of December 2017, more than 250,000 clinical studies are registered on ClinicalTrials.gov, which is recognized as the oldest and largest registry of clinical trials managed by the National Library of Medicine at the National Institutes of Health in the US Notably, 41% of the clinical studies are registered under the map of the US (U.S. National Library of Medicine, 2017).

Roles and Responsibilities of the PI in Clinical Trials

The existence of the PI is a driving force behind the successful execution of clinical trials as per the defined standards and regulations. The diligence of the PI promotes the rights, safety, and well-being of the study subjects. Likewise, investigations involving human subjects are collaborative activities, and the role of the PI as a team leader is inevitable in this regard (Baer et al., 2011; Katz et al., 2011).

PIs must perform several functions, including extensive clinical research documentation, and abide by policies and regulations after the initiation of a trial at the study site. A well-acquainted PI transfers knowledge in an effective way to the entire staff involved in clinical investigations while cultivating a proactive team mind-set and optimizing communication. Moreover, a PI ensures that clinical trial personnel are aware of their responsibilities and comply with the study protocol, hence generating high-quality clinical data. It is a prerequisite for PIs to demonstrate the training and experience required for a clinical program prior to their selection, which is crucial to perform responsibilities in a diligent manner (ICH, 2016). PIs are given adequate time by the sponsor to review the study documents such as the protocol and the investigator's brochure; the investigator's brochure is a document that contains clinical and nonclinical data on the Investigational Medicinal Product (IMP) (ICH, 2016). The following are the core responsibilities of the PI in clinical trials (ICH, 2016; Kay et al., 2018):

- Organizing GCP training

It is a common practice for the study sponsors to provide GCP training to personnel involved in clinical trials. GCP training is conducted either through the specific web portal of the trial, CDs, training sessions and/or workshops.

- Seeking IRB approval

Clinical trials are commenced at the study site after IRB approval. A PI is responsible for submitting all the required documents to the IRB. If the selected PI is a member of the IRB, then he or she will not participate in the decision process or voting. However, any information pertinent to the clinical trial can be provided by the PI to the IRB (ICH, 2016). The PI is also responsible for submitting progress reports to the IRB annually or frequently (when requested); these reports are also submitted to the study sponsor.

- Clinical trial's study file for the PI

Table 2 shows the sections and content of a PI study file provided by the sponsor for conducting a randomized, double-blind placebo-controlled trial. This table is merely used for the guidance of novice PIs and is based on previous experience in multinational clinical trials sponsored by Novartis Oncology, F. Hoffmann-La Roche AG and the London School of Hygiene and Topical Medicine. Section 8 of the ICH-GCP also discusses the essential documents that are used before, during and after the conduct of clinical trials. Data collection should follow previously established guidelines. The concept of ALCOAC (Attributable, Legible, Contemporaneous, Original, Accurate, and Complete) is followed for maintaining high standards in clinical research documentation. ALCOAC is also specified in the joined version of the ICH-GCP under the section entitled "Records and Reports" (ICH, 2016). The US FDA initially introduced the ALCOA concept, which later evolved into ALCOAC (Bargaje, 2011). There is a common saying in clinical trials, "if it wasn't documented, it wasn't done." During audits and inspections, a lack of ALCOAC

Table 2 PI study file index for clinical trials

Section	*Contents*
Inside cover	• Laminated protocol summary • Protocol • CD containing training presentations, data forms and guidance, patient and representative information sheet, consent form, adverse event form, screening log, randomization log, delegation log • Guidance for trial materials • Materials order form • Participating sites—trial website address is included for updated list
Contacts	• Contact information
Protocol	• Trial protocol version submitted to local ethics committee • Master copy of patient/representative information sheets and consent form for hospital/study site • Master copy of brief information leaflet and wall poster for the family • Protocol amendments
Training materials	• DVD training film • Trial overview • Manual of Operating procedures • Power point presentations on CD in front cover • ICH-GCP guidelines summary. website address is also provided for complete ICH-GCP guidelines • GCP training and test guidance • Further training materials on secure collaborator's intranet
Trial drug guidance and information	• Drug administration guidance • Investigator brochure • Summary of product characteristics
Consent procedure	• Consent procedure overview • Guidance for completing the consent form
Data handling	• How to complete the data entry form • How to submit data online • How to send data by upload, email and fax • Guidance on protocol violations and deviations, data discrepancies, data queries and corrections • Serious data discrepancy form sample • Protocol breach form sample
Adverse events	• Adverse events reporting guidance • How to complete AE form • Unblinding forms • AE/SAE forms—also on CD • Notification of SAE/SUSAR by trial coordinating center • Reports from PI to local ethics committee

attributes in source documents is a common finding (Bargaje, 2011); PIs and other team members should follow the concept of ALCOAC during the course of a clinical trial.

- Risk Assessment Form for Investigational Medicinal Product

An IMP is defined as "a pharmaceutical form of an active substance or placebo being tested or used as a reference in a clinical trial, including products already with a marketing authorization but used or assembled (formulated or packaged) in a way different from the authorized form, or when used for an unauthorized indication, or to gain further information about the authorized form" (Directive 2001/20/EC, 2001).

The IMP Risk Assessment Form is filled out by the PI in collaboration with the clinical trials pharmacist and lead research nurse. Risk is assessed by the study sponsor, and risk level is usually categorized into three levels: (1) low, (2) medium, and (3) high. The study sponsor does not release the IMP before the receipt of this form. The purpose of the IMP Risk Assessment Form is to solicit information pertinent to the IMP storage facility, the policy of the IMP at the study site, locked cabinet/cupboard and its location, other drugs to be stored in the same cabinet/cupboard, labels (For Clinical Trial Use Only and Packs May Contain Placebo) on cabinet/cupboard, monitoring frequency of the IMP stock/drug accountability log/randomization log, and the name and role of a person responsible for monitoring the IMP stock.

- Signing/endorsing treatment box receipt

The PI is required to sign the box receipt form after receiving the shipment of the IMP and check that the packs have been received in good condition; this form is sent to the sponsor either by fax or email.

- Consenting process

Informed consent is collected by the PI from all study subjects prior to their inclusion in the clinical trial, and in particular cases, from the subject's legal representatives, depending on the nature of the population involved (ICH, 2016). The consenting process is done without coercing, and study subjects have the right to withdraw from the study at any time (ICH, 2016).

- Randomization procedures and reporting of unblinding

A PI should abide by the randomization procedures specified in the study protocol and ensure that the breaking of code follows the standard procedures. Moreover, PIs also document and inform the study sponsor regarding unbinding issues that arise either accidently or due to the occurrence of serious adverse events (ICH, 2016).

- Drug accountability log

As per the ICH-GCP, the PI is accountable for the management of the IMP at the study site. A prepopulated form is sent to the PI by the study sponsor with each drug box. The PI records the usage of all treatment packs and destroys any partly used packs or any packs that are damaged and cannot be used for randomization. The drug accountability form is sent to the sponsor either by fax or email after ensuring that all packs have been used/destroyed, or when requested.

- Delegation of trial-related duties

The PI maintains a list of all qualified research personnel that were assigned any trial-related duties by the PI. A PI also ensures that the trial team has adequate knowledge regarding their role in the clinical trial and is aware of the protocol and investigational products (ICH, 2016).

- Safety reporting

Serious adverse events/serious adverse drug reactions and unexpected adverse drug reactions are reported by the PI to the sponsor and applicable authorities (regulatory authority and ethical committee) following the reporting timelines specified in the study protocol (ICH, 2016).

- Retention of trial records

After the completion of a clinical trial, the PI/study institution is informed by the study sponsor to retain all trial-related documents for a specific time period; destroying documents is carried out after the written notification of sponsors to the PI/study institution (ICH, 2016).

Clinical Pharmacists in Clinical Research

Direct patient care is defined as "a practice which involves the pharmacist's direct observation of the patient and his/her contributions to the selection, modification, and monitoring of patient-specific drug therapy; this is often accomplished within an interprofessional team or through collaborative practice with another health care provider" (Carter, 2016). As per the ACCP, residency training and board certifications are indispensable for direct patient care. According to the ACCP, clinical pharmacists are pharmacy professionals concerned with the science and practice of rational drug therapy (ACCP, 2008). From 2003 to 2014, there was a fivefold increase in the total number of board certified clinical pharmacists in the US alone (Carter, 2016).

The action of clinical pharmacists before, during and after prescribing a drug influences the outcomes of drug therapy, thus improving patient care. The before the prescription role is pertinent to their participation in clinical trials, representation in ethical review boards and regulatory bodies, and preparation of drug therapy guidelines. The during the prescription role is related to their influence on the prescribers at the time of prescribing medications, while the after the prescription role includes medication reconciliation, patient counseling, medication compliance, and drug monitoring (Bhatt, 2014).

Clinical pharmacy professionals are uniquely qualified in therapeutics and provide comprehensive medication management to patients and health care professionals (Kaboli et al., 2006). Safety evaluation is a fundamental component of the entire drug development process, and it is crucial to monitor patient safety during clinical trials (Yao et al., 2013). There are several cases in which high-profile approved drugs were withdrawn from the market due to safety concerns. The presence of clinical pharmacists at the bedside improves the quality, safety and efficiency of care (Kaboli et al., 2006). Clinical pharmacists play an integral role in the routine care of hospitalized patients by promoting the rational use of drugs and patient safety. Previous reports found an inverse relationship between the rates of medication errors and the number of clinical pharmacists per occupied bed (Bahrani et al., 2014; Kaboli et al., 2006; Kuo et al., 2013). Clinical trials are conducted on a target population with a specific medical condition. Likewise, findings of 49 systematic reviews reported that the clinical pharmacists exerted a positive impact on the outcomes of patients with a specific disease (Rotta et al., 2015). Physicians also acknowledge the impact of clinical pharmacists on patient health outcomes (Tegegn et al., 2018).

The following are the activities of clinical pharmacists in a health care setting: assessment of current medication management, clinical review, therapeutic drug monitoring, provision of drug information to health care professionals and patients/caregivers, drug use evaluation, and conducting clinical research (ACCP, 2014). Clinical pharmacists have profoundly improved patients' outcomes by improving patients' knowledge regarding diseases, increasing patients' compliance to their prescribed therapy, and reducing the incidence of adverse events, hospitalizations and admission rates (Jacobi, 2016). Clinical pharmacists can also eliminate insecurities surrounding their profession by performing clinical interventions, participating in outreach programs, establishing professional relationships with other health care professionals and publishing scientific articles by executing clinical trials. Interventions by clinical pharmacists proved to be an effective practice to reduce treatment cost in health care and clinical research settings (ACCP, 2000b; Dalton and Byrne, 2017). Counseling the patient is one of the clinical pharmacist's interventions that tends to improve patient adherence and compliance with the treatment protocol (Martinez et al., 2017). Clinical pharmacists also assist in identifying eligible study subjects, thus increasing the research capacity and revenues of the study site (Smith et al., 2010). Pharmacists must be involved in all aspects of clinical research, from preclinical investigations to clinical studies (Koshman and Blais, 2011).

Prior to 1983, pharmacists were mostly involved in traditional pharmacy practice, and they could not obtain ample opportunities to lead drug trials for pharmaceutical companies; their roles were mainly supportive in clinical trials. In addition, research activities were confined to the university level and were common among undergraduate pharmacy students. The evolution of the pharmacy profession from the dispensing of medications to direct patient care has profoundly increased the importance of pharmacists among other health care providers. This paradigm shift also provided opportunities for clinical pharmacists in clinical research. Pharmacists are an integral part of the clinical research team, and their role is crucial for quality assurance and executing successful clinical trials (Gamboa et al., 2011; Ise et al., 2017). The process of maintaining data integrity is crucial in clinical research (ICH, 2016; Kay et al., 2018). Clinical pharmacists are required to maintain the highest standards of integrity and honesty, which is one of the core elements of their competencies put forward by the ACCP in a publication entitled "ACCP Clinical Pharmacist Competencies." Clinical pharmacists should serve as role models/leaders for other health care professionals and uphold the standards of professionalism (Saseen et al., 2017). Pharmaceutical aspects of clinical research are better managed by clinical pharmacists, thus ensuring the rights, safety and well-being of human subjects (Gamboa et al., 2011). Likewise, an increasing number of clinical trials requires the inclusion of qualified and trained clinical pharmacists (Gamboa et al., 2011). A clinical pharmacist's expertise that is pertinent to the pharmaceutical aspects of the drugs warrants them to advise patients on the correct use of investigational drugs. Consequently, clinical outcomes of the clinical trials can be improved by the presence of clinical pharmacists on a clinical research team (Kay et al., 2018; Luisetto, 2016). The Royal Pharmaceutical Society and Pharmacy Research UK (PRUK) play an important role in promoting pharmacist-initiated research studies (Crilly et al., 2017). PRUK also introduced a mentoring scheme for novice clinical researchers. The PRUK Mentoring scheme is intended for clinical pharmacy professionals who want to develop their professional capacity within clinical research and are seeking advice, guidance or support from experienced clinical pharmacy scientists (Crilly et al., 2017). The PRUK mentoring scheme provides guidance to clinical pharmacy professionals working in the UK and abroad. Time and resources are the major limitations of today's pharmacy research. The ACCP report underlined a scarcity of clinical pharmacy scientists or pharmaceutical research mentors, which has been one of the barriers for clinical pharmacists to pursue research projects (Parker et al., 2013). The other most common barrier is research funding, which remains problematic for pharmacist-initiated studies (Crilly et al., 2017; Parker et al., 2013).

The role of clinical pharmacists as PIs was first discussed in 2000 by the ACCP in a commentary article (ACCP, 2000a). Moreover, the National Institute of Health (NIH), a US government entity for the promotion of biomedical and public health research, also substantiated the role of clinically oriented pharmacists as trial investigators in a special conference on pharmacy research held from December 13–14, 2006 in Maryland, US (Figg et al., 2008). Previously, pharmaceutical companies used to show reluctance in the selection of pharmacists as PIs in clinical trials and promoted them in only pharmacokinetic studies (ACCP, 2000a). This is evident from a fivefold increase in the selection of US physicians as PIs from 1990 to 2010, particularly for industry-sponsored clinical trials.

Consequently, pharmaceutical companies retain more control of clinical trial data, which raises issues pertinent to conflict of interest and publication bias (Fisher and Kalbaugh, 2012).

A retrospective analysis revealed that a large number of pharmacists published clinical research studies in major peer-reviewed scientific journals in 1993 and 2003 (Touchette et al., 2008). The US FDA explicitly clarified their policy in 1983, 1989, and 1990, based on a query pertaining to the role of clinical pharmacists as PIs in clinical trials (ACCP, 2000a). The FDA's response document was later used as an educational tool by clinical pharmacists to educate pharmaceutical sponsors, which eventually proved to be an effective activity for acquiring PI status. Following these developments, a large number of clinical pharmacists supervised clinical trials as PIs (ACCP, 2000a). As per the ICH-GCP guidelines and Form FDA 1572, a PI should be qualified by education, training and experience; merely having a pharmacy or medical degree is not enough to serve as a PI in clinical trials (ICH, 2016). The ICH-GCP clause 4.3 explicitly states the role of physicians in the provision of medical care for trial subjects in case of any adverse events and as a decision maker in medical conditions; these guidelines do not reflect the mandatory appointment of a physician as a PI in clinical studies. The general section of Form FDA 1572 also states that the selection of a physician as a PI is not mandatory according to regulations. The US Code of Federal Regulations contains 50 titles of different sections; title 21 (21CFR 312.53), which represents "Food and Drugs," also confirms these statements regarding the eligibility of PIs. Clinical pharmacists must acquire required training, credentials and clinical experience, which are the determinants in the selection of PIs by pharmaceutical sponsors. An ideal approach is to start participating in clinical trials either as a research coordinator, clinical research associate or monitor, or subinvestigator, which will eventually pave the way for junior pharmacy professionals to acquire experience alongside an experienced clinical research professional. Mentorship and nurturing from experienced clinical researchers are also crucial for enhancing the competency of novice investigators (Ward et al., 2017). The study sponsor intends to give preference to health care professionals who demonstrate relevant experience in a population group that will be selected for the proposed clinical trial (ACCP, 2000a). There are plenty of opportunities in a health care setting or hospital where pharmaceutical companies conduct their drug trials, whereas clinical pharmacists' direct interactions with patients and physicians ease their way into the clinical research field. Consistent with this notion, an interprofessional collaboration of clinical pharmacy professionals for improving patient outcomes makes them ideal candidates for multidisciplinary clinical research. In contrast, pharmacists working in a community pharmacy setting are deprived of these opportunities due to a prerequisite of conducting drug trials in an ideal environment with basic necessities, which, in turn, facilitates the recruitment of human volunteers following the ICH-GCP guidelines.

Currently, clinical trials are being carried out under the supervision of clinical pharmacists in conjunction with a qualified physician. Likewise, there is no formal hindrance by research foundations, the pharmaceutical sector or government entities for the selection of clinically oriented pharmacists as PIs. Since the 2000 publication of the ACCP commentary regarding the role of clinical pharmacists as PIs, there has been a surge in the number of clinical trials supervised by clinical pharmacists; this surge includes both industry-sponsored and clinical pharmacist-initiated trials (Burton et al., 2010). Professionals with a PharmD degree have been successful in acquiring financial grants from different stakeholders, particularly the NIH, and executing research projects as PIs. An unwavering support from the employers of pharmacists is also a key determinant in the professional transition of novice pharmacy scientists to a veteran study investigator (Burton et al., 2010). However, clinical pharmacists in developing countries are still facing impediments to building their reputation as a PI. In the UK, 237 pharmacists were registered with the clinical trial network of the Royal Pharmaceutical Society (Malson, 2015). There are no recent statistics regarding the total number of clinical trials being carried out under the supervision of clinical pharmacists; ClinicalTrials.gov provided a hit of 523 clinical trials performed by clinical pharmacists in 2009 (Burton et al., 2010). Despite the associated prestige, the role of a clinical pharmacist as a PI has yet to be explored.

The ACCP's Position Statement for Clinical Pharmacists Working as PIs (ACCP, 2000a; ACCP, 2014)

The ACCP believes that clinical pharmacists, as PIs, are crucial for the management of successful clinical trials. Furthermore, clinical pharmacists, as PIs, play a vital role in administrative (institutional approvals and IRB logistics) and operational (physical and human resources) plans. The PI should assess the feasibility of conducting a clinical trial in his/her institution before participating in a trial. PIs are required to assess whether the study contract or investigator's agreement are acceptable to the study institution, thus avoiding issues and delays in the conduct of a clinical trial. The handling of financial contracts and the distribution of study expenses to the PI vary by institution, which needs to be figured out during the initial correspondence with the sponsors.

PIs should also determine the meeting frequency of the IRB and their requirements for conducting clinical trials; it is prudent for PIs to familiarize themselves with the review process of the IRB.

PIs are also required to locate a specific area where a clinical trial will be conducted and assess the available resources that are crucial for conducting clinical trials. PIs should also confirm a secure place for record keeping; trial documents are usually retained for a specific period of time after the completion of a clinical trial in the study institution. PIs should also determine the total number of members that will be required for clinical trials, such as coinvestigators, study coordinators and research fellows.

Recommended Education and Training for Clinical Pharmacists to Work as PIs

The dearth of clinical pharmacy scientists in universities and the industry sector prompted the ACCP to recommend necessary education and training for preparing future leaders in clinical research. Due to the establishment of a large number of pharmacy colleges, academic institutions have faced a shortage of skillful clinical research faculty for pharmacy students, whereas experienced clinical researchers are indispensable for pharmacy institutions. There is a huge demand for clinical pharmacy scientists in clinical

trials, and professionals with pharmacy backgrounds have the potential to contribute to clinical research after acquiring the necessary skills and education. Phase 1 clinical trials are conducted to assess clinical pharmacology, and other phases are designed to ascertain the efficacy and safety of investigational drugs. Pharmacists have strong knowledge on pharmacology and therapeutics, which gives them an edge to enhance the quality of clinical trials. Graduate programs in clinical pharmaceutical sciences open doors for clinical pharmacists to work with experienced PIs. Globally, a doctoral degree or PhD in clinical pharmaceutical sciences is offered by several pharmacy institutions; this degree is particularly for candidates interested in clinical research (Dowling et al., 2009). In 2009, an editorial published by the ACCP in favor of PhDs for preparing future generations of clinical pharmaceutical scientists exerted a substantial impact on the clinical research environment (Parker et al., 2013). The shortage of clinical pharmacy scientists in clinical research enterprises can also be reduced by increasing awareness among students to pursue PharmD/PhD combined degree programs. However, PharmD graduates without a PhD degree have also demonstrated their expertise in the field of clinical research, but their number is quite limited.

Clinical Research Training Programs for Clinical Pharmacists

A 2-year post-PharmD fellowship of a minimum of 3000 h is offered by the ACCP for enhancing research skills and conducting clinical trials as an independent investigator. This fellowship aids PharmD graduates in developing skills for different aspects of research, such as the formulation of a hypothesis, study design, protocol preparation, research grant writing, data collection, study management, interpretation of study results, scientific writing, and publication. It is preferred to acquire residency training or practical experience prior to the initiation of the ACCP fellowship. PharmD graduates receive clinical research education and training from experienced investigators who serve as preceptors throughout the fellowship program. The selection of preceptors is based on their qualifications, earlier experience as PIs in clinical trials, scientific publications in peer-reviewed journals and clinical research collaborations with other researchers. The participants of this fellowship are required to conduct at least one research project or participate in multiple clinical research studies, thus providing hands on experience in clinical research that is imperative to manage a study independently (ACCP, 2016).

Other Clinical Research Training Programs

The National Institute of Health (NIH) also provides funding for several research programs. The NIH Clinical Center provides clinical research training to students, residents/fellows, and mid-career professionals, thus preparing the next generation of clinical research scientists (NIH, 2017). The Office of Clinical Research Training and Medical Education at the NIH Clinical Center also provides distance learning courses, and the theme is "Core Curriculum in Clinical Research." The following three courses are provided under this theme: (1) ethical and regulatory aspects of clinical research, (2) introduction to the principles and practice of clinical research, and (3) principles of clinical research. It is the best opportunity for pharmacy students and professionals not residing in the US and those who have difficulty attending in-house programs due to professional commitments. The NIH Office of Extramural Research also offers a free web-based training course, "Protecting Human Research Participants," for health care professionals. This certification is usually requested by the Institutional Review Board or ethical committee of health care institutions before grating an approval for research projects that involve human subjects. Although not mandatory, it remains an important certification for protecting the rights, safety and well-being of human subjects. Moreover, this course consists of seven modules that take approximately 3 h to complete.

Mid-career clinical pharmacy professionals with at least 7 years of clinical research experience may join a program entitled "Sabbatical in Clinical Research Management"; participants of this program work with NIH experts. This program is not intended for novice clinical research scientists; they should consider the NIH clinical research curriculum for appropriate programs. The Clinical Research Training On-Line Course for PIs is a free web-based course that provides an ideal opportunity for clinical pharmacists and other health care professionals willing to work as a PI in clinical trials. This web-based course is mandatory for all NIH intramural PIs and is recognized as an essential standard in terms of education and training (NIH, 2017).

Clinical pharmacists should acquaint themselves with the GCP guidelines, as they also contain informative sections such as the glossary of all technical words that are used in the process of conducting clinical trials and the list of essential documents for the conduct of a clinical trial, thus serving as a strong foundation. The compliance of the PI, study sponsor and study monitor is ascertained by the evaluation of the essential documents specified in the GCP document. In addition, the validity of the clinical trial conduct and the clinical trial's data integrity also depends on the essential documents.

The core activities of clinical pharmacists in clinical trials are: (1) dispensing medications, (2) managing investigational medicinal products, (3) coordinating clinical studies, (4) providing drug information to health care professionals and patients, (5) reconciling medication, (6) representing pharmacists in a research committee to provide expertise on drug use, and (7) overseeing clinical trials as PIs or subinvestigators (Brown et al., 2017; Kay et al., 2018). Research pharmacists maintain a pharmacy file that is provided by the study sponsor for their clinical trials prior to the initiation of the subject recruitment process. **Table 3** shows the sections and content of a pharmacy file provided by the sponsor for conducting a randomized, double-blind placebo-controlled trial; the pharmacy file is managed by a clinical trial pharmacist. This table is only for the guidance of clinical pharmacists and is based on my earlier experience in multinational clinical trials. Clinical pharmacists also contribute to the development of research protocols, particularly in providing expertise for the management of drugs, which is one of the basic elements in pharmacy practice. Likewise, they also contribute to the preparation of drug information and safety tools, thus ensuring the appropriate use of investigational drugs in a clinical trial setting (Brown et al., 2017). The presence of clinical pharmacists in a trial setting is paramount for assessing protocol adherence (Shehab and Tamer, 2004). Pharmacists exert a

significant impact on the quality of clinical research by improving protocol compliance due to reconciling medication, reducing the occurrence of drug-related deviations, and decreasing medication discrepancies, which eventually improve patient care in a clinical trial setting (Redic et al., 2017). Pharmacists also effectively enhance the drug-related aspects (dosage, indications, drug–drug interactions, contraindications, and adverse drug events) of clinical trials, thus strengthening the backbone of drug trials. Drug-related issues exert a significant impact on patient outcomes; clinical pharmacists are experts and are skillful in tackling the aforementioned issues (ACCP, 2000b).

The safety practices of investigational drugs have not been standardized, unlike commercially available or approved medications (Cruz and Brown, 2015). The majority of research pharmacists have consistently raised serious concerns pertinent to the safety practices of investigational drugs during the conduction of clinical trials (Brown et al., 2017). Safety concerns related to naming, labeling, packaging and storage, are also highlighted by the Institute for Safe Medication Practices (ISMP). In addition, the ISMP recommended Institutional Review Boards (IRBs) to include pharmacists for the review of all investigation drug protocols, thus mitigating safety concerns of investigational drugs (Cruz and Brown, 2015). These concerns are not new to clinical research and were also addressed in a survey during the 1980s. Cruz and Brown (2015) also addressed safety concerns of investigational drugs in the findings of a national survey; these findings were based on more than 80% of pharmacists who had safety concerns (Cruz and Brown, 2015). The ICH-GCP requires all investigators to acquire thorough knowledge regarding the investigational drugs and ensure correct use of drugs, whereas clinical pharmacists are also deemed to be the best choice to qualify for PIs owing to their pharmacy qualification and training. Moreover, investigational drugs are also managed by pharmacists during clinical trials, requiring them to ensure drug use as per the approved protocol. The management and control of investigational drugs is crucial for executing successful

clinical trials, and clinical pharmacists are deemed to be the ideal choice in a clinical research team for effectively handling these matters. Pharmacists have a vital role in the receiving, handling, safe keeping, dispensing, safe disposal, and return of investigational drugs (Brown et al., 2017). According to the Joint Commission, the safe management of investigational drugs is essential in all accredited hospitals and is solely a responsibility of a pharmacy. In addition, pharmacists place auxiliary labels containing expiry and lot number details during the dispensing of these drugs, thus ensuring safe use during clinical trials. These measures reduce medication errors and promote subject safety (Brown et al., 2017). Thirty-nine percent of prescription orders for hospitalized populations have been reported to cause medication errors (Franklin et al., 2005). Prescribing errors can be minimized by employing pharmacists to review and verify prescription orders; moreover, they can provide expertise on therapeutic drug monitoring (Brown et al., 2017; Cohen and Sanborn, 2008). Clinical trial pharmacists ensure that the transportation of an investigational drug follows all standard protocols specified in the sponsor documents and promptly notify the former in case of any divergence from this process. Therefore, the inclusion of pharmacists in clinical trials is crucial in promoting medication safety and producing high-quality data (Brown et al., 2017).

The Role of Clinical Pharmacist in Improving Adherence Issues in Clinical Trials

The act of following instructions or directions given by health care professionals or research personnel during routine clinical care and clinical trials is termed adherence (Robiner, 2005). Fear of investigational drug's side effects, polypharmacy, dose frequency, and lengthy duration of treatment eventually lead to a higher incidence of poor medication adherence, thus making it difficult to evaluate the clinical efficacy of an investigational drug. Furthermore, prevalent nonadherence in clinical trials makes it difficult to ascertain the long-term effects of drugs (Kvarnström et al., 2018). It is prudent that additional efforts be directed toward maintaining medication adherence to generate a high-quality clinical trial data. The existing literature reports subjects' poor adherence or compliance to investigational drugs during clinical trials (Martinez et al., 2017). Another study revealed a 40% decline in adherence during clinical trials over a period of 1 year (Blaschke et al., 2012). Clinical setting, drug–drug interactions, side effects, comorbidities, psychological issues, and communication problems are recognized as possible causes that lead to poor adherence (Robiner, 2005). Poor adherence profoundly affects treatment goals and increases drug resistance, thus affecting morbidity and mortality rates (Martinez et al., 2017). Moreover, it exerts a negative impact on the quality of clinical trial data and prolongs study duration, which eventually inflates trial expenditures. The research team may not obtain a satisfactory response from interventional drugs due to nonadherence; hence, statistical power is tampered. Adherence for taking long-term medications in clinical trials was found to be 59%, while it was 78% for short-term medications (Robiner, 2005). Bouwman et al. (2017) reported that 50% of patients do not adhere to the treatment protocol. Such statistics advocate for a need to enhance adherence during the conduction of clinical trials (Martinez et al., 2017). The rapport between trial participants and caregivers is correlated with adherence and retention rates (Robiner, 2005). The positive effect of the pharmacist-trial participant relationship on the medication adherence of diabetes patients was also documented (Chung et al., 2014; Jin et al., 2008). Pharmacists' expertise in drugs plays a vital role in decreasing poor adherence rates and the success of clinical trials. Consistent with this notion, pharmacists are also able to respond to drug-related queries over the course of a clinical trial in a timely manner (Martinez et al., 2017). Pharmacists keep the dispensing record of investigational drugs, which gives them an edge to scrutinize the patient's adherence to medication regimens (Kay et al., 2018). A systematic review of 38 clinical studies showed improvement in medication adherence and treatment outcomes mainly due to clinical pharmacists' interventions (Tan et al., 2014).

The Importance of Integrating Clinical Pharmacists in Clinical Trials

A randomized controlled trial in the UK found that pharmacist counseling is crucial to decreasing cardiovascular risk and medication-related issues in patients with diabetes. Participants in an intervention group showed lower levels of hemoglobin A_{1c} compared to the control group. Moreover, participants in the intervention group showed significant improvement in their quality of life (Ali et al., 2012). Likewise, a prospective randomized controlled trial in Malaysia demonstrated a decline (9.6%–8.2%) in hemoglobin $A_{1c,}$ and medication adherence in an intervention group was also significantly improved due to pharmacists' consultations (Chung et al., 2014). Failure of drugs due to the clinical trials or failure of clinical trials due to the drugs are the two important notions in an experimental setting. Pharmacists are drug information experts with specialized training in drug therapy, and their role in clinical trials is paramount. Their counseling and rapport with study subjects improves the accuracy of outcomes (Martinez et al., 2017).

A prospective, cluster randomized, controlled clinical trial in the US showed that drug therapy recommendations by clinical pharmacists resulted in a significant improvement in the control of blood pressure (Carter et al., 2009; Weber et al., 2010). Similarly, evaluations of drug regimens and the provision of recommendations to patients and physicians reduced inappropriate prescribing and safety issues (Hanlon et al., 1996).

Enhancing Medication-Related Aspects of Clinical Trials by Integrating Clinical Pharmacists

The study protocol is a mainstay for clinical trials, whereas deviation from the protocol can be managed by the principal investigator. In addition, the protocol contains all trial-related information, including the management of investigational medications (Kay

et al., 2018; Redic et al., 2017). A protocol specifies prohibited concomitant medications for the study volunteers, which prompts study personnel, particularly pharmacists, to avoid drug-related nonconformities during clinical trials; medication history is crucial in this regard (Redic et al., 2017).

Pharmacists review medication history with the study protocol requirements and identify prohibited medications. A retrospective study in the Michigan Clinical Research Unit revealed that only 20% of the investigational drugs were recorded in the electronic health records of patients, while 40% of cases lacked the correct dose. Furthermore, this study demonstrated that 21% of protocol-prohibited medications were listed in the electronic health record (Redic et al., 2017). The potential concerns regarding the accuracy of investigational drugs can be avoided by pharmacists, and their role in medication reconciliation improves the quality of clinical research (Redic et al., 2017).

Pharmaceutical Industry Considerations

Pharmacists serve in multiple industrial domains, such as research and development, manufacturing and quality assurance, drug information, patent applications and drug registration, clinical trials and postmarketing surveillance, sales and marketing/management (Thakur et al., 2016; WHO, 1994). Based on their complex and pivotal role, pharmacists are quite competent to lead clinical trials and collaborate with different stakeholders. Their apparent knowledge regarding drugs and health care provisions strengthens multifaceted collaboration with stakeholders (WHO, 1994). Pharmacists have also been involved as principal and subinvestigators in industry-sponsored clinical trials (Kay et al., 2018; Smith et al., 2010; Thakur et al., 2016).

According to the WHO report on the role of pharmacists in the health care system, the selection of pharmacists for a managerial role promotes an ethical approach within industrial settings (WHO, 1994). Qualified pharmacists as principal investigators will rigorously follow all ethical aspects of clinical trials. The WHO report explicitly mentioned that the pharmaceutical industry should not operate without pharmacists (WHO, 1994). A survey by the American Pharmacists Association demonstrated that pharmacists in a corporate environment spend most of their time handling multiple tasks, interacting with colleagues and working with teams (American Pharmacist Association, 2013).

Summary and Conclusions

Clinical research is historically linked to advances in clinical practice. The former is performed under strict guidelines and is regulated by various national and international health care bodies accordingly. The role of the principal investigator has been essential in the development of clinical trials; however, research is currently becoming more versatile by implementing multidisciplinary teams, thus enhancing the collective mind-set. In that sense, the integration of qualified clinical pharmacists as key members of multidisciplinary research teams could indeed be an asset in launching clinical trials and optimizing research team performance.

Evidence-Based Pharmacy Practice Research in Low- and Middle-Income Countries: Issues, Challenges and Synthesis

Huma Rasheed*, **Mohamed Izham Mohamed Ibrahim**†, **Zaheer-Ud-Din Babar**‡, *Institute of Pharmaceutical Sciences, University of Veterinary and Animal Sciences, Lahore, Pakistan; †Qatar University, Doha, Qatar; ‡University of Huddersfield, Huddersfield, United Kingdom

Pharmacy Practice in Low-Middle-Income Countries

Pharmacy expertise and services are important for achieving optimal public health. The pharmaceutical practice seeks to optimize health outcomes for patients and add value to health systems. Moreover, pharmacists can also act as advisors to physicians and nurses and contribute to policy decisions. However, in many lower-middle-income countries (LMICs), pharmacists are still underutilized (Anderson, 2002; Azhar et al., 2009). There are various pharmacy practice models in LMICs due to the obstacles that each country has experienced. Mohamed Ibrahim et al. (2016) noted that the pharmacy practices vary in the 19 countries explored, even within each country, due to lack of infrastructure and resources. In addition, differences can also be attributed to service compensation, low salaries, poor benefits, inadequate training and education, poor regulatory systems, and ineffective pharmaceutical policies. The authors further recommended a few aspects that pharmacists and pharmacy organizations need to consider to close the gaps in practice between countries to meet the Good Pharmacy Practice Guidelines (Mohamed Ibrahim et al., 2016).

The umbrella term pharmacy practice covers the various roles of the pharmacist in the health-care system, including the classic duties of pharmacists related to the provision and management of pharmaceutical supplies as well as the expanded role of the pharmacist in clinical settings. Pharmacy practice is the professional skill required of pharmacists that is needed to ensure the optimal use of medicines in society. "It includes clinical pharmacy, pharmacotherapy, social and administrative sciences, and pharmaceutical care" (Scahill et al., 2017). The pharmacy profession has undergone a transformation from "The Era of Count and Pour" to the modern concepts of '"Clinical pharmacy" and "Pharmaceutical Care" and "Managed Care" (Higby, 2005). This change has mainly been recognized with the emergence of the pharmaceutical care concept in the 1990s (American Society of Health-System Pharmacists, 1999). The new role of the pharmacist was adopted as part of "reprofessionalization" that occurred mainly in

high-income countries (Babar et al., 2013). During the last four decades, significant progress has been made in both academic and research approaches in the pharmacy profession; however, these approaches are not equally reflected in the developing world.

The low-middle-income countries (LMICs) must keep up with the latest advancements and adoption of the new roles identified through consensus by international professional organizations and health-care leaders (e.g., the International Pharmaceutical Federation (FIP) and the World Health Organization (WHO)). Among new themes introduced in the revision of the landmark document of the Basel Statements by FIP are the collaboration of hospital pharmacists with hospital health technology assessment committees and the development of specialty practices in hospitals (International Pharmaceutical Federation (FIP), 2015a). In addition to the commitment to implement the rational use of medicine as defined by the WHO, there was the adoption of a new and comprehensive goal for the "responsible use of medicines" introduced by the FIP in 2012 (Vermeulen et al., 2016).

The new role expands the responsibility of the pharmacist to the complete drug use process and requires assurance of safe disposal and waste management of unused pharmaceuticals. The concept of a Green Pharmacy Practice has evolved, developing a need for reviewing the complete drug use process to ensure the minimization of pharmaceutical waste, as well as the environmental impact of that pharmaceutical waste, as it finds its way to water, soil, and the atmosphere (International Pharmaceutical Federation (FIP), 2015b). Safe and responsible waste practices for "antimicrobials" are important to reduce the emergence of antimicrobial resistance, a current global challenge in health care. The use of information technology, automation, and digitalization is gaining role in the regular process of medication use. Paperless electronic health records and the implementation of a merged system of medication supply, use and safety monitoring as part of the "Track and Trace System" to control the penetration of substandard and falsified medicines in the supply chain are two examples of rapid transformation in the way medicine use is going to be handled and recorded globally (Barlas, 2011; European Medicines Agency, 2011; Wirtz et al., 2017). The future of pharmacy practice research is expected to focus on the needs of the information technology-aware population; addressing social and cultural disparities and economic growth shifts; promoting multidisciplinary approach (Almarsdottir and Babar, 2016).

All of these topics are changing the image of pharmacy practice and developing new areas of pharmacy practice research. This process of change is inevitable for the developing world, and the promotion of quality research is critical to developing an informed health-care system where policies are backed by sound scientific evidence (Young et al., 2013).

The change in adopting a new and more demanding role for the pharmacist has occurred at varying levels and paces in different parts of the world. "Research, development and evaluation strategies for pharmaceutical education and workforce: A global report" by the FIP shows that there are varying degrees of progress in attaining the 13 Pharmaceutical Workforce Development Goals (PWDGs), and almost every country has made some progress in developing competency-based training frameworks, as well as increasing advanced and specialist development. The document includes case reports for 22 countries, including Argentina, Brazil, China, Costa Rica, Ghana, Kenya, Malaysia, Namibia, Paraguay, South Africa, Uganda, Zambia, and Zimbabwe, which are all LMICs (Bader and Bates, 2017). A few developing health systems, including Malaysia, Taiwan, Korea, South Korea, Singapore, and Saudi Arabia, are highlighted in the literature for their investments in the pharmacy profession workforce and systems (Babar and Scahill, 2014). Disparities in economic status between the two income groups of LMICs should be studied separately to assess their health system designs and progress in the delivery of pharmacy services (Babar and Scahill, 2014; Gray and Suleman, 2015).

The triad of practice, policy, and research acts synchronously to achieve the adoption of the new professional role of the pharmacist (Bond, 2015). Research has placed major emphasis on documenting the impact of interventions by pharmacists at different levels of clinical care settings, and this has driven policy changes in health-care systems (Bond, 2015). Research interacts with policy in four different ways: research that informs policy, research that supports a planned policy, research that confirms the appropriateness of implemented policies, and research that is aimed at understanding the processes in place (Bond, 2015).

LMICs are still in the evolution phase of the health-care system, where legal protection of the expanded role of the pharmacist within the health-care team has not yet been achieved. The acts of dispensing and prescribing are not segregated, and the availability of pharmacists in communities and institutional health-care settings are not mandatory (Babar et al., 2007). The dispensing of prescriptions by nonpharmacists and the sale of crucial medicines such as antibiotics without prescriptions are still common practices in certain LMICs (Ansari, 2017). Apart from the poor regulatory standards, compliance with existing pharmacy regulations is also not met (Hussain et al., 2012). The number of pharmacists and the quality of their academic training have been repeatedly questioned in this respect. The FIP technical document on the workforce presents a baseline to develop national action plans to develop an evidence-based workforce.

Is Pharmacy Practice Research Lacking In LMICs?

Many LMICs have failed to keep up with new trends and are not able to invest in the human resources. This deficit is also evidenced by the lack of research work in this important domain of the pharmacy profession, affecting the research quality, number, and diversity. The lack of funding, leadership, and the visionary approach to set long-term professional goals; the failure to identify and prioritize local needs; the lack of development of local solutions; the need of ownership by stakeholders, especially policymakers; and the lack of professional skills are some of the reasons that these countries have fallen behind.

There exists a wide gap between the developing and developed world with respect to evidence generation through systematic reviews and clinical trials (Alemayehu et al., 2018; Bennett et al., 2015). The literature reports several publications on the need for research capacity building in LMICs in the health sector. However, a concrete document addressing the gaps in pharmacy practice

research in LMICs is not available. Research is an essential component of pharmacy education and training. Pharmacy education and training have been outlined as one of the three impeding factors in the establishment of pharmacy practice in LMICs (Babar and Scahill, 2014). A bibliometric review on pharmacy education identified a deficiency in empirical research on pharmacy practice in Central and South America, Africa, and Eastern Europe (Babar et al., 2013).

Keeping in mind the current trends and recent advances in pharmacy practice, it is necessary for pharmacy researchers in LMICs to identify the gaps and challenges in pharmacy practice research and devise strategies to catalyze the process of change in the right direction (Mohamed Ibrahim et al., 2016).

The current chapter aims to identify the gaps in the evidence of pharmacy practice research in LMICs. The authors will explore the following questions with respect to pharmacy practice in LMICs:

1. What is the current status of pharmacy practice research in LMICs?
2. What are the individual health-care needs in LMICs and is pharmacy practice research in informing policy makers regarding ways to address these needs?
3. Is pharmacy practice research in LMICs elaborating the consequences and implications of the absence of adequate pharmacy practice?

This involves research on the current status of the pharmacy practice in LMICs, identification of the barriers and drivers, and evidence on the benefits and costs related to having a pharmacy practice in the health-care systems of an LMIC.

Broadly, research on pharmacy practice is directed toward designing new service models, measuring their quality and impact as well as identifying the implications of the absence of these services. Hence, a lack of capacity to carry out pharmacy practice research has a profound negative effect on the health-care system and the development of the professional role of the pharmacist in society. The scarce resources of LMICs demand justified investments in health services, pointing to a dire need for research in pharmacoeconomics, an area that needs to be evaluated for the presence of necessary skills in resource-limited settings. The analysis will help to identify the countries with some form of success with respect to progress in research contributions.

Historically, the research on pharmacy practice carried out in developed countries underwent phases of introspection and strong criticism to redefine its directions and produce research that was helpful in defining the role of the pharmacist. Lessons from the developed world can be used as a stepping stone by the developing world. There is a need for a multidisciplinary approach involving the expertise of other health system researchers as well as social scientists, epidemiologists, statisticians, psychologists and others, as well as the incorporation of long-term outcomes, including clinical, humanistic, and economic outcomes, to create sound evidence that can inform policy (Bond, 2015). Future pharmacy research is anticipated to include a further broadened group of potential collaborators (Almarsdottir and Babar, 2016).

The large amount of poor-quality research has become a growing problem in pharmacy practice research and is adversely affecting the image and strength of the professions' potential to inform policy and integrate with the decision-making process within the health system.

A review of systematic reviews provided a six-point recommendation for the overall improvement of systematic reviews conducted in pharmacy practice (Charrois et al., 2009). These recommendations include the coordination of a network of practice researchers, development of guidelines for reporting practice research studies, development of standardized indexing terms for identification of pharmacy practice research, registration of clinical trials of pharmacist interventions, encouragement of reporting clinically relevant outcomes and development of pharmacy research trialist collaboration for cumulative systematic reviews in chronic diseases.

Pharmacy practice research is a growing and evolving area that entails many challenges for its correct conceptualization and implementation. In this context, it is pertinent to conduct gap analysis for the evidence in pharmacy practice research regarding LMICs.

Major Health Issues of LMICs

Before determining what kind of evidence is expected for pharmacy practice in LMICs, one needs to understand the actual health-care issues of LMICs and how they differ from health concerns faced by high-income countries (HICs). Apart from sharing the historical struggle of nations in improving standards of health care, new challenges are emerging that create added complications for the developing world. These challenges include illnesses such as parasitic diseases, malaria, HIV, tuberculosis, and diarrhea that can be cheaply managed and prevented; antimicrobial resistance; natural disasters and other forms of humanitarian crises; environmental pollution; food shortages; undernutrition; increasing economic burdens; poor living conditions; and an alarming number of mental health conditions (The Health and Environment Linkages Initiative (HELI), 2018; Wiblin, 2016; worldwatch Institute)

The type of pharmacy practice needed by a region or country strongly depends on the nature of the health problems faced by their population. Communicable diseases, maternal health issues (conditions arising during pregnancy and childbirth), and nutritional deficiencies, collectively named "Group 1" conditions, account for 52% of deaths in low-income countries, whereas for high-income countries, only 7% of deaths are reported to be caused by these conditions (World Health Organization, 2018a). Likewise, 78% of global noncommunicable disease (NCD)-related deaths occur in LMICs. Heart disease and diabetes mellitus are the leading NCDs globally (World Health Organization, 2018a). Infectious diseases, including lower respiratory tract infections, HIV/AIDs,

tuberculosis, hepatitis, and malaria, are prevalent in LMICs. Global life expectancy has improved over the past decades; although, it is still low in some of the African countries (Angola, Central African Republic, Chad, Côte d'Ivoire, Democratic Republic of the Congo, Lesotho, Mozambique, Nigeria, and Sierra Leone) (World Health Organization, 2018b). The major contribution to progress in LMICs is improved under-five mortality rates. Diarrhea, preterm birth, birth asphyxia, and lower respiratory tract infections constitute the major under-five mortality causes in LMICs (Sayem et al., 2011).

The gap in life expectancy between female children and male children differs threefold between high income countries (9 years) and LMICs (3 years). Does access to health resources and pharmacy services differ more between the two genders in LMICs? In patriarchal societies with high out-of-pocket expenses, gender disparities in access to pharmaceutical supplies and decisions regarding the purchase of medicines and bearing other health costs pose an important research question with respect to both behavioral sciences and access to medicines (Sayem et al., 2011). Marginalized communities, people with poor socioeconomic status (Barakat et al., 2018), females (Barakat et al., 2018), migrants, older and pediatric populations and, in particular, female children are particularly prone to limited access to quality health services, including pharmaceutical supplies and services. Fathelrahman et al. (2016) highlighted several critical pharmacy situations in LMICs. These and many other questions invite the exploration of medication and health facility use behaviors in communities with respect to gender and other social disparities. It is not uncommon for patients in the health-care systems of developing countries, which are often criticized for shortages and poor-quality of medicine, to consider public health facilities to be lacking in quality and to be a suboptimal option (Aziz and Hanif, 2016).

Role of Evidence in Health-Care Systems

The best evidence can be employed with confidence (Bond and Watson, 2003). Scarcity of resources and the increasing demand for services call for the justified expenditure of public and private (out-of-pocket) money in the health sector. Cost and efficacy are the two historical parameters that are together employed in the health-care decision-making process, although patient satisfaction has also been advocated as an important marker in this regard (Bond, 2015). A wider application of the process advocates the use of the term evidence-based practice (EBP) instead of evidence-based medicine, hence, applying to a range of care providers in the health-care process (Bond and Watson, 2003). The need for evidence in pharmacy practice includes evidence synthesis on the role of pharmacists and pharmacy services as well as on the choice of various systems and technologies (Vermeulen et al., 2016) involved in the medication use process. Nevertheless, evidence is also needed for developing sound human resource plans in pharmacy practice (Vermeulen et al., 2016) to meet the local needs.

Pharmacists must recognize the use of EBP as central to providing high-quality care and decreasing unwarranted poor quality in service and practice. EBP includes more than just applying the best evidence. However, the concerns and obstacles to using EBP are mostly related to finding and applying research. EBP involves the integration of the best available pharmacy-related research; the pharmacist's knowledge and skills; and the wants, needs, and values of the patients, clients, and consumers (Sackett et al. 2000).

The purpose of conducting research is to generate new knowledge or to validate existing knowledge based on a theory. Research studies involve systematic, scientific inquiry to answer specific research questions or test hypotheses using disciplined, rigorous methods. While research is about investigation, exploration, and discovery, it also requires an understanding of the philosophy of science. For research results to be considered reliable and valid, researchers must use the scientific method in orderly, sequential steps.

In general, the literature on pharmacy practice does not comment on the data with respect to the economic grouping of the countries, and very few studies have commented on the trends in practice research with respect to the economic standing of the country. The Global Survey of Hospital Pharmacy Practice conducted in 2009 discusses the hospital pharmacy practices of countries with respect to their Human Development Index (HDI) analysis (Doloresco and Vermeulen, 2009). Only a few reviewers have discussed their data directly in the context of income groups of the countries (Atif et al., 2017; Bowry et al., 2011; Doloresco and Vermeulen 2009). Initiatives for evidence synthesis in pharmacy practice targeted toward the developing world have been sparse; only a single example has been found until now (Bowry et al., 2011).

In this chapter, we have studied systematic reviews and major regional and global reports on selected themes of pharmacy practice to retrieve information on the situation in LMICs. The tabulation of these studies with income group wise contributions from countries provides an overall picture (**Table 1**). This enables the performance of a gap analysis for pharmacy practice research carried out by LMICs. The analysis is based on three discrete parameters, that is, quality, diversity, and quantity of research that are detailed as follows:

Quality

The confidence in making guidelines, judgments, and decisions in practice depends very much on the quality and strength of the research evidence (Atkins et al., 2004). Having misleading or flawed evidence is worse than having no evidence at all (Berger and Alperson, 2009). The publications discussed in this chapter can be classified into two sets: systematic reviews and reports and reviews by international organizations (FIP/WHO) (summarized in **Table 1**) with individual studies elaborated within the main text. Systematic reviews have an undoubted position in evidence synthesis and act as a tool for learning the strengths and weaknesses of the primary research (Young et al., 2013). Hence, both conducting and use of systematic reviews build the capacity of health-care decision-makers and researchers (Young et al., 2013).

Different quality assessment tools are employed for various studies, including the Jadad score for randomized controlled trials (RCTs), the Newcastle-Ottawa Quality Assessment Scale for observational studies, the Agency for Healthcare Research and Quality (AHRQ) tool for rating cross-sectional studies, and the Quality Assessment Tool for Quantitative Studies (Berger and Alperson, 2009; Health Evidence, 2013; National Collaborating Centre for Methods and Tools, 2018; National Heart Lung and Blood Institute). Systematic reviews are mostly accompanied by a quality assessment of the studies analyzed, thus, forming quality evidence. Different quality assessment methods are outlined for the evaluation of systematic reviews, among which the Jadad score for systematic reviews involving RCTs is most commonly used (Charrois et al., 2009).

Quantity

Two aspects are documented with respect to the literature discussed: The number of studies and the participating LMICs (The World Bank, 2018). Gaps in themes and initiatives regarding practice research among various LMICs are identified from these data, maintaining relevance to the individual needs of the country. In contrast to the fact that a higher proportion of the world population resides in LMICs. **Table 1** shows that the participation and input in quality research are quite low from LMICs.

In a review covering 10 publications from the period of 1995–2015 on the identification of barriers to conducting clinical trials, more than 25 different LMICs described a lack of funding as the one major cause followed by obstacles due to ethical and regulatory systems that also included untrained regulatory setups, a lack of research environment, operational barriers such as unsupportive administration, difficulty in recruiting volunteers/patients, and competing priorities such as most of the researchers having to carry out clinical roles as their primary responsibilities (Alemayehu et al., 2018).

Diversity

Thematic classification of the study areas/themes explored includes (A) hospital pharmacy, (B) community pharmacy, and (C) public health pharmacy, including pharmaceutical policy and key health-care issues with respect to LMICs. These themes are discussed below in detail, primarily with respect to the diversity in themes, relevance to the health care needs of LMICs, and critical appraisal of their quality as undertaken by the authors of the systematic reviews. **Table 1** compliments this discussion by quantifying the research evidence according to the method described under "quantity."

A. Hospital Pharmacies

Hospital pharmacies represent a major component of pharmacy services at the institutional level in health-care settings.

The Basel Statements were initially issued in 2008 (Am J Health-Syst Pharm, 2008) and were revised in 2016 by the FIP to represent the current global vision of hospital pharmacy including 65 statements (75 in the initial Basel Statements) that are categorized into six themes with a set of overarching statements (Vermeulen et al., 2016). These themes include procurement; influences on prescribing, preparation, and delivery; administration; monitoring of medicine use; and human resource training and development.

Reviews on the current global status regarding each theme were also developed as a foundation for creating statements under each theme (Cousins, 2009; Nissen, 2009; Oishi, 2009; Ombaka, 2009; Shane, 2009; Wuliji, 2009). The revision process involved a global survey using an online survey, internal review, and initial revision, an online forum and a World Café workshop. Sixty-two countries responded to the global survey, with major input provided by the Philippines, South Africa, and the United States. The percentage of responses from low-income countries was the lowest (8%). The contribution rates from the SEARO and EMRO regions were the lowest, with 3 and 6 respondents, respectively (see **Table 1**). During the internal review process, the representatives from LMICs, including Ghana, Nepal, South Africa, and Pakistan, were involved in the 2-day face-to-face meetings along with participants from the United States, the Netherlands, Australia, Japan, and France (Vermeulen et al., 2016). Insufficient participation by LMICs was observed in the international survey on the current state of hospital pharmacy practice for the formulation of initial Basel Statements. The number of respondents from the SEARO and EMRO regions was only five and seven, respectively, and only nine countries belonging to the low Human Development Index group participated in the survey (Doloresco and Vermeulen, 2009). However, 98 countries around the globe participated in the final consensus process at the Global Conference on the Future of Hospital Pharmacy Practice (Am J Health-Syst Pharm, 2008). The low participation level from the LMICs in these global initiatives represents the lack of ownership and political willingness to establish a harmonized approach to hospital pharmacy systems. Poor responses at the national level represent a failure to endorse pharmacists as an integral component of the health-care system and a lack of the leadership that is needed for involvement in global collaborative research.

The Basel Statements have also been used for the evaluation of hospital pharmacy practice as compiled in the review by Penm et al. (2016). This review categorized the research as adaptation and implementation of the Basel Statement as well as monitoring of hospital pharmacy practices on the basis of these statements (Penm et al., 2016). Only the European region took initiative to develop a tailored version of the Basel Statement suited to patient needs and relevance of hospital pharmacy practice to local needs, which are available as four individual publications. The studies comprised two quantitative studies, one documenting the process of studying the Basel Statements in the European context and reducing them to 48 statements including overarching statements and sections including selection, procurement, and distribution of medicines; production and compounding; clinical services; quality assurance and patient safety; and education and research (Batista and Preece, 2014). The new versions defined the statements for minimum requirements and the additional or advanced statements to improve and advance hospital pharmacy practice.

The other two qualitative studies from Europe involved documentation of the views of the stakeholders, including health-care professionals, and the patients on the benefits of the Basel Statements (Maskrey and Underhill, 2014). This whole rigorous exercise is important for the assimilation of the generalized version of the standards to the local settings, and other regions are encouraged to carry out similar adaptation processes (Maskrey and Underhill, 2014; Vermeulen et al., 2016). The effort has still not been replicated in any other region or countries. The LMICs need to generate a similar set of minimum standards or a stepwise approach to address the sequential adaption of the Basel Statements with clearly set priorities. Key elements or foundation points, such as the formulary-based drug utilization system, good procurement, computerized physician order entry system (CPOE), and the right to access patient records as well as the availability of information sources, can be identified as priority areas. The 2009 global survey of hospital pharmacy reported that less than 3% of the hospitals in the low HDI countries provide pharmacists with access to patient medical records, and similarly, there is less availability (33%) of medical libraries to the pharmacist (Doloresco and Vermeulen, 2009).

The largest group of studies was documented by Penm et al. for the monitoring of hospital pharmacy practice on the basis of the Basel Statements in the Pacific Islands (22 countries) and the Western Pacific Region (37 countries). Apart from these studies, three studies on the implementation of the Basel Statements from upper–middle-income countries (China and South Africa) as well as from low-income countries (Uganda) are also included in the review by Penm et al. (2016).

A qualitative study using interviews with regulatory personnel, hospital pharmacy directors, and medical experts was conducted to record the post-2012 development of hospital pharmacy systems in Madagascar (Ratsimbazafimahefa et al., 2018), a low-income country in Sub-Saharan Africa. Severe deficiencies were identified, including the heterogeneity of the health system affecting the management of pharmaceutical product inventory. The other deficiencies involved uncontrolled drug supply chains, lack of procedures for the selection of pharmaceutical products, complexities in the quantification of needs and supervision of stock management, lack of standard prescription protocols, dispensing by unqualified staff, absence of facilities for pharmaceutical preparation in hospitals, and lack of involvement of pharmacy experts in administration (Ratsimbazafimahefa et al., 2018).

Variations in the service levels across the country and within large and small hospitals have been reported in Saudi Arabia, which is a higher income country with a developing health system, in the pretext of the Basel Statements (Al Sabban et al., 2018). In short, to a certain extent, evidence related to hospital pharmacy practice from LMICs is sparse and is mainly confined to a limited number of countries and regions.

Rational Use of Medicine

A review on the global utilization of essential medicines presents the extent of rational use of medicine worldwide as documented through studies conducted using the WHO/INRUD methodology. The review covered 60 studies, out of which 10 studies were from high-income countries (Atif et al., 2017). For countries with multiple studies available, only three studies, or the studies with the maximum number of indicators were included. Only six countries had three studies included in the review, including Serbia, China, India, Ethiopia, Nigeria, and Tanzania (**Table 1**). The review reported suboptimal values in patient care and facility indicators; however, the evaluation of drug use indicators based on the World Bank Income groups showed that the lower-middle income countries had the highest average number of drugs, the number of antibiotic drugs, and the number of injectable drugs per encounter. Similarly, both the upper- and lower-middle income countries had a lower percentage of medicines prescribed from the essential medicines list. The trend of prescribing generic brands was higher for the countries with lower income.

Patient care indicators and facility indicators were documented in half of the studies ($n = 29$). Theoretically, better scores in these indicators should directly affect the values of prescribing indicators. The median values for consultation time were low in LMICs, with the lowest values in the lower-middle-income countries. The median dispensing time of $\leq$30 s for the middle-income countries is contrary to the dispensing time of high- and low-income countries of approximately 75 s. The review documented good scores for the LMICs for adequacy of labeling and patient knowledge. Upper-middle-income countries scored the lowest in the availability of key drugs among LMICs.

Evidence for the rational use of medicines in a country requires more primary data at the national and regional levels. However, it is to be recognized here that the worldwide awareness campaigns for health professionals on the rational use of medicines carried out by the WHO and INRUD have been successful in establishing the importance of the concept in health-care systems, thus inviting researchers and funding agencies to take up with this area of research. However, it is more likely that the reviewed studies cover only particular facilities and do not cover the wide geographical and socioeconomic diversity that many of the LMICs, such as China, India, Pakistan, and Bangladesh, experience. The difference in urban and rural facilities with respect to the availability of manpower and resources (especially medicines), population density, and health-care choices may reflect an entirely new set of results.

It is also worth mentioning that the overall results are better for the low-income countries than for the middle-income countries. The lower-middle income countries had the lowest scores. The funding sources of health-care systems and facilities can be further explored to answer this question.

It is also notable that foreign-funded projects in health that cover medicine supplies are mostly implemented using standard protocols to ensure the rational use of resources. Such projects are also a resource for health education of patients and capacity building of the local health professionals on the fundamental principles of safe and effective use of medicines.

Pharmaceutical Care/Managed Care

The extended role of the pharmacist in the community pharmacy and the provision of pharmaceuticals, managed care, and other cognitive roles of pharmacists are examples of clinical services provided by pharmacists in the developed world. This sharing of the clinical workload is, however, not paralleled in the LMICs despite the high population growth rates and scarcity of resources. It is theoretically a sound proposal to incorporate more health professionals to share clinical roles with physicians in LMICs. A systematic review comprising 54 randomized controlled trials (RCTs) of pharmaceutical care included 21 studies from LMICs. No studies were performed on older adults in LMICs (Babar et al., 2017). Seven out of 14 studies on diabetes included Malaysia (1), Jordan (2), Iraq (1), Brazil (2), and China (1); 8 out of 24 studies on the provision of pharmaceutical care in cardiovascular disease included Brazil (3), Jordan (2), Thailand (1), and China (2); and 1 of the two studies on depression was from Brazil. Two out of three studies related to asthma and COPD were from Sudan and China. One study from Jordan on medication management review, another study from Malaysia related to osteoporosis in women, and a study from Colombia involving epilepsy and seizures were also included in the review. The quality of the studies was mostly graded as a 3 using the Jadad score, with studies from Malaysia and Chile receiving the lowest score of 1.

Formulary and Procurement Systems

In the initial global hospital pharmacy survey by the FIP in 2009, one WHO region did not come up with even a single respondent confirming the minimum status (at least 3%) for the involvement of a pharmacist as a key focal person in the committee or procedures adopted for the selection and prescription of medications. The report does not state which WHO region did not respond. However, 77% of the respondents confirmed the role of the pharmacist in formulary development (Doloresco and Vermeulen, 2009).

Preparation and Distribution of Medicines

The review of medication preparation and distribution in hospitals identifies key interventions that help minimize medication errors and improve accuracy and efficiency in the medication use process (Oishi, 2009). These interventions include computerized physician order entry system (CPOE), pharmacy-based intravenous admixture service, unit dose drug distribution system, bar-code technology, automated medicine storage, distribution devices, and prescription filling systems. The extent to which LMICs have adopted these technologies and how cost-effective their implementation is, weighed against the high risk of medication errors and serious effects resulting therefrom must be included in the evidence reported in the literature to promote evidence-based policies and choices.

Medication Error Reporting

Older populations are more vulnerable to medication errors due to a higher prevalence of polypharmacy and the presence of comorbidities. Though the proportion of the older population (aged above 65 years.) in LMICs is far smaller than that seen in developed countries, the older populations still account for a large number of people due to the large overall population of many LMICs, for example, 8.5 million (4.3% of the total population) in Pakistan.

The results of clinical studies may or may not correspond to data in western countries. A study conducted in Pakistan reported that 64% of elderly patients in a tertiary care setting were prescribed potentially inappropriate medications (PIMS), mainly including the use of NSAIDs with antihypertensive medications and long-term NSAIDs in 90% and 75% of cases, respectively (Mazhar et al., 2018). A similar prevalence was reported for European countries (Gallagher et al., 2011), whereas a lower prevalence was observed in studies conducted in some cities of India (Pradhan S et al., 2015) and the United States (Gleason et al., 1998). However, the heterogeneity in study design and the different sociocultural settings of each country as well as the different health system designs warrant the need for indigenous data and identification of the factors contributing to the variation in the results among various populations.

Moreover, in a systematic review on medication error reporting in an aging population conducted without any language or time-period restriction, no studies were documented for Africa, Latin America, Australia, or Oceania, and only three studies were reported from Asia (Salmasi et al., 2018). Indonesia and Malaysia were the only LMIC countries included in this review, with one study each.

B. Community Pharmacies

Community pharmacies provide the pivotal pharmacy service that works at the broader interface of the public and health-care professionals (pharmacists). It has the potential to produce both professional credibility and provide health- and pharmaceutical-related care and information. In the systematic review discussed earlier in the hospital pharmacy section, 7 out of 54 RCTs were carried out in community pharmacy settings, and none of these RCTs originated from LMICs (Babar et al., 2017).

In a review of trends in pharmacy services and patient satisfaction over a decade (2006–16), the services were classified as (1) standard practice, (2) service requiring training specifically for study purpose, (3) expanded practice such as vaccination, and (4) collaborative practice services. In total, 104 studies identified on the basis of title and abstract were reviewed on the basis of the

inclusion and exclusion criteria and the availability of full text, excluding studies due to nonavailability of the full text; 50 articles were analyzed. The review did not include a quality evaluation of the studies, and out of fifty articles (Melton and Lai, 2017), only one interview-based study was from a low-income country; the study explored patient satisfaction with receiving an intramuscular contraceptive dose from trained staff at drug stores in Uganda and recorded a positive assessment (Akol et al., 2014).

A systematic review of the retail settings in Asian LMICs (Miller and Goodman, 2016) documented system inadequacies as well as determinants of poor pharmacy practice in retail pharmacies in LMICs in Asia. The reviewers identified the shift of the focus to profit incentive strategies and regulatory strengthening in comparison to the previous trend of focusing on knowledge expansion and education. The key inadequacies outlined in the review included insufficient history taking, lack of referral of patients in need of medical attention, illegal sale of prescription-only medicines without a prescription, sale of clinically inappropriate medicines and/or medicines in wrong doses, sale of incomplete courses of antibiotics, and limited provision of information and counseling. The determinants of poor practice include lack of knowledge, fewer monetary incentives for pharmacy personnel, and poor regulation. The need for intervention research is emphasized by the reviewers with a focus on the sale of medicine from medicine retail shops run without a pharmacist and unregistered drug stores.

A meta-analysis was conducted on pharmacist-led medication reviews in community pharmacy (Jokanovic et al., 2017). The meta-analysis shows that limited data were available from LMICs; most of the reviews did not provide information on the country studied or other related details. In the review on medication reviews in children, none of the studies were reported from LMICs (Costello et al., 2004). A review by Evans et al. covered interventions by community pharmacists for diabetic and cardiovascular patients with 40 studies, 20 of which were included in the meta-analysis of medication review. The meta-analysis reported the issue of an overall low quality of studies, with some improvement in the quality of studies published after 2004. The analysis provided information about the inclusion of the studies from the United Kingdom, the United States, Australia, and Canada, whereas the rest of the countries were grouped as others without mentioning details of the selected study. The majority of the primary data were from the United States (**Table 1**).

Two systematic reviews of studies on lowering cardiovascular disease risk factors were conducted by Santschi et al. (2011, 2012). One review discussed the impact of pharmacist-directed care and pharmacists in collaborative practice with physicians and other health-care professionals. The review comprised 30 studies with only three studies from LMICs, one study on pharmacist-directed care from Thailand, and two studies on collaborative practice from China and Brazil. Most of the studies were from North America. Only two studies were performed in European countries. Out of the 30 studies, 19 were identified as good quality based on the number of items with bias and the study score using the Cochrane Risk of Bias Tool. The study from China by Lee et al. (2006) was included in this category. The majority of the studies were conducted in outpatient clinics of hospitals of specialized clinics, and only a few included community pharmacies.

A qualitative study was conducted on the perceptions and attitudes of community pharmacists about extended community pharmacy services (ECPSs) in Lahore, Pakistan, documenting a positive attitude of pharmacists toward ECPSs and highlighting the need for support and facilitation in the process, mainly to overcome the lack of confidence of patients regarding advice from pharmacists and the compulsion to visit a physician even in cases in which it is not needed (Hashmi et al., 2017).

Bowry et al. (2011) conducted a systematic review for evidence synthesis regarding medication adherence for drugs used in cardiovascular diseases by including only those LMICs using the 2009 list of emerging and developing economies by the IMF (154 countries). This is one of the only initiatives for evidence synthesis aimed at LMICs. Seventy-six articles were included in the study. The pooled data from 55 cross-sectional, 16 cohort, and 5 randomized trials showed an overall adherence of 57.5%. Adherence recorded in the RCTs (42.6%) was lower than the adherence reported in observational studies (59.0%). One of the open crossover trials conducted in 1990 in Zimbabwe had a higher adherence of 97% with respect to the other four RCTs (15%–61%). A lack of family support and significant changes in symptoms were the two major predictors documented in all or the majority of the 29 studies related to the factors associated with adherence. Other significant factors included poor knowledge, negative perceptions about medications, the occurrence of side effects, and high medication costs. However, the prevalence of adherence for cardiovascular diseases was found to be suboptimal, and similar to the resource-rich countries, the difference could be in the predictors. The review did not discriminate in the clinical settings and included both inpatient- and outpatient-based studies. Adherence was highest with methods employing pill count, followed by the methods labeled as "other" methods (electronic pill bottles, e.g., medication event monitoring system, assessments by a healthcare professional, reviews of health records, and biochemical assay) and was lowest on self-reports. Quality assessment of the studies was carried out and reported as a percentage of the score on the relevant scale (Jaded, AHRQ, NOQAS); however, no studies were excluded on the basis of the quality scores. The quality scores for RCTs ranged from 40% to 75%, for cohort studies 11%–75%, and for cross-sectional studies, the quality scores were reported to be 0%–100%. The review identified the need for evidence on strategies for improving medication adherence in resource-poor settings.

C. **Public Health Pharmacy**

Access to Essential Medicines

One important determinant of the rational use of medicines is its access, primarily its affordability and availability. Access to essential medicines is advocated as one of the five key issues related to universal health coverage (Wirtz et al., 2017). A household

survey in eight counties of Kenya reported that only 57.2% of diagnosed asthma patients with a prescribed medication possessed asthma medication at home. Salbutamol was the most frequently purchased medicine for treating asthma, and approximately one-third of patients were using it orally instead of via inhalation (Barakat et al., 2018). Better therapeutic modalities, including nebulization solution and metered dose inhalers with and without steroids, are much more expensive and may often not be available in regular public supplies. Hence, poor access to medicines leads to irrational or poor choices as well as lesser control of diseases. It is not uncommon for patients to link nonavailability and poor-quality of medicine to public health facilities, as identified in the survey of hospital supplies in the teaching hospitals of Southern Punjab in Pakistan (Aziz and Hanif, 2016). This reduces the level of patient trust in the public health facilities and health system. Patients are more inclined to seek alternative medicine, spiritual therapies, and home remedies, much of which lack scientific evidence and ethical practices.

Quality of Medicine

Quality of medicine has been identified as one of the five issues regarding essential medicines that need to be addressed to achieve the goals of universal health coverage (Wirtz et al., 2017). The WHO published two landmark reports in this regard in 2017 (World Health Organization, 2017a,b).

A comprehensive literature review was carried out for the published papers, reports, and field surveys on the quality of medicine for the period of 2007–16 using defined inclusion and exclusion criteria to estimate the public health and socioeconomic impact of substandard and falsified medicines. The review covered 88 countries with more than 76% of the samples from middle-income countries, whereas low-income countries contributed only 23%. An estimated annual cost of 300 billion US$ has been calculated based on the observed (10.5%) failure rate of medicine in LMICs (World Health Organization, 2017a).

A detailed gap analysis was drawn from the review. A significant difference was identified in the failure rate of samples collected using random sampling and convenient sampling, which were 19.5% and 7.8%, respectively. The review also shows a marked gap in the sampling source from the public sector. Moreover, an under- and overrepresentation of data is expected in the review results due to the risk-based approach of sampling in most of the surveys. The samples were concentrated in certain therapeutic classes (mainly antimalarials and other antiinfectives) and specific geographical regions of the world.

These observations led to recommendations for ensuring better quality studies in the future, which included assurance of sufficient sample size with random sampling, choice of technique based on study goals such as field testing, introduction of modeling-based approach for prevalence studies, avoidance of heterogeneity of study methods, and defining of poor-quality medicines by using standardized study protocols. Other identified gaps include a lack of economic data on LMICs, including total health care spending, out-of-pocket spending, and break up of household survey data with respect to therapeutic categories. Data on actual acquisition cost (spending) for the potentially substandard and falsified medicines and the quality assured products and the necessity of funding to carry out systematic and well-planned research involving manufacturers and governments were also emphasized (Wirtz et al., 2017; World Health Organization, 2017a).

Transparency and access to public laboratory surveillance data by LMICs are rare. Access to surveillance data is also advocated in the policy advice developed by the health system researchers (Wirtz et al., 2017). The document also shared the results of two health impact models using severe childhood pneumonia and malaria in sub-Saharan Africa estimations based on a 10% prevalence figure. Up to 72,430 childhood pneumonia deaths can be accounted for by the use of poor quality medicines, which can go up to 169,271 deaths if the antibiotic has no activity at all. For malaria, the incremental deaths due to the use of substandard or falsified medicines account for approximately 2.1%–4.9% malaria deaths (World Health Organization, 2017a).

Managing Medicine Supply Chains

Managing supply chains is one of the fundamental duties attributed to the pharmacy profession. The definition of essential medicines highlights the importance of good inventory management, by emphasizing the availability of the medicinal supply at all times in suitable dosage form and strength. Ensuring the availability of medical supplies in maternal settings can have a profound effect on ensuring the safety of mothers and children during birth and better health outcomes in the postnatal period. Maternal and neonatal mortality is a major health care issue in LMICs. Countries such as Pakistan and Afghanistan have shown no or insufficient progress in these areas (Ahmed and Won, 2017). The WHO has developed a priority list for maternal and child health to aid in this respect. Prevention of stockouts is carried out through the provision of maternal and child health medicines selected on the basis of evidence, packaged as kits. The uninterrupted provision of medicinal supplies positively influenced maternal and child morbidity and mortality with negligible heterogeneity among sites in a large, stepped-wedge, cluster-randomized controlled trial carried out in Mozambique (Betrán et al., 2018). The introduction of customized disease-specific kits in the inventory management systems has also proven to be an effective approach in postdisaster and emergency situations in other LMICs (Bukhari et al., 2010). The report of the Lancet Commission on universal health coverage recommends medicine benefit packages to be introduced to ensure availability and procurement at low prices; however, evidence is needed from health technology assessment surveys to determine the effectiveness of this approach (Wirtz et al., 2017). The overall use of WHO/UN prequalification procedures is recommended for ensuring quality procurement in LMICs, and the same is being adopted by many donor agencies involved in donating medicine to LMICs (Bukhari et al., 2010; Tordrup et al., 2013; Wirtz et al., 2017).

The Need for Basic Household Data on Medicine Use

LMICs spend the least amount (less than 5%) of their gross domestic product on health, resulting in poor infrastructure and health provisions for the patient, which are insufficient in both quality and quantity. According to the World Bank reports, 50%–75% of health expenditure is funded as an out-of-pocket expense in LMICs. In a survey on asthma medication in Kenya, 55.4% of patients were found to purchase medicine from private pharmacies (Barakat et al., 2018). Alarming results are reported for a number of households in India for 2010–12 at a 10% consumption threshold of 17.9% and 11% for total out-of-pocket expenses and OOPs for medicine, respectively (Selvaraj et al., 2018).

Low Literacy and Health Education

Low health literacy leads to poor health choices, which further promulgates the high disease burden found in the LMICs. These poor choices include unhealthy lifestyles, alcohol consumption, addiction, substance abuse, lack of physical activity, lack of facilities and habits for proper sanitation, availability of clean drinking water, and unhealthy and unhygienic food. In resource-poor settings with high disease burdens and population and understaffing in the health sector, the average consultation and dispensing time have been found to be suboptimal (Atif et al., 2017). Incorporating strategies to engage pharmacists in raising health education and encouraging proper use and understanding of medication is an important tool that can prove to be more effective in resource-poor settings than in developed countries.

In the United States, the Pharmacist Intervention for Low Literacy in Cardiovascular Disease (PILL-CVD) study group has documented that pharmacist-delivered health-literacy-sensitive interventions were particularly effective among patients with inadequate health literacy (Bell et al., 2016). A study in Saudi Arabia showed that poor understanding of medication use labels is related to poor literacy and low socioeconomic status (Alburikan et al., 2018), and similar results were recorded in a study on the inappropriate use of medicines in Pakistan (Husnain et al., 2018).

Maternal, Neonatal, and Child Health and Micronutrient Deficiency

Several interventions in the last decade have advocated effective and evidence-based use of simple pharmaceutical supplies for ensuring positive outcomes regarding maternal and child health. The WHO has formulated a priority list for Maternal and Neonatal Child Health (MNCH) in this regard. Magnesium sulfate injections (The Eclampsia Trial Collaborative, 1995) and tranexamic acid for use in the prevention and treatment of preeclampsia (Li et al., 2018; Vogel et al., 2018) and postpartum hemorrhage have been extensively researched to create sound evidence. The prevention of neural tube defects by overcoming folic acid deficiency through folic acid. Pharmacists, through their multifaceted role in the health-care system, can play a key role in the implementation of this evidence in routine clinical practice. The incorporation of the priority MNCH medicines in EMLs, formulary and standard treatment guidelines, assurance of availability and proper use of these medications, and facilitating the change in practice to promote the evidence-based use of medicines in these crucial health-care settings are necessary (Lotufo et al., 2016). The use of folic acid for the prevention of NTDs has been successfully documented using pharmacist-led action research in the developed world and can prove to be a good example for this and many other potential interventions for a parallel approach to scientific study, dissemination of knowledge, and sensitization of stakeholders to achieve required health outcomes (Norgaard and Sorenson, 2015).

Dietary supplementation is an important aspect of community pharmacy services, and pharmacy personnel share an undivided role in advising and counseling on this class of medicinal supplies (Waddington et al., 2015). A thorough knowledge of pharmacists on rational nutritional supplementation for use in iodine, vitamin D, vitamin A, calcium, and iron deficiency has the potential to minimize large scale health-related issues that evolve because of a lack of timely attention to these problems (Waddington et al., 2015).

Neonatal mortality is an important health indicator that poses a challenge to many developing nations. The neonatal mortality rates in Pakistan and Nigeria are constantly on the rise (Ahmed and Won, 2017). Promotion, knowledge, and confidence in exclusive breastfeeding, child spacing, maternal health, and nutritional status are various areas where a pharmacist can provide the community with correct advice and promote essential health education. Knowledge on the ethical marketing of breast milk alternatives and awareness among health professionals, including pharmacists and pharmacy personnel, are important, especially with respect to the fact that infant formulas and supplements are mainly sold by community pharmacies and drug sale outlets.

Many women of reproductive age from LMICs are not aware of the nutritional status needed for positive health outcomes of pregnancy (Stephenson et al., 2018). This lack of preparedness calls for action shortly before conception, psychological and personal understanding of the role of nutrition in child health and long-term societal attitudes aimed to achieve a healthy future generation by discouraging obesity, smoking, alcohol consumption, etc (Stephenson et al., 2018). Overcoming nutritional deficiencies using pharmacist-related interventions can be a helpful public health strategy. In contrast to Misuse and overuse of food supplementation can also pose risks during pregnancy by increasing risk to pregnancy-induced diabetes and hypertension as well as childhood obesity. Rational and ethical advice in retail settings can discourage such trends.

Diarrhea is an important cause of under-five mortality in LMICs. In the last decade, the WHO has introduced zinc supplementation as a recommendation for the management of acute watery diarrhea along with oral hydration solution (ORS) (World

Health Organization, 2011). A Cochrane review conducted on zinc supplementation in diarrhea supports its use in children above 6 months of age, especially in areas with a prevalence of zinc deficiency and malnutrition (Lazzerini and Wanzira, 2016). However, the availability of zinc dosage forms suited to the pediatric population and its accessibility, promotion, and awareness among health professionals, including pharmacists, needs (Oyetunde and Williams, 2018) to be assessed (Kung'u et al., 2015). To promote this intervention, bundle packages of zinc preparation and ORS are in use in many countries (Gebremedhin et al., 2016).

Preterm birth is another major contributor to neonatal mortality, and pharmaceutical issues that need to be addressed in this context include the cost and availability of pulmonary surfactants as prophylaxis and management of respiratory distress syndrome. As a high-cost biopharmaceutical, the product has limited manufacturers and involves the expertise of specialists and sophisticated facility settings for its appropriate use.

Review Contributions of LMICs in Top-Tier Pharmacy Journal(s)

The contributions of LMICs were assessed by the authors of this chapter using a review of systematic reviews published in the International Journal of Clinical Pharmacy from 2010 to 2015 (MacLure et al., 2016). Out of the 17 reviews, only six were submitted from LMICs, including three from Brazil, two from China, and one from South Africa. Two articles from Brazil were funded by the Brazilian government and the article on pharmaceutical policy from South Africa by the WHO. The topics of the reviews from Brazil included a review of the quality of systematic reviews on pharmacist health interventions (Melchiors et al., 2012), assessment of pharmacist-led patient counseling using RCTs (Okumura et al., 2014) and the effectiveness of clinical pharmacy services by reviewing systematic reviews (Rotta et al., 2015). Apart from a review on pharmacist care by Zhong et al., all other reviews clearly mentioned the review questions (Zhong et al., 2014). None of the 17 studies had a reference protocol. Two studies had defined their methodology as systematic in the title, whereas two studies did not provide a clear outline of the systematic methodology in the text despite using the word systematic in the title. One of the studies did not claim to be systematic; however, it was conducted systematically using the Cochrane collaboration recommendations. This indicates the gross situation of the quality of systematic reviews. Producing a good quality systematic review is a demanding task, and for resource-limited settings, this becomes more difficult due to lack of time, training, and resources. Evidence of team support was mentioned at all levels in all six reviews from LMICs except one in which it was only at the quality assessment level. A clear search strategy was missing in three of the reviews. All the reviews employed some form of quality assessment checklist (AMSTAR, Jadad, PRISMA, RevMan, GRADEpro, R-AMSTAR, DEPICT) except one on the pharmaceutical policies in LMICs.

The Way Forward

Promoting Quality Evidence Through Systematic Reviews

Cochrane reviews are the leading initiative with respect to evidence synthesis for use in medicine selection and use. With the goal of being self-sufficient rather than dependent, the Cochrane Collaboration has enabled people in LMICs to conduct high-quality Cochrane reviews, an example being the work of Ian Chalmer in pregnancy and childbirth (Young et al., 2013). This capacity building is aimed at developing globally competitive researchers from LMICs. This is to carry out "sensitive and intelligent" research that helps prioritize indigenous issues and creates quality evidence (Young et al., 2013).

National agencies in the developed world also conduct meta-analyses and scientific reviews to generate evidence for use in establishing and updating clinical recommendations, especially the STGs (Bond, 2015). Initiatives similar to NICE, the Scottish Medicines Consortium (SMC), the Common Drug Review for Canada (CDR), and the Pharmaceutical Benefits Advisory Committee for Australia (PBAC) need to be established in LMICs to promote the generation of locally relevant evidence in medicine and pharmacy practice.

The biggest facilitators for creating evidence to inform policy can be none other than the policy makers themselves. It is important to sensitize the policy makers in LMICs to invest the human resource as well as public and private funding for generating timely and sound evidence. The Cochrane initiative and other similar efforts also carry out advocacy for evidence-informed decision-making (Young et al., 2013). The gap in this respect in LMICs is one of the barriers to conducting quality studies, especially in the domain of public health. As evidence-based practice has evolved in just the last century, the traditionally modeled health systems in developing countries are still resistant to adopt the new approach and changing the health system processes accordingly (Young et al., 2013). For this reason, translational research is gaining importance in the scientific scene. LMICs are not only challenged by the limited involvement in the generation of evidence but are also hindered by the inefficient information dissemination and adoption of new practices.

The WHO has established systematic review centers in Bangladesh, Chile, China, Lebanon, South Africa, and Uganda under the Alliance for Health Policy and System Research. These centers work on ways to improve the performance of health systems. Approximately 20 systematic reviews and review protocols have been produced, and more are in process. The identification of this and other available resources and collaboration to ensure capacity building are necessary initial steps for LMICs to participate in the evidence synthesis process (International Initiative for Impact Evaluaton-3ie, 2018).

Use of Standard Protocols

Standardized methodologies and research protocols are a valuable tool to produce good quality evidence with less possibility of methodological flaws and bias. The WHO/INRUD methodology for assessing the rational use of medicine and drug utilization review is one such example. It has also been identified in this chapter that the largest number of studies were carried out under the WHO/INRUD protocol. This also leads to less heterogeneity in the data, allowing more room for qualitative analysis. However, proper conduct of these protocols may involve training of researchers. Moreover, like INRUD, these methodologies must be disseminated through interactive forums, research organizations, and public institutions to create interest and awareness of the importance of generating primary data on the subject. Another example of standardized methodologies is the Health Action International (HAI) methodology to measure drug prices. While more protocols are needed to be developed focusing directly on the pharmacy practice areas, the existing protocols need to be constantly circulated and encouraged for use. One important area of such template research is undergraduate student projects. The expertise and close mentorship needed to design an entirely new project for pharmacy students is a demanding task in a system where there is limited faculty; many of whom are overburdened or lack the necessary pharmacy practice research skills. With time, more schools are adopting research projects as part of undergraduate curricula. The use of standardized study designs in themes pertinent to basic pharmacy practice data and drug use indicators as well as other key issues in LMICs will help expose young researchers with locally relevant research themes and quality research design.

Completeness of Search in Reviews

Language is one of the factors limiting the collection of primary research and ensuring the completeness of the literature search. Almost all the discussed reviews included only English language publications. Even studies by international bodies such as the WHO were limited to English (World Health Organization, 2017a). Very few studies included all languages (Salmasi et al., 2018) or additional languages along with English. This is particularly important for the incorporation of literature that is present in popular languages in LMICs, including Chinese, French, Spanish, and Arabic. Translation assistance initiatives or specialized digital aids are needed in this respect. The need for an index catalog for pharmacy practice was discussed earlier, and the availability of accessing the terms in multiple languages can be a valuable tool for ensuring the completeness of the review. Moreover, it is very rare to include gray literature, such as thesis and dissertation catalogs, in the search methodology (Evans et al., 2011). Poorly funded and unfunded studies are more prone to end up in unindexed journals or have limited dissemination through conferences and poster presentations.

Source of Research Funding

Among the 17 reviews, 1 conference proceeding and 1 article on the development of the Basel Statement that was discussed in the current chapter, 6 were funded projects. The regional and national professional bodies, public universities, and regional research centers must be encouraged to develop a mechanism for funding pharmacy practice research in LMICs. Professional bodies in LMICs can carry out advocacy with funding institutions to promote pharmacy practice research by highlighting the gaps and it's potential to inform policy for developing evidence-based policies and improving people's health.

One of the novel mediums of the arrangement of funding is the use of a central fund under the Community Pharmacy Agreement in Australia. The community pharmacy contract global sum is a model practiced in Australia for the integration of pharmacy practice and research. The successful implementation of home medicine reviews has been established and refined through research using these funds (Bond, 2015). Regulatory or professional bodies of practicing pharmacists can generate a similar funding mechanism to promote research in pharmacy practice and to aid capacity building projects in this regard. However, close collaboration of policymakers, practitioners, and researchers is needed to design and implement such initiatives.

Gaps in Academic Training in Research Methodologies

Knowledge of sociobehavioral sciences constitutes an integral segment of pharmacy practice; for example, medicine use, counseling, adherence by the patient, and interaction with prescribers to influence prescribing to promote rationality and evidence-based practice need the additional knowledge of communication, interaction, and effective dissemination of knowledge. Socio-behavioral sciences were introduced in western curricula in the 1950s to early 2000s (Mohamed Ibrahim and Wertheimer, 2018); however, they are still not present in the courses taught in many LMICs. Moreover, adequate capacity building at the postgraduate level and encouragement of postgraduate diploma courses in research methodologies in pharmacy practice are critical to ensure the development of quality evidence from LMICs. The research methodologies in pharmacy practice are not adequately taught in the pharmacy schools of LMICs.

Take Home Message

- The goal of health-care professionals globally is to ensure evidence-based practice.
- The stakeholders including practitioners, researchers, academicians, funding agencies, and the policy makers must identify "The type of EVIDENCE" that matters for uplifting the standards of care and improvement in health-care indicators of the LMICs (based on their indigenous needs and they are in many ways different from HICs).

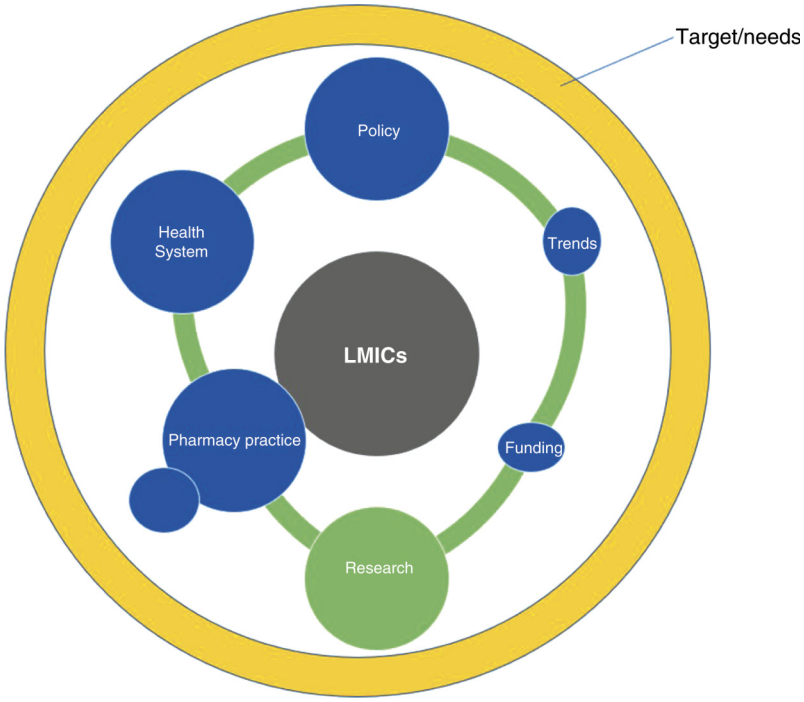

Figure 1 Proposed components of action plan for improvement in pharmacy practice research evidence in LMICs. (The outer circle refers to global trends and advancement in pharmacy practice. The central sphere refers to the indigenous needs. The magnitude of the blue green circles refers to the quantity/magnitude of progress in the related sector. The color of circles may represent the quality of the component. The closer the circle moves to the central sphere the more it caters to indigenous needs)

- The chapter identifies the gaps in pharmacy practice and evidences needed to deliver these goals and elaborates on the barriers faced in developing such evidences.
- The key stakeholders should develop a clear action plan to facilitate the process by focusing on their individual roles. Proposed components for a possible plan are shown in Fig. 1.
- In short, the global picture of evidence in pharmacy practice research cannot be built without active contribution of the LMICs that constitute 80% population of the world.

Conclusion

It is clearly depicted from the discussed analysis that the contribution of LMICs to the overall evidence synthesis process in pharmacy practice is quite low. Only a few countries have conducted quality research to be included in the systematic reviews by indexed journals. These countries include China, South Africa, Brazil, and Malaysia followed by Jordan and India (Table 1). Of the low-income countries, Nepal, Bangladesh, and Tanzania were the main contributors. A clear action plan is needed to proactively and effectively engage LMICs in quality research on pharmacy practice.

Along with the above-suggested recommendations, it is reiterated by the authors that a methodology of systematic reviews in pharmacy practice must include the identification of contributing countries from which the primary data were collected. A short analysis should be conducted with respect to country income groups to ensure appropriate interpretation of the review in different health systems and country settings.

Implementation Science

Joanna C. Moullin, Curtin University, Perth, Australia; Child and Adolescent Services Research Center, San Diego, CA, United States

Introduction

The road to evidence-based practice (EBP) is long and complex. In medical disciplines, the traditional research pipeline usually begins with biomedical inquiry and preclinical or animal studies. Translational research follows, involving phase I and II clinical trials and case studies, moving discoveries to human trials, from "bench to bedside". Next, a second translational stage, involving phase III and IV human clinical trials and controlled observational studies are conducted, moving the evidence to clinical practice. However, it has been proposed that this second translational stage is sufficiently complex to warrant further division: translation to patients (synthesizing the evidence including systematic reviews and guidelines), translation to practice (diffusion, dissemination, implementation, and sustainability), and translation to population (scale-up and spread) (Colditz, 2012; Westfall et al., 2007). Each one of these translations is a research field that require theoretical bases, study designs, and indicators for evaluation. Studies are required to understand and improve the evidence of each phase of the pathway.

A similar evidence pathway is promulgated for human services, including health services and professional pharmacy services. Research begins with developing a service and testing its efficacy and effectiveness in improving patient outcomes (health and quality of life) and economic outcomes (cost-effectiveness) from the perspective of the [pharmacy] organization and health care system. Next, diffusion and dissemination (communication) studies are required, to gather evidence of how to spread the research findings in order to increase awareness and interest. Finally, the service is expected to be adopted, implemented, and sustained into routine practice. As with the traditional medical research pipeline, this "implementation process" has been posited as being sufficiently long and complex to consist of multiple phases rather than being a single event. Furthermore, each portion or subphase of the service evidence pathway is a research field that requires theoretical bases, study designs, and indicators for evaluation.

Service developers and researchers should consider the final goal, of integration and sustained delivery, and the factors influencing the achievement of this goal, throughout the evidence pathway. As an example, when an innovation or service is developed, consideration should be given to, "how will the service be received?" and, "how difficult will the service be for practitioners to apply in practice?" Such questions are crucial to achieving sustainment and scale-up. In addition, the move for integrated implementation involves collaboration or coproduction, alternative research approaches, and the measurement of novel outcomes. For many years, services were created by researchers, with the primary objective of attaining evidence of efficacy (Glasgow et al., 2003). As such, study

designs such as randomized-controlled trials were used, but which may not have been reflective of the real-world, nor considered future wide-spread implementation.

The evidence pathway and research focus of other human service disciplines are analogous to pharmacy practice research. Internationally, community pharmacy is attempting to introduce and integrate pharmacy and professional pharmacy services (Moullin et al., 2013). Numerous professional pharmacy services have been conceptualized, and in some cases, their clinical effectiveness, cost-effectiveness, and remuneration structures studied, yet many have failed to be successfully implemented (Patwardhan et al., 2014). So on the one hand, there is scope for improvement in the development and testing of services. Service developers would benefit from using implementation science and conducting research that integrates implementation principles across the entire evidence pathway, such as expanding the contexts and stakeholders involved in the studies to develop new services. On the other hand, there are developed services ready to move onto practice, and researchers should consider conducting implementation research to investigate their diffusion, dissemination, and implementation, and subsequently develop theoretically based implementation programs.

Foundations of Implementation Science

There is increasing recognition and priority being placed on dissemination and implementation research around the World (Eccles and Mittman, 2006). Internationally, across multiple disciplines, there is a realization of gaps between research and impact and disconnections in the innovation and research processes. "Science to service", "research to reality", "evidence to practice," "know-do", are all terms used to indicate gaps in the approval and application of innovations (Brownson et al., 2018). More recently there has been discussion of an "implementation gap" and a "quality chasm" referring to services not being implemented and/or sustained over time and not being delivered with fidelity to how they were originally designed and intended (Fixsen et al., 2013). An extension of this fidelity debate is whether it is necessary to safeguard results achieved in controlled clinical trials by pushing fidelity, versus allowing and encouraging adaptation, which has been shown to assist introduction and integration (Durlak and DuPre, 2008).

Implementation science and knowledge translation have arisen to move innovations into practice, drive research utilization and EBP, and by doing so improve the value of research. Implementation involves change but is further complicated by necessitating change within and across multiple contextual levels, by multiple stakeholders (Kitson et al., 2018; Wandersman et al., 2008). Implementation may require innovation adaptation/change, behavioral change, organizational change, and systems change. In light of this, it is not surprising that there is an implementation challenge nor that this challenge is not unique to pharmacy practice, but is shared among all human services (Fixsen et al., 2005). Implementation science is a cross-disciplinary field that engages practitioners, service providers, policymakers and researchers from clinical, education, community, and policy contexts. Implementation science is about opening the "black-box" of implementation to develop logical, useable approaches that can be easily understood and utilized by researchers and practitioners to close the implementation "gaps".

Implementation science is a research field directed toward building evidence on how (effective implementation strategies and programs), by whom (facilitators/coaches, purveyors, intermediaries, and stakeholders), where (enabling contexts including policy, clinical and community settings) and for whom, any innovation, in any given situation, may be introduced and integrated into practice (Fixsen et al., 2005). Implementation research is needed for all these implementation questions while incorporating implementation evidence across the whole research pipeline to create professional services that are more marketable, acceptable, and workable.

The propagation of implementation science is widely attributed to Everett Rogers's seminal "Diffusion of Innovations," although its advent is traced to much earlier anthropology and social science research (Rogers, 2003). Roger's work was based on initial research conducted in 1943 on the adoption, or lack thereof, of hybrid corn seed by farmers in Iowa USA, together with a synthesis of other studies, from diverse fields, which also utilized the diffusion of innovations theory. The diffusion process and rate of adoption are explained by innovation attributes, adopter innovativeness, innovation-decision process, communication channels, and the social system. The popularity of diffusion studies spread from rural sociologists into general knowledge utilization by social and political scientists, where policymakers were the adopters, as well as to technology transfer and knowledge translation in large organizations (Dearing and Kee, 2012). At a similar time concepts and theories on research utilization, and evidence-based medicine/practice were gaining momentum (Estabrooks et al., 2008).

In many ways, the principles from diffusion theory have remained constant, but have been explored further and subsequently expanded, with research investigating the ensuing stages, post the adoption decision, of the implementation process (Rycroft-Malone and Bucknall, 2010). With time and further evidence, multiple other approaches have been added to the communication-based diffusion theory, and frameworks and models have proliferated (Moullin et al., 2015; Nilsen, 2015). Interest in the diffusion of innovations continues, as is recognition of the importance of the ensuing introduction and integration stages postawareness of the innovation. These stages or phases have been termed the implementation process and the study of this process, its influences and the strategies to improve successful implementation, called implementation science. Implementation science amalgamates different theories and various lenses are offered to view processes and outcomes. Regardless of the lens, the notion is moving an innovation or knowledge among individuals and contexts by various means to achieve outcomes.

Terminology

Alongside implementation science, the term knowledge translation is commonly used, particularly in the health and policy sectors in Europe and Canada. Knowledge translation was used by the World Health Organization (WHO) in their policy to close the "know-do-gap" (World Health Organization, 2006). Subsequently, WHO have released a practical guide to implementation research in health, blurring the terminology boundaries (Peters et al., 2013). Initially, knowledge translation included a greater focus on problem identification or needs assessment, and the creation and/or synthesis of knowledge; however, implementation science has broadened to include these areas. Other distinct, but similar terms regularly used interchangeably to knowledge translation include research or knowledge, utilization, transfer, mobilization, or exchange (Ottoson and Hawe, 2009). Within these fields, the terminology and inclusion of concepts within their frameworks vary; however, the goals and principles are largely analogous.

The terminology of the implementation fields can be confusing. Not only does implementation science use different terms to knowledge translation (KT), but within the fields and within the same disciplines different terms are often used to mean the same thing (synonymy), or the same term is used to indicate different things (homonymy). For example, the word "intervention" may refer to an "implementation intervention" or a "clinical intervention". Another example is the end-user, which in implementation usually refers to the individual who will deliver the innovation (i.e. pharmacist), as they are the end-user of the implementation intervention. Whereas in pharmacy practice, other health services, and public health disciplines, the end-user is the individual receiving the innovation (i.e. patient). A small glossary of terms has been included at the beginning of the chapter and further implementation science-based pharmacy practice definitions have been published (Moullin et al., 2016a, 2016b).

Theoretical Approaches: Frameworks, Models and Theories

One valuable aspect of implementation science is that it incorporates concepts from an array of disciplines and theories to provide a holistic view of the implementation process and its determinants. Disciplines drawn upon include sociology, psychology, political science, business, and communications (Nilsen, 2015). Theories include cognitive, behavioral, organizational (Davies et al., 2010) and complexity, network and systems thinking cross-social ecological boundaries (Foster-Fishman and Watson, 2012; Kitson et al., 2018).

There has been increased recognition of the importance of using established change theories, models and/or frameworks, as well as developing theoretical bases from within the implementation science discipline. Theoretical grounding may be used to determine and assess factors, create and evaluate strategies and develop tools and measures to gain evidence into the mechanisms of implementation and how implementation is more likely to succeed (The Improved Clinical Effectiveness through Behavioural Research Group, 2006). It is largely accepted that research should be theoretically driven and implementation research is no exception; however, the debate on frivolous theory over common sense and empirical evidence lingers (Bhattacharyya et al., 2006; Oxman et al., 2005).

Implementation theories, models, and frameworks have been classified as being concentrated toward, content and context (determinant frameworks, classic theories or implementation theories), process, or evaluation (Nilsen, 2015). Within these classifications there are broach overarching frameworks (e.g. lists of factors, strategies or measures; stages, steps or evaluations across the entire implementation process; multi-level context derivations; general theory of implementation). Additionally, there are frameworks for specific concepts (e.g. fidelity, organizational readiness, implementation climate, adoption stage, and sustainability stage). Moreover, frameworks, models, and theories from related fields are used (e.g. intervention development models such as intervention mapping; behavioral motivational, action or stage theories; organizational or quality improvement theories; systems, complexity, and network thinking). There is an occasion for all frameworks, models and theories depending on the research question, the contextual level being targeted, setting and point in the evidence pathway.

Along with realization of the importance of the later dissemination and implementation phases of the evidence pathway, there has been insight that for successful implementation, implementation evidence should also be considered during the early, innovation, or service development phases (Kitson et al., 2013; Kothari and Wathen, 2013). Examples of frameworks that incorporate principles of implementation into the development phases include: the Medication Research Council of UK's Framework for Complex Interventions (Craig et al., 2008, 2013); knowledge translation frameworks that are based around theories of planned action such as Knowledge to Action (KTA) (Graham et al., 2006); the KT complexity network model (Kitson et al., 2018); and intervention mapping (Bartholomew et al., 1998).

Core Concepts of Implementation Science

In basic terms, implementation success (**Fig. 1**) is impacted by

- What is to be implemented (the innovation)
- Where and for whom is the innovation to be implemented (the context)
- How and by whom is the innovation to be implemented (the implementation process and program)

Figure 1 Active implementation framework formula for success (Fixsen et al., 2013).

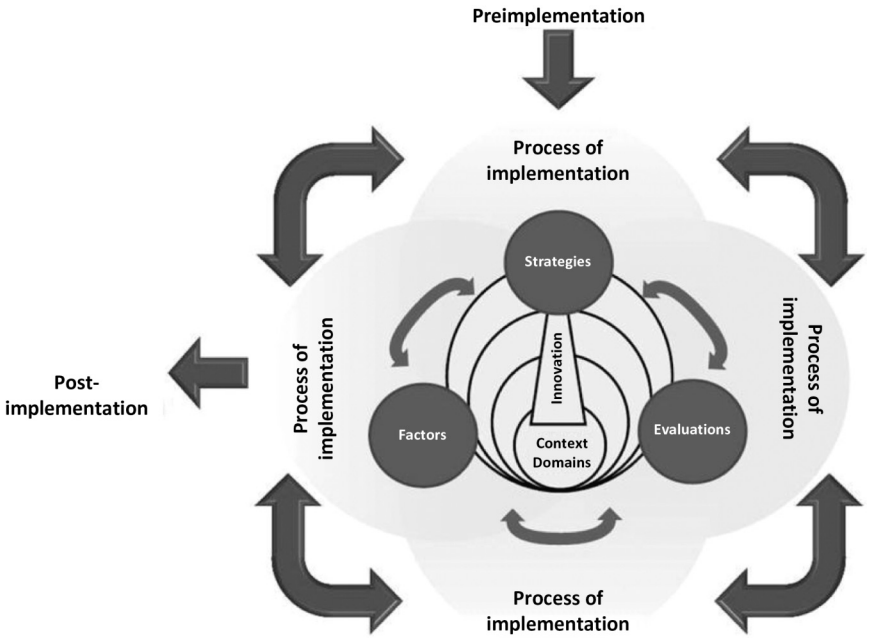

Figure 2 Generic Implementation Framework (GIF) (Moullin et al., 2015).

Developing evidence on what constitutes effective implementation, for which innovations, in which contexts, is the primary focus of implementation science. Knowledge translation has mirrored concepts, where successful implementation has been postulated to be calculated from evidence, context and facilitation in the Promoting Action on Research Implementation in Health Services (PARIHS) framework (Kitson et al., 2008). Similar components have also been voiced as the essential ingredients of change management and organizational change (Worren et al., 1999). By being multiplications, the implementation equations signify that all components are imperative and must be considered and that if any component equals zero, the outcome of the equation will be zero, i.e. unsuccessful implementation.

Generic Implementation Framework (GIF)

The GIF collates the key components involved in implementation (Fig. 2) (Moullin et al., 2015). These components are described as (1) the innovation (e.g. professional pharmacy service), which is being implemented into (2) a multi-level context, which consists of and is influenced by a number of (3) implementation factors, throughout a (4) multi-phase implementation process, that is facilitated by (5) strategies and assessed with (6) evaluations and outcomes. It is a central structure into which meta-frameworks, model of theories should be added to operationalize each component.

Innovation: What is to be Implemented?

Implementation science arose as innovations, evidence-based practices (EBPs) and evidence-informed treatments, sat idle in academia and empirical evidence and knowledge were not spreading. Innovations are defined as "a novel set of behaviors, routines, and ways of working within a setting" (Greenhalgh et al., 2004). Innovations vary from a new technology or guideline to a service or program, or a novel way of working, such as continuous quality improvement initiatives or EBP. The characteristics of innovations influence the ease and likelihood of successful implementation. The innovation's attributes effect all stages of the implementation process, from exploring and appraising the service and deciding whether or not to implement (adoption decision), to how much preparation is required, how difficult the innovation is to introduce, the challenge of gathering support and integrating into practice, to finally influencing the spread across diverse settings.

It appears professional pharmacy services are largely developed prior to considering implementation and sustainability. It is therefore possible, that research projects may produce innovations that are not implementable. Integrated implementation would be desirable to increase their feasibility, acceptability, implementability, and sustainability. In addition, investigating the

components of services is recommended so that adaptations to the innovation may be made while ensuring the positive outcomes obtained in the trials are transferred to real-world practice. Pharmacy practice research could benefit from service development and optimization studies, which incorporate implementation science, as well as implementation research on services that are already developed and available for implementation.

Contextual Domains: Where and for Whom is it to be Implemented?

The context into which an innovation is to be implemented is gaining increasing attention in implementation science literature. The notion of contextual domains is to acknowledge and embrace the complexity of the system and consider influences across all social-ecological levels, at all stages of the process. Contextual domains may be defined as groupings of related influences regarding the circumstances that surround the innovation to be implemented (Aarons et al., 2011; Damschroder et al., 2009).

Ideally, throughout the implementation process consideration would be given to: the characteristics and readiness of all stakeholders involved with an innovation and/or the implementation process; the conditions and characteristics of the setting(s) in which the innovation is to operate; the circumstances immediately surrounding the organization(s) including the community, and patients (for whom the innovation is targeting) and their social network; and finally the economic, political, and professional milieu (Moullin et al., 2016a). Mendel et al. (2008) use complexity theory in their framework to include multiple levels of context and illustrate the importance of capacity building. The Interactive Systems Framework (ISF), a community service implementation framework, also focuses on building the capacity of the service delivery system and the service support system, as well as acknowledging the interrelationships between these levels (Wandersman et al., 2008). Their latest framework the Evidence-Based System for Innovation Support (EBSIS) builds on the ISF by delineating an implementation program specific for capacity building (Leeman et al., 2015). Implementation science emphasizes the importance of considering and involving stakeholders from both the inner and outer context (Aarons et al., 2011) such as community, patients and policy-makers (Kitson et al., 2018, 2013).

Implementation factors

Implementation factors are the variables that may affect the implementation process. Also termed influences, facilitators and barriers or determinants of practice (Flottorp et al., 2013). List-style frameworks of factors include the Consolidated Framework for Implementation Research (CFIR) (Damschroder et al., 2009), integrated checklist to identify determinants of practice (TICD checklist) (Flottorp et al., 2013), Theoretical Domains Framework (TDF) (Michie et al., 2005), and Behavioral Change Wheel (BCW) (Michie et al., 2014). The CFIR list of factors influencing the implementation process has been adapted for community pharmacy in a paper by Moullin et al. (2016a). Some researchers have narrowed down the scope of the factors and developed models that link to aid in the selection of strategies, such as the PRECEDE-PROCEED (Green and Kreuter, 1999).

Use of factor frameworks facilitates consistent terminology across disciplines, linkage to theories, and impact evaluation, where mechanisms of action and determinants of implementation are evaluated. Factors may act as moderators, where they modify direction or strength of an effect, or as mediators, where they account for part of an effect (Flottorp et al., 2013). Once target factors have been determined, appropriate strategies may be chosen, including the operationalization and reasoning of the strategy, so that the proposed mechanism of action may be tested (Dalkin et al., 2015; Eccles et al., 2005). As mentioned, barriers and facilitators to professional pharmacy service implementation have been tested, however using a typology that links to strategies, and assessing the factors influencing the implementation by multiple stakeholders, at different time points may advance implementation evidence for the implementation of professional pharmacy services (Moullin et al., 2016a).

Tools and theories of contextual factors have been developed and tested, such as implementation climate, leadership, implementation citizenship behavior, organizational readiness, organization context (Aarons et al., 2018). The "fit" of the innovation to context (innovation fit) is an example of one factor associated with implementation that may be evaluated to guide tailoring of implementation strategies and adaptations of the innovation and/or the context (Aarons et al., 2012).

Implementation Process: How and by Whom is it to be Implemented?

The crux of implementation science is to answer the question, "How and by whom should an innovation in a particular context be implemented?" Or "What constitutes effective implementation?" The answer is not simple. Implementation consists of a complex process, often to implement complex innovations, across complex social systems.

It is widely accepted that implementation is not a single event, but a long and complex process. The process is delineated into numerous different arrangements and typologies of stages. In addition, in some derivations, the stages are further divided into a series of activities or steps, as is the case for the Framework for Implementation of Services in Pharmacy described later in this chapter.

Examples of the implementation process stages include:

- Knowledge, persuasion, decision, implementation, and confirmation (Innovation-decision process up until point of adoption) (Rogers, 2003).
- Knowledge creation (tailoring knowledge): knowledge inquiry, synthesis, product tools; Action cycle (application): identify problem, identify, review, select knowledge, adapt knowledge to local context, assess barriers to knowledge use, select, tailor,

implement interventions, monitor knowledge use, evaluate outcomes, sustain knowledge use (Graham et al., 2006; Straus et al., 2009).
- Problem identification, knowledge creation, knowledge synthesis, implementation, and evaluation (Kitson et al., 2018).
- Awareness, adoption, implementation, and institutionalization (Steckler et al., 1992).
- Exploration, installation, initial implementation, full implementation (Fixsen et al., 2005).
- Exploration, preparation, implementation, and sustainment (Aarons et al., 2011).
- Training, adoption, implementation, and practice improvement (Simpson and Flynn, 2007).
- Development or discovery, exploration, preparation, testing, operation, and sustainability (Moullin et al., 2016a).

The stages and steps are criticized for their linear derivation, as the process appears to be iterative. Frameworks, such as Greenhalgh et al. (2004), are less linear in appearance, where system antecedents and system readiness occurring parallel to diffusion and dissemination, both leading to adoption/assimilation, followed by implementation and finally consequences. Conversely, Kitson et al. (2018) removed the linear representation all together depicting only separate domains. Regardless, for illustrative and planning purposes many frameworks do take a temporal, stage-based approach. And branded implementation programs and frameworks that include the development or synthesis phase, such as in knowledge translation, quality improvement and intervention mapping, appear to be more prescriptive of the implementation process.

The second aspect of the implementation process is the individuals involved in the implementation effort (those delivering the implementation strategies) as well as those in the enabling context(s) (those delivering the innovation). Staff selection, implementation teams and leadership are particularly prominent implementation topics. In addition, the use of knowledge brokers, purveyors and intermediary organizations has received attention (Gagnon, 2011; Oosthuizen and Louw, 2013). Research, funding and use of implementation facilitators may be valuable for professional service implementation.

Implementation strategies

Implementation strategies are the efforts (method, technique, or activity) designed to enhance the movement of an innovation into use and its integration into routine practice (Curran et al., 2012; Flottorp et al., 2013). "Implementation strategies are inherently complex social interventions, as they address multifaceted and complicated processes within interpersonal, organizational, and community contexts" (Proctor et al., 2013, p. 3). In a similar vein as clinical interventions being designed to affect behavioral or environmental determinants of patients' health, implementation strategies are designed to affect the behavioral or environmental determinants of practitioners' practice. Strategies may need to adapt innovations, behavior, organizational structure, climate, culture, shift perceptions of communities or enable policy amendments. Implementation strategies include:

> 'how to translate interventions to encourage uptake and implementation in ways that preserve scientifically validated components of evidence-based practices, how to obtain buy-in of various stakeholders in settings over which researchers have little control, and how to sustain interventions beyond initial demonstrations and funding, particularly in settings with highly constrained resources'.
>
> (Mendel et al., 2008, p. 22)

Taxonomies and frameworks of implementation strategies include the EPOC checklist (Cochrane Effective Practice and Organisation of Care Group, 2010), Behavioral Change Techniques (BCT) (Michie et al., 2013) and Expert Recommendations for Implementing Change (ERIC) discrete strategies list (Powell et al., 2015). Other frameworks which combine a number of discrete strategies have been termed branded, manualized, multifaceted implementation strategies or implementation programs (Proctor et al., 2013). These include the Availability, Responsiveness and Continuity model (ARC) (Glisson and Schoenwald, 2005), Replicating Effective Programs (REP) (Kilbourne et al., 2007), Getting to Outcomes (GTO) (Chinman et al., 2004), Quality Implementation Framework (QIF) (Meyers et al., 2012), and Leadership and Organizational Change for Implementation (LOCI) (Aarons et al., 2017). Examples of commonly used implementation strategies include education, audit & feedback, outreach (opinion leaders, knowledge brokers, facilitators/coaches, and purveyors) infrastructure & technology, and financial incentives.

Implementation science has shown that generally neither changing a single implementation factor nor employing a single implementation strategy is sufficient for successful, sustained implementation (Grimshaw et al., 2001; Scott et al., 2012). In other words, factors such as a strong desire, motivation and knowledge alone are not sufficient to drive implementation (Green et al., 2009). Neither are strategies such as payment, training, continued professional development (CPD) including conferences, or mass mailings of clinical guidelines (Forsetlund et al., 2009; Grimshaw et al., 2001; Hakkennes and Dodd, 2008). In pharmacy practice, great emphasis was placed on securing payment and providing CPD, believing this would be sufficient to drive implementation. From the experiences in many countries, it can now be seen that although a benefit must be realized for the pharmacy business, remuneration and training alone are not going to lead to successful implementation. Implementation science deems that theoretically driven strategies are needed to target key factors that influence implementation for a particular setting for a particular service (Palinkas et al., 2011). On the contrary, the evidence for tailored interventions is currently mixed (Baker et al., 2015).

A research team headed by Susan Michie at University College London have combined psychological frameworks and models for determining factors and tailoring implementation strategies. The factors determined from the Theoretical Domains Framework (TDF) or Behavioral Change Wheel (BCW) may be mapped to the COM-B model (Capability, Opportunity,

Motivation – Behavior) (French et al., 2012; Michie et al., 2014). This model determines whether greater capability, increased opportunity, and/or stronger motivation is required to drive behavioral change. From the results, strategies and finally techniques, the active ingredients that may achieve the desired change to the determinants, are identified (Michie et al., 2014). Although COM-B and the BCW have been used in policy and organizational contexts, as the name suggests, the associated models are largely focused on individual behavior.

Quality improvement approaches such as UK's Institute for Healthcare Improvement (IHI) breakthrough series (Institute for Healthcare Improvement, 2003) and US Department of Veteran's Affairs, Quality Enhancement Research Initiative (QUERI) projects (Stetler et al., 2006) are particularly helpful at the organizational level. Alternatively, an option is to follow an intervention development framework (e.g., Medical Research Council (MRC) guidance, intervention mapping, IHI etc.), but for the development of an implementation strategy or program, rather than the clinical intervention.

The design of implementation strategies should be deliberated, strategically and systematically, and this design process explicitly reported. When researching implementation programs, it is essential to report each strategy as would a clinical intervention. In this way, the fidelity of implementation and essential strategies for a particular innovation in a particular context may be evaluated. In addition, it allows for replication and meta-analyses (Michie et al., 2009; Proctor et al., 2013). Recommendations, manuals and protocols have been made by the Workgroup for Intervention Development and Evaluation Research (WIDER) group for the reporting of behavioral change interventions and implementation strategies, for quality improvement interventions standards have been developed (Standards for Quality Improvement Reporting Excellence (SQUIRE checklist)), and a statement of Standards for Reporting Implementation Studies (StaRI) (Pinnock et al., 2017) has been published.

Implementation evaluation/outcomes

All implementation efforts and implementation studies should include a plan to evaluate the impact of the chosen implementation approach and ways to measure success. Implementation evaluations measure the effects of implementation and may include: process evaluation of progression, impact evaluation of factors, formative and summative evaluation of strategies, as well as the degree of implementation, and innovation outcomes. Frameworks based on implementation evaluations include Glasgow et al. (1999), Green and Kreuter (2005), Lehman et al. (2011), Moullin et al. (2016b), Proctor et al. (2011), Stekler et al. (1992), and Stetler et al. (2006).

In recent years, implementation science has focused heavily on the development and testing of implementation measures and large databases have been developed as repositories (Lewis et al., 2015; Rabin et al., 2012). Over 500 measures have been described. Literature reviews on implementation tools have been conducted, tools developed for particular implementation concepts (e.g. Stages of Implementation Completion), specific factors (e.g. implementation climate), theory suitable for formative evaluation of normalization and models of particular outcomes (e.g. implementation fidelity).

Formative evaluation is an assessment process designed to identify influences on the progress and effectiveness of implementation to guide ongoing tailoring of implementation strategies. Formative evaluation is often used as part of an audit and feedback implementation strategy and in quality improvement. Four progressive, integrated stages of formative evaluation are described by Stetler et al. (2006): (1) developmental evaluation prior to implementation to explore and assess current practice: determinants of current practice, barriers and facilitators to implementation, and feasibility and tailoring of implementation strategies; (2) process focused evaluation to monitor the progress; (3) implementation focused evaluation to reduce type III errors and enhance result analysis, assess modifiable barriers to refine implementation strategies, and assess innovation adaptation, critical components and/or strategies to replicate outcomes; (4) interpretative evaluations postimplementation to explain the summative implementation and innovation outcomes, assess evidence of the factors and strategies, develop tools for wider spread and scale-up, and develop hypotheses for future studies.

RE-AIM (Reach, Effectiveness, Adoption, Implementation, Maintenance), is one implementation evaluation framework that may be used to guide implementation science protocol design and measurement (Glasgow et al., 1999, 2005, 2006). This framework includes effectiveness testing (of the professional service and/or implementation program), in combination with reach (participation rate and representativeness of the participants), organizational measures of adoption (uptake by providers and organizations, including proportion and representativeness), implementation (quality, consistency and integrity of provision, and implementation cost) and maintenance of both health benefits in patients (or determinants of benefits such as behavioral changes) and changes in the organization in terms of integrating the service as routine. Another useful tool is the Stages of Implementation Completion (SIC), which may be used as both a formative and summative tool to measure the rate and depth of implementation (Chamberlain et al., 2011). It may be used to investigate which steps or strategies are essential for implementation success. These frameworks have been used to help guide the development of an evaluation model for implementation programs and pharmacy services as described in the next section.

Framework for the Implementation of Services in Pharmacy (FISpH)

For application in pharmacy practice, the Generic Implementation Framework (GIF) was contextualized and operationalized from the results of a qualitative study (Moullin et al., 2016a). The Framework for the Implementation of Services in Pharmacy (FISpH) demarcates the stages and activities of the implementation process, the contextual domains or ecological levels, implementation influences, tailored from the Consolidated Framework for Implementation Research (CFIR), and provides a

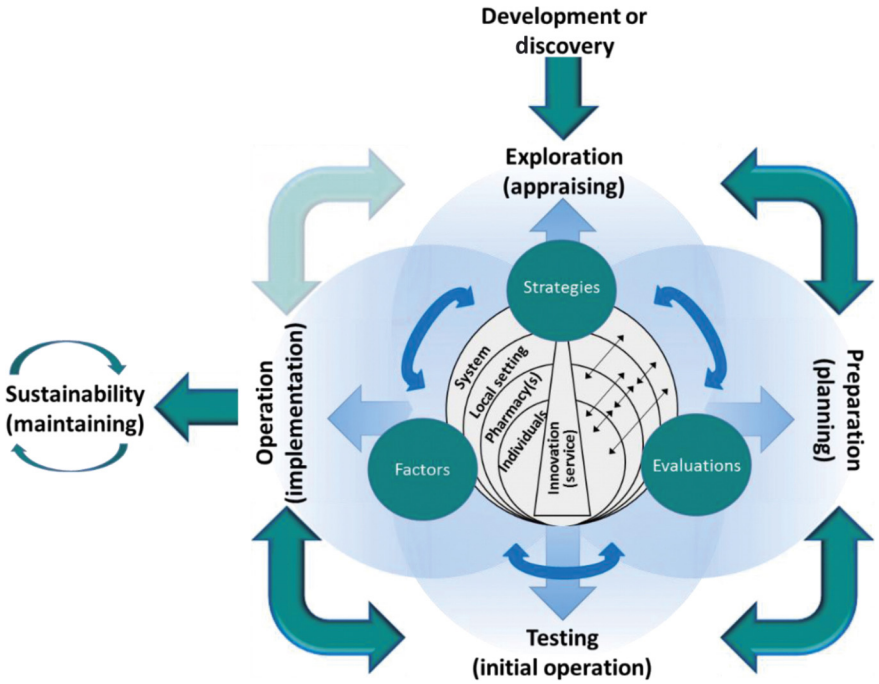

Figure 3 Framework for the Implementation of Services in Pharmacy (FISpH) (Moullin et al., 2016a).

model for evaluation of the service and the implementation program for pharmacy practice (Figs. 3–5). Other models or theories are currently required for selecting implementation strategies. Thus far the framework has been applied in Australia (Roberts et al., 2015), New Zealand (Pharmaceutical Society of New Zealand and New Zealand Medical Association, April 2017), Spain (Moullin et al., 2014), Belgium (Lelubre et al., 2018), Switzerland, and Mexico.

At the center of the framework is the innovation or professional pharmacy service to be implemented. A professional pharmacy service has been defined as "an action or set of actions undertaken in or organized by a pharmacy, delivered by a pharmacist or other health practitioner, who applies their specialized health knowledge personally or via an intermediary, with a patient/client, population or other health professional, to optimize the process of care, with the aim to improve health outcomes and the value of health care" (Moullin et al., 2013).

Surrounding the professional pharmacy service to be implemented are the contextual domains specific to pharmacy practice, defined as:

- Individuals: the people involved in the implementation process including the pharmacy owner, the service provider (often a pharmacist), and other pharmacy staff such as technicians and assistants. It may also include individuals from the pharmacy group, such as a professional services manager, or external assistance sought to aid the implementation effort.
- Organization: the characteristics of the pharmacy or group of pharmacies.
- Local setting: the environment surrounding the pharmacy including patients, friends and relatives, clientele, the community and other health care professionals.
- System: the political and economic context, as well as the professional situation (such as the pharmacy bodies and the organizations of other health care professionals).

The process of implementation in the FISpH is divided into six stages. These stages are development or discovery, exploration, preparation, testing, operation, and sustainability. The preimplementation stage of development or discovery is where a pharmacy or pharmacy group internally develops a service(s) and/or discovers an externally developed service. Once a pharmacy is aware of a service they move into the exploration stage where they are deliberating or appraising the service, and deciding whether or not they want to take it up (adopt). If the decision is to go ahead, they move to preparation, where the pharmacy, pharmacist and all other factors are planned and primed for service delivery. The service is then trialed, by being delivered either for a short, defined period, with a limited number of patients, or by a single pharmacist, rather than the whole team. From here a pharmacy may move back into preparation stage to make improvements or move directly into the operation stage. The operation stage is the long process of integrating the service into routine practice. During this stage, staff need to gain confidence while trying not to revert back to their old habits and way of working. Finally, moving from operation to sustainability occurs when service delivery continues after a period of time or when any implementation program (or external assistance) has ceased. This displays that the service is integrated as a routine in the pharmacy, there is ongoing support and capacity, and outcomes persist both for the patients and the pharmacy business.

During the stages, a range of activities were exposed from interview data (Fig. 4) (Moullin et al., 2016a). The activities were *Exploration*: Organizational fit assessment, value assessment (relative advantage), service assessment (service characteristics), organizational capacity assessment (supporting conditions & staff capacity), community fit assessment, decision; *Preparation*: Assign leader, research requirements, organize supporting conditions, plan service procedure, rearrange workflow, staff arrangements, team communication (buy-in and foster climate), training, community awareness & recruitment; *Testing*: Initial adaptations, familiarization & improve staff conviction, test patient demand; *Operation*: Modification of plans & procedures, maintain patient demand, staffing, teamwork, team input and internal communication, integration tactics, ongoing training, goal setting, monitoring, adaptation, improvement; *Sustainability*: Few pharmacies had reached sustainability however activities were posited as continuing the last three activities of the operation stage: monitoring, adaptation and improvement.

The stages nor activities are not mutually exclusive, nor linear. There will be wide variation in the duration of stages, movement back and forth between stages, differences in the order of performing implementation activities and not all activities will be completed. The framework, however, provides a structure to the process and guidance on some useful activities to target for an implementation program [Fig. 4].

Analysis of the factors influencing the implementation of professional pharmacy services, revealed five influences that affected all stages of the implementation process: a pharmacy's direction and impetus, internal communication, staffing, community fit and support. However, many other factors influence the process profoundly at various stages. A refined list of the implementation factors for community pharmacy has been developed and published (Moullin et al., 2016a). This adaptation of the Consolidated Framework for Implementation Research for pharmacy practice provides a typology of influences that can be used to code qualitative studies and to develop implementation hypotheses, models, and measures.

Conceptual frameworks are a perpetually evolving through revisions and enhancements. In addition, it is possible to contextualize and adapt frameworks for individual situations, such as further dividing the context domains depending on the desired analysis and research question. As an example, the domain of the local setting surrounding a pharmacy may be split into three subdomains: patients, community, and local health care professionals. Adaptations may also be required as pharmacies within and across countries will show cultural and contextual differences. For example, compared to Australia, Spanish pharmacies are commonly owned by single proprietors, who can only own one pharmacy, are smaller in size and have longer employer tenure. Therefore, an example of theoretical adaptation would be removing "team" based strategies or evaluations as they may not be applicable or suitable for Spanish pharmacy settings.

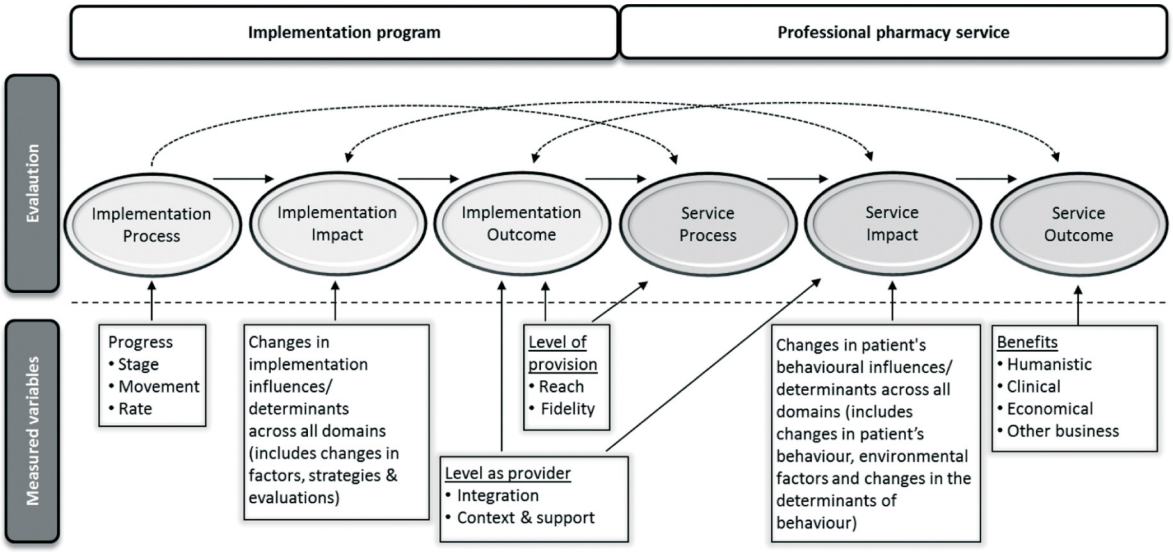

Figure 5 Model for the evaluation of implementation programs and professional pharmacy services (reprinted from Research in Social Administrative Pharmacy, Vol 12, Moullin, J. C., Sabater-Hernández, D. & Benrimoj, S. I. Model for the evaluation of implementation programs and professional pharmacy services, pages no. 515-522, 2016, with permission from Elsevier)

Note: Domains are the divisions or categories of the implementation influences and determinants of a patient's behavior, they include characteristics of the service being implemented, and the context (individuals, organization/pharmacy, local setting and system).

Model for the Evaluation of Implementation Programs and Professional Pharmacy Services

Based on the FISpH and implementation science literature (Carroll et al., 2007; Glasgow et al., 1999; Lehman et al., 2011; Proctor et al., 2011; Slaghuis et al., 2011; Steckler et al., 1992) a model for the evaluation of implementation programs and professional pharmacy services was developed (Fig. 5) (Moullin et al., 2016b).

The evaluation model involves indicators for both implementation process, impact, and outcome evaluations as well as service process, impact and outcome. The model recognizes evaluations for implementation, including indicators of (1) movement through the implementation stages (formative and summative implementation process evaluation), (2) influencing factors and changes in factors over-time (implementation impact), and (3) overall measures of implementation (implementation outcomes). The arrows indicate the flow of effect, while the curved arrows hypothesized relationships between the implementation and service evaluations.

The evaluation model may be used to evaluate the level of implementation by assessing the level of service delivery (reach and fidelity) and the level as a service provider (integration and strength of support in the service environment). The level of service provision may be described as "how much and how well" the service is performed, while the level as a service provider explains the extent to which the service is integrated into the pharmacies' principles and practice, their capability, and the support throughout the service environment.

Pharmacy practice research has been heavily focused on patient outcomes and cost-effectiveness in a bid to gain recognition and remuneration for professional services. As such, studies have needed to be conducted in controlled conditions, often prior to real-world implementation. Exacerbating the issue is poor monitoring within the pharmacy profession (Australian National Audit Office, 2015; Patwardhan et al., 2014). This combination has led to governments pushing for an increase in implementation and impact evaluations, both within academic research proposals and reports, and by the profession. To conduct implementation research, quality assurance, performance assessment and impact evaluations, evaluation models and practical tools to assess implementation indicators should be used.

Implementation Science Research Methods

The objective of implementation science is to understand the mechanisms required to improve adoption, utilization, sustainment, and scale-up. This has been described as seeking 'to understand the processes and factors that are associated with successful integration of evidence-based interventions within a particular setting' (Rabin et al., 2008, p. 119). It therefore can be seen that dissemination and implementation research addresses different questions to clinical research. Implementation research is specific for researching the effect of implementation strategies and programs, while health services and clinical research revolve around developing health innovations and clinical interventions, and studying the efficacy and effectiveness of such interventions. In other

words, implementation science is focused on the processes, influences and outcomes of implementation, rather than the processes, determinants or outcomes of the innovation. The study of implementation strategies needs to be scientifically tested, as would a clinical intervention. A group has been formed at the Cochrane Institute to evaluate the effectiveness of implementation strategies (Cochrane Effective Practice and Organisation of Care Group, 2010).

To produce rigorous implementation evidence study designs, tools and analyses need to relate to implementation objectives and indicators. A prerequisite for this to occur is for implementation strategies to be recorded and reported in detail as would clinical interventions (Bartholomew et al., 2011; Michie et al., 2009; Proctor et al., 2013). This also will facilitate future replication, comparison and assessment across studies. Proctor et al. (2013) describe the principles of naming, conceptually defining, and specifying (actor, action, target, temporality, dose, implementation outcome affected, justification) to operationalize and contextualize implementation strategies. Ideally, implementation strategies should follow an evidence path, from theory building to phase I modeling, Phase II exploratory studies before phase III implementation and phase IV sustainability trials (Eccles et al., 2005).

External validity and generalizability are central to implementation science as the research addresses the introduction and integration of innovations within real-world, complex, service systems. While in many health service fields, including pharmacy practice research, internal validity has been emphasized in order to look at the extent to which the innovation produces an effect. This has led to the reliance on randomized control trials (RCTs), testing in restricted populations with narrow interventions, and meta-analyses that exclude nonrandomized trials to strengthen causal inference. Subsequently, moving innovations into diverse settings became a haphazard process as was unknown if the innovations would be feasible, or even if they would produce the outcomes shown in the controlled setting (Eccles et al., 2009). The Consolidated Standards of Reporting Trials (CONSORT) statement recommends researchers summarize the extent a study is pragmatic versus explanatory to increase the external validity data available for systematic reviews (Zwarenstein et al., 2008), and the Pragmatic-Explanatory Continuum Indicator Summary (PRECIS) has been developed to provide guidelines (Loudon et al., 2015). In addition, the extended Consolidated Standards of Reporting Trials statement (CONSORT statement) includes recording recruitment (reach) and maintenance (sustainability) details (Calvert et al., 2013). It follows that future pharmacy practice research should also consider the addition of reporting implementation indicators and outcomes.

Study Design

The overall implementation research process mimics efficacy and effectiveness research. Similarly, the use and reporting of theory to guide implementation research is recommended. Study designs for implementation research include an array of experimental, quasi-experimental/observational, alternative randomized (staging), hybrid (effectiveness-implementation combination designs), adaptive protocols, and designs that allow for collaboration with stakeholders (Brown et al., 2017). While RCTs and cluster RCTs predominate implementation research (Mazzucca et al., 2018), alternative designs offer advantages. For example, the interrelationships within and across social-ecological levels require novel study designs that offer flexibility during innovation development, dissemination and implementation (Lindamer et al., 2009; Mendel et al., 2008).

Experimental Design

Although RCTs are possible and suitable for some implementation research studies, there are some issues that should be considered. These issues include the unit of observation, possible contamination, breakdown of randomization, and statistical power. Furthermore, in implementation research, randomization may be precluded by ethical, legal, practical, or policy concerns.

Quasi-experimental and/or Observational Design

Quasi-experimental and/or observational study designs are often suitable for conducting implementation research as external validity is prioritized. These designs may be useful when randomization is not feasible or appropriate. In addition, they may provide useful information on the implementation context. Three types of quasi-experimental and/or observational designs are frequently used in implementation science to enable causal inference: controlled before and after study, interrupted time series, and regression discontinuity designs.

Controlled before and after study designs involve non-randomized allocation of intervention and control site/groups and the measurement of outcomes preintervention (baseline), and postintervention. Pre- and postintervention periods for intervention and control sites should be equivalent, and comparable sites should be selected based on their characteristics, script volume, setting, staffing, patient population, etc. Two sites are a minimum.

Interrupted time series designs involve measurements of the outcome variable at equally spaced intervals (i.e., daily, monthly, annually) over a long period of time. An innovation and/or implementation strategy is introduced at a specified point in time and is expected to affect the outcome variable(s), often indicated by a change in slope of the outcome measured over time, as a function of the innovation and/or implementation strategy being introduced.

Regression discontinuity design is where a clinical intervention or implementation strategy is assigned based on a cut-point on a quantitative measure. For example, the number of medication reviews a pharmacy completed in the previous three months may be used to assign pharmacies to the intervention or control implementation strategy conditions. In this case, it may be that pharmacies who conducted less than 15 reviews would be assigned to a tailored implementation strategy, whereas those who performed more

than 15 reviews are assigned to an implementation-as-usual control condition. The outcome of interest could be the number of medication reviews performed in the next 3 months as a function of implementation strategy condition.

Alternative Randomized Design

Traditionally, implementation occurs as the final stage of the translational evidence pipeline. This depiction although still prevalent, has received criticism, and led to more integrated approaches and consequently, alternative research study designs. In addition, as discussed previously to address concerns regarding generalizability designs that attempt to increase the strength of external validity while maintaining the strength of internal validity are common in implementation research.

Effectiveness-implementation hybrid study designs are one alternative randomized design where both implementation and clinical data are gathered (Curran et al., 2012). Hybrid designs are categorized into three types. Type 1 hybrid designs occur when the primary outcomes collected relate to the clinical effectiveness of the clinical intervention/innovation, while secondary data are collected on implementation. In type 2 hybrid designs equal emphasis is placed on clinical effectiveness and implementation. Finally, in type 3 hybrid designs the primary focus is investigating the implementation strategy and thus primary outcomes are implementation indicators, while secondary information is collected on the clinical intervention's impact.

Roll-out designs, such as the stepped wedge design, are another useful alternative design to RCTs. In these designs, all pharmacies/pharmacists would begin the study simultaneously, either all receiving an implementation strategy or continuing practice as usual. Next, at randomly assigned time intervals, pharmacies would cross over to a new implementation strategy/condition, resulting in between-unit (comparing those with practice as usual versus the implementation strategy) and pre-post within unit comparisons, at each time point.

Other alternative design options include: *Cumulative trial designs* which aim to improve intervention impact evaluation by combining a sequence of trials or replicate cohorts to increase statistical power; *Randomized encouragement trial and the randomized consent design* where participants are randomized to condition, but are offered the option to adhere to their assigned condition or switch to a preferred condition, in an attempt to strengthen external validity; *Randomized factorial designs* test combinations of two or more implementation strategies (experimental conditions) and two or more variations/levels of each implementation strategy simultaneously. For example, a 2×2 factorial design may test the implementation strategies of consultation type, with remote and in-person consultation as distinct variations, and feedback, with monthly versus as-needed variations. Pharmacies would be randomly assigned to one of the four conditions; *Sequential Multiple Assignment Randomized Trial (SMART) designs* are a type of factorial design that accommodates participant responses. For example, pharmacies that do not respond to an implementation strategy may be randomized to receive additional support from an external facilitator or both an external and internal facilitator. Then pharmacies which were randomized to receive an external facilitator only, and are still unresponsive, may be randomized again to continue with only an external facilitator or both the external and internal facilitators (Kilbourne et al., 2014).

Stakeholder Involvement

The involvement of stakeholders in all stages of research is strongly encouraged in implementation science. It is recommended that developers consider methods such as community-academic partnerships, stakeholder mapping, social network analyses, intervention mapping and/or participatory action research in their methodologies to engage stakeholders and to design services and innovations that are feasible, implementable and produce relevant outcomes for all parties.

Data Collection

The types of data collected in implementation studies emulate efficacy and effectiveness research, although a greater emphasis is placed on mixed methods where quantitative and qualitative data are combined. Mixed method designs achieve a depth of understanding often unobtainable if one approach or data source was used alone. For implementation research, mixed method designs offer particular advantages of contextualizing and understanding nuances in the implementation process, such as identifying and understanding implementation influences (facilitators and barriers), explaining implementation outcomes, and assessing the feasibility, acceptability, and utility of an innovation and/or implementation strategies.

Understanding the unique combination of factors influencing implementation in each context is crucial to implementation research. Surveys, completed either by respondents about themselves or their actions (self-report), or asking about their perceptions on a different person or phenomena, are a common collection method. However, qualitative data, as the sole data collection method or in combination, is beneficial to evoke multifaceted, rich responses, that may be unforeseen by the researcher and are needed to understand the diverse perspectives of stakeholders across settings. Furthermore, the use of mixed methods has been recommended "to enhance the value of implementation research for end users" (Neta et al., 2015). As an example, for the implementation outcome fidelity, the degree to which an innovation is delivered as it was designed or intended, it is important to consider how to collect the data. Fidelity may be evaluated in multiple ways such as quantitatively by surveys or clinical documents, or qualitatively via interviews or direct observation. Qualitative approaches may be more reliable and increase the depth of information, yet are often costly.

A distinguishing feature of implementation research is that the data includes indicators of implementation process, influences and/or outcomes, either with or without collection of economic, clinical or humanistic outcomes. Moreover, implementation outcomes may serve as intermediate outcomes to health outcomes (Moullin et al., 2016b). For instance, "reach" defined as the

absolute number, percentage and representativeness of an eligible population who receive an innovation, is both an implementation outcome and an output necessary to determine the impact of a clinical intervention (Glasgow et al., 2006).

One issue that should be considered in collecting data for implementation research in pharmacy practice is the "level" of the data. Implementation data is commonly multilevel as all contextual levels (e.g. pharmacist, pharmacy staff/team, pharmacy, local setting, and system) may influence the implementation effort. Therefore, the referent level of the data to be collected should be carefully decided. As an example, in an investigation on the implementation of a new asthma guideline, data may be collected from the pharmacist, pharmacy staff and/or patients. This data may be regarding their attitudes toward the guideline but equally it may be useful to evaluate the pharmacy team's functioning, the workflow of the pharmacy or their perceptions of asthma prevalence etc.

Finally, to cultivate implementation evidence, the timing of data collection needs to be consciously chosen. As implementation is a multistage process, ideally implementation indicators should be collected at multiple time-points. It is also encouraged to collect implementation data during effectiveness studies as this will increase knowledge on the mechanisms of action of the intervention and generalizability of findings.

Data Analysis

Evaluating complex interventions such as health programs and professional pharmacy services is challenging. There is rarely a single outcome or stakeholder, but a large number of groups and individuals with an interest and consequently a large pool of potential measures of success. Funders are often interested in "reach," wanting to know the number of participants and if the service has reached those most in need. Program developers may be interested in milestone attainment such as the level of "adoption" and "implementation". These measures may be further augmented by indicating if practitioners accept the innovation and subsequently use the innovation with fidelity. To correctly attribute observed outcomes of an innovation to those achieved in efficacy or effectiveness studies, the researcher should have empirical evidence on the extent to which innovation components were implemented, known as the degree of fidelity. Only by understanding and measuring whether an intervention has been implemented with fidelity can researchers and practitioners gain a better understanding of how and why an intervention works, and the extent to which outcomes can be improved.

As with data collection, data analyses in implementation science largely mimic that of efficacy and effectiveness research. However, some considerations are more pertinent due to the increased use of alternative research designs. Firstly, statistical methods to enhance internal validity and reduce inferences being made because of differences between groups in nonrandomized designs, such as covariate analysis, propensity score analysis, and sensitivity analysis, may be beneficial. Secondly, mediation, moderation, and path analyses, as well theoretical process evaluation techniques, are often employed. Finally, as data collected is often multilevel, statistics to analyze the nested structure of data are needed. Common techniques include intra-class correlation coefficient (ICC) and within group agreement (rwg and rwg(j)) analyses. If a nested data structure is present and aggregating data to a higher level is indicated data analyzes such as multilevel modeling and multilevel structural equation modeling are useful methods for assessing quantitative data.

Pharmacy practice research needs to disentangle the effectiveness of implementation strategies. As with complex clinical interventions with patients, implementation strategies are complex interventions with pharmacists or other stakeholders across the ecological contextual domains. Therefore delineating the core components of implementation strategies is an area requiring attention. One method being used to analyze implementation is realist evaluation. This approach is based on program theory where the focus is on studying the mechanism or the response implementation strategies trigger in stakeholders, and the resulting outcome (Dalkin et al., 2015). Realist evaluation investigates the causes, mechanism and factors associated with an outcome, rather than just the outcome, and therefore is an approach targeting the questions that consume implementation "what works, for whom, in what circumstances?" (Salter and Kothari, 2014, p. 2)

Summary

EBP, programs and services must be widely available and offered to achieve improved economic, humanistic and clinical health outcomes. Internationally professional pharmacy services and health innovations are being developed, disseminated and being implemented into pharmacy practice; however, there appears to be a pervasive challenge to achieving timely implementation, widespread incorporation and sustainment. Both a lack of implementation research and the compartmentalized nature of research in other stages of the evidence pipeline may be implicated. Implementation science aims to increase the evidence base on the process and influences affecting implementation including the support required to assist pharmacy practice move services into reality. Conducting implementation studies, using implementation frameworks and models, employing suitable research methodologies, and assessing implementation indicators may assist community pharmacy move toward the ultimate goal of integrated service provision and improved health outcomes for the communities they serve.

Endnote: Sections of this chapter have been modified from the doctoral thesis "Implementation in community pharmacy: development of frameworks, models and tools for the introduction and integration of professional services," stored in the online library repository of the University of Technology Sydney.

Glossary

Implementation science The scientific study of the influences and mechanisms that promote the systematic uptake, utilization and integration of innovations and research findings into routine practice.
Implementation process The progression of commencing to use and integrating a novel innovation. The implementation process consists of multiple nonlinear, recursive phases.
Implementation factors Variables that influence the implementation process, either positively or negatively. Also termed facilitators and barriers, influences, or determinants of practice. Factors may be grouped as domains of related implementation influences across contextual levels.
Implementation strategies Targeted efforts (methods, techniques or activities) to enhance the movement of an innovation into use and integration into routine practice. Packages of implementation strategies form an implementation program.
Implementation evaluations Indicators of the effects of implementation efforts including both formative and summative evaluations of the implementation process, impact (mediator and moderator analyses), and outcomes.

Network Meta-Analysis in Pharmacy Practice Research

Puttarin Kulchaitanaroaj*, Ratree Sawangjit†, Piyameth Dilokthornsakul‡, Nathorn Chaiyakunapruk‡, *Division of Health Service Research, College of Pharmacy, The University of Iowa, Iowa, IA, USA; †Clinical Trials and Evidence-Based Syntheses Research Unit (CTEBs RU), Mahasarakham University, Maha Sarakham, Thailand; ‡Center of Pharmaceutical Outcomes Research, Naresuan University, Phitsanulok, Thailand

Introduction

Using best evidence in decision making is crucial in health care. Randomized controlled trials (RCTs) are typically considered to provide high-quality empirical information. They are the standard approach to evaluating efficacy of medications, interventions, and services in a controlled condition. Randomized controlled trials compare one or more standard treatment or placebo (control arms) with one or more alternative/new treatments (intervention arms) by randomizing treatment allocation to minimize bias and confounding. Nonetheless, comparing multiple treatments by conducting a large RCT with multiple arms or a mega-trial is difficult to conduct and require greater resources (Shrier et al., 2007). They are also complex in design, analysis, and reporting (Baron et al., 2013).

In addition to RCTs, systematic review and meta-analysis are considered to produce high-quality evidence by summarizing empirical evidence from previous studies (e.g., RCTs). Meta-analysis is a statistical tool used in a systematic review to provide summarized quantitative evidence. Traditional meta-analysis (pairwise meta-analysis) of RCTs generates pairwise comparisons or comparing two treatments at a time. Comparing treatments in a pair but not simultaneously in a traditional meta-analysis limits its ability for decision making. Therefore, statistical techniques that are able to compare all treatments simultaneously are needed, and network meta-analysis (NMA) addresses this problem.

Network Meta-Analysis

Concept

Network meta-analysis (NMA) is also called indirect comparison, multiple treatments meta-analysis, and mixed-treatment comparison (MTC) and is a new statistical tool to compare and rank multiple treatments at a time (Salanti, 2012). Conceptually, NMA creates a network of multiple pairwise-comparison analyses and calculates relative effects between different treatments from direct comparisons found in studies (mostly from RCTs). This also indirectly makes comparisons through one or several common comparators. A common comparator is an anchored arm served as a linkage to enable all treatments, which are not compared directly in studies to be compared indirectly. For example, if there is a trial comparing treatment A versus treatment B and a trial comparing treatment B vs treatment C, treatment B is a common comparator. Most common comparators are placebo or a standard treatment. A comparison between treatments that is not done directly by experiment but through a statistical method is referred as an indirect comparison. Network meta-analysis needs at least three treatments in a network. Network meta-analysis connects control arms and treatment arms together based on a selected collection of RCTs.

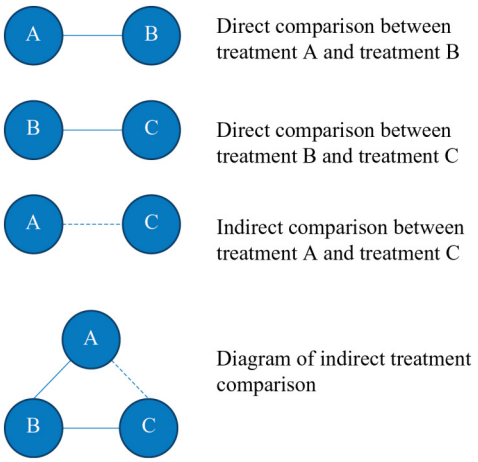

Figure 1 Examples of evidence networks.

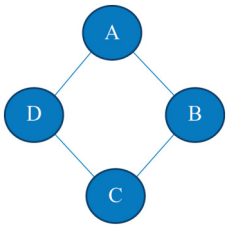

Figure 2 A closed-loop network.

History

Historically, the first model of NMA was the indirect treatment comparison (ITC), and it was proposed by Bucher et al. (1997). The model explains that if treatment A is directly compared with treatment B and treatment B is directly compared with treatment C from RCTs, an indirect comparison between treatment A and treatment C via treatment B can be performed by a statistical method. In other words, the ITC of treatment A and treatment C is anchored on treatment B or linked through treatment B. Fig. 1 shows the diagram of the aforementioned direct and indirect comparisons of treatments A, B, and C; a node represents a treatment and a line means a direct comparison or a head-to-head comparison obtained from RCTs. A dashed line represents the indirect treatment comparison between A and C.

Thomas Lumley published an article in 2002 to present ITC methods and to address the problem of differences in treatment effects estimated from ITCs when there are multiple sources of information (Lumley, 2002). Lumley created a diagram of networks of evidence from RCTs, hence coined the term NMA. Fig. 2 shows an example of a closed-loop NMA where there are direct comparisons between A vs B, B vs C, C vs D, and D vs A. The indirect comparison of AC can be obtained through B or D. When there are multiple pathways in a closed-loop NMA to estimate indirect treatment effects, it is possible that these estimates differ or disagree.

Subsequently, Lu and Ades further developed a method to combine relative effects from both direct comparison from RCTs and indirect comparison in NMA (Lu and Ades, 2004). Due to this combination, it is called MTC. This type of NMA particularly helps to add to direct-comparative evidence and allow simultaneous comparison of all treatments and ranking.

Fundamentals of Network Meta-Analysis

Based on the history, NMA can be categorized into two groups (Fig. 3). First, ITC is referred to open-loop networks or star-shaped networks (treatments are compared with a standard treatment/placebo but not with each other). Second, MTC contains at least one closed-loop network of evidence (Jansen et al., 2011; Tonin et al., 2017).

Using the network of evidence from Fig. 3A, a relative effect of ITC between treatment A and treatment C is calculated from the difference between the relative effect of treatment A vs B and the relative effect of treatment B vs C (Chaiyakunapruk et al., 2014). Suppose $D_{AB\text{-}direct}$ represents the relative effect of treatment A compared with treatment B from a study, and $D_{BC\text{-}direct}$ represents the relative effect of treatment B compared with treatment C from a study. Then, $D_{AC\text{-}indirect}$ represents the indirect effect of treatment A compared with treatment C in Eq. (1).

$$D_{AC-indirect} = D_{AB-direct} - D_{BC-direct} \quad (1)$$

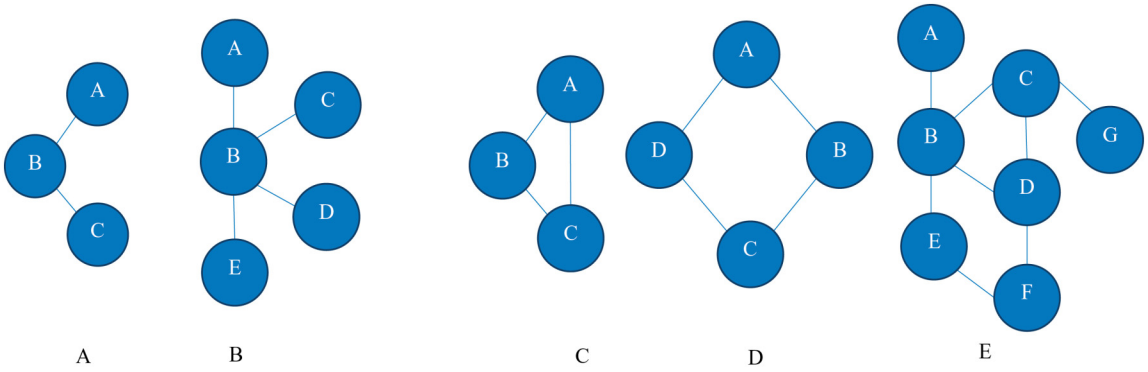

Figure 3 Open-loop networks and closed-loop networks.

Fig. 3C is a closed-loop network of evidence where there are direct comparisons of AB, BC, and AC. The pooled relative effect of treatment A vs treatment C is weighted from both direct and indirect comparisons (Chaiyakunapruk et al., 2014). Suppose $D_{AC\text{-}direct}$ represents the direct relative effect of AC from an RCT, and $D_{AC\text{-}indirect}$ represents the indirect relative effect of treatment AC from Eq. (1). $W_{AC\text{-}direct}$ represents the weighted relative effect of $D_{AC\text{-}direct}$ calculated by an inverse variance of studies, while $W_{AC\text{-}indirect}$ represents the weighted relative effect of $D_{AC\text{-}indirect}$ calculated by an inverse variance of the indirect comparison. $D_{AC\text{-}pooled}$ is the relative effect derived from both direct and indirect comparisons and is shown in Eq. (2).

$$D_{AC-pooled} = \frac{(W_{AC-direct} * D_{AC-direct}) + (W_{AC-indirect} * D_{AC-indirect})}{(W_{AC-direct} + W_{AC-indirect})} \quad (2)$$

Assumptions of Network Meta-Analysis

Two assumptions, namely transitivity and consistency assumptions, are required in NMA to provide valid results. Transitivity is defined as being able to apply in a successive object of a sequence. For example, if treatment A is better than treatment B and treatment B is better than treatment C, then treatment A will be better than treatment C. In NMA, transitivity is the ability to apply an indirect comparison through a common comparator. Transitivity assumption (or similarity assumption in some literature) aims to state that this indirect comparison is valid. Transitivity assumption cannot be tested quantitatively. It needs to be carefully examined by both logic and similarity in study characteristics (Salanti, 2012). To explain, studies that are included in systematic review and meta-analysis need to be similar in terms of effect modifiers. Effect modifiers are defined as factors that affect study outcomes, and these include study design, study population, treatments, and outcome measures. It is best to have homogeneous study characteristics and if not the level of heterogeneity should be similar across pairwise comparisons. Consistency assumption requires that the relative effects from the direct evidence are aligned with those obtained from the indirect evidence.

Analytical Methods

To conduct an NMA, a general process involves writing a research and statistical analysis plan, conducting a systematic review, creating networks of evidence, carrying out statistical analysis for checking assumptions and estimation, evaluation of quality of NMA results, and reporting.

Network meta-analysis can be performed by using either frequentist or Bayesian approach to give a point estimate of relative treatment effect. The effect measures commonly used in NMA are relative measures such as odds ratios (ORs), relative risk (risk ratios) (RRs), difference in change from baseline or hazard ratios (Jansen et al., 2011). In addition to the effect measures, rankings of treatments can be generated by both approaches (Jansen et al., 2008; Rucker and Schwarzer, 2015).

Frequentist approach is a traditional way in which statistical hypothesis testing and confidence intervals are carried out. It takes the sample data to test against the null hypothesis stating that treatment effect is null for all studies by using the probability calculated from the sampling distribution compared with the predetermined significance level (e.g., 0.05). Probability in frequentist approach is viewed as a fixed value. On the other hand, Bayesian approach considers probability as likelihood that is expressed prior to a trial, and then it is updated after gaining more information from the trial.

Bayesian probability takes into account of both prior information, which can be taken from opinion or previous studies and empirical data. Due to the differences in probability view when compared with frequentist approach, Bayesian approach treats treatment effects obtained from RCTs as random variables, which require prior probability distributions. Bayesian approach is

done by using Markov Chain Monte Carlo simulation. The simulation creates a random sample by taking a value of a parameter (e.g., treatment effect) from a specified prior probability distribution and calculates a result. The simulation is repeated in a predefined number of times (e.g., 1000 times), and eventually an aggregate result of each random sample is produced (Salanti, 2012).

Several methods attempt to detect and improve consistency in NMA. Investigators should put effort to explain observed inconsistency and explore the causes. Inconsistency can be detected by comparing estimates or posterior distributions using statistical tests (Hoaglin et al., 2011).

Critical Appraisal of Network Meta-Analysis and Findings

Evaluating quality of NMA results is very important because simply looking at statistical results such as odds ratio or ranking from NMA results without any judgment can be misleading. For example, teriparatide is concluded to be the best treatment for reduction in bone fracture by the statistical numbers; however, when applying quality assessment on NMA, it shows that the quality of this information is very poor (Puhan et al., 2014). Decision makers, especially clinical guideline developers, policy makers, and clinicians, need to assess quality of NMA studies prior to making decisions.

Several guidelines of NMA reports are available to assist NMA appraisal. International Society for Pharmacoeconomics and Outcomes Research (ISPOR) provides a checklist to evaluate an NMA (Jansen et al., 2011). The checklist suggests what to look for in an NMA article and to examine essential components. The PRISMA-NMA extension was published in 2015, and it provides guidance for reporting systematic reviews comparing multiple treatments using direct and indirect evidence in a network meta-analyses (Hutton et al., 2015).

The Grading of Recommendations Assessment, Development and Evaluation (GRADE) Working Group devised a guideline to rate quality of evidence in NMA into four levels including high, moderate, low, and very low reflecting a degree of confidence of how the true effect lies close to the estimate of the effect (Puhan et al., 2014). Further detail and examples can be found in the literature (Puhan et al., 2014; Salanti et al., 2014).

Reporting and Interpreting Results

This section focuses on report on network geometry, consistency and transitivity assumptions, relative treatment effects, and treatment rankings.

Network geometry is strongly recommended to present in NMA results (Hutton et al., 2015; Mills et al., 2012). Network geometry is a network graph or a network plot showing the interactions among the articles included in NMA. An NMA graph provides important information in establishing analytic strategies and interpreting the results such as the presence of direct or indirect evidence. The directly compared interventions are linked with a line. The size of the nodes and the thickness of the lines are weighted according to the number of studies assessing each treatment. An example of network geometry is shown in Fig. 4 (Kengkla

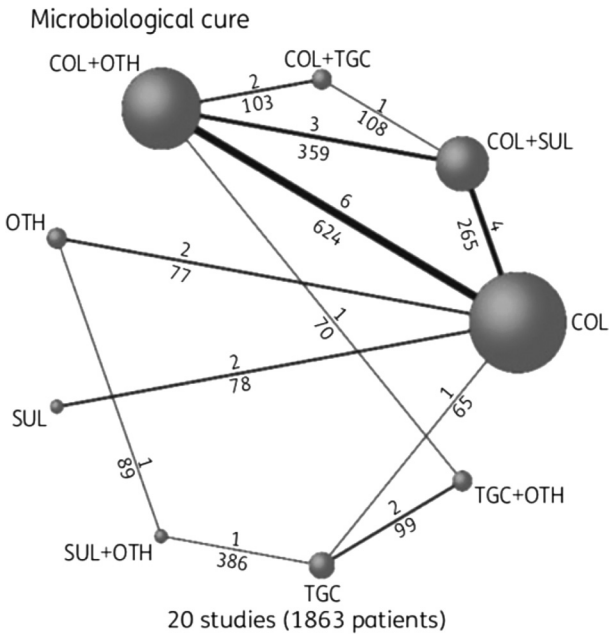

Figure 4 Network comparisons of studies included in the analyses for the microbiological cure outcome. The numbers above and below the lines indicate the number of studies and the number of patients, respectively. *COL*, colistin; *OTH*, other antibiotics; *SUL*, sulbactam; *TGC*, tigecycline (Kengkla et al., 2018).

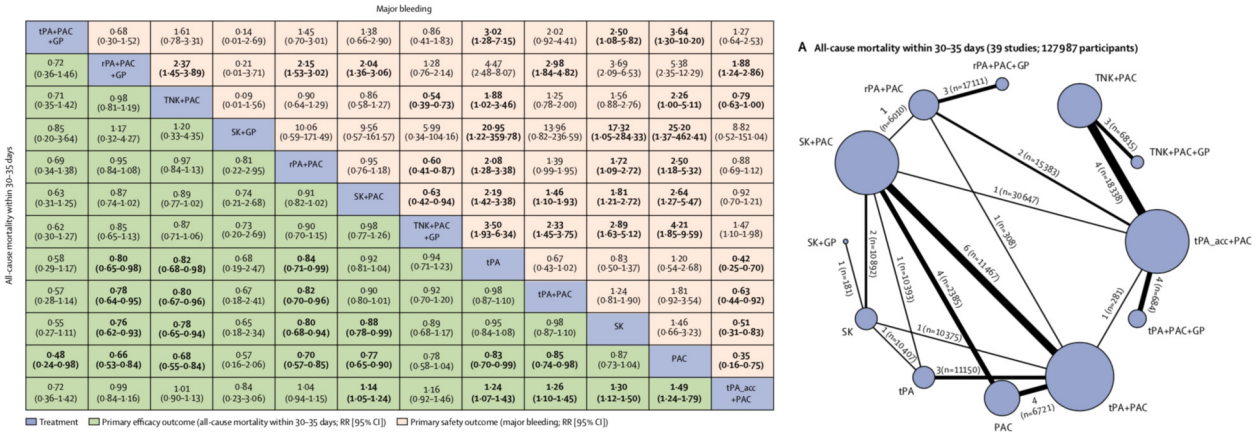

Figure 5 NMA results (on the left) of primary efficacy (all-cause mortality within 30–35 days) and safety (major bleeding) with the network geometry (A; on the right). Interventions (in violet color) are ordered by ranking for all-cause mortality within 30–35 days. Results are the RRs (95% CIs) for all-cause mortality within 30–35 days (green) and major bleeding (pink). Comparisons must be read from left to right. The text in bold represents statistically significant results. *tPA*, alteplase (nonaccelerated infusion); *PAC*, parenteral anticoagulants; *GP*, glycoprotein IIb or IIIa inhibitors; *rPA*, reteplase; *TNK*, tenecteplase; *SK*, streptokinase; *tPA_acc*, alteplase (accelerated infusion); *RR*, risk ratio (Jinatongthai et al., 2017).

et al., 2018). In this figure, 1863 patients from 20 studies were included in the network and used for performing both direct and indirect comparisons. This network has nine interventions including colistin, colistin plus sulbactam, colistin plus tigecycline, colistin plus other antibiotics, tigecycline plus other antibiotics, tigecycline, sulbactam plus other antibiotics, sulbactam, and other antibiotics.

Consistency and transitivity assumptions are also another important area of NMA because the validity of results in an NMA relies on the assumptions made (Salanti, 2012). Inconsistency can arise from effect modifiers such as baseline patient characteristics. An example of patient characteristics reported in an NMA study is shown in **Table 1** (Bunmark et al., 2018). This information helps readers to empirically evaluate the validity of the assumption of transitivity by reviewing the distributions of potential effect modifiers across trials.

Treatment effects or effect sizes reported in relative measures such as ORs, RRs, or mean difference with 95% confidence intervals (CIs) for frequentist approach or 95% credibility intervals (CrIs) for Bayesian approach are usually presented in a league table (Jinatongthai et al., 2017). As exhibited in **Fig. 5**, the network geometry shows 12 interventions, and the reference regimen is tPA_acc + PAC. Both direct and indirect comparisons were performed, and the combined results were presented in the league table. Based on the league table, comparisons between treatments must be read from left to right such as a comparison of tPA + PAC + GP versus rPA + PAC + GP. This example shows the negative outcomes including all-cause mortality (the lower part of the table) and major bleeding (the upper part of the table). Therefore, the RR less than 1 means that the left-hand-side treatment produces fewer negative outcomes, whereas the RR more than 1 means that the left-hand-side treatment produces more negative outcomes. For instance, the RR of PAC versus tPA_acc + PAC for the all-cause mortality is 1.49 (95%CI: 1.24–1.79). It means that the all-cause mortality from PAC is statistically significant and is 1.49 times more than that from tPA_acc + PAC.

By Bayesian approach, interpretation of 95% CrIs is similar to that of 95% CIs, but it is in terms of probability. For example, if the RR of treatment A versus B is 0.40 (95% CrI: 0.10, 0.70), it means that the probability of treatment A is 40% less likely to produce an outcome compared with treatment B and there is a 95% chance that the true likelihood will be between 10% and 70%.

In addition to a league table, NMA results can be presented in a forest plot (**Fig. 6**). The interpretation of the results is similar to those from traditional meta-analysis by illustrating the relative treatment effects of each pair. In **Fig. 6**, the RR of OCA compared with placebo is statistically significant and is 1.91 times higher than the placebo (Sawangjit et al., 2016).

Clinicians and pharmacists should carefully interpret results of rank orders and use the information with caution when making decision analyzing both clinical and statistical significance.

In addition to report rankings by such as efficacy of treatments, cluster rank plots can simultaneously portray rank positions based on multiple aspects such as risk (e.g., a side effect) against benefit (e.g., efficacy of treatment). **Fig. 7** depicts the scatter plot based on reduction in mortality presented in terms of risk of mortality on the graph (representing benefit) and risk of major bleeding (representing risk) (Jinatongthai et al., 2017). Based on this figure, treatment options in the lower left quarter comprising tenecteplase (TNK) plus parenteral anticoagulants (PAC), reteplase (rPA) plus PAC, and alteplase accelerated infusion (tPA_acc) plus PAC should be recommended in patients with myocardial infarction. This is because these regimens show the reduction in mortality and the low major bleeding. Also, among these three treatments, TNK plus PAC is preferred because it has the lowest risk of bleeding with the similar efficacy.

Table 1 Characteristics of participants of included RCTs (Bunmark et al., 2018)

Study group/First author	*Regimen*	*Age (year)*		*Male (%)*	*DM (%)*	*HTN (%)*	*DLP (%)*	*Smoking history (%)*	*Previous MI (%)*	*Previous PCI (%)*	*CKD (%)*	*Bleeding history (%)*	*Ejection Fraction (%)*

NA, Not available; *DM*, diabetes mellitus; *HTN*, hypertension; *DLP*, dyslipidemia; *CKD*, chronic kidney disease; *MI*, myocardial infarction; *PCI*, percutaneous coronary intervention; *IQR*, interquartile range; *A + C + VKA*, aspirin + clopidogrel + vitamin K antagonist; *C + VKA*, clopidogrel + vitamin K antagonist; *A + C + r*, aspirin + clopidogrel + very low-dose rivaroxaban; *C + R*, clopidogrel + low-dose rivaroxaban; *C + d*, clopidogrel + low-dose dabigatran; *C + D*, clopidogrel + high-dose dabigatran.

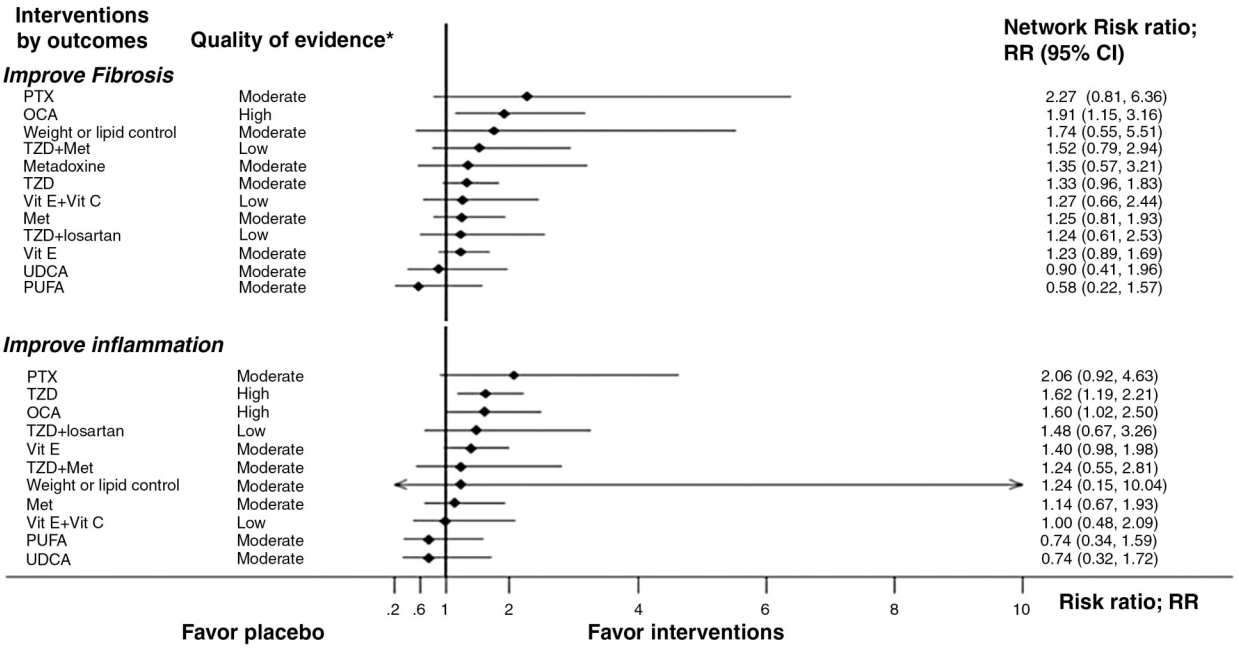

Figure 6 Forest plots showing the effects of interventions on improving outcomes on fibrosis and inflammation conditions among patients with nonalcoholic fatty liver disease (NAFLD). *RR*, risk ratio; *95% CI*, 95% confidence interval; *Met*, metformin; *PP*, phospholipid; *PTX*, pentoxifyline; *PUFA*, polyunsaturated fatty acid; *TZD*, thiazolidinedione; *UCDA*, ursodeoxycholic acid; *Vit C*, vitamin C; *Vit E*, vitamin E; *OCA*, obeticolic acid. *Quality of evidence was graded based on GRADE Working Group: high = we are very confident that the true effect lies close to that of the estimate of the effect, moderate = we are moderately confident in the effect estimate: the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different, low = our confidence in the effect estimate is limited: the true effect may be substantially different from the estimate of the effect, very low = we have very little confidence in the effect estimate: the true effect is likely to be substantially different from the estimate of effect (Sawangjit et al., 2016).

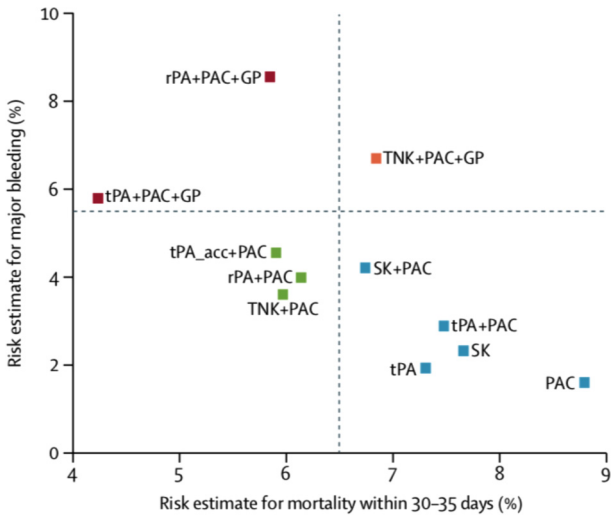

Figure 7 A cluster rank plot explaining ranking of each intervention when considering both (A) mortality reduction presented in the form of risk of mortality within 30–35 days (showing efficacy of the treatment) and (B) major bleeding (showing the safety issue). The risk estimates were estimated in percentage. The plot of treatment with streptokinase plus glycoprotein IIb/IIIa inhibitors was omitted because it was out of the range of the plot. The dashed lines represent the different quadrants of the risk estimates dividing treatments based on their risk magnitudes. *rPA*, reteplase; *PAC*, parenteral anticoagulants; *GP*, glycoprotein IIb or IIIa inhibitors; *TNK*, tenecteplase; *tPA*, alteplase (nonaccelerated infusion); *tPA_acc*, alteplase (accelerated infusion); *SK*, streptokinase (Jinatongthai et al., 2017).

Use of NMA in Pharmacy Research

Pharmaceutical Products Evaluation

To date, there are over 400 NMA studies evaluating pharmaceutical products used in Western and Chinese medicine (Tonin et al., 2018a, 2018b; Yang et al., 2018). Network meta-analysis is of interest among researchers worldwide as witnessed by those 400 NMA studies published by authors from more than 30 countries. The United States, China, the United Kingdom, Canada, and Italy are the top five countries that published such research. Additionally, the trend of use of NMA for pharmaceutical products is increasing globally. Of those NMA studies evaluating pharmaceutical products, very few studies were published prior to 2008, but over the past decade its use has markedly increased. Around 50% of the 400 studies were publications from 2014 onward (Tonin et al., 2018a, 2018b; Yang et al., 2018). A number of medicines were evaluated using NMAs, and the most commonly evaluated clinical conditions include cardiovascular diseases, oncological disorders, autoimmune disorders, mental health disorders, and infectious diseases. Among NMA studies assessing pharmaceutical products, only 33% followed the PRISMA or PRISMA-NMA guidelines (Tonin et al., 2018a; Yang et al., 2018). Since the quality of NMA research is evaluated from study reports, researchers should use PRISMA-NMA (Hutton et al., 2015) to ensure that essential features are reported. This would improve quality of research and understanding of NMA.

Evaluation of Pharmacy Services

Since network meta-analysis is considered a relatively new approach in summarizing evidence, its application in understanding the impact of various pharmacy practice models has remained limited. However, there are a few NMA studies evaluating pharmaceutical care services such as pharmacist counseling and medication reconciliation.

Van Spall et al. (2017) assessed a number of transitional care services for patients with heart failure who discharged from the hospital by comparing usual care, education-alone interventions, pharmacist interventions, telemonitoring, telephone support, nurse home visits, and disease management clinics (DMCs). A total of 43 RCTs were included in the NMA. The study found that nurse home visits and DMCs significantly decreased the mortality and all-cause readmissions relative to usual care. It was also observed that pharmacist services tended to improve the clinical outcomes in patients with heart failure; however, no statistical significance was observed.

Bukhsh et al. (2018) conducted an NMA to compare the effects of pharmacist-based education methods on clinical outcomes in adults with type 2 diabetes mellitus. Thirty-nine studies involving 6259 type-2 diabetic patients were included in the NMA. The findings revealed that the pharmacist-based education was superior in terms of reduction in glycosylated hemoglobin (HbA1c) levels, when compared to usual care. However, there was no significant difference between various diabetes education programs provided by pharmacists. In addition, the pharmacist-led diabetes education plus pharmaceutical care significantly lowered systolic blood pressure and plasma triglyceride levels when compared to other interventions. It was interesting to note that the study by Van Spall et al. (2017) compared pharmacist interventions with services provided by other health-care professionals or in the form of multidisciplinary teams, while the study by Bukhsh et al. (2018) focused on comparisons within pharmacist-based education programs.

The lack of NMA studies assessing pharmacy services might be due to several potential reasons. First, it might be that there have been a smaller number of RCTs in pharmacy services, contributing to challenges in performing NMAs. Second, the NMA approach might have been less adopted among the health service research community. Third, a lack of standardized definitions of pharmaceutical services might prohibit the use of NMA in understanding the comparative effects of all interventions.

In summary, the use of NMA in pharmacy practice-based research is still limited. There is a need to adopt this technique to better understand and evaluate pharmacy service.

Conclusion

Network meta-analysis is an extension of pairwise meta-analysis that simultaneously compares the effects of all interventions of interest. There has been an increasing trend in using such a technique to understand the effects of pharmaceutical products. However, studies investigating pharmacy services interventions remain limited. Pharmacy professionals should have a better understanding of the foundation and the interpretation of NMA.

Glossary

Pairwise comparison A comparison between two treatments at a time in meta-analysis
Network meta-analysis A statistical method to compare and provide ranking of multiple treatments at a time using both direct evidence from empirical studies and indirect evidence through common comparators.
Indirect comparison An indirect comparison means a comparison between treatments through a statistical method rather than directly from studies.

Common comparator A common comparator is an anchored arm served as a linkage between randomized controlled trials to enable treatments, which are not compared directly from studies to be compared indirectly. If there is a trial comparing A versus B and a trial comparing B vs C, B is a common comparator.
Inconsistency Disagreement in treatment effects between direct evidence and indirect evidence which are beyond chance.
Effect modifiers Factors that can affect outcomes such as a treatment dose.
Heterogeneity Differences in treatment effects across studies which are beyond chance.
Transitivity Ability to apply an indirect comparison through a common comparator in a network of evidence.

Ethnography in Pharmacy Policy and Practice

Claire Mann, Division of Pharmacy Policy and Practice, University of Nottingham, Nottingham, United Kingdom

Introduction

Recently there has been an expansion in the use of qualitative methods in an effort to understand human behavior. This rise is particularly prevalent in health services research, and hence has impact on understandings of pharmacy policy and practice.

Ethnography is a qualitative research method used to understand cultures. Ethnography is rooted in anthropology and is concerned with exploring and understanding social interactions of individuals within the communities in which they work, live or otherwise regularly inhabit and participate.

Qualitative research has a number of strengths, not least, an ontological basis that truth has a number of representations. The most common form of qualitative data collection is the semi-structured interview which allows exploration of the truth from the perception of individuals. The most common limitation cited against use of such research is that it is often small scale and unlikely to be able to claim to be representative.

Ethnography represents multiple truths and overcomes the limitations of relying on individual experiences by utilizing a wide range of tools to capture a range of social experiences. Multiple perspectives of the experience are examined. Observation affords the opportunity to gain insight into cultural practices including those that are hidden or intangible. The ethnographic researcher becomes "immersed" in the setting, collecting data from a range of sources over a period of time, which are triangulated to generate transferable findings. Other methods commonly used alongside participant observation are interviews, online observations and social media, and document analysis conducted at varying and often repeated time points.

Ethnography is messy and complex and the ethnographer employs a number of techniques, from reflexivity and iterative development of approaches to triangulation and thick description, to ensure the rigor of their work. This cyclical and ongoing reflexive approach offers the opportunity to develop links between issues that arise over time and is a strength of this approach over more time limited qualitative approaches.

Ethnography is difficult and resource intensive and as a result there are a limited number of studies. Obstacles to undertaking ethnographic research include the need to spend significant time in the field, whilst managing the need to be both flexible and responsive to sites. Gilmartin (2015) suggests that although ethnography is resource intensive and "not cheap" it should not automatically be disregarded. The high research cost of ethnography is rewarded with a depth of output unrivaled by other approaches. The richness of findings from rigorous ethnographic studies makes them a valuable tool to use to understand health services from a cultural perspective.

For those interested in pharmacy practice, reading ethnographies can provide a useful insight into unfamiliar cultures and contexts. I would recommend all Pharmacy students, and interested researchers, should read van der Geest et al.'s 'Anthropology of Pharmaceuticals' (1996) to give a broad introduction to the field of Pharmacy Practice and useful insights into the relationship between anthropology and pharmacy research.

This chapter is an introduction to ethnography; it offers a brief history and outline of ethnographic research practices, and the role of this approach in pharmacy policy and practice. The aim of this chapter is to introduce colleagues in pharmacy policy and practice research to the ethnographic traditions to enable them to read ethnographic works, support ethnographers and consider using ethnographic approaches in their own work.

What is Ethnography?

Introduction

Ethnography is embedded in a naturalistic epistemology, and reflects a social constructivist approach to understanding the world. Ethnography assumes that the social world does not exist without or outside of individuals, but instead is a system created by interactions between individuals; therefore, any effort to understand people as subjects of experience is not appropriate without significant in-depth analysis of the context in which it occurs.

Defining Ethnography

Ethnography is the study of people and their interactions in cultural groups and comes from the Greek *ethnos* (people) and graphei (to write). Stories about people and how they interact in specific contexts in order to understand them is the desired outcome of ethnographic research. Beyond these broad assertions there is little consensus about what ethnography is (Reeves et al., 2013). Miller (1997) suggests that ethnography is even more than a method or methodology, since it applies to both practices and products of research. Walford (2001) suggests that the term can be understood in three ways: as a research approach, or as a set of research methods, or the product of these as a written account. In this chapter, I adopt this multifaceted definition and use the term ethnography interchangeably to mean each of these things in turn. This first section explores the development of ethnography as a methodology and different types of ethnographic methodologies. Explicit ethnographic methods (including data collection, analysis, and writing) are explored in later sections.

Origins of Ethnography

Ethnography is a derivative approach of social anthropology which aims to develop knowledge through immersion in a culture. Ethnography emerged from anthropology—the approach to understanding unfamiliar cultures made popular by those researchers (Malinowski, 1961/1922; Mead, 1961) who spent several years living as part of indigenous unfamiliar cultures to explore, explain and write about the world from the perspective of a member of that society. Malinowski is often cited as the first researcher with a declared interest in an immersed, native point of view. Others agree that the principle aim of the ethnographic approach is to "explore and represent unfamiliar cultures", to understand meaning and events as they are understood by people in those cultures. Other major authors in fields of ethnography both in the wider field (McCalla-Chen, 1996; Walford, 2001) as well as in the specific health-care fields (Murphy and Dingwall, 2003; Savage, 2000) concur with this aim. More recent developments in ethnographic studies show that unfamiliar cultures have become more widely understood to be located "closer to home" and there is now a wide range of ethnographic studies that consider familiar practices from particular cultural perspectives (Brown and Bellaby, 2002; Duckett, 2015; Harvey et al., 2015; Latif et al., 2013, 2016; Lim et al., 2011).

Different Types of Ethnography

There is a wide range of ethnographic types and whilst this list is not intended to be exhaustive or all-encompassing, it is clearly useful to outline some of the key ethnographic types and their similarities or differences. This includes full traditional ethnography, rapid ethnography, critical ethnography, feminist ethnography, auto-ethnography and the recently emerging trends toward digital or visual ethnographies.

Full traditional ethnographies tend toward longitudinal studies with long periods where the researcher is immersed in the field. This approach has the limitations of being time and resource intensive and as a result tends to be most popularized as an approach in doctoral work. Several authors of papers reviewed mention these limitations as reasons for not choosing

ethnography as a method for study despite its apparent appropriateness for investigating the area of research (Austin et al., 2010; Miller et al., 2007; Walpola et al., 2017; Wang et al., 2014). By contrast, rapid ethnography allows users to take the ethnographic approach to a shorter and often more intense period of time spent in the field (Baines and Cunningham, 2013; Reeves et al., 2013).

Critical ethnographic studies are value-laden and use existing theories with, and often to emancipate disadvantaged cultures, through challenging existing structures. The main aim in critical ethnography is reporting on not just how things are but how they could be better (Barton, 2001; Oladele et al., 2012), for example, seeking to establish why urban children do not engage with Science (Barton, 2001). Feminist ethnography takes a similar approach, focusing on areas of female culture, or applying feminist principles to ethnographic methodologies, or both (Visweswaran, 1997; Williams, 1993). This is an approach and discourse in health services research which features predominantly in the Nursing domain (Manias and Street, 2001; Muecke, 1994).

Auto-ethnography has parallels with biographical studies since they are centralized around the researcher as author of his own experiences. In differing from biographies which centralize the author within the story, in auto-ethnographic studies the culture of the author provides the focal point for the work (Denzin, 2013; Ellis and Bochner, 2000).

In the technological era, a number of new studies have emerged that seek to understand experiences of digital and online cultures (Murthy, 2008; Wesch, 2008). Visual ethnographies overlap this somewhat as they are concerned with utilizing the consideration of a wide range of visual artifacts to give insight into the culture, often utilizing analysis frameworks related to symbolic interactionism (Pink, 2013).

This section has outlined some of the key variations of ethnographic methodology, all of which can give useful insights into the culture they examine but each has its best fit with a type of research according to the broad aim, research question, and type of culture under investigation. The choice of research methodology should be context sensitive, appropriate to the research question being asked and the desired outcome (Bryman, 2015; Green and Thorogood, 2018; Lincoln and Guba, 1985).

This section aimed to give a brief introduction to and broad overview of ethnography from a theoretical perspective.

Doing Ethnography

Introduction

The previous section introduced a brief history and definitions of ethnographic methodology. This section of the chapter outlines the practicalities of using ethnography as both a set of methods (for data collection and analysis) and as an output and impact method through writing.

Sampling

Ethnography requires ongoing access to sites and participants. There are a number of ways to negotiate access to sites, which differs from other types of research as access to the setting is not a one-off event but requires ongoing negotiation by the ethnographer. Building relationships is a vital part of ethnographic research (Hammersley and Atkinson, 2007).

Choice of sampling in research methods is also context sensitive, relates to the research question being asked, and the methodology used to find the answer. In Guetterman's (2015) review of sampling approaches in qualitative research he noted that ethnographic studies tended to have a small number of sites, for example, 1–2, with a wide variance in the number of participants at the sites depending on the site, culture and research questions. The ten ethnographic studies reviewed by Guetterman had a mean sample size of 128, with variance in sampling size from 6 to 586. Whilst the main sample of an ethnographic study will be a single or small number of sites, and the participants of the culture sharing group, other opportunistic sampling techniques are often used as the study progresses to respond to emergent areas of interest. A wide range of sampling strategies are often reported in ethnographic studies including convenience sampling, snowball sampling, critical case sampling for specific subgroup sampling, and purposive or purposeful sampling for maximum variation or representation.

Immersion

The key benefit of ethnography is the depth of understanding that emerges from time immersed in a cultural setting. It is difficult, however, to specify techniques for sampling or time immersion for ethnography as this is dependent on the setting and context. Wolcott (1994) suggests that time is the critical attribute of fieldwork in the ethnographic tradition. Ethnography assumes that we can only understand cultural ways of being in detail through an "insider's view" developed over a period of time which is needed to discern both the depth and complexity of social structures and relations (Jeffrey and Troman, 2004; McCalla-Chen, 1996; Walford, 2001). There is debate about what length of time should be spent in the field to qualify a study as being in the ethnographic tradition. Early anthropologists researching rural cultures recommended an ideal of 12 months minimum to study the annual cycle of the growing season. Wolcott (1995) described an ideal fieldwork term of 2 years as the standard. As well as debate about the length of a study, there is debate about the depth of immersion that qualifies a study as ethnographic. Jeffrey and Troman (2004) described three different "fieldwork time modes" which refer to the nature of the ethnographic methodology. A compacted time mode involves a short period of intensive immersion in all activities in the community. By contrast, a selective

intermittent mode is one where the length of time is longer but a more flexible approach is taken to frequency of observations. A recurrent research mode is one where projects aim to gain a picture by sampling the same temporal phases, for example, beginnings and ends of terms. More than one of each type of mode can be used within a single study. It is important that ethnographers describe the depths of immersion in their study and the amounts of time spent in the field to confirm that this study fits the ethnographic tradition.

Data Collection Tools

This section outlines a series of data collection methods that are often used in ethnographic research. Methods relate to the specific "working" methods and process for the work. It is important to note that whilst a set of tools is outlined here, it is the way in which they are co-utilized which is a unique feature of ethnographic research.

The most common form of formal academic writing reports the research process as data collection, analysis, and interpretation in a linear style appropriate to experimental or scientific design. It is important, however, to note that in ethnographic research, whilst these processes are followed, they are not as distinctly separated in practice as they might appear in written format. Naturalistic research is reflective and iterative and data and theory can both be simultaneously collected and analyzed. Data collection, analysis, and interpretation are ongoing and overlapping throughout ethnography. In ethnographic work, it is likely that the researcher will analyze data as it is collected, and interpret it during analysis, before repeating this cycle. Malinowski (1961/1922) suggests that in ethnography relationships between data and theory are more seamless than in other approaches.

Therefore whilst a distinct set of methods for data collection and analysis is described, the need for iterative development and reflexivity are also explored, along with appropriate measures for the rigor of academic ethnographic work.

Observation

The previous section introduced the importance of time spent in the field collecting data to be "immersed" in the context being studied. It is generally agreed that observation (participant and/or nonparticipant) forms the cornerstone of ethnographic studies (Denzin and Lincoln, 2011; Lincoln and Guba, 1985; Reeves et al., 2013; Smith, 1998a).

Savage (2000) notes that on occasion ethnography is mistakenly used interchangeably with participant observation. Hammersley and Atkinson (2007) suggested that any case study using participant observation methods with case study outputs might be classified as ethnography but others contradicted this arguing that it is the length and depth of participation that defines a true ethnography (Outhwaite and Turner, 2007; Spradley, 2016).

Periods of observation in ethnographic studies are often spaced apart in time to facilitate the iterative development of the research question. Woods (2013) suggested that an intermittent approach is:

> ' . . . the flexibility to follow a particular empirical or analytical path across people and contexts and to be able to focus more and more closely on any relevant aspect of a site just as a cinematographer who gradually zooms closer and closer on to his or her preferred subject. (Woods, 2013, p. 12)

The difficulty of conducting observation studies in health services should not be underestimated. Austin et al. (2010) suggested, for example, that it is difficult to conduct ethnography where there is access to (and sensitivity around) patient records. Ward et al. (1998) acknowledged the contribution of the participants in their research.

> 'The authors would like to thank all the staff at the 10 pharmacies who took part in this study. To subject oneself to the scrutiny of strangers for five days takes both courage and a sense of commitment to the development of the profession of pharmacy.' (Ward et al., 1998, p. 214)

While observation allows for a level of researcher immersion in context, it is inherently researcher-centric and in the majority of ethnographic studies it is used alongside other data to explore multiple perspectives.

Interviews

Whilst qualitative interviews alone do not constitute an ethnography, ethnographic studies often use interviews alongside periods of observation. The key aim of the qualitative interview is to gain insight into the participant's view of the research topic (Smith, 1998b). Interviews are often used to explore areas of interest which have emerged from observations and can occur at multiple time points and be either preplanned or spontaneous. Life history interviews focus on individuals and are often used in the early stage of ethnography as a tool to build relationships with participants, understand their social history and extend the research out to understandings beyond the fixed time period for the research. Semistructured interviews are most commonly used as they allow the researcher to have broad areas of questioning with underlying prompts but can also follow areas of emergent interest.

Ethnographic Content Analysis

Documents, an output of human creation, related to the context for study, can often provide useful insights as part of an ethnographic study. This method is called ethnographic content analysis and involves locating, identifying and analyzing documents for their meaning and significance to the context of the research study and their relationship to the emerging research question (Altheide, 1987). Visual artifacts including media items can also be analyzed (Glinert, 2005; Pink, 2013).

Mixed Methods and Ethnography

Some argue that ethnography is an inherently mixed methods approach since, as outlined above, ethnographic studies most often utilize a combination of qualitative data collection methods (Schensul et al., 1999).

A number of studies have emerged recently which take a broader approach and suggest that the qualitative tools of an ethnographic study can be used alongside quantitative methods to give a broad mixed methods overview and understanding of a context. This is complex since both are epistemologically opposed, nonetheless, this can give a holistic understanding of complex situations and as such has gained popularity as a combination of methods, for example, in implementation science in healthcare settings (Bunce et al., 2014; Palinkas et al., 2011; Rowley and Waring, 2011).

Data Analysis Process

The research process of ethnography is not linear in the same way as other types of studies and therefore it is unlikely for there to be a clear and distinct period of data collection and analysis.

Theory in Ethnography

There is broad agreement about the fact that there are variations in analytical approaches used in ethnography (Bryman, 2015; Hammersley and Atkinson, 2007; Walford, 2001). Any broad review of ethnographic literature will find a range of approaches on the deductive to inductive scale. At one end of the scale, there are fully inductive studies which explore an area and develop a theory according to the data, often using a broad thematic analysis. Some such studies take a grounded theory approach (Anto et al., 2013). There are other studies that fall in the middle of the spectrum. This is where the majority of ethnographic research sits, led by broad research areas initially and a desire to explore the field, and where a specific theoretical framework does not inform the earlier stages of research design but is useful to iteratively develop the ongoing data collection and make sense of findings toward the analytical stage of the study. At the inductive extreme of the spectrum are studies that use theory to inform every aspect of research from the origin of the research question through to findings. An example is provided by the "socialisation of Mistansini Cree children" study (Delamont and Atkinson, 1980), which was based on social learning theory from inception through to completion or, similarly, Kooienga's ethnographic study of e-prescribing in rural communities (Kooienga and Singh, 2017) where the Ecological Transactional model was used to inform research design, data collection and analysis. These examples are listed to show the polar ends of difference between the wide ranges of ethnographic subcategories. In between is also a wide range of studies that demonstrate the enormously varying ways that theory can be applied to studies of ethnography in the process of both data collection and analysis. **Fig. 1** shows Winit-Watjana's diagram which visually maps this process (Winit-Watjana, 2016, p. 430).

One key advantage of ethnography as a tool is the need for the researcher to iteratively develop the focus of the research according to the findings as they emerge which requires a reflexive approach to the research. Anderson (1989) suggested that working with ethnographic data

> '. . . requires a reciprocal relationship between data and theory. Data must be allowed to generate propositions in a dialectical manner that permits use of a priori theoretical frameworks, but which keeps a particular framework from becoming the container into which the data must be poured' (Anderson, 1989, p. 267).

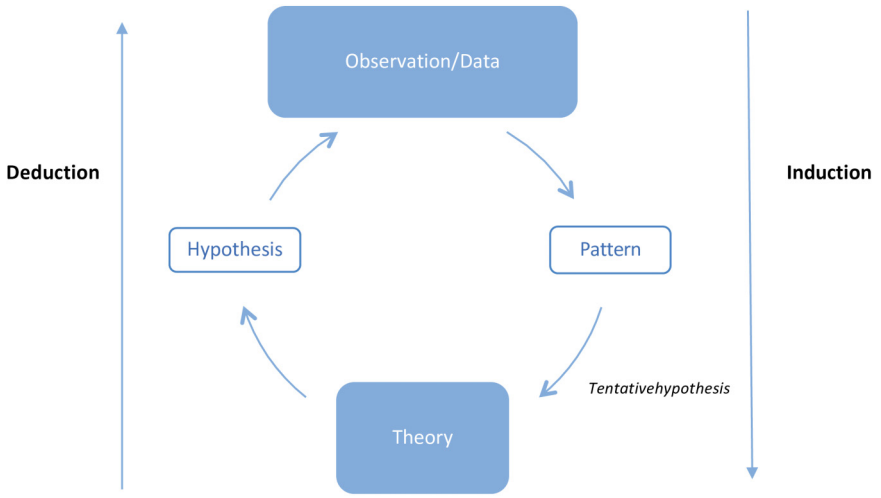

Figure 1 Research reasoning or logic of inquiry. *Source: Winit-Watjana, W. Research philosophy in pharmacy practice: necessity and relevance. Int. J. Pharm. Pract 24 (2016), 430.*

Ethnographic data analysis begins with coding data to identify areas of interest and overlap and their relationships. By applying labels to data through coding the researcher makes decisions about what the data collected represents and through arranging the coded data into categories can identify links between them. A range of tools can support this work. Software packages for analysis of qualitative data, such as NVivo, help the researcher to manage data and develop key themes. Some people prefer to use colored pens, stickers, electronic files or scissors and folders to organize data to aid in the identification of key themes and links. In an attempt to minimize subjective researcher impact, some studies use multiple coders to enhance (inter-coding) reliability (Denzin and Lincoln, 2011; Kooienga and Singh, 2017; Smith, 1998b).

By repeating the analysis at multiple time points through the research, as different sources of data are added, areas of interest can be iteratively developed. At each stage of coding, the researcher may revisit the literature, or iteratively develop more tools or methods for data collection. Coding and thematising data, in conjunction with reviewing the literature allowing emerging data to fit with emerging frameworks is a simultaneous, iterative process. The outcome is data that can simultaneously describe and analyze a context and culture through a vari-focal lens.

Rigor

Pharmacy has its' roots firmly in the Sciences, and as such can be reluctant to be open to Social Science which has many contradictions with traditional scientific approaches (Smith, 1998b). Some people suggest that because the health field has a strong tradition of biomedical research using conventional experimental and quantitative methods, qualitative research is often criticized for lacking scientific rigor (Mays and Pope, 1995). Early defenders of rigor in qualitative research (Lincoln and Guba, 1985; LeCompte and Goetz, 1982) identified that typical positivist measures of rigor used for scientific research were not transferable. More recent researchers suggest that the complex activity of ethnography and diverse epistemological positions and methods require different modes of evaluation from other methods more commonly employed in medical and healthcare research (Savage, 2000). Ethnography does not fit with traditional scientific methods of rigor and recent publications in qualitative research show that alternative methods of reflexivity, transparency and triangulation can be used as quality measures.

Reflexivity is a process where the researcher, actively and throughout their work, reflects on both the research process and their impact on it. Studies should clearly identify measures taken by the researcher to minimize impact on the conditions and participants of the research (Marshall et al., 2010). Barry et al. (1999) suggest that shared reflexivity significantly enhances the rigor of team based qualitative research. Hegelund (2005) discusses a range of ways for ethnographic researchers to distinguish between the problematic terms of subjectivity and objectivity. This paper suggests the ethnography can limit subjectivity through three key methods—firstly the study should correspond to the reality of the study (by including all relevant data, secondly methods of analysis should be objectively approached, and thirdly the perspective of the research and researcher should be transparent).

It is suggested that reliability in ethnographic studies is enhanced by transparent presentation of methods and analysis so that an audience can clearly understand the work undertaken, the context it is undertaken in and, through reflexivity, the impact of the researcher on each aspect of the research (Hegelund, 2005; Marshall et al., 2010; Murphy and Dingwall, 2003).

Data triangulation is a method inherent in the ethnographic approach used to minimize objectivity and achieve rigor in qualitative studies. Triangulation involves collecting and analyzing data from variations on one of the three types of data sources—time, space, and person (Denzin, 2013). The cyclical reflexive method of linking data to theory in **Fig. 1** (Winit-Watjana, 2016) demonstrates triangulation. For example a wide range studies use ethnographic interviewing as a technique to complement participant observation, ensuring a good in-depth fit between theory, data processing and researcher interpretation. Savage (Savage, 2000) argued that ethnography can be distinguished from other approaches by making the link between the micro and macrolevel of a context, with an interest in both individuals and their context and the interactions therein. Hirsch and Gellner (2001) provide an excellent visual representation of this approach as one with "one eye roving, the other focusing".

Ethnographic Writing

Since half of the etymology of the term "ethnography" relates to writing, it is important to emphasize ethnography as an approach to writing. Fetterman (2010) described ethnography as the art or science of describing a group. Harris and Johnson (2006) stated an ethnography is a written description of a particular culture, based on evidence and that this should include descriptions of the customs, beliefs, and behavior of the participants.

Ethnographic writing is often not just an output, but also a significant part of the analysis process, iterative and used as a method of enquiry to reorganize and refine ideas (Denzin and Lincoln, 2011). This approach to writing demonstrates progressive focusing (Strauss and Corbin, 1990); the writing occurs as a process of data analysis to focus the lens more specifically on areas of interest and significance.

Traditional ethnography sought to tell a story (Hammersley and Atkinson, 2007). Brown and Bellaby's (2002) article about community pharmacy is written in this true ethnographic style, using thick description and metaphor to invite the audience into the world of the community pharmacy from the perspective of the locum pharmacist. The imagery and creative prose generate strong understandings of what it means "to be" a community pharmacist: "Meticulous attention to clothing contributes to constructing the pharmacist's specific, respectable, trustworthy front" (p. 204). Through thick creative writing the reader is given insight into a range

of processes and perceptions that contribute to the pharmacist's professional identity. Brown and Bellaby (2002) used metaphors of dramatic performance allowing the reader to experience "what it means" to be a pharmacist in this context through the eyes of those who have experienced it, as the following extract demonstrates.

> 'Backstage: The pharmacist's performance is nearly finished for the day. He drinks strong coffee, in order to attempt to keep alert for the rush of prescriptions during the last 20 minutes, counts the pile of prescriptions, which is some quantification of the workload of converting drugs into medicines and returns the Controlled Drug key. He thanks his supporting cast, the assistant(s); they set the alarm and lower the roller blinds (stage curtain) in order to guard the stage props, especially medicines, overnight. In his car, the pharmacist relaxes, after his 12 hours of performance, by unbuttoning his shirt and loosening his tie.' (Brown and Bellaby, 2002, p. 210–211)

Many ethnographic works present data, full or partial findings, creatively as case studies or smaller vignettes for ease of reading (Oborn and Barrett, 2008). Reports of ethnography appear in a range of published press from full monographs to book chapters along with a wide range of peer reviewed journal papers and conference proceedings. Styles of writing are limited by the mode of delivery, with journal articles frequently focusing on one area of the ethnographic study rather than trying to report the full data of a study.

Ethnography in Health Services Research Pharmacy Practice and Policy Research

It is important to locate ethnography within the field of pharmacy practice for relevance.

Overview

Previous sections have outlined the reasons why ethnography is still a developing approach in pharmacy practice, a traditionally scientific and positivist environment.

There is, however, a wide range of colocated areas where ethnographic studies are more populous and interested readers and potential ethnographers are encouraged to explore literature in health services, medical and allied health qualitative research and education for a wider range of studies.

Literature Review

To understand and present a brief reflection of ways in which ethnography has been employed in pharmacy practice research, I undertook a small scoping literature review of two major peer reviewed journals focused on Pharmacy Practice research. The first, International Journal of Pharmacy Practice (IJPP) is the official journal of the Royal Pharmaceutical Society in the UK and published by Wiley; the second is Research in Social and Administrative Pharmacy (RSAP) a journal with international committee and audience, by Elsevier. It is acknowledged that this search is limited, but provides a useful introduction to the published research utilizing this approach. Further broader studies are recommended for a wider insights into the profession and its practices.

Both journals were searched for the terms "ethnography" and "ethnographic" from inception to April 2018. Initial searches returned a total of 83 papers; however, with duplications between findings from utilizing both terms removed, the total number of independent returns was 68.

Upon initial review a number of these papers (32) mentioned ethnography on a superficial level, or simply citing other ethnographic studies and these were withdrawn from further investigation (IJPP 15, RSAP 17). The total number of papers remaining for review after this initial skimming was 36.

Of these 36 papers, 9 (IJPP 6, RSAP 3) viewed ethnography as a method, usually within a wider view of qualitative research, or wider fields such as philosophy. While these were useful to review in the context of this chapter, they were excluded from further review.

The remaining 27 articles represented ethnographic studies (IJPP 13, RSAP 14) and these are presented below.

Lessons from Ethnographies of Pharmacy Practice

A small proportion of the papers reviewed described their work as taking an "ethnographic approach". Some of these studies could be categorized as clear ethnographic studies as they clearly fit the criteria outlined previously for ethnographic approaches to data collection and analysis. A number of studies that reported an "ethnographic approach" were reporting data collected by individual methods such as qualitative interviews, and this was justified as ethnographic in approach as they were conducted as part of a wider ethnographic study. Two authors had a different paper in each journal referencing the same ethnographic study but presenting findings from different themes or areas of the work.

The 27 ethnographic works reviewed can be broadly categorized into (1) Pharmacy Culture—the culture and role of the pharmacist and their profession broadly, or in specific locations such as community pharmacy or hospital pharmacy, (2) Patient–Pharmacy interaction culture, and (3) Global pharmacy culture (including the culture of pharmacists' relationships with others and pharmacy education).

Pharmacist Culture

Around half of the studies reviewed reflected on the role and identity of the pharmacist and the profession. These tended to be located in either the community or hospital pharmacy context.

Brown and Bellaby (2002) wrote creatively and used thick description about locum experiences in community pharmacy. This creative writing output from a period of immersive participant observation across a wide range of settings provides thick description about the experience of what it means broadly to work in a community pharmacy. This was a holistic, broad research study giving in-depth insights into the experiences of a community pharmacist and safety and responsibility emerged as two areas of key importance. Safety culture was a focus of other studies in community pharmacy. One study specifically focused on the safety culture in community pharmacy and explored strategies used by a range of pharmacists in this setting (Anto et al., 2013). Harvey et al.'s ethnographic study (2015) of safety in community pharmacy reviewed a wide range of factors that impact on safety within the community pharmacy dispensing culture and provided useful insight into the complexity of processes and relationships.

Other research in the community pharmacy setting was more specifically focused on understanding the experience of either unique settings, participants or Interventions. One study researched what it means to be a community pharmacist in one particular geographical and cultural area of the UK (Duckett, 2015). Another considered the role of the medicines counter assistant in community pharmacy, in particular in relation to the sale of deregulated medicines (Ward et al., 1998). Latif et al.'s (2013) study into the implementation of a new medicines review process took place in, and gave unique insight into, the community pharmacy context.

The remaining ethnographic studies relating to context provided insight into changing practices in hospital pharmacy culture. One study reported on the experience of automation implementation in hospital dispensary and showed the impact of the change on working culture (Oborn and Barrett, 2008). Another study explored the relationship between electronic prescribing in hospital and patient involvement with their medicines (Garfield et al., 2015).

Finally, some studies focus on interactions between pharmacists and others. One American-based study considers the relationship between pharmacists and industry (Saavedra et al., 2017).

Patient–Pharmacy Interaction Culture

A wide number of studies focused on interactions between pharmacists and patients, within the broadest culture of medication and health. Whilst those reported here featured in pharmacy practice publications, they are likely to be replicated on a much larger scale across broad health services research.

Studies took place in a wide range of contexts including studies of treatment culture in home settings (Norris, 2012) care homes (Shaw et al., 2013), the culture of patient-facing medication reviews in community pharmacy (Babalola and Erhun, 2001; Latif et al., 2013; Tulip et al., 2002) or the discharge process in hospital (Laugaland et al., 2014). Each of these offers a unique multifaceted insight into the cultures under examination. Kooienga and Singh (2017) ethnography of rural e-prescribing identified important points about relationships between patients and pharmacists and how different cultural areas respond to innovations differently.

Some studies focused on particular patient groups. Lau's (2014) ethnographic account of nonadherence to statins in 40–80-year-old men gives an interesting insight into the decision making process within this particular patient group. Norris (2012) study in New Zealand was a comprehensive ethnography of medicines use in the home that employed a wide range of techniques including participant diaries and mapping. This study gives useful insights into the way patients talk about medications, and their use of metaphor, in relation to medicines and, in particular, antibiotics. Ahiabu et al.'s (2018) ethnographic study of Ghanaian households' illness and medication use gives interesting insights into self-medication in this context that can usefully inform the development of health services.

> 'Medication use was for both treatment and illness prevention. Oppong (H4) believed he has had chronic typhoid fever for over 20 years and takes ciprofloxacin as often as every month; in his own words "anytime I sense the fever and headache. (Ahiabu et al., 2018, p. 5)

Whilst these studies could be categorized by their context of study (home, community) they are categorized here by their focus on patient's experiences. For example Latif et al.'s (2013) ethnographic study of medicines use reviews in community pharmacy were reported from the patient perspective.

Some studies focused more broadly on the patient experience. For example, one study focused on the culture of patient interaction with pharmacy practice research (Sutton and Weiss, 2008) and the work gives valuable insight into patients' understanding of the research process. Montagne's (2014) study of antidepressant use can be classified as a digital ethnography since all observations were online of activity conducted online. This was supplemented by online documents and online behavioral tracking statistics. The exploratory study by Traulsen et al. (2014) reported through conference proceedings was a groundwork scoping study focused on students and, through detailed fieldwork at two international sites, reported some of the reasons why students were taking "study drugs" and this identified a gap for further work.

Global Pharmacy Culture

As mentioned ethnography is useful for exploring unfamiliar landscapes and capturing cultural baseline data to inform future research in a wide range of studies both local and international.

One study, based in Malawi, resulted in two different publications, the first explored the involvement of practizing pharmacists in the development of education (Lim and Anderson, 2011) and the second investigated the notion of "drug pilferage" in the Malawi context (Lim et al., 2011). Several of the papers previously mentioned located their work in a specific culture (Ahiabu et al., 2018; Norris, 2012).

Discussion

What we learn about pharmacy practice from ethnographic accounts is invaluable. These published accounts give any audience a unique insight into the processes involved in pharmacy practice from the perspectives of those mostly deeply involved with them.

From the above reviews, we have interesting insights into community pharmacy, hospital pharmacy, and patient's interactions with their medicines.

The studies highlighted in this review are useful representations of what it means to be a pharmacy professional or work within the context of health and medicines. They also provide unique insights into what it means to be a user of medicines. They provide grounding data and identify gaps for further research.

Conclusion

This chapter has covered ethnography as both a broad methodology and a series of precise methods for data collection, analysis, and writing. A brief insight into ethnographies published in the UK about pharmacy practice provides an introduction to the field but also identifies gaps for further research about what it means to be a pharmacist or a patient in various cultures and contexts.

Philosophical Perspectives and Theories Applied in Pharmacy Practice Research

Lotte Stig Nørgaard, Janine Marie Traulsen, Copenhagen University, Section for Social and Clinical Pharmacy, Copenhagen, Denmark

Philosophical Perspectives

Paradigms/Belief Systems

Four characteristics distinguish science from nonscience. Science is theory-based, uses systematic research techniques, is cumulative and predictive (Mount, 1989). All science is embedded in different belief systems also known as paradigms, world views or research types, not only in choices of method and theory that guide the investigator, but also in fundamental ways both ontologically (nature of being) and epistemologically (investigation of what distinguishes justified belief from opinion). One can identify four types of paradigms: positivist, post-positivist, interpretivist/critical theory, and constructivist (Guba and Lincoln, 1994).

These theoretical paradigms differ to such a degree that they are said to be inconsistent (Guba and Lincoln, 1994; Launsø, 1991). Research carried out within the positivist/post-positivist paradigm strives toward objectivity and neutrality, and typically employs quantitative studies with the focus on numbers, precision, and generalizability. These studies rarely have an explicit theoretical foundation and are characterized by distance between researchers and that being researched.

On the other hand, studies done under the interpretivist paradigm are most often qualitative studies focusing on understanding and grasping the wholeness of the study object. Often theoretically-based, these studies feature a closeness between researcher and that being researched. The constructivist paradigm and to some extend the interpretivist paradigm cover research (either quantitative or qualitative) whose focus is to criticize, suggest change, learn, and/or develop. These studies often have an emancipatory agenda for groups involved (might be all kind of groups, but would often be different types of vulnerable patient groups). Historically, there has been heavy emphasis on quantification in science, and thus research emanating from a positivist/positivist paradigm has traditionally been viewed as "hard", whereas research carried out under the other two paradigms is often referred to as "soft". See Sørensen et al. (2003) for a mapping of core questions, typical design, dominating method and quality criteria attached to each of the paradigms.

To illustrate the difference between research done in pharmacy practice under the first two paradigms, one might consider different theories of compliance/adherence or self-regulation. From a positivist point of view, a theory on how to make a drug user compliant by using different electronic or chemically marked methods would be useful. A researcher with an interpretivist view studying adherence would be more likely to employ theories that emphasize the patient's ideas, values and attitudes—most likely interpreting adherence as "self-regulation". Broadly speaking, the positivist researcher attempts to predict and control, whereas the interpretivist researcher focuses on understanding the patient's reflections in relation to medication behavior (Nørgaard et al., 2000).

History of Philosophical Perspectives and Theories in Pharmacy Practice Research

Underlying all belief systems are many different theories relating to specific topics. This is also true for PPR. The first decades of PPR were characterized by relatively few theoretical reflections and tended to be "hard" quantitative research carried out under the positivist paradigm. However, in recent decades a growing awareness of and interest in the critical paradigm has fostered efforts to

teach and conduct research using this tradition. The result has been an increase in the number of qualitative studies and studies with a specific theory base Bissell et al. (2001). Today, PPR is carried out under all three of the above-mentioned paradigms, and various theories have been developed under the umbrella of all three paradigms, as will be described below.

No one theoretical perspective is "better" than another. The methodologies and methods that follow the theories all serve different purposes. An example from PPR could be: If you want to map the number and types of drug-related problems in a population, an interpretative paradigm and qualitative methods will be of limited use. In contrast, if your aim of inquiry is to know more about individual patients' thoughts and ideas in relation to medicine use, using a positivist approach and quantitative methods will not make much sense.

The Why and How of Theory Base in Pharmacy Practice Research

The explicit use of theories serves various purposes ranging from explanation and prediction in the positivist research tradition to understanding, sense making and critiquing in the interpretivist, and critical theoretical research traditions (Buchanan, 1998). There are many definitions of theory, but suffice it to say that a theory is an account of the world that goes beyond what we can see and measure. Theory embraces a set of interrelated definitions and relationships that organize our concepts and understanding of the empirical world in a systematic way (Marshall, 1998). The above definition suggests that theories are bodies of knowledge that allow a more elaborate/complex or sophisticated framework for understanding the world. Theories can thus range from explicit hypotheses to working models and frameworks of thinking about and studying reality. A theory constitutes a classification system, a taxonomy, consisting of categories that organize and summarize empirical observations, thus providing the researcher with a framework for understanding and organizing empirical findings.

Decades ago, it appeared that while research in nursing practice was acknowledging the benefits of theory-based research, this was not the case in PPR (Nørgaard et al., 2000). Some researchers argued for theory-based PPR, because, as they pointed out, there was an overwhelming tendency to focus on descriptive studies, addressing the "what" or "how many" questions, but rarely addressing the "why" questions. Although this is still true to some extent (Lau and Traulsen, 2017), it is fair to say that PPR has moved on, and it is no longer rare to find theory-based studies in peer-reviewed journals, which will also be seen in the rest of this chapter.

Much if not all of PPR deals with human beings. People go to a pharmacy with their personal problems related to illness, health, and drugs. Although not obvious on the surface, these "personal problems" are often interconnected with or reflections of political and administrative constraints found in societal structures, including the cultural and social environment: questions of access, affordability, beliefs about health and illness and the effects of poverty, to name a few. Given the acceptance that social factors play a key role in the determination of health and illness, there is a need for those involved in pharmacy practice to understand the nature and effects of those factors, and hence the need for social theories grounded in sociological knowledge.

Researchers use theories and think theoretically, even if they do not make it explicit. In research all observations and interpretations have some theoretical assumptions. No study of reality is presented independent of the preconceptions one has about them. Consciously or unconsciously, researchers include their own expectations and theoretical basis as the starting point of their work, which influences the method and strategies as well as the results of the project. The manner in which observations are organized, analyzed and interpreted determines what is "found". Thus, clarifying the theoretical background for one's research enables others to assess the validity of the research and judge the relevance of the theories in relation to the specific research area. Using a specific theoretical background also allows researchers to assess the relevance of their research findings to the available literature.

Existing social science theories can assist the pharmacy practice researcher in identifying questions and topics that need to be addressed. Instead of being stuck with a "trial-and-error" approach, social science can provide the researcher with an explanatory framework for interpreting questions and answers (Mount, 1989). On the one hand, researchers should consider the theoretical basis at the outset of planning a study. Conversely, the application of theory in research can be confusing, with a multitude of terms and definitions and many approaches described. Theories can be applied at many stages of quantitative and qualitative (and mixed) research processes and for many reasons: for example, providing rationale for the study, defining the aim and research questions, considering the methodological stance, developing data collection and generation tools, providing a framework for data analysis, and interpretation (Stewart and Klein, 2016).

It is clear that working with models has been more accessible and easier to apply to PPR than hardcore sociological and psychological theory. Although they both share common elements, the distinction between theories and models is as follows. A theory is a set of statements developed through a process of continued abstractions. Where a theory is often a generalized statement aimed at explaining a phenomenon, models are purposeful representations of reality, often stylized, graphic drawings. Although both share common elements in their definitions, a model is often used to describe and simplify an application of a theory, and its aim is to provide a tool for understanding specific phenomena (modeling).

Main Theories and Models Applied in Pharmacy Practice Research

An exhaustive description of how PPR researchers have worked theoretically is not within the limits of this chapter. However, a description of the main areas in which PPR has used theory follows. Each section concludes with one or two concrete examples of the theory used in PPR. Focus is on social science theories, which include political science, demography, epidemiology,

economics, management, and organization. Theories from the humanities (anthropology, ethnology, ethnography, pedagogy, psychology, linguistics/language, law, and politics) are also presented, as they are often used for understanding pharmacist's communicative, interdisciplinary and interactive tasks. For a more thorough description of sociological theories used in PPR, see the chapter "Sociology for Pharmacists" by Traulsen, Bissell and Ryan in this encyclopedia. The chapter presents theories of beliefs about health and illness, risk theories, theories of pharmaceutical policy, and theories of the professions. Other sociological theories, such as feminist theories, theories of ethnic minorities, materialist/structuralist theories, and interactionist theories are covered in an article series and a handbook, both of which deal with sociological theory and PPR (Bissell and Traulsen, 2005; Bissell et al., 2001).

Grounded Theory

Grounded theory was developed by Glaser and Strauss (1967). It is an investigative research approach with no preconceived hypothesis or theoretical approach. A study in this tradition presupposes that a theory will "emerge" from the empirical data. The goal of such a study is to generate a theory that explains how some aspect of the social world works. Grounded theory is criticized because it is often used—and has become popularized—by people with no prior knowledge or experience with theory, since it does not require a time-consuming and in-depth argument for a specific theory prior to or during the research process (Lau and Traulsen, 2017). In addition, the analysis and results in grounded theory studies often suffer from an all too obvious naiveté and ignorance of prevailing knowledge in the field (Sandelowski, 1993). PPR has used grounded theory extensively, see for instance Cunningham et al. (2016) who used a grounded theoretical approach for describing GPs and pharmacists perception and experiences of learning together in an interprofessional project.

Behavioral Change Theories and Models

Some of the first explicit theories and pharmacy-based patient adherence studies were carried out in the late 1970s/early 1980s in Denmark and Wisconsin, USA (Svarstad, 1979; Larsen and Hansen, 1985). The Danish contributions in particular spotlighted the development of a user perspective in medicine use, with focus on patient autonomy and self-regulation. In more recent times, the scientific literature on how pharmacy staff can come to understand and thereby help the individual person/patient change behavior (also in terms of medication intake) has exploded with theory-based PPR studies.

Understanding socio-behavioral aspects of patients in the medication use process is paramount to achieving optimal clinical and humanistic outcomes from therapy. Many PPR studies have undertaken the task of trying to understand the extent to which patients' medication-taking behavior is consistent with the recommendations of health care providers. A variety of theoretical underpinnings have been used in PPR regarding studies of pharmacy-based advice and counseling on medication adherence/compliance and concordance. A recent meta-review including almost 20,000 patients by Conn et al. (2016) on theory use in medication adherence intervention studies showed that the most frequently used theories and models were motivational interviewing (34 studies), social cognitive theory (31 studies), health belief model (15 studies), trans-theoretical model (14 studies), and self-regulation/common sense model (11 studies). These theories/models all originate from the health psychology area. The review concludes that theory- and model-linked interventions have a significant but modest effect on medication adherence outcomes. A concrete example of theory-based PPR research in the field was conducted by Alatawi et al. (2016), who successfully created new multidimensional adherence measures by taking patient preferences into account and combining models, such as the trans-theoretical model in combination with the health belief model (Alatawi et al., 2016). Another example is the safe and effective medicine use model (SEM-model) by Henriksen et al. (2008), which combines different types of compliance with motivational interviewing, self-efficacy, a WHO-model of adherence, stages of changes theory, coaching techniques, and narratives.

A long list of PPR studies includes in particular social cognition models/theories such as the Theory of Reasoned Action (Ajzen and Fishbein, 1980), Common Sense Model of Self-regulation (CSM) (Leventhal et al., 1997) and Bandura's concept of self-efficacy (1977). In fact, the social cognitive theory and theory of planned behavior are the most frequently used frameworks in driving change within health care practices (Durks et al., 2017). According to Bandura, the reproduction of an observed behavior is influenced by the interaction of three determinants: personal, behavioral, and environmental. Perceived self-efficacy is a pivotal concept in social cognitive theory. It refers to beliefs in one's abilities to organize and execute the courses of action required to manage prospective situations, and has had an impact on several adherence counseling programs and models used in pharmacy practice research. The key construct of the CSM is the idea of illness representations or "lay" beliefs about illness. The representations integrate with existing schemata, the normative guidelines that people hold, enabling them to make sense of their symptoms and guide any coping actions. Leventhal et al. (1997) describe five components of these illness representations: identity, cause, timeline, consequences, and curability/controllability. While these theories can and do provide some explanation for intentional nonadherence, they do not address the widespread, unintentional nonadherence in relation to medicine intake.

For decades, community pharmacy has contributed to public health in terms of medicine use and other health interventions (Anderson et al., 2003), such as smoking cessation, obesity and weight reduction, skin cancer prevention, nutrition, and physical activity. In particular, the Trans-theoretical Model (TTM), also known as the Changes of Stage Model, has been used for pharmacy-based smoking cessation and has been described extensively in the literature (Greenhalgh et al., 2016). The TTM (Prochaska et al., 1992) is an integrative, bio-psychosocial model used to conceptualize the process of intentional behavior changes based on the six phases: precontemplation, contemplation, preparation, action, maintenance, and relapse. Whereas other models of

behavioral change focus exclusively on certain dimensions of change (e.g. theories focusing mainly on social or biological influences), the TTM seeks to include and integrate key constructs from other theories into a comprehensive theory of change that can be applied to a variety of behaviors, populations, and settings.

Other examples of behavioral theoretical models used in medication adherence programs are the Health Belief Model (Yue et al., 2015), Theory of Planned Behaviour (Bane et al., 2006), and locus of control theory (Rickles, 2010).

A recent review of 47 papers based on theories of planned behavior and pharmacists' personality traits revealed how pharmacists' attributes and attitudes favor the implementation of cognitive and patient-focused health care services and should not be regarded as major barriers to the uptake of extended pharmacy practice roles (Luetsch, 2017).

Patient Safety Theory and Models

Medical error is estimated to be the eighth leading cause of death in the USA (Kohn et al., 1999). Patient safety is a growing major public health issue, since the knowledge, skills and experience of health professionals, including pharmacists, are very much essential for improving patient safety. Patient safety is the reduction of risks of unnecessary harm associated with health care to an acceptable minimum (World Health Organization, 2009).

Since the landmark publication *To Err is Human* (Kohn et al., 1999) by the Institute of Medicine, improving patient safety and reducing medical errors has been a priority for health care researchers around the globe, including PPR.

A systems model often used to study patient safety issues in the pharmacy practice area is the Swiss Cheese Model (SCM) by Reason (1990). The original intention for the model was to provide an essentially cognitive psychological account of the nature, varieties and mental sources of human error. The underlying question is: What can the appearance of relatively nonrandom forms of error tell us about the largely hidden processes that govern our thoughts and actions? The model is used in many fields for risk analysis and risk management, including health care. It likens human systems to multiple slices of Swiss cheese, stacked side by side, in which the risk of a threat becoming a reality is mitigated by the differing layers and types of defenses "layered" behind each other. Therefore, in theory, lapses and weaknesses in one defense do not allow a risk to materialize, since other defenses also exist to prevent a single point of failure. The model thus focuses on the necessity for systems to change and learn.

A series of health care tools have been developed based on the SCM to facilitate the investigation of incidents in clinical practice and to identify educational opportunities at a systems level, also in relation to medicines. For instance, it has been used for the creation of the human error theory (Barber, 2002; Franklin, 2001). Both authors argue that much can be gained in terms of insight into noncompliance, if theories developed to explain human error in organizations are also applied in patient safety studies. The resultant framework encompasses intentional and unintentional noncompliance, shifts blame from the patient, and recognizes the influence of other factors, including organizational ones. There are also consequences for the measurement of compliance and new strategies to improve it.

Learning Theories

Basically, learning is the foundation of what it means to be human. Pharmacists are currently developing so many new roles in both primary and secondary health sectors, developing skills as care providers, prescribers, coaches, and discussion partners, that a strong theoretical focus on pharmacists' learning ability is pivotal for this field of research. Several theories and models of learning styles have underpinned much PPR. Learning styles are considered by many to be one factor of success in higher education. A benchmark definition of "learning styles" is "characteristic cognitive, effective, and psychosocial behaviors that serve as relatively stable indicators of how learners perceive, interact with, and respond to the learning environment" (Romanelli et al., 2009).

Several models and measures of learning styles have been described in the literature. Kolb proposed a model involving a four-stage cyclic structure that begins with a concrete experience leading to a reflective observation and subsequently an abstract conceptualization that allows for active experimentation (Kolb, 1985). Kolb's model is associated with the so-called Learning Style Inventory Instrument (LSI). The LSI focuses on learners' preferences in terms of concrete versus abstract and action versus reflection. Learners are subsequently described as divergers, convergers, assimilators, or accommodators. Primarily adapting aspects of the Kolb LSI, Austin developed and validated the first pharmacy-specific instrument to assess pharmacists' learning styles, entitled the Pharmacists' Inventory of Learning Styles (PILS), to measure dominant and secondary learning styles (Austin, 2004). PPR conducted with both the LSI and the PILS recommended that educators take into consideration the learning style preferences of future pharmacists (Wallman, 2010).

How to educate the next generation of pharmacists in the most appropriate way has long interested pharmacy practice teachers and researchers, with learning during the pharmacy internship in particular drawing academic attention. Learning as such can be categorized according to one of the following three theoretical perspectives: learning as acquisition, learning as participation, or a combination of the two (Wallman, 2010). Learning as acquisition implies that the individual possesses and is aware of the activity, whereas learning as participation implies an ongoing process that is produced and constantly reconstructed through relationships and interactions. Hence, from a participatory point of view, knowledge is not something individually "possessed", but rather a social construction. One of the leading educational researchers Etienne Wenger states that, in practice, learning is a combination of the following four subtypes: learning as doing (practice, i.e., what are we doing?); learning as belonging (community, i.e., where do we belong?); learning as becoming (identity, i.e., who are we becoming?); learning as experience (meaning, i.e., what is our experience?) (Vestergaard et al., 2017).

Theories on the reflexive practitioner and single/double-loop learning by Donald Schön (1983) and Argyris and Schön (1978), among others, have also been used in PPR studies on learning by pharmacists and pharmacy interns (Droege, 2003; Kansanaho et al., 2015; Schumann et al., 2004; Sørensen et al., 2005; Wallman, 2010). Schön (1983) states that reflection is the means by which the complex epistemology of practice may be uncovered.

Patient–Pharmacist Interaction Theories

Although patient-centered communication is extensively described and studied among doctors and nurses, it is not well defined for pharmacists. This is the case even though since the 1960s, community pharmacies have been recognized as being ideally located within the community to provide health education (inspired by Gatherer, 1966). However, patient–pharmacist interactions at the pharmacy in particular have been studied, and several theories have been used to describe interactions, including PRECEDE-PROCEED theory (Paluck et al., 2003; Aslani et al., 2006), interpersonal perception theory (Assa and Shepherd, 2000), patient satisfaction models (Ried et al., 1999; Larson and MacKeigan, 1994), health communications model (Svarstad et al., 1986), and role theory (Guirguis and Chewning, 2005).

Only role theory applied in PPR will be described here, because the theory has been widely used in pharmacy, and because it allows us to account for both actors in an interaction (in contrast to the other theories). In a review by Guirguis and Chewning (2005), the two authors identified no fewer than 30 PPR papers in which four out of five perspectives of role theory (functionalist, symbolic interactionist, organizational, and cognitive) had been applied. Role theory concerns itself with *"a triad of concepts: patterned and characteristic social behaviors, parts or identities that are assumed by social participants and scripts or expectations for behaviors that are understood by all and adhered to by the performer"* (Biddle, 1986).

Among other things, role theory has been used to investigate the pharmacist's role (business, clinical, and professional) (Quinney, 1964), to describe the patient's role in counseling (Schommer et al., 1995), for job satisfaction descriptions (Ralph and Langenbach, 1987), and to examine perceptions of health care providers other than pharmacists (Nørgaard et al., 2001).

Theories of GP–Pharmacist Collaboration

Much has been written about the need for greater cooperation and collaboration in the primary sector, specifically between general practitioners (GPs) and community pharmacists. The advantages of better and increased collaboration for the health care sector include improving patient care, continuity of care, and consistency in the information to patients, as well as optimizing pharmacotherapy. All of these improvements contribute to increased visibility of the pharmacy profession (General Pharmaceutical Council of Spain, 2015). This chapter only covers the main theories on the pharmacist's collaboration with GPs, since the GP is the most important and common cooperation partner for community pharmacists. It is on this collaborative relationship that the majority of theoretically informed papers are written. However, one must bear in mind that pharmacists cooperate to an increasing degree with a variety of other health care practitioners such as nurses, dieticians, and physiotherapists.

Several conceptual models have been developed as a tool to describe and aid understanding of the stages and characteristics of collaboration and integration between health and/or social care professionals and services (Bradley et al., 2012). Relatively little theoretical attention has been given; however, to understanding how these concepts and their characteristics relate to the community pharmacy and general practice relationship. A popular topic of study in PPR on GP/pharmacist collaboration has been the facilitators and barriers to collaboration (e.g. Hughes and McCann, 2003). The most developed theoretical model on GP–pharmacist collaboration is McDonough and Doucette's (2001) collaborative relationship model for pharmacists and physicians. This model was synthesized from previous models of interpersonal relationships, including theories of social exchange, business relationships such as the buyer–seller relationship and organizational behavior, and collaborative care models primarily relating to nurses and physicians. The model attempts to demonstrate factors that influence the level of collaboration, including participant characteristics (level of education, training experience, age), context characteristics (practice environment, type and size) and exchange characteristics (trustworthiness, relationship initiation, and role specification).

In 2012, Bradley et al. further developed the McDonough and Doucette model (2001), and the result was a conceptual model with three main stages of collaboration between GPs and community pharmacists, with level 1 being "isolation", level 2 "communication" and level 3 "collaboration". The model also describes how the three stages of collaboration are characterized by a number of factors, such as locality, service provision, trust, "knowing each other", professional roles, communication, and professional respect. Examples of PPR based on the model can be found in Doucette et al. (2005) and Zillich et al. (2004).

Organizational Theories

Although there is no consensus on whether pharmaceutical care (also called "medicines management" or "medication therapy management" in the USA and UK) is a theory, a model or a practice, there is no denying that studies of pharmaceutical care have had a tremendous impact on PPR and inspired an entire generation of pharmacists to re-evaluate and re-orientate their profession. According to Cipolle et al. (1998), pharmaceutical care (PC) is a professional model of practice that provides medication management services to patients. Cognitive pharmaceutical services, clinical pharmaceutical services, and medication review involving identifying, solving and preventing medication/drug therapy problems are concepts identical to or closely related to PC.

PC was supposed to revolutionize the way pharmacy staff deal with and counsel their patients. Three decades later, one might question whether this has now come to pass (Costa et al., 2017). Pharmaceutical care models and practices differ from country to country. For example, reimbursement for cognitive services varies across countries in Europe, Asia and the Americas. Practice-based research has blossomed in many countries, but with different emphases and challenges. Each country has perspectives of pharmaceutical care and pharmacy practice that impact the implementation and practice model of pharmaceutical care (Farris et al., 2005).

There is one aspect/issue, however, that binds all pharmaceutical care initiatives together throughout the world, namely how to implement and maintain PC in pharmacies on an organizational level. Many studies have been conducted on the facilitators and barriers involved in implementing PC in pharmacies, but there is far less literature on the explicit use of theories for implementing PC and other cognitive services. Roberts et al. (2006) investigated models and frameworks for the implementation of cognitive pharmaceutical services (CPS) in community pharmacy, and divided them into theories dealing with the individual, the internal pharmacy environment, the external pharmacy environment and business-related/financial components. The process of implementation was the focus of just half the models identified, with others focusing on specific services and often seeming to overlook the importance and complexity of the implementation process. Many relied on behavioral theories, with an assumption that changing pharmacists' knowledge, skills or attitude will automatically result in successful change, often ignoring organizational aspects of change (Roberts et al., 2006). However, since 2006 several of these broad frameworks have been utilized. One example is the Active Implementation Frameworks (AIFs), an evidence-based set of frameworks to use when attempting to put into practice any innovation of known dimensions. It consists of five core components: a usable innovation, implementation drivers, implementation stages, improvement cycles, and implementation teams (Blanchard et al., 2017). Another example is Moullin et al. (2016), which described and used the so-called Generic Implementation Framework (GIF). The GIF is an overarching, broad framework that collates and illustrates the core implementation concepts and is suitable across disciplines. It has a skeletal structure into which specific, detailed meta-frameworks, models or theories should be chosen for each concept: innovation, process, contextual, domains, factors, strategies, and evaluations.

Certainly pharmacists work within quickly changing organizations, whether they are embedded in hospital pharmacies, community pharmacies, the pharmaceutical industry, government or nongovernment organizations, or within general practices. Organizational theories (meso-level theories) are thus relevant for framing and analyzing research in this field (Scahill, 2015). As shown below, theories on organizational effectiveness, organizational change, leadership style and entrepreneurial orientation have been applied in PPR. Pharmacy practice researchers have not yet capitalized on the application of management/organizational theories to the extent they could (Scahill, 2015). In PPR especially, the theories resource-basing, double-loop-learning, organizational cognition and managing organizational knowledge could fruitfully be applied (Smith and Hitt, 2005).

With regard to organizational effectiveness theories, the Donabedian model of quality of care in particular has dominated the PPR literature (Jackson et al., 1975; Panyawuthikrai et al., 2005; Rai and Wood, 2018). This model focuses on quality of care as one indicator of high performance, with the impetus on the structures and processes shaping health services delivery and outcomes achieved.

Organizational theories have been used as the basis for describing, understanding and changing community pharmacies, but only to a minor extent. A consistent finding in articles on quality improvement in health care is that change is difficult to achieve (Grol et al., 2007), a conclusion that has also been put forward in several PPR projects, such as Sørensen and Haugbølle (2008). According to the research literature, the majority of interventions are targeted at health care professionals. However, success in achieving change may be influenced by factors other than those relating to individual professionals, and theories may help explain whether change is possible.

A Danish-Australian research cooperation resulted in several theory-based studies describing community pharmacy leadership using Borum's Theory of Organizational Change, which categorizes change strategies as rational, natural, political or open, and Social Network Theory, which helps identify and explain the relationships between key people involved in the change process (Roberts et al., 2003). The transition of a pharmacy practice from focus on dispensing to one that embraces pharmacy service delivery requires the rearrangement of resources and organizational changes. American researchers have used theories of entrepreneurial orientation (EO) and resource adequacy to describe this transition (Doucette et al., 2012). EO consists of elements such as "proactiveness," "autonomy" (decentralization), and "innovativeness". Another theoretical framework, organizational flexibility, has also been used to assess the capacity of community pharmacy to implement change programs and guide capacity-building initiatives (Feletto et al., 2011).

Leadership style theory by Bolman and Deal (2003) has also been applied in a study on the implementation of a new inhaler service in pharmacy (Kaae et al., 2011). Bolman and Deal (2003) distinguish between four mental frames when defining how leaders perceive organizations and their resulting actions. The four frames are defined as structural, human resource, political and symbolic.

Behavioral change is key to increasing the uptake of evidence into health care practice. Designing behavioral-change interventions first requires problem analysis, ideally informed by theory. Yet the large number of partly overlapping theories of behavior makes it difficult to select the most appropriate theory.

A range of theories, models, and frameworks has been proposed to understand the complexity surrounding implementation in different health-care settings, including pharmacy (Garcia-Cardenas et al., 2017). The development of health interventions is receiving increasing attention within scientific literature. In the past, interventions were often based on the ISLAGIATT principle: that is, "It seemed like a good idea at the time" (Hughes et al., 2016). However, the large number of partially overlapping theories makes it difficult to select the most appropriate and utilized theory in PPR. The need for an overarching theoretical framework of behavioral change was actually addressed in a research project in which 128 explanatory constructs from 33 theories of behavior

were identified and grouped. The resulting Theoretical Domains Framework (TDF) appears to be a helpful basis for investigating implementation problems (Francis et al., 2012). The TDF is a theoretical framework rather than a theory. It does not propose testable relationships between elements, but provides a theoretical lens through which to view the cognitive, affective, social and environmental influences on behavior. The TDF was initially developed for implementation research to identify influences on health professional behavior related to implementation of evidence-based recommendations, and has been cited in over 800 peer-reviewed publications (Atkins et al., 2017). For example, in PPR the TDF has been used to identify the relationship between barriers and facilitators to pharmacist prescribing and self-reported prescribing (Isenor et al., 2017), to investigate prescribing errors (Duncan et al., 2012), and to create a model for use in patient-centered, pharmacist-led interactions to improve medication adherence (Wiener et al., 2015).

Technology Theories

The number of services and goods for consumers in community pharmacies has grown concurrently with technological advances, resulting in an interest in research dealing with new and innovative technologies in PPR. These studies have dealt with topics ranging from what happens when a new product/therapy/service enters the pharmacy to how new organizational models are introduced in the pharmacy and their effects. The theoretical basis for these studies can be found in the field of social studies of science and health care technology assessment.

One theory that has caught the imagination of PPR has been the diffusion of innovation theory developed by Rogers (1995). The theory attempts to explain how over time, a product or an idea gains momentum and diffuses (or spreads) through a specific population or social system. This theory can be classified as a "behavioral change model" in that the end result of this diffusion is that people, as part of a particular social/organizational system, adopt a new idea, behavior, or product and thereby do something differently than previously (i.e., purchase or use a new product, acquire and perform a new behavior). The core of this adoption is that the person perceives the idea, behavior, or product as new or innovative, and in this way make diffusion possible.

According to this theory, if the organization has a positive assessment of a new innovation, it is likely to adopt it, and conversely, if the organization has a negative assessment of a new innovation, it is likely to reject it (Pronk et al., 2002).

Rogers' Diffusion of Innovations model has been used in a variety of PPR studies, such as an American study that used it to identify the associations between perceived characteristics of immunization services and backward/forward transitions in pharmacy-based immunization services (Westrick, 2009). This theory was widely used in PPR in Holland. One Dutch study used it to explore the perception of an innovation aimed at implementing patient education and the preconditions for implementing this innovation among Dutch pharmacists (Pronk et al., 2002).

Health Technology Assessment (HTA) is the comprehensive form of policy research that examines the technical, economic and social consequences of technological application. HTA is especially concerned with unintended, indirect or delayed social impacts of technology (Traulsen and Klinke, 2004). HTA has developed an arsenal of tools/methods for evaluating the pros and cons of new therapies including pharmaceuticals. Becoming aware of and subsequently using these tools in PPR can contribute to the acceptance and thereby implementation of improvements and innovation in pharmacy services (e.g. pharmaceutical care) by creating the evidence and documentation necessary to make the advantages of these services visible to a wider audience, including politicians and policymakers (Traulsen and Klinke, 2004; Simoens and Laekeman, 2005; Manfrin et al., 2018). Whereas researchers in 2004 suggested using technology assessment to put pharmaceutical care on the political agenda, almost 15 years later Manfrin et al. (2018) continue to point out the lack of HTA tools in pharmacy practice and in the collection of real world evidence in community pharmacy.

Political Science Theories

The importance of evidence derived from clinical pharmacy on high-level decision-making about pharmaceuticals has made it necessary for PPR to engage in and become more active in the policy arena using its clinical and practice-oriented knowledge base. A necessary precursor to this increased political activity is a thorough understanding of what issues are important in pharmaceutical policy, how they have been dealt with in the past, and how they can be tackled in future (Traulsen and Almarsdóttir, 2005). This requires becoming familiar with and using theories from the political sciences.

One example is the Advocacy Coalition Framework (ACF) Theory. Sabatier and Jenkins-Smith (1999) developed the ACF to describe and explain an otherwise complicated policymaking environment. One of ACF's key terms is belief systems, that is, people engage in politics to translate their beliefs into action.

According to ACF, coalitions are formed and learn from policy implementation. ACF was used in the PPR arena to design a study to analyze some of the mechanisms involved in the political process of deregulating the sale of OTC medicines in the Danish pharmacy sector. The conclusion of this study was that ACF produced results that were detailed, although not clear-cut, generating new insights about policy formation within the pharmacy sector in Denmark. The study showed that both policy ideas and technical information are independent variables that partly explain the course and outcome of the reform process (Larsen et al., 2006).

Another theory, which originates from economics and is used by sociologists, political scientists and recently in PPR, is the theory of regulatory capture. This takes place when a regulatory agency, formed to act in the public's interest, eventually acts in ways that

benefit the industry it is supposed to be regulating rather than the public. This theory has been used to look at how and to what extent this happens in the interactions between regulatory agencies such as the FDA and the EMA and the pharmaceutical industry (Abraham, 2002; Carpenter and Moss, 2014; Borup and Traulsen, 2016).

Ethics

The field of ethics (or moral philosophy) involves systematizing, defending, and recommending concepts of right and wrong behavior. Ethics deals with questions of what should be done and how we should do it. It is about making the best decisions or choices in difficult situations (Sporrong et al., 2005). In general, ethical theories are used to guide decision making and emphasize various aspects of an ethical dilemma. Guidelines are normally used in the search for the most ethically correct solution. These guidelines are based on four broad categories of ethical theory: deontology, utilitarianism, rights, and virtues.

Pharmacists are health professionals who help individuals make the best use of medications. Ethical codes, prepared and supported by pharmacists, are intended to state publicly the principles that form the fundamental basis of the roles and responsibilities of pharmacists. These principles, based on moral obligations and virtues, are established to guide pharmacists in relationships with patients, health professionals, and society.

Ethical guidelines for pharmacists are associated with several factors. Ethical codes in health care are formulated to protect the patient and the reputation of the profession as a whole, and to be attuned to the growing consciousness of professionalism among various categories of professionals (Sporrong et al., 2005).

An Australian study developed and validated a psychometric measure of cognitive moral development in professional ethics in pharmacy (the psychometric instrument Professional Ethics in Pharmacy). The theoretical foundation of the instrument was based on a hypothesized theory of cognitive moral development in professional ethics, which was integrated into a selection of scenarios pharmacists experienced in practice (Chaar, 2009).

The Future

PPR has been criticized for failing to look outward and thereby concerning itself with narrowly focused evaluations of specific pharmacy services (Almarsdóttir et al., 2014). The added challenge of diminished funding for research and the pressures on researchers to publish results has forced this field of research into "answering questions" and "finding solutions" rather than being free to do basic PPR (i.e. theory and methods development). One sure way to weaken the field is to resort to "writing reports" rather than pursuing scientific research.

Given that pharmacy practice is constantly changing and facing new external challenges, it stands to reason that research in the field must move beyond traditional pharmacy-specific problems by placing them in a context broader than how to use medicines. Some examples are: what are the current trends in pharmaceuticals, organization of work, health care sector services and effective communication with patients/clients. A broader context can be achieved by widening the scope of the research and including a societal perspective to a larger extent than today: for example, including the analysis of other health care professionals and the effects of the continuous expansion of patient power. Widening the scope of the research means simultaneously being aware of and open to adapting new theoretical approaches, which can be found in the scientific literature on public health, health services and societal and economic challenges.

It goes without saying that when considering the future of PPR, it is important to reflect about the future of pharmacy practice itself, more specifically, the community pharmacy. The following is one likely scenario based on current trends. Research conducted on each of these issues would benefit from a theory. The pharmacy of the future will offer even more patient and individual-based services other than medicine than it already does: for example, point of care testing (POCT) (measuring cholesterol, hepatitis, glucose, vitamin D, etc.), vaccination services (already provided by more than 320,000 trained pharmacists in the USA today) and the like. Another service that will expand in future and is already available in some countries is prescription renewal and the prescribing role of the pharmacist. Theories on the pharmacist's clinical judgments and decision making will be beneficial in studying the pharmacist's point-of-care testing and prescribing activities. Previous theoretical models of GP's clinical judgments and prescribing decisions have been described in a review by Murshid and Mohaidin (2017). The review includes a suggestion for a value conceptual model that explains the theoretical linkages existing between marketing efforts, patient and pharmacist, and the physician's decision to prescribe the drugs. More specifically, the review identifies and uses several valuable perspectives such as the "persuasion theory—elaboration likelihood model", "stimuli–response marketing model", "agency theory", "theory of planned behavior", and "social power theory", in developing an innovative conceptual paradigm (Murshid and Mohaidin, 2017). Theories on (and training in) clinical decision making is needed (Duffull et al., 2018).

A closer inter-professional collaboration will increasingly be necessary to coordinate transitional care for patients transitioning from hospital to primary care. This requires pharmacy staff to work even closer with other health care professionals. A meta-analysis of pharmacists located in general practice has favored pharmacist intervention, with significant improvements in patients' blood pressure, glycosylated hemoglobin, cholesterol, etc. in intervention patients compared to control patients. Thus pharmacists located in general practice clinics deliver a range of interventions with favorable results in various areas of chronic disease management and quality use of medicines (Tan et al., 2014). Theories on inter-professional cooperation will increase the quality of research carried out in this area in future.

The ways in which medications are prescribed, dispensed and administered are rapidly changing in pharmacies. Health information technology is central to this transformation and includes a broad array of tools used in managing and sharing patient information electronically, replacing paper records and traditional phone and fax methods. Theories are needed on how to interpret, share and inform about data from apps etc.—and to whom.

New advances in medicine production technology are contributing to a whole new age of therapies, such as 3D printing of medicines and cell therapies. This could mean that medications/treatments will no longer depend on large batch productions from industry, but will provide a niche for individualized treatment originating once again from the local pharmacy. Last but not least, the pharmacy of the future will be green and sustainable through the reduction of plastic and medicine waste, and new methods of protecting the environment from pharmaceutical waste (Nørgaard, 2018). Theories and methods can and should be adapted from the vast literature produced in recent years dealing with environmental issues.

In 1968, Garrett Hardin authored a paper entitled "The Tragedy of the Commons", an economic theory describing how people often use natural resources to their advantage without considering the good of a group or society as a whole (Kümmerer, 2010). When a number of individuals consider only their own welfare in this manner, it leads to negative outcomes for everyone, as the natural resource becomes depleted. This theory can be applied in future research concerned with how we can solve the huge problems associated with the growing antimicrobial resistance in the world, as well as being useful for research on how pharmacies in the future can act responsibly in an effort to reduce the environmental impact of the life cycle of a pharmaceutical in society.

One thing that is certain is the enormous impact on pharmacy practice of the unprecedented rapid increase in technology and automation often referred to as the Fourth Revolution. According to a recent World Economic Forum report (WEF, 2016), more than one-third (35%) of the skills considered important in today's workforce will change. By the year 2020 the Fourth Revolution will have introduced more advanced artificial intelligence, biotechnology and genomics, all of which will transform the pharmaceutical industry, and pharmacy practice including the work and careers of pharmacists. The skills that are foreseen as being important include complex problem-solving, critical thinking, people management and the ability to coordinate others (WEF, 2016). The report also points out that negotiation skills and flexibility, skills high on the list in 2015, will be taken over by machines capable of processing masses of data. Pharmacy practice research must be proactive if it is to stay abreast of these scientific, societal, technological, and organizational trends. If PPR hopes to steer practice and avoid the potential negative effects of these developments, it needs a strategy, preferably one based on specific theoretical grounds. Some of the key drivers of change that will influence the future of pharmacy practice include population demographics, technology (informatics and health/pharmaceutical/device technologies), pharmacy as both institution and profession, consumers of health care services and new research capabilities building on technological changes (Babar and Almarsdóttir, 2015).

eHealth innovations have been identified as enablers of transition from traditional institutional-centered health care to a more patient-centered approach. To enhance the contribution of community pharmacies to the effectiveness and efficiency of health systems, community pharmacy should be ready to play an even more active role in primary health care teams in future. Therefore the use of eHealth solutions in the community pharmacy should be supported, and national medicine management eHealth services and systems can act as a catalyst for the redesign of traditional health services and facilitate the implementation and development of innovative dispensing practices, pharmaceutical care and new pharmacy services. Theories on how to use e-health solutions for patient care are thus needed.

In conclusion, continually renewing PPR requires the willingness to collaborate with social scientists as well as to engage in and become familiar with theories from the social and behavioral sciences. Be bold. Dare to use theories that criticize and challenge the status quo. The problem-solving approach to research is fine for making adjustments in the daily running of pharmacies, but research that strives to innovate requires studies of pharmaceuticals, pharmacies and pharmacists in a broader societal context. A more systematic use of existing theories, particularly for planning and evaluating clinical practice, also within pharmacy, will provide a very useful knowledge base for developing strategies for the future of pharmacy (Grol et al., 2007). Theories will provide a framework for understanding the current and future trends and drivers of change, which in turn will ultimately provide a basis for new and innovative strategies for the future of pharmacy practice and the pharmacy profession.

Principles, Paradigms, and Application of Qualitative Research in Pharmacy Practice

Banan Mukhalalati, Ahmed Awaisu, Qatar University, Doha, Qatar

Learning Objectives

Upon completing the chapter, the reader should be able to:

1. Discuss the value of qualitative research in deeply explaining investigated phenomena in pharmacy practice.
2. Describe the interpretative frameworks and the philosophical assumptions in conducting qualitative research.
3. Discuss the classification of qualitative research based on the research question and the investigated phenomenon.
4. Describe the most common data collection and data analysis methods used in conducting qualitative research.
5. Discuss the trustworthiness criteria and measures used in qualitative research to ensure quality and rigor.

Qualitative Research Designs in Pharmacy Practice and the Limit of the Evidence

The use of qualitative research methods in health services research in general and pharmacy practice research in particular has been increasing over the past years (Rosenthal, 2016; Tonna and Edwards, 2013). The place and immense value of this approach in pharmacy practice research cannot be overemphasized (Austin and Sutton, 2014). A quick search into the published pharmacy practice literature will confirm that there are several published studies utilizing qualitative methods. These studies have undoubtedly added to the existing body of evidence globally and several might have ultimately informed policy and practice changes in certain countries (Tonna and Edwards, 2013).

In a letter to the editor, Gardner described the immense value of qualitative research to pharmacy practice (Gardner, 2016). The commentator felt that a recent qualitative investigation conducted by Gregory et al. on how community pharmacists make decisions represented an exceptional scholarship in the research question, methods, analysis, and writing (Gregory et al., 2016). Gardner believed that the article has inspired him as a researcher, advanced his knowledge, and would influence his teaching and contributions as a researcher and educator. Therefore, these type of studies may create strong impressions and enthusiasm in other pharmacy practice scholars within the profession. Nevertheless, an examination of a sample of these studies would clearly show that many pharmacy practice researchers utilizing qualitative methods do not report important aspects of the methodology that should have been reported (Lau and Traulsen, 2017) and might have even misunderstood some important methodological aspects. For instance, many researchers have described "interviews" and "focus groups" as their methodology or approach to inquiry in qualitative research. Here, we are not referring to the guidelines for reporting and evaluating qualitative research, but certain fundamental methodological issues that should be known by all qualitative researchers.

Furthermore, several articles in the published pharmacy literature and book chapters have given some overview about qualitative research method in pharmacy practice (Austin and Sutton, 2014; Kaae and Traulsen, 2015). In recent years, pharmacy practice journals such as the International Journal of Clinical Pharmacy (Chen and Hughes, 2016), Currents in Pharmacy Teaching and Learning (Rosenthal, 2016), Research in Social and Administrative Pharmacy (Lau and Traulsen, 2017), and the Canadian Pharmacy Journal (Austin and Sutton, 2014) have published series, special issues, or a part of these, to promote knowledge and utility of qualitative methods in pharmacy research and education. Some of these important resources are comprehensive in nature and cover most important components related to qualitative research that a scholar should know.

However, there are several that are lacking in terms of their inclusivity, and omit important aspects such as interpretative frameworks and philosophical assumptions underpinning qualitative research. Furthermore, attempts have been made by scholars to provide novice and experienced researchers with the nitty gritty of conducting pharmacy practice research using qualitative approach through training workshops or professional development seminars. Our personal experiences and those of colleagues have proven that many teachers of this important methodology do not comprehensively cover several important aspects, even in advance qualitative research methodology courses. In an effort to bridge these gaps, this chapter is primarily intended to provide an overview of philosophical paradigms, approaches to inquiry, quality perspectives, and other fundamental elements of qualitative research as it applies to pharmacy practice research. We made every effort to minimize duplication with other related chapters and ensure that the content would be complementary.

Qualitative research has its origin in the social science disciplines such as sociology, psychology, and anthropology, and has struggled to gain credibility in the health science disciplines, often because of concerns about its robustness and perceived differences in structure for presenting the results (Tonna and Edwards, 2013). For example, the viewpoint, methods, and presentation of findings may vary among a sociologist, an anthropologist, a psychologist, and a pharmacists for a similar research question that requires a qualitative study design. Qualitative research within the health science disciplines has developed as a means to gain an in-depth understanding of human behavior (e.g., patients' needs and preferences), as well as to discover the underlying reasons, attitudes, and motivations that govern such behavior (Kaae and Traulsen, 2015). It provides a deep explanation of the investigated phenomena, settings and procedures that clarify the link between all factors, by revealing unexpected information (Ping, 2008). This description cannot be attained through quantitative research approaches, as they describe phenomena in discrete means (Bryman, 2015; Sofaer, 1999) that might not be appropriate for the research questions and investigated problem (Silverman, 2013).

In pharmacy practice research, qualitative research is used to identify and improve current practices and beliefs by understanding patients' and health-care providers' perspectives about medicine and treatment, which ultimately strengthen the research impact (Kaae and Traulsen, 2015; McLaughlin et al., 2016). However, pharmacy academics, researchers, and practitioners need to develop a certain level of expertise and confidence in conducting qualitative research, which can be achieved by carefully planning and implementing appropriate professional development opportunities related to qualitative research methodology (Behar-Horenstein et al., 2018). Most pharmacy practice textbooks and published studies do not present important philosophical paradigms, approaches to inquiry (methodologies), and quality perspectives related to qualitative research. In fact, most published research studies and textbooks in pharmacy practice assume that the methods of data collection (e.g., focus group discussions or one-on-one interviews) are synonymous with the qualitative research designs or research methodologies. Companion chapters related to qualitative research in this Encyclopedia have extensively discussed topics related to data collection methods, sampling and recruitment of participants, conducting data collection sessions, data analysis methods, ethical issues, and reporting and writing qualitative research. Furthermore, there are chapters exclusively dedicated to some of the approaches to enquiry such as ethnography and phenomenology.

This chapter discusses significant foundational elements for conducting high-quality qualitative research in pharmacy practice. It is structured in six sections. In Section Qualitative Research Designs in Pharmacy Practice and the Limit of the Evidence, the significance of qualitative research in pharmacy practice and some contentious issues surrounding its application in pharmacy are discussed. In Section Interpretative Frameworks and Philosophical Assumptions, the interpretative frameworks and philosophical assumptions underpinning qualitative research are described, so that the qualitative researcher can justify the research methodology and research methods selected. In Section Approaches to Inquiry (Methodology) and Case Applications, the five approaches to inquiry (methodology) are explained, giving practical case examples and applications from the pharmacy practice literature.

In Section Methods in Qualitative Research, a brief overview of the most commonly used data collection and data analysis methods used in health science research in general and in pharmacy practice research in particular is provided. Detailed information

about data collection methods (e.g., observations, documents, individual and group interviews, and Delphi technique), sampling and recruitment of participants, conducting data collection sessions, and data analysis methods (e.g., content analysis, thematic analysis, framework analysis, discourse analysis, and interpretative phenomenological analysis) are discussed in the companion chapter. In Section Quality Perspectives in Qualitative Research, the importance of ensuring rigor in conducting qualitative research is stressed, indicating various measures to ensure quality and to achieve trustworthiness criteria in qualitative research. Finally, in Section Conclusion and Take-home Messages, key conclusion remarks and take-home messages are provided.

Interpretative Frameworks and Philosophical Assumptions

Discussions on research philosophical orientations are usually found in the social science literature, in which the research questions are linked first with a pertinent research philosophy and methodology, before selecting a research method. Nursing and health sciences disciplines have also considered philosophical issues underpinning research because scientific philosophy cannot fully examine human perceptions and behaviors (Winit-Watjana, 2016). However, this research philosophy has not been well developed and expressed in pharmacy practice research (Gray et al., 1999; Winit-Watjana, 2016). This section discusses various philosophical orientations and guiding principles of qualitative research in pharmacy practice because they are the first few decisions and steps in conducting qualitative research.

Interpretative Frameworks

Qualitative research should start with the choice of a problem to be studied, an interpretative framework that guides the study, and a suitable approach to enquiry for the research question(s) (Creswell, 2013).

Interpretative frameworks are the conceptual structures for the researcher's comprehension, which form the researcher's reasoning and views of truth and knowledge (Babbie, 2015). Cohen et al. (2013) defined these frameworks as research traditions, selected according to the research purpose. Interpretative frameworks have also been referred to as social research strategies (Bryman, 2015).

Different scholars, researchers, and academics have categorized qualitative research paradigms or interpretative frameworks differently (Winit-Watjana, 2016). For example, Creswell categorized interpretative frameworks as social constructivism, postpositivism, transformative, feminist, critical frameworks and disabilities theories, postmodern, and pragmatism frameworks (Creswell, 2013). On the other hand, Cohen et al. called interpretative frameworks research traditions and categorized them into positivism, interpretive, critical theory, complexity theory, and feminist research (Cohen et al., 2013). Furthermore, Bryman categorized them either as ontological considerations, which comprise objectivism, and constructionism, or as epistemological considerations, which comprise positivism, realism, and interpretivism (Bryman, 2015). Finally, Silverman suggested that interpretative frameworks represent either naturalism or constructionism (Silverman, 2013).

The following are examples of interpretative framework categories that are used in health services and pharmacy practice research based on the categorizations of Creswell (2013) and Winit-Watjana (2016). Case applications about the use of these interpretative frameworks in pharmacy practice research are provided in **Box 1**, the majority of which are adopted from the work of Winit-Watjana (2016).

Box 1 Case applications about the use of interpretative frameworks in pharmacy practice research

The postpositivism framework was used in pharmacy practice research to:

1. assess patients' experiences in receiving their influenza vaccination in a community pharmacy by conducting a survey with telephone interviews (Poulose et al., 2015).
2. describe the doses and routes of administration of the most frequently used drugs at admission and at day of death in a palliative care center by conducting quantitative content analysis (Masman et al., 2015).

The social constructivism framework was used in pharmacy practice research to:

1. determine the issues that patients taking long-term medicines consider affect their day-to-day lives, including quality of life, by conducting face-to-face interviews (Krska et al., 2013).
2. examine how elderly patients are defined and considered within Australian clinical guidelines for the use of pharmacotherapy by conducting integrative reviews (Singh and Bajorek, 2014).
3. examine the process of adherence to oral chemotherapy in Hispanic and Caucasian children and adolescents with acute lymphoblastic leukemia by conducting semi-structured interviews with patients, parents, and caregivers (Landier et al., 2011).

The pragmatism framework was used in pharmacy practice research to:

1. develop Patient-Reported Outcomes Measure of Pharmaceutical Therapy for Quality of Life (PROMPT-QoL) and evaluate its content validity and preliminary psychometrics by conducting a mixed methods study (Sakthong et al., 2015).
2. determine communication strategies associated with smoking cessation in the National Health Service community pharmacy Stop Smoking program, by conducting a mixed methods study (Rivas et al., 2017).

1. *The positivism (or empiricism) framework* focuses on exploring the objective reality, which is controlled by the researcher, by conducting theory-based research.
2. *The postpositivism (or realism, postempiricism) framework* employs a scientific approach to research, with cause and effect and a priori theories orientation.
3. *The social constructivism (or interpretivism, relativism) framework* opposes the postpositivism framework and focuses on examining and describing the meanings of the world in a complex and subjective manner, emphasizing processes and social and historical contexts, while recognizing the effect of researchers' values and experiences on the research conduction.
4. *The pragmatism framework* accepts multiple realities and focuses on offering practical solutions to the investigated problem.
5. *Transformative, feminist, critical frameworks, and disabilities theories* focus on developing societies or investigating marginalized clusters or examining social patterns, liberty and control, for the purpose of modifying and minimizing these phenomena and associated problems.
6. *The postmodern framework* focuses on the race, class, or gender of participants, while highlighting the influence of variable discourses.

Philosophical Assumptions

Philosophical assumptions are theories and perspectives about ontology, epistemology, axiology and methodology that underpin the interpretative frameworks selected by a qualitative researcher. These philosophical assumptions facilitate the comprehension of the universe, which is enlightened through perspectives and interpretations (Cohen et al., 2013). Some literature refers to these assumptions as **paradigms**, broadly conceived research methodologies, epistemologies, ontologies, and alternative knowledge claims. The choice of philosophical assumptions is important for numerous reasons. First, they influence the selection of the interpretative framework or theories that lead a research process. Second, those assumptions are informed by the researcher's experiences and background and are strengthened by the research activities that researcher conducts. Lastly, the researcher's philosophical assumptions and interpretative frameworks should be clear to the research reviewers, which enables transparency and helps in resolving differences related to diverse interpretative frameworks.

There are numerous means to explain and categorize the philosophical assumptions that are folded within the interpretative framework. For example, Bryman (2015) categorized them as epistemological considerations and ontological considerations, while Cohen et al. (2013) indicated that ontological, epistemological, and methodological considerations influence each other. However, Creswell and Winit-Watjana categorized philosophical assumptions as ontological, epistemological, axiological, and methodological assumptions (Creswell, 2013; Winit-Watjana, 2016) as follows:

1. *Ontological assumptions:* Define the nature of reality, being or existence.
2. *Epistemological assumptions:* Clarify the knowledge of reality, that is, what comprises an acceptable knowledge.
3. *Axiological assumptions:* Explain the role and influence of the researcher's values on knowledge.
4. *Methodological assumptions:* Identify approaches to inquiry strategy or plan of action use to know the reality based on the researcher's reasoning.

Table 1 provides a clarification of how positivism, postpositivism, social constructivism, and pragmatic interpretative frameworks are distinguished because of their underpinning philosophical assumptions. The table is adapted and modified from the

Table 1 Interpretative frameworks and their underpinning philosophical assumptions

Philosophical assumptions	*Interpretative framework*			
	Positivism	*Postpositivism*	*Social constructivism*	*Pragmatism*
Ontological assumptions	A single, objective and external reality exists with universal laws used to describe it	A single reality exists beyond ourselves, but it is known only imperfectly and probabilistically	Multiple realities are constructed through experiences and interactions	Reality is what is useful, practical and works well
Epistemological assumptions	Reality in the form of facts can be measured using reliable and valid tools	Reality can only be approximated through research and statistics	Reality is constructed between researchers and participants	Reality is known through objective and subjective evidence
Axiological assumptions	Researchers are independent of the data with an objective stance and distance	Researchers' biases need to be controlled and not expressed	Individuals' values are honored and negotiated	Values are discussed reflecting knowledge obtained from researchers and participants
Methodological assumptions	Quantitative or scientific and predetermined methods, followed by scientific style of writing	Use deductive methods, followed by scientific style of writing	Use inductive methods, followed by literary style of writing	Use qualitative and quantitative approaches to data collection and analysis

works of Creswell (2013) and Winit-Watjana (2016), and it does not include transformative, feminist, critical frameworks, and disabilities theories or postmodern frameworks because they are not usually utilized in pharmacy practice research (Gray et al., 1999; Winit-Watjana, 2016).

Approaches to Inquiry (Methodology) and Case Applications

In qualitative research, it is important to select an approach to inquiry to attain methodological congruence. Methodological congruence implies that research questions, aims, objectives, and methods are coherent and compatible (Creswell, 2013). The five approaches to qualitative research inquiry as identified by Creswell (2013) are described below:

Narrative Research

Narrative research describes participants' written and spoken stories about their experiences with a phenomenon being investigated. Narrative research considers the phenomenon's series of events and actions that are chronologically connected, highlighting turning points in the story, as it develops through interaction and collaboration between the researchers and the participants. The narrative could be a life story of an individual, or a story of an illness, or a story of a specific phenomenon (Anderson and Kirkpatrick, 2016; Creswell, 2013; Czarniawska, 2004). Case applications about the use of narrative research in pharmacy practice are provided in **Box 2**.

Phenomenological Research

Phenomenological research describes the essence of participants' common experiences of a phenomenon so that the description is a universal essence rather than an individual experience. This description focuses on what participants experienced and how they experienced it, while bracketing the researcher out of the research, by having him/her disclosing his/her personal experience with the examined phenomenon. The described phenomenon could be a feeling, such as anger, or an experience, such as undergoing a surgery (Creswell, 2013; Giorgi, 1997; Moustakas, 1994). **Box 3** provides some case applications about the use of phenomenological research in pharmacy practice.

Grounded Theory Research

Grounded theory research aims to generate or discover a theory grounded in participants' data that conceptually explains a social phenomenon, such as human motivation or patterns of behavior, through a systematic methodology, rather than only describes the social phenomenon. Grounded theory has been developed from being too structured to becoming more constructivist-driven by identifying key explanatory constructs of the phenomenon and the relationships between those constructs (Creswell, 2013; Strauss and Corbin, 1990; Woods et al., 2016). Human phenomena could involve social processes or actions or interactions, such as dealing with death or quality of care or chronic illness. Case applications about the use of grounded theory research in pharmacy practice are provided in **Box 4**.

Box 2 Case applications about narrative research

1. Narrative research was used to examine patients' experiences of taking antidepressants by placing the meanings that patients assign to their stories at the heart of the study process (Anderson and Kirkpatrick, 2016).
2. Researchers made a thematic overview of moral dilemmas experienced by community pharmacists in daily pharmacy practice. The participants wrote a narrative about a moral dilemma they had experienced in clinical practice (Kruijtbosch et al., 2018).

Box 3 Case applications about phenomenological research

1. The phenomenological approach to enquiry has been selected to explore the essence of experiences of African American type 2 diabetes patients with adherence to diabetes medications and their perceived solutions to nonadherence based on these experiences (Shiyanbola et al., 2018).
2. Todd et al. utilized the phenomenological approach to explore the lived experience of patients, caregivers, and health-care professionals in the context of medication use in life-limiting illness (Todd et al., 2016).
3. Shoemaker et al. evaluated patients' medication experiences using unstructured interviews through a phenomenological approach (Shoemaker and De Oliveira, 2008).

Box 4 Case applications about grounded theory research

1. Grounded theory research was used to create a theoretical framework model for the process of adherence to oral chemotherapy in children with acute lymphoblastic leukemia (Landier et al., 2011). However, Woods et al. (2016) argued that there is generally limited literature engaging with theories based on grounded theory in pharmacy practice.
2. Jonsson et al. explored how individuals with medication overuse headache use medications and other strategies to manage headaches in their daily lives and their thoughts about their own use of acute medications. In this study, the data collection and analysis were conducted according to grounded theory methodology (Jonsson et al., 2013).

Box 5 Case applications about ethnographic research

1. Ethnographic research was used to examine interdisciplinary medication decision-making by pharmacists in pediatric hospital settings (Rosenfeld et al., 2017).
2. Rivas et al. (2017) used the focused ethnography approach to explore counseling strategies used in consultations between pharmacy Stop Smoking advisers and smokers. Their aim was to use the findings to develop an intervention intended to improve both service uptake and quit rates in the community pharmacy Stop Smoking program (Rivas et al., 2017).

Box 6 Case applications about case study research

1. Case study research has been used to explore the perceptions of health-care professionals about the provision of clinical pharmacy services in the public health sector in Mexico (de León-Castañeda et al., 2018).
2. Case study research has been used to examine the disconnect between the communities of practice (CoP) learning theory and the educational practices in the Doctor of Pharmacy program at Qatar University (Mukhalalati, 2016).
3. Ryan et al. (2018) provided a descriptive report of stakeholders' experiences and outline their views on the practicalities of setting up and maintaining pharmacy services in general practice in the UK (Ryan et al., 2018).

Ethnographic Research

Ethnographic research involves describing and interpreting the culture of a group by describing the shared patterns of values, behaviors, and beliefs of culture-sharing participants who are located in the same place or who interact frequently. An ethnographic approach is usually conducted in a natural setting through extensive fieldwork and participant observations so that the researcher is immersed in close interactions with the culture of the participant. This immersion enhances a deeper understanding of participants' perspectives, behaviors and actions (Creswell, 2013; Harris, 1968; Rosenfeld et al., 2017). Ethnographic research could focus on participants who share a primitive culture or on participants who have common theoretical orientations, such as marginalized ethnic groups. **Box 5** provides case applications about the use of ethnographic research in pharmacy practice.

Case Study Research

Case study research provides an in-depth examination and understanding of a real-life contemporary bounded system or a particular phenomenon that researchers cannot change over time, to illustrate the significance of another general topic. Case study research most commonly aims to answer why, what, and how research questions, which are explanatory and descriptive rather than exploratory, through multiple data collection methods. Case study research usually ends with the development of a case study-developed theory, which facilitates the understanding of complex interrelated factors that influence the investigated phenomenon. The development of a theory is specifically significant to research in health science because it enhances its rigor. Based on the research question, examined phenomena, and context, the researcher could decide whether it is better to conduct a single case study to understand a phenomenon or multiple case studies (Baker, 2011; Baxter and Jack, 2008; Creswell, 2013; de León-Castañeda et al., 2018; Nisbet and Watt, 1984; Yin, 2014). Case applications about the use of case study research in pharmacy practice and pharmacy education are provided in **Box 6**.

Table 2 summarizes the differences between the characteristics of the five qualitative approaches to inquiry in terms of focus, unit of analysis, and data collection and analysis tools. The table is adapted and modified from the work of Creswell (2013).

Methods in Qualitative Research

Data Collection Methods

Data collection methods can be categorized into five categories: (1) observation, (2) documents, (3) individual interviews, (4) focus groups, (5) audio visual materials, and (6) emails, chat rooms, weblogs, life journals and instant messaging

Table 2 Characteristics of the five qualitative approaches to inquiry

Qualitative approach	*Characteristic*			
	Focus	*Unit of analysis*	*Data collection tools*	*Data analysis tools*
Narrative research	Explores the stories of individuals about their experiences	One or more individual	Primarily interviews and documents	Retelling stories and developing themes using chronology
Phenomenology	Understands the essence of the experience with a phenomenon	Several individuals who have shared the experience	Primarily interviews, but documents and observation are also used	Analyzing data of significant statements about the description of the "essence"
Grounded theory	Develops a theory grounded in data from participants	A process, an action, or an interaction involving many individuals	Primarily interviews with more than 20 participants	Analyzing data through open, axial and selective coding
Ethnography	Describes and interprets a culture-sharing group	Several individuals who share the same culture and values	Primarily observations, interviews and extended fieldwork	Analyzing data by describing themes about a culture-sharing group
Case study	Develops an in-depth description of a case or of multiple cases	An event, a program, an activity or more than one individual	Multiple: interviews, observations and documents	Analyzing data by describing themes of the case and cross-case

(Creswell, 2013). The most commonly used data collection methods in health science research, including pharmacy practice, are discussed below.

Documents

Documents support, tap, and offer explanations of the argument developed from other data collection tools (Hanson et al., 2011; Yin, 2014).

Individual Interviews

Semistructured individual interviews are focused, guided, open-ended, and flexible discussions (Cohen et al., 2013; Crabtree and Miller, 1999; Nunkoosing, 2005; Sofaer, 1999).

Focus Groups

A focus group is an organized discussion about a research topic with a group of participants to gain their joint perspectives (Gibbs, 2012; Hanson et al., 2011; Morgan, 1997).

Data Analysis Methods

Data analysis comprises several fundamental steps that involve continuous revisions, such as reading the transcribed text, arranging and preparing data, coding, summarizing the codes into themes, and presenting the analyzed data as results (Cohen et al., 2013), as illustrated in **Fig. 1**. The most commonly used data analysis methods in health science research, including pharmacy practice, are discussed below.

Thematic Analysis

Thematic analysis is the primary data analysis method that researchers should apply because of its flexibility and compatibility with various interpretative frameworks (Braun and Clarke, 2006; Castleberry and Nolen, 2018).

Content Analysis

Content analysis is a research method that comprises systematic coding followed by quantification of the analyzed data in a logical and unbiased way (Berelson, 1952; Vaismoradi et al., 2013).

Discourse Analysis

Discourse analysis emphasizes the core format and the structure of texts or meanings to examine the assumptions, rules, and concealed aspirations (Brown and Yule, 1983; Gee, 2004).

Quality Perspectives in Qualitative Research

Qualitative research validation helps researchers to conduct quality research. This involves ensuring the rigor of the data collection, management, and analysis methods, by utilizing validation approaches. Approaches to ensuring the quality of qualitative research

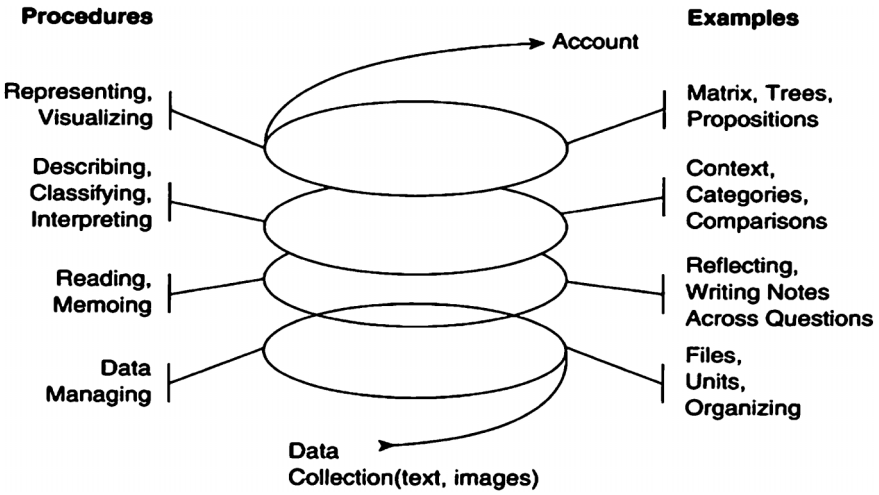

Figure 1 Data analysis spiral. *Source: Creswell, J.W., 2013. Qualitative Inquiry and Research Design: Choosing Among Five Approaches. Sage., p. 183*

are either the same as approaches usually used to ensure the quality of experimental or experiential research, such as internal, external, and construct validity, and reliability (Yin, 2014), or internal validity, external validity, reliability and objectivity (LeCompte and Goetz, 1982), or they are different from approaches used in experimental or experiential research by using qualitative terms such as the trustworthiness criteria, including credibility, conformability, transferability, and dependability (Lincoln and Guba, 1985), or the structural corroboration, consensual validation, referential adequacy, and ironic validity (Eisner, 2017).

In healthcare-related qualitative research, the use of reliability, validity, and generalizability to assess quality should be operationalized carefully because of differences in the methods and in the nature of knowledge produced by conducting qualitative research (Pope et al., 2000). However, while maintaining the efforts for identifying specific operational quality criteria for judging qualitative research in health sciences, it is important to avoid rigidity in defining these criteria and to give the researcher the flexibility in selecting the suitable criteria, based on the research field, goals, and specification (Santiago-Delefosse et al., 2016).

In pharmacy practice research, Hadi and Closs argued that the "quality in qualitative research" topic has not been discussed extensively in the literature compared to other health care disciplines (Hadi and Closs, 2016), and therefore, suggested using at least two trustworthiness strategies to ensure the quality and rigor of qualitative study in the clinical pharmacy discipline. These strategies are categorized under (Lincoln and Guba, 1985) trustworthiness criteria for ensuring quality in qualitative research, which are explained in the following sections.

Trustworthiness Criteria for Ensuring Quality in Qualitative Research

The approach of Lincoln and Guba (1985) to evaluate the quality of qualitative research follows a naturalistic perspective, which is equal to that used in social sciences and quantitative research and includes internal and external validation, reliability and objectivity. The naturalistic perspective to quality proposes the following trustworthiness criteria and approaches (Lincoln and Guba, 1985).

Credibility

This criterion resembles internal and construct validity in social sciences and quantitative research. Applying credibility measures aims to ensure that the results are true and increases the possibility that the conclusions are credible (Cohen and Crabtree, 2008). Credibility can be ensured by applying several measures, including (1) triangulation of data types and sources so that the phenomena is studied from several views, (2) peer review process by other researchers, (3) member checking step, which allows sharing the transcripts and or results with research participants to check that they reflect their actual views, (4) implementation of appropriate data analysis methods, and (5) conduction of reflexivity analysis in order to disclose the researcher's biases and influences in research methods and findings (Lincoln and Guba, 1985).

Dependability

This criterion resembles reliability in social sciences and quantitative research. Applying dependability measures aims to indicate that the research results are repeatable and consistent (Cohen and Crabtree, 2008) and to ensure that the conceptualization of the research, the collection and analysis of data, and the interpretation and reporting of the results are correct (Krefting, 1991). The dependability criterion is achieved by applying several measures, such as (1) collecting data with more than one method so that limitations in one method are balanced by the strengths of other methods, (2) fully describing the research methodology, (3) conducting peer review, (4) maintaining a database of the research that is comprised of all research records and procedures and that

acts as an "audit trail, and (5) conducting intracoder and intercoder reliability testing, which involves independent coding, analysis, and interpretation of the data by the same researcher (intra) or by another researcher (inter) and then comparing the results (Lincoln and Guba, 1985).

Confirmability

The confirmability criterion is similar to the objectivity in social sciences and quantitative research. It aims to confirm the neutrality in interpretation by ensuring that the perspectives of participants, rather than the bias of researchers, influence the results, which allows the findings and conclusions to be supported by other researchers. This criterion can be established by applying the following measures: (1) audit strategy, which requires the researcher to record and maintain all research-related activities and documents, so that an independent researcher can examine the evidence of the results in order to reach similar findings, given the same research context (Krefting, 1991), (2) data triangulation, so that more than one set of evidence is available to support the research findings, (3) oversight of the research activities by senior or peer researchers, (4) describing the research procedures and methods so that they can be followed by other researchers, and (5) conducting a reflexivity analysis (Lincoln and Guba, 1985).

Transferability

This criterion resembles external validity in the social sciences and quantitative research. Transferability involves identifying the contexts and fields to which the study results can be generalized (Yin, 2014) and indicating whether the study conclusions can be applied in similar settings and contexts (Lincoln and Guba, 1985). Hence, comprehensive and rich descriptions of the research context and participants, as well as credible interpretation of the data should be provided. The transferability criterion can be achieved by applying several measures, such as (1) recording and maintaining research-related information and activities, (2) member checking, (3) comprehensive presentation of data interpretation and discussion, and (4) writing up the research (Krefting, 1991; Tuckett, 2005).

Reflexivity in Qualitative Research

In qualitative research, researchers have two roles, as investigators and as participants. Hence, researchers have to position themselves correctly during all research phases and to reveal, evaluate, and reflect about the influences and biases that they can possibly bring to the research process (Creswell, 2013). Researcher influence can be due several factors, such as: gender, class, socioeconomic status, history, perspectives, and experiences (Yin, 2014). Reflexivity can be achieved by applying several measures, such as (1) keeping a research diary, which includes three kinds of information: (a) day-to-day activities and schedules, (b) issues associated with data collection and analysis, and (c) ideas, insights and views generated by interaction with respondents and during results interpretation (Krefting, 1991; Lincoln and Guba, 1985); (2) explaining the researcher's opinion, feelings, and experience with the phenomenon in question; and (3) explaining the influence of this experience on data collection and analysis, on findings interpretation, and on writing up the research (Creswell, 2013).

Conclusion and Take-Home Messages

Qualitative research methodologies have become increasingly recognized and popular in pharmacy practice research. The approach is now frequently used to investigate medication use behaviors of patients, health-care professionals, and caregivers. Qualitative research aims to answer the "why" and "how" questions and to identify and develop current practices by providing a complete and detailed description of the attitudes, values, and perceptions underlying these practices. For the potential of qualitative research to be fully realized and appropriately utilized in pharmacy practice, appropriate considerations of important methodological issues surrounding qualitative research are warranted. With that in mind, qualitative researchers should be well-oriented and well-trained on qualitative research paradigms, philosophical assumptions, methods, and approaches to ensure rigor before conducting qualitative research. This training will ensure that researchers conduct high quality qualitative pharmacy research, while avoiding researcher's personal biases and idiosyncrasies, leading to valuable improvements in pharmacy practice.

Medicines Management: The Core of Pharmacy Practice

Asam Latif, The University of Nottingham, Queen's Medical Centre, Nottingham, United Kingdom

Introduction

The term "responsible use of medicines" has been used to describe how medicines ought to be used and implies that the "activities, capabilities, and existing resources of health system stakeholders are aligned to ensure patients receive the right medicines at the right time, use them appropriately, and benefit from them" (IMS Institute for Healthcare Informatics, 2012, p. 12). However, despite their benefits, a significant body of evidence suggests medicines are failing to reach their full potential and that the gains are not always capitalized upon. In the United Kingdom (UK), as well as internationally, the profession of pharmacy is increasingly being called upon to better manage medicines. Services are being reappraised and reconfigured to support patients' medicine-taking and to make better use of the pharmacist's skills.

This chapter is divided into four sections. The first considers the broad question "*what is medicines management*?" Following some examples of definitions used to describe the term, we briefly look at where the philosophy of medicines management had emerged from, the synonymous terms used in other countries and the scope of activities that fall within medicines management. In Section 2, we explore the reasons underpinning the medicines management agenda and why this is increasingly being perceived as an important part of healthcare. We draw attention to three "drivers," namely a changing demographic, policy motivations, and lastly pharmacy's professional ambitions to and role extension. In Section 3, we touch on a broad range of pharmacists' medicine management activities within the different sectors of the profession and in the last section we comment on future medicines management opportunities and draw some overall conclusions.

What Is Medicines Management?

In this section we start by reviewing the more common definitions of medicines management. We outline and discuss associated terms and finally outline the scope of activities that falls within medicines management.

Common Definitions

Medicines management is a complex process involving patients and professionals and encompasses the entire way medicines are used. Effective medicines management ensures patients receive the best from their pharmacotherapy, underpinned by the cost-effectiveness of treatment for the best possible outcomes. The process incorporates the ways medicines are selected, procured, delivered, prescribed, administered, and reviewed. In the literature, multiple definitions exist to describe "medicines management." Earlier definitions sought to describe the broad range of activities that encompass medicines management, for example:

> Medicines management . . . encompasses the entire way that medicines are selected, procured, delivered, prescribed, administered and reviewed to optimise the contribution that medicines make to producing informed and desired outcomes of patient care.
>
> Audit Commission, 2001

Other definitions of the term focused more on individual patient care activities:

> Medicines management encompasses a range of activities intended to improve the way that medicines are used, both by patients and by the NHS. Medicines management services are processes based on patient need that are used to design, implement, deliver and monitor patient-focused care. They can include all aspects of the supply and use of medicines, from an individual medication review to a health promotion programme.
>
> MeReC Bulletin, 2002

> [Medicines management is] the systematic provision of medicines therapy through a partnership of effort between patients and professionals to deliver best patient outcome at minimised cost.
>
> Tweedie and Jones, 2001

Later attempts also sought to focus on the broad range of services, the cost-effectiveness of care and safety:

> Medicines management (MM) includes the clinical, cost-effective and safe use of medicines to ensure that patients get the maximum benefit from the medicines they need, while at the same time minimising potential harm.
>
> DH, 2004

Associated Terms

The concept of medicines management appears to have originated from an organization perspective where medicines were paid for and therefore the desire to "manage" them (Barber, 2001). This movement to manage medicines differs from a more patient focused concept of "pharmaceutical care." Whereas medicines management has its origins in policy and organizations seeking to manage medicines, the philosophy of "*pharmaceutical care*" has been conceptualized as a patient-oriented practice (Hepler and Strand, 1990). Emerging from the United States in the 1990s, this concept significantly differed from the traditional "pharmacist as supplier" model that had persisted in the pharmacy profession since the creation of the NHS in 1948. Pharmaceutical care is defined by Helpler and Strand as the "responsible provision of drug therapy for the purpose of achieving definite outcomes that improve a patient's quality of life" (Hepler and Strand, 1990).

It has been suggested that whereas pharmaceutical care focuses on the individual, when provided as an organized service, this is experienced, documented, evaluated, and paid for as a medication management service. The term "medication management service" is therefore seen as "those identifiable events in practice surrounding the professional responsibility of managing a patient's medications" (Cipolle et al., 2012). Whereas pharmaceutical care may be more commonly perceived as pharmacist led, medicines management has been suggested as the joint responsibility of all those involved in initiating or reviewing medications (Blenkinsopp and Bond, 2008). Today, pharmaceutical care in the United States has largely been substituted for the term "*medication therapy management*" (MTM). MTM describes the broad range of professional activities and responsibilities within the licensed pharmacist's, or other qualified health care provider's, scope of practice. It is defined as "a distinct service or group of services that optimize therapeutic outcomes for individual patients [that] are independent of, but can occur in conjunction with, the provision of a drug product" (Bluml, 2005).

In the Australian context, "*cognitive pharmaceutical services*" is a commonly used term in the literature. Having its roots in the concept of pharmaceutical care, this strategy also aims to enhance public health and the quality of drug therapy. It has been defined as "professional services provided by pharmacists, who use their skills and knowledge to take an active role in patient health, through effective interaction with both patients and other health professionals" (Roberts et al., 2006). In the United Kingdom, the concept of "*medicines optimization*" (RPS, 2013) has been developed. Medicines management (the safe and efficient process of issuing medication)

is described as a cornerstone of "medicines optimization" (supporting the best outcomes for patients) (RPS, 2013). Being patient-focused, this newer concept contrasts with medicines management to encompass all aspects of a patient's medicines' journey from prescribing through to ongoing review and support. It therefore shares similarities with the concepts of pharmaceutical care and clinical pharmacy. Medicines optimization is based around the following four key areas:

1. To understand the patient's experience
2. Ensure evidence-based choice of medicines
3. Embed medicines optimization as part of routine practice
4. Ensure medicines use is as safe as possible (RPS, 2013).

Although it may appear synonymous terms for medicines management exist, the proliferation of these concepts reflects the pharmacy professions vibrant thinking and inclusiveness in this area. In the following section we further explore what is meant by medicine management by detailing its scope.

The Scope of Medicines Management

There are many steps involved that eventually enable the patient to take their medicines. This process has been conceptualized as a medicines management "pathway" (Stowasser et al., 2004). Stowasser and colleagues have identified nine steps (cognitive and physical) that describe this process. These are namely: (1) decision to treat and prescribe, (2) record medicine order, (3) review of medicine order, (4) issue of medicine, (5) provision of medicine information, (to the patient) (6) distribution and storage of medicine, (7) administration of medicine, (8) monitor for response, and lastly (9) transfer of verified information. Three background processes are also acknowledged 1. Medicines Procurement and Materials Management; 2. Reporting and Quality Safety Audit Review and 3. Communication (both interprofessional and patient directed). This medicines management framework provides opportunities to identify weak or error-prone processes and so allowing improvements to services to occur (Bajorek, 2011).

To support implementation, the UK Department of Health has produced a summary of the components of medicines' management (**Box 1**).

It is evident that medicines management encompasses a broad range of variegated activities that may have different interpretations to different stakeholders and according to whether medicines management is delivered in primary (community pharmacy/general practice), secondary/tertiary (hospital) or at the interface between these. To further illustrate this scope, five broad groups of services have been outlined by the UK National Prescribing Centre (NPC) namely (1) Clinical medicines management (assessment, monitoring review of patient prescribed medicines, and involvement in specialist disease management clinics), (2) Systems and processes (to deliver safety and efficiency), (3) Public health to meet the needs of the local population (e.g., smoking cessation services), (4) Patient-centered medicine services (e.g., medication reviews), and (5) Interface medicines management (between primary and secondary/tertiary care) (NPC, 2002a,b). A more detailed discussion of pharmacy's involvement in medicines management is presented in Section 3.

Box 1

Summary of the Components of Medicines' Management (DH, 2004)

- Involving patients in the choice of treatment, respecting their views and priorities and enabling them to take a more active role in self-management.
- Deciding whether a medicine is needed.
- Selecting appropriate treatment.
- Providing patient-centered information.
- Monitoring for benefits and safety.
- Reviewing effectiveness of treatment.
- Deciding when to stop treatment.
- Identifying under-treatment as well as over-treatment.
- Reducing medicines wastage.
- Using nonpharmacological options where possible, including health promotion advice.
- Developing patient-friendly ordering and collection systems.
- Promoting better communication between prescribers, patients, carers, and other health professionals.
- Making the best use of resources—evidence-based formularies and guidelines; generic prescribing; synchronization of quantities; medicines no longer needed; optimization of doses.
- Identifying further areas of investment in treatments to produce improved health outcomes, for example prescribing aspirin or statins in patients at risk of coronary heart disease.
- Improving repeat prescribing systems.
- Using professionals appropriately.
- Managing demand.

Why Is Medicines Management Increasingly Becoming Important?

It is well recognized that poor management of medicines may lead to patients not deriving the full benefit of the medicine. Reasons for suboptimal use of medicines are multifactorial and may be related to the patient, the prescribed process, disease state, or inadequacies in the health system (Sabaté, 2003). The opportunities for medicines management to improve patient use of medicines are becoming more pronounced. Broadly, these include increased evidence-based treatment, improved patient safety, increased patient satisfaction, patients' improved knowledge of treatment, improved disease-related outcomes, improved quality of life, reduced practical difficulties in taking of medications, reduced adverse drug events and increased compliance (Blenkinsopp and Bond, 2008). Despite these more apparent benefits, there are other factors that are driving the medicine management agenda. In this section, we look at some of the sociopolitical drivers, in particular, the influence of a changing societal demographic, policy drivers and pharmacy's professional ambitions to extend its role.

Factors Driving the Medicines Management Agenda

A Changing Demographic

The world population is rising and rapidly ageing. The World Health Organization estimates that between 2015 and 2050, the proportion of the world's population over 60 years will nearly double from 12% to 22% and that the number of people aged 60 years and older will outnumber children younger than 5 years (WHO, 2015a). For European health systems, it is acknowledged that an aging population, coupled with low birth rates and a higher life expectancy, is one of the greatest social, economic, and public health challenges of the 21st century (Abbing, 2016). With little evidence to suggest that older people today are experiencing better health than their parents, aging brings with it an inevitable rise in chronic health conditions (WHO, 2015a). People with limiting long-term conditions have been found to be the most intensive users of the most expensive health services and as a result their use of health resource, including medicine, tends to increase (DH, 2012). Chronic medical conditions (e.g., heart disease, stroke, arthritis, osteoporosis, frailty, etc.) are the largest cause of disability and death in the world and the global response to the epidemiological and economic impact has been described as inadequate (Yach et al., 2004). Innovative solutions are therefore needed to ensure older people have equitable access to good quality healthcare and support to manage long-term illness.

Given the rising numbers of older people with chronic conditions, polypharmacy is a becoming more prevalent. The burden of taking multiple medications (polypharmacy) is associated with greater healthcare costs, increased risk of adverse drug events (ADEs) and drug-interactions, reduced functional capacity and medication nonadherence (Maher et al., 2014). Work undertaken to optimize safe medication use has highlighted the potential value of appropriate polypharmacy (e.g., prescribing for individuals with multiple conditions where medicines use has been optimized and where medicines are prescribed according to best evidence) but cautions about inappropriate polypharmacy (prescribing multiple medicines inappropriately or where the intended benefit of the medicines are not realized) (Duerden et al., 2013). Reconfiguring health services, roles, and responsibilities is therefore necessary to ensure that the increasing use of medicines is used effectively. In the case of pharmacy, there has been an evident shift in pharmacists' role in primarily the provision of patient education involving acute medications toward consultation-type services for chronic medications (Barnett et al., 2009).

Policy and Economic Drivers

Health policy development and implementation involves complicated processes engaging civil servants, managers, elected members of an authority, professional bodies, pressure groups, and other stakeholders (Ham, 2009). Policy and economic drivers are important factors that shape the drive for the more effective use of medicines. Health economics is increasingly becoming an important decision tool to ensure that medicine resources are used in the most cost-effective way (Babar, 2016).

Growing cost of care and medicines

The complexity and cost of medicines is increasing and ensuring the most effective use of medicines is growing. In most developed healthcare systems, the prescribing of medicines is the most common patient-level healthcare intervention, and is often the second highest level of spending after staff costs (NHS Digital, 2017). With an aging population and such a high spend, policymakers are conscious that medicine will be used most effectively. It has been estimated that about US $500 billion spend may be avoided through better responsible medicine use by health system stakeholders including policymakers/commissioners, clinicians, nurses, pharmacists, and of course patients (IMS Institute for Healthcare Informatics, 2012). The greatest inefficiencies in the health system have been identified as patient nonadherence, untimely medicine use, antibiotic misuse and overuse, medication errors, suboptimal generic use, and mismanaged polypharmacy (IMS Institute for Healthcare Informatics, 2012). As a consequence, medicine management interventions such as medication reviews to improve patient adherence to medicines are becoming a routine part of pharmacy practice. As a response, adherence interventions are increasingly becoming a priority for policymakers and commissioner of health services.

Improving medicine adherence

The term "adherence" is typically used when referring to medicine-taking and is defined as "The extent to which the patient's behaviour matches agreed recommendations from the prescriber" (Horne et al., 2006, p. 33). Unintentional nonadherence occurs when patients experience difficulty in following treatment recommendations due to individual constraints such as inadequate

treatment understanding, forgetfulness, or physical difficulties that prevent them from using their medication effectively. Problems of accessing prescriptions or the cost of medicines may be further causes of patient nonadherence. However, there is recognition that patients may intentionally decide not to take medications as instructed (Horne et al., 2005). This intentional nonadherence arises from beliefs, attitudes, and expectations that influence patients' motivation to begin and persist with the treatment regimen (Nunes et al., 2009).

There is recognition that nonadherence to medicines causes reduced quality of life, increased hospitalizations, and premature death (Ho et al., 2006; Vestbo et al., 2009). It has been estimated that in developed countries, adherence to long-term therapies in the general population is around 25%–50% and is much lower in developing countries (DiMatteo, 2004; Sabaté, 2003). The impact of poor adherence also grows as the burden of chronic diseases grows worldwide and as a consequence leads to poor health outcomes and increased healthcare costs (DiMatteo, 2004; Sabaté, 2003). Moreover, it has been estimated that nonadherence contributes 57% (US $285 billion) of the world's total avoidable cost due to suboptimal medicine use (IMS Institute for Healthcare Informatics, 2012). One report suggests that improving adherence from current levels to 80% across these five areas would save the NHS £500 million per annum (Trueman et al., 2010).

Intentions to develop interventions to improve medicine adherence have also been influenced by the considerable body of evidence that suggests patients have practical problems with taking medicines, may be reluctant to take them because of concerns about side effects, the consequences of dependency, or being unclear about the benefits (Pound et al., 2005). Some patients may not feel that physicians (General Practitioner GPs) have time to discuss and address such concerns (Dugdale et al., 1999; Moen et al., 2009). Furthermore the continuing conformity to the traditional patient role and deference to professional authority has been suggested to limit discussions about treatment (Barry et al., 2001). Shared decisions making has been shown to be appealing and desirable to most patients and to improve medicine adherence. Results from one meta-analysis indicated better patient-physician collaboration is associated with better patient adherence with the relationship being sustained for pediatric and adult populations, chronic and acute conditions, and primary physician and specialists (Arbuthnott and Sharpe, 2009). With pharmacy playing a crucial role in optimizing the use of medicines, they are uniquely placed to improve adherence to treatment. Pharmacist involvement in such activities are discussed in Section 3.

The cost of adverse drug events (ADEs)

Adverse drug events (ADEs) occur in all healthcare systems and can cause serious harm to patients. An adverse drug event (ADE) has been defined as "an injury resulting from medical intervention related to a drug" (Bates et al., 1995) and can include medication errors, adverse drug reactions (ADR's), allergic reactions, and overdoses. ADEs can result in serious patient injury, leading to hospital admission, disability, and even death. ADRs have been implicated in 6.5% of patient hospital admissions (Pirmohamed et al., 2004).

Recognizing the serious personal consequences and costs associated with ADEs, patient safety movements have increasingly grown and are now high on the healthcare quality agenda in many countries of the world (Donaldson, 2002). Building on early initiatives such as "*Pharmacy in the Future*" (DH, 2000), the implementation of medicines management schemes are now seen as a means to reduce the amount of illness caused by medicines not being used correctly, and cut waste. Interventions are being developed to reduce the impact of medication errors and "problematic polypharmacy" (Duerden et al., 2013). Although the majority of errors will be identified before a medicine reaches the patient (near miss), the rates of medication errors and preventable drug-related morbidity are unacceptably common. It has been estimated that a total of 0.7% of global total health expenditure, or US $42 billion worldwide, can be avoided if medication errors are prevented (IMS Institute for Healthcare Informatics, 2012).

Pharmacy's Professionalization Project

Alongside policy ambitions to improve the use of medicines and make better use of the skills that pharmacy can offer, there have been long standing calls within the pharmacy profession itself to develop new roles beyond the supply/dispensing function of pharmacists (Department of Health, 2000; Nuffield Committee of Inquiry into Pharmacy, 1986). Before the creation of the NHS in 1948, community pharmacists were often the first port of call for healthcare advice (Silcock et al., 2004). However, following the creation of the NHS, these pharmacies became independent contractors with payments chiefly coming from dispensing rather than sales of over-the-counter (OTC) medicines (Silcock et al., 2004). Since then, the rise in large scale manufacturing of medicines and predominance of original patient pack dispensing (with patient information sheets supplied), has seen pharmacists exclusive field of knowledge in compounding and formulating medicines, as well as their advisory role, diminish. With pharmacist's work increasingly becoming routine and deskilled, threats to professional claims led to suggestions that pharmacy had become an "incomplete" or "quasi-profession" (Denzin and Mettlin, 1968).

In response, pharmacy has embarked on a process of reprofessionalization (Birenbaum, 1982; Edmunds and Calnan, 2001). Macdonald (1995) uses the term "professional project" for occupational groups who are involved in a strategy of professionalization. A professionalizing project aims to convince the state and the public that the work of the occupational group is reliable and valuable. Professional initiatives have sought ways for pharmacists to move away from the mechanical aspect of dispensing and sale of retail products toward extending the pharmacists' role in more patient-centered and advisory services (Hepler and Strand, 1990). Whereas some have suggested that the criterion for pharmacy professionalism lies in its patient counseling and rationalizing medicine use (Gosselin and Robbins, 1998), others have expressed caution about developing the extended role agenda as a means of enhancing professional status. Harding and Taylor (1997) argue that reprofessionalizing strategies to extend the pharmacist's role in trying to redefine their role may serve to deprofessionalize the pharmacy profession further. Nevertheless, new models of care are

being developed, and medicines management practices are emerging, to ensure the current healthcare needs of the population are met (Murray, 2016; Smith et al., 2013).

Pharmacy's Involvement in Medicines Management

The term "responsible use of medicines" is used to imply the "activities, capabilities, and existing resources of health system stakeholders are aligned to ensure patients receive the right medicines at the right time, use them appropriately, and benefit from them" (IMS Institute for Healthcare Informatics, 2012). Medicines management services help facilitate responsible medicine use by addressing unmet pharmaceutical needs, support patient medicine-taking and develop approaches which improve service efficiency and so reduce medicine waste. Pharmacists are involved in a broad range of medicines management services.

In this section, we initially discuss the influence of the patient-centered care agenda. An overview is then given of the various ways pharmacy is contributing to medicines management in primary care, secondary care, and at the primary-secondary care interface.

The Patient-Centered Care Agenda

A key component to modern medicine management is the patient-centered care agenda which gained prominence in 2001, when the Institute of Medicine (IOM) adopted the concept of as one of the six essential aims of improving healthcare in the United States (IOM, 2001). With patient-centeredness now considered an accepted part of a modern health system and morally valuable (Duggan et al., 2006), reforms of health policies have focused to redesigning care around the patient and provide greater choice (Porter et al., 2013). Berwick (2009) defines patient-centered care as "the experience (to the extent the individual patient desires it) of transparency, individualization, recognition, respect, dignity, and choice in all matters, without exception, related to one's person, circumstances, and relationships in health care." He argues that health professionals should recalibrate their work in order not to act as "hosts" for patients in the healthcare system, but "guests" in patients' lives. This patient empowerment challenges assumptions that health professionals "know best" and there are ongoing efforts to transition away from more "pateralistic" views of healthcare toward a patient-centered and self-management agenda (Barlow et al., 2002).

Patients are increasingly seen as central to the philosophy of medicines management. This has come from calls for patients and professionals to work together in order for patients to perceive a greater degree of control, choice, and therefore influence over their health and healthcare (Darzi, 2008). The rise of patient empowerment, as well as progressive deregulation and the rise of consumerism has also contributed to this movement (Nettleton, 2006). Increasing evidence suggests that patient-centered care is associated with satisfaction, self-management, and decreased health care utilization (Bertakis and Azari, 2011; Rathert et al., 2013). Medicines management services such as the activities described in this section, are constantly being influenced by the patient-centered agenda to ensure the patient remains central to their own healthcare.

Medication Review

It is acknowledged that medicines will fail to realize their potential to reduce the burden of chronic illness if there is poor adherence. As Haynes suggests increasing the effectiveness of adherence interventions may have a far greater impact on the health of the population than any improvement in specific medical treatments (Haynes et al., 2002). One prominent strategy to improve medicine use is medication reviews. This has become an established role for pharmacists and their involvement is integrating them further into the wider multidisciplinary team. Reviews of medicines can occur in different healthcare service settings such as in community pharmacies, primary and secondary care, care homes, and so on. During such reviews practical problems with the use of medicines and adherence is discussed thereby improving the clinical effectiveness of medicines taken by patients. A medication review has been defined as a "structured critical examination of a patient's medicines with the objective of reaching an agreement with the patient about treatment, optimising the impact of medicines, minimising the number of medication-related problems and reducing waste" (Shaw et al., 2002, p. 12). A framework has been proposed that classifies medication review into three types:

- Prescription review—Intended to identify prescription anomalies such as duplicate prescribing and does not require the patient or their clinical notes to be present at the review (includes Prescription Intervention MURs).
- Concordance/compliance review—Addresses patient medicines-taking behaviors and designed to discover patient views of their medicines and their willingness to take them (includes MURs).
- Clinical review—Includes consideration of both prescribed and purchased medicines and must be undertaken with the patient and with their clinical notes to enable a holistic view of the appropriateness of the medicines in relation to their conditions.

(Clyne et al., 2008)

Evidencing Medication Review Outcomes

Despite policy and professional drives to develop pharmacy medicine review services, trials to determine the efficacy of such interventions in improving patient health outcomes have been equivocal (Perraudin et al., 2016; Viswanathan et al., 2015). For example, several studies suggest that pharmacists are able to improve the appropriateness of prescribed medicines and reduce the use of high-risk medicines (Chrischilles et al., 2004), identify adverse effects (Bond et al., 2000), reduce inappropriate waste of

medicines (Jesson et al., 2005) and improve quality use of medications, and health outcomes (Jokanovic et al., 2016). Small scale studies conducted by committed pharmacists and GPs have tended to show the most benefit (e.g., Jesson et al., 2005; Zermansky et al., 2001). Larger scale studies or investigations of the impact in practice have also indicated that there is improved clinical outcomes, cost savings, and patient satisfaction following a pharmacist intervention (Elliott et al., 2017; Ramalho de Oliveira et al., 2010). Despite this positive evidence, evidence for medication reviews to improve patient outcomes have come under scrutiny. Some have found little difference in appropriate prescribing or ambivalent health outcomes following a review (MEDMAN Study, 2007; Holland et al., 2008; Krska and Avery, 2008; Latif et al., 2011), whereas others suggest that pharmacist home-based medication review could even increase hospital readmissions (Holland et al., 2005).

Community Pharmacy Medication Review Services: An International Perspective

Several countries have developed the community pharmacist's role toward reviewing patients' prescribed medication. Alongside the UK, Australia, the United States (US), New Zealand, and more recently Switzerland have the most established services. However, there is recognition that these medication review services vary in their comprehensiveness, minimum competency requirements for pharmacists, levels of interprofessional collaboration and remuneration (Chen and de Almeido Neto, 2007; Roberts et al., 2006).

Home medicines review (HMR)

Introduced in 2001, the Australian Home Medicines Review (HMR) service is one of the longest established community pharmacy medication review service. The HMR service was developed following negotiation by the pharmacy profession with the Australian Government to incorporate new, remunerated professional services into community pharmacies to better utilize the skills of pharmacists and for the community pharmacy network in Australia to remain viable (Roberts et al., 2006).

Medicines use reviews (MURs) and the new medicines service (NMS)

Commissioned by the NHS in 2005, the English MUR service is the first national NHS funded service that remunerates community pharmacists for undertaking a documented face-to-face consultation with a patient specifically to discuss their medication. The underlying purpose of MURs "aims, with the patient's agreement, to improve his or her knowledge and use of drugs" (DH, 2005). Outcomes resulting from MURs have been mixed (Latif et al., 2011; Latif et al., 2013a) but has spurred on policymakers to support other services such as the New Medicines Service (NMS) which was launched in 2011 to support people starting a new medicine for asthma/COPD, type 2 diabetes, hypertension, or antiplatelet/anticoagulant treatment (PSNC, 2011). Evidence suggests that the NMS is effective and cost effective compared with normal practice, more specifically, increased patient adherence to their new medicine translated into increased health gain at reduced overall cost (Elliott et al., 2017). However, adopting such services has been shown to be a multifaceted and complex process with workflow, infrastructure, and public and professional relationships all affecting NMS implementation (Latif et al., 2016a; Waring et al., 2016; Waring and Latif, 2017).

Medication therapy management (MRM)

In the United States, Medication Therapy Management (MTM) services provided by community pharmacists began to develop in the 1990s to assist GPs in managing clinical services and contain cost outcomes of drug therapy. MTM services have been described as a partnership between the pharmacist, the patient or their caregiver, and other health professionals and are designed to optimize therapeutic outcomes by improving adherence to medicines, enhance patient understanding of their medication and to reduce adverse drug events (Burns, 2005). Formal MTM services were introduced more widely across the United States in 2006 following reforms resulting from the Medicare Prescription Drug, Improvement, and Modernization Act of 2003 (Barnett et al., 2009). This act required insurers to offer a MTM program to a target population of high-cost patients who are users of the social insurance programs "Medicare" and "Medicaid" and so have led to greater opportunities for community pharmacists to be reimbursed for medication management services (Barnett et al., 2009).

Medicines use review and adherence support services (MURs)

In New Zealand, Medicines Use Review and Adherence Support services (MURs) were introduced in 2007 and aimed to support adherence to medicines for selected patients (Lee et al., 2009). The New Zealand MUR has several similarities to the UK model. The MUR is a structured consultation involving review of a patient's medication, identifying any practical or medication-related problems, and providing relevant information about these. Similar to the UK model, an MUR accreditation training course provided by the New Zealand College of Pharmacists must be completed before the service can be offered. One difference is that MURs are not nationally funded as they are in the UK and local schemes must be agreed with the local health authorities (Lee et al., 2009).

Polymedication-checks

More recently Swiss community pharmacies have been given reimbursement opportunities to offer Polymedication-checks that have been fashioned on the UK MUR (Messerli et al., 2016) and other countries developing medication review services include Finland, Portugal, Canada, and Germany (Blenkinsopp and Celino, 2006). In less developed countries there are less well evolved programs and in these countries, insufficient training of professionals and lack of pharmacists have been cited as barriers for pharmacists' involvement in medication review services (Silveira de Castro and Correr, 2007).

Community Pharmacist Involvement in Other Medicines Management Activities

In this subsection we detail pharmacists' involvement in general practice settings and briefly explore pharmacist prescribing.

Pharmacists in General Practice

The extent to which healthcare professionals work together influences the quality of the healthcare that they provide to patients. Collaboration is defined by Zwarenstein and colleagues as "the process in which different professional groups work together to positively impact health care" (Zwarenstein et al., 2009, p. 2). Despite the well-known limitations of GP-pharmacist collaborations, including pharmacists working in silos, poor communication, and lack of time and remuneration for collaborative activities (Dobson et al., 2006), pharmacists are increasingly being integrated into general practice clinics. For example, evidence suggests the benefits of pharmacists colocated in general practice clinics (e.g., improve management of chronic conditions such as cardiovascular disease and diabetes) were more likely to be seen when there was interprofessional communication and collaboration (Tan et al., 2014). Positive outcomes have more frequently been observed when there was interprofessional telephone or face-to-face verbal communication when compared with pharmacists delivering medicine management interventions in isolation (Tan et al., 2014).

Pharmacists within general practice are increasingly becoming more common to deliver patient-centered interdisciplinary medication management services. Practice-based pharmacists may not only help reduce prescribing errors (Avery et al., 2012), but could help adherence to good practice guidance such as that from the National Institute for Health and Care Excellence (NICE), and the Medicines and Healthcare Products Regulatory Agency (MHRA). There are mounting calls for new models of care that introduce new roles or change existing roles in General Practice (Bienkowska-Gibbs et al., 2015). With their independent prescribing status, pharmacists are well placed to add value in improving safety, manage medicines, and acute illnesses and so directly alleviating GP workforce pressures (Stone and Williams, 2015).

Pharmacist Prescribing

As prescribing legislation in countries such as United States, Canada, Australia, New Zealand, and the United Kingdom continues to develop, there are more and more opportunities for pharmacists to extend their medicines management expertise into the field of prescribing (Tonna et al., 2008). For example, in Great Britain, legislation that came into effect in 2003 allowing pharmacists to undertake "supplementary" prescribing (a voluntary partnership between an independent prescriber (physician or a dentist), the supplementary prescriber and the patient, within the scope of an agreed named patient clinical management plan). In 2006, this further developed to allow for suitably trained pharmacists to become independent prescribers (Baqir et al., 2012).

Prescribing is defined as "to give directions, either orally or in writing, for the preparation and administration of a remedy to be used in the treatment of any disease" and is distinguished from diagnosing which is "the determination of the nature of a disease, injury, or congenital defect" (Pharmacist Prescribing Task Force, 2010). Prescribing has been described as a four-step process, the first which is to gather information (e.g., presenting complaint, medication history-taking), the second is clinical decision-making (e.g., diagnosis, medication appropriateness), the third is communicating prescribing information (to other health care professionals and the patient), and lastly to monitor and follow-up to ensure the treatment is working (e.g., review patient outcomes, adherence) (Coombes et al., 2011).

Today, pharmacists have been shown to undertake prescribing in various settings such as within primary care, community pharmacies, secondary care, and at the primary/secondary care interface; however the impact on pharmacist workload, patient outcomes, and how this role crosses professional boundaries has yet to be determined (Tonna et al., 2007). In secondary care pharmacist prescribing has been shown to improve medicine safety, enable efficient pharmacist medication reviews, and increase pharmacist integration into the multidisciplinary team (Bourne et al., 2016). However, the challenges of lack of support (financial and time resources), lack of acceptance by medical staff, and barriers to adoption by the pharmacy profession itself exist (Bourne et al., 2016).

For pharmacists to assume an increased role as prescribers, the pharmacy profession will need to ensure there is professional training that will help them develop not only the necessary skills for prescribing but also the scope of practice for individual practitioners. It has been envisaged that pharmacist involvement in prescribing will increasingly allow them to deliver more "comprehensive" medicines management. This may include the following steps: drug therapy selection; prescribing, initiating a monitoring plan, modifying therapy on the basis of ongoing assessments, and discontinuing therapy if deemed appropriate (Pharmacist Prescribing Task Force, 2010). With patients generally reporting a high level of satisfaction with pharmacist prescribing (Famiyeh and McCarthy, 2017) prescribing will continue to be an important area for future engagement in the medicine management process.

Medicines Management in Hospitals: The Role of Clinical Pharmacy

Since the 1980, pharmacists have sought "clinical pharmacy" roles that promote greater integration into the multidisciplinary care team (Harding and Taylor, 1997). Today these roles allow them to apply their pharmaceutical expertise to help to maximize medicine efficacy, minimize medicines toxicity and improve patient health outcomes (Kaboli et al., 2006). The hospital pharmacist oversees the complete medicine distribution cycle including assessment of the prescription according to the diagnosis, dispensing, preparation, through to administration to minimize waste and ensure quality care for patients. Pharmacists also have an important

role in assessing the suitability for patients' own medicines for use and reissue following discharge to avoid waste. For example, medication is designated unsuitable for reuse if:

- there is insufficient quantity,
- the dosage is changed,
- the medicine is stopped,
- use-by dates have expired,
- tablets in the container are mixed,
- there is evidence of physical deterioration,
- the medicine is inadequately labeled, or
- the container had no label or batch number (Spoon full of Sugar 2001)

The Role of the Drugs and Therapeutics Committee (DTC)

Drugs and Therapeutic Committees (DTCs) establish an agreed formulary and clinical advice in line with national guidelines which contribute to effective medicines management. DTCs also have a strategic role in monitoring prescribing practice, ensuring the most cost-effective medicines are prescribed and ensure adherence to nationally agreed treatment guidelines. They vary in numbers and it has been suggested that membership beyond 14–18 members may be more challenging to chair (Stephens, 2005). Typically committees include a prescribing lead or senior clinician, chief pharmacist, commissioners or financial experts, and lay representation.

Formularies and clinical guidelines should be based upon the principles of "evidence-based medicine." Sackett defines this as "the conscientious, explicit, and judicious use of current best evidence in making decisions about the care of individual patients" (Sackett et al., 1996). DTCs have wide impact on prescribing habits beyond the hospital environment, for example, hospital DTCs has been shown to influence GP prescribing as a GP's choices of medicines is likely to be guided by local consultants' treatment protocols. The importance of pharmacist involvement for interprofessional work was recognized in the 1980s (Nuffield Committee of Inquiry into Pharmacy, 1986) and their recognition to contribute to formulary adherence (Baker et al., 1988). Although the core function of a DTC has been largely consistent over the past three decades, with expensive medicines being developed in a climate of austerity, pharmacists' unique medicine skills as well as greater involvement in general practice settings will mean the opportunity for further involvement on such committees will increasingly become important.

Medicines Management at the Primary-Secondary Interface

It is increasingly being acknowledged that transferring patients between care providers, such as on hospital admission or discharge represents a high-risk area period potentially leading to adverse drug events. It has been found that around half of the medication errors that occur in hospital are estimated to occur on admission or discharge (Vira et al., 2006). Medication reconciliation at transitions of care (admission, transfer, and discharge) aims to ensure the correct medications are supplied to the patient at all transition points, avoid medication errors such as omissions, duplications, dosing errors, or drug interactions, and therefore to promote seamless care. Internationally, medicines reconciled at admission is a high priority intervention and has been integrated into the World Health Organization's High 5 s Project due to its evidence of preventing medication-related harm (WHO, 2014a). The medicine reconciliation process has been defined as the "formal process in which health care professionals partner with patients to ensure accurate and complete medication information transfer at interfaces of care" (WHO, 2014a).

Pharmacists' unique training in medication management provides them with the skills to deliver and support medication reconciliation. Despite the heterogeneity between medication reconciliation interventions and how they are evaluated (Mueller et al., 2012), prevention of medication errors through pharmacist-driven medication reconciliation has been shown to avoid medication discrepancy-related errors (Bishop et al., 2015; Gillespie et al., 2009). It has been estimated that up to 67% of inpatients have at least one error in their prescription medication history at the time of admission (Tam et al., 2005), the most common of which is often the omission of a medicine (Cornish et al., 2005). Interventions aimed at reconciling patients' medications at admission have been found to be cost-effective (Campbell et al., 2007). One meta-analysis of pharmacist-led medication reconciliation programs indicated these to be beneficial at reducing ADE-related hospital revisits, all-cause readmissions, and Emergency Department (ED) visits, and supports the implementation of pharmacist-led medication programs (Mekonnen et al., 2016). Innovative and integrated pharmacy-led approaches to medicines management (from admission through to discharge) have been shown to reduce the length of hospital stay and instances of readmission (Scullin et al., 2007) and innovative ways to achieving effective seamless care should be promoted.

When a patient is discharged from hospital there is a transfer of responsibility from the inpatient provider to the patient and primary care physician. The medicine challenges during discharge may be more complex resulting in more discrepancies than on admission (Varkey et al., 2007) as medicines may be discontinued, switched to a new dosage schedule, or new treatments may be initiated. The medicines at discharge will be required to be reconciled with those medicines supplied in primary care and even with those still within the patients home and so medicine discrepancies may occur more frequently on hospital discharge than on admission. Patient discharge summaries are used to communicate between inpatient and outpatient providers. However, it has been highlighted that discharge summaries sometimes fail to provide important information, such as the primary diagnosis, discharge

medication, laboratory test results or may not reach the outpatient provider in a timely manner (Kripalani et al., 2007) and so may adversely affect patient care.

Medication Errors

Medical errors can occur at all stages of the medicines management process. A medication error has been defined as "any preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is in the control of health professional, patient or consumer" and consistently reported to account for between 10% and 20% of all adverse events (Smith, 2004, p. 20). Key areas where medication errors can occur during the process of medicine delivery include inappropriate prescribing, preparing and dispensing, errors during administration (administering the incorrect dose, the incorrect medicine; administering the medicine via the incorrect route) and errors during medicine therapy monitoring.

Pharmacists in both primary and secondary care have a key quality control responsibility in checking patients' medication is appropriate and reducing incidents of medication errors. They initially have a responsibility to ensure their own systems and practices are robust and they adopt models to help identify and address system failures in error management (Garfield et al., 2009; Nesbitt et al., 2017). Other ways pharmacists can reduce medicine error rates may include enhancement of decision-support resources, better labeling/packaging of medications, more effective communication between professionals and patients, pharmacists' medicine review and counseling (Aspden et al., 2006). The incidence of medication administration errors has been reported to be high in long-term residential care (Szczepura et al., 2011). The prescribing in such settings has also been shown to be suboptimal for reasons including inappropriate polypharmacy, inadequate communication and poor handover protocols between staff, interruptions during drug rounds and the lack of clear responsibility for the review of patients' medicines (Parsons et al., 2011). Guidance and ways to optimize prescribing and medicines management in these settings are increasingly becoming important (Millar et al., 2017; NICE, 2014).

The role of technology is also becoming more prominent as a means to reduce medication errors. Pharmacist review of medication delivered on a clinical decision support software platform has been shown to reduce ADR incidence in acutely hospitalized older people (O'Sullivan et al., 2016). Automated Communication Tools and Computer-Based Medication Reconciliation have similarly been shown to reduce hospital discharge medication errors in medically complex patients (Smith et al., 2016). Electronic prescribing also significantly reduces medicine errors by providing timely, legible information. Electronic prescribing support programs offer the prescriber a list of possible medications and can also provide varying levels of decision support, including alerts for drug-drug interactions, drug-allergy contraindications, or checks of prescriptions concerning the patient's recent laboratory results. In the United States they are often referred to as Computerized Physician Order Entry (CPOE) systems and in hospital-related settings, implementing CPOE is associated with a greater than 50% decline in preventable ADEs (Nuckols et al., 2014). The expected outcome is for a more efficient and safer means for patients to obtain the medicines they need. Medication errors can occur in the pharmacy during the interpretation of a clinician's handwriting. E-prescribing is a system of electronically generating and filling patient prescriptions intended to reduce errors associated with handwritten scripts. There is evidence suggesting that e-prescribing can contribute to reduced ADEs of between 30% and 84% (Ammenwerth et al., 2008).

More extended interventions may include the deployment of pharmacists in general practice. In one trial, an information technology-based pharmacist intervention was shown to be more effective than simple feedback in reducing the number of patients at risk of measures related to hazardous prescribing (Avery et al., 2012). In this study, pharmacists received training to identify and intervene on clinically important errors namely: the prescribing of a nonselective, nonsteroidal antiinflammatory drugs (NSAIDs) prescribed to those with a history of peptic ulcer without coprescription of a proton-pump inhibitor; a β blocker prescribed to those with a history of asthma and lastly, long-term prescription of angiotensin converting enzyme (ACE) inhibitor or loop diuretics to those 75 years or older without assessment of urea and electrolytes in the preceding 15 months (Sadler et al., 2014). Although more work and better quality data is needed, marginal health gains at a slightly reduced overall cost have been recorded (Elliott et al., 2014).

Medicines Management in Industry

An aging population with growing multimorbidity presents challenges for the pharmaceutical industry in light of increasing the complexity of independent drug therapy management and administration. Pharmacists' distinct body of knowledge in pharmacology, pharmacodynamics, pharmacokinetics, as well as awareness of patient use of medicines enables them to have a unique skill set for working in the pharmaceutical industry. A patients' age, levels of cognitive decline, and physical disease pattern (e.g., arthritis) can all impact on a patient's handling and administration of medicine and attention must be paid so the pharmaceutical drug product design adequately addresses the particular patient's needs (Stegemann et al., 2016). Older people are a heterogeneous patient population often with comorbidities and may require greater attention. Often polypharmacy is present and the changes in drug metabolism as well as other declines in functional attributes (e.g., visual, hearing, sensory, and motor functions) as well as swallowing difficulties, present unique challenges to ensure medicines are designed and packaged appropriately (Drumond et al., 2017).

Pharmaceutical design teams have the opportunity to improve medicine use by ensuring appropriate routes of administration, that there is ease in opening the packaging and containers and that user instructions are clear and easy to read. Drug packaging

technologies generally have remained the same over the years and further work is needed to ensure medicines are more user-friendly (Drumond et al., 2017). Patient-centric pharmaceutical drug product design is one strategy proposed to explore the interface between a drug product and an individual patients' use of a medicine. As well as being based upon sound scientific principles, there is acknowledgment of the layperson's response to the product design. It has been defined as "the process of identifying the comprehensive needs of individuals or the target patient population and utilizing the identified needs to design pharmaceutical drug products that provide the best overall benefit to risk profile for that target patient population over the intended duration of treatment" (Stegemann et al., 2016).

Facilitators and Barriers

Research into pharmacists' involvement in medicine management services has identified several facilitators and barriers to successful implementation. The more common facilitators and barriers are outlined later.

Common Barriers to Medicines Management

Pharmacists are widely regarded as the most accessible health professionals in the community but currently spend the majority of their time involved in activities associated with the dispensing of prescriptions rather than providing consultations or in medicine management services (Hassell et al., 2011; Lea et al., 2012). Undertaking extended medicines management role activities is challenging and there are many factors that have been shown to hinder the adoption of new extended roles including insufficient integration of community pharmacy input into patient pathways (Blenkinsopp and Bond, 2008). The variability in outcomes and influences that affect the successful adoption of medicine management services appear to be determined by a lack of perceived time to undertake such services, poor use of staffing within the pharmacy and lack of remuneration for undertaking such activities (Bradley et al., 2008a; Niquille et al., 2010). A lack of readiness to change by pharmacists and a perceived lack of workable strategies to adopt newer roles (Blenkinsopp and Bond, 2008; Bryant et al., 2009). Furthermore, their professional performance has been shown to be affected by a variety of factors. One literature search indicated that suggested that performance (particularly in relation to errors) is influenced by multiple factors, including personal characteristics such as age, gender, ethnicity, place of primary qualification, factors associated with the workplace (pharmacist workload and in particular prescription volume) as well as mental and physical health (Schafheutle et al., 2011).

Another barrier faced by pharmacists is the value and acceptance of pharmacy interventions to the public which is not always clear Latif et al., 2013a; Latif et al., 2018. Pharmacists may underestimate the willingness of the public to take part in such interventions (Rodgers et al., 2016). Service users typically have low awareness of such services and pharmacists' advice tends to be welcome when in line with expected core responsibilities (i.e., dispensing prescriptions/advice and treatment of minor ailments), but is less readily accepted if extended beyond their perceived professional boundaries (Eades et al., 2011). Despite the range of extended medicines management services, peoples' use of pharmacies remains predominantly for prescription supplies and management of minor ailments with perception of the pharmacist's role largely portrayed as one of "drugs experts" rather than experts on health and illness (Anderson et al., 2004). Another key factor is a lack of awareness among other healthcare professionals about the pharmacist's skills and attributes (Latif, 2013b). Further barriers include lack of mandate and legitimacy over extended work and GP-pharmacist relationships (Bradley et al., 2008b; McDonald et al., 2010), a lack of privacy or availability of a private space within the pharmacy (Latif and Boardman, 2008) and limitation of services guidelines that may hamper provision to the medially under-served (Latif et al., 2016b).

Common Facilitators to Medicines Management

Reasons reported by pharmacists for becoming involved in extended role activities include enhanced job satisfaction, a break from the routine task of dispensing and the potential to improve their public image to patients and GPs (Grindrod et al., 2010; Roberts et al., 2006). It is clear that addressing the barriers mentioned would facilitate implementation of extended medicine management services such as medicines review. Facilitators to practice change have been cited as: further training and support for pharmacists to enable them to build confidence, reduction in administrative work, improved used of pharmacy support staff (including using Accredited Checking Technicians (ACTs) to reduce the pharmacists' dispensing / checking workload, and better pharmacy layout and workflow (Roberts et al., 2006). Other important facilitators include improving the relationship between pharmacists and GPs (Chen and de Almeido Neto, 2007), increase in public awareness and demand for medicines management services (Rodgers et al., 2016), improved remuneration and clearer messages from the pharmacy profession itself about the future of professional practice (Roberts et al., 2006).

Emerging Medicines Management Opportunities

Healthcare organizations face new challenges and novel areas of medicines management are emerging. Pharmacy is well placed to capitalize on these new opportunities, to foster interprofessional collaboration and so further support patients to take medicines appropriately. In this section we touch on four of the many developing area of importance, namely, eHealth, antimicrobial resistance and stewardship, deprescribing and pharmacogenomics, and personalized medicines.

eHealth

Increasingly, technology is being seen as a convenient means for patients to access health advice. For example, an automated telephone communication systems (ATCS) can provide round-the-clock access to professional advice, deliver voice messages or collect health-related information from patients using either their telephone's touch-tone keypad or voice recognition software (Posadzki et al., 2016). It has been suggested that ATCS can change patients' health behaviors, improve clinical outcomes, and increase healthcare uptake with positive effects in several important areas including immunization, screening, appointment attendance, and adherence to medications or tests (Posadzki et al., 2016). Other ways telecommunication can be used is via text reminders to support adherence (Kannisto, 2016), medicine reordering via a smartphone app (Car et al., 2017) but also more directly through patient-pharmacist telephone consultations about newly prescribed medicines, as in the case of the English New Medicines Service (NMS) (PSNC, 2011).

It is clear eHealth will increasingly be used to improve medicines management and support patient health. EHealth has been recognized as offering opportunities to transform medicines management pathways and every step of the patient's medicines' journey (Car et al., 2017). EPrescribing and the increasing automation of pharmacy dispensing functions allows not only greater efficiency and safer dispensing of medication, but also the freeing up of pharmacists' availability with implications for further advanced training for new and emerging roles (Knoer et al., 2016). In the future, the continuing innovation in eHealth technologies as well as the rise in social media usage are likely to increase demand for more flexibility and novel ways in accessing healthcare; further research is needed to add to this growing evidence base.

Antimicrobial Resistance and Stewardship (AMS)

It has been well-documented that a causal relationship exists between antimicrobial use and misuse leading to the emergence of antimicrobial resistant pathogens (Bartlett, 2011). The pharmaceutical industry is unable to develop new antibiotics to keep up with the emergence of resistant bacteria (Nathan and Cars, 2014). The increasing prevalence of multidrug resistant bacteria led the World Health Organization to identify antimicrobialiotic resistance (AMR) as one of the major threats to human health (WHO, 2014b). Unless this is addressed, it has been suggested there could be up to 10 million deaths resulting from multidrug resistant bacteria with an economic impact of £66 trillion by the year 2050 (Public Health England, 2015). An EU initiative attempting to raise awareness of multidrug-resistant bacteria suggests that there are going to be no new classes of antibiotics in the foreseeable future (ECDC/EMEA Joint Technical Report, 2009).

Many local and global initiatives have been set up to combat antibiotic resistance using antimicrobial stewardship programs. The National Institute of Clinical Excellence (NICE) defines "antimicrobial stewardship" as "a healthcare-system-wide approach to promoting and monitoring rational use of antimicrobials to preserve their future effectiveness" (Cefai et al., 2015). Recently, the World Health Assembly adopted a global action plan on antimicrobial resistance, which outlines five objectives:

- To improve awareness and understanding of antimicrobial resistance through effective communication, education, and training,
- To strengthen the knowledge and evidence base through surveillance and research,
- To reduce the incidence of infection through effective sanitation, hygiene, and infection prevention measures,
- To optimize the use of antimicrobial medicines in human and animal health,
- To develop the economic case for sustainable investment that takes account of the needs of all countries and to increase investment in new medicines, diagnostic tools, vaccines, and other interventions.

(WHO, 2015b)

It is clear that significant investment in research into current practices and stewardship is needed globally and pharmacists will need to play key medicines management roles to ensure these are a success. As part of their professional role, pharmacists clinically screen all prescriptions to ensure legality, safety, and clinical appropriateness. Pharmacists can therefore play a significant role in the development and implementation of AMS initiatives in both primary and secondary care. Given their professional ambitions to extend their role, community pharmacists have the potential to significantly impact on all five of the above objectives. The effective utilization of AMS programs has the potential to reduce rates of AMR and consequently improve mortality and economic outcomes (Howard et al., 2014; Huttner et al., 2014). All pharmacists therefore have an important role in AMS, not just specialist antimicrobial or infectious diseases pharmacists. Community pharmacists are particularly well positioned to develop and implement new AMS initiatives. This is because they are often the last health professional seen before patient administration. It is therefore imperative to understand the perceived importance of AMS to community pharmacists, if extended roles into this area are to be contemplated.

Deprescribing

The process of deprescribing is receiving considerable attention in the literature (Tjia et al., 2013). Deprescribing has been defined "as the systematic process of identifying and discontinuing drugs in instances in which existing or potential harms outweigh existing or potential benefits within the context of an individual patient's care goals, current level of functioning, life expectancy, values, and preferences" (Scott et al., 2015). Inappropriate polypharmacy, particularly in the older population has been shown to account for emergency hospitalizations (Budnitz et al., 2011), increased risks of falls, (Bennett et al., 2014) and

other adverse drug events (Opondo et al., 2012). A simple five-step protocol to deprescribing has been proposed with the following key steps:

1. Ascertain all medicines the patient is currently taking and the reasons for each one
2. Consider overall risk of drug-induced hazard in individual patients in determining the required intensity of deprescribing intervention
3. Assess each drug for its eligibility to be discontinued (e.g., no valid indication, actual or potential harm of a drug clearly outweighs potential benefit)
4. Prioritize drugs for discontinuation
5. Implement and monitor drug discontinuation regimen

(Scott et al., 2015)

It has been suggested that deprescribing should be considered in older patients presenting with a new symptom suggestive of adverse drug effects; medicine use in advanced or end-stage disease, terminal illness, dementia, extreme frailty; receiving high-risk drugs or combinations; and receiving preventive medicines where there is no evidence for continued use (e.g., use of statins in frail patients) (Scott et al., 2015). Pharmacists' greater involvement in deprescribing has the potential to relieve medicine burden, unnecessary suffering, and disability in older patients. Further research is needed to identify the circumstances under which pharmacists can undertake deprescribing and how good practice guidelines can be further developed to confer maximal benefit to patients.

Pharmacogenomics and Personalized Medicines

Drug design and development has conventionally been focused on identifying therapies based on targets of entire populations. At the time of prescribing a person's age, lifestyle, existing comorbidities, and other medications are taken into account. However, an individual's response to medicines may also vary in light of their unique and constant genetic predisposition. It is increasingly recognized that personalized healthcare that incorporates shared patient-professional decision-making can lead to better health outcomes, engagement, and increases the level of trust (Denford et al., 2014). Personalized medicine seeks to tailor treatment to the unique genetic make-up to promote more effective drug therapies, reduced incident of adverse effects and improved quality of life (Agyeman and Ofori-Asenso, 2015). It is likely that medicines management services will become increasingly important in facilitating personalized and integrated care for patients managing long-term conditions (Murray, 2016).

Pharmacogenomics is becoming a reality as it shifts from the research arena into routine clinical practice. The terms pharmacogenomics or pharmacogenetics are often used interchangeably to refer to how the use of the genetic information can be used to better target medicines to individual patients. More specifically, the term "pharmacogenetics" has been defined as "the study of interindividual variations in DNA sequence related to drug response" and "pharmacogenomics" as "the study of the variability of the expression of individual genes relevant to disease susceptibility as well as drug response at cellular, tissue, individual or population level" (Committee for Proprietary Medicinal Products, 2002). The potential of pharmacogenetics is yet to be realized and many opportunities exist for novel medicines management roles (Clemerson and Payne, 2008). Although Elhassan et al. (2017) suggest that pharmacists' roles are currently ill-defined and limited, they outline three areas where opportunities exist for pharmacy:

1. *Establishing tests involving pharmacogenetics in clinical practices.*

The use of pharmacogenetics data to inform drug choice and dosage is currently used in specialized areas (e.g., in oncology). Although typically used at the point of prescribing to inform drug choice and dose, as pharmacists develop their role as independent prescribers, these will increasingly become important and relevant. Pharmacists may also develop their role in analyzing how an individual's genetic makeup affects prescribed medicines and so advise on the body's response to medications pharmacologically.

2. *Developing methodologies*

Pharmacists employed in academia, the pharmaceutical, and biotechnology industries have expertise in pharmacokinetics, pharmacodynamics, and the pharmacoeconomics and so are well positioned to contribute to pharmacogenetic research and development.

3. *Educating healthcare providers and helping in the development of infrastructure and create technologies for pharmacogenetics toward its actual implementation in healthcare system*

Establishing pharmacogenetics into pharmacy practice would need to be supported by clinical evidence, infrastructure, and financial incentives. There are indications that pharmacists may not yet have the skill set or confidence to become fully involved with clinical pharmacogenomics (Schwartz and Issa, 2017). In an era where precision medicine is becoming a reality, appropriate education and training for the profession is also needed to ensure pharmacists keep abreast of the developments of pharmacogenetics as they translate to improved patient care to ensure pharmacists are prepared for the opportunities into this area (Clemerson and Payne, 2008).

Concluding Remarks

Societal views of medicines and health continue to change, develop and shape policy, professional, and organizational responses to medicines management. The appropriate, effective, and safe use of medicines is now a global health policy priority. Despite medicines prescribing being the most common patient-level healthcare intervention, the management of medicines presents many challenges. The mounting challenges of antimicrobial resistance, suboptimal prescribing, inappropriate polypharmacy, low patient adherence to treatment, adverse drug reactions and interactions, medication administration errors, and inadequate communication across the primary/secondary care interface are just a few examples of the challenges that are faced.

Helped by their accessibility and locations (Todd et al., 2014), policymakers and commissioners are increasingly seeing the value the profession of pharmacy can bring to address these challenges, reduce pressures on more expensive secondary or family practice services (Imison et al., 2014), and support medicines management. The extended role of pharmacists extended medicines management services aligns well with pharmacy's "professionalization project" and movement away from retail and dispensing toward patient-centered services such as advice-giving and medicines optimization (Mossialos et al., 2015). Many new opportunities therefore await the pharmacists of the future and the climate is right for pharmacists to move forward and expand their professional roles. However a fully integrated medicine management program involving all organizations and stakeholders will need strong professional leadership. New skills and strategies are needed to ensure pharmacists are equipped for the medicine management challenges for the future. This could range from building on existing skills, for example, developing the technique of motivational interviewing to engage more meaningfully with patients (Rollnick et al., 2010), through to developing a new skills set, such as will be required for the practice of pharmacogenomics. The scope of pharmacist involvement in medicines management will mean this remains a cornerstone of pharmacy practice and it will be up to the profession and individuals to decide on its future.

Historical Evolution of Pharmacy Practice

Jennifer L. Marriott, Monash University, Parkville, VIC, Australia

History and Definition

Pharmacy is an old profession established as early as 4000BCE by the Sumerians; apothecaries were healers with the combined roles of doctor, pharmacist and priest (Bonanno et al., 2012). Similar roles existed in civilizations in India, China, and Egypt; however, the pharmacy profession has always been linked to the regulation of medicines supply and use (Bonanno et al., 2012). Pharmacy practice may be defined as the application of scientific knowledge and cognitive skills to improve patient outcomes and meet the health needs of the population.

The separation of the role of apothecaries into pharmacists and medical practitioners occurred at various times in different parts of the world. One of the landmark events in this process was in England, where following the Apothecaries Act of 1815 there was a clearer definition of the two streams of practice involving medicine and pharmacy, and the pharmacists' main role became the preparation of products for medicinal use (Pearson, 2007). The Flexner report in 1910 was also a significant driver in the separation of prescribing and dispensing activities in the United States with doctors concentrating on disease management and pharmacists restricting the scope of their diagnostic activities (presumably to common ailments) and concentrating on compounding medicines according to doctors' prescriptions (Bonanno et al., 2012).

Following World War II (WWII) laws were enacted that restricted many medicines to availability only on a doctor's prescription and limited the information able to be provided to the patient by pharmacists, leaving them with predominantly a medicines supply function and they consequently spent less time in contact with the public, other than prescribing treatments for minor ailments (Anderson, 2002; Higby, 2002; Holland and Nimmo, 1999; Pearson, 2007). Pharmacists relied on prescriptions and associated dispensing fees, sales of over the counter medicines, and a variety of health and beauty products to sustain their businesses and were not compensated for their professional services (Bonanno et al., 2012).

Up until the 1980s there were predominantly two areas of pharmacy practice—community pharmacy and hospital pharmacy with small numbers of pharmacists employed in other areas such as industry, academia and regulatory affairs. Prior to that time undergraduate pharmacy curricula comprised mostly science subjects such as chemistry, biology, pharmacognosy, pharmaceutics or formulation, and pharmacology. Other areas, such as law and ethics, were minor topics. Communication skills were less essential, as pharmacists were discouraged from questioning doctors and were not permitted to counsel patients about their medicines.

A pharmacist graduating in the early 1970s had therefore completed a curriculum that had a strong science base. There was little or no formal grounding in common ailments or even the dispensing process, but the basics of making tablets, suppositories, and

sterile products were taught. It was assumed that all the necessary practical aspects of community or hospital pharmacy would be learned during the 1 year of supervised practical training (internship) that followed graduation and which relied solely on the enthusiasm and expertise of the supervising pharmacist, assuming both were present. The newly registered pharmacist, especially in community practice, had little use for much of the knowledge and laboratory skills obtained while an undergraduate, but had hopefully learned sufficient during their internship not to be a danger to the public. The registration exam at the end of the internship was in place to ensure a minimum level of professional competency and to ensure public safety.

In most countries professional pharmacy bodies were formed to regulate the profession and advise or administer appropriate education and training. These bodies developed professional standards and codes of practice to enhance the standing of the pharmacy profession and protect the safety of the public (Bonanno et al., 2012).

In the intervening decades major changes occurred that vastly expanded the scope of practice of the profession. The WHO recognizes seven broad roles for the pharmacist—the "Seven star pharmacist"—Care-giver, Decision-maker, Communicator, Leader, Manager, Life-long learner, and teacher, although sometimes an eighth (researcher) is added (Bonanno et al., 2012; WHO Consultative group on the Role of the Pharmacist, 1997). While a strong science background remains an important underpinning for clinical expertise, since the 1980s the importance of "cognitive skills" (communication, law, ethics, clinical pharmacy, and disease state management) has increased and these constitute "pharmacy practice" in pharmacy curricula.

One could ask, "what brought about the change in the scope of pharmacy practice?" This question does not have a simple answer, certainly economic and political factors were involved, but a complex conjunction of events occurred following WWII that influenced both the need for change in pharmacy practice, and the direction of change.

A Change in Medicines Production

The pharmacist in the early 1900s spent much of his time compounding medications, either according to a detailed formula written by the doctor or according to his own or a standard formula, such as those available in a pharmacopeia (Holland and Nimmo, 1999). Customers would seek the pharmacist's advice regarding minor ailments rather than visit the doctor, and on most occasions, a product would be prepared specifically for that person. There was a fairly limited number of preparations, largely for self medication, that were made in the pharmacy to standard formulas or to the pharmacist's own formula and a few proprietary preparations (Sonnedecker, 2001). This situation continued until after WWII when commercially manufactured medicines became widely available in standard forms and dosages with high standards of quality control and labelling guidelines (Bonanno et al., 2012; Pearson, 2007). Over time successful pharmaceutical manufacturing companies took the role of making medicines away from the individual pharmacist. Doctors progressively abandoned the practice of writing extemporaneous prescriptions in favour of commercial products and by the 1960s the majority of prescriptions written were for manufactured dose forms (Higby, 2002; Sonnedecker, 2001). The extemporaneous dispensing of medicines by pharmacists decreased accordingly and changed the nature of pharmacy practice (Sonnedecker, 2001).

Pharmaceutical research increased markedly after WWII and over the following decades, leading to the availability of an increasing number of new medications (Bonanno et al., 2012). With increased numbers of medications available to treat disease there was a rise in polypharmacy, especially for older patients and those with chronic illnesses, and a subsequent increase in drug related problems. As unnecessary polypharmacy and associated problems increased the cost of health care for the individual and the community and led to increased morbidity and mortality, pharmacists were in an ideal position to use their knowledge and skills to improve patient outcomes and decrease costs (Bonanno et al., 2012).

A Change in Education of Pharmacists

Pharmacists who completed an apprenticeship were designated "pharmaceutical chemists," an appropriate description for someone whose primary responsibility was the preparation and dispensing of medicinal substances (Benrimoj and Frommer, 2004). Following WWII the education of pharmacists in most countries changed from an apprenticeship system to college or university based courses (Benrimoj and Frommer, 2004; Sonnedecker, 2001). The early curricula, focused on science and compounding, led to a profession that saw themselves as "chemists" (Benrimoj and Frommer, 2004).

After WWII, the knowledge and skills required by pharmacists differed greatly from the formulation knowledge required to produce elegant extemporaneous medicines. For example, the introduction of pharmacokinetics was a significant change that linked pharmacy to the cause and mechanisms of disease. This also helped reposition pharmacy practice in health care systems and began the evolution toward clinical contemporary pharmacy practice (Benrimoj and Frommer, 2004).

Over the ensuing decades university courses increased in length from 2 years, to up to 6 years. Longer courses enabled the introduction of a range of pharmacy practice subjects aimed at improving pharmacists' competency in areas of communication, clinical pharmacy, public health, and therapeutics. This has led to graduates with enhanced knowledge and skills in patient-centered care and helped catalyze the change in the practice of pharmacy.

A Change in Information Availability

The use of computers to assist with dispensing became more common from the 1980s, and computerized dispensing and record keeping is now ubiquitous (Higby, 2002). The use of computers made it simpler and easier to maintain records of patients'

medicines, which enabled pharmacists to be aware of their patients' medicine taking history and to intervene more quickly if wrong doses or interacting medication were prescribed, contributing to better outcomes. The additional time available enabled pharmacists to counsel patients on the appropriate use of their medication.

The widespread use of the Internet has also meant that the public has easy access to a wide range of information about medicines and disease—not all accurate or evidence-based. This had led to a public that may be better informed, but that also demands information and expects accurate, informed answers to their questions. Pharmacists now have the ability to retrieve, synthesize and apply published literature to support evidence-based practice and provide appropriate medicines information to their patients and other health professionals.

A Time for Change

The profession of pharmacy was faced with a loss of function as a compounder. The majority of medicines were now available only on the prescription of a medical practitioner. At the same time, as a result of increased numbers of available medicines, treatment regimens became more complex. An expectation developed that information should be available to the patient and that supply of medicines alone was insufficient to ensure their safe and effective use. Laws that had previously restricted patient information provided by pharmacists were changed to encourage them to assist the public to use medicines as intended. In addition, changing community values, increased public sector health services, and increased health spending added to the impetus for improved patient outcomes from medical care.

A tension arose in the profession that was expressed in the need to expand the scope of pharmacy practice, to utilize the knowledge and skills of the pharmacist to assist patients to manage their medication regimens and improve outcomes and to move away from a product—focused service.

Universities recognized that in addition to a strong science base to pharmacists' knowledge they also needed "cognitive" skills to enable them to best fulfil their changing role and Pharmacy Practice departments were established to facilitate the teaching of these skills. Pharmacy graduates now have increased knowledge of the side effects and potential interactions of medicines, skills in communication, and medicines management, the time to utilize these skills in their practice and the legal obligation to do so. The practice of pharmacy was evolving.

Pharmaceutical Care

The concept of pharmaceutical care was introduced as early as the 1970s; however in 1990, the landmark paper published by Hepler and Strand (1990) formalized the concept and provided a definition (Weidenmayer et al., 2006). This encouraged the development of new practice standards, the recognition of the need for collaborative practice relationships, and changed the face of pharmacy practice. The amended definition that describes pharmaceutical care as "the responsible provision of drug therapy for the purpose of achieving definite outcomes that improve or maintain a patient's quality of life" has been accepted worldwide and is acknowledged as a means for pharmacists to use their knowledge, skills, and availability to improve patient outcomes (Farris et al., 2005; Weidenmayer et al., 2006).

Pharmaceutical care requires that pharmacists accept responsibility for the outcomes of pharmacotherapy in their patients—requiring the documentation, monitoring, and review of therapy. It is a collaborative process that aims to prevent, or identify and solve, medicinal product and health related problems, leading to team-based care where the patient is involved and responsible along with their other health care providers. It is designed to promote health, prevent disease and to ensure that drug therapy regimens are safe and effective (Bonanno et al., 2012; Holland and Nimmo, 1999).

Pharmaceutical care activities have been shown to improve the quality and cost-effectiveness of health care (Weidenmayer et al., 2006). Pharmacists assess therapeutic need, prevent or manage adverse drug reactions, develop patient-specific management plans, manage chronic disease and monitor outcomes. Pharmaceutical care has been broadened by use of the term "cognitive pharmaceutical services" to encompass outcomes related to general patient health and not simply related to outcomes of drug therapy (Moullin et al., 2013).

The implementation of pharmaceutical care services worldwide was strengthened following the International Pharmaceutical Federation Congress held in Tokyo in 1993 and the release of a WHO document on the role of pharmacists in healthcare. The full implementation of pharmaceutical care may, however, be somewhat limited by the difficulties associated with different cultures, languages, and health systems (Farris et al., 2005; van Mil et al., 1999).

Modern Pharmacy Practice

While dispensing by pharmacists remains an important activity, particularly in community pharmacy, the scope of pharmacy practice has broadened substantially since the 1950s, moving from a profession that was product-centered, with a focus on the preparation and supply of medicines, to one that is patient-centered. The current scope of pharmacy practice is focused on services that require specialist knowledge and skill, such as medication history taking, providing medicines information, initiating and

monitoring drug therapy, and counseling patients on their medication regimens and health promotion to improve health outcomes. The technical aspects of pharmacy practice, such as dispensing and medicines supply management can be delegated to trained technicians or to robotic dispensing systems (Holloway et al., 1986). While pharmacists are still needed to oversee these functions, their time is now free to provide cognitive services. The expertise of pharmacists and the services they are able to provide in a wide variety of roles still need wider recognition by the general public, other health professionals and governments (Speedie and Anderson, 2017). A remuneration system, not dependent on medicines supply, must also be in put in place to enable pharmacists to provide an expanded range of patient care services.

While it would be nice to believe that all pharmacists, in all settings, were providing optimal pharmaceutical care, sadly that is not currently the case. The ability to provide a comprehensive range of pharmacy services may vary and be restricted by local laws and a shortage of qualified pharmacy personnel (Bonanno et al., 2012). Where these restrictions do not apply there is still, however, marked inconsistency in the quality of pharmacy services provided, and in the willingness of pharmacists in practice to embrace change, maintain the professional development required and demonstrate the skills that the pharmacy profession has fought to have recognized. Pharmacists may be their own worst enemy in resisting efforts to introduce practice change and develop new roles that utilize their knowledge and skills (Rosenthal et al., 2010).

Whilst it should be recognized that pharmacy practice varies in different countries and also according to practice environment—community, hospital or other, the responsibility for ensuring safe, effective and rational use of medicines now lies with pharmacists. Many countries have now granted pharmacists prescribing rights, recognizing their ability to select appropriate therapy, monitor continuing therapy and manage complex patients. Pharmacists as supplementary prescribers and according to a specific area of expertise, have the ability to initiate, modify or discontinue therapy according to established protocols. Some countries have extended independent prescribing authority to pharmacists practicing in an area of specialty (Bonanno et al., 2012; Sosabowski and Gard, 2008).

Evolution of Community Pharmacy Practice

Between the end of WWII and the 1970s community pharmacy was principally focussed on supply of mass produced medicines and over the counter medicines, coupled with retailing of health and beauty products. With increasing numbers of prescriptions to dispense pharmacists spent more time in their dispensaries focusing of medicines supply and less time interacting with patients, other than for primary care purposes (Bonanno et al., 2012). While this is still the case for many pharmacists, practice is changing as a range of patient-centered services—provision of medicines information, medicines management services (e.g., "MedsCheck" and Home Medicines Review) provision of services to aged care facilities, public health programs (including immunization, blood pressure management, cholesterol testing, smoking cessation assistance), and chronic disease management (diabetes, asthma, hypertension) are implemented. Pharmacists are now increasingly being recognized and remunerated by governments and insurers for a range of these patient-centered services (Davies et al., 2014). Much of the pharmacists' role in medication management is, however, directed toward prescribers rather than patients (Duffall et al., 2017).

A modern pharmacy may use technicians to undertake aspects of dispensing or robots to manage the technical aspects, freeing the pharmacist to provide an expanded range of patient focused services (Holloway et al., 1986). The range of activities undertaken by technicians varies widely across the world from supervised practice to independent practice (Koehler and Brown, 2017). Where there is a shortage of pharmacists, technicians' and other pharmacy support cadres' provision of pharmacy services is fundamental to public access to medicines (Koehler and Brown, 2017). While regulation and recognition of the activities of technicians is generally lacking and education and training standards vary widely, it is recognized that they are integral to pharmacists' ability to expand their scope of practice (Koehler and Brown, 2017). Regardless of new services offered through community pharmacy and the use of technicians in some countries, dispensing still occupies the majority of time spent by pharmacists and many pharmacists are still reluctant to explore new roles and deliver patient-centred services (Davies et al., 2014; Farris et al., 2005; Holland and Nimmo, 1999; Rosenthal et al., 2010).

The public is also largely unaware of the extent of the changes to the pharmacists' scope of practice, perhaps due to an out-dated view of community pharmacy or lack of awareness of currently available services, and they are yet to take full advantage of pharmacists' potential as medical advisors and advocates (Adamcik et al., 1986; Speedie and Anderson, 2017). The ultimate goal, however, is for community pharmacies to be recognized as providers of professional pharmacy services, not simply as retailers of health-related products (Moullin et al., 2013).

New Community Pharmacy Services

As the community pharmacist is the most accessible health practitioner, pharmacists are, and are likely to continue to be, the primary source of advice and assistance regarding common or "minor" ailments. An increasing range of potent medications, from H2 antagonists to asthma medications, is available for supply over the counter requiring supervision and advice by the pharmacist, enhancing the pharmacists' role as providers of primary care.

Patients now have access to a diverse range of information, both reliable, and unreliable. As medical and medicines information is easily accessible the public will increasingly require assistance in its interpretation and pharmacists may find a role assisting others to understand the available evidence and as advocates for patients in health care settings. Through its direct access to the population

community pharmacy also has the potential to influence public health by promoting programs such as those aimed at improving oral health, smoking cessation, chronic disease management (Ibrahim et al., 2012).

Home Medicines Review for persons living at home and Residential Medication Management Review for persons living in aged care facilities are pharmacy services in Australia that are remunerated by the government. A Home Medicines Review is a comprehensive clinical review of a patient's medicines in their home by an accredited pharmacist on referral from the patient's general practitioner (Australian Government Department of Health). While these services are provided through a community pharmacy, the comprehensive reviews are time-consuming to produce and are generally conducted by specifically credentialed consultant pharmacists (Benrimoj and Frommer, 2004).

Although extemporaneous prescriptions have largely disappeared from most community pharmacies, there is still an occasional need for individualized medicine to be compounded to meet specific patient requirements and specialist compounding pharmacies have arisen to meet this need (Minghetti et al., 2014). These specialized pharmacies prepare compounded medicines for particular patients on behalf of noncompounding community pharmacies that do not have the facilities or the raw materials to compound medicines.

The advent of dose administration aids has facilitated development of medicines supply services by community pharmacies to aged care facilities and the general public (Silcock et al., 2004). These were initially offered free of charge in place of prepackaged/commercial preparations. Their use has contributed to increased patient safety through decreased administration errors and ease of monitoring of medicines. The wider use of this service, and the increased cost of providing it, has prompted the need for a charge and its continued viability will depend on a satisfactory remuneration model (Farris et al., 2005; Silcock et al., 2004).

Evolution of Hospital Pharmacy

Pharmacists in hospitals have demonstrated positive impact on improved outcomes of care, decreased adverse events and shorter lengths of stay thereby reducing health costs (Cruthirds et al., 2013; Dooley et al., 2003; Lucca et al., 2012).

Up until the 1970s the majority of hospital pharmacy departments were confined to larger hospitals, were likely to be located in hospital basements and primarily had a supply and manufacturing function. Other than for outpatient dispensing, hospital pharmacists rarely saw a patient or spoke to a doctor. Hospital pharmacists then recognized that there was a decreased need for compounded medicines, other than sterile or oncology patient-specific preparations, and increasing scope for improving the safety and effectiveness of drug therapy (WHO Consultative group on the Role of the Pharmacist, 1997). Pharmacy services in hospitals therefore changed to become increasingly patient-focused with pharmacists progressively included as members of the health care team. In some countries, hospital pharmacy services have not developed at the same rate, principally due to restrictive legal and professional frameworks (van Mil and Schultz, 2006). The transition of patients between hospital and home has also become a major focus for hospital pharmacists recognizing the potential for drug related problems to occur at these interfaces (van Mil et al., 1999; Vuong and Marriott, 2006).

The development of "clinical ward pharmacy" where the pharmacist, in possession of accurate patient information, constructively contributes to decision-making and patient care and intervenes to improve patient outcomes, was the result of decades of change and relationship building. Clinical pharmacy services required pharmacists to have unrestricted access to inpatient medical notes, results of tests, previous medical history, to interact with the healthcare team in addition to the ability to visit patients in the wards to obtain an accurate medicine history and counsel on prescribed medication (Weidenmayer et al., 2006).

The first move toward clinical pharmacy was the introduction of "satellite" pharmacies that positioned pharmacists closer to the wards and more available to answer questions from nursing and medical staff and to obtain necessary information about patients (WHO Consultative group on the Role of the Pharmacist, 1997). Counseling the patients on discharge was also more efficient if undertaken on the ward. Slowly pharmacists won the right to undertake ward rounds, mostly independently, to speak to patients to gather medication histories and view medication orders. This knowledge facilitated the identification of drug related problems such as missing medication, duplicated therapy, drug interactions, and dose discrepancies. Pharmacists were able to be present at ward nursing handover meetings, although it was some time before they were permitted to make notes in the patient's permanent medical record (Weidenmayer et al., 2006). As hospitals employed a number of pharmacists they were able to share experiences and educate each other about interpreting test results, drug related problems and disease management.

Clinical pharmacy requires an expert knowledge of therapeutics, disease state management and the ability to assess laboratory tests, together with excellent communication and interpersonal skills, promoted a strong pharmacist-patient relationship and a closer interaction with other health professions (Adamcik et al., 1986; Anderson, 2002). As the knowledge and skills of the pharmacist were recognized they assumed roles in a range of outpatient clinics where they manage complex patient medication therapies using evidence based decision-making and may have supplementary or independent prescribing rights. In practice a number of models may exist in different countries depending on their workforce capacity.

As qualified technicians may have responsibility for the majority of medicine supply functions in hospitals, pharmacists now also provide additional services such as medicines information including drug protocol design and drug policy development, formulary development, or clinical trials.

The evolution of hospital pharmacy has not proceeded at the same rate in many countries as it has in the United States, United Kingdom, Canada, and Australia. In an effort to increase the standard of hospital practice globally, in 2008 the International Pharmaceutical Federation (FIP) organized a meeting that led to the publication of a number of consensus statements that defined a

baseline standard of practice for hospital pharmacy (International Pharmaceutical Federation, 2014). While it is recognized that not all hospitals will be able to meet all/most of these standards, they provide a guide for pharmacists wishing to improve practices in the hospitals where they work (Bonanno et al., 2012).

Evolution of Academic Pharmacy

Over the period since WWII, there have been a number of significant changes to pharmacy education. For centuries, the exclusive mechanism for entry into the profession was through an apprenticeship (Bonanno et al., 2012). Under this system the aspiring pharmacist would work side-by-side with the established pharmacist, learning by observing and doing medication-related activities under the tutelage of the master pharmacist, leading to widely varying levels of expertise. The apprenticeship was supplemented, especially in later years, by coursework and examinations to ensure a basic level of competency prior to registration (Sonnedecker, 2001).

From the 1800s, many universities opened pharmacy schools; however, degrees in pharmacy as the means of entry into the profession appeared much later (Bonanno et al., 2012; Sonnedecker, 2001). Gradually pharmacy degree courses that were predominantly science-based were mandated as an alternative to apprenticeships and then as the sole means of obtaining registration as a pharmacist. Many countries have retained the requirement for a year in practice (internship) following the formal university degree before being eligible for registration. This year in practice is, in some countries, now being incorporated into the university curriculum. It is important that pharmacist education and pharmacy curricula are "needs-based." Pharmacy curricula need to be able to adapt to local needs and to changes in practice, however, no core curricula are able to be described that would suit the needs of all countries in producing pharmacists suited to their individual local needs (WHO Consultative group on the Role of the Pharmacist, 1997). The pharmaceutical services that are to be provided by graduates need to be considered when designing the curricula to ensure that graduates meet those needs and are "fit for practice" (Anderson et al., 2010).

The product-centered role of the pharmacist translated into an education that was geared to providing knowledge on the source of medicines, their action in the body and the formulation of medicines into appropriate dosage forms. Pharmacy degrees were therefore very strongly oriented toward sciences such as chemistry, pharmacology, and pharmaceutics, and the technical and legal aspects were associated with dispensing. The introduction of the concept of pharmaceutical care that heralded a change in direction of pharmacy practice also led to a change in the direction of pharmacy education. From the 1990s the majority of courses have increased in length and incorporated substantial experiential learning to embed knowledge and skills and attributes such as empathy, cultural competence, and clinical reasoning (Anderson, 2002; Bonanno et al., 2012).

In the United States, also in 1997, a decision was made that the entry-level pharmacy degree would be a PharmD, requiring a minimum of 2 years of pre-pharmacy courses and a four-year pharmacy degree with integrated practical experiences. Many other countries throughout the world are moving toward a PharmD to increase the supply of clinically trained pharmacists and change the scope of the pharmacy profession locally (Kahn, 2011). The difficulties faced in introducing a clinically oriented degree in many countries relate to the lack of appropriate clinical training sites, maintaining a contemporary curriculum and the dearth of academic staff with appropriate qualifications and experience (Kahn, 2011). In many of the countries where the PharmD has been introduced graduates face resistance from other health care providers such as doctors and nurses to establishing a new scope of practice for pharmacy (Kahn, 2011).

Whether the degree is a Bachelor, Masters, or Doctorate, curricula now have a strong emphasis on patient care, public health and health promotion activities and the necessary associated skills and the level of competency required for registration has become more rigorous (Bonanno et al., 2012). The changes to pharmacy curricula have also required a major commitment by universities to faculty development and the employment of clinical teachers and teacher-practitioners. Teaching methodology is moving away from formal, large lectures to more active learning strategies that are student-centric rather than teacher-centric to encourage students to be responsible for their own learning and to develop life-long learning skills (Weidenmayer et al., 2006; WHO Consultative group on the Role of the Pharmacist, 1997). The integration of science and practice is becoming more commonplace and helps students understand the relevance of the science they are learning to the clinical pharmacy and patient centred care they expect to practice. Experiential learning opportunities are recognized as important as pharmacists practice in a more collaborative, multidisciplinary environment.

Continuing professional development (CPD) is mandatory in many countries to ensure that pharmacists maintain their knowledge and skills in their area of practice, especially in view of the rapid pace of change and an increasingly well-informed general public. It is critical to the continued evolution of the profession that appropriate CPD opportunities exist (Council on Credentialing in Pharmacy, 2014; International Pharmaceutical Federation, 2016).

Many countries have numerous pharmacy schools and adequate academic capacity to produce more pharmacists than are necessary to meet that local need (Kheir et al., 2009). Pharmacists therefore find employment in countries with low pharmacist numbers attractive. Expatriate pharmacists are able to partly fill the need for pharmacists in countries that are unable to locally educate adequate numbers to meet demand (Hasan et al., 2011). Pharmacists educated in low-income countries may conversely find that employment in other countries is more lucrative than in their home country and choose to practice outside of their home country. Pharmacist mobility can have benefits for the individual in providing an opportunity to practice and learn skills in a new environment, but it can be detrimental to countries where there are insufficient local pharmacists.

Evolution of Other Areas of Pharmacy Practice

A diverse range of pharmacy practice opportunities exist as areas where pharmacists use their skill and knowledge to provide better patient outcomes, whether this is in providing interpretation of laboratory tests, developing or providing health and medicines information or responding to local or global emergencies. In addition to Community, Hospital, and Academic pharmacy, and recognition of pharmaceutical scientists, FIP includes in its Board of Pharmacy Practice, five additional broad areas of practice—Clinical biology, Health and medicines information, Industrial pharmacy, Military and emergency pharmacy, and Social and Administrative pharmacy.

Pharmacists in general practice clinics are variously termed Primary Care pharmacists, Consultant pharmacists or Ambulatory Care pharmacists, although these terms may not be interchangeable, but simply overlapping in their areas of responsibility. The services they provide include comprehensive medicines management and associated independent or supplementary prescribing (Carmichael and Hall, 2015).

Pharmacists in industry have a broad range of roles including research, formulation development, quality control, clinical trials and medicines information (Bonanno et al., 2012). Since the 1990s, roles for pharmacists in industry have been decreasing in many countries as specially trained personnel—analytical chemists, pharmaceutical scientists (who are not pharmacists) and administrators with business degrees are now fulfilling many of the roles traditionally undertaken by pharmacists.

Evolution of Pharmacy Practice Around the Globe

The role of pharmacists, and the practice of pharmacy, differs not only according to the laws and economic capacity of the country but also on workforce availability and capability.

USA and Canada

The pharmacy profession in the United States stemmed from the practice of medical practitioners to employ assistants to compound the medicines they prescribed (Anderson, 2002). Although formal education of pharmacists began in 1821 when the Philadelphia College of Pharmacy and Sciences was founded, the majority of those practicing as pharmacists had no formal qualification until after 1905 when states began to require graduation from a course in pharmacy to qualify for registration (Sonnedecker, 2001).

Much of the stimulus for change in the profession and the evolution of pharmacy practice globally occurred following events in the United States. In 1951 pharmacists' freedom to supply medicines without a medical prescription was restricted by law forcing pharmacists to spend more time dispensing and possibly changing the public perception of the scope of pharmacy activities (Bonanno et al., 2012). The USA Medicare and Medicaid legislation in 1965 was the stimulus for the creation of an organized health workforce and for the growth of hospital pharmacy practice (Higby, 2002). Funding was made available to universities to expand their enrolments in health science courses, including pharmacy (Higby, 2002).

Pharmacy education in the United States was initially 2 years, but had increased to 3, then 4 and 5 years before, in 1997, American Council on Pharmaceutical Education decreed that they would no longer accredit Bachelor of Science programs, effective from 2000 and all colleges of pharmacy must convert to the PharmD as the sole professional entry-level degree, including mandatory periods of experiential learning. Pharmacy graduates, particularly those planning to work in clinical care roles, commonly undertake an additional 1 or 2 year hospital residency program. Pharmacy graduates undertaking these residency programs are able to consolidate and advance their skills in delivery of patient care services.

The ethical code of the American Pharmaceutical Association in 1952 precluded pharmacists from discussing the composition or therapeutic effects of a doctor's prescription with the patient (Carmichael and Hall, 2015; Higby, 2002; Holland and Nimmo, 1999). The 1975 Millis report called for a shift in focus of the profession from product to patient and suggested that pharmacists should be trained to provide direct patient care to improve public health—the beginnings of clinical pharmacy. In 1976, The American Pharmaceutical Association established the Board of Pharmaceutical Specialties to recognize specialty areas of pharmacy practice (Keeley, 2002). Board certification is a voluntary process that is open to all registered, practising pharmacists following satisfactory completion of a qualifying examination.

Although the term "pharmaceutical care" was first introduced in 1985, it was not until 1990 that the provisions of the Omnibus Budget Reconciliation Act enabled, in fact required, US pharmacists to review drug use, counsel patients and document interventions in a patient profile. The law required pharmacists to screen for a full range of drug related problems and to incorporate this information into a patient-specific profile. This direction was very quickly extended to provision of these services to all patients (Hradecky, 2001).

A similar change in the scope of practice occurred in Canada due to recognition of increasing rates of morbidity and mortality and the value of the pharmacist in dealing with the increased complexity of medication and in improving patient outcomes (Bonanno et al., 2012; Schindel et al., 2017). Innovative models of practice have developed throughout Canada that provide medicines review services and integrate pharmacists into health care teams and specialty care clinics (Canadian Pharmacists Association, 2015). The province of Alberta was the first to legislate an advanced scope of practice and authorize pharmacists to prescribe, but most provinces have now recognized and remunerated this new model of pharmacy practice service delivery

(Canadian Pharmacists Association, 2015; Schindel et al., 2017). A compensation framework for pharmacy services was also introduced in 2012 (Schindel et al., 2017).

UK

Modern pharmacy developed after the Apothecaries Act of 1815, the formation of the Pharmaceutical Society in 1841 and the establishment in 1842 of the first school of pharmacy in Britain at the Society's headquarters in Bloomsbury square (Bonanno et al., 2012; Copeman, 1967).

The education of pharmacists was largely through an apprenticeship system until 1924. The University of London's BPharm course was the first degree specifically to be approved as part of a formal entry route to the profession. From 1954 to 1967 two routes to becoming a pharmacist were available—the three-year Pharmaceutical Chemist Diploma involving a minimum of 2 years apprenticeship in a pharmacy and passing the Royal Pharmaceutical Society's membership examination, or a three-year BPharm degree followed by a year's apprenticeship in a pharmacy and success at the Society's examination in forensic pharmacy. The three-year BPharm was discontinued in 1997 and replaced by the four-year undergraduate Master of Pharmacy with a yearlong internship (Anderson, 2002). This change occurred in response to the Bologna Agreement within the European Economic Area and the Nuffield committee recommendations to extend the scope of the pharmacy degree (Silcock et al., 2004; Sosabowski and Gard, 2008).

The introduction of the government funded National Health Service in 1948 undermined the existing primary care function of pharmacy by shifting consultations about illness to the general practice setting where they were free of charge (Bonanno et al., 2012; Davies et al., 2014). Pharmacist activity was consequently limited to dispensing of doctors' prescriptions.

Between the 1970s and 1990s hospital pharmacy in the United Kingdom underwent a period of change following the identification of an unacceptable level of drug administration errors in British hospitals (WHO Consultative group on the Role of the Pharmacist, 1997). Pharmacists in hospitals became aware of the opportunity for improving the effectiveness and quality of drug therapy, supported by the Gillie report that recommended the introduction of "ward pharmacy" (WHO Consultative group on the Role of the Pharmacist, 1997). Pharmacists working in the wards communicated with their nursing and medical colleagues and became more involved in the management of drug therapy and this developed into "clinical pharmacy." As pharmacists' time became more involved with clinical pharmacy activities a number of routine tasks were delegated to technicians. Pharmacists were encouraged to interact with patients and provide them with information and assistance regarding their medicines (Anderson, 2002).

The scope of pharmacists' activities and practice has now widened considerably. The Royal Pharmaceutical Society has introduced a comprehensive program to encourage pharmacists to continue their development over their career and recognizes several levels of a practitioner from novice to expert. Pharmacists in the United Kingdom may be employed in clinics alongside doctors, appropriately qualified pharmacists have been granted prescribing rights and the community pharmacists may provide medicines review services for their patients and for those in aged care (Silcock et al., 2004). The role of pharmacists who work in Primary Care Trusts or directly with GPs is now termed "primary care pharmacy" (Silcock et al., 2004; WHO Consultative group on the Role of the Pharmacist, 1997) While these roles were initially created to help make prescribing more cost-effective within National Health Trusts, their function has now expanded. Management of drug budgets is still an important role that also includes clinical governance, medication review, and prescribing or prescribing advice (Silcock et al., 2004).

Europe

The European Union is yet to introduce harmonization in the delivery of health care in member countries, and there are therefore many differences in healthcare policies and practices throughout the region leading to much diversity in pharmacy practice in community and in hospitals, and in the provision of pharmaceutical care (van Mil and Schultz, 2006). Pharmacies in Scandinavia are relatively large and focus primarily on medicines, whereas pharmacies elsewhere in Europe are smaller and also stock a range of health and beauty aids and other nonmedical items (van Mil and Schultz, 2006).

University education of pharmacists occurred much earlier in Europe than elsewhere with a university degree mandatory from 1875 in Germany (Bonanno et al., 2012). The predominantly science focus that continues in most European pharmacy curricula was important for the development of a robust pharmaceutical industry. The lack of a significant clinical component, however, limits the extent of adoption of patient-centered care, although this is changing as clinical pharmacy is being introduced into European curricula (van Mil et al., 1999; van Mil and Schultz, 2006).

The first approach to the introduction of pharmaceutical care was undertaken in 1992 by the Danish College of Pharmacy Practice (van Mil and Schultz, 2006). Other countries became aware of the concept through discussion at congresses and the FIP Statement of Professional Standards issued in 1998. In 1994, The Pharmaceutical Care Network of Europe was formed with the aim of stimulating research and assisting countries to embed pharmaceutical care in the health care systems; however, by 2000, it was evident that there was still little pharmaceutical care activity in many European countries (van Mil and Schultz, 2006). Pharmaceutical care standards were established in the Netherlands in 1996 and in Germany an agreement was signed in 2004 combining the family pharmacist with the family physician and providing remuneration by insurers for pharmaceutical care services (van Mil and Schultz, 2006). In 2005, the provision of pharmaceutical care also became a legal obligation for Belgian pharmacists, while in Italy it is generally the domain of hospital pharmacists. Programs currently exist in Portugal for pharmacist involvement in the management of disease states such as diabetes, asthma, and hypertension. In Scandinavian countries, pharmaceutical care in community pharmacies generally focuses on identification and resolution of drug-related problems (van Mil and Schultz, 2006).

Japan

The Japanese Pharmaceutical Association was formed as early as 1893 partly to support the separation of prescribing and dispensing (Bonanno et al., 2012; Nakagawa and Noriaki, 2017). Their efforts were not completely successful, however, although the proportion of prescriptions now being dispensed by doctors is decreasing, particularly in larger cities. The number of prescriptions dispensed by doctors in rural areas remains high (Yamamura et al., 2006).

The pharmacy curriculum is of 6 years duration, including 6 months experiential placement in hospital and community practice (Nakagawa and Noriaki, 2017; Yamamura et al., 2006). There is also an increasing emphasis on ensuring graduates have the competency to provide an increasing number of clinical services. Individual institutions have recently introduced two-year residency programs, similar to those in the United States and Canada (Nakagawa and Noriaki, 2017). A variety of board certification programs have also been developed to increase pharmacists' capabilities in a range of specialty areas, such as infectious diseases and oncology (Nakagawa and Noriaki, 2017).

As technicians are not recognized in Japan, pharmacists remain responsible for all dispensing in both hospital and community settings (Yamamura et al., 2006). In hospitals, pharmacists have responsibility for specific compounding services for hospital use, manufacturing of sterile preparations, drug information services, and management of clinical trials. Hospital pharmacists are also becoming involved in multidisciplinary teams and providing clinical pharmacy to individual patients on the wards - taking medication histories, monitoring drug use and educating patients on their medication (Nakagawa and Noriaki, 2017). In community settings, pharmacists dispense prescription medication, provide over-the-counter medicines, and advice and a limited range of clinical services, predominantly history taking and patient counseling. Primary Care pharmacists are able to manage all aspects of a patients medication needs and are available 24 h/day and may provide these services in patients' homes (Nakagawa and Noriaki, 2017).

Although pharmacists in Japan are not currently providing a full range of cognitive pharmaceutical services, their practice is changing toward a more patient-centered approach.

Middle East

Pharmacy education and practice vary markedly across the Middle Eastern region. This is largely due to ongoing conflict, the result of oppressive regimes, and economic factors. The pace of change in pharmacy practice, even in well-resourced middle-eastern countries has been slow. Those countries that are economically stable have, however, made significant advances in pharmacy practice.

To meet local needs within the region, there has been a change in education and an increase in the number of pharmacy schools (Al-Jumaili et al., 2013). Pharmacy schools are seeking external accreditation of their programs, and many are revising their curricula to place a greater focus on patient care skills (Kheir et al., 2009). The PharmD has been introduced in many countries to increase the clinical focus of pharmacy education and thereby influence practice (Hasan et al., 2011).

Many countries in the region are not graduating sufficient pharmacists to meet their local needs and rely on expatriate pharmacists from countries with an oversupply, such as Egypt, India or Jordan where education is generally very science-focused with little emphasis on clinical, patient-oriented skills (Hasan et al., 2011; Kheir et al., 2009). This limits the development of patient-centered services in the region.

The role of pharmacists in community pharmacies in the Middle East differs according to economic, regulatory, and organizational frameworks within each country (Hasan et al., 2011). While local graduates are employed in the hospital sector, in academia or in regulatory affairs, community pharmacies have a relatively poor public image and are manned mostly by expatriates (Kheir et al., 2009). Opportunities to practice clinical pharmacy and patient-centered care are generally limited, although this varies between countries (Al-Jumaili et al., 2013; Hasan et al., 2011).

Asia

Schools of pharmacy in Asia have predominantly focused on graduating pharmacists to be capable of working in the rapidly expanding pharmaceutical industry in the region. This is especially true in India where the majority of graduates find employment in industry (Azhar et al., 2009; Basak and Sathyanarayana, 2010). This is changing, however, as most countries evolve to education with a focus on clinical competencies (Basak and Sathyanarayana, 2010).

Pharmacy education in India has been rapidly expanding, due to rapid industrialization in the pharmaceutical sector, privatization, and economic growth (Basak and Sathyanarayana, 2010). The high number of graduates exceeds the local requirements and many seek employment elsewhere, often supplementing locally trained pharmacists in developing countries (Basak and Sathyanarayana, 2010). The Pharmacy Council of India introduced a PharmD program in 2008 that emphasizes the clinical and patient-oriented aspects of the pharmacy profession, however acceptance of the clinical expertise of pharmacists is low and clinical positions are limited (Basak and Sathyanarayana, 2010).

In many Asian countries, there is no separation of prescribing and dispensing, and the community pharmacists' role is significantly limited, demonstrating under-utilization of their expertise by the general public, other health practitioners and governments (Azhar et al., 2009; Chua et al., 2013). The main role for pharmacists in this setting is providing advice regarding minor ailments or direct purchase of a medication or supplement, including traditional therapies (Chua et al., 2013). Hospital

pharmacists have a somewhat expanded role as they have access to the patient's medical record and counsel patients on the use of their prescribed medication (Inoue et al., 2016).

In countries where prescribing and dispensing are separated, there is an expanded role for the pharmacist, both in the community and in hospital (Inoue et al., 2016).

Under-Resourced Countries

There are significant disparities in the number of pharmacists per 10,000 population in well-resourced countries compared to those that are under-resourced (Anderson, 2002; Azhar et al., 2009). Well-resourced countries such as USA, Canada, Australia, and the UK have more than nine pharmacists per 10,000 population, whereas under-resourced countries, such as Malawi, Zambia, Uganda, and Tanzania, have less than one pharmacist per 10,000. The low number of pharmacists per capita has implications for inequalities in access to medicines and medicine expertise, with many pharmacists employed in administrative positions. In addition, as most pharmacists work in large population centers, the number of pharmacists and the availability of pharmacy services in rural areas are much lower (Anderson, 2002; Azhar et al., 2009). Without pharmacists, the health care system is unable to cope effectively with most medicine-related issues (Azhar et al., 2009). The evolution of pharmacy practice in under-resourced countries is therefore hampered not only by economic realities but also due to the severe shortage of pharmacy workforce and lack of recognition by governments and other health professionals of the knowledge and skills of pharmacists (Anderson et al., 2009; Azhar et al., 2009). In many countries, doctors are able to dispense thus decreasing the opportunities for pharmacists to provide pharmaceutical care (Azhar et al., 2009; Kahn, 2011).

Health needs are generally serviced by a mix of privately owned pharmacies, NGO operated facilities, and public hospitals and clinics (Anderson, 2002). The main tasks of pharmacists working in hospitals and clinics must therefore focus on ensuring the supply and dispensing of appropriate, quality medications (Anderson, 2002). Pharmacy technicians, who may have some level of training and often work without supervision, supplement pharmacy services in many of these countries, but they may not be capable of providing an appropriate level of service (Azhar et al., 2009).

Counterfeit medicines are problematic and many governments are conducting campaigns to control this problem and assure the quality of both locally manufactured and imported medicines (Bonanno et al., 2012). Pharmaceutical care and clinical pharmacy cannot be introduced, while the number of registered pharmacists is below what is required to simply sustain the system and ensure a reliable supply of needed medicines. Ongoing efforts are needed to ensure capacity building of skilled medicine expertise to meet the pharmaceutical needs of populations (Anderson et al., 2010). The teaching of pharmacy practice skills helps to ensure that the workforce will be ready for change as workforce levels increase.

Increased pharmacy student enrolments and increased numbers of pharmacy schools are only possible when there is an adequate academic workforce (Anderson et al., 2009). Alignment of curricula with current pharmacy practice standards is important to graduate a pharmacy workforce able to provide the best health care for the population and the leadership skills necessary to change practice (Anderson et al., 2009).

A Look into the Future

In the future, the expertise of pharmacy practitioners will increase and be recognized by governments, other health professions and the public, and its potential to improve global health will be fully realized. Consumer health expectations will continue to rise and the need for a reliable and accessible source of health information will provide an important role for pharmacists. The education of pharmacists will continue to provide comprehensive clinical training to enable delivery of an expanded range of services; however, it is important that the scientific basis of this knowledge is not lost. With biotechnology, genomics, proteomics, and nanotechnology, the prospect of personalized medicine will become a reality—at least in high-income countries.

In many settings, even in well-resourced health systems, and particularly in community pharmacy, pharmacists are still mostly occupied fulfilling supply functions and spend little time on the provision of cognitive pharmacy services (Bonanno et al., 2012). This may, in part, be due to uncertainty concerning reimbursement for many of the new and innovative professional services and these may only expand when pharmacists are paid for their clinical expertise (Canadian Pharmacists Association, 2015). The most appropriate model for payment has yet to be established. Uncertainty may also be due to a lack of confidence or a perceived lack of skills, although a plethora of educational opportunities are available to meet gaps in knowledge and skills (Rosenthal et al., 2010).

Increased use of technology and technicians to assist with routine activities has provided pharmacists with more time for patient care activities, but many are not taking advantage of the opportunities available (Rosenthal et al., 2010). It may be that some current members of the profession are not fully committed to change (Holland and Nimmo, 1999; Rosenthal et al., 2010). There is some evidence that these attitudes are changing, and it is hoped that future generations of pharmacists, clinically trained and expecting to perform patient care activities will be less risk averse and willing to embrace change in pharmacy practice (Harrison et al., 2012; Luetsch, 2017). As the new generation of health professionals recognizes the expertise of pharmacists in medication management, and as the older, more traditional cohort retires, the existing opposition to changed pharmacists roles will likely disappear, a trend that is currently occurring in many areas of practice.

What will pharmacy practice look like in 10, 20, or 50 years? Over the past 50 years pharmacy practice has evolved from a medication-focused role to a patient-focused, role and it is likely that this trend will increase with pharmacists' knowledge and

expertise concerning the safe, effective, and rational drug use making them an integral part of the patient care team. Can we envision a future where community pharmacies are providing a wide range of patient care services that are recognized by governments and the public as an important health resource that is easily accessible and able to provide high standards of medicines information, primary care and medication management activities, improving health of the public and reducing health inequality?

Changes in the legislative framework to facilitate pharmacists' changing scope of practice and an acceptance of the pharmacists' skills by other healthcare professions, while apparent in some jurisdictions, are not yet widespread. Challenges to be overcome therefore include legislative requirements, lack of competent human resources, lack of support from other health professions and health system constraints, including lack of access to patient data.

Specialisation is already occurring in some practice areas where distinctly different knowledge and skills are required and in some countries, specialisation and advanced practice are formally recognized, credentialed and compensated (Carmichael and Hall, 2015; Council on Credentialing in Pharmacy, 2014; Waddell et al., 2016). The areas of pharmacy practice recognized by FIP could be considered areas of specialization—Academic pharmacy, Clinical biology, Community pharmacy, Health and medicines information, Hospital pharmacy, Industrial pharmacy, Military and emergency pharmacy and Social and administrative pharmacy. Other specialty areas that may require additional education or certification, such as oncology, geriatrics, diabetes, fertility, HIV, psychiatry, nuclear medicine, nutrition support, the compounding of specialty medications, and pharmacotherapy are also being recognized. Generally, specialization requires additional training and some level of postgraduate qualification in an area related to the area of advanced practice (Council on Credentialing in Pharmacy, 2014). It is likely that this trend will continue as the extent of knowledge in pharmacy increases and our profession follows the model of our medical and nursing colleagues. Pharmacy education, both undergraduate and postgraduate, will need to be reassessed frequently to ensure that graduates have the knowledge and skills necessary to allow them to provide advanced services as either generalists or specialists.

It would be wonderful to envision a future where all of the world's population have access to safe and effective healthcare and access to a range of quality pharmacy services delivered by competent pharmacists.

Codes of Conduct/Ethics in Pharmacy Practice

Cicely Roche, Trinity College Dublin, University of Dublin, Dublin, Ireland

Introduction

This chapter introduces the concept of codes of conduct/ethics in pharmacy practice, and explores what codes are, why and how they might be developed in a manner that positively impacts on the practice of pharmacy. It offers exploration of answers to four questions, namely: (1) What is a code? (2) Why might a code be developed? (3) How might a code be developed? (4) Why might a code fail to achieve its aims? Conclusions and recommendations incorporate key learning from the evidence base and exemplars in various jurisdictions, in a manner that aims to provide tangible guidance to those embarking on the development or revision of a code for pharmacists and other pharmacy professionals.

What Is a "Code"?

A "code" may be described as a public statement of what behaviors represent acceptable engagement between an organization (or profession) and other parties, including: the public, members (or employees), among members in the organization and/or, as with the health care practitioner-patient relationship, between individuals "inside" and "outside" the organization. Supported by the expectation that individuals and business entities will respect the policies and laws governing the society in which they exist, codes seek to guide decision-making through situations that cannot be resolved by the "letter of the law" or a literal interpretation of existing policy. Codes also provide all stakeholders with a benchmark against which questionable behavior might be evaluated.

Organizational codes commonly include reference to governance or control, and are generally underpinned by concepts, such as equity and justice, and a public commitment to corporate social responsibility or ethical management of the organization. Such public statements are increasingly prominent in public bodies, charitable organizations, business, banking, and the professions.

Professional Codes, Policies, Standards, and Guidelines

Professional codes align with policies, standards, and guidelines affiliate to that profession. Associated "standards" illustrate minimum requirements associated with demonstration of professional competence, and such standards may include reference to competency frameworks, that is, detailed lists of behaviors that collectively describe what a member of that profession should be able to demonstrate and does in practice. "Guidelines" provide, for example, sample approaches to the delivery of specific services, and generally detail the steps to be taken to assure appropriate conduct or behavior. As it is not possible to predict and construct standards and guidelines to cater for all circumstances a practitioner might face, a code infers what should be considered ethical and/or professional behavior when available standards and guidelines don't apply directly to the situation. Codes applicable to health care professionals generally include reference to the "four principles" of health care ethics, namely, respect for autonomy, beneficence (do good), nonmaleficence (do no harm), and justice (resource allocation) (Beauchamp and Childress, 2009). Most importantly, codes for health care practitioners should accommodate the application of professional judgment by individual practitioners and guide ethically defensible decision-making through professional dilemma scenarios (Exhibit 1).

Codes are generally referred to as codes of Ethics (e.g., Alberta, Australia, British Columbia, New Zealand, Ontario, and United States) or codes of conduct (e.g., Ireland and the Royal Pharmaceutical Society, United Kingdom). However, there are exceptions, such as the decision by the "General Pharmaceutical Council" (GPhC), the pharmacy regulator in the United Kingdom, to refer to "Standards for Pharmacy Professionals" rather than a Code (GPhC, 2017).

Some authors differentiate between "conduct" and "ethics" by referring to a code of conduct as being rules-based or a minimum standard that can be demanded of every member of the profession in a manner that can be regulated, and a code of ethics as an "ethical maximum" that derives from a belief that "being good is not enough" and/or identifies the pursuit of excellence as an attitude inherent to individual professional practice (Hernandez et al., 2017). While this is an important background debate and may be relevant when interpreting the range of perspectives that might contribute to the development of a code, comprehensive review of the literature underpinning this debate is beyond the scope of this chapter. Contemporary codes generally seek to accommodate a range of stakeholders, including members of the public and regulatory bodies. An ongoing challenge is to balance the desire to be precise and explicit, in a manner that members of the public can trust and regulators can enforce, while also providing guidance to members of the profession for situations where standards and guidelines do not apply and they need to employ professional values to decision-making through the resulting ambiguity.

For convenience, the generic term "code" is used throughout this chapter.

While the Ontario College of Pharmacists (OCP), College of Pharmacists of British Columbia (CPBC), and Alberta College of Pharmacists (ACP) refer to codes for technicians; and GPhC refers to registration of technicians, regulation of technicians is not constant among jurisdictions. Direct reference to pharmacist(s) is assumed unless otherwise indicated.

Most codes and/or policies refer to competency frameworks, against which to compare a pharmacist's behavior(s) in order to determine whether the behavior(s) represents a breach of the code. In context, each behavior represents a combination of relevant knowledge, skills, and/or professional attitudes that must be developed to an acceptable standard, and then demonstrated throughout the professional's lifespan. For example, the professional "understands and applies the requirements of pharmacy and medicines law" or "makes and justifies decisions in a manner that reflects the (code) for pharmacy and pharmacy and medicines law." A range of related behaviors underpin any given competency, for example, that a pharmacist "practices legally" or "practices ethically." Competencies are generally grouped into domains of responsibility. The collective of all competencies deemed essential for a practicing pharmacist forms a competency framework. The International Pharmaceutical Federation's (FIP) describes the role of the pharmacist through a seven-star concept in which the pharmacist is described as a caregiver, communicator, decision-maker, teacher, lifelong learner, leader, and manager (WHO, 2006), and provides one example of a collaboratively prepared "Global Competency Framework," which incorporates four domains as follows: (1) Pharmaceutical Public Health Competencies, (2) Pharmaceutical Care Competencies, (3) Organization and Management Competencies, and (4) Professional/Personal Competencies (FIP, 2012). Variations of this framework and other examples are available on the websites of national regulatory bodies and professional organizations.

Codes, standards, and guidelines are terms that might be used interchangeably or with nuanced interpretations in some settings or jurisdictions. Provided the reader is clear as to whether the focus is on minimum standards or on approaches to the delivery of services in a professional manner and/or represents a declaration of a profession's core principles and values, it is possible to align most discussions regarding concepts in ethical governance with Exhibit 1.

Exhibit 1 Codes, policies, standards and guidelines—concepts in ethical governance

Concepts	*Descriptions*
Professional code	Sets out expectations of members' behavior and articulates core values of the profession (in context).
Policies	Broad statements of how to adhere to the code, how breaches will be dealt with and, for example, whether the code is enshrined in legislation.
Standards	Specification of minimum acceptable requirements for behaviors, decision-making, and overall professional competence.
Guidelines	Description of recommended/sample approaches for behavior(s), decision-making, and demonstration of professional competence.

As society's "norms" change over time, most contemporary codes require revision at least every 5–7 years, and are reviewed at earlier intervals when societal issues demand more immediate consideration. Examples of changing societal "norms" likely to impact on the practice of pharmacy in the future include emerging technologies, such as genetic profiling or changing expectations regarding Medical Assistance in Dying (MAID). Evolving societal "norms" also engage professional values and ethical principles evident in codes for pharmacists as discussed later.

Professional Values and Ethical Principles Evident in Codes for Pharmacists

As highlighted in the "International Pharmaceutical Federation (FIP) statement of professional standards, Codes of Ethics for Pharmacists" (FIP, 2014), pharmacists' ethical obligations tend to be common across settings. The range of concepts likely to be found in most existing codes include: honesty and integrity, commitment to patient safety and best interests, accountability for actions and management of potential conflicts of interest, collaboration with relevant stakeholders, ethical allocation of scarce resources, respect for the confidentiality of patient information, respect for cultural differences, appropriate exercise of conscientious objection especially with respect to continuity of care, and a commitment to maintain competence through continuing professional development (CPD). FIP's stated objective is to enable national associations and regulators of pharmaceutical practitioners, through their individual Codes, to guide pharmacists in their relationships with patients and carers, and with other health professionals and society generally (FIP, 2014). FIP highlights that codes should also guide individual pharmacists in their daily practice of the profession. While its proposed Code remains focused on what the individual should do, the FIP also aspires to the development of transdisciplinary codes.

Professional Values as a Basis for Developing Transdisciplinary Codes

A comparative study of professional and interprofessional values (Tsou et al., 2015) compared values identified in professional codes, from 13 North American health care professional associations, with ethical principles identified as essential for interprofessional collaboration (IPC). The professions represented include medicine, dentistry, nursing, pharmacy, occupational therapy, physical therapy, and speech-and-language therapy. The six IPC principles, namely, altruism and caring, excellence, ethics, respect, communications, and accountability, were generally consistent across the professions' codes. Two further ethical principles, integrity and justice, were common across the majority of the 13 professions' codes reviewed. Apart from referring to "caring" rather than "altruism and caring," the American Pharmacist's Association's (APhA) Code referred to all eight of these principles, or "elements of professionalism." Comparison of codes in use in Australia, Canada (Alberta, British Columbia, and Ontario), Ireland, New Zealand, United Kingdom, United States, and FIP, indicates that key values underpinning pharmacy practice, as represented by these eight ethical principles, are also consistent across jurisdictions.

Why Develop a Code?

Codes may be developed to provide information, to guide, to govern, to provide grounds for sanction, to pledge commitment or any mixture of these functions. Appropriately developed codes may (1) provide clarity to members of the public, policy makers, managers, and other health care professionals regarding standards of conduct or behaviors that society can expect of members of a profession; (2) guide members regarding standards of conduct or behavior that is expected of members; (3) guide educators regarding standards of conduct or behavior that aspiring members should have demonstrated prior to registration with the regulatory body, or during educational remediation initiatives undertaken by registrants; (4) protect public interest by enabling the regulator to remove from the register any practitioner who breaches the code in a manner that poses a potential risk to public health or welfare; and/or (5) facilitate the profession's "social contract" with the public. Aspects of each of these objectives merit further consideration.

A Code as a Declaration of What Society May Expect of Members of the Profession

A code should provide clarity to patients and other members of the public, policy makers, managers, and other health care professionals as to what behavior(s) they may expect from the profession and its members. Every code will inevitably highlight the member's individual responsibility to maintain professional competence, including assuring a pharmacist's familiarity with professional standards and guidelines, and the appropriate application of knowledge and skills underpinning the practice of pharmacy. However, pharmacists are also required to behave with integrity, to demonstrate professionalism and ethical decision-making, and to be accountable in this regard for their actions and omissions. Qualities related to integrity, accountability, professionalism, and ethical decision-making can be underwritten by a code to which all pharmacists must subscribe. Any person or organization dealing with a pharmacist would then be entitled to (1) expect that a pharmacist will behave in accordance with the principles laid down in the code, and (2) judge the pharmacist's behavior according to the code.

A Code as a Guide to Practitioners

Codes for pharmacists are inevitably founded on the premise of a duty of care to the patient, thus obliging the pharmacist to always make professional judgments in the patient's best interests. The inference is, of course, that acting in the patient's best interests is not

always easy and, as a pharmacist has access to a body of knowledge or expertise generally not available to a patient, this results in information asymmetry between the pharmacist and patient. The pharmacist could use that expertise for his/her own benefit rather than in the interests of the patient. The patient would not necessarily know if the pharmacist was behaving appropriately . . . a concept commonly referred to as moral hazard. Moral hazard is what makes conflict of interest (CoI) possible, that is, "when an individual's personal interests would lead an impartial observer to question whether the individual's professional actions or decisions are unduly influenced by considerations of significant personal interest" (Beauchamp and Childers, 2009, p. 314). The perceived risk is that CoI will result in a set of conditions in which the exercise of professional judgment concerning a patient is unduly influenced by a secondary interest, such as financial gain, self-preservation against legal liability, or personal beliefs (Ruble, 2015).

As the pharmacist holds a position of trust, he/she must recognize the existence of information asymmetry, acknowledge that this asymmetry puts the patient at a disadvantage in the relationship, and realize that nondeclaration of any potential CoI would represent a breach of trust.

There are many such potential sources of conflict, both internal and external to pharmacists, which raise the possibility of impairing decision-making process to the extent that a pharmacist's, or his/her employer's, self-interest may inadvertently override the patient's best interests. The avoidance of situations, or dilemmas, where self-interest is at risk of prevailing is generally not possible for pharmacists—especially those working in patient-facing roles (Roche and Kelliher, 2009, 2014). As a code highlights core principles and values relevant to pharmacy practice, it can provide guidance for the exercise of professional judgment when negotiating professional dilemma scenarios and/or decision-making through potential CoI's in everyday practice and, when necessary, help outline grounds for identifying and/or justifying deviations from standards and guidelines.

A code may also provide pharmacists with a shared language to facilitate more robust discussion of conflicting ethical concepts in dilemma scenarios, so that differing individual ethical positions can be identified and debated, thereby fostering moral development in the individual practitioner (Rest et al., 1999; Roche et al., 2017).

A Code as a Guide to Educators

A code provides guidance against which the outcomes of educational programs may be evaluated. It guides educators by articulating standards expected at the point of registration with the regulatory body governing pharmacy, and by providing a tool that educators can use to underpin the professionalization process throughout an educational/CPD program. Legislation, standards, and guidelines may identify to the student what behaviors are expected of pharmacists; and policy documents and standard operating procedures may clarify how a practitioner should behave, but the code incorporates professional values underpinning pharmacists' responsibilities in a manner that cannot generally be accomplished when restricted by the demands of writing legislation. We might say that the code seeks to capture principles, such as not putting one's own interests ahead of a patient's interests, or not putting the interests of the profession ahead of society's interests and enables educators to expand beyond *what* a student should do, in order to focus on *why* student pharmacists should behave in a particular manner.

Student codes are common in higher education institutions internationally, for example, Australia, Canada, Ireland, New Zealand, United Kingdom, and United States. Notwithstanding that the profession's code may need to be adapted appropriately for the context of the university setting, for example, specifics related to interaction with patients may need amendment, student codes generally reflect the profession's underlying ethical principles. This approach has the added advantage that all institutions in a given jurisdiction can utilize the same version of the code as a baseline for student learning. Where "code of conduct" commitment ceremonies are utilized, they provide an additional opportunity to motivate student engagement with the professionalization process early in the pharmacy degree program.

In Trinity College, Dublin, (the author's home university) the commitment ceremony takes place early in the second semester in the program. During the first semester students undertake "professionalism and ethics" workshops, write a "professional identity essay," and engage in individual and group activities that focus their attention on what it means to be a professional and on how the code interacts with the professionalization process. Satisfactory completion of all activities and assignments is essential for eligibility to attend the commitment ceremony. Commitment to the code is an essential requirement prior to student's first experiential learning event, or practice placement, which takes place during the second semester. The student code therefore becomes a focus of attention for all students early in the degree program. While students are concurrently introduced to how fitness to practice (FtP) and remediation processes in the School of Pharmacy align with the code, it is the positive commitment to the code that is emphasized throughout, that is, a code can provide a tangible link to the profession's core values early in the students' university experience.

A Code to Serve the Public Interests and Support the Regulatory Process

Regardless of whether a code is a legislative provision or available as a voluntary guide, a code serves the public interests when it enables and motivates ethical relationships between pharmacists and patients or other individuals with whom pharmacists interact, and when it supports professional and ethical management of situations for which there are no clear standards or guidelines available. A code should assure that any member of the public employing the services of a pharmacist could expect to encounter the highest professional standards in the delivery of pharmacy care, treatment, or service. It should also reduce the risk of misunderstanding when differentiating between defensible behavior(s) on the part of the pharmacist, and when poor professional

performance (PPP) or professional misconduct (PMC) occurs. ("Poor professional performance," in relation to a registered pharmacist, means any failure of the registered pharmacist to meet the standards of competence that may be reasonably expected of a registered pharmacist (Pharmacy Act, 2007) and "Professional misconduct," in relation to a registered pharmacist, means any act, omission, or pattern of conduct that—(1) is a breach of the code of conduct for registered pharmacists, (2) is infamous or disgraceful in a professional respect (notwithstanding that, if the same or like act, omission, or pattern of conduct were committed by a member of another profession, it would not be professional misconduct in respect of that profession), (3) involves moral turpitude, fraud, or dishonesty of a nature or degree, which bears on the carrying on of the profession of a pharmacist, or (4) if the registered pharmacist has been granted a license, certificate, or registration by a body outside the state relating to the practice of pharmacy is a breach of a standard of conduct, performance, or ethics that—(a) applies to a person holding that license, certificate, or registration, and corresponds to a standard contained in the code referred to in *paragraph* (*a*) or a standard breach of which amounts to conduct of the kind mentioned in *paragraph* (*b*) or (*c*), *but does not include an act, omission, or pattern of conduct that consists of a wrongly but honestly formed professional judgment* (Pharmacy Act, 2007). The definitions for "poor professional performance" and "professional misconduct" provided are inferred throughout but readers should note that the terminology used, and associated definitions, may vary between jurisdictions. A code should therefore assure that patient interests are not subordinated, intentionally or otherwise, to the incompetence or interests of the pharmacist or the organization by whom s/he is employed.

However, a profession's code may also be used by wider society as a means of controlling professional behavior and of directly supporting the regulatory process. Reference to the code in legislation and/or alignment of reference to the code with the operation of Committees of Inquiry engaged with FtP hearings may integrate the code with the regulatory process, and related sanctions. As breach of the code may be one basis from which review of acts, omissions, or patterns of conduct might be deemed to constitute professional misconduct or poor professional performance (Pharmacy Act, 2007), a breach may therefore be the allegation in a complaint of "professional misconduct." Even in the absence of any harm to a patient being demonstrated, a FtP inquiry may result in sanction(s) being applied. Ireland is one example of a jurisdiction in which a breach of the code is grounds for an allegation of PMC during a disciplinary hearing or FtP Inquiry (Pharmacy Act, 2007).

As most legal systems operate on the basis of adjudicating on whether harm caused was the fault of an individual or organization, a process that admits "omissions," and patterns of conduct or behavior as evidence at an inquiry is atypical. Given the information asymmetry that exists between a pharmacist and a patient or member of the public, it is undoubtedly the case that some aspects of a pharmacist's behavior requires interpretation by peers in order to defend a related imposition of sanctions or penalties. Therein lies a core justification for "self-regulation" of the professions.

A Code to Facilitate the Profession's Social Contract with the Public

Society also envisages each profession as a collective and if an individual pharmacist is to be considered a professional, s/he must both personally meet the standards expected of a member of the profession, and have a profession to which s/he can belong. As it is a society that grants the status of profession, and the norms of a society change over time, a society may have changing expectations of a group to which it grants professional status. Welie (2004, 2012) describes this relationship as a dynamic social contract between the public and the profession. A code should articulate how the profession seeks to honor its social contract to society.

The distinguishing attributes of a profession traditionally include, for example, (1) *A systematic body of knowledge or theory*, (2) *authority recognized by clients*, (3) *broad community sanction of this authority*, (4) *a regulative code of ethics, and* (5) *a professional culture sustained by professional associations*' (Andersen, 2004). Continuing professional development, in addition to other supports, can provide structured access to the "body of knowledge" and the theoretical basis of the "regulative code of ethics," but knowledge alone is not a basis on which to assure understanding of the expectations inherent in a code.

Society's recognition of the potential benefit of medicines underpins its preparedness to take the risk that harm may be caused in pursuit of the desired benefits, but its acceptance that medicines can also cause harm underpins its justification for the restriction of access to available medicines by the general public (Roche and Kelliher, 2014). This restriction could otherwise be considered as an infringement of civil liberties—a risk managed by the granting of a custodian role, wherein legislation restricting access to certain "controlled" substances (medicines) identifies circumstances in which the pharmacist may hold and be a legitimate supplier of such substances, in the form of this social contract with the profession. Therefore, the public, believing that it has been promised an altruistic approach to this "custodian role," enters into a mutual agreement with the profession, and grants the profession privileges and social status. The code might be utilized by the wider society as a means of controlling professional behavior according to this perception of the mutual agreement. The public, in the form of its representatives, has an opportunity to impact on the development and amendment of national policy governing the practice of the profession as and when changing societal norms demand, and both public representatives and members of the public can engage directly with the development of a profession's code.

How Might a Code be Developed?

The process for developing a code should incorporate: (1) clarification of the profession's core values and/or principles that underpin professional practice; (2) identification of and engagement with relevant stakeholders; and (3) articulation of aligned policies, standards, and guidelines. A code may be enshrined in legislation to a greater or lesser extent, or it may be a voluntary code introduced, for example, by a professional body or representative organization. The nature and enforceability of associated policies,

standards, and guidelines will vary accordingly. National or jurisdictional legislation may dictate that the regulatory body will have authority and/or responsibility for the development of a code. Legislative underpinning of the code has implications for initiation and support for the process, the range of stakeholders likely to engage, and resourcing. Provisions for enforcement of a code will derive from the extent to which it is referred to and provided for in legislation, for example, whether the requirement is simply that a code exists or that, for example, breach of a code is specifically identified as a basis on which an allegation of PMC might be made (Pharmacy Act, 2007). While a "voluntary" code is likely to be supported by a large proportion of the membership of the profession, and peer pressure to behave according to the code may be in abundance, the members who choose not to engage cannot generally be forced to do so.

Strategies for Drafting "Pharmacy" Codes: Insights from the Literature

While codes proposed by FIP and in jurisdictions previously referred to [e.g. Australia, Canada (Alberta, British Columbia, and Ontario), Ireland, New Zealand, the United Kingdom and the United States], and their supporting policies, standards, and guidelines, are a publicly available source of information for any individual or group developing a code, review of the literature is inevitably recommended as a part of the process. The studies referred to in this section are neither exhaustive nor exclusive. However, they provide a range of perspectives and approaches that might further stimulate the reader to consider the benefits and limitations of choosing one format over another.

"Theoretical Considerations" for a Meaningful Code

A conceptual framework for drafting a code might distinguish "obligations" according to whether the identified responsibility is to patients/clients, fellow professionals, or society (Jamal and Bowie, 1995). Jamal and Bowie propose that provisions in a code should specifically address the need to (1) avoid "moral hazard" by assuring that decisions are objective and independent, bearing in mind that the *necessary conditions for objectivity are competence and diligence* (Jamal and Bowie, 1995, p. 709); (2) maintain professional courtesy, while also accommodating jurisdiction-specific controversy as to whether advertising should be restricted; and (3) serve the public. However, these authors caution that, while provisions related to the avoidance of moral hazard are generally uncontroversial, the public can be suspicious of provisions protecting professional courtesy and/or restricting advertising and competition, and public interest provisions can be controversial when the public and the profession disagree as to precisely what is in the public interest. For example, as codes might be seen to be self-serving and designed to protect the economic interests of the profession by restricting competition, rather than as a means of protecting the public from unethical behavior, reference to advertising emphasizes that professional recommendations should be objective and independent, and restrictions on advertising should be imposed only to prohibit deception.

Provision for a pharmacist's principled objection to take part in delivery of services that may be legally available in the jurisdiction can be a source of public-profession disagreement regarding what is in the public interest—contemporary examples being the use of medicines in Emergency Hormonal Contraception (EHC) or Medical Assistance in Dying (MAID). Jamal and Bowie (1995) find the obligation of confidentiality to be particularly problematic, especially when the best interests of society are pitted against the best interests of an individual. Disagreement among members of the public would probably arise if a code prioritized protection of the public interest by (1) decreasing the requirement for confidentiality (as breach, in a structured manner, has potential to positively impact on the public good) and (2) reducing the emphasis on duty of care to the individual patient (as this has potential to impact negatively on, e.g., resource allocation). Nonetheless, the conceptual framework proposed might be appropriate for some jurisdictions and discussion identifies key principles that might be included in the code.

"Reasons" for Having a Code of "Pharmaceutical Ethics"

Hernandez and coworkers emphasize that the Spanish Code's purpose is to provide a stimulus for pharmacists in their day-to-day work, with the aim of doing good and avoiding evil, and that it must apply at both an individual and group level. The process used in development of this code involved a review of "sources of information on the extant professional codes of conduct" (Hernandez et al., 2017: p. 403) that was undertaken by a multidisciplinary working group comprised of national experts in hospital and community pharmacy; a professor from each of the disciplines of Pharmacy Ethics, Communications Ethics, Bioethics and Philosophy of Law; and a Supreme Court Judge. They propose a code that sets out principles related to and underpinning pharmacist responsibilities to (1) patients, (2) other health care professionals, and (3) society. They differ from Jamal and Bowie (1995) by referring also to other health care professionals (rather than limiting reference to coworkers in one's own profession) and thereby introducing specific reference to interprofessional collaboration. Notable inclusions that refer to pharmacists' obligations to patients', including that "patients are entitled to the intervention of the pharmacists . . .in any of the processes in which medicine is involved" and "a pharmacist promotes the patient's right to avail of safe, effective treatment," incline toward a rights-based approach to pharmacy services. Obligations to other health care professionals include cooperation with others and avoidance of unfair competition, and specifies a responsibility to contribute to science by researching in his/her discipline. Professional responsibilities to society appear to be particularly demanding including that "a pharmacist ensures fair distribution of the health care resources based on objective, transparent criteria, particularly when those resources are limited," and if a pharmacist wishes to exercise a right to conscientious objection, s/he must inform the competent authority/regulator "so that the patient will not be deprived of the pharmaceutical care." The lists of obligations, to patients, other health care professionals and society, may provide baseline material for any pharmacists or groups developing or revising a code for their own jurisdiction.

Exhibit 2 Sample-guiding principles for the development of a code

1	Faculty, staff, and students should have significant input throughout the process.
2	It should apply to students as well as to all those who interact with them.
3	It should contain a preamble to set the tone for the code.
4	It should outline expectations that would apply across all settings.
5	It should be concise and written using the first person language.
6	It should contain a glossary of terms.
7	It should contain a section requiring a signature to indicate commitment to the code.

Gerber et al., 2015

Development of a Code of Conduct for a "University Faculty"

Development of an operational definition of "professional conduct" in the form of a code that would outline expectations around conduct was a key objective for the "Professionalism Committee," a diverse group of 11 staff and faculty members, at the Faculty of Pharmaceutical Sciences at the University of British Columbia (UBC) (Gerber et al., 2015). This Committee determined the need to model, foster, and articulate the values, standards, and expectations of students and faculty members in upholding professional attitudes and behaviors, in order to provide a framework for education and use as a tool to mentor students who fall short of expectations, that is, they envisaged a nonpunitive document aimed at raising awareness of expected conduct, and the code does not specify procedures for dealing with lapses in conduct.

The process by which the code was developed and adopted and the challenges encountered during the process are clearly outlined. The approach incorporated input from staff, consultation with students and University Senate approval of the final document. The literature review, undertaken by all Committee members, included an environmental scan of existing codes in schools of pharmacy in the United States and Canada, and consideration of professional documentation at the faculties of Medicine and Dentistry in UBC. The process of reviewing other codes was structured by providing template questions for consideration, for example, (1) "what elements of the format/structure do you like?" and (2) "would something similar . . .be relevant, worthwhile and doable for our faculty's code?" (Gerber et al., 2015, p. 147). Individual interviews, by the Chair, ascertained members' views on professional conduct—similarly structured by the provision of questions in advance. Views and opinions thus collected were analyzed into themes and presented to all faculty members as raw, unedited, and anonymized data. Subsequent development of themes, by committee members, was informed by this data. Faculty members and students were actively consulted throughout the process. As staff members raised concerns regarding the need to sign to indicate commitment, this requirement was removed from the final version of the code as approved by the University Senate.

The Committee ultimately developed key guiding principles for the development of a code in a university environment, summarized in **Exhibit 2**.

It is apparent that there are significant resource implications for this approach to the development of a code. Its findings also highlight the importance of peer-engagement in the development of a voluntary code, and that, when resistance develops, compromise may be required. The sharing of these and other key learning have the potential to provide support and insight to any group intending to develop or revise a code.

Codes for a "National Pharmaceutical System"

A multidisciplinary working group, including experts in medical ethics, history of medicine and pharmaceutical sciences, proposes a code for pharmacists, and separates sets of ethical guidelines for pharmaceutical manufacturers, pharmaceutical importers, pharmaceutical distributors, and policy makers (Salari et al., 2013).

The code incorporates discussion on key themes identified from literature review as follows: respect for patient's dignity and autonomy; beneficence; nonmaleficence; justice; empathy and resilience; honesty; and cooperation—a familiar list of values or principles in the context of contemporary codes.

The decision to produce separate sets of ethical guidelines derives from their expectation that ethics, which will be appropriate for manufacturers, importers, distributors, and policy makers will not be adequate for the patient–pharmacist relationship. This indicates that pharmacists in different sectors might be subjected to varying levels of control.

The conclusion reached, including that development of codes and guidelines is just the first step, and implementation relies on educational interventions that target the development of moral reasoning and include opportunity to discuss ethical dilemmas relevant to the principles in the code as they relate to the practice of pharmacy, should be accommodated when developing a code.

Enabling the Development of Codes

Literature review identifies challenges with respect to clarification of appropriate aims and underpinning legislation for enforcement of codes; the range of settings in which a code applies; differentiation between expectations articulated in codes and related standards or guidelines; consistency in alignment of codes with policy, standards, and guidelines; effective education for and understanding of the code's aims and application; and valid strategies for implementation and enforcement of codes.

Exhibit 3 Advantages of regulatory body oversight of the process of code development

1	The regulatory body has access to the legal, clinical, regulatory, and educational expertise to practically differentiate legislative requirements of conduct for pharmacists and develop a code that is congruent with the current legal and professional expectations of the profession in the jurisdiction involved.
2	The regulatory body has access to all registered pharmacists, thereby enabling relevant representative views of all pharmacists to be properly reflected in the code, and in order for associated standards to be meaningful and relevant to the diverse contexts in which the code would apply.
3	The regulatory body oversight enables collaboration and sharing of information with other regulatory bodies.
4	The regulatory body has the professional and statutory authority to conduct consultations and collate information in the development of a code.
5	The regulatory body can be publicly perceived as a more independent, objective voice than a professional body, thereby increasing the likelihood that members of the public and other stakeholders will engage with the process.
6	The regulatory body can provide resources and a structure for pharmacists, the public, and other stakeholders to engage and become involved in the code's development, implementation, and use.
7	The regulatory body can develop and disseminate aligned supporting documents (policies, standards, and guidelines).
8	The regulatory body can develop and provide continuous professional development (CPD) modules to help pharmacists understand the implications of the code, and to apply the principles outlined in the code to their individual practice setting.

GPhC, 2017 (adapted)

Despite these challenges, there are a number of factors that have the potential to support the development of effective codes, not least of which is the involvement of regulatory bodies—a range of potential advantages to their involvement is outlined in Exhibit 3.

The growth in the evidence base provides more comprehensive baseline from which to develop, or revise, a code. The evidence base relates to the potential structure and content of the code itself, and to appropriate processes applicable to development of an effective code. Literature related to interprofessional learning supports an increase in mutual understanding of the different roles provided by each profession and the different goals outlined in existing codes—potentially opening up opportunities to develop multidisciplinary codes. Questionnaires, responses to surveys, draft codes, responses to draft codes, and assessment of launches from other jurisdictions are available online which streamlines the process of development and allows partnership in addressing issues faced by pharmacists on a global scale (FIP, 2014).

Education for and Understanding of the Code's Aims and Applications

Many educational initiatives, incorporating ethical decision-making frameworks, dilemmas scenarios, and case studies, are openly available on regulatory body's websites throughout the world. Given a regulator's responsibility to provide accurate information in a public-friendly manner, these initiatives are expected to be methodologically robust and provide access to the literature and/or theory underpinning the material—at least to the extent that they may provide a baseline for those developing new educational interventions to support the introduction of a code. The advent of technology enhanced learning (TEL) initiatives, such as online modules and discussion fora, in addition to more traditional paper-based approaches to CPD, has expanded access to available educational initiatives for practitioners working in isolation and/or in geographically remote areas thereby enabling them to engage with evolving societal "norms" relating to their professional code.

Pharmacists' call for education or CPD regarding the implications of a code for practice has been reiterated in recent research in Serbia and Canada (Crnjamski et al., 2017; Gregory et al., 2016), among others. The more familiar that Serbian pharmacists were with their code, the more useful they found it as a guide in making ethical decisions in practice (Crnjanski et al., 2017), that is, findings confirm that pharmacists need to develop and maintain competence related to the practical application(s) of a code in order to effectively use it as a support and guide when exercising professional judgment to make ethically defensible decisions. Canadian pharmacists found that clinical reasoning strategies related to new responsibilities, such as immunizations and prescribing, inherently challenge the code's relevance to modern practice (Gregory et al., 2016). These findings highlight that as the scope of practice evolves, pharmacists need ongoing opportunities to discuss and debate how a code applies in new contexts and how to reason through dilemmas posed by conflicting ethical principles. Findings included that, where a code is enshrined in law, pharmacists reported placing priority on legislative requirements when facing ethical problems/dilemmas, indicating a preference for a "rules-based" approach to decision-making.

Notwithstanding distinction(s) that may be perceived to exist between regulated and voluntary codes and taking account of the literature as it describes various approaches to the development of codes for pharmacists and other relevant professionals, it is clear that an ideal process used to develop (or revise) a code should incorporate: (1) clarification of the profession's core values; (2) identification of and engagement with relevant stakeholders and, subsequently or in tandem; (3) publication of appropriate policies, standards, and guidelines as included in the sample process provided in Exhibit 4.

Why Might a Code "Fail" to Achieve its Aims?

A code, if the format likely to evolve from concepts outlined in this chapter, might fail to achieve its aims as a result of generally recognized challenges and barriers to the development and use of codes—summarized in Exhibit 5.

Exhibit 4 Literature informed guidelines to code development

1 If a code does not already exist:
   1. determine what jurisdictional organization is or will be responsible for the introduction of a code; development of associated policies, standards, and guidelines; review at appropriate intervals; education of pharmacists regarding application of the code and/or enforcement of the code;
   2. confirm the basis on which the organization intending to develop the code has responsibility and/or authority to do so; and
   3. agree to a strategy for development of a code, including allocation of resources and personnel, access to expertise, and the process for final approval and implementation.

2 Review existing literature and available resources (e.g., websites of regulatory bodies, and public services) to identify and investigate (1) existing codes in pharmacy and in other health care professions in the jurisdiction in question, and in relevant other jurisdictions and (2) supporting documentation, including policy documents, standards of practice, relevant guidelines, and/or additional guidance from regulatory or professional bodies.

3 Review relevant legislation and policy to assure that the code is congruent with the current legal and professional expectations of the profession in the jurisdiction involved, and to articulate, insofar as possible, what is acceptable conduct, and what is misconduct.

4 Clarify, in a manner that aligns with the agreed strategy for development of the code: to whom the code will apply, in what setting(s) the code will apply, whether the code will apply only in the workplace or also when the pharmacist is outside of the workplace, and whether all principles in the codes have equal standing or that one be considered primary, for example, the pharmacist's "duty of care" to the patient.

5 Complete a stakeholder analysis, that is, identify and list the individuals and organizations that will be contacted and involved, to include members the public, individual pharmacists, and representatives from pharmacy's professional organizations, pharmacist educators, representatives from relevant other health care professions, policy makers, and relevant experts. While the extent to which a code is legislatively underpinned (or not) will influence the process of stakeholder engagement, the ideal is to engage, as a minimum, the above stakeholders.

6 Design and prepare surveys, or other relevant data collection tools, for use with stakeholders. These may include a list of ethical concepts for consideration, tools derived from the literature. and/or an outline of one or more draft codes for consideration and comment.

7 Engage stakeholders.

8 Collate and review stakeholder feedback and action, as appropriate.

9 Prepare a draft code.

10 Engage stakeholders to obtain feedback on the draft code.

11 Collate and review stakeholder feedback and action as appropriate. Consensus among stakeholders, while preferred, is not necessarily required.

12 Agree, with the organization's own management team, a final draft of the code.

13 Attend to any legislative requirements, for example, approval by the Council of the regulatory body for pharmacists, approval by other regulatory bodies, for example, the Competition Authority, and/or approval by government official or minister.

14 Publish the code.

15 Disseminate the code, and relevant explanatory material, to all stakeholders that engaged in the process.

16 Implementation of the code should include, but not necessarily be limited to, the following: (1) assure understanding among the members of the profession, through ongoing CPD and appropriate quality assurance mechanisms, (2) enable mediation processes by which misunderstandings related to the code can be addressed, and (3) enable enforcement of the code if and as facilitated by legislation or other powers.

Exhibit 5 General challenges and barriers to the development and use of codes

1 A code cannot provide definitive answers for ethical dilemmas encountered in the course of professional practice, that is, where there is no obvious right or wrong way to proceed, and it cannot give firm justification for making one professional judgment rather than another.

2 Evaluation of professional conduct is a complex multidimensional construct that requires a combination of approaches at individual, interpersonal and institutional, or society-wide level.

3 A range of contributory factors, that is, person-specific, task-related, and organizational, serve to impact on an individual practitioner's conduct, so that both individual deficits and organizational or systems failures would need be considered when making a determination regarding the defensibility of observed behavior(s), for example, pharmacists may be responsible under the code for the acts or omissions of persons operating in the pharmacy under their supervision, where organizational deficits interfere with the availably of appropriate resources and/or expertise.

4 Health care has become multidisciplinary in nature and members of the health care team may be bound by different codes (or by none at all), potentially introducing conflicting responsibilities and obligations.

5 Health care has become multiagency in delivery and when resources are limited funding organizations and managers may influence the nature of the care which can be provided in circumstances where obligations imposed by them may not align with the practitioner's code, for example, resource constraints can bring the principle of societal benefit or the "greatest good" into conflict with the health care practitioner's primary duty of care to the individual patient.

6 The pace of scientific advance(s) combined with a complex array of "information" sources available to the public make "appropriately informed" status, as currently envisaged by the courts, increasingly improbable—thereby compromising the consent.

Adapted from Goldie et al., 2013; Phipps et al., 2011; Roche & Kelliher, 2009.

A code might also "fail" if it was found that, for example, expectations inferred by the code were unreasonable, that information provided was inaccurate, and/or that conflicts existed between a code and other relevant "rules," would risk making the Code unenforceable, and would be likely to prompt review and amendment as appropriate.

However, appropriate attention to the implementation process has the potential to identify unanticipated challenges and weaknesses in a proposed code as they arise, especially where implementation processes support pharmacists' understanding of how the

code should be applied in practice, enable mediation when misunderstandings arise, and where legislation enables sanction following a finding of "breach" of the code, implementation processes address matters related to enforcement.

The Need to Assure Understanding (of the Code) Among Members of the Profession

Pharmacists' familiarity with codes improves their use as a guide to ethical decision-making in practice, and pharmacists themselves recognize the need for ongoing discussion and debate regarding how a code applies in new contexts and how to reason through dilemmas posed by conflicting ethical principles, (Crnjanski et al., 2017; Gregory et al., 2016).

Obligations aligned with codes are not always obvious to the uninformed reader and/or pharmacists may be confronted with different interpretations from academics, peers, and tutors/managers within the education system and professional milieu (Bebeau, 2009).

If understanding is to be assured, then those developing the code should make available CPD initiatives in which obligations are made explicit, and which highlight conduct that might be a source of potential disagreement regarding the defensibility of behaviors. Initiatives already in use, with many examples freely available on regulatory body's websites, include paper-based and vodcasts/podcasts of animated scenarios and vignettes that raise, debate, and/or propose reasoned responses to professional dilemmas scenarios; "tests" of multiple choice questions addressing ethical concepts; and, in some jurisdictions, interactive e-learning modules that provide comprehensive review of the range of ethical concepts and conflicts that might arise.

Dilemma scenarios used in CPD initiatives should include recommendations from the literature and learning from inspections and legal cases in the jurisdiction in question. The material should be adapted to the "local" nuances of pharmacy practice, and to the code being introduced, in a manner that accommodates various learner styles and practice contexts.

Processes suited to decision-making through ethical dilemmas are increasingly included in guidance documents, and samples from the RPS and OCP provide examples that might support pharmacists' development. The RPS advocates a six-step approach to professional judgment formation when faced with a professional dilemma scenario (**Exhibit 6**), whereas the OCP takes a more extended approach to its advice regarding dilemma resolution and encompasses ethical decision-making and subsequent reflection in its prosed framework (**Exhibit 7**).

However, the moral reasoning competencies that underpin ethical reasoning, that is, the cognitive or thinking processes individuals go through to arrive at a decision when faced with a dilemma, must also be learned and practiced (Rest et al., 1999). Activation of "reasoning" depends on an individual having acquired the competencies to identify: (1) the ethical concepts that are in tension to create a dilemma, (2) what actions might be justifiable, and (3) how others might be affected by the behavior implied by each action option. Consideration of a professional dilemma scenario therefore involves deliberation(s) related to different courses of action an individual might take when faced with the dilemma proposed and the making of a judgment regarding which of the available actions would be most morally and/or professionally justifiable. To align with the evidence base, CPD initiatives should seek to incorporate the cognitive skills of logic (by providing frameworks for decision-making), role-taking (by utilizing scenarios that include multiple perspectives in conflict) and peer interaction and debate (Rest et al., 1999; Roche and Thoma, 2017; Roche et al., 2017).

The Need to Enable Mediation to Address Misunderstandings Among Stakeholders

Education of all stakeholders regarding the obligations of pharmacists and implications of the published code is a key component of their engagement in the development process. However, when true dilemmas arise, differentiation between defensible behavior(s)

Exhibit 6 Six-step approach to the exercise of professional judgment

1	Identify the ethical dilemma or professional issues
2	Gather relevant information
3	Identify the possible options—need a code to do this through ambiguity?
4	Weigh up benefits and risks of each option
5	Choose an option
6	Record

on the part of the pharmacist and perception(s) by others that the code has been breached can be problematic—and dissemination of generic information may not address concerns.

The availability of a publicly available, clearly defined, transparent, and easily negotiated process, by which any stakeholder can raise a concern or make a complaint regarding the behavior of a pharmacist, is an essential part of the process. Timely communication with complainants and comprehensive attention to concerns raised are essential components. However, complaints do not always merit disciplinary action or investigation at a "fitness to practice" inquiry. There may be occasions when, for example, disagreement arises as to whether a pharmacist had a "conflict of interest," or an unavailable service was anticipated. A mediation process should be available, where an impartial third party helps resolve the matter in a private, confidential, collaborative, and "nonbinding" manner, as this may provide an appropriate course of action in some cases.

The Need to Enable Enforcement of the Code: If Applicable to the Context

When sanctioning power is enshrined in legislation, a code can be one of a number of regulatory devices employed to protect the public by enabling, when proven to be necessary in a formal inquiry, conditions, or restrictions on practice by individual practitioners.

The standard of proof by which the regulatory body must prove allegations, such as an allegation of professional misconduct based on a violation of a code, will generally be either "beyond reasonable doubt" or "beyond the balance of probabilities"—although individual jurisdictions may vary in this regard. Expert witnesses may be used as a means of supporting such allegations—or, indeed, by registrants arguing that the expectations inferred by the regulatory body are not reasonable and/or impossible in the context of the exercise of professional judgment by pharmacists in the jurisdiction. These varying perspectives must be considered when developing a code and comprehensive differentiation between what "should" be done and what it is reasonable to insist "must" be done should be prioritized. Where principles in a code conflict, or where principles in a code are determined to conflict with legislation, policies, standards, or guidelines, such conflicts may undermine the likelihood of proving an allegation of professional misconduct (or poor professional performance) "beyond reasonable doubt."

Options related to sanction generally include the attachment of conditions to a pharmacist's registration, and/or removing the pharmacist's right to practice for a defined period or, where remediation is not envisaged, removal of the pharmacist's right to practice indefinitely. Options related to conditions generally include those of an educational nature. Guidelines regarding sanctions and conditions generally require them to demonstrate proportionality and leniency, and take account of aggravating and mitigating factors, that is, justified on the basis that they are the least restrictive means by which to protect public health, and underpinned by an expectation that the outcome of the proposal will remediate the professional deficits that are perceived to pose a risk to public safety. Mitigating factors might include health issues, such as addictions to alcohol, drugs or gambling, or the potential that the breach of the code resulted from a failure of understanding by the pharmacist. In cases where expert opinion identifies that relevant health issues may be remediated by treatment and/or public protection assured by a monitoring process, related conditions might be attached to the pharmacist's registration; where an inquiry determines that a failure of understanding underpinned the breach of the code that deficit may be addressed by appropriate mentoring and/or educational interventions.

The objective of such educational interventions will include, for example, (1) assessment of the extent of professional deficits underpinning poor practice identified during the disciplinary inquiry and (2) to prompt engagement with a remediation program involving learning and development activities including training and/or mentoring to remedy deficits identified. Knowledge and skill deficits may be addressed by existing programs and assessed by exam or observation. However, where deficits identified relate to professional identity formation and/or moral reasoning competencies, assurance that deficits with the potential to impact on public health are much more difficult to assure. To align with the evidence base, consideration should be given to individualized programs, incorporating specialist educational methodologies, described in the literature (**Exhibit 8**).

Exhibit 8 Evidence-based approaches to educational remediation further to disciplinary inquiries

1. Educational remediation should take account of a range of contributory factors, for example, person-specific, task-related, and organizational, which serve to increase or decrease the risk of breach of codes by individual practitioners.
2. Remediation begins with an identified problem or deficiency, and the process may need to consider the individual's "knowledge, skills, and attitudes" in the context of the system and organizational culture in which the behavior is observed.
3. Remediation should enable pharmacists to explore the extend to which their professional identity has formed, and differentiate where they are individual, team, or society-level oriented.
4. Remediation should enable pharmacists to become aware of, and develop the ability to manage potential conflicts of interest arising from, the personal, professional, and commercial influences on decision-making that exist in the practice environment.
5. Remediation should enable pharmacists to assure they have sufficiently developed competencies underpinning development, the four components of namely moral sensitivity (i.e., awareness of how actions chosen affect other people), reasoning (the ability to apply moral principles or ideals when developing a solution to a dilemma scenario), motivation (i.e., the prioritization of moral values over competing values and influences) and implementation (i.e., perseverance and courage to implement actions), operate as interactive elements in the development of a professional.

Community and Ambulatory Pharmacy Practice

John Papastergiou, Leslie Dan Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada; School of Pharmacy, University of Waterloo, Kitchener, ON, Canada

Introduction

Community pharmacy practice has evolved dramatically over the years. The role of the pharmacist in the early 1900s primarily involved the preparation and dispensing of pharmaceutical compounds for medicinal use (Pearson, 2007). The 1950s brought the expansion of large-scale manufacturing of medications as well as restrictions on most therapeutic products to require a physician's prescription (Pearson, 2007). These changes greatly impacted pharmacy, reducing the autonomy of the community pharmacist and limiting their role further. Between 1965 and 1990, pharmacy practice began to shift from one of primarily dispensing, to a more clinical, patient focused model (Penna and Knowlton, 2003, p. 38). Several critical factors influenced this evolution, including the increased number and complexity of available medications, more advanced pharmacist training, changes in health-care infrastructure and reimbursement, and a demand by patients for accurate, accessible health information (Rutter, 2013). In Hepler and Strand (1990) coined and described the term pharmaceutical care. This has become widely accepted as the current model of pharmacy practice in those countries with the most advanced health-care systems. The pharmacists' unique skill set is used to optimize pharmacotherapy in order to improve health outcomes and reduce drug costs.

This objective of this chapter is to discuss changes to the traditional dispensing business model and to explore the evolving role of the community pharmacist. New and innovative areas of pharmacy practice will be discussed including medication review, point-of-care testing, and pharmacogenomics.

Changing Community Pharmacy Landscape

Over the last few decades, the profession of pharmacy has dramatically changed. The scope of practice has expanded to help meet the health-care needs of the public and to reduce the pressures placed on the broader system. This section will further explore the different pharmacy business models and those factors that have contributed to the current evolution.

Ownership Models

Historically, community pharmacies were run as independent businesses by local pharmacists (Pearson, 2007). These pharmacies where generally not affiliated with each other or any other larger corporate body (Grootendorst et al., 2008). The pharmacist was the owner/operator of the business. Beginning as early as the 1900s, pharmacy chains, banners, and franchises started to appear and with time have acquired a large portion of the retail pharmacy market. A banner is an independent pharmacy affiliated with a larger group in order to capitalize on bulk purchasing and branding and uses a recognized name (Grootendorst et al., 2008). Chain pharmacies are owned by large corporations and employ pharmacy managers to run their pharmacies (Grootendorst et al., 2008). Franchises are licensed by larger corporations to individual pharmacist owners. These pharmacist owners are expected to adhere to a set of operational standards and generally pay fees and make purchases from the parent company (the franchisor) (Grootendorst et al., 2008). Currently, the retail pharmacy industry is comprised of over 61,000 pharmacies across the United States and includes a combination of independent pharmacies (36%), chains and franchises (33%), mass merchants (13%), and supermarkets (14%) (National Community Pharmacists Association, 2016). These numbers are similar across Canada, but with a larger portion of pharmacies being independently owned (49%) (Ontario College of Pharmacists, 2015). Some have argued that the movement away from independent ownership has reduced pharmacist autonomy and negatively impacted the profession. Others have suggested that this shift away from a retail focus is instrumental if the pharmacist is to take on a more clinical, primary health-care role. Additionally, newer models such as mail-order pharmacies, centralized fill operations, and specialty distribution networks will continue to challenge the historical business model.

Dispensing and Workflow

In recent years, pharmacists have seen their roll expand to include a portfolio of clinical service offerings such as medication reviews, prescription renewals, clinical adaptations, and vaccinations. **Table 1** summarizes the fees and claims data for government sponsored pharmacist services in Canada, by province. In addition, drug reform and generic deflation have placed increase pressure on the traditional dispensing model (Canadian Foundation for Pharmacy, 2018). As a result, pharmacists have found themselves challenged with time, workflow and staffing issues, and the ability to offer consistent, sustainable services to their patients. These challenges are the direct result of attempting to balance conventional pharmacy dispensing services with the consistent provision of clinical programs. In order to transition into a workflow model that allows for the provision of sustainable clinical services, it is necessary to understand a number of key concepts.

Drug Reform and Generic Deflation

As public and private payers struggle to meet increased health-care costs, they have looked to pharmacy as a source of cost reduction. Generic deflation, reduced fees, capped mark-ups, and banned professional allowances have all impacted the profitability and potential future sustainability of community pharmacies.

Ontario is an interesting case example that highlights the dramatic impact of such legislative change. The drug reform of 2006 prohibited pharmacies from accepting rebates from drug manufacturers and reduced the maximum price for generic medications listed on the Ontario drug benefit (ODB) formulary to 50% of the brand name (previously 63%) (Schill, 2010). Traditionally, rebates, or kickbacks, were provided by generic drug manufacturers directly to pharmacies for stocking their product and resulted in a significant proportion of pharmacy revenue. These were replaced with "professional allowances," which were to be used for patient care and had value restrictions (20% through publicly funded plans, but no restrictions for private plans). As a result of these changes, independent pharmacy revenue was reduced by 34%.

The drug reform of 2010 was comprised of three major changes: (1) reduction of the maximum prices for generic products listed on the ODB formulary to 25% of the brand name and which was to be phased in for private plans, (2) elimination of professional allowances immediately for ODB recipients and to be phased out for private plans, and (3) prohibit private label generic prescription drugs (Wood, 2010). At the time, up to 70% of professional allowance funds were used for operating costs of the pharmacy, so its elimination drastically reduced profitability. There was, however, $100 million CAD set aside to cover pharmacy professional services on a fee-for-service basis to offset a portion of the losses (Wood, 2010).

Table 1 Fees and claims data for government-sponsored pharmacist services, by province (Updated September 2017)

	British Columbia	*Alberta*	*Saskatchewan*	*Manitoba*	*Ontario*	*Quebec**	*Nova Scotia*	*New Brunswick*	*Prince Edward Island*	*Newfoundland/ Labrador*
Patient care plans		$100 per Comprehensive Annual Care Plan (CACP, 130,378 claims); $125 for pharmacists with additional prescribing authority (APA, 123,506 claims); $60 per Standard Medication Management Assessment (SMMA, 38,770 claims); $75 if pharmacist has APA (36,364 claims); $20 for follow-ups without APA (373,447 claims for CACPs, 47,140 for SMMAs); $25 for follow-ups with APA (463,930 claims for CACPs, 56,136 for SMMAs)								
Medication reviews/ management	$60 per Medication Review–Standard, max. 2 annually, 6 months apart (177,114 claims); $70 per Medication Review—Pharmacist Consultation, max. 2 annually, 6 months apart (17,794 claims); $15 per Medication Review Follow-Up, max. 4 annually (19,235 claims)	Medication reviews a component of CACPs and SMMAs (see Patient care plans above)	*$60 per Medication Assessment (seniors) (11,795 claims); $20 per follow-up, max. 2 annually (3465 claims)* *$60 per Medication Assessment and Compliance Packaging (1845 claims)*		$60 per MedsCheck (543,902 claims); $75 for MedsCheck for Diabetes (163,168 claims); $90 for MedsCheck for Long-Term Care Annual (69,833 claims); $150 for MedsCheck at Home (24,799 claims); $25 per follow-up (163,242 claims for MedsCheck; 44,308 claims for MedsCheck for Diabetes Education); $50 per quarterly follow-up for MedsCheck for Long-Term Care Quarterly (198,510 claims)		*$52.50 per Basic Medication Review (3728 claims); $150 per Medication Review Service (seniors) (669 claims); $20 for follow-ups, max. 2 annually (118 claims)*	*$52.50 per PharmaCheck (low-income) (12,318 claims)*	*$52.50 per Medication Review (2130 claims); $65 per Diabetic Medication Review (948 claims); $20 per follow-up for Medication Reviews, max. 4 annually (1047 claims); $25 per follow-up for Diabetic Medication Reviews (369 claims), max. 4 annually*	*$52.50 per Medication Review (seniors); $52.50 per Medication Review for Diabetes (all ages); max. 72 claims annually; (1629 claims)*

Table 1 Fees and claims data for government-sponsored pharmacist services, by province (Updated September 2017) (*cont.*)

	British Columbia	*Alberta*	*Saskatchewan*	*Manitoba*	*Ontario*	*Quebec**	*Nova Scotia*	*New Brunswick*	*Prince Edward Island*	*Newfoundland/ Labrador*
Immunization	$10 (557,533 claims for flu; 13,156 claims for pneumonia; 655 claims for pertussis; 620 claims for HPV; 11,218 claims for other)	$20 (533,053 claims for flu); authority for other immunizations, inc. travel vaccines (no public funding)	$13 (90,374 claims for flu)	$7 (79,050 claims for flu; data not available for pneumonia, HPV, Tdap [tetanus, diphtheria, pertussis])	$7.50 (1,010,548 claims for flu); authority for other immunizations, inc. travel vaccines (no public funding)		$12 (104,170 claims for flu)	$12 (63,315 claims for flu for seniors and high-risk groups)	$12.36 (9280 claims for flu); authority to immunize again other infectious diseases, no public funding	$13 (3757 claims for flu)
Administration of drugs by injection		$20 per assessment and administration of drugs by injection (169,419 claims)	Authority to administer drugs by injection; no public funding	Authority to administer drugs by injection; no public funding	Authority to administer drugs by injection and inhalation for education and demonstration; no public funding	Authority to administer drugs to demonstrate appropriate use; no public funding	Authority to administer drugs by injection; no public funding	Authority to administer drugs by injection; no public funding	Authority to administer drugs by injection; no public funding	Authority to administer drugs by injection; no public funding
Adaptation/ altering of prescriptions, including continuity of care and renewals	$10 to renew and adapt (226,296 claims)	$20 per assessment for renewal/adaptation/ discontinuation (533,393 claims for renewals; 151,679 claims for adaptations)	$6 to renew, alter dosage form or alter missing information (249,608 claims)	Authority for continuity of care prescribing and prescription adaptations; no public funding	Authority to adapt or renew; no public funding	$12.50 per renewal (30 + days), max. 1 per person annually (158,358 claims)	*$14 per Prescription Adaptation (293 claims)*	Authority to adapt or renew; no public funding	*$14.83 per adaptation (123 claims)*	*$11.96-$12 per Medication Management adaptation (33,918 claims)*
Refusals to fill	$20	$20 per assessment (8523 claims)	*1.5X dispensing fee, max. $17.10 (16 claims)*		*$15 as part of Pharmaceutical Opinions program*	*$8.96 for first 48,500 prescriptions; then $8.37 (67,444 claims)*	*$14 (49 claims)*		*$14.83 (14 claims)*	*$23.92-$24 (32 claims)*
Therapeutic substitutions	$17.20 (8753 claims)	$20 per assessment (claims included under adaptation)				Authority to substitute for out-of-stocks; no public funding	*$26.25 (366 claims, for proton pump inhibitors only)*	Authority to substitute; no public funding	*$14.83 (6 claims for eligible drug classes)*	*$11.96-$12*
Emergency prescription refills	Authority for emergency refills; no public funding	As part of prescription renewals	$10, max. 1 claim per patient per 28 days (claims data n/a)	Authority for emergency refills; no public funding	Authority for emergency refills; no public funding		Authority for emergency refills; no public funding	Authority for emergency refills; no public funding		$11.96-$12

Minor ailments	As part of CACPs, SMMAs by those with additional prescribing authority	$18 per Minor Ailment Assessment for 16 conditions (14,512 claims)	Authority to assess and prescribe for 12 self-limiting conditions ("minor ailments"); no public funding		$16 per assessment for 7 conditions where no diagnosis is required and for 12 where diagnosis and treatment are known (107,666 claims)	Authority to assess and prescribe for 31 conditions; no public funding	Authority to assess and prescribe for minor ailments; no public funding	Authority to assess and prescribe for 30 conditions; no public funding	Authority to assess and prescribe for minor ailments; no public funding
Initial-access prescribing or to manage ongoing therapy (exc. minor ailments)	$25 per assessment for initiating medication therapy with APA (206,395 claims) $20 per assessment for emergency prescriptions (26,777 claims)	Collaborative Practice Agreements with physicians enable pharmacists to select, initiate, monitor and modify drug therapies; no public funding	Authority for prescribing by Extended Practice pharmacists within the scope of their specialty; no public funding. Authority to prescribe in "state of emergency;" no public funding	Authority to initiate Schedule 1 smoking cessation therapy; see below for funding details for smoking cessation services	To reach therapeutic target: $15.50–$19.50 for initial evaluation (based on condition); $40 annually for min. 2 follow-ups for certain conditions; $50 annually for min. 3 follow-ups for insulin-dependent diabetes; $16 per follow-up for anticoagulation, max. 1/month. (128,557 claims for all)	Authority to assess and prescribe in emergencies; no public funding	Authority to initiate smoking cessation therapy; no public funding. Authority to assess and prescribe in emergencies; no public funding	Authority to assess and prescribe in emergencies; no public funding	Authority to initiate smoking cessation therapy; no public funding
Pharmaceutical opinions				*$15 per opinion (212,910 claims for "Change to prescription," 96,697 claims for "No change to prescription," 17,501 claims for "Not filled as prescribed")*	*$19.79 (198,552 claims)*

Table 1 Fees and claims data for government-sponsored pharmacist services, by province (Updated September 2017) (*cont.*)

	British Columbia	*Alberta*	*Saskatchewan*	*Manitoba*	*Ontario*	*Quebec**	*Nova Scotia*	*New Brunswick*	*Prince Edward Island*	*Newfoundland/ Labrador*
Smoking cessation	$10 per dispensing of nicotine replacement therapy, max. 3 annually (claims data n/a)	As part of SMMAs and follow-up SMMAs; max. 4 follow-ups	*Up to $300 annually ($2 per minute) for Partnership to Assist with the Cessation of Tobacco (PACT) (4940 claims)*	Authority to prescribe for smoking cessation; no public funding	*Up to $125 annually: $40 for initial consult; $15 for up to 3 primary follow-ups; $10 for up to 4 secondary follow-ups (6288 claims)*	$16 to prescribe for smoking cessation as part of minor ailments (30,423 claims out of total for minor ailments)	Authority to prescribe for smoking cessation as part of minor ailments; no public funding		Authority to prescribe for smoking cessation as part of minor ailments; no public funding	Authority to assess and prescribe for smoking cessation; no public funding
Other services	$10 for trial prescriptions (claims data n/a)	$20 for assessment of appropriateness of new prescription medications (trial prescriptions, 19,323 claims)	2X dispensing fee, max. $22.80 for emergency contraception prescribing (7721 claims); $25 for medication reconciliations (seamless care) with prescribing or *1.5X dispensing fee, max. $17.10 for medication reconciliations; $7.50 for trial prescriptions; $3.50/day for Direct Observed Therapy for Hepatitis C drugs; $3.50/day for methadone managed care*		Authority to perform a procedure below the dermis for education and demonstration; no public funding $70 for naloxone program, initial kit; $45 for replacement kit (17,543 claims)	$18.02 for emergency contraception prescribing (107,378 claims)				*$23.92-$24 for Antibiotic Medication Adherence; $11.96-$12 for follow-ups, max. 1 per antibiotic (96,286 claims); $23.92-$24 for COPD Medication Adherence; $11.96-$12 for follow-ups, max. 2 (163 claims). Authority for trial prescriptions; no public funding*

NOTE: All content in italics indicates that public funding is available only to eligible beneficiaries of the provincial drug plan.

Information current as of September 2017 and collected from provincial ministries of health and provincial pharmacy associations. Claims data are for fiscal year ending March 31, 2017, with the exception of Quebec where the data is for year ending December 2016.

*In Quebec, legislation requires private insurance plans to pay the same fees as the public plan for pharmacists' services, except for refusals to fill and Pharmaceutical Opinions. This chart gives claims data for the public plan only.

Reforms are not limited provincially. National programs such as the pan-Canadian Pharmaceutical Alliance (pCPA) aggressively negotiate drug pricing reductions across Canada. pCPA's goal is to achieve lower consistent drug prices, increase access to new drugs, and improve consistency of coverage nationally. The Alliance capitalizes on the combined buying power of the provinces and reduced duplication of negotiations (Husereau et al., 2014). On April 1, 2018, 70 of the most commonly prescribed drugs in Canada were reduced by 25%–40%, resulting in overall discounts of up to 90% of the price of their brand-name equivalents. Most are drugs to treat chronic diseases such as high blood pressure, high cholesterol, and depression. The changes are estimated to save an additional $3 billion dollars over the next 5 years.

In the end, drug reform and generic deflation have threatened the sustainability of community pharmacy. Dispensing profitability has greatly declined over the past decade, and this trend will likely continue as the fraction of generic medications increases (PMPRB, 2014). Pharmacists are beginning to explore expanded scope services as alternative revenue streams, with the hope that these services will drive profitability in the future. In order for pharmacies to successfully transition into a workflow model that allows for the sustainable provision of these clinical services, it is necessary to understand a number of key concepts:

1. Understand the evolving roles of all the key pharmacy players
2. Pharmacy labor investments are instrumental to sustainability
3. Traditional measures of pharmacy productivity are no longer applicable
4. Pharmacy contribution for professional services is higher than dispensing activities
5. Embrace technology to enhance productivity

Understand the Evolving Roles of All the Key Pharmacy Players

The ability to offer sustainable patient-centered services extends beyond the pharmacist. Dispensary assistants and regulated pharmacy technicians are instrumental in the successful implementation of these programs. Their primary goal is to:

Champion the dispensing function such that pharmacist time dedicated to technical tasks can be limited and devoted instead to patient-centered services.

As the roll of the pharmacist has evolved so as that of the technician. Many pharmacies have yet to capitalize on this expanded role. Integrating a registered pharmacy technician into practice offers a viable solution to the workflow issues faced by many pharmacists, particularly when maximizing the technician's scope. In order to do this, however, we must clearly understand what a pharmacy technician can do under their own authority as a regulated health-care professional.

In general terms, the division of responsibilities can be defined as:

- *TECHNICIANS* are accountable and responsible for the technical aspects of both new and refill prescriptions (i.e., the correct patient, drug dosage form/route, dose, doctor) and;
- *PHARMACISTS* remain accountable and responsible for the therapeutic/clinical appropriateness of all new and refill prescriptions and all therapeutic consultation.

More specifically, a regulated pharmacy technician can:

1. Ensure that a prescription vial contains the right drug and quantity
2. Accept verbal prescriptions (excluding narcotics/controlled/and targeted substances)
3. Receive and provide prescription transfers (excluding narcotics/controlled/ and targeted substances
4. Perform a procedure on tissue below dermis (e.g., using a lancing device)

While the objective of integration is to optimize the roles of the technician and pharmacist, workflow will be dependent on a number of individual variables including:

1. prescription volume
2. OTC traffic
3. physical layout
4. staff experience
5. patient demographics

There is no "cookie-cutter" approach to maximize workflow and productivity. It may be necessary for pharmacies to experiment in order to balance all these variables.

Moreover, in addition to diverting technical tasks, technicians can play an indirect role in the professional programs themselves. In order to do this, they must be able to:

1. Define the Service
    a. What are you offering the patient?
    b. Understand basic process to deliver the service
        - Nature of the consultation, duration of appointments, items covered

c. Inherent benefits of the service

- Personalized approach
- Maximum results from drug therapies
- Support through regular follow-up
- Answers to questions

2. Screen for patients
3. Notify the pharmacists about eligible patients
4. Call patients to remind them about appointments
5. Provide other follow-up support

By optimizing the integration of regulated pharmacy technicians, the efficiency of the dispensing function can be improved, and the focus of the pharmacist can shift to offering professional services.

Pharmacy Labor Investments are Instrumental to Sustainability

One of the fundamental errors made by pharmacy managers and owners when initially integrating clinical programs into their practice is that they fail to make the necessary investments in labor. The expectation is that the programs will be offered using the traditional labor model. This may work during periods of low prescription volume. However, during busy periods, the staff will almost always revert back to their traditional dispensing model and abandon any attempt to offer clinical programs. This sends a mixed message to customers and will fail to differentiate the pharmacy as a facility that excels in expanded scope.

Traditional Measures of Pharmacy Productivity are No Longer Applicable

The traditional pharmacy business model was entirely transaction based. Dispensary productivity was assessed using measures such as scripts per labor hour or wage cost per script. This was appropriate for a model centered on dispensing. A typical pharmacy would be deemed productive if it were able to achieve a productivity of anywhere between 5 and 8 scripts per labor hour or a cost to fill of about $4–5 per script.

Unfortunately, these productivity measures do not apply to a service-based model. Most clinical services are reimbursed according to a fee-for-service model. Fees are dependent on the time required to offer the service and the complexity of the program. Pharmacy management will find it difficult to evaluate the return on investment of these clinical programs if they rely on antiquated productivity measures. As such, productivity of these clinical programs must be assessed separately from the traditional dispensing services. A measure such as wages as a percentage of sales would address both the investment in labor required to offer the service and the resulting revenue generated from the fees. A return of 20%–25% works well for most currently funded programs. Consequently, the financial success of the programs could be more accurately assessed, and changes to labor investments could be made based on these thresholds.

Pharmacy Contribution for Professional Services is Higher than Dispensing Activities

Pharmacy contribution is defined as the net profit delivered to the overall business by the pharmacy department. This typically includes profit from dispensing and professional service fees. Services have improved pharmacy contribution and store profitability on an absolute dollar basis and on a net Contribution per Rx basis. Services do not carry some of the typical costs incurred by dispensing activity, namely, no costs of goods sold (COGS), no total loss, no other Rx expenses. Services have a higher cost per script for Rx Wages. The value-added function of this interaction solely rests with the pharmacist and their patient intervention. Figs. 1–3 help to explore these concepts.

Embrace Technology to Enhance Productivity

Finally, with today's steady prescription, growth pharmacy operators are looking for new and creative ways to handle prescription volume. They are experimenting with innovative solutions to help them reduce labor productivity costs, free up pharmacists' time, and maintain the important patient relationship. Technology can play a vital role in optimizing dispensary workflow, and technological advancements have dramatically changed the way that pharmacies fill their prescriptions and the way that pharmacists interact with their patients. The most significant of these changes include:

1. Paperless Workflow
2. Automated Dispensing
3. Centralized Fill
4. E-refills/Paging
5. E-prescribing
6. Medication Synchronization

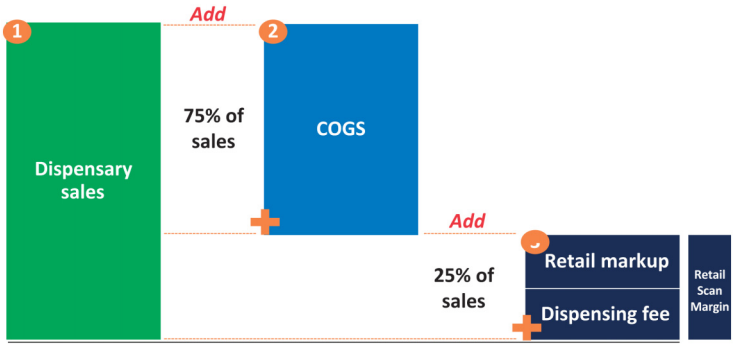

Figure 1 Dispensary sales include three key components: cost of goods sold (COGS), retail markup, and dispensing fee.

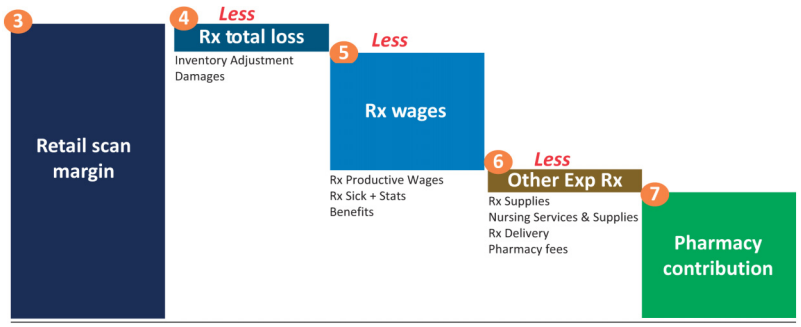

Figure 2 There are additional direct expenses incurred to deliver dispensary sales, which reduce the retail scan margin and equate to the pharmacy contribution.

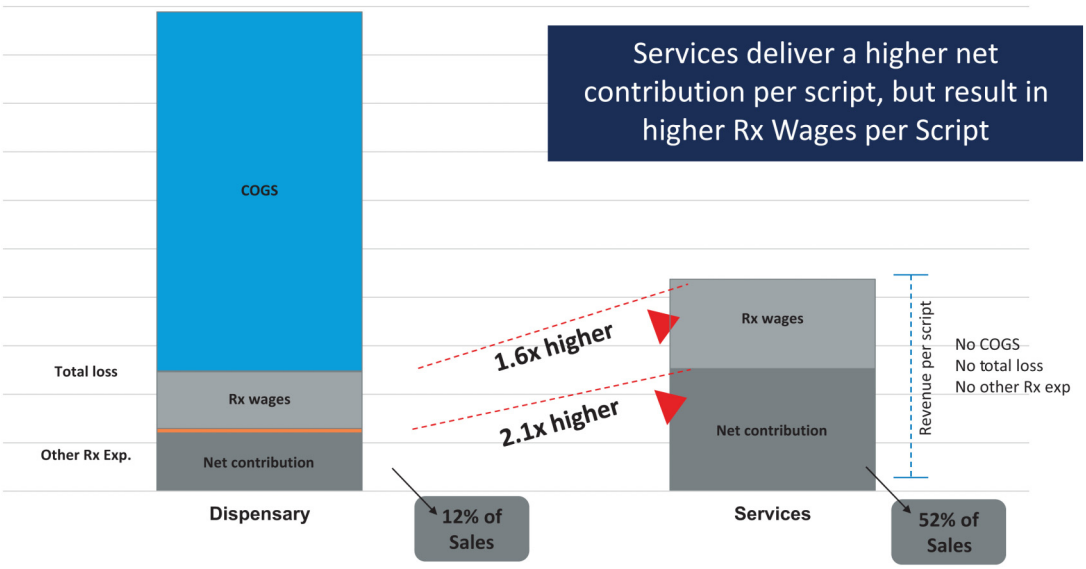

Figure 3 Pharmacy contribution for professional services is higher than dispensing activities.

Traditional dispensaries rely very heavily on paper. Everything from hardcopies, to logs, to transfers are documented on paper and manually filed. This is an extremely tedious, time-consuming process. Scanning technology has allowed us to transition to a paperless environment. Low-value tasks such as basket staging and prescription filing have been eliminated completely. All documentations are stored electronically and can be readily retrieved. The benefits to productivity and labor are enormous.

In the atmosphere of a busy dispensary, every minute counts. Automated dispensing machines or dispensing robots have the ability to fill and label prescriptions very quickly and accurately. They have been shown to improve both dispensary efficiency and patient safety. As pharmacists look for additional ways to free up time for direct patient care activities, and as the cost of these devices continues to decline, we are certain to see them more frequently in community pharmacies.

A natural extension of the automation process is central fill. Using central fill, pharmacies can aggregate prescriptions from multiple locations and funnel them to a centrally located prescription fulfilment center. Once there, prescriptions are assembled, verified, packaged, and are delivered back to the originating pharmacy. Although, this model is not yet common in Canada, it is widely used by national chains in the United States. The cost to fill a prescription can be reduced to as low as $1 per script, as compared to $4–5 in a traditional pharmacy. These productivity gains have the potential to dramatically change dispensary workflow.

Technological solutions also impact the way that patients interact with their pharmacies. E-refills allow patients to have access to e-mailed refill reminders and then to automatically request that their prescriptions be prepared. In addition to the obvious adherence benefits, these solutions relieve congestion at the pharmacy and allow for workload to be systematically completed in advance. For those patients that do chose to visit the pharmacy directly, paging systems allow them to wander the store and be contacted when their prescription is ready. Again, this allows for a more streamlined workflow and reduces the stress and anxiety experienced by pharmacy staff as a result of unplanned spikes in prescription volume.

E-prescribing, as defined by the Centre for Improving Medication Management (CIMM), is the computer-based electronic generation, transmission and filling of a prescription, taking the place of paper and faxed prescriptions (2008). A literature review by Porterfield et al. identified the benefits of e-prescribing, including reduced prescribing and medication errors, increased efficiencies for physicians and pharmacists, cost savings for the health-care system, and increased medication adherence (Porterfield et al., 2014). A nonrandomized prospective study by Kaushal et al. found an almost sevenfold decrease in error rates 1 year after implementation of e-prescribing (Kaushal et al., 2010). Efficiencies within the pharmacy were seen through reduced paperwork, less call-backs to physicians for clarifications, and less time spent faxing prescriptions and reauthorizations to pharmacies (CIMM, 2008). Cost savings can be expected through a reduction in adverse drug events, resulting in reduced visits to physician offices and emergency rooms (Surescripts, 2012). The implementation of e-prescribing has also led to improved medication adherence, with a study by Surescripts showing a 10% increase in number of prescriptions being picked up when compared to written prescriptions (2012).

Medication synchronization or medsync is defined as the synchronized filling and refilling of chronic disease state medications, all on the same day, using pharmacy software technology to coordinate and calculate fill quantities and streamline dispensing. Traditionally, community pharmacy dispensing has been reactive; waiting on a patient to request a refill. By syncing a patient's entire medication list to be due at the same time, it proactively addresses refill compliance, which can lead to improved medication adherence. A study by the National Community Pharmacists Association (2013) showed improvements of adherence by 50%, and first-refill abandonment was reduced by over 90%. There was also an increase in the number of prescriptions filled by patients by 0.75–1 per year. Software upgrades that coordinate the refilling of medications in a timely and effective manner promote these benefits to various stakeholders. This technology allows community pharmacy to increase efficiency, improve adherence, as well as reduce third-party payer health-care costs due to patient noncompliance.

Patient Care Services

Community pharmacy has expanded beyond the simple distribution of drugs to include a myriad of patient care services. This section will explore some of these opportunities and highlight the successes and challenges that pharmacists have faced with their implementation.

Medication Reviews

A medication review, in general, may be defined as a service in which a pharmacist uses their unique expertise in pharmacology and pharmacotherapy to review a patient's medication regimen with the goal of identifying actual or potential drug therapy problems. Medication reviews can vary widely depending on the jurisdiction's scope of practice, program requirements, and reimbursement. Examples of different types of reviews include comprehensive prescription and nonprescription reviews, adherence reviews, targeted clinical intervention reviews, as well as reviews focusing on deprescribing and therapeutic substitutions (Noseworthy, 2013). At minimum, these sessions are typically appointment-based and include reviewing the patient's prescription medications and collaborating with the patient and their circle of care, in order to optimize drug therapy. The pharmaceutical division within British Columbia's Ministry of Health defines a review as follows:

> "A medication review is a patient-care service that seeks to enhance a patient's understanding of, and improve the health outcomes of, their medication regimen" (Ministry of Health, 2016 p.12).

Medication reviews also offer a unique opportunity to engage the patient to play a larger role in their own medication management and to promote interprofessional collaboration with the ultimate goal of improving health-care outcomes.

Experience To-Date

Over the past decade, medication reviews, from the simplest to the most complex, have come under scrutiny from both government and third-party insurers. These payors have begun to demand evidence to substantiate the continued reimbursement of the programs. Theoretically, medication reviews provide an opportunity to optimize health outcomes and render cost savings through

the mitigation or amelioration of drug-related therapeutic issues (Malet-Larrea et al., 2017). Initially, several meta-analyses had found that medication reviews resulted in positive patient outcomes such as improved medication adherence, reduced hospitalizations, and achievement of biomarker targets (Hatah et al., 2014). The average compensation for a medication review in 2014 was $68.86CAN (Houle et al., 2014). In the United Kingdom, medication reviews with follow-ups (MRF) reimbursed at 22€ per patient-month yielded cost savings for the National Health Services (NHS) within 6 months, at 97€ per patient. For every 1€ invested to MRF, there was a return of 3.3–6.2€ (Malet-Larrea et al., 2017). This evidence has been met with some controversy as conflicting studies have concluded that medication reviews provide no cost savings relative to traditional care (Loh et al., 2016). These differences may be explained by the wide variation in program and documentation requirements, reimbursement, scope, and outcomes measured. Table 2 provides some examples of different medication review programs.

More recently, the Ontario Pharmacy Evidence Network (OPEN) evaluated billing data for medication reviews performed in Ontario as part of the government funded MedsCheck program. Pharmacies were less likely to conduct an annual medication review

Table 2 Examples of various medication review programs

Program	*Location*	*Payer*	*Service*	*Eligible patients*	*Fee*
Medication Review (15)	Newfoundland and Labrador (NL)	NL Prescription Drug Program	Medication Review	NLr Prescription Drug Program beneficiary (1) • All ages if diagnosed with diabetes on one or more diabetic agent • Over 65 with chronic conditions managed by 3 or more medications	$52.50 CAN
Pharmacare Insured Professional Services (18)	Nova Scotia (NS)	Government of NS	Advanced Medication Review Service	NS Beneficiary of Seniors' Pharmacare Program • ≥1 chronic disease and, • ≥4 chronic Rx medications or 1 high-risk drug and, • Not residing in nursing home or care facility or receiving compliance packaging	$150 CAN
			Basic Medication Review Service	NS resident on ≥3 chronic Rx medications	$52.50 CAN
MedsCheck (15)	Ontario (ON)	ON Ministry of Health and Long-Term Care	MedsCheck	Ontario Drug Benefit (ODB) or Youth Pharmacare (OHIP+) (2) beneficiary • ≥3 Rx medications for a chronic condition (2)	$60 CAN
			Diabetes MedsCheck	Ontario Drug Benefit (ODB) or Youth Pharmacare (OHIP +) (2) beneficiary • ≥1 Rx diabetic medication (2)	$75 CAN
			Home MedsCheck	Eligibility for MedsCheck or Diabetes MedsCheck and not able to visit pharmacy due to physical or mental issues (2)	$150 CAN
Rx Review Program	Colorado	Colorado Department of Health Care Policy and Financing (Medicaid)	Medication Review	Colorado Medicaid beneficiaries on ≥5 Rx medications for over 3 consecutive months (4)	• $150USD face-to-face • $90 USD • Phone appointment (5)
PharmAssist (6)	Montana	State of Montana Department of Public Health and Human Services	Medication therapy management	All Montana residents	• Initial: 50 USD (15 min) • Additional time or follow ups: 25 USD (15 min)

as their prescription volume increased (Pechlivanoglou et al., 2016). Also, pharmacists tended to more frequently conduct medication review on those patients with less complex medication regimens. Time and workflow were identified as barriers to sustained implementation. Documentation was also identified as an issue. Less than half of the reviews recorded the reason for medication use and only 75% indicated any assessment of medication-taking behavior.

In the end, pharmacy medication review programs, despite their widespread use across North America, have been scrutinized for quality and cost effectiveness. Although anecdotal reports indicate a high degree of patient satisfaction with the service, evidence to support cost savings and positive health outcomes is mixed, at best. Pharmacies that have been able to overcome the time, and workflow challenges have generally made an investment in pharmacist labor in order to ensure the sustainability of the program and, typically, utilize nontraditional appointment-based models in order to offer high-quality service.

Disease State-Specific Consultation Programs

Disease state-specific programs are variations of medications reviews that target patients with specific chronic conditions. Most commonly, these programs focus on cardiovascular disease, diabetes, and smoking cessation. The goals of these programs are to improve the overall health of these patients with the hopes of lowering their drug and disability costs. Several insurance providers have piloted disease state-specific consultation programs with varying reimbursement models for pharmacy.

Green Shield Canada (GSC), since 2015, has offered a pan-Canadian cardiovascular program for all Green Shield beneficiaries under the age of 65. The Pharmacist Health Coaching Cardiovascular Program was developed based on the positive evidence of the Rx Reach study which found that intensive hypertension control managed by pharmacists greatly exceeded those outcomes in patients receiving standard of care. Outcomes included statistically significant reductions in systolic blood pressure and in the percentage of patients that achieved blood pressure targets within the 6-month study duration (Ontario College of Pharmacists and Green Shield Canada, 2018). The goals of the cardiovascular program include:

1. Provide guidance and support to patients to achieve target blood pressure and cholesterol measurements.
2. Implement strategies that help improve patient adherence to cardiovascular drug therapy.
3. Offer effective coaching and follow-up to help patients adopt healthy lifestyle behaviors that will positively impact their cardiovascular and overall health.

This program offers compensation to pharmacists at $60 CAN for the initial visit and $20 CAN for scheduled follow-ups (Green Shield Canada n.d., p. 4).

Smoking Cessation

Tobacco-related health-care costs remain a huge public heath burden in both Canada and the United States. In Canada alone, these costs exceed $6.5 billion annually (The Conference Board of Canada, 2012). As such, governments and third-party payers have looked to the expertise of community pharmacists to help patients engage in quitting smoking. Several Canadian provinces and a number of insurers have offered reimbursement to pharmacists for participating in structured counseling services. As of 2018, Alberta, Saskatchewan, Ontario, and Quebec have publically funded pharmacy smoking cessation programs already in place (Canadian Pharmacists Association, 2015). Additionally, in provinces where pharmacists have prescribing authority, they can utilize this authority to prescribe smoking cessation therapies (Ontario College of Pharmacists, 2012). **Table 3** outlines the details of the Ontario model (Ministry of Health and Long-term Care, 2018).

Unfortunately, initial uptake of the Ontario smoking cessation program has been poor. Pharmacists have cited insufficient reimbursement and time and workflow challenges as the most common barriers to successful implementation. Only a small fraction of Ontario smokers participated in the program during the 2011–12 fiscal year (Wong et al., 2015), which has raised concerns about the future of the program.

Minor Ailment Prescribing and Assessment

Minor ailment is an umbrella term used to describe diseases or conditions that are self-limiting in nature. Despite the terminology, minor ailments result in a large number of annual physician visits. By expanding pharmacist scope of practice to include minor ailment prescribing regulators hoped to free up physician time, improve access to care for patients, and reduce overall health-care costs. In the United Kingdom, the National Health Service (NHS) has adopted a pharmacist/physician collaborative minor ailment model since 2000 (Paudyal et al., 2011). A systematic review of the program concluded that the introduction of pharmacy-based minor ailment services in the United Kingdom resulted in a high rate of symptom resolution, low rate of reconsultation, and a decrease in the number of consultations at general practices (Paudyal et al., 2013). These findings suggest pharmacy-based minor ailment programs do not jeopardize care and may alleviate work burden from general practitioners. In North America, several Canadian provinces have expanded the scope of pharmacist practice to allow for the assessment and prescribing of minor ailments. Public funding for the programs exists in Alberta, Saskatchewan, and Nova Scotia (Canadian Pharmacists Association, 2015). As an example, in Saskatchewan, pharmacists are publically reimbursed $18 CAN when the minor ailments assessment results in a prescription (Lynas, 2013). **Table 4** lists the schedule of drugs appropriate for prescription by pharmacists for specified minor ailment or self-care conditions in Saskatchewan. Despite the positive experiences reported by both patients and pharmacists that

Table 3 Criteria and points of contact for the publicly funded Ontario pharmacist smoking cessation program

Step	*Activity*	*Details*	*Interaction options*	*Recommended time*	*Reimbursement*
1	(Session #1) 1. Readiness assessment 2. Patient enrolment/consent	Patient completes questionnaire to identify desire to quit smoking Patient provides consent to program and sets an expected quit date with the Pharmacist	Any Pharmacist In person	5–10 min	$0.00 Unlimited provision
2	(Session #2) 1. First consultation 2. My quit plan	In-depth Pharmacist consultation to discuss the patient's smoking and medication history, health risks, triggers, quit date, and smoking cessation plan	Certified Pharmacist In person preferred Telephone (if agreeable to patient)	20 min	$40.00 Max: Once per 365 days
3	(Session #3) Primary follow-up	Pharmacist provides ongoing support to the patient by addressing concerns and issues, management of withdrawal symptoms, etc.	Certified Pharmacist In person Telephone E-mail	10 min	$15.00 Max: Three per 365 days
4	(Session #4) Primary follow-up				
5	(Session #5) Primary follow-up				
6	(Session #6) Secondary follow-up	Pharmacist provides ongoing support to the patient by addressing concerns and issues, management of withdrawal symptoms, etc.	Certified Pharmacist In person Telephone E-mail	3–5 min	$10.00 Max: Four per 365 days
7	(Session #7) Secondary follow-up				
8	(Session #8) Secondary follow-up				
9	(Session #9) Secondary follow-up				
10	Program evaluation	Pharmacist documents final patient outcomes	Any Pharmacist	2 min	$0.00 Required: Once per 365 days

Table 4 Schedule I drugs appropriate for prescription by pharmacists for specified minor ailment or self-care conditions

Condition	*Medications*
Migraines and headaches	Ibuprofen all strengths Naproxen all strengths Diclofenac Almotriptan Naratriptan Rizatriptan Sumatriptan Zolmitriptan Eletriptan (frovatriptan
Cold sore	Acyclovir cr/oint/oral Famciclovir Valacyclovir
Mouth ulceration (mild)	Triamcinolone dental paste
Oral thrush	Nystatin drops
Acne (mild–mod.)	Benzoyl peroxide (BP) up to 10% Clindamycin phosphate Clindamycin/BP Clindamycin/ tretinoin Erythromycin/BP Erythromycin/ethyl alcohol/avobenzone/octinoxate Erythromycin/tretinoin Adapalene cr 0.1%, 0.3%; gel 0.1% Adapalene 0.1%/BP 2.5% Tazarotene 0.05%, 0.1% cr or gel Tretinoin cr or gel all strengths Tretinoin/avobenzone/octinoxate cr all strengths

(*Continued*)

Table 4 Schedule I drugs appropriate for prescription by pharmacists for specified minor ailment or self-care conditions (*cont.*)

Condition	*Medications*
Atopic dermatitis (mild–moderate)	Hydrocortisone cream 1%, 2.5%
	Desonide 0.05%
	Betamethasone valerate
	Clobetasal butyrate
	Diflucortolone valerate
	Hydrocortisone valerate
	Mometasone furoate
	Triamcinolone acetate
Diaper rash	Clotrimazole hydrocortisone 1% cr/oint
Insect bites	Hydrocortisone 1% cr/oint
Skin infections	Fucidic acid cr/oint
(bacterial)	Mupirocin cr/oint
Tinea infections (athlete's foot, jock itch, ringworm)	Terbinafine 1% cr
	Ketaconazole 2% cr
Dyspepsia/GERD	Cimetidine 300, 400, 600 mg
	Famotidine 40 mg
	Nizatadine 150, 300 mg
	Ranitidine 150, 300 mg
	Esomeprazole 20, 40 mg
	Lansoprazole 15, 30 mg
	Omeprazole 10, 20 mg
	Pantoprazole 40 mg
	Rabeprazole 10, 20 mg
Hemorrhoids	HC/zinc sulfate
	HC/zinc sulfate, pramoxine
Dysmenorrhea	Celecoxib
	Diclofenac
	Ketoprofen
	Mefenamic acid
	Naproxen sodium
Pain	Diclofenac
	Diclofenac/misoprostol
	Naproxen
	Celecoxib
	Meloxicam
Allergic rhinitis	Levocabastine
	Beclomethasone
	Mometasone furoate
	Fluticasone proprionate

have participated in minor ailment programs, some stakeholders have raised concerns with respect to pharmacist training, diagnosing as a scope of practice, and inherent conflicts of interest (Lee and McCarthy, 2015).

Immunization

The role of pharmacists in immunization and vaccination varies across the world; in some countries, pharmacists are primarily involved in ensuring the safe supply and dispensing of vaccines, as well as advocating for immunization, while in other countries, they are empowered to play a more active role, as they are legally authorized provide vaccination. It is estimated that ten million lives per year could be saved by increasing access to medicines and vaccinations. Community pharmacists are therefore in a strong position to provide a major contribution to public health due to their accessibility, distribution, and available expertise. Pharmacists are also highly trusted health-care professionals and are ideally positioned to improve patient communication with respect to vaccine myths and hesitancy.

Influenza

Influenza (or the flu) is a common infectious respiratory disease that affects millions of people globally each year. In Canada, for example, there are up to 20,000 flu-related hospitalizations and 4000 deaths annually. Individuals with risk factors such as diabetes, cardiovascular disease, and respiratory conditions are even more susceptible to hospitalizations and complications. Influenza epidemics of variable extent and severity occur almost every winter. They impose an enormous burden in terms of morbidity, mortality, economic, and social costs.

Immunization remains the most cost-effective method in reducing influenza and influenza-related complications. The National Advisory Committee on Immunization recommends influenza vaccination for all Canadians aged 6 months and older. Despite this recommendation and the universal availability of the vaccine, Statistics Canada reports that only 28.9% of Canadians were vaccinated against the flu in 2012 (Papastergiou et al., 2014).

Pharmacists are highly trained and accessible health-care providers who are ideally positioned to provide flu vaccinations to the public. Their services are widely available and they typically do not require an appointment for consultation. Despite the benefits of immunization, scepticism about vaccination and general inconvenience continue to deter people from getting vaccinated. Pharmacists are a well-respected educational resource for patients with the potential to positively influence immunization rates. They are able to advocate for the importance of immunization, dispel common misconceptions, and screen for high-risk patients. As early as 1996, the American Pharmacists Association (APhA) had begun its training program for pharmacist-administered vaccinations. As a result, US pharmacists have increasingly become recognized as the vaccine experts. In Canada, this expansion in scope has also been received very positively. As of 2016, all pharmacists are authorized to administer influenza vaccinations, and all provinces have publicly funded compensation programs except for Quebec (Canadian Pharmacists Association, 2016). By the end of the 2012–13 flu season, more than 250,000 Ontarians were vaccinated by pharmacists, far exceeding the provincial government's initial target of 100,000. During the 2016–17 flu season, pharmacists provided over 2 million vaccinations nationally.

Overall feedback from patients regarding pharmacist-directed vaccination has been overwhelmingly positive. A 2014 study found that 92% of patients indicated they were very satisfied with the pharmacist's injection technique, and 98% of patients would recommend a friend or family to receive the same service (Papastergiou et al., 2014). Additionally, 28% of the respondents indicated that they would not have received a flu shot if the pharmacy program was not available, and 8% of the survey respondents received their first flu shot by a pharmacist (Papastergiou et al., 2014).

The impact of pharmacists on overall vaccination rates has also been positive. According to data from a US study in 1997, pharmacy-based influenza programs yielded a higher state level vaccination rate compared to states without programs in place in adults aged ≥65 years; 68.4% versus 64.7%, respectively ($P < 0.01$) (Steyer et al., 2004). A 2016 Canadian study produced similar results and showed a higher proportion of residents received flu shot in provinces where pharmacists provide them (30% vs. 28%).

In 2008, Posser and colleagues compared costs associated with administering influenza vaccinations in nontraditional settings and concluded that savings were significant when provided in pharmacies over traditional administration sites. In addition, Houle et al. reviewed 34 international pharmacy-based vaccination programs and their funding models. Remuneration ranged from $4.14 to $21.21 CAN (currencies converted in 2013), with an average of $13.12 CAN (SD $4.63) per injection. The availability of public reimbursement as well as the fee varied greatly between jurisdictions.

Vaccination Beyond Influenza

Pharmacists can play a major role in improving overall public health by becoming involved in immunization beyond influenza. The accessibility and distribution of community pharmacies make them a first point of contact with patients, providing an excellent opportunity to expand and increase access to immunization services. Convenient operating hours can be very attractive to busy patients and is particularly important in rural, isolated, and medically underserved areas, where access to vaccination can be challenging.

Unfortunately, vaccination policies vary dramatically across the globe, and the legal authority to immunize can differ significantly between jurisdictional regions, even within the same country.

In 2016, the International Pharmaceutical Federation (FIP) published a global report on immunization. The aim of the survey was to better understand the role of pharmacists in immunization across the world and the impact of these activities. FIP surveyed 137 member organizations and received responses from 45 countries and territories (33% response rate; 33% of FIP Member Organisations; 23% of WHO Member States). From all respondents, 71% (32 countries and territories) reported some level of engagement in support and advocacy activities connected with immunization service provision. The administration of vaccines was less common, with 29% (13) of respondents stating that pharmacist-administration was possible. Interestingly, 44% (20) stated that using pharmacies (as accessible health-care premises), including both pharmacists and other health-care professionals administering vaccines, was possible in their countries. There was also a clear association between advocacy and support for vaccination activities and being able to legally provide administration in pharmacy premises (by either pharmacists or other health-care professionals).

The integration of community pharmacies and pharmacists in national vaccination policies tends to develop as a gradual process over time. Several countries authorize vaccination in pharmacies and/or by pharmacists (e.g., in Argentina, Australia, Philippines, South Africa, UK, and USA); this practice has been initiated, in the majority of the cases, with pharmacy-based vaccinations against influenza and then expanded to include other vaccines from the immunization schedule. In most cases, it is associated with specific requirements such as pharmacist training, management of vaccination records, and specifications on premises, equipment, and waste management.

Pharmacist-Directed Travel Clinics

Pharmacy clinics that offer travel vaccinations have emerged as a recent but growing trend. These clinics offer yet another opportunity to expand pharmacist practice and generate an alternative revenue stream for pharmacies. Like other vaccination policies, state and provincial scopes of practice regarding travel vaccination vary greatly depending on the jurisdiction.

Travel vaccination services are highly personalized, and each visit requires an individual pharmacist consultation. Generally, these sessions involve (1) assessment of location of travel and patient's health status, (2) vaccine and other recommendations, and (3) physical administration of vaccine. That being said, depending on state and provincial laws, it is uncommon for all of the above steps to be covered under the pharmacist scope (Stewart et al., 2016). This has provided some challenges in the implementation of these programs. First, patient assessment requires health record access including access to immunization history if the patient cannot reliably provide the health information. This is limited in many settings. Second, vaccine prescribing and administration authority is often molecule dependent; pharmacist's may be able to provide some vaccinations without a prescription, but others will require a prescription from an authorized prescriber. These varying regulations can be problematic from the standpoint of being able to offer a "one-stop shopping" experience. For example, in Ontario, pharmacists have been authorized to administer vaccines for 13 preventable diseases including most travel diseases. Unfortunately, authority to prescribe these vaccines was not universal. In order to address these challenges, many pharmacies have adopted a collaborative approach with local physicians when offering travel consultation services. Standing order programs in the United States and medical delegation in Canada have been tried with some success.

Pharmacist confidence/competency in the area of travel has been identified as a possible area of education opportunity. Bascom and colleagues investigated community pharmacist knowledge on traveler's health (2015). Only 21% of interviewed pharmacists felt comfortable to effectively educate patients on travel-related topics (Bascom et al., 2015). Comfort levels increased to 66% with access to resources (Bascom et al., 2015). Bascom and colleagues suggested that further specialized education may be required for pharmacists to fully engage this opportunity (2015). The International Society of Travel Medicine offers a Certificate in Travel Health (CTH) that assists HCPs to build competency in this area. It is recommended that pharmacists considering offering a travel consultation service pursue this additional education.

In 2017, Houle et al. published a prospective cohort study among patients-seeking care from a pharmacist-managed travel health clinic in Alberta to identify (1) specific needs of travelers (e.g., demographics, health status, destination(s), itinerary), (2) acceptance of recommended vaccines, prescribed drugs, and nonprescription drugs, and (3) health status during travel and satisfaction with care and advice provided. In total, 103 participants were enrolled in the study. Pharmacists recommended 270 vaccinations, and acceptance was reported at 80%. Rabies was the most commonly declined vaccine (high cost, low perceived risk of exposure). About 14 participants reported a health concern during travel (traveler's diarrhea ($n = 8$), respiratory illness ($n = 4$), vomiting ($n = 2$), and allergic rhinitis, strep throat, altitude sickness, and eye infection ($n = 1$ for each). Five participants consulted a physician while traveling, and 2 consulted a physician upon return. Most patients visiting the travel clinic have some complicating factors affecting clinical decisions. While this may not be representative of all travelers, highlights the benefits of completing training in travel medicine to ensure optimal care. In the end, the authors concluded high patient satisfaction and adherence to vaccine recommendations in the pharmacist-directed clinics.

Point-of-Care Testing

Point-of-Care Testing (POCT) is defined as diagnostic testing performed outside the clinical laboratory in close proximity to where the patient is receiving care. POCT is typically performed by nonlaboratory personnel, and the results are used for clinical decision making. In recent years, advances in POCT testing have dramatically reduced the cost of the technology and made it available to a larger number of clinical care settings. Pharmacists, as the most accessible health-care provider, are ideally suited to offer POCT services. As such, many community pharmacy sites have embraced the concept and implemented testing into their daily practice. Most point-of-care tests do not require more than a finger prick and a couple of drops of blood or a throat or nasal swab; results are typically available within a couple of minutes and are easy to interpret. The goal of pharmacist-directed POCT is to improve chronic disease state monitoring, enhance patient education, and optimize medication adherence and patient outcomes. These tests allow pharmacists to have rapid access to laboratory quality results at the time of the patient interaction and are particularly useful to patients requiring more frequent monitoring as well as those living in remote areas without easily accessible laboratory services. Novel point-of-care testing technologies are available for both chronic disease monitoring and acute care diagnosis. The most common point-of-care tests conducted in community pharmacies include: HbA1C for diabetic patients, blood pressure monitoring for hypertensive patients, lipid screening and risk assessment for cardiovascular patients, and INR testing for patients requiring anticoagulation. Commonly utilized acute care tests include Influenza A/B screening and Group A Strep testing.

A1C Testing

Diabetes continues to affect an increasing number of Canadians each year and threatens the sustainability of our health-care system. There are currently 2.7 million Canadians (7.6%) living with diabetes. The annual cost of the disease to our economy is $11.7 billion and is projected to reach $16 billion annually by 2020. Many of these patients will develop diabetes-related complications including heart attack, stroke, kidney failure, blindness, limb amputation, and depression. These complications account for greater than 80% of overall diabetes costs. Besides its financial burden, diabetes can dramatically impact the patient's quality of life and can be a great stressor on family members and caregivers. One-third of those affected with type 2 diabetes are unaware that they have the disease (Papastergiou et al., 2012). More than half of Canadians with type-2 diabetes fail to achieve their A1c target or have their A1c regularly tested.

Historically, the testing of A1C required a visit to the physician and was limited to a laboratory blood test. With the introduction of point-of-care devices, patients can be tested by their community pharmacist without a laboratory requisition and A1C results can

be made available within 5 min. Meters have demonstrated an accuracy of 99% in three independent evaluation studies (Holmes et al., 2008).

A Canadian study described the impact of A1C screening by pharmacists. A total of 1111 patients (871 of which were included in the analysis) were screened in over 1200 pharmacies across Canada. The study found that the majority of patients (59.1%) did not have their blood glucose levels optimally controlled, 43.3% were hyperglycemic, and 15.8% had marked hyperglycemia. In fact, 59.1% had A1C levels above the target of 7%. Patients using insulin only (70%) or a combination of insulin and oral therapy (72.3%) were much more likely to be above A1c targets than those using oral therapy alone (54.3%).

In terms of clinical interventions, 1711 were conducted by pharmacists. Overall, there was an average of two interventions per person. The three most common interventions were lifestyle counseling (29% of all interventions), referral of patients to their doctor for follow-up (16.5%), and discussion of the A1C result with the pharmacist (13.7%). The prevalence of specific types of interventions showed an apparent shift from predominantly pharmacist-directed interventions in patients with better glycemic control toward an increased prevalence of physician-directed interventions in patients with poorer glycemic control. Pharmacists performed an average of 2.0 interventions, ranging from 1.4 in patients with optimal glycemic control to 2.8 in patients with marked hyperglycemia. Better technology and an expanded scope of practice have opened the door for pharmacists to play a far greater role in diabetes management support—and that door can open wide, based on the data from community pharmacies from across Canada.

Blood Pressure Monitoring and Management

It is estimated that 4.1 million Canadians are affected by hypertension. Hypertension is a chronic disease that requires long-term medication management and monitoring. If inadequately controlled, hypertension increases a patient's risk of cardiovascular events (such as stroke, myocardial infarction, angina, and heart failure) and mortality. Recent evidence has suggested that hypertension managed in collaboration with the community pharmacist can result in improved patient outcomes. Pharmacists can provide education to patients, help to prompt and monitor patients' blood pressure, and encourage patients to adhere to their medication regimen.

A 2014 study investigated the impact of community pharmacist managed hypertension on both patient outcomes and potential medication cost savings. Twenty-seven pharmacies across Ontario participated. In total, 118 patients with hypertension were randomly assigned to receive standard care or comprehensive care. In the comprehensive care group, pharmacists were trained to provide three components of patient-centered services: review and optimization of medications, education on lifestyle modification, and also promotion of adherence. After the 6-month study period, the intervention group had a 13.5 mmHg systolic blood pressure reduction while the control group had a 5 mmHg reduction. In addition, there was a 15% increase in patients' adherence to antihypertensive therapy, 4.6% decrease in patients' body mass index (BMI), and 31.2% decrease in average cost of antihypertensive therapy. These results provide the best evidence to date of the positive impact that pharmacist-directed POC blood pressure management can have on patient outcomes and cost savings. The current reimbursement offered to community pharmacists as part of the Greenshield Cardiovascular Health Coaching Program was a consequence of this study.

Lipid Screening and Cardiovascular Risk Assessment

Similar to hypertension, hypercholesterolemia is a condition that requires long-term medication management. With elevation of lipid levels, patients are at an increased risk for cardiovascular events and mortality. Hypercholesterolemia is also a common comorbid condition in patients with diabetes, hypertension, and other cardiovascular conditions. As frontline health-care providers, pharmacists are ideally positioned to calculate cardiovascular risk and empower patients to make lifestyle changes and improve adherence to their medication.

There are a number of POC cholesterol devices available for use by pharmacists. With a sample of blood, these devices are able to generate lipid profiles. Examples include CardioChek, Cholestech LDX, and Accu-chek Instant Plus. These devices are all validated against Abell–Kendall venous reference, a recommended cholesterol standard by the National Cholesterol Education Program (Haggerty and Tran, 2016).

Pilot studies that have shown the value of lipid screening and cardiovascular risk assessment programs. Most of these programs provide patients with a Framingham Risk Score (FRS). Interventions such as drug therapy changes and lifestyle modifications are made as required. Follow-up screening is also typically offered to those patients identified as moderate or high risk. Anecdotal results from pilot studies have showed a trend toward increased mean HDL and decreased mean LDL, total cholesterol (TC), TC/HDL ratio, systolic blood pressure, and 10-year CVD risk.

Chronic Kidney Disease Screening

Chronic kidney disease (CKD) is defined by reduced glomerular filtration rate of <60 mL/min or presence of kidney damage markers for longer than 3 months. CKD is a common comorbidity of patients with preexisting diabetes or cardiovascular diseases and is a progressive condition that may ultimately require dialysis for end-stage management. Although current therapies may help to slow and prevent rate of progression of CKD, CKD patients are still at elevated risk of cardiovascular events and death. With the prevalence rate of 10%, more than 2 million Canadian adults are affected by CKD. Due to the asymptomatic nature of early-stage CKD, it can be expected that CKD is underdiagnosed and undertreated. With early diagnosis and intervention, CKD progression can be slowed and prevented, reducing the need of dialysis, which requires intensive health-care services and resources. Early intervention can also help to improve patients' quality of life and reduce patients' cardiovascular and mortality

risks. It has been hypothesized that community pharmacists armed with novel POC technologies can play an active role in the early detection of CKD.

A recent study investigated the implementation of the CKD clinical pathway online tool in community pharmacies to screen targeted patients for CKD. Since patients with diabetes or cardiovascular conditions require extensive medication management through pharmacy services, community pharmacies are appropriate locations to explore implementation of targeted screening tools. Across 55 community pharmacies in Alberta, pharmacists identified 720 potential patients for targeted screening based on medications, including oral hypoglycemic, antihypertensive, lipid-lowering, antiplatelet, and anticoagulant agents. Of the 720 patients, 281 (39%) patients were found to have CKD, where 113 (40%) patients were previously not diagnosed with CKD. These finding are among the first to demonstrate the potential impact that pharmacists can have on patient outcomes using POC screening technologies or access to lab values.

Atrial Fibrillation Screening

Undiagnosed arrhythmias such as atrial fibrillation (AF) and drug-induced QT prolongation can lead to increased morbidity and mortality. However, despite the potential of catastrophic consequences, these conditions are asymptomatic, and patients' conditions are often undetected in routine physician visits.

Atrial fibrillation is the most common cardiac rhythm disturbances with an estimated prevalence of 350,000 Canadians. In addition, the prevalence of AF increases substantially with advancing age, from 0.5% at age 40 to 5% at age 50 and up to 15% at age 80. AF leads to electrical disturbances in the atrium introducing a loss of heart rate control, diminished atria contraction, and propensity for thrombogenesis. Combined, the pathogenesis of AF can cause ischemic stroke and systemic thromboembolism leading to impaired quality of life and frequent prolonged hospitalizations. An individual with AF has an increased risk of 3–5 times of stroke compared to individuals without AF. Consequently, AF is a large economic burden in the health-care system with an estimated annual spending of $815 million from emergency visits, hospitalizations, and same day surgical procedures, which can be largely preventable with early screening and proper treatment.

The high traffic of community pharmacies makes them the ideal location to screen for patients at high-risk AF. A number of devices are currently available for use by pharmacists. AliveCor is a smartphone electrocardiogram (iECG) device with an algorithm that detects AF from the two leads that connect to the back of the phone. The device was validated to have a 98% sensitivity and 97% specificity when used in the community pharmacy setting (Lowres et al., 2015). The HeartCheck PEN handheld ECG is a device that sends the reading to a center where it is read by experts and a report is returned to the pharmacy.

Screening high-risk patients with a handheld device at a community pharmacy can potentially result in improved detection, implementation of treatments, prevention of stroke, and improved health outcomes of patients. The International Pharmacist for Anticoagulation Care Taskforce (iPACT) created a partnership with the Atrial Fibrillation Association (AF Assoc) to promote the involvement of pharmacists actively participating in awareness campaigns. During the global 2017 Arrhythmia Alliance World Heart Rhythm Week, pharmacists from ten countries embraced this initiative and contributed primarily to raise the awareness of AF. In addition, active participants used pulse taking as recommended by the latest ESC guidelines to identify and refer people suspected of having AF. Whenever possible, pulse taking was confirmed using mobile technology. The use of mobile technology depended largely on the availability of mobile ECG technologies in that country and financial considerations.

Strep Testing

Acute bacterial pharyngitis, also referred to as "strep throat," is most commonly caused by *Streptococcus pyogenes*, or Group A streptococcus (GAS)—beta hemolytic, gram-positive cocci. GAS is responsible for approximately 2 million visits to family physicians annually with additional visits to walk-in clinics and the ER. Signs and symptoms of acute pharyngitis include sore throat, pain upon swallowing, tonsillar exudate, and tender or swollen anterior cervical lymph nodes, which may be accompanied by fever, nausea, and/or vomiting. Nonetheless, these symptoms are nonspecific and can be caused by a variety of bacteria and viruses. In fact, only 5%–15% of cases of sore throat in adults and 20%–30% of cases in children are caused by GAS. This poses a challenge for the treatment of acute pharyngitis and, if bacterial, for appropriate antibiotic selection. Inappropriate antibiotic use contributes to increasing antibiotic resistance as only 10% of sore throats require antibiotics, while 60% of patients receive antibiotic treatment.

The Infectious Diseases Society of America (IDSA) recommends swabbing the throat and testing for GAS via rapid antigen detection test (RADT) and/or throat culture to identify the causative agent. Throat culture on a sheep blood agar is the gold standard for the diagnosis of GAS. While the gold standard is 90%–95% sensitive for detecting GAS, it requires 18–24 h of incubation time, which can significantly delay the time to treatment. RADTs can obtain results within 15 min. One example of a RADT, the BD Veritor system, is a rapid chromatographic immunoassay for the direct and qualitative detection of the GAS antigen. It has 95.4% sensitivity (95% CI 90.3%, 97.9%) and 95.7% specificity (95% CI 93.7%, 97.1%), and results are available within 5 min.

As the most accessible health-care professional, pharmacists are well-positioned to provide RADT point-of-care testing (POCT) for GAS. Adoption of RADT by community pharmacists can lead to appropriate selection of treatment, health economic benefits via antimicrobial stewardship, and reduction in use of health-care resources. There have been some studies in both the United States and the United Kingdom that have evaluated POCT for GAS in the community pharmacy setting. These studies have been able to demonstrate feasibility of the service as well value for patient care.

In a recent Canadian study, a retrospective analysis of aggregate billing data was conducted to evaluate the effectiveness of a community pharmacist-directed strep testing program to 7050 patients across 204 Shoppers Drug Mart pharmacies in British

Columbia, Alberta, and Nova Scotia. Pharmacists trained in sample collection offered the screening to patients with symptoms suggestive of strep throat. The average age of patients presenting symptoms was 27.3 years with children (5–14) representing 30.7% of those screened. Throat swabs were collected and analyzed using the BD Veritor system for rapid detection of GAS. About 25.5% of patients tested positive for GAS. Same-day initiation of antibiotic therapy for strep-positive patients occurred in 68.7% of cases but varied by province. In Alberta, where pharmacists have advanced prescribing authority, same day initiation was 73.8% compared to a rate of 40.5% ($P < 0.0001$) in the other jurisdictions. These results highlight both the public readiness to access point-of-care services in community pharmacies and the ability of pharmacists to conveniently expedite management of patients with GAS.

Influenza Screening

Influenza (or the "flu") is a common infectious respiratory disease that affects millions of patients each year. During the 2013–14 influenza season, 5457 hospitalizations and 344 influenza-associated deaths were reported in Canada. Individuals with risk factors such as diabetes, cardiovascular disease, and respiratory conditions are particularly susceptible to hospitalizations and complications. Influenza epidemics of variable extent and severity occur almost every winter. They impose an enormous burden in terms of morbidity, mortality, economic and social costs. Early detection and management of influenza infections are key in controlling the extent and severity of annual influenza epidemics.

Influenza viruses are transmitted via respiratory droplets or from contact transmission of contaminated surfaces. Symptoms of infection typically include fever, nonproductive cough, chills, headache, and myalgia. Untreated patients with influenza exhibit peak viral shedding on the first day of symptom onset, with a steady decline in viral load over the following 7 days. This period of viral shedding has been shown to be prolonged in immunocompromized individuals. Successful treatment with antiviral agents has been demonstrated to significantly decrease both the period of viral shedding and viral load when compared to placebo. Ideally, antiviral treatment for influenza should be initiated as early as possible and is most likely to provide benefit when started within the 48 h of symptom onset. As such, early identification of influenza infection is instrumental in decreasing the duration of symptoms of illness, reducing the risk of influenza-related complications in high-risk individuals, and decreasing the risk of contact transmission as a result of decreased viral shedding.

The BD Veritor System for the detection of influenza is a rapid, point-of-care test used to detect influenza A and B viral antigens from the nasal and nasopharyngeal passages of symptomatic patients. The system uses a chromatographic immunoassay to differentiate between influenza A and B viral antigens. When the respiratory specimen is added to the test device, influenza A and influenza B antigens bind to the anti-influenza antibodies. The anti-influenza antibodies are conjugated to detector particles. The antigen–conjugate complex then migrates across the test strip to the reaction area where the membrane captures the antibody–-conjugate complex. A positive test for influenza A and or influenza B is determined by the BD Veritor System Reader when the antigen–conjugate complex is deposited on the corresponding position. The sensitivity of the BD Veritor System is 89.6%, and the specificity is 98.8% in comparison to real-time RT-PCR of nasal swabs.

Historically, patients that visit a pharmacy with fever, cough, and malaise are given recommendations for over-the-counter products and offered nonpharmacological supportive care. Often, patients are referred to a physician for further investigation. Additionally, many patients indiscriminately visit physicians' offices seeking antibiotics as a result of upper respiratory tract infections. These visits tie up physicians' time, result in inappropriate antibiotic use, and utilize public resources unnecessarily. For those influenza-positive patients that are not referred, delayed antiviral therapy can lead to prolonged recovery, transmission of disease, and/or disease complications. The availability of this new point-of-care technology will provide pharmacists with the ability to more effectively screen and triage patients and, ultimately, expedite access to care for those influenza-positive individuals.

During the 2014/15 flu season, a group of frontline community pharmacists investigated the impact of community pharmacy-based influenza screening. They recruited 59 patients, of whom 44% had at least one risk factor for influenza complications. Thirty-four percent tested positive for influenza, and 40 percent of these patients were prescribed antiviral therapy. All patients who tested negative had their symptoms managed with supportive care measures. It was concluded that community pharmacy-based influenza screening may facilitate prompt access to pharmacologic treatment for patients with influenza as well as decrease the burden on the health-care system. Timely physician communication remains a barrier for access to treatment, suggesting a potential key role for advanced pharmacist prescribing.

Helicobacter pylori Testing

Helicobacter pylori is a gram negative bacterium found on the surface of the gastric epithelium. The World Health Organization (WHO) has identified *H. pylori* as a major risk factor of gastritis, peptic ulcer disease, gastric adenocarcinoma, and gastric lymphomas. Almost 25% of Canadians with uninvestigated dyspepsia have evidence of an active *H. pylori* infection.

Pharmacists, as the most accessible health-care practitioners, are ideally positioned to improve access to *H. pylori* screening and increase the awareness of the potential consequences of untreated disease. The development of point-of-care screening devices, in combination with the expanding scope of pharmacy practice, has allowed pharmacists to become more actively involved in the screening and management of various chronic diseases. Specific to *H. pylori* infection, a few studies have demonstrated that early screening and treatment of *H. pylori* may be beneficial in both reducing health-care costs and decreasing morbidity and mortality. Furthermore, screening in the community setting has been shown to reduce resource use and may be linked to health gain in quality adjusted life years and cost savings pertaining to gastric cancers.

Recently, three pharmacies in Toronto, Ontario, offered *H. pylori* screening as part of their clinical programs. Pharmacists facilitated subject enrolment among patients who they believed would benefit from screening and met inclusion criteria. Decision to screen was based on the Canadian Helicobacter Study Group Consensus (CHSG). Patients were screened using the *Rapid Response H. pylori* test. In total, 65 patients were recruited with a mean age of 46.9 years. Patients were ethnically diverse with a significant proportion (61.5%) identified as being born outside of North America including Asia 26.1%, Africa 9.2%, Middle East 7.7%, Europe 12.3%, and South and Central America 6.2%. Overall, the detection rate of *H. pylori* infection was 21.5%. North Americans had the lowest incidence of an undiagnosed *H. pylori* infection 8%. Europeans 25%, Middle Eastern 20%, and Asians 23.5% had a moderate incidence followed by the highest prevalence for those of African 66.7% descent. These results highlight the readiness of community pharmacists to adopt *H. pylori* screening into practice and to leverage this novel technology to positively identify and treat undiagnosed *H. pylori* infection.

Pharmacogenomics

The field of pharmacogenomics (PGx) was established in the 1950s, but physicians and pharmacists have long been aware of the subtle differences in drug response between patients. Interpatient variability in drug response can result in lack of efficacy, intolerance, or even serious adverse reactions. It is routine for physicians and pharmacists to consider factors such as age, body mass, renal function, and drug interactions in an attempt to avoid unintentional drug consequences. Nonetheless, genetic factors alone can account for anywhere between 20% and 95% of the variability in drug response, yet these often go unrecognized. In recent years, clinical PGx research has made significant progress in defining which genetic variations are important for influencing interpatient variability in drug response. Historically, there has been no easy way for clinicians to screen or assess patients for these differences. It was not until very recently that the technology for PGx testing has been made available to practitioners in frontline clinical settings. This availability, in combination with the pharmacist's expertise in pharmacology and kinetics, make them ideally suited to champion implementation of this novel technology in order to optimize therapy.

In a survey conducted in the United States, 101 pharmacists were asked to assess their interest and readiness in providing personalized medicine care to patients. A total of 75% of the pharmacists expressed interest in providing such services to their patients, but 50% of the interested pharmacists felt uncomfortable making recommendations to physicians or counseling patients without further training in this field. As this important technology continues to evolve, comprehensive training programs must be developed to prepare pharmacists to provide this service at the point of care.

Recently, two community pharmacies in Toronto, Ontario, offered pharmacogenomic screening as part of their professional services program. Pharmacists facilitated voluntary subject enrolment among 100 patients who they believed would benefit from screening. Pharmacists cited the most common reasons for testing as ineffective therapy (44.6%), to address an adverse reaction (35.5%), and to guide initiation of therapy (11.8%). Patients were 57.4 years of age on average and taking a mean of 5.6 chronic medications. Eligible patients received a simple buccal swab followed by DNA analysis using PillCheck; a proprietary genotyping assay that translates genomic data and generates a personalized, evidence-based, report that provides insight into patients' inherited drug metabolic profile. Upon receiving the report, pharmacists invited patients back to the clinic for interpretation of the results. An average of 1.3 clinically significant drug therapy problems were identified per patient. Recommendations for medication optimization were then forwarded to the primary care physician, which included change in therapy (57.1%), dose adjustment (14.3%), discontinuation of a drug (7.1%), and increased monitoring (19.6%).

Generally, physician feedback was positive but did reveal an opportunity for a broader understanding of the technology. The results of this study highlight the readiness of community pharmacists to adopt pharmacogenomic testing into practice and their ability to leverage the results to positively impact medication management.

Conclusion

The evidence supporting the value of pharmacist-directed point-of-care screening continues to mount. That being said, implementation of these programs is not without its challenges. Pharmacists engaged in these activities have reported difficulties balancing time and resources, a lack of support from stakeholders, and concerns surrounding pharmacist training and confidence. As utilization of these technologies becomes more common, models will be developed to help overcome these barriers.

In the end, point-of-care screening initiatives provide an effective mechanism for improving patient education, enhancing disease management, and increasing pharmacist––physician communication. As we evolve our practice, the accessibility of the community pharmacist places them in a unique position to actively screen and monitor patients with both chronic and acute disease states. The wave of technology and innovation will arm pharmacists with the tools required to help meet these health-care needs.

Acknowledgments

The author would like to acknowledge pharmacy students Jeffrey Tso and Alexandra Kourkounakis for their contribution to the chapter.

Hospital Pharmacy Practice: A Case Study from Canada

Sarah Jennings*, Catherine Lyder*, Dana Lyons†, Glen J. Pearson‡, Myrella T. Roy*, *Canadian Society of Hospital Pharmacists, Ottawa, Canada; †Alberta Health Services, Edmonton, Canada; ‡University of Alberta, Division of Cardiology, Mazankowski Alberta Heart Institute, Edmonton, Canada

Mission

Hospital pharmacy professionals—pharmacists and pharmacy technicians—strive to optimize the safety, the effectiveness, and the appropriateness of drug therapy through patient-centered care in collaboration with patients and their health-care teams. Pharmacists practicing in the hospital setting have therefore much in common with their colleagues from the community setting. Their role in medication management is to:

- Assess patients and their medication-related needs and identify actual or potential drug therapy problems;
- Formulate and implement care plans to prevent and/or resolve drug therapy problems;
- Recommend, adapt, or initiate drug therapy where appropriate;
- Monitor, evaluate, and document patients' response to therapy;
- Collaborate and communicate with other health-care providers, in partnership with patients.

What typically differentiates the responsibilities of hospital pharmacists from those of their community colleagues is the provision of complex medication services, such as preparation of centralized intravenous admixtures, parenteral nutrition, and chemotherapy. However, hospital pharmacists are also distinctive in their contributions to medication management in that they routinely collaborate in the care of the most acute and complex cases for a broad range of health conditions across a wide variety of patients (e.g., in critical care) or in a specific patient group (e.g., in pediatrics) or for a limited range of health conditions across a wider variety of patient groups (e.g., in oncology).

Hospital pharmacy practice "is designed so that patients receive the most clinically appropriate, safe, and cost-effective therapy, supported by the best available evidence, to optimally meet the patient's needs on the basis of indication and effectiveness" (Canadian Society of Hospital Pharmacists, 2016). With their precise knowledge about drug therapy, hospital pharmacists can contribute effectively to better patient care in collaborative health-care settings.

Hospital Pharmacy Setting

The hospital setting itself offers unique conditions for the practice of pharmacy:

- The focus of the pharmacist can be solely professional in nature if health services provided at a hospital are insured publicly; strictly speaking, there is then no business obligation apart from the expectation of fiscal responsibility.
- The environment can facilitate the optimal integration of the pharmacist within the interprofessional health-care team.
- Patient care information, including treatment indications and laboratory test results, can be readily available to pharmacists in health records.
- Drug procurement and distribution can be extensively delegated to pharmacy technicians.

Governance

Many professional pharmacy associations around the world advocate a pharmacist with advanced training in hospital pharmacy be accountable for managing the medication use system in hospitals (American Society of Health-System Pharmacists, 2016; Canadian Society of Hospital Pharmacists, 2005; Vermeulen et al., 2016). Furthermore, many pharmacy regulatory authorities stipulate that the head of hospital pharmacy services must be a pharmacist. Given the complexity of hospital medication use systems and the specialized nature of hospital pharmacy practice, pharmacists are deemed most knowledgeable and best trained to lead the safe, effective, and efficient management of the medication use system with the ultimate goal of optimizing patient outcomes.

Basel Statements on the Future of Hospital Pharmacy

In 2008, more than 340 hospital pharmacists from 98 nations met at the inaugural Global Conference on the Future of Hospital Pharmacy in Basel, Switzerland, part of the 68th World Congress of Pharmacy and Pharmaceutical Sciences of the International Pharmaceutical Federation (FIP) (2009). At the close of this momentous conference, the participants had developed and endorsed 75 consensus statements reflecting the profession's preferred vision of practice in the hospital setting, a global roadmap that should lead to improvements in patient outcomes around the world. Responses to an earlier survey determined the 6 themes, which covered all areas of the medicine use process in hospitals (procurement, influences on prescribing, preparation and delivery, administration, and monitoring of medication practice) and human resources and training. Medication safety was also an important consideration in developing the consensus statements.

In late 2013, a revision process of the Basel statements was undertaken and involved a global online survey (334 survey responses received from 62 countries), a review through an online forum (by individuals from 28 countries, representing all 6 of the World Health Organization regions), and a "World Café" workshop (80 participants from 20 countries) at the 2014 FIP Congress in Bangkok (Vermeulen et al., 2016). The process resulted in the final 65 revised Basel statements, arranged under an overarching category and the 6 original main themes, which reflect new aspirational goals for the future of hospital pharmacy.

Patient Safety

The World Health Organization (WHO) (2009) defines a patient safety incident as an event or circumstance within the health-care system that could have resulted, or did result, in unnecessary harm to a patient. Unsafe health care is an alarming global concern. A working paper published by the Organization for Economic Co-Operation and Development (Slawomirski et al., 2017) concludes that patient harm is the 14th leading cause of the global disease burden, that up to 17% of all hospitalizations are affected by one or more patient safety incidents, with 30%–70% potentially preventable, and that as many as one in ten patients are harmed during hospital care. Not only does unsafe health care inflict unnecessary morbidity and premature mortality on patients, but it imposes exorbitant financial and resource costs on the health-care system owing to additional diagnostic and therapeutic services, emergency

room visits, hospital admissions or readmissions, and extended length of inpatient stay. Patient safety incidents most commonly relate to surgical procedures, health care-associated infections, and medications.

Medication Safety

Unsafe medication use systems are a leading cause of preventable patient harm in health care across the world. Medication incidents can occur along the whole continuum of the medication use system: prescribing, transcribing, communicating, procuring, manipulating and compounding, labeling and packaging, dispensing, administering, monitoring, educating, and using. Compared to the primary and long-term care settings, available evidence suggests that medication incidents in hospitals tend to cause more serious patient harm, most likely because of the more acute clinical situations and the more complex medication regimens.

Given the magnitude of the problem, WHO (2017) has initiated its "Global Patient Safety Challenge: Medication Without Harm" with the goal of reducing the level of severe, preventable patient harm related to medications by 50% over 5 years, globally. The Challenge aims to achieve improvements at each stage of the medication use system and focuses firstly on three priority actions to improve medication safety: high-risk situations, polypharmacy, and transitions of care.

Influence of Hospital Pharmacists and Pharmacy Technicians on Medication Safety

Hospital pharmacists and pharmacy technicians play pivotal roles in the prevention and review of medication incidents and in the improvement of medication use systems. Together they strive toward patient safety by reducing the risk of unnecessary patient harm to an acceptable minimum throughout the medication use system, such as removing hazardous medications from hospital wards, educating patients about their medications, and reconciling medications at transitions of care. Furthermore, compelling evidence shows that the inclusion of pharmacists in interprofessional care teams results in lower mortality rates, fewer medication incidents, decreased health-care costs, shorter lengths of stay, and reduced emergency visits and hospital readmissions.

Antimicrobial Stewardship

Antimicrobial-resistant infections increasingly threaten public health and the economy around the globe. Patients infected with microorganisms resistant to antimicrobial drugs undergo additional diagnostic tests, receive less effective and more expensive therapies, experience longer illnesses, and face higher risks of complications and premature death compared to patients infected with nonresistant strains of the same microorganism. In response to this threat, WHO (2015) has launched its *Global Action Plan on Antimicrobial Resistance*.

Misuse and overuse of antimicrobial drugs in human and veterinary medicine and in food production are known to accelerate the occurrence of antimicrobial-resistant infections. In hospitals, studies have revealed that 30%–50% of prescribed antibiotics are unnecessary or inappropriate. Resistance is already prevalent among bacteria that commonly cause serious health care-associated infections. Antimicrobial misprescribing and overprescribing are therefore reckoned patient safety and medication safety concerns.

Improving, monitoring, and evaluating antimicrobial prescribing practices in hospitals by means of stewardship programs can help curb resistant infections, improve individual patient outcomes, and reduce health-care costs. Hospital pharmacists should resolutely promote the judicious use of antimicrobial drugs and, where a formal antimicrobial stewardship program exists, they should play a prominent role in the interprofessional leadership team.

Drug Procurement and Distribution

Patients and staff deserve to benefit from a drug distribution system that safely, reliably, and effectively procures, stores, prepares, and distributes high quality medicines, in a timely manner. It is the responsibility of the pharmacy department to develop and oversee such a system.

Safety is never to be assumed: it must be deliberately built into the system from the point of procurement, through to storage, preparation, distribution, and administration to the patient. People must be adequately trained to execute their responsibilities; procedures must be set to guide and direct personnel (PIC/S Secretariat, 2014). The physical environment should be designed and used to safely support the drug distribution activities performed therein (PIC/S Secretariat, 2014). The movement of all medications and critical supplies used in the drug distribution system should be traceable from the point of purchase to the point of use or disposal (Clark, 2012). And, a quality management system should be established to assess whether the drug distribution system is functioning as intended—to ensure access to essential medicines in a timely, safe, and effective manner—and continues to improve.

People

Collectively, pharmacists and pharmacy technicians possess the knowledge and understanding of which medicines are available, how to store and prepare them, as well as the clinical condition under which the medicines should be used. They have a leadership role in the hospital regarding decisions about how drugs are acquired, stored, and used within the organization. Other persons such as pharmacy assistants and clerical staff may also have a role in the drug distribution system. In the end, the decision to assign

responsibilities related to drug distribution to different cadres of personnel must consider the legislated scope of practice, who is best equipped to perform the task at hand, and the human resources available.

The design of the drug distribution system should also draw on the expertise of other persons, as needed. For example, accountants and information technology specialists should be consulted to assist in developing processes to ensure that the drug inventory is adequately controlled to prevent or detect theft or pilferage of inventory.

Procurement

All medicines used in the hospital should be purchased, stored, and distributed under the direction of the pharmacy department. Adequate segregation of critical duties should be maintained throughout purchasing, receiving, and inventory management to strengthen internal controls against theft and fraud.

The medicines purchased should be those that are required to meet the needs of the community of people served by the hospital: typically the decision to purchase a drug is directed by the hospital's formulary system. Resources should not be squandered by obtaining medicines that are of poor quality or are not needed by the hospital's patients, or holding unnecessarily high volumes or purchasing at frequencies that unnecessarily compromise the hospital's capital available for other purchases (Chalker, 2012; Dias, 2012; Layloff, 2012; Olson, 2012).

Medications should be purchased only from vendors who can assure that the medicines are of high quality and pedigree. Drugs that could be counterfeit or whose quality is suspicious or compromised can cause harm (Alliance for Safe Online Pharmacies (2018)) and should never be purchased for administration to patients. The pharmacist should understand how counterfeit drugs enter the country, how to avoid purchasing counterfeit drugs, and what suppliers are legitimate.

The quantities of medicines purchased should reflect the usage patterns in the hospital for at least the period required to procure the drugs without lowering the stock levels below the minimum safety stock level (Dias, 2012). In many hospitals, just-in-time inventory practices are used, which are supported by a reliable computerized inventory management system.

For safety reasons, purchasing multiple strengths and sizes of the same product should be avoided, because they can result in selection errors and could introduce sound-alike, look-alike errors. If it is not possible to avoid such purchases, extra care and attentions should be given to reduce the likelihood of a medication error with these products.

Ideally, drugs that are purchased by the hospital are shipped directly to the pharmacy. If the drugs must be first delivered to the hospital's receiving area, the receiving personnel should check the outer packaging for signs of damage and compare the number of packages received against the shipping order. Any discrepancies should be reported immediately to pharmacy for follow up. (The shipping packages are only opened in the pharmacy department.) The shipment should then to be delivered to pharmacy without delay. The pharmacy staff should carefully inspect the contents of the shipment. Any errors in the order (e.g., wrong drug, damaged goods, wrong quantities) should be followed up with the organization that shipped the order. The quantity and identity of all drugs that will be added to the pharmacy's stock should be recorded in the pharmacy's inventory system.

Throughout the purchasing system, adequate segregation of duties should be maintained to prevent having one person with sole control over purchasing, receiving, and inventory management.

Drug Shortages

Drug shortages can have serious consequences on patient care and the drug distribution system. They can occur for a variety of reasons such as discontinuation of product, unanticipated high demand for drug, disruption in supply of ingredients or packaging components, regulatory decisions, compromised quality of the drug product, or natural disasters (Multi-Stakeholder Steering Committee on Drug Shortages in Canada, 2017a). The hospital should have a contingency plan in the event of a drug shortage: such a plan typically assesses the nature, extent, anticipated duration of the shortage, identifies alternatives to cope with the shortage, and includes a communication plan to inform key stakeholders. Strategic steps are taken when establishing contracts to purchase drugs that could help mitigate the negative effects of drug shortages. Guidelines and toolkits are available to assist in developing these plans and strategies (Multi-Stakeholder Steering Committee on Drug Shortages in Canada, 2017b; Multi-Stakeholder Steering Committee on Drug Shortages in Canada, 2017c).

Dispensary and Storage Areas

Medicines should be stored in an area that encourages the segregation of certain products and the safe, secure accessibility of drugs, and under conditions that maintains the integrity of the medicine for the duration of its expected shelf life. The area is designed to prevent unauthorized access; to be climate-controlled, clean (and free of vermin or other pests), and well-lit; and to be organized and constructed of materials that can easily facilitate cleaning. The area also supports infection control and prevention practices and protects people and products from unnecessary exposure to hazardous substances.

The following list provides examples of safe medicine practices related to the storage of medicines, which should be used by everyone who handles or stores medicines:

- To avoid cross-contamination, food is not to be stored in the same area as medicines.
- High-alert medicines (Institute for Safe Medication Practices, 2018) are easily identified: they are segregated from other medicines, warning labels are affixed to the container, and forcing functions employed to prevent certain medication incidents from occurring.

- If sound-alike, look-alike medicines must be held in inventory, strategies should be employed to minimize the likelihood of a selection error or name confusion (e.g., they are not stored adjacent to each other) (WHO Collaborating Centre for Patient Safety Solutions, 2007).
- Medicines that are intended for external use only are stored in an area away from medicines that are for internal use.
- Drugs that have the potential for abuse should have controlled access, and not be stored with other drugs.
- Hazardous drugs require special handling and storage provisions. For example, they are not stored with other drugs. They are each assigned their own designated area that is adequately externally ventilated, and in a manner that promotes their safe handling (e.g., on shelves that have guards to prevent the container from falling) (Power and Coyne, 2018).
- The hospital has a safe medication handling system that ensures personnel are not directly exposed to medications through handling. The pharmacy department takes responsibility for identifying and labeling medications that have potential to cause effects to those who may exposed. Persons working with hazardous drugs don personal protective equipment and follow safe handling procedures to avoid exposure to the drug. The National Institute for Occupational Safety and Health (NIOSH) is an agency that conducts research on work-related safety and recommends strategies to reduce these exposures. NIOSH has a list of hazardous drugs, which can be used as a starting point for pharmacies and health-care environments (NIOSH, 2016).

Wardstock

Drugs that are used in urgent or emergency situations should be readily available on the care unit. The decision to store a medication as wardstock should take into account the safety profile of the drug, the degree of urgency to access the drug, and the cost of the drug. Work practices should be set to mitigate the risks of medication incidents commensurate with the level of risk exposure. Concentrated electrolytes (e.g., potassium chloride 2 mmol/mL) should not be stored as wardstock. The quantity of drug supplied as wardstock should be small enough to reduce wastage due to the passing of the expiry date, yet large enough to meet the needs of patients. Access to the wardstock storage area should facilitate timely access to the hospital personnel who need to prepare the drugs, yet be inaccessible to the general public or patients.

Automated Processes and Dispensing Devices

Automated drug preparation and distribution systems and processes should be considered and adopted based on, and evaluated against, principles of safety. Advances in drug distribution and preparation technologies are rapidly changing. The pharmacy department should consider adopting technologies that improve the responsible use of resources, reduce overall costs to the health system, and improve medication safety within the system.

Automated dispensing devices (or cabinets) offer an alternative to storing medicines in a medication supply/preparation room in patient care areas. These devices are capable of storing wardstock supplies of medicine and medicines for specific patients. Ideally, such devices are integrated with the pharmacy information system and a bar-coding system to maintain an accurate record of the drugs dispensed to and withdrawn from the device, at both the patient and care unit level of enquiry. Furthermore, a stronger, safer distribution system can result when the automated dispensing device is coupled with a formulary system that places restrictions on the variety of strengths supplied in the device.

The use of automated processes and dispensing devices throughout the medication use system can produce efficiencies and other benefits, particularly when human resources are scarce. However, it is important to not become too reliant on them and assume that they are free of errors (Institute for Safe Medication Practices Canada, 2016). These devices and systems can introduce new, unanticipated, or different root causes of medication incidents and care should be taken to be mindful of such incidents and take corrective, preventive action (Grissinger et al., 2007; Institute for Safe Medication Practices, 2009; Institute for Safe Medication Practices Canada, 2016). Guidance to assist hospitals prevent medication incidents associated with automated processes and dispensing devices is available (Institute for Safe Medication Practices, 2009; Institute for Safe Medication Practices Canada, 2016).

Unusable Stock and Disposal of Drugs

Stock that is expired, damaged, or otherwise not usable should not be comingled with other stock to avoid being used or dispensed. It should be quarantined until it is removed for proper disposal. The hospital's waste management system and process should include provisions for the safe disposal of drugs. The pharmacist should be involved in the development of waste management procedures to ensure that drugs are properly disposed of (Vermeulen et al., 2016).

Access to Pharmacy

For safety and security reasons, the hospital should limit access to the pharmacy to pharmacy professionals only. However the pharmacy's hours of operations should not be an impediment to timely access of medications. A risk management strategy should be in place to give access to medications in an urgent or emergency situation (Canadian Society of Hospital Pharmacists, 2016). Such strategies may include an on-call system to bring a pharmacist (or pharmacy technician) to the hospital, or a night cupboard/dispensary, which contains urgently needed medications not found elsewhere in the hospital and which can be accessed by other health professionals (Olson, 2012). Records of all stock removed should be maintained.

Preparation

Under ideal circumstances, the medicines dispensed to patient care areas are supplied in ready-to-use, unit-of-use packaging, for a specific patient. The quantity supplied is usually for a 24-h period (Olson, 2012), knowing that medication orders can change quickly. This form of dispensing is considered the safest distribution method. It may require additional front-end expenses (Olson, 2012), but is usually associated with lower rates of wastage (because unused drugs returned to pharmacy can usually be safely returned to stock) and nursing invests less time in preparing the drug for administration.

Compounding and Repackaging

Medications that require compounding or repackaging are prepared in the pharmacy, unless doing so would compromise patient care in an urgent or emergent situation.

The medications that must be dispensed in a sterile formulation and require compounding or repackaging should be aseptically prepared in a clean room that is properly outfitted for that purpose (PIC/S Secretariat, 2014). Only specially trained personnel should be involved in aseptic compounding or repackaging activities. The clean room and the primary engineering control (or clean air device) must reliably provide air of a quality sufficient for the activities undertaken in the clean room: these specifications are laid out in pharmaceutical standards or guidelines such as the United States Pharmacopeia and other resources (Beaney, 2016; Canadian Society of Hospital Pharmacists, 2014a; Society of Hospital Pharmacists of Australia, 2010). Equipment and supplies used for aseptic compounding remain dedicated to the purpose of aseptic compounding. Supplies used in sterile compounding should be used as per the manufacturer's instructions. Sharps should be safety engineered to reduce workplace injuries, wherever possible single-use only sterile supplies should be used.

Medications that require compounding or repackaging but do not have the requirement of being sterile should be prepared in a dedicated area or room that is separate from the controlled work environment, and not in the immediate area where other pharmacy activities are undertaken. Only persons who are specially trained in nonsterile compounding are involved in such activities. Equipment and supplies used for nonsterile compounding remain dedicated to the purpose of compounding.

If a drug must be removed from its original primary container (that which comes in contact with the medicine) for repackaging, the new primary container must be fit for purpose (Jackson and Lowey, 2010) suitable for the dosage form, dose, and storage requirements for the medicine. It must not interfere with the medicine (i.e., it must not cause adsorption, absorption, or chemical reactions), rather it must maintain the integrity of the medicine to the point of administration to the patient. Furthermore, the method of repackaging must not damage the drug, introduce harm to the persons handling the drug, or contaminate other drugs that will be repackaged using the same equipment. Some drugs will leave a residue in the equipment or be hazardous: these drugs should not be repackaged using an automated repackager.

Labeling

The primary package must always be labeled to allow for accurate identification of the contents of the package, up to the point of administration of the drug. The use of abbreviations on labels should be minimized to avoid the risk of misinterpretation or miscommunication of the abbreviation (Institute for Safe Medication Practices Canada, 2017).

Information about the safe storage and handling of the drug should be provided to anyone who will handle or administer the product.

Safety Checks

At key stages in preparing certain high alert medicines for dispensing, independent, double checks should be employed to ensure that the correct medicine (identity, dose, formulation, and quantity) is selected and dispensed. Despite the value of independent double checks, processes should not rely solely on them to reduce medication incidents. The system should be bolstered with other strategies. Refer to recommendations from a variety of organizations that disseminate such information (such as the Institute for Safe Medication Practices and the Institute for Safe Medication Practices Canada).

Procedures

The hospital should have a robust set of procedures to guide every key step in the drug distribution system. At a minimum, procedures should be written for the following topics, describing the roles and responsibilities of personnel involved in the activity and the standard operating procedure:

- initial and ongoing training of staff
- selection of vendor
- receipt and storage of drugs
- conducting inventory counts (comparing physical stock-on-hand records to expected stock-on-hand records)
- traceability of drugs through the drug distribution system
- receipt of medicines through unconventional methods such as patient's own medicines, samples, donated medicines
- inspection of drugs at every stage of handling, to ensure the product is of high quality and safe for use
- distribution of medicines to patient care areas
- handling of special categories of medicines

- controlled substances such as narcotics, benzodiazepines
- hazardous medicines, such as chemotherapy
- investigational medicines
- high-alert medicines
- disposal of drugs that are deemed unusable (e.g., expired, damaged)
- compounding and repackaging of medications
- monitoring the safety of the drug distribution system

Staff should be encouraged and supported to "stop the line" whenever a product, service, or procedure is not correct. This step is critical to prevent an incident from occurring in the moment. And, if proper follow-up is conducted, it prompts people to learn from what contributed to the "near miss" and make changes to reduce the likelihood of an incident occurring in the future.

The people who perform drug distribution activities need to know about the importance of the activities, and the outcomes that can occur to patients or persons handling a drug if an activity is not performed correctly. To that end, it is important that personnel be informed of changes to policies and procedures and continue to develop their knowledge and skills.

Quality

The hospital's processes should be supported by a robust quality management system to help ensure the drug distribution system is functioning as intended. The quality system should include the following topics.

- Quality control
- Quality assurance
- Quality improvement
- Contingency planning

Key activities (such as compounding or repackaging) should have quality control measures in place to ensure that the product meets the required specifications. At a systems level, key performance indicators such as turn-around time regarding dispensing medications, medication incidents (including near-misses) should be regularly measured; looking for trends that serve as alerts of how well the system is working and where attention to make improvements is warranted.

Pharmacy departments should subscribe to medication safety bulletins to keep informed and up to date about risks or how to mitigate them or their effects. Such publications and alerts are available from the Institute for Safe Medication Practices or similar organizations (e.g., the Institute for Safe Medication Practices Canada).

Clinical Pharmacy Services

Evidence supporting the provision of clinical pharmacy services in hospitals has shown that increasing both the number of clinical pharmacists in hospitals and their involvement in patient medication management is associated with lower mortality rates. In the largest datamining study published to date, the observed mortality reduction was associated with seven specific clinical pharmacy services: management of drug protocols, participation in medical rounds, provision of in-service education, execution of drug-use evaluation, collection of admission drug histories, management of adverse drug reactions, and participation on the cardiopulmonary resuscitation team (Bond and Raehl, 2007). Another study, which evaluated the inpatient care provided by clinical pharmacists, confirmed that there were improvements in patients' outcomes in association with the following pharmacist activities: interacting with the health-care team during rounds, interviewing patients, reconciling medications, and providing medication counseling and follow-up to patients at the time of discharge and beyond (Kaboli et al., 2006). A more recent study found that the provision of direct patient care by hospital pharmacists was associated with numerous improvements in patients' outcomes, including mortality, length of stay, hospital readmissions, and emergency department visits, as well as improvements in various clinical parameters, such as low-density lipoprotein cholesterol, glycosylated hemoglobin, and blood pressure (Chisholm-Burns et al., 2010b). Evidence has also demonstrated that providing these clinical pharmacy services results in economic benefits (Chisholm-Burns et al., 2010a).

Education of Other Health-Care Professionals about Pharmacotherapy

In addition to their roles in providing direct patient care, hospital pharmacists play an integral role in educating physicians, nurses, and other health-care professionals about the rational and appropriate use of drugs. The increasing complexity and importance of medications in the health care system underscore the need for pharmacists to share their unique pharmacotherapeutic knowledge and expertise with other health-care providers. Arising from their collaborative and interprofessional practice exposure to physicians, nurses, and other health-care practitioners, hospital pharmacists are well positioned to educate and advise these professionals about various aspects of pharmacotherapy, including appropriate indications, safety profiles, and potential interactions with drugs and other consumed products, such as food and alcohol, as well as the expected therapeutic and potential adverse responses. Working in collaborative practices, hospital pharmacists can directly influence medication therapy decisions and optimize patient outcomes by sharing their medication knowledge and educating other team members.

Education of Patients about their Medications

Part of the direct patient care role fulfilled by hospital pharmacists is the provision of medication education to patients. Educating patients about their medications helps them to become active participants in their own health care by ensuring safer medication use, improved adherence, and better identification and appropriate management of adverse drug effects. This interactive educational exchange between the pharmacist and the patient occurs at various times throughout the hospital stay. Additionally, hospital pharmacists provide comprehensive education at the time of discharge, to help patients become further informed about their medications and to ensure that they are able to adhere to and receive the intended benefits of the accepted treatment plan after they have transitioned out of the institutional setting. Typically, discharge education includes the provision of a schedule for medications that are to be taken at home (with details of each drug's name, dose, frequency, and indication), a summary of changes from the patient's preadmission medication regimen, and education about any new medications. Commonly, medication education and discharge medication counseling can be provided in the same face-to-face encounter, depending on the pharmacist's clinical workload and the complexity of the patient's medication regimen (Fernandes et al., 2015). It is expected that this patient education will continue and be reinforced by other health-care professionals (e.g., the community pharmacist), as the patient transitions through the health-care system.

Education of Pharmacists

Entry-to-practice Education

To provide the quality of pharmacy care that is expected in modern health-care systems, professional educational programs must be designed to ensure that graduates are trained to fulfill the changing expectations of the patients and communities that they serve. In Canada, the Association of Faculties of Pharmacy of Canada (2017) has specifically defined the educational outcomes for graduates from programs leading to a first professional (i.e., entry-to-practice) degree in pharmacy. These educational outcomes are designed to ensure that graduates are grounded in a professional identity as a care provider and are able to approach pharmacy practice by skillfully integrating the roles of communicator, collaborator, leader-manager, scholar, and health advocate into their overall care provider role. Formal accreditation of these professional degree programs provides public recognition and assurance that they meet the established professional qualifications and educational standards needed to produce graduates capable of becoming licensed pharmacists (Canadian Council for Accreditation of Pharmacy Programs, 2018).

As regulated health-care professionals, pharmacists are responsible for and accountable to patients through legislation and through the standards and bylaws of the professional regulatory authority of the jurisdiction they practice. In Canada, the National Association of Pharmacy Regulatory Authorities (NAPRA) (2009) has set out model standards of practice for pharmacists, with the goal of specifying the standards against which a pharmacist's performance can be judged in practice by an individual regulatory authority. Although the requirements for licensure to practice are set out by legislation and standards, one additional requirement for initial registration and licensure is certification of an applicant's knowledge, skills, and abilities at entry to practice. This certification is granted by the Pharmacy Examining Board of Canada to those who successfully complete the organization's qualifying examination.

Training in Hospital Pharmacy Practice

Specialized training in hospital pharmacy practice after getting the entry-to-practice degree provides pharmacists with experience in a variety of roles. In Canada, a pharmacy residency program is a 12-month directed postgraduate learning experience in a hospital or collaborative health care setting. Through structured rotations in pharmacy practice, education, research, and administration, the residency program prepares pharmacists for challenging and innovative hospital pharmacy practices. The key objective of hospital pharmacy residency programs is to provide experiential learning under skilled practitioner role models. The necessary skills, knowledge, and values required to practice effectively as a hospital pharmacist can be acquired and applied by the resident in the promotion of exemplary patient care (Canadian Hospital Pharmacy Residency Board, 2009). The designation "Accredited Canadian Pharmacy Residency" (abbreviated as ACPR) is conferred on residents upon their graduation. These residencies are an important source of highly qualified pharmacists trained in institutional practice.

Standards for a year 2 residency in advanced pharmacy practice have recently been defined by the Canadian Pharmacy Residency Board of the Canadian Society of Hospital Pharmacists (CSHP) (2016). The advanced (year 2) pharmacy residency focuses on additional training in direct patient care, teaching, and research. It is intended to increase or refine pharmacists' knowledge, skills, and attitudes, to ensure they are equipped for the interprofessional management of patients with more complex clinical needs, by focusing on a specific therapeutic area (e.g., cardiology, oncology, infectious diseases), a specific patient population (e.g., pediatrics, geriatrics), or a specific type of practice (e.g., primary care, ambulatory care, critical care). As these advanced residency programs evolve, it is anticipated that pharmacy practitioners will be able to provide increasingly complex pharmacy care to patients in hospitals and other collaborative health-care settings.

Provision of Expertise

In addition to core functions of drug distribution and patient care, hospital pharmacists provide crucial infrastructure to support the appropriate use of drugs. They may provide drug information services in their hospital or region or manage the hospital formulary.

They may also participate in clinical trials or practice research, serve on research ethics boards, champion medication safety or quality improvement programs, lead the development of treatment protocols or preprinted orders, or deliver in-services and other educational materials.

Pharmacists who work in these areas require a specialized skill set. They must have skills in critical appraisal and evidence-based medicine. They must have the ability to find and critique scientific literature, relying on a thorough understanding of study design, statistics, and common sources of bias. They must be able to interpret and apply the evidence to clinical practice, both at a patient level and a population level. Importantly, they must also have the ability to synthesize and communicate their findings in a clear and timely manner.

Drug Information

Standards of practice for pharmacists commonly include the provision of medication information as a core competency. Standards from FIP (Vermeulen et al., 2016), Canada's NAPRA (2009), Great Britain's Royal Pharmaceutical Society (2017), and the Society of Hospital Pharmacists of Australia (2013) all include expectations that pharmacists critically evaluate drug information and present it in a manner that is tailored for the recipient. American Society of Health-System Pharmacists (ASHP) guidelines (Ghaibi et al., 2015) place the provision of drug information "among the fundamental professional responsibilities of all pharmacists."

In hospitals, a specialized drug information service is often available. Guidelines from CSHP (2015) describe this as a formal unit of the pharmacy department, with dedicated staff and resources providing information on drug therapy. The service is often housed in a drug information center, physically separated from the pharmacy dispensary. The goal of a drug information service should be to support evidence-based care and discourage unproven therapies.

The drug information service is generally available to all health professionals in the hospital, with drug information pharmacists available by phone, fax, or email. There is occasionally a call center for patients as well. Such a service complements the day-to-day work of hospital pharmacists by assisting with urgent questions or questions requiring extensive research.

Dedicated financial resources are required to develop and maintain a library of high-quality resources. This may include print textbooks, but services are increasingly dependent on subscriptions to electronic databases, websites, and list-servers. Drug information pharmacists should also have the resources to join relevant societies and participate in continuing education events.

Key aspects of any drug information service are a systematic approach and thorough documentation. A systematic approach was first proposed by Watanabe et al. (1975). The approach has been modified over the years, but still includes the basic steps of gathering information to understand the true question, classifying the question, conducting a systematic search, analyzing and disseminating the results, and documenting the response.

A comprehensive documentation system is crucial for a drug information service. Documenting every request in a database that allows for easy retrieval by keyword or drug class prevents duplicating effort for similar requests. This information also allows for the provision of consistent information, particularly when the response makes reference to guidelines, policies, or protocols within the local health system. A documentation system allows for quality assurance because responses can be reviewed as needed. Finally, such a system can also provide important data trends to help inform the work of the drug information pharmacist.

The work of drug information pharmacists can be categorized as in-coming (reactive) or out-going (proactive). Reactive tasks are focused on responding to in-coming requests received through the drug information service. Proactive tasks are those that aim to disseminate information in advance of when it is needed, perhaps by creating patient information sheets and making them available on the hospital's website, or publishing a monthly newsletter for health professionals explaining new drugs or treatment protocols. Reactive tasks should inform proactive tasks. Pharmacists should be alert for trends in-coming requests. Many questions on the same topic may indicate that information is lacking on that topic and a more proactive approach is required to push information out across the organization, perhaps in the form of an in-service, newsletter, practice tool, or preprinted order set.

Formulary Management

Hospital pharmacists promote the optimal use of drugs through a formulary, a list of medications that have been approved for use in the hospital. The formulary lists approved drugs, along with dosage forms, dosage strengths, unit-of-use quantities, and unit cost for each drug product. CSHP (2008) calls the formulary a "dynamic compilation" of approved medications, emphasizing that the formulary should be constantly reviewed for potential additions and deletions.

Hospitals should have a clear policy on formulary governance, including the composition of the committee responsible for formulary decisions, and procedures for making changes, additions, and deletions. The formulary should be available to anyone who prescribes, dispenses, or administers medications in the hospital.

More than simply a list of medications, the formulary includes relevant policies and information to support appropriate drug use. Formularies may include helpful tools such as dosage charts or equivalency tables, criteria for the use of restricted drugs, or institutional policies on generic substitution.

Most formularies include information on the hospital's approved therapeutic interchanges. Therapeutic interchange is the automatic substitution (or "auto-sub") of one chemical entity for another, when the formulary management committee has deemed these different drugs to be therapeutically equivalent (CSHP (2008)). This often occurs within a class of drugs. By including only one of the drugs on formulary and automatically substituting that drug whenever any of the equivalent drugs are ordered, hospital pharmacies can simplify their inventory and distribution systems, and decrease costs by purchasing the preferred drug in bulk. There

may also be patient safety benefits in avoiding therapeutic duplication within the formulary. Standards for hospital accreditation in Canada (Accreditation Canada, 2017) mandate designing the formulary so as to minimize the number of medications that health professionals need to be familiar with.

Formularies can also prevent duplication and confusion by limiting the number of dosage forms available for each drug and standardizing the doses available. FIP (Vermeulen et al., 2016) recommends that hospital pharmacies stock only standardized concentrations of high-risk medications such as electrolytes, and that this standardization is guided by the hospital formulary.

A formulary system may facilitate the development of standardized treatment protocols and pre-printed orders. Such protocols may be managed by a separate committee, but they are excellent companions of the hospital formulary as both have the goal of promoting evidence-based, safe, and equitable care. Olson (2012) recommends that the hospital formulary align with any regional or national guidelines that have formally adopted as standards of care.

Olson (2012) calls the hospital formulary "the cornerstone of medication management in the hospital" and offers suggestions to promote formulary adherence, such as monitoring and acting on all nonformulary drug use, prohibiting the distribution of samples, providing easy access to the formulary, communicating changes to the formulary, and involving medical staff in formulary decisions.

Pharmacy and Therapeutics Committee

The committee responsible for formulary management is usually called the Pharmacy and Therapeutics Committee (P&T). P&T should have an official mandate and should be multidisciplinary (WHO, 2003a), including representatives from pharmacy, medicine, nursing, administration, and other disciplines. P&T should oversee all policies related to the use of drugs in the hospital (ASHP (2008); CSHP (2008)).

P&T should have a rigorous process in place for considering additions or changes to the formulary. Committee deliberations should cover therapeutics, safety, economics, access, and equity. Submissions to the committee should include evidence for the potential benefits and harms of the drug, reasons for adding it to the formulary, a comparison with other drugs already on formulary and whether these other drugs could be replaced, any special training or restrictions that should be required, and a pharmacoeconomic analysis (CSHP (2008)).

It is important to consider the overall budget impact of formulary changes. Some drugs may add new costs to the drug budget, but reduce complexity of care, nursing time, or length of stay. Some drugs may reduce drug costs, but add lab monitoring or nursing time.

P&T may also oversee a formal program of medication use evaluation (MUE). Also called drug use evaluation or drug use review, this is an ongoing, systematic evaluation of drug use (CSHP, 2014b) that looks at pattern of use, quality of use, determinants of use, and outcomes of use (WHO, 2003b). Such a program may include benchmarking levels of drug use, monitoring usage trends and costs, evaluating effectiveness, creating guidelines or criteria for drug use, and evaluating where additional education may be required (CSHP, 2014b). ASHP (1996) MUE guidelines offer criteria for choosing which drugs to review, such as drugs that are known to cause adverse reactions, are used in high-risk patients, are used in a large number of patients, are a critical component of care for a specific condition or procedure, or are expensive.

Conclusion

The evolving health-care landscape provides new opportunities for pharmacists and pharmacy technicians to deliver services that will enhance medication use and engage patients in improving their overall health. These services span the entire scope of pharmacy practice. As evidence about pharmacists' impact on clinical and economic outcomes continues to expand, the demand for and expectations of hospital pharmacists to help improve patient-specific therapeutic outcomes and reduce health-care costs will increase. Pharmacist and pharmacy technician education, training, and certification systems and processes must keep pace with these demands and expectations, to ensure that future pharmacy professionals can fulfill their roles and responsibilities for improving patients' mediation-related outcomes.

Expanded and Evolving Roles for Pharmacists

Sherilyn K.D. Houle, University of Waterloo, Waterloo, ON, Canada

Scope of Practice and the Pharmacist's Professional Role

The scope of practice by pharmacists has experienced, and continues to undergo, a substantial shift to meet the evolving needs of patients and health systems. Prior to large-scale pharmaceutical manufacturing, the pharmacist's primary role was the preparation of medicinal products for individual patients. The commercial manufacturing of drug products significantly reduced the need for pharmaceutical compounding, shifting the responsibility of pharmacists' knowledge and practice toward patient education and advice on self-care. In hospital pharmacies, pharmacists were increasingly adopting roles in pharmacokinetic drug monitoring—beginning to blur the boundary between drug dispensing and direct patient care. In 1990, Hepler and Strand defined the pharmacist's role in pharmaceutical care as "the responsible provision of drug therapy for the purpose of achieving definite outcomes that improve a patient's quality of life" (Hepler and Strand, 1990). This was instrumental in assigning responsibility to pharmacists for optimizing drug therapy outcomes of their patients, largely through the identification and management of drug-related problems. Their classification system for types of drug-related problems has been utilized in countless quality assurance measures, standards of practice and guideline documents, and research endeavors advancing pharmacy practice.

While the widespread definition of pharmaceutical care has not been revised since, the roles and responsibilities of pharmacists have continued to evolve. A number of factors can be credited with influencing this change. For example, growth in the number of approved pharmaceutical compounds has contributed to greater complexity in medication selection and use, creating the opportunity for pharmacists' drug therapy expertise to take on increased value within the multidisciplinary provision of patient care. Revised pharmacy curricula in many countries with greater emphasis on pharmacotherapeutic knowledge and clinical rotations—including the development of entry-level PharmD programs whereby new pharmacy graduates have the PharmD credential (Romanelli and Tracy, 2015)—have sought to produce pharmacy graduates with the knowledge and skills to be frontline healthcare professionals. Finally, an aging population and increasing prevalence of chronic disease (Prince et al., 2015) have placed financial and capacity burdens on many health systems, requiring consideration of how nonphysician health professionals can improve chronic disease management outcomes and improve medication use.

The scope of practice by pharmacists has therefore grown to accommodate these increasing demands and better utilize pharmacists' expertise in drug therapy. Often termed *expanded scope*, activities such as renewing and adapting prescription orders, prescribing drug therapy, ordering and interpreting laboratory tests, and administering drugs and vaccines by injection have been generally defined as services provided by pharmacists beyond those involved in routine dispensing and medication profile/chart reviews. In contrast to providing therapeutic recommendations to patients and other healthcare providers, expanded scope activities generally require decision-making and action on identified patient care needs by the pharmacist.

As other chapters of this resource specifically address the pharmacist' role related to a number of the services considered to be within the purview of expanded scope, this chapter will discuss broader considerations related to the enactment, uptake, and provision of expanded scope services as a whole, and the impact of this evolving role on the future of pharmacy practice.

Enacting Scope Expansion in Pharmacy

As a regulated health profession serving both the public and private sectors, enacting scope expansion in pharmacy is complex. At the highest levels in the organizational structure of the profession, scope expansion is pursued by pharmacy advocacy associations and regulatory bodies to meet identified care gaps in the health system and advance the profession. As a highly accessible profession with pharmacies located in many communities, expanded scope services are often intended to improve the timely and convenient access to health services for patients. As such, pharmacy regulatory bodies, with mandates to represent the needs of the public, play a key role in identifying expanded scope activities likely to be of greatest benefit to residents of their province/state/country, and establishing and enforcing standards related to the quality and safety of those services. Depending on the legislation of health professions in different countries, amendments to regulations at the state/provincial and/or national level may be required for pharmacists to legally provide these services. Additional information on the regulation of the pharmacy profession can be found in Chapter 710 of this resource. Consultations with the public, other health professionals, policy-makers, and payers further inform the specific design of the services introduced. These factors therefore lead to high variation internationally in services offered, patient eligibility for services, and payment (Houle et al., 2013, 2014a; Law et al., 2012; Taylor and Joubert, 2016).

As expanded scope activities involve pharmacists taking responsibility for any outcomes or risks associated with these decisions, standards of practice which may include required education or credentialing in order to provide the service, documentation and communication requirements, safety considerations and restrictions, and requirements for liability insurance may be mandated by regulators. Pharmacy advocacy organizations, universities, and continuing education providers commonly play a role in supporting pharmacists and pharmacy students to meet these requirements. Insurance companies and employers must ensure pharmacists and pharmacies are adequately insured for any potential losses or damages that may occur. Patients, institutions, and other health professionals must also be informed of the change in scope to ensure recognition of, and collaboration with, pharmacists as they adopt these new responsibilities. At the level of individual clinicians and practices, additional training or education may be required, modifications to workspaces and workflow are often necessary (Houle et al., 2017), and standard operating procedures may need to be developed. This complexity related to enacting practice change and scope expansion can result in great variation in uptake among jurisdictions—and individual practitioners within those jurisdictions (Guirguis et al., 2017; Rosenthal et al., 2015)—related to the uptake and provision of these services in practice.

Barriers to Expanded and Evolving Roles for Pharmacists and Potential Strategies to Overcome These Barriers

The enactment of legislation and standards of practice to enable expanded scope activities is a foundational step toward adoption by pharmacists, but does not ensure it. Indeed, pioneers of expanded scope activities worldwide have regularly reported hesitation to provide these services and suboptimal uptake by pharmacists and patients when initially introduced for a number of reasons. Those wishing to pursue similar opportunities are therefore strongly encouraged to both anticipate and proactively address the commonly reported barriers summarized below. While not an exhaustive list of all potential challenges, these represent barriers frequently reported in the pharmacy practice literature.

Time, Workflow, and Space

While the traditional activities of pharmacists as providers of medications is shifting, they will unlikely be eliminated entirely from a pharmacist's professional responsibilities. One cannot undervalue the importance of the safe preparation and dispensing of medications, as this process includes reviewing the patient's medical history and medication profile for potential interactions or contraindications, monitoring medication adherence and effectiveness, and providing patient counseling—all of which require the clinical expertise of a pharmacist. It is indeed during the dispensing process when many prescribing errors and drug-related problems are identified. As pharmacists introduce expanded scope activities in their practices, they must often be performed in addition to existing responsibilities rather than in place of them.

As a result, the impact of these additional services on pharmacists' time and workload cannot be underestimated. Due to the high level of individualization required to conduct most expanded scope services, considerable time is required to identify the patient's chief concern and goals of therapy, consult references to guide clinical decision-making, document care provided (McCann et al., 2011; Penm et al., 2017), and communicate these actions to other health professionals involved in that patient's care to ensure continuity and safety across care providers. Standardized documentation forms may also need to be completed to comply with legislative requirements and/or to receive remuneration for the activity.

Furthermore, the physical layout of many pharmacies has been designed to optimize the efficiency of the dispensing process. Additional requirements for the introduction of expanded scope activities may include private patient counseling or examination rooms with medical equipment for patient assessment (e.g., a blood pressure monitor), a waiting area for patients to complete forms for history-taking or remain for monitoring following the administration of an injection, and additional computer terminals where pharmacists can complete clinical documentation with minimal interruptions. Subscriptions to additional drug information resources may also be required to support clinical decision-making.

Pharmacies must also consider how expanded scope activities will be integrated into the existing workflow of processing prescription orders and providing advice on nonpharmacologic products (Houle et al., 2017; Penm et al., 2017). As a commonly

cited advantage of pharmacies as a primary care setting is their accessibility—often allowing patients to see a pharmacist without an appointment and across broader operating hours than many medical clinics—many pharmacies have opted to provide some expanded scope services on a walk-in basis. While optimizing patient accessibility to these services, walk-in availability introduces unpredictable disruption to the existing workflow of the pharmacy, which may require reexamination of staffing levels throughout the day to consider when walk-in requests appear to be most frequent. More time-intensive services, such as chronic disease monitoring/management or travel consultations, may be better suited to an appointment model, where additional staff can be present to minimize workflow disruption. This also allows the pharmacist the opportunity to prepare for the appointment in advance by collecting necessary background information or ensuring the required equipment is readily available for the interaction.

The corresponding expansion to the scope of practice of pharmacy technicians in some regions can further enable greater integration of these activities into existing workflow (Houle et al., 2014b). With technicians adopting larger roles in product ordering and inventory management, patient education on certain medical devices such as blood pressure and blood glucose monitors, and performing final checks on the dispensing of prescription products (following a review of its safety and clinical appropriateness by the pharmacist), these tasks may be potentially reduced from the pharmacist's workload, with the freed time now able to be allocated to expanded scope services. Additional information on pharmacy technician education and training is provided in Chapter 103 of this resource.

Education and Confidence

The addition of expanded scope services into a pharmacist's repertoire has largely been an occurrence of the 2000s—especially the past decade. While pharmacy schools in jurisdictions authorizing expanded scope services have integrated teaching and practice with these activities into their curricula for new graduates, such training was largely excluded from the education received by experienced pharmacists. As previously mentioned, expanded scope services often require the pharmacist to ultimately make a decision regarding a patient's pharmacotherapeutic needs, and act upon that decision. This is in contrast to the traditional role of pharmacists as information providers, trained to provide evidence-based recommendations on drug therapy which were ultimately decided and acted upon by physicians and other prescribers.

Pharmacists have therefore had to adapt professionally and personally to this added responsibility (Maddox et al., 2016; Penm et al., 2017; Rosenthal et al., 2010, 2015). Learning needs identified by practicing pharmacists to meet these responsibilities have included additional clinical education in physical assessment and laboratory test interpretation (Hoti et al., 2014), and documentation of care plans and actions for both clinical and legal purposes. As can be expected, competence or legislative ability to perform a particular service does not imply confidence (Teixeira et al., 2017), as the latter is generally achieved through practice and repetition. Pharmacists who do not feel confident in these skills may therefore not promote the availability of these services widely to patients, or may refer patients back to traditional prescribers for decision-making under situations of uncertainty. While referral of patients to other health professionals for concerns beyond the scope of pharmacists is encouraged and expected, the subjective interpretation of when referral is the preferred action for a given scenario is highly variable among pharmacists, and largely associated with their confidence in providing the service. This hesitation to perform a service due to lack of confidence may contribute to a cycle whereby attaining sufficient experience to achieve confidence is significantly delayed or not achieved.

Professional education and socialization is often highly reliant on the mentorship of new members of the profession by experienced practitioners. The challenge created by an expanding and evolving role for pharmacists is that newer practitioners may be more informed of legislative requirements and drug information resources specific to expanded scope services, and may have had more opportunities to practice expanded scope activities with standardized patients as part of their formal training, compared to experienced colleagues. Seasoned practitioners, on the other hand, have likely developed greater confidence in skills such as shared decision-making with patients, and communication with other health professionals than newer practitioners. This splitting of areas of confidence between new and experienced practitioners often becomes evident during practical education experiences or internships, when both generations must work together as part of the student's formal education. Conflict may arise if the new graduate feels discouraged from practicing to their full scope due to hesitation from the mentor, or if the mentor feels the value of their experience has been eclipsed by the expanded scope knowledge instilled into new clinicians. Experiential education must therefore consider the distinction between learner and teacher to be fluid when related to expanded scope services, with each party serving as both the learner and teacher depending on their areas of proficiency.

Continuing education programs for pharmacists must also consider and account for the potential for learners to lack confidence in multiple potential aspects of expanded scope service provision. The traditional approach to continuing education, focusing on improving learners' knowledge of a particular disease and associated drug therapy options, fails to address barriers in practice such as decision-making under clinical uncertainty, seamless care across health professionals and care settings, effective documentation of actions taken, and monitoring the patient's response to therapy. Case-based and interactive learning strategies are often employed to prepare pharmacists to apply their scientific knowledge to patient care decisions.

Support From Other Health Professionals and Patients

The expansion of the role of any professional contributes to a blurring of the roles in patient care, historically solely performed by specific health professionals. For example, prescribing and adapting drug orders is now a shared activity in some jurisdictions across physicians, nurse practitioners, physician assistants, and pharmacists. The administration of vaccines by injection is now largely

shared between public health nurses and community pharmacists in regions where this authorization has been granted to pharmacists. This shared scope has introduced complexity related to payment for services through government or third-party payers, concerns over the potential for unnecessary duplication of services by multiple health professionals caring for a mutual patient, and collaboration (Donald et al., 2017; McCann et al., 2012; Penm et al., 2017), as each profession is now struggling to maintain a unique professional identity and position of relevance in the health system. Efforts to contain growing healthcare costs due to an aging population has also created tension among professions who may now be competing for a share of the same market, negatively impacting the market value related to remuneration offered for these services. Codes of ethics for most professions include a focus on the best interest of the patient or client at all times; however, concerns over one's professional position and the sustainability of their practice cannot be ignored. Furthermore, pharmacists who anticipate or experience a negative reaction to their expanded scope activities by other health professionals may hesitate to provide such services to patients, to avoid disrupting established professional relationships.

Support for expanded scope services by pharmacists among members of the public has been mixed. Patients value the convenience and accessibility of community pharmacies as primary care sites (Hutchings et al., 1998; Mansell et al., 2015). Patients who have received care from a pharmacist are generally highly satisfied with the experience (Gardner et al., 2008; Hale et al., 2016; Houle et al., 2018; Mansell et al., 2015; Stewart et al., 2011; Tinelli et al., 2015), and view their pharmacist as a knowledgeable member of their healthcare team specifically related to drug therapy knowledge (Bishop et al., 2015). Concerns have been raised, however, related to the lack of private space for consultations in many community pharmacies (Famiyeh and McCarthy, 2017; Stewart et al., 2011), the need to ensure all members of the patient's healthcare team are made aware of any actions made by the pharmacist to ensure safety and continuity of care, and the impact that seeking care from a pharmacist may have on the patient's relationship with their other healthcare providers (Donald et al., 2017). Research has also reported low awareness among the public of expanded scope services available to them from their pharmacist (Feehan et al., 2016), which may be partly due to pharmacists' hesitation to advertise these services due to lack of confidence as mentioned above.

As such, changes to the scope of practice for pharmacists must be accompanied by awareness campaigns for other health professionals and the public by pharmacy regulatory bodies, advocacy associations, and individual pharmacists and pharmacies. Pharmacists are often legally required to document and communicate care they provide to patients to other health professionals also involved in that patient's care; however, this communication generally occurs after the care has been provided. Pharmacists are encouraged to meet with local health professionals that they share mutual patients with in advance, to inform them of new services being introduced, address any questions or concerns, and agree on how communication and collaboration will occur. Case-finding efforts should also be employed by pharmacists and pharmacy team members to proactively identify patients who may benefit from a service, as it cannot be assumed that members of the public will be aware of, and request, these services from their pharmacist.

Remuneration/Payment for Services

Community pharmacy revenues have traditionally been linked to the sale of prescription and nonprescription drugs, and other product purchases by patients and customers. As a result, the traditional focus of pharmacists' efforts on dispensing prescription drugs and counseling patients on nonprescription drug products have been congruent with the financial viability of the pharmacy business. As pharmacists increasingly adopt nondispensing patient care responsibilities, the business model of pharmacy practice must follow suit. To date, remuneration for clinical pharmacy care services by government and/or third-party payers beyond the dispensing of medications has been slow to develop, and inconsistent across services and jurisdictions (Houle et al., 2013, 2014a; Law et al., 2012). Fee amounts offered, when available, are set rather arbitrarily, as evidence to estimate actual costs incurred by pharmacies to provide these services, and to examine the cost-effectiveness of expanded scope interventions at the societal and individual patient levels, is generally lacking.

Remuneration decisions must consider not only the fee amount to be offered, but also: (1) whether fees should be based on the provision of the service regardless of actual time spent or outcome(s) achieved; or (2) if fees should be reflective of the time invested to provide care for each patient and/or the clinical effectiveness of the intervention in achieving health-related goals. Research comparing the effectiveness of different payment models such as fee-for-service, capitation, or pay-for-performance among physicians has produced mixed results (Houle et al., 2012), further complicating these decisions within the pharmacy profession. Initial research of performance-based payment for pharmacists suggests no impact (Houle et al., 2016). Furthermore, as many pharmacists are employed by licensed pharmacy businesses who provide the overhead within which the pharmacist operates, there is also debate around whether payments should be issued to the individual pharmacist(s) providing care, or the employer/company. Proponents for payment issued to individual providers feel this may reduce perceived pressure to perform services for the sake of profitability rather than patient need, and incentivize and reward individual pharmacists who provide these services. Proponents for payment issued to the employing organization feel this reduces competition among individual pharmacists and promotes collaboration, and is more consistent with business structures where staff pharmacists providing care are not owners of the business and therefore do not bear any of the operating expenses. As of the time of publication of this resource, the vast majority of programs currently provide remuneration for expanded scope services to the pharmacy/company, although some employers have enacted agreements where a proportion of each fee is redistributed to the individual who provided that service.

The introduction of payment for pharmacists' nondispensing services has also led to concerns about the potential conflict of interest associated with being both the prescriber and dispenser of a product, and receiving remuneration for each of these actions.

While not unique to pharmacy—it can be argued that a dentist prescribing an orthodontic appliance, for example, practices under the same potential conflict—the retail setting many pharmacists practice within may make this appear more pronounced. To reduce concerns about this conflict, it can be legislated that remuneration offered is for the assessment of the patient rather than the prescribing of a product (hence, payment is also received for the assessment even if it results in a decision to not use drug therapy or to refer to another health professional), and that patients issued a prescription by a pharmacist must have the ability to have that prescription dispensed from the pharmacy of their choice, even if it is not the same pharmacy where the expanded scope assessment was performed.

Access to, and Sharing of, Medical Records

While pharmacies have long maintained records of patients' medication histories, allergies, and other information relevant to the safe dispensing of medications, the documentation of detailed care plans, prescribing decisions by pharmacists, and the administration of injections is a recent addition to many pharmacy software programs. The added time required to complete this documentation related to expanded scope activities has already been addressed above.

The professional responsibility taken by the pharmacist associated with their decision to provide an expanded scope service requires more detailed patient information than standard dispensing records, in many cases. Unlike pharmacists who may practice in medical clinic or hospital settings, most community pharmacists lack direct access to the patient's complete medical chart. Information on diagnoses, laboratory test results, and goals of therapy established by the patient's physician or other primary care provider(s) may have to be requested directly from the other professional and communicated verbally, electronically, or via fax. The availability of this information by shared electronic medical record would be ideal, but is often delayed due to technological challenges and security concerns related with the sharing of patients' personal health information. In the absence of readily available medical records, pharmacists may feel unable to perform a particular expanded scope service due to the inability to fully assess its safety and appropriateness for the patient. While referral of the patient back to their primary care provider for this care may be in the patient's best interest, this may create a delay in accessing care that could have been prevented if this information was easily accessible by the pharmacist.

As discussed above, patients and other health professionals have expressed a desire for all members of the patient's healthcare team to be informed of any expanded scope activities provided (Donald et al., 2017). Indeed, the communication of these activities is often a required condition within the legislation authorizing that service to be performed by pharmacists. Pharmacists must therefore maintain detailed clinical records that not only are available for the pharmacist's reference, but also describe the action taken, the rationale for the decision made, and any required monitoring by other health professionals. Similar time investment and privacy implication concerns related to accessing patients' medical records also apply to the communication of these documents by pharmacists to other health professionals following the provision of an expanded scope service.

Efforts to streamline documentation through the use of standardized forms and the electronic sharing of records can be expected to improve the efficiency of this added responsibility. Pharmacists should aim to keep documentation concise and action-focused, clearly indicating which aspects of care they are taking responsibility for (such as monitoring for side effects after initiating a new therapy) and which aspects they are requesting collaboration with (such as the ordering of laboratory tests when outside the pharmacist's scope of practice to do so), to reduce the risk of care fragmentation and unintentional omissions when care for a mutual patient is shared across multiple professionals.

Concerns Related to Professional Liability

As pharmacists transition from recommendation-based to decision-based practices, they also adopt the professional liability associated with those decisions. Surveys of pharmacists have identified that concerns about errors or adverse events and their personal responsibility for those outcomes may impede the provision of expanded scope activities when there is perceived uncertainty or risk involved (Feehan et al., 2016; Maddox et al., 2016). As a result, pharmacists may choose to only perform these services in scenarios where there is low possible risk of an adverse outcome. However, it is rare that a healthcare decision presents with little to no risk, so this hesitation may result in few patients receiving the service. Pharmacists must also document their assessments, care decisions, and rationale in a way that ensures not only continuity of care, but also satisfies medicolegal requirements should an adverse outcome result.

Historically, many pharmacists were insured by their employer for any consequences related to errors in the dispensing process; however, many jurisdictions authorizing expanded scope services by pharmacists also mandate that the pharmacist holds personal liability insurance in addition to any insurance provided by their employer. Insurance specific to expanded scope services by pharmacists is therefore a relatively new addition to many professional insurance providers, and is being continually refined as the pharmacist's scope continues to expand. Pharmacists are encouraged to carefully review their insurance policies to ensure the protected actions included are consistent with their current service provision, and obtain legal advice for clarification as required.

Misunderstandings by other health professionals related to who retains professional liability for pharmacists' expanded scope activities have also been reported. Physicians and other prescribers have historically held sole responsibility for the outcome of prescribing decisions. Even when delegation of prescribing authorization to other health professionals has occurred by protocol, they have retained some responsibility for the outcome of that delegated prescribing. Some physicians and other prescribers have

expressed concern about potentially assuming some professional responsibility for a pharmacist's decision to make a pharmacotherapeutic decision for one of their patients. However, many jurisdictions that have enacted expanded scope legislation for pharmacists to date have very clearly specified that the pharmacist retains sole responsibility for the outcome of their actions. As such, adapting, renewing, prescribing, and the administration of injections by pharmacists are consistent with independent prescribing rather than delegated prescribing from a liability perspective.

Pharmacy regulatory bodies, advocacy organizations, and members of the profession are encouraged to make this responsibility for the outcome of the expanded scope decision clear to other health providers when communicating that an expanded scope service was provided. As the individual responsible for the outcome of that action, pharmacists must also perform monitoring and follow-up of patients to ensure the safety and effectiveness of the action taken. This may present a challenge when activities such as laboratory test ordering and interpretation are outside of a pharmacist's current scope or if physical assessment is required; however, effective collaboration with the other health professionals involved in the patient's care can ensure such follow-up is completed.

Practice Facilitation and Other Quality Improvement Strategies

Challenges experienced related to providing expanded scope services in pharmacy practice are highly individualized to each pharmacist and practice setting. Identifying these barriers and strategies to most successfully mitigate them requires both personal reflection and an objective analysis of the practice's space and workflow. Practice facilitation, also referred to as outreach, involves introducing a facilitator trained in change management to a professional practice, to provide assistance with identifying areas for improvement and implementing strategies to address them. As an external consultant for the practice, this individual applies both personal observation and information collected from interviews with staff members to create an individualized action plan to achieve a desired goal. While practice facilitation is a relatively new occurrence within pharmacy practice (Houle et al., 2017), it has demonstrated moderate effects on improving the adoption of evidence-based care in primary care medical practices (Baskerville et al., 2012).

Other strategies have been considered to improve the uptake and quality of pharmacists' expanded scope services, including audit and feedback, and pay-for-performance remuneration; however, little literature exists to date on the comparative effectiveness of these strategies in pharmacy practice.

Evidence Related to Expanded Scope Activities

A robust body of evidence exists showing clinical, economic, and humanistic benefits of nondispensing activities by pharmacists across a number of patient populations and disease states. However, most studies have focused on activities such as patient education, recommendation-based disease state management, and education of other health professionals, which are generally not considered to be expanded scope activities.

As the administration of injections by pharmacists was first introduced in the United States in the mid-1990s, the body of evidence for this expanded scope activity is the most established to date. The uptake of this service by pharmacists appears to be more rapid and significant than uptake of other expanded scope services. A number of factors may have contributed to this observation, such as the relatively technical and low-risk nature of administering an injection versus initiating a drug therapy, for example, or corporate and employer pressures to offer vaccination services to remain competitive in the community pharmacy sector. The uptake of this service by patients has also been noteworthy (Gai and Feng, 2017), although only modest improvements in overall population vaccination rates against influenza have been realized in a number of US states and Canadian provinces since the introduction of pharmacist-administered vaccination programs (Buchan et al., 2017). It is hypothesized that the increasing number of vaccinations administered in community pharmacies without a corresponding increase in the population vaccination rate represents a shifting of vaccine provision from medical and public health clinic settings to community pharmacies. Challenges remain with engaging individuals with vaccine hesitancy to improve overall population vaccination rates. The evidence also reports that pharmacist-administered injections are safe (Hattingh et al., 2016), with adverse event rates comparable to other settings where vaccines are administered. Patient satisfaction with these services has been rated as consistently high, with convenience and availability without an appointment cited as benefits unique to pharmacy-based vaccination programs (Hattingh et al., 2016; Papastergiou et al., 2014; Poulose et al., 2015). Patients have expressed some concern related to the lack of privacy available in many community pharmacies, as noted previously.

Pharmacist assessment and prescribing for minor ailments has also been evaluated. Results of pharmacy-based minor ailment programs have been generally positive, noting high patient satisfaction (Mansell et al., 2015; Taylor and Joubert, 2016), and more timely access to consultations from pharmacies than from medical clinics. Concerns over the lack of private spaces for consultations in some pharmacies have been voiced, and many patients lack awareness of both the availability of these services from their community pharmacist, and the pharmacist's level of knowledge and training related to minor ailment assessment and management. Surveys of patients receiving minor ailment consultations from pharmacists have reported that a high proportion of those patients would have visited a medical clinic for care had the pharmacy not been available to provide the service (Baqir et al., 2011;

Mansell et al., 2015), suggesting cost-savings to the health system, as care provided in pharmacies is often less expensive than that provided in other primary care settings (Rafferty et al., 2017).

Research on protocol-based prescribing by pharmacists in areas such as travel medicine (Durham et al., 2011; Hess et al., 2010; Tran et al., 2015) and anticoagulation (Zhou et al., 2016) has also identified high patient satisfaction and adherence to therapy. High patient satisfaction was also reported following a pharmacist prescribing in surgical preadmission clinics and sexual health clinics (Hale et al., 2016). A pharmacist prescribing in a US pain clinic was also found to be clinically effective and cost-effective (Dole et al., 2007). However, most evidence on independent prescribing by pharmacists (in other words, prescribing without a protocol) has been generated for chronic disease management. Trials of pharmacist prescribing for the management of diabetes (Al Hamarneh et al., 2013), hypertension (Tsuyuki et al., 2015), and dyslipidemia (Tsuyuki et al., 2016) have been conducted in Canada with results showing improvement in surrogate outcome measures such as blood pressure, lipid levels, and hemoglobin A1c, and the proportion of patients on guideline-adherent drugs for primary and secondary prevention of cardiovascular disease. Research evaluating the effectiveness of pharmacist prescribing on hard outcomes such as heart attack, stroke, and heart failure incidence remains to be conducted.

Next Stages in the Evolving Roles for Pharmacists

Expanded scope activities such as the adaptation and renewal of prescriptions, initiation of therapy, and administration of injections are expected to solidify the pharmacist's position among healthcare professionals as the drug therapy expert—allowing them to take greater responsibility for timely and effective patient access to needed drugs and vaccines. This application of pharmacists' expertise in a way that is visible and tangible to patients can be expected to enhance the public's awareness of the pharmacist as a primary care provider, and increase public demand for these services. However, great variation in expanded scope legislation among countries and at the state/provincial level has led to an inconsistent definition of what a pharmacist does, and which services patients can expect to receive from their pharmacist. Restrictions currently in place in many regions limiting pharmacists' expanded scope activities to certain patient populations, disease states, or specific products create inequities regarding patient access to these services and hinder pharmacists' ability to provide holistic care for a patient considering all of their healthcare needs and comorbidities.

Evolution of these services should therefore aim to optimize the breadth and depth of care that can be provided under this expanded scope. Minimization of the use of protocol-restricted prescribing and expansion in the use of electronic medical records that can be easily shared among clinicians will allow pharmacists to best tailor medication therapy to an individual patient's needs. The ability to order and interpret laboratory tests and perform basic physical assessment should be integrated into the scope of practice for pharmacists, and into pharmacy training (for both new graduates and as continuing education for current pharmacists), as required components to effectively monitor the safety and efficacy of expanded scope actions. It should be stressed that these physical assessment skills are not intended to replace assessment and diagnosis by physicians and other health professionals with diagnostic expertise, but should be focused on skills specific to monitoring a patient's response to a drug therapy after the diagnosis has been established. The ability to collaborate with, and refer patients to, physicians or other healthcare professionals for additional assessment and diagnosis will remain an important part of pharmacy practice.

Consistent with the ability to order and interpret laboratory tests, the greater adoption of point-of-care testing technologies is expected to occur in the pharmacy profession. These technologies, which allow for physical assessment measures to be taken, or blood or urine samples to be collected at the pharmacy and rapidly analyzed for screening and monitoring purposes, are described in Chapter 414 of this encyclopedia. Pharmacies will increasingly employ point-of-care testing to perform population screening for chronic and acute diseases for further assessment and diagnosis, or to monitor and subsequently adapt prescription drug orders (for example, performing point-of-care international normalized ratio (INR) testing and warfarin dose adjustment). The accessibility of pharmacies both geographically and due to extended operating hours enables pharmacists to interact with individuals who may otherwise not regularly access the health system. Building upon the success of pharmacy-based influenza vaccination programs, other pharmacy-based public health outreach initiatives such as needle exchange programs, safe medication disposal drop-off, smoking cessation clinics, and the distribution of at-home screening kits for colon cancer and HIV can be expected to increase in popularity.

Developments in the field of pharmacogenomics/pharmacogenetics (discussed in Chapter 417) are also expected to further expand the role of pharmacists related to the tailoring of drug therapy based on a patient's genetic profile. Finally, as pharmacists seek to further their knowledge and skills related to therapeutic areas of personal interest and of relevance to their patient population, the future of pharmacy is likely to demonstrate increased specialization in pharmacy practice, where some pharmacists practice to their fullest scope including patient assessment and prescribing but in a limited field that they possess specialized knowledge in. Menopause symptom management, pretravel consultations, and anticoagulation are examples of specialized pharmacist-led practices achievable under an expanded scope. Ultimately, collaboration between pharmacists and other health professionals is expected to be enhanced as pharmacists increasingly demonstrate their added value to the multidisciplinary team. Further experience with, and evidence to support, expanded scope activities will create countless additional opportunities for pharmacists to improve health outcomes through optimizing medication use, as this professional evolution continues.

Glossary

Adapt The decision, by a pharmacist, to modify an existing order for a prescription drug from a prescriber to account for patient-specific considerations or to correct prescribing errors. Examples of adapting may include modification of the dosage of the medication due to a patient's impaired hepatic or renal function or age, or modification of the route of administration of a drug from an oral to parenteral route due to swallowing difficulties. Adapting may also consider modifying the dosing regimen or duration of therapy for improved patient adherence or consistency with clinical practice guideline recommendations for a certain indication.

Capitation Payment model where the provider is paid a set amount per patient to provide care over a specified time. Patients are usually allocated to only 1 practitioner or clinic that must provide all necessary care out of the set payment provided for that patient.

Case finding The proactive consideration of patient demographics, risk factors, or symptoms to identify individuals who may benefit from a specific test or intervention.

Expanded scope Activities performed by pharmacists in the patient care process beyond those involved in routine dispensing and medication profile/chart review, often requiring decision-making and action by the pharmacist. These activities may include, but are not limited to, renewing and adapting prescription orders, prescribing drug therapy, ordering and interpreting laboratory tests, and administering drugs and vaccines by injection.

Fee-for-service Payment model where the provider is paid a set fee amount for each service delivered, with different services reimbursed at different rates depending on their complexity, time investment generally required, or other factors.

Pay-for-performance Any compensation system that links pay amounts for providers to the quality of care provided and/or outcomes achieved as a result.

Practice facilitation The involvement of a skilled individual to assist practices with identifying areas for improvement, implementing strategies, and monitoring the impact of these strategies toward attaining a particular goal.

Renew The decision, by a pharmacist, to extend an existing order for a prescription drug from a prescriber for an additional duration of time beyond what was specified in the order. This is done to ensure continuity of therapy until the patient is able to see the prescriber for further assessment and renewal of the order, as appropriate.

Professional Pharmacy Services

Lisa M. McCarthy[*,†], **Miles J. Luke**[†], *Women's College Research Institute, Women's College Hospital, Toronto, ON, Canada; [†]University of Toronto, Toronto, ON, Canada

Learning Objectives

By the end of this chapter, the reader will be able to:

1. Define professional pharmacy services.
2. Discuss the origin of related terms including:
   a. Clinical pharmacy
   b. Pharmaceutical care
   c. Cognitive pharmacy services
3. Describe seven categories of professional pharmacy services and list examples within each category.
4. Highlight factors impacting implementation of professional pharmacy services in community pharmacies.

Introduction

Pharmacists in diverse practice settings across the world use a variety of terms to describe their approach to practice, as well as their daily activities. Readers have likely encountered terms, including clinical pharmacy, pharmaceutical care, and cognitive (pharmacy)

services, to describe this concept, yet each of these terms has its own origin and particular nuances. Starting from what we hope is shared common ground, as a profession, pharmacists strive to partner with patients and other health providers to optimize medication therapy, and their patient's health in a broader sense, in pursuit of the best possible outcomes for patients while stewarding the use of health system resources.

Defining Professional Pharmacy Services

In this chapter, we focus on professional pharmacy services (PPS), a term that describes services offered by pharmacists and their teams in community settings. PPS are "an action or set of actions undertaken in or organized by a pharmacy, delivered by a pharmacist or other health practitioner, who applies their specialized health knowledge personally or via an intermediary, with a patient/client, population or other health professional, to optimize the process of care with the aim to improve health outcomes and the value of health care (Moullin et al., 2013)." Drawn from Donebedian's framework, the definition includes the structure, process, and outcome of pharmacy services. The term was developed to fill an important gap. Prior to its introduction, there was no consensus term to describe the entire package of health-focused services offered in community pharmacies.

Highlighted below are some of the fundamental components of the definition of PPS (Moullin et al., 2013):

1. Unlike other terms, which limit their scope to services offered by pharmacists, this definition focuses on all services provided by pharmacies. PPS can be provided by pharmacists but also by other care providers who possess unique health expertise, including regulated pharmacy technicians, nurses, or dietitians.
2. PPS may involve provision of care to patients directly or indirectly. For example, medication information provided to another health provider or participation in interprofessional discussions about patient care both fall within the definition.
3. The term applies exclusively to services conducted in community settings, that is, within or in partnership with a community pharmacy.

For further discussion about the rationale for all components of the definition of PPS, readers are encouraged to review the publication by Moullin et al. (Moullin et al., 2013).

Three criteria guide whether a service is considered PPS or its counterpart, a nonprofessional service. These are:

1. PPS require the use of specialized health knowledge possessed by health care professionals.
2. PPS focus on optimizing the processes of patient care.
3. PPS are concerned with "improving health outcomes and the value of health care (Moullin et al., 2013)."

To better elucidate the difference between PPS and a nonprofessional service, consider the following examples. Evaluating the therapeutic appropriateness of a prescription order and dispensing this medication to a particular patient satisfies these criteria and would be considered a PPS. Conversely, delivering a prescription medication to a patient's home does not involve the application of a health care professional's specialized health knowledge and, as such, would be considered a nonprofessional service.

Summary

PPS are "an action or set of actions undertaken in or organized by a pharmacy, delivered by a pharmacist or other health practitioner, who applies their specialized health knowledge personally or via an intermediary, with a patient/client, population, or other health professional, to optimize the process of care with the aim to improve health outcomes and the value of health care (Moullin et al., 2013)." The term professional pharmacy service will be used throughout the remainder of this chapter and shapes the content herein.

Related Terminology

Several terms exist to describe similar phenomena with respect to pharmacy services. Many have multiple definitions as they have been developed iteratively and some have origins within particular jurisdictions (e.g., medication therapy management in the United States). In this section of this chapter, we highlight three additional terms with which we believe "professional pharmacy services" are most closely linked. Readers are encouraged to review **Table 1** for a more comprehensive list of other associated terms.

To understand how these terms are linked, it is useful to briefly explain their origins. Historically, the role of pharmacists focused on using their expert knowledge about how best to combine drug ingredients to prepare and fill prescriptions for patients. In many jurisdictions (e.g., North America, the United Kingdom, Australia) by the 1960s, due to the growth of the pharmaceutical industry and industrial manufacturing of medications, it had become evident that pharmacists would need to expand their practices to find new ways to contribute their expertise to enhance care and add value for patients and the health care system. Thought leaders called for the reprofessionalization of pharmacy: "a process of occupational reconstruction and self-renewal (Hepler, 1988)." These tensions were not confined to pharmacists practicing in a particular setting (e.g., community, institutions, and so on) but rather rippled across the profession.

Table 1 Related terms

Terms	*Definition(s)*	*Comments*
Clinical pharmacy services	American College of Clinical Pharmacy: Services in which "pharmacists provide patient care that optimizes medication therapy and promotes health, wellness, and disease prevention" in all health care settings. Emphasizes direct patient care (American College of Clinical Pharmacy, 2008) European Society of Clinical Pharmacy: Services of the "clinical pharmacist to develop and promote the rational and appropriate use of medicinal products and devices." Encompasses all services performed by pharmacists practicing in any setting; applicable to direct patient, as well as population health care (Hepler, 2004)	A broad term that can be used to describe all functions of a pharmacist in all practice environments. Key differences noted between jurisdictions.
Cognitive (pharmacy/ pharmaceutical) services	"Any activity in which pharmacists would use their professional knowledge and abilities to improve pharmacotherapy and disease management by means of interacting with the patient or other health care professionals (Cipolle et al., 1998)" "Those services provided by a pharmacist or for a patient or health care professional that are either judgmental or educational in nature, rather than technical or informational (Cognitive Services Working Group, 1989)"	Nondispensing functions performed by pharmacists, including those that do not directly involve the patient.
Medication therapy management	"A service or group of services that optimize therapeutic outcomes for individual patients. Medication therapy management services include medication therapy reviews, pharmacotherapy consults, anticoagulation management, immunizations, health and wellness programs, and many other clinical services. Pharmacists provide medication therapy management to help patients get the best benefits from their medications by actively managing drug therapy and by identifying, preventing, and resolving medication-related problems (American Pharmacists Association, 2012)"	Term originates from the United States.
Medicines optimization	"A person-centered approach to safe and effective medicines use, to ensure people obtain the best possible outcomes from their medicines. Medicines optimization applies to people who may or may not take their medicines effectively. Shared decision-making is an essential part of evidence-based medicine, seeking to use the best available evidence to guide decisions about the care of the individual patient, taking into account their needs, preferences, and values (Cutler et al., 2011)"	Term originates from the United Kingdom.
Pharmaceutical care	"The Pharmacist's contribution to the care of individuals in order to optimize medicines use and improve health outcomes (Allemann et al., 2014)" "A professional patient care practice, which, when provided as an organized service, is experienced, documented, evaluated, and paid for as medication management services (Cipolle et al., 2012)" "Specialized knowledge [provided] by pharmacists for the patient or health care professionals for purpose of promoting effective and safe drug therapy (Cipolle et al., 1998)" "Includes the determination of the drug needs for a given individual and the provision not only of the drugs required but also of the necessary services (before, during, or after treatment) to assure optimally safe and effective therapy. It includes a feedback mechanism of care by those who provide it (Brodie et al., 1980)"	This term is used to describe nondispensing, direct patient care roles performed by pharmacists.
Professional pharmacy services	"An action or set of actions undertaken in or organized by a pharmacy, delivered by a pharmacist or other health practitioner, who applies their specialized health knowledge personally or via an intermediary, with a patient/client, population, or other health professional, to optimize the process of care with the aim to improve health outcomes and the value of health care (Moullin et al., 2013)"	Similar in scope to cognitive services, but includes health professionals other than pharmacists and is limited to the functions that are performed in association with community pharmacies.

Clinical Pharmacy

Over time, the pharmacist profession was reenvisioned as a clinically focused health specialty, commonly referred to as clinical pharmacy. Throughout the 1980s and 1990s, many pharmacists, particularly in institutional settings, adopted the term to describe their activities. The European Society of Clinical Pharmacy defines clinical pharmacy as a "health specialty, which describes the activities and services of the clinical pharmacist to develop and promote the rational and appropriate use of medicinal products and devices." It encompasses "all services performed by pharmacists practicing in hospitals, community pharmacies, nursing homes, home-based care services, clinics, and any other setting where medicines are prescribed and used." The term "clinical" refers to activities that impact the health of patients at both an individual and population level. Some argue that this definition is unnecessarily limiting in its focus on medication use. Another definition, from the American College of Clinical Pharmacy, defines clinical pharmacy as "a health science discipline in which pharmacists provide direct patient care that optimizes medication therapy and promotes health, wellness, and disease prevention (American College of Clinical Pharmacy, 2008)" in all health care settings. Some contend that this definition's focus on direct patient care is too limited because it precludes population level services.

Pharmaceutical Care

A chapter about professional pharmacy services would be incomplete without mention of pharmaceutical care. The earliest use of the term described pharmaceutical care as: "the care that a given patient requires and receives, which assures safe and rational drug usage (Mikeal et al., 1975)." Another definition was introduced in 1980, pharmaceutical care: "includes the determination of the drugs needs for a given individual and the provision not only of the drug required but also the necessary services to assure optimally safe and effective therapy (Brodie et al., 1980)." While other refinements to the definition were proposed through the 1970–80s the most notable revision appeared in 1990, as put forward by Hepler and Strand: "Pharmaceutical care is the responsible provision of drug therapy for the purpose of achieving definite outcomes that improve a patient's quality of life (Hepler and Strand, 1990)." The concept included both "drug-product control and clinical pharmacy services (Hepler, 1988)." The International Pharmaceutical Federation endorsed the Hepler and Strand definition in 1998 though amended the definition to emphasize that outcomes should improve or maintain a patient's quality of life (Wiedenmayer et al., 2006).

Further refinements and clarifications about pharmaceutical care have been put forward by both American and European groups. Most recently, the Pharmaceutical Care Network of Europe in 2013 defined pharmaceutical care as "the pharmacist's contribution to the care of individuals in order to optimize medicines use and improve health outcomes (Allemann et al., 2014)." Common across all of the definitions, pharmaceutical care refers to pharmacist services provided to individual patients that seek to optimize health outcomes related to medication therapy. Readers interested in a more in-depth exploration of the many definitions of pharmaceutical care are referred to resources created by the Pharmaceutical Care Network of Europe (Allemann et al., 2014).

Cognitive Services

Cognitive services are closely linked with those provided as a part of pharmaceutical care. In 1998, within the first edition of their foundational textbook about pharmaceutical care, Cipolle et al. defined cognitive services as "any activity in which the pharmacists would use their professional knowledge and abilities to improve pharmacotherapy and disease management by means of interacting with the patient or with other health professionals (Cipolle et al., 1998)." Interestingly, the term does not appear in subsequent editions of the text, which is consistent with the trend toward its declining use in the United States by the late 2000s.

"Cognitive service" was coined by D'Achille and coworkers (1989) as "those services provided by a pharmacist or for a patient or health care professional that are either judgmental or educational in nature, rather than technical or informational (Cognitive Pharmacy Services Working Group, 1989)." A revised definition was soon presented that explicitly included the provision of technical information as part of cognitive services (Martin, 1990). Examples of services included under the umbrella of cognitive services were patient education programs, counseling about medical conditions, and monitoring drug levels. Note that these early definitions of cognitive services did not link them to a particular practice setting, such as community pharmacies, as pharmacists in many settings were being called upon to transform their roles. Additionally, while both of these early definitions detail the actions or activities with patients or other health providers as the recipients, they lack a description of the intended outcomes of the services.

The list of services that could be described as cognitive services continued to evolve throughout the 1990s, as did efforts to articulate target outcomes of the services. Further complicating efforts to define the term, some authors refer to cognitive services as cognitive pharmacy or pharmaceutical or pharmacist services (Roberts et al., 2006).

The breadth of the definition is noteworthy. Cognitive services are neither constrained to interventions regarding medications nor are they solely concerned with outcomes involving medications (e.g., adherence or side effects). Instead, the term was intended to be more holistic, such that cognitive services encompassed all activities performed by pharmacists (and pharmacy teams) that focused on improving health outcomes for patients.

We appreciate the need for a term to describe emerging services offered by pharmacists and their teams beyond those connected with providing medications to patients. However, we feel that wide-scale use of the "cognitive pharmaceutical/pharmacy/pharmacist services" may be considered suboptimal for at least two reasons.

First, some argue that use of the word "cognitive" inadvertently denigrates services excluded from its definition. It implies that other services rendered by pharmacists or in pharmacies, such as dispensing or compounding of medications, do not require cognitive ability or effort. We know this to be untrue, as processes involved in these services, for example, verifying filled prescriptions for therapeutic appropriateness, are not only vital for patient safety, but are cognitively demanding as well.

Second, there is controversy about whether the term 'pharmacy', 'pharmacist', or 'pharmaceutical' should be used. While seemingly subtle in their differences at the outset, consider the following: "pharmaceutical," in the eyes of some, ties the services unnecessarily to a product. "Pharmacist" may be too limiting as it excludes the contributions of pharmacy team members like pharmacy technicians who provide patient care services (e.g., glucometer teaching, best possible medication history gathering) in some countries. "Pharmacy" may not be optimal either. Advocates for "pharmacy" contend that this is the broadest and thus most inclusive term. However, others are concerned that pharmacy will be interpreted by some to mean "pharmacy" as a physical location, such as a community pharmacy, and may not be inclusive of coworkers practicing in other sites, including hospitals and clinics. The authors of this chapter do not have a resolution for these controversies. As such, our leaning is to instead endorse the term "professional pharmacy service" (Moullin et al., 2013).

Summary

Clinical pharmacy, pharmaceutical care, and cognitive services are terms that have been presented in pharmacy discourse as synonyms for professional pharmacy services. Each term has its own origins, evolution, and finer points of distinction with respect to definitions. A globally accepted consensus-based lexicon for the profession would be useful in many applications. However, we expect that all of these terms will continue to be used within different countries. Our hope is that by articulating these nuances, readers will be better equipped to choose terms that best match their intentions.

Examples of Professional Pharmacy Services

Let us now turn our attention to further appreciating the breadth of professional pharmacy services offered by community pharmacists and their teams across the world. One could quickly become overwhelmed trying to list every service that could fall within this umbrella. Instead, we present categories of services that fall under the PPS umbrella and provide examples within them.

In their paper introducing PPS, Moulin et al. propose two broad categories for PPS, including pharmaceutical services (i.e., those relating to medication therapy) and other health care services (i.e., services not considered directly medication-related, e.g., health promotion). For readers new to the topic of PPS, we felt that a more detailed schema would be helpful. However, when preparing this chapter, we did not identify a single unifying taxonomy for the services that provided the depth we sought. Closest was a scheme proposed by Rotta and coworkers (2015) in their review of systematic reviews of clinical pharmacy services which featured seven categories that we adapted to fit the community pharmacy lens of professional pharmacy services. Most of these categories are consistent with the pharmaceutical services subtype of PPS in the model proposed by Moullin et al. Admittedly, these "categories" may not be comprehensive or all inclusive. As the profession continues to evolve into new avenues, so too will the categories and examples of services within each category.

Patient Education and Counseling (With or Without Medication Dispensing)

Educating patients about their health conditions and the roles for medication as part of their management is a central component of clinical pharmacy practice. Many jurisdictions mandate that pharmacists "counsel" patients (i.e., provide them with information about how a medication works, its intended benefits and potential risks) when a new prescription is dispensed. There are countless studies exploring the nuances of the optimal content, context, and setting in which these interactions between patients and pharmacists are ideally situated. Just as the nature of these interactions with patients are highly valued, so too are the outcomes associated with these activities.

In a systematic review of pharmacy services in low to middle income countries, Pande et al. (2013) found that low to moderate quality evidence from middle income countries suggested many benefits when pharmacists provided education and counseling to people living with chronic conditions (Pande et al., 2013). These included small improvements in health outcomes (including blood pressure and glycemic control) and quality of life, reduced use of health services, and potentially lower medication costs.

Medication Reconciliation

Medication reconciliation is a structured process that begins with interviewing patients and their caregivers to gather a comprehensive medication history. The information gathered through the history-taking process is then verified against other information sources (e.g., prescription vials, pharmacy dispensing records). The health care professional conducting medication reconciliation then takes responsibility for identifying and resolving any discrepancies between information sources. Lastly, a best possible medication history (i.e., a list of reconciled medications) is compiled and shared with the patient and other care providers.

In the institutional setting, medication reconciliation reduces medication discrepancies, adverse drug events, and can lead to detection of drug-therapy problems but impact on readmissions following hospital discharge, length of stay, and mortality is less clear (Kwan et al., 2013; Lehnbom et al., 2014; Mueller et al., 2012). When medication reconciliation is conducted by pharmacists at the time of discharge, reductions in emergency room visits and readmissions are reported (Mekonnen et al., 2016). Improved identification and resolution of discrepancies has also been found when community pharmacists conduct medication reconciliation following hospital discharge, though studies are generally found to be at moderate to high risk of bias and have not examined clinical or health system outcomes (McNab et al., 2018).

Medication Therapy Assessment

Coupled with medication monitoring, assessment services are best envisioned as those aligned with the provision of pharmaceutical care. After medication reconciliation is conducted, pharmacists use their knowledge and skills to assess patients' medications (as they appear on the best possible medication history) to ensure all are indicated, effective, safe and convenient (includes adherence and cost considerations). The names for these services and their exact components vary by jurisdiction and evolve over time. For example, in the United States, medication therapy management is commonly discussed. In Australia, pharmacists are remunerated for conducting home medicines reviews and in New Zealand Medication Use Review (MUR) and

Adherence Support services are offered (Jokanovic et al., 2016). Within the United Kingdom, community pharmacies in England and Wales are remunerated for medicines use reviews while a similar service, the chronic medication service, is remunerated in Scotland (Blenkinsopp et al., 2012).

A detailed review of the evidence at the level of primary studies exploring the impact of medication therapy assessment conducted in community settings on outcomes is beyond the scope of this chapter. An overview of systematic reviews explored clinical, humanistic, and economic outcomes associated with medication review services based on 31 prior systematic reviews of moderate to high quality (Jokanovic et al., 2016). Clinical outcomes (including those associated with medication management; blood pressure, glycemic, and lipid control) were most commonly reported across the reviews and on the whole, reported favorable outcomes. Humanistic outcomes, including medication adherence, quality of life, and patient satisfaction were reported by at least half of the reviews, also with generally favorable outcomes. The impact of medication therapy assessment and monitoring by pharmacists on health care costs were least well explored.

Medication Therapy Monitoring and Follow Up

Monitoring patient outcomes associated with medication therapy recommendations is a key responsibility of pharmacists who accept responsibility for providing pharmaceutical care to patients. Following up with patients about their experiences with changes to their medication therapy allows pharmacists to determine whether their recommendations had the intended positive impact on their patients. This may occur by monitoring therapeutic drug levels, laboratory tests, or discussing expected improvements in signs and symptoms associated with underlying health conditions.

Prescribing

Prescribing is "an iterative process involving the steps of information gathering, clinical decision making, communication, and evaluation, which results in the initiation, continuation, or cessation of a medicine (Weeks et al., 2016)." Pharmacists currently have the legal authority to prescribe medications in a number of jurisdictions, including the United Kingdom, New Zealand, Israel, the United States, and Canada (Hoti et al., 2011; Tonna et al., 2007; Yariv, 2015).

A more fulsome discussion about models of pharmacist prescribing (i.e., independent, dependent, supplementary models, and so on) can be found in Chapter 708: Prescribing. For this discussion, as outlined in the definition provided above, pharmacist prescribing can be thought of as pertaining to three key areas: initiation, management, and cessation of medications.

Initiation of Medications

The decision to prescribe a medication generally follows completion of an assessment by the prescribing health provider. Initiation occurs when a new medication (or one not currently being taken by a patient) is ordered to treat signs and symptoms associated with a particular diagnosis, slow or avoid the progression of a medical condition, or prevent sequelae related to a clinical indication.

Management of Medications

This involves prescribing to ensure continuity of therapy (i.e., renewing or refilling a medication) or changing the dose, route, or formulation of an already prescribed medication (known in some jurisdictions as adapting a prescription).

Cessation

The importance of deprescribing, "the process of withdrawal of an inappropriate medication, supervised by a health care professional with the goal of managing polypharmacy and improving outcomes (Reeve et al., 2015)" is gaining attention globally as one strategy for addressing the complex problem of harm related to use of potentially inappropriate medications. Given their expertise in medication management, many argue that pharmacists are well suited to help patients and other health professionals deprescribe medications.

As the number of jurisdictions with pharmacist prescriptive authority continues to grow, so does the need to evaluate the impact of these services on health outcomes. A Cochrane systematic review included pharmacist prescribing when examining the outcomes associated with medical and nonmedical prescribing on acute and chronic disease management across 46 studies, most of which focused on ambulatory settings (defined by the authors as primary care clinics, medical centers, general practices, hospital outpatient clinics, and community pharmacies) (Weeks et al., 2016). The authors concluded that nonmedical prescribers were comparable to medical prescribers for the management of high blood pressure, hemoglobin A1c for diabetes, high levels of low density lipoprotein cholesterol, adverse drug events, patient adherence to medication regimens, patient satisfaction with care, and health-related quality of life. Note though that the certainty of evidence for all outcomes, except hemoglobin A1c, was rated as moderate or low for varying reasons. For example, the certainty of evidence for blood pressure and lipids outcomes was downgraded to moderate due to considerable statistical heterogeneity and differences in prescribing models, settings (community pharmacies versus primary care settings), and scope of prescribing (initiating versus changing doses). Also, the review did not differentiate between studies featuring nurse and pharmacist prescribing for the purposes of reporting outcomes. As such, the impact of community pharmacist prescribing on outcomes, outside the context of individual randomized controlled trials, is still to be determined.

Randomized controlled trials (RCTs) of interventions featuring prescribing by pharmacists in community settings in Alberta, Canada suggest favorable impacts on glycemic and blood pressure control, achievement of lipid targets, and cardiovascular risk

reduction (Al Hamarneh et al., 2013; Tsuyuki et al., 2015, 2016). How well these interventions translate into real-world practice without the ongoing supports offered in the context of RCTs and whether these interventions lead to long-term impacts on outcomes, including mortality and health system use, are yet to be determined.

Information Provision

Rotta et al. (2015) describes this service as provision of information about medication or medical conditions by the pharmacist to other members of the health care team. In certain jurisdictions, this happens routinely in institutional settings through activities such as interprofessional team discussions and development of clinical protocols. There are examples, though, of health care professionals connected to community pharmacies participating in these activities while providing clients, for example, those receiving home care services or residing in hospices, with health and pharmaceutical information. Another opportunity in this realm involves academic detailing (Jin et al., 2012).

Detection, Prevention, or Control of Risk Factors

Increasing global attention is focusing upon opportunities for pharmacists' roles as public health providers. For those keeping track, this category of PPS services would fall into "other health care services" in the context of Moulin's model.

Health Promotion and Preventative Care

Health promotion occurs when pharmacists partner with patients to modify their health behavior to minimize the risk of disease and promote healthy living. Examples of associated services include (but are not limited to) supporting patients with smoking cessation, body weight management, and cardiovascular risk reduction. A 2016 systematic review explored the effectiveness of community pharmacy-delivered interventions in reduction of alcohol consumption, smoking cessation, and weight management (Brown et al., 2016). There was insufficient evidence to draw conclusions about alcohol reduction but the authors did find that community pharmacy-delivered interventions for smoking cessation are effective and cost-effective when compared with usual care. Despite heterogeneity across interventions types, community pharmacy interventions were reported to be as effective as other short-term primary care-based interventions for weight management with similar costs to comparators.

Immunization

Another public health role for pharmacists is connected with immunization. Pharmacists in Canada, Ireland, Portugal, the United Kingdom, and the United States can administer vaccines as a part of their scope of practice. In other countries, pharmacists may not administer vaccines themselves but serve as facilitators (i.e., by hosting other health professionals authorized to administer vaccines with the goal of enhancing patient access) or educators (i.e., providing education or recommending vaccination) about the importance of vaccination. Based on a systematic review of 36 studies, pharmacist involvement with vaccination, regardless of their role (as facilitators, educators, or administrators) or vaccination involved (influenza, pneumococcal), increased uptake of immunizations (Isenor et al., 2016).

Screening, Detecting, or Monitoring Disease

Another area of expansion for pharmacists' roles in community pharmacies involves screening for detecting and monitoring disease. Well known examples involve screening for hypertension (Kaczorowski et al., 2011), osteoporosis (Goode et al., 2004; Yuksel et al., 2010), cardiovascular disease, and diabetes (Willis et al., 2014). This may involve the use of point of care testing (laboratory testing done within the pharmacy), for example, glycemic control (blood glucose or hemoglobin A1c) (Saldarriaga et al., 2017), lipids (Haggerty and Tran, 2017), or rapid diagnostic testing for infectious diseases including HIV (Weidle et al., 2014), influenza, and group A streptococcus (Klepser et al., 2018). It may also involve use of evolving technology, for example, handheld ECG-devices for detection of atrial fibrillation (Sandhu et al., 2016).

Summary

Professional pharmacy services can be envisioned as consisting of seven categories beyond medication dispensing. Within Moullin's model of PPS, six of these (i.e., patient education and counseling, medication reconciliation, medication therapy assessment, monitoring and follow-up, prescribing, information provision) would be considered pharmaceutical services and one (i.e., services associated with detecting, screening for and preventing risk factors) would fall within other health services.

Implementation of Professional Pharmacy Services

Despite policy changes in recent years that have allowed pharmacists in numerous countries to start offering their patients a variety of professional pharmacy services (PPS), uptake of these services by pharmacists has been slower than expected in most jurisdictions. Implementation of these types of services is an intricate process—one that is often overlooked after new regulations allow them to be delivered by pharmacies. This oversight stems from an assumption that by granting expansions to

pharmacists' scopes of practice and providing general guidelines for their delivery, a practice change and widespread uptake of these services will be observable shortly thereafter (Roberts et al., 2006). This assumption disregards the manifold factors that govern pharmacy's position within the health care system and hold influence over the implementation of change to the profession's practice.

Considerable research has been conducted, primarily through semistructured interviews and focus groups with various stakeholders in community pharmacy, to tease out ways in which the implementation of PPS are enabled or inhibited (Luetsch, 2017). These "enablers and inhibitors of practice change" are frequently referred to in the literature as barriers and facilitators, but as many of these factors exist on continua (e.g., a community pharmacy can be oriented as a profitable business, a health care organization, or anywhere in between) or are binary in nature (e.g., presence or absence of private counseling area within pharmacy), this chapter will refer to each as a determinant of practice (Flottorp et al., 2013).

It is useful to categorize determinants of practice to further describe and conceptualize the magnitude and location of their impact on implementation of change in pharmacy practice. Again, several frameworks have been proposed to guide this categorization, but this chapter has chosen to ascribe each determinant of practice to one of the following levels: individual, interpersonal, organizational, or health care system. These categories are an adaptation of those first presented by Hossain et al. (2017), and best describe both the determinants of practice and where to target interventions aimed at addressing them (Hossain et al., 2017a). Of course, real world application of such organized thinking rarely allows for tidy categorization. Thus, some of the determinants of practice discussed in this chapter are connected to, and influenced by, one another across levels of our framework.

Individual Determinants

Determinants of practice that exist on an individual level are those that involve the beliefs, abilities, and characteristics of any person-possessing agency in the implementation of PPS in practice. These focus primarily on the characteristics of individual pharmacists, but also extend to those of patients, physicians, and other health care providers, and people involved in shaping health care policy. One of the most commonly identified individual-level determinants of practice is a pharmacist's attitude toward a particular PPS (Luetsch, 2017; Roberts et al., 2006). This has been demonstrated in both positive and negative capacities. Some pharmacists sincerely believe in the benefit that a PPS is providing to their patients or to the health care system, and are more likely to incorporate it into their practice; other pharmacists harbor doubt surrounding the PPS's value and are therefore less likely to invest the effort required to offer it to their patients. Identifying at least one staff pharmacist who is enthusiastic about the utility of a PPS to help lead its implementation in a pharmacy has been suggested as a potential way to overcome apathy and negative perceptions of it among other pharmacy staff (Roberts et al., 2006). Of course, having pharmacists who wish to provide the PPS under their own volition will likely result in more sustained and engaged participation, which is why demonstrating the benefits of a PPS can also be a useful intervention to improve the attitudes of pharmacists while implementing a PPS (Gastelurrutia et al., 2009). Typically, prior to initiation of a PPS on a large scale there are pilot studies and controlled trials that investigate the PPS's value and generate objective data supporting its utility. This information can be leveraged to persuade pharmacists and other frontline staff of the quality of a PPS and the importance of its uptake.

Two related determinants of practice also attributed to an individual pharmacist are the pharmacist's competence in providing a given PPS, as well as their confidence in doing so (Hopp et al., 2005; Luetsch, 2017; Roberts et al., 2006). If pharmacists lack the ability to competently provide a PPS then the service may not achieve its desired effect even if it is performed (e.g., a pharmacist conducting an incomplete medication review may overlook crucial drug therapy problems). If pharmacists lack confidence in their own ability to provide a PPS, then they may be unwilling to offer a potentially beneficial service to their patients. Similarly, the attitudes of physicians and patients about the service, as well as their opinions of pharmacists' competency, influence their willingness to refer to or participate in the service being offered (Hossain et al., 2017a; Hossain et al., 2017b). Qualitative interviews conducted with community pharmacists and physicians in Indonesia, for example, revealed discordance between the two groups of health care providers: all pharmacists included in the interviews believed that they should offer additional services beyond medication dispensing, while the majority of physicians interviewed felt that pharmacists' roles should extend no further into patient care (Wibowo et al., 2016). Interestingly, there was more agreement between the pharmacists and physicians regarding the competence of the pharmacists in providing patient care: neither group exhibited confidence in pharmacists possessing the requisite clinical knowledge for a greater role in health care delivery. This phenomenon is demonstrative of the fact that pharmacists often have the attitudes required to support the delivery of PPS in that they are willing. However, a positive attitude is sometimes not enough to overcome some of the other barriers that may impede the uptake of a PPS.

Pharmacist training, then, can be an important part of the implementation process for PPS (Feletto et al., 2010; Hopp et al., 2005; Hossain et al., 2017a; Luetsch, 2017; Wibowo et al., 2016). Numerous studies involving didactic and interactive educational sessions delivered to pharmacists in preparation for their positions in the delivery of a PPS suggest that this training helps to improve the uptake and implementation of the PPS. These educational sessions often focus on the diagnosis and treatment of specific disease states, up-to-date treatment guidelines, and clinical skills such as problem solving and communication (Patwardhan et al., 2014). Continuing education credits or other incentives were sometimes awarded to increase participation in these sessions, which were most effective when facilitated by clinical pharmacists who were not affiliated with the practice sites where the PPS was being implemented. The need for ongoing support and training was highlighted in a number of studies as an integral feature of interventions that resulted in more sustained uptake and implementation of the PPS (Roberts et al., 2006).

These individual-level determinants of practice are closely tied in with both physicians' and patients' perceptions of the role of pharmacists within the health care system, which are related to how the scope of practice for pharmacists has evolved over time. Some physicians and patients may be acutely aware of the expanding role of pharmacists in the delivery of health care—expansion that has seen them become a more integral player in optimizing patient outcomes and health care system usage—and these physicians and patients may be more likely to become actively engaged in various PPS than those that think of community pharmacies as medication dispensing-oriented retail businesses. These perceptions may even be accurate in the context of one pharmacy, but inaccurate about another a short distance away, as the professional orientation of the pharmacy owner largely determines whether the pharmacy is organized as a retail destination or as a destination for the delivery of health care (Hopp et al., 2005). This illustrates a distinction between pharmacists' positive attitudes toward PPS and sometimes the fixed attitudes that many pharmacists and pharmacy owners have about making changes to the way they practice. Despite evident enthusiasm from pharmacists for expanded clinical involvement, as in Indonesia and many other parts of the world, qualitative interviews with community pharmacists and pharmacy strategists in Spain demonstrated that pharmacists' negative attitudes about changing roles in health care are a determinant of practice that is currently impeding pharmacist uptake of PPS (Gastelurrutia et al., 2009). Practice change is not an easy or quick process. When imperatives from pharmacy owners are incongruent with the enthusiasm that staff pharmacists hold for PPS delivery, pharmacists may look for ways to increase efficiency in other areas of their practice so that they can undertake new PPS (Luetsch, 2017). An important tension arises when additional operational efficiencies are not easily identified or implemented which preclude pharmacists providing services they wish to offer.

Interpersonal Determinants

Interpersonal-level determinants of practice describe the relationships and interactions between all of the individuals mentioned previously. These determinants of practice are often intricately intertwined with those at the individual level. An example is how a nurse's perception of a pharmacist's competence would impact (either positively or negatively) the level of trust, communication, and collaboration between the nurse and pharmacist, likely influencing the nurse's perception of the pharmacist's role in the health care system and engagement in a PPS (Roberts et al., 2006). The existing relationship and the amount of trust between pharmacists and patients, again largely influenced by how their shared experiences in the past have shaped their perceptions of one another, are other common interpersonal-level determinants of practice (Hossain et al., 2017a; Hossain et al., 2017b). In countries, such as Indonesia or India, where the introduction of PPS is in its infancy and community pharmacies are very much medication dispensing- and retail-oriented businesses, neither physicians nor patients perceive them as health care destinations, but rather as storefronts attempting to turn a profit (Wibowo et al., 2016). These perceptions can become self-fulfilling prophecies that impede practice change and make it difficult for pharmacies to create demand for PPS.

Even interactions between patients and health care providers outside of the pharmacy setting can affect engagement in a PPS, such as when poor communication between a prescriber and patient results in inappropriately prescribed medications that necessitate a pharmacist's intervention (Hossain et al., 2017a). Communication is integral to any interpersonal relationship, which is why having formalized systems in place for communication between health care providers is another commonly cited interpersonal-level determinant of practice. Having systems in place that encourage both verbal and written communication between pharmacies and their local network of health care providers can enhance collaboration and engagement in a pharmacy's provision of a PPS, including referral into a PPS program and feedback from the pharmacy to the referrer about its impacts on the patient's health (Hopp et al., 2005; Hossain et al., 2017b). Established examples of systems to enhance collaboration between pharmacies and prescribers include both supplementary prescribing in the United Kingdom and collaborative practice agreements in the United States (Patient Access to Pharmacist's Care Coalition, 2015; Pharmacist Prescribing Task Force, 2010). These programs involve formalized agreements between pharmacists and physicians that use their respective medication and diagnostic expertise. Physicians assess the patient and formulate a care plan that is then implemented and managed by the pharmacist, possibly including the prescribing and monitoring of medication therapy. The enhanced clinical involvement in patient care that is afforded to community pharmacists by programs such as these both facilitate, and are facilitated by, strong lines of communication between health care providers. A similarly collaboration-centric model was used by Chen et al. (1999a,b) where a multidisciplinary group of pharmacists and physicians was formed to guide the implementation process for a PPS, from development to practice (Chen et al., 1999a,b). This group remained active even after the study ended, and led to the sustained implementation and delivery of the PPS.

Standardized communication mechanisms between health care providers would also help ensure at least some degree of accessibility of each health care provider to the other. The availability of prescribers to pharmacies, which is a concern given frequently heavy workloads, can be a deciding factor in the ease and amount of collaboration between them. Similarly, the degree of accessibility of patients to pharmacies also plays a role in governing the uptake of a PPS. Frequent, in-person patient visits (rather than by telephone, or through caregivers) help increase use of PPS. So too does being the sole provider of pharmacy services to a patient, rather than being one of several pharmacies caring for them.

Education and training that focuses on multidisciplinary collaboration and communication skills are commonly suggested interventions for improving performance in interpersonal determinants of practice (Hossain et al., 2017a; Luetsch, 2017). This can be done by including interprofessional elements into training sessions for delivery of the PPS, continuing professional development events, or within undergraduate curricula. Similar initiatives that emphasize a patient-centered approach to health care and communication are useful for enhancing pharmacist–patient relationships and the ability of pharmacists to provide care.

Organizational Determinants

Aspects of the pharmacy setting, such as its physical environment, organizational structure, policies and procedures comprise the organizational-level determinants of practice. Of these, staffing levels and pharmacist workload are among the most commonly described factors that either hinder or enhance the uptake of a PPS at a particular pharmacy. A key determinant of practice, then, is the degree to which a pharmacist is permitted to delegate PPS duties including compounding and dispensing medications to pharmacy assistants and technicians. In certain countries, such as Germany and Canada, pharmacy technicians must complete formalized training and licensure programs before becoming eligible to perform delegated acts in a pharmacy. This extensive preparation positions pharmacy technicians as heavily-relied upon contributors to the operations of a community pharmacy—coworkers to whom pharmacists can delegate a variety of tasks to free themselves for provision of certain PPS that require pharmacists' unique knowledge and skills. An example of successful delegation from the institutional setting is the involvement of pharmacy technicians in medication review and reconciliation programs in hospitals. When performed by technicians, these tasks, traditionally the responsibility of pharmacists, reduce medication discrepancies during transitions of care to the same degree as pharmacist-led programs (Mekonnen et al., 2016).

This is not limited to technicians practicing in institutions. Delegation is used advantageously in community pharmacies in the United Kingdom and parts of the United States where pharmacy technicians can become certified to check the technical accuracy of dispensed prescriptions before they are released to the patient, thereby providing the pharmacist with more time to participate in the PPS that require their unique skill sets and clinical knowledge. A pharmacy that has only a few staff members present at a time, however, may rely heavily on the pharmacist playing a part in the functions of medication dispensing (i.e., preparing packaging, confirming accurate dispensing) that could otherwise be delegated, leaving minimal remaining time for PPS that require pharmacists' expertise. In this scenario, it is evident that distribution of duties within a pharmacy is a major organizational-level determinant of practice. Noteworthy, though, is that delegation is imperfect in many settings: even if a pharmacy has numerous technicians and assistants who are capable of handling all dispensing-focused PPS, many jurisdictions (e.g., Australia, Canada, UK, and many other countries with established health care systems) require pharmacists to perform the final clinical check of a prescription before it can be dispensed to a patient (Koehler and Brown, 2017; Moleschi et al., 2009; Pharmacy Board of Australia, 2015; Quaye, in press). If this pharmacy processes a high number of prescriptions per day then it may still be difficult for the pharmacist to devote time to nondispensing PPS despite adequate staffing levels. A solution to this problem, then, may be to shift to a pharmacy model that employs proportionately more pharmacists to engage in the provision of clinical care, increasing the likelihood of successful implementation of nondispensing PPS. The operating costs associated with paying pharmacists wages would undoubtedly be higher, but could be offset by an increase in sales and patronage due to greater involvement of pharmacists with patients and an improved public image (Feletto et al., 2010).

While usually somewhat regulated across a country or territory, small differences in the physical layouts of pharmacies, including immunization booths and private areas for patient interviews or counseling, can facilitate or impede the provision of certain PPS. This was another common theme that emerged from the interviews conducted by Gastelurrutia et al. (2009), with both pharmacists and pharmacy strategists identifying a "need to change the structure of pharmacies (larger in size, having more pharmacists per pharmacy, and private areas for patient care)" to facilitate the implementation of nondispensing PPS (Gastelurrutia et al., 2009). The same is true about the technology and automated systems used in pharmacies; how the increased efficiency that is afforded by this technology is used (i.e., to free up more time for the provision of clinical PPS or to increase the number of prescriptions filled) is a related organizational-level determinant of practice. The way technology is used may also say a lot about the orientation and setup of the pharmacy, positioning itself somewhere on a spectrum between a profitable business that focuses on dispensing and front shop merchandising, to a health care destination that offers a comprehensive suite of health services. This organizational-level determinant, of course, will largely be influenced by the individual-level professional orientation of the pharmacy owner, but will also be shaped by local health care policy and regulations, the orientation of the pharmacy staff, and demand from the community.

Given that community pharmacies in most health systems are retail stores, the financial resources available to a pharmacy are a major organizational-level determinant of its ability to provide a PPS. A large pharmacy, or a banner group or chain of stores, will typically have far greater financial resources at their disposal than smaller, single location (sometimes called "independent") pharmacies. This provides larger pharmacies with added adaptability to change scopes of practice for pharmacists, such as by hiring additional staff or purchasing the equipment required to provide a new PPS. These resources can also be used to market or advertise a new service to the public, increasing community engagement, demand, and utilization of a PPS. Marketing a PPS differs from marketing other products in that pharmacists must be able to educate patients, as well as other members of the supply chain (i.e., prescribers and other health professionals) about the value of the PPS (Roberts et al., 2006). Engaging both stakeholder groups is necessary for optimal uptake of the PPS, however focus should be toward the general public so that a demand for the service is cultivated and the public's new expectations of pharmacists stimulate a change in pharmacy practice.

Health Care System Determinants

The influences of the jurisdiction in which the PPS is being delivered, that is, the broad political and social norms and regulations that impact the context of the PPS, are referred to as the health care system-level determinants of practice. These are overtly reflected in a jurisdiction's existing health care policies and health system structure.

One of the more common high-level factors affecting implementation of PPS that pharmacists discuss in the qualitative literature, understandably, is the reimbursement schedule for various PPS. Given that reimbursement often lags behind provision of the services, this is often touted as a major barrier for PPS implementation. There is a considerable geographical variability in the amount of compensation pharmacists receive for their services, with full reimbursement schedules established in certain regions and then others where pharmacists receive little or no pay for services beyond medication distribution (Wibowo et al., 2016). In Spain, there is a common feeling among community pharmacists that their reimbursement system requires substantial overhaul that decreases the revenue that pharmacies can generate through dispensing and increases the income from the delivery of other, clinically-focused PPS (Gastelurrutia et al., 2009). This is especially true when the administrative workload associated with PPS delivery that is required by some pharmacy regulatory agencies results in a decreased capacity for pharmacists to engage in other revenue-generating tasks for the pharmacy.

The dichotomy between how existing reimbursement schedules benefit individual pharmacists versus how they benefit the pharmacy owners must also be considered. A payment scheme that reflects the actual work being done (i.e., that favors the pharmacist providing the PPS) in the delivery of a service may be a greater impetus for the implementation and uptake of PPS (Roberts et al., 2006).

However, despite what pharmacists divulge in interview-based studies, numerous reviews of the literature have demonstrated that reimbursement alone does not result in sustainable uptake of newly implemented PPS (Hersberger and Messerli, 2016; Patwardhan et al., 2014). Contributing to this, perhaps, is that even when reimbursement schedules are established for nondispensing PPS, they often still lag behind the profitability of dispensing medications.

Australia took a dramatic approach to level the reimbursement for the two groups of pharmacy services: markups on prescription products were eliminated at the same time that the funding available for PPS was doubled (The Commonwealth of Australia and The Pharmacy Guild of Australia, 2015). In New Zealand, a new community pharmacy reimbursement schedule combines the existing fee-for-service payment structure with a funding model that rewards pharmacist involvement in the care of complex patients, incentivizing the use of their pharmaceutical expertise and their participation in PPS (Napier et al., 2018).

As reimbursement alone does not appear to drive successful implementation of PPS, other health care system-level determinants of practice must be considered. Public, health care authority, and overall health care professional awareness of the PPS and its benefits has a dramatic impact on its implementation and success. Of course, the quality of the PPS itself, both in terms of its impact on clinical outcomes and its cost-effectiveness, play a role in raising awareness of the service and obtaining buy-in to its uptake. How these costs are covered, that is, by third party payers or as out-of-pocket expenses paid by patients, partially determines public engagement. The same is true of whether a newly implemented PPS addresses a gap in health care, or if it merely presents an alternative method for a preexisting process.

The ideal PPS, then, provides an innovative way to efficiently improve patient health at little or no cost to patients; the ideal PPS creates its own publicity and demand and easily overcomes any health care system-level barriers to its implementation. The ideal PPS also does not exist. For this reason, another hugely important health care system-level determinant of practice is support for the PPS and its implementation from professional pharmacy advocacy bodies. The power that these professional organizations possess is often vital for fostering collaboration in a PPS from health care authorities and other health care professionals and their respective advocacy groups. Some contend that collaboration is best negotiated through professional organizations rather than by individual practitioners (Luetsch, 2017). Using these relationships, agreements form that lead to the development of useful tools for expanding pharmacy's involvement in clinical care, such as sharing of patient information and laboratory values with community pharmacists.

Through such partnerships between governing bodies and pharmacy professional organizations, regulatory frameworks are formed that facilitate greater involvement of pharmacists in health care and delivery of PPS. An example of such collaboration exists between the federal government of India and pharmacy professional groups, who have partnered on clinical pharmacy pilot programs that draw on the skills that pharmacists have learned in the Doctor of Pharmacy program introduced in 2008 (Cipolle et al., 2012).

Education is another way in which pharmacy advocacy groups can support the enhancement of the profession. After identifying a lack of clinical education for community pharmacists as a barrier for the successful implementation of PPS, the Swiss Association of Pharmacists sponsored professorships in the pharmacy programs at universities in Basel and Geneva for 5 years to increase the quality and amount of clinical, patient-oriented teaching that pharmacy students received (Hersberger and Messerli, 2016).

Lack of clinical education is not isolated to Switzerland, however, as pharmacy education appears to lag behind the evolution of the profession, and often does not reflect the increasing international emphasis on the benefits of clinically oriented PPS. Pharmacists in Vietnam, Egypt, and China, for example, all receive an education that focuses on basic sciences and the traditional compounding and dispensing roles of pharmacists (Cipolle et al., 2012; Vo et al., 2013). Further impeding the implementation of PPS in China, it is forecasted that, due to the success of their pharmaceutical industry, pharmacy curriculum will begin to feature manufacturing and marketing components rather than shifting to a focus on patient-centered care and clinical skills (Hu et al., 2014).

As in Switzerland, pharmacy professional organizations in these countries will likely have to play a role in reshaping the undergraduate education that pharmacists receive to better prepare them for the increasing clinical expectations of pharmacies around the world. This reconfiguration would benefit from an emphasis on multidisciplinary education sessions and practical rotations that place pharmacy trainees into the collaborative and patient-centered situations they will face upon becoming a member of the profession (Gastelurrutia et al., 2009; Luetsch, 2017; Vo et al., 2013).

University curriculum, however, is not the only way in which pharmacists receive instructional support for the delivery of PPS; in-practice training and clinical coaching are other commonly employed methods for improving these skills. Again, these programs are often facilitated by pharmacy professional groups. The availability of both pregraduate and continuing professional development that equips pharmacists with the practical skills they need to provide PPS is a key health care system-level determinant of practice.

Summary

Enabling and inhibiting factors that influence the uptake of professional pharmacy services by pharmacies, pharmacists, other health care professionals and members of the public are frequently referred to in the literature as barriers and facilitators. However, as many of these factors exist on continua or are binary in nature, we opted to refer to each as a determinant of practice. Four levels of determinants of practice were discussed including individual, interpersonal, organizational, and health care system.

Conclusions

Professional pharmacy services describes services for individual patients or populations that require health care professionals connected to community pharmacies to apply specialized health knowledge with the aim of optimizing health outcomes and values in the health system. Related terms that are commonly used in the literature, including clinical pharmacy services, pharmaceutical care, and cognitive services have relative merits and drawbacks. To enhance the readers understanding of the breadth of services encompassed under the umbrella of professional pharmacy services, seven categories of services were presented and associated evidence of their impact discussed when it was available. Lastly, factors impacting the implementation of professional pharmacy services at the individual, interpersonal, organizational, and health system levels were presented to illustrate the complexity of implementation.

Prescribing: Practices, Standards, Ethics, Behaviors, and Competencies: A Case Study in Alberta

Lisa M. Guirguis*, Chowdhury F. Faruquee*, Jennifer E. Isenor†, *University of Alberta, Calgary, AB, Canada; †College of Pharmacy, Dalhousie University, Halifax, NS, Canada

Introduction

"The doctor knows that it is the prescription slip itself, even more than what is written on it, that is often the vital ingredient for enabling a patient to get rid of whatever is ailing him" (Cousins, 1979).

The ability to prescribe has a powerful place in medical practice" (Cousins, 1979). In some countries, prescribing has been restricted primarily to physicians. In other parts of the world, citizens are able to select their own medication therapies using healthcare practitioners to guide choices at the citizen's discretion (Erku et al., 2016; Sakeena et al., 2018). Overall, citizens' access to prescription medication has been expanding (Bennadi, 2013). First, an increasing number of medications that were once prescription have been designated as non-prescription, allowing for citizen self-selection (Mahecha, 2006). Secondly, non-physician prescribers such as nurses, physiotherapists, chiropodists/podiatrists, radiographers, optometrists, and physician assistants have been granted prescribing privileges (Cope et al. 2016). Considering the elderly population, scarcity of physicians in some locations, increased healthcare cost, inflexibility of the healthcare system, and the challenge of chronic disease management, governments have expanded prescribing for non-medical healthcare providers so that they can use their expertise to address the increased demand for healthcare services. As a result, pharmacists around the world have obtained prescribing privileges (Emmerton et al., 2005).

Pharmacists have unique medication knowledge that should be harnessed to improve patients' access to medications and improve health system efficiency. Health care systems are not only striving for efficiencies but striving for ways to enhance the patient experiences. Enabling patients to choose where they access their prescribing needs can improve that patient experience. A recent systematic review found that non-medication prescribers including pharmacists, were as effective as usual care medical prescribers (Weeks et al., 2016). In this chapter, pharmacist prescribing will be characterized including prescribing practices, standards, ethics, behaviors, and competencies with a focus on the experience in Alberta, Canada. Alberta has a broad range of prescribing privileges that are unique in North America.

Pharmacy Prescribing Practices

The varying forms of pharmacist prescribing practices can be characterized by the level of autonomy and the type of prescribing activity.

Prescribing Autonomy: Independent or Dependent

The autonomy of pharmacist prescribing is broadly characterized by independent and dependent models. Independent prescribing is recognized by a regulatory authority and requires a prescriber to assess and manage the patient without the supervision of another healthcare professional. Independent prescribing does not require the pharmacist to diagnosis a patient (Emmerton et al., 2005). Note, this does not preclude collaboration with other prescribers in order to ensure pharmacists have complete information and are acting in the patient's best interest. Independent refers to the authority to prescribe and does not require care be provided in the absence of other providers. Collaboration has been recognized as a key component in independent prescribing models (Yuksel et al., 2008). The second form is dependent prescribing which requires the supervision of another healthcare professional. This

supervision could be at the individual or jurisdictional level. The authority to prescribe is granted by another prescriber. There are many forms of dependent prescribing that vary depending on the level of supervision and reliance on a formal protocol (Emmerton et al., 2005).

The most common forms of dependent prescribing are supplementary, collaborative, and protocol prescribing where pharmacists are allowed to prescribe a medication subject to a protocol and supervision of a prescriber such as a physician (Emmerton et al., 2005; Tonna et al., 2008). In supplementary prescribing, the agreement is generally limited to a patient-specific clinical management plan that is agreed by the prescriber and patient. Collaborative prescribing models require a relationship between a pharmacist or group of pharmacists and a prescriber group. Pharmacists are allowed to prescribe for a group of patients in collaboration with an individual prescriber or group of prescribers. Collaborative drug therapy management has been defined as "a collaborative practice agreement between one or more physicians and pharmacists wherein qualified pharmacists working within the context of a defined protocol are permitted to assume professional responsibility for a variety of functions, including patient assessment; ordering drug therapy-related laboratory tests; and selecting, initiating, monitoring, continuing and adjusting drug regimens" (Hammond et al., 2003). In prescribing by protocol, pharmacists provides care following a detailed protocol outlining the process of prescribing. A typical example is pharmacist management of aminoglycosides by a standing order in a hospital.

Prescribing Activities

A second way to categorize pharmacist prescribing is by activity which include: extending a prescription, adapting or modifying a prescription, prescribing for minor ailments, and initial access prescribing. In prescribing for refills or extension, pharmacists prescribe to continue or extend an existing prescription without altering the original prescription or directions.

A second form of prescribing is adapting or modifying a prescription initiated by another prescriber based on pharmacists' patient assessment. For example, a pharmacist may alter the dose of a prescription based on a patient's organ function, substitute dosage forms based on patients' preference or availability, or make a therapeutic substitution. The intent of the prescription remains the same, but the prescription is modified and signed in the pharmacist's name.

The third activity is prescribing for common or minor ailments which are conditions that do not require laboratory tests for diagnosis and do not mask more serious conditions (Lee and McCarthy, 2015). While prescribing for minor ailments is the internationally used term, some believe minor is demeaning as it implies less important conditions or patient's issues are of lesser concern (Taylor and Joubert, 2016). In place, pharmacists may prescribe medications which commonly have evidence for efficacy, a wide safety margin, self-diagnosed or self-limiting disease conditions, and straightforward self-care management (Taylor and Joubert, 2016). Lab tests and long-term follow-up are not required to prescribe (University of Saskatchewan, 2015).

Common examples where a pharmacist prescribes for common ailments are cold sores, allergic rhinitis, and oral thrush.

Finally, pharmacists can prescribe for initial access or to manage ongoing therapy without delegation (Law et al., 2012). This form best mirrors typical physician prescribing activities. This may include narcotics and controlled substances as designated by justification.

The Intersection of Autonomy and Activities

The level of prescribing autonomy and type of activities overlap (Fig. 1). Different pharmacists may perform the same activity with different levels of autonomy. For example, a pharmacist may have either independent or dependent authority to renew a medication refill. The act of writing the pharmacist's name on the physical prescription for the refill is the same, and the pharmacist may provide

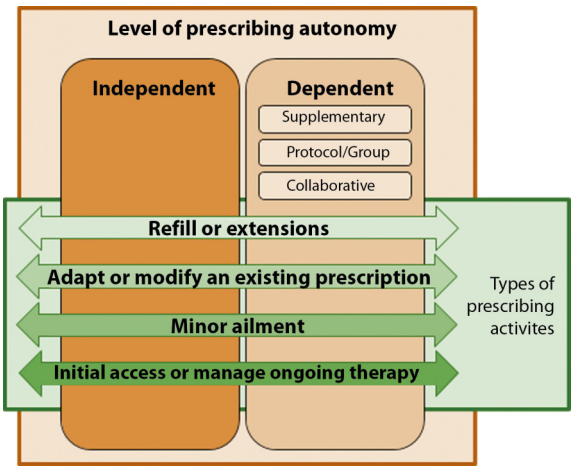

Figure 1 Intersection of pharmacist prescribing activities and degree of autonomy.

similar care to the patient, but the regulations that enable the pharmacist to require different levels of oversight. Conversely, a pharmacist may have a collaborative working agreement with a physician which allows them to initiate a new prescription and authorize refills. The complexity of the prescribing activity may vary, but both activities required a physician's protocol. Further examples on the intersection of autonomy and activities will be provided on the next section on the evolution of prescribing.

Evolution of Prescribing Standards

Pharmacist prescribing has been described as an evolution, not a revolution (Pearson, 2007). The practice of pharmacy has evolved from the initial compounding of medications for individual patients. With the advent of medication manufacturing in the 1950s, the pharmacist role moved to focus on medication distribution. Starting in the 1960s, Brodie documented the rise of clinical pharmacy with a focus on therapeutic drug monitoring and clinical services, predominating in hospital pharmacies. In the 1990s, pharmaceutical care characterized a practice that placed patients at the center of care. In the early 21st century, patient centered-care became the most common term to describe ideal pharmacist practice. The shared language with other professions highlights the inherent overlap in patient care activities. Pharmacists, nurse, and physicians all practice patient care activities around the selection, provision, and monitoring of medication therapy. Prescribing is a natural extension of these care activities and allows for a nimble health care system that can respond to patient needs.

Internationally, pharmacist's scope of practice has been expanding during the last two decades (Latter and Blenkinsopp, 2011; McBane et al., 2015; Raghunandan et al., 2017; Stewart et al., 2017). Pharmacist prescribing was first documented and operationalized in England and the US. England was the forerunner in this area and implemented supplementary prescribing rights in 2003 and independent prescribing rights in 2006 (Latter and Blenkinsopp, 2011). Independent nurse prescribing was sanctioned in several pilot sites in England, and eventually, the success of the pilot project enabled expansion to all nurses in England in 2001 (Cooper et al., 2008). In 2003, further changes in policy approved supplementary prescribing by trained nurses and pharmacists which allowed them to prescribe under the supervision of an independent prescriber, typically a physician. Physiotherapists, chiropodists/podiatrists, radiographers, and optometrists received similar prescribing authority in 2005. Legislation approved independent prescribing for both nurses and pharmacists in 2006 (Cooper et al., 2008). Pharmacists who prescribe independently are solely responsible to assess, initiate and manage medical conditions in different settings. In Scotland, pharmacist prescribing rules are similar to England (Stewart et al., 2017).

In the United States, pharmacist prescribing has been part of collaborative drug therapy management (CDTM) since 1979 (McBane et al., 2015). Pharmacists are allowed to prescribe drug therapy under the delegated authority of a physician (Hill et al., 2016). As a part of CDTM, pharmacists may order laboratory tests, assess patients, initiate and modify drug therapy, monitor patients, and administer drugs (Carmichael et al., 1997). Approximately 48 states permit some type of pharmacist prescribing, though the level of authority varies in each state's CDTM legislation (Centers for Disease Control and Prevention, 2017). The independent prescribing model was first introduced in a Florida Veterans Affairs' outpatient clinic and is found predominantly in the Veteran Affairs system (Ukens, 1997).

Pharmacists in New Zealand are also involved in collaborative prescribing (Pharmacy Council of New Zealand, 2013). Pharmacists are allowed to modify and initiate therapy associated with assessment and interventions in a collaborative health team environment. Australian pharmacists are eligible to prescribe specific over the counter medications and ensure a continuous medication supply by prescribing an "emergency prescription" or "repeat prescription" (Hoti et al., 2011). Australian pharmacists can prescribe medicines for minor ailments (e.g., non-sedative antihistamine, nasal spray containing steroids) as well as pharmacist only medicines (e.g., pseudoephedrine, salbutamol) which require a pharmacists' advice and follow-up. Finally, Australian pharmacists prescribe to extend a prescription provided by an authorized prescriber for up to one year.

In the last ten years, provinces in Canada have introduced different policies regarding the extended scope of pharmacy practice, mainly focused on prescribing activities (Emmerton et al., 2005). As pharmacists' scope of practice falls under provincial jurisdiction, prescribing authorities vary across Canada. Pharmacists can prescribe schedule 1 drugs (i.e., prescription only medications), except narcotic and controlled drug (i.e., opioids and its derivatives, barbiturates, and benzodiazepines) with a few provincial exceptions for seizure medications (Law et al., 2012). A summary of these evolving policies is maintained by the Canadian Pharmacists Association at: https://www.pharmacists.ca/pharmacy-in-canada/scope-of-practice-canada/. The following prescribing activities are considered independent prescribing unless otherwise noted.

Renewing prescriptions: Pharmacists in all ten provinces and one territory (i.e., Northwest Territory) can renew or extend it for continuity for up to three months as per provincial regulations (Canadian Pharmacists Association, 2017).

Modify or adapt an existing prescription: Pharmacists in all provinces are allowed to adapt a prescription by changing the dosage, formulation or regimen if needed (Canadian Pharmacists Association, 2017). Pharmacists can make therapeutic substitutions in all the provinces except three (i.e., Ontario, Manitoba, and Quebec) (Canadian Pharmacists Association, 2017).

Prescribing for minor ailments: Pharmacists prescribe for minor ailments and smoking cessation in all provinces except two (i.e., Ontario and British Columbia) (Canadian Pharmacists Association, 2017). Pharmacists in two provinces required additional training or authorization.

Initiating new prescription: There are two forms of independent prescribing—initiating a prescription and emergency prescribing. Pharmacists in four out of ten provinces can initiate a new prescription within a collaborative agreement (i.e., Saskatchewan, Manitoba, New Brunswick, and Nova Scotia) (Canadian Pharmacists Association, 2017). Albertan pharmacists with additional

prescribing authority can initiate a new prescription independently (Yuksel et al., 2008). Pharmacists in three provinces require additional training or authorization (Canadian Pharmacists Association, 2017). In six out of ten provinces (i.e., Alberta, Saskatchewan, Manitoba, New Brunswick, Nova Scotia, and Prince Edward Island) pharmacists can provide emergency supplies of prescribed medication when the patient does not have access to medical care but requires immediate attention (Canadian Pharmacists Association, 2017).

In Canada, pharmacist prescribing is guided by several professional components. Pharmacists must maintain a professional relationship with both patients and other healthcare providers. Pharmacist prescribing should be in the patient's best interest and not for their (i.e., pharmacists') own family members. Pharmacists need to maintain competence, have sufficient clinical knowledge, apply practice evidence, and prescribe for approved indications (Canadian Pharmacists Association, 2017). Prescribing decisions and their rationale should be documented and conveyed to other healthcare professionals involved in a patient's care (Yuksel et al., 2008).

Alberta was the first jurisdiction in Canada, to authorize pharmacist prescribing (MacLeod-Glover, 2011). Albertan pharmacists acquired this approval in 2007 under several timely and positive influences which included re-designation of scope of practice for all healthcare providers, support from the Alberta College of Pharmacists, a robust platform of pharmacists' knowledge and skill supported by the pharmacy education program, independent research support, and a requirement for timely and fair access to health care services (MacLeod-Glover, 2011). Pharmacists with additional prescribing authorization can initiate a new prescription independently or in collaboration with another health care provider after appropriate assessment within their limit of competency at the point of access (MacLeod-Glover, 2011). To receive this special authorization of prescribing, pharmacists have to submit a comprehensive application to the ACP providing evidence of quality patient care (Alberta College of Pharmacists, 2017b). In this application, pharmacists must demonstrate the ability to build a relationship with a patient, assess patients' needs, develop a care plan with appropriate follow-up, collaborate with other healthcare professionals, document patient care, and apply sound judgment.

Prescribing Ethics

The act of prescribing is an extension of the care pharmacists already provide to their patients. In Alberta, the Code of Ethics states that pharmacists must act in the best interests of the patient, maintain a professional relationship, and practice within their own competence (Alberta College of Pharmacists, 2009). The act of recommending non-prescription medications would require the same ethical duty of care as prescribing a new therapy. As such, the ethics of pharmacist prescribing are not explicitly raised in documents such as the Code of Ethics in Alberta (Alberta College of Pharmacists, 2009) or Standards for Pharmacy Professionals in the UK (General Pharmaceutical Council, 2017). Despite this, three issues around the ethics of pharmacist prescribing commonly arise: 1) ensuring patient consent for pharmacist prescribing, 2) separation of pharmacist prescribing and dispensing activities, and 3) perception of prescribing for financial gain.

Prescribing is a medical intervention, and as such, pharmacists must clearly seek the patient's voluntary consent. The patient must be informed and have the capacity to consent. Patients are often unaware of pharmacist practice beyond filling a prescription and may not be familiar with pharmacists' scope of practice (Faruquee and Guirguis, 2015; Perepelkin, 2011). Thus, pharmacists must use clear and specific language to explain pharmacist prescribing and ensure the patient understands the options. In the case of prescribing in Alberta, pharmacists are required to obtain patients informed consent to prescribe, but documentation of consent is not required (Alberta College of Pharmacy, 2018).

The second issue is the separation of prescribing and dispensing. Many prescribing standards or guidelines suggest the same pharmacist should not prescribe and dispense a medication unless in urgent situations (General Pharmaceutical Council, 2017; Kaae et al., 2011; Pharmaceutical Society of Northern Ireland, 2013). The rationale being that a pharmacist's role at the time of dispensing is to complete a second check for the effectiveness and safety of medications for individual patients. Physicians typically do not dispense in North America. In other jurisdictions, legislation has been put in place to separate physician prescribing and dispensing to remove any monetary incentive to prescribe medications (Chou et al., 2003). Thus, it seems contrary for prescribing pharmacists to dispense a medication they prescribed. Yet, pharmacists have been navigating the space for decades. In the case of minor ailments, pharmacists have been making recommendations for nonprescription medications and then providing the product—the equivalent of prescribing and dispensing.

In Alberta, the standards for practice state that pharmacists who prescribe at initial access should not dispense the medication they prescribed unless it compromises patient health, or the patient chooses for the pharmacist to dispense the medication (Alberta College of Pharmacy, 2018). In the latter scenario, the pharmacist must advise the patient that they can have this dispensed by another pharmacist, ensure the patient has sufficient information to participate in decision making, and obtain informed consent to dispense the medication (Alberta College of Pharmacy, 2018). This does not apply to pharmacists who are extending or adapting a prescription, as these forms of prescribing arise from a prescription from another provider and typically occur during patient care activities at time of dispensing.

The third is the inherent conflict of interest in prescribing for financial gain. In Canada, physicians have raised concerns about conflict of interest arising with pharmacist prescribing (Faruqee et al., 2018; Lee and McCarthy, 2015). Pharmacy is practiced in a retail environment. As such, pharmacists sometimes are perceived to straddle a role between a business person and healthcare professional (Resnik et al., 2000). McCormack first described this in the academic literature (1956). This debate assumes that other

prescribers do not have inherent financial benefit in prescribing. However, physicians, physiotherapists, and dentists are all reimbursed for assessing the need for treatment as well as providing treatment (Lee and McCarthy, 2015). In the end, it may be difficult to conclude that prescribing has inherently more room for abuse than other activities in health care. Interestingly, the majority of community pharmacists in Canada practice in a pharmacy where they are paid a salary which is not dependent upon the quantity of prescribing or billing. The codes of ethics must be honored in all situations.

Prescribing Behaviors

Behavior refers to real-world prescribing activities. Standards and regulations are enabling tools which do not compel a pharmacist to prescribe. In fact, many pharmacists choose not to prescribe as they feel they can influence prescribing decisions in other ways (Guirguis et al., 2017; Makowsky et al., 2013). This section will describe prescribing behaviors in Alberta with a focus on (1) pharmacists' adoption of additional prescribing authority (i.e., prescribing to initiate a prescription) and (2) pharmacists use of other forms of prescribing.

When pharmacist prescribing was initiated in Alberta in 2007, 15 pharmacists were granted additional prescribing authority, and the numbers slowly grew up to 220 pharmacists by 2012. Early research found pharmacists who obtained additional prescribing authority identified the relative advantages, were in ambulatory care settings and had relationships with physicians (Hutchison et al., 2012; Makowsky et al., 2013). Still, many pharmacists found the application process for additional prescribing authorization onerous (Charrois et al., 2012; Hutchison et al., 2012). In 2012, a new compensation framework was released for pharmacy practice (Alberta Health, 2012). Pharmacists would be reimbursed for the assessment that accompanies prescribing as well as care plans (i.e., a medication review with a treatment plan) and their subsequent follow-ups. Of note, pharmacists who had obtained additional prescribing authority would be reimbursed at a rate 25% higher for all services. In 2013, the rate of pharmacists with additional prescribing authorization rose to 435, and by 2016 that number had reached 1658 (31%) of pharmacists in Alberta. The number of additional prescribing applications is still increasing each year (Alberta College of Pharmacists, 2017c). In hospitals, pharmacists reported using additional prescribing authorization for nearly half of patients with antibiotics and anticoagulants (Heck et al., 2015). Oncology pharmacists report applying using additional prescribing authorization to prescribe antiemetic medications in ambulatory clinics (Au et al., 2018). In Alberta, research studies have shown that pharmacist prescribing has resulted in a three-fold reduction in cholesterol (Tsuyuki et al., 2016) and two-fold reduction in hypertension (Tsuyuki et al., 2014) when compared with usual care without pharmacist prescribing.

Most pharmacists in Alberta prescribe to adapt new prescriptions or ensure continuity of care. A 2012 survey found 93.4% of the pharmacists had prescribed. The most common practices were renewing prescriptions for continuity of therapy (92.3%), altering doses (74.3%), and substituting a medication due to a shortage (80.6%) (Guirguis et al., 2017). Pharmacists in rural areas prescribed more frequently supporting the need for services in these areas (Guirguis et al., 2017). Community pharmacists are more likely to prescribe to continue therapy while pharmacists in hospitals or clinics were more likely to adapt prescriptions. Despite the ability to prescribe to extend a prescription for continuity, many pharmacists still contact the physician first to authorize the refills (Guirguis et al., 2014; Makowsky et al., 2013).

Pharmacists' themselves are not clear on what behaviors constitute prescribing. For example, a 2017 newsletter from the Alberta College of Pharmacists clarified examples of unauthorized pharmacist prescribing. These included prescribing to extend prescription for medications that were several years old, adjusting a renewal of a medication, or changing medications due to intolerance issues. All of these forms of prescribing require additional prescribing authorization, but appear similar to adapting a prescription (Alberta College of Pharmacists, 2017a). This may be further confused by the language pharmacists use to describe prescribing. Many pharmacists use the term extending a prescription to ensure patients have a supply of an existing therapy and resist the term prescribing to describe this activity (Hughes et al., 2014). The term prescribing is commonly reserved for the process of initiating a new medication.

Stakeholder Perceptions of Pharmacist Prescribing

In Canada, several studies have looked at stakeholder perceptions. The general public in Saskatchewan and Nova Scotia were supportive of an expanded role for pharmacists in tasks familiar to patients, such as continuing ongoing medication therapy and prescribing for minor ailments, but less supportive for initiating new medication therapy (Perepelkin, 2011; Bishop et al., 2015). Similarly, a review of lay literature found a lack of clarity and contradictory views around pharmacist prescribing (Schindel and Given, 2013). Healthcare stakeholders perceived that independent prescribing increased patient convenience and efficiency of health care (Henrich et al., 2011; Pojskic et al., 2014), Still, physicians with limited experience with pharmacist prescribing expressed concerns about patient safety and delegation of authority (Henrich et al., 2011).

Jebara et al. reviewed 65 international papers (i.e., United Kingdom, Canada, and Australia) on stakeholder opinions toward pharmacist prescribing (2018). Views were overwhelmingly positive, particularly in response to improved patient access, use of pharmacist skills, and reductions in physician workloads (2018). Negative perceptions were more prevalent before experience with pharmacist prescribing and centered on a lack of pharmacist diagnostic skills, access to medical records, and workplace organizational issues.

Prescribing Competencies

Standards of Practice are generally provided for pharmacist prescribing by regulatory bodies; however, they often do not include explicit competencies. A notable exception is the Royal Pharmaceutical Society in the United Kingdom that has produced "A Competency Framework for all Prescribers" (2016). This framework will be used as an example to explain the general competencies required for prescribing, as it relates to pharmacist prescribing and will be referred to as "The Framework" for the remainder of this section. The Framework is divided into ten competencies within two domains—"The Consultation" and "Prescribing Governance". Although not an explicit competency within The Framework, professionalism is expected of all prescribers in all activities, including being patient-centered, maintaining confidentiality, and being responsible for continuing professional development.

The Consultation consists of: (1) assessing the patient; (2) considering the options; (3) reaching a shared decision; (4) prescribing; (5) providing information; and (6) monitoring and reviewing. When assessing a patient, pharmacists should consult with patients directly and complete clinical assessments within their scope (e.g., measuring blood pressure), review all available patient information (medication records, lab test results, when available), and if it is within their scope, request additional tests (e.g. drug levels). Pharmacists should consider all non-pharmacological and pharmacological options for management of the condition, considering the potential risks (including cost) and benefits of the options available, as they relate to the individual patient and their concomitant conditions and medications. Pharmacists often have a greater understanding of pharmacological options than other prescribers, so may take into account additional factors, such as pharmacokinetics or formulations. Discussion with the patient or caregiver around the potential benefits and risks of the available options should lead to a shared decision and the prescribing of therapy with all required information included on the prescription. Counselling on the therapy, per usual pharmacy practice, and establishment of the monitoring plan, which should also be part of usual pharmacy practice, complete the Consultation.

Prescribing Governance consists of (1) prescribing safely, (2) prescribing professionally, (3) improving one's prescribing practice and (4) prescribing as part of a team. When prescribing, pharmacists stay within their scope of knowledge and skill in order to maintain patient safety. Prescribing errors and near misses should be reported and discussed. An example of a reporting system used is SafetyNetRx (http://www.safetynetrx.ca/) that is used in Nova Scotia, Canada. Pharmacists prescribe professionally by accepting personal responsibility for their decisions and staying within their legal scope of practice. Continually reflecting on one's prescribing practices and those of others, which may include reviewing error reports, can improve prescribing practices. Prescribing as part of a team is a common aspect of pharmacist prescribing and may be a requirement of some prescribing models. Fostering collaborative relationships and ensuring continuity of care through communication are important to ensure team functioning.

The Framework offers specific guidance and statements around prescribing and is an excellent resource. Most pharmacists will find that they are generally practicing within this framework on a daily basis, including when they are providing "over the counter" or "non-prescription" medication advice as well as assessing and educating patients with prescription medications. It is important to recognize that the competencies used in the long-standing parts of practice (such as "over the counter" recommendations) align with those used for a potentially newer aspect of practice, such as prescribing.

Professionalism in Pharmacy Practice

Roy Thomas Dobson, University of Saskatchewan, Saskatoon, SK, Canada

Introduction

In addressing the topic of professionalism in pharmacy practice, the chapter has been organized to address a series of questions. First, what is meant by the term professionalism as it pertains to pharmacy? What are the attributes of pharmacy that elevate it beyond a mere occupation to that of a profession? As a profession, what are the attributes that must be displayed by members to assure patients, other health professions, and the public in general that professionalism is a part of pharmacy practice? If professionalism is a part of pharmacy practice, are its attributes and behaviors displayed in a manner that assures us that it is practiced consistently and at an acceptable level across the profession? Is our understanding of the concept of professionalism evolving? Would professionalism as it is understood and applied today be recognizable to those who came before, and will professionalism as it is understood today still be relevant to those who come after us? How do we ensure the values and behaviors associated with professionalism are instilled into new entrants, and promoted and maintained in practitioners after graduation? Finally, does professionalism have value? Does it allow the profession of pharmacy to better serve the larger society in which it exists, or is it merely affectation and a sentimental adherence to old norms?

Occupation as Profession

Professionalism has been defined as demonstrating the traits of the profession (Agomo, 2012). Before addressing the topic of professionalism more fully; however, it is necessary to first establish what is meant by the concept of a profession, and what differentiates a profession from other occupations. Once the concept of profession is understood, the next question to be addressed is to what extent pharmacy can assume the title of profession rather than merely an occupation? Only then can the concept of professionalism, as it pertains to pharmacy, be addressed properly.

For many, an occupation is deemed a profession if it possesses a number of the traits ascribed to a profession. While there is no consensus on the traits of a profession (Waterfield, 2010), there are many that are generally agreed upon, while others reflect similar values. These traits are categorized as either structural or attitudinal (Hammer, 2000).

Some of the structural traits of a profession include the following: specialized knowledge and skills; performing a service important to society; prestige, autonomy for the service provider; self-regulation, formal organizations and codes of ethics; and a system for training others in the knowledge, skills and values of the profession (ASHP, 2008; Hammer, 2000; Waterfield, 2010). In addition to shared ethical values, practice based on theoretical knowledge, and a professional culture passed on to new entrants, Waterfield (2010) expands the concept of professional authority to include power and privilege sanctioned by community; similar to the prestige trait noted by Hammer (2000).

Attitudinal traits include having a belief in service to the public and a sense of a calling, or dedication to the profession (Hammer, 2000). Other attitudinal traits identified in the literature include commitment to self-improvement; service orientation to patients and to the profession, creativity and innovation, trustworthiness, accountability, integrity, duty, honor, and leadership (ASHP, 2008; Poirier and Gupchup, 2010).

Also identified as a professional, trait is the confidential nature of patient-client relationship (Waterfield, 2010). This trait, in particular, speaks to the covenantal or fiduciary relationship seen as essential between a member of a profession and the person being served. In this way, one may argue that professions differ most from nonprofessional occupations, in that the relationship between provider and recipient is not merely or primarily commercial (ACCP, 2009).

While a professional is expected to charge a fee (in some cases substantial) for the services provided, the primary goal of the exchange is to maximize the benefit received by the patient or client rather than the provider of the service. The relationship is built

upon the ability of the patient or client to trust that the professional will be working in the interests of the patient or client, and, as such, is not required to adopt the philosophy of *caveat emptor* (let the buyer beware).

Finally, In addition to traits associated with a profession, the literature also presents the concept of types or levels of professional designation that have been used to differentiate professions from occupations, and professions from one another. Historically, these have included established professions such as medicine and law, new professions such as engineers and academics, semi-professions such as pharmacy and nurse, and those occupations aspiring to obtain professional status (Agomo, 2012).

For the most part, the degree to which an occupation is designated a profession appears to draw primarily on the extent to which a group possesses special knowledge based on a theoretical framework and the ethical underpinnings that dictate the behavior of members, rather than merely the application of skills *per se*.

Pharmacy as a Profession

Is pharmacy a profession? In the past, pharmacy has been viewed as not a profession due to a lack of control over its work (i.e. medicines) (McCarthy et al., 2012); semi-professional based on an over-reliance on the mastery of technical skills (Agomo, 2012); or quasi-professional due to a lack of autonomy and equivalency of members (Hammer, 2000).

While not intending to provide a history of pharmacy's march toward greater professional status, the rise of medical hegemony in the nineteenth century, and the resulting subordination or elimination of most nonphysician health care provider groups (Starr, 1982), had a profound effect on the work and professional standing of pharmacy. While medical hegemony did not eliminate pharmacists from the health care environment, pharmacy's scope of control was greatly curtailed; as a result, it was confined mainly to the compounding and dispensing of medicines prescribed by physicians. Interactions with patients of a clinical or therapeutic nature were generally limited to only the most basic information regarding the administration of medicines and minor medical complaints, with the expectation, indeed the obligation, to defer all substantial concerns and issues regarding drug therapy to the prescribing physician for resolution or redress (Troy and Beringer, 2006).

The restricted and marginal health care provider role taken up by pharmacists was further eroded by the fact that, unlike other health care practitioners, most pharmacists worked outside the formal structures of the health care system; existing instead within an environment affected more overtly and to a greater extent by commercial realities and interests (Agomo, 2012; Dobson and Perepelkin, 2011; Perepelkin and Dobson, 2010). These commercial interests invariably conflicted with, and at times, dominated professional interests (Bradley et al., 2018a). As a result, the pharmacist was often labeled, and not necessarily unjustly, with the pejorative "shopkeeper" (Hughes and McCann, 2003). Pharmacy was viewed, and continues to be viewed by some, as primarily a commercial activity (Perepelkin, 2011), and by extension, the interactions that occurred between pharmacists and those receiving pharmacy services.

The nadir of pharmacy as well as its claim to professional status in North America is seen to have occurred in the mid-twentieth century with the erosion of demand for traditional pharmacy skills such as the compounding of medicine, and the virtual relinquishing of the patient care role as articulated in the 1952 American Pharmaceutical Association (APhA) Code of Ethics (Buerki and Vottero, 2002; Troy and Beringer, 2006).

> The pharmacist should never discuss the therapeutic effect of a physician's prescription with a patron nor disclose details of composition which the physician has withheld, suggesting to the patient that such details can be properly discussed with the prescriber only.
>
> APhA, 1952

The Code effectively banned the communicating of additional therapeutic information by the pharmacist to the patient. At this point, the relationship between patient and pharmacist can be seen a little more than a commercial transaction. Pharmacy and community pharmacy, in particular, appeared to function as little more than an esteemed occupation, and not as the profession it claimed to be.

Since the mid-twentieth century, however, pharmacy has made great strides toward claiming full standing as a health profession. Pharmacists have expanded their role beyond the dispensing of medicines to a range of health and drug related services and activities (Kelly et al., 2014; Owens and Gibbs, 2001; Perepelkin, 2011), and increasingly display collectively many of the attributes associated with a profession (Waterfield, 2010). Indeed, some are so optimistic as to conclude that pharmacy is a profession (Agomo, 2012). However, it can be argued that there are still many challenges and much in the way of attitudes and behaviors that must change before such an assertion goes wholly unchallenged (Davies and Tsuyuki, 2014).

As noted previously, pharmacy has faced many external challenges to its status as a profession (Beales and Austin, 2006), and these challenges continue as other professions and groups seek to advance their own status and authority (Agomo, 2012); in part, by claiming scopes of practice and roles that contest pharmacy's claim of professional exclusivity (Gregory and Austin, 2017). As well, technological changes are reducing the need for traditional pharmacy skills and claims to special, unattainable knowledge (Waterfield, 2010). Pharmacists have also done much to curtail their claim to professional status in the actions undertaken by some of its members within the pharmacy practice environment (Agomo, 2012; Davies and Tsuyuki, 2014). These "self-inflected wounds" often arise out of the commercial aspects of community pharmacy practice; but, nonetheless, suggest diminished professional expectations regarding appropriate values and behaviors within the profession of pharmacy.

To be seen as a profession; therefore, pharmacy must move away from the mere provision of a product (the prescription) toward patient-centered care that may or may not include the providing of a product (ACCP, 2009; Hammer, 2000). Further, more than merely shifting the focus of work, pharmacy must more consistently demonstrate the structural and behavior attributes of a health profession. Pharmacy must possess the clinical knowledge and skills, and the ability to control how these are used to provide patient care through self-regulation and professional autonomy. In addition, pharmacy must possess and convey the attitudes, values, and habits that are at the core of a profession (ACCP, 2009). Attributes such as altruism, accountability, excellence, duty, honor, integrity, and respect for others (Hammer, 2000).

In effect, to be a profession, pharmacy must place the well-being of the patient at the center of practice, and commit itself to the betterment of the profession and society (ASHP, 2008). Indeed, recent versions of codes of conduct for pharmacists seem to reiterate these principles. In the United Kingdom (UK), for example, pharmacists are called upon to make the care of the patient their first concern. In addition, the UK pharmacist should expect to " . . . exercise professional judgement in the interest of patients; show respect to others; encourage patients to participate in decisions about their care; develop . . . knowledge and competence; be honest and trustworthy; and be responsible for (their) actions" (Agomo, 2012)

Professionalism as a Construct

In reviewing the literature, various definitions of professionalism are provided (Elvey et al., 2011; Hammer, 2000; MacKenzie, 2007). In addition to possessing the structural and attitudinal traits of a profession, professionalism is also confirmed through behaviors that demonstrate various profession traits (Bumgarner et al., 2007; Thompson et al., 2008). To that end, a bicycle wheel metaphor is often used to explain the nature of professionalism and the relationship between various professional traits (ACCP, 2009; Bumgarner et al., 2007; Hammer et al., 2003).

Attributed mainly to the work of Hammer et al., the bicycle wheel conceptualization of professionalism includes the following: the hub representing professional values such as altruism, caring, and integrity; the spokes representing behaviors seen to arise from these values such as respect, accountability, and empathy; and the outer rim of the wheel representing the more superficial aspects of professionalism such as professional dress (Bumgarner et al., 2007).

While helpful in explaining, the relationship between various professional attributes associated with professionalism, Hammer's metaphor is somewhat limited in linking professionalism to actions or consequences. A more recent version of the bicycle wheel metaphor is offered by the American College of Clinical Pharmacy (ACCP, 2009) that identifies the hub as "the fiducial or covenantal relationship between pharmacist and patients." Similar to earlier versions, the spokes are seen as the behaviors expected to arise from a commitment to patients. Unlike the earlier version that viewed the tire or rim as the surface of the profession, the ACCP version perceives the rim as the interaction between professionalism and the various pharmacy activities that are affected by professional values and behaviors such as patient care, teaching, scientific discovery, application and scholarship, professional service, and leadership.

Patient-Centered Professionalism

The concept of professionalism in pharmacy practice has evolved over time, and will continue to evolve to reflect the values and beliefs of the profession, and the larger society in which the profession resides and seeks to serve. For some decades, the focus of the profession has been moving away from a product focus to a service focus, and from a medicines-focus toward a patient-focus; a patient-focus that has culminated with the adoption of a patient-centered model of care.

Just as there are a number of definitions for professionalism, a similar observation can be made for patient-centered care. This is partly due to an evolving understanding of a concept. Patient-centered care initially focused on providers working in the interests and preferences of the patient before moving toward a patient-driven paradigm of care. A paradigm based on the needs and values of patients functioning as engaged and informed participants in their care decisions (Hutchings et al., 2010).

The features of patient-centered professionalism build upon the core attributes of a profession and professionalism, but, in addition, seek to more fully articulate the primacy of the patient. The concept highlights the importance of a positive relationship between the patient and the provider, and the obligation of the provider to respect and support the right and ability of patients to make decisions about when and what care will be sought and accepted. The provider facilitates the process by communicating all relevant information and options. Information and options based on the preferences and values of the patient (Hutchings and Rapport, 2012).

Elvey et al. (2015) identify three constructs associated with patient-centered professionalism; including competence (knowledge and accountability); ethical values (trustworthy and patient-focussed); and communication. The third construct is most notable in building upon existing and past models of professionalism and includes attributes such as communicating clearly, listening, being approachable, and staying calm, and remaining polite and pleasant (Elvey et al., 2015). A key feature of communication in patient-centered professionalism is the ability of the provider not only to communicate effectively, but also to possess the skills, attitudes, and values that ensure patients receive the information they need to make choices that best reflect their interests and preferences (Hutchings and Rapport, 2012). By holding and demonstrating the values that align with these goals, the provider best displays patient-centered professionalism.

As health care providers move toward patient-centered professionalism, the concept of patient-centeredness approach continues to evolve. Presently, patient-centered care is viewed as a partnership between the patient and the health care provider(s); a process that encourages participatory decision-making, reflects patient preferences, and supports self-management that builds upon the benefits of the health services provided by the pharmacist. In addition, patients and those advocating on their behalf are increasingly seeking to influence health research and health policy (Laurance et al., 2014; Thomson et al., 2005). This can be seen in the growing level of participation by patients and their advocates through: research advisory groups (Hersh et al., 2016); drug regulatory authorities such as the Food and Drug Administration in the United States (Salcido, 2016); drug and technology assessment committees such as the Canadian Agency for Drugs and Technologies in Health (Berglas et al., 2016); and various disease advocacy groups.

As patient engagement in various aspects of the health care system continues to grow, the potential for conflict with the health professions can also be expected to increase. Despite the rhetoric around patient-centered care (Epstein et al., 2010), the health care domain is still dominated by the values and preferences of providers. While patients are beginning to find their voice and are encouraged to participate more in their own care, the fundamental nature of the relationship is dominated by the provider due to various power imbalances in knowledge, prestige, and social status.

If the patient/public voice should actually come to dominate the discourse around health care, policy and research, disruption of current power relationships will invariably lead to role conflict. As new power dynamics emerge, what constitutes a profession will also need to evolve, as those seeking to meet a societal need must respond to changing demands and expectations. Some of the traits currently associated with a profession, such as specialized knowledge and skills; performing a service important to society; prestige; autonomy; and self-regulation (Hammer, 2000), may be redefined or possibly curtailed to better fit the needs and goals of an increasing influential group existing outside the profession. At the same time, the fundamental concept of professionalism, in which the best interests of the patient have primacy, will remain at the core of the profession, and the patient-pharmacist relationship.

The Professionalization of Pharmacy Students and Practitioners

Professionalism is generally seen as possessing and/or demonstrating the structural and attitudinal traits of the profession (Bumgarner et al., 2007; Thompson et al., 2008). The acquisition of these traits is seen to occur through the ongoing professionalization of students and practitioners (Khanfar et al., 2012). While an individual, prior to joining a profession, may possess some of the traits of the profession (Hammer, 2000), it is through participation over time as a member of the profession, first as a new entrant/student and then as a licensed practitioner that the full range of traits may be developed to a level beyond the minimal standard acceptable to the profession, and the society it serves. In addition to developing these traits over time, practitioners must also adjust to changing expectations within society and the profession as to what constitutes professionalism; changes that oblige the individual practitioner to acquire and to modify the attitudes and skills needed to meet evolving professional standards.

Much of the pharmacy literature on professionalization (the acquiring of professional traits) focuses on pharmacy students (Hammer, 2000; Hammer et al., 2003; Hanna et al., 2017; Poirier and Gupchup 2010; Thompson et al., 2008). In addition to therapeutic knowledge and clinical skills, it is during undergraduate pharmacy training that students begin to acquire the values and behaviors of the profession through professional socialization (Thompson et al., 2008); a process by which acceptable group norms, values, and behaviors are communicated to, and it is being observed and adopted by the new entrant (Hammer, 2000).

For much of the recent history of the profession, the socialization of new pharmacy entrants was a relatively unstructured and informal process, in which students were expected to acquire the necessary values and attitudes through their participation in a pharmacy training program and the observation of role models, both within the pharmacy faculties and the wider profession. More recently, in part due to growing concerns over a perceived decline in professionalism (ASHP, 2008), pharmacy training programs have begun to introduce formal activities and explicit curricular content to support the adoption of professional attitudes and values by students.

An activity designed to instill professionalism in students that is familiar to many health care professions is the White Coat ceremony. Often this event is seen as celebratory with families and friends of the students attending to witness the assuming of the professional role.

Usually occurring in the first year of a professional program, students will collectively don white lab coats as a symbol of their acceptance of professional values, duties and responsibilities (Agomo, 2012). White coat ceremonies may include other activities such as professional oaths and pledges of professionalism (Poirier and Gupchup, 2010). To further support the communicating of professional values, students are often directed to create a specific professionalism pledge for their cohort to be recited at the White Coat ceremony (Hammer, 2000).

Students are also encouraged to actively participate in student and professional organizations (Poirier and Gupchup, 2010). Taking on leadership roles or contributing in other ways to advance the profession can illustrate and reenforce the values and behaviors that will be increasingly expected of them as they move through their program and on into pharmacy practice.

In addition to these extracurricular activities, explicit curricular content in many programs has expanded to address the various aspects and importance of professionalism. The literature also suggests that an integrated rather than a diffused approach is more effective in communicating the relevance of professionalism to students (Schafheutle et al., 2013). The importance of

professionalism as an explicit part of undergraduate training can be seen in the inclusion of professionalism within the educational standards of accrediting bodies such as the Accreditation Council of Pharmacy Education (United States) (Akiyode, 2016) and the educational outcomes identified by national associations such as the Association of Faculties of Pharmacy of Canada (AFPC, 2017).

In addition to the content of the pharmacy program, fellow students and those that deliver that program also play critical roles in ensuring the professionalization of pharmacy students. In addition to explicit curricular content designed to advance professionalism, students are also informed by the "hidden" curriculum (Akiyode, 2016; Schafheutle et al., 2013). The hidden curriculum often consists of the observation by students of the behaviors of other students, faculty, and preceptors within the program, and the consequences associated with these behaviors. The effects of the hidden curriculum often have a greater impact on student values, and behaviors as cause and effect are generally more easily observable, and therefore seen to be more credible than the theory-based content delivered within the formal curriculum.

The credibility of curricular content is also affected by the behaviors and attitudes adopted and demonstrated by program faculty. Faculty that fail to demonstrate professionalism can adversely affect student adoption of the professional values and behaviors put for by the faculty and the program (Do as I say, not as I do).

In an effort to communicate professional values and acceptable behaviors, many training programs also develop codes of conduct/ethics for both students and faculty (Hammer, 2000). However, as with the hidden curriculum, it is the extent to which these codes are "lived" or seen to be relevant, rather than what is espoused that determine their impact on professionalism over the long term.

Once students complete their formal training and enter pharmacy practice, the concept of professionalism as understood by the new pharmacy graduate will continue to develop. The importance and impact of professional mentors (ASHP, 2008; Schafheutle et al., 2013), especially in the early years of practice, cannot be overstated. Even with a solid foundation of professional values, new practitioners are not immune to the pressure to conform with, "how things are done" once they enter practice. Appropriate role models within pharmacy practice are therefore essential to reenforce and further develop professional values, attitudes, and behaviors gained during their undergraduate training.

The historical separation of practitioners and academic faculty ("town vs. gown") is often reflected in the holding of very different views of how a profession must function to be successful, an incongruence not confined to pharmacy. New graduates and even undergraduates in clinical placements will often be told by seasoned and not-so-seasoned practitioners, "That may be what they do in the ivory tower; but, things work differently here in the real world." While not understating the value and importance of hard won practical knowledge and the need for new pharmacists to gain the experience needed to become the drug experts they aspire to be, pragmatic practices and solutions must be tempered with adherence to principles, both professional and personal. Professionalism defined as adherence to the attributes of a profession (Agomo, 2012) ensures that new practitioners will successfully merge newly acquired values and behaviors with knowledge and experience, and so, in their turn, become professional role models to those that follow.

Why Professionalism Matters

Professionalism as a topic and as an issue in health care in general, and pharmacy in particular has grown in prevalence and importance over the past two decades (Elvey et al., 2011). A perception of a general decline in professional behavior and performance has been attributed to creating this increased interest, and a number factors have been ascribed to this perceived decline (ASHP, 2008).

Some of the factors seen to adverse affect professionalism, such as limited resources and rising levels of demand for health services, put a strain on the ability of health care providers to effectively care for patients in a manner deemed appropriate by both patients and providers.

At the same time, the fundamental nature of the relationship between patients and providers has been and continues to change as patients seek a greater voice in the decisions that affect their care (Benson et al., 2009), and, through new technologies, acquire the capacity to challenge the knowledge and associated authority previously ceded to providers.

As patients seek new relationships with various health care providers, providers such as pharmacists are also evolving in terms of their expertise and scopes of practice that, in and of themselves are changing the relationship between pharmacists and those they seek to serve. With expanded scopes of practice and increased capacity to materially affect patient care, pharmacists are being called upon to accept more responsibility and accountability for the manner in which care is provided, and the consequences that result from that care (Benson et al., 2009; Elvey et al., 2015).

In this environment of change and uncertainty, the need for a high level of professionalism cannot be understated. Professionalism in our dealings with patients will be essential as the roles and responsibilities of both patients and pharmacists are redefined. By maintaining a high level of professionalism, pharmacy can confirm its value to the people it seeks to serve. As asserted by Hammer nearly two decades earlier,

> . . . to maintain the trust and respect that has been historically afforded to the profession by the public, pharmacists need to keep professionalism as the basis of all professional activities
>
> Hammer, 2000

In addition to changing patient relationships, pharmacists are finding that their relationships with other health professions are also changing. Pharmacists are engaging more with other health professions in more collaborative approaches to care due to a wider recognition of the value and expertise of pharmacists, and an increasing willingness by other professions to access that expertise (Bradley et al., 2008b; Makowsky et al., 2009). How well pharmacists successfully engage with other health professions will be affected, in part, by their demonstrated competencies, attitudes, and behaviors. In this way, the professionalism displayed by the pharmacist will be critical to their ability to participate in and contribute to effective patient care.

The importance of professionalism in practice is also illustrated when the pharmacist is faced with situations where professional values may conflict with personal values (Benson et al., 2009). While not the intent of this chapter to extensively address the issue of professional ethics, when these conflicts do arise, how the pharmacist chooses to act is fundamentally a reflection of the professionalism of the pharmacist.

To express it another way, as moral beings, when we are faced with a moral or ethical decision we may ask, "What should I do and how should it be done?" (MacKenzie, 2007). In deciding how to respond, the individuals will seek to do so a way that is consistent with their values. Through the lens of professional ethics, which are based largely on collective values articulated in professional codes of ethics and role models of the "good pharmacist," the question the pharmacist must answer is, "What kind of person should I be to fulfill my professional obligations?" (MacKenzie, 2007). In this situation, the moral individual is subordinate to the societal role of the pharmacist, with the understanding that individuals who accept this role are expected to fulfill that role based on society's expectations.

Whether it is a patient seeking a legal, therapeutically justified therapy with which the pharmacist has personal moral concerns, or a colleague behaving in a manner that the pharmacist finds unprofessional, how the pharmacist chooses to respond will reflect the tension between these two competing approaches to decision-making. Ultimately, whether or not the conflict is resolved, whether the pharmacist elects to adopt a solution more consistent with their values as a moral individual or the values of the professional collective, professionalism will be critical to ensure that the pharmacist, within his/her capacity to do so, will act in a manner that ensures optimal care, that is, care that reflects the best interests and preferences of the patient. To do otherwise, is to demonstrate a lack of professionalism.

Summary

Professionalism has been defined as demonstrating the traits of the profession (Agomo, 2012). While there is no consensus on specific traits (Waterfield, 2010), professional traits are categorized as either structural or attitudinal (Hammer, 2000). Among the traits identified is the confidential nature of patient-client relationship (Waterfield, 2010). Professions differ most from nonprofessional occupations, in that the relationship between provider and recipient is built upon the ability of the patient or client to trust that the professional will be working in their interests.

The concept of professionalism in pharmacy practice has evolved over time, and has culminated with patient-centered professionalism. Patient-centered professionalism build upon the core attributes of a profession and professionalism; but, in addition, seek to more fully articulate the primacy of the patient.

The acquisition of professionalism is seen to occur through the ongoing professionalization of students and practitioners (Khanfar et al., 2012). In addition to developing these traits, practitioners must adjust to changing expectations within society and the profession as to what constitutes professionalism.

A perception of a general decline in professional behavior and performance has been attributed to a number factors (ASHP, 2008). With expanded scopes of practice and increased capacity to materially affect patient care, pharmacist are being called upon to accept more responsibility and accountability for the manner, in which care is provided, and the consequences that result from that care (Benson et al., 2009; Elvey et al., 2015).

In addition to patient relationships, pharmacists are finding that their relationships with other health professions are also changing. Pharmacists are engaging more with other health professions in more collaborative approaches to care due to a wider recognition of the value and expertise of pharmacists, and an increasing willingness by other professions to access that expertise the professionalism displayed by the pharmacist will be critical to their ability to participate in and contribute to effective patient care.

Regulating Pharmacy Professionals

Greg Eberhart, Alberta College of Pharmacy, Edmonton, Canada

Introduction and Scope

The governance and regulation of pharmacy professionals provides the framework through which individuals and families are enabled to experience the knowledge and skills of pharmacy professionals. It is also the structure through which pharmacy professionals' authority, responsibility, and accountability are demonstrated. Simply stated, the effective governance and regulation of pharmacy practices enable access to knowledge, skills, and services and balances this with the authorities, responsibilities, and accountabilities necessary to ensuring that they are provided in a manner that serves the publics' interest (Health Practitioner Regulation National Law Act, 2009; Health Professions Act, 2000; Pickett, 2017; The Pharmacy Order, 2010).

The governance of pharmacy professionals includes many tools and processes. The manner and extent in which each of these is applied differs between countries, and often between jurisdictions within countries. Jurisdiction is usually determined through national constitutions that determine whether the delivery and funding of health care is a national or provincial/state responsibility (Health Workforce Regulation, 2016).

This chapter explores the purpose, structure, and processes common to governing and regulating pharmacy professionals and briefly discusses some differences in the approach used in different countries and jurisdictions.

The Alberta College of Pharmacists (ACP), which governs and regulates pharmacists, pharmacy technicians, and the operation of licensed pharmacies in Alberta, Canada, will serve as a case study. It has been selected, as since April 2007, pharmacists practicing in Alberta have enjoyed one of the broadest scopes of practice of pharmacists in the world. The case study will share insights about the processes and policy considerations that enabled these privileges, the challenges of change, and structures and processes developed to effectively balance the authority with accountability.

The chapter concludes with a discussion about some of the new challenges facing the governance and regulation of pharmacists and pharmacy technicians, inviting thought about emerging considerations important to the future.

Why are Pharmacy Professionals Regulated?

Pharmacy professionals perform two fundamental functions important to society.

1. They are the stewards and the trusted source of drugs that individuals receive either pursuant to a prescription, through a pharmacist's recommendation, or through self-selected purchase in a pharmacy. In this stewardship role, pharmacy professionals are responsible for the procurement, storage, handling, packaging, labeling, and distribution of drugs in a manner that ensures the appropriate security and integrity of drugs. Pharmacy professionals hold responsibility to individuals and to society to ensure the quality and integrity of drugs received by an individual, their guardian, or any other individual who has responsibility for their care (Operation of Licensed Pharmacies, 2007; Standards for Pharmacy Professionals, 2017).
2. Pharmacists support individuals pursue their health goals by assessing, care planning, and supporting them in the selection and use of health interventions that meet their personal preference and needs. This includes providing advice about drug and nondrug alternatives and in a growing number of jurisdictions such as Alberta, which includes prescribing. The scope of this role differs substantively between jurisdictions. Regardless, pharmacists in their professional capacity are recognized throughout

society as having a "higher level of knowledge" about drugs and their proper use, and therefore, individuals and society entrust that knowledge to be used ethically and effectively to improve and/or maintain their health (Standards of Practice, 2011a; Standards for Registered Pharmacies, 2018a).

These responsibilities provide opportunities and benefit to individuals and society; however, if not exercised properly it invite risk. Governments use legislation as a tool to mitigate this risk. While the development and administration of legislation differs between jurisdictions, its primary purpose focuses on the interests of the public. The acts of developing public policy, creating legislation, and administering the authorities and processes that flow from it form the discipline of "regulation" (Standards of Practice, 2011b).

What Authority Supports the Governance and Regulation of Pharmacy Professionals?

While the practice of apothecaries and pharmacists has a long and varied history, the regulation of pharmacy practice has evolved from the guilds in Europe that recognized unique bodies of knowledge and skills that were restricted to individuals of the guild. In some jurisdictions, pharmacists were regulated with physicians as part of the medical community. In the western world, recognition of the unique attributes of pharmacists' knowledge and skills became more prevalent in the 1800s, leading to the autonomous regulation of their practices (Standards for Registered Pharmacies, 2018b).

The formal recognition and regulation of pharmacy technicians continues to evolve and has an increasing presence in the 21st century. Where regulated, pharmacy technicians are often regulated collectively under legislation that governs pharmacists. For example, pharmacy technicians became regulated under the Health Professions Act in Alberta, Canada, on July 1, 2011, the same day that the General Pharmaceutical Council was authorized to regulate technicians in England, Scotland, and Wales.

Today, pharmacy professionals are governed and regulated through two distinct models: the privilege of self-regulation or directly by the government.

Where self-regulation exists, it is a privilege that is granted by government through legislation. It is based on the belief that pharmacy professionals are the most knowledgeable about their profession(s) and the practice expectations of their registrants; and, that within the authorities and accountabilities granted through legislation, are the best positioned to regulate and adjudicate the practices of their own registrants. The concept of self-regulation is a privilege that can be granted and can be taken away (Standards of Practice, 2011b). While it is common in western societies, there is a high degree of variability in legislation, the autonomy that is granted by government, and how accountability is demonstrated (Health Workforce Regulation, 2016).

Regulatory Cultures Differ

The specific wording of legislation authorizing the regulation of pharmacy professionals is the foundation for the scope, interpretation, and application of the legislation. For example, " . . . protection of the public . . . " may be interpreted to provide narrower authority than " . . . in the public's interest . . . " Therefore, the authority granted in legislation will impact the culture and the approach a council/board responsible for administering the legislation will take.

The Health Professions Act in Alberta requires the council of the Alberta College of Pharmacists to "carry out its activities and govern its regulated members in a manner that protects and serves the public interest" (Health Practitioner Regulation National Law Act, 2009). The council has adopted the following vision statement: "Healthy Albertans through Excellence in Pharmacy Practice." Its mission is to "govern pharmacists, pharmacy technicians, and pharmacies in Alberta to support and protect the public's health and well-being. We take responsibility for pharmacy practice by setting and enforcing high standards of competence and ethical conduct" (Abpharmacy, 2018). The governing council has interpreted its responsibility to "act in the publics' interest" to be broader than simply "protecting the public." This invites the vision to pursue excellence in practice. It also means that the council focuses on quality, not simply safety, which is often defaulted to when behaviors are restricted to "protecting the public."

The college has adopted the Health Quality Matrix of the Health Quality Council of Alberta to define quality. The matrix includes six dimensions that collectively define quality: acceptability, accessibility, appropriateness, effectiveness, efficiency, and safety (Alberta Quality Matrix Users Guide, 2005).

As safety is only one of the six dimensions, this invites broader discussion and thinking by the college in its pursuit of quality pharmacy practices. It also requires the college to think more systemically and to be a recognized partner in the development of health policy where pharmacy professionals and drugs play a role.

These interpretations impact the culture and behaviors of pharmacy regulators in other ways too. Considerations that may be impacted are the relative balances that a regulator places on:

- risk tolerance versus risk aversity;
- quality improvement versus quality assurance; or
- encouraging a "just culture" versus a punitive approach to managing errors.

Pharmacy regulators and pharmacy professionals are also impacted by other systemic factors. Legislation governing pharmacy professionals does not exist in isolation and is part of a larger body of law that governs societies. For example, there are still

jurisdictions where dispensing errors may be addressed as a criminal offense (The Pharmacist, 2017). Societies that are highly litigious may be less compelled to adopt a "just culture," which impacts the culture of regulation, how decisions are made, and consequences arising from them. Arguably, this may impact the courage of pharmacy professionals to exercise critical thinking and professional judgment for the fear of consequences. It certainly impedes opportunities to learn from honest mistakes, a foundation to quality improvement processes.

How are Pharmacy Regulators Held Accountable?

Legislation is the tool through which pharmacy regulators are held accountable, and in turn is the foundation through which regulators hold pharmacy professionals accountable to society. Depending on the country, pharmacy professionals may be regulated nationally, or within state or provincial jurisdictions. For example, pharmacy professionals in Europe (The Pharmacy Order, 2010) and Australia (Health Practitioner Regulation National Law Act, 2009; Health Workforce Regulation, 2016) are most often regulated by a national body, whereas in North America (American Pharmacy Regulatory Authorities, 2019; Canadian Pharmacy Regulatory Authorities, 2009; Health Professions Act, 2000), the governance and regulation of pharmacy professions is a state or provincial responsibility, especially legislation governing the professions is national and state/provincial in scope. Where pharmacy professions are governed at the state or provincial level, there is still usually some linkage to federal policy, which is often determined by the national constitution.

The legislative structures and processes through which legislation is developed differ slightly between jurisdictions, but again have a high degree of commonality. At the highest level, members of the national or state/provincial government (as the case may be) approve legislation. The legislation defines governance and regulation, its scope, and who is responsible for its stewardship. It also defines processes for the development and approval of additional levels of control through regulations, codes of ethics, and standards. The legislation provides the highest level of definition for the authority and accountability granted to regulators (Health Practitioner Regulation National Law Act, 2009; Health Professions Act, 2000; The Pharmacy Order, 2010).

Legislation defines who has what authority, to make what rules, and how the development and approval of these must be carried out. Legislation is usually debated and approved at parliamentary or legislative assembly levels, including all parties of the legislative forum. Regulations often require approval of an element of government (i.e., the Minister or Cabinet), however, not the approval of an entire parliament or legislative assembly. Governing councils/boards of self-governing professions usually have authority and responsibility to develop and approve codes of ethics and standards, albeit the scope of each of these is usually defined and/or restricted in legislation.

Where the privilege of "self-governance" is enjoyed, legislation will establish the need for a governing council or board, its membership and how that is determined, the scope of its authority (including limitations), and requirements for reporting (including to who). Depending on the jurisdiction, the council/board may include elected pharmacy professionals and/or individuals appointed by government on behalf of the public. The legislation usually defines council/board membership; prescribing the number of council/board members and how many must be pharmacy professionals vs. individuals appointed by the government; and, the extent to which democracy is accommodated through elections. Government appointments are one means through which accountability to the public is exercised by governments.

A second means through which legislation accommodates accountability is by prescribing the processes that councils/boards must use in carrying out their business, and specifically the means through which regulatory instruments such as regulations, bylaws, standards, and codes of ethics are developed and approved. Transparency, objectivity, and fairness are common principles often required by legislation that are reflected in the processes of regulators. Examples of these are the need to consult with registrants, other professions, interested parties, and sometimes the public prior to approving regulations, standards, or a code of ethics (Health Practitioner Regulation National Law Act, 2009; Health Professions Act, 2000; The Pharmacy Order, 2010).

The process of consultation invites transparency and inclusiveness as a means of contributing to objective and fair decisions that effectively address the issue, problem, or risk that they are intended to mitigate. The most effective consultations include engagement and discussion, as compared to traditional processes of simply inviting feedback to a DRAFT proposal that may be limited by the insights and biases of a few individuals who have contributed to its development. Inclusiveness through broader engagement invites more possibility through a diversity of ideas and can identify alternatives that are not feasible or that are less likely to be accepted.

Legislation also prescribes rules and processes for investigating complaints and how they are resolved. This again includes a variety of tools and processes, these being highly influenced by the national constitution, the culture, and the traditional philosophies of the government. Where self-governance exists, processes often balance objectivity and fairness through rules of natural justice and balance this with accountabilities demonstrated through open and transparent processes. This includes but may not be limited to advising the public about when hearings are scheduled, allowing the public to observe proceedings, and transparent reporting of the proceedings and decisions arising from them. Legislation often requires that tribunals include a minimum number of individuals appointed by government as representatives of the public. Accountability is further accommodated by processes for review and appeal. In some jurisdictions, processes are open to review by an ombudsman appointed by government. In most jurisdictions, legislation accommodates the right to appeal decisions of the regulator to the judiciary (Health Practitioner Regulation National Law Act, 2009; Health Professions Act, 2000; The Pharmacy Order, 2010).

Finally, accountability is demonstrated through reporting. Legislation usually requires that pharmacy governing bodies publish an annual report to the public through government. This is the means through which the public learns about the annual business and affairs of the regulator. A, legislation usually accommodates or requires the publication of the decisions of any tribunals established by the regulator.

In conclusion, the act of self-governance is a privilege that has been delegated to pharmacy regulators by governments on behalf of the public. Governments have ultimate authority to establish how pharmacy professions are governed, how the work of governance and regulation is carried out, and how accountability of the publics' interest is exercised. Where regulators do not conduct themselves in a manner that is seen to be in the public's interest, governments may intervene, and in some cases, repeal the privilege of self-governance (Legislative Assembly of British Columbia, 2003).

Models of Regulation

While the responsibilities of pharmacy regulators are highly common, different legislative models exist.

Historical models reflect legislation that is specific to professions such as pharmacists and pharmacy technicians, unique from that for physicians, nurses, physical therapists, dentists, and other health professions (Health Workforce Regulation, 2016). These models often reflect exclusive scopes of practice, restricting acts such as dispensing, compounding, and the selling of drugs exclusively to pharmacists, and the prescribing of drugs exclusively to physicians, dentists, and other select professions. Where the legislative model is unique to each profession, there can also be differences in the authorities and processes between pieces of legislation, often determined by the era in which the legislation was developed and passed. This inconsistency can create conflict in how services are delivered, and by extension, inconsistencies in how professional responsibilities are monitored and held accountable.

More recent legislative models, such as the Health Professions Act in Alberta, are omnibus legislation, governing multiple professions under a single Act (Health Professions Act, 2000). This results in common authorities, scope, and processes for every council/board governing a profession under the legislation. The legislation accommodates overlapping scopes of practice, rather than exclusive scopes of practice, inviting optimization of professionals' roles. Whereas traditional models differentiate professions through activities that are exclusive to specific professions (i.e., dispensing by pharmacists and prescribing by physicians), this newer model differentiates professions through role definition and restricted titles (i.e., only individuals who qualify and register with the Alberta College of Pharmacists can hold themselves out as a pharmacist).

Roles and Responsibilities of Regulating Bodies

In 2016, the Professional Standards Authority in Great Britain, in its discussion document "Regulation Rethought – Proposal for Reform" proposed that "the set of core functions that should be carried out by regulators should be":

- to *maintain a shared, public register of appropriately qualified health and care practitioners*
- *to award and renew licenses to practice in specific occupations*
- *to set common standards that all registrants must meet*
- *to investigate allegations that registrants do not meet the standards and take action.*
- *implicit within these core functions are such roles as assuring that once registered, practitioners remain appropriately qualified and that they continue to meet professional standard* (Professional Standards Authority, 2016).

These core functions are recognized in some manner in most regulatory schemes governing pharmacy professionals.

Regardless of the legislative model, the roles and responsibilities of pharmacy regulators may be simplistically described as:

"balancing
- the authority granted to individuals who qualify to be registered as pharmacy professionals; with,
- the accountabilities required to ensure that such entitlement results in the delivery of services that are in the publics' interest."

The root of all pharmacy regulator responsibilities is to define the educational requirements that candidates must complete and the competencies that they must demonstrate prior to being admitted to the register administered by the regulatory body. These are dependent on the culture of the health system, the health and health-care needs of the population being served, and the role that pharmacy professionals play in meeting these needs. Role definition and the development of competencies and educational requirements are highly interdependent and constantly evolve (Pickett, 2017; Standards of Practice, 2011b).

Pharmacy regulators are responsible for defining the roles of pharmacy professionals, and by extension the education that is required, and the competencies that must be demonstrated at entry to practice. Eligibility to practice as a pharmacy professional requires completion of approved and/or accredited learning and training.

Most pharmacy educational curriculums include classroom learning and structured practical training (SPT)/experiential learning through which candidates hone competencies and build confidence in applying the knowledge and skills that they have learned. Good SPT programs are competency based, structured, and supervized and mentored by standardized pharmacy professionals. They include opportunities for candidates to observe, demonstrate, and be evaluated on their competencies in real practice settings. This is important to building both professional competence and confidence.

Pharmacy regulators are responsible for establishing requirements for evaluating and admitting candidates at entry to practice. Depending on jurisdiction, evaluation may include one or more proctored, psychometrically standardized examinations. These often include case-based knowledge evaluation, objective-structured clinical evaluations (OSCE) where candidates must demonstrate clinical skills in mock situations, and jurisprudence exams through which candidates demonstrate their competencies in applying law and ethics.

Beyond minimal educational requirements and demonstrating competency at entry to practice, other requirements may be required at entry to practice. Examples include but are not limited to demonstration of good character and a requirement to hold a minimal amount of professional malpractice/liability insurance.

In summary, one of the most critical responsibilities of pharmacy regulators is defining requirements for entry to practice and ensuring that rigorous and effective processes are used to evaluate candidates applying for admission to the register. Once a candidate is admitted to the register and authorized to practice as a pharmacy professional, their practice and behavior will have a direct impact on the public and by extension the profession.

Pharmacy regulators are responsible for establishing requirements, and in some cases, administering processes, to ensure the competence of registrants throughout their professional careers. The knowledge and technologies important to pharmacy practice are rapidly evolving; therefore, pharmacy professionals must constantly learn and evolve their skills to best meet the needs of individuals in their care and to be relevant within the health system within which they practice. They must be relevant to and be responsive to the needs of their community.

The concept of "competence" was introduced to professional legislation in the 1990s. The definition of competence has evolved, most recently including the knowledge, skills, judgment, and attitude required to fulfil a professional role. Processes to effectively evaluate knowledge and skills and to a lesser degree judgment are common at entry to pharmacy practice (Austin, 2017).

Pharmacy regulators continue to search for means to meaningfully and effectively measure attitude; albeit, it may be the competence indicator that most substantively differentiates pharmacy professionals. While pharmacy professionals have access to common learning experiences, the manner and extent to which they choose to use and apply learning in their practices is in part determined by their attitude. This impacts (positively or negatively) their relationships with other professionals they practice with and the experiences of individuals in their care.

There is no "gold standard" for measuring competence. 16 Therefore, the way regulators address the competence of pharmacy professionals throughout their careers differs. Some processes used by pharmacy regulators to monitor competence include:

- standardized "onsite" practice evaluations,
- routine knowledge-based evaluations/examinations,
- reflection and documentation of professional practice experiences (maintenance of professional practice portfolios)
- prescribed hours, and sometimes content, of professional development,
- 360° feedback from peers, other health professionals, and patients, and/or
- Prescribed minimum hours of practice.

Each of these alternatives has their own weaknesses. Therefore, the way pharmacy regulators address continuing competence programs and requirements differs substantively. Most common are requirements to annually participate in a minimum number of hours of professional development. In many jurisdictions, this is enhanced with secondary requirements, often including one or more of the examples listed above.

It has been argued that regulators need to revitalize the concept of "professionalism" within the professions they regulate. He argues that competent behaviors are intuitive when "professionalism" is demonstrated with every individual served. If we accept his argument, then a culture of professionalism is critical in all pharmacy education, both undergraduate and post-professional and within the practice culture of every pharmacy team (Austin, 2017).

The third core responsibility of pharmacy regulators is to establish codes of ethics and standards for the practice of pharmacy professionals. Codes of ethics include broad principles that guide the behaviors and decisions of pharmacy professionals. A Code of Ethics withstands changes in time and addresses the responsibilities of pharmacy professionals to the individuals they serve, society, and their profession. Decision making and behavior in accordance with the Code of Ethics demonstrate ethical conduct.

Standards of practice are more codified, usually less principally oriented, and often more prescriptive. Standards of practice do not withstand time to the extent that a well-written Code of Ethics does and require frequent review and enhancement as changes in knowledge, technology, and health systems occur.

Standards of practice are the root indicators that pharmacy regulators use for monitoring and adjudicating the acceptability and appropriateness of pharmacy practice. Standards prescribe "minimum requirements", and they are therefore not a good tool for measuring effectiveness or levels of performance. At best, monitoring adherence to standards of practice is an indicator of compliance and conformance. Therefore, standards of practice are not good tools for encouraging innovation, diversity, or excellence.

Where legislation authorizes regulators to license pharmacies, it usually provides authority to develop standards for operating pharmacies (Pharmacy and Drug Act, 2018). These often complement those for pharmacy professionals, however, establish minimum requirements for the pharmacy. They identify the minimum requirements of the pharmacy environment, which impacts the abilities and performance of pharmacy professionals.

These standards may address infrastructure and system requirements important to maintaining the integrity and security of the drug supply and information systems that provide secure solutions for recording and accessing patient specific information. They either address or complement other legislation in setting minimum requirements for cleanliness, hygiene, and workplace safety about hazardous products. They protect both the public and the health professionals practicing in the pharmacy (Standards for the Operation, 2011).

Standards for the practice of pharmacy professionals and standards for the operation of pharmacies are renowned for being highly prescriptive. This reflects the traditional roles of pharmacists for highly technical processes such as dispensing and compounding. As the responsibility of pharmacists evolves to increasingly focus on patient care rather than drug distribution, there is an urgency for pharmacy regulators to change how standards of practice are written.

Where pharmacist practice is based on person-centered care, success requires pharmacists to use critical thinking and exercise professional judgment. When standards of care are overly prescriptive, these expectations may be difficult to meet.

The final core responsibility of regulators is to receive, investigate, and resolve complaints. Processes for carrying out these responsibilities are defined in legislation to ensure "due process." In the developed world, these processes are usually based on the laws of natural justice, to ensure objectivity and fairness in both investigating and resolving complaints (Health Practitioner Regulation National Law Act, 2009; Health Professions Act, 2000; The Pharmacy Order, 2010).

Alternatives for resolving complaints are established in legislation and differ between jurisdictions. Most legislation provides for review by a panel of peers to determine the merits of the findings arising from an investigation; and where determined to be well-founded, authority to prescribe sanctions. The latitude for prescribing sanctions is established in legislation and differs between jurisdictions.

Most legislation provides opportunity to appeal the decision of a tribunal. Again, depending on legislation and jurisdiction, the procedures and avenue for appeal differs; but in the end, often includes the judiciary.

The Role of Regulators in Developing Public Policy

Regulators play an important role in developing public policy. As their authority either lies with government or is delegated from government on behalf of the public, they are an important resource to governments when developing policy about health systems.

Pharmacy regulators provide knowledge and experience important to health system design (particularly involving the role of pharmacy professionals), drug therapy, quality, and patient safety. It is important that they promote policies consistent with the mandate granted them through legislation, with a clear view to the public.

Regulators are often called upon to address expansion in the "scope of practice" for pharmacists and other pharmacy professionals. As establishing the roles of pharmacy professionals, their education, competency, code of ethics, and standards fall within the responsibilities of regulators, they are a source of expertise important to these discussions. However, as their legislative mandate focuses on the public, advocacy for such changes should reside with pharmacy professional/advocacy organizations, with the regulator providing secondary support consistent with their responsibilities.

Case Study—Pharmacy Practice in Alberta, Canada

Pharmacists in Alberta, Canada, enjoy one of the broadest scopes of pharmacist practice in the world. Since 2007, Alberta pharmacists have been able to prescribe drugs (except controlled substances) and administer injections (Pharmacists and Pharmacy Technicians Profession Regulation, 2011). While all pharmacists can "adapt" prescriptions written by other prescribers to modify or extend them to meet unique patient needs, a subset who have successfully completed a peer evaluation process, may be authorized by the Registrar to initiate and manage ongoing drug therapy. During the 2017/2018 influenza season, pharmacists administered over 50% of the publicly funded immunizations performed in Alberta (Abpharmacy, 2018). That's significant because government did not provide public funding for immunizations performed by pharmacists until December 2009, at the height of the H1N1 outbreak.

Pursuit of this scope of practice began in 1995, when Alberta's Premier appointed a committee on Health Workforce Rebalancing. Alberta was in an era of rapid economic and population growth, and it was observed that there would be a shortage of health professionals to meet public need. The committee observed that Alberta's existing health workforce could be optimized, if every health professional was able to fully use their knowledge and skills. This resulted in recommendations to rescind "exclusive" scopes

of practice and to create new legislation that accommodated overlapping scopes of practice and restricted titles. This provided opportunity for pharmacy to pursue broader roles and responsibilities for pharmacists in patient care. Beyond compounding, dispensing, and selling drugs, there was now possibility for pharmacists to prescribe and administer drugs by injection.

At that time, the Alberta Pharmaceutical Association (APhA) was the sole provincial organization for pharmacists. It held two mandates: one as regulator and the second as an advocate for the profession. Therefore, it had both authority and a responsibility to lead pharmacy's pursuit of an expanded scope of practice. Certainly, there was an expectation within the profession for it to champion this role.

The Alberta Government requested that all professions develop a role statement, describing what members of every health profession provided the public and the health system. The APhA's advisory committee delegated with this responsibility was intent on ensuring that pharmacy's role statement was futuristic, focusing on the role of pharmacists in patient care.

In 2000, government passed new omnibus legislation to govern and regulate 29 health professions, including pharmacists. The Health Professions Act includes two distinct sections. The first which is common to all regulated health professions addresses governance, registration, competence, and complaints resolution. The second section provides a unique schedule for each profession, providing a role statement and restricted titles (Health Professions Act, 2000).

The legislation requires that each profession be governed by "a college." Colleges are prohibited from negotiating fees or reimbursement for a profession. Therefore, in 2000, the Alberta Pharmaceutical Association was replaced by two new organizations; the Alberta College of Pharmacists (ACP) as the regulator and the Alberta Pharmacists Association (RxA) as the professional/advocacy organization for the profession. Leadership within ACP continued from the APhA; therefore, it took the lead in pursuing and bringing the current scope of practice to fruition.

Before being governed and regulated under the new legislation, regulations needed to be developed; both for governing pharmacists and the operation of licensed pharmacies. The new Act provided the foundation for evolving pharmacists' scope of practice to include prescribing and the administration of drugs by injection.

The governing council appointed a steering committee to conduct literature research and to develop a "whitepaper" to support the proposal (Literature Review and Whitepaper, 2003). It addressed public needs that pharmacists were well prepared to address because of their education and training. Complemented by their accessibility, this presented a new opportunity for Alberta's health system. The whitepaper was also supported by discussions evolving in Great Britain that proposed a new role for pharmacists in prescribing. This demonstrated that the vision of Alberta pharmacists was not isolated.

Additionally, research to demonstrate the ability of pharmacists to monitor drug treatment and to prescribe was initiated. A pharmacist lead and managed anticoagulation program was introduced at the University of Alberta Hospital in Edmonton, Alberta. A research team led by pharmacist Dr. Tammy Bungard, and including a Medical Internist, a Cardiologist, and a Hematologist, oversaw and evaluated the project. The results substantively supported an expansion of pharmacists' scope of practice to include prescribing. Bleeding times decreased, hospitalization related to anticoagulation decreased, health system costs decreased, and the satisfaction of patients, physicians, and pharmacists all increased. The project was so successful and that the demand for pharmacists in this role expanded across hospitals in Alberta and into the community (Bungard et al., 2006). This local research contributed to a perfect storm in Alberta, where policy makers were quickly seeing new opportunities through pharmacist practice. They began to recognize that the monitoring and prescribing roles performed by the anticoagulation pharmacy team were transferable to other chronic disease conditions.

The whitepaper and the results of the anticoagulation project were the foundation for engagement with patients, health advocacy organization leaders, regional health authorities, other professionals, and government. A joint working group was formed with the College of Physicians and Surgeons of Alberta (CPSA) to study ACP's proposal. It included two physicians, a community and hospital pharmacist, two members of the public, and the registrars of the CPSA and ACP. This provided better understanding of pharmacy's proposal by organized medicine.

The College and Association of Registered Nurses of Alberta were pursuing enhancements to the educational requirements of registered nurses at the same time. They agreed to support the pharmacy's proposal for pharmacists to prescribe and administer drugs by injection, if ACP would support their proposal for broadened educational requirements at entry to practice.

This engagement and these partnerships were instrumental to the support ACP required when presenting its proposal that pharmacists be entitled to prescribe and administer drugs by injection to government's Health Professions Advisory Committee in November 2003. This committee was responsible for advising the Minister about whether an expansion to the scope of practice for pharmacists should be made in the regulations under the Health Professions Act.

In 2005, the Pharmacists Profession Regulation was passed, followed by the Pharmacy and Drug Regulation in 2006, both coming into effect on April 1, 2007. This was a significant milestone in the history of pharmacist practice as pharmacists were finally recognized as having the competencies to make drug use decisions, rather than having to receive the authorization of other prescribers when drug-related problems were identified. This success was largely due to the following critical success factors:

- Government Policy—the goal of the provincial government was to optimize the role of all regulated health professionals under the new Health Professions Act.
- Timing—organized pharmacy engaged and was ready to respond to this opportunity.
- Local Research—the anticoagulation project provided local context and demonstrated value.
- Engagement—the whitepaper and local research provided a solid foundation for discussions with the public, policy makers, and other professions, providing them evidence to be advocates for the proposal.

- External Champions—the anticoagulation project created physician champions that supported pharmacists in prescribing
- Partnerships—the partnerships with CPSA and CARNA, both mitigated risk and created opportunity to support the proposal.

Emerging Considerations in Regulation

The governance and regulation of pharmacy professionals is increasingly complex, and the concept of "self-regulation" is scrutinized.

The public and some governments are increasingly sceptical about whether self-governing professions truly act in their interest, or whether they are too "internally preoccupied." Governments have responded in many ways. In some jurisdictions, they have required that a greater percentage of governing councils be members of the public appointed by government. In others, legislation has been amended allowing the Minister of Health to intervene on decisions of regulatory colleges, if they felt that the college was not acting in the public's interest. In extreme cases, governments have rescinded the privilege of some professions to govern themselves. Therefore, pharmacy regulators must always be seen to be acting and making decisions that are in the public's interest (Legislative Assembly of British Columbia, 2003; Professional Standards Authority, 2016).

The advent of new technologies facilitates new possibilities in how health services are delivered. The distant delivery of pharmacy services is growing. This extends beyond drug distribution, and now includes patient care services. New transportation and communication alternatives facilitate the delivery of these services over jurisdictional boundaries. This presents both opportunity and risk. It clearly invites new discussions about the governance of services that span jurisdictions and that could become international in scope.

Dispensing and patient care records developed by pharmacists are no longer simply relevant to the pharmacist/patient relationship. These records are now used and relied upon by other members of each patient's team. Where services are delivered between jurisdictions, information systems are seldom integrated, resulting in gaps in the local patient record. This fragmentation perils decisions by other health professionals who rely upon this information to make informed patient care decisions.

An increased value is being placed on "team-based" care; yet, governance and regulation are usually profession specific. This makes collaboration and partnerships between health regulators critical. Some argue that profession-specific regulation should be replaced by team-based regulation as this may facilitate a more integrated approach to the quality and safety that is in the public's interest.

Summary

The regulation of pharmacy professionals is increasingly complex, yet an important privilege that contributes to the identity and definition of pharmacy professions. The roles and responsibilities of pharmacy regulators are clearly entrenched in legislation. Sentinel is the responsibility of pharmacy regulators to observe the public as their primary customer. Their "means" is to provide stewardship over the practice of pharmacy professionals, while their "end" is to ensure that the public's interest is served and safety ensured.

Regulations governing pharmacy professionals differ substantively between jurisdictions; however, include core common responsibilities. While authorities and processes differ, legislation supporting the regulation of pharmacy professionals usually addresses governance, registration, competence, standard setting, and complaints resolution responsibilities.

Pharmacy regulators have an important complementary role in defining the scope of practice of pharmacy professionals. Their expertise in establishing roles, competencies, education, standards, and codes of ethics is important to supporting proposals lead by pharmacy professional/advocacy organizations. Policy support provided by regulators should always address the publics' interest.

Internationally, there is interest in expanding the scope of practice of pharmacists. In Canada alone, there is diversity in the scope of practice of pharmacists between provinces. Success in expanding the scope of practice depends on the alignment of multiple critical success factors.

The regulation of pharmacy professionals is increasingly complex and scrutinized. New technologies and globalization have invited new ways of delivering services. This invites new governance considerations when services cross jurisdictional boundaries. Further, new technologies invite new ways of doing things; and therefore, the need for new standards, and sometimes threats to some pharmacy professionals. In responding to these threats, pharmacy regulators must constantly be conscious of their responsibility to make decisions in the publics' interest, to ensure the confidence of their morale owner.

Glossary

- *Drugs*—infer scheduled substances that are licensed through legislated processes for the prevention, maintenance, and treatment of health conditions.
- *Governance*—is how society or groups within it, organize to make decisions. In pharmacy, the group authorized to govern may be delegated by government, or it may be government itself, depending on the jurisdiction.
- *Jurisdiction*—infers a country, province, state, or other regional form of government that holds responsibility for legislation that governs the practice of pharmacy professionals.

- *Pharmacy professionals*—infers pharmacists and pharmacy technicians and any other associated class of individuals who are regulated to support the practice of pharmacy.
- *Premier*—means the leader of the provincial government in Alberta, Canada
- *Regulates*—infers both governs and regulates.
- *Rules of natural justice*—In English law, natural justice is technical terminology for the **rule** against bias (nemo iudex in causa sua) and the right to a fair hearing (audi alteram partem). While the term natural justice is often retained as a general concept, it has largely been replaced and extended by the general "duty to act fairly."

Public Health and Health Promotion in Pharmacy Practice

Claire Anderson, University of Nottingham, Nottingham, United Kingdom

What is Health?

There are numerous concepts and definitions of health and they can be narrowly technical to moral and philosophical. People's views on what health is vary considerably and an individual health professional's views might be very different from those of their patients. The Western scientific model of health dominates while being challenged by holistic and social models of heath. The common meaning of health is the absence of disease. In 1948 the WHO defined health as "a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity."

This model has been criticized for being very hard to attain and also for medicalizing society.

By 1984 the WHO definition was more of a wellness model health as defined as "The extent to which an individual or group is able to realize aspirations and satisfy needs, and to change or cope with the environment. Health is a resource for everyday life, not the objective of living; it is a positive concept, emphasizing social and personal resources, as well as physical capacities." The Jakarta Declaration for health promotion, 1997 defined health as a basic human right and essential for economic and social development.

Health should not be thought of as simply as the absence of disease or the basis of physical fitness.

Health is holistic and comprises physical, mental, emotional, social, spiritual, and sexual dimensions.

It is also influenced by societal, environmental, and global issues. To be a healthy society, a society needs a basic infrastructure such as shelter, peace, food, and income. Well-being is about feeling good and functioning well and is used widely to encompass physical and mental health.

Defining Public Health

Like health itself there are numerous definitions of public health. A commonly used definition is "the science and art of preventing disease, prolonging life and promoting health through he organized efforts and informed choices of society."

There are three domains of public health: the first is health improvement; this includes people's lifestyles, inequalities in health, and the wider social influences on health. Second is the health protection including infectious diseases, environmental hazards, and emergency preparedness. Third is the health service delivery and quality (healthcare public health) including service planning, efficiency, audit, and evaluation. Pharmacy can play a role across all three domains.

Activities to strengthen public health aim to provide conditions under which people can stay healthy and maintain their health, improve their health and well-being, or prevent the deterioration of their health. Public health focuses on the entire spectrum of health and well-being, not only the eradication of particular diseases. Many activities are targeted at populations such as health campaigns. Public health services also include the provision of services to individuals, such as vaccinations, behavioral counseling, or health advice.

Five Waves of Public Health

Public health has been characterized into five waves. The first wave focuses on overcrowding, poor sanitation, contaminated water, poor nutrition, and a poor built environment. The second wave was when medicine emerged as science and during this time paternalistic approaches to healthcare gained precedence. This was institutionalized in the third wave through the redesign of social institutions in the early 20th century and the birth of the welfare state in the UK. The fourth wave in the 1960s moved to the risk theory of disease and the role played by individuals' lifestyle factors, including smoking, diet and physical activity, alongside concerns with social inequalities in health. The more recent fifth wave is defined by a "culture of health and well-being," in which the value of health and well-being and incentives for healthy behavior are maximized, healthy choices are promoted by default so that they are easier choices, and factors that create a culture and environment which promote unhealthy behavior are minimized.

The health improvements that have been seen in high-income countries are due to the impact of cleaner air, good housing, improved education, as well as changes to legislation and fiscal policies for example, immunization, family planning, antenatal care, screening programs, universal healthcare, and advances in diagnosis and medical interventions. Despite improvements in health, major inequalities in health outcomes, reflecting social and economic inequalities, remain. For example, in England, average life expectancy in the poorest communities remains seven years lower than in the wealthiest areas. Disability-free life expectancy is 17 years lower in the poorest communities. Health inequalities persist, despite policies aimed at reducing them.

The UN Sustainable Development Goals

The UN developed the sustainable development goals (SDGs) to be completed by 2030, (https://sustainabledevelopment.un.org/sdgs) following on from the previous millennium development goals. The goals cover a broad spectrum of global development. Goals 1–6 in particular address key issues in global public health: no poverty, zero hunger, good health, and well-being, quality education gender inequality, and clean water and sanitation.

The UN Secretary-General at the time of their launch, Ban Ki-Moon, said that "The 17 SDGs are our shared vision of humanity and a social contract between the world's leaders and the people. They are a to-do list for people and planet, and a blueprint for success."

See http://www.undp.org/content/undp/en/home/sustainable-development-goals.html

SDG 3—Ensure Healthy Lives and Promote Well-Being for All at All Ages

Each SDG has a number of associated targets. The associated targets for SDG3 are wide ranging and aim at the reduction of global maternal mortality, the end of preventable deaths of newborns, the end of the epidemics of AIDS, tuberculosis and malaria as well as the reduction by one third of premature mortality from noncommunicable diseases, tobacco control, prevention of substance and alcohol misuse, providing access to medicines for all, access to family planning as well as substantially increase health financing and the recruitment, development, training, and retention of the health workforce in developing countries. Pharmacy and pharmaceutical science can have an influence on most of these targets.

Eradicating Malaria as an Example

If eradicating malaria is taken as an example, it can be clearly seen that many of the SDGs apply to it.

SDG	*Implications for malaria*
SDg1 no poverty	Malaria disproportionately affects poor and vulnerable people.
SDG3 good health and well-being	By reducing the prevalence of waterborne diseases, vector control will contribute to defeating malaria and reducing mortality.
SDG4 quality education	Malaria can cause a significant level of school absenteeism seriously impacting on children's educational opportunities and futures.
SDG5 gender equality	Pregnant women are more vulnerable to malaria, and occupational exposure may make men more vulnerable.
SDG 6 clean water and sanitation	Cleaner water and sanitation water play a crucial part in the malarial parasite's lifecycle. Cooperation with the water and sanitation sectors is essential for control of malaria.
SDG 7 affordable and clean energy	The construction of hydroelectric dams has been associated with changes to malaria epidemiology
SDG8 decent work and economic growth	Time off work due to malaria causes lost productivity in the workplace
SDG9 industry, innovation, and infrastructure	Towns and cities need to be designed to reduce mosquito habitats
SDG11 sustainable cities and communities	Successfully implemented malaria control will lead to cleaner, safer, and more sustainable cities and communities without the breeding ground for mosquitoes
SDG13 climate action	It is expected that global warming will lead to an increase in malaria, leading to a higher disease burden across more countries
SDG17 partnerships for the goals	Successful control of malaria will require concerted efforts by numerous global partners

TB as a Global Public Health Issue

Another example of a global public health issues is TB, which is a leading killer worldwide, alongside HIV/AIDS. TB disproportionally affects world's most poor and vulnerable, aggravating existing inequalities. Because of TB, people face costs or suffer income loss equivalent on average to more than 50% of their income. In 2014 9.6 million people fell ill with TB and 1.5 people died from it, 1.2 million people living with HIV developed TB, and 480,000 people developed MDR-TB (multidrug-resistant TB), with 190,000 associated deaths. The WHO wish to eradicate TB by 2035 and have developed the end TB strategy (http://www.who.int/tb/post2015_strategy/en/); the WHO's aim of ending the global TB epidemic is feasible with the dramatic decline in TB deaths and cases, and elimination of economic and social burden of TB. Failure to do so will carry serious individual and global public health consequences. Achievement of this goal by 2035 requires: expanding the scope and reach of interventions for TB care and prevention, with a focus on high-impact, integrated and patient-centered approaches. Collaborative HIV and TB activities; bold policies and supportive systems through engaging a much wider set of collaborators across government, communities, and the private sector, intensified research and innovation that can dramatically change TB prevention and care.

At a more local level public health England have developed a TB strategy that aims to achieve a year-on-year decrease in incidence of TB, a reduction in health inequalities, and ultimately the elimination of TB as a public health problem in England. The strategy has 10 key areas for action:

1. Improving access to services and ensuring early diagnosis.
2. Providing universal access to high quality diagnostics.
3. Improving treatment and care services.
4. Ensuring comprehensive contact tracing.
5. Improving BCG vaccination uptake.
6. Reducing drug-resistant TB.
7. Increasing awareness.
8. Providing context-specific information for professionals and patients on the prevention and management of TB.
9. Tackling TB in under-served populations, systematically implementing new entrant latent TB screening.
10. Ensuring an appropriate workforce to deliver TB control.

Pharmacists can be involved in this strategy at every level from increasing awareness, screening, and pharmaceutical care of people with TB and developing new and effective antimicrobial treatments.

Alongside global measures such as the UN SDGs which focus on health, health inequalities, and many of the wider drivers of health, a number of new ideas and concepts are emerging in public health, including "fifth wave of public health," "ecological public health" and "planetary health."

Ecological Public Health

Ecological public health focuses on the array of environments through which health is influenced and the complex interactions between them. Ecological public health proposes that ill health is the result of a "mismatch of bodies and environment," which can be improved by addressing the factors across four environmental dimensions: material, biological, cultural, and social.

Planetary Health

Planetary health recognizes "the health of human civilization and the state of the natural systems on which it depends." The global increase in life expectancy and decrease in poverty and child mortality rates over the past 50 years have coincided with a depletion of the Earth's natural resources and increasing environmental impact. Planetary health acknowledges that as population size and demands on the planet increase, maintaining the health of the planet is vital to protecting future human health. It calls for "promoting sustainable and equitable patterns of consumption, reducing population growth, and harnessing the power of technology for change."

What is Health Promotion?

Health promotion is a range of activities and interventions, which aim to help people maintain and enhance good health and prevent ill-health by taking greater control over their health. Downie argued that, "the overall goal of health promotion may be summed up as the balanced enhancement of physical, mental and social facets of positive health, coupled with the prevention of physical, mental, and social ill-health."

The term encompasses a range of activities including those which support healthy lifestyles, encourage access to services, and involvement in healthy decisions, and seek to promote an environment in which healthy choices become easy choices and educate people about the body and keeping healthy. These may include both individual and societal aspects, overlapping with public health. At one end of this range are government policy and legislation affecting health. These include actions with a direct influence on health (e.g., legislation to ban tobacco smoking in public places) as well as those which affect the determinants of health (e.g., social welfare and benefits policies). Until the 1980s these activities were referred to as health education and it is only more recently that the term health promotion became used. The WHO moved the definition of health promotion away from disease prevention and screening toward the health and well-being of whole populations.

Heath Education

Health education is part of health promotion and involves activities to facilitate learning about health. WHO define it as "any combination of learning experiences designed to help individuals and communities improve their health, by increasing their knowledge or influencing their attitudes."

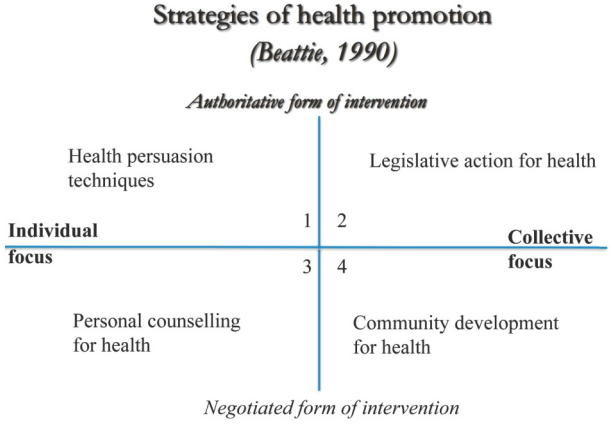
Tones and Tilford said that health promotion should be an umbrella term that includes all interventions to promote health and they proposed a smile formula health promotion = health education X healthy public policy.

Pharmacy and Health Promotion

Pharmacists and their teams provide information to promote and maintain good health, to support people's actions and behaviors related to health, and to contribute to improving quality of life. However, pharmacists often feel more comfortable linking such advice giving to the use of medicines and other health-related goods, as the provision of medicines and services focused around medicines remains their major role.

Health professionals engage in "people-centered health promotion," working over time with individuals and communities as well as policy makers and the overall political system empowering them to have the positive stares of and conditions for physical mental social and spiritual health.

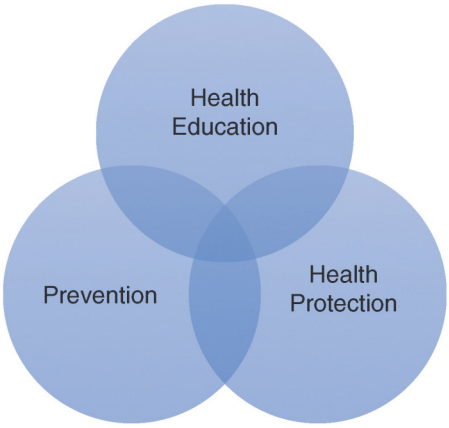
Beattie's strategies of health promotion are a useful way to explore the pharmacy team's contribution to health promotion. The grid provides a way of comparing the different philosophies of various health promoters through an analysis of the quadrant within which their work originates.



In Beattie's framework, pharmacists' involvement in health promotion has primarily fallen within quadrant 1, providing expert information to individuals. Health professionals may be tempted to act in a "telling" rather than a "discussing" mode. However, the evidence shows that people tend not to respond so positively to such approaches. Current thinking is that the pharmacist's most effective contribution would be through adopting an approach consistent with quadrant 3, working with individuals to negotiate change. Individual pharmacy teams may also be involved in community development for health, for example, providing interventions that seek to empower a group in the community, for example, running weight management or stop smoking clinics.

Health promotion embraces the concepts of both community and individual development. Tannahill's model for health promotion includes health education, prevention, and health protection.

Tannahill's model



The pharmacist has an important role as an advocate for their community, in lobbying at local and national levels, and supporting local community groups working for health improvement. However, to effectively engage with the health promotion agenda, pharmacists also need to understand its relationship with the social and economic context.

Pharmacists who want to develop health promoting activities need to adopt a style of consulting, which involves listening and negotiating rather than merely telling, taking into account the individual's social circumstances. This may involve the role of family members, carers, or friends in the management of medicines, while taking into consideration living conditions, health status and socioeconomic resources. Any pharmacist may participate in health promotion and those working in community and hospital practice are well placed to do so. Their level of input has been classified as:

Level 1: displaying leaflets on health topics and responding to requests for advice and information about health.
Level 2: in addition to level 1, offering information and advice opportunistically and proactively, working in a coordinated way with community-based healthcare workers.

The difference in these two levels is essentially that in the first, the pharmacist is passive and working at an individual level and in the second active and using community networks effectively.

The health promotion input from pharmacists is summarized below, and pharmacists should adopt a holistic approach and think creatively about the opportunities to promote health. A holistic approach means addressing issues not traditionally associated with pharmacy, but which may still be linked to the sale or supply of medicines or health-related goods. Pharmacists may be uncomfortable when providing dietary advice or recommending physical activity programs. This initial discomfort may be alleviated by targeting advice to particular groups of people, for instance:

- Target information about effective physical activity to those receiving prescriptions for medicines to prevent or treat osteoporosis. This might be the availability and timing of local sessions to promote strength and balance as part of a "falls reduction program."
- Asking patients presenting prescriptions for medicines for coronary heart disease whether they would like further information about diet and physical exercise.

Health Promotion in the National Health Service Contract in England

The National Health Service (NHS) contract in England includes health promotion as an essential service and states that this includes "the provision of opportunistic healthy lifestyle advice and public health advice to patients receiving prescriptions who appear to: have diabetes; or be at risk of coronary heart disease, especially those with high pressure; or who smoke; or are overweight, and pro-active participation in national/local campaigns, to promote public health messages to general pharmacy visitors during specific targeted campaign periods."

Prescription-Linked Interventions

Pharmacists and their staff will give opportunistic advice, as appropriate, on specified healthy living/public health topics to people presenting prescriptions with diabetes, those at risk of coronary heart disease, especially patients with high blood pressure,

those who smoke, and those who are overweight. The advice will be given verbally, but may be backed up by the provision of written information, for example, leaflets and a referral to another source of advice or assistance. A record of the advice given will be made on the patient's pharmacy record. This record will facilitate service audit and also future follow-up with the patient. Pharmacy contractors should have systems in place to ensure that appropriate advice is given to patients.

Campaign-Based Services

Pharmacists and their staff will proactively take part in and contribute to national/local campaigns for patients and general pharmacy visitors during the campaign period, including giving advice to people on the campaign issues. This advice may be supplemented by provision of written information and in-store displays. The pharmacy will provide this service for up to six campaigns per year. The pharmacy will record the number of people who receive advice if requested to do so by their primary care organization. The primary care organization will determine the topics of the campaigns and will provide any appropriate support, for example, briefing packs and patient literature to support campaign messages.

The Components of Pharmacists' Health Promotion Activities

- Using the pharmacy premises effectively to promote health through the display of posters and leaflets on health topics.
- Providing an advice or counseling area.
- Using written information opportunistically to supplement verbal advice (e.g., using a leaflet on healthy eating as well as selling a bulk laxative, as part of the response to a customer asking for advice on constipation).
- Offering one to one advice about individual behaviors (e.g., smoking cessation), this might often be linked with the sale of nicotine replacement therapy.
- Offering clinics (perhaps in conjunction with local medical practices) on specific topics such as the menopause.
- Targeting individuals known to be at risk (e.g., those receiving prescription medicines for angina, osteoporosis) and discussing management options, involving family, friends, and carers in management if appropriate and considering with the individual the effect of the treatment on their quality of life and offering further information if required.
- Networking with other health professionals and health agencies to participate in activities and campaigns that address the local community's health needs.

There is evidence that even the shortest of interventions can be effective providing they are delivered in a way that has been shown in research to work.

Types of Pharmacy Intervention Adapted From Nice

Very Brief Intervention

A very brief intervention can take from 30 s to a couple of minutes. It is mainly about giving people information or directing them where to go for further help. It may also include other activities such as raising awareness of risks or providing encouragement and support for change. It follows an "ask, advise, assist" structure. For example, very brief advice on smoking would involve recording the person's smoking status and advising them that stop smoking services offer effective help to quit. Then, depending on the person's response, they may be directed to these services for additional support.

Brief Intervention

A brief intervention involves oral discussion, negotiation, or encouragement, with or without written or other support or follow-up. It may also involve a referral for further interventions, directing people to other options, or more intensive support. Brief interventions can be delivered by anyone who is trained in the necessary skills and knowledge. These interventions are often carried out when the opportunity arises, typically taking no more than a few minutes for basic advice.

Extended Brief Intervention

An extended brief intervention is similar in content to a brief intervention but usually lasts more than 30 min and consists of an individually focused discussion. It can involve a single session or multiple brief sessions.

Local authorities in England have responsibility for commissioning a wide range of services, including most public health services and social care services. The following public health services provided by community pharmacies have been commissioned by local authorities:

- Supervised consumption
- Needle and syringe program
- NHS health check
- EHC and contraceptive services
- Sexual health screening services
- Stop smoking
- Chlamydia testing and treatment
- Weight management
- Alcohol screening and brief interventions

The Evidence Base for Pharmacists' Role in Improving the Health of the Public

A 2013 public health England commissioned review of pharmacy's role in improving the health of the public identified twenty relevant review papers on the contribution of community pharmacy to public health. The review found that a considerable body of evidence exists for the role of community pharmacy for a range of services, not only aimed at improving general health, but also at maintaining the health of those with existing disease. The evidence for positive outcomes is strongest in services including smoking cessation, supply of emergency hormonal contraception, cardiovascular disease prevention, blood pressure management, diabetes and possibly asthma, and heart failure. There was strong evidence of improvements in lipid levels that were sustained for at least 1 year in both primary and secondary prevention of coronary heart disease. Community pharmacists can also make an important contribution to the management of people with diabetes for screening, improved adherence with medicines, and reduced blood glucose levels or HbA1c.

Although published evidence is currently less strong in other areas such as COPD, infection control, substance abuse, weight management, and minor ailments schemes, there are some reports of successes in the community pharmacy provision of these services. The authors concluded that further research is necessary to justify the role of community pharmacy in these areas.

Greater efforts to prevent ill health and promote well-being are recognized globally as being crucial for the future. Various interventions are being made to encourage individuals to improve their diet and become more physically active, lose weight if they are overweight or obese, stop smoking, reduce their alcohol intake, and practice safe sex to prevent unwanted pregnancies and a range of infectious diseases such as HIV and chlamydia. Community pharmacists and their teams are ideally placed to act as health promoters.

Smoking Cessation

There is strong evidence for community pharmacy-based smoking cessation services and smoking cessation is the most common public health activity in UK community pharmacies. The evidence suggests that community pharmacy-based stop smoking services run by trained pharmacy staff are effective and cost-effective in helping smokers quit. The studies included are RCTs and therefore of high levels of evidence. A Cochrane review found some evidence to suggest that properly trained community pharmacy staff may have a positive effect on smoking cessation rates. A later publication that community pharmacists trained in behavior-change methods are effective in helping people to stop smoking based on high quality RCTs and that the service is cost-effective. The authors found that training was fundamental to the success of stop smoking services provided by community pharmacists.

Community pharmacy interventions are effective for smoking cessation. Twenty-four relevant studies of pharmacy-delivered interventions were identified; most of the evidence was focused on smoking cessation interventions. Pharmacy-based smoking cessation interventions, including behavioral support and/or NRT, are effective and cost-effective in helping adults to stop smoking, particularly compared with usual care.

A recent realist review and analysis of smoking cessation support from community pharmacists and their staff that although there is evidence that smoking cessation interventions in pharmacy are effective and cost effective, there is very limited empirical evidence on organizational and system influences on this role. Key findings from the realist analysis were that for the community pharmacy to become the site of smoking cessation, they must view themselves as a public health professional rather than (merely) a dispenser of medicines, and the authors stated that this was something that is far more likely to happen if undergraduate training, professional bodies, and national policy depict them in this way and endorse the role positively. Training needs to be accessible and include a broad curriculum that goes beyond "tasks and facts." Pharmacists are more likely to be motivated (from a professional, business, and personal perspective) if other pharmacists locally and nationally are also delivering smoking cessation services; if the work is received positively at appraisal and performance review; if structural and logistical issues including avoiding excessive paperwork and adequate remuneration are addressed; and if the work is adequately remunerated. Finally, pharmacists must have the confidence of other health professionals and the trust of the wider public, professional bodies, and the media.

Emergency Hormonal Contraception Supply

A review of the international literature on emergency hormonal contraception supply through community pharmacies found that pharmacies provided timely access to treatment and the service was well received by women. The one randomized controlled trial included in the review showed that provision of EHC through community pharmacies did not reduce the use of other contraceptives, leads to an increase in risky sexual behavior or increases the incidence of STIs. An observational study showed that the average time to access EHC was 16 h through community pharmacies compared to 41 h through family planning clinics. It is clear that the service is unlikely to provide unwanted effects, is well received, and reduces access times which is known to improve treatment effectiveness but evidence for cost-effectiveness of EHC supply services provided through community pharmacy is not available.

Chlamydia Screening and Treatment Services

Chlamydia screening is designed to identify and treat Chlamydia infections early and before they may progress to pelvic inflammatory disease and ultimate infertility. A national screening program was introduced in England in 2010 and included community

pharmacies where treatment was also offered for those screening positive. A systematic review of the literature regarding community pharmacy provided chlamydia screening, and treatment services found that Chlamydia screening from community pharmacies is feasible and can provide an accessible, convenient venue to get a test.

Case Finding Type II Diabetes Screening

It has been shown that community pharmacists can effectively screen for type II diabetes enabling early diagnoses. Research in the UK suggests that while screening with intervention for diabetes and impaired glucose tolerance for those between 45 and 75 is likely to be cost-effective, the cost-effectiveness of diabetes screening alone is uncertain. Strategies to improve cost-effectiveness of diabetes screening services include focusing screening on those at greater risk, for example, those with known high-risk ethnic groups with an increased body mass index and using more specific and sensitive screening methods specificity. The UK government recommends that diabetes screening should be focused on patients from known high-risk ethnic groups with increased body mass index and those prescribed lipid lowering and hypertensive treatments. The community pharmacist has access to sufficient information to enable them to use such criteria to identify people with those risk factors and provide a diabetes case finding and intervention service. In Australian pharmacies, a diabetes risk assessment followed by a blood test resulted in fewer referrals and greater uptake by patients than when using risk assessment only.

Harm Reduction Services

Community pharmacists contribute to the health of opioid-dependent patients through supervised consumption of opioid substitution medicines like methadone and buprenorphine to ensure that the individual prescribed the medicine actually takes it and prevent diversion or sale to other users which can result in accidental overdosage. A review of pharmacist supervision's effect on methadone-related deaths between 1993 and 2008 found that the number of deaths in Scotland reduced from 20 per 1 million defined daily doses of methadone to 2 and in England from 25 to 6. The reduction has been sustained and with the main change in practice being the introduction of supervised consumption, this can largely be attributable to the contribution made by community pharmacy. The cost-effectiveness of the service is currently unknown and therefore the question is whether the cost is justified by the significant reduction in deaths resulting from methadone seen.

Needle and syringe programs, which may or may not include the provision of other related materials to minimize harm to users, are commissioned throughout England by local authorities. Needle exchange services are a cost-effective use of resources

Weight Management

A recent systematic review reported that community-based weight management services were as effective as other primary care strategies. The actual cost of service delivery, however, seemed to be greater than private providers and consequently the cost-effectiveness of commissioning services via this route was stated to be unclear.

Brief Alcohol Interventions

A number of interventions for brief alcohol interventions for problem drinkers have been implemented within community pharmacies in the UK. Two RCTs showed no long-term benefits. A recent systematic review identified the need for more research and evidence for brief alcohol interventions in community pharmacies before they can be adopted. A large RCT is currently being set up.

Case Finding in Pharmacy

The Community Pharmacy Future group, a collaboration between community pharmacy chains and independent pharmacies in the UK, introduced a person-centered service for patients with multiple long-term conditions in 50 pharmacies in Northern England.

After 3 months, 683 patients had baseline clinical data recorded, of which around 87% were overweight or obese, 54% had hypertension, and 81% had high cardiovascular risk. 77% patients set themselves at least one goal during the first consultation and 22% set multiple goals. The majority of goals were identified as improvement in condition, activity, or quality of life. Pharmacists acknowledged the patient benefit and the service provided.

Pharmacy and Health Inequalities

A recent review of pharmacy smoking cessation, weight management, and multicomponent interventions that included pharmacotherapy and lifestyle changes in participants with diabetes mellitus, dyslipidemia, or hypertension concluded that the effect of community pharmacy interventions on health inequalities remains unclear. The authors stated that future research in this area is warranted, and trials should include the assessment of age, sex, ethnicity, socioeconomic status, and contextual factors, and present analysis of how these factors moderate effectiveness.

Professional Standards for Pharmacy and Public Health

The Royal Pharmaceutical Society has developed a set of professional standards for public Health (https://www.rpharms.com/resources/professional-standards/professional-standards-for-public-health).

The nine standards provide a framework to help pharmacy teams, commissioners, and those contracting services to design, implement, deliver, and monitor high-quality public health practice through pharmacy, regardless of the pharmacy settings from which services are delivered.

1. Surveillance and assessment of the population's health and well-being
2. Public health intelligence
3. Assessing the evidence of effectiveness of health and healthcare interventions, programs, and services
4. Health improvement
5. Health protection
6. Health and social service quality (also known as healthcare public health)
7. Policy and strategy development and implementation
8. Strategic leadership and collaborative working for health
9. Academic public health

So to take, for example, standard 4, the standard states that: pharmacists and their teams improve the health and well-being of the population and help to reduce health inequalities by proactively promoting health and well-being messages and supporting and enabling people to adopt healthier lifestyles and take responsibility for their own and their family's health and support self-care. Pharmacy teams use every interaction as an opportunity to provide health-promoting messages, contributing to improving population health and reducing health inequalities, making every contact count.

Advice and Information

Pharmacists and their teams are confident and knowledgeable and provide healthy lifestyle advice and information that is clear and consistent with national and/or local public health messages; seek opportunities to provide patients and the public with advice and information to enable people to look after their own and their family's health and support self-care; work in partnership with other practitioners and agencies to provide evidence-based advice and information to improve the health and well-being of their local communities and improve health literacy.

Communication

Pharmacists and their teams are aware of the wider factors influencing health (including health literacy, socioeconomic, ethnic, and genetic factors) and the health needs of their local population or community; communicate and signpost public health advice and information in a clear, non-judgmental and consistent way; are appropriately trained in evidence-based communication techniques, for example, motivational interviewing techniques and brief intervention skills; provide nonjudgmental support to improve health literacy and access to health-related information to enable people to set their own health goals to achieve better population health outcomes.

Service Delivery

Pharmacists and their teams are competent in the effective delivery of public health services and interventions designed to improve people's health; are aware of, and signpost to relevant local and national public health services to support people to live healthier lives (when appropriate and when they are not themselves able to provide support) deliver services which support self-care and enable people to take responsibility for their own and their family's health; are aware of the groups and communities within their local population at most risk of experiencing health inequalities and take steps to assist them in accessing and delivering public health services to meet their needs; seek opportunities to deliver public health services, based on local public health need. Pharmacy leads promote personal, team and organizational development to ensure a skilled pharmacy public health workforce that is integrated with the wider public health workforce and fit for purpose to deliver high-quality public health services and outcomes.

Ethical Health Promotion

Ethical health promotion practice is based on a commitment to health as a human right, which is central to human development. It demonstrates respect for the rights, dignity, confidentiality and worth of individuals, groups and communities; and for diversity of gender, sexual orientation, age, religion, disability, and cultural beliefs. Ethical health promotion practice addresses health inequities and social injustice, and prioritizes the needs of those experiencing poverty and social marginalization. It acts on the political, economic, social, cultural, environmental, behavioral, and biological determinants of health

and well-being. A health promotion practitioner ensures that health promotion action is beneficial and causes no harm; and is honest about what health promotion is, and what it can and cannot achieve. In all areas of health promotion practice, he/she acts professionally and ethically by:

Enabling change by providing individuals, groups, communities, and organizations to build capacity for health promoting action to improve health and reduce health inequities.
Advocating for health advocate with, and on behalf of individuals, communities, and organizations to improve health and well-being and build capacity for health promotion action.
Mediating through partnership work collaboratively across disciplines, sectors, and partners to enhance the impact and sustainability of health promotion action.
Communicating health promotion actions effectively using appropriate techniques and technologies for diverse audiences.
Leadership contributes to the development of a shared vision and strategic direction for health promotion action.

Assessment

Conduct assessment of needs and assets, in partnership with stakeholders, in the context of the political, economic, social, cultural, environmental, behavioral, and biological determinants that promote or comprise health.

Planning

Develop measurable health promotion goals and objectives based on assessment of needs and assets in partnership with stakeholders.

Implementation

Implement effective and efficient, culturally sensitive, and ethical health promotion action in partnership with stakeholders.

Evaluation and Research

Use appropriate evaluation and research methods, in partnership with stakeholders, to determine the reach, impact, and effectiveness of health promotion action.

Ethical Values Underpinning the IUHPE Core Competencies and Professional Standards for Health Promotion

Ethical values and principles for health promotion include a belief in equity and social justice, respect for the autonomy and choice of both individuals and groups, and collaborative and consultative ways of working.

Ethical Health Promotion practice is based on a commitment to:

- Health as a human right, which is central to human development, respect for the rights, dignity, confidentiality and worth of individuals and groups; and respect for all aspects of diversity including gender, sexual orientation, age, religion, disability, ethnicity, race, and cultural beliefs.
- Addressing health inequities, social injustice, and prioritizing the needs of those experiencing poverty and social marginalization.
- Addressing the political, economic, social, cultural, environmental, behavioral, and biological determinants of health and well-being.
- Ensuring that health promotion action is beneficial and causes no harm.
- Being honest about what health promotion is, and what it can and cannot achieve.
- Seeking the best available information and evidence needed to implement effective policies and programs that influence health.
- Collaboration and partnership as the basis for health promotion action.
- The empowerment of individuals and groups to build autonomy and self-respect as the basis for health promotion action.
- Sustainable development and sustainable health promotion action.
- Being accountable for the quality of one's own practice and taking responsibility for maintaining and improving knowledge and skills.

Core Competencies for Health Promotion

The IUHPE http://www.iuhpe.org/images/JC-Accreditation/Core_Competencies_Standards_linkE.pdf

Core competencies and professional standards for health promotion are underpinned by an understanding that health promotion has been shown to be an ethical, principled, effective and evidence-based discipline and that there are well-developed theories, strategies, evidence, and values that determine good practice in Health Promotion (Fig. 1).

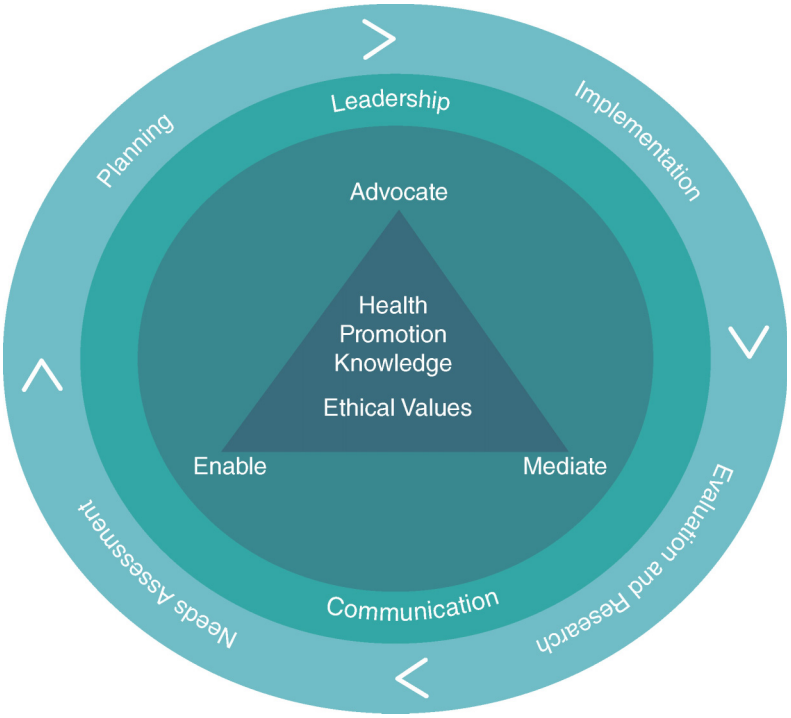


Figure 1 IUHPE core competencies for health promotion.

Healthy Living Pharmacy

The UK continues to be at the leading edge of health promoting pharmacy practice in community pharmacy with the healthy living pharmacy movement providing a focus for development. The concept of healthy living pharmacies (HLP) was developed alongside national policy and a direction of travel published in the 2008 White Paper, Pharmacy in England: building on strengths, delivering the future. The healthy living pharmacy (HLP) is a tiered framework (levels 1–3) aimed at achieving consistent delivery of a broad range of health improvement interventions through community pharmacies to meet local needs, improve the health and well-being of the local population, and help to reduce health inequalities.

The HLP framework is underpinned by workforce development; a skilled pharmacy support team to proactively support and promote behavior change, improving health, and well-being; premises that are fit for purpose; engagement with the local community, other health professionals (especially general practitioners), social care and public health professionals and local authorities (who commission public health services in England).

A HLP builds on existing pharmacy services with provision of NHS locally commissioned enhanced services at three different levels of engagement.

Level 1

The pharmacy has a consultation room

- In the past year, the pharmacy has participated in the provision of both medicines use reviews (MURs) and the new medicine service (NMS), and has proactively engaged in health promoting conversations.
- In the past year, the pharmacy has participated in the provision of the NHS Community Pharmacy Seasonal Influenza Vaccination Advanced Service or has actively referred patients to other NHS providers of vaccinations.
- The pharmacy complies with the General Pharmaceutical Council's Standards for Registered Premises and Standards of Conduct, Ethics and Performance.
- The pharmacy complies with the NHS community pharmacy contractual framework (CPCF) requirements.

Achieving HLP level 1 (self-assessment) is now a quality payment criterion for the quality payments scheme part of the English community pharmacy contract.

An example of the stepwise approach that HLP takes would be for smoking cessation. A HLP level 1 service provides brief interventions, assessing willingness of patients and signposts over services as appropriate. Level 2 may provide an NHS smoking cessation service, health checks, or cancer awareness service. Level 3 may provide COPD and cancer risk assessment with referral and be a prescriber for the stop smoking service.

Participating pharmacies are expected to deliver a range of commissioned services in line with local needs rather than selectively provide enhanced services of their own choice. The principle categories of service delivery are based around promotion, prevention, and protection.

An Example of a Health Promoting Pharmacy

Mrs P's pharmacy is much more patient and health-orientated than it used to be. She has refitted her pharmacy, making a number of special consultation areas. She put a pharmacist computer workstation next to the over-the-counter medicines. She has also installed wireless Internet. Her pharmacy counter assistants all roam the floor with ipads to enable them to answer queries in a timely manner. She has a window display about dental health that she has developed with the local dental practice as part of her towns' contribution to national dental health week. She is auditing customers' responses to it.

While Mr. G is waiting for the technician to dispense his prescription, he picks up a booklet about healthy eating from a display rack and starts to read it. He looks around at the posters about the pharmacy's smoking cessation services. While the technician gets his prescription ready, he sees Mrs. Ps second pharmacist talking to a patient seemingly explaining her medicines in detail and another about using insect repellents containing DEET, as well as taking antimalarials during her visit to Kenya. Mrs P then takes a phone call from a pharmacist colleague to discuss a patient's medicines he has noted a problem during a medicines use review in the local care home. They agreed that he should contact the patient's doctor and suggest he cancels the prescription.

As well as providing the locally commissioned public health services chlamydia Screening, supply of emergency hormonal contraception, stop smoking support, supervised consumption of methadone, needle exchange service, and supply of medicines during emergency situations, for example, supply of antivirals during an influenza epidemic.

Mrs. P considered the key health needs for her local area and decided that she should also concentrate on developing those areas rather than trying to do everything. These included diabetes care and reducing hypertension. After a meeting with her local GPs, with whom she already had a close relationship, she decided she would use her patient medication records for identifying people with diabetes and people with hypertension invite them in for a review and that they would refer them to her. She was one of the first community pharmacists in her area to become an independent prescriber and is now prescribing for many of these diabetic they have been diagnosed by the GP. She often contacts the other community, primary care, and hospital pharmacists whom she met on the prescribing course. She works closely with them and has developed a discharge medicines review service. She works closely with the pharmacist in the local GP surgery too improving the transfer of care. She also did a critical appraisal course and regularly uses computer-based systems to evaluate the evidence and to check guidelines.

At 8.30pm one evening Mr G returns to the pharmacy and asks for a quiet word. Mrs P greets him warmly and takes him to a private consultation area. He is worried about the effects that his "water tablets" might have on his bladder as he often has to attend long board meetings and does not want to always be excusing himself. Mrs P tells him that it should not cause too many problems and that he should take his tablets on rising in the morning. He also tells her that his cholesterol level was raised and the GP has told him to change his diet. The pharmacist reinforces this advice and asks him if he is taking any exercise. He plays golf once a month, but that is all he can manage now, owing to pressure of work and so on. She discusses with him some simple things he can change, like walking instead of always going short distances by car, and using the stairs instead of lifts, and she encourages him to think about taking up another sport, or playing golf once a week.

He returns a month later with a repeat prescription. He tells her that his tablets do not seem to be causing him any problems and that he has lost half a stone; he has been cutting down on business lunches and he is walking a bit more. His blood pressure has come down too. He notices a poster and asks Mrs. P if she can come along to his business and talk about heart health and smoking cessation.

Mrs P had been concerned that other pharmacies needed to change like she had and approached her local commissioning group to see if they could arrange a mentoring system whereby other pharmacists could visit her pharmacy and see what she was doing.

Mrs P has had to invest in her premises and in IT. She has also had to employ a second pharmacist and two checking technicians so that she can continue to advise people opportunistically as well as provide appointments for medicines review. She employs a nurse on Saturdays to run a travel clinic and to help her with flu vaccinations in season. She has more than recouped her investment.

Collaborative and Interprofessional Pharmacy Practice

Jennifer D. Lake, University of Toronto, Toronto, ON, Canada; Institute of Health Policy Management and Evaluation, University of Toronto, Toronto, ON, Canada

Introduction

This chapter will briefly review collaborative and interprofessional pharmacy practice (CPP/IPP). This chapter has been set out in four sections to give you an overview of the topic. The first section will introduce the topic and definitions, the second is a review of the general evidence for collaboration and CPP/IPP, the third uses primary care as an example for CPP/IPP and describes how three jurisdictions have instituted CPP/IPP. The last section reviews available instruments to measure collaboration. By the end of this chapter, pharmacists should recognize the aspects and evidence for CPP/IPP and use this to apply to their own CPP/IPP.

Collaboration is common. Collaborative teams have been the foundation of practice in many settings (e.g. inpatient units in hospital, rehabilitation settings) but are becoming more prevalent in other settings. This spreading of collaborative teams is due the significant healthcare reforms across many jurisdictions. One of the largest areas for new collaborative teams is primary care. The reason to increase collaborative practice is that it has demonstrated improved outcomes for the patient, the team-member, and the health-care system.

All professionals should be prepared to work together successfully. This is a common competency for pharmacists and other healthcare professionals (e.g. physicians and nurses). As such, many universities and professional programs are dedicating time and resources to teaching this competency using various strategies captured under interprofessional education. Interprofessional education is a new pedagogy which has happened in parallel and supporting the new emphasis on collaboration in healthcare. Interprofessional education is out of the scope of this section but it is an important facilitator to success.

Pharmacists and other pharmacy professionals must be prepared to work with others. Many pharmacist will have participated in collaborative practice for their entire career. However, CPP/IPP is an opportunity for all pharmacists to improve patient and healthcare outcomes. With the recent spread of collaboration into primary care, pharmacists have the opportunity to collaborate more than ever before. Pharmacists practicing in community settings have historically worked with physicians but this relationship may have been perceived as one-way or reactive. CPP/IPP is deliberate integration with all members working towards patient-centered care and common goals.

Collaboration

Collaboration is becoming the foundation for health care delivery across all sectors, and a focus of curricular, research, and policy activity. This can be attributed to various policymakers calling for the use of collaboration as a key approach to the quality and safety of patient care (World Health Organization 2010; Centre for Advancement of Interprofessional Education (CAIPE) 2007; Health Canada 2007; Institute of Medicine (US) Committee on Quality of Health Care in America 2000). The reason for this transformation in health care delivery is that collaborative practice improves efficiency and care by maximizing the professionals' scope. Collaboration is expected to be more cost-effective by: substituting non-physician labor inputs for physicians (increased access); coordinating health services for multiple treatments and assessments to deal with co-morbidities; generating scales of efficiency; and performing better through sharing of knowledge and skills (Howard et al., 2011; Jesmin et al., 2012). CPP/IPPs are a subgroup of collaborative practice which includes a pharmacist or other pharmacy professionals.

To discuss collaboration, one area that must be addressed is the lack of clarity in the language to describe these endeavors. There have been overlapping definitions and poor conceptualization around collaboration. Recent reviews investigating the language used in research and description of collaboration have discussed the following terms potential used for collaboration: collaboration, coordinated, interdisciplinary, integrated, interprofessional, multidisciplinary, network, and teamwork (Reeves et al., 2011; Boon

Table 1 Definitions of health care collaboration (Canadian Interprofessional Healthcare Collaborative (CIHC)., 2010; Health Canada, 2012; Mitchell et al., 2012; World Health Organization, 2010)

World Health Organization (WHO): Collaborative practice in health-care occurs when multiple health workers from different professional backgrounds provide comprehensive services by working with patients, their families, carers and communities to deliver the highest quality of care across settings. The practice includes both clinical and nonclinical health-related work, such as diagnosis, treatment, surveillance, health communications, management and sanitation engineering.
Canadian Interprofessional Health care Collaborative (CIHC): Interprofessional Collaboration is a partnership between a team of health providers and a client in a participatory, collaborative and coordinated approach to shared decision-making around health and social issues. The six competency domains are: (1) interprofessional communication; (2) patient/client/family/community-centered care; (3) role clarification; (4) team functioning; (5) collaborative leadership; (6) interprofessional conflict resolution.
Health Canada: Interprofessional Collaboration (IPC) involves "working together with one or more members of the health care team who each make a unique contribution to achieving a common goal, enhancing the benefit for patients. It is a process for communication and decision-making that enables the separate and shared knowledge and skills of different care providers to synergistically influence the care provided through changed attitudes and behaviors, all the while emphasizing patient-centered goals and values."
Institute of Medicine (IOM): Team-based health care is the provision of health services to individuals, families, and/or their communities by at least two health providers who work collaboratively with patients and their caregivers—to the extent preferred by each patient— to accomplish shared goals within and across settings to achieve coordinated, high-quality care.

et al., 2009; Reeves et al., 2018). To break down some of the terms that have been used: Discipline is linked to academic domains; Profession is linked to occupations; Multi- refers to different professions or disciplines working autonomously; Inter- refers to them working closer together on a common goal and sharing a team identity (Reeves et al., 2011). Although these definitions vary they do share commonalities and can be viewed as along a continuum of health care professionals working in tandem. In clinical practice, collaboration can refer to the process in which different professional groups work to positively impact patient and health care (Dey et al., 2011). To further highlight the use of different definitions of collaboration and how specific organizations have defined it are listed in **Table 1**. This list is not exhaustive but are commonly used for policymakers and allow a comparison of common elements of collaboration.

Despite the lack of conceptual clarity, pharmacists must understand collaboration and its various meanings adequately to ensure their full participation in CPP/IPP. Since each team is unique, comprised of different members and with its own purpose and setting, a common set of elements for collaboration should be identified. These elements can be competencies for the professional, are integrated knowledge, skills, or attitude that is required, or elements regarding the team which enable the CPP/IPP. These elements that can be delineated for collaboration are: accountability, coordination, interdependence, respect/ trust, responsibility, and role clarity (Reeves et al., 2018; Canadian Interprofessional Healthcare Collaborative (CIHC) 2010; Bradley et al., 2012; Van et al., 2012, 2013; Zillich et al., 2005, 2004; Mitchell et al., 2012; Agency for Healthcare Research and Quality, 2016). Several authors have looked at collaboration involving pharmacists, in most cases with physicians, and described collaborations using these elements (Zillich et al., 2005; Mcdonough and Doucette, 2003; Bradley et al., 2012; Van et al., 2012, 2013). These frameworks are available for clinicians or researchers to use when describing or evaluating their own local CPP/IPP context.

1. Accountability
2. Coordination
3. Interdependence
4. Respect/ Trust
5. Responsibility
6. Role clarity

In addition to the elements of team based care described above, there are enabling factors which are often cited as essential components of collaboration or components which improve collaboration. These are not specific to CPP/IPP but can help a pharmacist to implement or integrate with a collaboration.

1. Leadership
2. Patient centeredness
3. Proximity or co-location

Even within the review of the core elements of collaboration, it is easy to identify potential areas of conflict, multidisciplinary participants, shared authority and resources, and high levels of interaction and interdependence. These endeavors can be well-meaning but can devolve if professions feel their own values and culture are being supplanted. These may be role/boundary disputes, status issues, or clinical orientation to patient/client. Management of conflict is essential for effective collaboration.

Evidence for collaboration

The new focus on collaboration is based on the theory that collaboration between multiple professionals provides effective and comprehensive care, and produce the best outcome for the patients (Xyrichis and Lowton, 2008). Research has been complicated by

the previously discussed clarity issues with terminology. Despite the variation among collaboration which can make it difficult to collate and assess the evidence in its entirety, overall it appears to lead to positive results (O'leary et al., 2012; Lemieux-Charles and Mcguire, 2006; Xyrichis and Ream, 2008).

The Canadian Health Services Research Foundation (2007) demonstrated benefits in patient outcomes such as increased access, timeliness of referrals, improved screening for chronic diseases, and increased patient/client satisfaction (Barrett et al., 2007). Other notable system outcomes summarized in the Canadian Health Services Research Foundation demonstrated changes in scopes for many health care providers (e.g. pharmacists and midwives), increased after-hours access, and improved utilization (e.g. reduced emergency room visits). Initial improvements were shown in providers' understanding of roles, provider satisfaction, provider confidence, and increased information sharing (Barrett et al., 2007). In an updated systematic review in 2017, Reeves and colleagues evaluated the impact of collaborative activities on specific outcomes (Reeves et al., 2017). The studies identified were very low/low-GRADE evidence indicating concerns with the certainty of conclusions. However the systematic review did demonstrate that interprofessional activities and meetings may improve prescribing and other practices, and may slightly improve resource use, length of stay and cost (Reeves et al., 2017).

Although most studies do report positive outcomes there are common concerns including training and workload, changing professional roles, and impact on patient–professional relationships. An important area of benefit for collaboration is to the providers themselves. This is an area of great interest due to the high level of known burnout and turnover in health care. Evidence is available for increased job satisfaction (Körner 2010), improved team climate (Deneckere et al., 2013), and decreased burnout (Deneckere et al., 2013) and job turnover (Xyrichis and Ream, 2008; Grumbach and Bodenheimer, 2004).

Evidence for CPP/IPP

The evidence for general collaborative relationships shows benefit, it is important to review the evidence specifically for those collaborations which include pharmacists (CPP/IPP). The rationale for including pharmacists in collaborations has a significant theoretical basis. With the changing health care needs of patients and populations, there is a high reliance on medications. Medications represent the single biggest intervention for most health care jurisdictions. Pharmacists may provide contributions towards efficacy, safety, and costs of care related to medications. In a meta-analysis by Chisholm-Burns and colleagues (2010), adding pharmacists as team members improved clinical outcomes (e.g. lipid lowering, reducing glycated hemoglobin (HbA1C) and blood pressure (BP)) but as well improved medication adherence and improved quality of life (QoL) and general health (Chisholm-Burns et al., 2010). Although the medication adherence result is not as robust due to the heterogeneity in the studies included, it is similar and supported by another large meta-analysis about medication adherence by Conn and Ruppar (2017) which showed improved adherence with face-to-face pharmacist interventions (Chisholm-Burns et al., 2010; Conn and Ruppar, 2017). Another more recent meta-analysis by Tan et al., 2014 demonstrated that pharmacists who are co-located with general practitioners (GP) delivered similar beneficial effects in clinical outcomes specifically in diabetes and cardiovascular diseases (Tan et al., 2014). These authors concluded that positive effects were seen for pharmacists and teams using combinations of medication review and interprofessional verbal communication. If there were additional incorporation of adherence assessment, health advice, medication adjustment, and monitoring along with medication review, patients were more likely to show improved clinical outcomes (Tan et al., 2014). This finding that a more holistic involvement or multi-prong approach is supported by previous research by Zillich et al. (2004). Overall, CPP/IPP has shown improvement in clinical outcomes and adherence. Along with clinical outcomes, it is important to recognize that medications may contribute to important negative outcomes. In the United States, medications contribute to ~100,000 premature deaths annually and medication related problems cost $200 billion of which half is related to non-adherence (Lewis et al., 2014). The World Health Organization has stated adherence among patients with chronic diseases averages only 50% (World Health Organization, 2003). Both adverse reactions and non-adherence are important issues in healthcare, and pharmacists have been shown to benefit patients for both of these issues. In Chisholm-Burns and colleagues' meta-analysis (2010), the authors reported that when a pharmacist is added to a team medication errors are reduced in 80% of studies and improved reporting of adverse drug reactions in 60% of studies (Chisholm-Burns et al., 2010). Pharmacists practicing in team is well supported by evidence, and by their specialized education and clinical expertise. The addition of a pharmacist to a team has been shown to improve clinical outcomes in chronic diseases, reduce adverse reactions, and potentially contribute to reduced costs related to health care.

Although pharmacists can be included on many different types of teams and settings for collaborations. This chapter will use the primary care setting as an example. Primary care an area of health care with significant recent reformation and has focused on new ways to integrate and include pharmacists. One of the largest changes in primary care is the formation of teams which place pharmacists with providers such as physicians, nurses, nurse practitioners, social workers, dietitians, and others. While professional practice is guided by each provider's regulated scope of practice, it is recognized that the working relationships between members of the team will also be impacted by individuals' expertise, preferences and skill set, team dynamics, and systemic factors. No two teams will function exactly alike (Dolovich et al., 2008). However, as previously discussed there are common elements throughout examples of collaboration. Three jurisdictions (Canada, United Kingdom, United States of America) will be reviewed to highlight similarities and differences between their institution of CPP/IPP in primary care. It is essential to recognize that there is no structure or format of CPP/IPP that has been shown to deliver more effective or higher quality care. As such, each jurisdiction is implementing CPP/IPP with differences. Although each shares the qualities of CPP/IPP, there are important distinctions which may impact pharmacy practice, provision of patient care, and health care outcomes.

Table 2 CPP/IPP Organizations in Canada

Province	*CPP/IPP Organization Name*
British Columbia	Primary Health Care organizations
	Integrated Primary Care Centre
Alberta	Primary Care Networks
Saskatchewan	Primary Health Care Teams
Manitoba	My Health Team
Ontario	Aboriginal Health Access Centre
	Community Health Centre
	Family Health Team
	Nurse-led Practitioner Clinics
Quebec	Family Medicin Groups
Nova Scotia	Family Health Team
Prince Edward Island	Primary Health Care Networks
	Family Health Centre

Canada

The initial work for CPP/IPP in Canada was based on a demonstration project in Ontario called Integrating Family Medicine and Pharmacy to Advance Primary Care Therapeutics (IMPACT) (Dolovich et al., 2008). IMPACT evaluated pharmacists placed in primary care teams on a part-time basis. The project had components which were simultaneously employed to support integration and optimal medication management. The four components were: individual patient assessments, health care provider education, system practice enhancements (e.g. clinical pathways and transition care), and integration activities. The results of IMPACT were presented in several papers and they demonstrated several different aspects of pharmacists within primary care teams. The elements that were facilitative: trust and pharmacists demonstrating value; and barriers: role clarity and underutilization. Physicians appreciated drug information, confidence in prescribing, and new medication related protocols. Pharmacists appreciated a mentor to assist with integration and their complementary skill set to physicians. A common finding across all the different research questions was that time in practice tended to mitigate any concerns the physicians had prior to the integration of the pharmacist. The outcomes seen were 94% of patients had at least one drug therapy problem with 27% of patients having an adverse drug reaction (Dolovich et al., 2008; Farrell et al., 2008a, 2008b; Pottie et al., 2008, 2009).

After IMPACT there was a proliferation of pharmacists placed in primary care teams in Ontario and across Canada. Within Canada there are several types of primary care CPP/IPP (**Table 2**) which can be described as embedded (e.g. Community Health Centre, Family Health Teams), affiliated (e.g. academic faculty in British Colombia, Manitoba), and regionally affiliated (e.g. hired by government and centralized). Overall, each CPP/IPP organization has a similar vision: By employing a variety of health care professionals who work together to improve access to primary care, and provide patient care and improve clinical outcomes to a community of patients. As these pharmacists are hired by the organizations with which they are providing care, this allows the pharmacist to build relationships within the team. However, because the leadership and accounting structures for each of these teams are different, there may be specific differences between each CPP/IPP.

Ontario is Canada's largest and most populous province, the CPP/IPP organization that constitutes more than 50% of all its teams is the Family Health Team (FHT). There are 184 FHTs in Ontario, each FHT is its own corporation with a board of directors. Most boards are comprised of a physician majority (51–100%), as the physicians have created the corporation and maintain leadership over the activities of FHT (Ministry of Health and Long-term Care 2016). FHTs bring together a variety of health care professionals including pharmacists, minimally there must be a physician, a nurse, and one other health care professional. The choice of health care professionals beyond the physicians and nurses is meant to be selected based on the patient population that is being served. Currently, there are ~150 pharmacists working in 120 FHTs (Gillespie et al., 2014). In all cases, pharmacists are salaried employees of the FHT, their salary being provided annually to the FHT via a transfer from the Ministry of Health but they have no specific reporting centrally to the Ministry. In some cases, the pharmacists' salary is supplemented by additional funds from either a hospital or university. There is no official job description or role description for the pharmacist, as it is expected that the pharmacist will contribute by "Optimizing drug therapy through patient assessment, medication management, education, advocacy, and collaboration with physicians and other health care providers" (Gillespie et al., 2014). A recent review by Gocan et al. (2014) of the published literature for Ontario's Family Health Team (FHTs) concluded:

> "Patient and provider perceptions around the outcomes of collaborative care in a FHT setting indicate that interprofessional teams were able to provide enhanced access to care and extended health care services compared to what had previously been offered in a uniprofessional model of care. Both patients and providers experienced more time for care and enhanced quality of health services. Interprofessional collaboration also assisted providers with shifting their approach to health care, addressing mental health or chronic disease concerns they previously avoided given their lack of professional resources or expertise. Providers described changes to health management approaches that were directly related to having access to skilled interprofessional healthcare providers (IHPs) who could assist patients to effectively cope with diverse aspects of their health condition(s)."

One of the strategies that FHTs use to improve access or quality of care for patients is to create workgroups ("teams within teams") for specific patient populations. These programs usually serve complex patients by having multiple providers working together, or by caring for less complex patients instead of using an outside referral to subspecialty physicians. They are often staffed by a combination of providers (e.g. nurse (RN) and pharmacist providing hypertension management), or by hiring specialists (e.g. addictions counselors, diabetes educators). Examples of these types of programs in Ontario's Family Health Teams are: hypertension (Tobe et al., 2013), diabetes (Gucciardi et al., 2015), mental health (Kates et al., 2011), pain management (Angeles et al., 2013), dementia (Lee et al., 2014), and elderly or complex multi-morbidity patients (Tracy et al., 2013). All of these workgroups had a pharmacist involved either directly or as an opportunity for referrals. These services require coordination of multiple providers, and may need to be adapted to local contexts depending on the provider complement at CPP/IPP. The benefits seen in these types of programs are improved function of the interprofessional team, increased convenience and access to care, enhanced patient experience, patient empowerment and self-management, and improved quality of life and health care utilization (Tobe et al., 2013; Gucciardi et al., 2015; Kates et al., 2011; Angeles et al., 2013; Lee et al., 2014; Tracy et al., 2013). However, research into Ontario's FHTs has not always borne all of these benefits in each team. Recent research has shown that interprofessional teams have not consistently improved access to primary care for vulnerable populations (e.g. multimorbidity, or mental health illness) (Glazier et al., 2012; Jaakkimainen et al., 2011; Steele et al., 2013; Hutchison and Glazier, 2013; Rudoler et al., 2015). Additionally, economic evaluations do not show overall benefits to the FHT model and no specific cost-effectiveness analyses are available for CPP/IPP.

United Kingdom model

In the UK, general practitioner (GP) practices provided ~400 million consults and almost 1 billion prescriptions (Primary Care Pharmacy Association, unknown). In the General Practice Forward report, National Health Service (NHS) CEO Simon Stevens talks about the importance of primary care and why changes are needed.

> "The strength of British general practice is its personal response to a dedicated patient list; its weakness is its failure to develop consistent systems that free up time and resources to devote to improving care for patients. The current shift toward groups of practices working together offers a major opportunity to tackle the frustrations that so many people feel in accessing care in general practice." Simon Stevens NHS CEO (National Health Service (NHS) England, 2017)

One of the ways for the NHS to improve primary care was the call to have greater involvement of a pharmacist in medical practices (Stone and Williams, 2015). This pilot project started in 2015 and was for 450 pharmacists to be contracted to ~650 GP. This number will increase to 1500 pharmacists in 2020 (~1 pharmacist for every 30,000 population) (National Health Service (NHS) England, 2017). An important feature of the redesign for pharmacists in GP practices is that pharmacists will work together in a given geographical area (British Medical Association (BMA) 2017). This will allow for mentoring and sharing across the pharmacists' network, however the pharmacist will not be available onsite to every GP clinic. The key outcomes for adding a pharmacist to a GP service were: (1) To support the GP by working with patients and wider primary care workforce; and (2) To utilize their knowledge and skills to support primary care transformation (Snow-Miller 2016; British Medical Association (BMA) 2017). The addition of clinical pharmacists was given a significant financial investment (~ £30 million) which will triple with the expansion over the next stage (National Health Service (NHS) England, 2017). The funding is being provided for three years in a tapering manner, with 100% being covered in the first year only. In subsequent years, GP practices will be required to find larger percentages of funding resources for the pharmacists' salary. This funding requirement will ensure that the GP practice is recouping enough money from the addition of the pharmacist and their practice to make the CPP/IPP tenable. Practice-based pharmacists work as part of the general practice team to resolve day-to-day medication issues, and consult with and treat patients directly. The pharmacist may provide additional expertise in managing long-term conditions, medication optimization, advising patients at risk of polypharmacy, and increasing access to health care screening (Royal Pharmaceutical Society (RPS) 2016; British Medical Association (BMA) 2017). Along with the direct patient care that a pharmacist may provide, there will be population level activities, such as leadership about medications and quality improvement, including contributing to the general practice by the Quality & Outcomes Framework (QOF) (Primary Care Pharmacy Association, unknown, Royal Pharmaceutical Society (RPS) 2016). QOF is a voluntary incentive in United Kingdom's GP contract but can be a major source of potential income. The funding is based on a GP practice meeting certain quality indicators thereby incentivizing care that meets specific standards. By redesigning primary care, it is hoped to open up opportunities in pathway design, case management and shared care with specialists, increased use of technology, and sharing best practices. In different parts of England general practices have started to include clinical pharmacists in their multi-disciplinary teams. In many cases experience suggests that there have been significant benefits for patients and for the practice teams. Bush et al., 2017 looked at one clinical commissioning group (CCG) in England where ~5.5 pharmacists were integrated. Over 9 months, pharmacists' interventions completed were estimated to save in excess of 1 million pounds and save >600 h of GP time and >600 additional GP appointments. This early research demonstrates return on investment for the UK model for CPP/IPP (Bush et al., 2017).

United States of America

In mid-2000s, the emergence of the patient-centered medical home (PCMH) came about to improve care, costs, and patient satisfaction with primary care in the United States (Nigro et al., 2014). The concept of PCMH does not reflect a building or house but is the approach to providing comprehensive and coordinated care. PCMHs are the centerpiece of primary care

Table 3 Comparison of CPP/IPP in Primary Care

Parameter	*Canada (FHT)*	*United Kingdom*	*United States (PCMH)*
Accountability	Local (Family Health Team)	Clinical Commissioning Group	Varied
Role Clarity Provided	No	Yes	No
Leadership	Local	Clinical Commissioning Group	Local (PCMH)
Proximity	Co-located	Not co-located but geographically close	Co-located
Payment	Ministry via FHT (100%)	Ministry 1st year only then reducing % until GP Clinic (100%) after 3 years of pilot	PCMH or parent institution
Governance	Local FHT board of directors (MD led with community members)	CCG (Majority MD with other clinicians)	PCMH or parent institution board of directors (MD led)
# of clinics	1 but can be multiple sites	Multiple clinics	Varied

transformation in the US. They are intended to improve care coordination and communication, enhance health care quality and patient experiences, and lower health care costs by linking patients to a physician-led interdisciplinary health care team. The Agency for Healthcare Research and Quality (AHRQ) defines five main attributes for PCMH are: (1) Comprehensive care is provided by a team; (2) Patient-centered care; (3) Coordinated care across the spectrum of settings; (4) Increased access; and (5) It should also provide improved quality and safety using system-based approaches while incorporating evidence-based therapeutics and tools that make decisions easier and more transparent to patients across the health care system (Lewis et al., 2014; Nigro et al., 2014).

Pharmacists integrated with PCMH can improve many aspects of care including multiple medication issues (e.g. quality and safety) and drug safety issues (e.g. transitions in care). The PCMH model is meant to encourage pharmacists to work at the top of their scope by expanding patient-centered pharmaceutical care (Smith and Nigro, 2011; Nigro et al., 2014). Pharmacists in PCMHs are similar to those in the family health team model in Canada and can be embedded (e.g. employee, faculty member) or have an external role (e.g. contract, consultant) to the team (Smith and Nigro, 2011). Reasons for these differences may be due to the size of the PCMH, available partnerships with an academic faculties, and the geographic area serviced by the PCMH or parent institution. Context for the pharmacist's employment is important, as accountability structures and responsibilities may be different. General roles such as medication therapy management (MTM) and improving continuity of care, can be done by all pharmacists within any PCMHs. Another important aspect of a pharmacist role is those population initiatives which can be embedded into a quality and safety initiatives. These types of initiatives rely on information technology to help identify undertreated patients (e.g. patients with missing medications as per guidelines), those at risk of adverse effects (e.g. declining renal function), and opportunities to decrease costs (Nigro et al., 2014). Pharmacists can create registries to improve standardization and ensure that patients are optimally managed. An early study of roles in PCMH by the American College of Clinical Pharmacists surveyed their members and found an equal distribution (1/3) described their role as: no formal role, key team member, and leading medication-specific initiatives (Nigro et al., 2014). A more recent study by Kennedy et al. (2015) done in a single PCMH in Vermont evaluated the impact of pharmacists. This PCMH had pharmacists were partnered into five primary care practices 1 day per week to provide direct patient care, population-based medication management, and prescriber education. Pharmacists' recommendations to correct drug therapy problems were accepted by prescribers 86% of the time and in a cost avoidance model suggests $2.11 in cost was avoided for every $1.00 spent on a pharmacist ($373,092/$176,690) (Kennedy et al., 2015). This study shows a return on investment for pharmacists in the PCMH model.

Across the three jurisdictions, there was clear value in integrating pharmacists into primary care teams. Their inclusion improved clinical outcomes, processes within CPP/IPP, prevented adverse drug events, and improved health care costs. Although CPP/IPP has been reviewed here as formal team-based organizations, much primary care is delivered by community pharmacists who are not embedded. This can be visualized as "weak-tie" collaborations with primary care providers (e.g. physicians or nurse practitioners), or themselves as independent prescribers to offload health care delivery. These partnerships are essential collaborations as it likely is how the majority of pharmacists interact with physicians in primary care. The elements of CPP/IPP can be applied similarly to community practice.

The reason to highlight the three variations on CPP/IPP in primary care is that implementation differences may contribute to the reason for the varied outcomes have been shown in the literature. If there is no "optimal" CPP/IPP structure or form this leaves each jurisdiction or team to plan a best possible strategy. However, throughout the descriptions the elements can be reviewed in **Table 3**. One of the most important issues for CPP/IPP will be rigorous and pharmacy-led research to demonstrate and evaluate the role of the pharmacist.

Instruments to measure collaboration

After reviewing the evidence for collaborations including CPP/IPP, it may be helpful for clinicians and researchers to have instruments to measure collaboration. To assist the reader, a comparison of available instruments is presented in **Table 4**. To assess each

Table 4 Comparison of Instruments on Performance and Psychometric Properties

	AITCS	*ATCI-GP*	*CATME*	*ICAR*	*MIIC*	*PPCI*
DOMAINS (Number of items testing domains)

Construct	No	No	Yes, in same study	No	No	Yes, in same study.

instruments' performance, the COSMIN guidelines were used (COSMIN 2015). Each instrument will be compared for performance and psychometric properties. The characteristics are (Bryan et al., 2013; COSMIN 2015):

1. Performance properties
    a. Domains covered – refers to the elements previously discussed, and the number of items which fall into each domain category;
    b. Response options – refers to the type of questions and scoring on the particular instrument. Common types of response are: Binary (yes or no), Likert scale, Free-text, or Ratings;
    c. Respondent burden – refers to the number of items, or the time required to complete when available;
    d. Reported method of administration – refers to how the survey is provided to the respondent, and common methods are self-administered, and interviewer.
2. Psychometric properties
    a. Internal consistency – provides an estimate of relatedness between different questions. A positive rating will be given to instruments with Cronbach's $\alpha > 0.7$, and when subscales are available they are unidimensional.
    b. Reliability – usually assessed by examining correlation between score at two time points. This may be measured using intraclass correlation coefficients (ICC), Kappas, or Pearson's *r*.
    c. Content validity – an assessment of comprehensiveness and relevance of an instrument for the population being used.
    d. Construct validity – an assessment to the degree that an instrument's items measures the aspects it is hypothesized to measure.
    e. Criterion validity and responsiveness – will not be used, as there is no gold standard to compare other instruments.

The six instruments which will be compared are:

1. Assessment of Interprofessional Team Collaboration Scale (AITCS) (Orchard et al., 2012)
2. Attitudes Towards Collaboration Instrument for GPs (ATCI-GP) (Van et al., 2013)
3. Comprehensive Assessment of Team Member Effectiveness (CATME) (Loughry et al., 2007)
4. Interprofessional Collaboration Assessment Rubric (ICAR) (Curran et al., 2011)

5. Modified Index for Interdisciplinary Collaboration (MIIC) (Oliver et al., 2007) and
6. Physician-Pharmacist Collaboration Index (PPCI).(Zillich et al., 2005)

This section provides an analysis of six instruments which can be used to measure collaboration in many health care settings. These six instruments were selected from an original 58 instruments (unpublished information, Jennifer Lake). Each of these six instruments have appropriate performance and psychometric testing. As well, each covers the majority of domains that are important to collaboration and interprofessional practice. Using a reliable and valid instrument will support research involving collaboration and interprofessional practices.

Conclusion

CPP/IPP is a clinical and research area which is increasing and moving into many different settings. This is leading to pharmacists being integrated into well-developed teams, or creating new types of teams that include a pharmacist. Although there is a lack of clarity around the concept of collaboration, there are some essential elements defined which include accountability, responsibility, trust, respect, and role clarity. Strong leadership, proximity and a common mission such as patient-centered (or client-centered) care will help to enable CPP/IPP.

There is evidence in both general collaborations and CPP/IPP which can help guide the pharmacist. Overall, the evidence for collaboration is positive, however the lack of standardized definitions and structure lead to a lack of consistent outcomes. Pharmacists can use previous work to help assist them in new CPP/IPP work. Additionally, there are instruments to measure collaboration which can help teams assess their current collaboration or their progress with new initiatives.

Interpersonal Communication in Pharmacy Practice

Sharon L. Youmans, Department of Clinical Pharmacy, University of California San Francisco School of Pharmacy, San Francisco, CA, United States

Introduction

Methods used by people to communicate information, ideas, and opinions(interpersonal communication) have evolved over many millennium, and we continue today to strive, develop, and implement the best strategies to communicate. Communicating health information is perhaps one of the most challenging tasks that health-care providers have, and we use this process to engage patients in taking care of their own health. The definition of communication by Merriam-Webster is "a process by which information is exchanged between individuals through a common system of symbols, signs, or behavior" (Merriam-Webster, 2018). The art of interpersonal communication is a "work in progress," one that requires ongoing iterative processes that allow for continuous improvement and increased confidence in our communication strategies with patients and others involved in their care.

This paper aims to discuss (1) what comprises effective interpersonal communication and (2) the impact of a pharmacist's relationship with patients, caregivers, and other health-care professionals on communicating effectively.

Depending on where you are in the world, the messages you are trying to communicate and with whom you are communicating influence the type of methods and techniques a pharmacist may choose to use. Today, pharmacists are not only counseling patients on how to properly take their medications, but also how to use nonprescription medications, dietary supplements, and implement appropriate lifestyle behaviors. Oftentimes, there is a lot of information to convey; many times it may be more than a patient can process in one encounter. In addition, pharmacists as members of health-care teams are communicating with family members, caregivers, and other health-care professionals about information that directly impacts a patient's treatment plan (Chisholm-Burns et al., 2010).

Pharmacists are the respected and trusted health-care providers. They often are the first-line and most accessible health-care provider to patients. Today, it is much easier to gain access to a pharmacist than perhaps a general primary care physician. Pharmacists are public health servants and are available to reinforce healthy practices that can reduce the risk of disease as well as prevent disease. The incidence of chronic diseases is rising and is the leading cause of death worldwide (Gerteis et al., 2014; World Health Organization, 2018). The use and number of medications to treat chronic diseases has grown making medication adherence vital to achieving desired patient outcomes (Brown and Bussell, 2011).

Factors Influencing Interpersonal Communication

Technology plays an important role in today's transmission of information. No matter where you are in the world, one can gain access to information through a variety of technology platforms. Written words in digital form are at our fingertips, and many patients will access information as a way to educate themselves on their medical conditions as well as the medications they take to treat their conditions and symptoms. The ongoing challenge is determining the accuracy of the information patients find through

their searches, and this provides an opportunity for the pharmacist and the patient to partner to evaluate the quality of the information (Hesse et al., 2005; Hou and Shim, 2010).

The growing use of technical devices designed to help patients monitor their medications, clinical outcomes, diet, and exercise routines will provide important information that should be included in the conversations related to assessing the patient's progress. Pharmacists then collaborate with patients to develop plans to manage their conditions. It is important for the pharmacist to take this into account and make it part of the discussions with patients.

Telemedicine is another option that has changed the way we can communicate with patients. It can be an important method for providing counseling and education. For patients who are not able to come to the clinic or to the community pharmacy, the use of this technology has increased the convenience for those patients. The use of telephones or videoconferencing has shifted the traditional norms of working with patients in person, and will continue to force the pharmacist as well as other health-care professionals to maintain skills that can be used in face-to-face encounters and those over the Internet (Hesse et al., 2005). Technology is here to stay and will be more advanced over time. The challenge will be how to find the balance of using technology to enhance our communications and strategies to deliver information to patients as well as to assist patients in their Internet searches for health information (Hargie et al., 2000; Hou and Shim, 2010).

There is an incredible amount of information that is available in a variety of forms to patients. Information is being discovered and published on a daily basis at a rapid pace. Traditional means of reading books, magazines, direct-to-consumer advertising, Internet sources, and well-meaning family and friends are all available sources of information for patients.

Individuals, including pharmacists and other health professionals, may feel overwhelmed with the amount of information. As medication experts, the pharmacist will be sought after for their expertise to sort out the relevant and accurate information. Patients, nurses, and physicians, as examples, may come to pharmacists with information that requires discussion and explanation to ensure that the correct information is available to help inform the decision-making process about their medication regimens. The relationship and rapport developed with the various parties involved will enhance pharmacist interpersonal communication with increased trust and collaboration.

Pharmacist–Patient Relationship and Communication

The patient–pharmacist relationship is the critical component of an effective communication. As the role of the pharmacists has evolved, the ways in which pharmacists interact with patients have changed. With the increasing use of medications and management of chronic diseases, worldwide the relationship between the pharmacist and the patient has evolved to one where both the pharmacist and patient have responsibilities to maintain the professional relationship. Pharmacists are providing more services, education, and counseling, and patients, to the extent possible, are taking on more responsibility for managing their conditions and carrying out the agreed-upon plan to pursue the desired goal of improved health outcomes.

Developing a rapport with a patient takes time, and the community pharmacy or clinic is an ideal setting for this to concur. However, even in the shortest of encounters that can occur in a hospital setting, how the patients feel when they walk away from the experience will influence how the patients will behave in the future, and whether or not the patients will return for services provided by the pharmacist (Antunes et al., 2015).

Due to the complexities of patient counseling, taking a holistic approach to communicating involves much more than just the transmission of information. All factors, internal and external to the patient, are considered in developing strategies for interpersonal communication with patients. Patient specific factors include age, level of education, literacy levels, what patients expect from pharmacists, culture, health beliefs, social support mechanisms, socioeconomic status, and past experiences with the health-care system. All of these shape the perspectives of patients and their level of trust with the health-care system.

Research has shown that the characteristics that they look for in their pharmacist include trustworthiness, ability to listen, and approachability (Donald et al., 2017). These same qualities help to engage others that the pharmacist has to communicate with in order to ensure smooth transitions of care.

Verbal and written communication skills are the hallmark of how we provide care for patients. As medication experts, pharmacists have many techniques and resources to call upon when counseling and educating patients. As individuals use a variety of communication styles and techniques (Chong et al., 2014; Maguire and Pitceathly, 2002), our body language that includes facial expressions, the way we sit, and the use of our hands collectively send messages to our patients. The tone and inflexion of our voice, as well as the choice of the words we use, influence how our messages are received and interpreted by the patient.

Communication is a collaborative bi-directional process that includes the flow of information, viewpoints and perspectives of patients. Patients may or may not be the experts on specific medications, but they are experts on who they are as individuals, their bodies, their opinions, and their feelings.

Other Pharmacist Relationships and Communication

Caregivers

Whether the caregiver is a hired professional or an immediate family member (spouse, significant other, parent, grandparent, or friend) establishing a relationship that includes clear lines of communication can be very helpful to the caregiver. As an example,

communicating with parents, who oftentimes become immediate at-home medical care providers, has added pressures to continually doing the right thing for their child even when they have no formal training to do so. The discussions not only include what the purpose of the medication is and how it works, but also in some cases when and how the medication is to be administered to the patient.

A pharmacist, serving as a resource for caregivers, provides level of assurance that the caregiver can reach out to ask questions and clarify information previously provided. Awareness, acknowledgment, and discussion of the challenges that caregivers experience and the associated stressors contribute to healthlines of communication with the pharmacist. The pharmacist plays an important supportive role to caregivers in addition to being an educator and counselor (Noureldin et al., 2016).

Pharmacist–Other Health-Care Professionals Relationship

Although the pharmacist–patient relationship is paramount, effective communication with the health-care team has a tremendous impact on patient outcomes making sure that the health-care team goals (including the patient as a team member) are aligned when it comes to the details of the treatment plan and how all of the other nonmedication recommendations integrate and support the patient's entire plan. Research has shown that medication errors have stemmed from poor communication or miscommunications among health-care professionals.

The increased attention given to interprofessional team-based care all the more supports the need for effective communication that cuts across our specific disciplines and roles in taking care of patients. The Interprofessional Education Collaborative (IPEC) competencies that have been endorsed say that interprofessional communication and effective, open communication lead to better integrated care for our patients (Interprofessional Education Collaborative, 2016).

A major challenge that pharmacists face in their attempts to provide health care is the lack of a universal health care record that includes accurate medication lists, recorded medication adverse reactions, and hospital and clinic visits. The various health systems include hospitals, clinics, pharmacies, and even insurance companies that for the most part are not connected in a way to provide complete and up-to-date information about the patients' encounters with the system units. The patient is the one individual who knows what has transpired, but the records are not necessarily written down in an organized fashion. This is a disadvantage for pharmacists because they may not have all of the information needed in order to piece together the rationale for certain medication decisions or to even have access to an accurate patient medication list. This is an ongoing struggle particularly with community-based pharmacists.

Pharmacist–Public Society Relationship at Large

Historically, the practice of pharmacy has focused on the individual; however, it has become increasingly important for the attention be turned to the public at large. Pharmacists communicating health information to the public at large is key to informing the public of the role and responsibilities of the pharmacist as a member of the health-care team. The pharmacist is viewed as a health-care professional in the community, and the message to the public at large is that the pharmacist is available to help the community address its health-care concerns.

The "public" voice of the pharmacist is an extension of public health that addresses issues concerning the health of the individual and the community. The presence of a pharmacy in the community is more than a building where one goes to get medications; it supports the health of individuals and the community at large.

Theoretical Foundation for Interpersonal Communication

An in-depth description and discussion on communication and health behavior theories and models and their role in effective interpersonal communication are beyond the scope of this paper. It is important to note that there is a theoretical basis for why and how individuals act related to health behaviors, and that theoretical underpinnings can guide and shape the communication strategies used to convey information. Particularly in understanding that patients may not necessarily act upon just receiving instructions, but that the communication should go deeper into how the patient is supported in carrying out the instructions and recommendations.

A "theory" is defined as a set of concepts, definitions, and constructs that are used to explain or predict an activity or behavior (Kerlinger, 1986). A "model" can include a number of theories to help understand a specific problem (Earp and Ennett, 1991). Effective interpersonal communication is about changing behavior. Examples of classic models and theories of health behaviors include the Health Belief Model, The Transtheoretical Model and Stages of Change, and Theory of Planned Behavior and Theory of Reasoned Action. These provide the concepts of the theories and models and real-world health-related examples of each concept for consideration.

These models and theories are part of the curriculum in public health but not so much in pharmacy degree programs. A brief description of these with real-world examples can shed light on how one can strategize their communications with their patients. Depending on the task at hand, the pharmacists can use multiple strategies when communicating health information. The choice of

strategy can also be influenced by theories and models of health behavior in understanding what motivates individuals to carry out recommendations and instructions.

Components of Effective Communication

Decades of research has described the elements of effective communication and overtime the descriptions have evolved and expanded. As health providers, communication of information is the mainstay of our role and these concepts should be revisited from time to time.

When thinking about your communication style you can refer to the seven Cs of clear communication (Mind Tools, 2018) and apply them in any encounter of communicating information to anyone.

Seven Cs of clear communication are as follows:

- Clear
- Concise
- Concrete
- Correct
- Coherent
- Complete
- Courteous

Communication Techniques

There are many communication techniques available in the literature. The two most popular used in health care and in pharmacy curriculum include motivational interviewing (Berger and Villaume, 2013) and the teach-back method (Tamura-Lis, 2013). Books, classes, and workshops are available for health-care professionals, and once these techniques are learned these can be added to your communication toolbox.

Factors Associated With Ineffective Communication

Being equipped with effective communication skills and techniques, being aware of the barriers to effective communication is just as important. These barriers exist at the level of the patient, the pharmacist, and the health system. The following are factors that have been studied and are associated with ineffective communication, and should be taken into account when communicating any messages to patients and their caregivers (Schillinger et al., 2003).

Patient-Level Barriers to Effective Patient–Pharmacist Communication

- Age $>$ 65 years or age $<$18
- Cognitive and physical impairments
- Culture
- Education level
- Health beliefs
- Language (e.g., English as a second language)
- Low health literacy
- Low socio/economic status
- Mental health issues
- Minority racial/ethnic background
- Substance abuse issues
- Underserved communities (e.g., rural, LGBTQI)

Pharmacist-Level Barriers to Effective Patient–Pharmacist Communication

There are barriers that pharmacists must overcome at the professional level for effective communication with patients, family members, and caregivers (Collum et al., 2013).

- Level of cultural sensitivity (e.g., taking into account a patient's health beliefs about the medical condition and the role of medications to treat their condition)
- Patient care setting (e.g., providing adequate space to have a private conversation)

- Privacy (e.g., providing a place away from other patients or customers and even pharmacy staff)
- Time restraints (e.g., very busy pharmacy with additional responsibilities and not enough time to adequately counsel a patient)
- Use of open-ended questions (e.g., instead of asking "Do you have any questions," you ask, "What questions do you have for me today?")
- Use of lay language instead of medical jargon (e.g., instead of saying "hyperglycemia," you say instead, "High blood sugar")

Patient Scenarios With Suggested Communication Strategies

The following scenarios try to depict the various encounters where pharmacists have to strategically use their communications skills and techniques in order to address the concerns of patients and/or their caregivers. These examples are by no means a complete list of possible scenarios. As you read the scenarios you can draw on their professional experiences and recall similar situations. The purpose of the scenarios is to provide a starting point that can be tailored to an individual's communication style and use of communication strategies and techniques.

Negotiating with patients

Patient TA is a 56-year-old who has been experiencing increased difficulty with breathing, but he says that he is not ready to quit smoking. He has tried to quit smoking several times in the past, but has not been successful. He is stressed most of the time and says smoking helps "calm my nerves." As a pharmacist what strategy would you use to help Patient TA make a decision about his smoking status? What factors would you consider? What challenges exist for this encounter?

A conversation to achieve the goals of getting patients to agree to carry out the recommendations to change their behavior is challenging. As health-care professionals, the intent is to encourage and support patients to make a decision and then to sustain the behaviors required to make the change. Quitting smoking can be difficult, even if the patient believes it is what's best for their overall health.

There are resources available to assist pharmacists in counseling patients who want to quit and to approach patients with the idea of attempting to quit, to inquire from the patients where they are in their thinking about quitting. A curriculum that provides the steps on how to initially approach a patient about quitting smoking to recommendations for a variety of nicotine replacement therapies—"Rx for Change"—is developed and is available online, hot lines for counseling, and prescription medication options (Rx for Change: Clinician-Assisted Tobacco Cessation, http://rxforchange.ucsf.edu/.).

Negotiating a timeline for patients is to make decisions about quit dates and nicotine replacements plans, all taking into consideration the preferences of the patients and their sense of self-efficacy in following through on the agreed-upon steps in the action plan. As with all negotiations, it is important to try and understand what the patient factors are that cause the resistance to change and what does it take to get the patient's buy-in that will have a positive impact on the patient's overall health. In the process of developing a communication strategy, one may want to consider the following: How as a pharmacist can I collaborate with the patient to achieve their goals? How do I encourage the patient to voice their ideas and concerns? How would I go about creating a "safe space" for patients to express their concerns about not being able to quit smoking? With all negotiations, knowing how to compromise and continue the process if the first encounter is not successful in having the patient agree on concrete steps to quit smoking or any other behavior that needs to change is essential.

Patient counseling

Patient SK is at the pharmacy counter with a product to help relieve symptoms she has been experiencing this past week. She complains of feeling a burning sensation in her chest and she is belching more than normal for her. What strategies would you as a pharmacist use to counsel the patient on how to provide self-care to relieve her symptoms? What factors would you take into consideration in providing the counseling she needs?

What are the main objectives for providing counseling to patients? Deciding the purpose may be driven by the encounter, if it is the very first time that the patient is taking the medication or if a review is needed for how the patient is experiencing after the medication. Counseling a patient to take a seven-day course of antibiotics is different from counseling on taking a new medication for high blood pressure and is different from taking a self-care medication for heart burn symptoms due to the seriousness and complexity of the condition.

In the above scenario, the pharmacist is imparting information and teaching the patient about the medication, but, in addition, information is provided for how the patient will carry out the instructions of how to use the medication, how it will personally impact their health, and to consider the impact of other medications or lifestyle behaviors may have on the medication(s).

In this self-care scenario, the objective is to determine if self-care treatment is appropriate or if a referral is required, or perhaps both. Examples of strategies that can be used may include:

- Use of open-ended questions to get the patient to describe the experience is important to make the right recommendations for the patient.
  - Describe for me what you are feeling?
  - How long have you been feeling the burning sensation?

  - How often do you feel the symptoms?
  - What foods are associated with when you feel the symptoms?
- Taking a complete medication history would be important to identify a possible drug-induced problem.
  - What nonprescription medications do you take?
  - What dietary supplements and/or vitamins do you take?
- What have you used before to treat these symptoms?

The answers to these questions will help in guiding the pharmacist to determine the severity of the symptoms and engage the patient as a partner to determine the best approach to remedy the problem.

Patient education

Patient JK is interested in learning about vaccines. He has heard that vaccines are important, but as an adult he has no idea what vaccines, if any, he should get. He has also heard that perhaps vaccines may not be safe, especially for children. What would be your strategy or approach to educate Patient JK about vaccines?

This scenario provides the opportunity to consider both counseling and education. For some individuals, this is a controversial topic, and the goal is to provide objective information to the patient for consideration. Keeping personal opinions to oneself is important, unless asked. Just present the evidence and facts and answer the questions as completely as possible. Providing resources that the patients can access in the future is part of the education session. Listening to what the patient is really asking, and asking that patient to voice their concerns and describe the information they have read or heard can assist in building a sense that you want to help the patient and not necessarily convince the patient to your way of thinking. In this situation, referring the seven Cs for clear communication can help frame our approach to sharing information with this patient.

In this education scenario, the objective is to provide the patient with factual information about immunizations, to hear the patient's perspective, and to have the patient share where they have gotten the information that informs their opinions. Examples of strategies that can be used that are not all inclusive:

- Tell me about your concerns regarding vaccines?
- Where do you go to get information about vaccines?
- What questions do you have about vaccines in general or any specific vaccine?
- May I have your permission to share with you information I have about vaccines?

Assessing medication adherence

Patient RM has experienced many challenges in the management of his heart failure, hypertension, and diabetes. He has frequent hospitalizations with medication regimen changes upon discharge. He currently takes seven medications to manage his heart disease and diabetes. Patient RM's primary care physician has asked that you assess RM's adherence to the medication prescribed. What would be your strategies to begin this conversation?

Assessing medication adherence is a difficult task as there is no one gold standard for measuring adherence (Lehmann et al., 2014). For patients taking medications, poor adherence is increasing with the increase in number of medications being used to treat the growing number of chronic diseases across the world. A WHO report states that nonadherence rates are as much as 50% in developing countries (World Health Organization, 2003). Medications taken improperly or not at all result in increased hospitalizations, increased use of health-care resources, and overall poor health outcomes for patients (Iuga and McGuire, 2014). Many factors are associated with patients being nonadherent to medication regimens, and the goal is to identify those factors and suggest interventions tailored to the patient.

Questions pharmacists can ask to assess medication adherence (each medication):

- Can you tell me what this medication is for?
- Tell me how you take this medication?
- What specific times of the day do you take this medication?
- How does this medication make you feel?
- What were you told to expect from this medication in terms of side-effects?
- How many doses of this medication have you missed in the past week?
- If you are not able to take your medications, what are some of the reasons and why you missed the medication dose?

Overall approach to medication adherence:

- If you could change anything about your medication regimen, what would it be?
- What tools or devices do you currently use to assist you in remembering to take your medications?

In addition to asking the patients to describe how they take their medications, there are risk factors that can be a signal that the patient may not be adherent with their medications.

Risk factors for poor medication adherence include but are not limited to (Jimmy and Jose, 2011):

- Medication side effects—For example, patient may unknowingly take more medication than is prescribed, and therefore may experience adverse effects of the medication.
- Complex medication regimens—For example, the more medications a patient is prescribed, the more confusing it is for patients to keep track of medications.
- Confusion—For example, patient may be confused with sound alike (clonidine and colchicine) and look alike (all round white pills).
- Cognitive/physical impairment—For example, patients with visual impairments unable to read labels.
- Low health literacy—For example, patient's inability to not only read words but also not understand how to carry out instructions (take one tablet twice a day, is that 8 a.m. and 8 p.m. or is it 9 a.m. and 10 a.m.).
- Cost—Medications that are not affordable are not bought. Multiple co-pays not affordable. Medication is not covered by prescription insurance.
- Substance use—Under the influence of substances that interview with the cognitive ability to follow through on medication instructions as intended.
- Poor patient-provider communication—Communication that is not clear or direct or if the patient is not trusting of the pharmacist.

Communicating with caregivers

PJ is taking care of his father who is diagnosed with Alzheimer's disease. PJ is concerned that the medication is not working and wants to know if there is an alternative that can be prescribed for his father. PJ is feeling helpless and you, the pharmacist, see the strain on his face and can hear the frustration in his voice. What is your communication strategy to address PJ's concerns?

As the population ages and more children are taking care of their parents, the caregiver has become an increasingly important member of the team taking care of the patient. As a partner, the pharmacist must have a relationship with all who are close to the patient, especially those administering medications, whether it is a child or an adult. Being a sounding board for the caregiver can give insight into the realities of providing care and what strategies are and are not working to ensure that the patient is adherent with the medication regimens. Using the same principles of communication and keeping the lines of communication open and clear will strengthen the partnership that has the end goal of providing the best care for the patient.

The pharmacist may not be able to do anything but refer the caregiver to other resources specially trained to support caregivers. As it is important to simplify regimens for patients, a simple, easy-to-follow regimen can also be helpful to the caregiver or the person responsible for administering the medications to the patient. The following are examples of strategies that can be used that are not all inclusive:

- Tell me how are you doing caring for your father?
- Tell me what you are most concerned about with your father's medications?
- Tell me about your expectations about how the medicines are to work for your father?
- How can I best support you with your job of administering medications to father?
- What do you think would be helpful to support you with administering the medications to your father?

Communicating with children

Patient JT is being discharged from the hospital with several medications to manage the side-effects of her chemotherapy treatment. JT is eight years old and understands her condition and the medications prescribed by her doctor. Her parents will administer the medications at home. What would be your approach to counseling JT and her parents on the prescribed medication regimen?

It is incumbent upon the pharmacist to determine in their discussions with parents if it is appropriate for their child (pediatric patient) to be included in the medication counseling sessions. Children can be well aware of what is happening, and depending on the age, can have some understanding of their medications.

Interactive and educational technologies may enhance this interaction. Pharmacists can reach out to include age appropriate pediatric patients as often as possible (Abraham et al., 2017).

Examples of strategies that can be used that are not all inclusive:

- What questions do you have about JT's medications?
  - Purpose of medications?
  - Duration to continue taking the medications?
  - Special measuring devices to administer the medications?

- What questions do you have about administering JT's medications?
- What concerns you most about JT's medication regimen?

Disclosing medication errors

Patient MEW has picked up a new prescription at the pharmacy. After the patient has left the pharmacy and returns home, it is discovered that the wrong strength of the medication has dispensed. Patient MEW has taken one dose of the new medication. You asked that he return to the pharmacy as soon as he can to get the correct medication. How do you go about discussing this issue with MEW?

Patient safety is the ultimate objective as patients interface with the health-care system at many junctures. When dispensing medications, the objective is to get the right medication, to the right patient, in a timely fashion. Wherever a pharmacist is working to provide medications to patients, safety is paramount. Not only is the medication the correct one for patient but also the dose, frequency, and dosage form are appropriate. Due to the fact that pharmacists are human, errors do occur, and it is our responsibility to disclose these errors to patients and caregivers (Kim et al., 2017).

There are a wide variety of reasons why medication errors do occur and one source is poor or miscommunication between health providers or between the health-care provider and the patient. There are a variety of reasons even for the miscommunications stemming from the characteristics of the patient (culture, language, and literacy), factors in our health-care systems (complex processes to access medications, insurance issues), and characteristics of the health-care provider (communication skills and techniques, use of medical jargon). As health-care providers, our responsibility is to use the most effective techniques available that are appropriate for our individual patients. There is no "one size fits all" approach or one "golden standard."

Pharmacist can disclose with patients when there are errors in prescribing and the delay that will occur until the problem is resolved. The timelines and professional handling of the situation keep the patient informed with the goal being to resolve the issue as soon as possible.

Pharmacists disclosing errors made in dispensing is disheartening and serious. Given that humans make errors, one should be honest and disclose the error as soon as possible and communicate the plan to correct the error. All appreciate a sincere apology that is empathetic and sympathetic. Take into account the emotional state of the patient. Answer all questions as clearly as possible. Pharmacists closely involved with the error are the one to talk with the patient. Explanation of how the error occurred and what will be done to prevent it from happening again. Identify any adverse effects of the error and what the patient should look out for

Communicating through conflict

Chief Pharmacist HP has received multiple complaints from a patient because of the way the pharmacy staff treats him. Today he is in the pharmacy and is not only visibly upset, but he is yelling and threatening to never come back to the pharmacy and he will tell all of his friends to avoid using this pharmacy. At this point Pharmacist HP does not have all the facts of what has transpired. What strategies can Pharmacist HP implement to resolve this conflict?

Providing high-quality customer service and patient care is what we all strive for. However, there are occasions when issues that upset the patient arise. Reasons may range from patients being unwell and was thus short with their patience with everyone, to miscommunications between the patient and staff, to other personal issues experienced by both the patient and staff that are unknown.

The first step in managing a conflict is how we speak with the individual who is upset and wants the results immediately. What communication strategies can be used to de-escalate the situation in order to come to a reasonable solution?

An important component of a strong interpersonal communication is being an active listener and giving individuals the opportunity to state their case in a compassionate and empathetic way. It is not, all the time, about who is right or who is wrong; it's just making space for the person who is upset, and in this case, the customer to be heard in an authentic way. Asking lots of questions and for elaboration on the circumstances can allow for relief of frustration. For example, asking questions like tell me about your experiences? Tell me how the issues we dealt with up to this date? What solutions would you suggest to resolve the issue? How do you suggest that we try to resolve this issue together? In every case, there is no guarantee that the situations will be resolved. There is often a reasonable compromise for both sides that could be agreed to. In your role as the pharmacist, it is not the goal to be right, but to do what is right to come to some understanding together and then to move forward.

Conclusion

Effective interpersonal communication is essential to providing high-quality patient care. Over time individual styles develop but the core components to effective communication are basic and should be part of every pharmacist's communication toolbox. Pharmacists can seek a variety of trainings, books, and articles on the art of communication. Nothing takes the place of real-life situations experienced in daily work routines. Constant practice and refining of the art of communication is a lifelong journey. More research is needed to understand how to best engage patients and those who care for them into the conversation as a total team effort

to achieve positive health outcomes. It's all about changing behavior, which is not accomplished in one visit or one encounter. It's a constant effort, and both the pharmacist and the patient have a role and responsibilities in communicating effectively.

Evidence-Based Medicine: An Overview for Pharmacists

Caitlin A. Carter[*], **Sherilyn K.D. Houle**[†], [*]University of Waterloo Library, Waterloo, ON, Canada; [†]University of Waterloo School of Pharmacy, Waterloo, ON, Canada

What is Drug Information (DI)?

Definition

One of the pharmacist's main responsibilities is to educate patients on the safe and proper use of medications. In addition to educating patients, it is the pharmacist's role to create and provide advice to other health care practitioners on medication management decisions. In order to be experts in medication management, pharmacists must master the ability to effectively retrieve drug information (DI) from credible resources. "DI" is a broad concept, but the practice of DI has been defined as "the efficient retrieval, evaluation, and communication of medication information in order to assist in care decisions, develop evidence-based recommendations, and improve patient outcomes" (Gabay and McKeever, 2016, p. 2). Pharmacists regularly retrieve, evaluate, and communicate answers to DI questions about adverse effects, cost, compounding, dosing, drug interactions, natural health products, pharmacokinetics, drug composition, toxicology, and much more.

Primary, Secondary, Tertiary Literature

Pharmacists answer DI requests using a variety of literature. These sources of information can be classified as either primary, secondary, or tertiary. Primary literature is considered "original," as the author(s) have carried out their own research and reported on the results of their experiment or discovery (Yale University Library, 2017). Some examples of primary literature include

randomized controlled trials (RCTs), cohort studies, case-control studies, and case reports. Primary literature is often sought and consulted when very little secondary or tertiary information exists on a topic, as it may be the only option for learning more about a new drug, rare disease, or emerging evidence. A limitation of primary literature is that the reader must spend time critically appraising the study design and results, as the study may have been improperly conducted (Gooch Wright et al., 1998, p.155). There may be errors in how the results have been analyzed, which means the reader must also have some knowledge of interpreting statistical tests. In addition, a significant amount of primary literature is published everyday, which poses difficulties for the pharmacist in terms of staying abreast of the latest information.

Secondary literature describes, analyzes, evaluates, or interprets information reported by the authors of primary literature (University of Toronto Libraries, 2015). Some examples of secondary literature include review articles, such as narrative, scoping, or systematic reviews, and clinical practice guidelines (CPGs). Secondary literature aims to collect many, if not all, primary research studies on a given topic via a thorough literature search. After the literature search is complete, the included primary research studies are read and the appropriate data is extracted. In systematic reviews, the included studies are critically appraised to assess validity and the data which is extracted may be combined to form overarching conclusions of greater power and precision (Cook et al., 1997, p. 378). If a pharmacist can find secondary literature related to their DI request, this will save a considerable amount of time, as they will not be needed to read several primary studies, appraise each one individually, and then form their own conclusions. However, secondary literature does have some limitations. For example, the literature search for finding primary studies may be very weak, or the authors may have only included primary studies which support their research objectives (Crowther and Cook, 2007, pp. 494–496).

Tertiary literature summarizes information from the primary and secondary literature (Yale University Library, 2017). Some examples of tertiary literature include online and print textbooks, handbooks, encyclopedias, and online DI databases like Lexicomp. This type of literature is excellent for acquiring background information on a topic, such as an overview of a drug's clinical use, interactions, mechanism of action, and much more. Tertiary literature is easy to use and navigate, but it too has some limitations. These limitations include the lack of an exhaustive overview of a subject due to chapter length restrictions or for print tertiary literature—the likelihood that it does not incorporate the most current research, as the publication process can take a long time (Kee and Duba, 2016, p. 32). In addition, the reader cannot determine whether all of the appropriate information was consulted to write the content or whether it was appraised by the authors (Gooch Wright et al., 1998, p. 151).

One can find both primary and secondary literature in databases, such as PubMed (MEDLINE), Embase, International Pharmaceutical Abstracts, as well as many others. As mentioned earlier, tertiary literature can be found in textbooks, such as *Goodman's and Gilman's Pharmacological Basis of Therapeutics*, or handbooks such as the *Handbook on Injectable Drugs*. In addition to Lexicomp, other online DI databases, such as MicroMedex, or Natural Medicines, provide access to tertiary information.

The typical order of consulting literature is tertiary-secondary-primary (Shields and Blythe, 2014). The pharmacist should acquire the appropriate "background" knowledge about a disease or drug before attempting to search for and interpret the secondary or primary literature. The tertiary literature may also prompt the pharmacist to ask further questions about the DI request before trying to navigate the secondary and primary literature. In situations where the DI request involves a new and emerging topic, rare situation, or there is no agreement among experts, the pharmacist should consult the secondary and primary literature, as there would not be enough evidence in the tertiary literature to formulate a response (Conrad, 2016, p. 84).

Responding to a DI Request

The role of the pharmacist is not simply to provide an answer to a DI request. It involves clarifying the question, finding an answer through use of multiple resources, synthesizing the DI in order to provide guidance to the requestor, and effectively communicating the response based on the requestor's level of health literacy.

Brown and Choy (2016, p. 12) outline a "4 Rs" approach—receive, research, respond, and record—for handling DI requests. The first step of this process is "receive," which focuses on identifying the requestor-specific question, acquiring background information, and collecting requestor demographics, which will aid in formulating an answer to the request. What may seem like one simple question may morph into multiple questions or a more complex question. It is not uncommon for requestors to be vague or omit pertinent details, as requestors are not always aware of what information is needed by the pharmacist in order to answer the question. Gathering background information, such as patient specifics, may lead to the actual question being asked. Patient specifics, like previous medical history or known allergies, are two of many factors to consider when formulating an answer to a DI request. Identifying a requestor's demographics (e.g., nurse, physician, Department of Critical Care) is also helpful, as it will help the pharmacist determine what level of information to include in the response. Asking the requestor whether they have conducted any of their own previous research on the request and how quickly they expect an answer will help the pharmacist to prioritize which resources to search. Once the pharmacist has obtained all of the required information, they can categorize the request (e.g., drug interaction, alternative medicine, pregnancy), which may also dictate resource selection (Brown and Choy, 2016, pp. 13, 15, 16). Asking the right questions of the requestor will significantly reduce the chance of misinterpretation and the potential risk of negatively impacting patient care.

After identifying and categorizing the requestor's question, the second step is to "research" an answer (Brown and Choy, 2016, p. 18). The order of consulting resources is tertiary, followed by secondary and primary, as many DI requests can be answered using tertiary resources (Shields and Blythe, 2014). However, for complex or rare DI requests, the pharmacist will need to consult the secondary or primary literature, as requests of such specific nature would not be addressed by the tertiary literature.

There are many databases, which pharmacists can use to locate primary and secondary literature, such as PubMed (MEDLINE) or International Pharmaceutical Abstracts. Pharmacists should look for an answer in more than one resource, in order to compare answers, as each resource may provide different rationale for their recommendations, or contain differences in information itself (Brown and Choy, 2016, p. 19). The caliber of evidence should be considered when looking for an answer, as answers should be based on the best available evidence, such as meta-analyses, systematic reviews, or RCTs, if available (Brown and Choy, 2016, p. 20).

The information from multiple resources, as well as the patient's background information, should be assessed for validity and synthesized into a response for the requestor, which leads to the third step, that is, "respond" (Brown and Choy, 2016, p. 20). The pharmacist should consider all information found, whether it is negative or positive, when formulating a response to the requestor, as objectivity is important. Responses should be accurate and concise and include the requestor's original question, an overview of the available evidence, as well as a summary of recommendations based on the evidence and the pharmacist's expertise (Brown and Choy, 2016, p. 20). In anticipation of follow-up questions, the pharmacist should be thorough and provide additional information of potential relevance, like the side effects of the treatment recommendation and what to monitor (Brown and Choy, 2016, p. 21). Recommendations should be supported by references from unbiased, high-quality literature. Pharmacists should only consider weaker evidence, such as case series, case reports, or expert opinion, if evidence of higher quality does not exist. The inclusion of weaker evidence should be clearly communicated to the requestor. Prepared responses can be formatted and delivered depending on the requestor's preferences—either via telephone, email, or in-person.

Once the answer has been communicated, the pharmacist completes the "4 Rs" approach by documenting the process used to address the request, otherwise known as "record" (Brown and Choy, 2016, p. 22). A file containing the specifics of the request, classification, the search process, recommendations, and supporting evidence should be kept for legal reasons and in case a similar request is posed again by another requestor. If a similar request surfaces, the pharmacist should complete another search, as new evidence may have emerged since the original request was submitted. Pharmacists should document any new evidence and also provide this to previous requestors, as this will have implications for patient care (Brown and Choy, 2016, p. 23). Finally, follow-up with the requestor should occur, in order to assess if their needs have been met, if the information impacted patient care, and if further assistance is required. This will strengthen the pharmacist's relationship with the requestor.

What is Evidence-Based Medicine (EBM)?

Origins and Definition

In 1981, David Sackett, a physician and professor at McMaster University, wrote several articles for the Canadian Medical Association Journal about the "critical appraisal," or evaluation of scientific research, which laid the foundation for the rise of the evidence-based medicine (EBM) movement (Smith and Rennie, 2014, p. 366). EBM is defined as the "conscientious, explicit, and judicious use of current, best evidence in making decisions about the care of individual patients" while "integrating individual clinical expertise with the best available external clinical evidence from systematic research" (Sackett et al., 1996, p. 71). This definition has since been modified to also include patient "values and preferences," as the patient's circumstances or feelings toward risk or cost may ultimately influence whether therapy is pursued (Guyatt et al., 2015b, p. 8). A primary aim of EBM is to demonstrate that patient care decisions should be influenced by scientific fact and that relying solely on clinical expertise, or the expertise of more experienced coworkers, is no longer sufficient (Evidence-Based Medicine Working Group, 1992, p. 2421).

Practicing EBM is not an innate skill; pharmacists must make a conscious effort in order to become proficient at integrating EBM into their patient care decision-making. Straus, Glasziou, Richardson and Haynes (2011, p. 3) outline the process of EBM in five steps, which include: (1) based on the information request, construct an answerable question; (2) search the literature for the best evidence; (3) critically appraise the search results for validity and applicability; (4) integrate the appraised evidence with your clinical expertise, and patient values and preferences; and (5) evaluate your performance and assess whether the integration of EBM had an effect on patient care. This 5-step approach to EBM will be outlined in further detail later in the chapter.

How do Pharmacists Practice EBM?

Pharmacists are well-positioned to exercise the components of EBM. As pharmacists are usually the patient's first point of contact to the health care system (Ontario Pharmacists Association, 2016), they are faced with a multitude of unique questions—some based on what the patient has read on the Internet or from family and friends. This presents the pharmacist with an opportunity to educate the patient about evidence-based information and the importance of using credible sources. In addition to counseling patients, pharmacists may be called upon by physicians or nurses in order to provide guidance on how to properly administer medications, titrate doses, switch therapies, or how to monitor and avoid adverse effects. Hospital pharmacists are often a part of pharmacy and therapeutics committees, which provide information and guidance to all healthcare practitioners on drug safety, evaluation, and complying with drug use guidelines (Bernknopf et al., 2009, pp. 339–340). During student work placements, internships, or co-op terms, supervising pharmacists can provide education around the importance of finding and using evidence to inform patient care decisions. Pharmacists contribute to the body of evidence-based literature as well, by publishing and presenting research findings in journals and conference proceedings.

Levels of Evidence and Study Designs

Levels of Evidence

There is an insurmountable amount of research available online and in print. The challenge for pharmacists is wading through this sea of information and determining what should be considered the "best evidence" when answering a DI request, as not all evidence is equal. Fortunately, there are researchers who have developed useful tools, like evidence pyramids, which can be used to categorize the quality of research studies, based on the strength and precision of the research methods.

Fig. 1, "hierarchy of evidence," is an example of one of these EBM pyramids. This pyramid ranks the highest quality research at the top of the pyramid, with a reduction in the strength and quality of the evidence as you work your way to the bottom.

At the top of the pyramid is the meta-analysis and systematic review. Systematic reviews focus on a specific research question and defined eligibility criteria for the inclusion of studies. A thorough search of the literature is conducted and all results are screened based on the eligibility criteria. The included studies are critically appraised and the data is extracted and summarized from the remaining studies. If the data is similar enough across studies, it can be combined to form an overall conclusion of greater statistical power, otherwise known as a meta-analysis (Green et al., 2008, p. 6). Systematic reviews are ranked one level below the meta-analysis on the evidence pyramid, as not all systematic reviews contain meta-analyses, due to the heterogeneity of some systematic review results.

Beneath the meta-analysis and systematic review, you will find an experimental study design known as the RCT. In a RCT, an intervention (e.g., medication) is introduced to the study participants in order to change the course of a disease. Patients are randomly assigned to either an intervention group or a control group (placebo or standard treatment) and then followed forward to an outcome (Guyatt et al., 2015a, p. 670). RCTs are considered high-quality evidence because the study participants have an equal chance of being placed into either the intervention or control group; the researchers and participants usually do not know which treatment is administered to each group and causation can be proven, due to randomization of the patients and reduced risk of bias.

After RCTs, you will find two types of observational study designs: cohort and case-control studies. The cohort study follows a group of patients with an exposure over time and compares them for outcomes with a group of patients without the exposure (Guyatt et al., 2015a, p. 649). They are useful for answering questions related to etiology, incidence, prognosis, and harm. The case-control study is the opposite; patients with and without a specific condition are compared by the researchers in an attempt to identify which exposures may have contributed to the condition (Guyatt et al., 2015a, p. 647). Case-control studies are useful for acquiring information related to rare outcomes, which may otherwise take a long time to appear in other types of study designs.

Case series and case reports describe the characteristics, diagnosis, and treatment of a few patients or one patient, and they do not utilize a control group (Guyatt et al., 2015a, p. 647). They highlight rare or new and emerging issues, such as the side effects of a new drug, and their statistical significance is low, due to small sample size.

At the bottom of the pyramid, you will find editorials, expert opinion, and animal research, which are considered to be weaker evidence. Editorials and expert opinion pieces are published commentary, based on a clinician's experience in a particular area, with greater risk of bias or selective reporting (Mayer, 2010, p. 27). Animal research is self-explanatory—it can provide useful background information, but the findings cannot always be applied to humans.

Another type of evidence pyramid is the "6S hierarchy of preappraised evidence" (Fig. 2), first developed by R. Brian Haynes and revised by Alba DiCenso and Liz Bayley, all from McMaster University. The sources near the top of this pyramid contain high-quality preappraised evidence, meaning the user does not need to spend time conducting their own appraisal of the evidence. These sources are easy to use while with a patient, or at the immediate point-of-care. "Systems," also known as decision support tools, are at the top of the pyramid and they link relevant preappraised evidence to the patient's electronic health record, based on the patient's profile and circumstances (Dicenso et al., 2009, p. 100).

"Summaries" are also considered high-level evidence. Clinical practice guidelines (CPGs) are considered summaries, as many base their care recommendations on high-quality evidence. You can find CPGs in resources like the National Institute for Health and Care Excellence and the Turning Research Into Practice (TRIP) database. Another example of a summary is the electronic

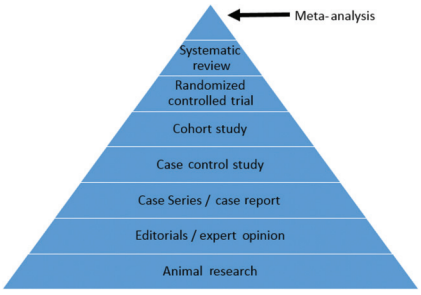

Figure 1 Hierarchy of evidence. Adapted from Mulimani, P.S., 2017. Evidence-based practice and the evidence pyramid: a 21st century orthodontic odyssey. Am. J. Orthod. Dentofacial. Orthop. 152 (1), 1–8.

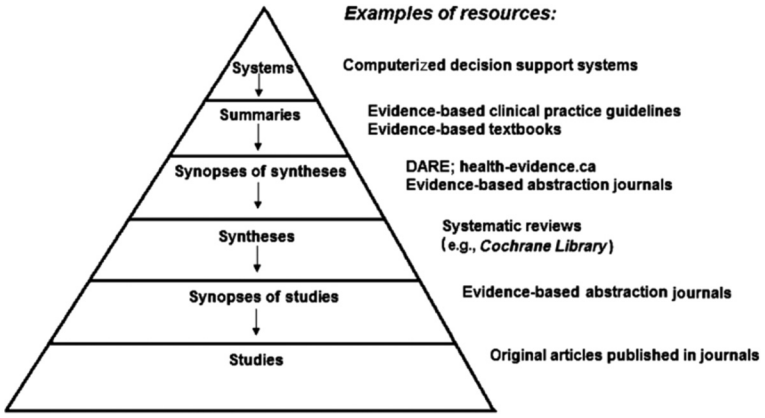

Figure 2 6S hierarchy of preappraised evidence. From Dicenso, A., Bayley L., Haynes, R.B., 2009. Accessing pre-appraised evidence: fine-tuning the 5S model into a 6S model. Evid. Based Nurs. 12 (4), 99–101.

evidence-based textbook or handbook, such as BMJ's Clinical Evidence, DynaMed, or UpToDate. These resources summarize evidence from the literature about specific clinical problems and the content is updated as new evidence becomes available (Dicenso et al., 2009, p. 100).

"Synopses of syntheses" are next on the pyramid. These synopses summarize the results from systematic reviews and often include commentary, which can help inform patient care decisions (Dicenso et al., 2009, p. 100). Systematic reviews may be very long—sometimes up to 100 pages in length. It is simply not realistic to read through this much content while with a patient, making "synopses of syntheses" a useful alternative. "Synopses of syntheses" can be found in journals like the ACP Journal Club, Evidence-Based Medicine, and the Database of Abstracts of Reviews of Effects (DARE) (Dicenso et al., 2009, p. 100).

Unfortunately, "synopses of syntheses" are not available for every systematic review. When this occurs, the original systematic review will need to be consulted. Systematic reviews are referred to as "syntheses" on the 6S pyramid. "Syntheses" take time to read through and digest, requiring more time investment from the user. They are lower on the pyramid, meaning the user will need to appraise the systematic review for validity and reliability on their own. "Syntheses" can be found in most databases, but perhaps the most well-known database for finding "syntheses" is the Cochrane Library's Database of Systematic Reviews (CDSR) (Dicenso et al., 2009, p. 101).

The bottom two levels of the 6S pyramid include "synopses of single studies" and "studies." The former refers to a concise overview of an appraised single study, which may include commentary that can guide clinical practice (Dicenso et al., 2009, p. 101). The latter refers to a single study, which is the last stop on the 6S pyramid, if none of the other types of appraised evidence can be found. You can find "synopses of single studies" in the same journals as "synopses of syntheses" and individual "studies" can be found in resources like PubMed (Medline) and the EBSCO and Ovid databases (Dicenso et al., 2009, p. 101).

These pyramids are meant to serve as guides and do not suggest that you must find a meta-analysis or always use a "system" in order to answer your DI requests. High-quality and pre-appraised evidence does not exist for every patient care scenario. This means there will be situations when evidence of lesser value will need to be reviewed and assessed, as it may be the only evidence available. Understanding the levels of evidence and various study designs will help you determine which type of study can best answer your DI request.

EBM Step 1: Constructing an Answerable Question

Background/Foreground Questions and PICO

The most important step of the EBM process is the formulation of an answerable question, as poorly structured questions will lead to disorganized and unproductive searches of the literature. Before constructing an answerable question, the pharmacist may need to answer some general background questions, in order to construct a focused, overall answerable question. Background questions are usually related to topics studied in pharmacy school, such as pharmacology or pharmacokinetics. Fig. 3 contains a case scenario, as well as associated background questions of potential relevance.

Once the pharmacist has gathered the appropriate background information, the more complex foreground question can be constructed, as asking a very broad question like "should I change the patient's osteoporosis therapy?" will not lend itself well to the literature-searching component of the EBM process. Foreground questions can be constructed using the PICO model. The PICO mnemonic stands for: patient or problem (P), intervention (I), comparison (C), and outcome(s) (O) (Richardson et al., 1995, p. A12). The "patient" or "problem" may include the patient's characteristics, such as gender, age, disease, condition, or comorbidities. The "intervention" focuses on what will be introduced to modify the course of the disease, like a new drug therapy. "Comparison" includes any alternative to the intervention, which may be the standard therapy or placebo. It is important to note that in some scenarios, there may be no comparison, which is acceptable. The "outcome(s)" include what you wish to do, or would

A pharmacist has been asked by a physician to find evidence supporting the use of denosumab over bisphosphonates for the treatment of osteoporosis in a 65 year old female patient. Over the course of several years, the patient has experienced many bothersome side effects, suspected to be caused by the use of different bisphosphonates, and the physician would like to know if denosumab will be better tolerated, with less risk of fracture. The pharmacist learns that the patient is also taking melatonin for sleep disturbances, as well as rosuvastatin for high cholesterol and levothyroxine for hypothyroidism. Before constructing an answerable question, the pharmacist may want to research and answer some background questions, such as:

- What is the pathophysiology of osteoporosis?
- What is denosumab?
- What is denosumab's mechanism of action?
- Are there known interactions between denosumab, melatonin, rosuvastatin, or levothyroxine?

Figure 3 Case scenario.

Table 1 PICO

P-patient or problem	65-year-old female with osteoporosis
I-intervention	Denosumab
C-comparison	Bisphosphonates (remember, "comparison" is optional, but in this situation, there is a comparator)
O-outcome(s)	Better tolerance, less side effects, and risk of fracture

like to improve for the patient, such as reduce side effects, mortality, or pain (Richardson et al., 1995, p. A12). Based on the scenario in Fig. 3, the PICO in Table 1 would be as follows:

Once the PICO has been identified, the foreground or answerable question can be constructed. For the aforementioned PICO, a possible foreground question could be:

In a 65-year-old female patient with osteoporosis, is denosumab better tolerated than bisphosphonates and more effective for reducing side effects and risk of fracture?

Schardt, Adams, Owens, et al. (2007, p. 2) add that the PICO formula can be expanded from PICO to PICOTT, which takes into account the type (T) of question (therapy, harm, prognosis, etc.) being asked and the type (T) of study (meta-analysis, RCT, etc.) that may best answer the question. The PICOTT approach can help the pharmacist further narrow their foreground question. Furthermore, Straus, et al. (2011, p. 21) identify that "clinicians who are taught this structured approach ask more specific questions, undertake more searches for evidence, use more detailed search methods, and find more precise answers."

Creating the right answerable question does take practice and can be quite difficult—especially in scenarios with greater complexity. In these situations, it is best to create more than one answerable question, rather than try to combine all elements into one overarching question. This will also make the question(s) easier to articulate to other health care practitioners. The precise wording of the question guides the search of the literature and helps to reduce the amount of irrelevant results.

EBM Step 2: Choosing Your Sources and Performing the Literature Search

Identifying Search Terms and Using AND/OR/NOT

Once an answerable question has been decided upon, the next step is to isolate the most important concepts from your PICO, which can be used to build a search strategy. Once you have isolated these main concepts, you should think of synonyms or alternative ways of referring to these terms. For example, in the scenario from the previous section, "female" was identified as a part of the "P—patient" component. Other ways of referring to "female" would be women or woman. Additionally, you may wish to further break down "bisphosphonates" into specific drugs from this class, such as alendronate, or risedronate.

After coming up with a list of search terms and synonyms, the next step is to combine the terms using Boolean operators, such as OR/AND. The "OR" operator connects similar concepts and the "AND" operator connects different concepts. Figs. 4 and 5 illustrate these operators in action.

Another operator that is sometimes used is "NOT." The "NOT" operator can be used to exclude specific search terms from your results. An example of this operator is depicted in Fig. 6. This operator should be used with caution, as it can exclude results, which are actually of relevance.

Once you have thought about how to combine your concepts, you can begin to draft some search strategies. Your first search strategy will not likely be your last, as searching is a very iterative process and several strategies are usually tested before finding a

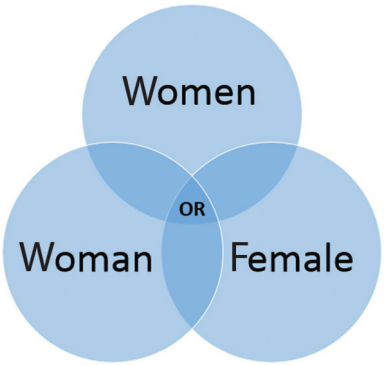

Figure 4 OR operator.

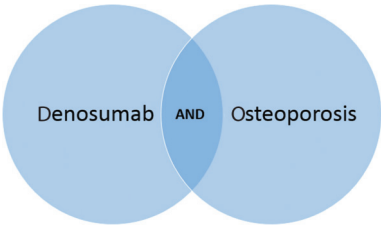

Figure 5 AND operator.

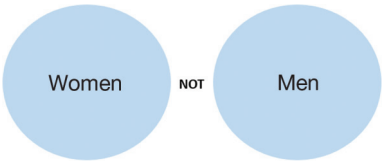

Figure 6 NOT operator.

strategy which yields the best results. If possible, it is a good idea to consult a medical librarian, as these librarians can provide guidance on building and running effective search strategies.

PubMed (MEDLINE)

The next step is to think about the databases or resources to be searched for high-quality evidence. PubMed (MEDLINE), run by the National Library of Medicine, is one of the world's most commonly searched databases. PubMed contains the entire MEDLINE collection, which is why it is often referred to as PubMed (MEDLINE). As of this writing, PubMed (MEDLINE) contains over 28 million references to research articles published in the health and life sciences disciplines. Due to its extensive coverage, it is often the first stop for health care practitioners. In addition, it is free to search; although, access to certain full-text articles may be behind a paywall.

A simple PubMed (MEDLINE) keyword search, based off of the PICO in Table 1, would look as follows:

(female* OR woman OR women) AND osteoporosis AND denosumab AND (diphosphonate* OR bisphosphonate*)

The *asterisk*, also known as "truncation," can be used to search for word ending variations, such as the singular or plural variations of a word. Synonymous terms, connected with "OR," like (diphosphonate* OR bisphosphonate*) must be enclosed with parentheses, as these terms are searched as one unit. Boolean operators must be capitalized in PubMed, or PubMed may change all "OR" operators to "AND" operators.

Upon entering your search strategy into PubMed's main search box, PubMed will try to match or "map" the keywords in your search strategy to the appropriate MeSH terms or medical subject headings. What is MeSH? When an article is added to PubMed, it is read by a content expert, who selects the MeSH terms from the MeSH thesaurus, which best describe the main subjects or topics of the article. MeSH terms can be compared to modern-day hashtags. In Fig. 7, PubMed has attempted to automatically

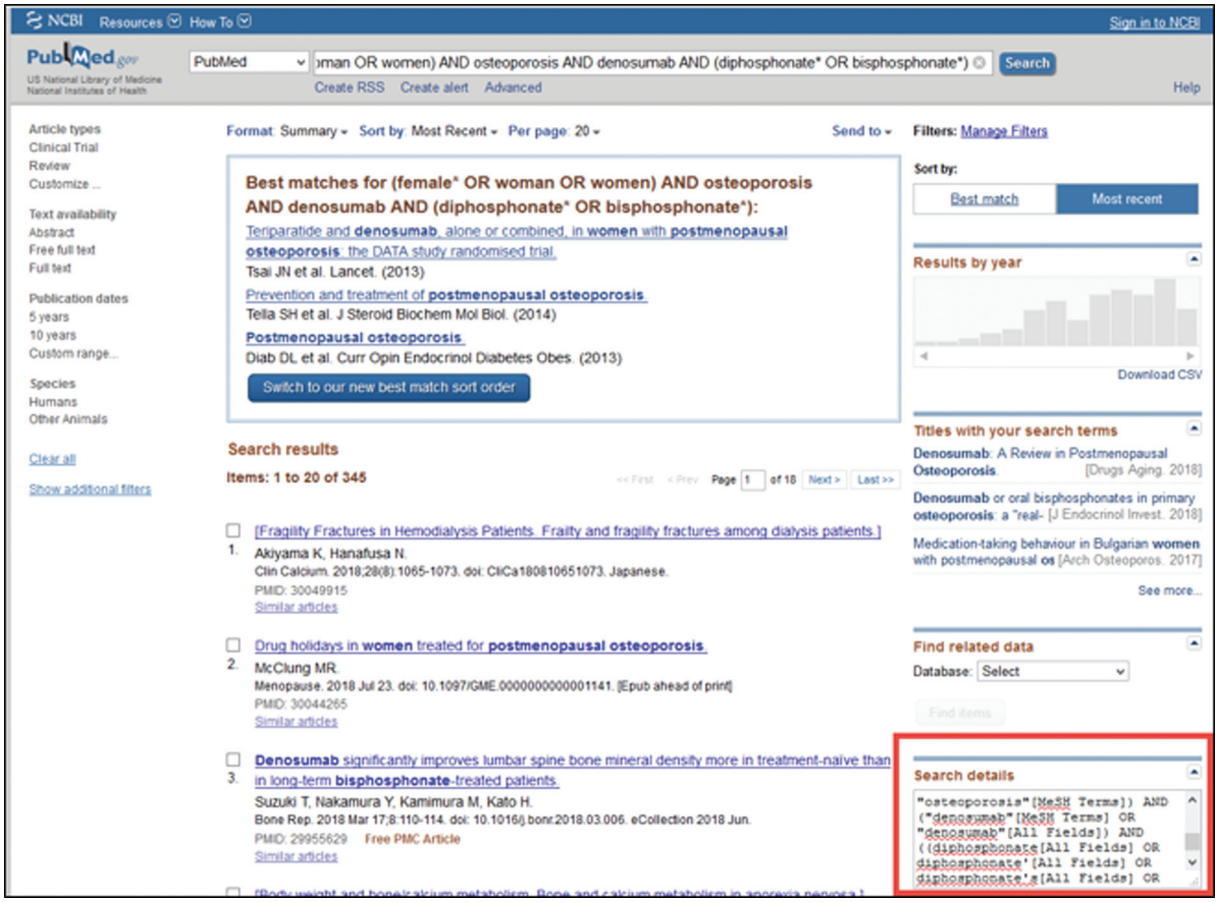

Figure 7 Automatic term mapping function in PubMed.

match or "map" the keywords in the search strategy to the applicable MeSH terms. The "search details" box shows this feature in action.

Note: When applying truncation to a keyword (e.g. female*), this turns off the automatic term mapping feature on that particular keyword, so keep this in mind when building your searches.

If your keyword search has not "mapped" to the appropriate MeSH terms, then you will have to look in the MeSH thesaurus yourself, to find the applicable MeSH terms to add your search. Figs. 8–10 demonstrate how to find MeSH terms using the MeSH thesaurus. If you are conducting a literature search for a publication, like a systematic review, you should build a search strategy, which is comprised of *both* keywords and MeSH terms, so that you construct a truly comprehensive search for all possible literature.

After clicking "search," (Step 4 in Fig. 8) you are presented with a list of potential MeSH terms (Fig. 9). Click on a term to read more about it and to decide if it will add value to the search strategy.

The next screen depicts the MeSH term record (Fig. 10), where you will often find a definition, the year the term entered the MeSH thesaurus, the additional terms the MeSH term will search for automatically (entry terms) and where the MeSH term fits in the MeSH hierarchy of terms. By looking at this hierarchy, you can determine if you would like to select a broader or narrower term to use in your search.

Once you find your applicable MeSH terms, you can incorporate them into a search strategy. A potential combined MeSH and keyword search would look as follows:

(female[MeSH] OR female* OR woman OR women) AND (osteoporosis[MeSH] OR osteoporosis)
AND (denosumab[MeSH] OR denosumab) AND (diphosphonates[MeSH] OR diphosphonate* OR bisphosphonate*)

Enter your search strategy into the PubMed main search box and make sure the drop-down menu to the left of the main search box says "PubMed." Once you have your results, you can apply filters (Fig. 11), like publication type, date range, and language (found under "show additional filters"), to further narrow the amount of results.

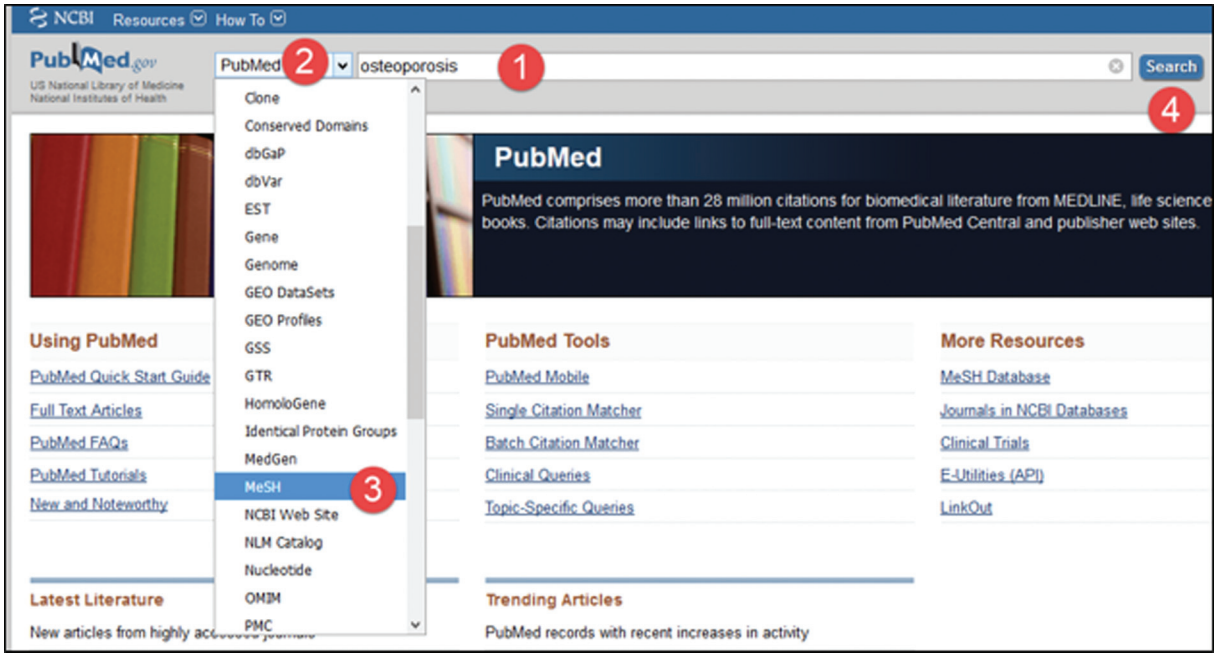

Figure 8 How to search for a MeSH term.

Tips to Consider

A useful tip is to input the title of a relevant article you have already found through another source into PubMed (MEDLINE) and take a look at the MeSH terms, which have been applied to that article (Fig. 12). This may provide you with additional terms you can add to your search strategy.

Additionally, you can use the "similar articles" option to view a list of other possible articles of interest (Fig. 13).

Lastly, always save your search strategies. You can create a free "MyNCBI" account with PubMed and save your searches in your account permanently. You can login at a later date and rerun the search again, or set up email alerts, in order to receive emails every time a new article is added to PubMed on your search topic.

Clinical Queries

A unique feature of PubMed (MEDLINE) is the "clinical queries" function, found on the homepage (Fig. 14). This feature can be used to quickly find clinical studies, systematic reviews, and genetic studies. Simply enter in your search terms in the search box and click "search." After the results are returned, you have the option to change the "category" of the search topic and the "scope" of

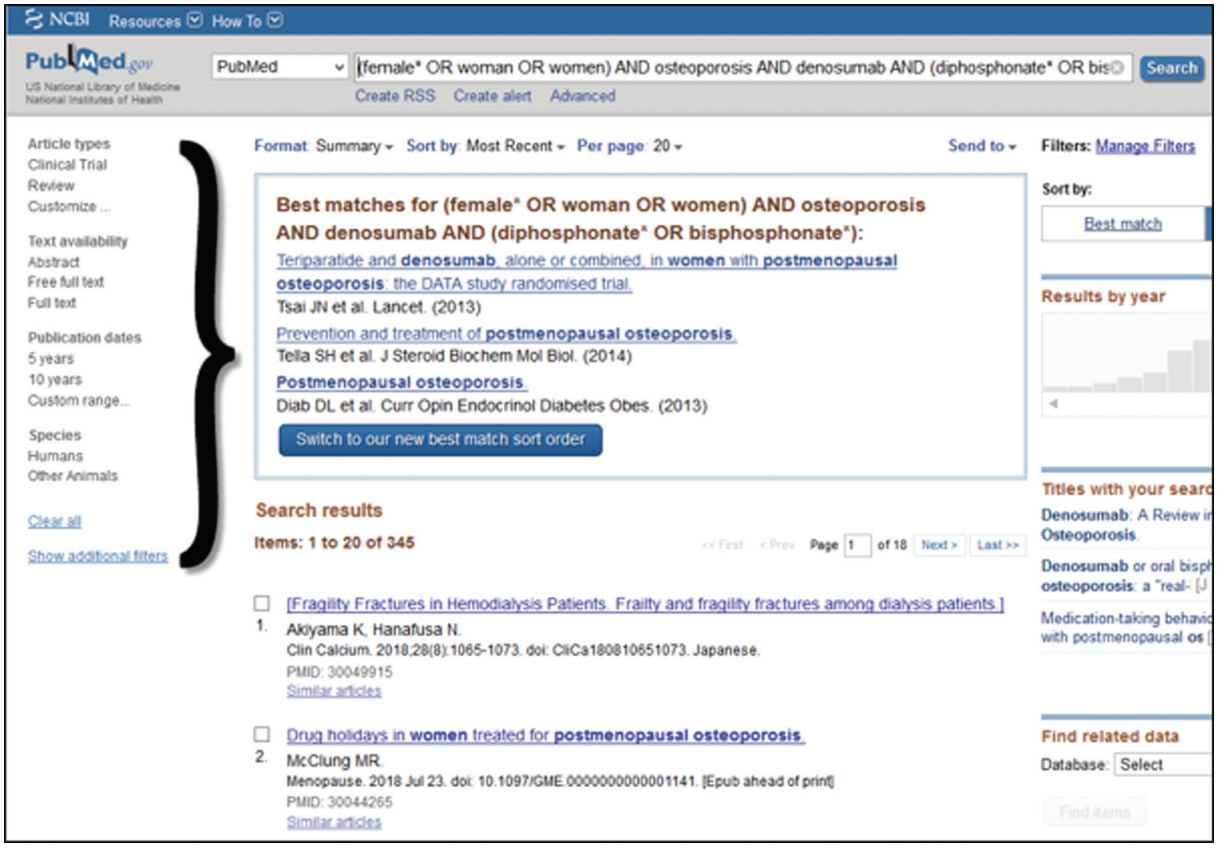

Figure 11 Limiting your search results with filters.

the results from broad to narrow. The "scope" automatically defaults to broad, so that the user is able to assess the relevancy and amount of results, before choosing to narrow the results instead.

Other Databases

In addition to PubMed (MEDLINE), there are several other databases a pharmacist will want to consider searching, in order to obtain a comprehensive overview of all of the literature on their subject. Table 2 outlines some of these databases of relevance.

Clinical Practice Guidelines

CPGs are used by health care practitioners in order to assist with making decisions related to the diagnosis and treatment of specific medical conditions. CPGs are often created by multidisciplinary teams and are defined as "statements that include recommendations intended to optimize patient care that are informed by a systematic review of evidence and an assessment of benefits and harms of alternative care options" (Institute of Medicine, 2011, p. 4). Not all guidelines are created equally, some are more credible than others, due to heavier reliance on research evidence and less on expert opinion. CPGs may be retrieved via a database search, but they can also be found through guideline-specific websites. Table 3 lists a few of these commonly used websites.

Gray Literature

There will be occasions when no, or very little evidence-based information can be found to answer a clinical question. Sources considered to be "gray literature" may offer a solution in this type of situation, as gray literature is often niche research. Gray literature includes information which is not typically peer-reviewed, challenging to find, and is inaccessible via traditional or commercial publishing (Mahood et al., 2014, p. 222). Examples of gray literature include, but are not limited to, reports from organizations, companies, or associations, government publications, unpublished clinical trials, PowerPoint presentations, conference proceedings, theses and dissertations, white papers, policy briefs, and blogs.

Simple keyword searches can be used in search engines, such as Google, to search for gray literature, but this is difficult, as most searches yield hundreds of thousands, if not millions, of results. As it is impossible to go through this many results, it is best to target

Table 2 Useful databases for pharmacy and medicine

Databases	*Content*	*Subscription required*
Embase	• Biomedicine and pharmacology • Includes 1000's of journals not indexed by MEDLINE • International, with significant European coverage • Includes abstracts from conferences	Yes-through various vendors
International Pharmaceutical Abstracts	• Pharmacy literature covering topics like biopharmaceutics, pharmacokinetics, drug reactions, ethics, liability, drug delivery, drug interactions, toxicity, and much more • International coverage • Includes abstracts from conferences and major pharmacy meetings	Yes-through various vendors
The Cochrane Library	• Collection of six healthcare databases: CDSR; CENTRAL; DARE; CMR; HTA; and EED	Yes, but full-text access may be free for your country or region—see the Cochrane Library's website for more information on countries with free or reduced cost access
TRIP	• Simultaneously searches for high-quality research, such as systematic reviews, evidence-based synopses, clinical practice guidelines, primary research articles, and much more • Offers a PICO search option on the homepage, which allows the user to structure a search query using the PICO formula	No, but a subscription-based version with additional content and search features is also available. See the TRIP website for more information on countries with free or reduced cost access.
BMJ Clinical Evidence	• Systematic reviews of the best available evidence on the effects of treatments • Evidence is formatted to answer key clinical questions and categorized by level of effectiveness	Yes-see BMJ Clinical Evidence's website for more information on pricing for shorter time periods, like 48 h or 30-day access

CDSR, Cochrane Database of Systematic Reviews; *CENTRAL*, Cochrane Central Register of Controlled Trials; *CMR*, Cochrane Methodology Register; *DARE*, Database of Abstracts of Reviews of Effects; *EED*, NHS Economic Evaluation Database; *HTA*, Health Technology Assessment Databases; *TRIP*, Turning Research Into Practice.

Table 3 Practice guideline websites

NICE	• A UK-based website of NICE-authored guidelines on a number of health conditions • Includes summaries of the best available evidence on medicines (NICE Advice) and flowcharts which bring together everything NICE has prepared on a topic (NICE Pathways)
CPG Infobase	• A Canadian-based website of guidelines authored by Canadian health organizations
NHMRC Clinical Practice Guidelines	• An Australian-based website of guidelines specific to Australian practice • Offers a guideline registry, so authors can register guidelines in development

NHMRC, National Health and Medical Research Council; *NICE*, The National Institute for Health and Care Excellence.

websites of important organizations, associations, or government agencies, as well as online academic institutional repositories, in order to search them individually for potentially useful gray literature.

When conducting gray literature searches, it is important to remember that you must assess the quality of any research you find. There are checklists available to assist with this process, such as Jess Tyndall's AACODS checklist (2010), which can be used to identify the authority, accuracy, coverage, objectivity, date, and significance of gray literature.

For drug-related clinical questions, various clinical trial websites may be relevant. These websites often provide access to clinical trial data, which was not published because the trial was suspended, terminated, or the results did not meet the researchers' expectations. Table 4 lists websites, which can be used to find unpublished clinical trial data.

EBM Step 3: Critical Appraisal of the Results

Before the results from the articles found during your literature search can be applied to the patient, they must be critically appraised for validity and reliability, as publication in a journal does not automatically guarantee a high level of quality. Before delving too far into the specifics of a study's validity, it is important to think about some general overarching questions from the outset. The following list includes some points to consider, derived from Greenhalgh's checklists (2014, pp. 243–44):

- Who authored the study? What are their credentials?
- Was the study peer-reviewed?
- Is the research original?

Figure 12 Locating MeSH terms applied to a relevant article.

Table 4 Clinical trial websites

The World Health Organization's ICTRP search portal	• An international database of clinical trial registration data • Includes data, such as recruitment status, sponsorship, study type, inclusion/exclusion criteria, outcomes, and links to the original records
The US National Institutes of Health (ClinicalTrials.gov)	• A US-based international trial registry • After a study is registered, more information is added to the study's record as the trial progresses; and in some cases, even the final results
ISRCTN.org	• A UK-based international registry and database of trial results • Not all registration records contain study results, or publication and dissemination plans
UMIN-CTR	• Japanese-based international registry and database of trial results • Not all registration records contain study results
PACTR	• A registry for all clinical trials conducted in Africa • Records may include a link to a publication
EU Clinical Trials Register	• Registry of trials conducted in the European Union • Includes important trial data, such as subject disposition, baseline characteristics, adverse events, trial amendments, interruptions, or limitations

ICTRP, International Clinical Trials Registry Platform; *PACTR*, Pan African Clinical Trials Registry; *UMIN-CTR*, University Hospital Medical Information Network Center.

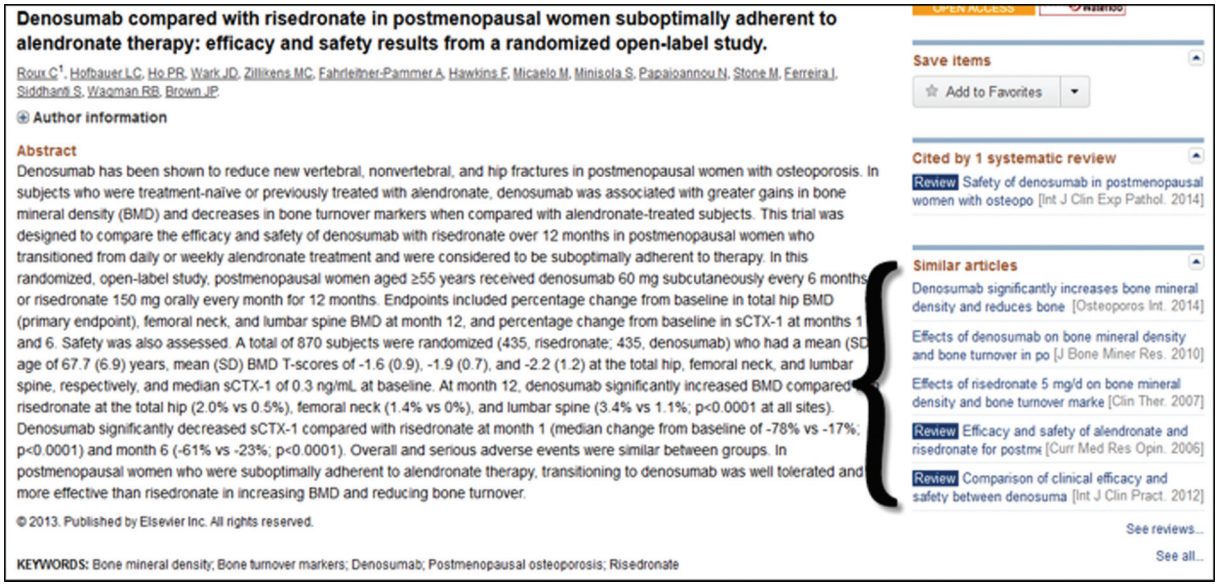

Figure 13 Similar articles feature.

- What is the purpose of the study? What problem is the study attempting to solve?
- Is the study's methodology described? Was the appropriate study design used to address the study question?
- How long was the study? How large was the sample size? Will this information have an effect on the applicability to your patient?
- What are the study's results? Have the right statistical tests been used to analyze the results? Do the results look like they may be applicable to other patients?
- Have the authors of the study met ethics standards and disclosed any possible conflicts of interest, like support from pharmaceutical companies?
- Do the conclusion(s) support the study's main objective(s)?

If you are satisfied with the answers to the above questions, you can proceed to a more critical examination of the articles and their results. Take into account that not all study designs can be appraised using the same questions, as some questions will be more relevant to certain study designs compared to others. For example, different criteria will need to be used to critique a systematic review, or meta-analysis, versus a RCT. As these study designs are of the highest rigor, the following is a list of questions

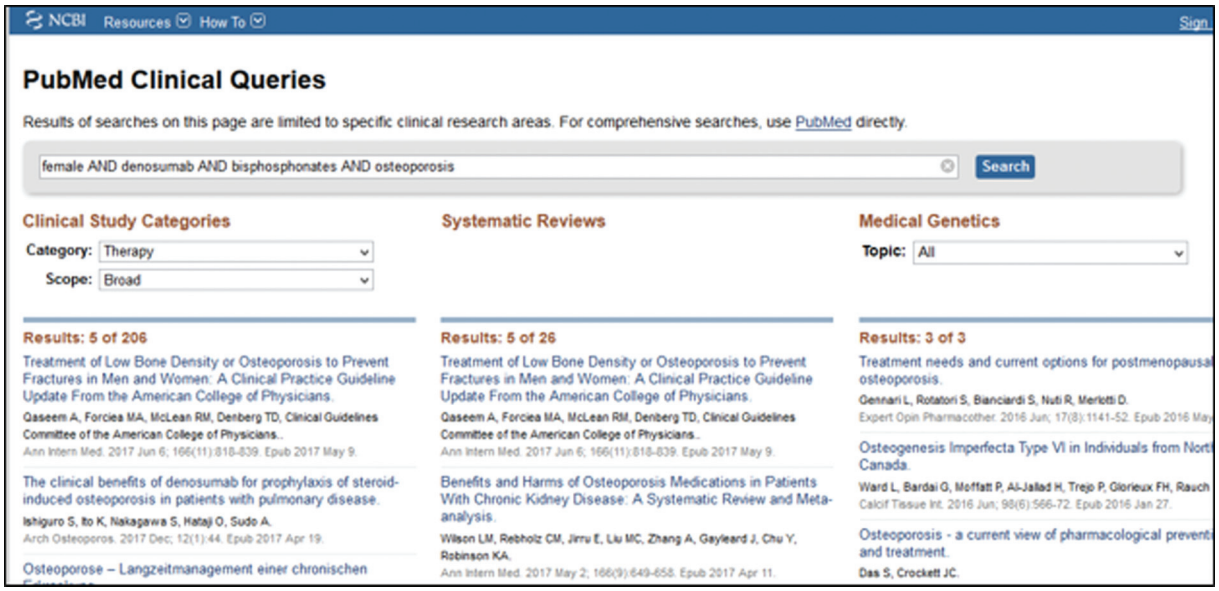

Figure 14 PubMed clinical queries feature.

specific to systematic reviews, meta-analyses, and RCTs. These questions should be considered in addition to the more general questions listed earlier.

Systematic Reviews/Meta-Analyses

Derived from Oxman and Guyatt (1993, p. 128)

- Was the main clinical question, or objective, narrow and focused?
- How thorough was the literature search? What is the likelihood that it has captured everything? Does the search strategy contain both MeSH terms (where applicable) and keywords? Have search "limiters" been used appropriately (e.g., publication date range, study type)?
- Can you identify the inclusion criteria used to determine eligibility?
- Was the process for screening and including eligible articles documented?
- Were each of the included studies critically appraised?
- How many individuals performed the critical appraisal and extracted the data?
- How homogenous was the data? Was it similar enough to perform a meta-analysis? If so, was the data combined and presented in the appropriate manner (e.g., forest plot)?
- How precise are the results? Do the results support the author's claims?
- What was the "overall scientific quality?" Will this influence or change how you practice as a pharmacist?

Randomized Controlled Trials

Derived from Walsh, Perkovic, Manns, et al. (2015, p. 61)

- Were the intervention and control groups similar at the start of the trial?
- How were the patients randomized? Was their allocation to treatment groups concealed?
- Was the study blinded? Did the patients or researchers know who was receiving which treatment?
- Were patients analyzed in the groups to which they were randomized?
- Were the patients in the intervention and control groups treated differently?
- Was follow-up complete? Did any patients drop out of the study?
- How large and precise was the treatment effect? Can you apply the results to the patients in your care?

Describing Study Results

While a review of statistical tests used in pharmacy research is beyond the scope of this chapter, readers of EBM resources should be familiar with the values commonly used to describe the magnitude of effect observed in quantitative research.

Quantitative research results are generally reported in the format of *point estimate* (*variability*), where *point estimate* is defined as "the single value that best represents the value of the population parameter" (Guyatt et al., 2015a, p. 667) and *variability* is a measure of the amount of consistency within the data—essentially, a measurement of how broadly or narrowly the data points are dispersed from the point estimate.

Measures of Central Tendency and Precision

Clinical and physiologic parameters among populations often result in data that follows a bell-shaped curve, or normal distribution. In this distribution, the most frequent values are those observed in the midpoint of the total range observed, with reducing frequency as one moves to each end of the range. When data follow a normal distribution, the *mean* (or average) is the most commonly used measure of central tendency, and the *standard deviation* is the common measure of variability used, as illustrated in Fig. 15.

When the data follows a skewed distribution, where the resulting curve is not symmetrical around the measure of central tendency, but rather is more gathered at one end of the range, the *median* (mid-point value when all observations are listed in order from smallest to largest) is the most commonly used measure of central tendency, and the *interquartile range* is the corresponding measure of variability used. Unlike the standard deviation, which is defined by cut-points at equal distance from the mean in

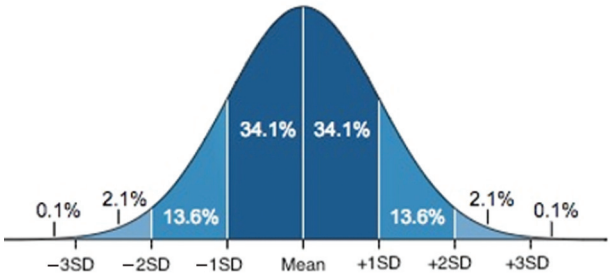

Figure 15 Standard deviation. Adapted from Toews, M.W., 2007. Standard Deviation Diagram. Available from: https://commons.wikimedia.org/wiki/File:Standard_deviation_diagram.svg.

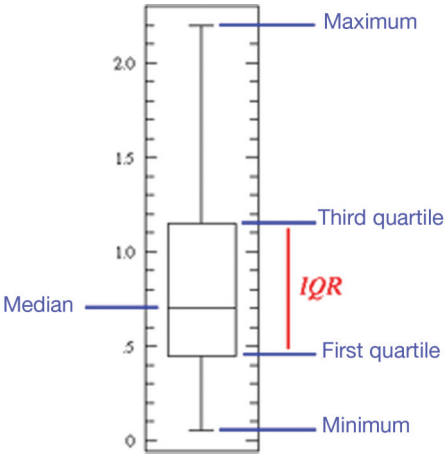

Figure 16 Box plot. Reprinted with permission from Kirkman, T.W., 1996. Display of Statistical Distribution—Box Plot. Available from: http://www.physics.csbsju.edu/stats/display.distribution.html.

each direction, the interquartile range instead presents the difference in the values that form the 75th and 25th percentile of the data. Therefore, the distance between the 25th percentile value and the median may or may not be the same as the distance between the median and the 75th percentile value, as illustrated by the box plot below (Fig. 16).

Describing Results in Relation to a Comparison Group

When a study involves an intervention group(s) and a comparison group (e.g., a placebo control, or comparison to another active agent or intervention) the difference in the observations across each group or exposure is most valuable to clinical decision-making.

Even in a placebo-controlled study, some study subjects may still experience the event of interest. The *control event rate* (CER) is the proportion of subjects in the control group who experience the event (or outcome) of interest, while the *experimental event rate* (EER) is the proportion of patients in the experimental (or intervention) group. Fig. 17 provides readers with an example of the CER and EER calculations, as well as all other calculations mentioned in this section.

The *relative risk* (RR) of the event occurring is "the ratio of the risk of an event among an exposed population to the risk among the unexposed" (Guyatt et al., 2015a, p. 671). An RR of 1 represents an equal event rate in both groups, while an RR >1 represents a greater event rate in the exposed population versus the control, and an RR <1 represents a lower event rate in the exposed population versus the control.

Absolute risk reduction (ARR) is the difference between the CER and the EER. In the event that the ARR calculation results in a negative value, it can instead be termed as an *absolute risk increase* by that magnitude. For example, an ARR of -0.25 actually represents an absolute risk increase (ARI) of 0.25 or 25%.

Many EBM resources further translate the absolute risk reduction into another value called the *number needed to treat* (NNT). This value is calculated as the inverse of the ARR (1/ARR) and represents the number of patients who need to be treated over a specific period to achieve one additional good outcome (Guyatt et al., 2015a, p. 665). The lower the NNT, the more effective the intervention is for that outcome. In the event that the intervention has a negative effect in relation to the control, the *number needed to harm* (NNH) can be similarly calculated (1/ARI) and represents the number of patients who need to be treated over a specific period in order to observe one negative outcome. In this case, a higher NNH is preferred as it means that more subjects can receive the intervention before the negative outcome is observed.

Another measure of association reported in EBM is the *odds ratio* (OR). A discussion on the specifics of comparing OR to RR and the specific uses and differences in interpretation among each are outside the scope of this chapter, but readers are provided with an article by Schechtman as a reference at the end of this chapter, for further reading. The OR is a ratio of the odds of an event in an exposed group to the odds of the same event in an unexposed group (Guyatt et al., 2015a, p. 665). Odds differ from relative risks in that the value is calculated as a comparison of the probability of an event compared to the probability of a nonevent in odds, while a relative risk calculates the proportion of subjects experiencing an event versus the total number of subjects. In situations where the event or outcome is rare, the OR and RR produce similar results; however, as an event becomes more frequent, OR generally overestimates the RR. For this reason, some recommend reporting both measures (Schechtman, 2002, p. 435).

Checklists

Many organizations have created critical appraisal checklists, which are freely available online. Table 5 lists several examples of these checklists, which can be used to assess the quality of various types of evidence. These checklists help to organize and structure the critical appraisal process, ensuring that the most important questions are addressed. This permits an easier comparison of the results from many research articles.

A 2x2 table can be helpful with these calculations, where the intervention and control arms occupy the first and second rows, respectively. Unfavorable and favorable outcomes occupy the first and second columns, respectively. The values in the cells represent the number of subjects in the study experiencing each outcome under each exposure.

	Unfavorable Outcome	Favorable Outcome	Total Patients
Intervention	a	b	a + b
Control	c	d	c + d

A randomized controlled trial evaluated the prevalence of fatigue among users of a drug versus a placebo control, with the following results:

	Adverse Event	No Adverse Event	Total Patients
Drug	349	23	372
Placebo	584	154	738

Experimental Event Rate (EER) = $\left[\frac{a}{a+b}\right] = \left[\frac{349}{372}\right] = 0.938 = 93.8\%$

Interpretation: 93.8% of subjects receiving the drug experienced fatigue

Control Event Rate (CER) = $\left[\frac{c}{c+d}\right] = \left[\frac{584}{738}\right] = 0.791 = 79.1\%$

Interpretation: 79.1% of subjects receiving placebo experienced fatigue

Relative Risk (RR) = $\left[\frac{EER}{CER}\right] = \left[\frac{0.938}{0.791}\right] = 1.186 = 118.6\%$

Interpretation: A subject on the drug had 118.6% of the risk of experiencing fatigue compared to a subject on placebo. Put another way, a subject on the drug has 1.18 times the risk of experiencing fatigue compared to a subject on placebo

Absolute Risk Reduction (ARR) = CER – EER = 0.791 – 0.938 = -0.147 = -14.7%

Interpretation: The absolute difference in event rates between subjects on the drug versus placebo is -14.7%. Put another way, the difference between the rate of fatigue among subjects on the drug versus on placebo is an Absolute Risk *Increase* of 14.7%

Number Needed to Treat (NNT) = $\left[\frac{1}{ARR}\right] = \left[\frac{1}{-0.147}\right] = -6.8$

Interpretation: As this result is a negative number, it actually represents the Number Needed to *Harm*. This means that for every 6.8 subjects taking the drug, 1 of them will experience fatigue from the drug.

Odds Ratio (OR) = $\left[\frac{a/b}{c/d}\right] = \frac{a*d}{b*c} = \frac{349*154}{23*584} = 4.00$

Interpretation: The odds of experiencing fatigue on the drug are 4 times higher than the odds of experiencing fatigue on placebo

Figure 17 Sample calculations for a study on adverse events from a drug.

EBM Steps 4 and 5: Applying the Evidence to Your Patient and Evaluating Your Results

After completing the critical appraisal, the next step is to determine whether the results apply to your patient and if so, how this information will be communicated. It is important to note that not all study recommendations can be applied to your particular patient, no matter how promising they may be, as every patient has different characteristics and experiences different circumstances (Fuller, 1997, p. 516). For example, an article demonstrating a positive drug treatment effect for young adult males may not be that helpful for elderly female patients. In addition, the route of administration, or differences in drug dosing, can affect the relevancy of the results for your patient. Factors such as age, race, ethnicity, and gender can all play roles in the applicability of evidence. Other factors such as the patient's socioeconomic status, lifestyle, support from family, religious beliefs, and potential for medication adherence can influence the relevance, or practicality of the evidence to the patient's situation (Haynes

et al., 2002, p. A13). Before attempting to apply evidence to your patient, it is crucial that you can identify similarities between your patient and the study participants.

The patient's opinion and feelings toward the evidence should be gauged and strongly considered before any integration of new information into the treatment plan. As mentioned earlier, patients come from diverse backgrounds and do not necessarily possess similar concerns, or views, when deciding on the best course of action. For example, one patient may indicate that it is not worth taking a medication because the side effects are too unpleasant, while another patient may not be bothered at all about the possible side effects. Ultimately, the patient should have the final say as to the treatment plan and should not be subjected to a treatment simply because the evidence states it is the best option.

Patients may expect certain results based on what they have seen in the media, or read on the Internet, which the pharmacist will need to take into account and discuss (Wiffen et al., 2013, p. 325). Communicating with the patient can pose various challenges. Health literacy, as well as comfort level with numerical information can affect patient understanding and it is important that the pharmacist provides an explanation in a clear manner, using the least amount of technical concepts or medical terminology. Various communication strategies can be used to assist with the facilitation of the exchange. Montori, Elwyn, Devereaux, et al. (2015, p. 550) encourage the use of a "talk model" approach, which emphasizes the partnership between clinician and patient in the decision making, while ensuring understanding of all possible therapy options and determining what is most important to the patient.

Once a decision has been made, you can look at the overall process and assess your work. Are you satisfied with how you performed each step of the EBM process? Were there steps that you were more comfortable performing, as opposed to others (e.g., literature searching vs. critical appraisal)? Perhaps the most important question you can ask yourself is how effective was the treatment option you decided upon with the patient and did it change how you practice (Johnson, 2008, p. 170)?

Acknowledgment

We would like to thank Marie Rocchi, Associate Professor of Pharmacy and Academic Director of the International Pharmacy Graduate Program at the University of Toronto, for reviewing this chapter and providing feedback on the first draft.

Patient Counseling and Education: Models and Methods in Pharmacy Practice

Kyle J. Wilby*, Hilary Rowe†, Shane A. Pawluk‡, Bridget Paravattil‡, *University of Otago, Dunedin, New Zealand; †Surrey Memorial Hospital, Surrey, British Columbia, Canada; ‡Qatar University, Doha, Qatar

Objectives

By the end of this chapter, learners will be able to:

1. List five theoretical models relating to patient counseling and education
2. Apply theoretical models of behavioral change to develop targeted educational interventions
3. Compare and contrast communication norms from an international perspective
4. Explain patient counseling and education challenges and strategies relating to pregnancy and lactation, pediatrics, and mental health

Introduction

There are many images that come to mind when considering the phrase, "patient education in pharmacy practice" (Paolini and Rouse, 2010). A typical image may be a traditional drug store with medication usage information being communicated "over the counter." This image may also include details, such as a printed leaflet and/or warning labels appearing on the dispensed medication. A second image may be of a pharmacist approaching a patient in the aisles of a pharmacy to offer assistance in self-selection and self-treatment of minor ailments. Perhaps, one may envision a private counseling area for more detailed-patient interactions, a pharmacist's office in a primary care clinic, or space designated for group education sessions. Or it is possible, that one may remember seeing a pharmacist in a hospital setting providing education to admit patients and/or their primary caregivers. Finally, the image may be of pharmacists at an outreach event, educating the public about disease prevention, awareness, or medication safety. No matter what image comes to mind, they all share the same common theme: a pharmacist attempting to translate information into learning the health and safety of the patient or public.

This chapter will introduce different theoretical perspectives related to patient education, while introducing specialized educational models and strategies for international comparisons and special populations. The specialized knowledge and skills that pharmacists provide will only be effective if communicated appropriately and in a manner that supports end-user learning and behavior change (Hargie et al., 2000). Therefore, pharmacists must be aware of theoretical models of education, in addition to considerations of unique populations outside the usual communication norms. After providing an example-based approach to introduce the educational theories and models, this chapter will relate these concepts to special populations (international comparisons, pediatrics, pregnant and lactating women, and mental health patients) that may require greater emphasis on sensitivity, cultural humility, and use of nonverbal communication strategies when providing patient education. The information provided in this chapter adds to the existing health education literature by providing a theoretical, yet practical approach to patient-education models and also provides a platform for the development of future pharmacy-practice-research initiatives to better understand the role of communication and education methods, especially when considering special populations with unique communication needs.

While common images of patient education in pharmacy practice are associated with information giving (dosage instructions, expected benefits, adverse effects, etc.), the term patient education should be the thought of facilitation of behavior change, rather than transfer of knowledge or skills (Bellamy, 2004). This means education is much more than simply providing information from one person to another. It is a complicated process, such as counseling or instruction that aims to influence how patients act, make choices, and follow through with intended therapeutic plans. Any educational intervention is dependent not only on the pharmacist, but on the patient themselves (Marcus, 2014). This team's approach to behavioral change is essential to consider while designing the educational interventions targeted toward achieving better patient health outcomes.

In order to gain a better understanding of patient education in pharmacy practice, one must be familiar with theoretical approaches to how behavior can be changed. This includes awareness of the theoretical models applicable to patient counseling and education for pharmacy practice. Examples, throughout this chapter will be used to highlight the key points and areas of controversy, when encountered. The chapter will also highlight considerations for international perspectives of patient counseling and education. Finally, models of counseling and education will be discussed using three examples, arising from pharmacy practice initiatives in special populations.

Theoretical Models of Patient Education

As discussed previously, education refers to more than simply providing information to patients. As such, many theoretical models based on behavioral change have been developed to explain a patient's health-related behavior. The following sections will provide an overview of the most relevant models for patient education and discuss applicability to pharmacy practice, using examples commonly encountered in educational activities.

Health Belief Model

The health belief model is a theoretical model that attempts to explain health-related behavioral changes across three different concepts (Rosenstock et al., 1988):

1. There need to be sufficient motivation or health concern to ensure that health-related issue is relevant.
2. There need to be existence of a perceived threat, for which one is susceptible in developing a disease or a complication of a specific illness or condition.
3. A belief must exist that by following a recommendation or advice, the perceived threat can be avoided and it can occur with minimal barrier to the individual in terms of time, cost, or other factors.

The best way to explain this model is to use an example. A common educational initiative encountered by pharmacists in community practice is to improve adherence to prescribed therapeutic plans. This is especially important for chronic-disease education, such as hypertension. Imagine a 55-year-old patient, prescribed with two antihypertensive medications, Ramipril and hydrochlorothiazide. The patient is not adherent (misses doses at least 3 times weekly). He has no relevant past medical history but his father died of a heart attack at the age of 60. His blood pressure is rarely monitored but usually is stable around 160/100 mmHg. Based on this patient case, we can use the health belief model to design an educational intervention that may best support this patient's adherence to medications.

First, we must consider the patient's motivation or how he conceptualizes the severity of the disease itself. Perhaps he requires background information on the disease and/or its complications. Secondly, we need to determine the perceived individualized threat of the disease on the patient himself. In this case, discussions on the patient's consistently elevated-blood pressure or the relevant family history could assist in modifying the patient's overall disease beliefs. Finally, instruction regarding the benefits of medications, including discussion of clinical study results, may modify the health beliefs of the patient and motivate behavioral change. It is likely that a combination of all these factors work together to promote patient understanding and engagement with the therapeutic plan.

The concepts discussed previously translate into six key dimensions of the theory (Glanz et al., 1997):

1. Perceived susceptibility
2. Perceived severity
3. Perceived benefits
4. Perceived barriers
5. Cues to action
6. Self-efficacy

Pharmacists must design educational interventions along the spectrum of dimensions listed previously, in order to maximize success of uptake. For example, they may need to provide individualized epidemiological information in order to confirm susceptibility, yet need to provide more practical instruction if the patient is already "cued to action." Recognition of these dimensions and how patients perceive their own health related progress and risks, is essential for promoting healthy behavior change.

Table 1 Transtheoretical model of behavioral change stages (Prochaska and Velicer, 1997)

Stage of change	*Definition*
Precontemplation	Not serious about change and not seeking help to change
Contemplation	Aware of consequences of negative actions and may start to consider the possibility of change
Preparation	Made commitment to change but are attempting to gather information to determine what is required for change
Action	Believe in own abilities to change and take active steps to modify behavior
Maintenance	Successful avoidance of temptations to return to negative behavior

Transtheoretical Model of Behavioral Change

A second common model used for patient education is the transtheoretical model of behavioral change (Prochaska and Velicer, 1997). This model attempts to explain a patient's behavior through a temporal process that involves progress through different stages of change. The five different stages of change and their definitions are provided in **Table 1**. Relapse (or re-initiation of negative behavior) may occur at any time during any stage.

The most well known example that relates to pharmacy practice that can be explained using the Transtheoretical Model of Behavioral Change is that of smoking cessation (DiClemete et al., 1991). Pharmacists, as primary healthcare providers, are well suited to lead smoking cessation initiatives yet achieving success with patients is not an easy task. Consider a 27-year-old female patient, who smokes one pack per day for the last 10 years. Upon routine questioning when dispensing a refill of her oral contraceptive, the pharmacist discovered her smoking history and approached the subject of quitting. It soon became quite clear to the pharmacist that she is currently "precontemplative" as she appeared disinterested and somewhat defensive throughout the interaction. At this stage, any educational intervention should be designed to create awareness and self-evaluation for eventual openness to change, rather than suggesting any immediate actions (personalizing risks, information provision). As the patient moves into the contemplative stage, the pharmacist should focus on promoting evaluative behaviors, including personal pros and cons identified by the patient herself. During the preparation phase, the pharmacist would be most effective by helping to identify and assist in the solving of barriers to the change, as well as encouraging small steps for the patient to take to ensure optimal readiness (building social supports, removal of triggers). If the patient is motivated and moves to actually implementing the change (i.e., stop smoking), the pharmacist needs to be ready to support through education to identify and overcome obstacles and to focus the patient on the benefits of the change, especially if the patient experiences feelings of loss or relapse (peer pressure, social pressure, stress/anxiety). Finally, the maintenance phase of the behavioral change should be supported by plans for follow-up, reinforcement of personalized rewards/beneficial outcomes, identifying and removing newly emerged triggers, and continued discussions of coping with the ongoing threat of relapse. As demonstrated by this example, it is very important for pharmacists to recognize specific education needs of their patients, in order to provide the most effective care. The transtheoretical model can be used collaboratively with patients to discuss progress along the continuum of change and to help recognize when positive or negative change is occurring (Miller, 2016).

Locus of Control

The concept of locus of control originates from personality psychology and refers to the extent to which people believe they can influence outcomes in their lives versus external forces acting beyond the individual's control (Lefcourt, 1991). While this construct relates to many aspects of society (i.e., religion, politics, employment), it also relates to health and education (Adolfsson et al., 2005; Brincks et al., 2010). More specifically, it has been found that those with a higher internal locus of control adapt healthier behavior more frequently and more successfully (Steptoe and Wardle, 2001). These patients are likely to respond better to educational interventions designed to promote patient autonomy and empowerment. Those with a high-external locus of control, however, likely to have difficulty in implementing behaviors based on their own choices, and require more direct guidance and action promoted by those perceived to be respected or in a powerful societal position. In order to be effective educators, the pharmacist must recognize how a patient responds to instructions and whether or not they value being engaged as a decision-maker within the active therapeutic plan.

Adult Learning Theory—Andragogy

Adult learning theory was established in the 1980s as to describe the way the adults approach and succeed in learning experiences (Knowles et al., 2015). The main point from this theory is that adults and children learn differently, resulting in "pedagogy" transforming into "andragogy." This theory is based on both assumptions and principles. Assumptions include, self-concept (one's self-concept moves from being dependent toward self-directed with time), adult learner experience (accumulated experiences contribute to learning potential), readiness to learn (readiness to learn becomes focused on personal social roles), orientation to learning (orientation shifts from subject-centered to problem centered), and motivation to learn (maturity promotes internal motivation to learn). Based on these assumptions, one can recognize that learning must be tailored toward an individual's specific needs and should be outcome-oriented, rather than simple provision of information.

The principles of adult-learning theory are the following:

1. Adults need to be involved in the planning and evaluation of their instruction
2. Experience provides the basis for the learning activities
3. Adults are most interested in learning subjects that have immediate relevance and impact to their job or personal life
4. Adult learning is problem-centered rather than content-oriented

For example, if we consider a typical over-the-counter interaction between a pharmacist and patient, we can use adult learning theory to increase the chances of achieving the intended outcomes. Instead of simply spewing information at a patient and assuming they will understand and implement the behavioral considerations of taking a new medicine, the pharmacist must tailor this information and involve the patient in the plan of care. Considering the first principle, a pharmacist may engage a patient to determine the most appropriate time of day to take a daily dosed medication (instead of automatically assuming morning time). Perhaps the patient is a shift worker or has an altered lifestyle routine. Using the second principle, the pharmacist may dwell on the patient's health-history to relate the instruction specifically to their past experiences. If adherence is the goal of taking a diuretic consistently for heart failure, the pharmacist may discuss past times when the patient was experiencing adverse effects from fluid overload and then relate these experiences to the benefits expected with regular diuretics use. For principle three, a pharmacist may choose to educate the patient on surrogate markers, that can measure impact of the medication on their health status in a shorter time than perhaps more long-term benefits, such as prolongation of life. An example could be educating on expectations for fasting glucose or hemoglobin A1c values for patients with diabetes. Finally, principle four speaks the individualization of patient's health-needs. Instead of listing benefits and risks of therapy, the pharmacist may choose to instead engage the patient about their expectations and fears of therapy, in order to recognize and overcome potential barriers to successful treatment. As demonstrated through these examples, adult learning theory can be applied in most typical pharmacist-led educational sessions to improve overall effectiveness of educational interventions (Peeters, 2011).

Self-Efficacy Model

Self-efficacy, otherwise referred to as confidence, is the optimistic belief that one is able to successfully accomplish a task to produce a favorable outcome. Pharmacists are actively involved in disease prevention and lifestyle interventions, which require education of patients to change unhealthy behaviors into healthy ones. Bandura (1994) introduced a model that aims to describe four sources of efficacy beliefs. The first source of self-efficacy is stated to come from mastery beliefs. Consider a patient who had quit smoking 2 years ago for a period of 18 months but then relapsed. Self-efficacy may play a major role in the patient's current need for behavioral change, as he or she may have confidence from this past success. The second source of self-efficacy comes from vicarious experiences. These are ones that we observe from people around us, including mentors and role models. Witnessing successful accomplishments of others can stimulate the confidence needed for one to complete the task on their own. The third source of self-efficacy is verbal persuasion. This directly relates to pharmacist education, as persuasion can be used to modify behavior by attempting to instill confidence for patient success. Finally, the last source proposed by Bandura is emotions and physiological stress. Stress and its related symptoms can directly affect how one perceives their abilities to complete the task. Therefore, education regarding stress management and coping skills can greatly contribute to self-efficacy. A fifth source was proposed that suggests visualization as a tool to improve self-efficacy (Williams, 1995). Pharmacists may utilize this technique when providing patient education in hopes of maximizing success of achieving target outcomes.

International Perspectives

Patient-pharmacist interactions occur all around the world. These interactions are essential for the delivery and uptake of health services worldwide (Ha and Longnecker, 2010; Simpson et al., 1991). Provision of diagnostic testing or treatments without effective and safe communication with patients can lead to poor-health outcomes and mistrust in health systems. Pharmacists, professionals that almost entirely relying on communication for professional service are commonly the first access point for many patients seeking care. Therefore, it is vital that pharmacists are safe and effective communicators (Shah, 2006). It should be noted, however, that the same communication standards or rules should not apply in all settings, as communication norms greatly differ between regions.

Let us explore this from a theoretical perspective. In 1976, Edward Hall published a book entitled *Beyond Culture* that introduced the terms of high- and low-context cultures. The concept describes, how people relate to one another in both social and communicative aspects. Hall's view was that high-context culture is defined as one that is intimate, hierarchical, and communicates through simple messages with deep meaning. Conversely, low-context culture is defined as highly individualized, somewhat fragmented, and one that has little involvement between others. Communication in low-context cultures is more explicit and less personal (Kim et al., 1998).

It is well established that cultural context can affect the way people interact and communicate. Persons originating from high-context cultures, such as Asian and Arab populations, place great emphasis on nonverbal components of interactions, use implicit and indirect verbal messages, and personalize disagreement. In order to effectively communicate, messages must be placed in the appropriate context or environment for the receiver to understand the intended meaning (Kim et al., 1998). Conversely, persons from low-context cultures (primarily Western) do not emphasize nonverbal components, use explicit and direct verbal messages,

and depersonalize disagreement. The importance lies on what was said, not how it was said or the environment in which it was said (Onkvisit and Shaw, 1993).

Although Hall's theory only accounts for ethnicity and does not factor other aspects of culture (gender, sexual orientation, religion, etc.), the general premise of cultural contexts does appear to have weight. Hofstede's Cultural Dimensions Theory attempts to further breakdown culture into different components, namely power distance, uncertainty avoidance, masculinity/femininity, individualism/collectivism, and long-term orientation (Hofstede, 1983). Whichever theory is used to explain cultural differences in communication, it can be recognized that not all individuals communicate in the same way and these differences occur both across and within global populations.

For the purposes of an example, let's use both of the theories described aforementioned to explore international differences in patient education. Consider a patient been newly prescribed a narcotic for advancing cancer pain but who has reservations about initiating, such a "powerful" and "addictive" medication. A pharmacist working in the Middle East (i.e., Qatar) versus Europe (i.e., Switzerland) will likely approach this situation quite differently. According to Hofstede (1983), Arab patients originate from high-context cultures and respond better to affective communication strategies with simple messages that may come people in positions of power (high-power distance). These patients may also prefer to have family involvement in the decision-making process (collectivism). Pharmacists need to recognize these preferences and tailor education accordingly. Instead of spending time providing detailed verbal messages, it may be more effective to focus on developing relationship with the patient and their family members. Conversely, a pharmacist practicing in a European setting may instead choose to focus on the "facts" and provide detailed information without an emphasis on nonverbal communication strategies. Tailoring information to make the message more simple and meaningful, may make the patient distrust the pharmacist by believing some information is being with-held.

As we are currently living and working in an age of globalization, pharmacists must be ready to interact with patients from many different cultures and backgrounds. Recognition of times of cultural conflict and being able to subsequently reflect and learn from these interactions is the key to stimulating the self-awareness and personal growth required to be effective educators. Promoting these practices within training experiences and continuing professional development opportunities will help to equip pharmacists with the necessary attitudes and skills for achieving optimal patient educational outcomes.

Models and Methods of Patient Education in Special Populations

Pharmacists are front-line caregivers and require the knowledge, skills, and attitudes to provide counseling and education to all types of patients. As such, background information and theory regarding interventions within different populations needs to be discussed. This section provides an overview of models and methods of patient education relating to women's health, pediatrics, and mental illness.

Patient Education for Pregnancy and Lactation

Since more than 90% of women require at least one medication in pregnancy and lactation, healthcare practitioners have a significant role in educating pregnant and breastfeeding women about their drug therapy (Temming et al., 2016). The added risks of medication exposure to the fetus in pregnancy, or the infant in lactation can greatly impact medication safety and adherence (Temming et al., 2016). Women often question the value of their drug therapy once pregnant and consider discontinuing their medications to avoid fetal risk. Without proper medication counseling regarding fetal safety, and the potential consequences of untreated maternal medical conditions, the health of both mother and fetus may be at risk (Temming et al., 2016; Trønnes et al., 2017). Over 70% of women, who require medication during pregnancy, use this medication at the most critical time, organogenesis (Kaplan et al., 2017; Temming et al. 2016). In addition, medications with limited data and/or greater fetal risk are used more frequently in women with chronic medical conditions in pregnancy, thus timely medication counseling can have a major impact on maternal and fetal health (Temming et al., 2016; Trønnes et al., 2017).

A recent cross-sectional survey that included 102 pregnant women demonstrated that medication counseling significantly reduced women's own perception of teratogenic risks and probability of termination (Kaplan et al., 2017). Women in this study were motivated to find medication safety information in pregnancy and called a teratology counseling service. These women were primarily in first trimester (7.5 weeks gestation), and were taking an average of 3.3 medications that were not known to be teratogenic. The most common medications women sought counseling for were nonsteroidal antiinflammatories, antibiotics, central nervous system, and gastrointestinal therapies. This study confirms that a patients' understanding of the potential increase in teratogenic risk from medication use in pregnancy is higher than the actual risk and that intervention and education regarding the actual risks can impact the health of both the woman and the fetus.

Another interventional counseling-based survey confirmed that medication counseling could impact women's attitudes toward and understanding of medication use in pregnancy (Devkota et al., 2017). This study included 229 women that were prescribed at least one medication at the out-patient obstetrics ward in Nepal. The majority of women in this study were primigravida (59.4%) and in third trimester (58.6%). A structured knowledge, attitude, and practice (KAP) questionnaire was administered prior to medication counseling and at the next follow-up visit. Prior to medication, counseling 65.9% of women knew that not all medications are safe in pregnancy, 71.6% knew that unnecessary medications in pregnancy could cause harm, and 30.6% knew

that unwanted medications could affect organogenesis and development. Interestingly, 75.6% of women felt they should ask their physician or pharmacist about their health condition and medications, and 75.9% felt that medication harms in pregnancy could be reduced with help from a healthcare provider. In addition, 64.2% of women reported self-medicating. After medication counseling, 100% of women knew that not all medications are safe in pregnancy, 99.1% knew that unnecessary medication in pregnancy could cause harm, and 95.6% knew that unwanted medication could affect organogenesis and development. Furthermore, 97.4% felt that medication harms in pregnancy could be reduced with help from a healthcare provider and thus only 2.2% of women reported taking medication without advise. Thus medication counseling can greatly impact women's KAP of medication use in pregnancy.

Finally, the medication safety assessment in pregnancy must also consider the physiologic changes in pregnancy and how these changes affect the efficacy and safety of drug therapy (e.g., absorption, metabolism, and elimination) (Temming et al., 2016). Patients need to be counseled that their medications might require dose adjustments in pregnancy and again in postpartum to ensure efficacy and safety in both pregnancy and lactation.

Far too commonly, women are given misinformation and advised to cease breastfeeding in order to treat a maternal medical condition (Davanzo et al., 2015; Nice and Luo, 2012; Schirm et al. 2004). Knowing that breast milk is the preferred nutrition for infants and that 65.9% of breastfeeding women require at least one medication in lactation, medication counseling and optimization of therapy to avoid interruption of breastfeeding is key.

A survey, based in the Netherlands, revealed that 30% of women with children under 6 months of age hesitated to take a medication because they were breastfeeding, 16.9% of women would have taken a medication if they were not breastfeeding and 11.5% of women did not breastfeed because they had to use a medication (Schirm et al., 2004). A review article by Hussainy and Dermele (2011) identified some of the key reasons why women may be hesitant to breastfeed while taking drug therapy by examining healthcare professionals' and women's KAP toward medication used in lactation. This review highlighted that physicians and pharmacists had limited knowledge of medication suitability in lactation and often provided inconsistent advice about medication suitability in lactation. In addition, physicians and pharmacists often based their advice on potential risks to the infant, rather than data in lactation. Thus, women were frequently disappointed with the advice they were given and either stopped breastfeeding or choose not to take drug therapy (Hussainy and Dermele, 2011).

In response to similar findings in clinical practice and a lack of quality data guiding drug safety decisions in lactation, numerous organizations and journals have published articles to increase the general knowledge of medication safety in breastfeeding (Davanzo et al., 2015; Hussainy and Dermele, 2011; Nice and Luo, 2012; Temming et al., 2016). In addition, these organizations and journals have recommended a unified approach to assessing medication safety in lactation and counseling the patient (Davanzo et al., 2015; Hussainy and Dermele, 2011; Nice and Luo, 2012; Temming et al., 2016). Specialists in lactation are encouraged that with proper education of healthcare providers, drug therapy can be optimized to treat maternal health condition(s) while supporting breastfeeding (Davanzo et al., 2015; Hussainy and Dermele, 2011).

Healthcare practitioners have a significant role and responsibility in educating pregnant and breastfeeding women about the benefits and risks of their drug therapy. Based on the available data, the education provided will have a lasting impact on the health and well-being of both mother and child.

Pediatrics

Effective communication with children is dynamic and complex that often involves three people: a healthcare provider, the child, and the child's parents or caregivers. Special consideration of the level and depth of interaction with a child must be adapted to the child's cognitive developmental level as to efficiently convey their intended messages.

A patient-centered interaction framework of communication with children about their medications is an important model to adopt in all interactions with this population. This model of communication fosters the child's opinions about treatment while empowering them to seek information about their medications and illness. Strategies for promoting a patient-centered interaction with children may include: asking the child about priorities for improved quality of life, assessing how well the child perceives their medication working, and directly interacting with the child whenever possible, and allowing opportunities for the child to ask questions throughout the interaction (Sleath and Bush, 2012). The inclusion of the child in the treatment decision process is empowering and influences the child to seek information about various aspects of their illness (Holmström and Röing, 2010).

Healthcare professionals must consider the cognitive development level of the child when communicating with pediatric patients. Pediatric cognitive development has been classified into four stages: the *sensory motor* stage, the *preoperational* stage, the *concrete operational* stage, and the *formal operational* stage (Piaget, 1932). To gain insight into the child's stage of cognitive development, healthcare professionals must consider age as well as ask open-ended questions in early communications (O'Brien and Bush, 1999). In the *sensory motor* stage (birth to roughly 2 years of age), all learning is child centered with little connection between self and external factors. At this stage all patient-centered communication about medications is difficult and likely ineffective. The *preoperational* stage (age 2 through 6 years), a child's reasoning is connected to the present now. The connection between what they do in relation to their health, such as taking a medication, needs to be presented in a very simplistic format (i.e., this medicine will make you feel better) (Lau and Klepper, 1998). The *concrete operational* stage (7 through 12 years of age) occurs when children begin to distinguish between internal and external influences on their health, and develop the understanding that disease is preventable through actions taken that affect one's own health (O'Brien and Bush, 1999). Children in this stage might able to understand what is

causing their illness and how medicine can help them. As children move into adolescence, they begin the *formal operational* stage (age 13 years through adulthood) where they can reason through their decisions and develop awareness of the degrees of illness. The understanding that they have control over their own decisions continues to develop. It is imperative to determine the cognitive developmental level of a pediatric patient in order to effectively tailor communication methods and foster understanding. It can be argued that age appropriate information and participation were prerequisites for allowing children to make competent decisions about their own health (Mårtenson and Fägerskiöld, 2007).

While challenges may arise, such as parents taking a protective stance toward children and thus may choose to limit the child's involvement, effective communication with children about their medications may potentially improve adherence and overall clinical outcomes (Coyne and Harder, 2011; Curtis et al., 2004). Healthcare professionals must use a patient-centered approach to communication with children while acknowledging their cognitive development level.

Mental Health

Patient-counseling and education becomes intricate and complex when dealing with mental-health patients. Cognitive deficits and side effects associated with medications often times interfere with educational sessions leaving healthcare providers and patients feeling frustrated (Hatonen et al., 2008). Lack of adequate training and comfort level of healthcare professionals contribute to limited provision of counseling mental-health patients (Bell et al., 2006; Hatonen et al., 2008; Phokeo et al., 2004). Nevertheless, patient education has been shown to be beneficial among mental-health patients in terms of medication adherence, lifestyle regularity, and ability to cope with their disease (Hatonen et al., 2008).

Privacy and having a sense of security and trust is important for patients with mental-health disorders. For example, a schizophrenic patient who has paranoid delusions may not accept the information being provided by a healthcare provider. It is important in this case to make the patient feel safe and gain trust from the provider. Nonverbal communication, such as maintaining eye contact, being close without invading personal space, speaking calmly, and showing positive facial gestures plays a significant part in provision of patient care for this patient. Likewise, a patient coming to pick up a new psychotropic medication from a community pharmacy would value having a private counseling area to be able to communicate openly with a pharmacist is a safe environment.

Mental-health patients consider respect to be an important aspect when communicating with providers (Hatonen et al., 2008). Although most healthcare professionals do not intentionally display stigma, it may often be expressed through their body language, facial expressions, and verbal comments making patients feel undervalued (Calogero and Cale, 2017). Engagement in continuing education opportunities by healthcare professionals is one way to overcome mental illness stigma. These professional development opportunities should not only address education related to mental disorders, but should provide the healthcare professional with the ability to understand and relate to mental-health patients and the effect the disease has on their daily life. This method has been shown to be effective in reducing stigma toward depressed patients as reported in a study using consumer educators during a pharmacy continuing education session (Liekens et al., 2013).

Patient education must be a team-based approach for mental health patients. The role of the pharmacist among this team is crucial to ensure the safety and efficacy of psychotropic medications to improve patient outcomes (Finley et al., 2003).

Conclusions

Patient-counseling and education are vital roles of the pharmacist and they must be ready to adapt to the ever-changing needs of patients, including those of special populations. The shift in focus of pharmacists as educators, rather than simple providers of information, also comes with greater responsibility to take ownership of their role within the healthcare team to do their part to support the patient's achievement of intended outcomes. Pharmacists must recognize a patient's needs and tailor interventions accordingly. Familiarity with educational theory, such as the models discussed in this chapter, will facilitate effective communication, establish therapeutic relationships, and promote provision of optimal patient care.

Moving forward, pharmacy practice research must focus on how pharmacists can optimize therapeutic relationships through communication and education strategies that will allow for provision of effective patient care. Changing landscapes in terms of immigration and diversity are especially important considerations for pharmacists and pharmacy programs that will require continual evaluation and modification of practice and training to ensure the profession is able to address the needs of those it serves. As many (if not most) professional pharmacy activities are largely based on communication, there is an urgent need for researchers to study the most effective ways to address diversity in patient care and how to optimally train students and practitioners to fluently employ such methods.

This chapter provided an overview of theoretical models relating to patient education, including evidence-based methods of working with populations that have special communication needs. Key concepts discussed included the need for an informed and systematic approach to patient education, as well as highlighting difficult situations that may require more emphasis on responding and adapting to a patient's individual needs. Daily patient encounters in pharmacy practice cannot be predicted, therefore pharmacists must be prepared to identify a patient's educational needs and consequently tailor their communication strategies accordingly. Doing so will allow for provision of better patient care with a goal of ultimately achieving better patient health outcomes.

Technology and Social Media Applications in Pharmacy Practice

Kelly Grindrod, University of Waterloo, Waterloo, ON, Canada

Introduction

Pharmacy is navigating a time of enormous technological advancement, both inside and outside the workplace. The rapid evolution of personal computing and social networking has major implications for patients and health-care providers alike. In particular, pharmacists can now find the answer to almost any question with a quick search online. They can produce patient information and share it with other pharmacists, health-care professionals, patients, and their local, national, and international communities. At the same time, individuals can use the Internet to identify possible causes of illness or medication side effects by connecting with other individuals who have similar illnesses or medical conditions. Handheld devices such as smartphones and tablet computers are also ubiquitous and can be used to access and create social media throughout the day. However, with great change comes great upheaval. The challenge for pharmacists is to navigate social media both at home and in clinical practice. In particular, it is becoming essential for pharmacists to understand how to make the most of the increasingly connected world while also being mindful of the risk. The following chapter will review the evolution of social media over the last decade, the research on social media use in pharmacy and pharmacy education, and the safe use of social media in health care.

Overview of Social Media

Social media refers to material that is created, edited, and shared online (Kaplan and Haenlein, 2010). Social networks, by comparison, refer to online communities where social media are shared (Boyd and Ellison, 2008). Facebook is the most popular social networking site worldwide (Statista, 2018), with active users numbering in the billions. The video sharing website YouTube has over a billion users worldwide, as do the immensely popular instant messaging applications such as Facebook Messenger and WhatsApp (Statista, 2018). Other popular social networking sites with hundreds of millions of users worldwide include Twitter, Snapchat, Instagram, LinkedIn, and QQ (Statista, 2018).

Across social networks, the social media that are shared include text-based posts, photos, videos, and links to resources such as published research papers, practice tools, and news articles. What differs is how users create, share, and interact with the information on the various networks, and this process has evolved over time. In early social networking sites, users could develop a profile and connect with other users—usually individuals that they already knew. For example, in 1997, the first social networking sites were "Six Degrees," which allowed users to create profiles and "friend" each other, and America Online (AOL) Instant Messenger, which allowed users to connect with friends and converse online in real time (Wikipedia, 2018). This was quickly followed by the first blogging website, Open Diary, which allowed users to write posts that could be shared with and commented on by friends.

Over the next decade, social networking sites were developed to allow users to connect in new ways and to share audio and video content (Varis, 2015; Wikipedia, 2018). For example, 2003 brought the launches of Myspace for sharing music and videos, LinkedIn

for professional networking, and Skype for video messaging. The following year in 2004, the photo-sharing site Flickr was launched, as was Facebook that allowed users to make a profile and share their status with friends. In 2005, the video sharing site YouTube and the news aggregation/discussion site Reddit were both launched. The microblogging sites Twitter and Tumblr launched in 2006 and 2007, respectively, to allow users to post short-form blog posts. Around this time in 2006 and 2007, MySpace was the most popular social networking site, but it was quickly overtaken by the popularity of Facebook in 2008. Facebook has consistently remained the most popular social networking site over the last decade (Statista, 2018). More recently, the photo and video-sharing site Instagram launched in 2010 followed by Snapchat in 2011 (Wikipedia, 2018).

Uptake of Social Media

The Pew Research Center (2018a) reports that as of 2017, over two-thirds of all adults in many developed countries are consuming social media, including the United States (US, 69%), Australia (69%), South Korea (69%), Canada (68%), Israel (68%), and Sweden (67%) (Pew Research Center, 2018a). Social media use is also high in some developing countries, such as Jordan (75%) and Lebanon (72%), and lower in some developed counties such as Italy (48%) and Germany (42%). While Facebook is generally the most popular social networking site across demographic groups, research from the US shows that young adults aged 18–24 are more likely to use Snapchat, Instagram, and Twitter compared to older cohorts, including those in their mid to late twenties (Pew Research Center, 2018b). Further, younger users are more likely to use multiple social networking sites, while older users are more likely to only use one to two sites (Pew Research Center, 2018b).

Common Features of Social Networking Sites

Over time, many social networking sites have evolved to share similar features (Varis, 2015). Most sites allow users to create a profile where they can post content and follow the content of other users or organizations to generate a "content feed." For sites such as Facebook, Twitter, and LinkedIn, the content feed contains text, videos, images, polls, and links to websites that users can "like," comment on, or share. Posts can also be organized and searched by hashtags (e.g., #pharmacy), which are a form of meta-data that allow text to be findable (Zappavigna, 2011). Users can also use many of the sites to exchange private messages with other users. Instagram and Snapchat are similar to the platforms mentioned above, but their content is limited to photos and videos. The launch of Snapchat was also notable because it was the first mainstream social networking site that allowed content to be posted for a short time before it disappears. Finally, YouTube operates slightly differently. On YouTube, users generate a video feed by subscribing to video channels and can like, dislike, or comment on individual videos.

Notably, Facebook allows users to make private groups, such as for a group of pharmacists in a single state or a group of students in a single-year cohort of a pharmacy school. Facebook also offers a "pages" feature, where businesses can develop a profile that users can follow without friending the organization. This is particularly advantageous for pharmacies and pharmacy undergraduate course instructors who may not want to "friend" customers or students, for example. Instead, business owners and instructors can create a page to share information, organize events, host discussions, and post live video feeds. Followers can follow the information in their content feed and engage with it by posting reviews, questions, or feedback. The page feature also allows administrators to moderate comments to remove offensive or inaccurate information, to answer questions, and to track analytics such how often the various content is viewed.

Creating Social Media Content

At present, the users of social networking sites have two roles: content creators and content consumers. Individuals and organizations may have both roles or may simply create content or consume content. For creators, social media content can be created either on or off of a social networking site. For example, a video can be developed using private video-editing software and posted directly to Facebook, Twitter, YouTube, and Instagram. Alternatively, the video can be posted to YouTube and the YouTube link can be shared on other social networking sites. A video can also be filmed directly using Instagram and shared to Facebook, or vice versa. Similarly, some social networking sites allow users to connect their social networking sites to automatically post across multiple sites at the same time, so a video shared to Twitter can be automatically posted on Facebook. As described above, content consumers then access the content through their content feeds, where they can like, share, and comment on the material.

The roles of content creator and consumer can also overlap. Memes are popular example. A meme is defined as "an image, video, piece of text, etc., typically humorous in nature, that is copied and spread rapidly by Internet users, often with slight variations" (Oxford Dictionary, 2018). With memes, users often add text to adapt a photo or video to their own context. For example, a pharmacist meme could contain the words "beta-blockers make me lol" over a photo of a famous actor laughing. Other users may then take the same words and apply them to a picture of an animal that appears to be laughing. Alternatively, they may take the same photo of the actor or animal and apply new, unrelated words. Memes offer a good example of social media, in that they are continuously being adapted to new contexts. The graphics interchange format (GIF) videos are another example of adaptable content. GIFs are very short, repeating videos that are often added to posts in social networking sites to convey additional meaning. For example, a post about a busy day at the pharmacy may be accompanied by GIF of someone falling onto the floor or falling into bed.

Finally, the term "viral" is often used to describe content that is shared and spreads rapidly across a single social networking site or multiple sites (Varis, 2015). In their paper on social media virality, Varis and Blommaert (2015) point out that "'liking' is a responsive uptake to someone else's activity while 'sharing' is the initiation of another activity directed at another (segment of a) community." In this process, information can be liked and shared in its original format or it can be slightly modified over time, as seen with the popular examples of memes. The information can also be shared or commented on with other forms of media such as GIFs. Thus, with the enormous popularity of social media, the constantly evolving nature of the individual social networking sites, and the evolution of the social media content itself, social media is changing the way the world communicates. The following section will focus on how social media is being used in pharmacy in relation to other health-care providers, pharmacists, patients, and the broader public.

Social Media in Health Care

Over the last decade, a growing number of consumers have been accessing health information online, including through social networking sites. In the US, over 70% of people who use the Internet look up health information online (both through websites and social networking sites), including 60% who look up drug information, 57% who look for a diagnosis based on symptoms, 52% who look for information on supplements, and 49% who look for treatment options based on a diagnosis (Gandhi and Wang, 2015). As with the US, it can be assumed that patients in most developed countries and some developing countries are also accessing some health-care information through social networking sites.

The wide availability of health-care information online is having a direct impact on the patient–clinician relationship. Tan et al. (2017) found that the growth of online information is shifting the traditional information balance, forcing health-care providers to develop new ways to make treatment decisions with patients—specifically, patients are now more informed and may require a more collaborative decision-making process (Tan and Goonawardene, 2017). Smailhodzic et al. (2016) also noted that social media use by patients can have several beneficial effects such as improved self-management, control, and subjective well-being while also having some risks such as social media addiction, loss of privacy, and being targeted for advertising.

For health-care providers, the benefits to using social media can include facilitated communication within teams, support for education and training, and access to updates on health-care news and professional development (Chan and Leung, 2018). In particular, health-care providers appear to use social networking sites to develop virtual communities and share expert knowledge (Rolls et al., 2016). However, research also suggests that health-care providers prefer to use social networking sites to connect with their own profession—a form of "tribalism"—that can limit information sharing across different disciplines or specialties (Rolls et al., 2016).

Social Media in Pharmacy

For pharmacists, one of the clearest advantages of social media is that it facilitates networking outside the workplace—both within pharmacy and with other health-care professions (Royal Pharmaceutical Society, 2018). The benefits of social media address some of the key barriers pharmacists face when adopting new services and practice models, including the culture of pharmacy, time constraints, and difficulty keeping up with daily workflow (Rosenthal et al., 2016).

In the early days of social media, some pharmacists avoided the expectations of professionalism by creating anonymous profiles. These early accounts occasionally mocked patients, used profanity, and were critical of the profession (Clauson et al., 2010). However, in recent years, the pharmacy profession's use of social media has expanded to include many pharmacy organizations, students, pharmacists, and researchers from around the world. In the last decade, the evolution of pharmacist Facebook groups and pharmacist-specific social networks such as Skipta (https://pharmacistsociety.com/) now offer pharmacists a platform to ask questions and share experiences, advice, or mentorship. Similarly, pharmacists can use social media to keep abreast of continuing professional development opportunities, such as through the social networking profiles of the Centre for Postgraduate Education in the United Kingdom (https://www.cppe.ac.uk) or the American College of Clinical Pharmacy (https://www.accp.com) in the US.

As the use of social networks expands, pharmacists need to exercise a certain degree of caution. Research on pharmacists and social media have found that while use is growing, little is known about the best ways for pharmacists to engage with social networking sites (Benetoli et al., 2015; Grindrod et al., 2014). When building a profile, for example, pharmacists and other professionals need to decide if the profile will be for professional use, personal use, or a hybrid of the two. A pharmacist creating a personal account on a social networking site must decide if they will also identify as a pharmacist in their profile. Similarly, a pharmacist creating a professional account must decide if they will share any personal details, such as details about family, sports interests, or hobbies. In a qualitative study with pharmacists around the world, Benetoli et al. (2017) noted that many pharmacists address this dichotomy by either having two separate accounts or by being a "dual citizen" on a single account. It should be noted, though, that regardless of whether pharmacists are creating personal accounts, professional accounts, or dual citizen accounts, there is an expectation that they will abide by the professionalism standards set out by the profession (Royal Pharmaceutical Society, 2018).

e-Professionalism and Social Media

As described in the previous section, pharmacists may choose to engage with any of the social networking sites or communities using either an anonymous or an identifiable handle. The challenge is to build an online identity that aligns with their professional identity.

Professional behavior online is often referred to as "e-professionalism." Cain and Romanelli (2009) define e-professionalism as the "attitudes and behaviors reflecting traditional professionalism during the use of digital media." In other words, e-professionalism is the expectation that members of a profession behave online as they would in their place of work. Oftentimes, these tenets of professionalism will be outlined for pharmacists through codes of ethics, standards of practice, and workplace policies from regulatory bodies and employers. By the definition outlined above, all pharmacists who use social networking sites are expected to behave according to the professional standards of their own jurisdiction regardless of whether a social network account is private, personal, anonymous, or identifiable.

Beyond professional development, pharmacists may also wish to use social networking sites to advertise their services to the public. Some social media polices have emerged to provide guidance. For example, the social media policy from the Pharmacy Board of Australia cautions pharmacists to adhere to both the professional and advertising guidelines that apply in their jurisdictions (Pharmacy Board of Australia, 2018). Similarly, the National Association for the Boards of Pharmacy in the US routinely monitors social media to identify pharmacies that are advertising and selling products outside of the current regulations (National Association of Boards of Pharmacy, 2018). As the use of social media by pharmacists matures, greater attention will be paid to monitoring pharmacists' use of social media and e-professionalism.

Another aspect of e-professionalism is the relationship between the pharmacist and patient. Pharmacists can be disciplined by their regulatory bodies for unprofessional behavior, such as using an instant messaging site to pursue a romantic relationship with a patient or sharing private patient information on a social networking site such as Facebook. Both in response to and in anticipation of unprofessional conduct, some pharmacy organizations have developed guidelines to support pharmacists in using social networking sites safely. The guidelines are typically written for pharmacists in a single jurisdiction or country, but many of the principles apply universally. For example, the Royal Pharmaceutical Society in the United Kingdom advises pharmacists to be aware of the rules of their employment and of liability, copyright, and data protection laws (Royal Pharmaceutical Society, 2018). They also caution pharmacists against providing specific medication advice to patients on social networking sites. Similarly, the Pharmaceutical Society of Australia urges pharmacists to keep online information, such as that created on blogs or on pharmacy websites, up-to-date and to clearly communicate how the information was developed, including the sources of information and any relevant government regulation that applies to the medications being discussed (Pharmaceutical Society of Australia, 2018).

Pharmacy Communities Online

When used professionally, social networking can be a powerful tool for connecting with both the larger pharmacy community and with the general public. Individual pharmacists can use social networks to connect with colleagues, both in pharmacy and other health-care professions. For example, on Facebook, there are many closed pharmacy groups that are organized based on location. In the Canadian province of Alberta, for example, pharmacists established the "Pharmacists of Alberta Unite" Facebook page to organize protests and discussion around funding cuts by government. Over the years, the group evolved to support pharmacists in managing drug shortages, prescription billing, and to navigate new or emerging information on clinical topics such as the administration of drugs by injection or in response to updated clinical practice guidelines. On Instagram, for example, Hindman et al. (2017) observed that the most common posts shared with the hashtag #pharmacy were celebrating pharmacy or relating a work experience, with around 10% of posts related to education in pharmacy.

Health-care professionals tend to use social networking sites as a one-way communication platform, where information is consumed, rather than an interactive forum where users engage in discussions over content (Campbell et al., 2016; Rolls et al., 2016). As such, professional social network accounts may appear to have low engagement but may actually be closely read by individuals in practice. For example, the Royal Pharmaceutical Society is very active on Twitter with over 20,000 followers. The account frequently shares information on professional development and leads discussions on topics such as gender in the profession and interprofessional collaboration.

Other communities that connect a more general health-care community include Skipta (https://skipta.com/), which was founded by a pharmacist, and the "Figure 1" mobile application that allows health-care providers to share images of interesting patient problems such as rashes or radiographs and seek guidance from the community. Pharmacists can also participate in topic-specific communities, such as the Free and Open Access Medical Education (identified by the hashtag #foamed) community, which shares information related to emergency medicine and pharmacy across social media sites.

Social Media in Pharmacy Education

One of the most important reasons to integrate social media into pharmacy education is to teach and model professional social media behavior. Social media has been explored in several pharmacy programs, with positive results (Benetoli et al., 2015).

Examples include the use of Twitter to support classroom engagement and reflection (Desselle, 2017), and the use of Facebook to provide updates on current events (Kostka-Rokosz et al., 2014) and to support exam preparation (Mawdsley and Schafheutle, 2015). Social media is also being studied to support education in other health-care professions. In medicine, for example, instructors have provided senior medical students with credit to update medical and health-care pages on Wikipedia (Azzam et al., 2017).

In addition to supporting education, the incorporation of social media into the pharmacy curriculum also supports students in developing social media literacy and e-professionalism skills. For example, a study of young rheumatologists and basic scientists identified that 30% of those who do not use social networking sites struggle with a lack of knowledge of the platforms (Nikiphorou et al., 2017). Other research has also identified that low uptake can result from the one-way flow of information in an educational setting and a lack of trainee engagement (Chan and Leung, 2018). Thus, effective learning opportunities will likely need to encourage students to participate and to provide technical support for those who have less familiarity with the platforms.

Unlike more experienced pharmacists, pharmacy trainees are likely to have been using social media before joining the pharmacy profession. For health-care trainees, the opportunities to develop e-professionalism skills occur both in the classroom and during experiential learning opportunities. Trainees who enter a health-care professional program as active users of social media may need to routinely audit and refine their social media presence as they learn about the various facets of professionalism. For example, after it was identified that 60% of medical schools faced challenges related to the inappropriate social media use by medical students (Chretien et al., 2009), one US medical school developed a two hour social media education program that led almost two-thirds (64%) of students to make changes to their social media account (Gomes et al., 2017). A 2017 study of medical residents also identified that while students can learn e-professionalism behaviors in school, exposure to unprofessional behavior during their third-year experiential rotations can erode their professionalism, especially as it relates to information security (Mostaghimi et al., 2017).

Teaching Pharmacy Students to Use Social Media

The American College of Clinical Pharmacy outlines the tenets of professionalism for pharmacy students in the following way: altruism (unselfishness), honesty and integrity, respect for others, professional presence in both professional and personal settings, engagement in the profession and community, and dedication and commitment to excellence (American College of Clinical Pharmacists, 2009). These same principles apply for students' use of social media. Several recent surveys of pharmacy student perceptions of social media have noted that students have high adoption rates, use social media as part of their education, but have little concern about unprofessional content being shared on social media such as posts including profanity or representing drug or alcohol use (Augustine et al., 2015). Thus, pharmacy educators and trainees must continue to find opportunities to incorporate social media and e-professionalism education into the pharmacy curriculum.

The Safety of Social Media

Over the last two decades, social media has become ubiquitous. As the various social networking sites have become established in our daily lives, society has grown more aware of the challenges. From a health-care perspective, patients and health-care providers must pay close attention to privacy and security. Most social networking sites are not designed to be used to convey sensitive health-care information and do not meet the requirements of privacy legislation. As seen in recent years, the information can be aggregated, stolen, and sold to private organizations. In 2017, it was revealed that researchers in the United Kingdom were able to download or "scrape" the personal information of 50 million Facebook users and sell them to a political campaign in the US. This led to a series of hearings in Europe, with the British Information Commissioner's Office concluding that "Facebook contravened the law by failing to safeguard people's information . . . and failed to be transparent about how people's data was harvested by others" (Satariano and Frenkel, 2018). The CEO of Facebook was also required to apologize to the European Parliament (Frenkel, 2018).

At the same time, Europe recently enacted tighter privacy laws that are changing the way information is collected about users online, including through social networks. The new General Data Protection Regulation (GDPR) has several impacts, including the requirements for better transparency around data collection and use; stricter controls around the collection of information on race, political affiliation, and sexual orientation; and even ensures that users must be able to delete photos from social media that were posted when they were a minor (Tiku, 2018). There is also a growing interest in the sharing of false information, often called "fake news" and hate speech, with Germany being among the first countries to pass legislation allowing them to fine sites that do not remove fake news and hate speech up to 50 million (Zhou, 2018).

Conclusion

Social media has changed the way society communicates. With the majority of adults in developed countries using social media, it is no longer optional for health-care providers to understand how and when to participate in social media. In the coming years as social media continues to evolve, pharmacists, pharmacy students, and pharmacy educators will need to continuously develop and refine the expectations of how the profession will engage. Particular attention must be paid to help pharmacists and trainees develop social media literacy and e-professionalism skills and behaviors.

Glossary

e-professionalism the expectations and standards ascribed to professionals during the use of digital media
Social media online content that is created, modified, and shared
Social network an online space where users connect with others to share information that has been created
Meme an often humorous image, video, or piece of text that is copied and rapidly shared online with slight changes or variations

Pediatric Pharmacy Practice

Sabrina B. Teskey[*,†], **Aleksandra B. Mejia**[*,†], [*]University of Toronto, Toronto, ON, Canada; [†]Hospital for Sick Children, Toronto, ON, Canada

Providing pharmaceutical care to pediatric patients relies on the application of specialized pharmacy knowledge including pharmaceutics, pharmacokinetics, therapeutics, drug information, safety practices, and communication skills as an active member of the health-care team. This chapter provides an overview of pediatric pharmacy practice that includes the role pharmacists play in the delivery of pharmaceutical care to pediatric patients including information and examples of pharmaceutical calculations, pharmacokinetics and therapeutic drug monitoring (TDM), and special considerations required to care for this unique population.

Responsibilities of All Pharmacists Working Within a System That Cares for Pediatric Patients

A child is not a scaled down version of an adult. All pharmacists who work with pediatric patients must keep this in mind when delivering care. Pharmacists working in pediatric settings have adopted the pharmaceutical care practice model (Cipolle et al., 2012). However, beyond following this defined process of delivering care, pharmacists practicing with pediatric patients must maintain a foundational knowledge of how age impacts all aspects of medication management services and the patient care process. Beyond this, a day in the life of a pediatric pharmacist includes understanding how child development, medication dose availability, and the child's family circumstance may impact the pharmacist's approach to applying the pharmaceutical care process.

All pharmacists are accountable to deliver the best care possible to their patients. A pharmacist working with pediatric patients must also practice with the recognition that their decisions may have long term impacts to the health, wellness, and development of the child. In addition, pharmacists will need to consider recommendations that may also impact siblings and family members.

In this chapter, we consider some of the prescription focused (e.g., accurately auditing prescriptions) and patient-centered activities (e.g., TDM, medication education) to caring for infants and children.

Roles of the Pharmacist Caring for Pediatric Patients

The medication use process involves the management of prescribing, dispensing, administering, and monitoring of drug therapy. The roles of pharmacists have evolved in the field of pediatrics requiring application and development of specialized knowledge and skills. The common practice is one that is accountability for the delivery of the knowledge and skill that is provided. Traditionally pharmacists have worked in the role of a Dispensing Pharmacist, a staff pharmacist role that is primarily

responsible for the auditing of prescriptions, entry of the prescription into the medication delivery management system, and dispensing of the medication product to the patient. Over the past 25 years, pharmacists have evolved to an advanced practice model, working in the role of Clinical Pharmacist, a clinician who primarily works directly with patients actively involved in the assessment, decision-making, prescribing, monitoring, and counseling of patients.

Examples of other specialized pediatric pharmacist roles are listed below.

- Drug Information
- Drug Use Evaluation Pharmacist
- Compounding Pharmacist
- IV Resource Pharmacist
- Parenteral Nutrition Pharmacist
- Subspecialty Pharmacist (i.e., Cardiology, Critical Care, General Pediatrics, Hematology/Oncology, Infectious Diseases, Neonatal Care, Neurology, Nephrology, Transplant, Stem Cell Transplant, Surgical Services, others)
- Medication Safety Pharmacist
- Antimicrobial Stewardship Program Pharmacist
- Informatics Pharmacist
- Administrative Leaders (e.g., Director, Manager, Clinical Coordinator)
- Clinician Scientists

Working in these specialized fields often requires additional training (i.e., residency training) or education (i.e., Masters of Science, Masters in Business Administration), postgraduate training (i.e., Leadership training) or several years of work experience.

Age Terminology and Definitions

Age is an important factor to consider when dosing medications as it serves as a surrogate delineation for growth and development. The definitions of each age group can vary depending on the resource used and this may vary among countries.

Dosing guidelines may require the health professional to consider age definitions before recommending a dose (or drug) due to differences related to development, pharmacokinetics, and pharmacodynamics in children compared to adults. When employing a recommendation from a resource or literature to practice, imprecise use of age terminology may result in an inaccurate application.

The United Nations Convention on the Rights of the Child defines child as "a human being below the age of 18 years unless under the law applicable to the child, majority is attained earlier" (United Nations Human Rights Office of the High Commissioner, 1990). The practice of pediatrics may continue up to the age of 21 years and beyond in some countries; however, arbitrary limits for transition to adult care may depend on funding models such as health-care insurers or health-care policy. Pediatric pharmacy practice should consider the appropriate age of transition to adult care with the health-care team to best serve the individual patient.

Pediatric age group classifications have been proposed by different organizations including the World Health Organization (Knoppert et al., 2007), resulting in some variability of age categories depending on the source used. In 2009, the Eunice Kennedy Shriver National Institute of Child Health and Human Development's (NICHD) Pediatric Terminology Harmonization Initiative aim to standardize terms to promote consistency in the reporting of age-related data in child health research (**Table 1**) (Williams et al., 2012). This classification is the most differentiated and will be used in for the purposes of this chapter.

It is essential for the pediatric pharmacist to be knowledgeable of key periods of development as it relates to achieving desired outcomes in patients. The perinatal period, the timeframe just before and after birth, is a time when there is rapid developmental growth and is further defined considering gestational age. The American Academy of Pediatrics (Engle et al., 2004) provides definitions to aid in the calculation of age (**Table 2**). The neonatal period is a critical time frame where prematurity is a leading cause of death in newborns. Specifically, morbidity and mortality data show maternal and neonatal adverse outcomes differ over the neonatal period. **Table 3** is a summary of terms used in the neonatal period that are based on gestational age. Birth weight is a

Table 1 Age stages defined according to NICHD pediatric terminology stage definitions

Preterm neonatal: The period at birth when a newborn is born before the full gestational period
Term neonatal: Birth to 27 days
Infancy: 28 days to 12 months
Toddler: 13 months to 2 years
Early childhood: 2–5 years
Middle childhood: 6–11 years
Early adolescence: 12–18 years
Late adolescence: 19–21 years

NICHD, Eunice Kennedy Shriver National Institute of Child Health and Human Development (Williams et al., 2012).

Table 2 Summary of age terminology recommendations by the American Academy of Pediatrics Committee on Fetus and Newborn, 2004.

Neonatal age term	*Definition*	*Recommendation*
Gestational age	Time elapsed (in weeks) between the first day of the last menstrual period and the day of delivery	If pregnancy was achieved using assisted reproductive technology, gestational age is calculated by adding 2 weeks to the conceptional age
Chronological age	Time elapsed (in days, weeks, months, years) since birth	
Postmenstrual age	Gestational age plus chronological age (in weeks)	Preferred term during hospital stay to describe the age of preterm infants
Corrected age	Chronological age (in weeks or months) reduced by the number of weeks born before 40 weeks of gestation	Preferred term after the perinatal period This term should only be used for children up to 3 years of age who were born preterm

(Engle et al., 2014)

Table 3 Neonatal age definitions based on gestational age

Neonatal term based on gestational age	*Definition*
Extreme prematurity of newborn	<28 weeks
Preterm	<37 weeks or 259 days gestation
Early term	37 weeks to 38 6/7 weeks
Full term	39 weeks to 40 6/7 weeks
Late term	41 weeks to 41 6/7 weeks
Post-term	≥42 weeks

(ACOG, 2013; Spong, 2013; WHO, 2018).

Table 4 Neonatal definition based on birth weight

Neonatal term based on birth weight	*Definition*
Extremely low birth weight (ELBW)	<1000 g
Very low birth weight (VLBW)	1000 to <1500 g
Low birth weight (LBW)	1500 to <2500 g

(WHO, 2018).

predictor of neonatal health and survival thus neonates as a group can be further divided into groups based on weight as defined by the World Health Organization (WHO, 2018) (**Table 4**).

Dosing in the perinatal group requires special attention to definitions of weight and gestational age. Careful calculations are often required to determine the appropriate dose for pediatric patients for safety and effectiveness.

Fundamentals of Pediatric Pharmaceutical Calculations

Working with pediatric patients requires an additional level of focus as there is no "one size fits all" approach to dosing medications. It is good practice to check a minimum of two dosing resources particularly when encountering a medication for the first time. It is also good practice prior to auditing a prescription or recommending a medication dose for a pediatric patient to minimally consider the age and weight of the patient. This is important because pediatric drug handbooks provide medication dosing recommendations based on age and weight (dose of medication in milligrams or grams per kilogram of body weight). A decision about the accuracy of a medication dose cannot be calculated without these two crucial pieces of information. In addition, for some potentially toxic medications (e.g., cyclophosphamide, methotrexate), the height/length of the patient is also required. This is because height is needed to calculate body surface area to allow for accurate dosing of some medications.

To determine the patient's BSA, use a pediatric nomogram and the following equation to double check your work:

$$\text{Patient's BSA } (m^2) = \text{square root } (\text{patient's height [cm]} \times \text{patient's weight [kg]}/3600) \quad \text{(Mostellar, 1987)}$$

Additional information that the pharmacist must consider prior to auditing a prescription or recommending a patient specific dose includes the following:

- What is the referenced recommended dose for the specific indication the medication is being prescribed?
- Is the dose consistent with treatment or prophylaxis doses?
- Is treatment or prophylaxis necessary for siblings or other close family contacts?
- Is the infant or child's weight accurate, up-to-date, and provided in pounds or kilograms?
- Has the patient had a recent growth spurt or weight gain?
- Is the prescribed medication available in the appropriate dosage form required for the age and condition of the patient?
- If the medication is available in a fixed dose combination, what is milligram strength of each component (e.g., milligram per milliliter of solution/suspension)?
- On what component of the fixed dose combination is the dosing recommendation based?
- What is the maximum recommended single dose?
- What is the maximum recommended total daily dose?
- Is the daily dose recommendation provided in divided doses?
- If only an intravenous solution is available, can the product also be given orally?

These are some of the fundamental questions that the pharmacist must address to ensure accurate dosing in the pediatric population.

Pharmacokinetics, Pharmacodynamics, and Pharmacogenomics

An understanding of age-related developmental changes is required to appreciate the rationale for some of the differences in dosing among different age categories. A pharmacist's role relies on application of this knowledge in order to achieve desired outcomes.

Pediatric Pharmacokinetics and Pharmacodynamics

Age-related changes in pharmacokinetics and pharmacodynamics can, in part, be explained by physiologic differences between children and adults. Historical examples that highlight pharmacokinetic and pharmacodynamic differences unique to children (Table 5). Changes in body water, body fat, plasma proteins, hormonal composition, and organ function occur during aging and influence drug disposition in absorption, distribution, metabolism, and elimination. In addition to growth and maturation considerations, children are also exposed to medicines from transplacental transport and from breast milk. Knowledge of these differences is required for the pharmacist to rationalize dosing recommendations between age groups, aid in the assessment of alternatives for pediatric patients, determine appropriate dosing when a recommendation does not exist, as well as for extrapolation from adult literature for novel therapies. Comprehensive reviews of pediatric pharmacokinetics have been published elsewhere (Kearns et al., 2003a; Pai and Nahata, 2017), and application of this knowledge is imperative for the pediatric pharmacist clinician.

Pharmacodynamics is the study of how a drug may affect the body. The developing nature of a child may pose a changing target for a drug. Examples include tetracyclines staining developing enamel, and thalidomide causing phocomelia during limb formation. Pharmacodynamic factors that may affect response in early life are not well defined, and studies investigating new therapies in pediatrics should focus on understanding these factors. When recommending or assessing drug therapies for pediatric patients, the pharmacist's role involves an assessment of risk based on the patient's stage of development.

Therapeutic Drug Monitoring

TDM can offer insight to individualized drug concentration and response. Given the many challenges with changing development, dosage form limitations, and limited pediatric evidence, TDM serves as a tool to help individualize dosing by interpreting drug concentrations to achieve surrogate efficacy and safety endpoints. Indications for TDM are to ensure dosing is within range for agents with a narrow therapeutic window (e.g., digoxin, phenytoin, aminoglycosides, and vancomycin), adherence, change in route of administration, influence of concurrent medications, or distribution to site of infection. Knowledge of pediatric pharmacokinetic and pharmacodynamics changes during development assists in the interpretation of bodily fluid concentrations and how this relates to therapeutic endpoints. With advanced training (i.e., TDM certification), it is common practice for pharmacists to lead TDM programs with the ability to monitor pediatric patients and adjust regimens independently with the use of expanded scope and medical directives for prescribing. Pharmacists are also involved in determining timing and number of samples (i.e., when trough or peak levels should be drawn, determining the area-under-the-curve estimations for selected therapies), recommended sampling sites, repeated sampling when feeding status or routes of administration may influence achieving desired endpoints. It is also important to liaise with laboratory staff in understanding limitations with drug assays, sampling, and processing.

Table 5 Historical examples of adverse outcomes related to differences in pediatric pharmacokinetics and pharmacodynamics

Year	*Medication*	*Indication*	*Adverse patient outcome*	*Pathophysiological mechanism*	*Regulation/Recommendation*
1956	Sulfisoxazole (Harris et al., 1958; Silverman et al., 1956)	Antibiotic	Kernicterus in premature neonates Mortality	Displacement of bilirubin in plasma Decreased glucuronidation of bilirubin due to decreased glucuronyl transferase activity Free bilirubin crossing immature blood–brain barrier in neonates	Not recommended in infants < 2 months of age
1959	Chloramphenicol (Cummings et al., 2017; Mulhall et al., 1983; Nahata and Powell, 1983; Sutherland, 1959)	Antibiotic	Gray baby syndrome (lethargy, abdominal distention, hypoxemia, decreased perfusion, cardiovascular collapse, mortality) in neonates	Decreased hepatic glucuronidation Decreased renal elimination	Therapeutic drug monitoring (Mulhall, 1983)
1961–1962	Thalidomide (Rehman et al., 2011)	Hypnotic and antiemetic	Embryonic teratogen causing phocomelia (limb and bone abnormalities) when used in pregnant women for morning sickness	Potential oxidative stress, antiangiogenesis in utero	Withdrawn from market 1961 Later studied under strict regulations for other indications (i.e., erythema nodosum leprosum (1965), graft-versus host-disease (1988))
1982	Benzyl Alcohol (CDC, 1982; Gershanik et al., 1982; Liston, 1983)	Bacteriostatic preservative in intravenous products	"Gasping syndrome" (acidosis, respiratory distress, circulatory failure, seizures), death	Immature liver of neonate is unable to oxidize benzyl alcohol to benzoic acid	Avoid use of benzyl alcohol or other preservatives in intravascular flushes (Liston AJ. 1983)
1993	Ceftriaxone (Martin et al., 1993)	Antibiotic	Kernicterus	Displacement of bilirubin in plasma Free bilirubin crossing immature blood brain barrier in neonates	Contraindicated in neonates

Medications where TDM is commonly utilized are listed below:

- Aminoglycosides
- Antiretroviral agents (amprenavir, atazanavir, darunavir, efavirenz, etravirine, indinavir, lopinavir, maraviroc, nelfinavir, nevirapine, raltegravir, ritonavir, saquinavir, and tipranavir)
- Antituberculosis medications (cycloserine, ethionamide, isoniazid, p-aminosalicylic acid, pyrazinamide, and rifampin)
- Carbamazepine
- Cyclosporine
- Digoxin
- Methotrexate
- Mycophenolic acid
- Phenobarbital
- Phenytoin
- Sirolimus
- Tacrolimus
- Valproic Acid
- Vancomycin
- Voriconazole

Pediatric pharmacokinetic data can lead to further understanding about the ontogeny of physiologic parameters that may affect metabolism and elimination of substances. Recommendations for pharmacokinetic research in children have been published (Barker et al., 2018). Moreover, a decision-making algorithm has been published to help clinicians critically assess the drug concentration and response for agents with limited literature to aid in determining the utility of clinical pharmacokinetic monitoring as a surrogate marker of outcome for selected agents and patients (Ensom et al., 1998). These approaches are welcome in a pediatric practice when medications are not well studied outside of an adult population, and an understanding of drug disposition and attainment of therapeutic endpoints can be tailored to patients.

Pharmacogenomics

Differences in drug responses in the pediatric population also include those that may be explained by genetic variation. An example is that of codeine. Codeine is metabolized to morphine for its therapeutic effect. Safety risks associated with the genetic polymorphism of CYP2D6 (rapid metabolizers), such as in the case for a 2-year-old child (Ciszkowski et al., 2009) and in nursing mothers (Health Canada, 2008), have led to an institutional recommendation to avoid use of codeine (Chen et al., 2011). This example highlights the role pharmacogenomics could play in the prevention of predictable adverse outcomes for individual pediatric patients.

Advances in the field of pharmacogenomics may result in significant impact in areas of childhood cancer, psychiatry, hematology, asthma, seizure disorders, and use of biologics for a variety of diagnoses to better predict potential outcomes of therapy. As medication therapy experts, pharmacists have an opportunity to incorporate pharmacogenomics into daily patient care practice. The role of pharmacists can include providing education on, and active participation in, testing, clinical interpretation of results, and recommendations for personalized drug therapy to promote effective and safe medication use for children. This has been endorsed by the American Pharmacists Association (Owen, 2011) and the Pediatric Pharmacy Advocacy Group (Kennedy et al., 2011). Potential barriers to implementation have been also been identified (Cohn et al., 2018) and should be considered when expanding practice into this field.

Pediatric Dosage Forms

A pharmacist must ensure that patient's medications are indicated, effective, safe, and useable/feasible. After determining the appropriateness of a selected drug based on indication, effectiveness, and safety, and adherence, dosage form selection should also undergo a similar assessment.

Case Example:
Desmond is an 18-month-old (12 kg) male who requires treatment for his first episode of acute otitis media. He lives with both parents and a 3-year-old brother. He developed a fever while at daycare and was seen by his pediatrician. He is being prescribed amoxicillin 500 mg PO BID. He has no known allergies. Amoxicillin is available in 500 mg capsules and 50 mg/mL suspension. Which dosage form would be most suitable for Desmond?

Medications are manufactured in specific dosage forms during drug development. These include solid dosage forms (i.e., tablets, capsules), liquid dosage forms (drops, solutions, suspensions), topical (i.e., patches, creams/ointments), and injectable

Table 6 Enteral dosage form selection based on age

	Enteral dosage form selection				
	Liquids	Solids			
Age	Drops/Solutions/Suspensions	Dispersible tablets/powders/sprinkles	Chewable tablets	Gummies	Tablets/Capsules
Neonates	•				
Infants to Child (1 month to 2 years)	•	•			
Child (2–5 years)	•	•	•	•	
Child (6–11 years)	•	•	•	•	•
Adolescent–Teens (12–18 years)	•	•	•	•	•

(for IV admixture or IM/SC injection). Factors to consider when selecting a dosage form most suitable for a pediatric patient include:

- Patient acceptance (age (Table 6), development, palatability)
- Pharmaceutics
- Pharmacokinetics/pharmacodynamics
- Therapeutics (interchangeability and effectiveness for disease)
- Feasibility to measure intended dose
- Safety (hazardous medications)

Challenges with developing pediatric formulations have been published (Gupta and Khan, 2013), and there are situations when the commercially available dosage forms would not be suitable for pediatric patients where alterations of existing formulations or extemporaneous preparations are required. It should be noted that alterations of existing formulations are not without consequence since this is an unregulated practice and prone to risk for error. The NICHD and the United States of America Food and Drug Administration (FDA) have developed the Pediatric Formulations Initiative (PFI) to promote the development of pediatric-friendly formulations and to address barriers during drug development (NICHD, 2018).

Case Example:
Mathieu is a previously healthy 18-month-old (12 kg) male who requires treatment for an enterococcus urinary tract infection (UTI)/cystitis. The organism was susceptible to both amoxicillin and nitrofurantoin. He has a history of an urticarial rash with amoxicillin and is awaiting allergy testing. Your assessment is that nitrofurantoin is the treatment of choice given his allergy history. Based on weight, you determine that his dose should be nitrofurantoin 20 mg PO q6h (6 mg/kg/day). Nitrofurantoin is only available in 50 mg capsules.
How can the dose of nitrofurantoin 20 mg be delivered to Mathieu?

The above case highlights concerns related to limited dosage form availability. Will alterations of the dosage form affect its effectiveness, safety, or adherence?

In resolving this problem, assessments may include:

- Does the dosing frequency need to be every 6 h?
- Are there any published data with alterations of this dosage form?
- Can a suspension be compounded?
- Can the dose be prepared by compounding capsules to make the 20 mg dose?
- Does the drug interact with food?
- Will stability be compromised if the dosage form is altered?
- Will palatability be a factor?

Pediatric pharmacists are often faced with questions related to medication delivery to children and are responsible for offering solutions to such drug therapy problems. Knowledge, skills, and resources should be used to justify recommendations with an assessment of efficacy and safety. Special consideration should be made to address potential consequences of dosage form alterations. Examples of when altering dosage forms warrant some caution are listed later.

Drug Properties

Therapeutic interchangeability is a consideration for both the expected treatment outcomes as well as for formulary considerations for insurers and payers. To crush a sustained/controlled/extended-release product to be able to administer in a child may result in

loss of the sustained release (SR) property of the drug and consequently peak serum levels potentially toxic effect (e.g., sustained release morphine, controlled release oxycodone). The Institute for Safe Medication Practices (ISMP) organization has published recommendations for oral dosage forms that should not be crushed (ISMP, 2016). Like adult practice, pharmacists are expected to be resources for this type of dosage manipulation. In pediatric practice, awareness of sustained release products that can be altered (e.g., opening tamsulosin SR capsule to be sprinkled and not chewed) may aid in available dosage forms for children.

In the pediatric population, palatability is a factor that contributes to adherence (Baguley et al., 2012), consideration of products that result in poor taste is of value when recommending changes to dosage form (e.g., topiramate tablets, imatinib tablets). A common question is whether a medication can be mixed with food to aid with adherence. Awareness of changes to the stability or change in potency of the desired medication when mixed with selected foods is required. For example, ciprofloxacin is known to chelate with calcium-containing products, thus mixing doses of ciprofloxacin in a child's cereal, may result in decreased amount of drug available for systemic absorption. As a general principle, mixing medications with food is not recommended if there is a risk of the child not receiving the entire dose, the development of food aversions or decreasing the effectiveness of the drug.

Enteral Tube Administration

Enteral feeding tubes may also serve as an alternate route of enteral medication administration, particularly when children are unable to feed orally (i.e., developmental delay, risk of aspiration), require supplemental nutrition, or are receiving a medication that is poorly palatable. An assessment of the compatibility of a drug via the enteral tube route is required because there are situations when it would be not be recommended: administration of enteric coated products (due to risk of coating clogging the tube and/or risk for gastric irritation after product is crushed), viscous products due to the risk for blockage (e.g., ciprofloxacin suspension), drug properties known to clog small bore feeding tubes (e.g., pyridoxine), or where administration via enteral tube results in decreased absorption, particularly when patients are receiving enteral feeds (e.g., phenytoin). If this route is being used, appropriate resources such as texts (i.e., White and Bradnam, 2015), manufacturers, and/or primary literature should be consulted.

Short Bowel Syndrome

Short bowel syndrome is a condition when the body cannot absorb enough nutrients due to absent or poorly functioning portions of the bowel (i.e., congenital or acquired). Examples of conditions that can lead to short bowel syndrome in a child include necrotizing enterocolitis (more common in premature neonates), intussusception, volvulus, gastroschisis, intestinal atresia, or trauma. Symptoms may include diarrhea, bloating/gas, inability to gain weight, and vomiting. Complications can include dehydration, malabsorption, malnutrition, bacterial overgrowth, vitamin/mineral deficiencies, or diaper rash from frequent diarrhea. Medical therapy may include agents that aid in slowing transport in the gut to promote nutrient absorption (i.e., loperamide), antireflux medications due to increased gastric secretion in some patients (i.e., omeprazole), and antibiotics to prevent bacterial overgrowth.

Factors affecting drug absorption include intestinal length, presence of a stoma, mucosal integrity, gastric emptying, intestinal motility and transit, pH, and drug formulation (Sood et al., 2013). The dosing regimen and/or formulation may need to be modified to promote bioavailability in this population. Hyperosmolar agents or simple carbohydrates (often found in syrups and suspensions) may contribute to diarrhea, abdominal cramps. It is generally recommended that consideration is taken to the ingredients when selecting a dosage form for this patient population to prevent worsening diarrhea, cramping, and decreased absorption.

Ketogenic Diet

The ketogenic diet is a strategy to control refractory childhood epilepsy. It is a diet that involves high fat intake along with restricting carbohydrate and controlled protein intake. It's indication for epilepsy dates back to the 1920s (Bailey et al., 2005) and is used when patients have had unsatisfactory control with medications. It results in the body relying on fat as the sole energy source; rather than the brain using glucose as its primary energy source, fat is converted by the liver to ketone bodies which can cross the blood brain barrier and provide the brain with energy. The mechanism by which the ketogenic diet controls seizures is not well established; however, the theory is that ketones exhibit an anticonvulsant effect once they cross the blood–brain barrier (Runyon and So, 2012).

Case Example:
Neel is a 5-year-old (18 kg) boy with developmental delay, intractable epilepsy, and is g-tube fed with an enteral formula. He has failed multiple anticonvulsant regimens, and he was admitted to hospital to trial a ketogenic diet for seizure management. During the admission, he developed a fever and requires treatment for a possible pneumonia. After initial treatment with IV ampicillin, he will be deescalated to an enteral antibiotic. You review this patient with the Ketogenic Dietitian and note that you need to ensure minimal carbohydrate content of medications to optimize ketosis and seizure control. What are the additional factors to consider when recommending an enteral antibiotic in this case?

When selecting the dosage form, questions may include:

- Which medication dosage forms are compatible with enteral tubes?
- What is the carbohydrate content of the dosage forms available?

Pharmacists play an important role in ensuring medication therapies do not disrupt achievement of ketosis for seizure control. Pharmacists should review carbohydrate contributing nonmedicinal ingredients as part of the assessment of selecting the dosage form appropriate for the child's age, route of administration, as well as for ketosis. In general, carbohydrate content is typically highest in syrup and suspension dosage forms and lowest among tablets and capsules. For hospitalized patients, awareness of intravenous fluids containing dextrose or intravenous medication admixtures prepared in dextrose-containing solutions should be avoided (e.g., ciprofloxacin in dextrose 5%). Strategies to prevent the inadvertent administration of high carbohydrate-containing medications to patients are to list "carbohydrate restriction" or "ketogenic diet" to alerts in the patient chart. Communication with the medical team is also vital; explaining that the medications have been selected to ensure minimal carbohydrate content as to not disrupt ketosis and risk compromised seizure control, can assure nursing staff that the dosage forms to be administered have been selected with pharmacist input.

Hazardous Medications

Dosage form selection requires special consideration when dealing with hazardous medications (i.e., chemotherapy or cytotoxic medications). Special equipment or supplies (i.e., gloves, masks, gowns, and disposal containers) may be used to help protect inadvertent or unintended exposure to medications considered hazardous. Recommendations for the safe handling, administration, and disposal of chemotherapeutic agents have been published by the Pediatric Oncology Group of Ontario (POGO, 2016). Selection of dosage forms should consider ease of measurement and extent of exposure to hazardous substances. For example, dissolving tablets in water contained within an oral syringe versus crushing a tablet and then mixing in water is usually recommended to prevent risk for spillage and aerosolization of hazardous substances. When recommending therapies for patients, a pharmacist would be required to consider the dosage form appropriate for the patient age, route and with medication preparation factors in mind when children are required to take medications that may pose a hazardous risk to others and the environment. These medications should also be appropriately stored and labeled to ensure appropriate safe handling.

Patient Education

Due to the complexity of medication administration, differences in presentation, pharmacokinetics, and safety considerations, written information is often provided in addition to verbal counseling to best inform patients and their caregivers. During patient and family counseling, pharmacists have a role in the delivery of medication information, which may help with better understanding of therapies and disease states, the importance of adherence, accommodate schedules (i.e., school), and awareness of potential for side effects (El-Rachidi et al., 2017; Horace and Ahmed, 2015; Trivedi, 2017).

Counseling for pediatric patients should include communication that support:

- Medication information based on evidence (verbal and written)
- Medical information in lay language (verbal and written)
- Inclusion of children according to their level of development (i.e., demonstration)
- Adherence (i.e., medication schedules/calendars, mobile device applications)
- Expanded scope for pharmacists (i.e., pharmacist demonstration of devices, monitoring)
- Measurement devices and tools with instruction upon dispensing to ease dosage delivery (i.e., syringes with clear markings, pill splitters, pill crushers)

Drug Information

In general, drug information for the pediatric patient is vastly limited in comparison to information available for adults. This is due to a multitude of factors primarily related to limited research performed for pediatric patients. A pharmacist may be asked to share information on medication use for pediatric indications when there is limited published literature and may need to perform detailed literature searches, contact manufacturers, work with other drug information centers to collate available data and apply to the clinical setting. The availability of drug information sources specific to this population continues to grow, and use of pediatric-specific dosing reference guides, clinical practice guidelines and resources is strongly recommended.

Pediatric drug information services may also serve as resources to institutions for direct patient care and/or to support medication management (i.e., Drugs & Therapeutics Committee, Antimicrobial Advisory Groups), provincial centers, pharmaceutical companies, and the community. The responsibility may vary between answering a general drug information question, review a class of products for inclusion on the institution's drug formulary, provide therapeutic alternatives in the case of drug shortages, perform drug-use evaluations, participate in committees evaluating drug use, development of standardized patient information leaflets, and/or produce a drug dosing guideline handbook. The skill set required to provide evidence-based pharmaceutical care to pediatric

patients is one that can navigate and exhaust information resources, apply knowledge specific to the pediatric population, and communicate it to the stakeholder(s).

Common pediatric specific drug information resources include:

- AboutKidsHealth (www.aboutkidshealth.ca)
- Canadian Pediatric Society (www.cps.ca)
- American Academy of Pediatrics (www.aap.org/en-us)
- Pediatric & Neonatal Lexi-Drugs database (online.lexi.com)
- NeoFax and Pediatrics (neofax.micromedexsolutions.com)
- Red Book: Report of the Committee on Infectious Diseases (www.redbook.solutions.aap.org)
- Handbook of Drug Administration via Enteral Feeding Tubes (White and Bradnam, 2015)

Medication Safety

It is understandable that by virtue of the calculations, pharmacokinetic considerations, frequent need to manipulate dosage forms which may be required to deliver drug therapy, the pediatric population is vulnerable and at high risk for medication errors. This risk can exist at each stage of the medication use process: prescribing, order entry, dispensing, administration, and monitoring. Examples have been published in the community (Poon and Ho, 2011) and hospital (ISMP, 2015) with the aim to learn from these cases.

Strategies recommended to improve patient safety include:

- Dose-range checking software
- Use of an institutional drug formulary
- Separation of sound-alike and look-alike medications
- Use of barcoding
- Clinical Pharmacist's participation in interdisciplinary rounds and direct patient care
- Single concentration of high-risk medications (electrolytes, heparin, opioids) in hospitals
- Removal of concentrated electrolytes on nursing units
- Double checks for reconstituted products and extemporaneous preparations
- Use of referenced extemporaneous formulations
- Pharmaceutical compounding standards (USP, 2018)
- Prohibiting use of error-prone abbreviations (ISMP, 2017)
- Demonstration of device use
- Use of calibrated measurement utensils
- Medication reconciliation

Medication Reconciliation

Pediatric pharmacy practice includes the involvement of pharmacy professionals in the process of obtaining and reviewing medication histories of patients. Medication reconciliation is the formalized process of obtaining a best possible medication history in collaboration with patients, families, and care providers and to ensure continued care involves evaluation of each medication added, changed, or discontinued. The process of medication reconciliation has become a requirement for accreditation standards in some countries (Accreditation Canada, the Canadian Institute for Health Information, the Canadian Patient Safety Institute, et al., 2012). The intent is to ensure accurate communication at each transition points of care.

In pediatrics, specific attention is devoted to:

- Inclusion of dosage forms, details of compounded preparations (references, correlation to clinical outcomes), units of measure
- Use of multiple sources of information (i.e., all caregivers, contacting all pharmacies)
- Prompting for herbals, vitamins, topicals, inhalation
- Use of tools (medication lists, calendars), storage (original vials, locked cabinets for hazardous medications)
- Assessment of patient/family understanding of medication use, adherence, side effects

Special attention is required to be aware of dosage form differences and interchangeability, assessment of doses, decimal places, and units of measure to actively identify and resolve drug therapy problems during this process.

Expanded Scope of Practice

In Canada, pharmacists can practice with an expanded scope with prescriptive authority to initiate selected therapies, adapt or manage (e.g., renew, refuse to fill, adjust or substitute), injection authority (with some limitations on age and drug products),

order and interpret laboratory tests. The extent of the scope varies between the provinces (CPA, 2018) based on regulatory and legislative bodies.

For pediatric patients, pharmacists can make changes in dosage form, recommend treatments for minor ailments, provide the annual influenza vaccine (and other vaccines), in some regions. In hospital settings, pharmacists can utilize their expanded scope with medical directives or collaborative practice agreements to monitor patient's drug therapies with the ability to order lab tests and tests for TDM. As the medication expert on the team, the role of the pharmacist continues to evolve to better apply the specialized knowledge and skill to direct patient care.

Use of Complementary/Alternative Medicines in Pharmacy Practice

Candace Necyk, University of Alberta, Edmonton, AB, Canada

What is Complementary and Alternative Medicine?

Defining CAM

Complementary and alternative medicine (CAM) refers to a set of medical practices, services, and products usually considered outside of or complementary to standard care (WHO, 2018). Standard care, in this context, is considered accepted medical practices that are fully integrated into any given country's dominant health care system (WHO, 2018). Often, standard care is considered interchangeable with Western medicine practices since many of these practices have been adopted worldwide. CAM, therefore, would be considered outside of these practices and is not usually fully integrated into the health care system in terms of guidelines and funding models. CAM can be classified into five main domains (Tabish, 2008) that include the following:

1. Whole medical systems: naturopathic medicine, homeopathic medicine, and traditional medicine systems (i.e., traditional Chinese medicine [TCM], ayurvedic medicine, indigenous medicine, etc.)
2. Mind–body medicine: meditation, prayer, and mental healing as well as creative therapies using artistic outlets (e.g., dance);
3. Biologically based practices: herbs, foods, vitamins, and dietary supplements
4. Manipulative and body-based practices: chiropractic, osteopathic manipulation, rolfing, and massage
5. Energy medicine: biofield therapies (Qi Gong, reiki, therapeutic touch) or bioelectromagnetic-based therapies (pulsed fields, magnetic fields, and current fields)

Within whole medical systems, it is important to highlight the guiding principles between the commonly identified systems. Naturopathic medicine is a primary care practice focused on identifying the root cause of symptoms and disease and supporting the body's innate ability to heal itself; this is done through various therapeutic approaches, including use of herbs and nutrients, clinical nutrition, physical medicine (i.e., hydrotherapy), and others (CCNP, 2018). TCM incorporates philosophical worldviews of Taoism, Confucianism, and Buddhism (NIH, 2013). This medical system emphasizes the significance of Qi (pronounced "chee"), which is defined as a vital energy that manifests physically, mentally, and spiritually in all individuals (NIH, 2013). Through various therapeutic approaches, including acupuncture, acupressure, moxibustion, cupping, and other herbal and dietary interventions,

the overarching goal of TCM is to reestablish and maintain an orderly flow of Qi since this system believes that disturbances in the flow of Qi manifests as disease (NIH, 2013). Ayurvedic medicine is one of the oldest medical systems in the world and even today remains a dominant health care system in India (NIH, 2015). Ayurveda focuses on healing approaches that consider the interconnections between people, their health, and the universe as well as the constitution of the body and life forces, referred to as *prakriti* and *dosha*, respectively (NIH, 2015). This is carried out using compounds of herbs and other materials, physical activity, diet, and other treatments (NIH, 2015). Homeopathy was developed by a German physician and is based on the guiding principles that a disease or symptom can be cured by giving an individual a substance that causes similar symptoms in an otherwise healthy individual and that the lower the dose of the substance given, the greater its effect (NCCIH, 2015). Homeopathic medicine systematically dilutes an active substance and believes that the remaining liquid or solid retains the energy of the medicinal product originally used that can then create a therapeutic effect (Tabish, 2008; NCCIH, 2015). While the whole medical systems described here are examples of the most common systems used worldwide, others also exist and may play a strong role in influencing an individual's health practices and beliefs. One such example, significant in North America and Australia, is indigenous traditional healing principles and practices (Robbins and Dewar, 2011; Dudgeon and Bray, 2018).

Chiropractic, osteopathic manipulation, and massage therapy are all considered manipulative and body-based practices. Chiropractic focuses on the critical interrelationship between the spine and the nervous system, believing that a degradation of the integrity of the spine can affect surrounding neurological tissue and cause health consequences for an individual (NCCIH, 2012). Chiropractors, referred to as musculoskeletal experts, perform manual adjustments and manipulations on the spine to restore such integrity (NCCIH, 2012). Chiropractic also incorporates lifestyle and nutritional recommendations into their individualized treatment plans (NCCIH, 2012). Massage therapy manipulates soft tissues to influence the surrounding musculoskeletal, circulatory, lymphatic, and nervous systems to enable the body to heal itself (College of Massage Therapists of Ontario, 2018). Massage incorporates different techniques to deliver treatment, including compressing or stretching soft tissues, as well as reflexology, which is based on the idea that pressure on one part of the body can affect another part of the body (College of Massage Therapists of Ontario, 2018; NCCIH, 2017a). Osteopathic medicine utilizes a diagnostic assessment skill called a palpation that is able to detect scarring, stiffness, density, hydration level, mobility, and other states of tissues and systems being examined (Campbell et al., 2012; AACOM, 2018). The osteopathic practitioner, who in some countries such as the United States are also licensed medical doctors with additional training, will then proceed to use pressure, resistance, and stretching to restore balance in the body (AACOM, 2018).

The practice of acupuncture encompasses the strategic insertion of solid acupuncture needles into the skin at particular points on the body to induce a therapeutic effect (Berman et al., 2010). Acupuncture is often classified as a type of energy medicine, however, is commonly incorporated within different CAM domains. It is commonly practiced as a part of TCM, since it also follows the guiding principles of restoring the balance of Qi, as well as in naturopathic medicine (NIH, 2013; CCNP, 2018). This is similar to biologically based practices such as herbs and dietary supplements, which are commonly utilized in a number of different CAM medical systems and practices.

The Regulation of CAM Practices and Products

Regulation of CAM Practitioners

Access to the various products and services that encompass CAM is greatly influenced by how such practices are regulated in a particular country or jurisdiction. When considering CAM practitioners who offer specific services, the quality of their practice relies heavily on the regulations set out in the jurisdiction they practice in. Whether or not a CAM profession is governed by a set of regulations varies considerably across the world, and even within a country itself. For example, in Alberta, Canada, naturopathic doctors (ND) are governed by the College of Naturopathic Doctors of Alberta; this professional college mandates standards of practice that must be adhered to and restricts membership and the use of a reserved professional title to only those individuals who have completed a certain level of education from an accredited institution, passed national licensing exams, and carry malpractice insurance (CNDA, 2018). In this sense, individuals who visit a ND can be assured that there is a professional board governing the services provided to them. It also prevents unqualified individuals from using this reserved title (ND), as such action would be subject to discipline by a court of law (CNDA, 2018). Without this professional regulation, any individual can refer to themselves as a ND and provide services that they may not be qualified to which is a risk to the public. Interestingly, within Canada, only 3 of 13 provinces and territories regulate naturopathic doctors by a professional college (CNDA, 2018; CNPBC, 2018; TCNO, 2018); currently, other provinces are in the process of such level of regulation and many others attempt to regulate the profession through a professional association, such as Saskatchewan (SANP, 2018). In the United States, only 20 states regulate naturopathic doctors by a state board similar to a professional college in Canada (The American Association of Naturopathic Physicians, 2018). Likewise, naturopathic doctors are not yet considered a regulated or registered health profession in Australia (CMA, 2013). The regulation of naturopathic doctors is one example of a CAM practice; the regulation of other CAM practitioners is also varied and even less common for certain practices such as homeopathy. Since the regulation of such professions aims to protect the public and ensure high-quality, safe medical care, it is important for individuals and health professionals to be aware of what regulations exist in their jurisdiction and how appropriate care can be sought when considering CAM.

Regulation of CAM Products

Products prescribed by many CAM practitioners and used inherently within a number of CAM domains are called natural health products (NHPs), dietary supplements, or herbal medicines (Briggs, 2002; Government of Canada, 2015; FDA, 2018)—various names are used across different countries. Such products encompass a broad category of health products that are available without a prescription from a medical doctor and most commonly include vitamins, minerals, herbs, homeopathic remedies, traditional medicines, probiotics, amino acids, and fatty acids (Government of Canada, 2015). Marketing approval processes differ significantly across countries, leading to a wide variety of products available to patients for use. In many developed countries, NHPs are considered medicinal products and are regulated as a subset of other medicines or under their own separate regulations. NHPs in Australia are called herbal medicine products (HMPs) and are regulated by the Therapeutic Goods Administration as medicines or registered medicines based on their premarket assessment of ingredients, dosage forms, efficacy claims, and safety risks (Briggs, 2002). Similar processes are followed in the European Union by the Committee on Herbal Medicinal Products and in Canada by the Natural and Non-prescription Health Products Directorate within Health Canada (CHMP, 2018; Government of Canada, 2018). In Canada, a Natural Health Product Number (NPN) is provided to those products that have undergone an efficacy and safety evaluation and are deemed appropriate to be sold on the market (Government of Canada, 2016). Contrary to processes followed by the countries described above, the United States regulates NHPs under the Dietary Supplement Health and Education Act of 1994 as a subset of food and refers to them as dietary supplements (FDA, 2018). Manufacturers of dietary supplements do not have to apply for premarket approval and the United States Food and Drug Administration is only involved in repercussions for unsafe dietary supplements that are already available on the market (FDA, 2018).

While Europe and Canada outline a premarketing approval process for NHPs, it is important to point out that the criteria required for approval and the rigor applied to this process vary across products. Applications for products may be submitted through a traditional use pathway, which specifies that products that have been used traditionally for 30 years or longer do not require clinical trials on efficacy or safety for approval. In the European Union, for example, products seeking approval under the "traditional use registration pathway" only require the demonstration of "sufficient safety data and plausible efficacy" (European Medicines Agency, 2018). Likewise, in Canada, NHPs that seek approval through the "traditional use pathway" are asked to submit evidence of efficacy through "two independent references supporting efficacy based on belief /theories/experiences within a single system of traditional medicine" (Government of Canada, 2012). Of particular concern, it is often unknown or unclear to which extent such submitted data are reviewed and the quality assurance mechanisms in place to protect consumer safety. An example of this was highlighted recently in a Canadian television show titled "CBC *Marketplace*" in which a fake homeopathic product claiming to treat fevers in children was approved for licensing (Grundig, 2015). This action was highly criticized given that the only effectiveness claim for this product was based on a 1902 homeopathy textbook of ingredients (Grundig, 2015).

Complementary and Alternative Medicine Use

Prevalence of CAM Use

Complementary and alternative medicine use is prevalent worldwide (NHPD, 2011; Walji et al., 2011; Vicki Wood, 2012). Greater than 70% of the population reports CAM use in many countries around the world, including Canada, the United States, and Europe (WHO, 2013a). This use has increased significantly over the past decade (WHO, 2013a). CAM use is often sought for the management of acute conditions such as pain and headaches (Barnes et al., 2009a) but is also commonly used by individuals living with serious and chronic diseases. For example, the rate of CAM use by individuals with multiple sclerosis is 41%, 70%, and 82% in Spain, Canada, and Australia, respectively (Skovgaard, 2012). In patients living with cancer, global rates of CAM use ranges from 6–91% and has grown significantly in recent years (Werneke et al., 2004; dams et al., 2013; Bonacchi et al., 2014).

The rates of specific CAM practices vary worldwide. CAM practices such as massage, chiropractic, and acupuncture are commonly used around the world; in fact, over 50% of countries in the world utilize and recognize the use of acupuncture within the health care system (WHO, 2013b). One of the most commonly reported CAM therapies is NHPs. Over 70% of Canadian adults reported the use of at least one NHP in 2010 (NHPD, 2011); utilization data are similar across other countries such as the United States, Europe, and Australia (Xue et al., 2007; Corazza et al., 2009; Barnes et al., 2009b). NHPs are also commonly used in children, with such use being largely influenced by whether or not their caregiver or parent use CAM (Sawni-Sikand et al., 2002; Barnes et al., 2008; Kim et al., 2012). It has been reported that over three-quarters of children with type 1 diabetes mellitus use at least one NHP (Haliloğlu et al., 2011). In Norway, nearly 40% of pregnant women report utilization of herbal products (Nordeng and Havnen, 2004).

Traditional medicines, including TCM and Ayurveda, are deeply rooted within the cultures of many countries such as China, Africa, and India (WHO, 2013b). These medicine practices have been passed along from generation to generation and are widely accepted amongst individuals of these cultures (WHO, 2013b). For example, nearly one-fifth of all medical visits in China in 2009 were to TCM practitioners; in fact, 90% of publicly and privately funded hospitals in China have a traditional medicine department and both conventional medicine and traditional medicines are offered concurrently in all institutions (SATCM, 2009; Government of China, 2011; WHO, 2013b). In Singapore, where more "Western" conventional practices are commonly accepted and utilized, three-quarters of the population still report using traditional medicines (WHO, 2012). Traditional medicine use has been reported to be as high as 60–90% in Africa and 70% in India (Bach Hernán et al., 2014). It is important to recognize that given the extensive use of traditional medicine in certain cultures around the world, immigration patterns may also impact the use of CAM in other

countries that do not integrate such practices to the same extent. In the United States, immigrants from China accounted for the second highest proportion of all immigrants between 1986 and 2016, and India was the third highest (USDHS, 2018).

Homeopathy, despite current controversy around the lack of efficacy surrounding such practices, is still prevalent in many countries. Given its development by a German physician in 1796, its use tends to be greater in Europe and countries within close proximity to Europe (Relton et al., 2017). While rates of use across Canada, the United States, the United Kingdom, and Australia have remained quite consistent over nearly 30 years at 0.2–4.4%, countries such as Italy and Switzerland report much higher use (Relton et al., 2017). In Italy, 8.2% of the adult population and 7.7% of children used homeopathy in 1999 (Relton et al., 2017). The highest rates of use are reported in Switzerland where, interestingly, the cost of homeopathy treatment is covered by health insurance (Relton et al., 2017).

Reasons for CAM Use

Reasons for CAM use are complex and often multifactorial, based on values and different sources of information. Many consumers utilize CAM in their health care based on traditional cultural values, as discussed previously. Outside of cultural traditions, individuals often link the assumption of a product being "natural" to inherently mean it is safe, and therefore it is a healthier or safer alternative to conventional drugs used in the Western medical system (WHO, 2013b). In fact, one in five Canadians believe that NHPs do not have any adverse effects associated with them (NHPD, 2011). Since NHPs are available over-the-counter (OTC) without a prescription in most countries, patients often self-select and incorporate NHPs into their treatment plans based on information gathered from sources such as the Internet, media sources, popular health-focused talk shows, and friends/family (Felix, 2009; NHPD, 2011). Additionally, much of the world's population, especially in more developed countries, are demonstrating a drive to focus on health prevention and increased attention to natural approaches for overall health (NHPD, 2011). Within less developed countries such as Africa, access to traditional healers who use CAM is much greater than to medical doctors (Abdullahi, 2011). Data from the World Health Organization show that there is one medical doctor for every 40,000 people in Africa, compared to one traditional healer per 500 people; as a result, traditional medicine is more accessible and often costs less money (Abdullahi, 2011).

The treatment approach practiced by many CAM providers often differs from that which individuals are accustomed to in the Western medical system; in turn, this often leads to an improved sense of client-centered care and acceptance by patients to engage in CAM treatment strategies (Kaptchuk, 2002). For example, a patient may get to see a medical doctor for 5–10 min for a typical encounter, depending on the practice setting, whereas with a CAM provider that interaction may be upward of 60 min of time. This increased time together with what may be perceived to be a more complete history gathering often leads to improved patient satisfaction with care and willingness to engage in treatment options recommended by a CAM provider (Kaptchuk, 2002). In fact, a strong therapeutic relationship that results from the entire therapeutic encounter, not just the specific treatment modality itself, has been demonstrated to improve treatment outcomes based on the concept of the placebo effect (Kaptchuk, 2002). A placebo is defined as a "harmless, unmedicated treatment used for its psychological effect, often as a comparison with other treatments" (Wall and Wheeler, 1996). It has been proposed that a placebo effect is likely impacted by the therapeutic relationship itself, especially one that focuses on care rather than just cure, and may directly result from a patient's perception of their provider's qualities instead of just the treatment itself (Wall and Wheeler, 1996). Likewise, individuals who are dissatisfied with the care they have received by conventional health professionals, or with the therapies they have received, may likely seek care from a CAM provider in an attempt to better manage their medical condition (Chao et al., 2006).

Complementary and Alternative Medicine and Pharmacy Practice

Sale and Marketing of NHPs in Pharmacies

Pharmacies are a common retail source of NHPs. Canadians spent over $1.5 billion in 2015 on over 70,000 licensed NHPs in Canada; within pharmacies, NHPs are the top-selling OTC products, even when considered next to commonly used OTC product categories such as pain relievers (Felix, 2013, 2015; Smith et al., 2014). Similarly, in the United States, consumers spent over 7 billion dollars on herbal dietary supplements in 2016, which was a 7.7% increase from 2015 (Smith et al., 2017). Such growth in NHP sales has been reported in many other countries around the world as well, such as Asia, Europe, and Australia, and the global market is expected to reach US$115 by 2020 (Ung and Harnett, 2017). Interestingly, pharmacists who have been surveyed admit to feeling required to increase OTC inventory of NHPs to meet the growing demands by their clients (Boon et al., 2009). As a result, many pharmacy chains worldwide have a large number of aisles dedicated to NHP sales due to both consumer demand and the significant potential for generating revenue. Such a profit-driven environment surrounding NHP sales has led to an abundance of NHPs available within a community pharmacy setting or used by patients in other pharmacy settings (Gunawan et al., 2016; Stub et al., 2016; Ogbogu, 2017).

Role of the Pharmacist in CAM

CAM undoubtedly impacts pharmacy practice given the prevalence of use of such therapies worldwide, and the availability of NHPs in retail pharmacies. Pharmacies and pharmacists are very much involved in the sale, marketing, and education of NHPs. Research

has found that 89% of community pharmacists report spending at least 30 minutes a day counseling patients on NHPs (Charrois et al., 2007). Similarly, other studies demonstrate that consumers of pharmacies frequently ask pharmacists for information and advice on NHPs (Robinson and Lorenc, 2011; Volmer et al., 2011). While pharmacists are taking on a larger role in the NHP industry, a defined scope of practice has yet to be established to guide exactly which responsibilities pharmacists should be incorporating into their practice (Ung and Harnett, 2017). The World Health Organization's International Pharmaceutical Federation states that "pharmacists should take steps to update their knowledge and skills about complementary and alternative therapies in order to maintain and improve professional practice" (World Health Organization, 2011). A majority of the literature highlights the need for pharmacists to inquire about NHP use and document such use in a person's medication record, as well as to take an active role in preventing drug–herb interactions and educating individuals on the safety risks associated with NHPs (Miller et al., 2000; Chavis, 2001; Abahussain et al., 2007; Olatunde et al., 2010; Ung and Harnett, 2017). Pharmacy consumers value pharmacists' expertise in medicines and strongly support the role of pharmacists in providing safety information about NHPs (Braun et al., 2010). A growing body of research, however, also suggests that pharmacists should have the knowledge to advise patients on the efficacy and use of NHPs and major stakeholders consider a pharmacist's role in CAM products to be a "legitimate extension of their established roles in pharmaceutical care" (Miller et al., 2000). Likewise, major stakeholders, such as professional colleges and national organizations, also feel that pharmacists should be able to educate individuals on NHPs in the same way they do with OTC medications (Miller et al., 2000). In practice, this is likely what is occurring given the extensive sales of NHPs within pharmacies and the consumer demand on pharmacists for information. A study out of Alberta, Canada, surveyed community pharmacists about practices related to NHPs and found that nearly one-fifth of pharmacists recommend NHPs often to patients, and almost half report doing so at least sometimes (Ogbogu and Necyk, 2016). Recommending a product for use entails more than general knowledge around safety and drug–herb interactions; up-to-date knowledge and a critical evaluation of the literature is required to ensure the product is efficacious for the desired indication, and that it is in fact the best alternative for the patient given other products on the market. Pharmacists require the training and confidence in order to provide such a scope of practice, and yet, they may have neither. Indeed, research has shown that pharmacists lack the adequate training and knowledge to deliver such care related to CAM, and as a result, they also lack confidence (Ung and Harnett, 2017). A comprehensive standard of practice is required at both a national and international level to outline both the ethical and professional responsibilities of pharmacists in this role, which would then inform undergraduate pharmacy education programs and professional organizations to train and support pharmacists in this area of practice.

Integrative Medicine Approaches

The National Center for Complementary and Integrative Health in the United States defines Integrative Medicine as "bringing conventional and complementary approaches together in a coordinated way" (NCCIH, 2016). Approaches to integrative medicine may differ based on the country and primary health system utilized. Ultimately, the goal is to combine the best evidence from all health systems in order to optimize health care for all patients. Such an approach can be found in disease-specific clinical practice guidelines that may incorporate CAM approaches supported by strong research infrastructure and evidence to the treatment algorithms. Examples of this are demonstrated in the inclusion of acupuncture and massage therapy into chronic noncancer pain treatment guidelines (Busse, 2017), as well as supporting the use of omega-3 fatty acids and yoga in depression treatment guidelines (Ravindran et al., 2016). Specific NHPs are also supported in the management of other medical conditions; examples of this include recommendations for calcium and vitamin B6 use in premenstrual syndrome management and the use of bulk-forming laxatives such as psyllium for constipation (Wyatt et al., 1999; Douglas, 2002; Williams et al., 2005; Longstreth et al., 2006; Whelan et al., 2009). The uptake of this approach to practice by pharmacists may be increasing, given that research has demonstrated that not only are pharmacists recommending NHPs for use, but 85% are recommending NHPs to be taken concurrently with prescription drugs and 31% are recommending NHPs as an alternative to conventional drugs (Ogbogu and Necyk, 2016). The evidence base behind such recommendations, however, is unknown and it is still unclear whether pharmacists are embracing an integrative medicine approach in their practice or whether external factors, such as consumer demand, potential for profit, and recommendations from other health professionals, play a role. Pharmacists should be aware of clinical guidelines and emerging literature that support the use of CAM, and specifically NHPs, with strong evidence backing their use in order to provide a holistic care approach for their patients. Likewise, pharmacists that do not possess the intricate knowledge behind the pharmacologic, pharmacokinetic, and safety profiles of NHPs should refrain from making recommendations outside of published guidelines and should collaborate with other health professionals trained in this area to prevent misuse of products and patient harm. This, again, supports the need for a pharmacists' role to be better defined around CAM in order to establish appropriate training and support mechanisms for the profession.

Safety of Complementary and Alternative Medicine

Safety of CAM Procedures

If pharmacists are involved in recommendations of CAM treatments, especially referrals of individuals to CAM practitioners, it is important to be aware of the efficacy and safety data that exists for such practices. First, this relates back to Regulation of CAM Practitioners in terms of being knowledgeable about the training and qualifications of CAM practitioners in their area and help guide

patients to those who are credible and guided by established scopes of practice by a professional college. This in itself, however, does not dictate whether such practices are considered efficacious and safe. It is important for pharmacists to educate both themselves and their patients on efficacy and safety data around a specific CAM procedure or practice (i.e., acupuncture, chiropractic, etc.), and for the specific indication it is being considered for. Pharmacists who make specific recommendations or referrals should do so with full knowledge of what they are recommending to a person and how it relates to their care plan; pharmacists who are approached by patients inquiring about this information should direct patients to where they can find credible information if they are not comfortable supporting such a recommendation or referral within their own scope of practice.

While CAM is often considered "natural" and, therefore, safe, procedures that fall under the common domains of CAM are not without risk (Walji et al., 2010). Acupuncture, for example, has been associated with adverse events (AE) such as bacterial infections, pneumothorax, central nervous system injury, syncope, and organ injury (Wu et al., 2015). One systematic review determined that reused needles were the most common source of hepatitis infection due to acupuncture (Lao et al., 2003); once again, this speaks to the need for standards of practice and standardization of practice protocols to govern CAM practitioners. While chiropractic is most often associated with mild and transient AEs such as vertigo or muscle pain, spinal manipulation has also been associated with more severe AEs, including dissection of the vertebral arteries, dural tear, nerve injury, disc herniation, and bone fracture (Ernst, 2007). It has also been suggested, with some controversy, that spinal manipulation in the cervical spine area should be avoided in any individual who present arteriosclerotic disease, calcified arterial walls, or tortuosities of the vessel as this may increase the risk of subdural hematoma (Cagnie et al., 2006).

Many other CAM procedures exist, all with their own potential risk profiles. While these risks may be further increased by inadequate training and regulation of CAM practitioners, it is critical that pharmacists are aware of such risks to be able to educate their patients and the public, especially when recommendations of CAM treatments and referrals to CAM practitioners are made. Literature is ever growing in this area as well, so it is also the responsibility of pharmacists to stay abreast of new knowledge when incorporating various aspects of CAM into their scope of practice.

Safety of Natural Health Products

The extent to which NHPs are being sold in retail pharmacies and the current demand on pharmacists to provide the public with information and guidance on such CAM products is well-documented. Much of the literature to date supports the role of pharmacists in assessing and educating on the safety of NHP use for individuals under their care or who visit the pharmacy. Indeed, it is critical that pharmacists are aware of the potential safety considerations of NHPs.

NHPs are pharmacologically active substances that have the potential to lead to adverse reactions (AR). An AR is defined as "a noxious and unintended response to a marketed health product, which occurs at doses normally used or tested for the diagnosis, treatment or prevention of a disease or the modification of an organic function" (Health Canada, 2011). In the United States between 2000–07, NHPs were associated with one of the highest rates of hospitalization due to ARs reported to poison control centers (PCC) (Vassilev et al., 2009). Similarly, in 2003, 30% of all AR reports to PCC in the United States related to dietary supplements were considered moderate to very severe in nature (Perharic et al., 1994).

The causes of ARs may be complex and can be both intrinsic and extrinsic in nature. Extrinsic causes are those that may be related to the manufacturing process of NHP, such as contamination, adulteration, or incorrect preparation and labeling (Jordan et al., 2010). Contamination of NHPs through the growing and manufacturing process may lead to the presence of dirt, pesticides, pollutants (including PCBs), bacteria, molds, mycotoxins, processing impurities, and solvent residues in the final product that becomes available to consumers (Chan, 2003). Of particular concern is the potential for contamination of NHPs by toxic heavy metals. During the growing process, plants used to manufacture NHPs may accumulate heavy metals from the environment they are grown in (Street et al., 2008; Gasser et al., 2009). One type of Ayurvedic medicine, *rasa shastra*, entails the intentional addition of metals, minerals, and gems into herbs for therapeutic purposes (Saper et al., 2008). If manufactured and used properly, experts in this field feel that these products are both effective and safe; however, a large proportion of Ayurvedic products manufactured in India, South Asia, and even the United States have been found to contain detectable levels of lead, mercury, and arsenic that exceeded daily acceptable intake limits (Saper et al., 2008). Interestingly, one study found the prevalence of metal-containing Ayurvedic products to be similar whether manufactured in the United States or India (Saper et al., 2008). Perharic et al. reported that out of 1040 NHP-related reports to the National Poisons Unit in London, UK, 8 cases involved heavy-metal poisoning due to contaminated NHPs (Perharic et al., 1994). Adulteration of NHPs involves the addition of other pharmaceutical drugs, or their analogues; these drugs are undeclared for the purposes of monetary profit due to increased sales of products (Jordan et al., 2010). Weight loss products adulterated with sibutramine and sleep products adulterated with benzodiazepines are a few examples of adulteration that have occurred in NHPs (Jordan et al., 2010). The potential for harm is great with adulteration, especially given that these added products are undeclared and have the potential to reach the consumer. Another possible extrinsic cause of ARs related to NHPs involves species misidentification or substitution (Jordan et al., 2010). Black cohosh (*Actaea racemosa*) has been linked to hepatotoxicity in the literature, however, further analysis and evidence has linked this hepatotoxicity to a Chinese *Actaea* species present in the product rather than the *Actaea racemosa* itself (USNLM, 2018).

Intrinsic causes of NHP ARs are those effects that are related directly to the NHP itself, including its mechanism of action, pharmacokinetics, and interactions with other herbs and drugs (Perharic et al., 1994). NHPs such as bitter orange and ephedra can cause adverse events related to stimulation of the nervous system, such as increased heart rate and blood pressure (Jordan et al., 2010). Woolf et al. found that hazard rate of toxic reactions due to nonephedra herbal products was 96/1000, while the

hazard rate of products containing ephedra ranged from 250 to 267/1000 (Woolf et al., 2005). This rate has grown significantly over the years as well (Woolf et al., 2005). Other NHPs, such as fish oils and Gingko biloba L., can affect blood coagulation and or/platelet aggregation and have been associated with ARs related to bleeding events (Calder, 2004; Bent et al., 2005; Cohen et al., 2011).

Given their pharmacological activity, NHPs also contribute to both pharmacodynamic and pharmacokinetic interactions with other drugs. For example, St. John's wort increases serotonin levels and can increase the risk of serotonin syndrome when taken alongside other drugs that elevate serotonin, such as selective serotonin reuptake inhibitors, dextromethorphan, and triptans (selective serotonin agonists) (Henderson et al., 2002). Ginseng can worsen psychiatric conditions, such as bipolar disorder, due to its stimulating pharmacological profile (Joshi and Faubion, 2005). Other NHP-drug interactions continue to be debated, such as cranberry's effect on coagulation when taken alongside warfarin, but are critical for consideration when delivering patient-centered care (Ge et al., 2014). A scoping review was completed by Kutt et al. in 2016 that reviewed all literature related to NHP–drug interactions, both documented and theoretical (Kutt et al., 2016). Out of 29 NHPs included in the review, 28 were identified as having interactions with pharmaceutical drugs and in total, 97 clinically documented interactions were found (Kutt et al., 2016). Those NHPs with three or more clinical interactions documented are summarized in **Table 1**, along with the drug classes they have the potential to interact with (Kutt et al., 2016). Further details on the nature of the interactions are summarized in the publication (Kutt et al., 2016). Interestingly, St. John's wort was found to interact with 15 different drug classes (Kutt et al., 2016); such interactions are likely due to the pharmacokinetic profile of St. John's wort that is known to induce cytochrome P450 3A4, 2C9, and 1A2, as well as P-glycoprotein (Henderson et al., 2002). While **Table 1** reviews those NHPs with three or more interactions,

Table 1 NHPs with three or more clinical interactions documented

NHP	*Drug class*
Echinacea	Antiplatelet/anticoagulant drugs
	Sedative drugs
	Hepatotoxic drugs
Ephedra	Antihypertensive drugs
	Corticosteroids drugs
	Hepatotoxic drugs
Gingko	Antiulcer drugs
	Antiplatelet/anticoagulant drugs
	Diuretic drugs
	Analgesic drugs
	Antipsychotic drugs
	Antidepressant drugs
	Sedative drugs
	Antiretroviral drugs
Licorice	Diuretic drugs
	Sex hormones
	Antidiabetic drugs
	Antibiotic drugs
Milk thistle	Antihypertensive drugs
	Antidiabetic drugs
	Antiretroviral drugs
	Antibiotic drugs
St. John's wort	Antiulcer drugs
	Antiplatelet/anticoagulant drugs
	Lipid-lowering drugs
	Antihypertensive drugs
	Cardiac glycoside drugs
	Anti-allergy drugs
	Antipsychotic drugs
	Antidepressant drugs
	Antiepileptic drugs
	Sedative drugs
	Sex hormones
	Antifungal drugs
	Antiretroviral drugs
	Antidiabetic drugs
	Antiasthmatic drugs

many other NHPs have clinically relevant interactions as well such as ginger and garlic with antiplatelets/anticoagulants and aloe vera with antihyperglycemic drugs (Kutt et al., 2016).

Given the high prevalence of NHP use worldwide, it is very likely that individuals are taking NHPs and drugs at the same time and are at risk of experiencing such interactions. In the United States, 38% of individuals take NHPs alongside prescription drugs, and 42% take NHPs alongside an OTC medication (Rashrash et al., 2017). In Australia, 87% of individuals over 50 years-old that took NHPs were found to do so concurrently with prescription drugs (Morgan et al., 2012). Of those, 14.2% were at risk of a potential NHP–drug interaction; when 5 or more products were taken in combination this risk increased to 23.7% and in 10 or more to 38.4% (Morgan, 2012). This is concerning, especially since we know individuals with chronic diseases such as cancer, diabetes, and heart disease, who are likely taking one or more prescription drugs, are also more likely to take NHPs as well (Rashrash et al., 2017). It is also important when we recall that up to 85% of pharmacists may be recommending concurrent NHP–drug use (Ogbogu and Necyk, 2016). Within Canada, nearly half of patients visiting community pharmacies take NHPs and prescription drugs concurrently and of those, 7.4% reported experiencing an AE as determined in a national Pharmacy SONAR (Study Of Natural health product Adverse Reactions) research initiative (Necyk et al., 2014). Pharmacists are highly trained to detect, prevent, and manage interactions occurring with pharmaceutical drugs, including those involving NHPs. In fact, Charrois et al. found that 47% of community pharmacists reported recognizing a potential NHP–drug interaction in their patient population (Charrois et al., 2007). Pharmacists should stay abreast with current and emerging literature identifying NHP–drug interactions and be able to apply such evidence to the patients in their care to reduce the AR rate in this population.

Monitoring and Reporting Adverse Events Involving Complementary and Alternative Medicine

Adverse Event Reporting for CAM Practices and Procedures

An AE is an event to which a patient experiences unintended harm and is related to the care or services provided to them, or to products consumed (FDA, 1995). An AE may not yet be determined to be causally associated with the service or product, with which it would then be classified as an AR. The monitoring and reporting of AEs related to specific CAM practices delivered by a CAM practitioner during a patient visit often depends on the extent to which the CAM practitioner is regulated in a particular country. Just as it is expected that conventional medical doctors and other health professionals disclose any AE experienced by a patient in their care to the patient themselves, and to whatever institutional and regulatory body is required to ensure a quality review process occurs to prevent further harms from occurring in the future (CPSA, 2018; TCMPA, 2009), CAM practitioners should be held to the same practice standard. AEs as well as inappropriate, unethical, or unprofessional practices are most often investigated by the professional college to whom the specific practitioner belongs to. Such complaints may come from the public or from another health professional. Investigations, when reports are made to the professional college, are undertaken for the purpose of ensuring that the professional standards of practice and codes of ethics were being followed when delivering patient care. It is for this reason, among many others, that professional colleges and the regulation of health professions aim to serve the best interests of the public.

As previously discussed in Regulation of CAM Practitioners, many CAM practitioners around the world are not governed by a professional regulatory body. As such, it is the responsibility of individual practitioners to monitor AEs that may arise and disclose it to the patient and any other professional body that may exist. Without any professional body overseeing such a process, it is unlikely that AEs or complaints from the public will be managed in a way that can accelerate widespread change.

Adverse Event Reporting for CAM Products
