- General recommendations include regular exercise, stress management, and dietary considerations.
- Explanation and enthusiasm for psychological therapies may convince the patient to try them or retry them with a different psychologist. Direct referral to a psychologist or referral through the patients' general practitioner should be considered.
- Explanation of the benefit of consultation with a dietician. Direct referral or referral through the patients' general practitioner should be considered.
- The placebo response rate in IBS treatment trials has been found to be 30%–40%.
- Personal factors as warmth, empathy, duration of interaction, and the communication of positive expectation might indeed significantly affect clinical outcome
- A therapeutic trial of a bile acid sequestrant could be useful in the treatment of patients with IBS-D.
- Evidence for the use of antidepressants, antispasmodics, and motility agents appear to be poor.

Management of Wounds and the Pharmacist's Role: Woundcare

Geoff Sussman, Monash Institute for Health and Clinical EducationMonash University, Melbourne, Vic, Australia

Wounds, whether acute, postsurgical, or chronic, are a growing area of practice, and it is important to review the current methods of management and developments in diagnosis, assessment, and treatment. How do you define "wound management" what is wound management ?

"The provision of the appropriate environment for healing by both direct and indirect methods together with the prevention of skin breakdown" (Sussman, 2014).

To clarify this definition, no longer should we look on wound management as the application of a dressing to an acute or chronic wound dressings don't heal wounds they optimize local environment for healing.

Wound management is, and must be, a holistic approach to the patient to ensure the best practice is applied in treatment. This approach is best expressed as "treat the whole patient and not just the hole in the patient" (Sussman, 2014).

Pharmacy and the pharmacist continue to play an important role in the delivery of wound management to their customers. No longer must the profession see their role as only the supplier of products but as a clinical service. Quality wound care is multidisciplinary and it involves Medicine, Nursing, Pharmacy, Podiatry, etc. Pharmacy is the supplier of therapeutic products, but wound management involves therapeutic decision making some products required are prescription-only medicines. Many drugs impact on wound healing by both stimulating and retarding healing, and some drugs even cause wounds. Wound management and wound pharmaceuticals are as much the responsibility of Pharmacy as are drugs.

Wound management is a stimulating practice, but the problem of both chronic and acute wounds an underestimated problem. The prevalence is increasing at a rapid rate due to the ageing of the population and the significant increasing rates of diabetes worldwide.

Patient-Centered Care

The patient has the wound and is a partner in the discussions and decisions about treatment and other activities. The patient is treated holistically, and you must consider the wound, whole body, personal values and experiences, and environment (social, occupational, familial, etc.).

Best Practice Resources

The benefits of using best practice resources is that we are all working on same page, evidence-based, patient-focused, interprofessional, this will achieve cost-effectiveness, streamline and simplify services, and provide consistency of care across settings and location.

The Basic Principles of wound management

1. Define etiology.
2. Control factors affecting healing.
3. Select appropriate dressings.
4. Plan for management (Grey et al., 2006; Sussman, 2001).

Define Etiology

Wounds are either acute or chronic in nature and the approach to each type can be different.

Acute wounds	*Chronic wounds*
Higher risk of infection	Lower risk of infection
Due to debris contaminating wound	Symptom of underlying condition
Inflammation occurs	Heal by secondary intention
May heal by primary intention	Not sterile
May require antiseptic use and systemic antibiotics	May be sloughy and exudative

Wound Healing Principles

Wounds heal either by primary intention or by secondary intention.

Primary Intention

Involves the apposition of the wound edges and the reunion of tissue structures and should result in minimal scaring.

Secondary Intention

Open gaping wounds where there is loss of tissue, or infected closed wounds, heal by the formation of granulation tissue (vascular and fibroblast proliferation), which fills the defect and by contraction of the wound edges. Healing by secondary intention is slow and can result in a large distorted scar.

Physiology of Wound Healing

There are three phases of wound healing—inflammatory (destructive), proliferative (regenerative), and maturation (reparative). During all of these phases, there are a number of cells that are essential to the healing process including platelets, neutrophils, macrophages, and fibroblasts. Some of the cells are only present for one particular phase; however, most are there from the very beginning of the wound, through to the ultimate healing of the wound.

The critical thing is that the phases of healing are parts of a continuum. Each phase continues on in a steady process merging with the next phase. In fact, one wound may be in more than one phase at one time (Grey et al., 2006; Sussman, 2001, 2016).

Phases of Healing

The Inflammatory Phase

The inflammatory phase is normally the shortest, a wound is either surgically created, caused by trauma or some other reason. There will be bleeding and a clot will develop to induce hemostasis. Wound exudate is often manifested during the inflammatory phase.

The most important cells are the platelets whose task is not only hemostasis but also the production of a growth factor. During this phase, the neutrophils are involved in phagocytosis of bacteria as well as aiding in the extracellular release of proteases, enzymes used by the body for the destruction of necrotic tissue (Grey et al., 2006; Sussman, 2001; Sussman, 2016).

The Proliferative Phase

During this phase, the new vascular bed is formed by angiogenesis, collagen is deposited by the fibroblasts the essential framework for the connective tissue which will eventually fill the wound. The collagen realigns itself by cross-linking, resulting in tensile strength in the wound. During the proliferative phase wound contraction occurs pulling the wound margins together. Contraction and granulation are the processes by which the wound becomes smaller. During the latter stage of the proliferative the epidermal cells over the surface of the granulation tissue, a process which is completed most efficiently in a moist, clean environment (Grey et al., 2006; Sussman, 2001; Sussman, 2016).

The Maturation Phase

The maturation phase is the final stage of healing. During this stage, the fibroblasts decrease in number, vasculization decreases, and the tensile strength of the wound increases. Maturation is the most misunderstood phase of healing. It is assumed that a wound is healing once the epithelium has closed the surface of the wound. Tensile of strength of the wound may, in fact, take quite a considerable time and in some patients it can take up to 12 months. The lack of tensile strength in a wound will increase the risk of breakdown that may be related to tension the tissue below the surface.

Moist Wound Management

Traditional theory has always held that wounds should be kept clean and dry so that a scab forms over the wound, the wounds should be exposed to the air and sunlight as much as possible, and where tissue loss is present, the wound should be packed with gauze to prevent surface closure before the cavity is filled, and then the wound should be covered with dry dressing.

The disadvantages of these principles are that the scab, which is made up of the dehydrated exudate and drying dermis, is a physical barrier to healing, because the epidermal cells cannot move through the scab and this may ultimately result in a poor cosmetic result, even scarring. Exposure to the air reduces the surface temperature of the wound and further delays healing causing peripheral vasoconstriction affecting the flow of blood to the wound. This lower blood flow will also affect the supply of oxygen, nutrition, and other factors to the wound. Air exposure will also cause the wound to desiccate and form a scab (Sussman, 2014).

Where a wound is packed with dry gauze, the quality of healing is impaired due to the adhesion of the material to the surface of the wound causing it to dry out. Equally, covering the wound with a dry dressing that adheres to the wound surface may traumatize the wound surface on removal.

Wounds covered by an occlusive dressing do not form a scab, so epidermal cells are able to move rapidly over the surface of the dermis through the exudate that collects at the wound/dressing interface. The application of a totally occlusive or semipermeable dressing to a wound can also prevent secondary damage as a result of dehydration. It facilitates wound cleansing, since the wound exudate is part of the healing cascade and it also protects granulation and encourages epithelialization. It has now been shown to carry a number of growth factors essential to the healing of wounds (Grey et al., 2006; Sussman, 2001).

There are a number of factors that affect the healing of a wound both intrinsic and extrinsic,

The Intrinsic factors that influence healing (Guo and Dipietro, 2010; Thomas Hess, 2011).

Health Status

This includes the circulation, because without good arterial and venous circulation, healing becomes a problem. Anemia, regardless of type, reduces the capacity of the blood to provide oxygen to the tissues, since hemoglobin transports oxygen to the cells. As a number of other blood cells are critical to the healing process both directly and indirectly by their production of growth factors or other functions—anemia may certainly be a problem.

Immune Function

Normal immune system function is required for the inflammatory phase and the cleansing phase of healing. A reduction in immune function slows the cleansing of the wound bed and reduces the ability of the body to fight invading pathogens. This is likely to be due to a reduction of the number and activity of the white blood cells.

Diabetes

Diabetes is one of the major problems for chronic wounds. Diabetics have a delayed capillary response to injury, reduced cellular function at the injury site, and defects in collagen synthesis and wound strength. This can be attributed to age, obesity, malnutrition,

and vascular disease; however, hypoglycemia caused by reduced insulin availability and increased insulin resistance appears to be major predisposing factors in delaying healing in diabetic patients.

Age Factors

As we age, our skin and tissue change. First, we lose the sensory cells, and then we lose the secretary cells which are so essential for the maintenance of skin moisture and flexibility. We lose the vasculature within the skin, and we lose the hair follicles. The skin becomes far more prone to destruction either by physical or by chemical means.

Body Build

Because of the adipose tissue being poorly vascularized, an obese patient will have a great deal of trouble healing due to the inability to deliver oxygen and nutrients to the wound site. Underweight individuals may also experience difficulties in the healing process.

Nutritional Status

Nutrition is one of the most important factors in the healing of wounds. Proteins, vitamins, carbohydrates, fats, and fluids all play a vital role in wound repair. Of the vitamins and trace elements, vitamins C, A, K, and B are particularly essential in the maintenance of bodily function and consequently wound healing.

Trace elements, such as iron, copper and zinc, are all necessary for a cell proliferation and tissue regeneration. Iron is necessary for hemoglobin synthesis, and deficiency can lead to anemia. Copper is necessary for collagen synthesis. Known zinc deficiency will show a retardation in the synthesis of collagen and a reduction in epithelialization.

Extrinsic factors that influence healing (Guo and Dipietro, 2010; Thomas Hess, 2011).

Mechanical Stress

When a patient is immobile and pressure is exerted locally, especially over a bony prominence for more than 2 h, at a pressure exceeding 30 mm of mercury, localized microvascular ischemia will occur, ultimately leading to tissue destruction both at the surface and deeper into the wound, leading ultimately to a pressure sore. Equally, shearing forces and friction occur when the tissue below the skin is forced to move while the skin itself is restrained by contact to a surface such as the bed sheet. This is particularly evident in the patientsr' heels.

Debris

Debris, such as slough, eschar, scab, wound dressing residues, gauze fibers, sutures, will impede wound healing. Their presence will prolong the inflammatory phase, as well as predisposing the wound to infection. They are act as a physical barrier to the healing process. Debris should be removed, either surgically or by the use of hydrogels, proteolytic enzymes, or hydrocolloids.

Temperature

The optimum temperature for the growth of human cells is 37°C. It is therefore essential to maintain the wound environment at body temperature. A drop in body temperature will lead to peripheral vasoconstriction, affecting the flow of blood through the wound, and it will markedly reduce the activity of growth factors and proteases.

Desiccation

If a wound dries, healing is either delayed or will cease. Exposed, dry wounds are more inflamed, painful, and itchy and have more scab material during the early stages of wound healing. Desiccated wounds present several barriers to efficient wound healing, which can be overcome by maintaining a moist environment.

Maceration

Maceration may be caused by incontinence, perspiration, or excessive exudation. If there is maceration, this will cause the destruction of tissue and slow down the healing process. It is essential to maintain the moist environment without excessive exudation.

Infection

The presence of erythema, discharge, fever, pain with elevated white blood cell count, and sometimes odor is evident that the wound is infected. If clinical signs of infection are present, the use of systemic antibiotics is mandatory. If there are no clinical signs of

infection, there is little reason to use either systemic or topical antibiotics. An exception to this may be the use of very specific topical antibiotics in very specific cases to reduce the level of bacteria in wounds of compromised patients.

Chemical Stress

Iodine, peroxide, chlorhexidine, alcohols, hypochlorites, and acetic acid are commonly used antiseptics and cleansing agents. Use of these agents is often responsible for delayed healing, since they are nonselective in their activity and will kill healthy cells as well as bacteria. It is preferable to avoid the prolonged use of these products on a granulating wound. Their use even in infected wounds is somewhat dubious, they may reduce the surface load of bacteria in an infected wound, they do not penetrate below the surface, and have no real effect on the infection in the tissue itself. They may be of use in dilute forms when applied to some chronic wounds and left in place for no more than 5 min and then washed off.

Systemic Medications

There are a number of drugs that will affect healing, and these include the anti-inflammatory drugs. The use of steroids or non-steroidal anti-inflammatory drugs reduces the normal inflammatory response, which is necessary to prepare the wound for subsequent healing (Karukonda et al., 2000a, 2000b; Pollack, 1982; Sussman, 2007).

Chemotherapeutic agents, such as cytotoxic drugs kill cancerous cells but will also affect and delay the inflammatory phase, suppress protein synthesis, and inhibit cell reproduction. Immuno-suppressive drugs will reduce white blood cells, while penicillin may prevent efficient cross-linking of collagen thereby reducing the tensile strength of wounds. In infected wounds, however, antibiotics enhance the wound healing as they kill infecting organisms and allow wound healing to proceed (Karukonda et al., 2000a, 2000b; Pollack, 1982; Sussman, 2007).

If possible, avoid drugs that inhibit healing, even if this is possible only for the short term. If this is not possible, realize that the wound may never heal; at best, it can be managed so that there is as little pain and discomfort as possible.

Lifestyle

Smoking

The adverse effects of smoking and the potentiation of cancer in various parts of the body have been understood for many years. However, it is clear that the toxic constituents of smoking such as nicotine, carbon monoxide, and cyanide have a dramatic and inhibiting effect on healing (Sussman, 2005). Nicotine will diminish red blood cells, fibroblast, and macrophages and increases platelet adhesiveness. This will produce cutaneous vasoconstriction. Carbon monoxide has an affinity for hemoglobin 200 times that of oxygen. This will have a major effect on the oxygen-carrying capacity of the blood and will lead to a potential ischemia. Hydrogen cyanide inhibits enzyme systems necessary for oxygen transport at the cellular level, as well as oxidative metabolism. Smoking can therefore be a major cause of the nonhealing of wounds (Sussman, 2005).

Alcohol

Excessive and/or *chronic alcohol* intake can lead to health problems affecting wound healing. Alcohol-induced digestive problems may lead to malnutrition and anemia. Liver damage can result in chronic disturbances due to a reduction in platelet levels, and subsequent circulatory damage that may reduce required for wound healing.

Wound Assessment

Patient Assessment

When assessing the status of the patient, the areas to be addressed should include a general health status, medication review, nutritional status assessment, and an evaluation of the awareness and involvement of the patient's family concerning wound care (Grey et al., 2006).

Wound Assessment

After patient assessment, the next step is to carefully assess the wound. Wound assessment includes the wound's etiology, its location, and its size and depth. A thorough wound assessment also includes evaluation of the wound bed in terms of type of tissue present, observation of the quality and amount of exudate, and determination of the presence or absence of infection. It also involves assessment of the condition of the peri-wound area and evaluation of any past and current treatments (Grey et al., 2006).

Wound assessment is now based on the principles of wound bed preparation this clarifies the need to examine all of the aspects of the wound and to address an ongoing debridement phase, management of exudate, and the resolution of bacterial imbalance. From this, the TIME acronym was developed. This consists of the **T**issue, the presence of inflammation/**I**nfection, the level of **M**oisture and the importance of wound, Edge/**E**pithelialization. This simple principle enables a wound to be assessed for most of the important aspects of the wound this enables the health professional to consider the factors for healing or delayed healing and what must be considered in the choice of treatment (Rodrigues et al., 2016; Sibbald et al., 2000).

Wounds are dynamic and as such the choice of dressing will vary and will change as the Wound changes. The product you may commence treating the wound with initially will in many, cases change as the wound itself changes. The choice should be based on a three simple rules. C.D.E. This indicates the three major aspects of any wound Color, Depth, and Exudate.

Color

The Pink wound is in the final stages of healing with new epithelium covering the wound, the major aim is to protect this very delicate tissue, prevent the wound from drying out so as to maintain a moist environment, and to insulate.

The Red wound is a granulating wound with new tissue filling the deficit and with some islets of epithelium present. The aim is to absorb any excess educate, maintain a moist environment, and protect the wound.

The Yellow wound contains a level of slough. This is nonviable tissue that must be removed or healing will not take place. The methods of removal are surgical, re-hydration with dressings such as hydrogels or hydrocolloids. The aim is slough removal by rehydration and absorption of exudate.

The Green wound is most likely infected; this should be confirmed by microculture from the wound to establish the infecting organism. The other signs of infection include

The Black wound has an outer layer of thick hard eschar; this must be removed to commence the healing process. The fastest and most effective method is by surgical removal. The use of dressings such as hydrogels to aid autolytic debridement will at best be slow.

Depth

The wound may be superficial, partial thickness deep, or a cavity. The product choice will depend on the shape, position, and type of wound.

Exudate

Most wound will contain some exudate; this will vary from very little to copious levels. The choice of both primary and secondary dressing will depend on this level and the depth of the wound.

Peri-Wound Area

Assessment of peri-wound skin, or wound margins, can give indications of problems. Erythema of the wound margin can signal infection. A blue-gray or blanched margin can indicate an undermined area. White margins can result from maceration. Stained, dry, cracking, inflamed areas should be noted and documented.

Complex and Chronic Wounds

A large proportion of wounds seen in clinical practice are chronic in nature. The epidemiological studies indicate that one percent of the population has a chronic wound, and of that group some twenty percent have had the wound for more than 2 years. Chronic wounds may be classified into the following groups: (Grey et al., 2006; Sussman, 2014).

Leg ulcers Pressure wounds Chronic infected wounds

The difficulty in the management of any chronic wound is that there is always an underlying physiological cause of the wound that must be treated, but many patients have multifactorial shortages, as discussed earlier. For best results, the basic cause of the problem must be attacked, and the negative factors altered.

It must be understood that some patients may never heal due to the basic pathophysiology of the disease process and our inability to alter some or all of the major factors influencing the nonhealing of the wound. However, even in the most extreme cases, good wound care can be a great help in minimizing the worst effects of such chronic wounds (Sussman, 2014). The complications of leg ulcers include neoplasia, calcification, infection, and hemorrhage.

The main leg ulcers are venous leg ulcer due to venous insufficiency, arterial ulcer due to PVD, mixed venous/arterial, and then atypical ulcers such as vasculitic ulcers (Australian and New Zealand, 2011; Grey et al., 2006; Sussman, 2014).

The Diabetic Foot

Many diabetics may have small and minor skin breakdown, which they may not consider important; however, due to their disease, these minor wounds have the potential of becoming serious. Minor tissue injury was reported as the pivotal event in 86% of cases resulting in amputation every 30 s someone loses a leg to diabetes (Green, 2013; Rodrigues et al., 2016). The pharmacist is in a

unique position as they know their diabetic customers as they dispense their medication and they are able to discuss measures to help the prevent foot ulcers and if necessary treat early skin breaks.

How does Diabetes affect wound healing

- Diabetics have a fivefold risk of infection.
- Diabetics have the inflammatory response impaired.
- Diabetes is associated with atherosclerosis (small vessel disease).
- Diabetes will damage the nerves, which diminish pain sensation and nerve response.

Management of diabetic wounds will depend on diagnosis either a neuropathic or ischemic ulcer. It will involve other health professionals, e.g., a Podiatrist as off-loading to reduce direct pressure is essential.

A simple diabetic wound should be treated with a topical antiseptic, e.g., Cadexomer Iodine and covered with a foam dressing. If there is ischemia present, then urgent referral is critical as surgical intervention may be required (Schwartz, 2013). The pharmacist need to work with the patients GP, Podiatrist, and other health professionals fort the best outcome.

Pressure Injury

Pressure wounds may be as simple as the blister most of us may have experienced over the years from footwear to the extensive pressure sores experienced by bedridden patients suffering from stroke, spinal injury, multiple sclerosis, or dementia. A pressure injury develops when the capillary blood flow to the skin and tissue over a bony prominence is decreased for a sufficient period of time. The consequence of this restricted blood supply is a reduction in oxygen supply and nutrition to the tissue, accompanied by the problem of waste products not being removed from the site (Australian Wound Management Association, 2012; Brink et al., 2006; Lyder, 2003).

The result of this is hypoxia, tissue acidosis, increased capillary permeability, which allows intravascular fluid to escape causing edema and cell death. The main causes of pressure wounds are pressure, friction, and shear.

Risk Assessment

The most important management principle in pressure wounds is to identify any patient at risk of developing such a wound. There are a number of assessment tools that may be used to aid in the identification of such patients. The most commonly used assessment tools are Norton, Waterlow, and Braden. They rate the patient against criteria such as mobility, incontinence, activity, physical condition, mental status, and nutrition (Lyder, 2003; International Wound Infection Institute (IWII), 2016)

Evidence shows nutrition support can prevent pressure ulcers in at risk groups: "Nutritional support, particularly high protein oral nutritional supplements, can significantly reduce the risk of developing pressure ulcers (by 25%)" Nutrition is also an important factor in both prevention and management of pressure wounds (Australian Wound Management Association, 2012; Brink et al., 2006).

Incontinence-Associated Dermatitis

This is skin damage cause by urine or feces and this is sometimes confused with stage 1 or 2 pressure injury. This is in fact a skin damage issue and needs to treated as such gentle cleansing with a cleanser with pH range similar to normal skin, moisturization to maintain the skin's normal barrier function, and application of a moisture barrier product, e.g., a petrolatum-based, dimethicone-based, zinc oxide-based, or liquid film-forming acrylates (Doughty et al., 2012).

Wounds and the Older Person

As a person ages, changes in the skin, such as loss of dermis, collagen, sebum, and sweat production, are reduced. The epidermal layer separates more easily from the dermis, and elastin fibers decrease in number but increase in size, thus making the skin stiff. There is also a decrease in Langerhan cells impacting on the immune system functions. Small blood vessels diminish by 40% and become fragile. There is a loss of vitamin D production, lower migration of capillary epithelial cells, and less epidermal turnover.

Skin tears are the most common simple wound found in older people.

The management of skin tears will include surface contact dressings, e.g., Silicone Tulles, with a secondary dressing of a Silicone Foam dressing, as a general rule never stick any product in the skin of an older person as its removal with most likely cause a new skin tear. It is important to identify patients at risk of skin tears and to institute prevention practices (Sussman and Golding, 2011; Sussman, 2016).

The other issue is maintaining good skin tone by the use of appropriate moisturizing agents to ensure suppleness and to minimize the drying effects of the ageing process on the skin. Recent studies in the *British Journal of Dermatology* have shown that

aqueous creams have a significant increase in transepidermal water loss, and another study reported impacts on cellular and molecular level of the skin. Soap should also never be used as most common soaps are alkaline and have pH from 9 to 12, which will have impact on both permeability barrier formation and skin antimicrobial defense. There are newer liquid detergents with pH in the available acid range (Carville et al., 2014; Mohammed et al., 2011; Tsang and Guy, 2010).

Acute and Simple Wounds

Most wounds resulting from trauma can be managed and treated as part of everyday practice. The critical aspect of emergency first aid is to be aware of your own limitations and know when to refer on to the local medical practitioner or hospital. There are some simple rules for the management of such wounds, covering decontamination, cleansing, hemostasis, wound closure, and dressings bandages.

The types of wounds most commonly seen in pharmacy practice fall into the following categories:

- Lacerations cuts: minor lacerations, major lacerations.
- Grazes.
- Bites: Insect/animal bites.
- Burns: sunburn scalds; superficial burns, partial thickness or full thickness.
- Postoperative wounds: hospital setting or home setting.

Management of Simple Trauma Wounds

In most of the trauma, stop the bleeding by either direct pressure or by the application of a hemostatic alginate dressing, e.g., Kaltostat™, then clean the wound with water or saline, dry and apply a simple waterproof island dressing. If the injury is contaminated, then after cleaning the wound apply a topical antiseptic, e.g., povidone iodine, leave on for 3–4 min, and wash off and apply the dressing. In the case of a laceration if necessary apply several strips, e.g., Steri strips™ to hold the edges in place. If the laceration is large or deep, dress the wound and then refer the patient to a GP or hospital.

Burns

Many burn injuries are minor in nature. They involve pain, discomfort, and disruption to the patient's normal routines of life. Most minor bums will heal spontaneously without any major consequences.

On the other hand, major bums are different, in that they are associated with scarring functional defects, psychological problems, cost to the community, and contractures. It is essential with major burns to establish an accurate diagnosis as to the cause and extent of damage.

Primary Requirements

It is most important to obtain

- type of burn thermal burns, chemical burns, cold injuries
- depth and area of burn
- general medical status of the patient.

Pathophysiology of Burns

The degree of injury will depend on the temperature of the burning agent and the duration of application. The site of the burn (with regard to thickness of skin/keratin layer) will also influence the resultant injury. Certain agents are more likely to cause deeper burns, in particular, electrical burns or flame. Likewise, it is possible for a partial thickness burn to convert into a full thickness burn even when the source of the burn is removed unless the area is cooled then the dynamic heat in the burn will cause deeper damage.

First Aid

Removal from the burning agent is essential first aid in the case of electrical bums. Flush with cold running water for 30 min in order to cool the burn tissue wash away any chemical agents. Care with hypothermia in the young and the elderly do not use ice. Wrap the burned area in a clean, absorbent dressing sterile if possible (e.g., foam). If the burn area is greater than 15% in adults, or 10% in children, it is advisable to transfer the patient to a burns unit. Medical assistance is necessary in major burns of all sizes.

In simple burns, after the cool water treatment apply either a sheet or amorphous hydrogel to maintain the coolness to the burn. In some cases, it may be necessary to apply a silver dressing as the major issue with the burn is infection (Cuttle and Kimble, 2010)

Infection Versus Contamination

It is important to determine if a wound is infected before treatment is initiated. Most chronic wounds with tissue loss are contaminated, but this contamination only becomes significant when local defences can no longer contain the bacterial growth. Therefore, culturing is of little use unless true signs of infection are present. Many strains of bacteria will be found, but this is not an indication of true infection, only contamination (International Wound Infection Institute (IWII), 2016).

The following signs and symptoms of infection are well known:

- Induration
- Fever
- Erythema
- edema

Monitoring for infection in acute wounds, such as surgical wounds and burns, is of great importance. Wounds that are considered contaminated by virtue of their location and procedure are at particularly high risk. In these cases, prophylactic antibiotics are indicated. For management, see antibacterial dressings (International Wound Infection Institute (IWII), 2016; Sussman and Weller, 2006).

Wound Dressing and Bandages

The choice of dressing will depend on the wound it is to be applied to and what the dressing is required to achieve. Once a correct diagnosis of the wound is done, then the wound condition, wound type, exudate level, depth, and potential bacteria are considered and the choice will depend on the ability of the product to address these issues.

Passive Dressings

For many years, the products used were of the "passive" or the "plug and conceal" concept including gauze, lint, nonstick dressings, and tulle dressings and fulfil very few of the properties of an ideal dressing, have very limited (if any) use as primary dressing, but some are useful as secondary dressings (White, 2006). It is clear that there are a number of negative aspects in the use of gauze.

- Gauze a fibrous material sheds readily to contaminate the wound.
- Gauze is absorbent and will tend to dry the surface of the wound
- Gauze is permeable to bacteria, and moist gauze does tend to be an environment for the growth of bacteria.
- Gauze is also adherent and will further traumatize the wound on removal risking damage to granulating tissue and pain.

In addition to gauze, lint, and cotton dressings, other simple modified absorbent pads covered with a perforated plastic film to prevent adhering to a wound such products include Melolin,™ Cutilin,™ and Telfa™ are used both as primary and secondary dressings. They are used in minor and low exudating wounds.

Modern inert more absorbent dressings, e.g., Exudry™, Mesorb™, and Zetuvit plus ™ are products with a highly absorbent pad and a nonstick nonshear surface. It can be used as secondary dressing over moderate to highly exudating wounds (White, 2006).

Tulle Dressings

These are nonabsorbent passive dressings, e.g., paraffin gauze (tulle) dressings are among the earliest dressings, the older style of these dressings are no longer considered appropriate as they are open weave in construction and allow tissue to pass though causing them to stick to the wound and cause trauma on removal they may lead to maceration in that exudate may not pass through and be trapped within the wound. They also require a secondary dressing. They are also used as a primary dressing over skin grafts. Newer forms of Tulle have been developed by changing the composition to synthetic fibers tightly meshed and impregnated with materials that allows moisture to pass through minimizing maceration, e.g., Adaptic™ and Cuticerin™, and Atrauman™ (White, 2006). There are also silicone-coated forms for fragile skin, e.g., Mepitel, adaptic silicone.

Interactive Dressings

These dressings help to control the microenvironment by combining with the exudate to form either a hydrophilic gel or by means of semipermeable membranes, controlling the flow of exudate from the wound into the dressing. They may also stimulate activity in the healing cascade and speed up the healing process.

There are six classes of interactive dressings and are classified according to their functionality (White, 2006).

Film Dressings (for Wounds With no to Low Exudate)

These dressings consist of a thin, polyurethane membrane coated with a layer of acrylic adhesive and island version with a pad

- waterproof
- gas/vapor permeable
- flexible, transparent
- protects from shear, friction, chemicals, microbes
- spread tension forces

They are useful in superficial, clean wounds and in the prevention of breakdown and preulcers in pressure wounds. They are also used as a postoperative dressing over sutures and to reduce subtissue tension over closed sutured wound after removal of the sutures or clips, e.g., clued Opsite,™ and Tegaderm,™. If there is a small amount of exudate in the wound, then an Island film that include a nonstick pad is the best, e.g., Opsite post op and™ Tegderm™ with a pad (White, 2006).

Absorbing Dressings

Hydrocolloid Dressings (for Wounds With Low Exudate)

Hydrocolloids are a combination of polymers held in a fine suspension and often contain polysaccharides, proteins, and adhesives. When placed on a wound, the polymers combine with the exudate and form a soft, moist gel-like mass. They also encourage autolysis to aid in the removal of slough from a wound.

- *flexible, thin available (transparent), waterproof*
- provide physical barrier
- gel with exudate
- debriding
- no secondary dressing

Hydrocolloids should be applied over the wound with at least 3–4 cm extra product greater than the size of the wound. The skin should be dry and free from creams, ointments, or oil to ensure good adhesion. The dressing should be placed 1/3 above the wound and 2/3 below it, this will prolong the wear time of the dressing. The dressing can remain in place for up to 7 days, the removal will depend on the level of exudate and are removed when strikethrough has occurred, i.e., the exudate has migrated to the edge of the dressing. Please note that these dressing are contraindicated in diabetic wounds. Hydrocolloid products are used in low exudating wounds, including ulcers and granulating wounds. The paste or powder forms are used in a deeper ulcer or cavity. These convert to the same hydrophilic gel and are covered with the normal hydrocolloid wafer, e.g., Duoderm®/Comfeel™ and Hydrocoll® (White, 2006).

Foam Dressings (for Wounds With Medium to High Exudate)

These products are soft, open celled hydrophobic/hydrophilic nonadherent dressings that may be single or multiple layers and meet many of the properties of an ideal dressing,

- Absorbent allows the passage of exudate through the nonadherent surface to be absorbed in the main body of the product
- maintain a moist environment
- Thermally insulating
- Cushioning
- Nonadherent
- Nonresidual

Foams are mainly used in moderate to heavily exudating wounds, including ulcers, donor sites, and minor burns, and they act as a secondary dressing, particularly as a covering with the use of amorphous hydrogels

In addition to standard and waterproof foams, there are also shaped cavity devices, which may be inserted into cavity wounds or dehisced surgical wounds, e.g., Lyofoam Max™, Allevyn™, and PermaFoam®.

Foams are also available with a soft silicone coated surface, this allows the dressing to adhere to the skin but are able to be removed without trauma this of particular importance in patients with fragile skin reducing the risk of trauma on removal, e.g., Allevyn Life™ and Mepilex® (White, 2006).

Hydroactive Dressings *(Foam-Like)* (for Wounds With Medium to High Exudate)

These multilayered highly absorbent polymer dressings some with a surface adhesive are similar to foams; however, instead of absorbing exudate by a simple syphon action, the exudate is trapped within the product itself allowing the polymer to swell, they are

- highly absorbent polymer dressing maintain a moist environment.
- waterproof
- expandable
- nonresidual

Hydroactive dressings are indicated for use in highly exudating surface and cavity wounds including leg ulcers and pressure wounds. They are particularly useful over joints such as elbows, knees, fingers, and toes due to their ability to expand and contract without causing constriction. Hydroactive dressings are not indicated for dry or lightly exudating wounds, e.g., Cutinova Hydro™, Biatane™, Tielle™, and TenderWet Active® (White, 2006).

Alginate Dressings (for Wounds With Medium to High Exudate)

Alginates are the calcium or sodium/calcium salts of alginate acid, obtained from seaweed. There are two forms the gel produce with be either firm or soft. When applied to a wound, the sodium salts present in the wound exchange with the calcium in the alginate to form sodium alginate a hydrophilic gel. This gel has the ability to absorb exudate into itself while maintaining a moist environment.

- highly absorbent
- form gel with exudates
- moist interface
- easily removed
- hemostatic (some)

Some alginates are used on donor sites, bleeding sites, e.g., Kaltostat® and Algisite M™, and also in exudating wounds, e.g., Kaltostat®, Algisite M™, Sorbsan™, and Comfeel Seasorb™ (White, 2006).

Alternate Fiber Dressings (for Wounds With Medium to High Exudate)

These dressings have some of the properties of alginates, and they come as a fiber rope or dressing that forms a firm gel in contact with fluid.

- Synthetic fibrous mat—forms a firm gel in contact with exudate
- highly absorbent
- no lateral wicking—protects peri-skin

Aquacel™ Durafiber®, Exufiber® (White, 2006)

Hydrogels (for Dry or Sloughy Wounds)

Hydrogels have the properties of both rehydrating dry tissue and absorbing certain amounts of fluid into themselves. They are provided as either amorphous gels or sheet forms. They are used to help rehydrate slough and necrotic tissue to aid in the autolytic debridement. They are also used in the management of burns, including sunburn, scalds, and other partial thickness burns. Amorphous hydrogels have also been used in the management of chicken pox and shingles, and are applied to the eruptions three to four times a day. They provide a moist environment and relieve the discomfort of the lesion and also reduce the probability of scarring. Hydrogels are also available in sheet form consisting of a cross-linked polymer and water held in a backing. These products are particularly useful in the management of burns and also to aid the management of in pressure wounds, e.g., IntraSite gel™, Purilon Gel™, Solosite™, DuoDERM Gel®, Solugel™; Nugel Hydrogel Sheet, e.g., Hydrosorb™, Nu-gel™ (White, 2006).

New Hydrogels

Flaminal® hydrogels are based upon gelled alginate and not on other polymers Flaminal® hydrogels use the enzymes glucose oxidase and lactoperoxidase to control the bioburden and acts as an important natural antimicrobial (Banks et al., 1986). They have been shown to be bacteriostatic against Gram-positive organisms and exhibit pH-dependent bactericidal action against Gram-negative organisms in the presence of hydrogen peroxide and thiocyanate (Fleischer and Reimer, 1997; Vandenbulcke et al., 2006).

Antibacterial Dressings

Antiseptics are completely nonselective and have the potential to damage all cells. These compounds can be bactericidal or bacteriostatic, and they may inhibit reproduction, inhibit metabolic activity, change pH, and liberate oxygen—mechanical effects. They come as both organic and inorganic compounds.

In open wound, there is some risk of systemic absorption. There are a number of specialized antibacterial dressings for use in particular wound types (International Wound Infection Institute (IWII), 2016).

Iodine

Iodine in its various forms has been used as a topical antiseptic since 1840.

The newer forms of iodophores have been used since the 1950s. Most of these new forms combine iodine in a complex with a polymer, e.g., Povidone and Cadexomer, which slowly release the iodine. Iodine is active against bacteria, mycobacteria, fungi, protozoas, and viruses. There is no evidence of resistance to iodine (Leaper and Durani, 2008; Sibbald et al., 2011).

Cadexomer Iodine Dressings

This is a nontoxic iodophor that combines iodine with a polysaccharide polymer. When applied to the wound, the iodine is released over 72 h at 0.1% (not cytotoxic). The iodine and absorbes exudate—forms gel, breaks down slough, kills bacteria, and stimulates wound healing.

It is used for sloughy/infected wounds, diabetic wounds, recalcitrant wounds, and may stimulate growth factors, e.g., Iodosorb®/ Iodoflex® (Fitzgerald et al., 2017; Leaper and Durani, 2008; Malone et al., 2017; Mertz et al., 1999; Schwartz, 2013; Sundberg, 1997).

Inadine

This dressing consists of a low adherent knitted viscose fabric impregnated with a polyethylene glycol (PEG) base containing 10% povidone iodine; equivalent to 1.0% available iodine.

Inadine® dressings are designed to protect the wound, even if infected. Inadine® is indicated for the management of ulcerative wounds and may also be used for the prevention of infection in minor burns and minor traumatic skin loss injuries (Sibbald et al., 2011; Sibbald and Elliott, 2017).

Povidone-Iodine

A commonly used antimicrobial agent is povidone-iodine, a complex of iodine, the bactericidal component, with polyvinylpyrrolidone (povidone), a synthetic polymer. The most common commercial form is a 10% solution in water yielding 1% available iodine. Povidone-iodine is available as a surgical scrub or skin cleanser with a detergent base (0.75% available iodine) or in other forms, e.g., Betadine® (Durani and Leaper, 2008; Fleischer and Reimer, 1997; Sibbald et al., 2011).

Silver

Silver has been used for many years, and it has proven to have a broad-spectrum antimicrobial activity, and they inactivate most bacteria including MRSA and VRE.

No documented cases of bacterial resistance have been reported.

Silver has been used in particular in the treatment of burns as a silver sulphadiazine cream. This cream has also been applied to some wounds. Contemporary silver dressings allow for continued release up to 7 days. The difficulty is that the cream must be formulated to be applied to intact skin. When applied to a wound, it encourages the development of muscilagenous slough on the wound surface and is now not used as frequently.

The level of silver contained in the various dressings varies greatly. Their mode of action also varies some release the silver into the wound and some partly release the silver and hold some in the dressing and some keep the silver within the dressing. The choice of dressing will depend on the level of infection, the size, depth, and amount of exudate. Silver dressings may be based as high-density polyethylene dressings, foam dressing, alginate dressing, hydroactive dressing, hydrofiber dressing, or tulle dressing, e.g., Acticoat®, Mepilex Ag®,Biatain Ag®, Aquacel Ag™, and Urgotul SSD (Lansdown, 2002a; Lansdown, 2002b).

New Antiseptics

Polyhexanide methyl biguanid (PHMB) is related to chlorhexidine but has superior antimicrobial effect to other cationic biocides. As with the biguanides, PHMB was shown to bind rapidly to the envelope of both Gram-positive and Gram-negative

bacteria, and in doing so displaces the otherwise stabilizing presence of Ca++. It is available as a cleaning solution in combination with a surfactant or as a topical dressing as a foam or a sheet gel, e.g., Prontosan® (Andriessen and Eberlein, 2008; Butcher, 2012; Hübner, 2010).

Dialkylcarbamoylchloride Coated Fiber (DACC)

DACC is presented as a fiber coated with a fatty acid DACC that has selective binding of microorganisms and only binds pathogenic microorganisms. This is a rapid action binding bacteria and fungus within 15–30 s, continues to bind and does not become saturated. Bacteria and fungus bind to surfaces via hydrophobic interaction. As this product does not contain any antiseptics, it is a natural process with no risk of resistance. No known side effects and no negative environmental effects. This product comes as a sheet, ribbon, gel, goam, high absorbent dressing, and a silicone dressing, e.g., Sorbact® (DACC, 2017; Ljung et al., 2006; Meuleneire, 2012).

Octenidine

Octenidine dihydrochloride is a cationic surfactant, with a gemini-surfactant structure, derived from pyridine, active against Gram-positive and Gram-negative bacteria. Octenidine is not absorbed through the skin, nor through mucous membranes, or wounds. It is available as a solution or gel, e.g., Octenaline® (Braun et al., 2014; Hämmerle and Strohal, 2016)

Hypochlorites and Hypochlorous Acid

Sodium hypochlorite was used for many years as an antiseptic, for example, being EUSOL and Dakins Solution. Its use has mostly been discontinued due to its toxicity. Hypochlorous acid is a more recent form of chlorine/oxygen antiseptic that is considered as less or nontoxic, e.g., Microdacyn® (Cheryl, 2016).

Other topical antiseptics have been used in clinical practice including hydrogen peroxide, acetic acid, citric acid, and clorhexidine with or without cetrimide. Most have only limited use.

For recommendation for antiseptic use see **Table 1**

Most topical antiseptics are cytotoxic to tissue and cells; this must be considered when choosing an antiseptic for application to a wound. In the case of acute wounds, they are best applied left in place for 3 to 4 min then washed off. In the case of application to a chronic wound, then the choice should be to use a nontoxic or minimally toxic product (Kempf et al., 2011; Zhong, 2015).

Bandages and Bandaging

Bandages may be used for a number of purposes: keeping a dressing in place (retention), supporting an injured joint (support), assisting venous return in the lower leg (compression), providing a pressure gradient to encourage the flow of blood back to the heart and reduce edema and swelling by compression, as a prophylactic in sports to prevent injury, as a pressure bandage to help control bleeding, and postsurgically to help control venous oozing (Sussman, 2003; Thomas, 1990).

Table 1 General rules for the topical use of antiseptics

Wound Type	*Management*
Cut/laceration	Clean the area with water or saline. If there is any contamination use a surfactant antiseptic, e.g., Savlon® or Betadine scub® to remove any foreign material that may be a focus for infection. Apply an antiseptic around the area and cover with a simple dressing, e.g., a film dressing
Graze	Due to the presence in most grazes of dirt, gravel And other material, scrub the area with a surfactant antiseptic, e.g., Savlon® or Betadine scrub®. Apply an antiseptic around the wound and cover With either a film dressing or an Island Film dressing.
Burn	Most minor burns do not require the use of a topical antiseptic. The use will depend on the depth of the burn and if there is damaged and necrotic tissue present. If there is, then the use of a silver dressing is considered appropriate in the early management. If the burn is minor and there is little tissue damage, e.g., minor blisters then apply an amorphous or sheet hydrogel
Chronic wounds, e.g., Leg ulcers and Pressure wounds	The most important issue with any chronic wound is to clearly identify the underlying cause. In general chronic wound need to be managed by a wound specialist. The pharmacist role is to help with product selection using the rules above and identify the need for recommending specialist help if the wound is not progressing.

Retention Bandages

The role of the retention bandages is effectively to hold a dressing in place. For this purpose, for many years, cotton crepe bandages have been used to hold dressings in place. However, today, there are a number of more effective and appropriate bandages that may be used to hold a dressing in place. The first is the light weight conforming cohesive bandages coated with a thin latex. As a result of this coating, the bandage sticks to itself but not to skin, hair, or clothing. You only require a very small length to hold the dressing in place, compared with using a complete roll of a standard crepe bandage. This type of bandage comes in widths that are appropriate for fingers and toes and also for limbs and larger size for the head. The bandage becomes very cost-effective in that you do only need to use a small amount each time when holding the dressing in place. Examples of this type of bandage are Handigauze Cohesive® and Easy Fix Cohesive® (Sussman, 2003; Thomas, 1990).

The other type of product is the elasticized tubular bandage available in a light weight form that may be cut to the size required and be placed over the dressing, again holding it in place. An example is Tubi Fast®.

Support Bandages

Support bandages are of a heavier construction and are made from both natural and synthetic fibers. They achieve their stretch by the use of high twist yarns and the heavier construction. The main role of strong support bandages is the support of joints in strains and also in the management of muscular injuries. Examples of this type of bandage are the heavy duty crepe bandage, such as Elastocrepe® and Handycrepe®; however, they are of limited use as they do not maintain compression heavier weight cohesive bandage that are able to provide the support with only a few layers and provide about 25 mmHg of compression, e.g., Coban®, Coplus®, and Handygrip® (Sussman, 2003; Thomas, 1990).

Tubular Compression

There are two types of tubular compression bandages: straight or shaped.

Straight tubular compression provides approximately 8 mmHg, and the shaped tubular compression provides between 18 and 20 mmHg at the ankle.

To apply either bandage, invert a length of the bandage equivalent to the length of the patient' foot. Slide the bandage on up to the ankle. Grasp the dangling end of the bandage and in one motion slide the rest of the bandage over the foot and up to the knee. Multiple layers of straight tubular bandage are used for compression, e.g., Tubi Grip®, Handyplast Tubular®, and Tensogrip® (Sussman, 2003; Thomas, 1990).

Compression Bandages

Compression bandages are used as one of the main treatment modalities in the management of venous disease, especially where there's an association between venous ulcers and varicose veins both to aid the healing of the ulcer and ultimately in the management of the venous return to help prevent reformation of a venous ulcer. Effective therapeutic compression starts with a subbandage pressure of 18 mm of mercury at the ankle. Anything lower, while appropriate for support, is not considered appropriate for the treatment of venous leg ulcers or their prevention. The primary aim of compression is to reduce the pressure in the superficial veins to encourage venous return to the heart by increasing the velocity flow in the deep veins, also discouraging edema by reducing the pressure difference between the capillaries and the tissue. The most effective method is to apply graduated compression from the toe to the knee. The highest pressure should be exerted at the ankle, gradually falling to about 50% at the knee. The accumulated fluid and waste products are removed from the affected tissue by the accelerated rate resulting from the application of the pressure bandage. Compression bandages are also used in the management of lymphedema and in sport soft tissue or joint injury (Sussman, 2003; Thomas, 1990).

There are two types of compression bandages are available

High Stretch Compression Bandages

These have an extensibility from 130% to 200%, have high elasticity, high to medium resting pressure, and high to medium working pressure. They exert their effects mainly superficially in working combination with the muscles, and they are indicated for the treatment of venous edema and the management of venous ulcers. Examples of high stretch compression bandages include Tensopress®, Setopress®, Surepress®, and Eloflex®. High stretch must only be applied with a spiral technique with a 50% overlap of layers. These bandages apply compression of between 30 and 40 mmHg at the ankle (Sussman, 2003; Thomas, 1990).

Short Stretch Bandages

These have an extension from 30% to 90%, low elasticity, low to slight resting pressure but high to very high working pressure. They exert their effects mainly deep within the limb and they are indicated for both venous edema and lymphedema. Examples of short stretch bandages are Comprilan® and Tensolan®, which may also be applied in figure of eight manner (gives more compression and stays in place better). These bandages only apply pressure when the wearer is active and the calf muscle is being used. If inactive, little extra pressure is applied (Sussman, 2003; Thomas, 1990).

Other Forms of Compression

The other forms of compression garment include the straight tubular bandage. When used for this purpose, it is usually applied in multiple layers commencing with a full bandage from toe to below knee, a second from toe to mid-calf and a third from toe to ankle. This type of product is also available in a shaped version, which provides the graduated compression. The application of a single layer of shaped tubular bandage will produce from 18 to 24 mm of mercury, and this may also be used in multiple layers. To apply bandage, invert a length of the bandage equivalent to the length of the patient's foot. Slide the bandage on up to the ankle. Grasp the dangling end of the bandage and in one motion slide the rest of the bandage over the foot and up to the knee. When applying three layer straight tubular bandage use the following method; Layer one from Toe to Knee, Layer two over layer one from Toe to mid-calf, Layer three over layer two from Toe to just above the ankle bone. This will provide 24 mmHg at the ankle, 16 mmHg at the mid-calf, and 8 mmHg and the knee (Sussman, 2003; Thomas, 1990; Weller, 2012).

Multilayer Bandages

A recent development in bandaging has been the introduction of the Charing Cross fourlayer system. This combines an orthopedic wool, a crepe bandage, a compression bandage, and a cohesive bandage in multiple layers. This combination achieves 40 mm of mercury at the ankle, graduating to 17 mm of mercury at the knee. A number of published studies have shown good healing rates in 12 weeks with this particular system. The example of the multilayer system available is Profore®, Profore Lite®, Coban-2®, and Coban-2 lite® (Sussman, 2003; Thomas, 1990).

Farrow wraps are a newer form of compression that allows a more simple method of application. In cases where the patient is unable to wear compression, then the use of intermittent pneumatic compression devices may be considered.

Contraindication for the Use of Compression Bandages

Great care must be taken before applying compression where there is an indication of arterial disease. It is therefore important that before compression bandages or similar are used on the patient, that their peripheral arterial circulation is checked to ensure that they may not be compromised by the application of compression bandages. Some of the hazards of the use of compression can include skin necrosis, direct trauma, and ulceration from inappropriately applied compression bandaging and ultimately, where used inappropriately leading to amputation. If you do not have a Doppler available to obtain the ABI, then simple observation will help identify potential risk patients. If any of the negative signs are observed, then do not apply compression until a proper vascular assessment is done (Sussman, 2003; Thomas, 1990). All bandages for compression should be applied from the base of the toes to the knee (finishing at the lower edge of the patella). The actual stretch in the bandage for compression begins at the ankles.

Caution

It is essential when applying a compression bandage to a leg, especially where there is unevenness of circumference that the area around the ankle in particular is padded out with orthopedic wool to ensure even distribution of the compression along the leg. This is to reduce the risk of damage from the bandage or if the patient has inverted champagne bottle legs (Sussman, 2003; Thomas, 1990).

Compression Stockings

Compression stockings are used in the management of venous disease post-ulcer healing and in the treatment of lymphedema. Stocking are also used to prevent and treat deep vein thrombosis for many years; antiembolic stockings have been used in hospitals pre and postsurgery to help prevent DVT's More recent studies have questioned their role, and the use of low molecular weight heparin in combination with them or with calf stimulation is seen as a better option. Once the patient is fully ambulating, antiembolic stocking have no role as they only provide 6–8 mmHg compression when the minimum required is 18 mmHg (Kapelle, 2011; Mosti et al., 2011; Patel et al., 2013).

Table 2 Simple leg physical circulation assessment

Observation	*Positive*	*Negative*
Foot temperature	Warm	Cold
Foot color	Pink	White
Toe refill after squeezing	Fast	Slow
Foot pulse	Present	Absent

If a customer is observed to have some of the negative results they may need to be referred for a vascular assessment before compression is used. The application of compression in a patient with arterial disease is generally contraindicated.

Table 3 Recommended levels of compression

Specific condition	*Level of pressure*
Prevention DVT	18–24 mmHg
Superficial/early varices	
Medium varices	25–35 mmHg
Ulcer prevention	
Mild oedema	
Gross varices	35–45 mmHg
Postthrombotic syndrome	
Gross oedema	
Ulcer treatment	
Lymphoedema	35–50 mmHg

Stocking Measurement

The measurement should be taken with the patient standing and as early in the day as possible after the leg has been rested and when any tendency for the leg to swell is a minimum. If this is not possible, and particularly if there is evidence of edema, the limb should be raised in a horizontal position until the swelling has subsided. If the edema is a severe problem, the patient may need to be remeasured for a smaller sized stocking when the initial garment begins to reduce the swelling (Sussman, 2003; Thomas, 1990).

Conclusion

The pharmacist has an important role as a primary health provider in both the areas of wounds and skin diseases. It is essential for them to have a sound knowledge of all aspects of the wound healing process and are in fact the product advisor of treatment (**Tables 2 and 3**)

Direct Oral Anticoagulants and the Patient-Reported Outcomes: Synthesis and Advances

Saima Afzal, Syed Shahzad Hasan, Zaheer-Ud-Din Babar, University of Huddersfield, Huddersfield, United Kingdom

Introduction

Atrial fibrillation is the most commonly seen arrhythmia in patients in Europe. Patients with AF are at an almost four times higher risk of stroke, which is a leading cause of morbidity with significant disability and mortality in the United Kingdom (Kirchhof et al., 2016a). Treatment and prevention of venous thromboembolism is another problem within the United Kingdom requiring anticoagulation, which particularly occurs postorthopedic surgery of due to prolonged hospitalization stays (Miesbach and Seifried, 2012). Vitamin K antagonist, warfarin, has previously been the standard treatment of venous thromboembolism and prophylaxis of stroke from atrial fibrillation. The introduction of novel direct oral anticoagulants in the past decade has transformed anticoagulant treatment providing alternatives to the complicated monitoring and resource intensive warfarin treatment. Patient-reported outcomes (PROs) are a distinctive method of evaluating patient's response to health care or treatment, such as patient satisfaction, adherence, and quality of life. The chapter aimed to analyze the impact of PROs in patients on DOAC treatment using a systematic searching of PUBMED, CINAHL, EMBASE, SCOPUS, Google Scholar, and Springer Link databases.

Twenty-one original studies (6 controlled trials and 15 observational studies) were included from 3231 screened studies. Health-related quality of life (HRQoL) was assessed by 6 (n = 1 for controlled trials and n = 5 real-world studies) studies and reported that HRQoL scores were similar in patients on DOACS and warfarin. Patients prescribed with DOACs presented higher HRQoL scores, which were attributed to lack of intense monitoring required compared with warfarin but this was not statistically significant. The majority of studies (n = 5 for controlled trials and n = 9 for real-world studies) investigated patient-reported satisfaction indicating greater satisfaction with DOACs with significantly lower burden and increased benefit scores for patient on DOACs. Patient-reported expectations, compliance, and adherence were similar for patients on DOACS and warfarin. Patients appear to prefer treatment with DOACS versus warfarin. This has been exhibited by the higher QoL, satisfaction, and adherence described in the studies. This enhanced patient preference of treatment would in turn increase adherence, thereby significantly reducing costs associated with the complications.

This chapter provides an overview of the use of PROs in anticoagulant treatment and has categorized an increasing body of evidence to establish the importance of PROs in patients treated with DOACs.

Advances in Anticoagulants Use

Vitamin K antagonist, warfarin, has been the mainstay of treatment for venous thromboembolism (deep vein thrombosis and pulmonary embolism) and nonvalvular atrial fibrillation for prevention of stroke. The introduction of new (or direct) oral anticoagulants over the past decade has revolutionized the treatment and thromboembolic conditions. These direct oral anticoagulants (e.g., apixaban, rivaroxaban, dabigatran, and edoxaban) have made rapid progress in revolutionizing anticoagulation and been extensively investigated and researched in clinical trials for their clinical effectiveness and safety profile in comparison with standard treatment (Brunton et al., 2018).

Use of warfarin effectively is associated with a significant reduction in the risk of stroke and mortality associated with AF (Brunton et al., 2018). However, warfarin use is limited by its narrow therapeutic index requiring regular monitoring of INR,

multiple drug interactions, and dietary restrictions (Gomez-Outes et al., 2013). DOACs have also been recognized as a safe and effective treatment option in thromboprophylaxis postorthopedic surgery. However, these agents have been known to carry a potential risk of bleeding with no actual method of anticoagulation reversal (Miesbach and Seifried, 2012; Saliba, 2015).

Vitamin K antagonist (warfarin) was first approved for human use in 1954 and proved to be a cornerstone in the treatment of atrial fibrillation and stroke prevention (Pirmohamed, 2006). Until recently, warfarin has been the mainstay of therapy and was recognized as being the only oral pharmacological treatment option available for long-term management of nonvalvular atrial fibrillation and prevention of ischemic stroke.

Direct (or new) oral anticoagulants were introduced to the UK market in the past decade. Dabigatran was the first agent approved for use for patients with nonvalvular AF and stroke prevention. It exerts its activity through competitive direct inhibition of thrombin (Miesbach and Seifried, 2012). Dabigatran was first approved for use within the United Kingdom for AF and VTE in 2011 following results of the RELY trial (Connolly et al., 2009). Rivaroxaban, apixaban, and edoxaban exert their effects by reversible and direct inhibition of Factor Xa in the clotting cascade. Rivaroxaban approval followed showing noninferiority to warfarin for the prevention of AF and VTE in the ROCKET AF study in 2011 (Patel et al., 2011).

The ARISTOTLE trial led to the licensing of apixaban in 2012 showing that apixaban was superior to warfarin in preventing stroke in AF patients and VTE (Granger et al., 2011). Edoxaban was approved in 2015 after the result of the ENGAGE-AF trial displaying noninferiority of edoxaban to warfarin (Giugliano et al., 2013). These clinical studies emphasized the clinical efficacy of the DOACs versus warfarin with the enhanced benefit of a reduced intracranial and major bleeding however showed a higher risk of GI bleeding. Nevertheless, the European society of Cardiology and NICE have recommended DOACs as a suitable option for nonvalvular AF over warfarin (Kirchhof et al., 2016b; NICE, 2016). DOACs are accredited with a number of advantages over warfarin. These include the achievement of rapid onset of action negating the need for bridging anticoagulation. DOACs have a relatively short half-life, therefore allowing ease of anticoagulation control. There are little food–drug and drug–drug interactions with DOACs therefore reducing dietary and other medication restrictions.

The principle benefit of DOAC treatment is the predictable pharmacokinetics displayed by these agents therefore removing the need for blood monitoring and dose adjustment. Hence, these agents are fast becoming the anticoagulation treatment of choice for prescribers in order to enhance patient satisfaction and adherence (Miesbach and Seifried, 2012). In comparison to warfarin, however, DOAC treatment is significantly more expensive, and the lack of monitoring has led to questions of adherence and ensuring clinical effectiveness. This has led to the establishment of patient-reported outcomes in anticoagulation and is an optimal method to assess patient adherence and overall clinical effectiveness of the treatment.

Patient-Reported Outcomes

PROs offer a unique perspective of treatment effectiveness without the invasive blood testing and monitoring requirements associated with warfarin. These can often be more reliable that physiological parameters and informal interviews through the use of optimal validated tools as a method of categorizing and measuring patient outcomes (Valderas et al., 2008).

PROs are testimonies from the patient about how they feel about any particular condition or treatment they are receiving without any intervention or bias from the clinicians (Green and Higgins, 2005). PROs include any evaluation of treatment or outcome directly from patient interviews, questionnaires, or specifically developed tools to capture and enable analysis of valuable patient-reported data. PROs provide valuable data from the patient's perspective and are sometimes used as primary outcomes from clinical trials. However, more often PROs are conveyed as subanalyses after the initial trials have been published (Doward and McKenna, 2004).

Tools for Measuring Patient-Reported Outcomes

PROs are subjective measures relating to patent experience and quantify assessment of patient satisfaction, adherence, or HRQoL (Kingsley and Patel, 2017). HRQoL can be defined as an evaluation of impairment, disability, or handicap (Doward and McKenna, 2004; Wang et al., 2015). Patient satisfaction determines perceived burden or benefits of the perceived treatment being appraised (Doward and McKenna, 2004).

PROs can be collected using validated tools or instruments to ensure the data obtained are valid and reliable. A number of tools have been developed and utilized to quantify or measure PROs. These include the EuroQol 5-dimension 3 level, (EQ-5D-3L), Visual Acuity Score (VAS), and the Sawicki questionnaire to assess HRQoL (Devlin and Krabbe, 2013; Sawicki, 1999; Wang et al., 2015). The Anticlot Treatment Scale (ACTS), Treatment Satisfaction Questionnaire for Medication (TSQM), and Perception of Anticoagulation Questionnaire (PACT) are tools used to assess satisfaction (Atkinson et al., 2004; Cano et al., 2012; Prins et al., 2009). The Duke Anticoagulation Satisfaction Scale has been specifically developed to measure both satisfaction and HRQoL (Samsa et al., 2004; Wild et al., 2008). Patient-reported adherence can be evaluated using self-report scales, such as the Morisky 4- or 8-item adherence scale (Tan et al., 2014). These tools measure disease or treatment-specific objectives describing severity of symptoms, benefit, adverse drug effects in order to capture the patients' well-being and experience with the intervention. Such tools have been developed to measure PROs in patients-receiving anticoagulation and have been scrutinized and validated prior to use.

DOACs and Patient-Reported Outcomes: Evidence Synthesis Method

The review process was conducted by applying the eligibility criteria to examine abstracts of original journal articles published in English that (1) PROs and (2) new or direct oral anticoagulants (DOACs), namely, apixaban, rivaroxaban, dabigatran, or edoxaban were included. Finally, abstracts had to report PROs based on a recognized PRO tool with measurable outcomes. The following types of studies were excluded: review articles, observational studies, and articles on compliance or persistence, which focussed on tablet count or prescription monitoring (Appendix 1).

For population attributes, studies were included that assessed PROs in adults being treated with a DOAC. The search was restricted to studies involving humans and original journal articles. Titles and abstracts were screened to remove studies that were irrelevant to the aim of the review, and full texts of the remaining studies that analyzed the required data but did not utilize a recognized PRO tool were excluded.

The following databases were searched between September 2018 and October 2018 with no filters set on publication date: PubMed (United States National Library of Medicine), Cumulative index to Nursing and Allied Health Literature (CINAHL—Elsevier, Amsterdam, Netherlands), MEDLINE (Medical Literature Analysis and Retrieval System Online, or MEDLARS Online), Embase (Excerpta Medica database) from 1974 until September 2018, SCOPUS, and Springer Link databases. Google scholar was also searched to identify articles not indexed in scientific databases. References cited in the reference list of each identified original research were scanned for any additional articles that would be relevant to this review; these were subsequently also scanned for reviews and studies, which may have been relevant and which were subject to the same eligibility evaluation.

The search strategy identified original research on patient-reported outcomes associated with the use of new or direct oral anticoagulants. Search terms were Anticoagulant* OR oral anticoagulant* OR novel oral anticoagulant* OR Non Vitamin K antagonist oral anticoagulant* (NOAC) OR vitamin K antagonist oral anticoagulant* OR coumarin* OR dabigatran OR rivaroxaban OR apixaban OR edoxaban OR warfarin OR direct factor Xa inhibitor* OR direct thrombin inhibitor* AND Patient reported outcomes OR patient reported satisfaction OR patient reported adherence OR quality of life.

After possible studies were identified, all retrieved titles were screened to determine their potential relevance. The abstracts were assessed against five inclusion criteria: (1) original research studies, (2) recognized and validated tool to measure PROs, (3) patients were taking a DOAC for >4 weeks, (4) adult subjects (≥19 years of age), and (5) reported in English.

The data from all the retrieved studies were subsequently collected and tabulated using a form developed by the lead author that were verified by the second reviewer. Extracted information from studies is mentioned in **Table 1**. The extracted information included study design, study participants and settings, objectives of the study, and main findings of the study.

The outcome measures were categorized into three main groups, namely, HRQoL, patient-reported satisfaction, and patient-reported adherence/compliance or expectations related to anticoagulation treatment with DOACs.

DOACs and Patient-Reported Outcomes: Search Results

The search yielded 1964 unique abstracts from PubMed, CINAHL, Medline, and EMBASE with an additional 1321 abstracts from SCOPUS, Springer Link, and Google Scholar were identified. After removal of duplicate records, 3231 abstracts were screened. Of these, 3104 studies were excluded. Of the remaining 127 articles, 97 were excluded as they did not describe original research or did not illustrate patient-reported outcomes or focussed on warfarin alone. The search yielded 19 articles that were excluded because they involved investigations on adherence or persistence based on pill taking patters, tablet counting or prescription fill analysis rather than patient-reported outcomes.

A total of 21 studies were ultimately included in the review, 6 controlled trials and 15 observational studies (Appendix 1). The 21 studies evaluated patient-reported outcomes or quality of life, using a validated tool, associated with the use of DOACs. The controlled trials (n = 6) included 5 randomized and 1 nonrandomized trial (**Table 1**). Controlled trials were used as they provide larger-scale trials within controlled environments, however, due to being sponsored by industry often may contain an element of bias and not present the full patient overview. Real-world observational and cross-sectional studies provide actual patient experience and use of the treatment in practice. Of the 6 controlled trials, 5 were conducted in multiple countries (including the United Kingdom, the United States, Canada, the Netherlands, France, Germany, and Italy) (Bamber et al., 2013; Coleman et al., 2016; Hohnloser et al., 2016; Monz et al., 2013; Prins et al., 2015), and one was conducted in Japan (Koretsune et al., 2017). The observational studies (n = 15) used the following study designs: 11 prospective studies conducted in Spain, France, Canada, Japan, the United States, Australia, and Europe. Four of the studies were cross-sectional studies conducted in Spain, France, and Canada (**Table 1**).

Patient-Reported Satisfaction

Greater satisfaction with DOACs was reported in five of the included studies using the ACTS tool. These studies showed a significant reduction in the burden score and a higher benefits score illustrating more satisfaction with DOAC treatment (Bamber et al., 2013; Coleman et al., 2016; Hanon et al., 2016; Okumura et al., 2018; Prins et al., 2015; Suarez Fernandez et al., 2018). One study demonstrated a reduced ACTS burden score but stable or no change in the benefit score (Koretsune et al., 2017, 2018). Only two studies showed increased satisfaction in the DOAC group based on the PACT Q2 tool (Benzimra et al., 2018; Larochelle et al., 2018).

Table 1 Summary of controlled trials and observational studies

Author-year of publication	*Data collection period*	*Treatment/population*	*Study details*	*PRO assessment*	*Main findings of the study*
Randomised controlled trials					
Monz et al. (2013)	December 2005 to December 2007	*Treatment*: Dabigatran versus dose adjusted warfarin *Population*: for nonvalvular AF *Mean age*: 71.5 years *Female*: 36.4%	*Design*: RCT Subgroup of RE-LY population RE-LY = Prospective, randomized open-label, blinded end point evaluation *Setting*: 44 countries and 951 clinical centers	Patient-reported health-related quality of life using EQ-5D utility and visual analog VAS scores, assessed at baseline, 3 and 12 months	*HRQoL*: No statistically significant difference between dabigatran groups or warfarin groups Utility weighted scores for Dabigatran 150 mg BD ranged from 0.805 to 0.811 for dabigatran 110 mg BD and did not change over the 1-year observation period. No difference between dabigatran and warfarin group except dabigatran 150 mg at 3 months None of the in-groups or between-group analyses were significant
Bamber et al. (2013)	March 2007 to Sept 2009	*Treatment*: Rivaroxaban vs enoxaparin/warfarin for *Population*: patients with DVT *Mean age*: 56.8 years *Female*: 42.4%	*Design*: RCT Substudy analysis of EINSTEIN DVT study *Setting*: Conducted in seven countries (the United States, the United Kingdom, Canada, the Netherlands, France, Germany, and Italy)	Patient-reported treatment satisfaction using ACTS score, assessed at 12 months of treatment	*Satisfaction*: Clinically significant reduction in ACTS burden (55.2 vs. 52.6, $P < 0.0001$) and improvement in ACTS benefit (11.7 vs. 11.5, $P = 0.006$) in rivaroxaban group (compared with warfarin)
Prins et al. (2015)	March 2007 to March 2011	*Treatment*: Rivaroxaban vs standard therapy (enoxaparin/warfarin) *Population*: patient with PE *Mean age*: 58 years *Female*: 44%	*Design*: Subanalysis of EINSEIN PE study, *Setting*: conducted in seven countries the United States, the United Kingdom, Canada, Netherlands, France, Germany, and Italy	Patient-reported treatment satisfaction using ACTS and Treatment satisfaction questionnaire for Medication Ver II, assessed at 1, 2, 3, 6, and 12 months	*Satisfaction*: Rivaroxaban group reported statistically significant increase in ACTS benefit (11.9 vs. 11.4, $P < 0.0001$) and less ACTS burden (55.4 vs. 51.9, $P < 0.0001$) Statistically significant improved TSQM II scores in the rivaroxaban group $P < 0.0001$ for all four factors, effectiveness, side effects, convenience, and global satisfaction
Hohnloser et al. (2016)	October 2012–September 2013	*Treatment*: Rivaroxaban vs standard therapy for cardioversion *Population*: Patients with AF requiring cardioversion *Age range*: 18–65 years *Female*: 52.7%	*Design*: RCT Post hoc study of X-VERT trial, *Setting*: conducted in seven countries the United States, the United Kingdom, Canada, Netherlands, France, Germany, and Italy	Patient-reported treatment satisfaction using User Treatment Satisfaction Questionnaire for medication Version II, completed after 42 days of treatment	*Satisfaction*: Rivaroxaban group reported increased score for convenience (81.74 vs. 65.78), effectiveness (39.41 vs. 32.95), and global satisfaction (82.07 vs. 66.74), $P < 0.0001$
Coleman et al. (2016)		*Treatment*: Rivaroxaban for stroke prevention *Population*: Patients with nonvalvular AF prescribed rivaroxaban *Mean age*: 71 years *Female*: 36.3%	*Design*: Nonrandomized controlled trial Xantus ACTS substudy prospective international noninterventional phase 4 study, *Setting*: 308 investigational sites in 21 countries	Patient-reported treatment satisfaction using ACTS implemented at baseline and 3 months after switch	*Satisfaction*: Baseline ACTS burden and benefit scores 50.51 and 10.30, respectively, scores improved after 3 months to 54.5 and 11.4, respectively
Koretsune et al. (2017)	September 2015 to October 2016	*Treatment*: patients switched from warfarin to apixaban *Population*: Patients with nonvalvular AF *Mean age*: 76 years *Female*: 37.9%	*Design*: RCT Prospective short-term multicenter single-arm observational study AGAIN study *Setting*: 149 institutions in Japan	Patient-reported treatment satisfaction using ACTS, implemented before switch and after 12 weeks of treatment with apixaban	*Satisfaction*: No significant changes in ACTS benefit scores (10.5 vs. 10.4) but significant changes in ACTS burden scores vs baseline (55.6 vs. 49.7, $P < 0.0001$)

(*Continued*)

Table 1 Summary of controlled trials and observational studies (*cont.*)

Author-year of publication	*Data collection period*	*Treatment/population*	*Study details*	*PRO assessment*	*Main findings of the study*
Observational studies					
Alegret et al. (2014)	1st February to 30th June 2012	*Treatment*: on VKA or NOAC *Population*: Patients with AF undergoing electrical cardioversion *Mean age*: 62 years *Female*: 19%	*Design*: Prospective study Patients included in the CARDIOVERSE study *Setting*: conducted in 67 hospitals in Spain	Patient-reported HRQoL in patients on oral anticoagulants using Sawicki Questionnaire, assessed at baseline and 6 months	*HRQoL*: No significant differences seen at baseline between the two groups. At baseline general treatment satisfaction score was significantly lower in the NOAC group (better HRQoL). Global score was also lower indicating better HRQoL in NOAC group (10.3 vs. 9.6). No significant differences seen at 6 months between the 2 groups
Carrothers et al. (2014)	May 2010 to December 2011	*Treatment*: Patients prescribed rivaroxaban *Population*: VTE prophylaxis following lower limb arthroplasty *Mean age*: 66 years *Female*: 61%	*Design*: Prospective study *Setting*: conducted in single orthopedic center in Canada	Patient-reported compliance using self-administered questionnaire, administered 14 days postsurgery and 6 weeks after treatment at the follow-up appointment	Compliance: Majority of patients were compliant with rivaroxaban treatment (83%), noncompliance was associated with older age, smaller BMI, and lower preoperative hemoglobin
Castellucci et al. (2015)	September 2012–September 2013	*Treatment*: Patients on oral anticoagulants (VKA, rivaroxaban, dabigatran, and apixaban) *Population*: VTE and AF patients *Mean age*: 63 years *Female*: 42.7%	*Design*: Cross-sectional survey *Setting*: conducted in 1 anticoagulant clinic in Canada	Self-reported anticoagulant adherence using 4-item Morisky score, administered once	*Adherence*: Self-reported adherence using the 4-item Morisky scale was 56.2% on VKA and 57.1% on DOAC. Adherence was similar in both groups
Hanon et al. (2016)	April 2013 to June 2014	*Treatment*: patients previously treated with warfarin and switched to rivaroxaban *Population*: Nonvalvular AF patients *Mean age*: 74.8 years *Female*: 37%	*Design*: Prospective, observational study *Setting*: conducted in French multicenter	Patient-reported treatment satisfaction using ACTS, administered at baseline, 1, 3, and 6 months	*Satisfaction*: At 3 months, statistically significant patient satisfaction with rivaroxaban compared with VKA warfarin. Mean ACTS burden score (46.5 vs. 54.9, $P < 0.001$) and benefit scale (10.4 vs. 10.9, $P < 0.001$) between rivaroxaban and VKA
Marquez-Contreras et al. (2017)	May 2013 to April 2015	*Treatment*: patients on rivaroxaban *Population*: Patients with nonvalvular atrial fibrillation *Mean age*: 75 years *Female*: 50.3%	*Design*: Observational, prospective, multicenter, longitudinal study *Setting*: Conducted in 160 primary and specialty care centers in Spain	Patient-reported quality of life using Sawicki Questionnaire, administered at baseline and at 6 and 12 months	*HRQoL*: Global compliance was 84.1% and 80.3% at 6 and 12 months, respectively. Average QoL rating was 112.85 in noncompliant and 111.80 in the compliant group ($P > 0.05$). After 12 months, 124.67 in noncompliant group and 83.47 in the compliant group ($P < 0.0001$) showing a significantly improved QoL
Keita et al. (2017)	July 2014 to July 2015	*Treatment*: Patients prescribed warfarin or switched to DOAC or initiated on DOAC treatment *Population*: VTE patients *Mean age*: 60.4 years *Female*: 46%	*Design*: Observational descriptive study, *Setting*: Conducted in multicenter in France	Patient-reported adherence, satisfaction, and quality of life using Morisky Medication Adherence Scale, MMAS-8, EQ-5D, perception of anticoagulation questionnaire part 2, administered after 3 months treatment, and 6 months treatment	*HRQoL*: VKA patients reported more negative experience than DOAC group in EQ-5d questionnaire. No significant difference in overall quality of life in favor of DOAC group (71 vs. 65, $P < 0.063$) *Satisfaction*: Satisfaction with PACT-Q2 >90% of patients were satisfied with their VKA or DOAC treatment *Adherence*: Adherence with MMAS-8 7.2 in VKA group vs 7.7 in DOAC group greater adherence in DOAC group, especially after 6 months' treatment

Contreras Muruaga et al. (2017)	September 2014 to March 2015	*Treatment*: *Population*: Patients with nonvalvular atrial fibrillation *Mean age*: 75 years *Female*: 44.2%	*Design*: Observational cross-sectional study *Setting*: 63 neurology departments in Spain	Patient-reported satisfaction, QoL and perceptions of VKA versus DOACs (only QoL included)	*HRQoL:* Mean EQ-5D 3L score was 75.9 Patients taking VKA with longer time in therapeutic range were more satisfied. DOAC = 76.26 and VKA = 75.05—showing no significant difference in HRQoL. HRQoL for all 3 DOACs were comparable
Stephenson et al. (2018)	October 2011 to June 2014	*Treatment*: Patients prescribed warfarin, dabigatran, rivaroxaban, or apixaban *Population*: Patients with nonvalvular AF *Mean age*: 65.6 years *Female*: 39.4%	*Design*: Hybrid US observational study *Setting*: conducted in 14 institutions in the United States	Patient-reported adherence using Morisky Medication Adherence Scale MMAS-8 duke anticoagulation treatment scale, administered at baseline, and at 4, 8, and 12 months	Adherence: Mean MMAS scores were similar among all four groups in the initial and follow-up surveys *Satisfaction*: DASS scored were lower for dabigatran and rivaroxaban cohort indicating greater treatment satisfaction
De Caterina et al. (2018)	2012 to 2013	*Treatment*: On stable VKA or switched to NOAC (rivaroxaban, dabigatran, or apixaban) *Population*: Patients with atrial fibrillation *Mean age*: 72 years *Female*: 37%	*Design*: Prospective study PREFER in AF Registry Substudy *Setting*: Conducted in 7 European countries	Patient-reported quality of life and satisfaction using PACT-Q2 and EQ-5D-5L questionnaires, administered at baseline and at 1 year follow-up	*Satisfaction*: Switched patients more often reported bruising or bleeding, dissatisfaction with treatment, mobility problems, and anxiety/depression traits with VKA that may have influenced the switch to NOAC
Koretsune et al. (2018)	April 2012	*Treatment*: Rivaroxaban in patients previously on warfarin *Population*: Nonvalvular AF patients *Mean age*: 73.6 years *Female*: 35.5%	*Design*: Postmarketing surveillance study of a prospective study *Setting*: Conducted at 124 sites in Japan	Patient-reported treatment satisfaction ACTS and treatment satisfaction questionnaire for Medication Ver II, administered at baseline and at 3 and 6 months	*Satisfaction*: Statistically significant improved TSQM scores in the rivaroxaban group at 3 and 6 compared to baseline in all 4 domains ($P < 0.001$). Significantly ($P < 0.001$) less burden at 3 months (54.6) and month 6 (54.5) vs baseline (51.0), and benefit remained stable in the rivaroxaban group
Larochelle et al. (2018)	February 2013 to December 2014	*Treatment*: Patients newly prescribed an oral anticoagulant (either warfarin or DOAC, apixaban, rivaroxaban, or dabigatran) *Population*: Patient with nonvalvular atrial fibrillation *Mean age*: 71.35 years *Female*: ~60%	*Design*: Prospective, observational study *Setting*: Conducted in hospitals in Canada	Patients expectations and satisfaction with oral anticoagulation treatment using PACT Q1 and PACT Q2 questionnaires, administered before treatment and at 3 and 6 months postdischarge	*Expectations*: No significant differences in treatment expectations, patients prescribed warfarin had a slightly higher expectation of having side effects *Satisfaction*: Convenience scores were similar at 3 months but much higher in DOAC group at 6 months (86.29 vs 90.97, $P < 0.05$). Satisfaction scores were similar between both groups

(*Continued*)

Table 1 Summary of controlled trials and observational studies (*cont.*)

Author-year of publication	*Data collection period*	*Treatment/population*	*Study details*	*PRO assessment*	*Main findings of the study*
Benzimra et al. (2018)	June 2013 to November 2015	*Treatment*: Patients receiving oral anticoagulants VKA/DOAC (dabigatran, rivaroxaban, or apixaban), or switched treatments *Population*: patient with atrial fibrillation *Mean age*: 74.3 years *Female*: 41%	*Design*: Real-life observational descriptive cross-sectional study *Setting*: Conducted in various recruitment sites in France	Quality of life, treatment satisfaction, and adherence using 3 validated questionnaires-Euro-QoL 5 dimensions 3 levels visual analog scale EQ-5D, Perception of anticoagulation treatment Questionnaire PACT-Q2, 8-item Morisky Scale Medication Adherence Scale MMAS-8, administered once over the phone to patients for at least 3 months treatment	*HRQoL*: HRQoL—EQ-5D scores were similar in all groups but higher in the DOAC group Overall QoL on the EQ-5D VAS tended to be better in the DOAC group but this was not statistically significant. *Satisfaction*: Convenience and satisfaction scores were high in all 3 groups but significant difference in favor of the DOAC group ($P < 0.001$) *Adherence*: Adherence scores were high for all 3 groups with no significant difference between the groups
Okumura et al. (2018)	September 2013 and December 2015	*Treatment*: Patients on anticoagulation (VKA/DOAC) *Population*: Patients with nonvalvular atrial fibrillation *Mean age:* 72 years *Female*: 22.6%	*Design*: Substudy of SAKURA AF registry Questionnaire-based prospective study *Setting*: Conducted in 40 institutions in Japan	Patients satisfaction with anticoagulant treatment using ACTS and Treatment Satisfaction questionnaires for medication II, administered once	*Satisfaction*: There were no significant differences in the TSQM II questionnaire between the 2 groups. The ACTS burden scores were significantly higher for the DOAC group than the warfarin group showing greater satisfaction with treatment
Suarez Fernandez et al. (2018)	*ALADIN Study*: September 2014 to March 2015 *ESPARTA Study*: October 2015 to March 2016	*Treatment*: Patients prescribed VKA or DOAC *Population*: Patients with nonvalvular AF *Mean age*: 78.5 years *Female*: 48.95%	*Design*: 2 different cross-sectional studies combined (ALADIN and ESPARTA studies), *Setting*: Conducted at various departments in Spain	Patient satisfaction with anticoagulant treatment using ACTS questionnaire, administered at regular single visit, patients on at least 3 months treatment	*Satisfaction*: Overall satisfaction with oral anticoagulation was high Patients taking DOACs showed a lower perceived burden with anticoagulation therapy (48.8 vs. 53.1, $P < 0.001$) Perceived benefits were higher in DOAC group (11.06 vs. 11.99, $P < 0.001$)
Obamiro et al. (2018)	Not specified	*Treatment*: Prescribed oral anticoagulants *Population*: Patients with atrial fibrillation *Age range*: 18 to >65 years *Female*: 68%	*Design*: Secondary analysis of the Australian oral anticoagulation survey *Setting*: Conducted through online recruitment in Australia	Predictors of adherence and patient-related factors of adherence using Morisky Medication Adherence Scale (MMAS-8), anticoagulation knowledge tool and PACT Q1 and Q2 questionnaires	*Adherence*: No significant difference in adherence seen between patients taking warfarin and DOACs Patients in the high adherence group showed a higher anticoagulation knowledge *Satisfaction*: Satisfaction scores were greater in the medium adherence groups

Another study that used the PACT Q2 tool showed high satisfaction in both anticoagulation groups, VKA and DOAC (Keita et al., 2017). One of the studies reported inconclusive results or dissatisfaction with DOAC therapy; however, these patients had been switched from warfarin, and the questionnaire may correlate to the patients' experiences of warfarin treatment (De Caterina et al., 2018). Three of the studies that utilized the TSQM questionnaire reported greater patient satisfaction with DOAC treatment scores (Hohnloser et al., 2016; Koretsune et al., 2017; Prins et al., 2015). Okumura et al. (2018) reported no difference in satisfaction when utilizing the TQSM score. Stephenson et al. (2018) used the Duke anticoagulation treatment scale, which confirmed patient satisfaction with DOAC treatment. Satisfaction with VKA versus DOAC was also analyzed by Contreras Muruaga et al. (2017); however, the patient population was the same as another study (Suarez Fernandez et al., 2018), and therefore these results were excluded from this review to avoid duplication.

Health-Related Quality of Life (HRQoL)

HRQoL was investigated by six different studies, which utilized either the Euro Qol 5 dimension of the Sawicki questionnaires. All six studies reported that HRQol was similar among patients on VKA and DOACs (Alegret et al., 2014; Benzimra et al., 2018; Contreras Muruaga et al., 2017; Keita et al., 2017; Marquez-Contreras et al., 2017; Monz et al., 2013). Contreras Muruaga et al. (2017) demonstrated that a higher QoL was associated with longer time in therapeutic range and better INR control. Four of the studies described a higher HRQoL score in the DOAC group, but this was not statistically significant (Alegret et al., 2014; Benzimra et al., 2018; Keita et al., 2017; Marquez-Contreras et al., 2017). Keita et al. (2017) showed that this higher QoL score can be attributed to the lack of blood monitoring associated with DOACs. Marquez-Contreras et al. (2017) highlighted that a significantly higher QoL score was confirmed in patients with established compliance after 12 months of treatment.

Patent-Reported Expectations, Compliance, or Adherence

Larochelle et al. (2018) used the perception of anticoagulation treatment questionnaire to determine patient expectation with anticoagulation treatment prior to initiation. The study found that there was no statistically significant difference between the groups; however, there was a greater expectation of adverse effects in the warfarin group.

Patient-reported compliance was explored by Carrothers et al. (2014) using an investigator developed questionnaire and showed that the majority of patients prescribed rivaroxaban were compliant with the treatment.

Patient-reported medication adherence was investigated by five studies using the 8-point Morisky Medication Adherence Scale (MMAS-8) (Benzimra et al., 2018; Keita et al., 2017; Obamiro et al., 2018; Stephenson et al., 2018). Castellucci et al. (2015) used an abridged 4-point version of the MMAS tool. All five studies indicated that adherence was similar among patients treated with VKA and DOACs. Obamiro et al. (2018) highlighted that a higher adherence score was observed in the patient group that exhibited a higher knowledge of anticoagulation treatment.

Patient Acceptance and Preferences

Warfarin and DOACs are equally as effective in the prevention or treatment of VTE and stroke (Sindet-Pedersen et al., 2015). DOACs are associated with less bleeding risk and net benefit when compared to warfarin (López-López et al., 2017). However, the simple medication regime and lack of therapeutic monitoring associated with DOACS are likely to result in more patients and physicians opting and preferring DOAC treatment with proven satisfaction, adherence, and likely HRQoL. Satisfaction has been reported with warfarin treatment that comprises less complicated regimes and monitoring and management methods including self-monitoring, pharmacist inclusion, or single point of testing at home (Carris et al., 2016; Hixson-Wallace et al., 2001; Meyer et al., 2013).

Near patient testing and self-monitoring with warfarin have shown improved satisfaction rates than standard clinic monitoring with warfarin treatment. Studies have shown an improved quality of anticoagulation in patients who self-monitor and self-adjust their doses, which results in an overall reduced incidence of VTE by around 50%, a 33% reduction in major hemorrhage, and a reduction in mortality from all causes (Heneghan et al., 2006).

The World Health Organization has reported that half of the patients prescribed regular medication for chronic illness do not adhere to their prescribed regimes (Brown and Bussell, 2011). Factors that affect adherence are multiple and complicated in nature. Factors of nonadherence can be patient-related (lack of literacy, involvement, or engagement), physician-related (prescribing of complex regimens or ineffective communication), or can be health-care system related (Brown and Bussell, 2011). Barriers to adherence and medication taking behavior are complex and challenging to overcome therefore patient satisfaction to treatment plays a fundamental role in enhancing patient concordance, experience, and overall preference for taking their medications for chronic conditions. Further evidence suggests that enhanced patient knowledge about anticoagulation treatment results in enhanced patient satisfaction therefore pharmacist are best placed experts in medicines to provide thorough counseling to patient through effective communication (Obamiro et al., 2016; Sahm et al., 2011; Wang et al., 2014).

Therefore, health-care professionals play an elemental role in educating and motivating patients to engage with their treatment plan to ensure maximum adherence with medication. Empowering and motivating patients as well as involving them in the decision making process is likely to provide profound benefit to the patient and overall health-care economy due to reduced incidence of complications and costly hospitalizations. A clear link has been established between greater treatment satisfaction resulting in

enhanced adherence to treatment for chronic conditions (Barbosa et al., 2012). Patients reporting greater satisfaction, improved quality of life, and therefore higher adherence to DOACs they are more likely to concord with DOAC treatment, resulting in successful treatment, fewer complication of stroke or VTE, and reduced mortality.

Cost Implications

Warfarin, although an inexpensive drug, requires monitoring and is resource intensive which patients are known to dislike due to the regular clinic appointments and blood tests with up to 13 appointments a year and less than 65% of time spent in therapeutic range with a consequent increase in risk of stroke (Anticoagulation UK, 2018). DOAC on the other hand are costly drugs, and this has been a nature of debate in order to achieve the most cost-effective anticoagulant treatment available on the NHS.

Various studies have demonstrated that treatment with DOAC compared with dose-adjusted or genotype-adjusted warfarin is as economically beneficial in the long term despite higher short-term costs involved (Carles et al., 2015). High-dose edoxaban versus dose-adjusted warfarin in nonvalvular AF showed that cost of treatment with edoxaban was economically beneficial compared to the monitoring requirements associated with warfarin and a similar risk of stroke (Nguyen et al., 2016). However, another study by Carles et al. demonstrated that self-monitoring of warfarin is as effective as dabigatran; however, short-term costs were lower (Carles et al., 2015). Janzic and Kos (2014) investigated treatment with DOACS versus genotype-guided dose adjustment warfarin, which showed that satisfaction with warfarin treatment was dependent on warfarin therapeutic control and method of monitoring (Janzic and Kos, 2015). Cost-effectiveness of DOACs is highly dependent and directly related on the costs of the alternative, VKA, with the associated adequate quality of monitoring and therapeutic control (You, 2014). However, this can be balanced with the enhanced patient preference of no monitoring with DOACs, therefore indicating higher satisfaction, preference, and overall QoL with DOACs.

It is well-known that costs of hospitalization due to VTE or stroke place a profound burden on the NHS (Xu et al., 2018). In the United Kingdom, stroke is one of the leading causes of death and disability costing the NHS £3.6 billion for the first 5 years of treatment after occurrence of the event and accounts for approximately 5% of the NHS budget, which shows the significant long-term investment required for stroke patients in order to provide an adequate quality of life (Saka et al., 2009). Hence, reducing the incidence of avoidable stroke caused by AF through well-managed anticoagulation is a priority for NHS England. NICE estimates that implementing recommendations to initiate DOAC treatment can lower the stroke burden by about 69% and around 10,000 strokes per year (NICE, 2014). Accordingly, designing medication regimes for anticoagulation in AF which patients prefer and are satisfied with is of primary importance to ensure adherence and decrease the incidence of stroke and associated complications. Furthermore, it is estimated approximately 58,000 incidents of VTE occur in the United Kingdom every year costing the NHS almost £340 million showing the clear burden placed on the NHS (NICE, 2015). NICE have shown that using appropriate treatment and prophylaxis with DOACs can result in a 60%–80% reduction in this burden, leading to considerable cost savings as well as a reduction in morbidity and mortality.

EDITOR BIOGRAPHIES

Editor-In-Chief

Zaheer-Ud-Din Babar

Zaheer-Ud-Din Babar is Professor in Medicines and Healthcare and the Director of Centre of Pharmaceutical Policy and Practice Research at the University of Huddersfield, United Kingdom. He has worked as an academic in Pakistan, Malaysia, New Zealand, and in the United Kingdom, and understands the health systems and pharmacy globally. He is known for his work in pharmaceutical policy and practice, including quality use of medicines, clinical pharmacy practice, access to medicines, and issues related to pharmacoeconomics. Previously, he was the Head of Pharmacy Practice at the University of Auckland and received Vice Chancellor's Research Excellence Award from the University. He has published in high impact journals, such as *PLoS Medicine* and *Lancet* and has acted as a consultant for World Health Organization, Royal Pharmaceutical Society, Health Action International, International Union Against Tuberculosis and Lung Disease, World Bank, International Pharmaceutical Federation (FIP), and for the Pharmaceutical Management Agency of New Zealand.

His other work includes *Economic Evaluation of Pharmacy Services*, *Pharmaceutical Prices in the 21st Century*, *Pharmaceutical Policies in Countries With Developing Healthcare Systems*, and *Pharmacy Practice Research Methods*. Published by Elsevier and Adis/Springer, the books are used in curriculum design, policy development, and for referral all around the globe. Professor Babar is also the Editor-in-Chief of *BMC Journal of Pharmaceutical Policy and Practice* and can be contacted at z.babar@hud.ac.uk.

Section Editors

Zubin Austin

Zubin Austin BScPhm MBA MISc PhD FCAHS is Professor and Koffler Chair in Management at the Leslie Dan Faculty of Pharmacy and the Institute for Health Policy, Management, and Evaluation—Faculty of Medicine at the University of Toronto. His research focuses on the professional and personal development of the health workforce. He has published over 160 peer-reviewed manuscripts and authored four reference texts. In 2017, he was installed as a Fellow of the Canadian Academy of the Health Sciences, the highest award for health services researchers in Canada. He is the only faculty member of University of Toronto to have ever received both the President's Teaching Award for excellence in education and the President's Research Impact Award for the societal significance of his work. He has also been named undergraduate Professor of the Year by students on 18 separate occasions.

Ahmed Awaisu

Dr. Ahmed Awaisu is an Associate Professor of Clinical Pharmacy and Practice in the College of Pharmacy at Qatar University. He received his Bachelor of Pharmacy degree from Ahmadu Bello University Zaria, Nigeria in 1999, his masters and PhD degrees in Clinical Pharmacy from Universiti Sains Malaysia (USM) in 2004 and 2009, respectively. He is also a licensed pharmacist and has practiced in the hospital setting since 1999. Dr. Awaisu has a unique privilege of past academic experiences in international pharmacy degree programs. He has made substantial and tremendous contributions that impact teaching and learning, research, curriculum design, as well as professional development of students and healthcare practitioners in Qatar and other countries. He received the Qatar University Merit Award for Outstanding Faculty for 2016–17 Academic Year. He is a member of the American College of Clinical Pharmacy (ACCP), and the International Society for Pharmacoeconomics and Outcomes Research (ISPOR), among others.

Professor Awaisu has extensive experience in the conduct of pharmacy practice and clinical research involving various types of study designs including case-control and cohort studies, quantitative surveys, mixed-methods designs, randomized control trials, and systematic reviews mostly on diabetes, cardiovascular diseases, tobacco dependence, and other chronic diseases. He has published over 100 peer-reviewed articles in internationally reputable pharmacy and healthcare journals and 10 book chapters related to the field of pharmacy. He has successfully supervised several postgraduate and undergraduate research projects, including MSc and PhD.

His research interest includes pharmacy practice especially pharmacists' expanded scope of practice, outcome-based research, pharmacoepidemiology and medication safety, and health promotion. Dr. Ahmed Awaisu has conducted training sessions and workshops on research methodology and biostatistics, drugs in sports, developing cognitive pharmacy services, and responding to symptoms in pharmacy practice. He presents regularly at continuing professional development programs for healthcare professionals in Qatar and other countries.

Timothy Chen

Professor Timothy Chen is a registered pharmacist and Professor of Medication Management, School of Pharmacy, The University of Sydney, Australia. Tim is nationally and internationally renowned for his research in medication management review and strategies to reduce medication related harm. Tim's research directly informed the Australian Government funded Home Medicines Review programme (MBS Item 903). Tim is an experienced educator and health services researcher, with experience in both community pharmacy and hospital pharmacy practice. Tim leads a productive research team (>160 peer-reviewed papers) and has completed main supervision of 15 PhDs, amongst other postgraduates. Tim has delivered >70 invited presentations at conferences and meetings across the globe. Tim has received university and national awards (Australian Government) for teaching, is an International Pharmaceutical Federation (FIP) Fellow (2016), and is President of the Social and Administrative Pharmacy Section, FIP.

Louise Curley

Louise Curley is a pharmacist and Senior Lecturer in Pharmacy practice at the School of Pharmacy. Louise's area of research focuses on the effects of recreational drug use in humans. She began her research as an undergraduate by investigating the subjective and electrophysiological effects of the Party Pill drugs using electroencephalography (EEG) and graduated with a PhD in pharmacy in 2012. Her thesis investigated the effects of the main constituents of "Party Pills" benzylpiperazine (BZP) and trifluromethylphenylpiperazine (TFMPP) on executive functioning and reward using functional magnetic resonance imaging (fMRI). Currently, her focus is developing new fMRI paradigms to investigate different aspects of risk, specifically by comparing populations of dependent versus non-dependent participants. Louise also has an interest in pharmacy practice research including innovative methods of teaching undergraduate students using different technologies and evaluating the effects of these innovations. She has recently been awarded the Butland Teaching Award: Innovation in Teaching.

Danijela Gnjidic

Dr. Danijela Gnjidic (BSc PhD MPH) is an NHMRC Dementia Leadership Fellow and Senior Lecturer at the School of Pharmacy, Faculty of Medicine and Health, University of Sydney. Her research expertise is in clinical and geriatric pharmacology, clinical studies on polypharmacy, high risk prescribing, and deprescribing in older people, pharmacoepidemiology, and the quality use of medicines. Danijela's academic track record includes 115 publications, 3-book chapters, with over 2500 citations on Scopus and $4M in research funding. Danijela was awarded the Australasian Society of Clinical and Experimental Pharmacologists and Toxicologists (ASCEPT) Denis Wade Johnson & Johnson New Investigator Award in 2012. Internationally, Danijela's contribution to the filed was recognized with the 2018 American Society of Clinical Pharmacology and Therapeutics William B. Abrams award in Geriatric Clinical Pharmacology. Danijela is an Associate Editor of the *Journal of Alzheimer's Disease* and Academic Editor of the *PloS One Journal*.

Arijana Meštrović

Dr. sc Arijana Meštrović, MPharm, FFIP has been working as a community pharmacist and she was responsible for education, services, and competency development in the biggest pharmacy chain in Croatia. She is now independent consultant and educator in Pharma Expert international agency, providing lectures and workshops in CPD programs for pharmacists, pharmacy technicians, medical representatives, implementing new services in pharmacy chains, and teaching Social Pharmacy and Pharmaceutical Care at universities in Croatia and Cyprus as Assistant Professor. Her Doctor's degree is in biomedical sciences—competency development in pharmacy. Arijana serves as member of the International Services Program Advisory Group the Accreditation Council for Pharmacy Education (ACPE, USA), member of PCNE (Pharmaceutical Care Network of Europe), ExCo member of FIP (Pharmaceutical International Federation) Academic section, and WHO international expert consultant in Pharmaceutical care field. She used to serve as Co-Chair of the FIP World Congress Programme Committee, Expert Member of the Board of Pharmacy Practice at FIP. In Croatia, she is a leader in Croatian Pharmaceutical Society and Croatian Chamber of Pharmacist as a Lecturer and Co-author of New services model in community pharmacy practice. Arijana is dedicated to promoting competency-based education in CPD cycle, so her teaching usually addresses all components of competencies—knowledge, experience, and motivation. In collaboration with ACPE International Services, she has founded and implemented SMART Pharmacy CPD model for pharmacists in more than 12 countries all over the world. She was invited speaker and consultant in more than 40 countries.

Kath Ryan

Kath is Professor of Social Pharmacy at the University of Reading, and Visiting Professor at Bournemouth University, United Kingdom. She has 45 years of experience as a pharmacist in the pharmaceutical industry, community practice, and academia. She has held posts at the University of Otago, New Zealand; Bournemouth University, United Kingdom; La Trobe University, Melbourne, Australia; and the University of Reading, United Kingdom. She also has experience in academic nursing and midwifery. Her research interests include extended roles for pharmacists, especially in general practice; application of the behavioral sciences to pharmacy practice; personal experiences of health and illness; and public and patient involvement, engagement and participation in research, and the education of health professionals. She has expertise in quantitative, qualitative, and mixed methods research. She also has an interest in infant feeding,

particularly breastfeeding research, promotion and support, from lay, professional, and academic perspectives. She has been a health advisor to La Leche League International and La Leche League New Zealand. Kath has been on Scientific Committees for the International Social Pharmacy Workshops and the Australasian Pharmaceutical Sciences Association. She has consulted for the National Institutes of Health, USA; Canadian Forces; Health Technology Assessment, NHS UK; and the NZ Ministry of Health.

Kath has over 100 publications in peer-reviewed journals and several book chapters and reports. She produced two multimedia, online resources for Health Talk: women's experiences of breastfeeding in the United Kingdom, and people's experiences of ageing in Australia. She was a Founding Co-Director of Health Talk Australia.

FOREWORD

This first edition of the Encyclopedia of Pharmacy Practice and Clinical Pharmacy is one-of-a-kind and the most comprehensive amalgamation of an inclusive range of topics relevant to the pharmacy profession brought together to ensure safe and effective provision of pharmaceutical care across the world. Professor Zaheer Babar is a Professor in Medicines and Healthcare at the University of Huddersfield and also a global expert in pharmacy practice and pharmaceutical policy. He has united over hundreds of researchers and practitioners from across the world in a collaborative endeavor to provide a unique insight into current best practice and strategies for the future for the profession of pharmacy and its practice.

As patient care becomes more complex with advances in medicines and new developments in practice, including pharmacogenomics and pharmacoeconomics, there is an ever-evolving demand for practice and policy to keep pace. This encyclopedia contains 180 chapters, from all fields of pharmacy practice and clinical pharmacy, providing an in-depth coverage of modern approaches to the practice of pharmacy and highlighting the directions that will enable advancement to continue.

This encyclopedia includes definitions, concepts, theories, and applications of clinical pharmacy and pharmacy practice, providing background knowledge of the area that will provide valuable information for students of pharmacy practice. By providing relevant and topical summaries on a broad range of subjects, this book is also an excellent resource for those seeking information beyond their specific areas of expertise. In addition, the information contained in this book and its communication is of importance to a range of stakeholders, such as physicians and other healthcare professionals, health regulatory authorities, and the pharmaceutical and health industry, in addition to patients and their caregivers.

This encyclopedia also provides an excellent insight into pharmacy practice research and methods, as well as pharmacovigilance, pharmacoeconomics, social and administrative pharmacy, public health pharmacy, pharmaceutical systems research, the future of pharmacy, and new interventional models of pharmaceutical care. In addition, new treatments, algorithms, standard treatment guidelines, and pharmacotherapies regarding diseases and disorders are also covered.

The six key strands around which this encyclopedia is arranged pay testament to the complex and broad nature of the topic and are key topics of interest in pharmacy today and drivers of change for the future, for the benefit of public health across the world.

1. Pharmacy practice
2. Pharmacy practice research methods
3. Clinical pharmacy education, professional standards, and workforce
4. Clinical pharmacy and pharmacotherapy
5. Pharmacoepidemiology and pharmacovigilance
6. Socio-behavioral and administrative pharmacy

Topics range from the education and training of pharmacists, technicians and assistants to counterfeit medicines, pharmaceutical pricing policies, and implementation of change. As pharmacy practice evolves to meet the ever-more-complex health and medicines needs of patients, practitioners need an understanding of the social, political, and economic contexts across the world, noting particular highlights and challenges in developing countries to reach high standards. While it is acknowledged that there are differences between countries in terms of legislation, regulations, and guidelines (as detailed in individual chapters), the vision for the profession must be for a world in which everyone can access safe, effective, and affordable medicines and pharmaceutical care. The chapters include many examples of innovation and best practice in delivering health

services for the future, embracing additional roles beyond the supply of medicines in a robust manner underpinned by scientific and evidenced practice. Quantitative, qualitative, and mixed methods of pharmacy practice research are presented alongside expanded and evolving roles for pharmacists and where technology may take us. More quality research and coordinating efforts will bring a range of theoretical concepts and an evidence-based practice to the forefront of our activities, to focus a global workforce to meet the challenges of this exciting new era for pharmacy practice. This timely volume exemplifies the willingness and ability of the profession to work collaboratively on global issues, representing an unprecedented opportunity to shape the future of pharmacy practice.

With ever-increasing demands on healthcare systems, alongside growing financial pressures, it is essential that we work collaboratively with other pharmacists and the wider public health workforce who have the expertise, opportunity, and capacity to support and inform development.

In this context, this encyclopedia is an important resource with far-reaching impact on global healthcare community, and I hope this will be well liked by students, researchers, and academics.

Professor Barbara Conway
Department of Pharmacy, University of Huddersfield, Queensgate, Huddersfield, United Kingdom

March 2019

PREFACE

Encyclopedia of Pharmacy Practice and Clinical Pharmacy

This encyclopedia has 180 chapters in total and it covers all domains of pharmacy practice and clinical pharmacy, including pharmacy practice research, socio-administrative and behavioral pharmacy, pharmacy education, pharmacoepidemiology, and the pharmacotherapy. One main question being asked is the need for this work. *What encyclopedia of pharmacy practice and clinical pharmacy adds to the current body of literature and what it means for global pharmacy community?* The answer to that is, though there were a number of books available on pharmacotherapy, however, current landscape lacks material comprehensively covering aspects, such as pharmacy practice, pharmacy practice research, social pharmacy, pharmacoepidemiology, pharmacy education, and the linking of clinical pharmacy with the health system. This encyclopedia aims to provide a collection of chapters on the above-mentioned areas. It also developed, synthesized knowledge, and provided policy guidance in the areas where there were gaps in the literature. For example, filling the gaps and including chapters on health systems, pharmaceutical policy, evidence and impact in pharmacy practice research, and on pharmacy education.

Here is a brief summary of what is being covered in its three volumes: Volume 1, 2, and 3.

Volume 1 includes chapters on pharmacy practice and pharmacy practice research. The pharmacy practice section starts with the historical evolution of pharmacy practice, medicines management, expanded roles of pharmacists, cognitive pharmacy services, community, and ambulatory pharmacy practice, ethics and regulation, and the new models of pharmaceutical care. There are also chapters on prescribing standards, practices, and competencies, interpersonal communication, evidence-based medicine, models on patient counseling, innovative pharmacy services, technology in pharmacy practice, and the pharmacist's role in substance misuse. The case studies chapters include pharmacy practice in high, low, and middle-income countries; United Kingdom, Western Europe, Australia, New Zealand, China, India, Gulf States, Philippines, and Portugal.

It is vital to understand and discuss the quality of evidence in pharmacy practice research, for example, how the evidence is produced and how it could impact on health outcomes. This is a niche section in the encyclopedia covering chapters on quantitative and qualitative methods in pharmacy practice research, quality of qualitative research, philosophical perspective and theories applied in pharmacy practice research, meta-synthesis, mixed methods research, discrete choice experiments, and the use of network meta-analysis in pharmacy practice. There are also chapters on evolution and definition of practice research, evidence, impact, and gaps in pharmacy practice research in low- and middle- and high-income countries.

Volume 2 covers pharmacovigilance, pharmacoepidemiology, and the socio-behavioral and administrative aspects of pharmacy and medicines use. The knowledge regarding pharmacoepidemiology and pharmacovigilance significantly impacts on medicines safety. The chapters included are on definitions, principles, and application of pharmacoepidemiology, descriptive and drug utilization studies, case-control and cohort studies, methodological challenges in epidemiological studies, data sources, and the issues related to medicines safety and comparative effectiveness research.

The socio-administrative and behavioral pharmacy section covers two broad aspects, namely, social pharmacy and pharmacy administration. Social pharmacy section covers concepts, development, and theories related to social pharmacy, public and patient engagement, sociology for pharmacists, implementation of change in pharmacy practice, and the social perspectives in addiction. There are also chapters on medicines adherence, compliance, and concordance, medication narratives, investigating medicines use among elderly

from a sociological perspective, changing nature of pharmacy as a profession, the impact of culture and religion on medicine use, and the issues related to disease mongering.

The understanding of health system is vital when promoting access and the use of medicines, hence in this context understanding administrative aspects of pharmacy are crucial. This section explores the dynamics between public policy, pharmaceutical policy, pharmacy practice, health systems, and patient-health outcomes. It covers a range of pharmaceutical policy and health system issues including access to biosimilars, access to high-cost medicines, counterfeit medicines, factors influencing pharmaceutical policy implementation, funding mechanisms for community pharmacy services, generic drug policies, national medicine policies, essential medicines list, pharmaceutical company sponsored medication assistance programs, and the pharmaceutical pricing policies.

Volume 3 covers clinical pharmacy education and pharmacotherapy. Pharmacy education training and the workforce have a great impact on global health. There are 25 chapters or more on pharmacists' training, and certification exploring the relationship between education, regulation, and practice. This is one of the largest collection of chapters covering pharmacy education and regulation at the global level. This includes chapters on pharmacist workforce, competency standards for clinical pharmacists, quality assurance in the pharmacy education, developing and evaluating clinical skills, continuing professional development, experiential education, inter-professional learning, leadership in pharmacy education, and the needs-based education. There are also case studies chapters on clinical pharmacy professional standards in the United States of America, Canada, the European Union, and in the low- and middle-income countries.

The pharmacotherapy section covers over 70 chapters discussing standard treatment guidelines, pharmacist's role in the central nervous system, infectious diseases, cardiovascular disorders, skin and endocrine disorders, musculoskeletal disorders, neurology, gastrointestinal disorders, and the respiratory disorders. The other key chapters include clinical pharmacy concepts, history, and development, clinical governance principles, pharmacokinetics, therapeutic guidelines, end of life care, palliative care, long-term care, fundamentals of pharmaceutical care planning, health outcomes and quality of life, the role of the pharmacist in the military and prisons, and the pharmacotherapy and deprescribing.

It has been a challenging task to complete this encyclopedia within a short span of 2 years. However, I am very thankful to the support of my section editors, reviewers, and hundreds of authors from all over of the world to come together and to contribute to this exciting project.

I hope you will like this effort and it will serve its purpose.

Becoming A Pharmacist: Education and Training

A Stepwise Approach to Competency-Based Pharmacy Education

Pierre Moreau, Dalal Al-Taweel, Mohamed Qaddoumi, Maryam Alowayesh, Faculty of Pharmacy, Health Sciences Center, Kuwait University, Jabriya, Kuwait

Introduction

The pharmacy profession has been adapting to an ever-changing external environment (Bonanno et al., 2012). From creating and preparing medicines to counseling on their proper usage, to optimizing health outcomes, the profession's identity has been in a state of flux, and so has been the underlying education. Today, pharmacists are increasingly expected to provide direct patient care (cognitive services) aimed at optimizing patient's usage of medicines, to improve safety and efficacy (Saseen et al., 2017). We are seeing an expansion of the scope of practice for pharmacists in several countries, as the health-care system is increasingly under economical pressure, physicians are overwhelmed with increasing and aging populations, and medication therapy increases in complexity. It is important for the initial pharmacy education to keep abreast of the population needs and the professional expectations in order to provide a relevant workforce (Anderson et al., 2012; Bader et al., 2017a). The pace at which each country has embraced and implemented these changes, both at the professional and educational levels, probably explains the rather heterogeneous landscape of pharmacy education today. Recently, the International Pharmaceutical Federation (FIP) proposed educational statements (The Nanjing statements) in an effort to try to provide a reasonably homogenous "template" for pharmacy educators of different countries to align better with each other (Bader et al., 2017a). Anyone contemplating a revision of their curriculum should review and aim to satisfy these statements.

To add to the complexity related to the timing of professional and curricular changes worldwide, the current transition, from a predominantly scientific-based pharmacy education to the one that includes more clinical sciences and experience is conducted with a plethora of denominations and length of studies (see **Table 1**). Since 2000, North America, with the United States as a lead, has embraced the PharmD (doctor of pharmacy) avenue, which requires 6–7 years (2–3 prepharmacy + 4 pharmacy) of education. Other countries are following in this path, including examples in Asia, Middle East, and Africa. In the European Union in general, the directives require at least 5 years of training, including at least 6 months of residency in a pharmacy setting. This can be done as a single program (leading to master) or as two separate programs of Bachelor and Master. The qualification's expectations are similar, irrespectively of the name or structure, to allow pharmacists mobility within the Union (Atkinson and Robinson, 2011). The United Kingdom has chosen a 4-year MPharm (Master of Pharmacy) path, with a 1-year residency performed afterward in order to be eligible for practice. Other countries, like Australia, continue to offer Bachelor of Pharmacy degrees to access the profession (**Table 1**). Some countries even graduate pharmacists with a degree in pharmaceutical sciences. For the unexperienced outsider, the landscape is very confusing, especially when professional graduate programs are added to the mix.

Although program names differ, the name is not what defines the preparation of future pharmacists, it is what the curriculum contains. Indeed, Baccalaureates in pharmacy (BPharm) can incorporate as much clinical pharmacy education as PharmD

Table 1 Examples of pharmacy curriculum length and structure across the world

		Structure of requirement for pharmacy practice			
University	*Country*	*Prepharmacy*	*Duration of the pharmacy program*	*Posteducation practice training*	*Notes*
Monash University	Australia	3 years Requires a bachelor's degree in sciences Or none	2 years BPharm +Master degree Or 4 years BPharm +Master degree	1 year internship	Pharmacy education normally takes 5 years in Australia (including the internship)
National University of Singapore (NUS)	Singapore	None Either GCE-A level, or equivalent examinations	4 years Bachelor of Science (Pharmacy) degree. Includes 6 months preemployment competency training	12 months preregistration training	Registered pharmacists may also study a full time 2-year PharmD program for advanced clinical care
University of California San Francisco (UCSF)[3]	United States	3–4 years Requires a bachelor's degree in sciences	3 years (year-round) PharmD program	None	Pharmacy education normally takes 6 years (2 + 4) in North America
University of Nottingham	United Kingdom	None Requires A-level courses for admission	4 years Master of pharmacy (MPharm) program	1 year pre-registration training, followed by the GPhC[a] exam to become a qualified pharmacist.	The University also offers an MPharm (with Integrated preregistration), which is 5-years and at the end the graduate is ready to be a UK pharmacist
Utrecht University	Netherlands	None Requires a diploma or an A- level for admission	3 years Bachelor of science followed by 3 years Master's degree (MSc) in Pharmacy		The EAFP[b] states that 5 years is the minimum for pharmacy education in Europe

Universities were selected based on their region and their ranking in the QS pharmacy and pharmacology classification and are presented in alphabetical order.
[a]GPhC, General Pharmaceutical Council.
[b]EAFP, European Association of Faculties of Pharmacy declaration in 2008.

programs, as is the case in Australia. As often required by accreditation bodies, most curricula will contain courses in biomedical sciences (anatomy, biochemistry, microbiology, physiology, pathophysiology, and molecular biology), pharmaceutical sciences (medicinal chemistry, pharmaceutics, biopharmacy, pharmacokinetics, pharmacodynamics, toxicology, biotechnology, and pharmacogenomics), social and administrative sciences (biostatistics, pharmaco-epidemiology, pharmaco-economy, ethical and professional standards, health systems, practice management, laws and regulations, and cultural diversity), and clinical sciences (pharmacotherapeutics, medication therapy management, clinical pharmacokinetics, health promotion and disease prevention, public health, medication and patient safety, self-care, and primary care) (Anonymous, 2014). The proportion of each discipline and their integration within a curriculum varies widely and there is no easy way of summarizing the situation (Atkinson and Rombaut, 2011), except to say that obtaining the right balance between the scientific and clinical influences is a current preoccupation for most schools of pharmacy (Fielding and Regehr, 2017).

Generally, clinically oriented programs will include more time for trainees to gain experience by engaging into practice sites supervised by preceptors. In the PharmD model, the experiential training component is integrated within the curriculum to offer a transition between theory, laboratory practice, and real-life experience. This learning continuum has required a very strong collaboration between the faculties and the professional environment, to allow all students to have a very significant amount of hands-on training. In a 4-year PharmD (accessible after 2 preparatory years), the early pharmacy practice experience (EPPE) and advanced pharmacy practice experience (APPE) normally account for more than a full academic year (Anonymous, 2015). In other programs, such as the MPharm of the United Kingdom, graduates are generally required to complete 1 year of prelicensure experience before they can obtain their independent license to practice the profession. Thus, although some programs may appear longer to complete (such as a 2 + 4 PharmD), the mandatory year of practice experience requested by registrars is actually included within the university coursework.

Another aspect that cannot be determined from the name of the degree is the method by which education is provided. Like the pharmacy profession, education as a whole has also undergone major transformations. The past 100 years has witnessed three generations of higher educational reforms, from a scientific-based focus, through a problem-based approach, to professional competency development (Frenk et al., 2010). As regulatory and accrediting authorities move toward competency frameworks to define the expectations of a graduating pharmacist, the way by which students are taught has to follow suit in order for them to be competent, and not just knowledgeable (Anonymous, 2014, 2015; Saseen et al., 2017). With the support of information technologies, offering a massive amount of information available in a split second, the time is probably ripe to move toward learning to use information rather than memorizing it (Summers, 2012).

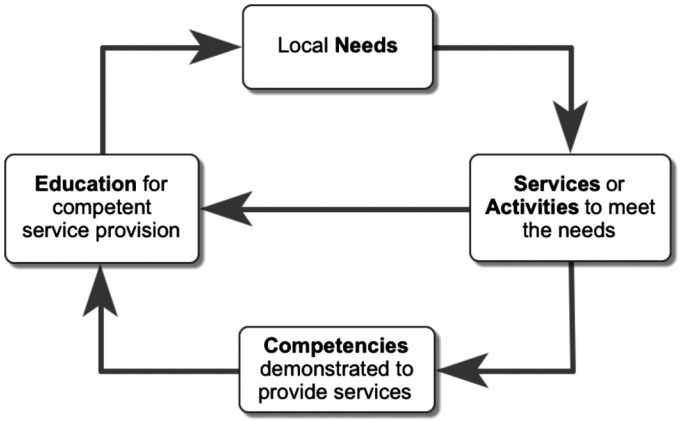

Figure 1 Needs-based professional educational model. *Source: Adapted from Brock, T., Brown, A.N., Rennie, T., Rouse, M.J., 2012. Global pharmacy education: are we nearly there yet? Int. Pharm. J. 28(1) (2012) 4–11. An arrow from Services to Education was added from the original model (see text for details).*

Needs-Based Education

In an ideal setting, there should be a very strong alignment between a professional practice and the underlying education so that graduates are optimally prepared, accelerating their integration to serve the population efficiently (Hawkins et al., 2015; Saseen et al., 2017). According to the recent literature, it seems that the gap between education and practice is unfortunately widening rather than narrowing (Frenk et al., 2010). As health-care professionals are expected to competently address the increasingly complex and changeable needs of the population, education has not followed and seems to be rooted in a pattern of discipline-based structure that allows for very little flexibility and adaptation (Noble et al., 2011). According to the Lancet commission, current professional education has not kept pace with emerging challenges and has created a gap between the graduate competencies and population needs; in addition, it has failed to nurture team working skills, has fostered narrow technical focus, and has contributed to the fragmentation of care (Frenk et al., 2010). Thus, education continues to evolve; however, its evolution trajectory and speed is not in sync with the practice evolution. Considering the years required for a freshman to graduate, universities should feel an urgent motivation to reform their education in order to improve health-care outcomes in the not too distant future. Currently, discipline-based curricula structure drives the learning objectives, rather than learning objectives driving the curriculum (Frenk et al., 2010). This translates into knowledgeable professionals who lack in their ability to solve problems in the real world (Hawkins et al., 2015). As we reflect on what should be the educational framework to prepare the future generations of pharmacists, being accountable to the workforce needs should be a fundamental concern and objective (Bader et al., 2017a; Brock et al., 2012).

Needs-based education brings the local necessities at the forefront of curriculum transformation, instead of relying on a universal curriculum that may prove to be maladapted in countries with different challenges (including educational capacity) and realities (Anderson et al., 2012). In other words, trying to standardize pharmacy education should aim at the outcomes (what is a competent pharmacist in a given community) rather than on the nature of the courses that should compose a pharmacy curriculum. This is further emphasized by the recent International Pharmaceutical Federation (FIP) Nanjing statements that gives direction, but does not determine how to reach the goals (Bader et al., 2017a). The need-based education process first defines the local needs, then the professional activities or services needed to address those needs, followed by the competency required to offer the services and, finally, by the education to prepare a competent workforce (**Fig. 1**). According to Anderson et al., defining a common set of competencies (competency framework) seems easier than anticipated, even in countries with different needs (Anderson et al., 2012). To support an outcomes-based education transformation, the FIP has proposed a global framework to guide schools of pharmacy to develop their education with this new mind-set of preparing competent pharmacists (Bruno, 2012). What appears more challenging, however, is translating such list of competencies, organized in a comprehensive framework, into an efficient educational model that will prepare graduates to their professional challenges (Hawkins et al., 2015; Koster et al., 2017).

Competency-based Education

Competency-based education does not have a uniform definition or meaning (Frank et al., 2010). The Competency-Based Education Network has a proposed definition on their website (C-BEN, 2015), while Frank et al. (2010) have proposed the following: *"Competency-based education (CBE) is an approach to preparing physicians* for practice that is fundamentally oriented to*

* The word "physicians" could be substituted by "professionals" or "pharmacists"

graduate outcome abilities and organized around competencies derived from an analysis of societal and patient needs. It de-emphasizes time-based training and promises greater accountability, flexibility, and learner-centeredness."

One of the barriers of progressing toward competency-based education (CBE) is that it involves moving away from traditional discipline-based courses, to knowledge integration and competency development in practice-relevant contexts (Hawkins et al., 2015). It is a huge shift that requires courage and trust that the outcomes will be better for the students and, ultimately, for the patients. This is often the question that allows a certain opening to new ideas, as discussion with stakeholders often confirms that current curricula have important deficiencies, as outlined by the Lancet Commission (Frenk et al., 2010). To be successful, such a bold shift in the educational vision for the profession requires leadership, expertise, and skilled change management.

In addition to affecting the teaching culture from disciplinary to integrated and patient-focused, CBE will also affect the teaching and learning methods used. Indeed, one does not develop competencies the same way one acquires knowledge. The science clearly demonstrates that students fare much better when they can actively engage in learning, rather than passively receiving what the instructor has prepared for them (Dean Jr and Kuhn, 2007; Kober, 2014; Waldrop, 2015). In his article about the science of teaching science, Waldrop concludes that knowing the consistent message of the literature regarding the benefits of active learning, lecturing should be unethical, just like it is unethical to put a patient on an old medicine when evidence overwhelmingly confirms that the new medicine is safer and more effective to obtain the therapeutic goals (Waldrop, 2015).

Finally, assessments have to adapt to measure the degree or level of competence that the learners have achieved after a certain time during their education. Competencies take time to mature, and expectations at the beginning of the curriculum cannot be the same as the expectations at the end. These "levels and ranges" are therefore necessary to make sure that students are progressing appropriately, and that remediation can be started when students show signs of deficiency in core competencies early in the program. Defining expectations at different time points within the curriculum is another challenge brought about by CBE. This is over and above the development of new assessment methods that must be devised and mastered to assess student's proficiency. These may include Objective Structured Clinical Examinations (OSCE), mini-Clinical Evaluation Exercise (mini-CEX), or other methods that evaluate students in action (observation), a sharp departure from relying solely on multiple-choice and short-answer questions.

CBE seems to be the way to go forward, but it comes with an array of challenges and educational practice changes that meet strong resistance and impede a more enthusiastic shift toward what appears as the holy grail (Hawkins et al., 2015; Koster et al., 2017). However, it brings the opportunity of having a more flexible educational approach that can be tailored to the local expansion of the scope of pharmacy practice within a specific country or region (Brock et al., 2012). Considering the shifts that are currently happening in pharmacy practice worldwide, there is a need for more open, flexible, and adaptable learning architectures that can evolve together with the local development of pharmaceutical services.

Competence and Competency

Competence can be defined by having a complete repertoire of competencies (Brown et al., 2012). There are several definitions of a competency, and Nash et al. published a whole list of possibilities in their review of the use of competency standards in pharmacy education (Nash et al., 2015). We propose a combination of previous definitions to define competency as: knowledge, skills, behaviors, and attitudes that an individual accumulates, develops and acquires through education, training and work experience that can be mobilized to perform job-relevant tasks effectively within a given professional context. Thus, competency defines effective action in a certain context. Competencies describe what graduates should be able to do in practice rather than simply what they should know or the skills being able to demonstrate during training (Thistlethwaite et al., 2014). Accordingly, a competency framework, or the list of competencies expected from a graduate, represents the abilities of the professional at the outcome of the program (ten Cate, 2013). Clearly, then, competency implies a sense of professional judgment that goes beyond theory. This resonates with a suggestion to put students regularly in gray zones, similarly to their future professional career, as patient care is not black or white (Noble et al., 2011). In a knowledge-based curriculum, we stack knowledge and skills separately for each discipline and we expect students, as they progress, to combine them to solve problems, using their judgment.

Unlike knowledge and skills, competencies take time to develop, and the pace of acquisition varies between students. When a knowledge or skill element comes again in a curriculum, students complain of redundancy and it can be corrected by tweaking the curriculum, often to make room for even more knowledge. But unlike knowledge and skills, competency development needs several iterations and most of the time, different levels of expectations over time. Redundancy is crucial, but context can vary. This gradual appropriation of a competency has a profound impact on a CBE program, as time must be devoted to use the knowledge and skills in meaningful and context-relevant learning activities. Some may object by saying that there are so many things a pharmacy student needs to know that there is no time for revisiting competencies on multiple occasions. However, one should consider that if, as research shows, students retain only 10%–20% of what is being taught after the exam period by conventional methods, cramming even more knowledge will just be detrimental to the major concepts that are professionally relevant (Waldrop, 2015). By using active learning methods, and time and space to practice becoming competent using these major concepts, retention will be much better, and learning will be improved (Dean Jr and Kuhn, 2007; Waldrop, 2015). Pharmacy

educators must move away from the compulsion of covering everything to embrace the expansion of the key concepts underpinning the professional activities.

The knowledge acquired during the pharmacy program rapidly becomes obsolete, due to the advancement of science, medicines, and practice. In that context, active learning and competency development provide a foundation for life-long learning, in addition to helping students develop their autonomy, judgment, confidence, and leadership. Guiding the students to find the right sources of information and making sound interpretation is much more important than providing a snapshot of today's wealth of knowledge, especially in this day and age where information can be retrieved quickly (Summers, 2012). The debate between covering "all" knowledge and allowing students to construct their own knowledge as they become competent has to occur before CBE can be considered.

Numerous universities are already developing CBE programs to bridge the gap between education and practice (Hawkins et al., 2015; McIntyre-Hite, 2016). Few competency-based pharmacy education (CBPE) initiatives have been reported so far, if one looks at published accounts (Nash et al., 2015). The jury is still out as to how one can translate a competency framework into an effective curriculum that will graduate competent health-care providers (Lurie and Garrett, 2017). One approach for CBPE development and implementation has been recently proposed by Koster et al. (2017). In this chapter, it is our intention to propose an alternative (although often similar) stepwise approach for developing a student-centered CBPE curriculum in the context of a patient-centered care role for pharmacists, relying on a solid scientific foundation.

A Model for Competency-Based Pharmacy Education

Guiding Principles

The creation or the major overhaul of an existing curriculum into an entity that is radically different from past experiences is a major endeavor. It requires the collaboration of all faculty members and stakeholders. Because the efforts are significant, the planning process should not be underestimated or rushed. Initial efforts should be aimed at defining internal and external needs and expectations to devise a visionary curriculum that will be relevant to the population it serves for years to come. Before embarking on external consultation, it is worthwhile to have an internal reflection on the outcomes of the curriculum in its new form. **Table 2** presents the results of such an exercise done at the Faculty of Pharmacy of Kuwait University. A core group of academic staff, representing all departments, were free to express their wishes and expectations in the form of keywords or short sentences. At the end, the keywords were integrated into vision statements. From what was expressed, it became clear that knowledge and skills were not sufficient to fulfill the vision. To be coherent with the outcomes, the new curriculum had to allow the development of a series of competencies. The same group then reflected upon the impact to be anticipated from this new vision on four domains: (1) the global curriculum structure (macro level), (2) the course material and delivery methods (micro level), (3) the assessment and grading modalities, and (4) the University and Faculty rules and regulations for admission and progression. These guiding principles were defined early in the process in order to steer the development of the curriculum towards the vision. They had to be explicit, widely accepted and respected to maintain the desired vision.

As an example of guiding principles for the global curriculum structure, consensus was reached on students developing competencies, working with a locally relevant competency framework, putting experiential learning (labs, projects, and practice experience) as a major component, integrating disciplines toward problem resolution, implementing interprofessional education, and engaging in continuous curriculum assessment and improvements. For the course creation and delivery domain, the guidelines propose that the learning material be context relevant for pharmacy practice, using active learning approaches and to prioritize disease states that are more prevalent in Kuwait. The methods chosen encourage peer teaching, regular feedback, and critical thinking (working in gray zones). In addition, this domain outlines the student support, individualized remediation, as well as the use of technology.

The third domain, concerned with the assessment strategy, dictates that the global assessment framework focuses on higher dimensions of learning (deep learning) and measures the progression towards the expected level of competency. The methods of assessment are to be coherent with the learning objects and incorporate some level of feedback. Formative assessment is mandatory before each summative examination. The fourth and last domain of the guiding principles deals with rules and regulations, such as admissions, number of students, progression criteria for the second year, and conditions for success. They respect the general policies of Kuwait University.

Table 2 Guiding vision statements for the reform of the existing pharmacy curriculum in Kuwait

Each graduate is expected to be a:
1. Patient-centered, collaborative health-care provider
2. Self-guided, lifelong learner using evidence to support decisions and practice
3. Accountable practitioner with reputable professionalism and ethical behavior
4. Community-oriented professional conceiving value-added services and public health promotion activities
5. Engaged professional leader and advocate with significant mentoring and communication skills

From these guiding principles, it was concluded that at least four frameworks had to be created to allow the development of a curriculum aligned with the vision. The main steering committee focused on the development of the competency framework and three subcommittees were formed to work on an active learning framework, an assessment framework (later combined in an integrated active learning and assessment framework), and an experiential training framework defining capacity building and preceptor training. Using several subcommittees was also part of the change management strategy, as individuals involved in the change process are less likely to resist it (Kotter, 1996).

Needs Assessment

Several competency frameworks are available and can be used as a starting point for curriculum development (Koster et al., 2017). Ideally, however, a thorough local needs assessment should be conducted in order to set the stage for competency identification and professional requirements (Anderson et al., 2012). The external stakeholder consultation is also a recommended tool to inform and involve the pharmaceutical community to the curriculum reform. The FIP Pharmacy Education Taskforce, together with the WHO, published a needs-based education development model that can be used as a template for linking population needs to education development (**Fig. 1**) (Anderson et al., 2012; Bruno, 2012). Needs-based education requires the identification of local needs as a basis for the development of a relevant curriculum (Anderson et al., 2012). Then, services to fulfill those needs are identified and competencies in order for pharmacists to provide those services are delineated. In this way, the curriculum becomes relevant to the needs of the local population.

Knowledge of the external expectations requires the input from a wide range of stakeholders, and the information has to be gathered in a structured or semistructured focus group setting, with guiding questions, in order to prevent the discussion from straying off into undesired tangents. A stakeholder map, where all relevant stakeholders are identified, is a good exercise to perform at this stage. It is important to be aware of the impact of hierarchy within the study population, which might affect the quality of data generated. Therefore, it is advisable to have homogenous focus groups, where participants with similar backgrounds are grouped together, as this facilitates the discussion and is more productive in terms of depth of discussion and participation of group members (Krueger, 1994).

In order to make sense of these focus groups, two simple questions were asked. The first one dealt with the current population needs (or pharmacy services) that are currently met by pharmacists in Kuwait. The second asked what needs were currently not met by pharmacists, according to the experience of the stakeholders. For each need identified (met or not met), expectations for pharmaceutical services were discussed with a strong emphasis on the competencies that pharmacists should hold to deliver each service in a professional and effective manner. During such diverse focus groups interviews, it is vital to define certain terms in the introduction to ensure that discussions are consistent. In our experience, the following terms were defined: competencies, pharmaceutical care, and medication therapy management. At the end of the session, stakeholders were also asked to discuss barriers that they felt could limit the development of certain services within the country. This was aimed at guiding our work to bridge the gap between the curriculum and the regulatory framework of the practice.

During each focus group, notes were taken with an emphasis on collecting and clarifying needs, services, competencies, and barriers. This aided in organizing the content by combining entries that had a similar meaning. Population needs, whether met or unmet, were quantified in terms of the number of times they were discussed within a focus group. This was then linked with the services proposed by the participants to meet those needs, as well as the competencies needed to fulfill those services. This formed the basis of the competency framework (see below). We identified five population needs that were further defined in terms of fifteen currently offered or expected pharmaceutical services. **Fig. 2** presents the relationships between needs and services.

Competency Framework

As alluded to previously, several pharmacy-related competency frameworks have been developed and can guide the development of a local set of competencies (Nash et al., 2015). Our needs assessment yielded a series of competencies supporting the provision of pharmaceutical services. The most frequent competency domains mentioned for any service (total occurrences from 8 focus groups) were communication (33 times), patient-centered care (18), life-long learning (16), Intra- and interprofessional collaboration (12), professionalism (12), and information access and critical appraisal (11). Interestingly, there was a very strong alignment between what the steering committee had in mind in terms of graduates (educational outcomes, **Table 2**) and the competencies that were identified by our external stakeholders.

The global occurrence for the competencies, and the service they were part of, became a guide to develop our competency framework. Starting from this list of competencies, a series of competency frameworks and national pharmacy standards of practice were reviewed to identify the elements of competencies that would define, at a more comprehensive level, the expected outcomes. The following five competency documents were considered very much aligned with our initial results and were used for that purpose: (1) the core competency framework for pharmacists by the Pharmaceutical Society of Ireland (Anonymous, 2013), (2) the CAPE pharmacy education outcomes (Medina et al., 2013), (3) the FIP global competency framework (Bruno, 2012), (4) the Educational outcomes or the Association of Faculties of Pharmacy of Canada (Brown et al., 2010), and (5) the professional competencies for Canadian pharmacists at entry to practice by the National Association of Pharmacy Regulatory Authorities (NAPRA) (Anonymous, 2013). Of these five documents, the competency framework developed by NAPRA had the greatest coherence with our competencies and pharmacists' activities identified and was used as a reference tool to delineate our

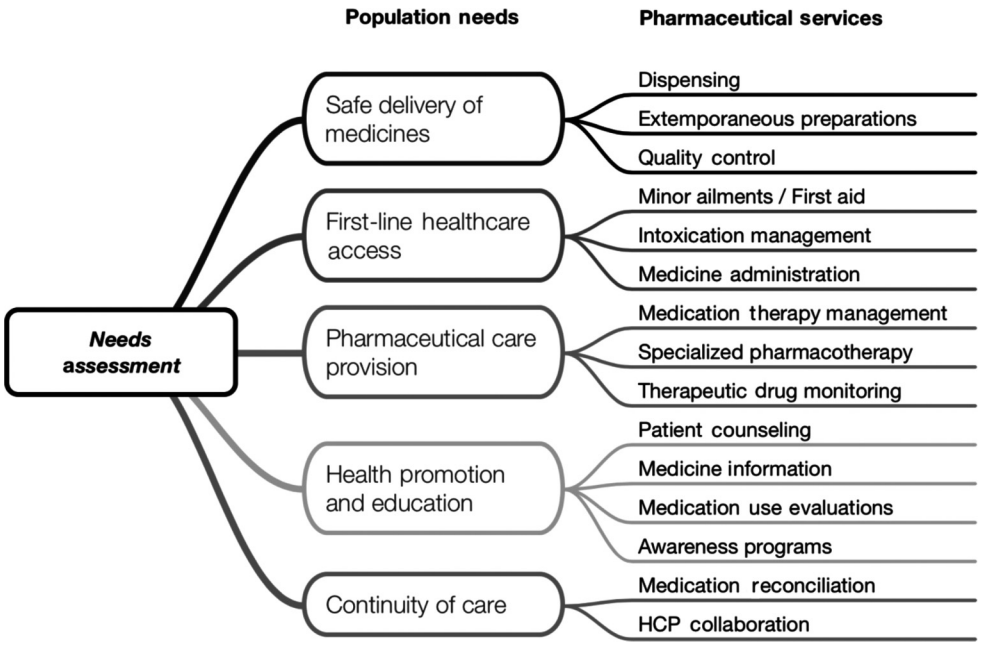

Figure 2 Results of the needs assessment in terms of population needs (*boxes*) and pharmaceutical services expected to be provided, by pharmacists, to fulfill the population needs. *HCP*, Health-care professionals.

competency framework, including definitions of competency domains. Other frameworks were then used to refine and finalize our competency element statements.

We ended up with eight transversal (or generic) competencies and three professional competencies. However, instead of using a linear model to describe and detail them, we used a matrix that crosses the professional competencies with the transversal competencies to define the elements of competencies (Table 3). Indeed, after reviewing several competency frameworks, we realized that there were several redundancies by using a linear model. As an example, communication was detailed in terms of elements of competency, as it constitutes a major transversal competency, but communication skills were also part of delivering direct patient care, managing the operations and providing educational activities, which are professional competencies. Thus, communication was expected to be developed both as a stand-alone competency and as part of professional competencies related to practice. The matrix model went through several rounds of revisions to reduce redundancies to a minimum and making each

Table 3 Matrix competency framework for Kuwait

	Provide pharmaceutical care	*Engage in health promotion and education*	*Manage pharmacy practice*
Communicate	• Develop and maintain a professional relationship with the patient by using effective communication and having a caring attitude • Listen actively to and assess the patient's health, needs and goals for their medication therapy • Obtain all needed information using appropriate interview techniques with patients, caregivers and HCP +3 others	6	2
Access and critically appraise information	3	2	1
Solve problems and make decisions	7	3	3
Collaborate	3	1	3
Engage in lifelong learning	2	2	1
Act professionally	3	2	5
Manage	4	2	8
Are proactive	2	3	3

Three professional competencies intersect with eight transversal competencies. The first intersecting cell is partially detailed in terms of competency elements. The number in the other cells represents the number of competency elements.

HCP, Health-care professional; *MTP*, Medication therapy plan.

element as specific as possible. It also allows the assessment of transversal competency proficiency in the context of professional competence (and vice versa).

Pharmaceutical Services

The need-based education model suggests that the competency framework underpinning expected professional services is translated in an education curriculum to complete the circle to fulfill the population needs (**Fig. 1**). According to Thistlethwaite, "competency frameworks should promote the alignment of competencies with appropriate activities and subsequent assessment to verify that learners have attained the competencies (Thistlethwaite et al., 2014). For educators, this is a significant challenge, since competency-based education is not widespread and there are few examples (Koster et al., 2017). Relying on an experienced consultant to guide curriculum development may be a wise thing to do. The main challenge is to transform a list of competency elements into meaningful learning activities that will allow time and space for knowledge acquisition, skills practice, and competency development. As Koster et al. described it, competence is contextual, developmental, and multidimensional, meaning that it has a significant impact on curriculum design (Koster et al., 2017).

How can competency development be integrated within knowledge and skills? What is the best approach to allow students to become competent? How can all the competency elements be visited and revisited until mastered? One could rely on the pharmaceutical services identified during the needs assessment (**Fig. 2**). The provision of each service (or professional activity) requires a unique subset of competency elements (a "competency profile") that form the framework. An example of the competency profile for medication reconciliation is provided (**Table 4**). Students can then practice and gradually master each competency element by practicing the delivery of a complete service. In other words, services contextualize the learning activities so that the students can focus on achieving specific results while developing their competencies.

This approach resonates with what is a current trend in work-based assessment. Indeed, in the medical education field, the apparent disconnect between competency frameworks, defining the abilities of the graduates, and professional activities, defining what a professional does, has been the source of an interesting development (Mulder et al., 2010). To reconcile the two in the context of work-based assessment, ten Cate et al. have conceived that professional activities that trainees can be trusted to perform (entrustable professional activities or EPA) actually uses a subset of the competency framework (ten Cate, 2013). In other words, performing a single professional activity will require students to mobilize only a part of the global list of competency elements (what we defined as a competency profile). Each professional activity will have its own subset of competency elements, and by combining different professional activities, all competency elements should be covered. Some competency elements may be needed only by one professional activity, while others may be common to several ones. If a competency element is not covered by any service, maybe it is not central to the professional development of the students, or may be it is something that can be acquired after graduation, in a continuing professional development strategy.

By using the EPA model to guide the curriculum, graduates would be able to perform all the expected professional activities and services in a competent manner. This idea is also set forward by Koster et al. in their model of CBPE (Koster et al., 2017). Focusing on services rather than on disciplines within a profession allows the desired integration of knowledge, skills, and competence. The number and definition of professional services become the backbone of the curriculum, rather than disciplinary knowledge. This is where the local influence will be apparent, as some countries may need more emphasis on developing a medicine distribution service, while others may focus on drug manufacturing and quality assurance services. This new paradigm allows for a wide range of professional activities to be included in the curriculum and also for new or emerging ones to be added at a later stage.

In our experience, it is worthwhile to define each service and try to limit the overlap between them. For instance, we separated medication therapy management (MTM) from patient counseling, as combining the two was redundant, increased the number of

Table 4 Competency profile for the medication reconciliation professional service

Professional competency domain	*Transversal competency domain*	*Competency element description*
Provide pharmaceutical care	Communicate	Develop and maintain a professional relationship with the patient by using effective communication and having a caring attitude
Provide pharmaceutical care	Communicate	Obtain all needed information using appropriate interview techniques with patients, caregivers, and HCP
Provide pharmaceutical care	Access and critically appraise information	Assess the relevance, accuracy and completeness of the information in relation to patient-needs, and interpret this information
Provide pharmaceutical care	Collaborate	Engage in and facilitate continuity of care within the pharmacy, with other pharmacists, and with other HCPs
Provide pharmaceutical care	Manage	Maintain complete and accurate patient records to document actions, interventions, and results

This service is defined as: "Performing the necessary actions to verify the completeness and accuracy of a patient's current medicines at critical points (admission, transfer, and patient discharge)."

competency elements, and made the assessment more challenging. Dispensing also had to be defined as a separate entity from MTM. Each professional activity or service has to be performed by students in learning activities. Having a very lengthy competency profile will make the scenarios that have to be developed for students to perform, and instructors to assess, more complex. In our experience, a maximum of 12–15 competency elements should compose the profile of a single professional activity. At the other end of the spectrum, less than 5 competency elements within a profile will make it difficult to discriminate the performance of the students.

Each professional service should be introduced and revisited on several occasions during the curriculum in order to allow students to reach the level of performance expected at the end of the program. When students perform a service for the first time, the level of mastery of each competency element within the profile cannot be expected to be ideal. However, expectations have to be set to a challenging but reasonable level for students to feel confident and build on previous experiences to progress in the mastery of their competencies. By changing the setting or context, students can revisit a professional service, but with some added knowledge that makes the redundancy worthwhile. For example, students could learn about and practice community pharmacy dispensing in a first course, but focus on inpatient dispensing on the second iteration of the service.

Essential Knowledge and Skills and the Curriculum

Most pharmacy curricula are based on a defined list of disciplinary knowledge and skills that allow students to become familiar with each pharmacy-related discipline. For example, the pharmacology department will cover basic pharmacology concepts and then review the pharmacology of different classes of medicines, sometimes even covering the therapeutics aspects for each class. However, professional practice also requires a set of more generic or transversal competencies (often called soft skills) that are seldom the focus of any formal learning activity. Students are asked to present their work and we expect good presentation skills, without providing the theoretical background of what constitutes a good presentation. The same goes for communication, scientific writing, professionalism, leadership, and the list goes on. Soft skills are sometimes addressed in add-on courses that try to reduce gaps in the education.

Thus, one important step in preparing a competency-based curriculum is to define the essential knowledge and skills required to learn about and practice components of all the competency elements that are part of the framework. For example, medication reconciliation includes "Obtain all needed information using appropriate interview techniques with patients, caregivers and HCP" as a competency element (Table 4). This requires knowledge of the techniques of conducting an interview and the skill of conducting an effective interview. These knowledge and skills, combined with those for other competency elements, can then be applied to performing a medication reconciliation service.

After mapping all competency elements with the essential knowledge and skills required, this content should be added to the disciplinary knowledge and skills required to create the scientific and clinical base for pharmacists. With a known set of knowledge, skills, and professional activities (each with a competency profile), one can start to think about the course structure of the curriculum. In our current reform, some pharmaceutical services have actually become distinct courses, while before, they were parts of less structured pharmacy practice laboratories. Courses on dispensing now integrated theory and practice. Courses on extemporaneous preparations include the legal framework as well as the aspects of pharmaceutics. Instead of seeing a course as a disciplinary possession, courses have to become a setting for a professional activity to be introduced (knowledge and skills) and performed (competency development).

The longitudinal (horizontal) iterations allowing students to become competent for each professional service have to be defined within the new curriculum. The second iteration of a service can rely on its first iteration to allow a progression in the challenge offered to the students. One academic staff can be nominated to champion this longitudinal continuity for a given service. Ideally, as the service is revisited, less time is devoted to knowledge and skills, and more time is allowed for practice. This is the reason why theory and practice have to be better integrated, and the two components should in fact be part of the same course for optimal coordination. Also, the integration provides a better platform for the assessment of both surface and deeper learning within a professional context, encompassing different levels of the bloom taxonomy (Bloom, 1956).

Active Learning and Assessment Frameworks

To foster the development of proactive professionals, an environment where the responsibility of learning is shared between the learners and the instructors has to be created. Indeed, passive learning is more likely to generate passive graduates (Kober, 2014). Proactivity is a competency that will develop when students are faced with challenges and allowed to construct their own knowledge. Active learning approaches have been shown to be superior to the more passive teaching that most of us currently use (Dean Jr and Kuhn, 2007; Waldrop, 2015). As Linda Kober puts it in her report: "Applying findings from research on teaching and learning to improve instruction involves the same type of thinking one would use to solve a scientific or an engineering problem in a discipline. Why do outstanding scientists who demand rigorous proof for scientific assertions in their research continue to use and, indeed, defend on the basis of their intuition alone, teaching methods that are not the most effective?" (Kober, 2014).

One important question is whether active learning should be done independently by individual instructors or should be part of a global effort embedded within the curriculum. The educational literature is filled with examples of active learning activities tested in one course within a curriculum. Considering the evidence-based advantages of active learning, we believe that a more structured

approach is more efficient. It will also help the student find a more "predictable" learning environment if there is a global framework for active learning. In other words, each course could be developed by adhering to some guidelines in order for students to focus on the goals they have to achieve and not on learning how they have to behave in an unknown pedagogical environment. The framework needs some flexibility to accommodate variations in disciplinary content and student competency development across the various courses. As alluded to above, a course becomes a learning continuum of theory and practice, prepared by the same instructors with the final goal of competency development in mind. This should challenge the learners sufficiently enough to anchor knowledge for future retrieval and foster optimal application.

This active learning framework can be easily communicated, with workshops and examples, to prepare students for what lies ahead. This will greatly reduce the anxiety of the learners as they embark on this new journey of competency development. The same framework should also be used to train the educators and instructors to develop coherent learning activities. They can take part in workshops and discuss their experiences to help others transition and empower them (Kotter, 1996). By preparing and guiding instructors, we can ease the transition from their current method of teaching to embrace a more open environment of learning through shared responsibilities.

As new learning methods are introduced, assessment tools also have to be adapted and relevant. "Assessment drives learning" is a very powerful statement that should guide our assessment activities. It means that the students will do all they can to pass the assessment, thus making the assessment, and not the learning objectives, the true reflection of their knowledge and competence. Aligning the assessment with the learning objectives will ensure that the students are learning what is really important. For competency-based education, assessment is a significant challenge, because students should be assessed "while performing." The synchronous assessment can be resource intensive, and solutions have to be devised to keep the assessment as closely linked as possible to the performance. This can be facilitated by video recording or paper-based reporting by students (of a case resolution, for example) to allow asynchronous assessment. Objective Structured Clinical Examinations (OSCE) and mini-CEX are examples of methods that can be used to assess competence.

Competency assessment normally has two dimensions. First, one has to determine which competency element has to be assessed. Second, the level of competence has to be defined and will depend on the progression of the student within the curriculum. Expectations should be higher for students in their final years. This implies that for each competency element, different levels of expectations have to be described and the student's performance graded according to the expected level. Thus, if a competency framework has more than 50 competency elements and 3 levels are expected (beginner, intermediate, and expert), then more than 150 definitions of expectations have to be created.

To address the first dimension, one can rely on competency profiles, one for each professional activity, as discussed above. Each profile represents the competency elements that are assessed each time students practice a given service. The level of competence (the second dimension) for each competency element can become quite complicated. However, one can borrow from the evaluation of work-based EPA, which rely on five generic levels, reflecting the level of trust a supervisor has toward a trainee performing a task (Mulder et al., 2010). This concept can be used and modified according to the setting. For example, for laboratory and simulation assessment, we have identified four levels of competence:

- Level 1: not sufficient to perform the activity
- Level 2: sufficient to perform the activity with moderate feedback (dependent)
- Level 3: sufficient to perform the activity without feedback (independent)
- Level 4: sufficient to teach or become supervisor

This generic grading scale is easy to understand and use and allows flexibility for the assessors to ask additional questions or "prompt" students to determine their level of independence. Competency profiles and the expected level are known by the students and the assessors before the learning and assessment activities. The same format can be used as a formative assessment before the summative assessment so that students can get feedback on their performance before it is marked.

In order to detect if a student frequently fails competency elements in the same competency domain, the individual scores of competency elements can be included into a portfolio and revised periodically. The goal is to identify early students with competence shortcomings and help them to get back up to speed.

Developing an appreciation that "knowledge is only as good as its application" is relevant for both the instructor and the learner. It should be the driving force to resist reverting back to old habits of using solely knowledge assessment. Accordingly, programmatic assessment is emerging as a structured way of considering assessment as part of the learning strategy, rather than as an imperfect but necessary tool to determine the extent to which students have achieved their learning objectives (Fielding and Regehr, 2017; van der Vleuten et al., 2012). It includes periods of formative assessment and feedback to allow students to pursue the development of their competencies. Student grading is then based on a collection of assessments (data points) measured on several activities with appropriate examination methods.

Experiential Training

The learning continuum, from theory to practice, has a third component; professional experience (or experiential training). Students have to be confronted to real-world scenarios to ensure that they are ready to take care of patients. Simulations and

case resolutions done within the university setting do not have the emotional range experienced with real patients. The level of responsibility and accountability are clearly not the same. Practice experience is engrained in most pharmacy programs to allow students to test their preparedness and work more in gray zones under supervision from their preceptors. The preceptors provide input on behaviors and attitudes that are difficult to reproduce outside a practice context, even with role-playing.

Although this part of the curriculum occurs outside the university, most often with practitioners that are not faculty members, there needs to be a clear continuity with the curriculum. The learning outcomes become extensions of the ones started within the university. Experiential training can be seen as another form of active learning and can still fit within the active learning framework. The difference would be that the course (the placement) is fully in the competency development mode, and there is very little room for knowledge acquisition. In that context, the assessment of students during their rotation could follow the same model as with the university courses, as they were based on EPA with competency profiles. Entrustable professional activities were in fact developed for work-based assessment to start with (Mulder et al., 2010). Thus, irrespective of the fact that a student practices a professional service in a practice laboratory or in a clinical setting, the same assessment tool, based on the competency profile, can be used. Students will be familiar with the expectations. However, like faculty members, preceptors have to be trained to use the tools by conducting hands-on workshops with them. During the placements, support will have to be provided to make sure that the assessment tools are used properly both as formative (with feedback) and summative instruments.

As it is the case with competency assessment done *intra muro*, different levels of performance can be expected during early pharmacy practice experiences or advanced experiences. A generic grading scale, based on the EPA literature, should be used to facilitate the work of the preceptors who will have to grade students according to their performance for each competency element (Mulder et al., 2010; ten Cate, 2013). To be intuitive, the assessment follows the trust that the preceptor feels when the trainee performs a certain activity or service.

Each practice experience placement within the program will allow students to practice a subset of all the professional services, and one has to make sure that the selected sites are offering these services to allow students to develop as they conduct the activities. Distinct placements will focus on different pharmaceutical services to cover the whole range in a real-life setting. Including the same professional activities (or services) within the practice experience will allow a smooth transition and optimal continuity from the *intra muro* curriculum. Thus, placements become part of the longitudinal competency development structure.

Conclusion

Pharmacy is an evolving profession (Bonanno et al., 2012), and the professional education curriculum must adapt to changing needs and expectations from the population. Its evolution trajectory and speed are not the same in all countries and there is a need for conducting local need-based assessment of what is expected from the graduates (Atkinson, 2014; Brock et al., 2012). Competency-based education is recognized as a model that allows a better alignment to the societal needs, by focusing on the desired outcomes rather than on disciplinary knowledge (Frenk et al., 2010). Because there are not many examples, competency-based education is still difficult to grasp, let alone to develop (Hawkins et al., 2015; Koster et al., 2017). It involves significant changes in basic academic activities, such as the need to move toward active learning methods, discipline integration, direct observation assessment, and experiential learning. There is a need for a longitudinal structure allowing students to reach increasing levels of competence mastery over time.

Although there is a different view on which courses should compose a pharmacy curriculum (and this is expected in countries with different challenges), there is a greater homogeneity on the outcomes expected from the curriculum: pharmacists that are competent to fulfill the local needs (Bader et al., 2017b; Bruno, 2012). The challenge is to translate these outcomes into meaningful learning activities that will compose courses. For too long, we have worked backwards, by defining courses first, then learning objectives and expecting competent pharmacists at the outset (**Fig. 3**). We are proposing a step-by-step approach that starts from the outcomes in the form of a competency framework that, through pharmaceutical services, can be practiced and mastered during the curriculum. This approach was used to develop the new PharmD curriculum at Kuwait University and can be adapted to serve local needs and realities.

To our knowledge, one of the first pharmacy curriculum based on competency development was first offered at the Faculty of Pharmacy of Université de Montréal in 2007 (Mailhot et al., 2006). The impact on the students' confidence and overall preparedness to offer pharmaceutical services was phenomenal (personal observation). We are currently seeing similar outcomes in Kuwait in a competency based 2-year add-on PharmD program. We are thus convinced that beyond knowledge and skills acquisition, CBPE generates change leaders that can have a significant and positive impact on the scope of practice and quality of care. Unless these are not desired outcomes, educators involved in preparing students to "becoming a pharmacist" should seriously consider joining the growing community moving toward competency-based education.

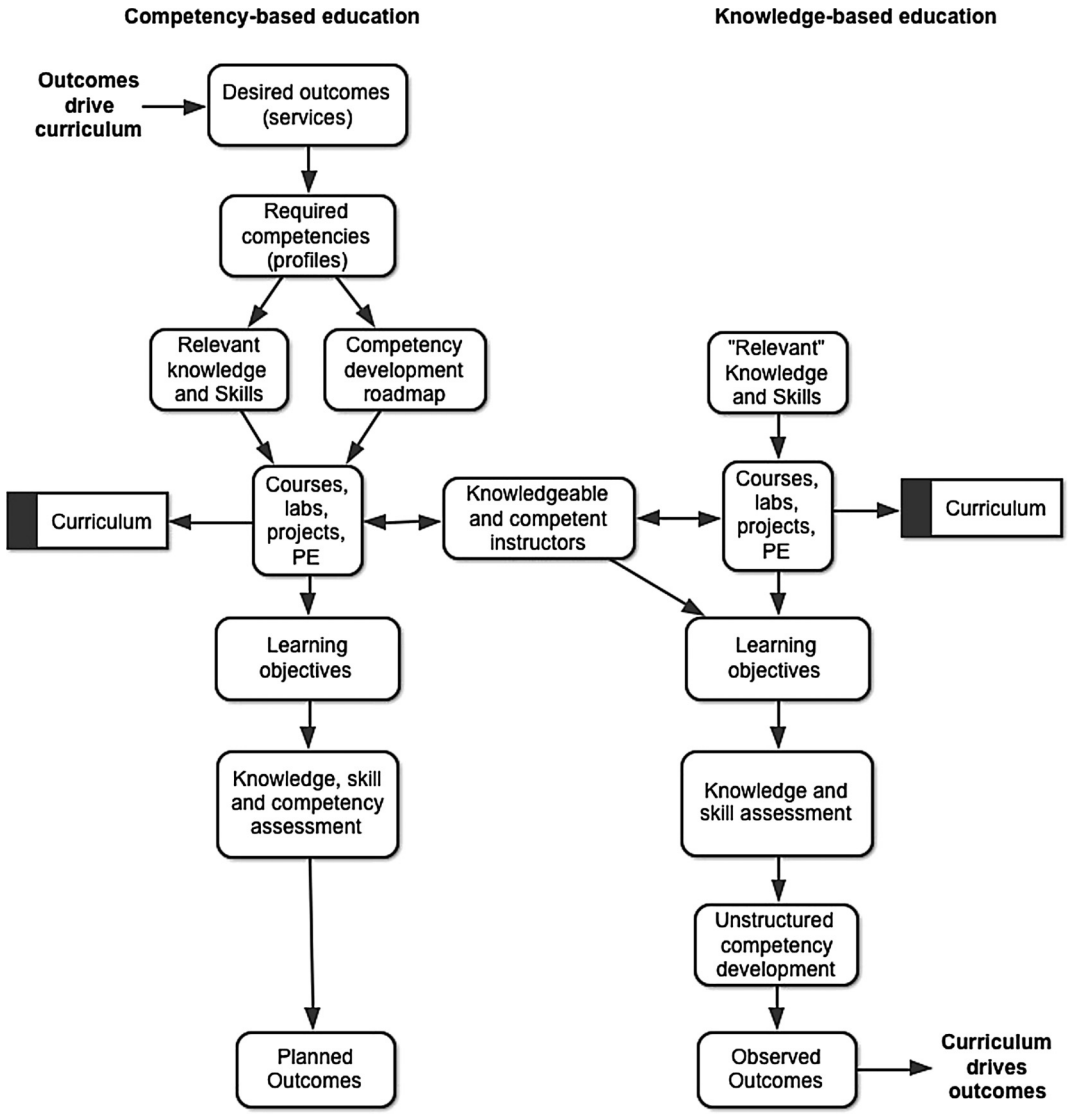

Figure 3 Comparison between competency-based education (*left*) and a more traditional approach to curriculum design (*right*). Both share competent instructors, but in a knowledge-based model, the outcomes are not driving the curriculum, and one should expect only partial preparedness to offer the scope of professional services. PE, practice experience.

Glossary

Active learning: a form of learning in which teaching strives to involve students in the learning process more directly than in other methods (en.wikipedia.org).
Bloom's taxonomy: a set of three hierarchical models used to classify educational learning objectives into levels of complexity and specificity. The models were named after Benjamin Bloom, who chaired the committee of educators that devised the taxonomy (Bloom, 1956).
Competence: having a complete repertoire of competencies (Brown et al., 2012).
Competency: mobilization of knowledge, skills, behaviors and attitudes that an individual accumulates, develops and acquires through education, training and work experience, to perform job-relevant tasks effectively within a given professional context (from the authors, summarizing several definitions from (Nash et al., 2015)).
Competency-based education: an approach to preparing professionals for practice that is fundamentally oriented to graduate outcome abilities and organized around competencies derived from an analysis of societal and patient needs. It deemphasizes time-based training and promises greater accountability, flexibility, and learner-centeredness (Frank et al., 2010).
Competency framework: a list of competencies and competency elements that define a professional (from the authors)

Direct observation (or observational) assessment: Assessing a performance related to knowledge, skills, or competence by observing the participant (from the authors)
Entrustable professional activity: is a key task of a discipline that an individual can be trusted to perform in a given context, once sufficient competence has been demonstrated (www.royalcollege.ca/rcsite/documents).
Experiential learning: is the process of learning through experience, and is more specifically defined as "learning through reflection on doing" (en.wikipedia.org)
Knowledge: facts, information, and skills acquired through experience or education; the theoretical or practical understanding of a subject (Oxford Dictionaries).
Needs-based education: an assessment of the needs of the community and then development, or adaptation, of supporting educational systems accordingly. Implementing such a needs-based approach requires ongoing consultation and cooperative partnerships between all stakeholders within countries and within institutions (Anderson et al., 2012)
Skill: the ability to do something well; expertise (Oxford Dictionaries).

Becoming a Pharmacy Assistant and Technician: Education and Training

Shirley-Anne Boschmans, Pharmacy Consultant, Johannesburg, South Africa

Introduction

In many professions a support workforce has evolved to assist the professional in the successful completion of their professional activities. In pharmacy this support activity has evolved into the role undertaken by the pharmacy technician. The pharmacy technician functions in the role of assistant to the pharmacist although with the continued evolution of both the roles of the pharmacy technician and that of the pharmacist there is increasing responsibility devolving to the pharmacy technician.

The education and training of the pharmacy support personnel (pharmacy technician) who support the activities of the pharmacist has evolved in response to many factors: the evolution of the role of the pharmacist; legislation; requirement for support personnel certification or registration; and extended roles for pharmacy technicians. This chapter will explore the education and training of pharmacy technicians and the factors influencing the evolution of this education and training.

Influence of the Evolution of the Role of the Pharmacist

With the advent of the concept and practice of pharmaceutical care the role of the pharmacist has evolved from being product (medicine) focused to a patient focus with the pharmacist assuming responsibility for outcomes relating to medicine therapy (Anderson et al., 2009; Toklu and Huddain, 2013). This has required pharmacist activities to shift from the more technical tasks, such as stock control, order entry and distribution, prescription capture and filing, to tasks requiring higher-level cognitive skills such as interpretation and evaluation of the prescription, assessment of possible drug/drug or drug/disease interactions, and patient counseling (Anderson et al., 2009).

In countries such as the United States, United Kingdom, and Australia the driver for a greater utilization of pharmacy technicians is indeed the task shifting of pharmacists toward a more clinical role (Zellmer, 2012). The increased utilization of pharmacy technicians frees the pharmacist for participation in a more clinical role with a higher cognitive demand. However, in countries where the number of pharmacists is lower the situation is more complex. The increased demand for or possibly the more expanded practice of pharmacy technicians is greatly driven by the great need for a larger number of personnel to provide pharmaceutical services in the absence of sufficient pharmacists (Brown et al., 2011; World Health Organisation, 2011) supplemented by the additional driver of the movement of pharmacists to the more clinical role.

Europe has on average >7.5 pharmacists per 10,000 population while the WHO regions of Eastern Mediterranean, Western Pacific, and the Americas have between 5 and 7.5 pharmacists per 10,000 population with South East Asia having between 2.5 and 5 pharmacists per 10,000 population and Africa less than 2 pharmacists per 10,000 population. Interestingly WHO regions of Europe, Western Pacific, Americas, and Africa have more Pharmacy Technicians than pharmacists per 10,000 population while South Eastern Asia has fewer pharmacy technicians than pharmacists (Bates et al., 2016). This indicates that factors other than evolution of the role of the pharmacist and country income play a role in the demand for pharmacy technicians. These factors include absence of supporting legislation.

Legislation

Scope of Practice

The scope of practice of a pharmacy technician is directly linked to education and training as the education must be fit for purpose, i.e., the education and training must provide the knowledge, skills, and attitude required to fulfill the requirements of the scope of practice (Schafheutle et al., 2015).

Scopes of practice for pharmacy technicians vary from country to country (Frost and Adams, 2017; Kohler and Brown, 2017). Areas of greatest variation are: accepting verbal/telephonic prescriptions; performing a final accuracy check for dispensed medicines; supervisory powers; administering vaccinations; participation in medicine reconciliation; and functioning under indirect supervision. Additionally, in some countries such as Canada (National Association of Pharmacy Regulatory Authorities, 2014) and the United States (National Association of Boards of Pharmacy, 2017) the scopes of practice of pharmacy technicians will vary from state to state creating in-country variations.

In Australia the role includes: ordering and unpacking of stock; repackaging stock; preparing dispensing labels; attaching dispensing, cautionary and advisory labels; gathering nonclinical information; collating prescriptions; and compounding of medicines. A pharmacy technician may not offer any information to a patient about the safety and efficacy of medicines. The duties of the pharmacy technician are assigned by the pharmacist and must align to the technicians' education and training as well as experience. A suitably trained and experienced pharmacy technician may compound simple as well as complex medicines but the ultimate responsibility for the compounded medicine lies with the pharmacist. Compounding may only be undertaken under direct supervision of the pharmacist (Pharmacy Board of Australia, 2015; Pharmaceutical Society of Australia, 2003).

In Ontario, Canada pharmacy technicians may prepare a prescription and perform the final technical accuracy check. The technician may also provide information and education to the patient, but, the pharmacist is responsible for the therapeutic assessment and or education relating to the prescription. A pharmacy technician may also compound a medicine required for a prescription and may receive verbal prescriptions (Ontario College of Pharmacists, 2018).

In Denmark the pharmacy technician is known as a pharmaconomist. Activities of the pharmaconomist are undertaken at a higher level of responsibility than that of pharmacy technicians in most other countries. In community pharmacy the pharmaconomist can dispense a prescription including the final check without the input of the pharmacist although the pharmacist must be available (in person or telephonically) to respond to any queries from the pharmaconomist (Hansen and Brown, 2017). More information about and a comparison of the scopes of practice for pharmacy technicians in the various countries in Europe can be found in a survey published in 2017 by the European Association of Pharmacy Technicians (2017a).

In Malawi, largely due to a scarcity of pharmacists, pharmacy technicians work almost entirely without supervision and provide the backbone of personnel involved in provision of pharmaceutical services. In 2008, of the 300 strong pharmacy workforce only 2% were pharmacists. Pharmacy technicians, in the public sector, work mainly in hospitals where they are in charge of all aspects of provision of pharmaceutical services including drug supply management and dispensing services. Pharmacy technicians also supervise pharmacist assistants (a lower level of pharmacy support personnel) who provide pharmaceutical services at health centers (Larsen-Cooper et al., 2017).

Activities of entry level pharmacy technicians in Singapore include supportive roles in stock control and dispensing processes. An advanced role is also envisaged with career progression allowing for participation in supervisory and managerial tasks. Activities associated with an advanced level of practice include involvement in: distribution services including automation processes; compounding of sterile and nonsterile medicines and participation as part of the team for clinical trials; dispensing processes including medicine management and patient education; and quality assurance and medicine safety (Chew et al., 2017).

In South Africa although the scope of practice for pharmacy technicians was published for comment in 2011 the scope has not, to date, been formally legislated requiring pharmacy technicians to practice within the scope of practice of a pharmacist assistant post basic—a lower scope of practice. Activities in the proposed scope of practice for the pharmacy technician include: assist with manufacture, compounding manipulation or preparation of a sterile or nonsterile medicine; packing and re-packing of medicines; picking, packing, and dispatch of medicine orders; management and ordering of medicines; dispensing of medicines; general housekeeping and administrative tasks; supervision of other pharmacy support personnel; and technical support for screening tests. The supervisory capacity and involvement in technical aspects of screening tests is not included in the pharmacist assistant post basic scope of practice (Boschmans et al., 2017).

The role of the pharmacy technician has evolved in two main areas of practice in the United Kingdom, namely, community pharmacy and hospital pharmacy although pharmacy technicians also practice in education and the pharmaceutical industry. Although there are ongoing discussions relating to a greater shift of responsibility in community pharmacy to the pharmacy technician in hospital pharmacy the autonomous role of the pharmacy technician has evolved to a greater extent. Entry level activities for pharmacy technicians include: preparation of medicines for prescriptions and the supply of medicines to patients; compounding and manufacture of medicines; procurement and stock control of medicines; provision of health education; and supervision of other pharmacy staff (Boughen et al., 2016; General Pharmaceutical Council, 2018a).

There is great variation in the role of the pharmacy technician in the different states in the United States. Although the Pharmacy Technician Certification Board (PTCB) has been in existence since 1995 not all states require certification of pharmacists (Pharmacy Technician Certification Board, 2017a). However, generally the role is seen as a supportive one including the following activities: receipt of prescriptions; counting tablets; labeling of medicine containers; administration associated with processing of prescriptions such as updating of computerized patient profiles and submission of insurance claims; stock control; and other administrative functions include answering phones and operating cash registers (National Association of Boards of Pharmacy, 2017).

In summary, activities commonly included in the pharmacy technician scope of practice/role are:

- Prepare prescription;
- Provide information and education (nontherapeutic);

- Compound medicines (sterile and nonsterile);
- Stock control management;
- Ordering and procurement of stock; and
- Participate in health promotion activities.

Activities allowed in certain jurisdictions and not in others include, but are not limited to:

- Accept verbal prescriptions;
- Supervision/delegation;
- Supervision of a pharmacy;
- Administration of vaccines;
- Medicine reconciliation; and
- Technical accuracy check of dispensing process.

Supervision

Three aspects relating to supervision are important influencers of pharmacy technician education and training. These are, the ratio of pharmacy technician to supervising pharmacist permitted, whether the pharmacist supervision is direct (the pharmacist is in the same venue as the pharmacy technician and personally supervises the pharmacy technician's activities) or indirect (the pharmacy technician is operating in a geographically distinct site), and whether the pharmacy technician has supervisory capacity over other pharmacy support personnel. The greater the ratio of pharmacy technicians to supervisory pharmacist ideally the greater the required knowledge and skills base of the pharmacy technician. It stands to reason that the pharmacist will not be able to directly supervise every single activity undertaken by the pharmacy technician if the pharmacist is allowed a greater number of pharmacy technicians to supervise. If a pharmacy technician practices under indirect supervision, especially if there is not a direct video-link facilitating supervision, one would also expect greater autonomy of activity thus requiring a more extensive knowledge and skills base. Lastly if a pharmacy technician is permitted to supervise other pharmacy personnel or perform final accuracy checks the education and training would need to include supervisory practice knowledge and skills and accuracy checking (Kohler and Brown, 2017; White Paper on Pharmacy Technicians, 2002).

Supervisory ratios, for direct supervision, are stipulated by the Pharmacy Board of Australia in the "Guidelines for dispensing of medicines" (Pharmacy Board of Australia, 2015). The ratio that should not be exceeded is two pharmacy technicians to one pharmacist. A pharmacist may, however, motivate for an increased ratio. The Society for hospital Pharmacists of Australia is more conservative and recommends a ratio of 1.5 pharmacy technicians to everyone pharmacist (O'Leary and Allinson, 2009). Generally direct supervision of the pharmacy technician is required. There are some circumstances in remote areas where indirect supervision may be allowed. A video-link is required under these circumstances.

Canada is another country where there are remote areas with inadequate provision of pharmaceutical services. In these circumstances indirect supervision of a pharmacy technician is permitted as long as there is a live audio-visual link and the supervising pharmacist is present in the pharmacy that operates the remote dispensing site. The designated pharmacist is responsible for ensuring that supervision of support staff is appropriate (Ontario College of Pharmacists, 2014).

In Denmark the pharmaconomist functions relatively independently with the requirement that the pharmacist must be available to handle queries either in person or telephonically. Thus, a pharmaconomist does not have to function under direct supervision. The ratio of pharmaconomists to pharmacists is 3.5:1 (Hansen and Brown, 2017).

As a consequence of the need for pharmaceutical services in the rural areas and inadequate numbers of pharmacists ratios for both direct and indirect supervision of pharmacy support personnel have been legislated in South Africa (South African Pharmacy Council, 2016a). A pharmacist may supervise not more than three pharmacy support personnel (irrespective of role played, e.g., pharmacy intern, learner post basic pharmacist's assistant) under direct supervision. When the pharmacy support personnel are functioning at a primary health care clinic under indirect super vision a pharmacist may supervise up to five pharmacist's assistant post-basic. These two supervisory roles are not mutually exclusive.

In the United States the pharmacist to pharmacy technician supervisory ration differs greatly from state to state (Malacos, 2016). Some states do not even stipulate a ratio leaving the decision to be determined by the pharmacist in charge. Examples of some of these states are Delaware, Iowa, Kentucky, Oregon, and Vermont. In states where the ratios are stipulated these ratios vary from two pharmacy technicians to one pharmacist to six pharmacy technicians to one pharmacist. As examples more detail will be provided below on the ratios in a few states with legislated ratios.

California stipulates a ratio of one pharmacist to one pharmacy technician initially, thereafter two pharmacy technicians for each subsequent pharmacist are permitted (California Board of Pharmacy, 2018). This ratio does not include pharmacy support personnel involved in administrative tasks such as filing or cleaning. In a licensed health facility the initial ratio will be one pharmacist to two pharmacy technicians. In addition to direct supervision, a pharmacist in California may also indirectly supervise two pharmacy technicians who are working at a remote dispensing site. Requirements for indirect supervision are a direct audio and video link that allows the pharmacist to clearly observe all steps of the dispensing process and to communicate with the patient in order to provide patient counseling.

Colorado has a much higher ratio, namely one pharmacist to six pharmacy technicians. Pharmacy interns are included in the ratio but the total of six may not include more than two pharmacy interns. Additionally if three or more technicians are on duty at the

same time the technicians must be certified or have passed an accredited exam or have completed at least 500 hours of experiential training (Colorado General Assembly, 2017).

Idaho has one of the higher ratios. Under direct supervision six pharmacy technicians may be supervised by one pharmacist (Adams, 2017).

Mississippi allows a ratio of one pharmacist to three pharmacy technicians (Mississippi Board of Pharmacy, 2017). This ratio also excludes any support personnel involved in administrative duties such as filing prescriptions and general record keeping.

Although Montana also has a ratio of three to one the rule clearly states the requirements for application for a higher ratio (Montana Board of Pharmacy, 2006). The pharmacist must submit a pharmacy services plan illustrating how the standards of providing pharmaceutical care will be maintained. The plan should include information pertaining to the following aspects: design and equipment; information systems; work flow; and quality assurance.

In New Mexico the ratios for both direct (New Mexico Board of Pharmacy Regulation and Licensing Department, 2016) and indirect supervision (New Mexico Board of Pharmacy Regulation and Licensing Department, 2017) may be determined by the pharmacist in charge. Indirect supervision, similar to California, requires the use of audio-visual communication so that the pharmacist can supervise all required aspects of the dispensing process. Additionally the pharmacist may not supervise, directly or indirectly, across more than four pharmacies.

Culminating in 2016, the Tennessee Board of Pharmacy led a process to institute legislation concerning the supervisory ration for pharmacy technicians. The drivers were concerns for safety and quality (Todd et al., 2014). The ratio decided on was that of one pharmacist to every two pharmacy technicians. A ratio of four to one may be allowed if at least two of the pharmacy technicians are certified. The greater ratio would be considered bearing in mind aspects relating to public safety considerations.

In Virginia the ratio may be determined by the pharmacist in charge but may not exceed four pharmacy technicians to one pharmacist (Virginia Board of Pharmacy, 2018). The conditions for direct supervision are clearly delineated. The pharmacist must be physically present (no other means of communication, such as electronic or written, is acceptable) and have personal control over all aspects of the dispensing process.

Registration/Certification of Pharmacy Technicians

Registration or certification of pharmacy technicians leads to standardization of gateway examinations for certification. Standardized examinations prior to registration ensure that pharmacy technicians have the prerequisite knowledge and skills for the expanding roles they are adopting (National Association of Boards of Pharmacy, 2017). Once again there are differences across countries and even within countries with variations between provinces/states.

A pharmacy technician is not required to register in order to practice in Australia (and New Zealand). Although the Pharmacy Board of Australia does require any formal educational qualification to practice as a pharmacy technician there are recommendations that pharmacy technicians complete recommended training courses. There are variations in the recommendations for the technicians practicing in community pharmacy and those in hospital pharmacy.

Prior to 2010 pharmacy technicians in Canada were not registered/certified (Ontario College of Pharmacists, 2018). At the end of 2010, following legislative changes Ontario became the first province to regulate pharmacy technicians and require registration. Eight years later, in 2018, registration is required for pharmacy technicians in all provinces (nine provinces) except for Quebec (Canadian Institute for Health Information, 2018). Additionally, although Newfoundland and Labrador allow unregistered pharmacy technicians to practice this is an interim measure and this province is moving toward registration being a requirement for all pharmacy technicians to practice. In Manitoba pharmacy technicians are regulated but are not registered they are only listed (National Association of Pharmacy Regulatory Authorities, 2018). By 1 January 2018 there were 8185 registered technicians in Canada (Canadian Institute for Health Information, 2018).

Pharmacy technicians or pharmaconomists in Denmark do not require registration as authorization to practice (Hansen and Brown, 2017). The only requirement is the certificate from Pharmakon. Pharmakon, a college of pharmacy practice, is the only academic institution in Denmark that trains pharmacy technicians. Foreign pharmacy technicians are not required to register in order to practice. The permission of the Danish Medicines Agency is required in order to practice as a pharmacy technician (Danish Medicines Agency, 2016).

As of July 2017 there were 283 pharmacy technicians and 242 pharmacist assistants registered with the Pharmacy, Medicines and Poisons Board of Malawi (2018). Registration is a requirement to practice. A pharmacy technician registration examination is administered by the Pharmacy, Medicines and Poisons Board of Malawi. Pharmacy technicians must pass the examination prior to applying for registration as a pharmacy technician.

In Singapore pharmacy technicians are not regulated. However, the pharmacy technician functions under the close supervision of the pharmacist (Chew et al., 2017).

Pharmacy support personnel in South Africa may not practice without registration with the statutory body for pharmacy—the South African Pharmacy Council. Registration for pharmacy support personnel was first introduced in 1987. There were two categories of pharmacy support personnel on the original register: qualified pharmacy assistants and unqualified pharmacist assistants (students who exited from the pharmacist qualification prior to completion) (Boschmans et al., 2017). Currently, there are three categories of pharmacy support personnel in South Africa: pharmacist's assistant basic; pharmacist's assistant post basic; and pharmacy technician. The legislation has not been finalized to allow for a register for pharmacy technicians to be established.

Therefore, graduates from the pharmacy technician qualification are registered in the register of pharmacist's assistant post basic. A preregistration examination will be introduced within the next two years.

Prior to 2011 pharmacy technicians in the England, Scotland, and Wales were not required to register with the Royal Pharmaceutical Society of Great Britain/General Pharmaceutical Council (the General Pharmaceutical Council was founded in September 2010) in order to practice (Boughen et al., 2016). In 2001 the Audit Commission which looked at medicines management in local hospitals recommended that pharmacy technicians should be registered (Audit Commission for Local Authorities and the National Health Service in England and Wales, 2001). Voluntary registration with the Royal Pharmaceutical Association of Great Britain commenced in 2005 and compulsory registration was instituted by the General Pharmaceutical Council in 2011 (Boughen et al., 2016). In order to be eligible for registration as a qualified pharmacy technician candidates must have completed the required educational requirements and have spent a minimum of two years in the practice environment (Rosado et al., 2015).

In the United States certification of pharmacy technicians is undertaken by the Pharmacy Technician Certification Board which was founded in 1995. In order to achieve certification candidates must: have a high school diploma; disclose all criminal and State Pharmacy Board records; comply with Pharmacy technician Certification Board certification policies; and pass the pharmacy technician Certification Examination (Pharmacy Technician Certification Board, 2017c). Successful completion of a training program is not required in order to write the Pharmacy Technician Certification Examination. In 2012 the Pharmacy Technician Certification Board published an additional requirement for writing the certification examination: completion of a Pharmacy Technician Accreditation Commission accredited training program. The additional requirement was to be implemented by 2020. However, in 2017, the decision was suspended to allow for further consultation (Pharmacy Technician Certification Board, 2017d). Postcertification pharmacy technicians are required to participate in continuing professional development.

Certification requirements in the United States differ greatly from state to state. At the end of 2017 there were still five states (Colorado, Hawaii, Michigan, New York, and Pennsylvania) which did not regulate pharmacy technicians (Pharmacy Technician Certification Board, 2017b). Only 23 states and the District of Columbia require certification in order to practice. Twenty-two states regulate pharmacy technicians but do not require national certification. Regulation by the state with required registration with the state board of pharmacy is beneficial in that it allows the board of pharmacy to determine the number of pharmacy technicians practicing in the state.

Basic Education and Training

A requirement for a minimum qualification linked to registration can be a driver for the development and progression of a workforce such as pharmacy technicians. Such a requirement would set minimum standards for education and training required for pharmacy technicians and would additionally serve as a basis for development of advanced roles in terms of both practice and required supporting education and training (Society of Hospital Pharmacists of Australia, 2016). However, the establishment of such a requirement for a minimum qualification linked to registration has not been implemented in all countries where pharmacy technicians participate in the pharmaceutical services workforce.

Legislation in Australia does not enforce any requirement for a formal educational qualification for pharmacy technicians (dispensary technicians). The Pharmacy Board of Australia does, however, recommend that a relevant educational program should be completed by all pharmacy technicians (Pharmacy Board of Australia, 2015). In addition to the initial program the Pharmacy Board of Australia (2015) also recommends ongoing training in areas relevant to the pharmacy technician's area of practice.

There are three routes pharmacy technicians can use toward attaining competence. These are: an appropriate qualification; and/or achievement of specific competencies from within the qualifications; and/or practice experience. A combination of one or more of the three can be used as a measure of the pharmacy technicians' ability to practice. The judgment is made by the supervising pharmacist.

In Australia the Australian Qualifications Framework (AQF) is responsible for standard setting of recognized qualifications. For community pharmacy the AQF accredited Certificates III and IV in Community Pharmacy from the Retail Service Training package are recommended for pharmacy technicians practicing in community pharmacy (Training.gov.au, 2013a). For Pharmacy Technicians practicing in hospital pharmacy the AQF accredited Certificates III and IV in Hospital/Health Services Pharmacy Support from the Health Training package are recommended (Training.gov.au, 2013b). O'Leary and Allinson (2009) reported, in a 2007 hospital pharmacy survey, that only 52% of hospital pharmacy technicians held a postschool qualification. The qualification held by most of the pharmacy technicians was a certificate at level III or IV.

The topics covered in the core community pharmacy modules for Certificate III include: respond effectively to difficult or challenging behavior; comply with infection control policies and procedures; accept prescriptions and return dispensed medicines to customers; support the supply of Pharmacy Medicines and Pharmacist Only Medicines; assist customers seeking to relieve cough and cold symptoms; assist customers seeking to relieve skin and fungal conditions; assist customers seeking relief from gastrointestinal conditions; assist customers seeking to relieve common allergic symptom reactions; assist customers seeking analgesic and antiinflammatory products; apply point-of-sale handling procedures; interact with customers; organize and maintain work areas; communicate in the workplace to support team and customer outcomes; work effectively in a customer service environment; perform stock control procedures; minimize loss; and apply safe work practices (Training.gov.au, 2013a). Whereas the modules in the hospital pharmacy level III certificate include: contribute to effective workplace relationships; contribute to team effectiveness; organize workplace information; promote innovation in a team environment; create and use spreadsheets; interpret and apply medical terminology appropriately; organize personal work priorities and development; facilitate responsible behavior; participate

effectively in the work environment; recognize healthy body systems in a health care context; respond effectively to behaviors of concern; communicate and work effectively in health; work effectively with culturally diverse clients and coworkers; work effectively with Aboriginal and/or Torres Strait Islander people; comply with infection control policies and procedures; maintain pharmaceutical ward stock; pack pharmaceutical products; procure, store, maintain, and distribute pharmaceutical stock; assist with dispensing of prescriptions and medication orders; conduct small scale compounding and labeling of pharmaceutical products; conduct small-scale compounding and labeling of aseptic pharmaceutical products; and contribute to workplace health and safety processes (Training.gov.au, 2013b).

The Canadian Council for Accreditation of Pharmacy Programs is the body in Canada that accredits all pharmacy technician education and training programs. Accreditation of pharmacy technician programs commenced in 2008. All pharmacy technicians must have successfully completed an accredited program. There are 46 providers of accredited pharmacy technician programs. The duration of the programs varies from one to two years (Canadian Council for Accreditation of Pharmacy Programs, 2018).

The programs in Canada must fulfill the requirements of the standards for accreditation of pharmacy technician programs in Canada (Canadian Council for Accreditation of Pharmacy Programs, 2015). Typical content would include modules such as: anatomy and physiology; community pharmacy computers; pharmaceutical calculations; community practice theory; community pharmacy dispensing practice; home health care and nonprescription products; compounding; introduction to pharmacology; aseptic technique principles; institution dispensing; institution communications and operations; advanced pharmacology; and pharmacy management. Work-based placement periods are also included.

In Denmark the qualification for a pharmacy technician (pharmaconomist) is the equivalent of a three year degree course (Raagaard, 2016). There is only one provider of the pharmacy technician qualification, i.e., the Danish College of Pharmacy Practice or Pharmakon in Hilleroed north of Copenhagen. The students spend 23 weeks each year completing coursework at the institution. The remainder of the time is spent in the workplace either community pharmacy or hospital pharmacy. Therefore, the students spend the majority of the three years in the workplace with e-learning and workplace tutoring supplementing the coursework completed at the institution.

The training includes modules on: knowledge of pharmacology; anatomy and physiology; communication; and instructional skills and practical skills acquisition (Danish Association of Pharmaconomists, 2018). Education and training requirements vary across Europe. A useful summary of requirements across European countries is presented by the European Association of Pharmacy Technicians (2017b).

In Malawi the two levels of pharmacy support personnel, pharmacy technician and pharmacy assistant, are required to complete a diploma (pharmacy technician) or certificate (pharmacy assistant) course at an educational institutions. The pharmacy assistant program is of two years duration and covers content such as: anatomy and physiology; first aid, microbiology; parasitology; chemistry; counseling; communication; computer skills; pharmacology; pharmaceuticals; and medicine management (Kasiyamphanje, 2014). During the period of training blocks are spent in the workplace. The diploma course for pharmacy technicians is a three year qualification and covers similar topics but at a higher cognitive level.

The pharmacy technician course in Singapore is a part time program presented on two to three evenings a week over a year (Pharmaceutical Society of Singapore, 2018a). In order to register for the program workplace experience (minimum of six months) is required and the candidate must remain in the workplace for the duration of the course. The program is presented by the Pharmaceutical Society of Singapore and accredited by Workforce Skills Qualifications (WSQ). The content for the Advanced Certificate in Healthcare Support (Pharmacy Support) includes: coach for service performance; assist with procurement and storage; support and guide team members; demonstrate professionalism in work practices; maintain workplace safety and health policies and procedures; solve problems and make decisions at supervisory level; demonstrate understanding of basic pharmacology and drug development process; assist in basic dispensing and good pharmacy practice; assist in compounding of sterile and nonsterile pharmaceutical products; and provide drug information services and use of information and communication technology (ICT) in work activities (Pharmaceutical Society of Singapore, 2018b).

Successful completion of the relevant qualification is a requirement for registration as a pharmacy technician with the South African Pharmacy Council. There are two parallel routes via which the pharmacy technician qualification can be achieved in South Africa, via the: Higher Education and Training (HET) subframework or Quality Council for Trades and Occupations (QCTO) subframework. The HET qualifications are presented by universities while the QCTO qualifications can be workplace based. The qualifications are developed by the South African Pharmacy Council in consultation with stakeholders.

The HET (university presented) qualification consists of two full-time on campus one-year certificate programs (South African Qualifications Authority, 2018a,b). A two year diploma course has subsequently been developed and will be implemented once the required regulations allowing for registration as a pharmacy technician have been legislated (South African Pharmacy Council, 2016b). On successful completion of the university qualification graduates are required to complete a supervised six-month traineeship prior to registration as a pharmacy technician with the South African Pharmacy Council (South African Pharmacy Council, 2017).

The QCTO (work-based) qualification is the Occupational Certificate: Pharmacy Technician. Part qualification exit points exist within the occupational certificate (South African Pharmacy Council, 2016b). After completion of 62 credits (approximately 6 months) the learner can exit and register as a pharmacist's assistant basic. Completion of a further 130 credits (approximately 12 months) will allow for registration as a pharmacist's assistant post basic. Completion of the remaining 152 credits in the Occupational Certificate: Pharmacy Technician will allow for registration as a pharmacy technician. Workplace-based training is included in the occupational certificate therefore, the graduate is not required to complete a period of traineeship prior to

registration with the South African Pharmacy Council. The QCTO occupational certificate will replace the further education and training certificates currently in place for pharmacist's assistant basic and pharmacist's assistant post basic. There is no further education and training certificate for pharmacy technician. Providers have been invited to submit courses for accreditation against the QCTO occupational certificate.

The content of the HET qualifications and the QCTO occupational certificate are similar and cover the following topics: basic pharmaceutics; manufacture of medicines; extemporaneous compounding of medicines (sterile and nonsterile); dispensing of medicines; pharmacy operations and management; communication and counseling; anatomy and physiology; pharmacology; disease management; and relevant legislation.

In the UK, since July 2011, pharmacy technicians have been required to register with the General Pharmaceutical Council (Boughen et al., 2016). In order to register two education and training programs must be completed within a two year period. During the period of enrollment in the programs the pharmacy technician must be employed in a pharmacy environment. The qualifications are: Level 3 Diploma in Pharmaceutical Science (knowledge program) and Level 3 Diploma (NVQ) in Pharmacy Service Skills (competency-based program). The qualifications have been approved by the General Pharmaceutical Council in line with the General Pharmaceutical Council's Initial Education and Training Standards and Criteria (General Pharmaceutical Council, 2010).

Since the publication of the Initial Education and Training Standards and Criteria for pharmacy technicians in 2010 (General Pharmaceutical Council) there have been many changes in the practice environment of pharmacy technicians. The responsibilities of pharmacy technicians have changed extensively requiring an update to the standards for training to ensure that newly qualified pharmacy technicians can practice effectively in the workplace. In 2015 Rosado, John, Puaar, and Bates completed an investigation for the General Pharmaceutical Council on the initial education and training standards for pharmacy technicians and whether they were aligned with practice requirements. Various findings were published in the report among which was that due to the expanding and changing scope of practice of pharmacy technicians the standards required updating to include aspects such as accuracy checking activities (accredited checking pharmacy technicians) and other activities such as medicine reconciliation and medicine counseling to patients at discharge. Subsequently the General Pharmaceutical Council, in 2017, published updated standard for initial education and training of pharmacy technicians which took cognizance of the changing role of the pharmacy technician (General Pharmaceutical Council, 2017). Training providers may continue (during 2018) to present programs accredited against the 2010 standards but must develop new programs aligned to the 2017 standards and commence presentation of the new programs as from 2019 (General Pharmaceutical Council, 2018b).

In the USA the Pharmacy Technician Certification Board is a body which advocates for a single national standard for pharmacy technician certification (Pharmacy Technician Certification Board, 2017a). In 2013 the Pharmacy Technician Certification Board announced amendments to the requirements for certification that would be phased in by 2020. One of the suggested amendments was the requirement for completion of an accredited educational program (Pharmacy Technician Certification Board, 2013). However, in 2017, the Pharmacy Technician Certification Board suspended the implementation of the requirement for completion of an accredited training course (Pharmacy Technician Certification Board, 2017e). The Board, following consultation with stakeholders, felt that further thought, research and stakeholder consultation was required prior to implementation of the requirement for completion of an accredited course. Therefore, in the USA, there is currently no requirement for completion of an educational program prior to certification/registration. There are, however, recommendations in various stares which support the completion of relevant education and training.

Accreditation of pharmacy technician educational programs in the USA is undertaken by the American Society of Health-System Pharmacists/Accreditation Council for Pharmacy Education Pharmacy Technician Accreditation Commission (American Society of Health-System Pharmacists, 2018a). The Commission is a collaborative activity between the two organizations. The American Society of Health-System pharmacists has been accrediting training programs for pharmacy technicians since 1982 while the Accreditation Council for Pharmacy Education has been involved in accreditation of pharmacist education since 1932. A collaboration between the two organization for accreditation of Pharmacy Technician programs commenced about four to five years ago. Model curriculums (American Society of Health-System Pharmacists, 2015), accreditation standards (American Society of Health-System Pharmacists, 2018b), and guidance documents (American Society of Health-System Pharmacists, 2016a) have been published by the American Society of Health-System Pharmacists. The accreditation standards were updated in 2018 (for implementation in 2019) and the updated guidance document and model curriculum are due for publication in late 2018 (American Society of Health-System Pharmacists, 2018c). Content required in the programs includes: personal/interpersonal knowledge and skills; foundational professional knowledge and skills; processing and handling of medications and medication orders; sterile and nonsterile compounding; procurement, billing, reimbursement, and inventory management; patient- and medication-safety; technology and informatics; regulatory issues; and quality assurance (American Society of Health-System Pharmacists, 2015). Thus, although completion is not a requirement for certification a system does exist for accreditation of pharmacy technician education and training programs in the USA.

Extended Role for Pharmacy Technicians

The curriculums for education and training programs for pharmacy technicians should be directly linked to skills required in the workplace as the training must provide the pharmacy technician with the knowledge and skills they will require to function effectively in practice.

This implies that the development and updating of such programs must be ongoing as the workplace is an ever evolving space. The role fulfilled by the pharmacy technician has evolved over the past 10–15 years requiring new knowledge and skills. Areas that have developed to be included in technician scopes of practice include not only product related skills (e.g., accredited checking technicians) but also patient related skills (e.g., medicine reconciliation).

As the scope of the pharmacy technician continues to expand so will new knowledge and skills areas be required in the education and training programs. Some of the areas, around the world, which are devolving to the pharmacy technician role include supervisory roles and extended patient related roles.

In Australia possible areas for implementation of an extended role for pharmacy technicians are: clinical roles including medication reconciliation, counseling, and inpatient unit technician; accuracy checking technicians; technician led dispensaries; research, data collection, and education; and dispensing and ward stock management. In provision of pharmaceutical services to remote areas in Australia pharmacy technicians in Australia assist with: outreach services to remote areas where the pharmacy technician provides support to remote clinics in terms of stock control issues—this includes visiting the sites; medication profile maintenance; and dealing with queries about remote access to medicines (Society of Hospital Pharmacists of Australia, 2016).

In South Africa the scope of the pharmacy technician, although not yet implemented due to lagging legislation, includes supervisory capacity and the ability to work under indirect supervision with only a telephonic link to the supervising pharmacist to deal with queries.

In 2017 there was extensive debate in pharmacy circles in the UK relating to a General Pharmaceutical Council proposal to allow pharmacy technicians to supervise and sign off the training of preregistration pharmacy technicians (Torjesen, 2017). The supervision of pharmacy technician training by pharmacy technicians will be implemented as from 31 August 2018 (Cox, 2018; General Pharmaceutical Council, 2018c). Further debate in the UK involves a possible role for pharmacy technicians in the supervision of community pharmacies (Clews, 2018). Consultation relating to this matter is ongoing in 2018. Possible future areas for expansion of the general role of the pharmacy technician, in the UK, include skills which currently exist as post registration qualifications. Some of these qualifications are: accuracy checking pharmacy technician; medicines management skills program (including medicines reconciliation); clinical pharmacy/medicines management for pharmacy technicians; patient consultation skills; community pharmacy training, e.g., healthy living; national vocational qualification assessor; internal quality assessor; management; medicines information technicians training; pharmaceutical technology and quality assurance; procurement and supply; and teaching qualification.

The American Society of Health-System Pharmacists (2016b) has stated that extended roles for pharmacy technicians exist in the following areas: accuracy checking; purchasing or fiscal management; supervisory positions; assistance with medication history; medication therapy management; immunizations; quality improvement; hazardous drug handling; patient assistance programs; education and training; community outreach; drug use evaluation; adverse drug event monitoring; industry; and informatics. Generally in the USA the roles of pharmacy technicians are restricted to those activities not requiring professional judgment. The opinion is that further education and training and experience would be required for pharmacy technicians who would assume an extended role (Mattingly and Mattingly, 2018).

In Idaho, USA, legislative changes have allowed for an expanded scope for pharmacy technicians. The additional roles permitted include: accuracy checking activities; ability to accept verbal prescriptions; transfer of prescriptions; and performing remote data entry and vaccine administration (Adams, 2017).

Certification, Credentialing, and Privileging in Clinical Pharmacy

William Ellis, Board of Pharmacy Specialties, Washington, DC, United States

Introduction

Health care providers and the systems they work in are becoming increasingly accountable for the quality of the care delivered to patients. An important part of this accountability involves certification, credentialing, and privileging. While these processes traditionally involve physicians, they are starting to include pharmacists and other healthcare professionals as they take on greater patient care responsibilities, particularly in managing more complex patients and their medication regimens (Council on Credentialing in Pharmacy, 2010a; Forster et al., 2011).

There is often misunderstanding and confusion about the meaning of key terms when discussing certification, credentialing, and privileging in clinical pharmacy, as well as in the broader context of health care. The definitions for certification, credentialing, and privileging are defined in the glossary, and are approved by the Council on Credentialing in Pharmacy, a coalition of 10 United States-based, pharmacy organizations who are committed to providing leadership, guidance, public information, and coordination for credentialing programs in or relevant to pharmacy (Board of Pharmacy Specialties, In press d).

The proper use of the aforementioned terms is important because they help stakeholders, such as patients, physicians, other healthcare providers, legal/regulatory agencies, administrators, and payers, understand the readiness and authority of a healthcare professional to provide patient care services, and in the case of accreditation, the readiness of a site or program to deliver certain services. While stakeholders may misunderstand or confuse the meaning of these terms, it is a provider's professional responsibility to accurately convey their meaning to them so they can assess the knowledge and skill of a healthcare professional delivering services and better understand their scope of practice (Council on Credentialing in Pharmacy, 2009).

It is also important to understand that a credential (i.e., academic degree, license, certificate, or any number of other documents) is evidence signifying various professional qualifications, whereas credentialing and privileging are processes. Those processes will most likely include the requirement for evidence, essentially a credential, which represents a certain level of training, knowledge, and/or skill. Credentials focus on individuals while the term accreditation focuses on organizations, sites, and programs (i.e., an ASHP-accredited pharmacy residency or a hospital that is accredited by The Joint Commission.) In summary, individuals hold credentials while places or programs hold accreditations (Council on Credentialing in Pharmacy, 2010b).

Certification

Certification of individuals is internationally accepted in many industries and professions as a means to assure that the individual meets the requirements identified by the certifying agency. Certification, as opposed to other types of assessments, has a defined process to develop and validate the content outline for the certification and always includes an examination. Objective criteria and established standards to score the examinations are in place, which helps assure fairness and consistency in assessing competence to hold the certification. Because certifications are issued by bodies specifically designed to do so, they help assure impartiality and manage conflict of interest. Certifications can give confidence to stakeholders that the certification holder or certificant has been independently assessed and that there is a uniform standard being applied to award certification to an individual. Another important feature of certification is the process for maintenance of certification, which includes requirements for ongoing continuing education and/or reexamination. The maintenance of certification is important because the knowledge base of a given profession is almost always evolving as a result of new research and technological advances. It is through the maintenance of certification

process that stakeholders can have a measure of assurance that the certification holder maintains the level of competence that was initially achieved when the certification was first awarded (Institute for Credentialing Excellence, 2009).

Specialization and board certification in healthcare are inextricably linked; board certification is the process that independently evaluates whether a healthcare provider meets the eligibility criteria and demonstrates the knowledge and skill to achieve a designation in a specialty or specific health care practice area (Board of Pharmacy Specialties, In press a).

In the United States, specialty practice in medicine has been recognized for over 100 years and serves as a model for other professions. As medical practice became increasingly specialized, physicians practicing in those areas, along with various medical schools, saw a need to design a process to recognize which practice areas were specialties and to issue credentials to assure the public of a physician's qualifications to deliver specialized care. Established in 1917, the American Board of Ophthalmology was the first medical specialty board in the United States. The American Board of Otolaryngology was formed in 1924 with other medical specialty boards being formed throughout the 1930s and later (Talbert and Ellis, 2013). Today, there are 24 medical specialty boards that comprise the American Board of Medical Specialties (ABMS), whose mission is to serve the public and the medical profession by improving the quality of health care (American Board of Medical Specialties, In press).

By comparison, pharmacy in the United States did not begin to address specialization until a Task Force on Specialties in Pharmacy was formed by the American Pharmaceutical Association, now American Pharmacists Association (APhA), in 1973 (APhA Task Force, In press). While the APhA Task Force on Specialties in Pharmacy did not identify any existing pharmacy specialties, the group concluded that an official board with independent decision-making authority should be formed and granted authority to recognize pharmacy specialties based upon approved criteria. Furthermore, it was deemed that the board should have the responsibility to determine, which pharmacists are qualified to hold certification as specialists in officially recognized pharmacy specialties. To carry forth these tasks, the Board of Pharmaceutical Specialties, now the Board of Pharmacy Specialties (BPS), was created in 1976 as an autonomous division of the APhA (APhA Task Force, In press).

The criteria to recognize pharmacy specialties established by the APhA Task Force on Specialties in Pharmacy have remained largely unchanged since the founding of BPS (Board of Pharmacy Specialties, In press b).

These criteria are as follows:

- Need as a condition of requiring supply
- Demand defined as a willingness and ability to purchase the services of a Board Certified Pharmacist
- Number of practitioners and the amount of TIME spent in the practice of the specialty
- Specialized Knowledge based upon one or more of the pharmaceutical sciences and the biological, physical, behavioral, and administrative sciences which underlie them
- Specialized tasks/skills describe in detail, specialized tasks performed routinely by practitioners in the proposed specialty, which are not performed by pharmacists in general, as well as the special skills required to perform the tasks specified
- Education and/or Training describe in detail the education, postgraduate training programs, and/or experience required to acquire the specialized knowledge and skills and
- The area of specialization shall be one in which there is an adequate Transmission of Specialized Knowledge through professional, scientific, and technical literature directly related to the specialty area (Board of Pharmacy Specialties, In press b).

The mission of BPS is to improve patient care and increase awareness of the need for BPS Board Certified Pharmacists as integral members of multidisciplinary healthcare teams. BPS aims to achieve this through recognition and promotion of specialized training, knowledge, and skills in pharmacy, and through specialty board certification and recertification of pharmacists throughout the world. Board Certification through BPS has become recognized as a standard for determining which pharmacists are qualified to contribute at advanced practice levels as a result of the rigorous standards mandated by BPS board certification and recertification. As of 2017, BPS recognizes 11 pharmacy specialties and over 31,000 pharmacists in more than 26 countries hold BPS certification (Board of Pharmacy, In press). The pharmacy specialties currently recognized are: ambulatory care pharmacy, cardiology pharmacy, compounded sterile preparations pharmacy, critical care pharmacy, geriatric pharmacy, infectious diseases pharmacy, nuclear pharmacy, nutrition support pharmacy, oncology pharmacy, pediatric pharmacy, pharmacotherapy, psychiatric pharmacy, and solid organ transplantation pharmacy (Board of Pharmacy Specialties, In press c).

The Growth of Certification and Specialization

An assessment of Canadian community pharmacists by Jorgenson, Penm, MacKinnon, and Smith noted that pharmacy practice is evolving clinically on a global basis, and as the profession expands clinically, pursuit of certification is a natural outgrowth of that progression. The study concluded that the majority of community pharmacists in Canada would support a certification process to recognize pharmacist specialization. The authors also cite an example in New Zealand that once specialty practice was established, the government provided funding for services including prescribing and anticoagulation management and further noted that pharmacists in Canada are following this global trend (Jorgenson et al., 2017).

Suzuki et al. report that board certification maintains quality in the Japanese healthcare system and is also required for reimbursement. Their study concluded that board certification was more prevalent in designated specialty cancer hospitals with better adherence to adequate chemotherapy. The certifications in this report were Board-certified Pharmacists in Oncology Pharmacy and Board-certified Oncology Pharmacy Specialists (Suzuki et al., 2016).

Ignoffo et al. concluded, via a review of data and a Delphi panel process, that BPS Board Certified Oncology Pharmacists (BCOP) can provide clinical services that could help alleviate a projected shortfall in needed patient visits for cancer treatments in the United States (Anon, 2016).

Steeb et al. note that certification has advanced the case for provider recognition in the United States. They also reported that the Certified Pharmacy Technician (CPhT) enables pharmacists to grow their patient care services and that this is consistent with national goals to provide quality, cost-efficient care (Steeb et al., 2015).

In Australia, the government funds medication management reviews (MMRs) through the Society of Hospital Pharmacists of Australia (SHPA). The MMR program is a team-based model, which looks to help consumers make the best use of their medicines. To be eligible to participate in this program, pharmacists must earn board certification through a specialty recognized by BPS or through completion of a master's degree in either Clinical Pharmacy (M. Clin Pharmacy) or Pharmacy Practice (M. Pharm Practice), as well as a portfolio review conducted by the National Alliance for Pharmacy Education (NAPE) (Lawson, 2017).

The American College of Clinical Pharmacy (ACCP) has issued a position statement on the board certification of pharmacist specialists. In this statement, ACCP affirms its vision that all pharmacists who have responsibility for managing patients with complex or special drug therapy needs will hold board certification. The statement also supports board certification for pharmacists who supervise students and/or residents when they provide services to patients with complex pharmacotherapy needs, teach students about therapeutics, and deliver continuing pharmacy education that focuses on therapeutics or complex drug therapies. The college goes on to state that they believe that board certification is a valid assessment of a pharmacist's level of specialized knowledge in a designated area of practice and that attaining board certification contributes to improved patient care (American College of Clinical Pharmacists, 2011).

The integrated health system at the University of Wisconsin-Madison (UW Health) has made the decision that all pharmacists employed there in direct patient care roles obtain board certification by 2018. The impetus to reach this decision included: evolving collaborative practice models requiring greater demonstration of competence through credentialing, voluntary approaches to achieving universal certification being unlikely to succeed, health-system leadership being assumed by physicians who understand board certification, and evolving payment models and insurance contracts increasingly requiring board certification. The authors also commented that the rigor of the certification and recertification requirements were deemed valuable by the leadership of the department (Hager et al., 2017).

These observations in multiple countries further reinforce the point that certification is valuable in assuring standardization of service and quality and to help distinguish those individuals with specialized knowledge and skills. What makes board certification stand out is that the process is an independent evaluation of the knowledge and skills of an individual. It provides stakeholders a level of assurance that the individuals they are hiring, approving, or utilizing for service delivery have met a consistent standard.

The physician community is ahead of the pharmacy profession in that more than 80% of all licensed physicians in the United States hold a certification from the ABMS (Anon, 2017). On the other hand, it is estimated that between 8% and 10% of U.S. pharmacists hold a BPS board certification (Board of Pharmacy Specialties, 2017). As described earlier, it should be noted that the growth of pharmacist board certification appears to align with the growth of clinical pharmacy services, not only in the United States but in other nations as well. Fig. 1 shows the growth of BPS Board Certification. Fig. 2 shows the international adoption of BPS Board Certification by country.

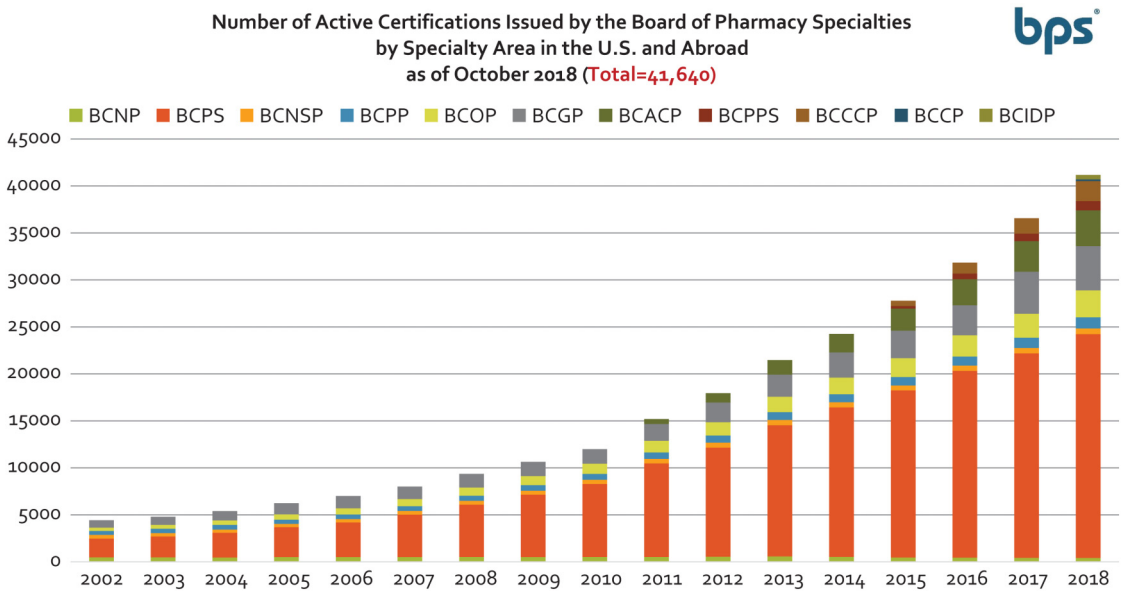

Figure 1 Growth of BPS Board Certification.

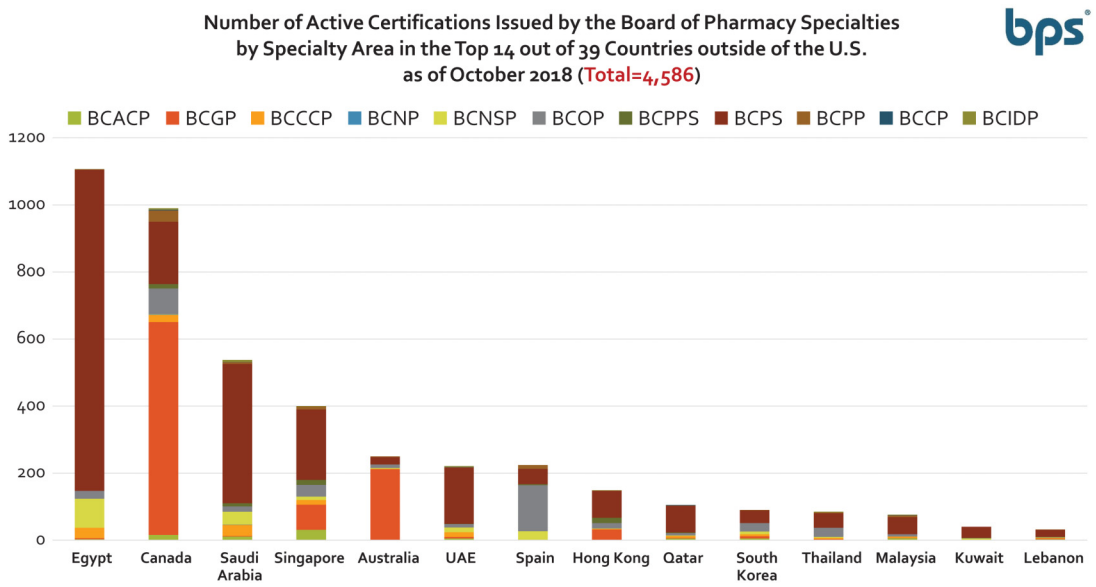

Figure 2 International adoption of BPS Board Certification.

Differences Between Certifications and Certificates

Some confusion exists over certificate programs and certifications particularly within pharmacy. The American Council for Pharmacy Education (ACPE) has renamed what were previously known as certificate programs to practice-based Continuing Pharmacy Education (CPE). ACPE states that the purpose of these programs is to instill, expand, or enhance practice competencies through the systematic achievement of specific knowledge, skills, attitudes, and performance behaviors. The content must be evidence-based and should include a live and/or home study component as well as a practice experience component. The minimum amount of credit for these activities is 15 contact hours (American Council for Pharmacy Education, 2009).

Essentially, practice-based CPE is an assessment-based certificate program. The certificate awarded upon the completion does not merely indicate that the participant was in attendance, but that they have met a predetermined competency threshold based upon the course materials. The fact that some training and educational programs may issue a document or certificate indicating successful completion of the course of study and the assessment does not make the program a certification (American Council for Pharmacy Education, 2009).

The Institute for Credentialing Excellence publishes the Standard for Assessment-Based Certificate Programs, and similar to CPE, this type of offering is defined as providing instruction or training to assist participants in gaining specific knowledge, skills, and/or competencies. Furthermore, this standard states that there is an evaluation of the learning, and a certificate is only awarded to those who meet the performance, proficiency, or passing standard for the assessment (Knapp and Kendzel, 2009).

The National Commission for Certifying Agencies (NCCA) Standards for the Accreditation of Certification Programs states in Standard 3: Education, Training, and Certification that "Appropriate separation must exist between certification and education or training functions to avoid conflicts of interest and to the protect the integrity of the certification program" (National Commission, 2004). Therefore, a major distinction between a professional or personnel certification and a practice-based CPE, assessment-based certificate program, or other certificate programs, is that certification is an independent assessment of predetermined knowledge, skills, and competencies, which requires that the certification be time-limited with a corresponding requirement for recertification (National Commission, 2004). Practice-based CPE, assessment-based certificate programs, and other certificate programs are based upon the provision of education and training, and the assessment measures whether the participant has achieved the stated learning outcomes for that particular program (American Council for Pharmacy Education, 2009; Knapp and Kendzel, 2009).

A hallmark of board certification is that the examination is not linked to a specific course of study, training program, or text. Instead, it draws on multiple references to assess whether an individual possesses the knowledge, skills, and competencies to earn the certification (National Commission, 2004). Individuals who earn board certification are often issued a certification mark or initials that designate their achievement (National Commission, 2004). One example of a widely recognized certification mark issued in pharmacy is the designation BPS Board Certified Pharmacotherapy Specialist (BCPS) (Board of Pharmacy Specialties, In press d). The initials and certification mark are important because they signify to various stakeholders, including the public, that an independent evaluation of the individual's knowledge and skill level has taken place. There is an implied trust extended by stakeholders to the certifying agency that the certifying agency knows the particular competencies that should be demonstrated in order to hold the certification and that the certified individual has the knowledge and skill to perform the related functions at a minimally competent level (Institute for Credentialing Excellence, 2009).

Table 1 Comparison of assessment-based certificate program and professional or personal certification program

Assessment-based certificate program	*Professional or personnel certification program*
Provides instruction and training (nondegree granting)	Assesses knowledge, skills, and/or competencies previously acquired
Goal is for participants to acquire specific knowledge, skills, and/or competencies	Goal is to validate the participant's competency through a conformity assessment system
Assessment is used to evaluate mastery of the intended learning outcomes; linked directly to the learning event	Assessment is best used to assure baseline competencies and to differentiate professionals; independent of a specific learning event
Assessment content may be narrower in scope	Assessment content is usually broad in scope
Awards a certificate to recognize mastery of the specific learning outcomes; it is NOT a certificate of attendance or participation, which is awarded to individuals who have attended or participated in a course or training program but did not have to demonstrate mastery of the intended learning outcomes	Awards designations to recognize achievement
To earn accreditation, complies with the ICE 1100 Standard and follows the ACAP application procedures	To earn accreditation, complies with the NCCA Standards for the Accreditation of Certification Programs and follows the NCCA application procedures

Whereas the "test" for certificate programs is based upon the course materials, certification examinations are based upon a job/practice analysis, also referred to as a role delineation study. The role delineation study is a process, which identifies the requisite knowledge and tasks performed by the individual in the delivery of distinct services. Typically, subject matter experts in the field will convene to identify the knowledge and task statements associated with the performance of a specific profession, occupation, or role being certified. The resulting knowledge and task statements are often grouped into broader performance domains and are validated by those practicing in the field based upon the criticality of the knowledge and task and the frequency with which the knowledge is used or the task performed. The results of the validated knowledge and task statements create a content outline with weightings assigned to each domain based upon the ratings derived from the frequency and criticality ratings for the knowledge and task statements. The content outline and related weightings become the "blueprint" by which a valid certification examination is developed (Institute for Credentialing Excellence, 2009) (**Table 1**).

Credentialing and Privileging

Credentialing and privileging are important for the primary purpose of protection. Most importantly, credentialing and privileging protect patients by helping assure that patients receive safe, high-quality care by individuals who have the appropriate qualifications to deliver such care. Credentialing and privileging also protect various institutions, organizations, and other health care entities that offer services because they provide a mechanism to evaluate the qualifications of practitioners working within them (McCarthy, 2006).

In the broader view of healthcare, credentialing and privileging continue to gain increased importance for multiple reasons: the increased complexity of patient care including specific procedures, greater emphasis on patient safety, and increasing legal liability. Patients also assume that the healthcare professionals they interact with are qualified to deliver services and that the institutions that employ these individuals have some type of process to verify competence (McCarthy, 2006).

In the United States, the *Darling v. Charleston Community Memorial* legal ruling propelled the credentialing and privileging processes into the mainstream of managing health care institutions. In this 1965 case, the court awarded a monetary judgment to the plaintiff by an Illinois hospital as damages for a leg amputation that came about because of the improper casting of a broken leg and medical mismanagement of a related infection. The results of this decision radically changed hospital liability law because the decision extended direct liability to the hospital as a provider of patient care and the established a duty of care on the part of the hospital. Prior to this ruling, no equivalent ruling related to hospital liability. In a 40-year span from 1965 to 2005, this ruling had been cited in over 300 state and federal cases. There were subsequent accreditation standards and various laws and regulations that grew out of this decision. It is interesting to note that part of the evidence in this case references the Illinois Department of Public Health regulations that state it is the hospital governing board's responsibility to, among other things, have clear standards for granting practice privileges including the ongoing review of clinical experience based upon patient medical records (Mitchell, 2005).

While the processes of credentialing and privileging are more common among physicians, as pharmacists assume a greater role in the delivery of health care, including patient safety, it is increasingly common to have pharmacists as part of these processes to verify competence (Jordan et al., 2016).

While the terms credential and credentialing sound very similar, they have distinct definitions and applications. A credential is documented evidence of attaining a professional qualification and is in fact often a paper document, although technology has now given rise to various digital credentials in some industries as evidence of professional qualifications. Common examples of pharmacy credentials can include a diploma, license, board certification, or residency certificate. Credentialing, as defined previously, can signify 1 of 2 processes. The first process is granting a credential, for example, when a school or college of pharmacy issues a diploma. The second credentialing definition refers to a process by which an organization or institution obtains, verifies, and

assesses an individual's qualifications to provide patient care services. Within healthcare, the more common use of the term credentialing refers to the second definition related to the verification and assessment of a provider's credentials to provide patient care (Council on Credentialing in Pharmacy, 2010a).

In summary, a credential is a document, either paper or electronic, and credentialing is a process. In the English language, credential is a noun referring to a thing (document) and credentialing is a verb referring to an action. One source of confusion is that the credentialing process used by health care organizations involves the verification of credentials. Privileging is also a process where the scope of services provided by a practitioner is authorized for delivery by that institution based upon a review of both credentials and performance (Council on Credentialing in Pharmacy, 2010a).

The best way to think about credentialing and privileging might be to examine the purpose of each. The credentialing process documents that a health care provider has attained the credentials needed to provide patient care within a particular practice setting. Privileging helps assure that the professional being considered to deliver specified services or have the "privilege" to do so at a specific organization has the defined competencies deemed necessary. The documentation required for credentialing usually supports broad-based service delivery and employment, while the documentation required for privileging can include some of the same documentation as credentialing but will also require additional and more detailed information (Council on Credentialing in Pharmacy, 2010a, 2014).

An example might be that in order to provide general services at a community pharmacy, a pharmacist would be required to hold credentials such as a diploma indicating graduation form an accredited college of pharmacy and a license or registration to practice in that jurisdiction (Council on Credentialing in Pharmacy, 2010a). The verification of these credentials could be considered credentialing. The process of reviewing documents for employment decisions is a form of credentialing. However, if that community pharmacy offers immunizations, they may decide that an additional credential is needed to immunize, such as the APhA Pharmacy-Based Immunization Delivery certificate (Pharmacist.com, In press). Documentation of that certificate would be required as well as other criteria set by the community pharmacy before the pharmacist would be granted the privilege to immunize patients in that pharmacy. However, some pharmacies may require an immunization certificate as part of the general employment requirement if immunization is part of the regular services offered.

It is important to note that institutions and health care organizations can have significant variations in their approach to credentialing and privileging. Those variations can even be greater when it comes to the credentialing and privileging of nonphysician health care providers. All pharmacists will usually participate in a credentialing process at the time of employment and as a condition on ongoing employment, although that process is often not thought of or labeled as credentialing and just referred to as the hiring process. The privileging process for pharmacists is not commonplace but is being seen with increasing frequency as pharmacists assume more direct patient care roles (Blair et al., 2007; Council on Credentialing in Pharmacy, 2010a).

Credentialing

Most health care organizations have credentialing processes in place. These processes can range from simple to elaborate and vary in degree of formality depending upon the needs of the organization. The Council on Credentialing in Pharmacy outlines 5 basic steps in a credentialing process (Council on Credentialing in Pharmacy, 2014).

1. Application
2. Verification
3. Analysis
4. Decision
5. Monitoring and Recredentialing

Application—This step involves the prospective employee completing paperwork to request formal consideration for a position. In the pharmacy profession, items on the application could include but may not be limited to:

- Education and training documentation
- Licensure information
- Proof of professional liability insurance coverage
- Signed and dated forms attesting to the accuracy of the information supplied and a release to allow the organization to verify the information provided.

Verification—When an application is received, it is reviewed and needs to be verified for accuracy. Credentials (i.e., licenses and certifications) are usually verified by contacting the primary source that issues the credential. In credentialing (as well as privileging), primary source verification of credentials is an important step to help assure that the credential being represented has in fact been earned by the individual and is not fraudulent. To verify credentials, the issuing body can be contacted in writing, via phone or facsimile or other electronic means, and their response should be recorded by the employer. In smaller organizations, the verification step may be performed by the hiring manager or supervisor; however, in other organizations, verification can be a function of the human resources department, or contracted to a Credential Verification Organization (CVO). Credential verification

organizations should be evaluated carefully by health care entities before contracting for services to assure that they have quality management processes in place that yield accurate results for the entity.

Analysis—Once the documentation is collected, it will need to be reviewed and evaluated. Some organizations use a staff committee to review credentials or even a multidisciplinary committee; in other instances, the analysis may be discussed between the hiring supervisor and the human resources department.

Decision—Once the analysis has taken place, a decision needs to be made regarding whether the candidate has met the requirements for the position.

Monitoring and Recredentialing—The monitoring process is ongoing and includes a general performance evaluation involving multiple factors such as work outputs, customer service, adherence to rules, policies, procedures, and legal/regulatory requirements. If there are performance deficiencies, a performance improvement plan may be utilized, which, in some instances, could result in limiting or restricting work activities. In extreme cases, the monitoring and recredentialing process could also lead to termination. On a more positive note, strong performance as documented through monitoring and evaluation could lead to expanded responsibilities and promotion for the employee. As part of the credentialing process, organizations should require individuals to promptly report any changes in the status of the information that they have submitted that impact their service to the organization and patients, ithat is, disciplinary action by a licensing or regulatory board, criminal activity, etc. Most organizations also have processes in place for recredentialing that can include certain in-house training, maintaining an active license or other continue professional development activities that are designated and deemed part of the ongoing credentialing process (Board of Pharmacy Specialties, 2017).

The credentialing process should be documented in a policy and procedure to assure that it is consistently applied and followed. Additionally, the credentialing process should contain a mechanism for candidates to review the information gathered, make corrections, and explain discrepancies. These processes are a matter of fairness to individuals and should be consistent with various employment laws within the jurisdiction.

Privileging

Privileging is a process where a practitioner is authorized by a health care organization to provide specific patient care services. Privileges are granted to an individual through a defined review process that is usually based upon a combination of education and practice experience. The basic process for granting and maintaining privileges is very similar to credentialing; the steps and the differences are outlined as follows (Council on Credentialing in Pharmacy, 2014):

Application—The application for clinical privileges should be initiated by the practitioner requesting permission to perform specific clinical activities. There may be a pre-application, which serves to determine if the individual meets basic eligibility criteria such as name and address, education, license status, and proof of current insurance coverage. Application for clinical privileges must include both a description of the privileges being sought and the required information and documentation that support the practitioner's ability to deliver the described patient care services. Privileging applications tend to be more in depth in the data required and very likely includes information such as a photograph, past or present challenges to licensure or registration, voluntary relinquishment of licensure or registration, voluntary or involuntary termination of health care staff membership, voluntary or involuntary limitations, restrictions or termination of clinical privileges at other institutions, as well as patient case data. Because clinical privileges tend to involve specialized services, it is very common to request information regarding board certification, residency training, or other relevant practice experience beyond the simple listing of employment. Applications for privileges will also include a number of attestations that the applicant must sign regarding items such as agreement to follow the institution's bylaws, various rules and regulations, accuracy and truthfulness of all information submitted, and a release of liability for the institution and staff involved in the peer review to make a decision on granting privileges. Most organizations have policies that establish timelines for the submission of information and the timeliness of the credentials and experience that are contained in the application (Council on Credentialing in Pharmacy, 2014; Lavalley, 2006).

Verification and Analysis—In some health care organizations, particularly health systems and hospitals, the initial application form may undergo a preliminary review to assure that it is complete. Once the application is accepted and begins to move forward, the health care organization must verify the information provided is accurate. Various accrediting bodies in the United States, such as The Joint Commission, require that much of the information undergo primary source verification. The verification step is usually conducted by a credentialing office. Once the information is filed, the application usually moves to the chair of the department in which the individual is applying for clinical privileges. It is the responsibility of the department chair to evaluate the validated application against the criteria established by the department related to the clinical privileges that are sought (Council on Credentialing in Pharmacy, 2014).

Review and Decision—The department chair will make a recommendation regarding the application to the healthcare organization's credentialing committee (usually a committee of peers) and that recommendation, along with the complete validated application, will be reviewed. The credentialing committee will interview the applicant to discuss any issues or concerns they have with the application and to further assess the readiness of the individual to provide services. The committee will then develop a written report and a recommendation, and that is submitted to the medical executive committee, which is usually comprised of the chair of each department. The medical executive committee reviews the information and makes a recommendation to the

organization's governing board for the final decision (Lavalley, 2006). The recommendation may include that direct supervision be provided by a privileged practitioner for a period of time when services may be at high risk or there are concerns regarding the individual's current competence or experience (Board of Pharmacy Specialties, 2017). Pharmacy administrators need to be aware of various laws and regulations that may define services that a pharmacist can provide both with and without supervision and to be sure that the privileging process is consistent with them. In the United States, this is largely governed on a state-by-state basis and involves not only the pharmacy practice act and regulations but can also be influenced by provisions in the medical practice act and regulations as well as any laws and regulations governing hospitals and other health care entities. This will also vary from country to country. Another example is within the European Union where there is variation among member states on the mutual recognition of professional qualifications.

Clinical privileges are usually time-limited, and reapplication is required. A 2-year duration is common. The reapplication process is very similar to the initial application and will always include performance data. Performance data can be very challenging in that objective data such as the number and types of procedures performed are relatively easy to obtain but offer little insight into outcomes. Outcomes can be highly subjective and impacted by issues such as severity of illness and comorbidities, although more institutions are looking to include performance data as a means to improve quality (Council on Credentialing in Pharmacy, 2014).

Designing a Pharmacist Credentialing and Privileging Process

Some would argue that developing a formalized pharmacist credentialing and privileging process may increase liability to the organization and the individual. Conversely, one could also argue that institutions and individuals are already exposed to liability through the normal process of delivering care and that establishing clear parameters for credentialing and privileging can help mitigate risk. Health care and pharmacy in particular are highly regulated (Council on Credentialing in Pharmacy, 2014). Credentialing, in its broadest application, is a form of self-regulation and if a profession does not monitor and regulate itself adequately, then it will most certainly face government imposed laws and regulations to address various issues. However, credentialing and privileging can only mitigate risk if both the institution and the individual agree to abide by their respective scope of responsibility and service.

As discussed earlier, the fact that pharmacy practice is evolving clinically speaks to the need for pharmacy to align their practices with the other health professionals and the systems in which they practice. The Council on Credentialing in Pharmacy states that pharmacists should be expected to participate in credentialing and privileging processes to ensure competency to provide quality care. The Council's guiding principles on post-licensure credentialing of pharmacists states that "for all practice settings, employers and payers should be encouraged to adopt and implement their own credentialing and privileging processes for pharmacists to determine and authorize the patient care responsibilities appropriate for the particular patient populations and care delivery" (Council on Credentialing in Pharmacy, 2011).

Pharmacists need to be at the forefront of designing credentialing and privileging processes for the profession because pharmacists have the subject matter expertise unique to the practice of pharmacy. A critical discussion that needs to take place within pharmacy administration is what training, skills, and credentials are needed for service delivery and if they are appropriately matched to the privileges being sought (Council on Credentialing in Pharmacy, 2014).

With that said, pharmacy leaders and pharmacists themselves need to be responsible for the delivery of patient services in a manner consistent with other professions including peer review and outcome reviews. Because the process of credentialing and privileging is not new in health care, the pharmacy profession should align with the general processes designed by the medical staff, human resources, and quality improvement departments within the organization while bringing to light the specific patient care responsibilities and unique health care contributions the pharmacist will be accountable for and is prepared to deliver (Council on Credentialing in Pharmacy, 2014).

The Joint Commission has outlined 14 steps to developing a privileging process that could serve as a useful template for pharmacy departments to consider (The Joint Commission, In press).

1. Define the scope of the care your organization is providing.
2. Review the various laws and regulations that define what a practitioner can do independently and what must be done with supervision.
3. Further review laws and regulations to determine the scope of practice. For example, does the scope or practice allow the pharmacist to order laboratory tests or administer vaccinations?
4. Based upon the above, what qualifications and credentials do you want the practitioners to possess? Advanced degree? Residency training? Board certification?
5. Establish methods/process to formally request privileges, formal application document, letter of request, etc.
6. Develop a verification process for the core credentials that are required, that is, is the license current? Are there pending or past actions taken against that practitioner's license? It is strongly suggested and may even be required by law in some areas that the verification step is primary source verification.
7. Establish a record keeping system to store information obtained through the verification step.
8. Identify any organization or department-specific requirements. Examples can include residency training, board certification, and insurance documentation.

9. Obtain a written statement from the applicant attesting that the individual has no issues that could impact his or her ability to deliver care described in the privilege requested. Areas for attestation include that the individual has no issues, past or present with his or her licensure, registration, or employment at another organization. Departments will need to consult with the human resources department within their health care organization to design this attestation in compliance with local laws and regulations.
10. Identify a pharmacy administrator, usually the director or head of service as the individual, to assess whether the information submitted in the privileging application meets the required qualifications.
11. Based upon your organization's governing structure, the pharmacy administrator should receive formal approval from another administrator(s) at the organization with a recommendation to the organization's governing body regarding the privileges requested by the individual who applied for them.
12. A formal process should be developed to notify the practitioner who applied for privileges in writing with the decision.
13. Develop a filing system to maintain evidence of the privileges granted in the practitioner's credential file.
14. Develop a system to track information that will change such as license status and board certification.

There are practical considerations and challenges that should also be considered when developing a clinical privileging process. The fact that patient services are now delivered within systems that have many care delivery sites including multiple hospitals, clinics, pharmacies, and physician office practices underscores the importance that credentialing and privileging processes need to reach all areas where care is delivered and not just focused on the traditional walls of the hospital. The expansion of health systems raises the question as to whether the process needs to be centralized or driven on a facility-by-facility basis. There are arguments that could be made for and against both approaches including workload, efficiency, and consistency. For example, if a pharmacist practices at multiple facilities, should he or she be privileged at each facility, and should each facility have variations in its privileging process? Can an argument be made for centralizing the application? If the application is centralized, is there a process to share this information across the various facilities within a system? If the privileging timelines are different between facilities, is there a mechanism to harmonize them so that practitioners could avoid reapplication annually, semiannually, or more frequently? Most privileging processes are still paper-based; is there physical space to store this information? Is there an efficient way to routinely access the files to make sure they are current?

Performance data will need to be developed that are appropriate to the scope of services delivered by the pharmacist. It is often difficult to attribute an outcome to an individual because of the fact that many health care professionals interact with and provide patient services; however, serious thought needs to be given to what will be measured. A starting point could be a discussion with the institution's quality improvement department to identify areas that the organization is looking to address such as length of stay, readmission rates, and adverse events. Often, these areas can be impacted by medication use and may be appropriate starting points for identifying the pharmacist performance data to be collected.

In developing a privileging process, it needs to be clearly stated that the responsibility to provide full and complete information and to update that information as needed falls directly upon the pharmacist seeking clinical privileges. The privileging process will not work properly unless the pharmacist accepts full accountability for transparency in reporting and in the regular updating of required information.

These are just some of the logistical issues that need to be addressed when designing a pharmacist privileging process; in most cases, the pharmacy department should align with the institution's processes but the institution also faces the same challenges and issues for physician privileging. None of these challenges and issues should be viewed as a reason not to embark on privileging but should be addressed in advance so that program functions appropriately and meets the goal of assuring quality patient care.

Conclusion

A fundamental driver in the advancement of certification, credentialing, and privileging in clinical pharmacy, particularly in the United States, has been in the increase in the complexity of patient care (Council on Credentialing in Pharmacy, 2010a). Medications are one of the society's most important weapons in the fight against both acute and chronic disease, and pharmacogenomics are also becoming an important tool in addressing genetic disorders. It is exciting to observe the advancement of clinical pharmacy services in a number of countries around the world because pharmacists have the training, knowledge, and expertise to help patients in all settings make the best use of their medications (Jorgenson et al., 2017).

With the advancement in clinical pharmacy and an increased role of the pharmacist in the provision of direct and indirect patient care services comes great responsibility and accountability. The responsibility and accountability extend to a number of stakeholders including the organizations that employ pharmacists, public, and private entities that pay for pharmacists' services, colleagues in other health care professions including but not limited to medicine and nursing and the most important stakeholder, the patient (American College of Clinical Pharmacists, 2011).

The accountability of clinical pharmacists in delivering patient care must include embracing the tenets of board certification, credentialing, and privileging. Participating in board certification, credentialing, and privileging demonstrates the willingness of the clinical pharmacist to assure all stakeholders of their education, training, skills, and ability to provide patient care and to serve as valuable members of the health care team. The role of the clinical pharmacist will not advance by simply stating to possess the

knowledge and expertise to deliver patient care; these competencies must continually be demonstrated and assessed if clinical pharmacy is going to continue to evolve (American College of Clinical Pharmacists, 2011).

While there are many intricacies and details associated with certification, credentialing, and privileging of all health care professionals including pharmacists, a foundational element of all three areas is the welfare of the public. In health care, that welfare includes patient safety, alleviation of pain and suffering, improved outcomes, and cost-effectiveness with the ultimate goal being full restoration of health. While there are other drivers such as reducing or mitigating liability, professional satisfaction, prestige, peer recognition, and reimbursement, the patient should always remain the most important reason to pursue any professional credential or designation (Council on Credentialing in Pharmacy, 2009; Council on Credentialing in Pharmacy, 2010a; Forster et al., 2011; McCarthy, 2006).

Glossary

Certification The voluntary process by which a nongovernmental agency or an association grants recognition to an individual who has met certain predetermined qualifications specified by that organization. This formal recognition is granted to designate to the public that this individual has attained the requisite level of knowledge, skill, and/or experience in a well-defined, often specialized, area of the total discipline. Certification usually requires initial assessment and periodic reassessments of the individual's knowledge, skills, and/or experience (Council on Credentialing in Pharmacy, 2006).

Credentialing (1) The process of granting a credential (a designation that indicates qualifications in a subject or an area). (2) The process by which an organization or institution obtains, verifies, and assesses qualifications to provide patient care services (Council on Credentialing in Pharmacy, 2006).

Privileging The process by which a healthcare organization having reviewed an individual healthcare provider's credentials and performance and found them satisfactory authorizes that individual to perform a specific scope of patient care services within that organization (Council on Credentialing in Pharmacy, 2006).

Accreditation The process by which an association, organization, or government entity grants public recognition to an organization, site, or program that meets certain established qualifications or standards as determined through initial and periodic evaluations (Council on Credentialing in Pharmacy, 2006).

Practice-based CPE activity [Previously named Certificate programs in Pharmacy] These CPE activities are primarily constructed to instill, expand, or enhance practice competencies through systematic achievement of specified knowledge, skills, attitudes, and performance behaviors (American College of Clinical Pharmacists, 2011).

Role Delineation Study Any of several methods used singly or in combination to identify the performance domains and associated tasks, knowledge, and/or skills relating to the purpose of the credential and providing the basis for validation (Institute for Credentialing Excellence, 2009).

Clinical Pharmacy Professional Standards in European Union

Martin C. Henman, Trinity College Dublin, Dublin 2, Ireland

Introduction

In the context of this entry/chapter, the term standards encompasses two of the many shades of meaning listed in the Oxford English Dictionary, namely (Oxford English Dictionary, 2018):

- A rule, principle, or means of judgment or estimation; a criterion, measure.
- A definite level of excellence, attainment, wealth, or the like, or a definite degree of any quality, viewed as a prescribed object of endeavor or as the measure of what is adequate for some purpose;

The first of the two, which derives from earlier references to standard measures such as those of weight and length, is a description which tells the reader what it is.

The second is clearly related to the idea of quality and of a desired level of quality.

In both, it is clear that comparison is facilitated by a standard and that bringing two elements to the same standard could be referred to as standardization.

In health-care practice, standards are usually introduced for at least one of three reasons:

- To describe the activities, roles, and responsibilities of a professional
- To describe what is specified by a level of quality
- To aid the measurement and monitoring of performance

Since providing health care is a complex activity of which pharmacy services comprise an important part, it is not surprising that there are many standards created by, and applied to, pharmacy and pharmacists. Individual pharmacists, pharmacy department and teams, hospitals and clinics, health service authorities and regulators, representative bodies, and international associations have all been authors of standards that meet their particular aims and objectives. Since individuals, teams, and departments operate within larger health service organizations and sectors, it is important that their standards align with the relevant standards of the health service and of the professional regulatory body. These larger organizations and sectors are subject to local or national regulations which, in turn, often lead to the creation of standards and frameworks.

Although many standards have been used to define the provision of pharmacy services and to monitor the quality of those services, the standards that apply to clinical pharmacy and to clinical pharmacy in Europe especially have been relatively few in number. Therefore, some context must be provided to make this understandable.

Context

Clinical pharmacy was first described in the hospital setting and the term was used to distinguish it from the other activities carried out by pharmacists, such as compounding, dispensing, and medicines information. It represented a ward-focused activity, and one that involved consultation with doctors and nurses. This change in the pharmacist's roles and responsibilities was most readily accepted in the United States, the United Kingdom, Australia, and Canada and gradually gained momentum from the late 1960s onwards. Initially, individual pharmacists and hospital pharmacies began to provide clinical pharmacy and subsequently, formal support and leadership came from pharmacy associations (American College of Clinical Pharmacy was established in 1979; United Kingdom Clinical Pharmacists Association was established in 1981). Subsequently, with the recognition of the role, the clinical pharmacist's job description was established and clinical pharmacy was spread to more hospitals.

In hospital practice, a group of activities can be readily classified as clinical pharmacy while in community practice, some service development can be classed as clinical, but pharmacists usually have to perform multiple roles and to be flexible so that the practice can respond to varying service demands and needs. In addition, in community practice, other terms, such as cognitive services, have also been used to distinguish them from dispensing and medication provision.

Across Europe, clinical pharmacy has developed at varying speeds and in different ways; in Italy (Lombardi et al., 2018), Austria (Rose et al., 2018), Germany (Rose et al., 2018), and the Netherlands (Bosma et al., 2008; Rose et al., 2018), there is little clinical pharmacy, whereas in Spain (Saavedra-Mitjans et al., 2018), France (Allenet et al., 2006), Portugal (Falcão et al., 2014), and Belgium (De Rijdt and Desplenter, 2016; Somers et al., 2018), there is significantly more, while in Denmark (Neilsen et al., 2013) and Sweden (Sjölander et al., 2017) development continues. National programs for the implementation of clinical pharmacy are rarely found; most development has been within hospital groups or individual hospitals. However, even today, there is also a considerable variation within countries, as a recent study of Switzerland shows (Rose et al., 2018).

In the United States and the United Kingdom, the intention had been for pharmacists to provide patient-focused care in collaboration with prescribers and nurses, but in some countries, this was not possible, and instead population-focused or institution-focused services, such as Therapeutic Drug Monitoring and Medicines Information, came to be referred to as clinical services since they support rational prescribing and formulary development. This distinction between the patient and population focused services continues to this day and is reflected in practice with some countries, such as Austria, Germany, and the Netherlands (Rose et al., 2018), providing more population-focused services. Countries with more of a patient focus employ more clinical pharmacists and this can be seen in the data gathered in the European Association of Hospital Pharmacists surveys (European Association of Hospital Pharmacy, Survey Results, 2016).

There are also other factors that ensured that clinical pharmacy developed first in hospitals: As large health-care institutions, hospitals must adopt structured procedures to function efficiently and some, because they are University Teaching Hospitals, have the added impetus of providing specialist clinical care for a regional or nationally, of providing education and of conducting clinical trials and research—in each of these instances, the greater complexity of healthcare requires more highly qualified specialists to deliver the care required (Gillespie et al., 2009). This has resulted in the development of advanced services such as the Integrated Medicines Management Service in Northern Ireland (Scullin et al., 2007), the Lund Integrated Medicines Management in Sweden (Hellstrom et al., 2001), and the team-based model in Ireland (Byrne et al., 2017).

The result of this varied and sometimes divergent pattern of development has been that within Europe in 2018, the most significant clinical pharmacy standards, in terms of their widespread application and the most accessible in terms of their publication, are to be found in the United Kingdom (Department of Health, 2013; Royal Pharmaceutical Society, 2017). In other countries, hospital groups and individual hospitals have their own service descriptions, and these are neither regional nor national standards. At the European level, the most relevant document for the development of clinical pharmacy in the next few years is not a set of standards, but a description of hospital pharmacy, published by the European Association of Hospital Pharmacists (The European Statements of Hospital Pharmacy, 2014).

Current Standards

Although the Northern Ireland Clinical Pharmacy Services Standards (NI 2013) (Department of Health, 2013) and the Royal Pharmaceutical Society Standards for Hospital Pharmacy Services (RPS 2017) (Royal Pharmaceutical Society, 2017) documents were published only 4 years apart, they differ considerably in both their scope and structure (**Table 1**) and their content (**Table 2**).

Notably, both documents come from pharmacy bodies/groups, even though the RPS drafting group comprised lay people and other health-care professionals as well as pharmacists. Furthermore, both documents encompass the individual and the system approaches and both organize their standards under the headings of Acute or Care services and General Support or System services with most of the individual activities being contained in the Acute or Care sections. Most notably, the RPS document begins with standards that relate to Care and this highlights the primacy of the patient and of clinical pharmacy practice in the United Kingdom.

The standards themselves are general statements of what should be done but while the NI document is primarily pharmacist task-oriented, the RPS document is more process- and outcome-oriented for pharmacist, pharmacy teams, and patients. Consequently, the Acute Services section of the NI standards is a clear description of the tasks that a clinical pharmacist and the pharmacy team should perform, and the inclusion of an audit document template shows the intent of the Health and Social Care Trusts of Northern Ireland to standardize and monitor the quality of the Clinical Pharmacy Services that they provide. The RPS document indicates the context of providing hospital pharmacy services in the United Kingdom—a strenuous and comprehensive attempt to ensure that patients are empowered, or at least informed about their treatment. Both documents reflect the importance in Northern Ireland and the United Kingdom of patient safety and of utilizing pharmacists to provide care through pharmacist led clinics and through prescribing. However, both also set out in considerable detail the multidisciplinary nature of much of the pharmacists' work and of the importance of teamwork and of communication. Some activities, such as those concerned with safety, whether medication errors or pharmacovigilance responsibilities, are grouped under Acute Services in the NI document whereas the RPS distributes these activities across both the Care and Systems Domains. Some of the activities referred to are more frequently discussed in the United Kingdom and Northern Ireland than elsewhere in Europe, such as the reuse of patient's own medicines and the self-administration of medicines, while others, such as the pharmacoeconomic evaluation of medicines and financial management, are common to all European countries.

The NI document serves an operational need of the health service, whereas the RPS document sets out a framework for the profession, which it is intended, will be used as the basis for the development of operating documents by pharmacists and others in any care setting within the NHS.

Table 1 Comparison of the Northern Ireland and Royal Pharmaceutical Society Standards documents

Northern Ireland Clinical Pharmacy Standards (Department of Health, 2013)	*RPS professional standards for hospital pharmacy services (Royal Pharmaceutical Society, 2017)*
Published by; type of body	
Pharmacy Service of the Health and Social Care Trusts of Northern Ireland; Health Service Regional Authorities	Royal Pharmacy Pharmaceutical Society; Professional representative body
Authors, contributors; composition process	
Heads of pharmacy service of each of the five Health and Social Care Trusts; not specified	Steering Group, multidisciplinary and lay representatives ($n = 27$) supported by RPS team and External Reference group; RPS standards development process, accredited by NICE – Literature review → draft prepared by Steering Group in consultation with External Reference group → published for consultation → revised draft developed and reviewed by Steering Group in consultation with External Reference group → consensus reached → standards published.
Aims and objectives	
"The principal objective of this document is to improve the clinical pharmacy contribution to patient care through the development of a structured, systematic approach to clinical pharmacy practice."	"To provide professional standards that are supportive, enabling, and professionally challenging is a key function of a leadership body." "The professional standards describe quality pharmacy services (what good looks like)." "The standards provide a broad framework that will support pharmacists and their teams to continually improve services, shape future services and roles, and deliver high quality patient care across all settings and sectors."
Intended audience	
Hospital setting is implied with pharmacist working in a multidisciplinary team in a "hospital area" for which the pharmacy staffing level and structure (pharmacists and technicians) are specified.	Chief Pharmacists, Directors of Pharmacy, pharmacy teams, Commissioners/ purchasers of pharmacy services, regulators, insurers, Governments, legislators, and patients.
How they should be used	
Standards "need to be supported by local standard operating procedures specific to individual trusts."	Applicable to all settings. For Chief Pharmacists and Directors of Pharmacy to consider accountability. For benchmarking an existing service(s). For continuous quality improvement and innovation of new services.
Structure	
Standards grouped in two sections; Acute (services)—11 standards; General Support (services)—12 standards	Standards are grouped into domains and defined by dimensions and statements.
Standards are divided into two sets of components: basic standard requirements and advanced requirements	The domains are labeled one, two, and three but not named; one is about care; two is about medicines governance and safety; and three is about leadership, systems, and workforce.
Potential value and purpose of each standard are set out in a section entitled "Why it is important"	Domain one contains three standards with eight dimensions. Domain two contains two standards and nine dimensions Domain three contains three standards and nine dimensions
Each standard is supported by and audit template that arranged as—indicators; audit results; comments on action to be taken and verification of completion.	The standards are supported by a handbook.
Examples of standard operating procedures are set out in an appendix and the time taken to complete specific clinical tasks in different specialties is set out in another appendix.	Examples of practice and case studies are hosted in the RPS website.
A glossary is provided.	A glossary is provided.

In France in 2010, the Société Française de Pharmacie Clinique (La Société Française de Pharmacie Clinique, 2010) published an update of its framework describing the scope of practice of hospital pharmacists in seven chapters, including one on clinical pharmacy (**Table 3**). This chapter sets out three themes of practice: dispensing; role of the clinical pharmacist in therapeutics and in the optimization of the use of medicines including sterile medicinal products; involvement of pharmacy in the education, concerning therapeutics, of the patient. The four standards (critère) that are listed for the clinical pharmacist include those of

Table 2 Detailed comparison of the Northern Ireland and Royal Pharmaceutical Society Standards

Northern Ireland (Department of Health, 2013)		*Royal Pharmaceutical Society (Royal Pharmaceutical Society, 2017)*	
Acute		*Domain One*	
Standard	*Basic requirements*	*Standard*	*Element*
1. Medicine History Interview and Medicines Reconciliation	An accurate medicine history is obtained on admission to hospital.	1: Putting patients first Pharmacy services enable patients to be fully involved in their own care and to make shared decisions about their treatment and their medicines.	1.1 Patient focused services The principle of "no decision about me, without me" underpins the design and delivery of pharmacy services.
2. Medicine Therapy Monitoring (Pharmaceutical Care)	Pharmacists provide medicine therapy monitoring routinely to all patients. Where this is not possible, criteria shall exist to identify patients, who would benefit most from medicine therapy monitoring.		1.2 Information about medicines. Patients have access to information and support in order to make shared decisions about the use of medicines or the implications of choosing not to take them.
3. Prescription Monitoring and Review	Patients' prescription charts are monitored and reviewed in conjunction with the patient's medical notes and relevant medical laboratory results by a pharmacist at regular intervals.		1.3 Support with effective medicines use. Systems are in place to identify patients who may need support, or to allow patients to request support with medicines choice and use.
4. Prevention, detection, assessment, and management of adverse drug reactions	Pharmacists play an important role in the prevention, detection, assessment, management, and reporting ADRs. Emphasis should be on the prevention of ADRs and on the prevention of re-exposure in patients who have already experienced an ADR.	2: Episode of Care Patients' medicine requirements are regularly assessed and responded to in order to keep patients safe and to optimize their outcomes from medicines.	
5. Prevention, Assessment and Management of Drug Interactions	Pharmacists monitor for potential and existing drug interactions when monitoring and reviewing patient's medicine therapy.		2.1 At pre-admission, on admission or at first contact Patients' medicines are reviewed to ensure an accurate medication history, for clinical appropriateness and to identify patients in need of further pharmacy support.
6. Therapeutic Drug Monitoring	Pharmacists to optimize therapy for medicines where there is a known, close relationship between serum concentration and therapeutic effect and adverse effect use TDM.		2.2 Care of the patient Patients have their medicines reviewed by pharmacy team members who play an active role in the clinical management of patients. Patients can access the pharmacy expertise that they need to ensure that their medicines are clinically appropriate, and their outcomes from medicines are optimized.
7. Prevention, identification, management, and reporting of medication incidents	Pharmacists contribute to the prevention, identification, management, and reporting of medication incidents.		2.3 Patients' outcomes Patients' goals and outcomes from, and experiences of treatment with, medicines are documented, monitored, and optimized.
8. Multidisciplinary Working	Where appropriate the pharmacist shall attend ward rounds and clinical meetings as a member of the health-care team.	3: Integrated Transfer of Care Health and social care practitioners receive and share relevant information about the patient and their medicines when a patient transfers from one care setting to another.

Acute		*Domain One*	
Standard	*Basic requirements*	*Standard*	*Element*
9. Provision of Medicines Information Advice by Pharmacists	Pharmacists have a responsibility to provide appropriate, evidence-based timely information and advice on medicine-related matters to meet the requirements of health-care providers and patients and/ or their carers.		3.1 Patient needs Patients are given information about their medicines and have their expressed needs for information met.
10. Discharge	The pharmacist ensures that all medicines prescribed at discharge are clinically accurate and appropriate. The patient is dispensed a supply of their prescribed medicines and is provided with accurate, up-to-date information about their medicines. Accurate and up-to-date information of a patient's medicines at discharge is safely and effectively communicated to primary care health-care professionals.		3.2 Professional responsibilities Accurate and complete information about the patient's medicines is transferred to the health or social care professional(s) taking over care of the patient at the time of transfer. Arrangements are in place to ensure a safe supply of medicines for the patient and ongoing support where necessary.
11. Patient Medicine Education	Medicine education services shall be provided to patients or their carers where appropriate. If this is not possible categories of patients where maximal benefit is likely should be identified.

Reference 5.2 Roles of the clinical pharmacist in the therapeutics and optimization of drug use and sterile medical devices	
	Criterion 5.2.1 To control therapeutic strategies and implement recommendations in the form of protocols
	Criterion 5.2.2 Know and understand patient data including clinical, biological and therapeutic
	Criterion 5.2.3 Know how to optimize drug therapies and sterile medical devices and integrate with équipes médicales et paramédicales
	Criterion 5.2.4 Propose protocols on the proper use of health products
Reference 5.3 Pharmaceutical involvement in therapeutic patient education (TPE)	
	Criterion 5.3.1 Acquire training in TPE
	Criterion 5.3.2 Be part of professionals involved in the TPE including drug therapies
	Criterion 5.3.3 Participate in the implementation of TPE programs

ensuring that the guidelines and protocols about the use of medicines are followed, as well as knowing and understanding the relevant data found in the patient's hospital charts and records. Some other aspects particularly relevant to clinical practice, such as risk management, are classed as systems-related roles. Similar to the NI Clinical Pharmacy Services Standards, the framework includes an explanation of the standard and suggestions for its implementation and evaluation. The authors and contributors and the methods used to prepare the document are clearly described.

Commentary on Practice in Europe

Many years ago, pharmacy was described as an incomplete profession (Denzin and Mettlin, 1968). In fact, all health-care professions are forced and seek to change as health care, technology, and society exert pressure on traditional practices and relationships (Henman, 2008). In pharmacy, these pressures are perhaps more acute. Hospital pharmacy has sought to define itself repeatedly over the last 40 years and since clinical pharmacy is most closely associated with hospital practice, that process of change has affected clinical pharmacy. As time has gone on, other ideas, such as pharmaceutical care (Hepler and Strand, 1990) and medicines optimization (National Institute for Health and Care Excellence, 2015), have been introduced and used in a number of ways in different European countries. This has changed the context and led to standards concerning clinical pharmacy being replaced or subsumed within other policy documents.

The International Pharmacy Federation (FIP) first published a description of hospital pharmacy in 2008 known as the Basel Statements but it was not until 2014 that the final version was approved and published (International Pharmacy Federation, 2015). The FIP statements do not mention clinical pharmacy, but instead, refer to "Influences on Prescribing" to group together some of the clinical activities of a hospital pharmacist (**Table 4**). In some European countries, the reception of the FIP Statements was one of muted approvals, and the representative body, the European Association of Hospital Pharmacists, set about creating a document to reflect its members' views (European Association of Hospital Pharmacy, 2018). This document entitles one section "Clinical Pharmacy Services" and it contains eight statements.

Comparison of the EAHP and FIP statements suggests that pharmacists globally are reluctant to use terms like clinical, whereas in Europe, this reluctance has been overcome. It can be argued that the differences between the two documents are structural and organizational, but equally, the EAHP statements on Clinical Pharmacy Services are patient-centered, whereas the first two of the FIP statements are about establishing formulary and participation in a drugs and therapeutics committee. Both documents clearly show not only the breadth of the scope of hospital pharmacy practice but also its highly structured and team-based nature. Although both documents are entitled, "statements," and set out to delineate the roles and responsibilities of hospital pharmacists, they are phrased as exhortations to pharmacists, and can be read as an agenda, a manifesto, which is undoubtedly one way in which they should be used.

EAHP have further developed their strategy regarding clinical pharmacy in three important initiatives:

- Support for the implementation of the statements is provided by the Statement Implementation Learning Collaborative Centres and a self-assessment tool (European Association of Hospital Pharmacy, 2018).
- They have adapted their annual hospital survey pharmacy to concentrate on selected aspects on a rotating basis, and so in the 2015–16 survey, clinical pharmacy was one of the themes (European Association of Hospital Pharmacy, Survey Results, 2016).

Table 4 Comparison of FIP (International Pharmacy Federation, 2015) and EAHP Hospital Pharmacy statements (European Association of Hospital Pharmacy, 2018)

Headings Overarching and Governance Statements Theme 1: Procurement Theme 2: Influences on Prescribing Theme 3: Preparation and Delivery Theme 4: Administration Theme 5: Monitoring of medicines use Theme 6: Human Resources, training, and development	Theme/Section Headings 1. Introductory Statements and Governance 2. Selection, Procurement, and Distribution 3. Production and Compounding 4. Clinical Pharmacy Services 5. Patient Safety and Quality Assurance 6. Education and Research
Theme 2: Influences on prescribing statements	*4. Clinical pharmacy services statements*
24. Hospitals should utilize a medicine formulary system (local, regional, and/or national) linked to standard treatment guidelines, protocols, and treatment pathways based on the best available evidence. 25. Hospital pharmacists should be key members of pharmacy and therapeutics committees to oversee all medicines management policies and procedures, including those related to off-label use and investigational medicines. 26. Hospital pharmacists should have a key role in educating prescribers at all levels of training on the access to and evidence for responsible use of medicines, including the required monitoring parameters and subsequent prescribing adjustments. 27. Hospital pharmacists should be an integral part of the multidisciplinary team responsible for therapeutic decision-making in all patient care areas. 28. Hospital pharmacists should promote seamless care by contributing to the transfer of information about medicines whenever patients move between and within health care settings. 29. Appropriately trained and credentialed hospital pharmacists should participate in collaborative prescribing.	4.1 Hospital pharmacists should be involved in all patient care settings to prospectively influence collaborative, multidisciplinary therapeutic decision-making: they should play a full part in decision-making including advising, implementing, and monitoring medication changes in full partnership with patients, carers, and other health-care professionals. 4.2 All prescriptions should be reviewed and validated as soon as possible by a hospital pharmacist. Whenever the situation allows, this review should take place prior to the supply and administration of medicines. 4.3 Hospital pharmacists should have access to the patient's health record. Their clinical interventions should be documented in the health record and analyzed to inform quality improvement interventions. 4.4 All the medicines should be entered on the patient's medical record and reconciled by the hospital pharmacist on admission. Hospital pharmacists should assess the appropriateness of all patients' medicines, including herbal and dietary supplements. 4.5 Hospital pharmacists should promote seamless care by contributing to transfer of information about medicines whenever patients move between and within healthcare settings. 4.6 Hospital pharmacists, as an integral part of all patient care teams, should ensure that patients are offered information about their clinical management options, and especially about the use of their medicines, in terms they understand. 4.7 Hospital pharmacists should inform, educate, and advise patients, carers, and other health care professionals when medicines are used outside of their marketing authorization. 4.8 Clinical pharmacy services should continuously evolve to optimize patients' outcomes.

- In addition, EAHP has developed and published a competency document to support their proposal for a Common Training Framework in Europe (European Association of Hospital Pharmacy, 2018)—and one of this document's domains is, "Patient care and clinical competencies."

Both of these initiatives will support the development of clinical pharmacy in Europe and as each hospital, each region, and each country pursues its own strategies to improve the care of patients in hospitals, standards will be developed and utilized.

Clinical Pharmacy Professional Standards in Low- and Middle-Income Countries

Andy Gray, University of KwaZulu-Natal, Durban, South Africa

Introduction

Clinical pharmacy is usually understood as referring to those services rendered by pharmacists which are directly involved with patient care. However, there is also a view that clinical services are those provided at the bedside, as opposed to in any other setting. Such a view would exclude services rendered in pharmacies as opposed to hospitals or other in-patient settings, such as long-term stay facilities or frail care facilities. That interpretation would seem overly restrictive. Another view holds that clinical services are those that are nondistributive in nature, sometimes referred to as cognitive services. However, while the practice of pharmacy cannot be equated only with the filling of prescriptions issued by an authorized prescriber, it is clear that the concept of pharmaceutical care would incorporate the provision of medicines, the distributive portion of what should be a comprehensive pharmaceutical service aimed at achieving desired patient outcomes. A final point of some debate is whether clinical pharmacy services can be delivered at the population as opposed to individual patient level. Many pharmacists are involved in medicines selection, in the development of clinical practice guidelines and in such fields as pharmacovigilance, pharmacoeconomics, and pharmacoepidemiology. Just as clinical epidemiology evolved as a clinical service offered at the population level, so public health pharmacy relies on the same set of clinical pharmacy skills that are employed in direct patient care.

Clinical Pharmacy in Low- and Middle-Income Countries

Although there are few hard data to support this claim, the extent of advanced clinical pharmacy services in many low- and middle-income countries (LMICs) is constrained by the shortage of skilled human resources. The 2017 International Pharmaceutical Federation (FIP) report entitled "Pharmacy at a glance" showed that the median pharmacist density, expressed as the number of pharmacists per 10,000 population based on a sample of 74 countries, was 5.09 (International Pharmaceutical Federation, 2017). However, the median density in high-income countries (7.61 per 10,000 population) was 12.6 times than that in low income countries (0.60 per 10,000 population). Across the 58 countries that provided data, 75% of actively practicing pharmacists worked in community pharmacies, 13% in hospital pharmacies and 12% elsewhere. The median density of hospital pharmacists was only 1.05 per 10,000 population, but was seven times higher in South-east Asian countries (2.74) than in Africa (0.40).

In 2018, the FIP published a report on pharmacy workforce, covering the period from 2006 to 2016 (International Pharmaceutical Federation, 2018). Over that time period, though mean global pharmacist density had increased from 6.63 to 7.36 per 10,000 population, that growth had not been equally spread across countries and regions. More than half of the total absolute global growth in pharmacist capacity had occurred in the World Health Organization's Eastern Mediterranean and European regions. Not surprisingly, growth in pharmacist capacity was lowest in low-income countries, and highest in high-income countries. The mean absolute change in capacity was only 0.24% in the African region, over the decade.

It is therefore reasonable to expect that the delivery of clinical pharmacy services would be limited in areas with an absolute lack of training pharmacy workforce, and especially of pharmacists with advanced clinical training.

Pharmacy Credentialing and Specialization

Statistical reports like those developed by FIP focus on the whole of the pharmacy workforce, which refers to the total of all registered pharmacist practitioners, pharmaceutical scientists, pharmacy technicians, and other pharmacy support workforce cadres, as well as preservice students/trainees, working in a diversity of settings with a diversity of scope of practice. While it is possible to differentiate between registered pharmacists and other cadres, it is more difficult to identify those within the pharmacist group who have specialized clinical training or formalized specialty status. Many countries still offer a Bachelor of

Pharmacy degree (usually of 4 years' duration) as the entry point into the professional register, perhaps preceded by completion of a preregistration "internship" and sometimes a preregistration examination. The gradual spread of the more clinically oriented PharmD degree or a clinically oriented Master of Pharmacy entry-level qualification has been seen to a greater extent in better resourced countries.

There are global attempts, though, to expand the number of clinically-trained pharmacists and pharmacy specialists, notably through the efforts of the Board of Pharmacy Specialties (https://www.bpsweb.org/). The BPS was established by the American Pharmacists Association (APhA) in 1976 and its mission is "to improve patient care and increase awareness of the need for BPS Board Certified Pharmacists as integral members of multidisciplinary healthcare teams through recognition and promotion of specialized training, knowledge, and skills in pharmacy and specialty board certification and recertification of pharmacists throughout the world". Importantly, the certification examination used by the BPS is now offered in sites outside of the USA, such as in Egypt and Saudi Arabia. The 2017 BPS Annual Report noted that while only 10% of US pharmacists were BPS-certified, there were over 4000 pharmacists in other countries that held this certification (Board of Pharmacy Specialties, 2017). At that point, there were probably about 2.8 million pharmacists registered to practise around the globe.

Professional Standards

Professional standards of practice can be issued by a wide variety of bodies. Legally enforceable standards may be issued by the body which is entrusted with registering pharmacists to practise. These structures are variably referred to as Pharmacy Councils, Boards, Orders or Chambers. What marks them apart from voluntary professional associations and societies is that they are created by statute and given regulatory powers, as well as the powers to discipline those who are registered. However, professional and learned societies may also be the source of professional standard, to which those who voluntarily belong to such groupings are expected to adhere. Such documents may be aspirational in nature, rather than prescriptive.

At a global level, the International Pharmaceutical Federation (FIP) issues periodic Statements of Policy (https://www.fip.org/statements) that may cover clinical pharmacy professional activities. Recent examples include the FIP Statement on "The role of pharmacists in reducing harm associated with drugs of abuse" (2018), on "Control of Antimicrobial Resistance" (2017), on "Strategic development of medicines information for the benefit of patients and users of medicines" (2017) and on "The Effective Utilization of Pharmacists in Improving Maternal, Newborn and Child Health" (2013). A particularly apposite example is the FIP Statement on "Collaborative Pharmacy Practice" (2010). FIP also issues Statements of Professional Standards, such as on "The Role of the Pharmacist in Encouraging Adherence to Long-term Treatments" (2003). FIP has also produced an over-arching document on "Codes of Ethics for Pharmacists" (2014). These Statements are, by their very nature, globally applicable, but aspirational and not legally enforceable.

In 2011, the FIP issued a set of Good Pharmacy Practice (GPP) standards jointly with the World Health Organization (WHO) (International Pharmaceutical Federation, 2011). The document states that "GPP is the practice of pharmacy that responds to the needs of the people who use the pharmacists' services to provide optimal, evidence-based care". Importantly, the GPP standards stated that "it is essential that there be an established national framework of quality standards and guidelines."

An example of such a set of quality standards, developed and implemented as legally enforceable requirements, is the Good Pharmacy Practice standards issued by the South African Pharmacy Council and regularly updated (South African Pharmacy Council, 2010). **Table 1** shows some of the standards that are applicable to clinical services in this upper middle-income country. As the South African Pharmacy Council is a statutory body, with disciplinary powers, it has the legal ability to ensure compliance with the GPP standards and uses them in its inspectorate function.

Although many of the South African GPP standards are specific to the distributive functions of pharmacists, and provide the basic details of what is expected in terms of infrastructure and equipment, they also cover a range of nondistributive functions, as shown in the table. However, there is one glaring omission, and that relates to the stipulation of enforceable staffing norms for different types of pharmacies, at different levels of care.

FIP's Hospital Pharmacy Section has developed an aspirational set of statements that are intended to guide the development of hospital pharmacy practice is all settings. The updated 2016 version of the Basel Statements on the Future of Hospital Pharmacy form the basis for local efforts (Vermeulen et al., 2016). There is good evidence of how these Statements have been used to assess and then to advance hospital pharmacy practice is LMICs (Penm et al., 2014, 2015a, 2016). In addition, validated tools for assessing such services have been developed (Penm et al., 2012, 2015b). **Table 2** shows some of the updated Basel Statements that have particular relevance to clinical pharmacy practice, as numbered by the Hospital Pharmacy Section. Basel Statement #2 expressly calls for the development of both global and hospital practice standards.

With specific reference to hospital-based clinical pharmacy, the most widely cited national standards are probably those developed by the American Society of Health-System Pharmacists (ASHP; https://www.ashp.org/Pharmacy-Practice/Policy-Positions-and-Guidelines). The ASHP differentiates between policy positions ("short pronouncements on one aspect of practice"), statements ("express basic philosophy"), guidelines ("offer programmatic advice"), therapeutic position statements ("concise responses to specific therapeutic issues") and therapeutic guidelines ("thorough, evidence-based recommendations on drug use"). However, the ASHP emphasizes that the "use of ASHP's guidance documents by members and other practitioners is strictly voluntary". They state that "their content should be assessed and adapted based on independent judgment to meet the needs of local health-system settings". They can, therefore be used, with appropriate judgment and adaptation, in LMICs.

Table 1 Examples of South African Good Pharmacy Practice standards (2010)

GPP Statement	*Text*
1.2.13.1	Every pharmacy must have at least one type of area for the furnishing of information and advice. In cases where a pharmacy only has a semi-private area(s) at each point where dispensing of medicine to the patient or the patient's agent/caregiver occurs, there must in addition be access to another separate private room/area where communication can take place between a pharmacist and a patient or the patient's agent/caregiver in private.
2.8.2	Pharmacists and other persons registered with Council must (within their scope of practice) give advice and information to patients on how to use medicines safely and effectively to maximize therapeutic outcomes.
2.11.2	Ward pharmacy is a patient-orientated, decentralized service where the pharmacist becomes an integral and indispensable part of the professional health team of the hospital/institution: 1. Ward pharmacists must utilize their knowledge and skills of pharmaceutical sciences and product awareness to promote safety, efficacy and economy in the use of medicines; 2. ward pharmacists must offer advice to clinicians and nurses on appropriate medication to ensure that medicines are used correctly and in the appropriate therapeutic context
2.13	A pharmacy can offer services relating to screening and testing a patient's biochemical and physiological parameters. Pharmacists who are competent to do so may provide such screening and monitoring services.
2.14	Although the pharmacist's involvement with immunization varies with each practice setting, the pharmacist can be actively involved in the following activities: 1. educating the public and other health care professionals about immunization; 2. advocating pediatric immunization; 3. providing immunization for international travel; 4. screening patients who are at risk of preventable infectious diseases by occupation, life-style or an underlying disease state; 5. administering immunization agents; 6. recording immunization data; and 7. using the immunization database to generate reminder letters for booster doses.

Table 2 Examples of the FIP Hospital Pharmacy Section Basel Statements (2016)

Basel Statement	*Text*
2	At a global level, evidence-based hospital pharmacy practice standards should be developed. These should assist national efforts to define standards for the extent and scope of hospital pharmacy services and should include corresponding human resource and training requirements.
30	Hospital pharmacists should assume responsibility for storage, preparation, dispensing, and distribution of all medicines, including investigational medicines.
36	Hospital pharmacists should support the development of policies regarding the use of medicines brought into the hospital by patients, including the evaluation of appropriateness of complementary and alternative medicines.
41	Hospital pharmacists should ensure that clinically relevant allergies, drug interactions, contraindications, past adverse events, and other relevant medication history details are accurately recorded in a standard location in patient records and evaluated prior to medicine use.
54	Pharmacists' clinically relevant activities should be documented, collected, and analyzed to improve the quality and safety of medicine use and patient outcomes. Activities that significantly impact individual patient care should be documented in the patient record.
65	Postgraduate clinical courses should be developed to prepare hospital pharmacists for collaborative prescribing of medicines, including instruction in legal and professional accountability.

However, there is no publicly accessible indication of the extent to which this has occurred in any resource-constrained environments.

Many other national and regional structures in high-income countries have produced similar documents. An example are the European Association of Hospital Pharmacy Statements issued in 2014, for which a self-assessment tool has been developed (http://sat.eahp.eu/en/home) (Anon, 2014). The European Statements on Hospital Pharmacy are intended to be implemented in the countries from which the Association draws its membership, which are predominantly high-income countries. However, the membership does incorporate a number of transitional economies, such as those from the former East bloc (Bulgaria, Croatia, the Czech Republic, Estonia, The Former Yugoslav Republic of Macedonia, Hungary, Latvia, Lithuania, Montenegro, Poland, Romania, Serbia, Slovakia, and Slovenia) and Turkey. The implementation plan for the European Statements therefore has to take into account the needs of such settings, and their very different resource bases. The Association has appointed Statement Implementation Learning Collaborative Centres (SILCC), which include hospitals in various countries which are willing to train pharmacists, and has also undertaken to provide national member associations with small grants to help hospital pharmacists take advantage of such training opportunities.

Conclusion

Although there are global professional standards for the provision of clinical pharmacy services, these are not always translated into applicable and relevant documents that can be applied or even enforced at local levels, particularly in LMICs. However, these are not aimed at clinical pharmacy in its full depth and range, but are mostly specific to hospital pharmacy practice. Clinical pharmacy cannot be simply equated to hospital pharmacy. The severe lack of skilled pharmacy workforce makes the provision of acceptable, professional clinical pharmacy services in resource-constrained settings extremely difficult. However, there are aspirational and at times legally enforceable standards in such settings, as well as global support for their development.

Clinical Pharmacy Professional Standards in United States of America and Canada

Daniel S. Aistrope, Michael S. Maddux, American College of Clinical Pharmacy, Lenexa, KS, United States

Background

Professional standards set specific expectations of a profession or discipline and the members of that profession/discipline. Such standards are commonly used to guide professional development, competence, attitude, behavior, ethics, and performance. In the case of a health profession or discipline, professional standards are often applied to create goals and expectations for students, postgraduates in training, and licensed and/or credentialed members of the profession/discipline.

Although rooted in the standards of pharmacy and other health professions, clinical pharmacy's standards are largely based on the definition of clinical pharmacy. The first contemporary definitions of clinical pharmacy emerged in the late 1960s. In 1967, Paul F. Parker described clinical pharmacy as "a concept or philosophy emphasizing the safe and appropriate use of drugs in patients. It is achieved only by interacting responsibly for drugs with all of the health disciplines who are in any way concerned with drugs" (Parker, 1967). Shortly thereafter, the American Association of Colleges of Pharmacy Committee on Curriculum defined clinical pharmacy as "that area within the pharmacy curriculum which deals with patient care with emphasis on drug therapy. Clinical pharmacy seeks to develop a patient-oriented attitude" (Lemberger, 1968). Gloria Francke commented further on clinical pharmacy in a 1969 article, noting, "The practice of clinical pharmacy . . . utilizes [the pharmacist's] professional judgment based on his theoretical knowledge while working with the members of the health-care team to foster safe and appropriate use of drugs in patients" (Francke, 1969).

The founding documents of the American College of Clinical Pharmacy (ACCP) defined clinical pharmacy in 1979 as "a health science discipline that embodies the application, by pharmacists, of the scientific principles of pharmacology, toxicology, pharmacokinetics, and therapeutics to the care of patients." In the preface to the 2003 Encyclopedia of Clinical Pharmacy, Dipiro noted, "Clinical pharmacy incorporates the patient-oriented practices of pharmaceutical care as well as drug policy management, research, [and] education" (DiPiro, 2003). ACCP subsequently published the most comprehensive definition to date, including a description of clinical pharmacy as:

> " . . . a health discipline in which pharmacists provide patient care that optimizes medication therapy and promotes health, wellness, and disease prevention. The practice of clinical pharmacy embraces the philosophy of pharmaceutical care; it blends a caring orientation with specialized therapeutic knowledge, experience, and judgment for the purpose of ensuring optimal patient outcomes. As a discipline, clinical pharmacy also has an obligation to contribute to the generation of new knowledge that advances health and quality of life" (ACCP, 2008).

Taken together, these definitions have been influential in the development of the US clinical pharmacy standards.

VII.	Research and scholarship
VIII.	Other responsibilities

Clinical Pharmacy Standards in the United States

ACCP published in 2014 the first set of comprehensive standards for clinical pharmacists (ACCP, 2014). The purpose of the standards is to define for the pharmacy profession, other health professionals, policy makers, payers, and the public what should be expected of clinical pharmacists (Table 1). In addition, they are intended to provide guidance to those engaged in developing and assessing clinical pharmacy educational curricula and training programs. Finally, the standards are designed to "set the bar" as clinical pharmacy practice, research, and education continue to grow and evolve around the world.

The Standards and Their Applications

Qualifications

Clinical pharmacists provide comprehensive medication management (CMM) (PCPCC, 2012) and related care for patients in all health care settings. They are licensed pharmacists with specialized advanced education and training who possess the clinical competencies necessary to practice in team-based, direct patient care environments (ACCP, 2008; Mitchell et al., 2012). Accredited residency training or equivalent post-licensure experience is required for entry into direct patient care practice. Board certification is also required once the clinical pharmacist meets the eligibility criteria specified by the Board of Pharmacy Specialties (BPS) (ACCP, 2013).

Process of Care

Patient care is coordinated among providers and across systems of care as patients transition in and out of various settings. The clinical pharmacist's process of care comprises the following components (Fig. 1).

- Assessment of the patient
- Evaluation of medication therapy
- Development and implementation of a plan of care
- Follow-up evaluation and medication monitoring (ACCP, 2014)

Documentation

Clinical pharmacists document directly in the patient's medical record medication-related assessments and plans of care to optimize patient outcomes. Documentation should be compliant with the accepted standards for documentation (and billing, where needed) within the health system, health care facility, outpatient practice, or pharmacy in which one works. Where applicable, existing institutional/organizational guidelines or requirements must be considered as they relate to the use of electronic health records (EHRs), health information technology and exchange systems, and e-prescribing.

The components of the encounter are essential to include in the documentation, which may be communicated in the form of a traditional SOAP (subjective data, objective data, assessment, and plan) note or other framework consistent with the standards of documentation within the practice setting. These include the medication history, the active problem list with an assessment of each problem, and the plan of care to optimize medication therapy and improve patient outcomes (ACCP, 2014).

Collaborative, Team-Based Practice, and Privileging

Clinical pharmacists work with other health professionals as members of the health care team to provide high-quality, coordinated, patient-centered care (Doherty and Crowley, 2013). They establish written collaborative drug therapy management agreements (CDTM) with individual physicians, medical groups, or health systems and/or hold formally granted clinical privileges from the medical staff or credentialing system of the organization in which they practice (ACCP, 2013). These privileging processes, together with the applicable state pharmacy practice act, confer certain authorities, responsibilities, and accountabilities to the clinical

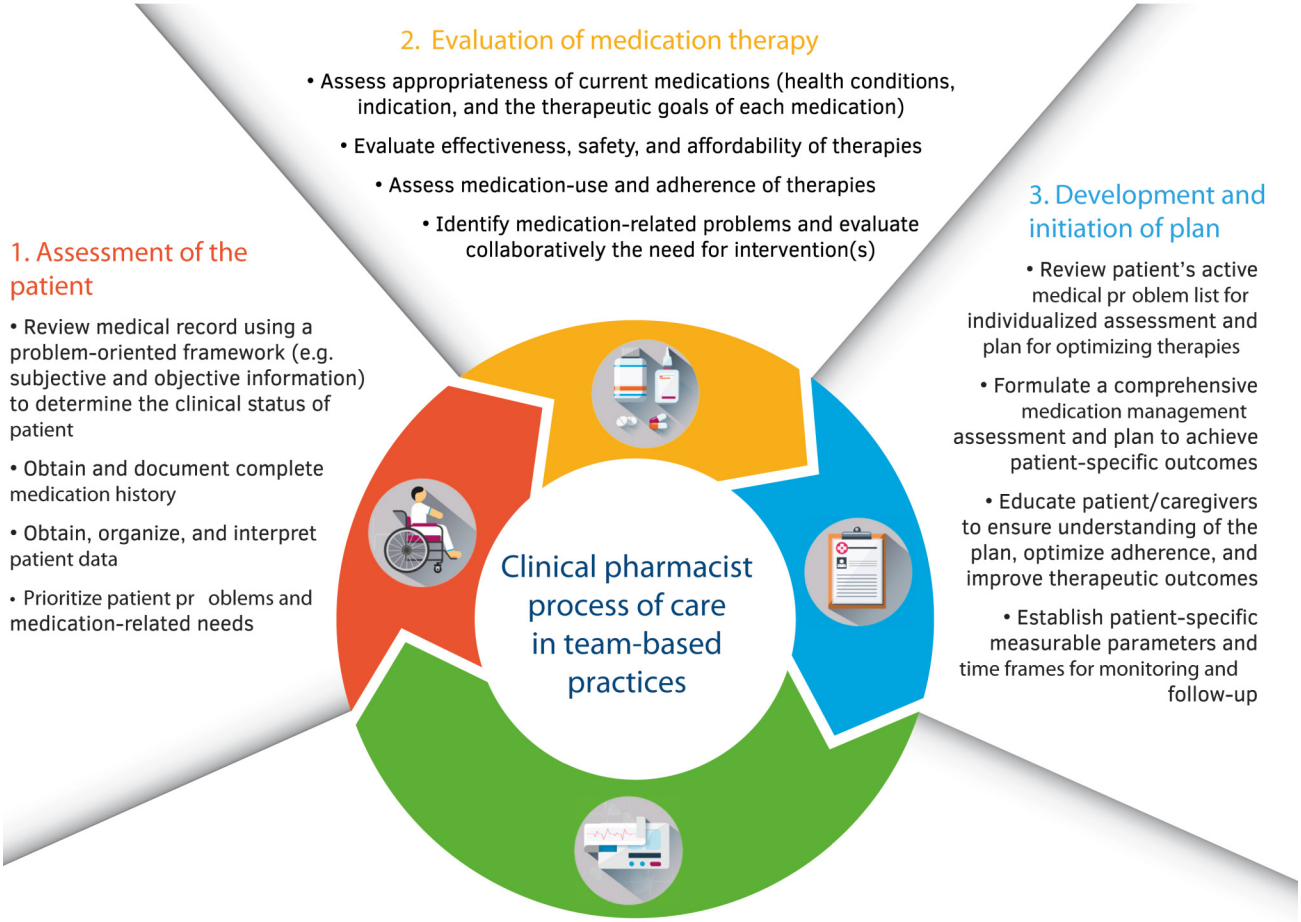

Figure 1 Clinical pharmacist process of care in team-based practices.

pharmacist as a member of the health care team and contribute to the enhanced efficiency and effectiveness of team-based care (ACCP, 2014).

Professional Development and Maintenance of Competence

Clinical pharmacists maintain competence in clinical problem-solving, judgment, and decision-making, communication and education, medical information evaluation and management, management of patient populations, and a broad range of therapeutic knowledge domains (Burke et al., 2008; Saseen et al., 2017). Clinical pharmacists maintain competency through:

- Certification and maintenance of certification in the appropriate specialty relevant to their practice, including those recognized by the BPS or other nationally recognized multiprofessional certifications;
- Consistent participation in continuing professional development (CPD) activities that enhance direct patient care practice abilities; and
- Maintenance of active licensure, including required continuing pharmacy education activities, through the appropriate state board(s) of pharmacy (ACCP, 2014).

Clinical pharmacists also pursue professional and career development by participating in activities that enhance research and scholarship, teaching, leadership, and/or management (ACCP, 2014).

Professionalism and Ethics

Clinical pharmacists have a covenantal, "fiducial" relationship with their patients. This relationship relies on the trust placed in the clinical pharmacist by the patient and the commitment of the clinical pharmacist to act in the best interest of individual patients and patient populations, within the context of legal and ethical parameters. Clinical pharmacists exhibit the traits of professionalism: responsibility, commitment to excellence, respect for others, honesty and integrity, and care and compassion (Roth and Zlatic, 2009). They subscribe to the pharmacy profession's code of ethics and adhere to all pharmacist-related legal and ethical standards (ACCP, 2014).

Research and Scholarship

Clinical pharmacists support and participate in research and scholarship to advance human health and health care by developing research questions; conducting or participating in clinical, translational, and health services research; contributing to the evolving literature in evidence-based pharmacotherapy; and/or disseminating and applying research findings that impact the quality of patient care (ACCP, 2014).

Other Responsibilities

Clinical pharmacists serve as direct patient care providers, but they may also serve as educators, researchers, clinical preceptors/mentors, administrators, managers, policy developers, and consultants. As the clinical pharmacy discipline grows, it must continue to familiarize more patients, families, caregivers, other health professionals, payers/insurers, health care administrators, students, and trainees with the full range of clinical pharmacists' responsibilities (ACCP, 2014).

Relevant Standards in Canada

Although Canada has not developed standards for clinical pharmacists, per se, they have issued several guiding documents that should inform clinical pharmacists and clinical pharmacy practice in Canada (**Table 2**). The National Association of Pharmacy

Table 2 Documents that set forth clinical pharmacy-related outcomes and indicators in Canada

Document	*Outcomes/indicators*
NAPRA/ANORP Model Standards of Practice (2009) [a]	• Expertise in medications and medication use • Collaboration • Safety and quality • Professionalism and ethics
AFPC[b] Educational Outcomes (2017)	• Care provider • Communicator • Collaborator • Leader–Manager • Health advocate • Scholar • Professional
CSHP[c] Key Performance Indicators for Inpatient Clinical Pharmacy Services (2015)	• Medication reconciliation on admission • Development of a pharmaceutical care plan • Resolution of drug therapy problems • Participation in interprofessional patient care rounds • Patient education during the hospital stay • Patient education at discharge • Medication reconciliation at discharge • Bundled patient care interventions
CPhA[d] Blueprint for Pharmacy (2015)	• Initiation of prescription drug therapy • Ordering and interpretation of laboratory tests • Medication review and assessment

[a]National Association of Pharmacy Regulatory Authorities and the Association des nationale organismes de réglementation de la pharmacie.
[b]Association of Faculties of Pharmacy of Canada.
[c]Canadian Society of Hospital Pharmacists.
[d]Canadian Pharmacists Association.

Regulatory Authorities (NAPRA) and the Association des nationale organismes de réglementation de la pharmacie (ANORP) have published the Model Standards of Practice (MSOP) for Canadian Pharmacists (NAPRA/ANORP, 2009). The MSOP are minimum standards of practice all pharmacists must meet. They are categorized into four domains:

- Expertise in medications and medication use
- Collaboration
- Safety and quality
- Professionalism and ethics

The MSOP include components that relate to emerging scope of practice activities but do not provide explicit standards of practice for clinical pharmacists.

The Association of Faculties of Pharmacy of Canada (AFPC) have recently updated the educational outcomes for first professional degree programs in pharmacy (AFPE, 2017). Identifying patient care as the core activity of the discipline of pharmacy prompted AFPE to make revisions in its most recent version of desired educational outcomes. These outcomes are intended to prepare graduates to fulfill a variety of roles beyond those to enter pharmacy practice in general, including those that are more clinically-focused. The AFPE educational outcomes are defined in terms of seven roles with associated key competencies:

- Care provider
- Communicator
- Collaborator
- Leader–Manager
- Health advocate
- Scholar
- Professional

The Canadian Society of Hospital Pharmacists (CSHP) has established, using an evidence-based, consensus-building process, eight key performance indicators for clinical pharmacy services provided to inpatients (Fernandes et al., 2015):

- Medication reconciliation on admission
- Development of a pharmaceutical care plan
- Resolution of drug therapy problems
- Participation in interprofessional patient care rounds
- Patient education during the hospital stay
- Patient education at discharge
- Medication reconciliation at discharge
- Bundled patient care interventions (provision of all seven of the foregoing services)

These performance indicators, particularly the "bundled intervention" indicator, are consistent with the ACCP standards' "process of care" component. However, the indicators are restricted to inpatient practice only.

The Canadian Pharmacists Association released in 2015 an update of progress in achieving its "Blueprint for Pharmacy" (CPhA, 2015), a long-term, multi-stakeholder effort designed to facilitate changes in Canadian pharmacy practice. Although the blueprint does not set standards of practice for clinical pharmacists, it provides a means of documenting the advancement across individual Canadian provinces of specific clinical services, including the initiation of prescription drug therapy, ordering and interpretation of laboratory tests, and medication review and assessment.

Extensions of the Standards

In addition to clinical pharmacy standards of practice, the discipline is shaped by other practice-related documents and resources that align with the standards. The ACCP standards have served as the foundation for development of clinical pharmacist competencies, evaluation, process of care, and scope of practice.

Clinical Pharmacist Competencies

The six ACCP core clinical pharmacist competencies apply to practitioners engaged in CMM in team-based, direct patient care environments. They are analogous to the competency expectations for practicing physicians (ACCP, 2013). Therefore, they align with the competencies embraced by the Accreditation Council for Graduate Medical Education (**Table 3**) (ACGME, 2017). Although the competencies of clinical pharmacists are similar to those of physician providers, clinical pharmacist competencies more aptly reflect a focus on pharmacotherapy and achieving optimal medication-related outcomes. These competencies are intended to ensure that a practitioner can provide CMM as outlined in the ACCP Standards of Practice (ACCP, 2014). The core competency domains are direct patient care; pharmacotherapy knowledge; systems-based care and population health; communication; professionalism; and continuing professional development. **Table 4** provides a detailed description of each domain. Clinical pharmacists may need to

Table 3 Comparison of physician and clinical pharmacist competencies in the United States (Saseen et al., 2017)

ACGME physician competencies	*ACCP clinical pharmacist competencies*
1. Patient care and procedural skills	1. Direct patient care
2. Medical knowledge	2. Pharmacotherapy knowledge
3. Systems-based practice	3. Systems-based care and population health
4. Interpersonal and communication skills	4. Communication
5. Professionalism	5. Professionalism
6. Practice-based learning and improvement	6. Continuing professional development

Table 4 Description of clinical pharmacist competencies.[a] (Saseen et al., 2017)

Competency domain	*Elements of the competency*[b]
Direct patient care	• Assess patients, including identifying and prioritizing patient problems and medication-related needs. • Evaluate drug therapy for appropriateness, effectiveness, safety, adherence, and affordability. • Develop/initiate therapeutic plans and address medication-related problems. • Follow up on and monitor the outcomes of therapeutic plans. • Collaborate with other members of the health care team to achieve optimal patient outcomes across the continuum of care. • Apply knowledge of the roles and responsibilities of other health care team members to patient care.
Pharmacotherapy knowledge	• Demonstrate and apply in-depth knowledge of pharmacology, pharmacotherapy, pathophysiology, and the clinical signs, symptoms, and natural history of diseases/disorders. • Locate, evaluate, and assimilate scientific/clinical evidence and other relevant information from the biomedical, clinical, epidemiological, and social-behavioral literature. • Use scientific/clinical evidence as the basis for therapeutic decision-making. • Possess the knowledge and experience commensurate with certification in one or more BPS specialties. • Enhance and maintain pharmacotherapy knowledge, including recertification or other appropriate methods of self-assessment and learning.
Systems-based care and population health	• Use health care delivery systems and health informatics to optimize the care of individual patients and patient populations. • Participate in identifying systems-based errors and implementing solutions. • Resolve medication-related problems to improve patient/population health and quality metrics. • Apply knowledge of pharmacoeconomics and risk-benefit analysis to patient-specific and/or population-based care. • Participate in developing processes to improve care transitions. • Design quality improvement processes to improve medication use.

Communication	• Communicate effectively with:
	  ◦ Patients, caregivers, families, and laypersons of diverse backgrounds.
	  ◦ Other health professionals and stakeholders.
	• Provide clear and concise consultations to other health professionals.
	• Develop professional written communications appropriate to the audience.
	• Use verbal communications tailored to varied clinical and patient-specific environments.
	• Communicate with appropriate levels of assertiveness, confidence, empathy, and respect.

Professionalism	• Uphold the highest standards of integrity and honesty. • Commit to a fiducial relationship with patients, always working in their best interests. • Serve as a credible role model/leader for students, trainees, and colleagues by exhibiting the values and behaviors of a professional. • Advance clinical pharmacy through professional stewardship, training of future clinical pharmacists, and active engagement in professional societies.
Continuing professional development	• Commit to excellence and lifelong learning. • Demonstrate skills of self-awareness, self-assessment, and self-development. • Continually identify and implement strategies for personal improvement through professional development. • Provide professional education to students, trainees, or other health professionals. • Maintain BPS certification to ensure that therapeutic knowledge is up-to-date.

[a]These competencies are necessary to provide CMM in team-based, direct patient care environments. Other competencies will be acquired as the clinical pharmacist progresses through his/her career and engages in additional professional activities.

[b]These elements help describe each competency but are not intended to be all-inclusive. Other related elements may apply, depending on the clinical pharmacist's practice setting and activities.

master additional areas of competence as they progress through their careers (e.g., leadership, research, or professional education). Therefore, it is not intended that the core competencies set forth all competencies that clinical pharmacists may acquire over time or that is needed to succeed in specific professional pursuits (Saseen et al., 2017).

Template for the Evaluation of the Clinical Pharmacist

The template serves as a tool to measure, evaluate, and document a clinical pharmacist's performance in any practice setting. It highlights the six core competency domains likely to be part of every clinical pharmacist's job description as listed in **Table 3**. For each domain, several tasks and examples of performance measures—including observations or reviews of clinical decisions or documentation based on encounters with patients, caregivers, families, laypersons, or other health professionals—can be found built into the template. For some tasks, a wide variety of assessments can be used to evaluate performance (Lee et al., 2017).

Those responsible for evaluating clinical pharmacists can modify the template and choose the type of assessment that best fits their institution and department. Clinical pharmacists may be evaluated by their supervisor, their peers, or other members of the health care team (e.g., physicians). Depending on the institution, the clinical pharmacist's peers may be appointed to a best practices, continuous quality improvement, or peer review committee (Haines et al., 2010). Each institution or organization will set its own criteria for success according to the clinical pharmacist's experience level, how long he or she has practiced within the department, and other factors. Finally, cut-points, as well as actions to take if the clinical pharmacist fails to meet the criteria for success, should be determined (Lee et al., 2017).

Although best practices for clinical pharmacists are highlighted in the template, each institution or organization can select the evaluable items within the domains that apply to the clinician's practice setting and the tasks most appropriate for the scope of clinical services provided. Similarly, some clinical pharmacists may also be responsible for conducting research, leading/managing others, or teaching. For these clinical pharmacists, other items (e.g., "optional tasks") may be added to the appropriate domains of the template (Lee et al., 2017).

Scope of Practice for Clinical Pharmacists

The first clinical pharmacist scope of practice document was released in 2016 (ACCP, 2016b). Although an individual professional's scope of practice is technically limited to that which state/provincial law or regulation allows based on specific education, experience, and demonstrated competency, this document provides additional information to facilitate a clearer understanding of clinical pharmacy practice by the public, health professionals, and policy-makers. It includes the following sections:

- Professional practice
- Education
- Accountability
- Responsibility

Comprehensive Medication Management in Team-Based Care

CMM is the foundational direct patient care practice of clinical pharmacists, provided in collaboration with other health care providers, to optimize each patient's medication experience and clinical outcomes. ACCP has published a guide that provides information about the practice, how it is structured and delivered, who is qualified to deliver it, and which patients it is likely to benefit most (ACCP, 2016a). This reference is intended for use by those employing or contemplating the incorporation of clinical pharmacists into team-based practice, designing and assessing clinical pharmacy education and training programs, and policy-makers seeking greater understanding of the practice of clinical pharmacists (ACCP, 2016a).

A variety of educational and training outcomes, objectives, and competencies have been articulated for pharmacists and/or clinical pharmacists, including, but not limited to the AACP CAPE Educational Outcomes (Medina et al., 2013); AACP Core Entrustable Professional Activities (EPAs) for New Pharmacy Graduates (Haines et al., 2017); and ASHP Residency Competency Areas, Goals, and Objectives (CAGOs) (ASHP, 2016). However, unlike the profession of medicine, there is limited alignment between pharmacy's professional degree outcomes, EPAs, residency CAGOs, and clinical pharmacist competencies. While great effort has been made by some to identify and articulate in detail the components that shape the discipline of clinical pharmacy, opportunities to more clearly align this work exist. The complementary nature of the clinical pharmacist standards of practice, competencies, and evaluation template, and the CMM guide, serves as an example of how such alignment can be developed.

The Future: Standards-Driven Professional Development

Establishing standards is an effective method for developing and advancing a discipline. The evolution of clinical pharmacy as the universally accepted core professional activity of the pharmacy profession remains in-progress. However, as the clinical pharmacy discipline continues to grow and mature across the globe, it is anticipated that clinical pharmacy standards will influence future national/international pharmacy practice guidelines or blueprints; standards for professional degree education; postgraduate

training competencies, goals, and objectives; credentialing and clinical privileging; research expectations; guidance for maintenance of competence; and codes of ethics and professionalism.

Competency Standards for Clinical Pharmacists

Andreia Bruno*, Stephen Eckel†, *Monash University, Parkville, VIC, Australia; †University of North Carolina, Chapel Hill, NC, United States

Introduction: Global Perspective

The United Nations (UN) Sustainable Development Goals (SDGs) are a universal call for action to, among others, ensure good health and well-being (SDG 3), which can be directly related to pharmacists, to their professional development and clinical expertise. One of the SDG 3 aims is to achieve universal health coverage, and provide access to safe and affordable medicines and vaccines for all (UN, 2015; WHO, 2015). Pharmacists have an important role, through the provision of medicine expertise, to support the achievement of this particular goal.

In the World Health Organization (WHO)—Global strategy on human resources for health: workforce 2030—published in 2016: the first objective 1 states "optimize performance, quality and impact of the health workforce (. . .)." WHO suggest as one of the policy options from countries to consider, is the adoption of transformative strategies toward scaling-up education supported by competency-based learning. There is a need for a coordinated approach linking human resources for health planning and education, to encourage inter-professional education and collaborative practice. Preparing healthcare professionals to work together as a team to effectively intervene on social determinants of health and expertise in public health is essential for better health outcomes (WHO, 2016). With a global shortage of healthcare workers undermining the delivery system in many countries, the critical effort to scale up training and education health workers demands vision, knowledge sharing, and tools to avoid common difficulties and to consider each training opportunity in the broader context of strengthening human resources for health (WHO, 2006, 2013; FIP, 2016a).

The International Pharmaceutical Federation (FIP), in supporting the implementation of the recommendations from the UN and WHO, has developed a roadmap for a needs-based pharmaceutical workforce transformation (FIP, 2017; Anderson et al., 2010, 2012). A globally shared vision was achieved—during the global conference on pharmacy and pharmaceutical education—so that pharmacists can accept responsibility and accountability for improving global health. The global conference aimed to address the education and developmental needs to create a competent pharmaceutical workforce, which included initial education and training for pharmacists and pharmaceutical scientists (FIP, 2017). One of the key outcomes of the conference is the Pharmaceutical Workforce Development Goals (PWDGs) that were created to activate and provide purpose to the other documents published (FIP, 2016b, 2016c, 2016d). The 13 PWDGs describe workforce development through education and the relevant one for this chapter is PWDG #5—Competency development, with the rational of the use of evidence-based developmental frameworks to support professional career development (FIP, 2016b).

As medications are getting more expensive, medication outcomes are less than desirable, and overall quality of healthcare is not at the standard desired. Healthcare needs to identify professionals to take the lead in improving the different parameters. Since pharmacy is the profession in all countries focused on medications, it is important to train and employ pharmacists that apply their knowledge, skills, and values toward direct patient care. Hence, clinical competent pharmacists improve health outcomes, minimize the risk associated with medicines use and ensure patient safety (Bond and Raehl, 2007; Jacknin et al., 2014). As an important professional within any healthcare system, it is essential to be competent and highly skilled, equipped with the knowledge and skills relevant for the health needs of the population (Austin, 2013; FIP, 2012b).

Competence and competencies are terms, which are increasingly accepted at a global level in healthcare and are being directly linked to professional roles. Competency-based approaches put professional practice at the core of education and practitioner development programs (Bates et al., 2004). Competency frameworks have become increasingly common due to the need for transparency in the training, development, and accreditation of healthcare professionals (Bates and Bruno, 2008). Published research demonstrates that when competency frameworks are used alongside standards of practice, it facilitates pharmacists' performance, promotes fitness to practice, supports the identification of knowledge gaps and learning needs, and promotes continuing professional development (CPD) —as they can form the foundation for educational and assessment tools, when designed according to educational outcomes (Mills et al., 2008; Coombes et al., 2010; Rutter et al., 2012; Stojkov et al., 2014; Meštrović et al., 2012).

Since competency is a complex construct, the authors have attempted to clarify concepts and to provide examples of the multifaceted information, by focusing on the following key questions:

What is competency?

What are the characteristics of competency?

How to develop competency standards or frameworks?

How to operationalize it?

Is there one that can be used as a guide?

What is the need for competency standards in clinical pharmacy practice?

How have other countries approached it?

The references, and examples provided will help the reader to navigate through this intricate topic and have the necessary resources and tools to further pursue a clinical pharmacy, or to design and implement competency standards or frameworks for clinical pharmacy.

For the purposes of this chapter, competency framework is defined as: a complete collection of competencies that are thought to be essential to performance; competencies: as the knowledge, skills, behaviors, and attitudes that an individual accumulates, develops, and acquires through education, training, and work experience; and competency: as a single item of knowledge, skill, behavior, and attitude.

What is Competency?

The concept of competence has been evolving from a concept representing knowledge to a more complex model, which includes expertise and the application of the knowledge, behavior, and skills to be able to perform in the workplace (Miller, 1990). There are diverse definitions of competency, theoretical views and ultimate objectives of defining competencies. Govaerts (2008) proposes that "*competency is the (individual) ability to make deliberate choices from a repertoire of behaviours for handling situations and tasks in specific contexts of professional practice, by using and integrating knowledge, skills, judgment, attitudes and personal values, in accordance with professional role and responsibilities*." The author adds that it should be contingent on task behavior, outcomes and the justification of the choice made, with reflection on the performance given (Govaerts, 2008).

In healthcare, a professional's competence is an evident expectation, but in reality, evidence shows that the level of professional competence is not always what it should be. The competencies expected to ensure skillful performance, in a certain work environment need to be clearly identified in order to ensure a proper assessment of competence. Healthcare professionals, patients, and society systematically redefine the quality of care expected to be delivered and make increased demands on "competencies" (McRobbie et al., 2001; Wass et al., 2001).

There is always some confusion attached to the term "competency" which poses challenges in reaching a consensus and creates the need to clarify what constitutes competence. However, there is no doubt that knowledge, skills, attitudes, and values are intrinsic to competence and competency development. Confusion will remain if there is no agreement on the motives for using the concept, whether it is competency versus a goal, an objective, or even an outcome. It should not be a list containing a summary stating what needs to be learned or checklists. It is important to reach an agreement on what is meant by competence and, more importantly, how it can be measured leading to a better understanding of professional practice (Bruno et al., 2010).

The advancement of medical knowledge in recent years has pushed education toward a competency-based approach, not only in pharmacy but also in medicine education as well. Documents and training modules in medical education frequently refer to concepts of competency (Ward et al., 2001). Competency-based approaches, then, put professional practice at the core of education and competence development programs, preparing students for the profession.

The use of the term "competency-based criteria" emphasizes the importance of competencies and diverts attention away from other critical factors. Criteria processes have drifted toward a primary focus on competencies. Many sophisticated criteria processes now assess only competencies. However, a thorough assessment of performance must at least take account of how well a practitioner completes work-relevant activities. For many organizations, improved selection criteria will be achieved if greater attention is given to using selection exercises and processes that are better matched to the job and by investing more time and effort into the training of assessors. Appropriate selection criteria are crucial for a good competency framework (Whiddett and Hollyforde, 2003).

Despite rapid changes in the work environment and advances in technology, it is possible to define with exact terms professional competence concerning attributes, such as knowledge, skills, and attitudes, which must be acquired. Healthcare providers should be able to adapt to changes by taking on new roles within their field as lifelong learners (FIP, 2014).

What are the Characteristics of Competency?

Confusion will remain if it is not agreed on the motives for using the concept and the number of definitions of competency will continue to grow. It should not be a list containing a summary stating what needs to be learned. It is important to reach an agreement on what it is meant by competence and, more importantly, how can it be measured (Whitcomb, 2002).

A contemporary definition of competence includes knowledge, skills-based and behavioral attributes and professional values. Competency is "a single item of knowledge, skill, behavior, and attitude" and relates to specific capabilities from these domains: competence is the full repertoire of competencies; performance is what the individual does rather than what they can potentially do; and effectiveness is the "bottom line"—the effect of the performance on the recipient (**Table 1**). This definition leads to the concept of behavioral competencies: a typical behavior observed when effective performers apply motives, traits, skills, etc. to a relevant task (Whiddett and Hollyforde, 2003).

Miller's pyramid describes competence as the ability to "do the job" and is a key area to be assessed in clinical practice, although this only applies when it is the combination of task orientated competence and the behaviorally related competencies that are required to deliver quality care (**Fig. 1**).

Competencies are not simply a list of characteristics such as motives, traits, or skills—for example, the ability to clearly communicate or prefer rewards to be based on results. Competencies provide examples of what would be seen when people use these characteristics effectively. Competencies help to assess how people combine and use knowledge, abilities, motives, etc., when tackling job tasks, rather than simply measuring knowledge, abilities, or motives in isolation.

Looking holistically, all the concepts directly contribute toward the development within an individual of effective and sustained performance (Mills et al., 2005; Obiols et al., 2007). Competence per se is about the overarching capacity of a person to perform. Competence can be a complex construct but it should provide a practical and realistic framework for individual practitioner development. There is a growing suggestion that a competency-based approach is sensible and sustainable for pharmaceutical workforce development (FIP, 2016a, 2016b).

It is an attractive concept as it can be measured and evaluated—not always easily—but it can be done. We are more than the sum of our competencies, but being competent is definitely on the route-march toward effective performance (Armitage and Raza, 2008). Simply knowing what should be done in certain circumstances does not translate into greater competence. To be a competent

Table 1 Key differences between competency and competence

	Competency	*Competence*
Focus	The person	The job/role
Outline	Behaviors observed in effective people	Related tasks in the job/roles
Performance indicators	Behavioral statements	Outputs from the job, task, or role

(Modified from Whiddett, S., Hollyforde, S., 2003. A Practical Guide to Competencies—How to Enhance Individual and Organisational Performance, second ed. Chartered Institute of Personnel and Development, New York.)

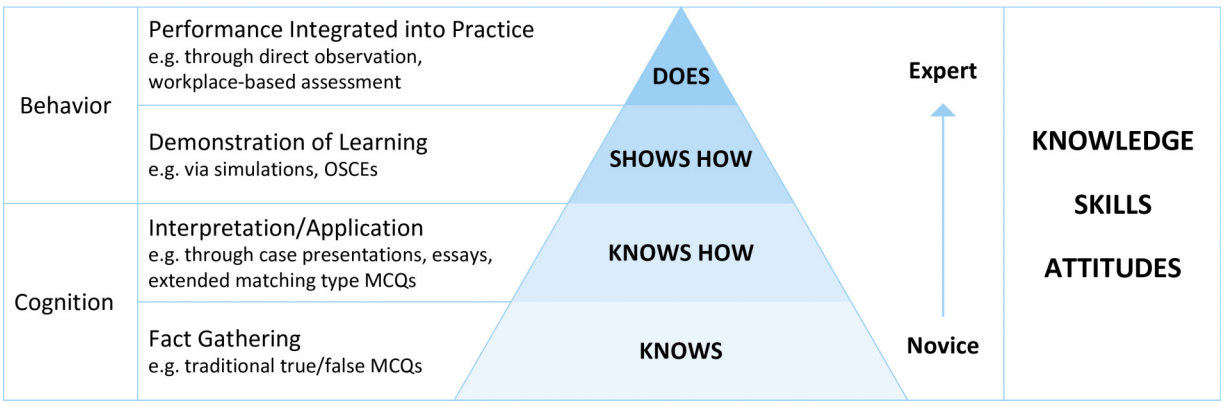

Figure 1 Miller's pyramid for assessing clinical competence. (*Modified from Miller, G.E., 1990. The assessment of clinical skills/competence/performance. J. Acad. Med. 65, 563–567.*)

practitioner, regardless of the profession, experience and reflection on the practice performed is required. The opposite side of competence is ineffectiveness (Bates and Bruno, 2008).

How to Develop Competency Standards or Frameworks?

The purposes of competency frameworks are diverse. Some look for descriptions of a hierarchy based on diverse competency thresholds, whereas others are more determining in nature and aim to promote pharmacists' competencies over time (Bates et al., 2004; Meadows et al., 2004; Mills et al., 2005, 2008; Obiols et al., 2007; Coombes et al., 2010). According to Whiddett and Hollyforde, a competency framework is a collection of competencies fundamental for valuable performance. These types of frameworks are normally used in training and development and as a means by which to measure fitness for purpose. The behavioral indicators are the basis for the framework. The closely related behaviors are organized into competencies and similar competencies are grouped into clusters.

A "competency framework" is the term given to the complete compilation of clusters, competencies (with or without levels), and behavioral indicators. Large, complex, and detailed frameworks are explicit about what is required for all applications and all roles. However, such frameworks run the risk of being impractical because they have to describe behavior in great detail and often cannot cater for minor variations between similar jobs. This detail also means that such frameworks can quickly become out of date (Whiddett and Hollyforde, 2003). Competency frameworks should be designed to help enhance individual performance. They should not compensate for poor practice. The behaviors within a competency framework should be the behaviors necessary for effective performance.

Miller's pyramid of competence is a simple conceptual model, which outlines the goal of valid development of competence by testing what the practitioner actually "does" in the working environment (**Fig. 1**). Traditionally, learning assessments have focused on what a practitioner "knows" or "knows how." However, the real challenge lies in the assessment of performance when completing tasks, i.e., competence in practice and how the practitioner performs in real situations (Miller, 1990).

The current impetus for developing competency frameworks in pharmacy is being driven by the different pharmaceutical sectors, often by using external consultants, and with limited scope for integration. The risk is that competencies that should be regarded as generic attributes may be described differently, leading to confusion and fragmentation. Any failure to ensure the appropriate generalization of competencies across the pharmaceutical advanced areas and sectors also has the potential to limit individual development.

To facilitate the development of the practitioner, workplace-based assessment is of importance, which should be conducted by a mentor or supervisor with appropriate tools. The role of a mentor or supervisor is to support the practitioner's development in the workplace without being connected with the assessment tools or directly managing their performance. The mentor can identify the appropriate level of his mentee regarding the overall performance, provide feedback on how development is progressing and also be a role model. There should be a mentoring program for the mentor or supervisor providing the mentorship, in order to become fully effective developmental organizational structure (Coombes et al., 2010).

Competency frameworks can be used to support a range of different professional activities. Normally, they are used to assist with training and development, by helping individuals and managers define gaps in skills and knowledge against accepted standards of practice, and to help identify specific training and development needs (RPS, 2013, 2014; PSA, 2016).

How to Operationalize it?

To be able to operationalize any competency framework in practice, a set of tools has to be developed in concurrence with the framework itself. These tools provide formative assessments, which inform educational planning, identify areas for development, and monitor performance. The developed framework needs to have an assessment grid, in which the practitioner and the observational practitioner can match the criteria against the practice. As mentioned before, other tools can be used to support the overall evaluation, such as mini-peer assessment tools (mini-PAT), a mini-clinical evaluation exercises (mini-CEX), multiple choice questions (MCQs), objective structured clinical examinations (OSCEs), and case based discussions (CbD) (CoDEG, 2007; QH, 2009). A portfolio based on a competency framework and associated assessment tools can be used to demonstrate a practitioner's capability at work, providing a platform for further development (RPS, 2014; PSA, 2016).

For a competency framework to be effective it must be usable and fit for its intended purpose. It should be clear and easy to understand, be relevant, take into account expected future changes, contain behavioral indicators that do not overlap, contain behaviors that are necessary and appropriate, and be fair.

Items for an effective competency framework

For a competency framework to be effective it must be usable and fit for its intended purpose. To be fit it should at least conform to certain quality standards, such as:

Clear and easy to understand;

Relevant to all people who will be affected by the framework;

Takes account of expected changes (versatility);
Has discrete elements (e.g., behavioral indicators do not overlap);
Elements should be of the same type;
Behaviors should be necessary and appropriate;
Fair to all affected by its use.

These standards provide a good base for evaluating and testing a framework, during and after it is finished. The language used in the framework has to be relevant to all of those who will be using it, whether the framework is generic or specific. The basic building-blocks of competencies are behaviors; all aspects therefore should be behavior-based (Whiddett and Hollyforde, 2003).

(*Modified from Whiddett, S., Hollyforde, S., 2003. A Practical Guide to Competencies—How to Enhance Individual and Organisational Performance, second ed. Chartered Institute of Personnel and Development, New York.*)

Therefore, a global competency framework has an important role in the international setting. Aiding in the creation of practitioner developmental frameworks and associated evaluation tools, should be able to meet the needs of any country. It supports pharmacist development and leads to better overall workforce performance, and thus better patient care outcomes.

Is There One That Can Be Used as a Guide?

The FIP Global Competency Framework (GbCF) for services provided by pharmacy workforce was developed based on documents that were closely related to education development frameworks for pharmacists. The GbCF regards the foundation of initial education and training and its intention is to act as a mapping tool or guidance. In the document, competencies are described using behavioral terminology, and should not be viewed as a functional "task list." The competencies that are based on behaviors are useful for developmental purposes, which are the primary intention of the GbCF. Due to the nature of the ever-evolving healthcare, it will continue to be developed as the profession changes (FIP, 2012a).

The GbCF v1 was developed through a robust research process with a literature search, content analysis consensus groups and global surveys (Bruno, 2011). Documents focused on educational development frameworks for pharmacists were used, originated from Australia, Canada, New Zealand, Thailand, United Kingdom, United States, and Zambia. Common behaviors within the different frameworks were identified, resulting in a comprehensive table of competencies categorized into four domains: Pharmaceutical Public Health, Pharmaceutical Care, Organization and Management, and Professional/Personal (**Fig. 2**). Clinical competencies can be found in two of the framework domains, in the Pharmaceutical Public Health Competencies domain (includes behaviors such as, "*advise on health promotion and disease prevention and control, and healthy lifestyle*", and all the behaviors included in the medicines information competency) and in the Pharmaceutical Care Competencies domain (includes behaviors such as, "*ensure appropriate medicines, route, time, dose, documentation, action, form and response for individual patients*" among several others).

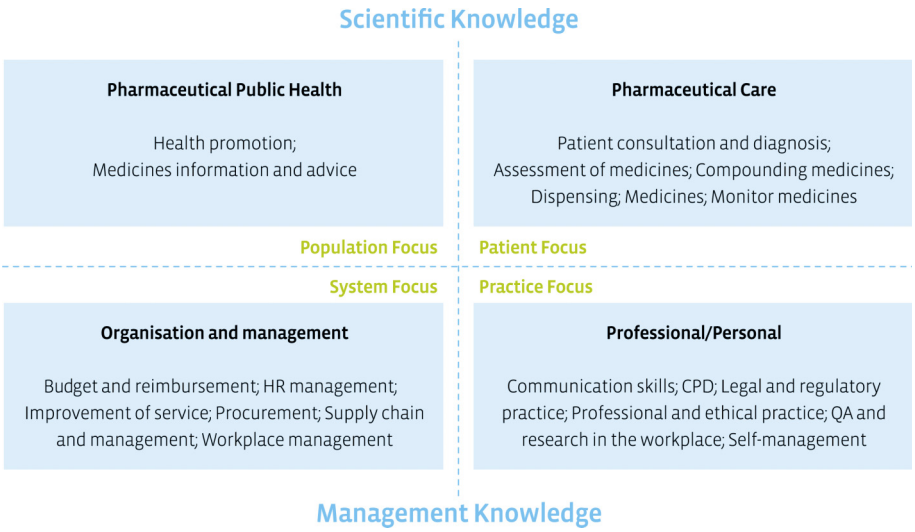

Figure 2 Domains and illustrative competencies from the GbCF v1 for pharmaceutical services. (*Reproduced with permission from International Pharmaceutical Federation (FIP) Education Initiatives (FIPEd), 2012b. A Global Competency Framework for Services Provided by Pharmacy Workforce. FIP, The Hague, Netherlands. Available from: http://www.fip.org/files/fip/PharmacyEducation/GbCF/GbCF_v1_online_A4.pdf (Accessed 31 March 2018).*)

Fig. 2 illustrates—as a visual concept—the GbCF division into clusters and competencies, allowing the reader to comprehend the focus of each cluster as well as what type of knowledge is needed to achieve the competencies included in the clusters or domains (FIP, 2012a). The intention behind is to facilitate adaption into the needs of the countries or local settings that use the framework as a starting point. The European Association of Hospital Pharmacists has used the concept to provide an overview of the Common Training Framework (EAHP, 2017).

The framework was specifically designed to provide global guidance on the practice-based expectations of foundational pharmacy practice. Evidence suggests that even though some country-specific variations occur in pharmacy practice, there exists a set of practice-related competencies that are globally applicable for foundation practice development (PSI, 2013; FIP, 2016a). Published evidence from the field of medicine also has shown transnational applicability of the Canadian CanMEDS Physician Competency Framework to medical practice in Netherlands, Denmark, and Australia (Ringsted et al., 2006; Scheele et al., 2008; DHMA, 2014; RANZCP, 2012).

Since the GbCF development, it has been successfully used to design pre-service education and training curriculum in a number of countries (FIP, 2013; Udoh et al., 2018). It has also been used to develop country-specific foundational pharmacy frameworks in Ireland, the Pacific Island Countries, Croatia, Singapore, and Serbia (PSI, 2013; Mucalo et al., 2016; Brown et al., 2012; Stojkov et al., 2016; FIP, 2016a). There are recent developments in several other countries, but not yet published—Kuwait, Montenegro, Oman, Jordan, Turkey, Indonesia, Philippines, and Vietnam (to name a few). In the United States, there exists the 2013 Center for the Advancement of Pharmacy Education (CAPE) Education Outcomes that exist to assist faculty in guiding curricular development and the follow-up assessment of these outcomes (Medina et al., 2013). For Europe, there exists the European Pharmacy Competences Framework (EPCF). This provides competency profiles for community, hospital, and industrial pharmacists (Atkinson et al., 2016).

What is the Need for Competency Standards in Clinical Pharmacy Practice?

Clinical pharmacy has been defined by the American College of Clinical Pharmacy as the "discipline in which pharmacists provide patient care that optimizes medication therapy and promotes health, and disease prevention" (ACCP, 2018). While there are no universal specific activities that clinical pharmacists undertake on a routine basis, there are general functions that are incorporated into their daily functions based upon work area. In the inpatient (acute care) setting, pharmacists are responsible for ensuring an accurate medication list at intake, and that the patient is taking optimal medications throughout their admission. These recommended therapies which the patient is receiving needs to be based upon clinical evidence, cost-effectiveness, and appropriateness for their disease state and laboratory parameters (i.e., renal function).

Upon discharge, the clinical pharmacists ensure that their prescriptions are appropriate when they transition to the next level of service without issues. On the outpatient (ambulatory care) side, pharmacists are playing increasing roles in the management of patients. While the historical role has been medication dispensing, it is much more than that now. These services extend from counseling patients on their medications, administering immunizations, conducting baseline physical assessment skills, undertaking medication therapy management, and initiating, modifying, and discontinuing medications on a patient (i.e., prescribing).

Due to the need of the patient and the positive impact of these services, clinical pharmacy is becoming an essential service. The result of this is that there is a need to have training and education in all schools of pharmacy as well as practitioners providing these services in all healthcare settings. Even if schools of pharmacy trained students appropriately in this discipline, there is still a need for practicing pharmacists to continually update their skills because new medications are introduced regularly and research is being conducted and published frequently, which can alter treatment goals and recommendations. The methods vary that individuals utilize to stay current.

Some countries do not have a requirement for ongoing education that is tied to re-licensure. Other countries require a minimum number of educational hours to be documented, whereas some require the upkeep of a learning portfolio that documents all activities undertaken throughout the year. While it is ideal that a practicing pharmacist takes it upon themselves to be a lifelong learner outside of the requirement of the regulatory authority, this does not happen for all. There is also the responsibility of the employer to have assurances that their pharmacists are competent.

How Have Other Countries Approached it?

Australia

In 2016, Australia developed a national competency standards framework for pharmacists in Australia. These describe the skills, attitudes, and other attributes to practice as a pharmacist. This has five domains listed: 1. Professionalism and ethics; 2. Communication and collaboration; 3. Medicines management and patient care; 4. Leadership and management; and 5. Education and research. Domains 1, 2, and some standards from domain 4 are universally applicable to all pharmacists. While many of these directly relate to clinical pharmacy practice, deliver primary and preventative healthcare and promote and contribute to optimal use of medicines are the most directly connected (PSA, 2016).

Canada

Canada published in 2014 the professional competencies to enter practice. There are nine that have been identified. These include ethical, legal, and professional responsibilities; patient care; product distribution; practice setting; health promotion; knowledge and research application; communication and education; intra- and inter-professional collaboration; and quality and safety. While all of these could be linked to clinical pharmacy, the patient care domain is most closely identified based upon daily responsibilities. This is described as "pharmacists, in partnership with the patient and in collaboration with other health professionals, meet the patient's health and drug-related needs to achieve patient's health goals" (NAPRA, 2014).

Ireland

The competency framework developed the Pharmaceutical Society of Ireland, aims to inform the educational standards, curriculum development, and learning outcomes for undergraduate students. It will also support the implementation of CPD that will aid pharmacists to enhance their practice. The framework was based on the FIP GbCF, one of the first countries to use it as a mapping tool through a number of sequential steps, to tailor to the Irish pharmacy setting. The core competency framework contains the following domains: professional practice, personal skills, supply of medicines, safe and rational use of medicines, public health, and organization and management skills. For Ireland, the framework will provide a useful benchmark for patients, other healthcare professionals, policy-makers and others of the key skills, knowledge, attitudes, and behaviors associated with and expected of pharmacists (PSI, 2013).

New Zealand

In the case of New Zealand, the Pharmaceutical Council of New Zealand, published the 2015 version of the standards that builds on past efforts, with several competencies re-grouped into domains of responsibility as well as new competencies have been added to ensure that standards remain relevant and applicable to evolving roles. It is important to revisit the competency standards and frameworks to make sure they are still relevant and valid for their purpose. Competence standards can also demonstrate to the public and other healthcare professionals the medication expertise that pharmacists bring to patient care, and the role they play in ensuring the safe and responsible use of medicines. The domains in the standards are divided into mandatory and optional. In the mandatory domains, it includes professionalism in pharmacy and communication and collaboration; as optional domains, there are health and medicines management, public healthcare, supply and administration of medicines, and leadership and organizational management (PCNZ, 2015).

United Kingdom

In the United Kingdom, through the Royal Pharmaceutical Society, has a series of competency frameworks. One that is used for the start of practice is called the Foundation Pharmacy Framework, as it focuses on the building blocks needed to start developing competencies (RPS, 2014). The next one in the series is for advanced pharmacy (RPS, 2013). This is to represent all sectors of practice and can form the basis of the professional portfolio. Six key areas have been identified to evaluate advanced stages of practice: expert professional practice; collaborative working relationships; leadership; management; education, training, and development; and research and evaluation (RPS, 2013). The Royal Pharmaceutical Society has also developed a competency framework for prescribers (RPS, 2016). This organizes the framework into two sections: the consultation and prescribing governance. The consultation, having six competencies, is focused on assessing the patient, consider the options, reach a shared decision, prescribe, provide information, and monitor and review, while the prescribing governance, having four competencies, is divided into prescribe safely, prescribe professionally, improve prescribing practice, prescribe as part of a team (RPS, 2016). While this area is not usually identified as a need for pharmacists since so few practices in this setting, pharmacists in the United Kingdom have been granted authority to do so. However, this framework is broader than just pharmacists as it is to be used for all prescribers.

United States

The Joint Commission, a healthcare accrediting body in the United States, requires an institution to ensure that the employee is competent to undertake the function in which they are employed. They specifically state that documentation should exist "in the personnel file that the employee's clinical knowledge, experience, and capabilities are appropriate for assigned duties per the requirements of the minimum data set for competency" (JC, 2017). To complete this function fully, one must determine what the needed competencies a clinical pharmacist should have for their job responsibility, a plan in place to accomplish them, and a method for documenting achievement. For example, some of the routine activities of the clinical pharmacist are anticoagulation management, antimicrobial stewardship, pharmacokinetic dosing, cardiopulmonary resuscitation, and medication counseling. Mastery of these functions and ongoing education to ensure this skill needs to be included in the personnel file for each employee that is engaged.

Recently, the American College of Clinical Pharmacy updated its competencies of a clinical pharmacist. These are provided to ensure that "clinical pharmacists possess the knowledge, skills, attitudes, and behaviors" in order to provide clinical pharmacy in the

patient care setting. They provided six different competency domains in which one should document their expertise: direct patient care, pharmacotherapy knowledge, systems-based care and population health, communication, professionalism, and CPD. These competency domains are consistent with those expected by physicians within the United States, as recommended by the Accreditation Council for Graduate Medical Education (Saseen et al., 2017).

Implement overview—US case studies

While it is important to discuss and describe which competencies are necessary as a clinical pharmacist, it is critical to implement a process to accomplish it within an organization. The following are highlights of three case studies that have implemented different programs for competency achievement and documentation within their institution. These are three case studies, all within hospitals in the United States, to demonstrate different methods to achieve it.

- *Ohio State University Wexner Medical Center:* All pharmacists that are involved in direct patient care, both in the acute and ambulatory care setting, are required to be credentialed and privileged for those roles. This process is managed by a pharmacy leader, but the rules governing the medical staff are followed and it is overseen by the hospital's credentialing department. They developed core privileges that would cover all clinical pharmacist activities, no matter the location. Peer review occurs to ensure that the pharmacist functions appropriately and maintains required competencies (Jordan et al., 2016).
- *Johns Hopkins Hospital:* They desired to enter into collaborative practice agreements (drug therapy management agreements) with their clinical pharmacists and their respective physician groups. These clinical pharmacists that desire this privilege must obtain them through the respective medical department in which they function. The protocols, which guide these activities and are subsequently reviewed by the Pharmacy and Therapeutics Committee, and their competencies are documented and evaluated by the medical departments (Jordan et al., 2016).
- *University of Wisconsin Health:* This organization undertook a departmental approach to require certification for all pharmacists in direct patient care roles. The certification required, for most individuals, were those awarded by the Board of Pharmacy Specialties. The department, because of this requirement, will pay for the expense for the individual to take the exam. The expectation is to be completed by 2018 for all pharmacists in direct patient care to obtain this credential to demonstrate their competency to provide this role (Hager et al., 2017).

Conclusion

Since pharmacy is a clinical profession, it needs to demonstrate to both society and other healthcare providers that it is competent to manage a patient's medication therapies. This begins with identifying what competencies one wants to require of a clinical pharmacist, and then develop a process to document and maintain competency.

To achieve a high-quality infrastructure for pharmacy, the educational system should be mapped to the required competencies of pharmacists to provide the relevant pharmaceutical services for meeting the health needs in any given country context. While no one national model may be appropriate for all systems, there are significant global health drivers that suggest that a competency-based approach is sensible and sustainable for the pharmaceutical workforce development.

To conclude, the global changing healthcare milieus with ageing populations have resulted in increased prevalence of chronic diseases and associated comorbidities. This mandates complex care services. The availability of a competent pharmaceutical workforce, capable of providing complex evidence-based medicines expertise and pharmaceutical care services is fundamental.

Glossary

Clinical pharmacy: Discipline in which pharmacists provide patient care that optimizes medication therapy and promotes health, and disease prevention.

Source: American College of Clinical Pharmacy (ACCP), 2018. Definition of Clinical Pharmacy. Available from: https://www.accp.com/stunet/compass/definition.aspx.

Competency: A single item of knowledge, skill, behavior, and attitude.

Source: Bruno, A., 2011. The Feasibility, Development and Validation of a Global Competency Framework for Pharmacy Education (Thesis for Doctor of Philosophy). University College London (UCL), School of Pharmacy, London.

Competency framework: A complete collection of competencies that are thought to be essential to performance.

Continuing Professional Development for Clinical Pharmacists

Dawn G. Zarembski, Michael J. Rouse, Accreditation Council for Pharmacy Education, Chicago, IL, United States

Introduction

As defined by the International Pharmacy Federation and the World Health Organization, Good Pharmacy Practice is "the practice of pharmacy that responds to the needs of the people who use the pharmacists' services to provide optimal, evidence-based care" (International Pharmaceutical Federation, 2018). Essential to the provision of Good Pharmacy Practice is the ability of the pharmacist to optimally provide evidence-based care to his or her patients (Davidoff et al., 1995). Professional degree programs, including pre-service educational and training programs, prepare students to enter professional practice but are not sufficient for equipping pharmacists for a lifetime of practice given the rapidly changing nature of healthcare (Institute of Medicine, 2010a). The constant evolution of science, technology, and medicine requires that pharmacists continue to not only maintain the knowledge and skills learned during pre-service education and training but also build upon this foundation through the acquisition of new knowledge, skills, attitudes, and values following entry into practice. For example, knowledge pertaining to newly released medications and updated disease-state management guidelines must be learned as healthcare continues to evolve. Similarly, new skills needed to optimize care must be learned and mastered. Attitudes and values, including a commitment to change, that are appropriate to evolving roles and responsibilities of pharmacists must be demonstrated (Pereles et al., 1997; Mazmanian et al., 1997; Mazmanian and Mazmanian, 1999; Wakefield et al., 2003; Wakefield, 2004). Education must be lifelong as continued learning is essential for individual pharmacists to maintain the competence for practice in a rapidly changing and advancing healthcare environment (Institute of Medicine, 2010a).

Options for ensuring that practitioners maintain competence can include a wide variety of methods ranging from periodic re-examination of practicing pharmacists to mandatory completion of continuing education (CE) activities. To circumvent the need for pharmacists to partake in periodic re-examinations or other forms of direct assessment of competence or performance, many countries instead require pharmacists to engage in lifelong learning through participation in a minimum number of hours of CE activities in the hopes of ensuring competence for practice is maintained (Tran et al., 2014). An expanded and more holistic approach to lifelong learning has, however, now been adopted by some countries such as Canada, the United Kingdom, Australia, and New Zealand (Pharmacy Board of Australia, 2015; Pharmacy Council of New Zealand, 2010; Canadian Pharmacists Association, 2018; General Pharmaceutical Council, 2017). The Continuing Professional Development (CPD) model aims to ensure that participation in CE activities and other forms of structured or unstructured learning is ultimately translated into enhanced competence and application of the learning in practice. CPD has been defined as "a self-directed, ongoing, systematic and outcomes-focused approach to lifelong learning that is applied into practice" (Accreditation Council for Pharmacy Education, 2015). CPD provides a framework or model through which pharmacists can approach their lifelong learning. The CPD process is intended to ensure that pharmacists maintain competency to practice and that learning is based on actual needs or professional development goals (Rouse, 2004a).

Important aspects of the CPD model include:

The process is **self-directed** in that it is driven by the individual pharmacist;
The process is an ongoing **cycle** proceeding through stages of self-reflection, planning, learning, evaluation, and application;
The learning is **outcomes-focused** addressing the needs and goals of the individual pharmacist;

The learning outcomes are **applied** to the individual pharmacist's practice to achieve performance and practice improvements; and

All elements of the CPD process are **documented** to provide a written record of the pharmacist's professional development and support future learning (Accreditation Council for Pharmacy Education, 2015).

With CPD, the pharmacist is responsible for identifying and addressing their own professional development needs and goals through a self-assessment process. The CPD process is centered firmly on the needs of the individual practitioner and encourages a systematic and intentional approach for maintaining competence (Rouse, 2004a). The educational needs of each pharmacist will be unique depending on his or her current knowledge, skills, and abilities in relationship to the individual's practice environment, roles, and responsibilities. Self-reflection forms the foundation and starting point from which the CPD process is built, as development of personalized learning goals stems from the identification of the specific learning needs of the pharmacist. In this regard, the CPD process assists the pharmacist in ensuring he or she maintains the necessary knowledge, skills, attitudes, and values to competently practice pharmacy within the individual's specific practice setting throughout his or her career. Self-assessment should identify both strengths and limitations in addressing the needs of the healthcare system in which they practice.

Findings from the self-assessment process referred to above are used to identify competency gaps that are the basis of the pharmacist's learning needs or goals (hereinafter, just referred to as needs). Once learning needs have been identified, the next step is for the pharmacist to create and implement a personalized learning plan. To close the "learning loop," the pharmacist should evaluate whether the educational plan sufficiently addressed his or her learning needs. The learner must identify any barriers or challenges and evaluate the reasons for any shortfalls in achieving objectives, as this should serve to inform future learning plans and strategies. Documentation is an essential component of the CPD process. A portfolio system (either written or electronic) is often used to document the pharmacist's progress through different stages of the CPD cycle, including the application and impact of learning. Once the CPD cycle has been fully implemented and routinely practiced by the pharmacist, ideally he or she will progress through the CPD cycle seamlessly.

The CPD Cycle

Fig. 1 graphically depicts the stages of the CPD cycle (Accreditation Council for Pharmacy Education, 2014a). The different stages of the cycle are described in detail in the following sections. The "infinity" CPD cycle depicted in Fig. 1 with five sequential stages and "Record & Review" integral to all stages of learning was offered by the Accreditation Council for Pharmacy Education (ACPE) in the USA. It has been adopted in several countries but it differs from earlier depictions of the cycle, which typically only include the four sequential stages of the learning cycle, along with recording (the portfolio). The "infinity" cycle was designed to stress the importance of application of learning in the CPD model.

Reflect

Reflection is the starting point for self-directed learning and the CPD process (Accreditation Council for Pharmacy Education, 2014b). Reflection is the process of identifying the pharmacist's individualized learning needs and areas for improvement (Walsh, 2006). Consideration should be given to the pharmacist's current practice setting as he or she reflects on his or her current competence in the context of the typical healthcare needs of the patient population under his or her care, the goals of the healthcare organization, and his or her roles and responsibilities in the organization. Educational needs, including the need for either additional knowledge or new skills, required to enhance patient care, implement a new service, and expand the pharmacist's role as a member of the healthcare team should be identified. It is essential for pharmacists to be as specific as possible when identifying areas for improvement. Efforts to identify educational needs should involve a comprehensive analysis of the pharmacist's workplace environment. In this regard, input from peers and supervisors can prove valuable to the reflection process.

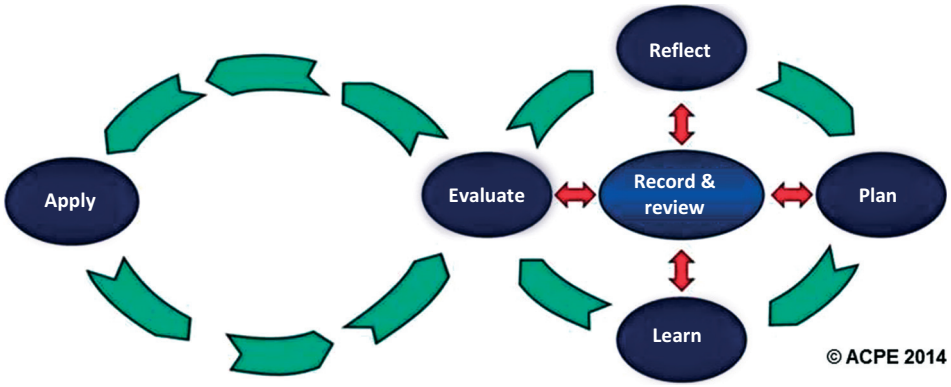

Figure 1 A CPD cycle (from ACPE).

The pharmacist should reflect on his or herself, his or her work, the workplace, and the patient population for which they provide care. Questions to consider during reflection can include:

- What are the needs of the patient population that I serve? With what disease states or medical conditions do patients commonly present in my practice?
- What do I currently know and am able to do that helps me address these needs/conditions?
- What additionally do I need to know or be able to do to address these needs/conditions?
- What are the current responsibilities of my job?
- What competencies do I need to have to be able to fulfill these responsibilities?
- Are there any areas in which I am not fully competent to fulfill my job responsibilities?
- What types of questions do I commonly receive from patients or other healthcare workers?
- What are the needs/goals of the healthcare organization in which I work?
- What are my current strengths for addressing these needs/goals?
- What are areas/opportunities for improvement or introduction of new services that would assist in addressing these needs/goals?
- Are there any areas in which patient care (access, quality, satisfaction, etc.) can be improved?
- What barriers (e.g., technical, logistical, organizational) currently impede my ability to effectively address my job responsibilities? What can I do to overcome these barriers?
- What are my personal career goals?
- What is my natural learning style? What learning methods work best for me? Are there learning methods that I must use to develop needed competencies, but which do not come naturally to me?

Several professional organizations have compiled lists of competencies that may be useful for pharmacists who are engaging in the reflection process. For example, **Table 1** describes pharmacist roles and responsibilities as outlined in the Joint FIP/WHO Guidelines on Good Pharmacy Practice (International Pharmaceutical Federation, 2011).

Alternatively, **Table 2** provides another option for self-assessment as it outlines the entrustable professional activities drafted by the American Association of Colleges of Pharmacy (American Association of Colleges of Pharmacy, 2017). EPAs outline tasks that pharmacists should be able to perform independently after graduation from a pharmacy degree program. A practicing pharmacist can periodically conduct a self-assessment of his or her ongoing ability to complete the activity described for those competencies relevant to his or her roles and responsibilities within the healthcare system.

Pharmacists providing high-level patient care services may find **Table 3** useful. **Table 3** provides the Core Clinical Competencies identified by the American College of Clinical Pharmacy for pharmacists providing comprehensive medical management services as a member of a healthcare team (Saseen et al., 2017).

Ideally, each pharmacist should be able to identify and list three to five learning needs and opportunities that he or she will work to address over both the short (e.g., within one year) and long-term (e.g., three to five years).

Reflection exercises can occur in both scheduled and unscheduled settings and timeframes (**Box 1**). An example of a scheduled reflection "*on practice*" would include an annual performance evaluation during which the individual reflects on his or her practice and job responsibilities and performance in the context of the needs of the organization. In such situations the competencies described above may prove useful to the pharmacist's self-assessment process. Inclusion of reflection exercises in the annual review and goal-setting process is one mechanism through which employers can support the CPD process and address needs and goals of individual employees as well as the larger organization.

Table 1 Pharmacists roles

Role	*Competency*
Prepare, obtain, store, secure, distribute, administer, dispense, and dispose of medical products	I can prepare extemporaneous medicine preparations and medical products
	I can obtain, store, and secure medicine preparations and medical products
	I can distribute medicine preparations and medical products
	I can administer medicines, vaccines, and other injectable medications
	I can dispense medical products
	I can dispose of medicine preparations and medical products
Provide effective medication therapy management	I can assess a patient's health status and needs
	I can manage a patient's medication therapy
	I can monitor a patient's progress and outcomes
	I can provide information about medicines and health-related issues
Maintain and improve professional performance	I plan and implement continuing professional development strategies to improve current and future performance
Contribute to improve effectiveness of the healthcare system and public health	I disseminate evaluated information about medicines and various aspects of self-care
	I engage in preventive care activities and services
	I comply with national professional obligations, guidelines, and legislations
	I advocate and support national policies that promote improved health outcomes

Table 2 Entrustable professional activities

Domain	*Assessment*
Patient Care Provider	I can collect information to identify a patient's medication-related problems and health-related needs (e.g., I can obtain a medication history from a patient).
	I can analyze information to determine the effects of medication therapy, identify medication-related problems, and prioritize health-related needs.
	I can establish patient-centered goals and create a care plan for a patient, caregiver(s), and other health professionals that is evidence-based and cost-effective.
	I can implement a care plan in collaboration with the patient, caregivers, and other health professionals.
	I can follow-up and monitor a care plan.
Interprofessional Team Member	I can collaborate as a member of an interprofessional team.
Population Health Promoter	I can identify patients at risk for prevalent diseases in a population.
	I can minimize adverse drug events and medication errors.
	I can maximize the appropriate use of medications in a population.
	I can ensure that patients have been immunized against vaccine-preventable diseases.
Information Master	I can educate patients and healthcare professionals regarding the appropriate use of medications.
	I can use evidence-based information to advance patient care.
Practice Manager	I can oversee the pharmacy operations for an assigned work shift.
	I can fulfill a medication order.
Self-Developer	I can create a written plan for continuous professional development

Table 3 Core clinical competencies

Competency domain	*Elements of competency*
Direct Patient Care	I can assess patients, including identifying and prioritizing patient problems and medication-related needs.
	I can evaluate drug therapy for appropriateness, effectiveness, safety, adherence, and affordability.
	I can develop/initiate therapeutic plans and address medication-related problems.
	I can follow up on and monitor the outcomes of therapeutic plans.
	I can collaborate with other members of the healthcare team to achieve optimal patient outcomes across the continuum of care.
	I can apply knowledge of the roles and responsibilities of other healthcare team members to patient care.
Pharmacotherapy Knowledge	I can demonstrate and apply in-depth knowledge of pharmacology, pharmacotherapy, pathophysiology, and the clinical signs, symptoms, and natural history of diseases and/or disorders.
	I can locate, evaluate, interpret, and assimilate scientific/clinical evidence and other relevant information from the biomedical, clinical, epidemiological, and social-behavioral literature.
	I can use scientific/clinical evidence as the basis for therapeutic decision-making.
	I possess the knowledge and experience commensurate with certification in one or more Board of Pharmacy Specialties.
	I maintain and enhance pharmacotherapy knowledge, including recertification or other appropriate methods of self-assessment learning.
Systems-based care and population health	I can use healthcare delivery systems and health informatics to optimize the care of individual patients and patient populations.
	I can participate in identifying systems-based errors and implementing solutions.
	I can resolve medication-related problems to improve patient/population health and quality metrics.
	I can apply knowledge of pharmacoeconomics and risk-benefit analysis to patient-specific and/or population-based care.
	I can participate in developing processes to improve transitions of care.
	I can design quality improvement processes to improve medication use.
Communication	I can communicate effectively with: (1) patients, caregivers, families, and laypersons of diverse backgrounds; and (2) other health professionals and stakeholders.
	I can provide clear and concise consultations to other health professionals.
	I can develop professional written communications that are appropriate to the audience.
	I can use verbal communications tailored to varied clinical and patient-specific environments.
	I can communicate with appropriate levels of assertiveness, confidence, empathy, and respect.
Professionalism	I uphold the highest standards of integrity and honesty.
	I commit to a fiducial relationship with patients, always working in their best interests.
	I serve as a credible role model/leader for students, trainees, and colleagues by exhibiting the values and behaviors of a professional.
	I advance clinical pharmacy through professional stewardship, training of future clinical pharmacists, and active engagement in professional societies.
Continuing professional development	I commit to excellence and lifelong learning.
	I demonstrate skills of self-awareness, self-assessment, and self-development.
	I identify and implement strategies for personal improvement through continuing professional development.
	I provide professional education to students, trainees, or other health professionals.
	I maintain Board of Pharmacy Specialties certification to ensure that therapeutic knowledge is up-to-date.

Box 1 Examples of Reflection

Reflection on Practice

During an annual review, a pharmacist and his supervisor discuss the organization's goals. The pharmacist notes areas of practice which may assist in achieving the organization's goals. The pharmacist and supervisor identify an individual practice-based goal for the pharmacist which is in line with the organization's goals.

Reflection in Practice

A pharmacist receives a prescription for a medication that he or she is unfamiliar with. On reflection, the pharmacist realizes the need to improve his or her knowledge regarding the new medication.

Unscheduled reflections occur "*in practice*" during daily work experiences when the pharmacist may encounter learning needs and opportunities that currently limit the pharmacist's ability to fully address his or her job responsibilities. Such reflection exercises may not be habitual at first, but with repeated practice, the incorporation of unscheduled reflection exercises can become part of the pharmacist's unconscious daily routine. Support mechanisms, such as a daily email triggers, can help facilitate such in-practice reflection exercises.

Documentation of the CPD cycle begins with findings from the reflection process. Fig. 2 provides one example of a form that may be used to capture findings from a more formalized, scheduled reflection process. Ideally, the form employed would be easy to use and capture sufficient documentation to fully facilitate the CPD process (Accreditation Council for Pharmacy Education, 2014c).

In summary, three simple overarching questions are needed for reflection:

- What? Reflection questions should be asked and answered that describe the pharmacist's situation and environment factually and objectively.
- So What? Reflection questions should be asked and answered that describe the situation subjectively; i.e., what does it mean for the pharmacist and others with whom he or she interacts?
- What Next? Reflection questions should be asked and answered to determine what the pharmacist will do in the future to address the "What" and "So What."

The "Reflect" stage serves to identify broad learning needs and professional development goals that are refined during the "Plan" stage of the cycle. Reflection is not used to determine the pharmacist's level of competence per se, although self-assessment of competence against a validated competency framework can be useful to assist with setting learning and professional development goals.

Reflect: What do you need to learn? What are your professional strengths and opportunities for development?
List work-related situations from the past learning month/year in which you felt confident or competent:
What knowledge, skills, attitudes, and values contributed to the successes above?
List work-related situations from the past learning month/year with which you need to feel more comfortable or satisfied:
What knowledge, skills, attitudes, or values would you want to develop or improve to better manage similar situations in the future?
What areas of improvement does your supervisor recommend from your performance evaluation?
What knowledge, skills, attitudes, or values do you need to work on or acquire for the coming year?

Figure 2 Sample reflection documentation form.

Plan

During the "Plan" stage, pharmacists formulate a personal learning plan to achieve the goals identified through reflection. Learning goals are summarized as objectives or statements of what the pharmacist intends to accomplish with regard to the learning need. These objectives may be centered on implementing new services, achieving identified organizational patient care benchmarks, expanding the pharmacist's role or responsibilities, improving patient care, etc. (Rouse, 2004b). Care should be taken to ensure the learning goals are written as SMART objectives. In this regard the objectives should be:

Specific—Objectives should describe the pharmacist's intended results in a clear, detailed statement. The objective should specifically describe the intended outcome. Pharmacists should capture specifically what they are trying to achieve. The objective should be sufficiently detailed to describe the intended outcomes and what the pharmacist intends to achieve. Lack of specificity makes it difficult to monitor progress with learning and evaluate achievement of the objective either by the learner or others, such as a supervisor.

Measurable—Objectives should be written in a manner that permits the pharmacist and others to determine whether the intended outcome has been achieved. When writing objectives, pharmacists are encouraged to consider how they will know that the learning need has been met. Considerations should be given toward indicators that can be used to track progress toward achievement of the objective.

Achievable—Pharmacists should be careful not to develop objectives that are over-ambitious and unachievable. The scope of learning and the timeframe must be realistic and appropriate given the learner's other responsibilities and commitments. While pharmacists are encouraged to develop objectives that may be a "stretch" to achieve with sufficient effort and adequate time, the objective should be achievable. Unrealistic objectives set up a pharmacist for failure and may decrease the pharmacist's motivation for addressing the current and future learning needs.

Relevant—The objective should be aligned with the pharmacist's roles and responsibilities as well as the learning needs identified during reflection. Opportunities should exist to quickly apply the learning in practice to ensure that the learning is sustained and reinforced.

Timed—A realistic deadline should be established by which time the objective should be achieved, taking into consideration the scope of the learning, availability of learning resources, other commitments and responsibilities, etc.

Table 4 Categories and examples of CPD activities (Accreditation Council for Pharmacy Education, 2015)

Category	*Examples*
Continuing Education	Formalized CE activities
Academic/Professional Study	Participation in conferences, workshops, and retreats
	Undertaking academic coursework or postgraduate education
	Completion of a certification course (e.g., advanced cardiac life support)
	Completion of an independent study (e.g., directed study with defined objectives, outcomes, assessment)
	Reading and reflecting on healthcare articles and literature
	Leading or participating in journal clubs
Scholarly Activities	Conducting research in one's professional field
	Preparing or writing grant proposals
	Presenting and/or publishing scholarly works
	Serving as a content reviewer for publications, dissertations, or other scholarly works
	Test-item writing (e.g., high stakes examinations, peer-reviewed self-assessment activities, or researching, drafting, and defending questions)
Teaching and Precepting	Developing, presenting, and/or authoring educational content (e.g., academic course, seminar/webinar, publication)
	Teaching and precepting students, residents, or other healthcare professionals
	Peer coaching or mentoring programs (e.g., mentor or mentee)
Workplace Activities	Engaging in point-of-care learning, i.e., self-directed learning on topics relevant to clinical practice
	In-service training
	Job shadowing (e.g., observing an experienced professional for a defined period of time with assessment of impact on one's professional role)
	Preparing for or participating in external review, accreditation, or certification process
	Implementing performance improvement projects (e.g., current practice assessment, implement PI changes, evaluate impact/change)
	Consultation with peers and healthcare experts to address a practice problem or learning need or goal
	Serving on committees (e.g., self-study, institutional review boards, pharmacy and therapeutics, medication safety, medication therapy management)
Professional/Community Service	Serving on a committee, workgroup, or holding office in a professional association
	Training for or involvement in advocacy
	Volunteer experiences or special interest groups, e.g., emergency preparedness
	Developing inter-professional and/or outreach initiatives for health professionals and students

Box 2 Planning Examples

Immediate

Following identification of the need to be better informed regarding a recently released medication, the pharmacist searched available information sources to research the mechanism of action, pharmacokinetics, adverse effects, and uses of the new medication.

Long term

A pharmacist wishes to establish a pharmacist operated clinic to enhance patient adherence and improve the management of patients with hypertension. The pharmacist plans to research the knowledge and skills that will be required to operate the clinic as well as the regulations and management issues that will need to be addressed.

Educational Need Identified	Goal or SMART Learning Objective	Resources or Planned Activities	Timeframe for Completion

Figure 3 Sample documentation of the learning plan.

SMART learning objectives help learners to measure progress and outcomes, keep focused when no-one else is directing the learning, and ensure that the learning has application to the "real world."

Within the learning plan, pharmacists are encouraged to prioritize the learning objectives to ensure more urgent objectives are addressed in a more timely fashion. Similarly, the timeframe for completion should be considered when developing the learning plan, and a clear timeline should be developed including short, medium, and long-term goals.

Once the pharmacist has identified his or her learning objectives, learning activities and other resources should be identified to assist the pharmacist in achieving the learning objectives. CPD, unlike traditional CE, incorporates everything that pharmacists learn. In this regard, learning plans can incorporate both structured (i.e., formalized courses, traditional CE activities, etc.) and unstructured learning activities and include activities both within and outside of the workplace environment, as noted in Table 4.

The pharmacist should consider his or her preferred learning style and environment. Does the individual learn best through reading material or listening to a speaker? Does the pharmacist prefer online or live, in-person activities. Will hands-on training activities be required to attain a new skill? Resources needed to achieve the learning objectives should also be identified. The learning plan should be reviewed against the learning objectives to ensure it adequately addresses all the pharmacist's identified competency needs (knowledge, skills, attitudes, and values) (Box 2).

Pharmacists should ensure that the learning plan is carefully documented. Fig. 3 provides an example of the types of information that should be captured in a pharmacist's personal learning plan. Periodic re-evaluation of the plan is also needed to ensure the learning plan remains timely and relevant and to monitor progress toward achievement of the learning objectives. The learning plan should be modified and updated as needed.

Learn

During the "Learn" stage pharmacists put the "Plan" stage into action. Learning occurs with implementation of the learning plan. Learning plans may incorporate a variety of learning opportunities and methods including formal, structured activities as well as informal and work-based activities (Box 3). The pharmacist should make use of all available and appropriate resources to support and enhance the learning. An essential requirement is to ensure that the activities chosen assist the pharmacist to meet the identified objectives and ultimately the learning need rather than merely fulfilling regulatory requirements. Documentation of participation in the learning activities should be captured and maintained in the pharmacist's written portfolio. Fig. 4 provides an example of the types of information that should be captured when documenting learning.

Box 3 Learning Examples

Immediate

The pharmacist reviewed the medicine in question and was able to educate the patient about the medication.

Long term

The pharmacist participated in a training program during which he developed and achieved the needed knowledge, skills, and credentials to operate a pharmacist-run hypertension clinic.

Learn: Learning Activity Completion Tracker			
Learning Activity	Date Completed/ Time Engaged in Learning	What I learned	Learning Objectives Addressed

Figure 4 Sample learning documentation.

Apply

During the "Apply" stage, pharmacists utilize the new competencies developed during the "Learn" stage to implement performance and practice improvements. The need to apply new knowledge and skills provides a purpose for pharmacists to participate in the learning activity. Additionally, application of learning serves to reinforce and sustain the learning. Adult learners, including practicing pharmacists, place greater importance on learning for which a purpose has been identified, as compared to learning for learning's sake (Kaufman, 2003; Rouse et al., 2018). The immediate use of knowledge and skills developed during the CPD process provides pharmacists with a sense of accomplishment and demonstrates the benefits of participation in the learning activities (Rouse, 2004a). Witnessing the impact of one's learning can improve the self-image of the pharmacist and be a motivator for continued learning and professional development (Baume, 2001).

Incorporation of the "Apply" stage within the CPD cycle emphasizes the need for integrating learning with practice. This is a key difference between the CPD model and more traditional approaches to lifelong learning. Learning must have a purpose and pharmacists must be willing and committed to embrace and implement the needed practice changes identified during the reflection stage.

Evaluate

Evaluation occurs in two distinct phases. The first phase includes the evaluation of the learning plan and learning activities. During this phase, following completion of the planned learning activities, the pharmacist evaluates the effectiveness of the plan toward achieving the outcomes described in the learning objectives. The learning plan itself should be evaluated as to whether the plan was appropriate for addressing the learning need; for example, was the timeline realistic and the scope of learning appropriate? The correlation between the activities in which the pharmacist engaged, the resources used, and the needs outlined in the plan should be evaluated. Pharmacists should assess if the learning methods and resources used were appropriate and what was the impact on the individual's competence and confidence. The pharmacist should consider whether the learning objectives have been sufficiently achieved and what documentation there is to support this assessment. If a structured competency-based assessment or self-assessment was previously undertaken, it would be valuable to repeat the assessment to measure and document the improvement. For objectives that have not been adequately addressed, the next steps need to be identified, including the possible identification of additional learning activities. Additionally, if any challenges or obstacles were encountered, how can things be done differently in the future? Alternatively, if the learning objectives were fully achieved, the pharmacist may complete this cycle and begin a new process of reflection to identify other learning opportunities.

The second phase of evaluation is to determine the impact of the learning after the "Apply" stage. An essential element of the CPD model is the evaluation of the link between participation in educational activities and the plan's intended outcomes and impact (**Box 4**). In other words, did completion of the learning plan lead to the intended outcomes? If the outcome was to improve patient care, has an improvement been measured and documented? Did the pharmacist's participation in the learning activities lead to measurable changes in performance? Have the pharmacist's role/responsibilities been expanded? Were any organizational changes or improvements implemented? How has patient care been impacted? **Figs. 5 and 6** provide examples of forms that may be used to facilitate the evaluation process.

The learning plan should be formally reviewed on an annual basis at a minimum but may be reviewed more frequently on an ad hoc or unscheduled basis due to changing needs within the pharmacist's practice or organization. The evaluation process should include an analysis of the pharmacist's progress toward achieving the identified learning objectives. Changes in the pharmacist's practice that may require changes to the objectives and plan should be identified and incorporated within the plan. Review of the

Box 4 Evaluation and Application Examples

Immediate

After reviewing the new medicine, the pharmacist was able to fully educate the patient on the medicine. The pharmacist will be prepared should another patient have a similar question.

Long term

The pharmacist initiates the pharmacist-run hypertension clinic. Using a quality-assurance process, the pharmacist routinely evaluates and documents the effectiveness of the clinic and the impact on patient-outcomes and healthcare costs.

Evaluation and reflection
What did you learn? Were your learning needs fully met? Partially met? Not met? What challenges or barriers to learning did you experience? How may they be overcome in the future? What new learning needs were identified as a result of this experience?

Figure 5 Evaluation documentation.

Outcomes
Identify which outcomes apply to this activity: How will you change practice based on this learning? (Set specific goals.) What additional information will you pursue? When and how will you pursue it?

Figure 6 Outcomes evaluation.

pharmacist's learning plan by supervisors or another entity can provide valuable insight, providing feedback on the validity of the individual's plan, and assisting individuals having difficulty fully completing the CPD cycle.

Record and Review—Learning Portfolios

Documentation of each component of the cycle—both learning and application of learning—is integral and essential to the CPD process. Personal learning portfolios are one mechanism that has been used to document the CPD cycle. The learning portfolio is "a structured collection comprising labelled evidence and critical reflection on that evidence, produced as a part of the process of learning to show evidence of that learning" (Baume, 2001). Learning portfolios provide a means to demonstrate involvement in educational activities and other components of the CPD cycle. Ideally, the learning portfolio demonstrates the individual's progression through the CPD cycle from reflection through evaluation and application. The learning portfolio provides a means to document learning and achievement of competency. Ultimately, the portfolio may provide a basis for review by employers or regulators of the individual's efforts to maintain competence.

As depicted by the bidirectional arrows in Fig. 1, recording and reviewing should be a dynamic process that supports the learner's CPD; what is recorded in the portfolio can subsequently be reviewed to further inform and guide the learner. If the portfolio is only a static repository of information and activities, it will have limited benefit. Documentation can enhance personal accountability of the pharmacist and can provide evidence of the pharmacist's efforts and achievements to maintain or enhance competence to relevant stakeholders; e.g., employers, regulators, and credentialing bodies.

To adequately document an individual's progression, learning portfolios should include evidence of learning such as learning artifacts and reflections. Learning artifacts are items that can provide documentation of the individual's learning experiences such as educational materials, projects, presentations, photographs, videos, etc. Increasingly, digital badges, symbols indicating completion of a course or attainment of a skill, are being incorporated within the learning portfolio. Reflections are a type of artifact in which individuals reflect on the learning experience. To be truly "reflective" when writing a reflection, the learner should do more than provide a simple recounting of the experience. Rather, reflections address the importance and context of the educational experience in which the learner was engaged. While documenting all components of the CPD cycle, the learner should strive to take their level of reflection as deep as possible, moving from the conscious to the subconscious level. The three key questions discussed under Reflect—What? So What? What Next?—can assist in this regard. New learning should be articulated in the context of the individual's practice.

Regardless of the actual process used, the learning portfolio should be personal to the individual learner. The process must be user friendly, readily accessible and easy to maintain to enhance usability by the individual learner (Accreditation Council for Pharmacy Education, 2015). Use of the portfolio should be ongoing and provide a comprehensive record of the pharmacist's identified educational needs, planning of and participation in learning activities, enhancement of competency and performance, application of learning, and, where applicable, implementation of practice improvements and impact on patient care. In several countries, electronic portfolios and smart phone applications have been developed, while in other countries paper-based systems are used (National Association of Boards of Pharmacy, 2018).

If maintenance of a portfolio is just perceived as "busy work" or too complicated and time-consuming to complete, it can become a barrier to learning instead of a tool that supports learning; this must be avoided at all costs. Requirements for maintaining a learning portfolio in practice will vary and will depend on the licensure or credentialing process maintained in the country or practice setting in which the individual practices. If portfolios are evaluated by third parties, such as regulators, they should be in a standardized format and have pre-defined evaluation criteria. Documentation of the CPD process has become useful for regulatory purposes, and maintaining a structured CPD portfolio, along with other elements of the CPD model, is mandatory in several countries (Tran et al., 2014; Pharmaceutical Society of Ireland, 2010).

As the scope of practice of pharmacists continues to expand and as payment models transition from product-based to service-based to performance/outcomes-based, there will be a growing expectation by stakeholders, such as employers and credentialing bodies, for pharmacists to provide evidence of their qualifications, experience, and performance; evidence that can ideally be provided in the form of a personal portfolio (Council on Credentialing in Pharmacy, 2014).

Closing Identified Gaps

Regulation of the pharmacy profession in many countries includes the assurance of quality of pharmacy schools and other educational and training programs (International Pharmaceutical Federation, 2014a; Fathelrahman et al., 2018). In this regard, pharmacy schools must meet rigorous standards to demonstrate that graduates are competent for entry into practice. Once in practice, however, pharmacists are not required in all countries to demonstrate ongoing, contemporary competence to practice. With constantly evolving technologies, increasingly complex medications and other therapeutic agents, new knowledge and treatment protocols based on accumulated evidence and research, changing societal needs and expectations, the competencies developed by pharmacists during their pre-service education and training are not sufficient for a life of practice. For many or most pharmacists in practice, the knowledge, skills, attitudes, and values needed for contemporary, patient-centered practice were not addressed in their pharmacy school curricula. For many, there was minimal coverage of the clinical, social, behavioral, and administrative sciences, and no experiential training until after graduation. New competencies—especially those to provide comprehensive clinical services—must be developed; existing competencies must be enhanced. This is a major education and training gap, which must be addressed through effective lifelong learning models that meaningfully engage learners and achieve the needed outcomes and impact.

Mandatory participation in CE activities was introduced in many countries as a means to ensure the maintenance of practitioner competence, and it remains the most common model in pharmacy and other health professions (Tran et al., 2014; Pharmaceutical Society of Ireland, 2010; Young and Willie, 1984). Research suggests, however, that participation in mandatory CE activities does not adequately impact practitioner performance (Vaughn et al., 2006). On the other hand, there is growing evidence of the effectiveness of the CPD model (McConnell et al., 2012; McConnell et al., 2010; Dopp et al., 2010). In order to re-engineer the profession to a clinical profession, new models for practitioners' lifelong learning are called for (American College of Clinical Pharmacy, 2000; Institute of Medicine, 2010b).

Participation in the CPD process encourages pharmacists to continually analyze competence and address any deficiencies noted. Gaps between what currently exists and what is desired or needed (by patients, an organization, society) can be identified at the individual level, a local/organizational level, or even at a national or profession-wide level. Identification of learning needs and other gaps that need to be addressed, therefore, should occur at all these levels. Fig. 7 illustrates how the needs-based education model can

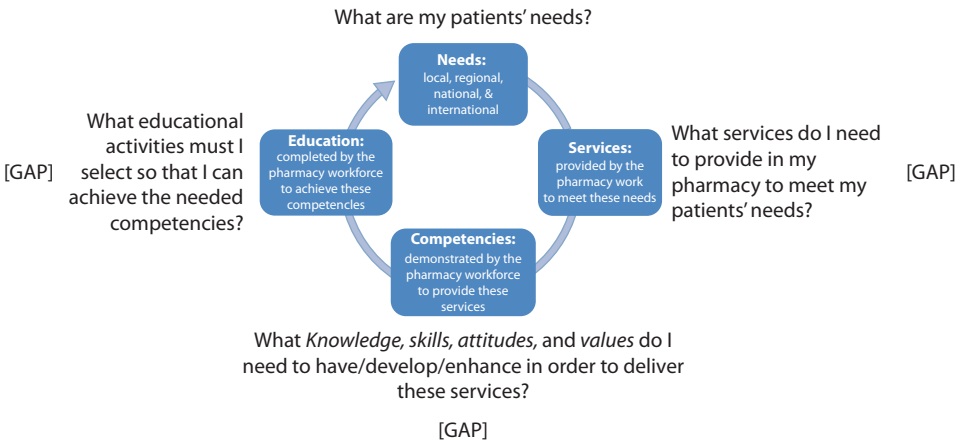

Figure 7 Personalized needs-based education.

Box 5 An Example of CE/CPD Requirements

Health professionals registered with the Health Professions Council of Namibia must complete 30 CE units annually, of which at least 5 CE units should be for ethics, human rights, and medical law (Health Professions Councils of Namibia, 2011b). Individuals who do not successfully complete 30 CE units are considered noncompliant. The consequences of noncompliance include the following: registration in a category that requires supervision; required participation in a remedial CE and training activity; completion of an examination; suspension from practice for a period of time; or another recommended action.

apply to an individual learner, with the initial focus being on the needs of the patient (International Pharmaceutical Federation, 2014a). The model helps to identify the gaps that may exist:

- A needed service is not being provided, or not at the needed level.
- All the competencies needed to provide a service have not been developed or enhanced to the needed level.
- The education or training needed to develop the competencies does not exist or has not been completed.

CPD Versus CE

CPD encompasses both traditional CE and training activities and unstructured self-directed learning activities; CPD does not eliminate the need for and value of participation in structured CE activities. CE and other formal training activities must be of high quality to produce the desired outcomes. Use of a formalized accreditation process provides quality assurance oversight to CE and training activities.

In various countries, requirements for completion of CE and/or CPD activities are often tied to maintenance of licensure (Tran et al., 2014; International Pharmaceutical Federation, 2014b). Many countries require completion of a certain number of CE hours on an annual or biannual basis for pharmaceutical professionals to be eligible to maintain licensure. Alternatively, countries that use a CPD approach to maintain licensure may require pharmaceutical professionals to accrue a certain number of CPD "points" or complete a certain number of learning cycles, complete periodic competency-based self-assessments, and maintain a personal learning portfolio or logbook (**Box 5**).

Additional Competency Assessments

In addition to focusing on scientific and clinical knowledge and skill competencies, pharmacy practitioners must also focus on maintenance of personal and professional development skills such as problem-solving, decision-making, communication, leadership, professionalism, and teamwork. Pharmacists are faced with scenarios requiring problem solving on a daily basis and must be able to successfully navigate the decision-making process to ensure the optimal solution is enacted (Martin et al., 2016). Similarly, pharmacists must be able to lead and function as a member of the healthcare team. The CPD process should ensure that pharmacists are incorporating not only knowledge and skills-based assessment, but assessment of personal and professional development skill needs as well. Identification of critical needs in these areas is essential to ensure continued competence of the pharmacy practitioner.

Challenges and Opportunities

Pharmacists engaging in CPD must identify and overcome challenges to the effective implementation of a CPD process. Of utmost importance is that the pharmacist fully embraces the CPD concept and process. Without the needed commitment to the philosophy and process, the model will break down and the effectiveness of the CPD process will be diminished. Adoption of the process and incorporation of the elements of the CPD cycle into the pharmacist's daily routine is essential but not intuitive (Haines, 2018; Motycka et al., 2010). In this regard, workloads must be amenable, and adequate time must be identified and made available for the pharmacist to engage in CPD. Adequate time and practice are essential to assist pharmacists with the CPD process (Redwood et al., 2010). Similarly, resources needed for professional development, including access to needed learning activities and funding, must be available as needed. Pharmacists employed in workplaces that support and advance the CPD process will likely incorporate the CPD process more readily and effectively. Pharmacists must become advocates for CPD within the workplace if the model has not yet been incorporated.

Meaningful support by employers will play a major role in advancing the CPD model; this is logical because in many ways the return on investment from an effective CPD model should be most evident for employers/organizations (Jeffrey et al., 2017). At the same time, however, providers of educational activities, the bodies responsible for quality assurance and accreditation of CE and CPD, and regulators (the main drivers to date in advancing the CPD model in early adopter countries) all have a role to play if the CPD model will be successfully introduced and implemented. At present the degree to which CPD has been incorporated in the regulatory system of countries worldwide varies extensively with some countries not having implemented a CPD process while

others have fully embraced it (Driesen et al., 2007). Early adopters of a regulatory model based on CPD concepts and components included the United Kingdom, some provinces in Canada, and New Zealand (Tran et al., 2014). Ghana, Kenya, Namibia, and South Africa are examples of other countries that have incorporated CPD concepts to some extent or another (Ghana Pharmacy Council, 2018; Republic of Kenya Ministry of Health Pharmacy and Poisons Board, 2013; South African Pharmacy Council, 2018; Health Professions Council of Namibia, 2011a). As identified by the Institute of Medicine (USA), more research is needed to provide evidence of what educational and regulatory strategies and models are most effective in pharmacy and other health professions (Institute of Medicine, 2010b). A regulatory model based fully on CPD principles (e.g., Ontario, Canada, and Ireland) is likely to be more complicated to administer and sustain, require more resources and expertise, and be more expensive, hence these models are still in the minority. Pharmacists' CE preferences have been studied, as have barriers to CE and CPD, including time constraints, lack of motivation and interest, lack of an accreditation system, and cost; however, having a better understanding of what intrinsically motivates a pharmacist to fully engage in meaningful CPD appears to be a key issue (Donyai et al., 2011; Austin et al., 2005; Driesen et al., 2005; Namara et al., 2009; Power et al., 2008; Ten Cate et al., 2004; Deci and Ryan, 2002).

Conclusion

The rapidly changing nature of healthcare demands that pharmacists engage in lifelong learning to maintain and enhance competency to practice. Maintenance of competency requires pharmacists to do more than complete a minimal number of hours of required CE. In this regard, pharmacists must move beyond the minimal regulatory requirements. To optimize practice and effect practice change, learning must have a purpose, a clear link to the educational needs of the individual, and strong alignment with organizational goals and priorities and societal needs. Participation in CPD requires effort, discipline, and commitment to change but, with continued implementation, benefits to individual pharmacists, patients and employers/organizations should be realized. Ideally the pharmacist's workplace would embrace and support the pharmacist's needs and the CPD process, recognizing the return on investment that can be achieved.

Evaluating and Developing Clinical Skills

Arijana Meštrović, Pharma Expert, Zagreb, Croatia

In this chapter, evaluation and development of clinical skills are being explained. The chapter also explains define, develop, and implement pharmacists' clinical roles in the health-care systems. In different countries all over the World, there is different dynamic of clinical pharmacists' skills development, determined by local context in pharmacy education and practice (International Pharmaceutical Federation (FIP), 2015). The level of clinical knowledge and skills should be defined in all countries, both at the graduate level, as well as on the specialization and subspecialization level (Lee et al., 2017).

Generational issues connected with the clinical skills and knowledge are occurring in many educational systems, as many biomedicine undergraduate programs are now increasing clinically oriented, comparing to the past years. Therefore, the differences in the clinical approach to the patients are visible among practitioners (Boysen et al., 2016).

Interesting theories are appearing recently, stating that not just clinical, but all pharmacists have clinical knowledge and skills, therefore they all are clinical pharmacists. American College of Clinical Pharmacy defines that clinical pharmacists "work directly with physicians, other health professionals, and patients to ensure that medications prescribed for patients contribute to the best possible health outcomes."

Introduction to the Clinical Skills in Pharmacy

Pharmacist in hospitals and community pharmacies are offering patient care in structured processes, starting with data collection and assessment, using their knowledge and experience to create individual plans for their patients' needs. As in the same time, effectiveness of treatment and patient safety should be achieved, this approach require careful judgments and decision-making process. Also, risk and priority management need to apply to all clinical decisions, and this requires clinical skills of pharmacists to be developed to the desired level (Kehrer et al., 2013).

Educational Requirements

Schools of pharmacy are required and encouraged to implement curricula changes and improvements to provide students with a real opportunity to achieve clinical skills and reasoning. In many parts of the World, this change is not fully implemented, and this is due to various reasons and circumstances (Health Foundation, 2012). But, many universities have taken integrated approach to this

important change. They are successful in this process and are now setting new standards for pharmacy education and development of clinical competencies (Marriott et al., 2008).

This approach requires implementation of the experiential component of curriculum, to allow students to test their understanding and reasoning in real clinical cases, under supervision of their mentors and preceptors in practice. More attention is focused on the assessment of the clinical skills, measuring performance and quality of services in practice, including components of clinical competence such as knowledge, skills, attitudes, and values (Urteaga et al., 2015).

Definition of the Clinical Skills

The term "clinical" in the literature is offering to consider few important aspects of pharmacy practice:

- Seeing the real patients in clinical setting
- Providing the services similar to nurses and medical doctors, touching the patients
- Prescribing and deprescribing medicines
- Medicine therapy management and rational pharmacotherapy
- Providing injections and taking blood samples for the screening procedures
- Individualization of therapeutical approach and management
- Consultation and communication

New generation of medicine experts is very skilled in clinical data interpretation and prescribing, but often lack communication skills and empathy, as well as understanding the context of the practice scope of pharmacists in the health-care systems (Dalton and Byrne, 2017).

Clinical Skills Content and Development

To be able to develop clinical skills, practitioners will need problem-based education with interactive content. That dynamic process should include reasoning and discussions among learners, led by clinical experts, ideally coming from practice. Work on realistic situations will increase level of empathy and understanding, making decision process more straightforward and clear. In this educational methodology, students (or adult learners) will have to solve a number of cases to gain self-confidence.

One of the biggest barriers in developing clinical skills is the impression that pharmacists should not take any important decisions connected with pharmacotherapy without involvement of medical doctor. This kind of thinking is just a preconception, lacking pragmatic reasoning based on clinical guidelines. It was proved in pilot programs in some countries (UK), when pharmacists were working in collaboration with general practitioners in the same consultation room with the patients. Medical doctors could have recognized the benefits of pharmacists' contribution in many ways (Sims and Campbell, 2017).

As the concept of pharmaceutical care and clinical pharmacy is not older than 25 years, we still have practitioners in practice who were never educated in those disciplines, not in their undergraduate programs, but maybe also not in their continuing education activities. Therefore, they have different approach to the patient care than their young colleagues who are just entering the practice. But the controversy lies in the fact that they need to mentor and supervise younger colleagues and students, being aware that their level of clinical competence is not sufficient for their task. Some of those disciplines are pharmacogenetics, pharmacovigilance, individualization of therapy, etc. (Kimberly, 2013).

There are many educational activities offered to enhance and develop the clinical skills of pharmacist during their life-long learning, including short courses, on-line activities, clinical summer schools, or certification courses in certain clinical areas of practice.

Tools and Principles to be Used in Clinical Decisions

To develop clinical skills and reasoning, it is essential to use evidence-based sources, existing guidelines and protocols relevant to the specific country or region. There are some tools and principles to help pharmacists in this process to be structured and safe for the patients, yet at the same time efficient and aligned with the sources used by medical doctors and other health-care professionals (Frieden, 2017).

Using Drug-Related Problems Classifications

First step to conduct pharmaceutical care is to be aware that in all cases, patients' therapy should be effective and safe. Therefore, pharmacist who developed clinical skills should start planning structured counseling with patients in two parallel directions: "Is the medicine effective?" and "Do you face any problems related to the medicine use?" With collected answers, drug-related problems should be tracked related, to the possible causes. To have successful cause analyses, DRP classifications have been introduced from various sources.

A drug-related problem (DRP) exists when a patient experiences or is likely to experience a new disease or symptoms that have a real or potential association with the pharmacotherapy that the patient is taking. The classification of drug-related problems has, for the primary purpose, emphasized the role of the pharmacist in caring for the patient, focusing on the patient's needs and outcomes of treatment. This approach brought a new vocabulary in the description of the process of pharmacy care and created the need for

these problems to be documented, processed, and interpreted, and to take interventions in which problems would be prevented or rehabilitated in the safest way for the patient.

Pharmacist needs to demonstrate all these skills in clinical pharmacy procedures and use the classification according to their scope of practice.

One example of DRP classification is Pharmaceutical Care Network of Europe (PCNE), one that is now used widely in research, teaching, and pharmacy practice. Primary domains are Problems, Cause, Intervention, Implementation, Outcome, with details subdomains, as follows (Table 1):

Table 1 PCNE Drug-Related Problem classification, version Classification V 8.01

Primary domain	*Code V8.01*	*Problem*
1. Treatment effectiveness	**P1.1**	No effect of drug treatment
There is a (potential) problem with the (lack of) effect of the pharmacotherapy	**P1.2**	Effect of drug treatment not optimal
	P1.3	Untreated symptoms or indication
2. Treatment safety	**P2.1**	Adverse drug event (possibly) occurring
Patient suffers, or could suffer, from an adverse drug event		
3. Others	**P3.1**	Problem with cost-effectiveness of the treatment
	P3.2	Unnecessary drug-treatment
	P3.3	Unclear problem/complaint
	P3.4	Compromised quality of the medicine

	Primary domain	*Code V8.01*	*Cause*
Prescribing	**1. Drug selection**	**C1.1**	Inappropriate drug according to relevant guidelines/formulary
	The cause of the (potential) DRP is related to the selection of the drug	**C1.2**	Inappropriate drug (within guidelines but otherwise contra-indicated)
		C1.3	No indication for drug
		C1.4	Inappropriate combination of drugs or drugs and herbal medication
		C1.5	Inappropriate duplication of therapeutic group or active ingredient
		C1.6	No drug treatment in spite of existing indication
		C1.7	Too many drugs prescribed for indication
	2. Drug form	**C2.1**	Inappropriate drug form (for this patient)
	The cause of the DRP is related to the drug form		
	3. Dose selection	**C3.1**	Drug dose too low
	The cause of the DRP is related to the selection of the dose or dosage	**C3.2**	Drug dose too high
		C3.3	Dosage regimen not frequent enough
		C3.4	Dosage regimen too frequent
		C3.5	Dose timing instructions wrong, unclear or missing
	4. Treatment duration	**C4.1**	Duration of treatment too short
	The cause of the DRP is related to the duration of treatment	**C4.2**	Duration of treatment too long
Dispensing	**5. Dispensing**	**C5.1**	Prescribed drug not available
	The cause of the DRP is related to the logistics of the prescribing and dispensing process	**C5.2**	Necessary information not provided
		C5.3	Wrong drug, strength or dosage advised (OTC)
		C5.4	Wrong drug or strength dispensed
Use	**6. Drug use process**	**C6.1**	Inappropriate timing of administration and/or dosing interval
	To the way the patient gets the Drug administered by a health professional or carer, despite proper dosage on the label instructions	**C6.2**	Drug underadministered
		C6.3	Drug overadministered
		C6.4	Drug not administered at all
		C6.5	Wrong drug administered
		C6.6	Drug administered via wrong route
	7. Patient related	**C7.1**	Patient uses/takes less drug than prescribed or does not take it at all
	To the patient and his behavior (intentional or non-intentional)	**C7.2**	Patient uses/takes more drug than prescribed
		C7.3	Patient abuses drug (unregulated overuse)
		C7.4	Patient uses unnecessary drug
		C7.5	Patient takes food that interacts
		C7.6	Patient stores drug inappropriately
		C7.7	Inappropriate timing or dosing intervals
		C7.8	Patient administers/uses the drug in a wrong way
		C7.9	Patient unable to use drug/form as directed
	8. Other	**C8.1**	No or inappropriate outcome monitoring (incl. TDM)
		C8.2	Other cause; specify
		C8.3	No obvious cause

(*Continued*)

Table 1 PCNE Drug-Related Problem classification, version Classification V 8.01 (*cont.*)

Primary domain	*Code V8.01*	*Intervention*
No intervention	**I0.1**	No intervention
1. At prescriber level	**I1.1**	Prescriber informed only
	I1.2	Prescriber asked for information
	I1.3	Intervention proposed to prescriber
	I1.4	Intervention discussed with prescriber
2. At patient level	**I2.1**	Patient (drug) counseling
	I2.2	Written information provided (only)
	I2.3	Patient referred to prescriber
	I2.4	Spoken to family member/caregiver
3. At drug level	**I3.1**	Drug changed to . . . .
	I3.2	Dosage changed to . . . .
	I3.3	Formulation changed to . . .
	I3.4	Instructions for use changed to . . .
	I3.5	Drug stopped
	I3.6	New drug started
4. Other intervention or activity	**I4.1**	Other intervention (specify)
	I4.2	Side effect reported to authorities
Primary domain	*Code V8.01*	*Implementation*
1. Intervention accepted	**A1.1**	Intervention accepted and fully implemented
(by prescriber or patient)	**A1.2**	Intervention accepted, partially implemented
	A1.3	Intervention accepted, but not implemented
	A1.4	Intervention accepted, implementation unknown
2. Intervention not accepted	**A2.1**	Intervention not accepted: not feasible
(by prescriber or patient)	**A2.2**	Intervention not accepted: no agreement
	A2.3	Intervention not accepted: other reason (specify)
	A2.4	Intervention not accepted: unknown reason
3. Other (no information on acceptance)	**A3.1**	Intervention proposed, acceptance unknown
	A3.2	
Primary domain	*Code V8.01*	*Outcome of intervention*
0. Not known	**O0.1**	Problem status unknown
1. Solved	**O1.1**	Problem totally solved
2. Partially solved	**O2.1**	Problem partially solved
3. Not solved	**O3.1**	Problem not solved, lack of cooperation of patient
	O3.2	Problem not solved, lack of cooperation of prescriber
	O3.3	Problem not solved, intervention not effective
	O3.4	No need or possibility to solve problem

Version 8.02 *is ready and available, incorporating some validation results of V7.0, and correcting some minor issues in V8.0 and V 8.01. Please note that Version V 8 is not compatible with earlier versions, due to some fundamental changes. The version 8.02 is being validated by an international group of experts.*

Creating PICO Questions—Clinical Significance and Interpretation

Once the pharmacist collects the data from the patient and/or patient medication record and notice some problems or inconsistencies in pharmacotherapy, it is important to develop the sense of reasoning and interpretation in ever clinical case individually. This skill also needs to be evaluated and developed for clinical pharmacy practice, as in the profession, there are still generational and other barriers which needs to be overcome. IT literacy, knowledge of English language, skill of interpretation of data are all skills important for clinical pharmacists For all those cases, pharmacists will first find evidence in reliable sources (such as publications, books, handbooks, guidelines, applications, databases, and regulatory documents). In any case, pharmacists should know how to identify the PICO question.

Without a well-focused question, it can be very difficult and time consuming to identify appropriate resources and search for relevant evidence. Practitioners of Evidence-Based Practice (EBP) often use a specialized framework, called **PICO**, to form the question and facilitate the literature search. **PICO** stands for:

- Patient Problem (or Population)
- Intervention

Table 2 PICO question structure

	Think about:
Patient Problem (or Population)	What are the patient's demographics such as age, gender, and ethnicity? Or what is the or problem type?
Intervention	What type of intervention is being considered? For example, is this a medication of some type, or exercise, or rest? What problem in pharmacotherapy is it all about?
Comparison or Control (if applicable)	Is there a comparison treatment or method to be considered? The comparison may be with another medication, OTC, another form of treatment such as exercise, or no treatment at all.
Outcome (should be measured)	What would be the desired effect you would like to see? What effects are not wanted? Are there any side effects involved with this form of testing or treatment?

Table 3 PICO elements change according to question type (domain)

Question type	*Patient problem or population*	*Intervention or exposure*	*Comparison or control*	*Outcome/Measures*
Therapy (Treatment)	Patient's disease or condition.	A therapeutic measure, e.g., medication, surgical intervention, or life style change.	Standard care, another intervention, or a placebo.	Mortality rate, number of days off work, pain, disability.
Prevention	Patient's risk factors and general health condition.	A preventive measure, e.g., a lifestyle change or medication.	Another preventative measure OR maybe not applicable.	Mortality rate, number of days off work, disease incidence.
Diagnosis	Specific disease or condition.	A diagnostic test or procedure.	Current "reference standard" or "gold standard" test for that disease or condition.	Measures of the test utility, i.e., sensitivity, specificity, odds ratio.
Prognosis (Forecast)	Duration and severity of main prognostic factor or clinical problem.	Usually time or "watchful waiting".	Usually not applicable.	Survival rates, mortality rates, rates of disease progression.
Etiology (Causation)	Patient's risk factors, current health disorders, or general health condition.	The intervention or exposure of interest. Includes an indication of the strength/dose of the risk factor and the duration of the exposure.	Usually not applicable.	Survival rates, mortality rates, rates of disease progression.

- Comparison or Control
- Outcome

In Table 2, basic elements are described:

When using the **PICO** framework, it is useful to think about what type of question pharmacists might have (is it about therapy, prevention, diagnosis, prognosis, etiology). Table 3 illustrates ways in which **P**roblems, **I**nterventions, **C**omparisons, and **O**utcomes vary according to the type (domain) of such a question.

Evidence-Based Practice in Health, University of Canberra, Library (accessed Aug 9, 2018)

Once PICO question is well formed, the best possible evidence should be found and applied to the individual patients' situation. That means that a pharmacist needs to know how to interpret collected data and apply the conclusion to the real-life situations (Schardt et al., 2007).

For example, when pharmacists find the evidence about drug–drug interactions in the literature, it is important to judge clinical significance in the patient case, individually. Not all interactions will obviously happen to anyone, so it is important to start from the facts and to modify interpretations according to the circumstances (e.g., age, gender, weight, kidney function, liver function, lifestyle, co-morbidities). Pharmacogenomic postulates can still change the decisions made in practice, as well as frequency of use and other conditions.

Once when decision is made and applied in real case, pharmacist should follow-up with the patient and review if the decision was right. In any case, patient opinion needs to be included and respected in the care process (Fineout-Overholt and Johnston, 2005).

Setting the Priorities

It could be that pharmacist will identify more than one problem in pharmacotherapy of the patient and will need to make clinical decision how to proceed with the patient case according to the urgency and order of interventions. We call that process prioritization.

Table 4 Choosing priorities in Patient care process

Was this problem a new issue, or did it occur earlier?
Why this is the problem right now?
If we do not solve the problem, what could happen to the patient?
Will there be side effects? If so—what side effects do we expect?
Will the overall state be out of control?
Can hospitalization occur?
Can a patient die?
What problems have to be addressed immediately?
What further problems can be expected?
Is the patient also recognizing the problem as a problem, or not?
Can we solve the problem without including someone else?
What do we need to solve the problem?

Source: A joint initiative of the American Pharmacists Association and the National Association of Chain Drug Stores Foundation, 2008

Deciding about priorities is a skill connected with time and risk management, especially connected with the patient safety and efficacy of the treatment. This process could be well supported by the potential electronic health records (if applicable), connecting more health-care professionals in the integrated care for the patient (Woolf, 2007).

In the process of prioritization, pharmacists can follow further scheme to make sure they are choosing right priorities to be primarily solved (**Table 4**):

Ability of the pharmacist to recognize that he cannot always set priorities without consulting other health-care professionals is also an important skill that can be developed with practice experience and teamwork.

Conducting Interventions

Once priorities are set, pharmacist should consider intervening. There is a whole range of interventions possible in the patient care process and again, it is a skill to recognize how and what to do.

One possibility is not to conduct any interventions. On the first sight that option might look as pharmacist do not take enough effort to do something for the patient, anticipating possible problems in communication, medical doctors' reactions, procedures in the health system, etc. But, sometimes "no intervention" can be the best solution for the patient. Those situations could be related with minor problems even at the end of antibiotic therapy or some acute disorders and intervention is actually not needed. Besides that, patient can decide that pharmacist do not intervene, for many various reasons. Sometimes, intervention is not possible, as it requires consultation with prescriber who might not be available or known. In pharmacy practice research, this situation should be noted and well interpreted, according to the circumstances.

Second option of intervention could be patient counseling and education, including practical instructions to the patients or just giving an educational leaflet to the patients. This intervention is most frequent, and it occurs in many situations that just do not require consultation with medical doctors. Research confirms that more than 50% of interventions fall into this category and problems are usually fully or at least partially solved, especially in chronic disease management (Ombini and Caserini, 2018).

Outcome of the intervention can be unknown, if patient does not come back for the follow-up, or pharmacists cannot track the progress of the individual patient for various reasons. With the pharmacists' intervention, problems can be fully solved, partially solved, or not solved, all for various reasons (agreement and support from medical doctor and patient might be missing, patient might lack understanding of the pharmacotherapy, some decisions could be made based on cultural, sociological, and religious beliefs of the patients or carer, etc.). It is very important to document all this outcomes and results and manage possible options to continue the process of care—that is also clinical skill, still to be fully developed for pharmacists all over the world. Pharmacists with developed clinical skills have to be able to choose research methods to publish their clinical data, also to make valuable conclusions and discuss the clinical outcomes of their intervention in neutral, unbiased way. From this type of research, we have today valuable information and proof how pharmacists' interventions can improve clinical, economical, and humanistic outcomes in the health care (Westerlund and Björk, 2006).

Planning the Process of Care

When all necessary data are collected and assessed, problems identified, priorities set, and intervention conducted, it is recommended to create individual care plan for the patient. The plan should focus on the patients' outcome and safety, considering the social profile of the patient, and desired life-style changes. The medication-related action plan will contain a list of recommendation for patients' self-management to achieve the desired goals. The care plan is an important component of the documentation and follow-up processes. To achieve the completion of the plan, the collaborative effort between the patient and the pharmacist is needed.

Often, the plan will contain goals that pharmacist and the patient can achieve without necessarily including other health-care professionals. Outstanding action items that still require physician or other health-care professionals' review or approval should be included in further plans. The patient can use the plan as a reminder and simple guide to track his own progress. He can take notes and fill the checklist that pharmacist has prepared for him, for better understanding and successful implementation. Patient can modify the plan according to the circumstances and possible outcomes of pharmacotherapy. Pharmacist needs to have a skill of education and guidance to the patient. It would be important that pharmacist count both on possible success or failure of the plan set, so that alternative plans could be predicted and implemented when needed. Therefore, follow-up is an important part of the care process. Plans and alternatives should be discussed in affirmative and assertive way with the patients to avoid any misunderstanding and safety risks for the patients.

(A joint initiative of the American Pharmacists Association and the National Association of Chain Drug Stores Foundation, 2008)

Managing the Risk

Risk management is a crucial part of effective and safe pharmaceutical care provided in pharmacy. It ensures that the health, safety, and well-being of patients are safeguarded, and risks are minimized.

Risk is defined as the chance or probability (high at one extreme and low at the other) that a person could be harmed or experience an adverse health outcome in pharmacotherapy process. It could be caused by medication error caused by medical doctor, pharmacist, or other health-care professional. The risk management is therefore very important. It involves:

- Efficient safety systems, including not just well-established process, but also skilled staff providing service, to minimize the likelihood of any harmful event
- Safety strategies and mechanisms to learn from situations where, despite all procedures implemented, something has gone wrong
- Management of minimizing the harm or adverse health outcomes if anything goes wrong as a result of a pharmacy's activities and services (Aronson, 2009).

Pharmacist need to have a skill to understand and manage the factors influencing risk and providing person-centered services in any activities in pharmacy. In this process, patients' health needs and vulnerability issues need to be considered. These activities should be conducted continuously and proceeded in sustainable way, not to allow any gaps in the process. Patient data should be collected in this process to track the impact of safety procedures. New potential risks should be considered on regular basis.

Some examples of the situations when risk management is beneficial are as follows:

- Internet-based orders and self-medication
- online counseling and giving instructions to the patients which might be misleading
- identity check
- lack of patient e-record or any other relevant information
- label checking systems
- communication with nursing homes or kindergartens
- universal rather than individual approach to the patient cases
- medication errors
- unsecure dispensing system
- lack of time
- insufficient number of the pharmacy staff
- lack of feedback to the pharmacy staff
- lack of reporting adverse drug reactions
- lack of the teamwork
- lack of self-confidence in pharmacy team, etc.

There are many resources to be used in implementing risk management in pharmacy, such as frameworks, tools, checklists, and guidelines, usually developed by national professional organizations of pharmacists working in hospital and community settings (General Pharmacy Council, 2016).

Communication, Motivation, and Counseling

Essential skill critically important to achieve outcomes in clinical practice is the ability of the pharmacist to communicate with the patient in professional way and to lead the conversation in nonjudgmental, nonthreatening way. Motivational interviewing is one of the skills that clinical pharmacist should develop to open the conversation in motivating and supportive way, especially when lifestyle change is involved. The skills needed for enabling communication in health care are, reflection, active listening, and open-ended questioning. Unlike Rogerian approaches, the technique can include elements of "direction" and is balanced with elements of "following". This shows a guiding style rather than the leading style seen traditionally in health-care consultations. Central to the motivational interviewing is the attitude of clinical pharmacist—belief in patients' inherent resources, rather than extrinsic problem solving, which include image of the patient as a partner in achieving the therapeutic goals.

Basic principles of motivational communication in the clinical setting are as follows:

- Showing empathy in the conversation is essential
- Motivation to change is elicited from patients, not imposed on them.
- It is designed to elicit, clarify, and resolve ambivalence.
- Resistance and denial is often a signal to modify motivational strategies.
- Eliciting and reinforcing patients' ability to carry out and succeed in achieving a specific goal is essential.
- The therapeutic relationship is a partnership that respects patient autonomy.
- It is both a set of techniques and counseling style.

(Miller and Rollnick, 2009)

It is also important that clinical pharmacist develop the skill to communicate collaboratively with medical doctors, nurses, and the whole pharmacy team. Assertive communication includes facts, feelings, and suggestions or requests. It sounds professional and opens the possibilities to collaborate interprofessionally, which is essential to achieve integrated care and comprehensive care for the patients.

Using the Clinical Guidelines

Using clinical practice guidelines is described as one of the basic competencies of the pharmacists in the FIP Global Competency Framework (International Pharmaceutical Federation FIP EDT, 2012).

Pharmacists should know how to find, use, interpret, and apply various clinical practice guidelines in their clinical practice and decision-making process for a variety of medical conditions. During practice experiences, students are often expected to quote an applicable guideline as justification for their clinical decisions. Recent Pharmacy students are usually knowledgeable in the latest guidelines for treating chronic diseases and conditions, and they are ready to use them in practice. Some students may learn those guidelines „by heart," not really thinking through the logic of choices that need to be made in patient care process. That means they would be memorizing clinical facts rather than learning clinical principles. Those who teach pharmacy, whether didactically or experientially, should be aware of this fact and use appropriate methods of teaching and learning to assure desired outcome.

For pharmacists to create sophisticated pharmacotherapeutic plans, they need to function beyond the written recommendations. With this goal in mind, it is time to consider the real role of clinical guidelines in the educational process and implement essential changes to the courses design and delivery (Brown, 2015).

Evaluation and Assessment of the Clinical Skills—How to Achieve it?

Both in undergraduate education and continuing professional development (CPD) for pharmacists, it is important to plan the learning, based on the real needs of clinical pharmacists. Needs can be assessed by reflection and self-evaluation, or by competency evaluation conducted by preceptors, professors at the faculty, or human resources experts, and managers at the work place.

Self-assessment is a skill in itself. It requires some experience in practice, good understanding of required standards and clinical procedures, objectivity, and self-motivation. Emotional and social intelligence is required for solid self-assessment, including the awareness, wish to advance in the profession, self-confidence, and ethical approach to the self-development process.

Some studies have shown that pharmacy students, even when attending faculty programs, which are strong in assessment and competency evaluation, do not always have the required skills for proper self-assessment. Their judgment appears not to be so accurate, even on senior levels of their degree, comparing with average assessments of their peers, standardized patients, and pharmacist-instructors. These differences are particularly visible and significant in the areas of showing empathy, and logic/focus/coherence of interviewing. It is evident that pharmacy schools in many parts of the World do not sufficiently prepare students to be life-long learners. Self-assessment of clinical competence should be a starting point in this process, as this skill will definitely be required for professional practice and continuous professional development (CPD) of clinical pharmacists (Austin and Gregory, 2007).

To maintain the licence or certificate for practicing clinically oriented pharmacists, continuing education (CE) activities are required in most countries. They are usually incorporated into the credentialing systems, where points to renew licence are just "hours-based." That would mean that for certain number of hours in the lectures or symposia, practitioners can "earn" certain number of points, collecting them to renew their licence (Tofade et al., 2015).

Accreditation Council for Pharmacy Education (ACPE) defines CPD as an ongoing, self-directed, structured, outcomes-focused learning cycle focused on maintaining and improving performance of professional practice. CPD cannot replace, but rather enhances CE in a broader approach ensuring improvement of pharmacist competence. CPD is rather dynamic than static learning process where the learner reflects, plans, learns, evaluates competencies, and applies gained knowledge and skills. That way, clinical pharmacist has the meaningful reason to learn. Central to each step in the CPD cycle is a personal learning portfolio where learners record self-evaluations, reflections, and further plans, as shown in **Fig. 1**.

As practicing roles and needs of clinical pharmacists are changing, their learning needs are changing too. The original concept of dynamic cycle and all components of CPD remain the same, but much greater focus has been given to the application of learning in

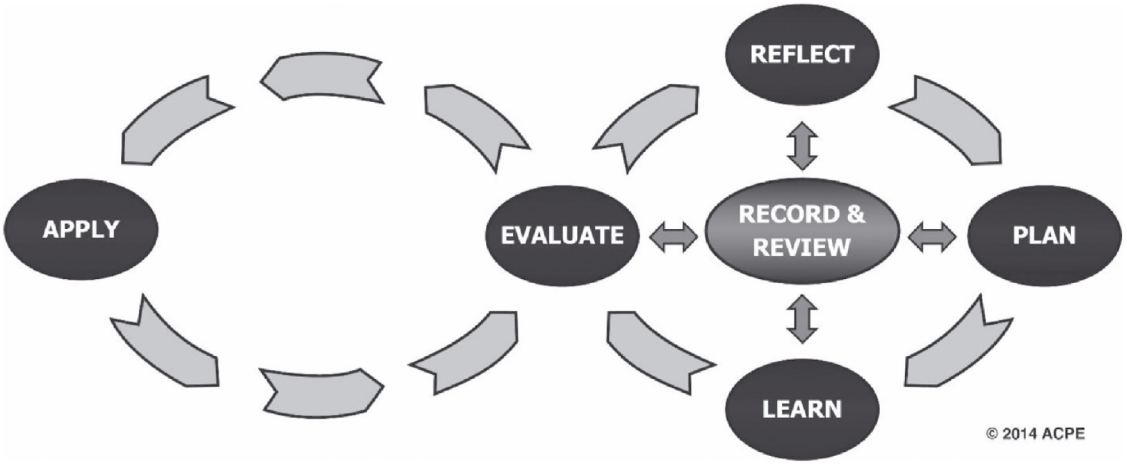

Figure 1 Continuing professional development cycle (ACPE, 2015).

everyday practice, connected with evaluation of the competencies before and after the application. Clinical skills can be developed only in this way, through the application and more reflection of the further learning needs. This approach will allow the clinical pharmacist to see individual benefits of his or her dedication to change and apply learning into practice. Seeing the impact of one's learning (especially in patients' outcomes and satisfaction) is always the strongest motivator for further advancements (Rouse et al., 2018).

No matter which methods are chosen to assess clinical skills, to start the process the competency list required for the desired level or aspects of practice should be available. It can serve as the checklist for the self-assessment (if required), and especially for the assessors, to define expectations in advance and to approach the assessment in organized, structured way. That means that all competencies should be well defined and described with the related behavioral statements. Both qualitative and quantitative methods could be applied to evaluate clinical pharmacists' behavior.

Competency framework for clinical pharmacists should be designed with all stakeholders' inputs, validated and piloted for quality assurance of the right context in certain organization, country, or region. It should be realistically aligned with educational programs and trainings, available for the pharmacists, both in undergraduate and CE programs. That way the clinical pharmacist can be encouraged to be assessed in objective, meaningful way, and objective goals and expectations could be set for the future development (Meadows et al., 2004).

Obviously, if behavior needs to be assessed, pharmacist should be ideally observed at his regular working place, where clinical skills are required and visible. If that is not applicable, there are some other methods to be used in the assessment of clinical skills and performance, such as OSCE-s (Objective structured clinical examination or mini CEX—Mini-Clinical Evaluation Exercise).

On Site Evaluation

Assessment in the working place can be organized in many different ways. It is highly recommended that the assessor has had the personal experience in practice to be able to assess the colleagues in the real situations. He could be known or unknown to the clinical pharmacists, and in both cases, there are some advantages and disadvantages, concerning bias in the evaluation, prejudices, and objectivity. Visits can be expected or unexpected, depending on the purpose of the evaluation and other circumstances. Also, assessor can be visible or invisible to the clinical pharmacist, which has been shown as a significant difference, as the fact that someone is observing, can cause behavioral changes in pharmacist's performance.

Checklist for evaluation can have different rating systems, but it is important to have some quantification, as qualitative, descriptive ratings are not easy to interpret, as well as measure and compare statistically. Whenever possible, qualitative aspects of the research should be portrait by numeric values, describing the level of competence. Some scales are designed to describe the frequency of achieved standard in repeated situations. In this case, we can say is the clinical pharmacists meets his expected standard always, often, rarely or never, using numbers 4, 3, 2 and 1 to rate the performance seen in practice.

During the assessment, assessor can interact with the pharmacists, asking additional questions, requiring additional explanations or making comments on the behavior just seen in practice. Before the assessor comes to the working place, it is recommended that pharmacist was introduced to the required standard, even better to conduct self-assessment, which can be then compared with assessor's ratings. Most common method of assessing the clinical pharmacist in practice is called "shadowing," when assessor follows the pharmacists and observe all aspects of his behavior (communication, time management, risk management, clinical approach and judgment, interprofessional collaboration, etc.).

Table 5 Mini-CEX evaluation examples

Delivery of patient care	
1. Patient consultation	Introduction to patient, conducting a patient-centered consultation, exploring the medical/surgical condition with the patient, considering the patient's own health beliefs, being aware of personal limitations, and making appropriate referrals
2. Need for drug	Establishing the patient's background, taking a drug history and gaining the necessary information from a range of sources in order to decide on the appropriateness of drug therapy
3. Selection of the drug	Appropriate consideration of evidence-based medicine and drug interactions (drug–drug, drug–disease, drug–patient)
4. Drug specific issues	Checking that the drug is prescribed correctly (route, formulation, dose, frequency, course length) and considering available results and what effect they have on drug therapy, e.g., U&Es, LFTs
5. Provision of drug product	Implementing an effective system for the supply of medicines
6. Medicines information and patient education	Provision of medicines and health advice to patients, carers, other pharmacy staff medical and nursing staff, and other health-care professionals
7. Professionalism	Identification and prioritization of medicines management issues, time management, patient confidentiality, appropriate application of guidelines such as formulary, therapeutic switching policies, etc
Problem solving	
8. Gathering information	Accessing and summarizing the information required and ensuring the information used is up-to-date
9. Knowledge	Knowledge of pathophysiology of common medical/surgical conditions encountered, pharmacology, side effects, and drug interactions
10. Analyzing information	Demonstrating the ability to evaluate information gathered (reliability or source, relevant to patient care), correctly identifying the problem, appraising options, making appropriate decisions, and demonstrating a logical approach
11. Overall clinical care	An assessment that summarizes all of the above in terms of outcome for the patient

Source: NHS Education for Scotland, 2014

Numerous factors within a pharmacy work system appear important to enable pharmacists to provide clinical services. To be successful in providing clinical services, pharmacists must be cognizant of the different components of the pharmacy work system and try to change environment to be optimal for clinical performance.

It is recommended that assessor share his observations with the pharmacist before the final marks are given. Sometimes, assessors and pharmacist's views are going to be different. In these cases, more resources should be considered to assure objectivity, such as additional interviewing or documentation sources available for the assessor to review. It would be ideal to achieve consensus in final record, but if it is not possible, it should be noted for the further analyses and procedures of assessment.

The site visit, when appropriately arranged, could be not just evaluation and assessment oriented, but also it could be beneficial for the pharmacist (Chui et al., 2012; Meštrović et al., 2011).

Mini CEX and CbD

If the random onsite evaluation is not possible or necessary, the mini-CEX (Mini-Clinical Evaluation Exercise) could be very appropriate to assess and evaluate clinical skills of pharmacists.

Mini-CEX originated in the United Kingdom and has been used within medicine for years. It was adapted for use within pharmacy in 2006, and then introduced into the Pharmacy Vocational Training Scheme to enhance learning, in 2011. A mini-CEX is a structured interactive examination based on the real-life case study. Following example can demonstrate what skills could be examined in Mini-CEX evaluation (**Table 5**).

Various rating scales could be used in the process. They should have large descriptive range, so the comparison can be made with what would be expected of any pharmacist at that stage of their vocational training or practice. The key part of mini-CEX is effective feedback and identifying learning needs. Here is one example, used in Scotland (**Table 6**):

Case-based Discussion (CbD) also adapted for use within pharmacy in 2006 by CoDEG (Competency Development & Evaluation Group). CbD is defined as a detailed discussion between the pharmacist and their assessor on a patient case. CbD can be suitable for more deep assessment of clinical reasoning and knowledge, such as discussing the pharmacokinetic or pharmacodynamics of a new medicine for a patient. Another example could be evidence base use of a drug in a particular patient, the legal or ethical issues around patient care, or behavioral changes with some social pharmacy aspects (NHS Education for Scotland, 2014).

Objective Structured Clinical Examination

The OSCE is an acronym for Objective Structured Clinical Examination, which has demonstrated validity and reliability for assessing medical and pharmacy students' and practitioners' clinical skills in various settings. Pharmacist is exposed to the unique clinical

Table 6 Rating scale in Mini-CEX process

Rating Scale	
Significantly below	Performs poorly; very rarely meets the standard expected
Below	Performs poorly; meets the standard required occasionally
Borderline	Performs satisfactorily; with appropriate support and direction should meet expectations
Meets expectations	Performs well and to the standard expected of a pharmacist at that stage in their training
Above	Performs to a standard higher than what you would expect from a pharmacist at that stage in their training
Significantly above	Performs to an excellent standard; trainee is ahead of his/her peer group
Unable to comment	Unable to comment as performance not observed while she/he was there

Source: NHS Education for Scotland, 2014

situation for evaluation of his clinical knowledge and competence, professional judgment, problem-solving skills, and interpersonal and communication skills.

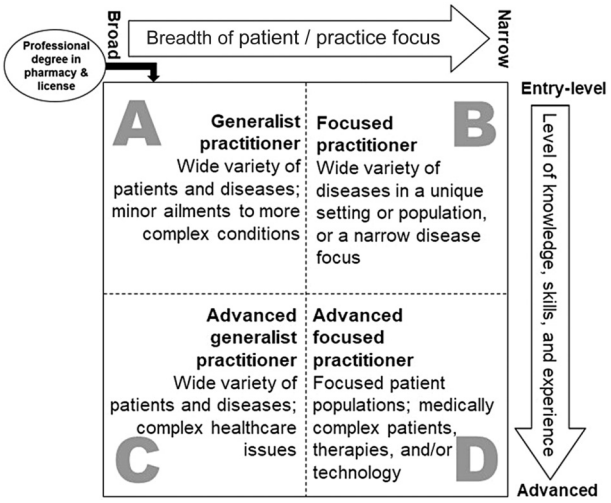
OSCEs are often used as part of certification at the end of specialization or as a part of licensing process. For instance, the United States Medical Licensing Examination and the Medical Council of Canada Qualifying Examination use OSCEs as part of their examination process.

The OSCE consists of various stations related to the direct patient care; so, the different competencies can be examined, depending on the learning (credential) needs and scope of pharmacists professional practice. Competencies such as collaboration and teamwork; ethical, legal, and professional responsibilities; drug, therapeutic, and practice information; communication and education; drug distribution; and management principles could be assessed and evaluated successfully.

Many pharmacy schools around the World are now used OSCEs in their curriculum, and this implementation is in progressive development. There are numerous publications proving the tremendous potential of using OSCE in clinical skills assessment (Urteaga et al., 2015).

Other Methods for Clinical Assessment

Various methods are available in pharmacy education to assess clinical competencies such as clinical counseling competitions, multiple choice questioners based on clinical cases, small group work, panels, poster presentations, seminars, etc. This area of assessment is under development, and new methodologies are emerging, both in undergraduate and postgraduate education.



Development of the Clinical Skills

The most important aspect of clinical skills development plan is the understanding that the clinical competences are much more than clinical knowledge in theory, as it was explained in the introduction of this chapter. It is clear that clinical skills, attitudes, and values are also important aspects of the clinical competences and should be taken into consideration when clinical competency development is concerned. The level of clinical pharmacists' performance varies depending upon scope of their practice at working place. Upon entry into the profession, pharmacy graduates are just starting to manage pharmacotherapy, and even if they have huge theoretical knowledge, the experience still needs to be gained. Due to some experiential learning during their program, they could be often able to competently perform basic clinical activities, but not always providing more complex clinical services.

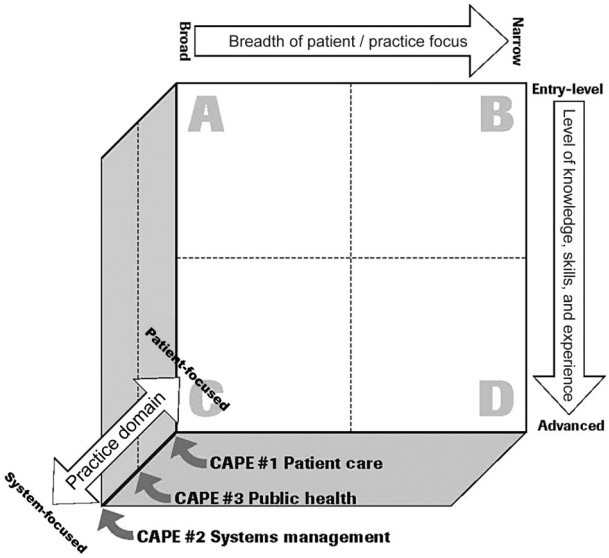


Figure 2 Development of the clinical skills (Paolini Albanese and Rouse, 2009).

In different countries, the clinical aspect of the pharmacy degree program varies. Only through continued clinical and additional learning opportunities, pharmacists can become proficient clinicians and experts in a field of practice. To conclude—clinical pharmacists develop proficiency through formal training and practice experience (Burke et al., 2008).

Later, in practice, the roles, responsibilities, and functions of clinical pharmacists could be developed in many different ways. The following concept was introduced by the US Council on Credentialing in Pharmacy to demonstrate how clinical skills in pharmacy could be developed on patient level, system management, and public health level. Looking from the different perspective: clinical pharmacist could advance as a general practitioner, but also as more focused on certain aspects of pharmacy practice (such as complex patient care, technology, pharmacogenetics, or specialized areas as oncology, paediatrics) (Fig. 2).

This concept cited sometimes as "Rouse cube" according to its conceptual author, demonstrate different dimensions and directions of clinical skills development. That is important in planning the learning of clinical pharmacist on individual, organizational, or even national and regional levels.

The axes of this three-dimensional framework lead to the planning and development of:

- breadth of patient or practice focus (x-axis)
- level of knowledge, skills, and experience (y-axis)
- practice domain (z-axis) of pharmacists

As explained in the Conceptual Framework for pharmacists' professional development in 2010, pharmacists are conceptually grouped in four quadrants, according to their practice and clinical skills development:

1. Generalist practitioner (quadrant A) covers different aspects of pharmaceutical care, but clinical approach does not have to be too complex. Majority of pharmacists develop and practice in this way.
2. Focused practitioners (quadrant B) serve patients with a wide variety of diseases but in a unique setting or population, or the practitioners have a narrow disease focus in their practice.
3. Advanced generalist practitioners (quadrant C) encounter a wide variety of patients and diseases for which the health-care issues are more complex. They need to develop clinical skills to the higher level of understanding and intervening.
4. Advanced focused practitioners (quadrant D) serve focused patient populations, with advanced approach and highest level of clinical skills, specialized in certain areas.

It is clear that for each of those groups, the CPD, training, specializations, assessment, and certifications, will aim to achieve and evaluate different competencies required for the pharmacist services provided (Rouse and Maddux, 2010).

Interprofessional Aspects of Clinical Skills in Pharmacy

Clinical pharmacists spend the majority of their time assuring that the pharmacotherapy is provided in a rational and safe way. Rarely, that could be achieved if they work independently, in isolation, more often the collaboration with other health-care providers is needed. In this context, the clinical skills are extremely important to be well demonstrated in daily communication.

Still not a large number of pharmacists have been educated and trained in interprofessional aspects of clinical pharmacy, meaning that they were not often learning in interactive communication settings with other health-care professionals. There is often one of the most important barriers that continue to prevent pharmacists from acting in the role as clinical pharmacists. Connected circumstances could encounter: inadequate leadership and management, failure to establish collaborative relationships with physicians and nurses, lack of reimbursement for clinical services, and provider status. Again, time in practice beyond pharmacy education and training is required to allow one to gain confidence in collaborative processes and experience with a wide range of medical problems and therapies, which require interprofessional cooperation in daily practice (Burke et al., 2008).

Teaching and Learning Clinical Skills

From the detailed and complex description what clinical skills for pharmacists are, and in which directions they are to be developed, it is clear that classic teaching approach (didactic lectures, teacher-directed learning, and guided instructions) will not be most appropriate teaching methodologies. As previously explained, in developing clinical competencies, all aspects of competencies must be addressed (knowledge, skills, attitudes, and values).

Knowledge should be properly addressed with solid foundational scientific facts and guidelines, following recent discoveries and updated information.

To develop clinical skills, learning should provide clear and evident links with real-life situations, as well as relevance and applicability to pharmacists' clinical practice. Clinical pharmacists learning needs can be met, only if they feel that the activity could be useful in and applicable to their daily work and if the instructor is personally experienced and skilled in the clinical pharmacy setting. Educational activities should include more interactive methods, such as small group discussions, round tables, problem-based learning including exchange of experience and workshops with practical examples. Moreover, it is crucially important that activities include demonstration of the practical aspects of the learning, with peers or teachers feedback (Tsingos et al., 2014).

Incorporating the ethical aspect in teaching process is important, both on undergraduate and postgraduate level. That way, the participants are also exploring their motives, values, and attitudes regarding clinical aspects of the patient care. Ethical issues should be addressed, providing clear solutions and answers, which allows pharmacists to develop decision-making skills and manage real-life situations. Behavior-shaping processes in education will increase motivation and professionalism and add an important value in the learning activities.

To achieve desired goals, teacher–practitioners should be included into the undergraduate and postgraduate educational programs and curricula designs must include clinical aspects of pharmacy practice in an innovative manner. Involving the patients or simulating real-life situations in the classroom could be successful, as well as interprofessional enhancement of the designed courses, including other health-care professionals as collaborative teachers and learners, together with the pharmacists (Meštrović and Rouse, 2015).

It is also important to keep in mind that for the clinical skills development, inspiring role models in practice are needed. Therefore, it would be recommended to set the criteria for preceptor selection and their education as high as possible. Working with competent mentor or tutor in practice, following not just the procedures but also their passion and dedication to achieve care plan goals for their patients is the key starting point to the clinical skills development. Students and practitioners need to believe in their capability to start getting out of their comfort zone.

Dynamic Relationship Between Education, Regulation, and Practice

Lina R. Bader*, Michael J. Rouse†, *International Pharmaceutical Federation (FIP), The Hague, Netherlands; †Accreditation Council for Pharmacy Education (ACPE), Chicago, IL, United States

Introduction

Pharmacists and health care workers are constantly faced with increasing and changing health care needs around the world. With the global strive toward universal health coverage—and with it the imperative for safe and effective use of and access to medicines for all—pharmacists are pressured to assess their current status, and advance and optimize their remits and practices to meet these demands. Re-professionalization is therefore an important path. However, there is no single definition of a "profession" in general, and while sociological interpretations of professions offer a solid foundation for theoretical understanding, their practical applications within the constantly changing health and pharmacy professions are limited. An alternative approach to the traditional theories of professions that can be used to analyze and identify challenges and improvement measures for the advancement of pharmacy was developed and validated. This new and simple conceptual framework redefines what constitutes a professional arena and lends itself as both a mapping tool and a diagnostic resource to support professional development and re-professionalization. This chapter presents the framework and refers to work of the authors to collate eight case studies and examples from around the world that have utilized the validated conceptual framework in their country or region to assess current professional challenges or successes, and identify drivers and barriers for advancement.

The conceptual framework describes that in any professional arena, there is a dynamic relationship between three interrelated professional sectors: practice, education, and regulation (International Pharmaceutical Federation (FIP), 2008, 2014). **Fig. 1** illustrates the conceptual framework, showing the relationship between its three principal components. "Education" refers to the sector of the profession that prepares members of the pharmacy workforce for practice; it includes both preservice entry-level education as well as continuing education (CE) and continuing professional development (CPD). "Practice" refers to the sector of the profession that provides a broad range of services to society in and from a variety of settings; practice varies according to country, context, or setting. "Regulation" refers to the sector that determines and enforces the statutory requirements for the organization and practice of pharmacy; regulation could be stemmed from within and/or outside the profession. In the chapter, accreditation of pharmacy education is included in the "regulation" sector.

The framework stipulates that any developments, changes, or innovations in any of these professional domains may drive, lead, or require an appropriately measured change or response from another. For example, changes in practice and service provision may force proportionate responses to be made in education; new regulations may impose new changes on the practice environment; and regulation changes, in the form of accreditation, may result in transformation in education provision. An appropriate "push-pull" relationship between these sectors (illustrated by the connection axes in **Fig. 1**) serves to advance the profession of pharmacy; and a disconnect or dysfunctional relationship between them usually results in complex professional challenges.

The framework illustrates that there is a dynamic relationship between the sectors; a relationship that could also be construed as a "tension" that continuously drives advancement and change. This tension or separation depicts "checks and balances" where a "push" from one sector or component can be checked (or opposed) by the other side. The absence of checks and balances between the three components may have a negative impact, for example, through conflict of interest or stagnation. It is also equally important that the separations between the sectors do not get too wide, or a complete disconnection may form. The lack of needed responsive changes by one professional domain can and should be challenged by another. Therefore, a proper "push-pull" relationship between these professional domains is crucial to advancing the profession; and disconnects between them may results in complex challenges and prove detrimental to the overall state of the profession.

The following examples may demonstrate these three relationships and how intersectoral disconnects may occur, but also how changes in one sector can drive innovation and development in another:

Practice-Education: If changes in the practice environment, such as, expansion in roles and service delivery are not met with appropriate responses by the education sector, the workforce may not be prepared to meet practice needs and hence pharmaceutical health care delivery may be negatively impacted. Alternatively, if educational institutions are not providing needs-based programs—exemplified by inappropriate adoption of foreign degrees locally—graduates of these programs may be disappointed to find that practice areas and sectors do not have the capacity to meet their expectation. Additionally, the workforce may be ill-prepared to meet real societal needs. In such situations, the educational institution fails to demonstrate social accountability. Another example strongly linking education and practice is training. Foundational training of the workforce is fundamental (and in many countries

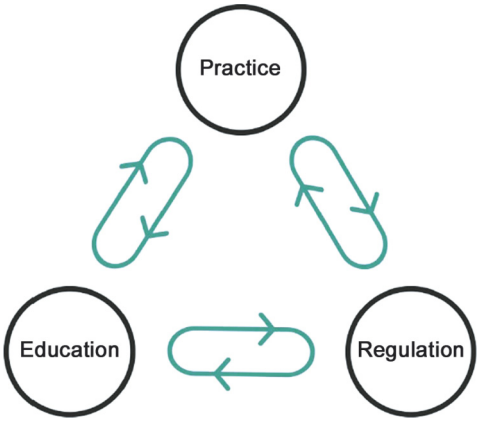

Figure 1 A conceptual framework depicting the dynamic relationships between practice, regulation, and education. *International Pharmaceutical Federation 2014, adapted with permission.*

required) for registration and practice. This results in the need for collaboration between the educational and practice sectors to provide optimal training opportunities; successful training program is one example that can demonstrate the positive impact a balanced practice-education relationship can have.

Regulation-Practice: General examples of the disconnect between regulation and practice may demonstrate the complexity and importance of this relationship too. Problems in practice may sometimes be traced to the lack of proper implementation or enforcement of regulations. Regulations may refer to practice laws, professional development and registration requirements, and medicines regulations. The "regulation" sector could, therefore, be a governmental or regulatory agency, the professional association, higher education ministries, drug authorities, etc. Improper implementation or enforcement in any of these areas results in problems with varying consequences, in some cases affecting the health and safety of patients. On the other hand, positive advancements and changes in practices may facilitate wider changes in regulations; for example, the development of advanced practice pathways starting in practice (e.g., private sector) could provide a proof of concept and therefore rationale for national strategic development of advanced practice systems.

Education-Regulation: The connections or disconnects between education and regulation can be described using the example of accreditation. Mandatory accreditation and quality assurance standards (i.e., regulations for education) established for pharmacy play an important role in shaping pharmacy education on a national level; the minimum standards of education can determine the overall quality of education. In this instance, educational regulators and stakeholders have a responsibility to regularly revise the standards established for pharmacy education to meet the national needs and changes in the profession. On the other hand—similarly to the practice-regulation relationship—advancements in education can positively impact regulation; a pharmacy school innovating in educational provision can trigger a healthy competitive effect on other institutions and force educational regulators to review and improve nationwide standards.

Existing challenges hindering the advancement of a profession may also be better understood by tracing them back to their corresponding "disconnected" axes. Hence, the framework may be used to "diagnose" existing challenges in development and prescriptive studies or initiatives. The framework may also be used to demonstrate a successful collaboration resulting in professional advances. In both cases, this diagnostic feature can facilitate the identification of barriers and facilitators, and assist to develop specific evidence-based policy-oriented recommendations or improvement measures.

The framework was first developed by author Rouse in the early 2000s as a result of his work with the Accreditation Council for Pharmacy Education (ACPE), the US national accreditation agency for pharmacy education. The conceptual framework was then used widely in presentations, depicting the need for collaboration and coordination between the entities responsible for practice, education, and regulation. The conceptual framework was first published in the Global Framework for Quality Assurance of Pharmacy Education (Version 1) which was adopted in 2008 by the International Pharmaceutical Federation (FIP)—the global leadership body for the pharmaceutical workforce worldwide (International Pharmaceutical Federation (FIP), 2008).

Between 2013 and 2014, the framework was validated and used in a country-level study in Jordan. Preliminary research resulted in the identification of eight major challenges facing the professional arena in Jordan. National stakeholders used the framework to map each of the challenges to the primary sector-to-sector disconnect that they perceived to explain it. Hence, the conceptual framework was used as a prescriptive tool. Stakeholders in Jordan used the tool to map the eight main challenges; this mapping exercise led to the identification of the primary source of the disconnect (professional challenges could be the result of multiple sectoral disconnects):

1. Unpreparedness of graduates for practice, which highlighted a disconnect between educational outcomes and practice needs (Education-Practice);
2. Inconsistencies of higher education accreditation and quality assurance mechanisms point toward a gap between educational regulations and their operationalization in educational institutions (Regulation-Education);

3. Unregulated and unorganized preregistration training is a result of a gap between appropriate training and regulation for practice placements (Regulation-Practice);
4. Absence of educational workforce development systems (i.e., CE and CPD) corresponds to a lack of regulatory policies on workforce education (Regulation-Education);
5. A growing supply of the workforce coupled with unclear market demands was identified as a symptom of a general lack of engagement between the educational and practice sectors (Education-Practice);
6. The reported occurrence of community pharmacists being paid below their nationally stipulated minimum wages is traced to the ineffective enforcement of minimum wage regulations in practice (Regulation-Practice);
7. The illegal dispensing by pharmacy assistants in community is another example of a regulation-practice gap (Regulation-Practice); and
8. A mismatch between the intended role of PharmD graduates and actual job fulfillment highlights another disconnect between the education and practice sectors (Education-Practice).

Using this participatory mapping approach, a list of evidence-based policy-oriented recommendations was developed for each of these challenges. Identifying the primary disconnect and related sectors helped formulate the most action-oriented and focused recommendations for solutions. It also helped identify the roles of different stakeholders in addressing the challenges; for example, in the case of Jordan, the national professional association carries regulatory responsibilities and the identification of "regulation" as a common source of a number of the challenges above further highlights the need for the association to review its roles and responsibilities—as well as its potential to lead reform and development. The results of this national study were published in 2016, and the conceptual framework became a global tool for identifying and analyzing challenges to the advancement of pharmacy (Bader et al., 2017).

Between 2017 and 2018, the authors further collected country and regional case studies using the tool. The purpose of this was to further utilize the tool's descriptive and prescriptive purposes in other countries around the world and to help national stakeholders reflect on successful developments and assess any existing challenges. An initial scoping survey was distributed to the authors' contacts around the world. The scoping survey served to identify preliminary case studies that were evaluated by the authors for inclusion in the Encyclopedia. A total of 10 initial submissions spanning 10 countries were received. In-depth case study templates were then sent to these country contacts and reminders were distributed. From this scoping survey, seven full case studies were received and results reported in a separate chapter in the Encyclopedia; these case studies span the following countries and regions: Brazil, Europe (with specific examples from Spain), Japan, Nigeria, Oman, Romania, and Taiwan. With the exception of South East Asia, all World Health Organization (WHO) regions are represented in this study. One additional case study from the USA was then purposively identified to provide an example of a country where a structure had been established to promote and facilitate active and ongoing communication, interaction and collaboration between the practice, education, and regulation sectors within the profession, thereby illustrating how the conceptual framework can and should work in a country. Fig. 2 depicts the dynamic relationships that are described in the case studies.

The case studies describe varying issues that touch on different sectors—demonstrating the usability of the whole conceptual framework. Each case study is accompanied by a descriptive, contextual background on education, regulation, and practice in the country or region and an analysis of the dynamic sectoral relationship(s) reported by the case study authors. Drivers and barriers to advancement, lessons learned, and implications for future planning are also discussed. The chapter authors carefully reviewed the case studies, edited them, and returned them back to their original authors for validation.

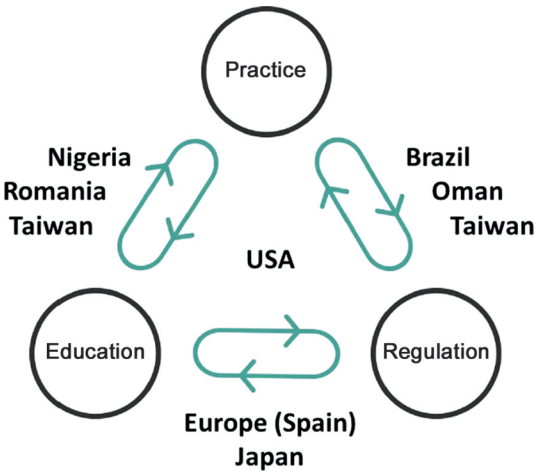

Figure 2 Summary of the dynamic relationships reported by the eight case studies.

Discussion and Conclusions

The Brazil case study demonstrated how the regulatory sector can be a positive driver for change in the practice sector, where changes in national legislation are resulting in broadened scope of practice for pharmacists; these resulting practice changes in turn drove responses from the education sector to cater to the new and expanded roles and services delivered by the workforce. In Brazil, a "domino effect" initiated by the regulatory sector demonstrates that a dynamic relationship indeed exists between education, regulation, and practice. At the same time, barriers to advancement in the country are interestingly also found within the regulatory sector, which shows that contradictory and complex forces usually exist within each sector and that strengthening drivers for advancement can support the successful impact of positive dynamics.

In Europe, as reported by examples from Spain, the effects of regional-level regulations (as stipulated by the European Union on its members) on harmonization of cross-country education is very prominent. "Soft regulations" that allow for relatively flexible adaptation as opposed to strict enforcement have proven to be a positive driver for changes in education. The regulatory harmony found in Europe has also carried a potentially positive effect on practice, via workforce mobility facilitated by mutual recognition. The Europe and Spain case study demonstrates successes of multinational frameworks and how they can be adopted and adapted based on country-level needs.

Regulation, in the form of accreditation of pharmacy programs, has had internal effects on institutional self-evaluation. In the case of Japan, the overreliance on external regulation has affected the dynamics of quality assurance in the educational sector. Institutions are dependent on external evaluation mechanisms to assure quality of educational programs, and in doing so are neglecting the establishment of strong internal quality assurance systems. While the recently established external (regulatory) accreditation has generally improved the national system for pharmacy education quality assurance in Japan, it has perhaps resulted in the unintended effect of weakened institutional-level, self-driven quality assurance, whereby "gaps" in the external evaluation system are not addressed in the internal system.

Nigeria reported an interesting case of multiple factors and drivers within education that have resulted in positive changes in the practice sectors. The case study demonstrates the importance of multinational collaboration and cross-country programs set up through strategic partnerships in catalyzing changes on a national level. It is important to note, however, that substantial donor funds have been a key factor in Nigeria's successful transitions. The prominent transformation in the provision of pharmacy education, namely its increased focus on clinical pharmaceutical care, has impacted positively on the provision of pharmaceutical care and the role of pharmacists in practice. Similarly, an international partnership with the support of funding between USA and Romania resulted in positive dynamics between education and practice in Romania.

In Oman, pharmacy regulations are not enforced effectively in all practice sectors and are sometimes in themselves lacking important elements to regulate practice. There is a high degree of variation between pharmacy practice in private versus public sectors. These factors, combined with the lack of a strategic vision for the profession, are negatively impacting the advancement of practice and the profession in general. However, acknowledgement by the Omani government of these issues—particularly of the sectoral disconnect—is considered one of the existing drivers for advancement. Despite this, review of the current regulatory enforcement process and of the regulations themselves is needed to drive positive change in practice.

An interesting case in Taiwan reported how changes in regulation drove advances in practice, advances which the education sector was not able to respond to as needed. The role of the professional body in successfully lobbying for the expansion of the role of pharmacists is evident in Taiwan. The advocacy efforts resulted in policy changes providing a wider scope of practice to pharmacists through the provision of pharmaceutical care and demonstrating the role of leadership in driving the profession forward. The positive changes on practice where especially evident in the community pharmacy sector, but educational institutions were not sufficiently preparing graduates to provide these patient-centered services. The close collaboration between the schools of pharmacy, however, coupled with the direction of the professional body may instigate the dynamic responses needed by the education sector.

The final case study from USA provides an example of a country, where a structure has been established to promote and facilitate dynamic relationships between the practice, education, and regulation sectors of the profession, which has been the focus of this chapter.

It is evident from the case studies that countries around the world report similar barriers and drivers to advancement. It is also evident that regulation plays a hugely important role in determining the status of the profession and its capacity to develop. In Brazil—the innovation in regulations drove changes in the two other sectors, showing the double relationships that can present themselves between all three sectors. Regulation in Europe, Japan, and Taiwan was also similarly seen as a positive driver. On the other hand, in Oman, the lack of regulations is a cause of professional problems nationwide. These results present important implications for pharmacy stakeholders that hold regulatory power and are consistent with findings from the validation study conducted in Jordan where regulation was also found to be a primary factor in many of the nation's challenges. Governments, regulatory agencies, higher education authorities, and professional associations with oversight responsibilities all should take note of these findings as they review their strategies and visions.

Common trends can be identified across all cases with cross-sectoral and, in some cases, multinational collaboration featuring as a prominent and main driver for positive changes across all sectors. Communication, collaboration, and concerted efforts by all stakeholders in pharmacy education, regulation, and practice are needed not only to drive positive changes in each sector but to also identify issues and barriers that need to be addressed through multistakeholder efforts. Leadership and strategic vision of a strong and stable professional leadership body, which closely works and aligns with the national government, is another driving factor for cross-sectoral collaboration.

Finally, the use of the conceptual framework by the case studies further proves its benefits in diagnosing and analyzing professional issues; by diagnosing the issues at hand, users of the framework can form specific and practical recommendations targeting the relevant stakeholders. Engaging with stakeholders to assess societal needs and professional standards is the key to ensuring that the recommendations, solutions, and improvement measures are implemented. This chapter demonstrated the dynamic relationships between education, regulation, and practice and describes how countries and institutions can use the framework for assessment of pharmacy professional challenges as well as successes.[1]

Experiential Education for Clinical Pharmacists

Jelena Parojčić, University of Belgrade, Belgrade, Serbia

Background

Experiential education represents an indispensable part of pharmacy education, where, historically (and similarly to medicine) competencies have been developed through the apprenticeship model of teaching and learning. With the rapidly increasing knowledge base in biomedical sciences in 20th century, the need for development of more formal didactic curricula has been recognized which included traditional classroom instruction with significant proportion of practical laboratory sessions. More recently, with the changing professional roles of pharmacist, and shifting emphasis from medicines dispensing to medication therapy management and direct patient care, the need emerged for integration of theoretical knowledge and clinical experience in modern pharmacy curricula (GPhC, 2018a; Husband et al., 2014; Knoer et al., 2016; Zebroski, 2016).

Traditionally, experiential learning in pharmacy has been part of the mandatory preregistration training/traineeship which took place after graduation and was a prerequisite for professional licensure. Significant increase in the number of pharmacy graduates worldwide has been followed with the rising concerns about the consistency and quality of learning experiences provided throughout preregistration training. These concerns, accompanied with the general expectation that first pharmacy degree should be "entry-to-practice" level program (e.g. graduates exhibit professional competencies of an entry-level practitioner) resulted in the recommendations that professional practice placements should be integrated into pharmacy curricula. Thus, planning, organization, quality assurance and evaluation of experiential education become responsibility of the academic pharmacy departments (ACPE, 2015; GPhC, 2018b).

Experiential education should complement the didactic curricula and provide student pharmacists with the opportunity to better understand theoretical knowledge, integrate it and apply in direct contact with patients and other healthcare professionals, develop critical thinking and decision-making skills, and build confidence necessary for future professional practice. Development of experiential pharmacy education is topic of intensive scholarly activity, and numerous excellent publications can be find in peer-reviewed pharmacy journals. This chapter tends to provide general overview and guidance for further inquiry.

Educational Theories of Experiential Education

Experiential education, as defined by the Association for Experiential Education, is "a philosophy that informs many methodologies in which educators purposefully engage with learners in direct experience and focused reflection in order to increase knowledge, develop skills, clarify values, and develop people's capacity to contribute to their communities" (AEE, 2018).

The emphasis in experiential education is on authentic experience in the real practice settings, quality of experience, interaction, active participation, self-directed learning, and critical reflection. Thus, experiential education is related to several constructivist, social, and situational learning theories. Yardley et al. (2012) discussed different experiential learning theories as applied to medical education.

Constructivist Theory of Experiential Learning

Experiential education is based on the principles of constructivist learning theory introduced by John Dewey, Kurt Lewin, and Jean Piaget, which assume that individuals construct their own understanding and knowledge through experiencing things and reflecting on those experiences. David Kolb (1984) defined learning as "the process whereby knowledge is created through the transformation of experience". Kolb's experiential learning model is probably the most widely employed learning model in experiential education. It is represented by the four-stage learning spiral which includes: (1) concrete experience, (2) reflective observation, (3) abstract conceptualization, and (4) active experimentation. Although learning process can start at any of the four stages identified, the most often trigger for learning in clinical pharmacy is student's engagement in authentic professional practice situation (i.e. concrete experience). In order for effective learning to occur practical experience should be followed by reflection on what has happened and how it relates to past experience. This is expected to lead to critical thinking, generalization and new ideas to be tested in practice which, thus, provoke new experiences.

Sociocultural Theory of Experiential Learning

While constructivist theories focus on developing individual knowledge, sociocultural theory (Vygotsky, 1978) emphasize the importance of social dimension and describes learning as social process. Lave and Wenger (1991) argued that knowledge needs to be presented in authentic contexts, settings and situations that would normally involve that knowledge. They developed situated learning theory in which social interaction and collaboration are essential components. It assumes that learners are involved in a "community of practice" which provides the necessary guidance and encouragement. The term "legitimate peripheral participation" has been used to describe that "as the beginner or novice moves from the periphery of a community to its center, he or she becomes more active and engaged within the culture and eventually assumes the role of an expert" (Lave and Wenger, 1991). Word "legitimate" indicates that learner is accepted as a member of the working community by participating in simple and low-risk tasks that are nonetheless productive and necessary and further the goals of the community. Gradually, as newcomers advance and gain a recognized level of mastery, their participation takes forms that are more and more central to the functioning of the community. Closely related to this theory is the Experience based learning theory (ExBL) described by Dornan et al. (2014) as a model for medical students workplace learning. This educational process has been described as the "supported participation in practice", in which students are taking responsibility for seeking out and engaging in learning experiences; are actively involved in the context of the task being undertaken in the work situation; reflect on their learning experiences with mentors, supervisors, teachers, and peers; interact with colleagues and other members of the healthcare team; receive on-going feedback from mentors, supervisors, teachers, and peers. In order to denote students' progress, Dornan et al. (2009) describe four levels of participation: (1) passive observer, (2) active observer, (3) actor in rehearsal, and (4) actor in performance.

Reflective Practice in Experiential Education

Reflective practice is defined as methods and techniques that help individuals and groups reflect on their experiences and actions in order to engage in a process of continuous learning. It forms the basis of deep learning from past experiences, as critical reflection on an experience is a key element of a process that creates meaning out of an experience. The importance of reflective observation and reflective practice in pharmacy education has been elaborated by Tsingos et al. (2014). The authors concluded that "reflective practice offers to assist with the integration of theory with complexities of practice by promoting critical thinking, problem-solving, and self-directed and lifelong learning".

Experiential Education Framework

Quality experiential education is based on quality practice experience which has been defined as "a well-planned, outcomes-focused training experience with adequate supervision and assessment by a qualified preceptor within a learning-rich practice environment" (Haase et al., 2008a, Haase et al., 2008b). It is expected that structured practical placements in the real work setting, and in direct contact with patients, should enable students to integrate and apply knowledge and skills developed through the didactic part of the curriculum. While in the traditional experiential learning model student pharmacists have been expected to learn by observing

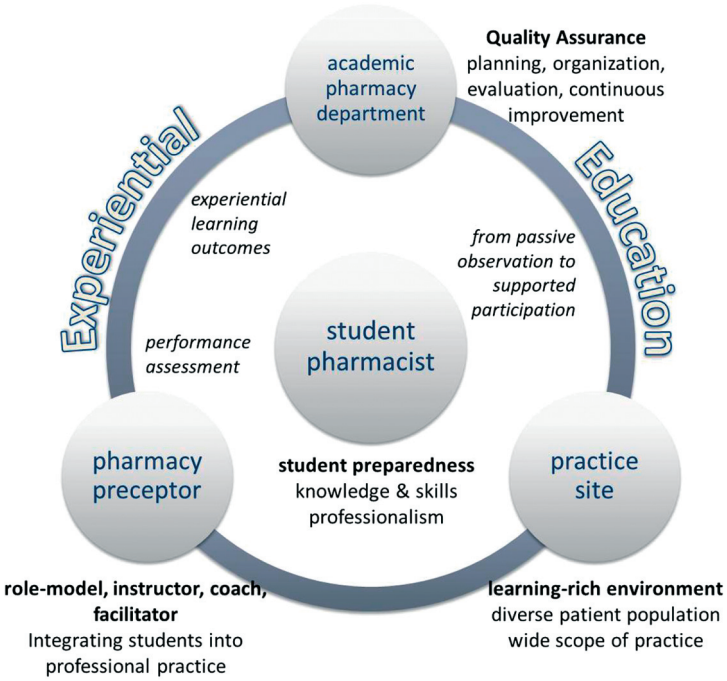

Figure 1 Framework for experiential pharmacy education.

skilled practitioners, in modern pharmacy curriculum they should engage in different professional activities including direct patient care. The importance of professional practice experiences in modern pharmacy education has been recognized and relevant guidelines and standards are provided by leading national and international professional organizations (ACPE, 2015; CCAPP, 2018; FIP, 2014; GPhC, 2011; PSI, 2013).

Development of framework for experiential education is challenging endeavor. While preregistration training in pharmacy is based, mainly, on the relationship between the recent graduate and relevant employer, experiential education model includes complex relationships and interactions in which higher education institutions, healthcare institutions, academic staff, clinical staff, students and patients are involved with their specific expectations, interests and challenges (Parojčić, 2014). General educational, professional and lawful standards and expectations related to the quantitative and qualitative aspects of experiential education, requirements for practice sites and preceptors development and qualification are outlined in the relevant quality standards (ACPE, 2015; FIP, 2014):

- practice experiences should be undertaken at approved practice sites under the supervision of appropriately qualified, experienced and trained preceptors;
- criteria for the selection, review and retention of preceptors and practice sites should be established and implemented in collaboration with the regulators of pharmacy practice;
- competency-based objectives for each pharmacy practice experience and the responsibilities of the student, preceptor, and practice site should be clearly defined and mutually agreed;
- relationship between the school and its preceptors should be clearly defined and articulated through a written agreement and/or appointment as a member of the academic staff of the school;
- practice experiences should include direct interaction with diverse patient populations in a variety of practice settings at a level appropriate to the education and experience of the student and in accordance with pharmacy practice regulations, and provide opportunities for communication and collaboration with other health care professionals.

Framework for experiential pharmacy education involves: (1) experiential learning curriculum; (2) professional practice sites; (3) pharmacy preceptors; (4) student pharmacists, and (5) academic pharmacy departments (**Fig. 1**). Overview of the relevant requirements, and responsibilities of each element are discussed in more details in separate sections.

Experiential Learning Curriculum

Experiential learning curriculum should be based on the well-defined educational outcomes which represent the basis for learning activities design and students assessment. Within the experiential curriculum, focus is shifted from teaching to learning - students are learning by observing, participating and reflecting on the experience, without much instruction received. The responsible academic staff and preceptors should jointly work on the development of experiential curriculum and define potential activities related to each

of the outcome statements. It is also important to generate practice site descriptions and reasonably define educational outcomes in line with the scope and extent of relevant professional practice.

Experiential learning should be initiated from the early stages of pharmacy curriculum (introductory professional practice experiences) and extended throughout the curriculum (advanced professional practice experiences). Learning activities should be carefully designed to accommodate increased level of student engagement from observation (at the beginning of experiential learning) to active participation in relevant professional activities and integration into the pharmacy practice model (ACPE, 2016; FIP, 2014; Hall et al., 2012; Kennerly and Weber, 2013).

EU Regulatory Framework for Experiential Pharmacy Education

In the European Union, in line with the EU Directive on the recognition of professional qualifications, "evidence of formal qualifications as a pharmacist shall attest to training of at least 5 years' duration, comprising at least: (1) 4 years of full-time theoretical and practical training at a university or at a higher institute of a level recognized as equivalent, or under the supervision of a university; (2) during or at the end of the theoretical and practical training, 6-month traineeship in a pharmacy which is open to the public or in a hospital under the supervision of that hospital's pharmaceutical department" (EU, 2013). While this directive provides common minimum standard, different models exist, and preregistration training of graduate pharmacist is still mandatory in some countries. However, the prevalent curriculum model is 5-year integrated Pharmacy program leading to the Master of Pharmacy (MPharm) degree. Integrated Pharmacy curriculum includes the requested minimum of 6-month practice placement and student pharmacists are entitled to take the licensure exam, and register as pharmacists upon obtaining the MPharm degree.

US Regulatory Framework for Experiential Pharmacy Education

In the US, pharmacy curriculum includes at least four academic years of professional studies following a minimum of two to three academic years of pre-professional, college-level study, leading to the Doctor of Pharmacy degree (PharmD). Experiential part of pharmacy curriculum in US includes at least 300 h of introductory pharmacy practice experiences (IPPE), and no less than 36 weeks (1440 h) of advanced pharmacy practice experiences (APPE) (ACPE, 2015). It has been reported that structured pharmacy practice experiences with increased complexity are being south as a strategy to provide student pharmacists with a set of skills and attitudes necessary for independent work (O'Sullivan and Sy, 2017).

The main focus of experiential pharmacy curriculum is direct patient care, where sufficient time must be provided for students to gain the core competencies in this domain. Extended periods of experiential learning placements are encouraged and may include variety of practice settings, beyond community and hospital pharmacies.

Experiential Learning Outcomes

Experiential learning outcomes should be defined in accordance with the overall programmatic outcomes of the pharmacy curriculum and aligned to professional activities at the particular practice site. Well defined educational outcomes serve as a guidance on teaching, learning and assessment for both students and practice preceptors. They should be timely communicated among all the interested parties—academic pharmacy department, students, and preceptors.

Experiential learning outcomes should be defined as clear statements of what student pharmacist is expected to be able to do after a period of practice placement within a particular learning environment, by integration of knowledge, skills and attitudes. They should be specific, relevant, attainable, and measurable. The importance of standardized learning outcomes has been emphasized in order to ensure that, although practice experiences may vary due to different site-specific activities and patient population encountered, student pharmacists will be expected to achieve similar goals. Outcomes statements are usually expressed in the form of relevant competencies, or abilities. More recently, the term "entrustable professional activities" has been introduced as a means to translate competencies into clinical practice in both medical and pharmacy education (Haines et al., 2017; Pittenger et al., 2016; Ten Cate et al., 2015). Entrustable professional activities (EPAs) are described as "units of professional practice or descriptors of work, defined as specific tasks or responsibilities that trainees are entrusted to perform without direct supervision once they have attained sufficient competence" (Ten Cate et al., 2015). It is expected that experiential learning outcomes defined in the form of entrustable professional activities may facilitate decision making about students' readiness for independent practice or progression to the next level of training (Pittenger et al., 2016).

Students Assessment

Students assessment in a complex and dynamic learning environment such as professional practice placement is challenging. Different performance-based assessment tools may be employed, as well as student portfolios (Beck, 2000; Monaghan and Jones, 2005; Swanson et al., 1995). Workplace-based assessment practices may include relevant in-training evaluation reports, mini-clinical evaluation exercises (mini-CEXs), patient reported outcomes, as well as direct observation of performance. However, students assessment generally requires highly standardized, reproducible exam environment. Therefore, performance-based assessments in health professions education are mostly based on simulated problems (case-based scenarios) from the real-world situations delivered in a form of an objective structured clinical examination (OSCE). OSCE is widely recognized as valid and reliable tool

for competency assessment, and can be used to complement traditional written tests, in order to assess students skills against the predetermined standards of performance (Austin et al., 2003; Kirton and Kravitz, 2011; Shirwaikar, 2015).

Introduction of OSCE in pharmacy curriculum is complex, resources intensive and time-consuming. It requires careful planning, and sufficient number of dedicated staff which will: (1) prepare relevant blueprint defining the number and topics to be covered at each OSCE station; (2) prepare database of relevant and realistic clinical case-based scenarios, and (3) provide training for all the examiners, as well as orientation of simulated/standardized patients engaged.

Student portfolios are widely used as both learning and assessment tool in experiential pharmacy education (Briceland and Hamilton, 2010; Driessen, 2017; Peeters, 2017; Plaza et al., 2007; Skrabal et al., 2012). It is expected that portfolio should provide comprehensive evidence of student's learning, performance and professional development. However, wider use of student portfolios has introduced certain criticism and controversy. Both students and teachers are sometimes reluctant to fully employ it. It has also been recognized that use of portfolios may become overly bureaucratic, and fail to meet the expected educational value. In order to be meaningful, portfolios should be integrated into curriculum as part of the assessment program, and contain diverse contents which can be used as the guide for discussion with preceptor, thus enabling relevant feedback and supporting further learning and progress (Eva et al., 2016).

Professional Practice Sites

It has been emphasized that "learning-rich" environment is one of the essential elements of quality experiential education. This is described as "practice site that allow the opportunity for students to engage in the direct care of a diverse population of patients and provide opportunities to interact with other healthcare professionals on a daily basis" (Haase et al., 2008a, Haase et al., 2008b).

Practice sites should be approved and continuously monitored by the academic pharmacy department. It has been stated in the relevant quality standards that "to support the pharmacy practice experiences in the curriculum and to collaboratively advance the patient care services of pharmacy practice experience sites, the school should establish and implement criteria for the selection of an adequate number and mix of practice facilities. The respective responsibilities, commitments, and expectations of the school and the practice site regarding the education and evaluation of students should be agreed and, ideally, formalized in a written agreement or contract" (FIP, 2014).

As mentioned in the previous section, student pharmacists can be placed in various practice settings. Mandatory placements include healthcare facilities involved in providing direct patient care, such as community and hospital pharmacy, as well as ambulatory patient care. Possibility for placements in pharmacy practice settings outside the traditional fields of community and hospital practice are also available, and referred to as alternative, role-emerging placements (Kassam et al., 2013). It should be taken into account that different practice sites may vary considerably with respect to services provided, patient population, number and professional structure of employees, preceptors experience, and opportunities for interprofessional interactions. Independent community pharmacy team, for example, can be quite small and with limited opportunities for student interaction with other health-care professionals, compared to large hospital pharmacy department. However, even the most advanced practice sites cannot secure per se that learning will occur if students are not looking for opportunities to learn and engage in work-based activities.

Pharmacy Preceptors

Qualified preceptors have vital role in experiential education. Pharmacy preceptor should demonstrate the ability to use clinical teaching roles, and act as instructor, role model, coach and facilitator. It has been recognized that, as instructors, preceptors encourage application of didactic knowledge through discussion with students during learning situations as they evolve, as role models, preceptors embody professional attitudes, values, and ethics by continually demonstrating these attributes over the course of the experience (Harris et al., 2012); as coaches, preceptors guide students through new experiences and difficult decision-making situations (Chase et al., 2015); as facilitators, preceptors create the infrastructure within a practice site that fosters and supports student learning (Littlefield et al., 2004).

Quality standards for pharmacy education state that schools should have "a sufficient number of preceptors to effectively deliver and evaluate students in the experiential component of the curriculum" (ACPE, 2015). It is also stated that "school should identify pharmacist preceptors who will be positive role models for students; who practice ethically and with compassion for patients; accept personal responsibility for patient's health outcomes; have professional training, experience, and competence commensurate with their position; have a desire to educate others; and have an aptitude to facilitate learning and evaluate the achievement of required competencies by students" (FIP, 2014).

In order to be effective instructors, preceptors must demonstrate expert knowledge and skills. Generally, preceptors should be recruited among the registered pharmacists who meet certain predefined criteria related to professional practice experience. They should attend initial orientation and periodical training and be certified by the academic pharmacy department. Further attributes of an excellent preceptor have been recognized as the ability to develop a relationship with the student, demonstrate skills and adaptability in teaching, encourage students to actively participate in discussion and problem-solving exercises, display positive preceptor attitude, and serve as a role model (O'Sullivan et al., 2015; Walter et al., 2017; Young et al., 2014). In the majority of studies, the importance of personal attributes of exemplary preceptors (rather than their credentials) has been highlighted. It has been emphasized that successful preceptors convey enthusiasm, professionalism, and knowledge of pharmacy to student pharmacists, and in doing so, enhance their own satisfaction and promote the profession (Skrabal et al., 2006). Being a preceptor should

be an expectation of the job. Preceptors should be provided protected time to educate students and be rewarded for their efforts (Cox, 2016).

Preceptor's responsibility is to engage student pharmacists in meaningful learning activities, ensure appropriate student interaction with patients, caregivers and other health professionals, support students and challenge them in a way that would make them "supported participants in practice at the highest level of involvement that their ability and the clinical situation permits, and adapt their behavior student-by-student and situation-by-situation" (Dornan et al., 2009). Preceptor is also expected to perform student assessment and confirm if student has attained the expected learning outcomes, as well as the level of achievement. Preceptor should clearly communicate relevant expectations, monitor student's progress and provide constructive and timely feedback. In order to serve as preceptors, pharmacy professionals should be prepared for the new role and challenges it might bring. While willingness and motivation to contribute to pharmacy education and advancement of the profession could be viewed as a prerequisite for successful preceptor, further re-training and orientation is necessary. Academic pharmacy departments are responsible for design of preceptor development programs which will address specific issues related to teaching and learning in clinical practice. These courses should be accredited continuing professional development courses and should be accompanied by regular preceptor orientation and development sessions.

Serving as preceptor is professionally rewarding and associated with certain advantages such as contribution to education of future pharmacy professionals and evolution of the profession, knowledge reinforcement through student interactions, continuing professional development and personal growth (Rathbun et al., 2012; Skrabal et al., 2006).

However, there are also numerous challenges related mainly to increased workload without financial remuneration, need to find the right balance between provision of direct patient care and students involvement, students assessment, and dealing with wide variations in student attitudes, knowledge and skills, as well as unprofessional students' behaviors. In order to successfully manage increased workload, precepting student pharmacists should be identified as job responsibility of the qualified preceptors and embedded in their professional practice. Academic pharmacy departments should provide continual support for pharmacy preceptors to develop "an advanced pharmacy practice patient care model where student learning is integral to the patient's care" (McGivney, 2009). Preceptors contribution to pharmacy education should be acknowledged by students and academic pharmacy departments, as well as professional organizations through relevant preceptors award and recognition program (Whalen et al., 2017; Worrall et al., 2016).

Student Pharmacists

Quality experiential education provide numerous benefits to student pharmacists. Experiential learning provides opportunity to better understand theoretical knowledge gained during the didactic part of the curriculum, integrate and apply it in direct contact with patients, develop critical thinking and decision-making skills, and build confidence necessary for future professional practice. Experiential education provides relevance, by focusing on real professional practice problems, active participation, feedback, individualization, interprofessional experience, career choice, and enhanced employment prospects, thus being a valuable professional and personal experience even for those student pharmacists who are not inclined toward clinical pharmacy career. In line with the current requirements that pharmacy graduates should be "practice ready", it is expected that through advanced professional practice placements student advance from competent to proficient practitioner.

Transition from the safe learning environment of the academic pharmacy department into real workplace may be quite challenging. Student pharmacists often develop anxiety and tension trying to cope with the differences in learning environment and teaching styles between the classroom setting and professional placement site. They may also worry about the workload and performance expectations, and making mistakes, as well. When involved in patient care delivery, responsibility for decision-making adds a dimension that turns mistakes from something that means a low grade to something that impacts a patient (Henman, 2015).

Therefore, student pharmacists should be well prepared for professional practice placements. Academic pharmacy department is responsible to provide students with the necessary orientation and support, and to assess student preparedness. In order to progress to professional placement, student pharmacists need to acquire certain competencies that facilitate experiential learning and assure patient safety. For that purpose, students must complete professional study modules determined by the academic pharmacy department, relevant orientation and readiness assessment. Different approaches based on early introduction of professional practice experiences into curricula, increased clinical contacts, and short transitional courses have been employed in health professions education in order to improve students preparedness for clinical practice. Chipchase et al. (2012) investigated clinical educators' views on the characteristics of health professions students that are important for preparedness for clinical learning. Six themes that can be used as indicators of student preparedness for the clinical learning environment have been identified as: (1) knowledge and understanding, (2) willingness, (3) professionalism, (4) communication and interaction, (5) personal attributes, and (6) professional and interpersonal skills (**Box 1**). Student pharmacists' professionalism is highly important for their integration into professional practice. Experiential learning provides excellent opportunities for improving student professionalism through interaction with role model preceptor, self-evaluation and feedback received (Hammer, 2006).

Academic pharmacy department should provide simulated experiences that provide students the opportunity to apply and practice concepts in a controlled environment before actually performing them (Hardya and Marshall, 2017; Lin et al., 2011). This may include interaction with simulated patients, or virtual patients. Simulated practice settings provide controlled learning environment which enables repetition, and where mistakes can be used to support learning. They should be used to develop

Box 1

Indicators of student preparedness for the clinical learning environment
(adopted from Chipchase et al., 2012)

- knowledge and understanding
- willingness
  i.e. to work as a team, ask questions, discuss, receive constructive criticisms, take responsibility to their own learning, etc
- professionalism
  understanding the code of conduct and ethics of the profession, timeliness, appropriate appearance, regular attendance, complies with confidentiality and other professional matters, etc
- communication and interaction
- personal attributes
  enthusiasm and interest, empathy, desire to learn, self reflection, helpfulness, politeness
- professional and interpersonal skills
  organizational and time management skills, social skills, problem-solving skills

communication and counseling skills and undertake performance assessments. Simulated practice settings can also be used to assess students preparedness to progress to experiential part of the curriculum. The need for standardized examination to document readiness for experiential learning has been recognized (Meszaros et al., 2009). In experiential learning, students are physically engaged in professional activities with real consequences (Hoberman and Mailick, 1994). Students learn by participating in the activities in the practice site, particularly ones that are challenging. According to the Experience-based learning model (ExBL), during experiential placement students progress through the four levels of participation starting from passive observation up to supervised care delivery (Dornan et al., 2009). It is expected that graduate pharmacist will exhibit intrinsic willingness and enthusiasm to entry professional practice; however, some student pharmacists may be somewhat less inclined to do so. For the majority of graduates, professional practice placement is a matter of choice, while some students may find it as additional, complex and demanding, curricular burden, especially if the individual is not inclined toward the pursuit of clinical pharmacy career.

Other challenges that student pharmacists may encounter during professional practice placements include situations in which students are perceived as burden, rather than a contributing member of the health care team, due to the fact that students often do not have clearly defined roles at practice site and they are not well integrated into the patient care, or working with preceptor who is being overprotective, allowing student virtually no independence, or working with an unprepared or inexperienced preceptor, which can also adversely affect the students' view of the profession.

In order to develop responsibility, self-confidence and professionalism, it is important that student pharmacists are recognized as part of the health-care team with tasks and activities which are defined in line with their level of competence, institutional rules and regulations, as well as relevant learning needs.

Quality Assurance in Experiential Education

In the modern pharmacy curriculum, experiential education is integrated with didactic teaching in such a way that on successful completion of the study program, graduates are eligible to apply for professional licensure. Academic pharmacy departments are responsible for planning, organization and quality assurance (QA) of experiential curricula, although its delivery is "outsourced" to other institutions. It is important to note that all standards of quality assurance in higher education pertinent to didactic curricula should be also met for the experiential education. Quality assessment of practice sites, preceptors and student's delivery of care is responsibility of the academic pharmacy department. Similarly to didactic curricula, consistency and quality across different placement sites should be accomplished in order to secure minimum common performance standards for all graduates (ACPE, 2015).

Quality assurance framework for experiential education is based on: (1) implementation of relevant standards related to practice sites and preceptors selection, subcontracting and evaluation, (2) assessment and certification of students compliance and readiness for practice placements, (3) monitoring preceptors and students performance (through regular site visits, timely communication and feedback obtained from students and preceptors), (4) periodical review, and (5) continuous quality improvement (**Fig. 2**).

Academic pharmacy department should define relevant standards based on the general quality standards available, and taking into account specific requirements and expectations related to national legislation, educational and health-care system.

Quality assurance framework for experiential education relies on a well-developed and maintained database and extensive documentation. Establishment of the appropriate e-platform is of great importance. Both students and preceptors should be informed in detail about the educational outcomes, curriculum, assessment and time frame of the practice experiences. Relevant information, procedures, QA documents and forms requested should be compiled in the guideline document (i.e. Experiential Education Manual/Handbook). Academic pharmacy department should timely provide necessary support for students, as well as preceptors, including relevant information, advise, students placements scheduling, remediation, or conflict resolution, when applicable.

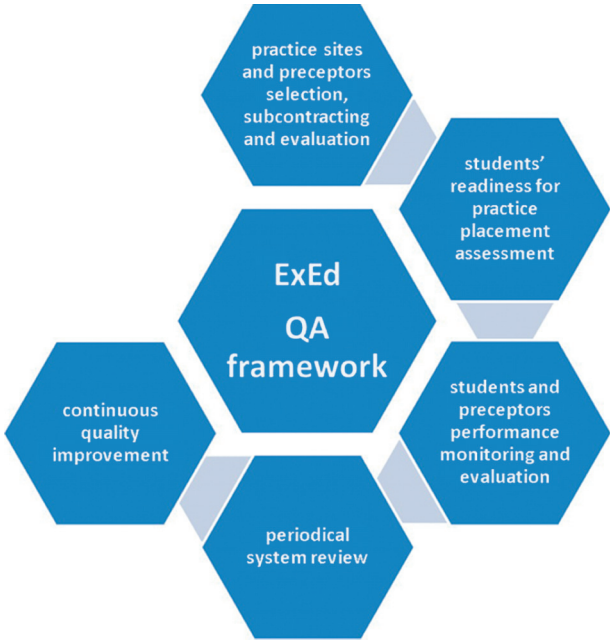

Figure 2 Quality assurance framework for experiential education.

In order to meet relevant quality standards, academic pharmacy departments have to provide financial and human resources necessary to operate a successful experiential education program (Danielson et al., 2014). Taking into account the complexity of activities related to management of professional practice placements and the adjacent workload, it is recommended to appoint person responsible for overall management and administration of experiential curricula, as well as to establish separate office/center with sufficient staff to take care of all the responsibilities.

Quality assurance of experiential education has been identified as priority area for improvement from a number of sources (Cox, 2016; Frail et al., 2017). ACCP Position Statement on ensuring quality experiential education (Haase et al., 2008a, Haase et al., 2008b) provides excellent reference for those aiming to establish new or improve the existing experiential curricula, as well as the more recent commentary on supporting quality in experiential education through enhanced faculty engagement by Frail et al. (2017).

Advancing Experiential Education in Clinical Pharmacy

In order to advance experiential education in clinical pharmacy, all the interested parties should share the common vision on the future prospects of pharmacy profession and emerging roles of pharmacists. Contribution to education of future pharmacists is one of the roles of pharmacists and should be considered professional responsibility and supported by employers, professional organizations, and regulators as advanced professional practice. Schools of pharmacy should act to instill this responsibility and professionalism in student pharmacists from the early stages of pharmacy education, and further nurture it through their professional career.

General concerns related to experiential learning in pharmacy education are that students are not actively involved in professional activities, but merely observing/shadowing, that they are most frequently engaged primarily in medicines dispensing, and that some placements sites do not provide level of pharmaceutical care which is requested in order to promote learning. However, contemporary pharmacy education is expected to prepare graduates to act as independent practitioners and provide patient care. Taking into account major challenges encountered within the experiential education framework, two points for action have been identified as crucial for further advancement and sustainability of experiential pharmacy education: (1) preceptor development program and (2) integrating students into professional pharmacy practice.

Preceptor Development Program

Quality experience and sustainability of experiential learning for student pharmacists depend on the availability and commitment of competent pharmacy preceptors. Preceptor development program should include recruitment, orientation, continuing professional development, evaluation, and recognition of qualified pharmacy preceptors. Academic pharmacy departments should collaborate with professional associations to develop comprehensive preceptor development program using variety of tools and methods

Box 2

Competency statements for pharmacy preceptors
(adopted from Walter et al., 2017)

- Demonstrate a commitment to teaching as a means for growth and skill development for each learner
- Create practice-based learning opportunities by promoting active collaboration in client care
- Engage in continuous reflection, self-assessment and lifelong learning to improve their effectiveness as educators
- Demonstrate effective communication skills
- Create professional relationships with students
- Adapt to students' learning needs
- Model best educational and clinical practices to facilitate development of skills
- Facilitate student development of critical thinking, problem solving and decision making skills
- Assess and document student pharmacist performance

of delivery (Assemi et al., 2011; Boyce et al., 2008; Worrall et al., 2016). It could include different online, and/or printed materials, e-learning modules, preceptor newsletter, as well as "face-to-face" training and networking events, including practice site visits (Vos and Trewet, 2012).

In order to develop core competencies of an effective preceptor and identify performance indicators to guide preceptor growth, Preceptor competency framework for pharmacists has been recently developed within the Canadian Experiential Education Project for Pharmacy (CanExEd). It is expected that this framework can serve as the foundation of a national preceptor development program, be integrated within the continuous professional development (CPD) process, serve as a critical component of experiential quality assurance programs (preceptor evaluation), help with identification and recruitment of quality preceptors, and be contributing criteria used for selection of preceptor awards and other recognitions (Walter et al., 2017). The list of proposed competency statements for pharmacy preceptors is presented in **Box 2**.

Recognition of excellent preceptors is important aspect of preceptor development program (Harris et al., 2012). The purpose of such program is to recognize preceptors for their sustained commitment to excellence in experiential education and professional practice. Criteria for candidates selection are based on demonstration of overall contribution to experiential education, pharmacy practice, and service to the profession. Majority of schools of pharmacy, as well as relevant professional organizations in US, have some preceptor recognition award established, such as the Master Preceptor Recognition Program established by the American Association of Colleges of Pharmacy (AACP) in 2014.

Integrating Students into Professional Pharmacy Practice

It has been recognized from a number of sources that effectiveness and sustainability of experiential pharmacy education can be achieved only if student pharmacists are adequately integrated into professional practice. It has been emphasized that "accommodating increased numbers of students for experiential training would only be possible if the hosting organizations perceived that they were receiving value in return for their contribution to the training of pharmacy students" (Hall et al., 2012). In order to achieve this, student pharmacists should be recognized as contributing members of the health care team. Reviews of the available literature on the value of student pharmacists in experiential education indicate that student pharmacists have positive impact on patient care through extended services, as well as positive economic impact through cost reductions (Mersfelder and Bouthillier, 2012; Whalen et al., 2017). Kennerly and Weber (2013) advocated that student pharmacists can assume an integrated and accountable role in the practice model by having defined responsibilities for patient care. Different ways to integrate students into clinical practice has been described as (1) stepwise incorporation into patient encounters, (2) planned integration into service-related activities, and independent projects (McGivney, 2009).

Incorporating students into patient encounters should be approached stepwise, beginning with a general overview of the patient service and the expectations of patients, preceptors, and other health professionals at the site. Independent projects can provide another level of learning for students at a clinical practice site. In addition to practice-related projects, students may be involved in other patient care-related activities, including responding to drug information questions and reviewing patient charts. Thoughtful planning of activities and integration of students into patient care can provide a wealth of resources to the site that enrich rather than overburden the faculty member (McGivney and Weber, 2009). Hall et al. (2012) argue that "experiential training would need to be designed to gradually increase, over the duration of pharmacy program, students' responsibility and accountability for patient outcomes associated with drug therapy". By assigning specific tasks to students, some of the time pressures placed on clinical pharmacists to perform these functions can be alleviated. In order to increase the accessibility, quality, quantity and variety of experiential learning opportunities, and promote and increase interprofessional and intraprofessional approaches to education and training, it is necessary to secure funding to design, evaluate, and disseminate best practices of experiential learning; create an inventory of best practices and examples of exemplary models in experiential learning; create, evaluate, and disseminate new learning models, and support mechanisms for practitioners to offer experiential learning opportunities (Task Force on a Blueprint for Pharmacy, 2008).

Acknowledgment

Jelena Parojčić would like to acknowledge Fulbright Visiting Scholar grant which provided an opportunity for a 6-month study visit with the Office of Professional Pharmacy Education, School of Pharmacy, University of Washington to explore the tenets of exemplary pharmacy experiential education program.

Glossary

Academic Pharmacy Department - organizational unit within higher education institution, which is responsible for planning, administration and evaluation of experiential education (typically, Office of Experiential Pharmacy Education, or equivalent);
Entry-level practitioner - practitioner who has the competencies required to practice safely and independently as a newly licensed pharmacist;
Experiential Learning - structured or semi-structured learning activity that takes place in a practice setting, under supervision of an experienced practitioner, and in direct contact with patients and other healthcare professionals, that involves authentic/real-life situations and interpersonal interactions (term often used interchangeably with: practice-based learning, situated learning, clinical learning, experience-based learning, learning from experience, traineeship) (FIP, 2014);
Fitness to practice - demonstration of the skills, knowledge, attitudes and abilities required to practice safely and effectively as an independent practitioner (GPhC, 2018);
Practice site - healthcare institution, or other appropriate setting, which provides learning environment for experiential pharmacy education (FIP, 2014);
Preceptor - practitioner who teaches, supervises, and evaluates students in his or her professional practice setting (often used interchangeably with: teacher practitioner, clinical instructor, practice supervisor, mentor) (FIP, 2014);
Professionalism - the demonstration of ethics, attitudes, values, qualities, conduct, and behaviors that characterize a profession, are expected of its practitioners, and that underpin the trust that the public has in the profession (FIP, 2014);
Role-emerging placements - placements in practice settings outside the traditional fields of community and hospital pharmacy (Kassam et al., 2013);
Student pharmacist - student enrolled in a pharmacy degree program (the term is used intentionally to reflect the role and responsibility of the student as a member of the profession of pharmacy from the day a student is admitted to pharmacy study program) (APhA–ASP, 2016).

Indicators of Quality of the Patient Care in Hospital and Community Settings

Arijana Meštrović*, Sherif Kamal†, *Pharma Expert, Croatia; †Children's Cancer Hospital, Egypt

Quality of Health-Care Services

Before implementation of indicators of quality of the patient care in hospital and community settings, it is important to understand the need to define, evaluate, and advance the quality of pharmacy practice.

Pharmaceutical care is the responsible pharmacist's practice, which provides safe and the best available therapy for the patient. It is the professional activity in which the pharmacist, using his knowledge and experience, identifies patients' needs, set priorities in the treatment process, and takes responsibility for a positive outcome of drug therapy (Hepler and Strand, 1990). That responsibility is shared with the medical doctor who has determined the diagnosis and prescribed therapy, but also with patients, encouraging them to compliance, frequent checks, and counseling about responsible treatment. There are many variations in providing patient care, but quality of services should ever be compromised.

Pharmaceutical care derives from the principles and postulates of clinical pharmacy; which pharmacists recognize as the scientific basis for intervention in the treatment of patients. The concept of clinical pharmacy clarifies the role of the pharmacist in the process of providing health care. It involves different ways of cooperation of health professionals in which science and practice can be linked to patient care. For such interventions to have the biggest impact possible, it is not only necessary to develop clinical knowledge, but also communication skills, judgment, and decision-making. Clinical practice should play an increasing role in the daily work of a pharmacist, instead of being just one of the possible options or specialty area of practice for a pharmacist (Hepler, 2004).

Today, the implementation of quality indicators for pharmacy practice will play a great role in the global effort of pharmacy advancement, while many countries are trying to incorporate clinical pharmacy and pharmaceutical care concepts in their health-care system. Although such attempts are of great interest to national and international pharmacy organizations, many challenges often appear in the implementation of this concept. Some of the difficulties may include: attitudes and opinions of other health professionals, lack of cooperation, and inadequate communication between them, and an insufficient number of pharmacists, space or equipment for the provision of pharmaceutical care, and the structure and organization of health care.

The quality indicators, when used to analyze those gaps in pharmacy practice, can provide a clear roadmap of implementation of pharmaceutical care, as well as the evidence that will help in closing the mentioned gaps.

Quality indicators can describe the possible ways to introduce innovations in pharmacy, shaping pharmacy future in a patient-oriented way. Innovative cognitive services are needed in rationalization of medicine therapy and patient education. Cognitive pharmaceutical services can be defined as professional services provided by pharmacists, who use their skills and knowledge to take an active role in patient health, through effective interaction with both patients and other health professionals. Various models of data collection, assessment tools and implementation strategies are needed to innovate and drive sustainable changes in pharmacy. All those aspects can be described and defined in the set of indicators (Smith et al., 2017).

Good Pharmacy Practice

Guidelines for Good pharmacy practice (GPP) were published by International Pharmaceutical Federation (FIP) and World Health Organization (WHO) with the intention to provide a description of ways in which pharmacists can improve access to health care, health promotion, and the use of medicines to the patients they serve (International Pharmaceutical Federation (FIP), 2011).

National pharmacy professional organizations are using the guidelines to implement them into their pharmacy practice, by setting national standards to assure the quality of services. The context of practice vary widely from country-to-country and each national pharmacy professional organization is adjusting the main principles to the local environment.

The vital element is the commitment of the pharmacy profession worldwide to promoting excellence and professionalism in practice for the benefit of the patients into practice in all settings, especially community and hospital pharmacy settings.

Besides the traditional role of pharmacists which is to prepare, procure, store, secure, distribute, expose, dispense medicines, and medical products, there are other roles described in those standards, such as role to provide rational pharmacotherapy to the patients. That would mean to assess the health status and needs of the patient, to manage the therapy processes, to monitor the outcomes of treatment and progression of the patients and to provide information on medications and treatment procedures. GPP also emphasize the need for pharmacists to achieve excellence and continuous improvement by planning and implementing continuous professional development for pharmacy competencies advancements. Public health aspect is described as the need for pharmacists to contribute to the effective functioning of the health system and public health activity by informing and educating patients about medicines, prevention and health, active involvement in the prevention, and treatment outcome procedures. There is to act in line with the national context, guidelines and legislation and to actively support and promote national strategies that aim at a good outcome of treatment and patient safety. FIP/WHO Guidelines on Good Pharmacy Practice (2011).

Indicators of Quality of Pharmaceutical Care

Indicators of quality of pharmaceutical care are equally appropriate for hospital and community settings, for hospital and community pharmacists, and other health-care professionals. The indicators should be applicable in any region of the world, providing information about the range, quantity, and quality of pharmaceutical care interventions/services delivered.

In the context of quality management, the pharmaceutical care is a process of medication therapy management and direct patient care, which is patient centered, drug focused and outcome oriented. The application of pharmaceutical care in various settings need to be standardized and measured to allow its management and improvement, and thus play a great role in setting smart standardized goals and a tool for measurement and improvement.

Indicators can help the pharmacists to organize to document and track the processes related to quality of care, to define benchmarking, decide on priorities, clarify accountability, set accreditation standards, and to ensure quality improvement.

In addition, the indicators provide information about the range, quantity, and quality of pharmaceutical care interventions/services delivered as well as an opportunity to gather in-depth knowledge on pharmaceutical care practices regionally, nationally, and internationally that will permit the sharing and follow-up of experiences over time by professional disciplines and the health sector in general, regionally, nationally, and internationally.

These indicators are rather broad, and can be further developed and refined over time, but they are easily understood and will help pharmacists, other health-care providers, and professional regulators to formalize and develop the pharmaceutical care philosophy and its working methods.

Indicators provide a quantification required to manage and improve the medication and patient care processes.

The pharmaceutical care concept is envisioned to assure the quality of services to maintain patient safety and achieving the outcomes through rational usage of medicines.

It is expected that pharmaceutical care programs will be reflecting positively on all health care programs within the strategic plans of many health-care systems in the world. Therefore, the competence of members of the pharmacy workforce is considered as the fundamental element to provide comprehensive and sustainable pharmaceutical care.

To achieve that, the strategy should be defined on the national, regional, and international levels. Indicators of quality of services should be developed for the current and targeted situations, with a concrete estimate of the desired level of implementation. The elements of regulation, education, and practice are described should be connected, in constant communication, to achieve the goal.

Classification of Quality Indicators in Health Care

In the era of universal health coverage, the indicators are the main tools that will provide a clear unified standardized roadmap for reimbursement based on performance (Joint Learning Network for Universal Health Coverage, 2018).

According to the Donabedian model, indicators can be used to assess the quality of a health care related to their structure, process, and outcomes. Those aspects could describe the setting of delivery of care, the procedures in health-care setting, and the effects of health-care services on the health status of patients and populations (Donabedian, 1983).

Structural measures indicate capacity of the health-care systems, and processes to provide care. Some examples are: the use of automation, electronic medical records, and medication order entry systems. Some indicators are describing the number of board-certified pharmacists, the ratio of number of pharmacists to the number of the patients.

The structural indicators are the measures that monitor variability in processes and focus on hospital or community pharmacy characteristics and need to have linkage to outcomes significant to the pharmaceutical care. If the quality improvement is the aim of the quality initiatives and monitoring, the indicators of the process need to be selected and implemented to the system of quality assurance. Interpreting process measures should be simple and more sensitive to small variability compared to the outcome indicators measurements (Mant, 2001).

Also, some processes, such as policies and procedures on medication reconciliation could be measured by indicators, as they are crucially important to assure patient safety (Van Sluisveld et al., 2012).

Other process measures can also indicate important compliance with standards, guidelines, and best pharmacy practice
Some examples could be:

- The percentage of patients receiving prophylaxis as indicated (immunizations).
- The percentage of patients that are treated according to first line guidelines.
- The percentage of patients with a certain disease for whom recommended laboratory tests are ordered.
- Percentage of encounters, where the pharmacist implemented guidelines

Outcome measures reflect the results of a certain service or intervention done for patients (Campbell et al., 2002)
For example:

- Mortality rates
- Hospital-acquired infections
- Patient satisfaction rate of a certain pharmacy services.

Indicators related to the outcomes are most useful for tracking care process given by high-volume providers over long periods of time, and for detecting problems in implementation of processes of care. Outcome indicators could be used when variations in health care might result in significant variations in health outcome of the patients, and where this occurrence is sufficiently common.

Palmer and Reilly (1979) recommended choosing outcomes measures if:

1. Outcomes can be measured that are affected by health care;
2. Long time-frames for measuring the outcomes are available;
3. Performance of the whole health-care systems should be studied;
4. High volume of cases is available.

A key consideration in the indicator's selection process is the practicality and capacity of its measurement. It is important that indicators can be understandable to the users, clear and precise, also applicable in the practice settings (Rubin et al., 2001).

Indicators are also used to measure the pharmacist's capacity, value, and importance in the health-care system. The indicators will allow many stakeholders to identify gaps and/or opportunities and threats to build a successful strategy to improve health-care services provision. Quality indicators are the first step in setting and operating a pharmacy service in a hospital setting. It is important to ensure that the members of the health-care team can assess all aspects of the health-care provision in the systematic way, to assure the awareness of quality analyses and improvements.

One of the most commonly used indicators classification in the health care are ECHO indicators. The abbreviation stands for Economic, Clinical, Humanistic and Outcomes and it could be applied in many sectors of the health care. There are tools developed to use the indicators and their rationale within the ECHO performance framework is explained, as well as some insights on their adequate use (Bunting, 2006).

A rate-based indicator lists compile the data about events that are expected to occur with some frequency. These can be expressed as proportions or rates (proportions within a given time period), ratios, or mean values for a sample population. To permit comparisons among providers or trends over time, proportion- or rate-based indicators need both a numerator and a denominator specifying the population at risk for an event and the period of time over which the event may take place.

A sentinel indicator identifies individual events or phenomena that are intrinsically undesirable, and always trigger further analysis and investigation. Each incident would trigger an investigation. Sentinel events represent the extreme of poor performance and they are generally used for risk management (Ansari and Collopy, 1997).

Examples of rate-based and sentinel indicators

Rate-based indicators	*Sentinel indicators*
Clean and contaminated wound infection	Numbers of patients who die during surgery
Hospital-acquired infections	Numbers of patients who die during the perinatal period
Contaminated intravenous preparation	Numbers of near miss
	Number of patient with MDR cultures

Generic indicators measure aspects of care that are relevant to the most patients, while disease-specific indicators are diagnosis-specific and measure particular aspects of care related to specific diseases.

Examples of generic and disease-specific indicators

Generic-specific indicators	*Disease-specific indicators*
Ratio of pharmacists to other health-care professionals	Ratio of patients with stroke treated with thrombocyte inhibitor <24 h after admission
STAT Medication ratio delayed more than 30 min	Ratio of patients dead after 30 days of antimicrobial treatment
Readmission within 15 days	Ratio of patients who receive restricted medications

How to Validate and Adopt the Set of Indicators in Different Pharmacy Settings?

The process of developing indicators will provide a framework that clarify accountability, allows benchmarking, and identifies areas for improvement of services in certain pharmacy setting. Set of indicators should be determined by the local context and national health strategies.

For every indictor it is recommended to set a benchmark (Fernandes et al., 2015). This can be done either by using historical data from the work setting or from literature, to set the baseline target.

The steps of developing indicators will involve:

1. Meeting and interviewing stakeholders (looking for what is critical for them)
2. Meeting with the pharmacy practitioners from different settings
3. Performing a workshop with panel group to summarize the critical to quality indicators mentioned by stakeholders and to establish a list of indicators
4. Compile the list of a draft of agreed indicators by the consensus
5. Meeting with quality department and top management to take official approval
6. Outlines of the set of indicators, determination of data collection, analysis and action plan
7. Indicators' implementation needs to be piloted for 3-month period
8. Revaluating the indicators after the 3 months period and reporting to top management, deciding on the future plan of action

An ideal indicator would have the following key characteristics:

1. Indicator is well defined and described in the indicator identification card
2. Indicator is specific and sensitive
3. Indicator is valid and reliable
4. Indicator is relevant to clinical pharmacy practice
5. Indicator permits useful benchmarking
6. Indicator is evidence-based.

A major focus need to be drawn to the validity and the reliability of the indicator, where validity is the degree to which the result of a measurement corresponds to the true state of what is being measured and Reliability is the extent to which repeated measurements show results that have no statistical significance (Sackett et al., 2000).

Fernandes et al. (2015) stated that the indicator should be:

1. Reflecting a desired quality of practice
2. Linked to the direct patient care
3. Evidence based
4. Pharmacy- or pharmacist-sensitive
5. Measurable

Incorporating indicators in Failure Mode and Effects Analysis (FMEA) processes will allow a new dimension of redesigning patient care and medication management process. FMEA is a structured approach to discovering potential failures that may exist within the design of a product or process.

Measurement and Documentation

The methods of measurements, evaluation, and documentation should be defined. In some cases, indicators can be defined as key performance indicators (KPI) and to be a part of the quality assurance systems in hospitals and community pharmacies.

Indicators can be described in the form of questions (e.g., Are pharmacists checking adherence when dispensing the medication?) or statements (Pharmacists are checking adherence when dispensing the medication.). To rate (measure) the indicators of quality for pharmacy services, they need to be quantified. Evaluation can be done with selected scale (e.g., Likert scale, a psychometric scale commonly involved in research that employs questionnaires). Ratings can be done in more descriptive way (e.g. What kind of improvement is needed (substantial, minor, etc.).

The results of measurement and documentation, when collected and analyzed in form of indicators ratios, will allow pharmacists to interpret the current situation and to plan the improvements (Bruchet et al., 2011).

When focusing on continuous improvement pharmacy practitioners will also need to balance the use of outcome and process indicators and to identify and build the link between process and outcomes of their services.

Pharmacy Services and Indicators of Quality—Some Examples

In the following text, some examples of quality indicators for pharmacy services will be described (Council of Europe (EDQM), 2017).

When the catalog of indicators is created, some of the further aspects can be selected:

CPD/CE Activities of the Pharmacy Workforce

Despite the differences in CE/CPD requirements all over the globe, it is expected that pharmacy workforce is well trained and updated in their knowledge and skills to provide quality services in different settings of health care. To assure quality of services, education, and training of pharmacists and their teams should be specific, self-directed, related to their daily practice, and applied to improve the quality of their performance. It is a good indicator if pharmacists and pharmacy technicians completed the specialized courses and training to even expand the scope of their practice and offer more services to their patients. Some of the examples might be: Immunization courses, Medicine therapy management trainings, Patient care process courses for various chronic diseases, Smoking cessation training courses, etc. It is especially visible if the pharmacy staff is changing and improving their communication and approach as the essential part of the patient care after completing the communication skills training, especially Motivational interviewing courses. What also makes difference in the quality of services is the existence of the competency and performance assessment of their learning and implementation in the practice. If pharmacists and pharmacy technicians are expected to be evaluated and encouraged to develop, if they are required to maintain the learning portfolio to plan and track their learning and application into practice, the quality of services will be higher (Bader et al., 2017).

To assess the indicators of quality in this area, some of the following questions might be used for the self-assessment or peer-assessment in community and hospital settings:

CPD/CE activities of the pharmacy workforce
Are pharmacists attending internally organized education activities?
Are pharmacists attending any other pharmaceutical care courses?
Does pharmacy team have enough number of specialists in pharmaceutical care or clinical pharmacy?
Are pharmacists regularly assessed to identify the level of competencies and to plan the improvements?
Are pharmacists maintaining a CPD learning portfolio?
Are pharmacists planning their individual learning?

Patient Safety

One of the most important indicators of quality of services is the existence of the patient safety policies and procedures in community and hospital pharmacy settings.

Patient safety should never be compromised; therefore, the system should assure that pharmacists and pharmacy technicians have standardized operating procedures to follow and to assure the patient safety is maintained during offering the services of the patient care.

Patient safety could be compromised on many levels of service delivery, such as storing and preparing the medicines, during administration and dispensing of medicines, during documentation process and discharge from the hospital, including both individual and organizational factors to influence the safety (Pronovost et al., 2006).

To assess the indicators of quality in this area, some of the following questions might be used for the self-assessment or peer-assessment in community and hospital settings:

Patient safety
Are medication safety programs, policies and procedures established and applied in the institution?
Are the symptoms that require physician/doctor intervention explored and identified before supplying medication?
Is the appropriateness of the medicine for the actual patient assessed before deciding whether or not to dispense the medicine?

Patient safety (cont.)
Are quality reports submitted regularly?
Are supplies arranged in a code-wise system?
Are items properly labeled (expiry dates, alerts, and special warnings)?
Does the institution have sufficient and adequate storage space, that comply with required specifications?
Are cleaning and hygienic standards obtained and checked regularly?
Is patient identity checked properly?
Is patient's understanding of dispensed drug checked and maintained?
Are pharmacists using evidence-based resources regularly?

Rational Pharmacotherapy

Pharmacists should take medication history from the patients regularly in primary, secondary, and tertiary care, setting the priorities in therapy management when they identify drug-related problems (DRP). All pharmacists should be able to set the priority using clinical guidelines and tools, such as START and STOPP criteria, to contribute in the rational pharmacotherapy and patient outcomes. It is important that individual therapeutic plan for patients is created in a structured and evidence-based way. Application of the STOPP/START criteria: a systematic review of the prevalence of potentially inappropriate prescribing in older adults, and evidence of clinical, humanistic and economic impact (Hill-Taylor et al., 2013).

Using Donabedian's framework, the majority of quality indicators related to the rational pharmacotherapy are process indicators, existing and used for the nervous system (ATC code: N), followed by anti-infectives for systemic use (J) and cardiovascular system (C). The most common indicators to document DRP were related to the 'drug selection', followed by 'monitoring pharmacotherapy' and 'drug use process' (Fujita et al., 2018).

A checklist for medicine therapy management could also be helpful, as some pharmacists are not focused on checking on patient adherence, drug–drug interaction, adverse drug reactions etc. These procedures should be in a primary focus of pharmacists in the health-care centers and community, as patients who are out of the hospitals need guidance, follow up and education. Pharmacists should check device usage regularly, and be are confident in the interpretation of laboratory results. More focus on the patient outcomes would help to improve all indicators in this cluster.

To assess the indicators of quality in this area, some of the following questions might be used for the self-assessment or peer-assessment in community and hospital settings:

Rational pharmacotherapy
Are pharmacists taking medication history from the patients?
Are pharmacists assessing and identifying DRP?
Are pharmacists able to set priorities in therapy management?
Are pharmacists creating individual therapeutic plans for the patients?
Are pharmacists reporting adverse drug reactions?
Are pharmacists identifying and preventing drug–drug, drug–food and drug–disease interactions?
Are pharmacists checking patient's adherence?
Are pharmacist taking into consideration relevant LAB tests?
Are pharmacists using START and STOPP criteria list for potentially inappropriate medications in elderly and other group of patients?
Are pharmacists checking device usage in appropriate way? (inhalation technique, etc.)
Are pharmacists performing medication review?
Are pharmacists educating the patients about rational drug usage?

Prevention and Public Health

Taking care of the prevention and public health are very important indicators of pharmaceutical care implementation and quality of services. There is great potential for quality improvement, taking into consideration that lifestyle changes, regular health checks, nutrition and physical activity are crucial in achievement of therapy outcomes and patient safety. Public health campaigns should be incorporated within national and/or international public health priorities and strategies to get more visibility and attention in the health care.

Often, patients are treated without considering what are their nutrition, sleeping, lifestyle habits and needs. Pharmacists should close that gap in the patient care processes. Standardized forms and leaflets, promotions and public health campaigns could be helpful in developing this important component of pharmaceutical care. Educating the patients and improving patients' health literacy is crucially important for their benefits and health improvements (EDQM, 2017).

To assess the indicators of quality in this area, some of the following questions might be used for the self-assessment or peer-assessment in community and hospital settings:

Prevention and public health
When counseling during medicines dispensing, is the medication regimen discussed taking into consideration patient's lifestyle and desired quality of life, needs, and expectations?
Does the patients attend an educational session before they are discharged from the hospital?
Are pharmacists offering advice about healthy lifestyle?
Are patients provided with leaflets, materials, self-control diaries?
Are patients included in the smoking cessation activities when needed?

Strategy, Management, and Organization

Clear strategy and organization in any pharmacy setting are needed in terms of time management, job description definition, skill mix usage and shared responsibility, open communication, human resources engagement, and standardization of processes. This cluster of pharmaceutical care indicators has great potential for improvement all around the globe. Rules and standards are in place in some hospitals in a very successful way, but not everywhere national standards are in place. Quality indicators, competency assessment, and patient care procedures should be nationally adopted and developed.

To assess the indicators of quality in this area, some of the following questions might be used for the self-assessment or peer-assessment in community and hospital settings:

Strategy, management, and organization
Are the standards for determining staff requirements and job descriptions existing and is implementation visible at all health care levels?
Is the existence and implementation of rules regulating the delivery of drug information and organizing drug promotion activities visible?
Are standards to assess pharmacists' competence and performance in place?
Are standards to evaluate the pharmaceutical services quality approved?
Are the management of time and resources well achieved?
Is the career advancement and criteria well described and transparent?
Is the patients' satisfaction obtained and measured?
Are incidences of drug shortages in the pharmacy/wards reduced to the minimum?

Interprofessional Collaboration and Integrated Patient Care

It is important to achieve interprofessional collaboration and integrated patient care in all community pharmacies and hospitals, as pharmacists' roles are becoming more and more clinically oriented. New working places are opening for clinical pharmacists in primary, secondary, and tertiary care, and that trend is likely to grow. Not all medical doctors are open to this collaboration on the same level, but some examples are showing great potential. Pharmacists should document and present more of their interventions and contribution to the other colleagues in the health care. Some hospitals and community pharmacy centers provide a good example by establishing a drug Information centers in the pharmacies, which are open to all health-care professionals in the system; the number of questions and requests is rapidly increasing, especially by the nurses, but also by medical doctors.

Common educational activities with other health-care professionals are still rare and not always well attended by the medical doctors. A multidisciplinary approach to prevention activities could be more implemented in all areas of practice and care.

It is also possible to observe the development of integrated care including other health-care professions, such as nutritionists, aromatherapists, physiotherapists, nurses, and others to provide integrated approach to the complex patients (International Pharmaceutical Federation (FIP), 2015).

To assess the indicators of quality in this area, some of the following questions might be used for the self-assessment or peer-assessment in community and hospital settings:

Interprofessional collaboration and integrated care
Are regular health-related interactions (calls, visits, etc.) with other health professionals and pharmacists in place?
Is the collaboration with other health-care professionals and primary care organizations established for the benefit of the patients?
Are any health prevention or other programs for the patients including multidisciplinary team (pharmacists, nurses, medical doctors, nutritionists?) organized and available to the patients?
Are common educational activities with other health-care professionals organized and attended?

Follow up and Documentation

The follow up and documentation aspect of the patient care services is usually neglected and far from achieving the real potential. Connection between primary, secondary, and tertiary care should be properly established, including data collection and sharing of results of their contribution. Patient follow up is the core activity in the pharmaceutical care process and should be maintained and documented at all levels of care. IT tools and facilities should be used more in these processes and results collected and presented. Pharmacists on all levels of practice should regularly check the outcomes of the treatment for the patients and arrange the follow up to maintain the focus of care and to achieve the outcomes.

To assess the indicators of quality in this area, some of the following questions might be used for the self-assessment or peer-assessment in community and hospital settings:

Follow up and documentation
Are pharmacists checking regularly the outcomes of the treatment for the patients?
Is patient follow-up after hospital discharge or leaving HC performed in the pharmacy (by phone or in the pharmacy)?
Are the key features of the explanation and recommended follow-up actions, interventions, including referrals to the physician/doctor documented on the service record form?
Are IT facilities in patient care process used (reminders, apps, personal records, etc.)?

Point of Care and Screenings in Community Pharmacy

Innovations are visible in point-of-care testing in various pharmacy setting, including rapid tests for important clinical parameters. Screening tests and questionnaires are in place for many indications and preventive programs. As laboratory testing cannot always be conducted close to the site of patient care, this is how some orientation testing is offered on the most accessible place for the patients. Recent advances in technology have made such testing possible for certain disease screening and prevention, across a wide range of conditions in virtually any setting. Numerous concerns have arisen about the quality and accuracy of such tests, comparability between multiple tests for the same endpoint, interpretation of test results, and whether and how results should be used for therapeutic decisions and included in a patient's medical record.

The pharmacist is well-positioned to manage and interpret POCT performed outside of the usual clinical settings. Educational and regulatory changes are needed to enable pharmacists to take on this emerging activity effectively (Kehrer, 2016).

Commonly used tests
- Blood glucose
- Blood gases/electrolytes
- Activated clotting time for high dose heparin monitoring
- Urine dipsticks including pregnancy
- Occult blood
- Hemoglobin
- Rapid strep

Available but variable use
- Cardiac markers
- Drug/toxicology
- INR/PT
- Heparin
- PSA, CRP
- D-Dimer test for thromboembolism
- Magnesium
- Lactate
- Transcutaneous bilirubin
- Lipids
- Hemoglobin A1c
- Microalbumin, creatinine
- HIV
- Influenza
- *H. pylori*
- Other bacteria

Emerging and future tests
- Complete blood count
- White blood cell count
- Coagulation for transfusion algorithms

(*Continued*)

- Platelet function
- Microbiology—outbreaks, epidemics, MRSA
- Endocrine testing to guide surgical therapy
- Parathyroid hormone
- ACTH
- Gastrin
- Growth hormone
- Testosterone
- Sepsis markers
- Stroke markers
- Cancer markers
- DNA testing

Conclusion, Summary, and Way Forward

The list of quality indicators should not only be presented as an evaluation tool, but also as a developmental and educational tool, helping the pharmacists to plan their improvement. Many organizations are using the indicators' list to plan in which areas of practice they can reach quality improvement. Pharmacists, both in hospital and community settings have shown an interest and great motivation to use indicators in their practice. Quality evaluation and improvement should be in the center of health-care leadership attention, on organizational, national, and international level.

Interprofessional Clinical Education

Jill Martin Boone*, John R. Kues†, *James L. Winkle College of Pharmacy, University of Cincinnati, Cincinnati, OH, United States; †College of Medicine, University of Cincinnati, Cincinnati, OH, United States

Introduction

Advancements in medical technologies, therapies, and models for health-care delivery over the last century have required enhanced education and training for professionals to prepare for a highly complex practice environment. When the expertise of each professional is optimally integrated, the overall quality of care is maximized, and patient outcomes are improved. Better chronic disease management, reduction in medical errors, and overall improvements in health outcomes have been widely demonstrated through effective collaborative practice including pharmacists as part of the team (Briggs 1999; Feldman et al., 2012; Giberson et al., 2011; Hirsch et al., 2017; Holland 2015; Hwang et al., 2017; Lovely et al., 2014; Manias 2018).

> "Collaborative practice happens when multiple health workers from different professional backgrounds work together with patients, families, careers and communities to deliver the highest quality of care. It allows health workers to engage any individual whose skills can help achieve local health goals" (Health Professions Network Nursing and Midwifery Office, 2010)

The recognition that interprofessional collaborative practice (IPCP) improves patient outcome emphasizes the need for a workforce that is prepared to work in a team environment. The landmark report from the Lancet in 2010, "Health professionals for a new century: Transforming education to strengthen health systems in an interdependent world," highlights the importance of the timing, duration, and relevance of Interprofessional Education (IPE) in promoting behavior changes among individual health professionals. IPE is a necessary response to the pressing needs of our increasingly complex and interdependent health-care systems and populations (Frenk et al., 2010).

IPE is seen as critical to both practice and education throughout the world to develop a collaborative practice-ready workforce. According to the World Health Organization (WHO), "Interprofessional education (IPE) occurs when students from two or more professions learn about, from and with each other to enable effective collaboration and improve health outcomes" (Gilbert et al., 2010). **Fig. 1** demonstrates the complicated interweaving of interprofessional training leading to collaborative practitioners. WHO emphasizes that an effective model of interprofessional collaboration should be regionally distinct, taking into account the unique needs and sensitivities of particular environments while striving to maintain the highest standards of care. Programs of excellence in preparing practitioners through interprofessional training, in both developed and developing countries, provide models that are being adopted and expanded through networks of academic and health-care institutions (Herath et al., 2017).

History of the Interprofessional Education Movement

Since the turn of the 21st century there has been an intensifying focus on IPE and collaborative practice. Among the causes for this are the shift to a chronic care model of health (National Center for Health Statistics, 2016), the defragmentation of care (Thomas and Wise, 2015), and a focus on cost efficiency (Porter, 2009). Calls for shifting health professions education to promote greater collaboration and team-based practice, however, have existed for over 50 years.

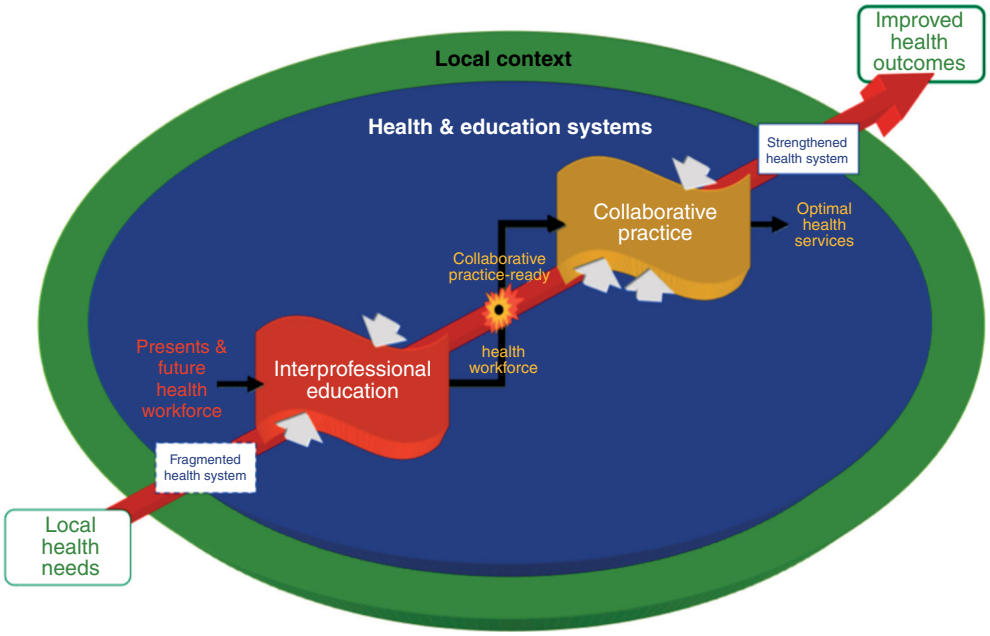

Figure 1 WHO: Framework for Action on interprofessional education and collaborative practice, 2010.

One of the earliest discussions of IPE was a conference on the interrelationships of educational programs for health professions sponsored by the Institute of Medicine. It was held in 1972 and resulted in 12 recommendations that focus on IPE in both clinical and nonclinical environments, development of faculty to teach new IPE skills, and the development of IPE competencies that promote collaborative practice and better patient care (Institute of Medicine. 1972). Although the vision was clear, implementation proved to be very difficult, especially at the prelicense level.

There are a number of examples of collaborative teams forming in clinical practice around the time the IOM was convening the 1972 conference. Surgery and emergency departments are two areas that recognized the need to develop integrated interprofessional teams to improve care delivery. Some teams were developed (e.g., Advanced Life Support) but most developed through on-the-job training.

The WHO noted the importance of training health workers to function as a team at its international Primary Health Care conference in 1978 (World health Organization, 1978). The report specifically recommended that effective health care " . . . relies . . . on health workers . . . suitably trained [both] socially and technically to work as a health team . . . ."(p5). The recommendation was primarily focused on practitioners, but there were strong implications for prelicense training programs.

In its 2010 report on IPE and Collaborative Practice, the WHO describes the need to integrate workforce planning and policy making in order to support IPE and collaborative practice. The report's call to action is primarily aimed at national and international policy makers and decision makers. However, it also recognizes the need for major changes in health professions education systems in an environment with severe shortages of health workers (Health Professions Network Nursing and Midwifery Office, 2010).

One of the first organizations that focused on IPE, The Centre for the Advancement of Interprofessional Education (CAIPE), was founded in 1987 in Great Britain and published the Interprofessional Capability Framework (Walsh et al., 2005) in 2004.

Over the last two decades, a number of events have catalyzed continued efforts to develop collaborative practice and IPE (Fig. 2) (International Pharmaceutical Federation, 2015), and a significant increase in conferences, organizations, and publications have coalesced to support expanding networks for advancing IPE efforts (Table 1).

Evolution of IPE: The Case of the United States

The IOM Quality of Health Care in America Project Impact on IPE

The evolution of IPCP in the United States is linked to political and social efforts for health reform. The stark contrast of health-care spending in the United States, compared to other countries, raised the alarm to address an unsustainable amount of spending while the quality of care was dropping. It is therefore important to look at IPE and IPCP development in terms of its unique context.

In June 1998, the Institute of Medicine formed the Quality of Health Care in America Committee. The charge of the committee was to develop a strategy that would result in a "threshold improvement" in quality during the following decade. It was their initial report, "To Err is Human," that captured the attention of providers, payors, policy makers, and the general public (Institute of Medicine, 2000). One of the more startling statistics from the committee's review of the literature was that as many as 98,000 deaths occured each year due to medical errors, with a significant proportion related to medications. They noted that the patient safety crisis

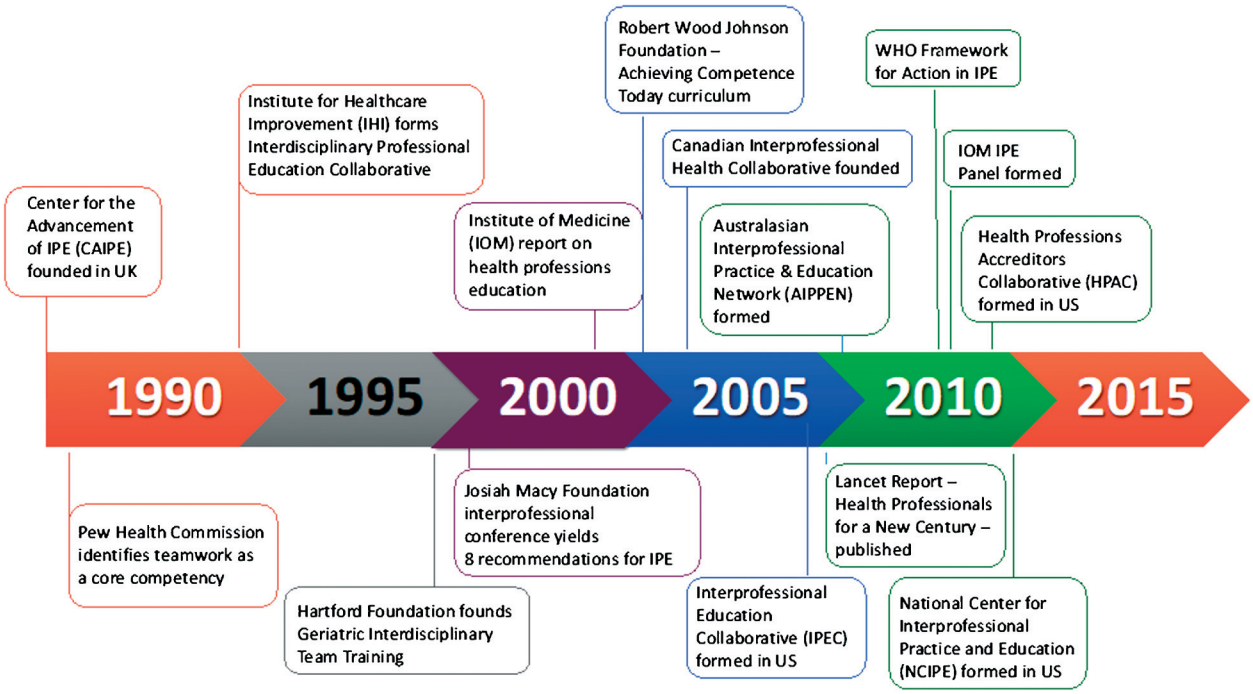

Figure 2 Timeline of select IPE events.

Table 1 Interprofessional education resources and current initiatives

A number of organizations, conference series, landmark documents, and journals have evolved over the last two decades supporting networking opportunities to facilitate development, implementation, and enhancement of interprofessional education. Most have shared focused for academics, practice, and policy surrounding IPE. Below is a brief summary of contemporary resources.

Resource

1. **All Together Better Health (ATBH)** is a biannual conference that started in 1997 devoted to sharing best practice, research outcomes and debate regarding IPE and collaborative practice. The World Coordinating Committee ATBH (https://waipe.net) consists of representatives from the following organizations.
   a. **AFRIPEN** - The Sub-Saharan African Interprofessional Education Network
   b. **AIHC** - The American Interprofessional Health Collaborative (USA), www.aihc-us.org/
   c. **AIPPEN** - The Australasian Interprofessional Practice and Education Network (Australia and New Zealand), www.aippen.net
   d. **CAIPE** - The (UK) Centre for the Advancement of Interprofessional Education, www.caipe.org.uk
   e. **CIHC** - The Canadian Interprofessional Health Collaborative, www.cihc.ca/
   f. **EIPEN** - The European Interprofessional Practice and Education Network, www.eipen.org
   g. **JAIPE** - The Japan Association for Interprofessional Education, www.jaipe.jp/
   h. **JIPWEN** - The Japan Interprofessional Working and Education Network, jipwen.dept.showa.gunma-u.ac.jp/
   i. **NIPNET** - The Nordic Interprofessional Network (Nordic countries in Europe), www.nipnet.org
2. **Collaborating Across Borders** is a North America interprofessional health-care education and collaborative practice conference through a joint effort between AIHC and CIHC. It has occurred biennially since 2007 (opposite ATBH) and has attracted participants from across the globe.
3. **Interprofessional Professionalism Collaborative (IPC)** has the collaboration of 12 American professional or practice organizations representing a variety of health disciplines. The purpose of IPC is to develop a definition of interprofessional professionalism, design and pilot an interprofessional professionalism assessment (IPA) instrument focused on health professions' entry into practice, and to develop educational resources for teaching interprofessional professionalism (IPP). http://www.interprofessionalprofessionalism.org/
4. **Interprofessional Education Collaborative (IPEC)** Founded in 2009 by six national associations of schools of health professions. Their purpose is to promote and encourage constituent efforts that would advance substantive interprofessional learning experiences. As of 2016–17, IPEC has 20 American association members representing schools of health professions. The mission of IPEC is "working in collaboration with academic institutions, will promote, encourage and support efforts to prepare future health professionals so that they enter the workforce ready for interprofessional collaborative practice that helps to ensure the health of individuals and populations." In 2011, and updated in 2016, IPEC published interprofessional collaborative competencies that are widely used in IPE.
5. **National Center for Interprofessional Practice and Education** (NEXUS) is a "unique public–private partnership charged by its funders to provide the leadership, evidence and resources needed to guide the US on the use of IPE and collaborative practice as a way to enhance the experience of health care, improve population health and reduce the overall cost of care." The National Center for IPE's website (https://nexusipe.org) provides resources that include free webinars, national data center repository, IPECP measurement instruments, forums and discussions with opportunities for collaboration, real stories about the implementation of IPECP with patients, students, networking with experts and organizations, and much more.

6. **World Health Organization (WHO) Interprofessional Education and Collaborative Practice** The Who developed the Framework for action on interprofessional education and collaborative practice in 2010, highlighting interprofessional collaboration around, identifying mechanisms to shape successful collaborative teamwork and outlining a series of action items that policy makers can apply within their local health system. "The goal of the Framework is to provide strategies and ideas that will help health policy-makers implement the elements of IPECP that will be most beneficial in their own jurisdiction". http://www.who.int/hrh/resources/framework_action/en/
7. **Institute for Healthcare Improvement (IHI) Open School** is a global learning community for students. It provides online education, local Chapters, and guided improvement projects. There have been more than 500,000 interprofessional learners from universities, organizations, and health systems around the world who have participated in building core skills in improvement, safety, system design, and leadership. http://www.ihi.org/education/ihiopenschool/Pages/default.aspx
8. **Selected Journals with a Focus on Interprofessionalism**

   b. Focus on Health Professional Education: A Multidisciplinary Journal—https://www.anzahpe.org/journal
   c. Journal of Interprofessional Care—https://www.tandfonline.com/toc/ijic20/current
   d. Journal of the Allied Health Professions—http://www.asahp.org/journal-of-allied-health/
   e. Journal of Continuing Education in the Health Professions—https://journals.lww.com/jcehp/pages/default.aspx
   f. Journal of Research in Interprofessional Education—www.jripe.org/
   g. Journal of Interprofessional Education & Practice—http://www.journals.elsevier.com/journal-of-interprofessional-education-and-practice
   h. Medical Education—https://onlinelibrary.wiley.com/journal/13652923
   i. Medical Teacher—www.informahealthcare.com/mte
   j. The Clinical Teacher—http://onlinelibrary.wiley.com/journal/10.1111/(ISSN)1743-498X

is multicausal but much of the problem is related to outdated and failed systems of care delivery. Among their recommendations is a call to " . . . establish interdisciplinary team training programs for providers that incorporate proven methods of team training . . . " (p. 14). The second part of the committee's report, released a year later, focused on designing a new health-care delivery system to address a range of quality issues (Institute of Medicine, 2001). This report emphasized the need to reexamine our current system of education of the health-care work force. A model of shared responsibility and team-based care requires a set of competencies that are ideally taught through IPE.

The third report in the Quality Chasm Series focused directly on the health-care workforce and the need for significant transformation in order to function effectively in the proposed 21st century delivery system (Institute of Medicine, 2003). The report identifies five competencies for all health-care professionals: (1) Provide patient-centered care, (2) work in interdisciplinary teams, (3) employ evidence-based practice, (4) apply quality improvement, and (5) utilize informatics. These competencies are interrelated and, taken together, provide a model improving patient care.

IPEC Competencies for Interprofessional Education and Collaborative Practice

After the reports from the first decade of the 21st century, the initiatives for IPE for most US trained health-care professions began to gain momentum. Among the several groups that began to coalesce around IPE and CP were the Institute for Healthcare Improvement (IHI), the Interprofessional Education Collaborative (IPEC), and the Josiah Macy Jr. Foundation. Donald Berwick, MD (founding President of IHI), and George Thibault, MD (President of the Josiah Macy Jr. Foundation) were the two most visible leaders of this early work. Their voices were channeled through IPEC to develop educational IPE competencies and to, subsequently, impact professional education. IPEC, formed in 2009, was a coalition of six accrediting bodies. They included: Accreditation Council for Pharmacy Education, Commission on Collegiate Nursing Education, Commission on Dental Accreditation, Commission on Osteopathic College Accreditation, Council on Education for Public Health, Liaison Committee for Medical Education.

IPEC developed a set of core educational competencies for interprofessional collaborative practice that were widely disseminated in 2011 (Interprofessional Education Collaborative Expert Panel, 2011). In addition to specifically identifying four competency domains and 38 specific subcompetencies, it also proposed the new field of "Interprofessionality." The report defined this concept as " . . . the field of interprofessional practice and interprofessional education." (p. 9). Tethering education and practice fostered a single discussion that includes learner, as well as, patient outcomes. It also expanded the participants in the discussion. The concept of interprofessionality was founded on the principle that working together with other providers and professionals needed to be deliberate and purposeful.

The four competency domains from the 2011 report include:

- Competency Domain 1: Values/Ethics for Interprofessional Practice (Work with individuals of other professions to maintain a climate of mutual respect and shared values.)
- Competency Domain 2: Roles/Responsibilities (Use the knowledge of one's own role and those of other professions to appropriately assess and address the health-care needs of the patients and populations served.)
- Competency Domain 3: Interprofessional Communication (Communicate with patients, families, communities, and other health professionals in a responsive and responsible manner that supports a team approach to the maintenance of health and the treatment of disease.)

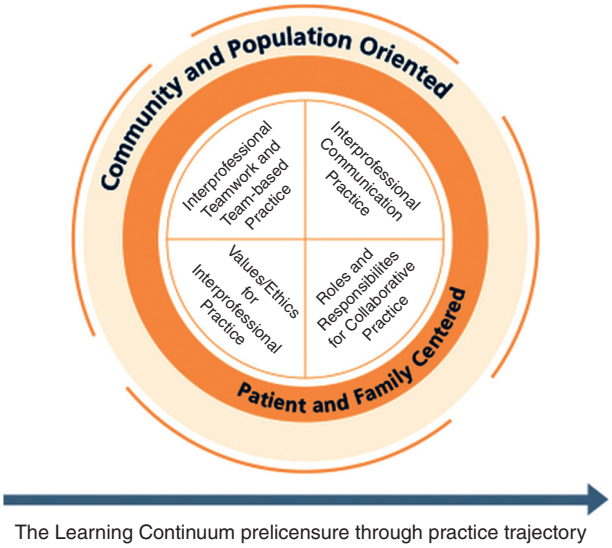

Figure 3 IPEC Framework for 2016 Revised Competencies for Interprofessional Collaboration.

- Competency Domain 4: Teams and Teamwork (Apply relationship-building values and the principles of team dynamics to perform effectively in different team roles to plan and deliver patient-/population-centered care that is safe, timely, efficient, effective, and equitable.)

The expanded model (Fig. 3) embeds the four competencies within a framework of patient- and family-centered care which, in turn, is embedded in a broader orientation of community and population health.

Dissemination and Revision of the 2011 IPEC Core Competencies

In 2014, the Health Professions Accreditors Collaborative (HPAC) was established to coordinate licensure-level training programs' IPE programs to ensure that the graduates were adequately prepared to practice in an interprofessional health-care environment. In 2017, there were 23 HPEC organizational members; almost a fourfold increase from the original six accrediting organizations.

Over the five succeeding years from the release of the 2011 IPEC competencies, three additional institutional members joined the original six founding organizations. They included the Association of Schools of Allied Health Professions (ASAHP), the Council on Social Work Education (CSWE), and the Physician Assistant Education Association (PAEA). Additionally, over 60 disciplines have sent representatives to IPEC-sponsored faculty development training programs.

In 2016, IPEC released a revision of the original core competencies and subcompetencies that reflected population health goals and the inclusion of many additional professions involved in health (Interprofessional Education Collaborative Expert Panel, 2011).

The revisions to the competencies and subcompetencies represent an expanded view of interprofessional collaboration that encompasses patient, family, and community health. While it is not clear whether the expanded focus is a cause of the many diverse organizations endorsing the domains or a consequence of the additional organizations, the ability to impact health can be found in many more professions that would not have been considered "health related" in the past. The 2016 IPEC revisions incorporate population health and health policy (Interprofessional Education Collaborative, 2016)

A Proposal to Change Pharmacy Practice for Improved Patient and Population Health

Pharmacists have had an escalating role in managing medication for patients over the last several decades. In the United States, prior to 1955, there were less than 200 FDA-approved medications. Today, in addition to multiple formulations and generics, there are more than 19,000 FDA-approved prescription products (FDA. Fact Sheet: FDA at a Glance.), and the growing number of treatments offers many more options for patients medical needs. It has also resulted in a number of complex medication-related issues to provide optimal care for patients, such as optimal medication selections, minimizing drug interactions and adverse effects, and selecting cost-effective therapies Pharmacists, have taken on many of these responsibilities within the health-care team. This has commanded changes over the decades in pharmacist education and training with enhanced clinical focus in addition to foundational scientific knowledge of medications. In the United States, the Doctor of Pharmacy (Pharm D) became the entry level degree for practice in the year 2000. A number of schools throughout the world have adopted the Pharm D degree (Accreditation Council for Pharmacy Education International Programs by Country), while others have revised their curriculum to become more clinically

rigorous or offer postgraduate Master's degree in a focused area such as hospital or clinical pharmacy (e.g., Europe, Australia). Postgraduate training (e.g., pharmacy residency programs) and credentialing (e.g., Board of Pharmaceutical Specialty) is also becoming preferred for many direct patient care positions.

Over the last 50 years, clinical pharmacy practice in hospitals and health systems has become a standard with pharmacists not only overseeing the medication distribution services but also being physically present on patient care units providing medication expertise and interacting with other health professionals and patients (Saavedra-Mitjans et al., 2018; Schneider et al., 2018; Vermeulen et al., 2018, Homsted) (Schneider et al., 2018). Ambulatory care practice is exploding with pharmacists integrated into the clinic setting providing advanced collaborative pharmacy services as part of a clinical team (Homsted et al., 2016, Buxton et al., 2015). Community practice has also advanced practice through a variety of models by not only providing medications to patients but also education, monitoring, and managing chronic diseases such as diabetes, hypercholesterolemia, and tobacco cessation (Alsaidan et al., 2018; Dokbua et al., 2018; Mansell et al., 2017; Saavedra-Mitjans et al., 2018). Evidence of improved patient outcomes is well documented when the pharmacist is included as part of the health-care team in these various settings.

These evolutionary changes have set the stage of pharmacists to be integrated fully into interprofessional collaborative practice at multiple levels and a variety of practice settings. In the United States, there were a number of other changes in health-care delivery that occurred during the time period from about 2008 through 2012 that further impacted pharmacists' role in the direct delivery of care and the spread of IPE and collaborative practice. The Affordable Care Act, enacted in March of 2010, expanded the number of individuals with health insurance by many million. It immediately created a critical shortage of providers, especially in primary care. Pharmacy education had already revised its license-level training programs to greatly expand direct patient care skills as described above. In a 2011 US Public Health Service report to the Surgeon General, a detailed plan was proposed to improve patient and health-care delivery system outcomes through advanced pharmacy practice. The plan included four focus areas: (1) Pharmacists integrated as health-care providers, (2) expanded recognition of pharmacists as independent health-care providers (including advanced practice models), (3) appropriate compensation mechanisms, and (4) evidence-based alignment with health reform (Giberson et al., 2011).

Implementation of IPE

Barriers and Success Factors

Several notable barriers have been identified in attempts to develop new IPE activities or programs. Differences in professional cultures, curriculum rigidity, scheduling challenges, distance in physical location, lack of common IPE vision, limited resources, and lack of leadership are commonly recognized challenges (Sunguya et al., 2014). Attitudinal differences regarding IPE are often present at multiple levels within in institutions including administration, faculty, and/or students. Despite these obstacles, many institutions have succeeded in implementing IPE, and there are a growing number of national and international resources available to support program development and improvement (**Table 1**).

There is a heightened global recognition regarding the value of IPE. Many countries have begun initiatives for supporting or requiring IPE through accreditation standards for pharmacy such as Australia (Dunston et al., 2018), Japan, multiple countries in the Middle East (El-Awaisi et al., 2017b), Canada (The Canadian Council for Accreditation of Pharmacy Programs), United States (Zorek and Raehl, 2013), and Great Britain (General Pharmacutical Council 2011). For pharmacy, the International Federation Pharmaceutical (FIP) hosted a landmark conference in November, 2016 "Global Conference on Pharmacy and Pharmaceutical Sciences Education," which included a focus on the importance of interprofessional collaboration in both the Nanjing statements and the Work Development Goals (Bader et al., 2017).

Several roadmaps are being developed for programs that are initiating or expanding their IPE efforts. Considerations for implementing a successful program have been described and identify key planning elements (**Table 2**) (Buring et al., 2009).

Development of IPE Programs

The delivery of a designated interprofessional curriculum in college and university programs throughout the world has been accomplished through a variety of modalities (Fox et al., 2018). After identifying interprofessional partner(s), a critical next step is agreement on IPE competencies. The five most cited frameworks are described in **Table 3**. While in the United States, the IPEC competencies are standardly used by schools of pharmacy, UK, Canada, Australia, and Japan have developed their own frameworks. All of the published IPE frameworks have content overlap as well as some unique domains. An international consensus statement on the assessment of interprofessional learning outcomes recommend assessment of the interprofessional learner in the following domains: role understanding, interprofessional communication interprofessional values, coordination, and collaborative decision making, reflexivity,and teamwork (Rogers et al., 2017)

Defining Competence

One of the differences among the frameworks is in terminology, especially around the term "competency." Early in the 1960s, a shift began from learning objectives to competencies to define behavioral objectives. Competency was then tied to learners having to demonstrate that they have mastered a set of skills or a body of knowledge (Carraccio et al., 2002). IPE competencies are typically directed at skills that complement uniprofessional expertise, but must be adaptable for life-long collaborative practice. IPE

Table 2 Elements critical for implementing interprofessional education

- Identify interprofessional education (IPE) as a goal of your college/school of pharmacy
- Identify administrative and faculty champions at your college/school to lead and support IPE initiatives
- Establish relationships with other health-care programs, considering geographical locations, university ownership/affiliation, and existing relationships
  - Schools/colleges of pharmacy without other health profession programs at their institution can still accomplish effective IPE by partnering with other institutions of higher education that may or may not be within the geographical area
- Identify the administrative and faculty champions at each of the partnering programs
- Establish an IPE planning team with engagement from every player
  - Choose IPE curricular theme
  - Evaluate equivalent levels of education; match students based on education level and maturity
  - Determine when and where this IPE will occur in the curricular schedule and who will teach/facilitate the interprofessional curriculum
  - Gradually implement based on level of preparedness (start small and go slow)
  - IPE planning team members must advocate for the acceptance of IPE curriculum at their individual schools/colleges
- Offer faculty development programs to support faculty teaching in IPE
- Establish faculty rewards and recognition for IPE involvement
- Determine an assessment strategy to evaluate the IPE initiative and share results with internal and external stakeholders, as well as the academic community via scholarship

Reproduced from Buring et al. with permission (Buring et al., 2009)

Table 3 Interprofessional competency frameworks

Competency framework	*Terminology used*	*Framework domains*
Interprofessional Capability Framework (U.K.), 2004	Capabilities	• Ethical Practice • Knowledge in Practice • Interprofessional working • Reflection
Canadian Interprofessional Health Collaborative (CIHC), Canada, 2010	Competencies	• Interprofessional communication • Patient/client-centered care • Role clarification • Team functioning • Collaborative leadership • Interprofessional conflict resolution
Core competencies for interprofessional collaborative practice, IPEC, U.S. 2011	Competencies	• Values and ethics • Roles and responsibilities • Interprofessional communication • Teamwork and team-based care
Interprofessional Capability Framework Australia, 2011	Capabilities	• Communication • Team function • Role clarification • Conflict resolution • Reflection

Interprofessional Competency Framework (Japan) 2018	Competencies	• Core Domains
		  ◦ Patient-/Client-/Family-/Community-centered
		  ◦ Interprofessional Communication
		• Peripheral Domains
		  ◦ Role Contribution
		  ◦ Facilitation of Relationship
		  ◦ Reflection
		  ◦ Understanding of Others

competency statements "identify specific knowledge, skills, attitudes, values and judgments that are dynamic, developmental, and evolutionary" (Bainbridge et al., 2010), which support the need to continually update curricula to meet the changing needs of populations over time. While some IPE frameworks use "competencies," there is a lack of consensus regarding the definition of "competence" (Nicolas et al., 2012) and some scholars have deemed "competence' too static for the dynamic nature of IPE. "*Capability*" has been used in preference to *competence* in other IPE frameworks, to encompass a more adaptive ability to meet the needs of a changing health-care environment (Walsh et al., 2005). IPE frameworks that have been developed throughout the world are described in **Table 3**.

Once competencies have been agreed upon, there are many available strategies for implementing IPE training programs. Barriers described above often result in a gradual building process for IPE programs. Abu-Rish and colleagues (Abu-Rish et al., 2012)

reviewed current trends in IPE. Of the 83 eligible studies they examined, small group discussions and problem-based learning were the most used strategies, followed by clinical teaching and simulation-based learning. There were a wide variety of instructional design formats being used across the curriculum. Some programs initiated entrée into IPE by having a single program, an IPE "day," or a series of activities for two or more professions. Knowledge-based IPE competencies are often addressed early in the curriculum through didactic/interactive classroom teaching, team-based projects, or case-based study. For more advanced learners, IPE practice simulations and clinical service learning have been integrated. Fox and colleagues (Fox et al., 2018) had similar findings regarding multitude of pedagogy and assessment strategies. In this work, almost all of the IPE implemented resulted in positive changes in student's perceptions and attitudes regarding IPE and practice.

Because of the wide variety, it is difficult to assess the overall impact of the numerous IPE strategies. **Table 4** provides a brief description of select published approaches and strategies to IPE including pharmacy learners.

Table 4 Brief description of example IPE initiatives and strategies including pharmacy learners

Single or Series of IPE events
• Singer et al. (2018) describe an "IPE Day" which devotes a full day of events designed to build toward IPE competencies with 438 first year students representing four professions. Through this experience, students demonstrated significant improvement of self-ratings using the Interprofessional Collaborative Competencies Attainment Survey (ICCAS).
• Nagge et al. (2017) in also had positive outcomes in their Healthcare Interprofessional Education Day (HIPED) among 2nd year pharmacy students and 1st year medical students with collaborative activities focused on communication, patient interviewing, and prescribing.
• El-Awaisi et al. (2017a) focused on a single event with a specific topic, delivering tobacco cessation content as well as highlighting professional roles. They engaged 50 students from four disciplines (pharmacy, pharmacy technician, medicine, and public health). Prepost assessment with Readiness for Interprofessional Learning Scale (RIPLS) indicated that students already had positive perceptions regarding IPE and further increased after event.
• Hadley et al. (2018) recently developed a pilot workshop with occupational therapy, physical therapy, pharmacy, and physician assistant students. The program included an ice breaker and a case-based activity with a jigsaw design. Student feedback and perceptions were positive based upon this experience.
• Lehrer et al. (2015) provided an interesting perspective with an analysis of a series of peer-led problem based learning (PBL) in IPE. The IPE perceptions of medicine and pharmacy students that participated in a weekly one-hour problem-based learning seminar over 16 weeks were compared, in a case–control design, to the perceptions of student who did not participate. Using the Interdisciplinary Education Perception Scale (IEPS), data showed significant higher perception of professional cooperation among medical and pharmacy students who attended seminars versus those who did not.
Interprofessional Courses
• Simko et al. (2016) developed a 3-hour credit course with a focus on pain management. Learners over two course offerings were 25 junior pharmacy and 35 senior nursing students. Instruction by multiple professionals as well as group IPE assignments was held throughout the semester. Activities included developing and presenting a patient care plan as well as simulations with a standardized patient as IP team. Significant improvement was seen in the IEPS, Collaboration and Satisfaction about Care Decisions (CSACD), and reported knowledge of the other profession for both nursing and pharmacy students.
• Kim et al. (2017) involved senior students (402) from nursing, pharmacy, allied health, and medicine completed an interprofessional course dedicated to critical event/disaster response. After completing online coursework, a 4-h synchronous team simulation focused on resuscitation, decontamination, and mass casualty triage. Pre/post evaluations resulted in improvement in team participation values, critical event knowledge, and 94% of participants reported learning useful skills. Most frequent qualitative response was value of interprofessional experiences in team communication and desire to incorporate this kind of education earlier in curriculum.
• Peeters et al. (2017) described first year health science students (554) from eight professions engaged in an impressive 14-week required course focused on the IPEC competencies. Activities included case-based communications exercises, standardized-patient interviews, simulations, vital signs training, and patient safety rotations. Student's self-assessed competency of course learning objectives based on Kirkpatrick's levels, student satisfaction with the course, and perceptions of other participating professions via word cloud. Competencies and satisfaction were significantly improved and there was change in students' perceptions of other professions.
• Shrader and colleagues involved pharmacy students longitudinally with IPE activities through a pharmacy-based clinical assessment course (Shrader and Griggs, 2014). Third year (71) pharmacy students engaged in 9 separate IPE activities as part of the course. The IPE events included participation of physician assistant, medicine, nursing students. Sixteen of the 18 items improved on the pre- vs postcourse Interdisciplinary Education Perception Scale (IEPS) score.
• Truong et al. (2018) reported an inter-institutional effort (Eastern Shore Collaborative for Interprofessional Education-ESCIPE), multiple intervention with nine disciplines to develop IPE toward IPEC competencies among nine disciplines (including pharmacy) and 18 faculty. Multiple activities were included in this effort such as an emergency preparedness point-of-dispensing (POD) drill, patient management laboratory simulation, geriatric assessment interdisciplinary team workshop, medical mission as public/global health rotation and service-learning program, rural health fair, and annual university health festival for community outreach at different stages of learning throughout the curriculums. Feedback has been positive and program evaluation plans are underway.
• Rotz et al. (2016) developed an impressive 6-semester experiential course series involving first and second year pharmacy and medical students. The courses consisted of a combination of teaching methods: orientation, reflective sessions, hybrid didactic/active-learning activities, and experiential component at student-run clinic and other practice sites. Students had both profession-oriented and IPE goals throughout the series. While still early in the course implementation, the results of standardized assessments so far showed that students expressed positive perceptions of interprofessional collaboration with respect to teamwork, roles and responsibilities, and patient outcomes, student perception scores, high team performance of collaborative behaviors, and a majority of teams demonstrated appropriate competence with respect to interprofessional communication and teamwork.
• Thompson et al. (2016) combined longitudinal, interactive classroom and interprofessional clinic experience with serving an inner-city charitable clinic. Eighty students representing 13 professions, worked together for an academic year. Pre/post assessments with RIPLS, T-TAQ, showed significant improvement in interprofessional attitudes. Results of the health-care professionals circles diagrams indicated increases in students' perceptions of the types of interprofessional team members, relationships, and communication between professions to provide medical care to patients.

Table 4 Brief description of example IPE initiatives and strategies including pharmacy learners (*cont.*)

Case-Based Interprofessional Learning

- Case-based learning has been utilized throughout the curricular levels and in both classroom and clinical settings.
- Posey et al. (2018) designed a case competition for Level 5 nursing students and third-year pharmacy students to work together as a pilot in the development of their IPE program. In addition to developing the clinical components of the case, participants were asked specific questions regarding interprofessional learning. A modified version of the Interprofessional Education Collaborative (IPEC) Competency Survey and the RIPLS Questionnaire were administered before and after the activity and demonstrated improved engagement with other health-care professionals.
- Nasir et al. (2017) implemented case-based interprofessional learning for undergraduate health-care professionals in the clinical setting teaching scenarios of real patients with student groups of four and including at least two professions. There were 329 students from 9 professional that attended one session during the academic year. One of the outcomes observed included that 70% of respondents stated they would alter their future professional behavior as the result of this learning.

Health Care Team Challenge™

- The Health Care Team Challenge (HCTC™) (Newton et al., 2013) is an innovative interprofessional learning activity that was created at The British Columbia University over 20 years ago. It is a case-based competition between two or more IP teams of students, representing at least two disciplines. A patient case is assigned prior to the event and, collaboratively, the teams develop a patient-centered plan of care. The teams present of their plan of care occur in front of a live audience and then are provided with additional relevant information pertaining to their case. While on stage, the team is asked to adjust their care plan accordingly. A panel of judges evaluates teams on both quality of care and IP collaboration. A number of programs (University of Queensland, University of Minnesota, Clarion, University of Washington, University of Toronto, Jikei Institute, Graduate School of Health Care Sciences, International Interprofessional Collaborative 2012: Kobe Japan) have adapted this activity and tailored it to their specific need. Through its broad implementation, the use of the HCTC™ has demonstrated impact on improved knowledge and attitudes toward collaborative practice, sustained changes in beliefs, behaviors, and attitudes related to socialization. An education research collaboration has been developed to further elucidate the role of HCTC™ in IPE.

Simulation

- Palaganas et al. (2016) reviewed the literature of simulation in IPE and concluded that while there is growing literature with some positive outcomes, data are still too limited to recommend how to best use simulation within IPE. Simulation IPE may include mannequin-based, standardized patients embedded-simulation persons, virtual platforms, or role play. Benefits of simulation include that it bypasses some of the challenges of being in a clinical environment, allows more control of the experience, and can be tailored to the level and type of learners; however, logistics of scheduling, costs, and alignment of goals and desired outcomes are some of the hurdles related to IPE simulation.

IPE Online and Distance Learning

- Online engagement of interprofessional students is becoming more prevalent.
- Evans et al. (2018) recently reviewed experiences of faculty facilitating online exchanges. Asynchronous group discussions were reported as the most common online approach, faculty perceived this to be a valuable approach despite challenges of involving all learners in this venue.
- Dow et al. (2016) developed a web-based case system for IPE training. During academic year 2012–13, 80 teams composed of 522 students from medicine, nursing, pharmacy, and social work participated were assigned to interprofessional virtual teams. Each team member had profession-specific information and was responsible for providing a summary of this information into the case system's electronic medical record. Each team member also answered knowledge questions about the case individually and then collaborated asynchronously to answer the same questions as a team. Team scores were significantly higher than individual scores. Students and teams with higher knowledge scores had higher case activity measures. Team score was most highly correlated with number of message board posts/replies and was not correlated with number of views of message board posts.
- Mccutcheon et al. (2017) reviewed the current status of IPE via distance learning. Based upon three questions: (1) Is this study implementing IPE? (2) Is this study utilizing the instructional delivery method of distance education? and (3) Does this study contain students from two or more health-care professions?, 15 of the 478 articles originally identified met inclusion criteria. Five of these including pharmacy students. Key finding from this review included that there were positive outcomes IPE outcomes such as recognizing roles of other professions, interprofessional teamwork, and interprofessional socialization, however, experiences varied by study. Further, some negatives identified were lack of personal contact, cumbersome programmatic layers, and technical difficulties. Facilitators sometimes lacked training and the online development was more time-consuming the in-person teaching. There were a wide variety of teaching models used including virtual towns, online learning communities, virtual interactive patients, and synchronous and asynchronous group forums.

TeamSTEPPS®

- TeamSTEPPS® is a teamwork system designed for health-care professionals to improve quality and safety of patient care developed by the Department of Defense's Patient Safety Program in collaboration with the Agency for Healthcare Research and Quality. Use of this tool has been used in numerous programs facilitating teamwork skills for students and practitioners (Welsch et al., 2018).
- Jernigan et al. (2018) engaged 715 first year learners from fifteen professions in the Level 1 TeamSTEPPS® program. Significantly positive attitude changes were documented among learners as well as increased appreciation for interprofessional communication and better understanding of the roles of other health-care professions. Other programs have also observed improvement in knowledge and attitudes when using this teaching tool in the acute care hospital setting (Fowler et al., 2018) as well as student-faculty primary care practices (Weinstein et al., 2018).

Student Run Clinics (SRC)

- Student-run clinics (SRC) have the advantage of providing a service while offering a learning environment, often to individuals in underserved settings.
- Haggarty and Dalcin (2014) described the growing number of voluntary SRCs that have developed in Canada over the last two decades with both IPE training and service to the community. The clinics have shown to provide similar outcomes to usual care and, while the IPE competency outcomes were limited, students were immersed in interprofessional care.

(*Continued*)

Table 4 Brief description of example IPE initiatives and strategies including pharmacy learners (*cont.*)

- Farlow et al. (2015), from the United States, similarly promoted SRC as an excellent IPE learning model.
- Lie et al. (2016) proposed a framework for understanding student learning during team-based care in an interprofessional SRC serving underserved patients. Analysis of the student focused groups resulted in six common themes about learning content from uniprofessional groups: role recognition, team-based care appreciation, patient experience, advocacy-/systems-based models, personal skills, and career choices. The authors also reported that "synthesis of themes from all groups suggests a learning continuum that begins with the team huddle and continues with shared patient care and social interactions. Opportunity to observe and interact with other professions in action is key to the learning process."

Clinical Practice IPE Experiences

- Nuffer et al. (2015) reported on the sustainability of a practice-based Interprofessional Introductory Pharmacy Practice (IPPE) experience course. The program has been ongoing for 13 years where third-year PharmD students were paired with community-based providers. The experience was a series of half-day visits for a semester and the learning objectives focused on enhancing the students' abilities to communicate and work closely with non-pharmacist health-care professionals and to gain an appreciation for the workplace pressures faced by those practitioners. Both pharmacy class size and the number of provider partnerships grew over the 13 years, with 154 students and 194 partners at the time of writing. Students consistently affirmed achieving the stated goals through the years and improved self-assessed level of confidence as a result of working with a non-pharmacist health-care practitioner. The authors conclude "The study provides indirect evidence through the long-term sustainability of the course that third-year pharmacy students have the competency to integrate themselves into medical and nursing practice sites and to contribute to patient care. It also provides evidence that the course is useful in socializing pharmacy students in the context of interprofessional health care teams".
- Boland et al. (2016) created an interprofessional immersion experience with 24 pharmacy, psychology, nursing, and family medicine trainees. The program was 1 week long side-by-side training focused on the IPEC core competency domains. Interprofessional teams observed, learned, and practiced working in teams. Upon completion, trainees reported more confidence regarding ability to work within an IP team a more likely to use the team-based approach.
- Anderson and Thorpe (2014) qualitatively assessed practice-staff, patients, and facilitators on how mid-level interprofession students team learning impacted practice. Results indicated that the students provided positive value, offered solutions to improve quality of care and propelled practitioners to maintain high professional standards.
- Brewer and Stewart-Wynne (2013) implemented a 2–3 week clinical placement for students from eight professions focused on six beds in a general ward. Authors reported the students attitudes improved overall regarding interprofessional education and the student's acquisition of a high level of interprofessional practice capabilities. Qualitative data from students and clients were very positive as well.
- Stubbs et al. (2017) developed an inter-institutional, community-based IPE student experience. Thirty students from 10 professions dentistry, dietetics, divinity, medicine, nursing, occupational therapy, pharmacy, public health, social work, and speech and hearing sciences worked in IP groups of six. The program included both a didactic, 2-month preparatory phase and a 4-month service-learning phase. The service-learning involved teams facilitating focus groups, interviews, and informal discussions with clients and organizations to identify specific needs and priorities and then working collaboratively to provide solutions. Significant improvements were observed in students' comfort working with others, value in working with others, and self-perceived ability by standardized assessments.

A recent report from the American Association of Colleges of Pharmacy Task Force on Intentional Interprofessional Education in Experiential Education (IIEE) (Grice et al., 2018) defined IIEE as "the explicit effort by preceptors and practice sites to create/foster educational opportunities or activities designed specifically to achieve interprofessional educational competencies." While there are many examples in the literature experiential-based IPE, the task force assessed that most occur in a nondeliberate manner. This group particularly highlighted opportunities in advanced pharmacy practice experiences (APPE), noting that an APPE that occurs in an interprofessional environment is not necessarily IIEE. The intentionality comes with targeting IPE competencies in design/developmental phases and building on previous IPE concepts in the curriculum. The task force challenged academic scholars for further advancement in IIEE.

Most institutions have aspirations of an IPE program that is multifaceted with longitudinal and is integrated throughout the curriculum to prepare practice-ready graduates. Some programs have made significant progress toward this goal and have become centers of excellence and share their resources. A sample of these progressive institutions includes University of Toronto (http://www.ipe.utoronto.ca/interprofessional-education-curriculum), University of British Columbia (https://health.ubc.ca/integrated-education/interprofessional-curriculum), University of Washington (https://collaborate.uw.edu), and University of Minnesota (https://www.health.umn.edu/our-impact/interprofessional-education).

Evaluation of IPE

Evaluation of IPE is essential for determining the effectiveness of educational goals and IPE competencies. Evaluation strategies work best when they are part of the curriculum development process. Recent reports from the IOM have called for both formative and summative assessments of IPE using qualitative and quantitative methods (Hovland et al., 2018; Zomorodi 2018).

A critical development of an overall assessment map of IPE programs is the evaluation of which IPE competencies are met by each program. Simmons and colleagues (Simmons et al., 2016) have proposed some reflective insights that are useful for planning and implementing IPE assessments. These included the fact that IPE "is a complex activity due to its involvement of both individuals as well as interprofessional teams/groups" and "[as part of] designing an IPE assessment a series of key questions needs to be posed and addressed, including, what is the purpose of the assessment? What is one going to assess? and How is the assessment to be

Table 5 Outcomes of interprofessional education

1 Reaction	Learners' views on the learning experience and its interprofessional nature.
2a Modification of attitudes/perceptions	Changes in reciprocal attitudes or perceptions between perceptions participant groups. Changes in perception or attitude toward the value and/or use of team approaches to caring for a specific client group.
2b Acquisition of knowledge/skills	Including knowledge and skills linked to interprofessional collaboration.
3 Behavioral change	Identifies individuals' transfer of interprofessional learning to their practice setting and changed professional practice.
4a Change in organizational practice	Wider changes in the organization and delivery of care.
4b Benefits to patients/clients	Improvements in health or well-being of patients/clients.

Modified Kirkpatrick's Model of Educational Outcomes for IPE, reproduced with permission (from Freeth et al. (2002, p. 14).(Freeth, D., Hammick, M., Koppel, I, Reeves, S., Barr, H. 2002)

performed?" It was suggested that an assessment blueprint is "vital to linking proposed learning outcomes with methods of assessment" and "the use of an assessment matrix can effectively collate key elements related to the assessment of IPE." Lastly, "entrustable professional activities and milestones are promising techniques to use in in IPE assessment."

It is essential for the evaluation to generate an understanding of the range of intended learning outcomes expected from an IPE activity. In measurable terms, an assessment needs to be made of knowledge, skills, attitudes, and beliefs, which can be focused on the individual learner, the learning community the institution, or the system as a whole. The modified Kirkpatrick's outcomes typology described in **Table 5** has been widely incorporated as an outcome-based framework for evaluating IPE, especially in the pharmacy literature. The original Kirkpatrick model had four levels: 1-reaction, 2-learning, 3-beahavior, and 4-results. It was expanded to the present version by adding two outcomes at levels 2 and 4 (Freeth et al., 2002) to further clarify the progression and distinguish between outcomes that relate to people and those that have an impact on service delivery. The complexity of behavioral change increases as evaluation of the interventions ascends in the hierarchy, and the model represents a sequence of strategies to evaluate programs.

A novel approach to the assessment of interprofessional competencies began at University of British Columbia (Charles et al., 2010). Their model was built on Miller's Learning Pyramid: "knows"(knowledge); "knows how"(competence); "shows how" (performance), and "does"(action) (Miller 1990). Early efforts for building IPE competencies focus on the knowledge and awareness and evolve into application and integration into professional practice. They proposed the process of exposure, immersion, and mastery for development of IPE competencies. The University of Toronto adopted a similar approach based on the preparation of their learners building from *exposure* (introduction) to *immersion* (development) to *competence* (entry-to-practice). **Table 6** demonstrates an example of assessment strategies applied to this IPE program. For both hierarchical learning models, the highest form of learning outcome is performance in practice on a daily basis in complex systems—a learned ability linked to formal training or the development of expertise over time.

A number of assessment tools have been developed for IPE competency domains. Areas of assessment include learner reactions, attitudinal shifts, behavioral changes, knowledge and skills acquisition, organizational practice changes, and benefits to patients (Bookey-Bassett et al., 2016; Oates and Davidson, 2015; Shoemaker et al., 2016; Shrader et al., 2017). **Table 7** lists some commonly used tools. While there are a few instruments that measure higher level learning, most tools and research have been focused on student attitudes toward, and readiness for, IPE as well as their achievement of individual IPE activity goals. Standardized approach to assessment with IPE is needed, yet there is still limited data to determine the best strategy. Continued focus on expanding research toward evaluating the impact of the IPE training on teamwork and patient care is needed.

Table 6 University of Toronto Assessment Strategy

Level	*Assessment*	*Notes (Domains and Format)*	*WHO*
Exposure	Quiz	Knowledge of foundational values, communication, collaboration	Faculty (via Learning Management System)
Exposure	Reflective writing	Values—Uploaded to Peer Scholar	Peer feedback
Exposure to Immersion	Reflective writing assignments (x3)	Reflective assignments (Values and Ethics, Communication and Collaboration)	Faculty
Exposure to Immersion	AITCS Assessment of Interprofessional Team Collaboration in Student Learning	Group process scale embedded in the Pain Curriculum (is being piloted in other group-based learning activities)	Group—Peer (guided by a facilitator)
Immersion	ICAR Modified Interprofessional Collaborator Assessment Rubric	Individual feedback embedded in the Pain Curriculum	Self and peer
Competence	IPCA Interprofessional Collaborator Assessment	Performance-based 360° assessment in a practice setting	Practicing team members

Table 7 Selected evaluation/assessment tools for interprofessional education based on Kirkpatrick model toward IPEC domains

Level	*Tool name*	*IPEC domain*
1a. Reaction	Readiness for Interprofessional Learning Scale (Parsell and Bligh, 1999)	Roles/responsibilities Interprofessional communication Teams and teamwork Values/ethics for interprofessional practice
1a. Reaction	Interprofessional Attitudes Scale (IPAS) (Norris et al., 2015)	Roles/responsibilities Interprofessional communication Teams and teamwork Values/ethics for interprofessional practice
1a. Reaction 2a. Modification of attitudes/perception	Collaborative Healthcare Interdisciplinary Planning Scale (CHIRP) (Hollar et al., 2012)	Teams and teamwork Values/ethics for interprofessional practice
1a. Reaction 2a. Modification of attitudes/perception	Interdisciplinary Education Perception Scale (IEPS) (Hawk et al., 2002)	Roles/responsibilities Teams and teamwork Values/ethics for interprofessional practice
1a. Reaction 2b. Acquisition of knowledge and/or skills (when used as part of TeamSTEPPS training)	TeamSTEPPS Teamwork Attitudes Questionnaire (T-TAQ) (Baker et al., 2008)	Roles/responsibilities Interprofessional communication Teams and teamwork Values/ethics for interprofessional practice
2a. Modification of attitudes/perceptions	Attitudes Toward Health Care Teams Scale (ATHCT) (Heinemann et al., 1999)	Roles/Responsibilities
2a. Modification of attitudes/perception	Student Perceptions of Physician-Pharmacist Interprofessional Clinical Education (SPICE-2) (Zorek et al., 2016)	Roles/responsibilities Teams and teamwork Values/ethics for interprofessional practice
3. Behavioral change	Assessment of Interprofessional Team Collaboration Scale (AITCS) (Orchard et al., 2012)	Interprofessional communication Teams and teamwork Values/ethics for interprofessional practice
3. Behavioral change	IPEC Competency Survey Instrument (Dow et al., 2014)	Roles/responsibilities Interprofessional communication Teams and teamwork Values/ethics for interprofessional practice
4a. Change in organizational practice	Index for Interdisciplinary Collaboration (IIC) (Oliver et al., 2007)	Teams and teamwork Values/ethics for interprofessional practice
4a. Change in organizational practice	Interprofessional Socialization and Valuing Scale (ISVS) (King et al., 2010)	Roles/responsibilities Interprofessional communication Teams and teamwork Values/ethics for interprofessional practice

Faculty Development

Faculties play a critical role in IPCP and IPE; thus, they need to understand IPE and have skills for facilitating IP learners (Egan-Lee et al., 2011; Simmons et al., 2011; Steinert, 2005). A majority of published descriptions of IP training have focused on the learner. There are limited outcome data on effective methods for faculty training. The timing of and resources for faculty development appear to be relevant to initiation and sustaining IPE. Ratka and colleagues (Ratka et al., 2017) provided an overview of faculty development programs for IPE. Based on their overview, five characteristics of an effective IPE faculty development program emerged: (1) institutional support, (2) objectives and outcomes based on interprofessional core principles, (3) focus on consensus building and group facilitation skills, (4) flexibility based on institution and participant-specific characteristics, and (5) incorporation of an assessment strategy. A variety of approaches including didactic, experiential, in-person, online, blended methods, and capstone projects have been used for faculty development. A standardized approach should be used for each institutional program, and strategies should be developed that are tailored to the needs of the organization.

Summary

IPE and collaborative practice have become not only helpful but also necessary for providing quality health care to patients and for promoting population health. The explosion of medical and biological sciences, the rapid growth of new health-care professions, and the shift from critical care to chronic care are among the most critical variables that have changed the nature of health and health care.

It is easy to see how a holistic approach to caring for patients became increasingly difficult and inefficient over time. In fact, the health-care delivery system itself became a common cause of morbidity and mortality. An examination of this alarming finding concluded that practitioner incompetence was a very small part of the problem. The system, itself, was the primary cause of most of the errors that resulted in patient harm. This growing problem is a global one, but countries with sophisticated and complex health-care delivery systems have felt the consequences more acutely. Professional organizations responsible for both training and professional practice in many different health professions have come together in search of solutions, and it has become clear that interprofessional collaboration is essential to improving care.

The discussions among the major health professions identified two major components to improving interprofessional collaboration: Training and Practice. While training and practice are closely linked, the recommended solutions are very different. Both areas, however, are served by the creation of competencies for health-care professionals. The approaches to implementing the competencies vary across the training and practice environments. The practice environment has focused on a wide range of quality initiatives that focus on patient outcomes, quality metrics, and system changes. There are also a number of training programs, such as TeamSTEPPS®, that support these efforts for practicing professionals.

The larger challenge, however, has been changing the training programs at the prelicense level to prepare professionals for lifelong team practice. Most professions have been siloed since their inception. With the recent revolution in health care, IPE initiatives have begun at academic health centers, and educators began to recognize that both students and faculty knew very little about the training of their colleagues in other professions. Institutions with successful IPE programs usually have IPE centers that stand apart from any individual health professions school. New IPE curricula, faculty training programs, and facilities are becoming more commonplace at academic health centers and many accrediting bodies now require it.

A parallel development to the rapid rise in IPE training and collaborative practice models has been the growing number of professional organizations, publications, and research in these areas. In addition to important manuscripts appearing in mainstream education and practice journals such as Academic Medicine, Lancet, and the Journal of the American Medical Association (JAMA), a number of new journals have emerged whose primary focus has been iIPE and practice as described earlier.

These multifaceted advancements are particularly important as more experience and research is needed to determine optimal models for IPCP and the best IPE strategies to achieve them. Both IPCP and IPE will continue to expand as health care continues to evolve.

Leadership in Pharmacy

Nadia Bukhari*, Jillian Foster†, Joseph Bonnarens‡, Tina Brock§, *University College London, London, United Kingdom; †Baptist Memorial Health Care Corporation, Memphis, TN, United States; ‡Manchester University, Fort Wayne, IN, United States; §Monash University, Melbourne, VIC, Australia

Introduction

The title of this chapter is Leadership in Pharmacy. You may have chosen to read this chapter because you want to become a leader in the profession. This is good news. We are entering a period of what could, and likely should, be great change in health care. Whenever change is needed, we have an even greater need for leadership. And the more transformational the nature of the change, the stronger and more flexible that leadership must be. We definitely need to develop and recognize leadership across many aspects of pharmacy practice and clinical pharmacy.

Before you read further, however, we want to make it very clear that it is beyond the scope of any book, video, or website to make a person into a leader. One can learn about leadership from such resources. Learning about leadership means being introduced to the underlying tenets and reviewing the key theories that describe and predict leadership behaviors. One can also learn from the stories told by leaders. Leadership stories that illustrate not only the successes but also the setbacks experienced along the way can be particularly valuable. Further, one can learn from other leaders and with other aspiring leaders. The most humbling and powerful way to develop skill is to invest in hands-on training that includes time spent practicing the often-difficult actions associated with leadership and then getting feedback from others on these actions. So, while reading this chapter will not, by itself, make you a great leader, we hope that it will be a positive influence on your personal leadership journey.

Our authoring team represents leaders across a range of career stages with experience in a variety of aspects of pharmacy practice across three different continents. Each of our journeys has been different, but despite this, we have taken comfort in some

commonalities along the way. It is these that we will share with you. Indeed, we have attempted to distill a great deal of pharmacy leadership information for you by focusing on the following key questions:

- How do pharmacy leaders come to be?
- How can you discover and document your pharmacy leadership abilities?
- What theories support leadership in pharmacy?
- What style of leadership is best suited for you, your audiences, and for the pharmacy decisions you face?
- How have other leaders approached challenges in pharmacy?
- Where can you go to continue your pharmacy leadership journey?

We hope that this approach will assist those of you who are interested in becoming pharmacy leaders and even those of you who have been placed into leadership roles by a supervisor or by peers. We also hope it will inspire you to discover your inner leader, learn more about what that inner leader needs to grow, and most importantly, connect with others who are striving in this area.

How do Pharmacy Leaders Come to be?

A longstanding debate swirls around the question of whether leaders are "born" (i.e., with innate leadership skills) or "made" (i.e., via purposeful development over time). One of the original philosophies of leadership is known as the "great man" theory. This theory, proposed in the 1840s by Thomas Carlyle (2008), suggests that leaders, who at that point in documented history would likely all have been men, are born with certain skills of power and influence. Despite a lack of rigorous studies to support this theory in the modern context, it is comforting to think that superhero-style leaders appear fully formed to save the day when a need arises. If we are not born as one of these superheroes, then we never have to face that responsibility.

In almost no aspect of work in health care are our inborn traits the primary driver of our successes. We were not born possessing the medication knowledge and clinical skills needed to care for patients. Rather, becoming a pharmacist is a journey that we undertake and refine in order to reach and improve that goal. This suggests that the likelihood that pharmacy leadership is solely an inborn skill is low. If it then follows that pharmacists become leaders through development over time, one would expect to find a clear definition of this leadership target. Interestingly, there are more than 4000 documented definitions of leadership and even more when you include some of the overlapping concepts from management in this mix. For the purposes of this chapter, we will define leadership as the framework of skills and abilities that are necessary for an individual to drive team success (Azad et al., 2017).

Pharmacists care for patients, guiding them directly or indirectly through the maze of appropriate medication use. Pharmacists must be persistent problem solvers, managing processes to formulate the best course of action for a specific patient in a specific care scenario. Pharmacists are responsible—according to legal requirements, corporate policies, and professional expectations—for the health and safety of patients. This chapter is written in the context that all pharmacists act as leaders at various points throughout their days, their positions, and their careers. In the next section, we will discuss how to better discover, develop, and foster that leadership to improve the systems in which we work.

How Can You Discover and Document Your Leadership Abilities?

Our individual personalities, tendencies and proclivities, in addition to our education and experience, all contribute to our leadership personas. Yet every pharmacy leader has a starting point from which that leadership persona emerges. The aphorism, "Know Thyself" was inscribed over the ancient Greek temple at Delphi and philosophers such as Socrates used it to emphasize that we must know ourselves deeply in order to fully develop (Ryff and Singer, 2006). This is also true for pharmacy leadership.

Throughout a given week, we may be offered glimpses into our specific personality traits, perhaps in the form of a social media survey that identifies which color, direction, animal, or Harry Potter character we are most like. These can be fun to complete and inherent in them are the more rigorous measures of (A) personality, (B) strengths/skills/talents, and (C) styles from which they have been adapted. While a multitude of these self-assessment tools exist, some open access and others, proprietary; **Table 1** offers a representative sample for your review. Many employers offer education and training programs that are founded in tools such as these. Consulting with your human resources representative to determine which may be available to you and potentially the teams who work with you is an excellent idea.

Once you have completed these self-assessments, where should you go next? We recommend creating a leadership portfolio to not only aggregate the results of these types of assessments, but also to place them into context. This can be done in printed format or electronically, using software like DropBox® or Evernote®. The creation of a portfolio and the reflection on the components included in it may highlight which leadership attributes are innate and which must be developed. It may also allow an individual to analyze where they are now and where they wish to be. Finally, the leadership portfolio can serve to document leadership development over time. This will aid you internally but may also help with any documentation required for continuing professional development activities, such as achievement of advanced practice status.

What Theories Support Leadership in Pharmacy?

As mentioned, there are more than 4000 documented definitions of leadership (Azad et al., 2017). Despite this, leadership is an under-researched abstraction within the pharmacy profession. Theory can both describe and predict effects so an understanding of leadership theories can assist in the leadership development process. For the purposes of this section, we will draw parallels from the wider health care domain but when possible, we will provide pharmacy-specific examples.

It is difficult to isolate exact qualities and behaviors that make good leaders. This is because the overall effectiveness of a leader is based on their traits, skills, and behaviors matched to the situation with which they are faced. Today, leadership theories have been broadly placed into five (at times overlapping) core groups:

- Trait theories—What type of person makes a good leader?
- Behavioral theories—What does a good leader do?
- Contingency theories—How does the situation influence good leadership?
- Power and influence theories—What is the source of the leader's power?
- Other theories—What more contributes to good leadership?

Trait Theories

Trait leadership is defined as integrated patterns of personal characteristics that reflect a range of individual differences and foster consistent leader effectiveness across a variety of group and organizational situations (Zaccaro et al., 2004). Trait theory is based on the assumption that we can identify a set of traits common to all leaders. This has proved more difficult than it sounds. A considerable number of studies have recognized certain traits; however, these results are neither comprehensive nor conclusive (Bolden et al., 2003). Another assumption of the theory is that the absence of these traits means that the individual is not a leader. Again, this has not proven true. Despite criticism, researchers continue to explore the correlation between various personality traits and skills with leadership effectiveness, the most widely explored of these being charisma. In an extensive review, Stogdill (1974) found some traits and skills of leadership that appeared more frequently than others. These are described in **Table 2**.

Behavioral Theories

Behaviorists view leadership as a key set of actions instead of as personal characteristics. To determine these behaviors, researchers evaluated what successful leaders did, developed a taxonomy, and identified broad patterns. Behavioral leadership theory incorporates B.F. Skinner's (1991) notions that reward and punishment are powerful mechanisms for leading. An example of this is a manager who motivates desired behavior by scolding employees who arrive late to meetings and showing appreciation when they are on time. There are several types of behavioral leadership theories, including those proposed by Kurt Lewin and Rensis Likert.

Table 2 Leadership traits and skills

Traits	*Skills*
Adaptable to situations	Clever
Alert to social environment	Conceptually skilled
Ambitious and achievement- orientated	Creative
Assertive	Diplomatic and tactful
Cooperative	Fluent in speaking
Decisive	Knowledgeable about group task
Dependable	Organized
Dominant	Persuasive
Energetic	Socially skilled
Persistent	
Self-confident	
Tolerant of stress	
Willing to assume responsibility	

Source: Stogdill (1974)

Lewin's Leadership Styles of Decision-Making

Kurt Lewin's leadership styles framework dates back to the 1930s and focuses on how leaders involve others in making decisions. He was a pioneering social psychologist who identified three different approaches (Gastill, 1994):

1. Authoritarian leaders, also known as autocratic leaders, make decisions and direct activities without any participation from others.
2. Participative leaders, also known as democratic leaders, involve their peers, team, coworkers in the decision-making process.
3. Delegative leaders, also known as laissez-faire leaders, give full autonomy to make decisions to their teams.

Likert's Leadership Systems

Rensis Likert, another pioneering social psychologist, expanded Lewin's work around the decision-making process and the degree to which people are involved in the decision to include four different leadership styles or systems (Katz et al., 1950):

1. Exploitative Authoritative—The leader has a low concern for people, using fear and threats to achieve outcomes. Communication is top down with all decisions made at the top.
2. Benevolent Authoritative—The leader is authoritative but has concern for people, using reward to encourage performance. Communication is better in this style; but almost all major decisions are made at the top.
3. Consultative—The leader makes an effort to listen to others; however, many decisions are still made at the top and the upward flow of information is still somewhat idealized.
4. Participative—The leader engages in participative methods, engaging all members of the team in decision-making. Communication flows both ways.

Contingency Theories

Contingency theorists suggest that there is no one leadership style, rather the uniqueness of each situation requires a different approach. Some examples of contingency theories include Fiedler's Least Preferred Co-worker Theory, Cognitive Resource Theory, Strategic Contingencies Theory, Path Goal Theory, and the Hersey-Blanchard Leadership Theory.

Contingency theories often see leadership on the continuum of relationships and tasks, sliding back and forth depending upon the speed required, the level of stress encountered, the motivation needed, and the perceived competence of the followers. Although these theories have subtle differences in their definitions and tools, in general they advocate that the effective leader adapts and interchanges their style in any given situation (Fiedler, 1967; Fiedler and Garcia, 1987; Hickson et al., 1971; Gill, 2011; House and Mitchell, 1974; Hersey et al., 2007)

Power and Influence Theories

Power theories involve influencing people via authority. This influence can manifest in the form of rewards or punishments and/or through personal and positional power. Two of the most common power and influence theories are transactional and transformational leadership, which both originated from the work of Burns (1978). **Table 3** summarizes key differences between the two approaches (Covey, 1992).

Table 3 Transactional vs transformational leadership

Transactional leadership	*Transformational leadership*
Builds on a man's need to get a job done and make a living	Builds on a man's need for meaning
Is preoccupied with power and position, politics and perks	Is preoccupied with purposes and values, morals and ethics
Is mired in daily affairs	Transcends daily affairs
Is short-term and hard data orientated	Is orientated toward long-term goals without compromising human values and principles
Focuses on tactical issues	Focuses more on missions and strategies
Relies on human relations to lubricate human interactions	Releases human potential—identifying and developing new talent
Follows and fulfils role expectations by striving to work effectively within current systems	Designs and redesigns jobs to make them meaningful and challenging
Supports structures and systems that reinforce the bottom line, maximize efficiency and guarantee short term profits	Aligns internal structures and systems to reinforce overarching values and goals

Source: Covey (1992)

Transactional Leadership

Transactional leadership occurs when there is an exchange of performance for either reward or penalty (Burns, 1978). Transactional leaders give followers something they want in exchange for something the leaders want (Kuhnert and Lewis, 1987). Transactional leadership is task-oriented, works within set organizational boundaries, and suggests a management focus for the leader.

Transformational Leadership

Transformational leadership is future-oriented; focusing on motivating followers to become leaders through a vision for the future. It suggests a more visionary focus for the leader. Burns (1978) defined transformational leadership as "the relationship of mutual stimulation and elevation that converts followers into leaders and may convert leaders into moral agents." His work was adapted by Bass and Avolio (1994), who described the integral role a leader plays in transforming their followers. Specifically, "the goal of transformational leadership is to transform people and organizations in a literal sense—to change them in mind and heart; enlarge vision, insight and understanding; clarify purposes; make behavior congruent with beliefs, principles or values; and bring about changes that are permanent, self-perpetuating, and momentum building."

Other Theories

Exemplary Leadership

Kouzes and Posner (2012) extended the theory of transformational leadership to identify transformational leadership behaviors, specifically, the following Five Practices of Exemplary Leadership that can be used to develop others as leaders:

1. Model the Way—Establish principles concerning the way people should be treated and goals should be pursued. Because complex change can overwhelm people, set interim goals so that followers can achieve small wins on the way to larger objectives.
2. Inspire a Shared Vision—Envision the future, creating an ideal image of what the organization can become. Enlist others in the dream to get people to see exciting possibilities for the future.
3. Challenge the Process—Search for opportunities to change the status quo, taking some risks along the way. Accept mistakes and disappointments as learning opportunities.
4. Enable Others to Act—Foster collaboration and build spirited teams. Create an atmosphere of trust. Strengthen others, making each person feel capable.
5. Encourage the Heart—Recognize the contributions that people make. Celebrate accomplishments to make people feel like heroes.

Servant Leadership

In medicine, nursing and pharmacy, the theory of servant leadership has received substantial attention because it aligns well with the professional and ethical duties of all health care providers—to serve their patients. Servant leadership is the desire to serve the needs of others even before aspiring to lead them (Greenleaf, 1970). This moral core of service represents a different calling as compared to that experienced by those who are drawn first to lead. Another aspect of servant leadership that is consistent with health care is a focus on "the least privileged in society" (Greenleaf, 1970). More recently, Trastek et al. (2014) have suggested that because there should be alignment with how we treat patients and how we work together as staff, there is a case for servant leadership becoming a more dominant model in delivering high value care.

There are more leadership theories than it is possible to discuss in this chapter. We have attempted to focus on those most commonly associated with the practice of health care professionals and those with overlapping constructs that may strengthen their applications to leadership development.

What Style of Leadership is Best Suited for You, the Audience, and for the Pharmacy Challenges You Face?

You may have identified with one or more of the leadership theories discussed above. To put these theories into action, however, we typically speak in terms of leadership "styles". There are several styles that have emerged directly from leadership theories (and may even share a common name) and others which combine elements of multiple theories (which may then have distinct or overlapping names). Some leadership styles are broad and linked to associated frameworks. Others prioritize a single construct. For example, servant leaders focus solely on using generosity to create the positive culture necessary for teamwork.

Table 4 summarizes the leadership styles that are most commonly described in health care, highlighting the best audiences for and potential pitfalls of each (Trastek et al., 2014; Faraci et al., 2013).

Table 4 Summary of advantages/disadvantages of key leadership styles

Leadership style	*Description*	*Advantages*	*Disadvantages*
DIRECTIVE	The team leader makes the decision based on their ideas.	• Style will work best with a newly formed team. • Style will work best with a team facing an unfamiliar situation. • Style needs an experienced leader in-order to combat difficult situations.	• Team members may experience lower self-esteem. • Team members will be "told" what to do, to which may result in lack of initiative, creativity, or self-confidence. ◦ Overcome disadvantage by: Using a researched directive leadership approach, where any necessary information is obtained from colleagues prior to decision making.
CONSULTATIVE	The team leader makes the decision based on everyone's ideas (including their own).	• Style will take other views into account. • Style will work best with a developing team. • Style will increase the knowledge and utilization of members.	• Overuse of this style can be seen as poor decision-making on the part of the leader. • Style can be time consuming. ◦ Overcome disadvantage by: Using a group consultative leadership approach.
DELEGATIVE	Team members make the decision based on their ideas.	• Style can be valuable when working with an experienced team that may have greater technical expertise, than the leader in different tasks.	• Underuse of the style can result in too little sharing of responsibility, which can lead to overload of tasks for the leader. • Overuse of style can lead to lack of control and loss of authority. • Overuse of style can result in less respect for the leader and increased amount of stress for the team members. ◦ Overcome disadvantage by: Using an informed delegative leadership process where the leader meets colleagues to provide them with necessary information, expectations, and objectives. The team can then proceed autonomously with problem-solving but keeping the leader informed about the work in progress.
CONSENSUAL	Decision is made by including everyone's idea.	• Style stimulates ownership and commitment throughout an experienced team. • Style is best used when facing situations that need to viewed through multiple perspectives.	• Insufficient use of this style can result in loss of team skills and involvement. • Overuse of the style can lead to a perceived lack of clear leadership role. • Style can discredit a leader. The leader will be displayed as being incapable to make their own decision without referring to others. ◦ Overcome disadvantage by: Using a chaired consensual leadership approach in which the leader will lead a collaborative process whereby all team members participate in making the decisions.

Table 4 Summary of advantages/disadvantages of key leadership styles (*cont.*)

Leadership style	*Description*	*Advantages*	*Disadvantages*
TRANSACTIONAL	Transactional leaders set goals and performance standards for their employees and in return promise to provide rewards if those standards are met, or punishment if not met.	• Style motivates the employees to contribute and perform their best (personal interest).	• Style does not require a leader to take the ethical and moral road, which may disengage members with ethical principles. • The transactional leadership model is unable to account for the complex motivations of health care providers and the professional and ethical duties to their patients. ◦ Overcome disadvantage by: Transactional leaders can offer tasks with some intrinsic rewards to cater to the team members who have high ethical morale. Leaders can forgo rewards and sanctions and incorporate a more transformational approach.
ADAPTIVE	Adaptive leaders enable a group to overcome challenges created by changes.	• Style is best used when situations and problems are constantly changing/evolving. • Style helps team members and organizations adapt and thrive in challenging environments.	• Style can put a tremendous amount of pressure on the leader to help organization successfully adapt, especially during an extremely difficult situation. ◦ Overcome disadvantage by: Enlightening the team members regarding the change and receiving input from all members on ways to evolve during the change.
TRANSFORMATIONAL	Transformational leaders inspire their followers to look past their own self-interest and to perform above expectations to promote team and organizational interests.	• Style involves leaders' providing large- scale inspiration and motivation for a new vision or mission that is incorporated to the company. • Style will allow members to perform beyond expectations and deliver lasting results, once they embrace the particular vision of the leader.	• Style requires the leader to advocate/ persuade followers to participate in the vision by their charismatic nature. • Style requires the leader to challenge the members to fully embrace the mission, and to give up old values in competition with the new mission. • Style imposes great importance on the vision since the leader's vision is central to the model. ◦ Overcome disadvantage by: Creating a shared vision with the team members, that will have a lasting effect on healthcare system. Leader should attend leadership seminars/classes that will aid them in improving their motivational skills.
SERVANT	Servant leaders serve the highest needs of others in an effort to help others achieve their goals.	• Style will contribute to strong relationships and trust between leaders and their members. • Style will promote leaders to inspire high performance and innovation throughout health care.	• Style requires leaders to develop great qualities/ characteristics such as: listening, empathy, healing, awareness, persuasion, conceptualization, foresight, stewardship, commitment to the growth of people, and building community which takes times. ◦ Overcome disadvantage by: Participating in a leadership development program to develop the desired characteristics

Source: Faraci et al. (2013), Hamilton (2008), Heifetz and Laurie (1997), Kreps (1997), Mark et al. (2014), Schwartz and Tumblin (2002), Scott (2016), Spears (2004), Trastek et al. (2014) and Zilz et al. (2008).

This is where the situation gets a bit confusing, though. The most effective leaders have the ability to move between styles depending on the needs of the situation. They have the aptitude and emotional intelligence to choose the right style for a given situation. Emotions play such an important role in leadership that Daniel Goleman (2000) highlighted six emotional leadership styles which overlap somewhat with an earlier three-style model suggested by Lewin.

1. Commanding (also called coercive or autocratic)—The commanding leader is demanding; "do what I tell you". This can be very effective in crisis management. Coercive style relies on order giving and the leader having a very tight control of their team.
2. Visionary (also called authoritative)—The best phrase to describe this style is "come with me". The leader states the overall goal but gives their followers the freedom to choose how they will achieve that goal, thereby using their own initiative. Empathy is the most important aspect of this style of leadership.

3. Affiliative—Affiliative leaders believe that "people come first". This style builds team morale and harmony and has a huge emphasis on emotional connectivity. This type of leader must have an enormous amount of emotional intelligence as they need to be aware of and value the feelings of others.
4. Democratic—"What do you think?" is the most appropriate phrase to summarize this leadership style. There is a huge focus on collaboration, giving followers a voice and giving the opportunity to generate fresh ideas. This is achieved by including team members in the decision-making and problem-solving processes.
5. Pacesetting—The pacesetting leader says "do as I do, now". This style emphasizes high performance and expects excellence from the team. This type of leader will step in to ensure that high standards are met.
6. Coaching—The approach of this style is "try this"; connecting team members' personal goals and values with that of the organization. This leadership style focuses on personal development.

How have Other Leaders Approached Challenges in Pharmacy?

So far, we have focused on how to self-assess your skills and strengths and then connect these to various theories and styles of leadership. We have also emphasized that the best leaders are those who are able to adapt their style to the challenge at hand. With this in mind, there are some key principles, for example, delegation, time management, mentors, networks, and work/life balance, that are associated with good leadership regardless of style. Table 5 summarises these shared principles and strategies for using them successfully (Mark, 2013).

Although all of these principles are important, the authoring team wants to bring some additional attention to the principle of work/life balance. Inexperienced leaders often feel pressure (internally or externally) to devote their full attention to work-related matters. However, self-care is a critical aspect of pharmacy leadership. Having a healthy approach to life is good for both leaders and their followers. If you have ever flown on a plane before, you will likely remember the flight attendant saying something like, "In case of emergency, air masks will drop from the ceiling...please put on your own mask before assisting others." If you aren't getting enough oxygen to your own brain, you should not be fooled into thinking that you can help anyone else. Taking time to ensure your environment is safe, positive, and inspiring will ensure that you can focus your attention on leading your team.

Table 5 Principles for all leadership styles

Principle	*What to do*	*What NOT to do*
Delegation	• Delegate, because one person cannot complete all the tasks by themselves, and a leader's success depends on the contributions of their followers. • Clearly articulate the needed outcome.	• Delegate as an afterthought. • Fail to explain the importance of the task and how it fits into the "big picture". • Delegate to the employees with the assumption that the employees are incapable of finishing the task. • Get into the habit of delegating to the same person.
Time management	• Organize your work and develop a system that caters to your liking. • Prioritize your work. • Delegate tasks. • Maximize email tools/ filters/reminders.	• Try to tackle all tasks at once. • Rank every assignment as high priority. • Let your paperwork/task manage you.
Work/Life balance	• Set professional and personal goals and protect them/pursue them equally. • Schedule your activities accordingly. • Create firm boundaries between time devoted to work and time allotted to personal activities. • Schedule buffer times for "thinking".	• Assume all responsibilities for the problems at work. • Self-impose pressure on yourself to achieve certain goals that will require you to work long hours many nights in a row.
Mentors	• Try to provide mentorship and receive mentorship. • Seek mentorship from a variety of sources, companies, and industries. • Have mentors for each aspect of your career or aspirations.	• Artificially constrain yourself with available mentors in pharmacy.
Networks	• Take advantage of networking. • Seek out good opportunities for networking, both planned and spontaneous.	• Go to a networking event without any preparation. • Go anywhere without copies of your resume or business cards. • Forget to thank everyone in your network who has been helpful to you.

Learning from and Leading through Failure

Despite extensive study and planning, all leaders will fail at some point. These failures can be humbling but are also important opportunities for strengthening one's resolve and personal growth. A leader who has never failed has probably also never achieved as much as they could have. This means while we should not strive for failure, we also should not fear it. A variety of circumstances can result in leadership failure. For example, some leaders struggle to blend tactics flexibly around the needs of a situation. Others may be frustrated when the direction of an organization changes. A leader may realize their efforts to complete a project are requiring much more energy than anticipated. These types of challenges signal a need for reflection about areas for further development. In the next section, we have outlined some of the most common leadership mistakes so that pharmacy leaders can avoid these "failures" from becoming repeated and career-limiting habits.

Failure to Communicate Clear Expectations

Failure to set clear expectations with team members is likely the most common leadership mistake. If the organizational goals change, the leader must communicate a credible plan to the team. Devising a clear set of expectations to meet a new goal involves considerable time, which may be the reason many leaders fail. Leaders should involve others in the development of the plan and when confirmed, there should be confidence in delivering the specifics. The expectations should be measurable and include as much background information as appropriate. Without clear explanations, teams may create rumors and spread misinformation about the scope of the project. Leaders should be consistent and steadfast in how they share expectations, ensuring that goals are not overreaching or unrealistic. Sharing personal goals as well as team goals may enhance employee engagement. Finally, the tone of voice and cadence when delivering expectations is important. For example, ending an expectation phrase with "if you possibly can" is counter-productive to the desire to produce solid results.

Failure to Follow through on Measuring and Presenting Results

As leaders share expectations and goals, they should also begin measuring the results. When consistency occurs in sharing results back with the team, it encourages team morale and the desire to push towards the goal. The leader loses credibility when commitments are made to measure and there is no follow through. Positive results are worth reporting often and negative results can also inform the team of focus areas that are needed. Leaders must be willing to change tactics if trends show progress is not realistic.

Failure to Delegate Appropriately

As expectations are clearly defined and measurements are put into place, the leader should decide on delegated tasks and make those known. Waiting until a deadline approaches and delegating in a panic may not prove effective. Additionally, when a leader is delegating, it should be with confidence and clarity. This is not the time to accept reverse assignments from a team member. Without such a focus on communication, the leader may walk away with more assignments than anticipated. Leaders should delegate often and perfect their ability to be descriptive instead of prescriptive. Information should not be withheld or minimized to belittle the recipient of the delegation. Instead they should be empowered and encouraged when approaching their assignment.

Failure to Hold Team Members Accountable

After delegation has occurred, leaders should not excuse team members from meeting deadlines. Often, leaders give benefit of the doubt and wait longer than necessary on others to prepare, plan, and execute. Leaders eventually may take the assignment back and complete it on their own. This can lead to burn out and/or passive aggressive tendencies towards the team. Instead, encourage individuals who have difficulty with closing out a big task to take smaller steps towards the goal. Failure should be encouraged as long as productive efforts are underway to produce results. Minimizing risk but using trial and error may offer early payoff toward achievement of a goal.

Failure to Use Coaching Strategies

Leaders are expected to coach their team when opportunities for improvement exist. But sometimes this does not result in individual behavior change. Inadequate coaching strategies include lecturing instead of listening, provoking resistance, and dampening the individual's personality. Instead a leader should explain the reason for the coaching session honestly. This can be difficult but is a necessity for transparency and changing of the unwanted behavior. After this, the leader should invite the individual to provide feedback. This feedback will include valuable insight on strategies for motivating this team member. Careful balance is needed to motivate without enabling the negative behavior. Leaders have to keep honesty at the center of their communications. When a poor performer is rewarded with the same benefits as strong performers, this enables the behavior and demotivates the team.

Consequences should be discussed and follow through must occur. Absence of any action from the leader also promotes low performance. As with all communication methods, consideration of the individual employee is important as similar words can evoke different emotions. Addressing an individual's ability barrier is key and suggesting strategies for them to overcome these is encouraging.

Failure to Engage in Mentoring and Networking

Leadership skills are not developed in one day or one week. The life experiences of the leaders and those around them build the character necessary for a successful leadership journey. Formal and informal mentors are important for emulating healthy skills. Watching and learning from others will demonstrate that having courage, perseverance, and benevolence are consistent in an effective leader. Honesty and integrity are developed through sharing honestly with oneself and with the team. Consistency fosters team engagement and teams work harder when treated with respect. These philosophies are witnessed when leaders surround themselves with other leaders and see the results. Leaders can learn how best to make hard decisions by talking with others who have faced similar challenges. Optimizing patient care is the core of decision making in pharmacy but must be balanced with resources and ability. Decision making skills are better observed than described. Therefore, having a mentor to walk through leadership experiences is vital for the development of the leader. Networking in pharmacy associations regionally, nationally, and even internationally is invaluable to the growth of a leader. Pharmacy leaders are usually very willing to share their successes and even their failures with others. As with clinical skills, leadership skills must be honed indefinitely. Things are ever changing and a leader must make intentional efforts to read literature, attend conferences, and engage in continuous professional development. Mentoring and networking should not only occur inside the profession of pharmacy. Other disciplines and professions offer meaningful insight and lessons in avoiding leadership pitfalls.

Failure to Balance Priorities

The overarching theme for leaders is balance in all things. Leaders may define work/life balance differently across a career. The following types of balance are key to address consistently:

- Coworker and friendship balance—A leader should get to know each team member and their role on the team. However, the leader plays a different role from other team members. Because of this, a leader must recognize when personal and professional issues may overlap. A leader will appreciate friendships but may also be asked to make hard decisions with upper management that could cause tension in the group. Having healthy boundaries for leader roles and staff relationships can protect unnecessary personal hurt and disappointment.
- Responsiveness and deadline balance—Leaders should prioritize their work related deadlines while maintaining credibility with their team. Perhaps responding to phone calls and emails is reasonable within 48 h instead of 24 h, and therefore, those parameters should be shared with staff. It is important to be realistic with what expectations a leader commits to in order to avoid burn out.
- Goals and resources balance—Leaders are routinely required to set and modify goals for their organization. The leader must balance resources to support team goals, even, at times, competing ones. Human resources and automation decisions are often difficult as both are costly and require some maintenance. Leaders should be optimistic but not unrealistic about such matters.

For a chance to assess your knowledge of leadership, in particular, learning from and leading through failure, review the case study and analysis shown in Fig. 1.

Where Can You go to Continue Your Pharmacy Leadership Journey?

Leadership is a journey, not a destination. The best leaders continue to grow and develop new skills over time. They learn to describe and predict results based on theory. They welcome feedback from supervisors and colleagues. They learn from their mistakes. They seek different types of mentors for different stages of their careers. They expand their networks to include leaders from other fields.

We began this chapter suggesting that it is not possible to master leadership by reading a book, watching a video, or accessing a website. Then we extended this by saying that one can learn about leadership from a variety of resources—alone or in groups with others who share the interest. One great way to engage with leadership development opportunities is to join a professional organization. This will increase access to leadership materials and activities developed specifically for health care and pharmacy situations. It will also help form connections between other new and experienced leaders.

There are many different options worldwide and there are advantages and disadvantages to each. Some are accessible freely, others are a condition of membership, and others require an additional fee. You should make the choice based on your needs and situation. We have summarized some representative English language opportunities in Further Resources.

Flu Vaccine ServiceImplementation

Description

M.J. is a community pharmacy owner. She employs a highly productive staff pharmacist, B.P. M.J. is busy with facilitating new marketing efforts for her store including signage and local news campaigns. Therefore, as flu season approaches, she delegates the responsibility of coordinating this year's vaccine efforts to B.P. She tasks B.P. with visiting with local physicians to encourage their referral of patients to the store. Additionally, she asks B.P. to ensure vaccine is ordered, all staff are trained, and the message of the details for the service is clear to all involved, including patients. B.P. is overwhelmed and not sure where to begin. He can tell M.J. is very busy and therefore, he attempts to proceed without further direction. B.P. thinks about the logistics of the vaccine service and gets input from the other pharmacy team members about steps to take to implement the initiative. B.P. and a technician visit several physicians and encourage them to send patients to the pharmacy. They also order 500 flu vaccines in June. B.P. has a staff meeting with the team and shares the information about expecting more volume this year than last year for flu vaccines. He tells the cashier they will charge $12 for each vaccine which is $2 higher than last year.

Analysis

M.J. used a delegation leadership style and trusted B.P. with the specifics of the implementation. Perhaps her delegation could have included written instructions with deadlines, including data to use for making decisions. For example, M.J. has a file with last year's flu vaccine volumes included. She also has information regarding vaccine manufacturer, and the deadline for best price purchasing for early delivery options. B.P. used a consensual leadership style where he engaged his team members but may not have checked in with his leader, M.J., as often as necessary to confirm his direction.

Impact

There is value and the opportunity to be very effective when using delegation and consensual leadership styles. However, the leader must be mindful not to compromise the integrity of the project with missed opportunity for communications. The flu vaccine program could have included a collaborative practice agreement with a few physicians to ensure the referrals were continued and aligned with State Board of Pharmacy regulations. Because the order was placed in June, the pharmacy did not receive those until October, which is after the competition has started their flu campaigns. The late order caused the cost of each vaccine to be more than anticipated at $20 per vaccine. This cost was below the charge to the patient so the pharmacy had an overall negative financial impact from the flu vaccine project. While logistics were communicated to the staff, clinical situations such as allergies were not anticipated and addressed. Overall, M.J. and B.P. were able to address issues throughout flu season to compensate for missed opportunity during planning, but many lessons were learned regarding careful leadership tactics that could have avoided the mistakes. Communication and repetition in planning sessions and follow up could have enhanced the campaign launch.

Learning and Teaching Methods to Develop Clinical Skills in Pharmacy

Dai John*, Stephen Riley†, *School of Pharmacy and Pharmaceutical Sciences, Cardiff University, Cardiff, United Kingdom; †School of Medicine, Cardiff University, Cardiff, United Kingdom

Learning and Teaching

There is a variety of methods that can be used by students to assist their learning. Teaching does not necessarily result in learning in that we know what is being taught but not what is being, or has been, learnt by the student. The focus needs to be on the learning. There are a variety of approaches that are used to facilitate learning, the choice of which is influenced by many factors including what we want our students to learn, for example, knowledge or a skill, and how we are assessing the learner. The alignment of learning with the methods of assessment is sometimes overlooked. Constructive alignment (Biggs and Tang, 2011) is a term used that acknowledges that students learn by constructing their own learning through appropriate learning activities and that the teacher helps to create an environment in which appropriate learning takes place. All elements of the curriculum, including the learning activities, desired learning outcomes, or competencies, and assessment methods are aligned. Further, the student is supported to achieve the required outcomes by the teacher/facilitator.

There are four steps associated with constructive alignment, namely

1. Defining the intended learning outcomes;
2. Selecting teaching and/or learning activities likely to lead to achieving the outcomes;
3. Assessing students' learning to see if and/or how well they match what was intended; and
4. Arriving at a final grade or determining the student has passed (reached the required standard) or has failed to reach the standard.

What Do We Mean by Clinical Skills?

Clinical skills have been defined in many ways. For example, a clinical skill is any discrete, observable act performed by an individual involved in direct patient care at any point during a patient's care. The following skills are examples of clinical skills within pharmacy contexts: communication/consultation skills, physical assessment skills (e.g., measurement of blood pressure, pulse, peak flow), handwashing/hygiene, and, increasingly, vaccinations and testing body fluids. Venepuncture and basic life support would be other examples. It is accepted that there are significant differences in the clinical skills routinely practiced within countries as well as between countries. Safe and effective clinical skills are often assessed and monitored due to their potential negative impact on patient safety.

Levels of Learning

Miller's pyramid (or Miller's triangle) describes four levels of learning (Miller, 1990). This approach has been applied widely in relation to assessing clinical skills in healthcare.

Level 1—Knows/knows about the skill, including any underlying theory

Level 2—Knows how to perform the skill

Level 3—Shows how: the student can demonstrate that skill and the demonstration could take place in a simulated or clinical environment. Demonstration of that skill on one occasion is usually considered as sufficient to demonstrate that the student has "shown how".

Level 4—Does: the student can independently perform the skill safely and effectively in a clinical environment

The method of assessment would depend on the level of learning, and considering the principles of constructive alignment, the methods of teaching and learning. That is, the learning activities need to be appropriate for the level of learning.

UK Example

The pharmacy regulator in Great Britain, the General Pharmaceutical Council (GPhC, 2018), has produced standards for the initial education and training of pharmacists. The GPhC accredits pharmacy programs in Great Britain. Typically, students in the UK undertake a four year MPharm degree and after graduation spend an additional 12 months as a pre-registration pharmacist under supervision. (A small minority of students undertake an integrated 5 year program where the 12 months professional training is incorporated together with the degree so that they graduate and qualify as a pharmacist co-terminously after 5 years.)

Students must demonstrate achieving a number of learning outcomes and these are listed in the professional standards document. The level (using Miller's pyramid) that must be achieved for each outcome is identified by the GB regulator, the GPhC. So, for example, the GPhC requires individuals to "Obtain and record relevant patient medical, social and family history." For an MPharm student the required level is "shows how," so a student before graduating must be able to demonstrate that he/she is capable of demonstrating this skill (within a classroom or simulated environment). For pre-registration pharmacists, however, before they can register as pharmacists, they must demonstrate that they can demonstrate this outcome at the "does" level. So, in a clinical context within a healthcare setting (e.g., community, primary/ambulatory care and hospital) they can independently perform this skill safely and effectively, and are observed so doing.

So using this example, "Defining the intended learning outcomes" of constructive alignment (Biggs and Tang 2011) the learning outcome (Stage 1) has been provided by the GPhC. The final stage is assessment of whether or not that outcome has been achieved. The second and third steps are "selecting teaching and/or learning activities likely to lead to achieving the outcomes" and "assessing students' learning outcomes to see if and/or how well they match what was intended," respectively.

Learning, Teaching, and Assessing Skills

So what methods are available to students to help learn taking a patients history as a skill and how can it be assessed? It can be helpful to refer back to Miller's pyramid and identify the four stages, with "does" at the top of the pyramid. We would need to assess that a pre-registration pharmacist can routinely, in a clinical environment with patients, obtain and record a relevant history. That is, they can demonstrate this particular outcome. So how might we assess this skill? There are a variety of assessment methods and these include essays, written reports, multiple choice questions (MCQs), modified-essay questions (MEQs), oral examinations, portfolio assessments, and OSCEs (Objective Structured Clinical Examinations). OSCEs are undertaken within a simulated environment and usually use standardized (trained) "patients", which can be staff or actors. Workplace-based assessments may use simulated or actual patients. So, of the many assessment methods, which would be appropriate to assess the "does," which requires repeated, safe, and effective demonstrating of this outcome in the performance standards? That is, using a constructively aligned approach.

Direct observation, which is repeated, and in the clinical environment is required using a validated tool. Examples of observation include the mini-CEX (mini-clinical evaluation exercise) which is a supervised learning event (SLE) involving direct observation of a clinical encounter with a patient by a trainer for teaching purposes. DOPS is another example of an SLE, and stands for the direct observation of a procedural skill. If we are evaluating at the "does" level then a series of SLEs need to be undertaken.

So how might we teach this skill? Or more importantly, how could the student learn how to perform this skill, accurately, repeatedly, and effectively and in the clinical environment with patients?

Lectures, Workshops, and Tutorials

Three well-known examples of teaching methods are the lecture, workshop, and tutorial. Brief descriptions of each, within the context of a cohort size of 160 students, follow.

Traditional didactic lectures with no or little interaction between students or between students and the facilitator. The teacher typically stands at the front of a large group of students and talks to or at them. The teacher may remain stationary or move around.

Lectures often, but not always, take place in a tiered lecture theatre or auditorium for a cohort size of 160 students. Such a format is not conducive to meaningful student learning as you may be able to recall from your experience as a student. Activities can also be introduced into lectures to make them interactive and hence more appropriate for learning in the environment of the lecture theatre/auditorium as outlined in workshops below.

Workshops are teaching sessions where tasks and discussion take place, that is, students are actively learning together. There is interaction between students, and between students and the facilitator. There is increasing use of a "flipped classroom" approach (Higher Education Academy, 2018) where students are required to undertake tasks and/or reading prior to a session and then use that preparation within the classroom. Providing the lecture notes in advance of a teaching session is one example, but it is not the only example. Unlike being in didactic lectures students are undertaking learning prior to the class rather than learning about something for the first time in the class. That is, when learning activities take place within the classroom, students learn by constructing their own learning (see constructivism as a learning theory below) through appropriate learning activities within an environment created by the teacher that has been designed to facilitate student learning (Biggs and Tang, 2011). Another benefit is that the students in the tutorial group learn with, from, and about each other, and from the facilitator. Facilitators would move between the groups and so there are times when students are working together without any facilitator input. Often, there would be time at the end to discuss and share the learning that has taken place within groups with the whole class. Typically there are groups within groups working together on activities so for a workshop with 40 students you may have eight groups each consisting of 5 students meaning these workshops are run four times (and not necessarily with the same facilitator/s).

Tutorials allow in-depth discussions with small groups of learners allowing greater opportunity to test individual student knowledge and understanding and to provide timely feedback "in the moment" to all participants within the tutorial. Compare the workshop where facilitators move around the groups spending time with each. There is opportunity to stretch the more able students in a tutorial. In a tutorial, the facilitator is part of the discussion group with all students present for all of the discussion. As with workshops students within each group learn with, from, and about each other and from the facilitator. Tutorials typically require pre-reading and/or activities to have been undertaken prior to the session. For a cohort size of 160 students, and a tutorial group size of 4 students, this would require scheduling 40 tutorials.

So when we are considering the choice of teaching method and the intended learning outcomes, there are other factors to consider in terms of resources, human and space, and scheduling. If we are looking at a 2 h teaching session for each student with one facilitator per session for a cohort of 160, then the total facilitator time will vary as outlined below.

Lecture	2 h
Workshop	8 h (2 h × 4 groups)
Tutorial	80 h (2 h × 40 groups)

This is a somewhat extreme example but serves to illustrate the continuing need to compromise ensuring meaningful student learning and effective use of limited, finite resources. If each student had 2 h of one-to-one time with a facilitator, and remember this is just for a single element of very many elements of a program, we would be looking at 320 h of facilitator time.

Other Methods of Learning and Teaching

The learning and teaching methods should be aligned with the assessment methods. Some examples of methods of assessing clinical skills include

DOPS—directly observed procedural skills
EPA tool—entrustable professional activity
ISCE—integrated structured clinical examination
Mini-CEX—clinical evaluation exercise
Mini-PAT—peer assessment tool
OSCE—objective structured clinical examination
OSATS—objective structured assessment of technical skills
Portfolio assessment.

In addition to didactic and interactive lectures, workshops and tutorials, there are other examples of a range of different teaching and learning methods and approaches. Not all will be appropriate for teaching clinical skills per se, but may be considered in developing underpinning knowledge and/or understanding.

- Demonstrations, e.g., of how to use a metered dose inhaler
- Practical classes, e.g., using placebo devices to learn how to administer epinephrine/adrenaline in an emergency
- Role-play, with or without expert patients of actors, e.g., patient request for a medicine from a community pharmacy
- Peer learning, e.g., 360° assessment, multisource feedback
- Self-directed learning—(resource-based learning)—including multimedia
- Directed study (resource-based learning)—including multimedia

- Seminar—a term used to describe different things by different individuals, for example, a workshop or a didactic lecture with question and answer component at the end.
- Tutoring, mentoring, and coaching approaches. Tutoring may involve imparting or facilitating acquisition of knowledge and skills to the learner. Coaching skills help the learner to reach their full potential and when using mentoring skills the facilitator can share specific personal and professional experiences to assist the learner to grow as an individual personally and professionally.
- Discussion groups (online) synchronous—working together at the same time enabling a real-time discourse
- Discussion groups (online) asynchronous—with a time lag, e.g., discussion forums and email
- Activity-based learning, problem-solving, and case-based learning, e.g., using patient notes, are examples of active learning
- Interprofessional learning (IPL) or interprofessional education (IPE) where members (or students) of two or more professions learn with, from, and about each other.
- Work shadowing, e.g., observation of others in a clinical or other work setting
- Workplace learning/experiential education
- Online-learning, e.g., MOOCs (Massive Open Online Courses)
- Blended learning, e.g., a combination of face-to-face and online learning
- Self-assessment, e.g., against certain criteria
- Observation, e.g., mini-CEX, DOPS
- Simulation, e.g., use of an orange, an injection pad, a high fidelity patient simulator injection arm to develop injection skills. This is a useful way of preparing individuals for clinical practice. It provides a safe, controlled environment in which new skills can be developed and competences assured. The type of simulation should be informed by the nature of the skills being developed, the level of expertise required and the learning outcomes (Lloyd et al., 2018).

They are not all mutually exclusive, for example, role-play could be used in a workshop or tutorial. Problem-solving could be used in various contexts, for example, the workplace, within a workshop, or as independent study. The mini-PAT is a peer assessment tool (PAT) consisting of an element self-assessment by the learner together with assessments from a number of the trainee's colleagues.

These are all appropriate substitutes for the clinical environment and should help build confidence to achieve the ultimate fidelity, where the individual is required to interact directly with patients under supervision. Formative assessments with feedback provided by faculty, clinical supervisors and senior students and, as appropriate, from peers help the learner develop skills in a safe environment, whatever the method used to develop clinical skills. [For more information on formative assessment and feedback, see Wood (2014)].

In addition to knowledge, understanding, and skills, demonstration of appropriate attitudes, values, and behaviors may be required and these may be incorporated into appropriate assessments. The reader is referred to Chapter 126 for further information on professionalism in pharmacy.

Reflection

Reflective learning, when learners take a step back from their learning (including feedback and/or assessment), helps them improve on future performance by, for example, critically analyzing their experience, and from using feedback, especially when formative assessment (Wood, 2014). Reflection is increasingly being used in healthcare and other settings as one component of revalidation of registered practitioners. Learners need to be prepared and so reflection is also increasingly found within initial education and training pharmacy programs for a variety of cadres. Reflection can be assessed, for example, via a portfolio and/or orally and can be incorporated as an element into formative as well as summative assessments (Driessen and van Tartwijk, 2014).

There are many different models of reflection. The learner can be informed to choose a model that they are most comfortable with or they can be given a choice of a small number of models. Alternatively, they can be told which model to use for a specific reflective writing assignment. For beginners the latter approach may be appropriate although for experienced practitioners requiring the use of a specific model would not usually be the approach used. Reflection is often associated with practice and so, for example, thinking of an incident that went well or did not go so well or when encountering something new. However, reflection can also be useful in the early stages of pharmacy education, even if they have had no real pharmacy experience. For example, learners may be asked to reflect on an assessment and its grade, their performance and the feedback they received. This should help students to incorporate the feedback received into improved performance in the future. Reflection can also be used following an interaction with a peer or faculty member that went well or did not go so well. It is important that students are facilitated to be able to reflect and develop into reflective lifelong learners. This requires formal evaluation of, and feedback on, reflective technique (Driessen and van Tartwijk, 2014).

Returning to Our Example

Let us return to the example of the outcome "Obtain and record relevant patient medical, social and family history" required of a pre-registration pharmacist prior to registration by the GPhC in Great Britain at the "does" level. We have established that direct observation would be an appropriate assessment method. Considering the principles of constructive alignment, which of the

teaching methods may be appropriate and which would be inappropriate? A didactic lecture on how to obtain patient history is highly unlikely to prepare an individual so that they are able to demonstrate that they are competent at this skill.

So when deciding on a method, or methods, we may wish to consider the following as possible options. The principles of curriculum design including identifying resources available, intended learning outcomes, and assessment methods will influence the choice of approach(es): demonstrations, observation, e.g., in a clinical setting, role play, peer assessment, self-assessment of video recording of the learner and reflection.

Directed study (resource-based learning), for example, using videos, may be selected as one element to assist learning. Although if students are required to identify videos themselves, for example, from the internet, the teacher has no influence on which videos the students use and there may be limitations or indeed errors within them. Direction to specific resources may be more appropriate, especially for novice learners as examples of good and bad practice can be highlighted.

The GPhC also requires MPharm graduates to show how they "Obtain and record relevant patient medical, social and family history." This is helpful for those training pre-registration pharmacists in that the trainers know they have a platform upon which to build and that the student has already been able to demonstrate they have, in a simulated environment, "shown how." This is an appropriate point to mention the concept of a spiral curriculum (Harden and Stamper, 1999). A spiral curriculum is one that is progressive and deals with issues in an increasingly more complex way, while revisiting previously learned material, until an appropriate level is reached. Integration with other knowledge, understanding, and skills is associated with this increasing level of complexity and facilitates clinical decision-making.

Students in the early stages of the MPharm would be informed of knowledge about the skill of history taking (the "knows") and would be expected to "know how" to take a history. The methods of assessment at this point might include examinations or coursework to assess knowledge and/or its application. The knowledge forms the platform upon which history taking can be learned, practiced, and assessed at the appropriate level. It is widespread practice in the UK that students are required to demonstrate history taking at the "shows how" level, at an OSCE station. The complexity of patients would increase year on year, aligning with the principles of a spiral curriculum so at graduation a student would be expected to be able to "show how" they obtain and record a history of more complex simulated patients, including those with co-morbidities, integrating knowledge and skills from across the MPharm curriculum. This should equate to the expected performance level of a newly graduated pharmacist in clinical practice.

So if we are going to select methods for teaching and learning of history taking in the early years of the MPharm degree we may wish to use something along the lines of the following:

An introduction to history taking as an interactive session at the beginning of a course (so at this point they have no knowledge upon which to build). This may well be a session on day 1 of the program. The session can still be made interactive though. Interactive introductory workshop/s following directed study (appropriate resources, e.g., written and video). That is, there is an element of a "flipped-classroom." Videos may include examples of pharmacists or pharmacy students or others taking a history from patients (simulated or otherwise). Discussion and application occurs within the group, so that there is interactivity, which lends itself to construction of learning by the students, with appropriate facilitation. One may wish to ask students about positive aspects of particular videos and areas for improvement. For a constructively aligned approach, the assessment tool/criteria that would be used for the final, summative assessment would be used for self, peer, and/or instructor assessment. There could be an opportunity to role-play with/without (audio or video) recording. Importantly constructive feedback and time for reflection by students would also be required. After one or more sessions a formative assessment would be appropriate. So if there is to be an OSCE as a summative assessment to assess learning, then a formative OSCE to help prepare the student would be appropriate, in addition to feedback provided "in the moment". It would also provide an opportunity for feedback to the student so they are able to use that feedback as feed-forward for subsequent learning, whether that occurs within an education/training or in a practice setting. All of these approaches benefit from supplementary early clinical exposure in the workplace ensuring that the learner is able to visualise expected future performance.

Choice of Methods and/or Approaches to Learning, Teaching, and Assessment

Choice of teaching and learning methods should be constructively aligned with the assessment whether or not as part of formal credit bearing course, for credentialing, certification, or for other reasons. Learners should be supported and if there is an associated assessment they need to be prepared for that assessment, including feedback as feed-forward in the form of a formative attempt at the planned summative assessment. It is important that teaching and learning methods, together with associated assessments are considered as part of the whole curriculum, module, unit of study, or as a stand-alone course. The principles apply whether there is face-to-face, online, or blended learning. The principles of curriculum development (or design) should be considered carefully, including the context of the learner (e.g., starting point in terms of knowledge and skills), for a student pharmacy technician or a foundation pharmacist or an experienced, expert specialist pharmacist practitioner with prescribing rights. The principles should also be applied to stand-alone courses or units of study especially so that learning methods are constructively aligned with the assessment of the intended learning outcomes/competencies.

So being clear about what students are expected to be able to do at the end of the learning is critical and then the teaching and learning methods can be selected based on their appropriateness (for a learning outcome or competency statement). This also facilitates effective course evaluation by comparing expected and achieved performance of the learners following the course closure.

How do Students Learn? Signposting to Learning Theory

Knowles, proponent of the "adult learner," defined theory as "a comprehensive, coherent and internally consistent system of ideas about a phenomenon" (Knowles, 1973, p. 5 in Kaufman and Mann, 2014, p. 7). Many theories exist that help us understand how learners learn. Eight such theories, including their implications for education practice have been outlined by Kaufman and Mann (2014) within the context of medical education and these are as follows.

Adult learning principles
Communities of practice
Experiential learning
Social cognitive theory (behaviorist)
Reflection and reflective practice
Self-directed learning
Situated learning (constructivist)
Transformative learning

An understanding of education theories can enhance learning from a student perspective as well as from that of the trainer or teacher. This applies equally to developing clinical as well as other skills and attributes, and to knowledge and understanding. Engagement with, and understanding of, learning theories helps us as educators to understand the different ways in students learn and how that learning can be facilitated or enhanced.

Constructivism as a Theory

The theory is used in the context of "constructive alignment" (see above). Others have used the terms "curriculum alignment" or "curriculum coherence" when referring to the same broad philosophical approach. Learners construct knowledge from activities, these may be undertaken alone or with others and these activities are often, but not always, selected by, or in partnership with the teacher. It is not the learning itself that brings about change but how the information is structured and applied that does. A number of constructivist models of learning exist. A model focusing on learners as independent individuals (e.g., what some refer to as psychological constructivism) and the social constructivist model which focuses on the social interactions between individuals with those who may have more expertise and assist individuals to learn. For more information on the various models please see Fosnot (2005) and Rockmore (2005). It is important to note that constructivism is a perspective on learning that is focused on how students actively construct or create knowledge out of experiences/activities.

Active Learning

Active learning can help to develop higher order intellectual capabilities such as analysis, synthesis, and evaluation, unlike the didactic lecture. However, group size and the number of facilitators each affect the quality of the learning, interaction, and feedback. Some curricula are based on problem-based or team-based learning, each of which is described below.

Problem-Based Learning (PBL)

This is a student-centered pedagogy where students use "triggers" from a scenario to identify their own learning objectives. Students undertake independent, self-directed study and then discuss their learning as a group. PBL uses well designed scenarios/cases and so requires significant resource from facilitators in the design of the cases and the step-wise process required to tackle the problem (different variations of PBL exist). It is also important that the groups are facilitated well. Problem-solving and PBL are not synonymous. The former can be used independently in any pedagogy and context and includes, for example, identifying an approach analgesic for a specific patient presenting with a tension headache.

Team-Based Learning (TBL)

TBL is an educational approach where students are more autonomous and have greater responsibility for their learning. Unlike group work, a critical component of TBL is that the groups (teams) are permanent so are able to develop into and function as effective teams of learners. The approach requires significant investment in preparing facilitators and students so this should be seen as allowing students to get on with their learning. TBL is more akin to directed or self-directed study in the form of a group. Significant time and thought is also required to develop the assignments/learning activities so that collective working and learning in a collaborative manner can be achieved.

Motivation for Learning

Motivation is having the willingness and/or desire to do something. Many theories exist that seek to explain motivation for learning, for example, expectancy-value theory, attribution theory, social cognitive theory, goal-orientation theory, and self-determination theory (Cook and Artino, 2016). Self-determination theory (SDT) is an established framework based on intrinsic motivation, extrinsic motivation, and amotivation and focuses on the human need for competence (ability to undertake a task), relatedness (a sense of belonging within the learning community), and autonomy (an element of choice and control over their learning). Intrinsic motivation is motivation relating to interest and/or enjoyment and promotes deeper learning, improved academic performance and overall wellbeing when compared with extrinsically motivating influences (Ryan and Deci, 2000a, 2000b; Niemiec and Ryan, 2009). Examples of extrinsic motivation include reward and recognition, by self or others and fear of failure/avoiding punitive measures. Kusurkar et al. (2011) identified a number of ways to stimulate intrinsic motivation in students through autonomy-supportive teaching derived from SDT and these can be applied to across a number of settings/contexts. Here are their 12 tips:

1. Identify and nurture what students need and want
2. Have students' internal states guide their behavior
3. Encourage active participation
4. Encourage students to accept more responsibility for their learning
5. Provide structured guidance
6. Provide optimal challenges
7. Give positive and constructive feedback
8. Give emotional support
9. Acknowledge students' expressions of negative effect
10. Communicate value in uninteresting activities
11. Give choices
12. Direct with "can, may, could" instead of "must, need, should"

Feedback and Feed-Forward

"Arguably the most powerful enhancement to learning is feedback during learning" (Biggs and Tang, 2011, p. 64). Formative feedback is that which is provided during learning, prior to any summative assessment. It helps the learner understand what they need to do and should be given in a timely manner so the feedback is meaningful, helps them with future learning and should be constructive, including a combination of reinforcing the positive elements and those in need of improvement (and if appropriate, sign-posting and/or support for the learner to improve). When feedback is helpful to future learning and/or assessment the term feed-forward is often used (Biggs and Tang, 2011).

Principles of Curriculum Development

The curriculum includes the syllabus but is more, much more than the content. It includes, but is not restricted to the following, in no particular order:

- learning, teaching, and assessment methods
- quality assurance and standards including criteria, e.g., what is a "pass"?
- sequencing and timing, including space and time to assimilate learning prior to any assessment
- the learners, including qualifications, experience, and numbers
- the learning environments, including online, plus within class and out of class support
- the teachers and facilitators of learning (including patients and practitioners) plus support staff, their attributes, experiences, and numbers
- finances

Input into development of a curriculum should be sought from a variety of stakeholder groups, for example, employers, prospective learners, patients and the public, other professions, professional bodies, regulators, and/or health and social care policy makers at local or other levels. That is, a needs-based approach should be used (see Chapter 123). How each element links with all other elements also needs to be planned, so horizontal and vertical integration and constructive alignment are considered. A final draft curriculum needs be communicated to stakeholder groups. It should be capable of being contested and must be responsive to change; indeed anticipate changes in practice. This is an opportunity to review the course or program and at this point further enhancements are usually made in response to stakeholders.

If the course is accredited, certified or credentialed, then compliance with the education provider's requirements (e.g., universities) and/or other bodies such as the appropriate pharmacy or other regulator, national or regional/state government and/or professional body must be adhered to. Such requirements include credits, course length, entry requirements, study hours, and

outcomes. There are additional complexities when accreditation or recognition for one course is required by two or more regulators, for example, by nursing, medicine, and pharmacy regulators and also when courses are designed for, and require accreditation in, two or more countries or other jurisdictions, for example, United States.

Importantly, the principles of curriculum design can also be applied to short courses or units of learning, as well as to a program curriculum, such as for a bachelor, masters, or doctorate level degree. So the principles can, and indeed, should be used when designing teaching/learning of clinical skills at all levels including CPD (continuing professional development) for practitioners. Please do not underestimate the time needed to communicate and meaningfully engage with colleagues and other stakeholders (and feedback) throughout the development, encouraging and listening to alternative views through the consultation. This will help result in a shared curriculum, that has ownership or "buy in" from its stakeholders.

Evaluating Courses

Once the course starts evaluation is important, and not only with the first cohort and provides valuable quality assurance for the stated aims of the course. Feedback from learners, teachers, employers, and patients of those who are developing/have developed knowledge and skills during a program should be sought in a number of ways (e.g., surveys, face-to-face review discussion groups, telephone interviews) and at various points. Curriculum review is an iterative process not an event. Adequate resource, including human, for evaluation also needs to be factored in, including, where possible evaluation by those who are independent of the course. Other forms of evaluation include review of student performance relating to any assessments, of the individual learner and also, cohort data. As further cohorts pass through, between cohort data should also be reviewed seeking to identify enhancements and reassure stakeholders, including regulators, of expected learner outcomes. (For further information on evaluation of courses and teachers see Kember and Ginns, 2012.)

Summary

In summary, seven elements of good learning contexts have been identified by others (Hattie, 2009; Biggs and Tang, 2011) namely

1. reflective learning
2. relevant learning activity
3. formative feedback
4. appropriate motivation
5. appropriate integrated/interconnected knowledge base
6. social learning
7. quality of the teaching/learning facilitation (teaching methods, attributes, and environment)

Each of these should be considered carefully when designing learning and teaching clinical skills, ensuring there is constructive alignment with the assessment(s). When used appropriately they will support independent and deeper learning, helping the individual to become a reflective, life-long learner who is able to use and apply new knowledge and develop new skills in an ever changing context.

Needs-Based Education in Pharmacy

Henri R. Manasse Jr., Brianna M. McQuade, Jennie B. Jarrett, University of Illinois at Chicago, College of Pharmacy, Chicago, IL, United States

The Foundation of Needs-Based Considerations in Pharmacy Education

In the contemporary world, the profession of pharmacy constitutes a wide-array of roles, scopes of practice and responsibilities. These roles range from a direct patient care provider who assures safe and effective therapeutic outcomes in patients to scientific experts engaged in all facets of drug discovery and development. Other roles focus on regulatory sciences and practices while yet other roles center on the manufacturing of drugs, biologicals, vaccines and other substances for human and animal consumption. Each of these areas of practice have a common core of competencies but then differ significantly as the expert skills are demanded by the scope of work (International Pharmaceutical Federation, 2017; Lutz et al., 2009).

Thus, a direct patient care role demands a different set of skills than the role of inspector for a national regulatory authority. A role in manufacturing technology, differs dramatically from that of a role as a dispenser of medicines in a community pharmacy (FIP, 2018; Lutz et al., 2009). While on the one hand, the variety of roles that can be taken up by an individual who is educated in a school of pharmacy and achieving a first degree in that discipline is a major advantage to new graduates, but on the other hand, the "jack of all trades but master of none" phenomena is a reality in the marketplace for employment. This dilemma is pressing on national pharmacy organizations, institutions of higher learning and on the wide array of employers who hire and utilize pharmacists.

Through the advocacy work of national organizations representing pharmacists around the globe, the issue of workforce development of pharmacists has gained some attention. In these cases, the pharmacy workforce is being described as ranging from pharmacy technicians/assistants, to generalist pharmacists, to pharmacy specialists at the highest scientific and professional levels. Along with such description of the workforce, comes the focus on length of training, content of the required educational program and ultimately, the title of the final degree that is conferred. Another critical element is the legal and regulatory infrastructure which grants practice privilege and determines the scope of practice of pharmacists in a given country (International Pharmaceutical Federation, 2017).

The majority of individuals pursuing formal higher education in pharmacy in most countries do so to become practitioners of the profession of pharmacy. That is, to prepare themselves for pharmacy practice roles that focus on patient care. Such roles typically comprise dispensing of medicines, counseling patients on their appropriate use, interfacing with prescribers to assure therapeutic rationality and various functions relating to managing the drug, vaccine and biological drug supply (FIP, 2018; WHO, 1993). In some countries where the pharmaceutical manufacturing industry secures a large portion of the national economy, the majority of graduates will gravitate to working in that industry (Lutz et al., 2009). In that case, graduates will work in areas from product manufacturing, quality assurance and control, to regulatory and marketing and sales.

Determining Needs

Given the complexity of the pharmaceutical armamentarium from both a clinical and scientific perspective, the education and training of individuals to be pharmacists is offered in institutions of higher learning (e.g. universities). The need for such high level educational programs is clearly established by the knowledge, skills, and behaviors that are necessary to assure safe, effective, and efficient use of medicines in patient populations as well as producing, distributing and utilizing pharmaceuticals, vaccines, biologicals, and contrast media (WHO, 1993, 2011). The skill set necessary for fitness for practice in any of these areas requires lengthy education and training from a faculty of pharmacy which is composed of a wide array of content experts. Such experts typically range from those who are engaged in drug discovery, drug formulation, pharmaceutical technology, analytical and quality assurance testing, and several of the medical sciences including pharmacology, microbiology, immunology, genetics, pathology, and physiology (Al-Wazaify et al., 2006; Knoer et al., 2016). More recently schools/colleges of pharmacy have added pharmacy

clinicians with specialization in specific areas of drug therapeutics and drug dosing using principles of pharmacokinetics and pharmacodynamics as well as genetic prediction of effectiveness (Knoer et al., 2016). Behavioral scientists from sociology, psychology, management, public health, and economics have also been added to some schools/colleges along with those trained in pharmacoeconomics, pharmacoepidemiology, and population-based health (AACP, 2018) (AACP colleges and schools of pharmacy). This great diversity of faculty skills and areas of expertise has come to define the scope, mission, and objectives of the curricula in schools of pharmacy.

Even though faculties of pharmacy have attempted to constitute their programs with capable and skilled content experts, the fundamental question of faculty is, "*What needs do we aspire to meet in our respective societies insofar as the pharmacist workforce is concerned?*" is often elusive. Many factors that are intrinsic to the university and the pharmacy profession contribute to the capacity to answer this policy question. Moreover, forces extrinsic to the pharmacy profession and its related university teaching program play an important part. The latter has been the focus of the World Health Organization (WHO) and leaders in the area of health professions workforce planning, through various initiatives under the banner of "social accountability in health professions education" (Boelen and Heck, 1995). The perspective embodied in these efforts seeks to construct a relationship between the nature, essence, and curricular objectives of the health professions educational program and the evident and real health care services needs of the population in a given country (Boelen and Heck, 1995).

Careful consideration of the phenomena described above might be examined from the perspective of the Millennial Development Goals (MDGs) of the United Nations (UN, 2015). These population-based goals include targets associated with acute health needs, chronic illnesses, neonatal and maternal deaths, nutrition, and environment. Clearly, pharmaceutical agents, vaccines and biological agents play a most serious role in the mitigation, cure and/or amelioration of infectious disease, other acute diseases, and chronic disease areas included in the MDGs (UN, 2015). Hence, pharmacists and pharmaceutical scientists should play a crucial role in addressing the MDGs in their respective countries. This would be reflective of acting in a socially accountable fashion and would address top priority health needs of a nation and across the world.

To assist Universities and professional pharmacy organizations in both understanding and implementing such a planning paradigm, the International Pharmaceutical Federation (FIP) has introduced a Needs-Based Educational Model depicted in **Fig. 1** (FIP, 2017a).

Key drivers in this model are VISION, LOCAL DETERMINATION, SOCIAL ACCOUNTABILITY, GLOBAL CONNECTION, and QUALITY ASSURED. The paradigm then assumes that these enumerated drivers will in turn create the competencies, educational programs and curricula, and skilled services provided by pharmacists and pharmaceutical scientists to meet the local, regional, national and global needs of the people for quality medicines, therapeutic rationality, and services (FIP, 2017a). While this idealized paradigm has witnessed broad study and discussion among educators and professionals in pharmacy, it is far from being universally adopted and utilized as an authoritative guidance for rational curricular planning (Olivera et al., 2018).

From among many challenges associated with aligning national needs related to its pharmacy workforce to an appropriately constructed pharmacy curriculum, one must focus especially on the depth, breadth and level of intensity (with respect to knowledge and skill acquisition) of the curricular program. That is, at what level and expectation do courses and instructional exercises have to be aimed, given the available human, physical and operational resources for the pharmacy program. It is not unusual when one considers all of the pharmacy curricular programs around the world, that there is also great variation in the resource levels allocated

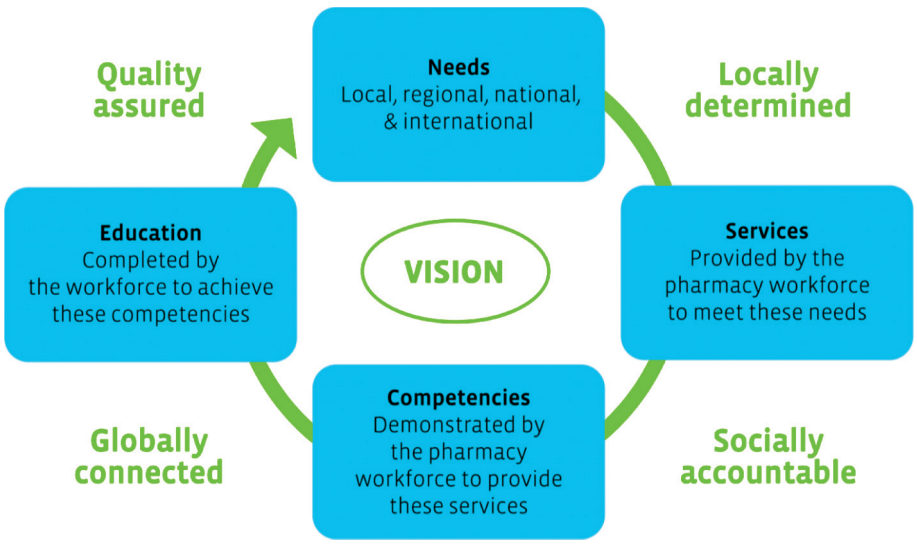

Figure 1 International Pharmaceutical Federation (FIP) needs-based educational model. *Source: Used with permission from International Pharmaceutical Federation (FIP), 2017. Research, Development and Evaluation Strategies for Pharmaceutical Education and the Workforce: A Global Report. The Hague: International Pharmaceutical Federation. Retrieved from:* http://fip.org/files/fip/publications/FIPEd_RDES.pdf (FIP, 2017a).

to the schools of pharmacy (Anderson and Futter, 2009; FIP, 2017b). Most notable are variations in facilities, numbers and types of faculty skill levels, coherent curricular pathways and support options such as financial assistance to students, library facilities, and career guidance (International Pharmaceutical Federation, 2017; FIP, 2017b; Anderson and Futter, 2009).

The Reality of Pharmacy Education Around the World and Barriers

The WHO currently boasts almost 200 countries in its membership. Among these 200 countries, it is estimated that there are over 3000 schools/colleges of pharmacy (FIP, 2017b). Careful examination of these programs demonstrates a wide-variation in content and scope of the curriculum, length of study to achieve the first degree of credential for completion, title of the degree or completion certification, numbers and skills of the faculty including areas of expertise and linkage of the program to the health care services system of the country (FIP, 2017b). Some programs produce individuals with strong skills in pharmaceutical sciences and pharmaceutical technology geared to employment in the pharmaceutical industry or national regulatory bodies. Other programs produce individuals capable of being drug experts in terms of the science and clinical aspects of comparative drug therapeutics (Anderson and Futter, 2009; FIP, 2017b; Lutz et al., 2009). Graduates from such programs find employment in hospitals, physician offices and clinics or community pharmacies (FIP, 2018). However, this great divergence in "types" of faculties of pharmacy and "types" of skill levels inherent in program graduates poses an important national and global policy problem, "*Whose needs are being met or not met?*" The corollary policy question that can be raised is, "*Can individual faculties of pharmacy produce individuals with sufficient skill and competence to carry out accountable functions in pharmaceutical industry as well as clinical management of patients?*". Additionally, "*Should the educational community continue to produce individuals called pharmacists for the pharmaceutical industry and regulatory arena at the expense of not producing pharmacists who can assure safe, effective and efficient use of medicines in the patient population and vice versa?*". These are crucial policy questions not only for the profession of pharmacy and its educators, but they are also important policy questions for ministers of health, ministers of education, consumer organizations, and patients themselves (Anderson and Futter, 2009; International Pharmaceutical Federation, 2017).

To highlight how the needs of a country shape the curriculum and focus of a pharmacy school, the comparison of Thailand to the United States reveals different approaches. In Thailand, the bachelors of science (BS) programs focus more on product-oriented topics, which is traditionally where pharmacists have been needed (Kapol et al., 2008). Of the colleges of pharmacy that offer a 6-year doctorate of pharmacy (PharmD) program, there are 4 tracks—pharmaceutical care, industrial pharmacy, specialized tracks, and an international program. This differs from the United States, whose colleges of pharmacy are more direct patient-care oriented with one track offered—pharmaceutical care. However, based on the local changing healthcare system, there is a growing need in Thailand for highly educated, practice-based pharmacists; correlating is the need for instructors who are qualified for teaching patient care (Chanakit et al., 2014; Kapol et al., 2008). Based on this, the country has several colleges planning to develop postgraduate residency programs to improve the number of pharmacists who are trained and experienced in direct patient care (Chanakit et al., 2014). Additionally, all schools of pharmacy (BS and PharmD alike) now teach from a competency-based standpoint, with eight competency domains that are mostly patient-oriented (compared to product-oriented) (Kapol et al., 2008).

In Singapore, the Ministry of Health has encouraged continued dialog regarding education, postgraduate training, and advanced practice credentialing for pharmacy-related personnel in order to address the growing need unique to their culture: combining westernized medicine with native customs. They aim to develop pharmacy into a practice that will reach their citizens in a meaningful way; "otherwise, optimization of the benefit of medications will not be within the reach of any Singaporean" (Parrish and Chew, 2018). Indeed, at National University of Singapore, Natural Products is a required class for its graduating pharmacy students (Chui et al., 2009). This ongoing work is based on Singapore's patient needs and thus they are adapting their pharmacy education force (Parrish and Chew, 2018).

Leadership in the Universities at the Faculty and Divisional levels of Faculties of Pharmacy is a critical determinant for answering policy questions such as those raised here. From among competing priorities and interests, choices have to be made, which then drive hiring, faculty development and promotion decisions. Assuring an appropriate and sufficient budgetary allocation, having utilitarian buildings and laboratories including libraries and electronic resources, and facilitating the teaching and learning process with appropriate space are elements of a leader's responsibilities as s/he administers a faculty of pharmacy. These executive tasks are challenging even in the best of circumstances and yet few individuals in these positions have formal training for such roles.

The lack of a linkage between the theoretical/didactic aspects of a university pharmacy program and the several elements of professional pharmacy practice is also a serious barrier in many countries. The lack of practitioner–teachers in many schools/colleges of pharmacy further divides the intentions of the pharmacy curriculum with the practice needs of patients and pharmacy practitioners. The profession of pharmacy is still universally rooted to the archaic notions of apprenticeship and often times institutes legal requirements for practice-based experiential education prior to licensure or other legal basis for entering into practice (Anderson and Futter, 2009; Anderson et al., 2012).

Variation in curricular content, depth and breadth among faculties of pharmacy has been a barrier to the development and utilization of a global universal model for defining the profession of pharmacy and its social tasks and accountabilities and scopes of practice (FIP, 2017b; International Pharmaceutical Federation, 2017). Hence, the expectations of policy makers, health system decision makers, other health professions and patients are oftentimes cloudy at best. This puts the profession of pharmacy in a challenging position when seeking public resources and public support.

Professional Services

Just as there is great variation in the offering of pharmacy education degree programs, there is a similar variation in the scope, depth, breadth, and extent of pharmacy services offered to patients and colleagues in the other health professions around the world. Likewise, there is great variation in how the various types of individuals comprising the pharmacist workforce are utilized.

Perhaps the most evident and universal role of the pharmacists is focused on the drug product. From its acquisition to its routes in the supply chain to the ultimate consumer, pharmacists and pharmacy technicians/assistants play an integral role in getting medicines from the source of manufacturing and/or preparation to the patient. Assuring the integrity of the supply chain is paramount since product integrity is key to therapeutic integrity in the patient. Since drugs, vaccines, and biologicals are high-tech products they require dedicated vigilance in movement, storage, and distribution. To the extent that a sufficient supply of pharmacists and pharmacy technicians are involved in all aspects of the pharmaceutical supply chain, in general it can be said and assumed that the system works effectively (WHO, 1993, 2011).

The challenge from a global perspective, is that pharmacists are not always present in the entirety of the supply chain. Many countries do not have pharmacists in hospitals (Anderson and Futter, 2009; FIP, 2018). Likewise, many countries do not have nor do they require pharmacists in local community shops where medicines are sold (Lutz et al., 2009). A number of countries have drug sellers—individuals neither educated nor controlled—who sell medicines to whomever is willing to pay under the credo "let they buyer beware" (Lutz et al., 2009). It is not known in such situations, what the incidence and prevalence of injury or death attributable to drug misadventures might be.

In the case of hospitals in a number of countries, they have left it to nurses to compound sterile admixtures on the patient floors, raising issues of scientific accuracy, sterility and chemical compatibility. They have also left the procurement task to individuals without knowledge of therapeutic appropriateness, duplication, or cost insensitivity (Anderson and Futter, 2009; Lutz et al., 2009).

Since the late 1940s, there has been contemplation and discussion of a more clinical role for pharmacists given their general knowledge of drugs and how these drugs behave in human systems (WHO, 1993, 2011). With the advent of the discipline of pharmacology and its drift into faculties of pharmacy as well as the development of knowledge in pharmacokinetics and pharmacodynamics, there have been growing pockets of practice around the world with a distinct clinical focus. In such practices, properly educated pharmacists work in tandem with prescribers to assure the most clinically effective and cost–beneficial drug therapy in patients. While early models of such a practice orientation occurred in hospitals, more recently these models have been instituted in ambulatory care environments including physician practices and freestanding clinics (Anderson et al., 2018). Several studies have demonstrated that pharmacists in such clinical roles improve patient outcomes and are economically effective and efficient (Chisholm-Burns et al., 2010). In countries with abundant resources, such as Canada and the United States, there exists advanced training for pharmacists to the level of autonomous and "full scope" practitioner. Pharmacists with sufficient training are expected to be involved in medication prescribing, disease management, ordering and interpreting of relevant tests, and vaccinations (Tsuyuki et al., 2018; Walton and Manasse, 2018).

The clinical role of the pharmacist is being advanced by a growing commitment to practice-based research (WHO, 1993). Most of these findings point to the utilization of pharmacists in assuring patient outcomes in chronic disease management, disease prevention initiatives through immunization and assuring patient adherence to prescribed therapies. Several countries have oriented their pharmacist services reimbursement systems to financially support such clinical efforts (Lutz et al., 2009). In its 2012 Declaration, the pharmacist member organizations of the FIP pledged to take on responsibility and accountability for patient outcomes that center on drug therapy throughout the world (FIP, 2012).

Moving the entire profession of pharmacy in this direction will be a significant challenge to both the profession and the educational institutions that educate pharmacists. These organizations will need to assure that a pharmacist workforce that is of sufficient size and competence will be available to all patients. Assumed in this evolution is the fact that university faculties will need to be constituted in such a way that they have sufficient and qualified faculty members that can teach and model clinical drug therapy management in real and simulated patients. It is also assumed that such faculty members have sufficient grounding in the basic, medical, and pharmaceutical sciences that roots their clinical skills in scientific evidence and clinical experience. Moreover, it will mean that faculties of pharmacy will need to align with university hospitals and medical centers as well as freestanding health care services facilities such as clinics and medical outposts for the purposes of education, training, and research.

As an example of such an undertaking, Saudi Arabia is currently expanding its number of pharmacy schools to supply the demand for pharmacists (according to a WHO report in 2006, there are only 20 pharmacists per 100,000 population in Saudi Arabia, compared to 88 in the US) (AlRuthia et al., 2018). This is a challenge for the developing country due to limited number and low quality of pharmacist–student training sites, lack of training assessments, and variety of practice models amongst sites (Aljadhey, 2012). The college of pharmacy at King Saud University, the country's oldest pharmacy school, underwent a curriculum renovation in the 2010s in order to incorporate more pharmacy practice experiences for accreditation purposes. The school increased the required number of contact hours in pharmacy practice from one semester to 500 h over two summer experiences. To support this influx of students, they created an experiential training unit that developed a preceptor training program, accredited training sites, and constructed training manuals and an assessment system (Aljadhey, 2012). In 2017, Saudi Arabia increased its number of pharmacy schools to 27 (compared to only one in 2000) (AlRuthia et al., 2018). While the country does not have its own pharmacy-specific accrediting body, three institutions are currently certified by the Accreditation Council of Pharmacy Education (ACPE) (including King Saud University) and three additional institutions are accredited by the Canadian Council for Accreditation of Pharmacy Programs (CCAPP) (ACPE, 2018; CCAPP, 2018). Additionally, increasing specialized roles for pharmacists in

hospitals, such as educating doctors and nurses on safe and appropriate use of medications, will increase the opportunities for postgraduate training (AlRuthia et al., 2018; Ministry of Health, 2017). With increasing numbers of schools and accreditation by international organizations to align global standards in pharmacy education, Saudi Arabia is working to meet the patient need for well-trained pharmacists.

As the scientific areas of discovery expand knowledge in precision medicine, genetics and population health, these findings will also find opportunity for a clinically educated and focused work force. Several practice models that focus on these areas of special expertise are already being established (Oji et al., 2013; Owusu-Obeng et al., 2014). And it is not outside of the realm of possibility that such practices will find welcome home around the world, especially where pharmacists, physicians, and clinical scientists work together effectively (WHO, 1993).

Health systems around the world are continuously confirming that the need for health care services at all levels far outpaces the financial and human resources available. Hence, these systems are constantly finding new ways to reduce budgets, create new ways of doing work, challenging the scope of benefits and implementing creative cost-cutting schemes. Pharmacy practice has not been immune to these efforts. It is incumbent on the pharmacy profession to determine cost-effective and efficient ways by which it can offer clinical services, assure the integrity of the drug supply and distribution system and keep patients satisfied with their efforts. Embracing appropriate responsibility and accountability will be the hallmark of socially-meaningful professional services.

Competencies

The wide variety of pharmacy services provided and academic pathways around the world for those positions calls into question how pharmacists and their support staff (technicians, interns, etc.) are educated and trained. Historically, a time-based model was utilized, where students who satisfactorily completed a specified course hour requirement were conferred at graduation with their degrees and eligibility for licensure (Medina, 2017). As the needs of pharmacy practice have evolved over time, so too has this education model, away from this traditional time-based requirement toward a demonstration of competency in practice by pharmacy learners for graduation (McGaghie et al., 1978). By focusing on competencies needed in practice, pharmacy education becomes up-to-date, relevant, and useful.

Outcomes-based education, also known as competency-based education, centers on a learner mastering functions necessary for practice within a practice setting (McGaghie et al., 1978). This unique curricular focus shifts pharmacy education and its accompanying assessment from merely a knowledge-based educational model, toward a knowledge, skills, and attitudes-based educational system where students are not only educated about medication products but also have the ability to function in patient care within multiple patient care settings. Under an outcomes-based educational model, the pharmacy student output is a competent practitioner ready for practice (McGaghie et al., 1978).

Outcomes-based education has been the standard of education in the United States since the early 1990s. The Center for Advancement of Pharmaceutical Education (CAPE) initially saw the need for an educational transition to outcomes-based mechanisms in an effort to support pharmacy curricular transformation toward producing practice-ready pharmacists with the growing pursuit of students for the Doctor of Pharmacy (PharmD) degree (AACP, 2004). These CAPE outcomes have been revised and updated significantly over the decades to help guide curricular change to meet the local and national pharmaceutical care needs. The Accreditation Council on Pharmacy Education (ACPE) now incorporates the CAPE outcomes as a part of their accreditation standards for colleges/schools of pharmacy (ACPE, 2015). This inclusion of outcomes-based education within the accreditation standards, forces colleges/schools of pharmacy to consider the evolving direction of pharmaceutical care provisions and the educational mechanisms to get there.

The Pharmacist Patient Care Process (PPCP) and Entrustable Professional Activities (EPAs) are additional forms of outcomes-based education and assessment that describe the pharmacist's professional competence outcomes in easy to understand language. The PPCP was devised by the Joint Commission of Pharmacy Practitioners (JCPP) to clearly describe and provide consistency to the patient care process that each pharmacist performs when providing direct pharmaceutical care (JCPP, 2014). The PPCP specifically incorporates evidence-based, best practices for the incorporation and utilization of pharmacists in direct patient care (JCPP, 2014). EPAs go beyond just the activities of pharmacists within the direct patient care settings. EPAs are tasks or descriptors of work that can be fully entrusted to a professional (Haines et al., 2017). EPAs use layman's language to describe the full scope of a pharmacists' practice, including patient care, administrative tasks and interprofessional team member related tasks (Haines et al., 2017). The PPCP and EPAs are useful resources that make outcomes-based education understandable for larger stakeholder groups, like patients and other healthcare workers, in order to communicate what a pharmacist can do, and how they perform that task in patient care settings.

There is a growing global utilization of outcomes-based education as core competencies, EPAs and ACPE's certification initiatives for pharmacy learners. The Pharmaceutical Society of Ireland has delineated a competency framework in practice for community pharmacists to elevate their education and training of pharmacy learners for practice and continuing development for practicing pharmacists (The Pharmaceutical Society of Ireland, 2013). Innovatively, The Royal Dutch Pharmacists Association has educational programming for advanced community pharmacist practice with outcomes-based education in a unique framework that incorporates both competencies from an educational level linked to EPAs within unique task areas (Royal Dutch Pharmacists Association, 2012). For global standardization of pharmacy education, ACPE and the Council for Higher Education

Accreditation (CHEA) International Quality Group (CIQG) joined forces to demonstrate their commitment to quality principles in pharmacy education that incorporate many outcomes-based educational initiatives (MOA, 2017).

Outcomes-based education is not only limited to undergraduate pharmacy education, but is also a cornerstone of postgraduate pharmacy training (Saseen et al., 2017). Pharmacy learners have postgraduate training opportunities within residency, fellowship or postdoctoral positions. While pharmacy residencies typically train pharmacists for clinical positions with further direct patient care responsibilities, fellowships and postdoctoral positions traditionally focus on intensive research training (Anon., 1987). Fellowships and postdoctoral positions for pharmacists are directed by the type of research performed by the program and have a bimodal distribution between academic institutions and pharmaceutical industry (Larochelle et al., 2009). These specialized postgraduate training opportunities are based on institution affiliation and collaborator experience and thus, do not have a listing of outcomes for the experience.

Pharmacy residency programs are wide-spread across the United States, and thus, outcomes-based education standards are critical for the support of standardization of learning and higher level pharmacy practice (e.g. beyond entry-level skills). The pharmacy residency accreditation body, the American Society of Health-System Pharmacy (ASHP), provides outcomes-based standards for residents according to the residency they are completing, postgraduate year 1 (PGY1) or postgraduate year 2 (PGY2) specialty residency. Through the formation of task forces of stakeholder groups, including the profession's leaders, residency program directors and preceptors, outcomes-based accreditation standards are devised for each type of residency program and utilized for accreditation purposes (ASHP, 2017a). Competency areas for PGY2 residency programs differ from PGY1 competency areas through specialty focus, such as infectious disease, critical care, or ambulatory care, as well as higher level clinical, administrative and/or educational functioning (ASHP, 2017b). As an element to elevate pharmacy practice across the globe, multiple international institutions have instituted pharmacy residencies and are accredited based on these same standards. International pharmacy residencies can be found in Singapore, Saudi Arabia, and the United Arab Emirates (ASHP, 2018). Nonaccredited pharmacy residency programs can be found in Spain and Argentina, as well as other countries. These programs mimic accreditation standards from the US, but are regulated by their national professional associations (ASHP, 2018).

Beyond pharmacy education and training, outcomes-based continuing education and practice are important for maintaining an acceptable level of pharmacy practice. Clinical pharmacist competencies are defined by the American College of Clinical Pharmacy (ACCP) for those postgraduate trained pharmacists who practice comprehensive medication management in direct patient care settings (Saseen et al., 2017). Uniquely, these competencies denote similarities to providers' domains by correlating the pharmacists' competencies to physician competencies in practice. Additional credentialing and privileging can occur for pharmacists at local and national levels. Each health system (e.g. individual hospital or group of hospitals) typically has their own requirements regarding credentialing at their institution or within their state jurisdictions. For example, the state of North Carolina has additional credentialing availability for qualified pharmacists to become a Clinical Pharmacist Practitioner or CPP. With this additional credentialing through the state board of pharmacy, CPPs are able to prescribe medications during the usual course of drug therapy management under the supervision of physician (North Carolina Board of Pharmacy, 2017). On a national level within the United States, pharmacists may become board certified by the Board of Pharmaceutical Specialties (BPS). Nuclear pharmacy was the first specialty to be certified in 1978; however, now there are eight recognized specialty areas including, pharmacotherapy, critical care, and ambulatory care (Board of Pharmacy Specialties, 2017). Board certified pharmacists are recognized and practicing globally.

Assessment strategies for outcomes-based education have evolved over time to match the pharmacist output. Historically, lectures were the mainstay in delivery of education in pharmacy schools (Medina, 2017). With the update of outcomes-based education models, didactic sessions are moving toward active learning models, such as case-based problem activities or lecture-discussions. These active learning models require students to prepare outside of the classroom through reading or listening to a lecture, and actively participate utilizing that information during the classroom time individually or in groups. These daily assessments of knowledge of the student prepare students for more active engagement in the patient care process, where they must take their knowledge and readily apply it to patient situations (Gleason et al., 2011; Stewart et al., 2011).

Outcomes-based education for clinical professions shifts assessment from the classroom into the clinical learning environment. In order for learners to demonstrate not only their knowledge, but also their skills and attitudes, experiential practice and assessment is important. Direct observation is the cornerstone for this type of practice-based assessment. Faculty members or trained preceptors in practice provide graded levels of supervision for learners in direct patient care activities, where novice learners are given low level tasks or are able to shadow mentors while higher level learners, such as residents, are able to perform a complete clinical task with only reactive or distant supervision. The EPA assessment framework, in conjunction with a shift to outcomes-based education, formalized this level of supervision scale to direct faculty and preceptors in their evaluations of learners. By increasing the amount of direct observation of the learner, there are increased opportunities for feedback for the learners, shifting the evaluation and feedback scheme from a summative evaluation to a progressive feedback and entrustment model (Haines et al., 2016, 2017).

A progressive, formative feedback model has multiple benefits within outcomes-based education (Downing and Yudkowsky, 2009). For the learner, this frequent feedback model can build transparency regarding the expectations of their performance through specific describing of their performance successes and areas of improvement for each activity. Additionally, learners can begin to validate the abstract outcomes into tangible healthcare scenarios building purpose into their work. For teachers, the progressive nature of this evaluation model is useful for objectifying learner performance. Previously, student evaluation required teacher gestalt and experience. With increased direct observations and documentation of learner performance, teachers can more objectively identify the level of the learner based on prescribed outcomes to provide objective summative evaluations as well as objectively compare learners within the same learning experience. Summative evaluations in this model become more useful

for learners and institutions to identify troubled learners and building of remediation plans as well as provide a scaffold for learners to self-reflect on their progress (Downing and Yudkowsky, 2009).

Education

As previously discussed within this chapter, the needs and services of pharmacy practice vary vastly across the world. And thus, pharmacy educational pathways and requirements are different across the world to meet those needs. Currently there are no accreditation standards for pharmacy education recognized internationally. This chapter will address the different pathways to pharmacy practice for pharmacists and pharmacy technicians.

The role of pharmacy is evolving rapidly around the world. A reconstructive or a reflective higher education adjustment approach can be utilized to transform curricula for the new practice models. Reconstructive approaches to higher education utilize educational innovation and visions of a desired future by implementing novel pathways initially in place of a standard (Duit et al., 2018). Reflective approaches tend to look back at current curricula, making minor adjustments over time to the education and activities to impart change (Lemberger, 1983). Reconstructive approaches rapidly shift educational mechanisms, while reflective approaches can be slow and minimal. However, reconstructive models have more risk by incorporating educational models or tools that may not be tested, while reflective approaches may be too slow and limited to adequately prepare students for practice.

The FIP most recently provided a statement to guide good pharmacy education practice. Within this statement, there are no recommendations regarding degree pathways for pharmacist practice. Instead, it recommends "*basic (first degree) education programs should provide pharmacy students and graduates with a sound and balanced grounding in the natural, pharmaceutical and healthcare sciences that provide the essential foundation for pharmacy practice in a multi-professional healthcare delivery environment*" (FIP, 2000). This recommendation and the overall standard document presents the notion that there is no one correct degree pathway for pharmacy practice. Yet, there are general principles and knowledge that every pharmacist must maintain and be tested on for practice across pharmacy settings, such as the community, hospital, and industry. At minimum, pharmacist should be exposed to: biological systems and their interaction with medications, dosage form design and development, medication actions and uses, pharmacy practice law, appropriate ethical conduct in practice, safety and risk management, pharmacoepidemiology and health economics, introduction to pharmacy practice across practice areas, introduction to effective management, and introduction to manufacturing good practices (FIP, 2000). These are broad recommendations that satisfy a cohesive pharmacy practice internationally.

Multiple degree types are available for pharmacists: a bachelor's degree, master's degree and doctor of pharmacy degree. The university requirements of these degrees vary by institution and country (Anderson and Futter, 2009). However, there are some typical themes to the type of practice allowed based on the degree awarded. A bachelor of science (BS) degree in pharmacy or pharmaceutical sciences is the typical entry level degree for pharmacist in staffing type positions, such as community pharmacy, where the main pharmacist function is distributive. A master's degree (MS) in pharmacy or pharmaceutical sciences prepares pharmacists with additive skills, typically management or research skills. Typical positions for those pharmacists with a master's degree are in industry, hospital or potentially in an administrative management position. The Doctor of Pharmacy (PharmD) degree is the highest level degree obtained by a pharmacist. This degree incorporates the basic elements of both the bachelor's and master's degree program but also has a clinical experiential component to the educational requirements. This additional experience is completed as supervised and structured rotations across different pharmacy practice sites, including community, hospital, industry, and academia. The PharmD curriculum provides the ability of pharmacists to practice across the spectrum of pharmacy, in distributive roles, managerial roles, and clinical positions (Anderson and Futter, 2009; Chanakit et al., 2014; FIP, 2018; International Pharmaceutical Federation, 2017; Knoer et al., 2016; Lutz et al., 2009).

Faculty and preceptors who enact these degree pathways differ widely across the world. Because the bachelor degree has a limited clinical focus, unfortunately, the faculty of these programs can be disjointed from actual pharmacy practice, where their understanding of educational need is different than the healthcare needs (Chanakit et al., 2014; Kapol et al., 2008; Lutz et al., 2009; Parrish and Chew, 2018). Additionally, faculty within the master's programs may be differently focused in their teaching and research skills and thus have limitations of education linking to patient care (Anderson and Futter, 2009). PharmD trained faculty have the potential for grounding their education in the clinical healthcare needs of patients and the health system because of their role in both clinical practice and education.

Skills training for pharmacists go beyond the university pathways of degrees for training in specialized areas. Pharmacy residency and pharmacy fellowship programs are skill-based training programs pharmacists may pursue after they receive their PharmD degree to prepare them for unique, higher-level practice. Pharmacist can choose to complete 1- or 2-years of pharmacy residency (ASHP, 2017a, 2017b). Pharmacy residency training focuses on additional clinical experience within a health system or practice site to prepare pharmacists for roles with direct patient care in a hospital or outpatient clinics (Anon., 1987). An 1-year pharmacy residency focuses on general knowledge, while a fellowship focuses on training pharmacists for research. These programs can be academic-based or industry-based and specialized based on the institution affiliation or industry sponsor (Larochelle et al., 2009). The diverse degree and training options for pharmacists leaves the question as to what the most optimal education for pharmacists should be. A needs-based and outcomes-based approach to education and training is critical.

Quality assurance of the educational pathways and the roles they provide for are necessary to ensure an adequate and appropriate workforce (FIP, 2009). Continuing education requirements, as mandated by pharmacy licensures, are a potential mechanism for regulating bodies to ensure the maintenance of knowledge of pharmacists in practice. However, there is a significant divergence

from the level of education required by higher education and a pharmacist licensure. While higher education models and degree pathways instill a reconstructive approach, where innovation is implemented swiftly, licensure bodies follow reflective models that are slower to adjust to the needs of practice. The disconnect between pharmacy education and licensure may cause pharmacists in practice to become outdated with time even though they are maintaining their continuing education hours. It may be warranted for pharmacy licensure regulations to implement novel approaches to keep practicing pharmacists at the highest level of knowledge and practice for the safety and efficacy of the patients they care for (Adams et al., 2018).

The FIP recognized the discordance between education and quality assurance in practice and released the *FIP Statement of Policy: Quality Assurance of Pharmacy Education* (FIP, 2009). This international statement identified key stakeholders: national governments and their regulating bodies, pharmacy member organizations and higher education institutions. A framework is provided through this statement for how each of these stakeholder groups can work together to meet the quality assurance needs of the healthcare system for pharmacy practice with innovative educational approaches in mind. While the recommendations are not explicit or prescriptive, the framework provides guidance and adaptability for application across local, regional and national systems (FIP, 2009).

While great strides have been made internationally to bring equity for pharmacist education pathways, pharmacy technician education, and training remains diverse. In many industrialized countries, pharmacy technicians tend to be more highly educated and trained based on the adequate number of practicing pharmacists. However, pharmacy technicians are commonly utilized for common pharmacy services when pharmacists are not available in underserved or less developed countries (Lemberger, 1983). Pharmacy support staff is crucial for provision of pharmaceutical needs and should be provided with the necessary education and training for safe and effective care of patients. A specific set of recommendations for education of pharmacy support staff would be useful, particularly with a focus on those skills needed for practice in underdeveloped environments where pharmacy support staff have lower levels of supervision by a pharmacist and thus, higher levels of practice (Koehler and Brown, 2017; Parrish and Chew, 2018).

Conclusion

This chapter has examined several policy questions and challenges related to national needs-based pharmacy education and how that relates to the outcomes of pharmacy education in terms of fitness for practice and preparation for roles outside of the patient care domain such as industry and regulation. Policy makers at various levels, ranging from members of a pharmacy Faculty through those whose work is at the ministerial level in education and public health are challenged to consider national needs for the pharmacist workforce.

This workforce needs to be prepared at high levels of competence to protect public safety regardless of place of employment since the focus of the workforce centers on consumption of a broad spectrum of medicinal agents. As one contemplates the future, both the variation and the scope of the pharmaceutical armamentarium will be subject to advances in science and clinical developments. These evolutions require careful analytical approaches to faculty hiring, deployment and development, curricular development, instructional strategies, performance evaluation, and overall programmatic outcomes measurement and assessment.

Assuring that there is little gap between what a nation requires from its pharmacist workforce and what its university programs produce is an important element of social accountability. This accountability lies with all levels of the decision-making process related to the educational and public health system.

Developing and Implementing Patient Safety Standards Within the Pharmacy Practice and Education Settings

Ramesh Lahiru Walpola[*,†], **Parisa Aslani**[‡], [*]School of Pharmacy and Pharmacology, Griffith University, Gold Coast, QLD, Australia; [†]Quality Use of Medicines Network, QLD, Australia; [‡]The University of Sydney School of Pharmacy, Sydney, NSW, Australia

Introduction

The acknowledgment that healthcare professionals are capable of doing harm to patients is as old as the Hippocratic oath. However, it was not until the publication of two landmark reports, *To Err is Human* (1999) (Kohn et al., 2000) in the United States and *An Organisation with a Memory* (2000) (Department of Health, 2000) in the United Kingdom, that the importance of patient safety was recognized by key stakeholders in health care. The reports highlighted the alarming number of patients that have been harmed as a result of receiving health care. For example, it is estimated that between 44,000 and 98,000 people die on an annual basis as a result of a medication errors in American hospitals (Kohn et al., 2000). Importantly, through the publication of these reports, the complexity of healthcare systems was acknowledged by key stakeholders for the first time, as was the understanding that any solutions to improve safety need to address this complexity in order to be effective.

In 2002, the World Health Organization (WHO) member states recognized the need to reduce the harm and suffering that patients and their families were experiencing from healthcare errors, and agreed on a resolution to improve patient safety. In Australia, a significant number of adverse events are attributed to medicines. In the 2002 *Second National Report on Patient Safety: Improving Medication Safety* which was published by the Australian Council for Safety and Quality in Health Care, it was estimated that approximately 140,000 hospital admissions per year are associated with adverse drug events (Australian Council for Safety and Quality in Health Care, 2002; Easton et al., 2009). This equates to a cost of about 380 million Australian dollars per year to the public healthcare system. In 2007, the number of hospital admissions due to medication error had increased to approximately 180,000, suggesting an upward trend in the number of people affected by medication errors (Roughead and Semple, 2009). Furthermore, it is estimated that 17% of all medication-related hospital admissions in Australia have resulted in permanent disability and that 3% of admissions have resulted in death (Wilson et al., 1995). Of particular concern is that 50% of such admissions are considered to be preventable, highlighting scope to improve patient safety (Easton et al., 2009).

Considering their training in medicines and evolving clinical care roles, pharmacists can play a key role in mitigating patient and medication safety incidents.

Concept of Patient Safety

Traditional Approach to Patient Safety

In 1994, medical practitioner and patient safety researcher Lucian Leape stated that "the professional cultures of medicine and nursing typically use blame to encourage proper performance . . . errors are caused by a lack of sufficient attention or, worse, lack of caring enough to make sure you are correct" (Leape, 1994). Prior to the publication of *To Err is Human* (Kohn et al., 2000) and *An Organisation with a Memory* (Department of Health, 2000), healthcare institutions and professional bodies took a relatively reactionary approach to patient safety (Leape, 1997). Traditionally, this encompassed isolating the healthcare professionals involved in an incident and blaming them for their forgetfulness, inattention, or moral weakness (Leape, 1994). In 1997, Leape went on to say that the "public preferred to believe that errors in medical practice were rare, and the professions sought to perpetuate that misconception both for medico-legal reasons and because of the difficulty physicians have in dealing with errors" (Leape, 1997). Following an error, based on the outcome to the patient, media coverage, and the public outcry, the healthcare professionals involved would be forced by their employer or regulatory bodies to undergo remediation or may even be deemed unfit to practice and lose their registration as a healthcare professional. Psychologist James Reason defined this as the "individual approach" to error, which has been colloquially described as the "shame, blame, and retrain" approach (Reason, 2000). Although this approach is emotionally satisfying for patients and is fostered by the punitive legal system, it only provides a quick fix for healthcare institutions and regulatory bodies, whereas the actual underlying issues remain unaddressed (Reason, 2000).

Changing the Safety Paradigm

Following the publication of the two seminal reports previously described (Department of Health, 2000; Kohn et al., 2000), a dynamic shift in the patient safety paradigm occurred. For the first time, healthcare stakeholders began to acknowledge the complexity of healthcare systems and proposed solutions that were needed to address this complexity in order to be effective (Helmreich, 2000; Vincent, 2011). In particular, stakeholders began to examine the approaches taken by other high reliability organizations (HROs) to mitigate safety issues. HROs are organizations or industries that have been able to significantly minimize serious adverse events or catastrophic failures despite operating in highly complex and risk-prone environments. The aviation and nuclear science industries are two highly cited examples of HROs. Four key characteristics have been identified across HROs:

1. preoccupation with failure, where the organization acknowledges and plans for the possibility of failure;
2. a commitment to resilience, where the organization proactively seeks out unexpected threats and develops mechanisms to contain them;
3. a sensitivity to operations, where the organization places attention on the issues experienced by frontline staff; and
4. an open culture of safety, where individuals feel comfortable drawing attention to potential hazards to the organization (Vincent, 2011).

In recognition of the practices employed by HROs to improve safety, healthcare stakeholders engaged safety science experts from HROs, in particular, psychologists, human factors engineers, and resilience engineering experts, to undertake evaluations and work toward improving the safety paradigm in health care. As a result, a systems approach to errors has evolved in health care.

A systems approach acknowledges human fallibility and that error is to be expected, even in the best environments (Fox, 1995). This approach views an error as a consequence of upstream systems failures rather than being caused by an individual. In this approach, defenses and safeguards are put in place to prevent incidents from occurring, and when incidents do occur, they are seen as a failure of the implemented defenses and safeguards (Reason, 2000). This approach is best illustrated by James Reason in the Swiss Cheese Model which was previously developed for complex industrial settings, primarily aviation. The model states that "in an ideal world each defensive layer would be intact. In reality, however, they are more like slices of Swiss cheese, having many holes although unlike in the cheese, these holes are continually opening, shutting, and shifting their location." In Reason's model, when an alignment of holes occurs, all the defenses have failed and subsequently an error or incident occurs (Reason, 2000). The Swiss Cheese Model allowed healthcare institutions and stakeholders to develop an understanding of the different factors that result in errors or patient safety incidents occurring. Charles Vincent, another psychologist, later developed an adaption of Reason's model that was more specific to health care (Vincent, 2011). Vincent's model (**Fig. 1**) takes a "human factors approach" to the Swiss Cheese Model and focuses on the human elements of the sociotechnical system that is used to describe health care. The model begins on the left side of the diagram, where latent failures relating to poor organizational processes set the accident sequence of events in motion. In the model, organizational processes relate to the planning, scheduling, maintenance, strategy, and policy of the healthcare organization or institution. When these latent conditions transfer from an organizational level to a department level, they become

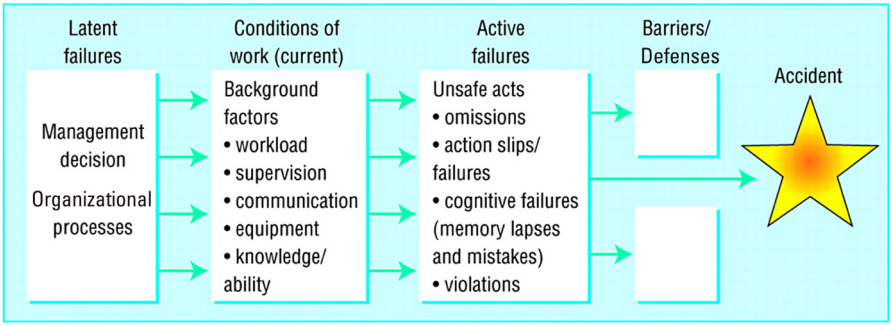

Figure 1 Vincent's Organisational Accident Model adapted from Reason's Swiss Cheese Model (Vincent et al., 1998).

Table 1 Vincent's framework of contributory factors influencing clinical practice (Vincent et al., 1998)

Factor types	*Contributory influencing factor*
Organizational and management factors	• Financial resources and constraints • Organizational structure • Policy standards and goals • Safety culture and priorities
Work environment	• Staffing levels and skills mix • Workload and shift patterns • Design, availability, and maintenance of equipment • Administrative and managerial support
Team factors	• Verbal communication • Written communication • Supervision and seeking help • Team structure
Individual (staff) factors	• Knowledge and skills • Motivation to undertake tasks • Physical and mental health
Task factors	• Task design and clarity of structure • Availability and use of protocols • Availability and accuracy of test results
Patient characteristics	• Condition (complexity and seriousness) • Language and communication • Personality and social factors

local-level conditions, which, in turn, promote the possibility of active failures to occur (Vincent, 2011). Examples of local-level conditions that can lead to failures include excessive workloads, stressful environments, inadequate supervision, inadequate communication systems, and departments lacking the equipment or resources they require. Active failures are defined by Vincent as "unsafe acts or omissions committed by those whose actions can have immediate adverse consequences" (Vincent, 1997), and include slips (e.g., being distracted while following a protocol) and failures (e.g., picking the wrong medicine from the shelf), cognitive failures (e.g., memory lapses or misreading a medicine name), and violations (e.g., deviating from standard operating procedures or best practices). This model hypothesizes that although many unsafe acts are likely to be committed, there are also a number of barriers and defenses that have been put in place to prevent a poor outcome, such as the use of alarms during the dispensing of medicines with similar names or packaging, product scanners during the dispensing of medicines, and having a dispensing protocol in place.

Vincent also identified that there are a number of contributing factors that affect the clinical practice of a healthcare professional (Vincent et al., 1998). **Table 1**, adapted from Vincent, presents a summary of common factors that affect healthcare professionals, which range from patient and individual practitioner factors to factors which arise from higher up in the health system, such as organizational and management factors. In the table, the contributory factors are listed in order of increasing effect on practitioners' behaviors and practices and in order of decreasing effect on the final outcome, that is, a patient's condition is more likely to affect how a practitioner treats a patient; however, staffing and resources available will be more likely to affect whether a patient is treated in the best possible way.

Clinical Example Demonstrating Impact of Latent Failures

Consider an elderly male patient who has been admitted to hospital and subsequently diagnosed with stage 4 pancreatic cancer. He has been scheduled to undergo a palliative stenting procedure and in preparation for the procedure, the patient is deemed to be nil by mouth. The procedure is subsequently delayed numerous times over the course of a 2-week period. The patient then reaches a critical state as he has been unable to eat properly while waiting for the procedure to occur. The procedure was delayed due to the surgeon's excessive workload and a decision was made by the hospital administration to reduce the number of operating theaters in use. In this example, the two factors that had the greatest impact on delaying the procedure were organizational and management factors (due to budget restrictions, fewer staff were available and less operating theaters were in use) and the work environment (due to reduced staffing levels). It is only at the point when the patient's condition becomes more critical, that is, a patient characteristic, that the problem is escalated and the patient is able to receive his palliative procedure.

The Need for Patient Safety Standards

One of the key findings that came out of the publication of the seminal reports was the need for a healthcare organization to prioritize patient safety. In doing so, it was acknowledged that one mechanism to force a shift toward safety-focused practices was through the use of standards. In *To Err is Human* (Kohn et al., 2000), the seventh recommendation made by Kohn et al. was to set performance standards, the concept of which could "either establish minimum levels of performance or can establish consistency or uniformity across multiple individuals and organizations" (Kohn et al., 2000). Kohn et al. described that these standards could be used for setting expectations of practitioners by the profession as well what the public should expect from their practitioners. Although, at the time the report was released, the "individual approach" to patient safety problems prevailed, both the recommendations made in this report in addition to the recording of harmful patient safety incidents have driven professional organizations to take actions (Kohn et al., 2000). Over the last 20 years, a "common law" approach has been adopted by professional organizations to develop practice standards. There has also been a shift to move away from the "individual approach," whereby individuals were penalized for harm, and for a systems focus to be adopted. When reviewing the standards that exist today it can be seen on a global scale that standards do not necessarily specify that they are specific to patient safety, the principles of patient safety are held at the core of each professional practice standard. Although this approach has had success in many developed nations, developing nations still struggle to develop standards that are adopted nationwide (World Health Organization Regional Office for Africa, 2014).

Developing Standards

A standard can be defined as " a voluntary document that sets out specifications, procedures and guidelines that aim to ensure products, services, and systems are safe, consistent, and reliable" (Standards Australia, 2018). Standards are developed as part of the introduction of a new service or practice; however, the many standards in health care have been developed as a result of reviewing practices, analysis of reports of patient safety incidents, or near-misses. As healthcare institutions and organizations transitioned from the personal approach to errors to a systems approach, methods were developed to understand the factors that were involved in the causation of errors or incidents, with the standards written to address these contributing factors. In order to undertake these analyses, data must be collected and aggregated (Leape, 1997). The five main methods of data collection that have been commonly used in safety analyses are direct observation, chart review, computer screening, focus groups, and spontaneous reporting.

Data Collection Methods

Direct Observation

Direct observation is the most labor-intensive method but advantageous as it generates the greatest amount of data. This method requires an individual to observe the practices of an individual or a group with activities ranging from simple behavioral observations to auditing (Leape, 1997). Although this method has been shown to be the best method for detecting errors, it also has a number of biases (Grote and Künzler, 2000). First, there is an inherent observation bias as even though a trained observer is required to conduct the process, the observer may be external to the system and may also misinterpret the actions or behaviors of practitioners. Second, this process is subject to the Hawthorne effect, by which those being observed change their behaviors based on whether they are being observed or not (Sacks et al., 2015).

Patient Chart Review

Patient chart review is a method whereby investigators review patient charts that are a part of the intended study group. This method involves looking through charts to identify any notes that describe an incident or a potential incident, and subsequently collating these notes in order to identify the key factors that resulted in the actual or potential incident from occurring (Leape, 1997). Although this is also a high yield method, it is limited by the quality of the patients' notes and the level of detail that is provided.

Furthermore, incidents that have caused harm are more likely to be recorded in a patient's notes as opposed to problems that have not noticeably affected a patient (Vincent, 2011; Vincent et al., 1998).

Computer Screening

Computer screening is a method that is both time efficient and cost-effective in detecting errors (Leape, 1997). This method uses computer algorithms to analyze potential and actual errors, and has been predicted to have an increasing level of uptake as health systems begin using integrated electronic patient records and medication charting. Although this method can generate a large amount of data in a small amount of time, it does have limitations in what can be detected particularly when data integrity failures occur; however, this will change as electronic record systems are advanced (Barber et al., 2007; Odukoya and Chui, 2013).

Focus Groups and Structured Interviews

Although focus groups and structured interviews cannot quantify a problem, they can provide a large amount of qualitative data to understand factors that may affect a phenomenon (Leape, 1997). The information-rich data from focus groups have been shown to be very effective in understanding the conditions faced by staff at the frontline and the underlying factors that may not be able to be measured in quantitative forms of analysis (Phipps et al., 2009). In particular, this can help identify potential or near-miss incidents that are not reported or documented. Multilevel ethnographic studies have been used by HROs to evaluate workplace culture and are increasingly being used in patient safety studies. They can also be combined with other forms of quantitative data to provide a more comprehensive analysis (Vincent, 2011).

Spontaneous Reporting

Incident reporting is one of the most common forms of quality improvement activities in health care (Leape, 1997). It is a legal requirement of many care facilities and hospitals for there to be a procedure to both report and review incidents in a timely manner (Vincent, 2011). For example, under the Quality Care Pharmacy Accreditation Program (QCPP) which is implemented in community pharmacies across Australia, it is first mandatory that incidents be recorded and reviewed, and second, that changes to practices or systems be implemented in order to prevent further incidents. The process of incident reporting involves completion of a paper or electronic version of a structured incident report form. Incident report forms aim to collect data to answer three essential questions: "what happened?"; "what were the contributing factors?"; and "how could the incident be prevented?". From this, incident data are then pooled and collectively analyzed (Mitchell et al., 2015). Although this method obtains the richest data about an incident or problem that has occurred due to the collection of both quantitative and qualitative data, the punitive methods in which incidents can be managed may discourage reporting, resulting in either poor quality of reports or a small percentage of incidents being reported (Boyle et al., 2011; Evans et al., 2007; Waring, 2005).

Investigation Methods

Following the collection of data, the two main analytical approaches that can be used to evaluate incidents are root cause analysis (RCA) and failure mode and effects analysis (FMEA), both of which have been adapted from HROs.

Root Cause Analysis

RCA was the first method used to evaluate incidents and is still one of the most common methods to be used in the healthcare industry today (Vincent, 2011). The RCA process follows a number of fundamental principles. First, this method is a retrospective method that analyzes the error or incident. The method views the incident or error as a result of a linear chain of events, which may or may not have a number of contributory factors. Ultimately, the RCA process aims to answer three questions: "what happened?"; "how did it happen?"; and "why did it happen?". At the conclusion of the RCA process, a single root cause or a small number of root causes are identified. The identified root causes are then subject to improvement strategies in order to prevent them from causing the same problem in the future (Iedema et al., 2006).

The London protocol

Although the RCA process is fundamentally good in theory, it originates from industries that are highly mechanical and, consequently, are not as effective in preventing errors or incidents from reoccurring in health care. In 2001, Vincent developed the London Protocol which is a method to perform RCA within the healthcare industry and is based on using a systems approach. This process is a multistep approach and is summarized in **Fig. 2** (Taylor-Adams and Vincent, 2004; Vincent, 2011). The process combines a number of quantitative data collection techniques as well as structured interviews or focus groups with key staff. The investigation team, which comprises practitioners ranging in experience, administrators, and experts, uses the data that they have obtained to answer the key questions of an RCA: "what happened?" (incident chronology); "how did it happen?" (care delivery problems, e.g., slips or lapses in a particular process); and "why did it happen?" (contributory factors). After this information has been ascertained, the contributory problems need to be classified into whether they are isolated to a single profession, unit, or department, or whether they are more general in nature so that an appropriate action plan can be put in place.

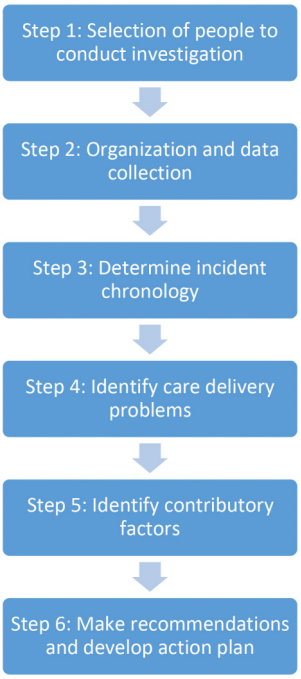

Figure 2 Summary of the London Protocol process (Taylor-Adams and Vincent, 2004).

Failure Mode and Effects Analysis

Failure mode and effects analysis (FMEA) is a prospective analytical method which has been used by HROs and adapted for the healthcare setting (Chiozza and Ponzetti, 2009). This method allows healthcare institutions and organizations to predict problems prior to their occurrence. The process of FMEA consists of five steps. First, the scope within the topic of interest is defined. Safety organizations recommend having a very specific aspect of a topic to investigate to ensure a beneficial outcome. The second step involves assembling a multidisciplinary team of experts who are involved in the specific topic being investigated. The third step involves creating high-level flow diagrams to map out each process. Within this step, subprocesses need to be identified and included within the flow diagram. The fourth step is to perform a hazard analysis. Initially, the potential failure modes for each of the processes are identified, along with their causes and the potential effects on patients. These are then rated for their severity, probability of occurrence, and likelihood of detection. During this process it is important to identify whether the particular failure mode requires further attention. The final step of the process involves determining the actions required to reduce the failure mode and prioritize the actions to be taken (Chiozza and Ponzetti, 2009; Woodhouse et al., 2003).

Investigation Method Limitations

Despite the high uptake of these two methods, they both have limitations. RCA and the London Protocol are both easily understood and adaptable methods that are useful in incident investigation (Taylor-Adams and Vincent, 2004). However, they do not allow for prospective analyses to be performed. FMEA provides a more comprehensive review of a process and can be performed in both a prospective or retrospective fashion. However, due to the costs involved in performing an FMEA, it is usually reserved for high priority or high-risk processes (Vincent, 2011; Woodhouse et al., 2003). A limitation of both RCA and FMEA is that they look at each of the factors that result in errors in isolation and do not account for the interrelationships between factors.

Standard Development Process

Following the analysis of either patient safety incidents or the observation of practitioners, there are a number of interventions that can be developed to prevent similar identified issues happening again. The implementation of standards is one such process and the development of which involves a number of steps, as summarized in **Fig. 3**. The process would usually commence with a demand from the industry, whether it be from a macrolevel organization such as a health department or professional bodies to a microlevel organization such as a pharmacy department. The standard would be drafted by an expert reference group, consisting of expert practitioners and managers and would include the scope and content of the standard as well as the adoption of key definitions. The drafted standard would then be reviewed by stakeholders from the relevant professional organizations, academics, and consumer organizations, prior to be being sent out for public comment by the targeted audience. Once the final draft of the standard has been composed, it must be formally adopted by the organization or institution, usually performed through a

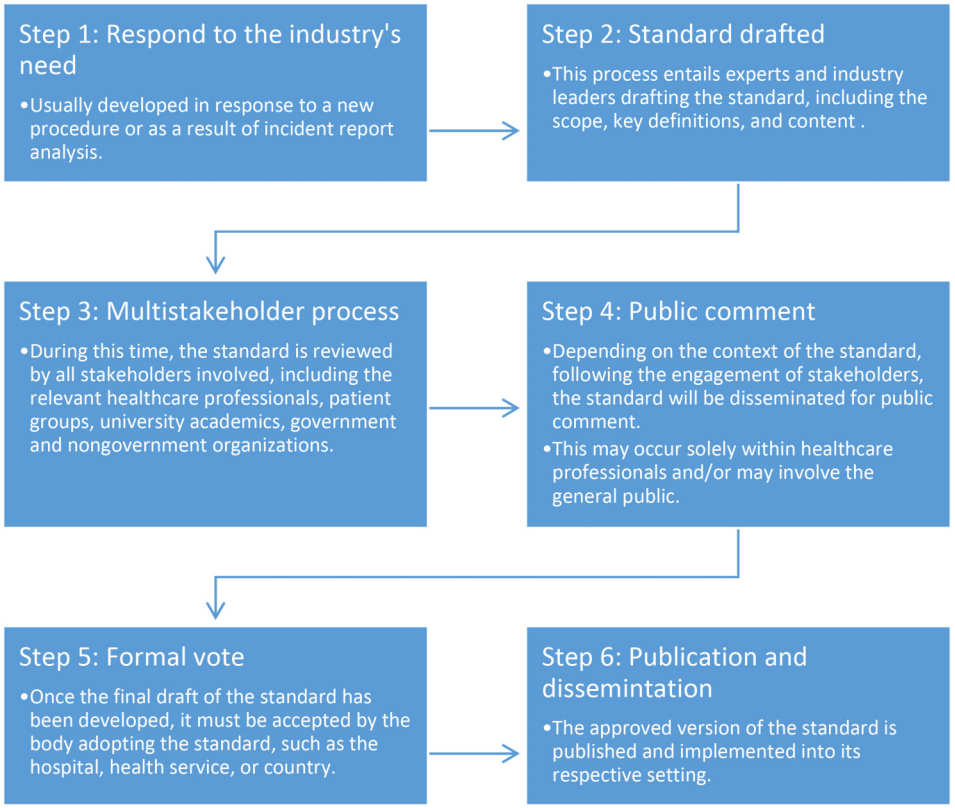

Figure 3 Summary of the Standard Development Process developed from the International Standardization Organization Standard Development Flowchart (International Organization for Standardization, 2018).

voting process. Finally, after the standard has been adopted, the standard must be disseminated to the affected practitioners and health system management.

Medication Safety Standards

Medication safety can be considered as the freedom from medicine-related harm, damage, or loss (Runciman, 2006). Medication safety standards are considered an integral part of the medication safety process. The development of many medication safety standards exists as a preventative strategy following the analysis of medication safety incidents, usually where harm has occurred. As a result standards have been implemented on a number of levels ranging from standards applied on a facility level to standards that are applied on a more global level such as throughout a health service to national and international levels.

Medicine Nomenclature

When medicines are developed, there are usually three names given to a new medicine: a chemical name (e.g., 4-chloro-*N*-furfuryl-*S*-sulphamoylanthranilic acid), a nonproprietary or generic drug name (e.g., Frusemide), and a brand name (e.g., Lasix). Although a new medicine will only have one chemical and nonproprietary name, it may have a number of brand names which can result in confusion. A strategy to mitigate this is through the standard use of nonproprietary or generic drug names. The WHO has also recommended the use of nonproprietary names for medicines in pharmacopoeias, labeling, product information, advertising and other promotional material, drug regulation and scientific literature, prescribing and dispensing of medicines (World Health Organization, 2017). In 1953, it developed a standardized global nomenclature register for nonpropriatory names of medicines (INN). Although a number of countries have their own register of medicine names. including British Approved Names (BAN), Dénominations Communes Françaises (DCF), Japanese Adopted Names (JAN), and United States Accepted Names (USAN), the vast majority of medicines have adopted the international nonproprietary nomenclature.

Although this standardization process can reduce confusion between different medicines, it still can cause problems. Look alike and sound alike medicine names have been the cause of a number of medication safety incidents, particularly when the products have very similar packaging. Typographical strategies have been one solution suggested to prevent this issue. Tall man lettering has been a typographical strategy that has been implemented by a number of health services. This strategy uses capitalization of the

letters of a drug name that make it different to other similar named products, for example, fluVOXAMine and fluOXETine. Although this strategy has had some success in preventing medication errors (Zhong et al., 2015), recent evidence has shown that this strategy has been ineffective in preventing errors (Lambert et al., 2016) as well as anecdotal evidence of it affecting readability of drug names by patients. Therefore, further work in this area is required (Lambert et al., 2016).

Safe Medication Practices

Standardization of medication practices has been another strategy that has been utilized to improve medication safety. The majority of safe medication practice standards and policies have been developed because of incidents occurring with regard to the use of medicines. Typically, national organizations such as the Institute for Safe Medication Practices and the Joint Commission in the United States or the Australian Commission for Quality and Safety in Health Care have developed a series of standards against which health institutions, such as hospitals, are assessed and accredited. Standards and standardizations are considered a moderately effective method of improving safety. However, some standards incorporate other types of interventions such as checklists, which are effective on a personal level as well as the highest level of intervention—a forcing function, a preventative strategy by which that would ensure an incident would not possibly occur. A classic example of this is potassium chloride ampules on hospital wards. These ampules looked very similar to sodium chloride and water for injection and sometimes were selected in error when reconstituting medicines for injection on the ward. In order to prevent this incident happening, a standard was implemented that potassium chloride was to be only available in large volume bags so as the confusion would not occur (Reeve and Allinson, 2005).

The Need for Global Standards

Although there are currently a number of standards that exist with regard to medication safety, as seen above, there are currently no standards that are applied to health systems on a global level. This issue was recognized by a number of patient and medication safety organizations. In 2017, the WHO launched its third challenge for patient safety—to improve medication safety. One of the key objectives of this global challenge was to develop a set of standards which could be implemented in health systems across the globe. The topic areas covered in these new standards had not been released at the time of writing.

Education Standards

Education has been recognized as one of the key strategies to improve healthcare professional and student knowledge and opinions on patient and medication safety. Globally, public health and patient and medication safety organizations have tried to fill the gap in patient and medication safety education for both students and health professionals. One such organization was the Institute for Healthcare Improvement (IHI), an American not-for-profit organization based in Cambridge, MA, that focuses on patient safety and quality improvement. In 2008, IHI released an online learning platform called the IHI Open School, with the intention of addressing the lack of training in patient safety and quality improvement provided to healthcare students. This platform allows students and healthcare professionals from around the globe to voluntarily develop their quality improvement and patient safety knowledge and skills using interactive web-based courses (Ward et al., 2013). Although these courses have been implemented in many health discipline curricula in North America, there is a need for a global set of standards of patient safety education for all healthcare students.

The World Health Organization Patient Safety Curriculum

The WHO recognized the need to develop an essential set of education standards for health professions in order to improve patient safety. In 2009, the WHO developed a *Patient Safety Curriculum Guide for Medical Students*, based around the *Australian National Patient Safety Education Framework* (Walton et al., 2010). This was later rereleased in 2011 as a multiprofessional edition (World Health Organization, 2011), to provide a framework for all health disciplines to deliver patient safety education to their students. The current framework consists of 11 topics, which can be incorporated at different levels into health students' curricula and include recommendations for the implementation of educational activities (**Table 2**).

Education as a Strategy to Improve Safety

Although education has long been considered one of the key strategies to improve patient safety (Oates et al., 2013), changing already full curricula, combined with capacity and capability issues within institutions, has provided a challenging environment for implementing patient safety specific education (Ahmed et al., 2013). Furthermore, it has been shown that despite the implementation of specific patient safety education, the pharmacy workforce has a bigger impact on the practice of junior practitioners (Walpola et al., 2017). If one considers the hierarchy of interventions, education is a very human-focused intervention and is considered to have limited efficacy on either the health system at large or the individual organization (i.e., hospital or community pharmacy). This has been demonstrated in the literature with pharmacy graduates' attitudes to

Table 2 Summary of WHO patient safety curriculum topics

Topic	*Title*	*Summary*
1	What is patient safety?	This topic introduces the concept of patient safety and the importance of understanding the factors that can affect patient safety.
2	Why applying human factors is important for patient safety?	This topic introduces the concepts of human factors, which traditionally were applied to engineering and psychology disciplines, and how the principles of human factors can be applied to improving patient safety.
3	Understanding systems and the effect of complexity on patient care	This topic introduces the conceptualization of the health system as a complex system consisting of a number of complex and integrating relationships, such as between departments, services, practices, and staff.
4	Being an effective team player	This topic covers a number of concepts that are critical to teamwork. A core focus for this topic is communication skills and in particular understanding the effects of miscommunication.
5	Learning from errors	This topic focuses on developing a positive safety culture through examining errors and understanding the factors that affect why things go wrong.
6	Understanding and managing clinical risk	This topic introduces the concept of clinical risk and the importance of managing clinical risk to ensure safe systems of care. The topic introduces concepts around managing complaints and making improvements to health systems.
7	Using quality improvement methods to improve patient care	This topic discusses the process for analyzing patient safety problems and frameworks to test improvements to combat the problems identified.
8	Engaging with patients and carers	This topic introduces concepts around the inclusion of patients and carers as part of the patients' own healthcare team. It also addresses how errors can be prevented through this process.
9	Infection prevention and control	This topic discusses the importance of managing infection prevention and controlling the spread of infection.
10	Patient safety and invasive procedures	This topic explores a number of safety issues associated with surgical procedures as well as discussion of safe surgical practices including the WHO Surgical Safety Checklist.
11	Improving medication safety	This topic provides a focused exploration of the factors that affect medication safety at the different points of the medicine use cycle. The topic also discusses strategies to improve medication safety.

patient safety being affected more greatly by other factors such as workplace culture on a longer term basis than whether they received education (Walpola et al., 2017). Therefore, education and educational standards are only one part of the overall strategy to improve patient safety.

Future Directions

As the core values of HROs are implemented into the health industry, the number of safety standards to improve patient safety is likely to increase. At the time of the writing of this article, there were no internationally adopted standards related to patient safety practices by healthcare professionals. Although the WHO has acknowledged the difficulty in achieving this, an objective of the WHO Third Patient Safety Challenge is to develop a set of standards that can be applied on a global scale. Although it is anticipated that the new standards will be developed, they only comprise one part of the solution to improve patient safety on a global scale. Future work should consider the principles of resilience engineering to evaluate the effectiveness of standards that have been developed and implemented.

Glossary

An error—unintentionally being wrong in conduct or judgment (Runciman, 2006).
An incident—an event or circumstance which could have resulted, or did result, in unintended or unnecessary harm to a person (Runciman, 2006).

Pharmacy Professional Standards Defining Quality of Services

Zinaida Bezverhni*, Olga Grintsova†, *World Health Organization Country Office in the Republic of Moldova, Chisinau, Republic of Moldova; †Department of Clinical Pharmacology and Clinical Pharmacy, National University of Pharmacy, Charkiv, Ukraine

Historical Development of Professional Standards

Since the middle of the 20th century the role of pharmacists in the healthcare system was continuously growing and changing from the traditional drug-focused pharmaceutical services toward patient-oriented care, where pharmacist was not only dispensing the drug, but also overtook the responsibility on its rational use. New area of pharmaceutical practice was first defined in the USA as pharmaceutical care in the mid-1970s (Mikael et al., 1975). The first official international definition of pharmaceutical care followed later in early 19th century by Hepler and Strand, as "Responsible provision of drug therapy for the purpose of achieving definite outcomes that improve a patient's quality of life" (Hepler and Strand, 1990).

Meantime, World Health Organization (WHO) as international standard setting entity in healthcare followed the recent developments in pharmacist profession and put it high on its agenda. For the first time the new role of pharmacists as one of the key elements in the rational drug use was discussed in 1986 during 39th World Health Assembly when a revised drug strategy was adopted by the member states (WHO, 1986). A series of meetings on this topic took place during the next decade (New Delhi, 1988; Tokyo, 1993, Vancouver, 1997 and Hague, 1998) under the aegis of WHO. This was followed by the adoption of two resolutions: WHA47.12 (WHO, 1988) on the role of the pharmacist and the WHO/DAP/98.13 (WHO, 1998) on the role of the pharmacist in self-care and self-medication.

New professional roles required new professional standards to define quality and safety of pharmacists' activities (WHO, 2000). Professional organizations are the key stakeholder in the process of developing professional standards. WHO and International Pharmaceutical Federation (FIP) worked together to define the full range of roles of pharmacists, as well as type and quality of pharmacy services. The first version of international professional standards was published by FIP in 1992 as "Good pharmacy practice in community and hospital pharmacy settings." In 1997 followed FIP/WHO joint document on good pharmacy practice (GPP). The practical handbook on implementation of services was published in 2006 (Wiedenmayer et al., 2006).

A pilot project on the implementation of GPP standards was conducted by technical assistance of FIP together with National Member Organizations in Cambodia, Moldova, Mongolia, Paraguay, Thailand, Uruguay, and Viet Nam (2005–07). The updated version of GPP standards was published in 2009 after several meetings (Bangkok, 2007; Basel, 2008) and an extensive review of existing national standards on GPP in at least 37 countries.

The most recent version of the Joint FIP/WHO guidelines on GPP: standards for quality of pharmacy services was adopted and published in 2011 (WHO&FIP, 2011). The guidelines provide the framework for the excellence in implementation of GPP. It needs to be adjusted and adopted by the national organizations of countries considering historic, political, economic, and social background.

Table 1 Roles and functions of pharmacists

Function	*Role*			
	Prepare, obtain, store, secure, distribute, administer, dispense, and dispose of medical products	*Provide effective medication therapy management*	*Maintain and improve professional performance*	*Contribute to improve effectiveness of the healthcare system and public health*
A	Prepare extemporaneous medicine preparations and medical products	Assess patient health status and needs	Plan and implement continuing professional development strategies to improve current and future performance	Disseminate evaluated information about medicines and various aspects of self-care
B	Obtain, store, and secure medicine preparations and medical products	Manage patient medication therapy		Engage in preventive care activities and services
C	Distribute medicine preparations and medical products	Monitor patient progress and outcomes		Comply with national professional obligations, guidelines, and legislations
D	Administration of medicines, vaccines, and other injectable medications	Provide information about medicines and health-related issues		Advocate and support national policies that promote improved health outcomes
E	Dispensing of medical products			
F	Dispose of medicine preparations and medical products			

(Based on Joint FIP/WHO guidelines on good pharmacy practice: standards for quality of pharmacy services, 2011)

According to the guidelines, there are four main roles where pharmacists' involvement or supervision is expected by society and the individuals they serve:

1. Prepare, obtain, store, secure, distribute, administer, dispense, and dispose of medical products.
2. Provide effective medication therapy management.
3. Maintain and improve professional performance.
4. Contribute to improve effectiveness of the healthcare system and public health.

Every role requires different functions and activities, which may vary for each individual pharmacist depending on their practice responsibilities (Table 1).

Specific standards of GPP can be developed only within a national pharmacy professional organization framework.

During the last 4 decades, the philosophy of pharmaceutical care and standards of GPP were continuously spreading and disseminating, providing a wide range of national professional standards and initiatives. Professional pharmacy practice standards are developed and adopted both by regulators (e.g., pharmacy councils, chambers, boards, etc.) and professional organizations (e.g., pharmaceutical associations, society, etc.). In this regard these norms are either mandatory, or recommended depending on country.

Concept of Quality of Pharmaceutical Care Services

The quality of pharmaceutical services can be defined, assessed, and evaluated in different ways (Curtiss, 2004; Bruchet, 2011; Rotta, 2015). Nevertheless, measurement and analysis of service quality is a key milestone in developing quality in services (Edvardsen, 1994; Cochrane, 2007; Francke, 2008).

The starting point is to state the perspective from which it will be assessed: patient, pharmacy professionals, or other stakeholders; public.

From the patient perspective, quality of service can be defined as an extent to which service meets customer's need or expectation. With other words, quality of service is a difference between customer's expectations of service and perceived service. If expectations are greater than performance, then perceived quality is less than satisfactory and the service provider has to deal with customer dissatisfaction (Wisniewski, 1996; Shiyanbola, 2015). One of the most popular methodologies for the quantification of patient's satisfaction is SERVQUAL model (Wisniewski, 2001). For the pharmacy settings there is also specific tools for the evaluation of patients' satisfaction available—PC Satisfaction (Patient satisfaction with pharmaceutical care questionnaire, US) (Larson, 2002), CPPQ (Community Pharmacy Patient Questionnaire, UK) (Pharmaceutical Services Negotiation Committee, 2013).

From the professional perspective, high-quality services ensure provision of the most effective and safe care. For the quality assessment it is important to define the aspect of care being measured. The classical approach proposed by A. Donabedian differentiates between structure, process, and outcome of care (Donabedian, 1988, 1980; Rupp, 2018). A wide range of instruments can be used for evaluation of quality of care in the community pharmacy: Community Pharmacy Contractual Framework (UK)

(Pharmaceutical Services Negotiation Committee, 2017), Maturity Matrix for Community Pharmacy (UK) (Morris, 2004), Manchester Patient Safety Assessment Framework (UK) (Ashcroft, 2005), Medication Safety Self-Assessment (US) (Institute for Safe Medication Practices, 2017), Medication Safety Self-Assessment for Community/Ambulatory Pharmacy Canadian Version (Canada) (Institute of Safe Medication Practices Canada, 2015), Pharmacy Safety Climate Questionnaire (UK) (Denham and Phipps, 2012), Internal (I-Val) and External Validation (E-Val) Instruments for Community Pharmacy (Malta) (Azzopardi, 2000), and Pharmaceutical Care Self Assessment Tool (EDQM). Most of the tools presume self-assessment of the practice by the pharmacy team (except Pharmaceutical Services Negotiation Committee (2017) and partly Azzopardi (2000)).

From both professional and public perspective, for quality assessment in community pharmacy is possible to evaluate the adherence to national guidelines for GPP or use quality indicators. National initiatives on the quality standards as described further focus on one or several of these possibilities. International initiatives focus to a greater extent on the public instruments that can be used across the countries.

National Initiatives

Australia

Pharmaceutical Society of Australia adopted already 5th version of professional practice standards (PPS) (PSA, 2017), that articulate the values of the pharmacy profession and expected standards of professional behavior of pharmacists toward other healthcare stakeholders and patients. The 16 individual standards in the PPS are grouped into streams—Foundations of Practice, Providing Therapeutic Goods, Providing Health Information, and Delivering Professional Services. The streams in the document are hierarchical. The two standards in the Foundations of Practice stream—Fundamental Pharmacy Practice and Leading and Managing Pharmacy Practice—are overarching, and apply to all pharmacists, regardless of setting or scope of practice. The standards in the Providing Therapeutic Goods and Providing Health Information streams detail key functions of pharmacists relevant to the provision of activities and services covered by the standards in the Delivering Professional Services stream. There are following professional services described: collaborative care, screening and risk assessment, vaccination service, minor alignments service, disease state management, medication review, dose administration aid service, and harm minimization service. The criteria and actions required are described for each standard. Two further tools support the quality improvement of the practice—a self-assessment tool for the pharmacists and an implementation tool with useful practical questions.

USA

American Pharmacist Association is providing a range of professional standards and practical tools for the delivery of treatment options (American Pharmacists Association). The pharmacy services include appointment-based model (ABM) which is a patient care service designed to improve patients' adherence to medications and build efficiencies in pharmacy operations, immunization services, pain management service, medication therapy management (MTM), and medication administration of various products beyond vaccines. Professional standards capture all services and describe in detail provision of service, required qualification of pharmacist, resources, processes, and collaborative care.

For the evaluation of individual pharmacists who are coordinating, developing, and/or actively providing MTM and other clinical services there is a fitted tool available—Pharmacist Clinical Services Performance Evaluation (American Pharmacists Association, 2009). In the tool are clinical core competencies in patient care, practice management, patient care projects/programs as well as mentorship/perception, professional/community outreach. After the evaluation new professional goals and objectives for professional development should be set. The performance is rated from 1 to 5; a total performance rating is evaluated in terms of achieving expectations.

Canada

The Canadian Pharmacy Services Framework (CPSF) is an implementation project, developed in collaboration between Canadian Pharmacists Association, Canadian Association of Chain Drug Stores and provincial pharmacy associations. It outlines the ways to deliver patient-centered pharmacy services that are based on the needs of population, are cost-effective and valuable for the healthcare system (Canadian Pharmacists Association, 2011).

In the standards the core dispensing services are separated from the technically focused, non-clinical dispensing services and include, i.e., assessment for adverse drug events, interactions, allergies; assessment for accessibility (e.g., formulary coverage, affordability); patient dialogue and callback (Canadian Pharmacists Association, 2011). These services are focused on the pharmacist's therapeutic role in core dispensing services, to ensure safe, appropriate and effective medication therapy. Another areas are specific pharmacy services, including adapting a prescription; therapeutic substitution; prescribing in an emergency; refusal to refill; administration of a medication by injection and immunization; comprehensive medication management; interpreting and ordering laboratory tests; minor ailments assessment and management; medication reconciliation; chronic disease management. For each specific service CPSF includes a range of standard operating procedures and workflows

that will help to ensure that professional services are delivered and measured consistently across the country (Canadian Pharmacists Association, 2016; Winslade, 2011). A template for the implementation of service is provided as a standardized tool for description of the service requirements, eligibilities and other considerations specific to a particular jurisdiction (Canadian Pharmacists Association, 2018).

The Framework also provides a guidance on financial viability of services. The standards are adopted to fit the health needs in particular provinces (Canadian Pharmacists Association, 2011, 2016).

UK

In United Kingdom, General Pharmaceutical Council supported by the Royal Pharmaceutical Society is the main regulatory body responsible for professional standards in pharmacy practice (General Pharmaceutical Council, 2018a).

There are two types of standards: standards for pharmacy professionals (General Pharmaceutical Council, 2017) and standards for registered pharmacies (General Pharmaceutical Council, 2018b).

The standards for pharmacy professionals reflect the requirements set based on patients' expectations and specialists' perspective on the profession. These standards include professional principles (provide patient-centered care, collaborate, maintain and develop professional knowledge and skills, use professional judgment), behavioral principles (show leadership, communicate effectively), and ethical principles (behave in professional manner, respect person's confidentiality and privacy). The basic principles for the operation are applicable for all services (General Pharmaceutical Council, 2017).

The standards for registered pharmacies set out the requirements for the provision of pharmacy services at or from a registered pharmacy. National Health Service (NHS) and Pharmaceutical Services Negotiation Committee (PSNC) provide the description and quality standards for essential and advanced services. The essential services are provided by all pharmacies and include dispensing of medicines, appliances, repeat dispensing; clinical governance; public health activities; disposal of medicines; signposting; self-care services. To provide advanced pharmaceutical services pharmacy should meet structure and staff requirements (including special training). The quality standards for the advanced services are available on PSNH website and include: medication use review, flu vaccination, new medicine service, appliance use review, stoma appliance customization as well as NHS urgent medicine supply advance service (Pharmaceutical Services Negotiation Committee, 2017).

Royal Pharmaceutical Society took over the conceptual work, providing the certified process for guidelines development, nursing homes, ambulance settings, etc.

Bermuda

Standards of practice for pharmacists were developed and adopted by Bermuda Pharmacy Council in 2013 and are effective since January 1, 2014 (Pharmacy Council, 2013). The Standards of practice are a statement of professional conduct that describes a pharmacist's responsibilities including the skills and judgment required in practice. They set out the principles upon which GPP is based and promote a consistent quality of professional performance. The Standards were developed during 2013 in collaboration with the Bermuda Health Council. A broad consultative process included input from practicing pharmacists and pharmacy owners as well as comparison with standards in Australia, Canada, United States, and United Kingdom.

Singapore

Good Pharmacy Practice Guide (Pharmaceutical Society of Singapore, 2017) was developed by Pharmaceutical Society of Singapore includes recommendation for suitable premise, equipment and storage of medications, good dispensing practices, inventory practice, review of medication orders, counseling points, recommendations to mitigate dispensing errors, role of pharmacists in health promotion, training and competency, code of ethics, disposal of medications, and hand carried export sales of medications.

South Africa

National GPP guidelines were published by the South African Pharmacy Council in 2010. They describe the underlying philosophy, the scope of practice as well as professional standards for premises of the pharmacy. For the minimum standards of pharmaceutical services there are five categories of pharmacies are defined: manufacturing pharmacy, wholesale pharmacy, consultant pharmacy, community pharmacy, and institutional pharmacy. The services which may be provided in the different categories of pharmacy are stated in the act Regulations relating to the practice of pharmacy (GNR. 1158 of November 20, 2000). Information relating to compliance with GPP standards should be submitted in support of an application for a license for a pharmacy premises.

National professional standards focusing on quality of services vary a lot between countries. Great examples of service excellence can be further found in Netherlands, Republic of Ireland, and New Zealand (see "Further Reading" section).

International Initiatives Focusing on Quality of Services

Pharmaceutical Group of the European Union

The Pharmaceutical Group of the European Union (PGEU) is the European association representing community pharmacists. PGEU's members are the national associations and professional bodies of community pharmacists in 33 European countries including EU Member States, EU candidate countries, and EEA/EFTA countries. PGEU's Ordinary Members are associations from EU Member States, while PGEU's Observer Members are organizations from non-EU European countries. The PGEU's main objective is to advance the contribution of community pharmacists to European health systems, society, and individual patients.

In 2012, a joint European Community Pharmacy vision, namely European Community Pharmacy Blueprint was unanimously supported by the PGEU General Assembly. In order to embrace current and future challenges, European Community Pharmacy Blueprint paves the way for a future where services offered at European community pharmacies, at the heart of the communities by highly qualified and independent healthcare professionals' community pharmacists—further support individual patients, public health, and the healthcare system (Pharmaceutical Group of European Union, 2012). European governments are seeking to optimize the use of medicines, achieve better value from pharmacotherapy of patients, and reduce the overall cost of healthcare. Making better use of the competences of European pharmacists can help them achieve these goals. To enhance the contribution of community pharmacies to the effectiveness and efficiency of health systems, community pharmacists are ready to play an active role in the primary healthcare team, therefore use of eHealth solutions in the community pharmacy should be supported, and national medicine management strategies need to be developed. The unique asset that is the community pharmacy network needs to be better exploited to improve access and safety of medicines, improve treatment outcomes of individual patients and public health as well as contribute to quality and efficiency of the health sector.

Forum of Americas

Forum of Americas (est. 2000) is one of the regional pharmaceutical forums established by the initiative of FIP in collaboration with the WHO in order to bring together national pharmaceutical organizations. Following the strategy of FIP for GPP implementation, the General Assembly of Forum of Americas adopted in 2008 a Declaration setting as one of the objectives: "To establish, apply and update pharmacotherapeutic quality criteria and to raise the quality standards of pharmaceutical services, for the health improvement of the population of the countries in the region" (Pharmaceutical Forum of Americas, 2008).

The adoption of the declaration by the member countries of Forum of Americas in 2008 was followed by the conference "Promotion of Change in Pharmaceutical Services in the Americas, From the new conceptual framework to reality" (Montevideo, Uruguay, October, 2011). The resolutions stated the need to create/strengthen National Technical Groups with the participation of professional associations, the academy, the Pan American Health Organization (PAHO), the Ministry of Health, and other relevant partners for the design, implementation and follow-up of a national strategy for improvement of the quality of Pharmaceutical Services based on Renewed Primary Health Care (PHC) and Good Practices in Pharmacy (GPP). The decisions were endorsed by the General Assembly of the Pharmaceutical Forum of the Americas in October, 2011 (Pharmaceutical Forum of Americas, 2011). The core document on pharmaceutical services in the primary care was published as a position paper in 2011 and in 2013 as guideline by the PAHO and includes definition of the services, requirement for resources, integration process, implementation, and quality assurance (PAHO, 2013). For the dissemination of the quality standards in the Americas region since 2012 a Virtual Course of Pharmaceutical Services based on Primary Health Care for Managers is offered in collaboration with PAHO and FIP (Emmerick, 2014). The activities and annual reports on the quality of the services in the member countries are available on the official website (see "Further Reading" section).

European Directorate for the Quality of Medicines and Healthcare (EDQM), Council of Europe

Recognizing the role of pharmacists in the provision of the rational drug use, EDQM contribute to the improvement of pharmaceutical care and pharmaceutical practices through public health oriented policies and practical programs. According to the EDQM program of activities in this area, the Committee of Experts CD-P-PH/PC commissioned a survey in 2008 on the key concepts in pharmaceutical care and the performance indicators used to evaluate the quality of pharmaceutical care and pharmaceutical services in the Council of Europe member states. The aim of the project was to find the indicators that would be equally applicable to a wide range of countries, and their development, testing, and validation had to involve the cooperation between countries with different background of pharmaceutical care, medical traditions, and healthcare systems.

The areas of PC relevant to be evaluated by indicators were defined in scoping studies and discussed with member states' experts and stakeholder associations at the expert workshops "Assessing the quality of patient-centred pharmaceutical care in Europe—where do we stand, where should we go?" (Strasbourg, 2009) (EDQM, 2009). The scientific rationale of model indicators was further explored on the basis of published literature and the experiences of the scientific collaborators involved, and discussed at the expert workshop "Indicators of the quality of pharmaceutical care" (Strasbourg, 2010) (EDQM, 2010). Based on these developments five sets of indicators were piloted in 2011–12 in 17 countries in Europe, followed by multinational validation study of four of the above five sets in 2013–14 in different countries in Europe (in and beyond EU member states), under real-life conditions, and in different healthcare settings (community, ambulatory, and hospital settings) covering four key areas of the pharmaceutical care process. Namely:

- Adherence to nationally agreed clinical practice guidelines (TG1);
- Monitoring of therapeutic plans and medication safety by pharmacists through data linking and exchange of information about therapy and patient's medical condition in anticoagulant and antibiotic therapy (TG2);
- Structured patient-pharmacist consultations (chronic therapy; polypharmacy; polymorbidity) via "My CheckList" (TG3);
- Pharmaceutical care: special needs in certain regions (developing countries in Europe) (TG4).

The aim of Topic Group 1 was to develop, pilot, and validate a quality indicator focusing on the impact of inter-professional collaboration on adherence to antimicrobial prescribing guidelines in ambulatory care settings. An international working group, consisting of representatives of Germany, Ukraine, Poland, and Georgia, defined the indicator.

The calculation formula is: TG1 = $(A - B)/B \times 100$, where A = patients prescribed in compliance with clinical practice guidelines after pharmacist's intervention (%). B = patients prescribed in compliance with clinical practice guidelines before pharmacist's intervention (%). A pharmacist's intervention included meeting with GP, discussion of the current clinical guidelines for antibiotic prescribing in three indications. For the piloting and validation a study protocol was prepared and agreed on one EDQM meeting in 2012 (Strasbourg, France). A pilot and validation studies were conducted in Ukraine, Poland, and Georgia, the data will be published soon. The results of the studies showed 25.6% ($P < 0.001$) increase in adherence to guidelines after the pharmacist intervention, the indicator was proofed to be specific, acceptable, and feasible. The indicator can be adopted for quality assurance of pharmaceutical services such as clinical governance, medication review, as well as some aspects of collaborative care.

Topic Group 2 focused on the development and validation of two quality indicators focused on the access to individual patient's medical and prescription data (patient health record) at hospital pharmacists' level. Health data availability would allow hospital pharmacists to play an active role in the development, implementation, and follow-up of the therapeutic plan (structure indicators).

Indicator 1: Number of patients who were prescribed an anticoagulant and suffered from a bleeding event where hospital pharmacists had information about this latter/Number of patients who were prescribed an anticoagulant and suffered from a bleeding event (%).

Indicator 2: Number of patients with a culture and sensitivity test (antibiogram) performed and available to hospital pharmacists/Number of patients with a culture and sensitivity test (antibiogram) performed (%).

Four countries participated in the study—Georgia, Hungary, Ireland, and Poland. The results showed that the evaluation of following indicators is rational only if electronic patient records are available. Both indicators could be used to monitor health data availability in hospital pharmacies and could play a role in promoting good and safe use of medications. In particular, in the case of high-risk medications, health information exchange between healthcare professionals could facilitate the availability of patient-specific health information, which, in turn, could be used to provide high-quality pharmaceutical services such as medication review or medication reconciliation at discharge.

Topic Group 3 aimed to measure the level of patient involvement and, hence, the quality of pharmaceutical care by evaluating the following items:

1. Documented counseling provided by a pharmacist during a patient–pharmacist consultation based on the so-called "My CheckList" at the start of a new chronic treatment;
2. Provision of documented medication reviews following the needs that arose during the so-called "My CheckList" consultations, in the case of elderly patients who are suffering from multi-morbidity and receiving polypharmacy.

The international working group to achieve the goals elaborated following indicators:

Indicator 1: Documented counseling during "My CheckList" consultation/Total number of patients receiving "My CheckList" (%).

Indicator 2: Documented medication review in patients having attended a "My CheckList" consultation/Total number of patients who attended a "My CheckList" consultation (%).

"My CheckList" is a form developed for the study purposes, representing a short checklist where patients can include the medications they are using, their experience with the new medication (indicator 1) or usefulness of their chronic treatment (indicator 2), and questions to be discussed with the pharmacists. Pharmacists were provided with additional education, the consultation lists were also peer-reviewed after the interventions to provide pharmacists with a feedback.

The limited number of countries participated in the validation did not give the possibility to make conclusions regarding validity of the indicators. But the feedback from pharmacists was positive in most of the cases (90%), highlighting the need for policy makers and professional bodies to consider that provision of education, mentoring, and peer review of consultations will help pharmacists improve their consultation and communication skills to engage more effectively with patients. These indicators also have a potential to evaluate processes of provision of pharmaceutical services such as new medicines service and medication use review.

A working group with focus on specific needs of certain areas in Europe (TG4) was established within this initiative. The working group consisted of members of the Committee of Experts of Council of Europe and scientific collaborators from different European regions developed a self-evaluation tool (PharmSAT) for pharmacists to assess their progress in pharmaceutical care implementation in daily practice. In particular, the working group decided to elaborate a checklist focusing on background information, pharmaceutical care initiatives, documentation/monitoring, qualification/training, communication, and involvement of further health professionals and patient's perspective, based on the so-called "easy pharmaceutical care concept" that was developed during

project. This concept is based on the principle that implementing pharmaceutical care is a continuous process which adds the quality of care principles to a given (one point of time) pharmaceutical service (e.g., medicines dispensing, blood pressure measurement, etc.). The pharmaceutical care process includes but is not limited to patient counseling and education, documentation of interaction (medication decision), follow-up of medication decisions (to stop, to go on, modify medication), inter-professional collaboration, and patient involvement with a view to meeting the patient's needs and expectations.

The PharmSAT was pre-tested and piloted in 10 countries of European region. The results of the studies demonstrated that the PharmSAT has a relevance to community pharmacy practice in most of the participating countries, but its applicability is limited in countries with a longer history of pharmaceutical care (e.g., Denmark and the Netherlands).

The results of the EDQM project and proposed quality indicators are published (EDQM, 2017). These indicators can be used by health authorities and healthcare professionals to evaluate pharmaceutical care practices and policies, and to promote the efficient and safe use of medicines, leading to the best possible medication outcome for the patient.

Pharmaceutical Care Network Europe

Pharmaceutical Care Network Europe (PCNE) is one of leading research groups on quality of services. The working group of PCNE conducted the extensive investigation of provision of pharmaceutical services in two large multinational studies in Europe in 2006 (Hughes, 2010) and 2012/2013 (Costa, 2017). The results showed that implementation of pharmaceutical care in Europe varies between countries and efforts are needed to minimize difference between developed and developing countries in the future. In the 2013 PCNE researchers reviewed all published definitions of pharmaceutical care and redefined the core term stating that "Pharmaceutical Care is the pharmacist's contribution to the care of individuals in order to optimize medicines use and improve health outcomes" (Allermann, 2014).

Summary

Since the middle of the 20th century the role of pharmacists in the healthcare system was continuously growing and changing, where pharmacist overtook the responsibility on medicines rational use. New professional roles required new professional standards to define quality and safety of pharmacists' activities. Professional organizations are the key stakeholders in the process of developing professional standards. World Health Organization and International Pharmaceutical Federation are working together to define the full range of roles of pharmacists, as well as type and quality of pharmacy services. The most recent version of the Joint FIP/WHO guidelines on GPP: standards for quality of pharmacy services was adopted and published in 2011. The guidelines provide the framework for the excellence in implementation of GPP and needs to be adjusted and adopted by the national organizations of countries considering historic, political, economic, and social background.

The quality of pharmaceutical services can be defined, assessed, and evaluated in different ways, but starting point is to state the perspective from which it will be assessed: patient, pharmacy professionals, or other stakeholders; public, as well as the aspect of care being measured. From the professional perspective, high-quality services ensure provision of the most effective and safe care. Many tools for professional evaluation of services in community pharmacy were developed and implemented in the UK, US, Canada, and Malta. From both professional and public perspective, for quality assessment in community pharmacy is possible to evaluate the adherence to national guidelines for GPP or use quality indicators.

National initiatives on the quality standards as described further focus on one or several of these possibilities (Australia, USA, Canada, UK, Bermuda, Singapore, and South Africa). National professional standards focusing on quality of services vary a lot between countries. Great examples of service excellence can be further found in Netherlands, Republic of Ireland, and New Zealand.

International initiatives reflect primarily professional and public perspective and offer guidance on provision of pharmacy services and their quality assessment in Europe (Blueprint, Pharmaceutical Group of the European Union), Americas (Forum of Americas), as well as on the transregional level (European Directorate for the Quality of Medicines and Healthcare, Council of Europe, Pharmaceutical Care Network Europe).

Professionalism as the Core Competency in Pharmacy

Thomas D. Zlatic, St. Louis College of Pharmacy, St. Louis, MO, United States

Consensus on the Importance of Professionalism

Professionalism has long been an expectation for pharmacists. As in other medical fields, pharmacy organizations have insisted on the need for practitioners to follow professional principles and guidelines that have been embedded in codes of conduct, oaths pledged by pharmacists, and statements or white papers disseminated by professional organizations.

Although there are many similarities in the identified traits of professionalism, there is also some divergence. For instance, in the United States a white paper on student professionalism endorsed by the American Pharmaceutical Association Academy of Student Pharmacists (APhA-ASP), American Association of Colleges of Pharmacy (AACP), and American Society of Health-System Pharmacists (ASHP) identified professional traits as: knowledge and skills of a profession, commitment to self-improvement of skills and knowledge, service orientation, pride in the profession, covenantal relationship with client, creativity and innovation, conscience and trustworthiness, accountability for his/her work, ethically sound decision-making and leadership (APhA-ASP, 2000). The American College of Clinical Pharmacy (ACCP) white paper on student professionalism listed as traits: commitment to excellence, respect for others, honesty and integrity, caring and compassion, accountability, responsibility (Roth and Zlatic, 2009). All agree on the importance of professionalism but not all identify it in the same way.

To promote global agreement on essentials of professionalism, the International Federation of Pharmacy (FIP) in 2004 encouraged all nations to create a code of conduct for pharmacists and recommended 14 "obligations" that undergird the evolving roles and responsibilities of pharmacists (International Federation of Pharmacy, 2004). Ten years later, in an effort to identify essential traits of professionalism that pertain to all nations of the world, the FIP Council adopted an Oath for Pharmacists which could be adapted according to the various countries' situations for use in events such as graduation ceremonies and conferences (International Federation of Pharmacy, 2014).

Around the world, nations have developed statements on professionalism and codes of ethics, which differ according to local historical, socioeconomic, cultural, and religious factors. For instance, the Saudis include such traits as "avoidance of trivialities and pettiness" and "passion and love" as ethical values, and in South Africa ubuntu (the bond that connect all humanity) is an important professional value (Pharmaceutical Society of Australia, 2017; Pharmaceutical Society of Ireland, 2009; Pharmacy Board Malaysia, 2009; Pharmacy Council Malta, 2008; Saudi Commission for Health Specialties, 2014; Singapore Pharmacy Council, 2015). In addition, the statements differ according to the people to which the codes apply, the level and scope of practice in that country, the degree of legality and institutional policy that is referenced, and other such factors.

However, although there is near universal agreement on the value of professionalism for pharmacy, there is not always consensus regarding what it is and what it entails.

Less Commonality on What Professionalism Entails

Abilities, Competencies, Objectives

As the assessment movement has increasingly permeated higher education over the last 21 years, organizations have established more detailed, criteria-referenced lists of outcomes that graduates must demonstrate. These include the requisite knowledge, skills, and attitudes/values required for professionalism. Although researchers from Great Britain and Australia in 2010 concluded, "to date, very few Schools of Pharmacy appear to formally teach it let alone assess students' acquisition of professionalism" (Rutter and Duncan, 2010). Currently, there is renewed interest in teaching and assessing profession, particularly in the United States but also extending to other countries (Schafheutle et al., 2010).

The American Association of Colleges of Pharmacy (AACP), Center for Advancement of Pharmacy (CAPE) Outcomes, formulated in 1994, 1998, 2004, and 2013 were attempts to describe educational outcomes for American pharmacy school graduates, some of which were adapted by the American Accreditation Council for Pharmacy Education (ACPE) to serve as accreditation standards (Accreditation Council, 2015). The first three iterations of CAPE Outcomes framed outcomes in terms of abilities, that is, as integrations of knowledge, skills, and attitudes/values—what a student must know, what the student must do, and the appropriate values that the student must demonstrate. In earlier iterations, professionalism was not listed as a distinct ability but was a component of valuing and ethical decision-making. CAPE 13 identified outcomes as competencies, that is, as more discrete, atomistic, measurable descriptions of knowledge, skills, or attitudes/values. Professionalism in that document is approached as a "domain": "Exhibit behaviors and values that are consistent with the trust given to the profession by patients, other healthcare providers, and society" (CAPE, 2013).

Entrustable Practice Activities (EPAs)

Another recent attempt at defining pharmacy educational outcomes is the entrustable practice activities (EPAs). According to an AACP special report, these "core EPAs for New Pharmacy Graduates are discrete, essential activities and tasks that all new pharmacy graduates must be able to perform without direct supervision upon entering practice or postgraduate training.... [they are] independently executable, observable, and measurable in their process and outcome." The EPA report further notes: "The first assumption is that professionalism must permeate every EPA statement. Without professionalism none of these tasks would be possible. Also, it was deemed that no single task can comprise the entire construct of professionalism" (Haines et al., 2017, p. 1). The implication is that professionalism may not be a "what," an activity, but a "how,"—that is, not a thing but a way of acting or being.

Some Components of Professionalism

Within college programs, thoughtful statements on student professionalism have included virtues, such as compassion, accountability, excellence, respect, duty, altruism (Brown et al., 2009; Kelley et al., 2011), but understandably in practice college definitions frequently focus on civility, academic honesty, and appropriate appearance, demeanor, and behaviors. Common among the latter are traits, such as promptness, attendance, grooming, and appropriate use of electronic devices. At the class level, professionalism is translated into the specific and concrete: address all medical professionals and patients by title, avoid clothing too short/long or too revealing, do not use strong perfumes, do not wear open-toed shoes, turn off your cell phone. Unprofessionalism is exemplified by terms such as complaining, being a nonteam player, uncaring, having a negative attitude, being obnoxious, being a know-it-all, and being disrespectful (Hammer, 2000; Hammer et al., 2003; Masters, 2005; Schafheutle et al., 2010). It may not be immediately obvious to some students how their choice of hairstyles is related to loftier goals of professionalism such as "selflessly serving humanity."

These attempts to identify the elements of professionalism also raise questions about the nature of professionalism itself (Brincat, 2006; Huddle, 2005; Kuczewski, 2006). Outcomes for professionalism are variously labeled as abilities, competencies, objectives, concepts, and domains. Sometimes these terms are used interchangeably; sometimes they denote distinct entities. It is appropriate to begin with an analysis of the quiddity or "whatness" of professionalism, for how professionalism is defined determines how it is taught and assessed. It is also important to establish what it means to be the "core" competency of pharmacy education.

The terms "objectives" and "competencies" imply that we can dissect professionalism into 40–50 or more traits that students must demonstrate in isolation of one another, and we can even create professional "report cards" to evaluate whether a student is a professional at the C+ or A-level. Such an atomistic approach ignores that a whole is not equal to the sum of its parts; the relationships between the parts create new components. Such an atomistic approach can blur the distinction between the unprofessionalism exhibited by unshined shoes and the illegal dispensing of drugs. Life, private or professional, is not compartmentalized that way. Professionalism intersects in many intricate ways with most of everything else in a professional degree program.

Our language reveals that neither is professionalism exactly the same as abilities such as thinking, communicating, collaborating. We think, communicate, collaborate but we do not "professoriate." Like self-awareness, professionalism is not something that we do but something that we are, as is indicated by the wording of many outcome statements: "be professional," "be self-aware." In short, though professionalism can be classified as an ability, objective, or competency, there are advantages to interpret it as an orientation. It is this orientation that justifies professionalism's designation as *the* core outcome.

"Presentation Professionalism" Versus "Existential Professionalism"

Our definitions are influenced by the models, paradigms, and metaphors that shape our worldviews. Often such paradigms are invisible to us, which enhances the power they have in influencing our perceptions and conceptualizations. The well-known cliché, "I would have to see it to believe it," is often unknowingly reversed: "I would have to believe it to see it." Similarly with professionalism, what we see as professionalism often is based upon unexamined concepts, principles, and values. Certainly, for example, professionalism can and must be assessed (Brown et al., 2009; Chisholm. et al., 2006; Hammer et al., 2000; Kelley et al., 2011; Rutter and Duncan, 2010), but the limitations of our assessment methods should not define professionalism for us (Brincat, 2006; Huddle, 2005; Kuczewski, 2006). Though professionalism emanates out of dimensions not easily observable or measurable, a demand for exclusively empirical assessment alone can circumscribe what professionalism encompasses and proscribe what is taught and how it is taught.

The meaning of professionalism depends upon the context and the purpose for its use. For example, Castellani and Hafferty observed seven different professional stances in the contemporary medical world, for instance, the "nostalgic" noncommercial autonomous professional who despises entrepreneurialism but revels in control and prestige, the "academic" who shares lofty values but puts less emphasis on autonomy and dominance, and the "activist" dedicated to social justice (Castellani and Hafferty, 2006). Each of these professional models would require different educational preparation and assessment.

Recent attempts to define and measure student engagement and professional engagement also provide evidence that the concept of professionalism cannot be exhausted by one definition, perspective, or methodology. A Delphi approach designed to uncover the cognitive, affective, and behavioral attributes of an engaged pharmacy professional resulted in 12 beliefs and 9 behaviors, with a major difference being, "the professionally engaged pharmacist thinks and behaves in ways that positively affect patients' health and advance the profession's values and societal mission." Although professionalism and professional engagement overlap in many aspects, "individuals who are engaged exhibit vigor, dedication, and absorption" (Aronson and Janke, 2018; Miklich et al., 2016, p. 406). The questions remains, what is the motivation and in fact the imperative for a person in any profession to exhibit the cognitive, behavioral, and affective traits that comprise professionalism.

Professionalism as a competency focuses on professionalism as "what," but professionalism can also be defined in relation to identity, with a focus on "who" (Hafferty, 2006a,b). For our purposes here—to justify the claim that professionalism is the core outcome of pharmacy education—we will distinguish two complementary conceptualizations of professionalism: a marketing or "presentation professionalism" and an interiorized "existential professionalism." That is, professionalism can be defined as something we have or something we are. Personalist philosophers and psychotherapists have noted a trend toward commodification that is subtly reflected in the increasing use of the word "have" in contemporary society (Marcel, 1935; Fromm, 1997). The difference between a "having" and "being" orientation can be illustrated by the answer to the question, is there a difference between having an education and being educated? The student who is at all costs intent upon maintaining a high GPA and getting a diploma with highest honors, and who thereby avoids challenging courses, does not engage in controversial discussions in class, writes on tests what he or she believes what the instructor wants to hear—this student is in a "having" mode. On the other hand, the student who is curious, wants to figure things out, makes learning rather than grades a primary goal, who challenges the instructor when he or she does not agree, and is working toward a personally constructed world view—this student is in a "being" mode. He or she does not want to "have" an education but "be" educated. Similarly, there is a difference in orientation when one says, "I have a guilt complex" versus "I am guilty." In the former, guilt is something I have; it is external to me. I can go to a psychotherapist to get it removed, like a wart—I do not need to change. To admit "I am guilty" requires a more interior response.

In the same way, professionalism can be seen from within the orientations of "having" or "being." There is an inner and outer face of professionalism. It is something that I can have and it is something that I can be. The American 19th century writer, Henry David Thoreau, observed: "A man [or woman] who has at length found something to do will not need to get a new suit to do it in.... I say, beware of all enterprises that require new clothes, and not rather a new wearer of clothes. All men [and women] want, not something to do with, but something to do, or rather something to be" (Thoreau, 1854; 2004). Professionalism requires neither simply an approved style of appearance nor merely a proscribed set of behaviors, but a transformation of self. Putting on a white coat does not make a student a professional; rather, the white coat is symbolic of an internal transformation that is beginning—the student is *becoming* a professional. Professionalism, in a deep existential sense, is rooted in being.

Again, definitions depend upon context and purpose, and thus two people using the same words may be talking about two different things. "Professionalism" is an honorific term that can be applied to athletes (who get paid for playing) and to plumbers or roofers who produce high-quality services reliably and efficiently, as opposed to a fly-by-night, uninsured, minimally-skilled worker in a tee-shirt and torn blue jeans who knocks on doors after a severe storm.

"Presentation professionalism" is not a pejorative term. Appearance is very important for a professional. Although not accurate or fair, the general public tends to place more trust in a well-dressed, well-groomed, well-spoken, polite individual than in the person with unconventional hair coloring, extravagant piercing, sloppy attire, and a sour attitude. Trust gets to the center of professionalism (Hall, 2005). In fact, one study suggested that "restoring public trust, particularly in medicine, is really what lies at the heart of attempts to define, describe, measure, and assess professionalism in the healthcare professions" (Schafheutle et al., 2010, p. 14). Of course the more important issue is not simply restoring trust but ensuring that such trust is warranted. In other words, presentation professionalism is necessary but not sufficient attribute for a professional health practitioner. Existential professionalism extends deeper, to the core of the professional.

Fiducial Relationships: The Essence of Professionalism

Occupations and Professions

The differences between an occupation and a profession are crucial for identifying professionalism as pharmacy's core competency. We sometimes do refer to a carpenter, receptionist, hairstylist, chef, soldier, and so on as "professional", that is, as a person who gets paid for rendering high-quality services in a business-like way in a reliable, conscientious, and pleasant manner. We can and do refer to such fields as professions, but more technically, they are classified as jobs or occupations. Traditionally-defined, elements of a profession have included such traits as extensive, esoteric knowledge; autonomy in practice; a code of ethics; self-governing and self-policing privileges; a covenantal relationship with patients/clients. The essential difference between an occupation and a profession pivots on the nature of the relationship that the provider has with those being served.

The four fields that historically have been identified as professions are medicine, law, teaching, and religion—doctors, lawyers, teachers, and clergy/religious leaders. To speak of any of these as "jobs" sounds a bit jarring or cynical. Instead, each of these fields is referred to as a "vocation" or "calling." People in occupations certainly can be better educated than professionals, can have an ethical code and a greater sense of integrity, can make considerably more money, and can have more control over their work environment—these are not the essential distinguishing traits of a profession. Similarly, occupational workers can exhibit altruism, integrity, respect; and they can be "engaged"—exhibiting "vigor, dedication, and absorption" in their work. While these traits are important for professionalism, they do not distinguish professionals from people with jobs.

An essential difference between a profession and an occupation is embedded in the language that surrounds the professions, specifically in the names applied to the persons whom the professionals serve (Ong, 1978). A doctor/medical professional/pharmacist serves patients, a lawyer serves clients, a teacher serves students, and clergy serve a flock/congregation/worshippers. The carpenter, barber, manicurist, cable operator interact with *customers*. If doctors or religious leaders begin referring to those they serve as customers, it may be time to get a referral or convert to another religion.

Mercantile and Fiducial Relationships

This is not a simple issue of nomenclature or tradition. In an occupation, a businessperson has a *mercantile* relationship with customers. This is not unethical or inappropriate. The businessperson's primary loyalty is to one's company/employer. The phrase "caveat emptor," let the buyer beware, alerts us to this fact. "The customer is always right" might be an adopted slogan of a businessperson, but the motivation is to ensure future business, not to actually act in the best interest of the customer.

In a profession, the primary relationship of a provider to patient/client/student/worshipper is not a mercantile but a *fiducial* relationship. "Fiducial," from the Latin word *fides*, means faith or trust, fidelity. The professional is obligated to put first the interests of clients (Ong, 1978). Certainly, someone in an occupation can choose to put the best interest of customers first (if only because it is good business), but he or she is not obligated to do so. A professional is a professional by nature of his or her obligation and pledge to do so.

Professions exist to help others in matters of extreme importance to their well-being: their freedom, knowledge, physical lives, and for the believer even their immortal souls. These matters of extreme importance require expertise, knowledge, and skills that the person served does not have and cannot have without similar extensive training. The person served cannot even adequately evaluate the services provided by the professional. As the American Pharmacists Associations Code of Ethics, asserts, the client/patient has little choice but to give the provider the "gift of trust," and in exchange the provider promises, "you can trust me," that is, he or she accepts the fiducial obligation to act in the best interest of the client/patient (American Pharmacists Association, 1994; cf. Cruess and Cruess, 2006). As is proclaimed in many statements of professionalism, this is a covenant established between the profession and society; it is not so much a contract, which implies distrust by its very nature—requiring documents, signatures, and notaries—but a covenant, a pledge, and a word of honor. It revolves around trust. This does not mean that occupational workers cannot be trusted, or that they cannot put the interests of their customers first. Again, the difference is that in a profession there is not only an expectation but also an *obligation* to do so. There is no room in professionalism for caveat emptor.

Because of its commercial interests, its diminished autonomy, divided loyalties between patients and customers, lack of authority to control medicines, and its inability to define its own role in the health care system, pharmacy over the year has been challenged to maintain its identity as a profession, being judged an "incomplete or marginal profession" (Denzin and Mettlin, 1968), a "profession in transition" (Adamcik et al., 1986), "not a true profession" (Agomo, 2012, cited in Chaar et al., 2013). Similarly in 1996 William Zellmer suggested that pharmacy then was not a profession but an occupation on its way to becoming a profession (Zellmer, 1996). Implicit in his critique was that most pharmacists at the time did not embrace fiducial relationships with patients as an essential element of their product-dispensing activities. The change in mission from a product-centered practice to a patient-centered practice enabled and necessitated fiducial relationships, that is, obligations of trust. This fiducial relationship is the core of professionalism.

This is not a modern claim. The obligation to put the patient first extends at least to Plato:

> No physician, in so far as he is a physician, considers his own good in what he prescribes, but the good of his patient; for the true physician is also a ruler having the human body as a subject, and is not a mere money-maker.
>
> There is no one in any ruler who, in so far as he is a ruler, considers or enjoins that which is for his own interest, but always that which is for the interest of his subject and of his art; to that he looks, and that alone he considers in everything which he says and does.

Except for the paternalism implied by the metaphor of a professional as a "ruler," the American Board of Internal Medicine's 1995 publication "Project Professionalism" echoes Plato in identifying professionalism as "those attitudes and behavours that serve to maintain patient interest above physician self interest" (Stobo et al., 1995, p. 2). FIP's Centennial Declaration of October 2012 echoes the commitment "to encourage pharmacists and pharmaceutical scientists to adhere to the highest standards of professional conduct, always giving top priority to serving the best interests of patients and society at large" (Chaar et al., 2013, p. 3). It is telling that many codes of ethics in pharmacy and medicine around the world mention this obligation to recognize the primacy of the patient, often as a first principle. The Code of Ethics for the Pharmaceutical Profession created by the Pharmacy Council of Malta is explicit:

> Establish and preserve a fiduciary relationship. Members of the pharmaceutical profession must endeavour to establish and maintain a professional relationship with their patients. Members of the pharmaceutical profession must uphold the trust granted to them by patients and society and build confidence in their commitment and competence to achieve the desired objective and maintain their trust. (Pharmacy Council Malta, 2008, p. 29)

If students are taught this, they will better understand how all the other traits of professionalism are interconnected: why appearance, ethics, honesty, demeanor, caring, empathy, life-long learning, reliability, all derive from the same source: to ensure professionals have the competence, will, and fidelity to act in the best interest of clients/patients who have few alternatives other than to put their trust in them. This is why trust, an obligatory fiduciary relationship, is the "core" of a profession.

However, there is some concern that in our evolving complex technological culture "existential professionalism" may not survive.

Challenges to Professionalism in the 21st Century

Many of the perceived threats to professionalism in the 21st century are related to this core element of a profession: to trust, to the fiducial relationship between provider and client. There is a growing skepticism about professional organizations' dedication to self-interest rather than promotion of the public good (Coulehan, 2006; Zlatic, 2010a). This diminution of confidence has led to questioning of the autonomy of professionals and has led a de-emphasis of professional judgment as governments, insurance companies, and regulatory bodies exercise more oversight. A resulting litigious culture encourages defensive practice and a suspicious if not adversarial relationship between provider and client. Further, the "best interest of patients" becomes more ambiguous in light of a complex health care environment in which populations in addition to individuals are the focus.

The obligation to maintain fiducial relationships is also at the center of the tensions between professionalism and the commodification and corporatization of pharmacy (Hafferty, 2006a,b; Relman, 2007). In a profession, there is a fiducial obligation to act in the best interest of patients. In a business there is a mercantile relationship between a supplier and customers. Keeping the allegiances distinct can be difficult. In South Africa, for instance, in 2007, one scholar theorized that definitions of professionalism were not adequate for the task of inculcating professionalism: "Although defining itself as a patient-centered profession, private sector (community and private hospital) pharmacy often appears to be that of a product-for-profit centered occupation" (Williams, 2007, p. 1285). According to the FIP Working Group on Pharmacist Ethics and Professional Autonomy, "evidence shows that increased corporatization of pharmacies creates a 'duality of interest,' diminishes pharmacist professional autonomy and threatens patient safety" (Chaar et al., 2013, p. 43). Mass media advertising of professional services also evoke in audiences business models for health care in which patients are targeted as health care consumers. It can be difficult for the shrewd consumer not to weigh the glitzy pitch of the medical professional with the same suspicion as the clever jingle of the used car salesperson (Zlatic, 2010b).

That being said, nostalgia is not the solution. A complex, global, technologized environment in which medical professionals seek expanded services to greater numbers of people and continually explores scientific and medical advances to improve health care outcomes—all of this requires management, centralization, efficiency, and marketing. This hopefully can be accomplished within a professional framework for what "best interest of the patient" means in this environment is different from what it meant in the 1940s community pharmacy. It will be important, though, first to acknowledge the ongoing tensions between corporate mercantile interests and fiducial relationships; and second, to work toward minimizing those tensions. Care must be taken that presentation professionalism becomes not an extension but a substitute for existential professionalism.

Another threat to professionalism is consumerism in schools. Pharmacy faculty can experience the same tensions as pharmacy practitioners regarding the nature of the relationship they have with students, the people they serve. Higher education continues to adjust to the contemporary social-political-economic environment. The number of college administrators has increased significantly in recent times, many administrators now having graduated from business programs (Michael, 1997). Although schools may be nonprofit, today they must be run like businesses—advertising for students, retaining them, and cementing relationships with faithful alumni who will provide future support. College planners talk unapologetically about identifying a "brand" for their program. To maintain enrollment—and to act in what they believe is in the best interests of students—administration sometimes urges faculty to treat students as customers. The intentions are honorable and laudatory. Too often students are not treated as customers in a restaurant. Although pharmacy students, even those working in pharmacies in retail settings, are instructed that they do not have customers but patients, faculty are asked to treat students as customers, without regard for the irony or the implications. In the two-tiered system of higher education of faculty and administration, administrators may need to treat students to some degree as customers, but once again professionalism, of the instructor as well as the future

pharmacist, is threatened if a faculty member's fiducial obligation to students is replaced by a mercantile one, when faculty are asked to adopt the customer paradigm for students. A student as customer model might not be a problem as long as the students' goals align perfectly with the needs of the profession, but frequently the personal goals of incoming students conflict with the needs of society. For faculty whose advancement and salary are contingent upon student (customer) satisfaction, the temptation to inflate grades, lower standards, and ignore breaches of professionalism may be hard to resist. The *reductio ad absurdum* of such a mentality are online "universities" that basically sell degrees, and customer satisfaction pledges that educational content, processes, and assessment will be designed to suit individual student preferences (Holdford, 2014; Zlatic, 2014). Teaching as a profession requires faculty to treat students not as customers but better than customers. If the warning, "caveat emptor" (let the buyer beware) is extended to "caveat discipulus" (let the student beware), students will learn lessons about professionalism that will not benefit their future patients.

The essential fiducial obligation to patients also clarifies another potential threat to professionalism: professionalization itself. The paradox is resolved by noticing two different interpretations of professionalism at work here. Professionalism does entail allegiance to one's profession and its advancement. However, if loyalty to the profession entails actions and decisions that are motivated by privilege, status, or economic gain, the results can be policies and actions that are detrimental to patients. Again, ironically, in the process of attempting to socialize students, professionalization could be transformed into "jobification" (Kuczewski, 2006; McKnight, 1977).

Quantum computing, robotics, artificial intelligence, medical apps, genetic engineering, and big data certainly will revolutionize many if not most aspects of our society, including pharmacy. Predictions that our children or grandchildren may expect to live to be 125 years old no longer can be quickly dismissed as complete science fiction. This technology can be a threat to professionalism, inserting machinery between the provider and patient (Wachter, 2015), and some worry that the efficiency, accuracy, and speed of robots and artificial intelligence will lead to the replacement of humans. But there is also room for optimism and opportunity. It currently seems highly unlikely that machines will be able to establish fiducial relationships with patients, to truly empathize and care for and about a patient. Artificial intelligence most likely will reach the point that it will pass the Turing test: one will not be able to tell whether he or she is interacting with a human being. But a computer cannot think; it calculates. A computer does not remember; it stores data. A computer cannot feel pain and thus cannot be empathic. A robot can be programmed to act empathically and appear empathic but cannot be empathic—for empathy means placing yourself in the position of another person. Some would argue from a behaviorist perspective, it does not matter whether a person is a professional, as long as he or she acts like one. The future appearance and behaviors of a machine may be indistinguishable from that of a human person, but at least as we now are as a people, most of us would not be comforted in our pain and sorrow by expressions of empathy by sophisticated programming, regardless of how tenderly the words were uttered.

Preserving Professionalism as the Core Outcome in Pharmacy

Although some pessimistically predict an "end of professionalism" or assert the impossibility or irrelevance of fiducial obligations in contemporary pharmacy interactions (Broadbent et al., 1997; Haddad, 2017; Pellegrino, 2000; Sullivan, 2004), pharmacy can take steps to enable pharmacists to earn patients' trust that the pharmacist will put their best interests first. The efforts can begin with pharmacy education.

To ensure that professionalism is in fact a core outcome in pharmacy, it is necessary first to come to consensus regarding a clear conceptualization of what it is and what it entails. Then it becomes necessary to ensure that all stakeholders understand and support the effort to inculcate professionalism, and for schools to recruit and admit students who are predisposed toward a professional orientation. Faculty members need to ensure that professional outcomes are clearly identified within their courses and experiential education, and that detailed criteria make explicit what good practice entails. The next step is to review all courses in order to map a curriculum in which professionalism is treated sequentially at more complex levels throughout the program, using consistent definitions and criteria. Within courses and experiential education, pharmacy faculty needs to create opportunities for students to practice and internalize professionalism, and to provide constructive feedback on improvement. Perhaps most important, professionalism must be modeled routinely in the classroom, clinic, elevators, and hallways.

Faculty and Administration

Developing a professional orientation can be the "core" outcome in a pharmacy program only if the administration and staff make it so. That requires an institutional commitment to the development of what professionalism means in their country and institution. Faculty workshops and retreats can provide opportunities for faculty and administrators to reflect upon professionalism and to agree upon what they want to accomplish with their students. Administration must endorse and promote the efforts of the faculty, and their commitment to professionalism must be evident in school philosophies, policies, procedures, contracts, and documents. School web pages and marketing should reflect professional values. Dancing dollars signs under an advertisement to recruit students into pharmacy does not send a message conducive to fiducial responsibility. A commitment to professionalism requires administration to recruit, hire, and reward faculty predisposed to core values. Faculty modeling of professionalism, making it an inextricable element of the program, is essential. The commitment to a culture of professionalism can also be evidenced by public recognition of faculty who personify professionalism.

Students

One way to better ensure student professionalism is to admit into the program students predisposed to such values. The school can disseminate promotional literature that attracts students with a desire to place patient needs as a priority. The school can then design an application process that prioritizes professional values, and can conduct interview process that queries applicants' motives and goals. Admitting students with a propensity for professional values and behaviors can help to foster a culture of professionalism.

Outcomes/Criteria

Once educators define what professionalism means at their institution, they can ensure that it is included in the outcomes and criteria created for courses. Faculty and students cannot intuit what professionalism involves. It must be clearly stated and identified with specific criteria. For instance, in teaching simulations on the ability of educating patients, often a given criterion is "maintain eye contact," which would be better stated as "establish rapport": in some cultures it is impolite to look people in the eyes, and most people are uncomfortable by prolonged staring. "Establishing rapport" is a more difficult and meaningful task. Similarly, it is important to be precise regarding what it means to be professional. Because they are easily observable, quantifiable, and assessable, usually the criteria for what is here called presentation professionalism are clearly listed, while the link to characteristics of honesty, fiducial obligations, and integrity is not so clear. The learning objective "dress in a professional manner" would be better stated as "instill trust in patients by dressing professionally" so that the connection between presentation professionalism and fiduciary relations is clear, and so that students understand that "unprofessional" is more of a matter than trendy hairstyles, full-body tattoos, piercing, and gum chewing.

Mapping a Curriculum

Once faculty establishes course outcomes and detailed criteria for professionalism, they can map a curriculum, which provides a systematic set of outcomes, practice opportunities, criteria, and assessment feedback over the length of the curriculum. In an integrated curriculum, professionalism would be an outcome across all years. Each course syllabus would clearly identify the outcomes regarding professionalism that are appropriate for that level of student, with the outcomes becoming more complex as the student progresses through the curriculum. Earlier courses would build a foundation by covering knowledge of professionalism and ethics and providing opportunities to practice skills such as empathic listening and ethical decision-making. In an addition to an ethics of action (which asks what is the right thing for me *to do*, a question often answered by invoking theories such as deontology and utilitarianism), students can learn an ethics of character or virtue (which addresses the question of what type of person must I *be*). In simulations and later in capstone courses and experiential education, more internalized traits of professionalism—honesty, integrity, empathy, establishment of fiducial relationships—can be taught, observed, practiced, reflected upon, given feedback, and learned, if the preceptor thematizes, models, and assesses them. Unfortunately, virtues such altruism, beneficence, honesty, and integrity are more frequently cited in school documents than in course syllabi and criteria.

Teaching and Assessing Professionalism

In order to develop professionalism, one must be given many opportunities to practice and get feedback regarding the knowledge, skills, and attitudes/values that constitute professionalism. Some may argue that professionalism, like empathy, cannot be taught: either you have it or you do not. This could be true, depending upon what one means by "professionalism" and what one mean by "taught." Lecturing students and testing them on professionalism can increase their knowledge of professionalism: what it is, why it is important, how it is communicated, how it can be breached. Additionally, students can be taught behaviors and skills required by professionalism, such as empathic listening: students can be taught how to act professionally. It is unlikely, though, that didactic education can teach students to be professionals.

While there is legitimate debate whether professionalism in a deep or existential sense can be taught didactically, it is more apparent that it can be learned, when the learning is directed by instructors who create experiences that engage students' minds, senses, and emotions. Empathy, for instance, involves putting ourselves imaginatively in the place of others: thus the wider our experiences, the greater the potential for empathy. With limited experience, we often do not put ourselves in the place of others but put others in our place, interpreting them from our own limited perspectives. Students can "learn" empathy by widening their experiences.

Disparity in health resources can be taught from a textbook; one can be stimulated to act upon those disparities by participating in a medical mission trip—seeing, hearing, touching, tasting, and smelling the effects of disparity of health resources in a community that lives in a garbage dump in which bare-foot 4-year-old children scamper with adults to be the first to get to the dumping garbage truck (Sims, 2011). Listening to a lecture about the difficulties of smoking cessation can provide useful knowledge about struggles with addiction, but empathy can be deepened by serving in an advanced practice experience at a smoking cessation clinic where one interacts with struggling patients, such as the woman whose mother watched her as a young girl be abused by the mother's boyfriends, the man whose son survived fighting in Afghanistan only to die of *Neisseria meningitidis* within a month of his return, and the woman who with her son was set on fire by a man who had doused them with gasoline (Wilken, 2011).

However, experience is not only the best teacher, it can also be the worst teacher. You can die from it. Additionally, the cost and logistics of international trips and community volunteering can be prohibitive. Sometimes it is better to learn from the experience of others. Novels, film, poetry, drama, reflection essays, and nonfiction such as *The Spirit Catches You and You Fall Down* allow us to relive the experience of others and thus increase the potential for empathy in ourselves. Stories that graphically depict the lingering effects of poverty, injustice, and racism provide a context for understanding the "difficult" and perhaps abusive patient who walks into a community pharmacy. The humanities capture dimensions of human experience that are omitted or—out of a misguided quest for a circumscribed idea of "objectivity"—even, are intentionally excluded from professional education (Bumgarner et al., 2007; Spiro, 1992; Wear and Bickel, 2000).

In didactic education experiences can be simulated, as in the Geriatric Game in which students' senses of sight, sound, and touch are muffled to give them an understanding of how an older person experiences the world, thereby enhancing the students' potential for empathy. Role plays, simulations, case studies that are rich in socioeconomic, cultural, ethical, emotional issues can heighten reflection on professionalism and allow students to internalize what they have read in codes of conduct and statements of professionalism (APhA-ASP Professionalism Toolkit for Students and Faculty).

Journaling is another strategy for developing and assessing professionalism. In journaling students reflect upon their experiences, analyze them, and plan strategies to be more effective, particularly after insightful, sensitive feedback from instructors/mentors (Brody et al., 2002; Schumann et al., 2004; Zlatic and Zellmer, 2011). Such journaling can orient students to the strategies of continuing professional development (CPD), and can encourage reflective practice that leads to life-long learning (Schafheutle et al., 2010). Structured, reflective journaling encourages cognitive and affective development that enables understandings that lead to knowledge that is not additive but transformative. Some evidence suggests that journaling can be helpful in Professional Identity Formation (PIF), "'the transformative process of identifying and internalizing the ways of being and relating within a professional role' by adopting characteristics of a professional, such as altruism, respect for others, honesty and integrity, and commitment to self-improvement" (Johnson and Chauvin, 2016, p. 1). This gets to the core of professionalism, both presentational and existential. One's professional appearance is not as a masquerade but an indicator of an inner commitment to trust. Becoming professional involves identity formation.

In the classroom and clinic, instructors and preceptors can share their own stories with students and coworkers, their encounters, successes, and failures related to professionalism. But more importantly, what instructors and preceptors do is perhaps much more compelling that what they say. The "hidden curriculum" refers to the actions, behaviors, attitudes, and values that are actually displayed rather than preached from a lectern or advertised on a web page. Unfortunately, "what is 'taught' in this hidden curriculum often can be antithetical to the goals and content of those courses that are formally offered" (Hafferty, 2000; Hafferty and Franks, 1994; Schafheutle et al., 2013). Eloquent statements of college mission, systematically designed curricula, and classroom-inspiring lectures regarding professional practice have less influence on professionalization than what students observe on a daily business in the classrooms, clinics, research laboratories, faculty and staff offices, and elsewhere on and off campus. White coat ceremonies and honor codes have important symbolic value in fostering professionalism, but students become cynical if the symbols prove empty by infractions they observe on a daily basis. Students need models and mentors that they respect and want to emulate. Ideally, each institution would inspire a "culture of professionalism" (Berger et al., 2004) in which the professional responsibility of working in the best interest of the patient is concretized by instructors and preceptors who exhibit a fiducial obligation to act in the best interest of students and the patients that they serve (Popovich, 1991).

Dissenting Views

Arguments against placing covenants or fiducial obligations at the center of professionalism raise important points: a professional code should not be aspirational but actual, reflecting current environment and practice; additionally, such codes should be applicable to all segments of professional practice. It is further argued that the physical resources, organizational structures, and legal authority required to form fiducial relationships are lacking (Haddad, 2017)—a position, in effect, which echoes William Zellmer's 1996 opinion that pharmacy was an occupation still on a path to becoming a profession. An alternative to identify pharmacy as an occupation would be to create a different definition of pharmacy professionalism, one that centers on a social contract, because covenantal or fiducial relationships are too paternalistic, too idealistic, and too contaminated by the world of finance. Perhaps fiducial relationships are the foundation only for pharmacy careers that involve patient care. For other career paths, the social contract offers a clear-cut statement that identifies and limits what the professional and patient owe one another.

Every advantage has its tax, and every statement of professionalism is open to criticism. The social contract, for instance, does offer clarity and limits provider responsibility to what is defined in the contract, but it also invites lawyers, lawsuits, and protective practice into the professional/patient relationship. Although, it would seem at first that a contractual model of professionalism would not result in significantly different outcomes from a fiducial relationship model if the first article of any social contract pledged to place patient interests first—for that is the essence of the obligation of a fiducial or trust relationship. However, more subtly, the contractual model contributes to an externalization of professionalism that moves it closer to a "having" orientation, de-emphasizing professionalism as an identity. Professionalism so understood tends toward a competency, but not one that would seem to justify the designation as the core competency in pharmacy. If pharmacy has not yet reached a stage at which it can include in codes of ethics a guarantee of trust or fiducial relationships to patients, perhaps a first step is to restrict such aspirations to statements on professionalism that inform programs for professional development.

It would be better, though, to interpret the covenantal and social contract models not so much as an agreement between individuals (provider and patient) as an agreement between a profession and society. The fiducial or faith relationship, the promise of trust, operates more intimately, interpersonally, between patient and provider—as a patient I do not trust the pharmacy profession, I trust you.

Summary

In summary, the term "professionalism" covers a wide range of practices, attitudes, commitments, and values that can extend from the color of toenails to a commitment to seek justice in the distribution of health care resources. All are important. In pharmacy, however, professionalism is a core outcome when it integrates the appearance of trust (presentation professionalism) and the willingness always to put the best interests of patients first (existential professionalism). Professionalism is a core outcome because it is a component of everything that is taught in a pharmacy program—whether the teaching is intentional; whether it is presented in the classroom, practiced in the clinic, or modeled in the hallways; whether it consists of positive lessons or negative examples. Pharmacy educations require the accumulation of knowledge, the honing of skills, and the demonstration of values, but professionalism is the core outcome because it is (or should be) transformative. It is the core outcome because it touches the core of the individual; it requires the assumption of an identity, the identity of a professional, a person of integrity who can be trusted to be competent, caring, and honest. Perhaps pharmacy practitioners and educators can best influence such a transformation through modeling that can be observed in organizational policies, positions, and practices and in the daily routines of their instructors, preceptors, mentors, supervisors, employers, and professional representatives.

Quality Assurance and Quality Advancement of Pharmacy Education

Dawn G. Zarembski*, Michael J. Rouse†, *Senior Program Associate, Accreditation Council for Pharmacy Education, Chicago, IL, United States; †Assistant Executive Director, Professional Affairs and Director, International Services, Accreditation Council for Pharmacy Education, Chicago, IL, United States

Introduction

The global healthcare workforce is in a period of change. Increasing demands for services associated with longer population lifespans and associated chronic disease burdens are impacting both the need for and scope of healthcare workers' practice (Bates et al., 2016). The World Health Organization (WHO) estimates that currently there is a 7.2 million global healthcare workforce shortage, which, by 2035, will grow to 12.9 million (Campbell et al., 2013). To adequately address this shortage, the WHO has identified the need to transform and scale up the education and training of health professionals worldwide (World Health Organization, 2013). Simply increasing the pipeline and increasing the production of healthcare workers is not the solution. Rather, education and training must ensure that graduates possess the needed skills and competencies to effectively address the evolving needs of the world's populations.

As noted by the International Pharmaceutical Federation's (FIP) Board of Pharmaceutical Practice, today's pharmacists should have expertise in all aspects of pharmacy including the supply and use of medications, providing cost-effective access to safe medications and assuring the responsible use of medications by individual patients and healthcare systems (International Pharmacy Federation, 2018). Countries are facing a critical need to assure the infrastructure exists such that educational institutions are able to produce graduates who possess the requisite competencies necessary to provide pharmacy services that address the healthcare needs of the country. In this regard, a national quality assurance process is essential to assuring the quality of the pharmacy workforce is maintained. The quality assurance systems of individual countries vary globally, with well-developed quality assurance systems already operating in some countries compared with a complete lack of a quality assurance system or an emerging system in place in others. Ideally, all countries will operate a national system for quality assurance of pharmacy education to assure pharmacy graduates are prepared to meet the unique needs of the individual country (International Pharmacy Education, 2009).

The system for quality assurance would assist in ensuring quality pharmacy education is provided. In general terms, quality education is education that:

- Adheres to established standards;
- Addresses national needs of the profession;
- Is appropriate to the national context and socially accountable;
- Undergoes continuous quality improvement to ensure dynamic needs of the profession are met;
- Is appropriately innovative, utilizing the latest active learning methodologies and pedagogy;
- Promotes life-long learning and facilitates the development of skills and attitudes required by graduates to self-direct their own life-long learning;
- Develops in students not only knowledge, skills and abilities but attitudes and behaviors; i.e., is competency-based; and
- Achieves the intended learning outcomes of the educational process (International Pharmacy Federation, 2014; Accreditation Council for Pharmacy Education, 2018a).

Purpose of the Quality Assurance Process

Implementation of a quality assurance process provides professional judgment of the quality of the educational program at a school of pharmacy and facilitates continued quality improvement. Responsibilities of the quality assurance process include:

- To develop and update quality standards which a school of pharmacy is expected to meet and maintain.
- To create policies and procedures which are used to govern the quality assurance process.
- To evaluate, both initially and periodically, schools of pharmacy in accordance with the quality assurance standards, policies and procedures.
- To maintain a public list of pharmacy schools that have been evaluated in accordance with the quality assurance standards (Accreditation Council for Pharmacy Education, 2018a).

The quality assurance process serves multiple stakeholders including:

- the **public:** Implementation of a national quality assurance process assures that pharmacy schools have conformed to general expectations for the pharmacy profession developed and validated through a broad-based process. It facilitates the identification of schools of pharmacy that have explicitly undertaken activities directed at improving the quality of their educational programs, and are carrying them out successfully. The quality assurance process also supports improvement of the professional services available to the public in that schools of pharmacy and institutions offering pharmacy education are expected to be socially accountable by modifying and updating their requirements to reflect contemporary national and societal needs, as well as advances in knowledge, technology, and practice.
- **students and prospective students:** Implementation of a quality assurance process provides an assurance that a pharmacy school has been found to provide satisfactory educational preparation for practice.
- **institutions of higher education:** A quality assurance process provides a framework for self-assessment and improvement as well as the opportunity for external, peer review and feedback, and the exchanging of experience with other pharmacy schools. Implementation of a quality assurance process can also provide a basis for evaluation and decision-making by private and public agencies (including universities evaluating the academic qualifications of candidates applying to graduate programs), national, state and local governments (Accreditation Council for Pharmacy Education, 2018a; Institute of Medicine, 2003).

Models for Quality Assurance

Ideally, a comprehensive quality assurance system will both assure quality and promote a culture of quality improvement (International Pharmacy Federation, 2014). Historically governments have been charged with oversight of the quality assurance process for education of healthcare professionals (World Health Organization, 2003). Typically, government oversight occurs through a department or ministry or a governmental agency specifically established for assuring quality education programs (World Health Organization, 2003). Other quality assurance models involve national pharmacy organizations or other independent agencies. In some countries, more independent and autonomous bodies have been established (World Health Organization, 2003). Such accreditation bodies typically maintain a large degree of independence and autonomy in their operations and decision-making processes. The use of an independent agency represents a growing trend (World Health Organization, 2003). While many different models for quality assurance exist, each with advantages and disadvantages, the differences of each model will not be addressed in this chapter, as it is believed that the principles identified apply universally to the quality assurance process. Rather, the principles and core elements of quality assurance apply regardless of the model of quality assurance system utilized. Countries in close proximity may collaborate via a joint quality assurance system to reduce costs and conserve resources.

There are a number of steps to consider when developing or enhancing an accreditation body. These steps include: (1) conducting an environmental analysis; (2) engaging stakeholders; (3) identifying the national vision/mission for pharmacy education including the mandate for the quality assurance process; and (4) developing the accreditation body (International Pharmacy Federation, 2014).

Environmental Analysis

Individual countries will be at different stages with regard to development of a quality assurance system for pharmacy education. The extent to which quality assurance systems are in place and actively used can vary greatly. Some countries have well developed quality assurance systems, which have been in place and operating for a considerable amount of time. In other countries, the quality assurance system may have been implemented recently or is completing lacking. An analysis of quality assurance systems conducted via European faculties of pharmacy revealed that roughly half of the 28 countries responding to the survey indicated that a quality assurance process was in place and operating within the country (Guimaraes Morais et al., 2011).

Ideally, every country will have a quality assurance system with well-developed standards that are reflective of the contemporary practice of pharmacy and the healthcare needs of the country and are used to evaluate pharmacy education programs (International Pharmacy Federation, 2014). Given that the principles and core elements utilized in the quality assurance process are common, limited resource countries wishing to implement or enhance their quality assurance system may utilize FIP's Global Framework for Quality Assurance of Pharmacy Education to develop or improve their quality assurance process (International Pharmacy Federation, 2014). This chapter summarizes many elements of the Framework and the Framework may be referred to for more detail in each aspect.

Regardless of the stage of development, and whether or not a quality assurance process is already in place, each country should begin by identifying an organization or entity to be in charge of the quality assurance process. For countries with a quality assurance processes already in place, these organizations will likely lead a process of reviewing the current process. For a country that does not have an existing quality assurance process an organization must be identified to assume responsibility. Such an entity may be appointed by the government or a professional organization. Regardless, a leadership group within the pharmacy profession should ideally lead the charge for development of the quality assurance process.

Development or improvement of a quality assurance process occurs within the context of existing systems and regulations. Environmental analysis involves mapping the existing environment to establish a baseline from which new interventions are considered or existing ones are adapted. While the main focus of the environmental analysis is on the quality assurance system, it will identify connections between the regulation of the pharmacy workforce, the education sector (pharmacy schools), and the practice sector.

The initial step then is to conduct an environmental analysis of the professional regulation of pharmacy practice and pharmacy education within the country. Some elements to consider include:

- What professional organizations or governmental agencies are already involved in regulation of the practice?
- What are the different cadres of pharmaceutical professionals practicing within the country?
- What legislation already exists regarding pharmacy education requirements?
  - If legislation mandating requirements for pharmacy education does not already exist, what steps would be needed to enact legislative changes? Are such legislative changes feasible? What organizations/entities need to be involved in the process to change the legislation?
- Does a quality assurance agency for pharmacy education already exist?
  - Does it have established standards and regulations to ensure quality?
  - What aspects should be modified in an effort to improve the quality assurance process?
- What organizations are involved in the provision of pharmacy education offered in the country?

Needs-Based Education

While some healthcare needs are universal, individual needs and priorities will vary between countries, given differences in economic, educational, cultural and societal issues. The national, societal and population needs, along with regulatory mandates and educational capacity within individual countries, will influence which healthcare services are provided by pharmacists within individual countries. Consequently, competencies needed to practice pharmacy between countries will vary. Entry-level pharmacy education programs (hereafter referred to as pharmacy schools) must graduate pharmacists that have been trained with the requisite competencies to address the needs identified within the individual country. The use of a needs-based educational model (**Fig. 1**: Needs-Based Education), as recommended by the FIP's Global Quality Assurance Framework, ensures graduates are trained to address the country's pharmacy workforce needs in terms of delivery of services to the public (International Pharmacy Federation, 2014). In this regard, a critical step in the quality assurance process is the identification of competencies needed by

Figure 1 FIP's Needs-Based Education Model. *Accreditation Council for Pharmacy Education, August 2018. ACPE Self-Study Workshop. FIP, Chicago, IL.*

the pharmacy workforce. Following initial identification, competency needs should be periodically reassessed to ensure education continues to meet the contemporary needs of the country.

Stakeholders

To ensure competency needs are adequately identified, input from a comprehensive array of stakeholders should be obtained. All stakeholders should provide input during the development of the profession-wide vision of practice that clearly articulates the nature and status of pharmacy practice within the country. The process of conducting an environmental analysis will assist in the identification of stakeholders vital to the quality assurance process for pharmacy education.

Ideally, all stakeholders relevant to pharmacy education will be identified for input into the quality assurance process. A commitment to quality assurance and improvement means a commitment to change which benefits most if stakeholders are committed and engaged in the process. Stakeholders are individuals or organizations with a direct or indirect interest in the process and outcomes of the exercise or project, whether positive or negative. A stakeholder should be thought of as any individual or group that can affect or be affected by the actions, decisions, policies, practices or goals of the project. As every country differs, not every stakeholder group will be relevant for every country. It is encouraged that each country initially conduct an environmental analysis to identify stakeholders and their perspectives.

In general, stakeholders with an interest in pharmacy education encompass a wide variety of demographic groups. Fig. 2 builds upon the FIP Needs-Based Education Model and outlines those stakeholders with a stake in pharmacy education.

Regulators and policy makers, such as the government and, where applicable, other specific authorities responsible for the regulation of the education and skills development as well as the practice of pharmacy, have the responsibility of ensuring the competence of the pharmacy workforce. This requires that the government assures the public that graduates are competent to deliver the range of services permitted by the country's Practice Act(s) and regulations. Invariably, as major (or exclusive) contributors to the financing of higher education, governments have another reason to desire continued competence of practitioners. These stakeholders then will have interest in all areas of the pharmacy education quality assurance process.

Pharmacy schools provide the education and must ensure compliance with the quality assurance standards. Engagement of pharmacy administrators and academic staff is essential to the quality assurance process. Similarly, input should be sought from pharmacy students, the consumers of the education process.

Employers are another essential group to include in the development of the model for the quality assurance for pharmacy education. Employers need reassurance that graduates will be competent to practice. In this regard, employers' knowledge and support of the quality assurance process is essential.

The profession as a whole, as it seeks to advance and better serve society and its members, relies heavily on the quality assurance system to ensure the competence, professionalism, and leadership of practitioners. Input from professional organizations, if functioning within the country, can be utilized as a means to obtain input from the profession as a whole.

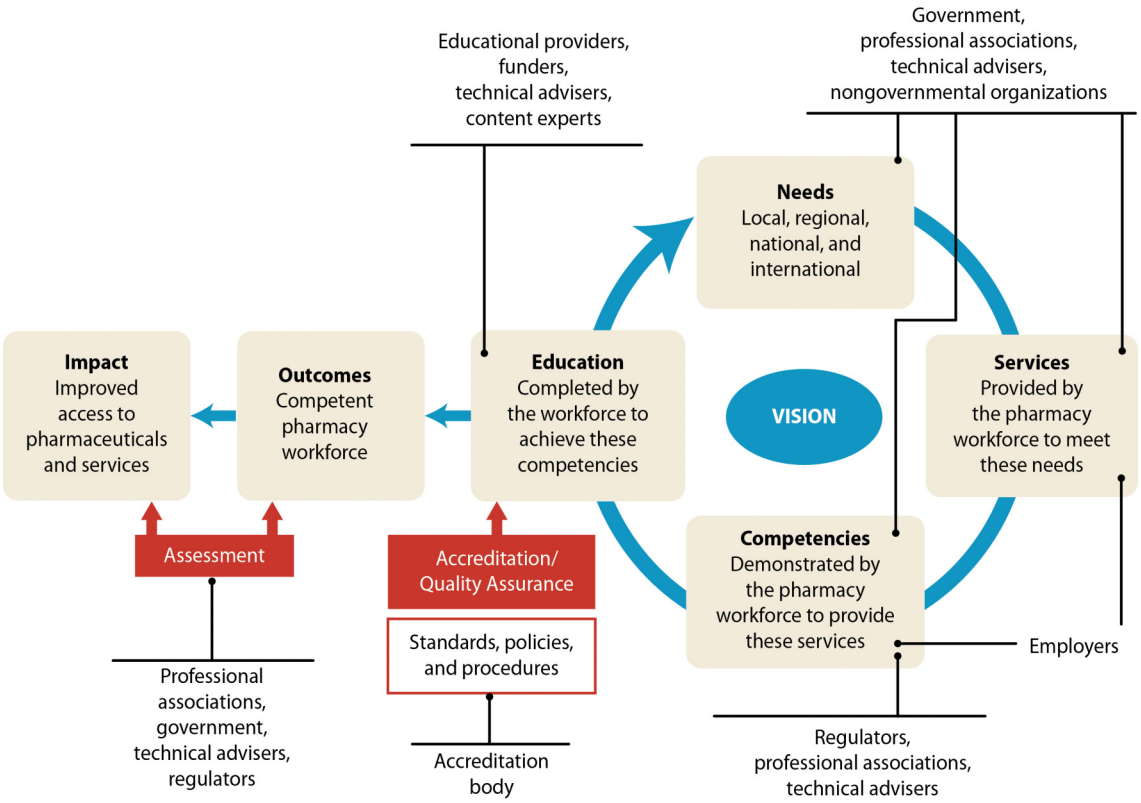

Figure 2 Involvement of stakeholders in pharmacy education. *Rouse, M.J., Vlasses, P.H., Wadelin, J.W., Zarembski, D.G., Joshi, M.P., Mabirizi, D., Saleeb, S.A. 2016. Continuing Pharmaceutical Education: Guide to Establishing Quality Assured and Accredited Programs. Submitted to the U.S. Agency for International Development by the Systems for Improved Access to Pharmaceuticals and Services (SIAPS) Program. Management Sciences for Health (MSF), Arlington, VA. Used with permission from MSH.*

Finally, it is the public, as the ultimate "consumers" of the wide range of services provided directly and/or indirectly by the pharmacy workforce, which derives the greatest benefit from a system that assures the quality of pharmacy education. Consequently, it is increasingly becoming standard practice that members of the public are involved in the quality assurance process.

National Vision

National health care needs and priorities, and the scope of pharmacy practice vary globally. Overall, the role and contributions of pharmacists has changed in recent history with pharmacists now assuming greater responsibility for the safe and effective use of medications (International Pharmacy Federation, 2013).

Countries are at many different stages in the evolution of pharmacy practice and many factors, including culture, history and politics, can influence the rate of change in practice. Infrastructure to support the change in scope of practice has included changes to the education of pharmacists and regulation of pharmacy practice.

Given the benefits that can be achieved by expanding pharmacists' roles and responsibilities, many countries are reviewing pharmacy education (Kheir et al., 2009; Bhuyan, 2013). As practice evolves, education will need to be changed to meet the shifting needs of practitioners.

Development of standards for educational programs should occur following identification and development of the vision for pharmacy practice. Within each quality assurance system, mechanisms should be in place to ensure that input from stakeholders is sought and utilized to assure and advance the quality of pharmacy education. In this regard, stakeholder input on the periodic evaluation and revision of the standards will assist countries in ensuring the standards remain relevant to the healthcare needs of the country. Accreditation standards should typically be reviewed and updated every six to eight years in view of the dynamic nature of pharmacy education and practice.

The Quality Assurance Organization

During development of any quality assurance organization, consideration should be given to the structure, governance, policies and procedures under which the organization will operate (International Pharmacy Federation, 2014).

Mission and Vision

The quality assurance organization should have a mission and vision that clearly articulate its scope of operations. It should be noted that, in many countries, the quality assurance organization will have a broad scope of operations; currently a minority of such agencies are profession-specific. The first step in the development of a quality assurance system is to determine the structure and purpose of the entity (e.g., agency/commission/committee) charged with assuring the quality of pharmacy education. In this regard, it will be essential to determine the quality assurance organization's mission and scope of operations. Methods that will be used to communicate the mission to stakeholders should be identified. An evaluation plan that will be used to determine if the mission is being achieved should be developed and implemented. The evaluation plan should clearly identify the assessment tools that will be used and the individuals responsible for the assessment process.

Legal Status or Other Oversight Requirement

A regulatory mandate or other oversight requirement should govern the operations of the quality assurance system, including its scope of practice. Other oversight bodies should also have a clear description of their scope of authority and who has provided it (e.g., professional organization). Accountable parties should be identified, along with entities that recognize the quality assurance organization. The organization's relationship with government, professional organizations and other stakeholders should be described. Any requirements or criteria that the quality assurance organization must meet should be clearly delineated when it is established. Methods that will be utilized to assure autonomy must be carefully identified and steps must be taken to ensure that the body is not impacted by undue influences and is free from conflicts of interest.

Governance

The organizational structure of the quality assurance program should be appropriate to discharge the obligations mandated by the legislation or other authority. The quality assurance organization will typically include a staff who runs the day-to-day operations of the quality assurance process and a decision-making entity (e.g., Board of Directors). The composition of the decision-making entity or board of the organization should be established and consideration should be given to incorporating representatives from the broad array of stakeholders (e.g., pharmacy school academic staff and administrators, regulators, employers, and members of the public). Once the composition has been determined, the process that will be used to select or appoint individual members of the decision-making body and the role and selection process of officers, if used, should be determined. The identification process and duration that the officers and members of the decision-making body will serve in their various capacities should also be established. In general, it is considered as a good practice to overlap the terms of some members of the decision-making body to ensure consistency.

However the system is structured, the possibilities for "conflict of interest" should be removed, minimized or effectively managed. Members of the decision-making body are typically trusted, knowledgeable, experienced and respected members of the profession and community. In their role on the decision-making body, these individuals have responsibility to the profession and the public. Members of the quality assurance program's decision-making body (e.g. board, commission, etc.) have a fiduciary obligation to act in the best interest of the quality assurance organization. Each quality assurance organization should develop and implement a conflict of interest policy, which requires signed statements by all members of the decision-making body and which is reviewed periodically. Consistent with this policy, representatives of the quality assurance organization's decision-making group and its employees should periodically identify any pharmacy schools for which a conflict of interest exists. Conflict of interest policies should require that any representative of the quality assurance organization (defined as its decision-making body and staff) should recuse themselves from participation in discussions or the decision-making process for pharmacy schools for which a conflict of interest exists or is possible.

Finally, the funding sources to support the quality assurance organization must be identified. Funding sources can include governmental or other grants and fees for services. Regardless of the source, funding should be provided free from conflicts of interest. The fee structure for services should be established such that the ongoing needs of the quality assurance organization and the costs of operating the quality assurance process are addressed without being too punitive to the individual pharmacy schools. The quality assurance organization should independently develop and determine its own budget, without review by or consultation with any other entity or organization.

Standards

Every quality assurance system should have a well-developed set of standards or quality criteria (hereafter referred to as standards) which clearly state their purpose and expectations, and are used to evaluate and determine the quality of the pharmacy education program. Standards should be developed using a clear and cooperative process involving key stakeholder groups described above.

Stakeholder feedback should be sought and incorporated throughout development of the standards. The final standards should be endorsed by the profession and readily available to the public and the profession. Given rapid change in the pharmacy profession, standards should be periodically reassessed and revised as needed to ensure education within the country continues to address healthcare needs identified and adequately evaluate the quality of education provided by the school. The standards review process should be comprehensive and obtain input from key stakeholders, evaluating the context and relevance of individual standards as well as the standards as a whole. Following adoption of any revised standards sufficient time should be provided to allow pharmacy schools to bring their program into compliance with the new standards prior to implementation of the revisions.

Quality assurance standards should provide sufficient specificity to provide a basis for assuring that all pharmacy schools, through evaluation of structure, process and outcomes, produce graduates who have achieved the required competencies. The standards should not be overly prescriptive as to how these outcomes are achieved; however, thereby allowing individuality of programs in line with mission, as well as opportunities for innovation.

Pillars and Foundations of Quality

The FIP QA Framework utilizes five pillars and three foundations for educational quality, which should be addressed within the standards. The five pillars are *context*, *structure*, *process*, *outcomes*, and *impact*, while the three foundations are *science*, *practice* and *ethics* (see **Fig. 3**: Pillars and Foundations of Educational Quality). Each of these eight aspects is briefly described below. Greater detail can be found in the full FIP Framework found on FIP's website at: http://fip.org/files/fip/PharmacyEducation/Quality_Assurance/QA_Framework_2nd_Edition_online_version.pdf (Accreditation Council for Pharmacy Education, 2018a).

Standards related to **context** address the situation in which the school is located and the circumstances in which the education is delivered, and ensure that the educational environment is evaluated. Standards related to context should evaluate the school's mission to ensure it: 1) is specific and measurable; 2) reflects the current and intended future practice of pharmacy within the country; 3) provides the foundation for a culture of assessment and quality improvement; and 4) includes a commitment to research and scholarly activity (Accreditation Council for Pharmacy Education, 2018a).

Quality indicators for context include analysis of the school's mission, goals and values in relation to the needs for pharmacy services within the nation and its alignment with the mission of the university. The analysis should review the school's mission, provide evidence that the school is achieving its stated mission and goals, and state how the school's stakeholders are involved in the process of development, review and revision of the mission.

Standards related to **structure** outline expectations necessary to ensure the development, delivery and sustainability of the pharmacy education program. Standards for structure ensure that the pharmacy school is adequately organized, and has sufficient resources to deliver the curriculum and achieve the school's mission and goals. Structure standards describe the quality assurance organization's expectations regarding the role of the administrative leadership, organizational and governance structure, committee structure, and collaborative relationships within and external to the institution. Structure standards also address the structure and duration of the educational program, as well as the academic and staff resources, financial resources, physical facilities, practice facilities and library and educational resources needed to deliver the educational program. Quality indicators related to a school's structure involve analysis of the school's dean/director, administrative leadership team, committees, internal and external collaborative relationships, curricular content, educational activities, quantity and credentials of academic and other staff including

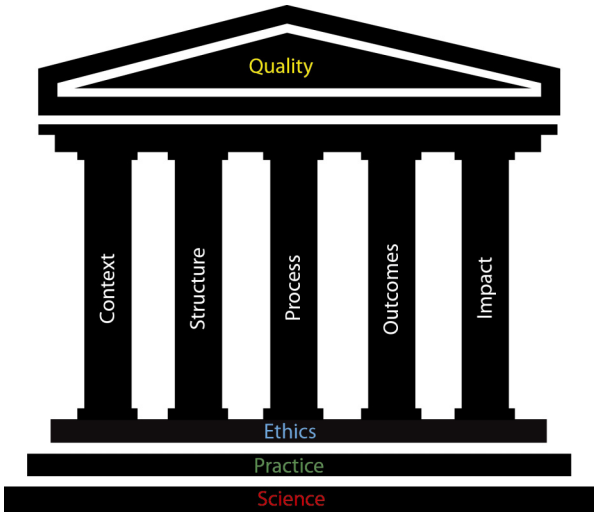

Figure 3 Pillars and foundations of educational quality.

pharmacy preceptors, number and nature of practice facilities, physical facilities including availability of simulated pharmacy practice settings, financial resources, and educational and library resources.

Standards related to **process** encompass the school's activities, policies and procedures including strategic planning, evaluation, assessment, admissions and enrollment management procedures, student services, student involvement, curricular development and improvement, and teaching and learning methods. Quality indicators related to the school's process ensure that the strategic plan is developed with broad-based input and addresses the external environment. Quality indicators also evaluate the school's enrollment against national pharmacy workforce needs and in relationship to resources available at the program to ensure an appropriate balance exists and expected quality of the school and its program(s) is achieved and maintained. Additional quality indicators for process include the adequacy of student services, incorporation of student feedback and input, the curricular development and revision process, incorporation of interprofessional education, adequacy of elective courses, adequacy of active learning strategies within the curriculum, and curricular assessment.

Standards related to **outcomes** address the short-term or immediate results of the educational program and mission-related activities. Analysis of a school's outcomes should involve review to assure that the learning outcomes and competencies are appropriate and aligned with national needs, and evaluate the extent to which they are achieved. The school's outcomes should address not only the knowledge needed for practice but the skills, attitudes and values (e.g., ethics, professionalism) of students as well. Research, scholarly, practice and service-based contributions of the school should also be assessed. Quality indicators for outcomes include that the school's programmatic learning outcomes are competency-based, specific and measurable; that the school uses validated measures to evaluate the extent to which the desired outcomes of the program are being achieved; and that through the research, publications, and other scholarly activities of its academic staff and students, the school contributes to the generation, dissemination, and application of new knowledge. It is expected that the school's outcomes will be aligned with national needs.

Standards for **impact** describe expectations regarding contributions to the advancement of education, practice and the profession. Evaluation in this regard should assess: the school's contributions to advocacy through the leadership of the school, its academic staff, and graduates; the development of graduates who are agents of change and contribute to advancements in pharmacy practice through the introduction of new activities and services; and contributions to addressing and solving national healthcare needs through research, innovation and generation of new knowledge. Quality indicators used to assess impact include evidence that demonstrates the school's contributions to changes, innovations and advancements in science, practice, professional and educational knowledge, and meeting the needs of society, thereby demonstrating social accountability.

Schools should also address the three foundations of pharmacy education, namely: *Science* (knowledge), *Practice* (skills and experience) and *Ethics* (attitudes and values) (Accreditation Council for Pharmacy Education, 2018a). Assessment of student competency should address all areas including knowledge, skills, attitudes, and values.

The school's curriculum should have a strong **science (knowledge)** foundation including adequate breadth and depth of the biomedical, pharmaceutical, social/administrative/behavioral and clinical sciences. Faculty should be adequately trained and experienced, and have the requisite credentials needed to deliver the curriculum. Knowledge and competence should develop, from introductory to mastery, as students progress through the curriculum. The curriculum should be evidence-based and relevant to the healthcare needs of the country. Graduates should be able to apply the foundational sciences to the provision of patient-centered care.

The curriculum should emphasize the relationship to **practice.** Teaching and learning activities should demonstrate clear links to practice and real-life scenarios. Simulations should be used to mimic actual and realistic pharmacy practice situations. Faculty of the school should include pharmacy practice (clinical) faculty—whether full-time, part-time or adjunct—with active, contemporary practice roles.

The school should incorporate professional **ethics** within and throughout the curriculum to ensure graduates develop competencies related to behaviors, attitudes and values necessary to demonstrate self-awareness, leadership and professionalism. Graduates should demonstrate self-awareness and be able to examine and reflect on personal knowledge, skills, abilities, beliefs, biases, motivation and emotions that may impact personal and professional growth. Graduates should demonstrate behaviors and values that are consistent with the trust given to the profession by patients, other healthcare providers, and society.

Policies and Procedures

The quality assurance process should be sufficiently rigorous. Policies and procedures should ensure consistency in the decision-making process. Decisions enacted by the quality assurance system must be fair and impartial to maintain the integrity of the evaluation process and the credibility of the organization.

Confidentiality should be assured and a policy in this regard is essential. Individuals involved at all aspects of the review process should receive adequate orientation and training to ensure correct and consistent evaluations. The criteria and process used to select and train individuals involved in evaluation needs to be developed as part of the quality assurance organization's policies and procedures.

Policies should outline the types of substantive change that would require providers to notify the quality assurance organization as well as the timing and the process that should be utilized to communicate such changes. The quality assurance organization's policies and procedures should provide for an appeals process for schools receiving an adverse accreditation decision. Similarly, the

quality assurance organization's policies and procedures should include the process through which any complaints received by the accreditation body will be addressed.

The duration that the quality assurance organization will maintain its records on each provider should be determined along with the location where the records will be maintained.

Eligibility Criteria

The requirements for eligibility and the components of the initial application for accreditation/recognition/approval (hereinafter "accreditation") will need to be established. The frequency that the quality assurance organization will review pharmacy schools and the process that will be used to periodically reevaluate pharmacy schools need to be established. The initial term of accreditation may be shorter to allow for greater oversight of the pharmacy school during this initial period.

Self-Study Process and Report

Each pharmacy school should complete an in-depth self-study, or self-assessment, of the educational program in relationship to the standards. The self-study provides the foundation for the quality assurance process. The school's self-study process should be in-depth and involve a broad base of internal and external stakeholders including the school's administrators, faculty, staff, students, alumni, and practitioners. A report produced after the conclusion of the self-study should document the school's self-assessment of compliance with each of the quality assurance standards and include relevant documentation and data as evidence to support the school's findings and conclusions along with an analysis of the school's strengths and limitations. In essence, the self-study report should answer three fundamental questions: *What? So What? What Next?* The "What" should be a factual, objective description of the school and its program against all the criteria in the standards. In line with a typical "SWOT Analysis" the self-study report should describe strengths, weaknesses, opportunities and threats of the program and school. The "So What" is more of a subjective reflection on the implications of the situation, as described, for the quality of the program and compliance with the standards. The "What Next" should describe specific, measurable plans to address deficiencies and desired quality improvements, including implementation strategies, timelines, and needed resources. Use of a self-assessment process facilitates development of a culture of assessment within the school.

On-Site Evaluation Team

An evaluation team, made up of "peer" members, conducts an on-site evaluation for purposes of validating the school's assessment findings. Peer members on the evaluation team should have the appropriate qualifications, expertise and experience commensurate with the school under evaluation. Credibility of the quality assurance process is enhanced using qualified and well-respected evaluation team members. All members of the evaluation team should receive training prior to participating in an on-site evaluation. Training should address the quality assurance standards, policies and procedures of the quality assurance organization (including confidentiality and conflict of interest), evaluation techniques, the team member's role in the on-site evaluation, and other protocols. Any credential requirements for evaluation team members, in terms of position or experience, should be well established and clearly communicated. Periodic re-training of evaluation team members should occur following any changes to the quality assurance standards or revisions to the process. A list of team members should be provided to the school under review and evaluation team members with real or potential conflicts of interest as identified by the school should be replaced with alternative individuals.

On-Site Evaluation

The duration and proposed schedule of the on-site evaluation should be clearly communicated to the school in advance to facilitate their planning. The schedule should provide sufficient time for a comprehensive evaluation of the school and the pharmacy degree program. Time should be provided to conduct interviews with the school's administrative leadership team, faculty, current students, graduates, experiential preceptors, staff from centralized university services, and institutional leadership. During the on-site visit, the evaluation team should conduct a survey of the school's physical facilities, the library and educational resources available to the school and a sampling of practice facilities, if available. Ideally, a standardized evaluation form will be utilized as a means to enhance consistency in the quality assurance process.

Accreditation Action and Term

Given the need to ensure ongoing compliance with the quality assurance standards, the quality assurance process should involve an initial term of accreditation with subsequent periodic evaluations on a regularly scheduled basis. Typically, an accreditation term is

defined for a set period. Schools demonstrating compliance with the standards can be awarded the maximum term while a shortened term may be awarded to schools with demonstrated deficiencies. Typically, at the end of the awarded term, the program is required to undergo a comprehensive evaluation for continuation of accreditation; such evaluation would include a self-study by the school and an on-site evaluation visit.

Monitoring During the Accreditation Term

Between comprehensive on-site evaluations, monitoring and reporting may be required depending on issues identified during the on-site evaluation. Annual monitoring (e.g., enrollment numbers, academic staff capacity, and graduates' performance on nationally standardized examinations) or other periodic reporting requirements may also be imposed as a means to continually monitor programmatic quality. If accreditation standards have changed in the period between comprehensive evaluations, the quality assurance organization may require the school to submit a report to indicate how it will meet the expectations of the new standards.

Adverse Actions

The consequence of noncompliance with the standards needs to be determined and stated clearly in policies and procedures. Possible consequences can include requiring additional reporting, placing the school on probation if noncompliance continues for an extended period, or withdrawal of the school's accreditation by the quality assurance organization. The method that will be used to communicate the consequence to schools should also be identified. While a letter to the school may provide sufficient communication regarding the quality assurance organization's findings of noncompliance, follow-up real-time interactions may be beneficial to provide greater depth regarding the quality assurance organization's concerns and expectations regarding resolution of the issues. Written communication to the key stakeholders should occur when the quality assurance organization has put the program on probation or withdrawn accreditation. With withdrawals, the quality assurance organization should communicate the effective date. Informing the public usually can be accomplished via the quality assurance organization's website; in addition, the accreditation organization is likely to require public disclosure by the institution, for example, via its website.

Most quality assurance organizations include in their policies and procedures the option for the institution to appeal against an adverse action.

Public Disclosure

The decisions of the quality assurance organization must be made public to increase transparency and credibility of the system. The quality assurance organization will need to make its criteria/standards, policies and procedures available to schools, stakeholders and the public. Posting such information on its website, if available, provides one means to accomplish this task. In addition, the decision-making body will need to communicate information regarding its decisions/actions. As noted above, this is especially relevant for programs on probation or whose accreditation has been withdrawn. In general, the quality assurance organization should provide the public with a list of programs accredited by the organization, along with the current term and any special requirements or conditions.

Quality Advancement of Pharmacy Education

The quality assurance process establishes minimum requirements and expectations for the evaluation of education provided at individual schools. An additional purpose of the evaluation process—both internal and external—is to advance the quality of education. This should be central to the mission of the quality assurance organization. Standards should be developed to allow programs flexibility in the manner requirements can be addressed. By allowing individual schools flexibility in meeting requirements outlined in a standard, the quality assurance process encourages and promotes innovation and quality advancement. For example, the quality assurance process will ensure that the individual school has a mission. The specific mission and how it is achieved and advanced, however, is determined by the individual school and university. Another example of a quality advancement centers on curricular delivery. The quality assurance process seeks to ensure that the teaching and learning methods used are effective in delivery of the curriculum. Quality advancement initiatives would seeks to maximize the number and nature of active learning techniques used in delivery of the curriculum to enhance student engagement within the curriculum and optimize learning. When so requested, peer review through external evaluation can provide many opportunities for schools to receive advice and quality improvement strategies from more experienced colleagues. By allowing flexibility in the quality assurance process, quality advancement is facilitated.

Quality assurance bodies can also be important drivers for change and quality advancement at a national level. Frequently, changes and advances in education that are recognized profession-wide as being necessary may be difficult and/or unpopular to

make. By setting new or higher expectations for educational institutions, accreditation standards can drive needed change. Good examples are the strengthening of clinical areas and integration of practice experiences within the curriculum, inter-professional education, promotion of the development of self-directed life-long learning skills and attitudes by students, and expanded student representation and participation in school and programmatic administration.

Quality Assurance and Advancement of Continuing Education and Continuing Professional Development Activities

Many national quality assurance organizations also have a role in the accreditation of continuing education and continuing professional development activities. Pharmacy professionals (including pharmacists and pharmacy support personnel) must maintain and advance their contemporary competence through self-directed life-long learning, which includes engagement in continuing education (CE) and continuing professional development (CPD) activities. Ensuring quality in CE/CPD involves three main groups of stakeholders: (1) the individual pharmacy professional who engages in CE/CPD to maintain competence; (2) the educational provider that offers the CE/CPD activities to the pharmacy professionals; and (3) the CE/CPD accreditation body that oversees the CE/CPD quality assurance or accreditation process. The CE/CPD process then can be considered from three different but inter-related levels:

- The **first level** involves the individual pharmacy professional who, through a CE/CPD process of reflection—which may include evaluation by a third party (such as their employer)—identifies individual educational and training gaps, needs or goals that must be addressed to maintain or enhance competence. Based on identified needs or goals, the professional develops and implements a personalized learning plan, which should involve both formal and informal learning activities and achieve desired learning outcomes. The learning should be applied in practice and its effectiveness, outcomes and impact evaluated.
- The **second level** involves the CE/CPD provider who offers activities, which must be of sufficient scope and quality to adequately address the individual pharmacy professional's educational and training needs and goals.
- The **third level** is the oversight of the overall process and involves development of a quality assurance or accreditation system.

The individual pharmacy professional forms the basis of the CE/CPD process (**Level One**). The continued competence of individuals is at the center of the CE/CPD process. Through participation in CE/CPD and training activities, the individual participates in a process of life-long learning that is designed to maintain and enhance his/her competence as a pharmacy professional. The first section of a CE/CPD quality assurance framework focuses on the process in which individual pharmacy professionals should engage to ensure life-long learning and the maintenance and enhancement of competence.

Level Two involves the quality of the individual CE/CPD and training activities in which pharmacy professionals engage. Consistently high quality CE/CPD and training activities are needed to ensure that the CE/CPD process is maximized and achieves the desired outcomes and impact. CE/CPD activities that are of poor quality in terms of structure, content and process will not optimally assist pharmacy professionals in the maintenance and enhancement of competence. The quality of individual CE/CPD and training activities can be assured via the use of quality assurance criteria/standards to which individual activities may be compared. These criteria/standards for quality should address the "Pillars of Educational Quality" (*Context*, *Structure*, *Process*, *Outcomes*, and *Impact*) as well as the "Foundations" (*Science*, *Practice*, and *Ethics*) that form the basis of the elements of quality (Mestrovic and Rouse, 2015).

In general, the CE/CPD quality criteria/standards should incorporate the following aspects:

- Educational need for the activity that is based on a pre-identified competency (knowledge, skills, attitudes and values) or practice gap
- Learning objectives that are specific, measurable, achievable, relevant and timed (SMART)
- Content and learning methods that are evidenced-based, cater to needs of diverse learners, and free of bias and conflicts of interest
- Presenters that are knowledgeable, experienced, and free of bias and conflicts of interest
- Instructional materials, including handouts, tools and resources, that can be used by the learners in the practice setting
- Use of active learning techniques that facilitate learning
- Assessment of learning to ensure the learning objectives have been achieved
- Evaluation of the CE activity

Individual organizations (e.g., employers, hospitals, professional associations) offering CE/CPD and training activities in countries that lack a process to accredit CE/CPD and training activities may use these criteria/standards during development of individual CE/CPD and training activities (e.g., a CE/CPD course). In addition, these can be used at the national level.

Level Three involves development of an oversight process that is charged with ensuring the quality of the CE/CPD and training activities. Ideally, an accreditation body would be established at the national or regional (multi-country) level and involve the review of CE/CPD activities or providers by an "external" group (i.e., evaluators not involved in the development or delivery of the CE/CPD activities). Development of an accreditation system should start with establishing the entity that will be responsible for the accreditation process. A legal mandate for the entity should be established along with the mission, scope of operations, organizational structure, and accreditation body's policies and procedures. The policies and procedures should ensure that the accreditation process is efficient, fair, transparent, credible and accountable. Disclosure of the entity's policies and procedures as well as findings and actions should be made public.

In the absence of sufficient resources to develop an accreditation body, countries, regions, professional organizations, or individual employers and health care organizations may consider adopting or adapting the quality assurance policies and procedures and standards utilized by other countries or regions. A description of these is provided in the full report (Rouse et al., 2016).

Quality Advancement in CE/CPD

Any comprehensive and robust system for quality assurance—whether it be an internal or external system—ideally should also promote and facilitate quality advancement. Accreditation bodies can and should be important drivers for change, with quality standards and expectations reviewed and revised on a regular basis. For example, the Accreditation Council for Pharmacy Education (ACPE), the U.S. national agency for accreditation of pharmacy education, sees its mission as *"assuring and advancing"* the quality of pharmacy education. In rapidly changing sectors, such as pharmacy education and practice, and in view of constantly evolving societal needs, technological innovations, and the growing base of evidence from research into successful models for teaching and learning, accreditation bodies need to communicate and collaborate with all stakeholders to identify and implement changes that are needed. Such changes, while necessary for quality improvement, may not be easy and are not always well received by those who have to make the changes. For this reason, it is important that such changes are identified through profession-wide consensus, and not arbitrarily imposed by one sector or body.

In the area of CE and CPD, new models for life-long learning and professional development are vitally important because the majority of practitioners did not receive pre-service education and training that fully prepared them with the necessary knowledge, skills, attitudes and values for contemporary—and constantly evolving—practice. Although not yet pervasively implemented on a profession-wide and global scale, in recent years, one of the most important innovations has been the transition from the more traditional, hours-based CE model to the CPD model, which is a more holistic approach to self-directed learning that focuses strongly on needed outcomes and impact of the learning. In some countries, this quality improvement has been driven by the body responsible for quality assurance of pharmacy education. In other countries, this has been by regulators, employers, and CE providers themselves.

Other notable quality improvements and innovation in CE and CPD include:

- Incorporation of inter-professional education within CE/CPD to better prepare practitioners from all health professions to work together in teams to improve the effectiveness, and outcomes of patient care and reduce cost in health care delivery. Two examples of innovations in this regard are the introduction of a joint accreditation system for providers of inter-professional CE ("education for the team, by the team") and the development of inter-professional competencies for health care professionals (Joint Accreditation Interprofessional Continuing Education, 2018; Interprofessional Education Collaborative, 2016; Canadian Interprofessional Health Collaborative, 2010).
- Greater incorporation of technology-enhanced learning (Scott et al., 2017).
- Consideration of a competency-based or outcomes-based credit versus a time/participation-based credit (Lucey, 2017; Austin et al., 2005a; Austin et al., 2005b; Pharmaceutical Society of Ireland, 2010; Pharmacy Council of New Zealand, 2018a; Pharmacy Council of New Zealand, 2018b).
- Increased focus on practice-related outcomes for CE and CPD activities. Some accreditation bodies have changed the classification of educational activities to promote awareness and encourage participation in a wider range of activities; that is, not just knowledge-based activities. In the USA, for example, ACPE categorizes activities as (i) knowledge-based, (ii) application-based, or (iii) practice-based (Accreditation Council for Pharmacy Education, 2018b).
- An emphasis on assessment and documentation of competence (performance) in the workplace and the role that CE and CPD plays in enhancing the competencies that have been identified as needing strengthening (Meštrović et al., 2011, 2012; Ontario College of Clinical Pharmacists, 2018).
- Evolution of the CE administrator from a "support person" to more of a CE professional; establishment of a certification credential for CE administrators (Alliance for Continuing Education in the Health Professions, 2018).
- Use of internet-based technologies, including smart phone applications, to improve systems to track CE activities and support learners in their CE/CPD (National Association of Boards of Pharmacy, 2018).

Conclusion

Pharmacy education must adapt to the changing needs of the profession. Implementation of appropriate policies, procedures and standards helps to assure and advance the quality of pharmacy education and provides assurances to the profession and the public. Development of a quality assurance process must consider the national context and vision for pharmacy practice and education and engage all key stakeholders. The quality of pharmacy education can be ensured through development of and adherence to quality criteria and standards that are based on the "Pillars and Foundations of Quality" model.

Using Patients and Other Forms of Simulation in Teaching Clinical Skills

James W. Torr, Kevin A. Clauson, Lipscomb University, College of Pharmacy and Health Sciences, Nashville, TN, United States

Introduction/Background

The development of clinical skills is a necessary component of the practice of pharmacy. Experiential learning through clinical training in patient care settings has been a cornerstone in enhancing clinical skills and competence. However, due to evolving healthcare professional education models, patient safety, and availability of clinical training opportunities, other avenues for teaching clinical skills are being utilized. Healthcare simulation is one teaching methodology with growing interest and an increasing body of evidence.

Simulation has long history of use for education and training in non-healthcare related industries such as space and aviation, military, business, and law education. Simulation modeling has also been utilized for predicting changes to the economy and forecasting the weather. The past few decades have witnessed an increase in the use of simulation for health professions education, including medicine, nursing, and pharmacy.

Simulation is currently utilized used in health professional education to recreate real-world experiences that supplement other teaching and learning methods. Simulation, as defined by David Gaba, "is a technique, not a technology, to replace or amplify real experiences with guided experiences, often immersive in nature, that evoke or replicate substantial aspects of the real world in a fully interactive fashion" (Gaba, 2007). The body of literature examining simulation methodologies in pharmacy education is growing. Currently the majority of this literature primarily focuses on training student pharmacists, however, the use of simulation for

training practitioners, including pharmacy residents, has been described. **Table 1** illustrates examples of simulation in pharmacy education.

This chapter will examine the use of simulation methodologies used for training within pharmacy education and clinical practice. Specifically, we will address how simulation is utilized to foster professional knowledge, skills, and attitudes of student pharmacists and practicing pharmacists. While a goal of training and education is to equip learners with knowledge, skills, and attitudes that are transferrable to practice and patient care, it is important to recognize there is limited data evaluating the impact of simulation on clinical pharmacy outcomes. Currently, examples of simulation education improving clinical practice are predominantly associated with medical and nursing education (Barsuk et al., 2009a, 2009b; McGaghie et al., 2014; Wayne et al., 2008; Ford et al., 2010). Due to the dynamic nature of this topic, this chapter will consider insights and applications of simulation from other health professions.

Rationale for Simulation-Based Education

"*Tell me and I forget, teach me and I may remember, involve me and I learn.*" This quote, attributed to Benjamin Franklin, resonates strongly with the principles of simulation-based education (SBE) because simulation immerses learners in the learning process and shifts the education model from teacher centric to learner centric. An essential process of health professional education is the transfer of knowledge, skills, and attitudes from the classroom to professional practice. However, this transfer and application of knowledge is not necessarily innate and may present a challenge for learners. Over the past few decades, there has been a growing body of evidence describing and evaluating the rationale for simulation learning methodologies in healthcare education. As the demand for the highly trained and practice ready healthcare professionals has increased, the need to explore new and innovative teaching methodologies and technologies has risen. The growing integration of SBE for training pharmacists and student pharmacists is multifactorial. Factors contributing to the rise in SBE in pharmacy education include: (1) alignment with principles of educational theory; (2) profession and curriculum evolution; and (3) demand for experiential education and clinical practice sites. This section will discuss these factors in more detail.

Educational Theory

The role of simulation in healthcare education draws from several educational theories. In particular, SBE aligns with concepts of (1) Malcom Knowles theory of adult learning, or andragogy; (2) David Kolb's experiential learning theory; and (3) Donald Schon's theory of reflective practice. Each of these educational theories contributes to the application of SBE for clinical and non-clinical training. A brief overview of these theories will now be discussed.

Andragogy

Knowles' theory of adult learning begins with the rationale that adults learn differently than children (Knowles et al., 2012). Principles of adult learning theory are illustrated in **Table 2**. Considering the vast majority of learners in pharmacy education are adults, simulation educators may enhance learning by developing curriculum around these core principles.

Table 2 Characteristics of andragogy

Self-directed
Experience based
Subject dependent on life or work needs
Problem solving
Internal
(Knowles et al., 2012)

Experiential Learning Theory

David Kolb's experiential learning theory emphasizes a four-stage cycle of how new knowledge is acquired and embedded. The foundation for experiential learning theory follows: (1) that learning takes place with a concrete *experience*; (2) followed by *reflection* upon the experience; (3) *analysis* and formation of abstract concepts; (4) then *experimentation* to create a new experience (Kolb, 2015).

Reflective Practice

Reflection has been described as a "rich source of continued personal and professional growth" (Killion and Todnem, 1991). Schön (1983, 1987) describes two forms of reflection, reflection-on-action and reflection-in-action. Reflection-on-action is described as thinking back on an experience to discover how or what we could change for the future experiences. Self-assessment, an example of reflection-on-action, and reflection-in-action have been identified as "missing links" in the development of higher learning in pharmacy education (Austin et al., 2008). Reflection-in-action and reflection-on-action are essential components of simulation through the scenario and debriefing, respectively. A discussion of the primary components of SBE will be discussed later in the chapter.

Profession and Curriculum Evolution

As the profession of pharmacy and scope of practice continues to expand, curricula for pharmacy education and training need to evolve. Competency-based training is a concept that has been utilized in many health-related educational programs (Carraccio et al., 2002). The Accreditation Council for Graduate Medical Education (2017) has shifted from a traditional knowledge-based model for graduate medical education to a competency-based curriculum. Other health disciplines such as pharmacy have been or are attempting to follow suit with their educational standards.

The profession of pharmacy has worked diligently to advance pharmacy practice and gain recognition of pharmacists as an essential member of the healthcare team. The implementation of new methods of defining and assessing pharmacy practice skills is an integral part of further advancing and achieving this goal (Pittenger et al., 2016). The concept of Entrustable Professional Activities (EPAs) represents a potential mechanism of defining and assessing pharmacy practice skills (Pittenger et al., 2016). EPAs are units of professional practice, defined as tasks or responsibilities to be entrusted to unsupervised performance of trainees once the trainee has attained sufficient competence. EPAs are independently executable, observable, and measureable in their process and outcome (Ten Cate, 2013a, 2013b; Haines et al., 2017).

A prime example of advancing the profession is the development of the Pharmacist's Patient Care Process (PPCP) which recognizes the need for a consistent process in the delivery of care across the profession, regardless of practice setting. The PPCP includes the following five steps: (1) collect; (2) assess; (3) plan; (4) implement; and (5) follow-up: monitor and evaluate. These steps incorporate collaboration, communication, and documentation around patient-centered care (Joint Commission of Pharmacy Practitioners, 2014). Simulation is well positioned to train and assess the ability to demonstrate this patient-care process.

In order for pharmacy education to transition to a competency-based model, innovative teaching and learning strategies must be developed. Simulation has been identified as an active learning methodology for training in a competency-based curriculum (Accreditation Council for Pharmacy Education, 2015). There has been a growing interest in the use of SBE to teach and assess cognitive (knowledge), psychomotor (skills/competency), and affective (attitudes) domains to individuals and increasingly with teams (Motola et al., 2013).

Simulation for Formative and Summative Assessments

The terms "formative" and "summative" were first formalized in the 1960s in relation to program evaluation (Scriven, 1967). Later in the same decade, Benjamin Bloom, expanded the context to include formative assessment as an integral component of the teaching and learning process (Bloom, 1968). Since then, they have become commonplace in assessment of education. The primary purpose of formative assessment is to provide feedback on student performance, specifically their strengths and weaknesses, during the course of study (Downing and Yudkowsky, 2009). Examples of formative assessments are reflective writing, student portfolios, and debriefing with simulation (DiVall et al., 2014). In contrast, summative assessments generally occur at the conclusion of a course or learning module, such as a midterm or final exam (Downing and Yudkowsky, 2009). Summative assessments may also be considered "high stakes," since they generally determine if a learner may progress to the next phase of curriculum (DiVall et al., 2014). When used in conjunction, formative assessments *for* learning and summative assessments *of* learning provide a constructive framework for assessment during the learning process and terminal data for learner progression and course modification.

If colleges and schools of pharmacy are expected to produce graduates that are both practice ready and team ready, methods for assessing preparedness must be developed. Benedict et al. (2017) designed a blended simulation progress test to assess for practice readiness. Practice readiness was measured through knowledge and performance evaluation for first- and third-year student pharmacists and first-professional year postgraduate pharmacy residents. This type of assessment stands to provide valuable insight on the progression of learners across the spectrum of their education.

Demand for Clinical Experiences

The quality and capacity of experiential education continues to be a top priority for pharmacy education (Gibson et al., 2017). Experiential education contributes to the development of clinical reasoning and problem solving skills that are essential to clinical

practice. Experiential education programs are faced with the challenge to secure clinical practice sites in areas such as ambulatory care and internal medicine (Plaza and Draugalis, 2005). Brackett et al. (2009) identified the need for quality experiential education as a significant barrier to the matriculation of the increased number of pharmacists. In the U.S. an additional burden on experiential education programs is the Accreditation Council for Pharmacy Education (ACPE) requirement to deliver at least 300 hours of Introductory Pharmacy Practice Experiences (IPPE) as a component of the pre-Advanced Pharmacy Practice Experience (pre-APPE) curriculum, of which 20% of these hours (e.g., 60 hours) may come from simulation (Accreditation Council for Pharmacy Education, 2015).

Patient safety and standardized experiences are additional challenges for experiential learning. For example, a practice site may limit student experiences for legal, ethical, or patient safety reasons. Full standardization of learning experiences in the clinical environment is not practical and generally impossible.

Early Evidence Examining the Roles in Experiential Education

SBE provides one avenue to reduce the burden on experiential education programs by creating standardized and safe learning environments (Maran and Glavin, 2003). Simulation may be particularly beneficial and appropriate for clinical experiences that are rare or inconsistently observed. It is worth noting that simulation is intended to supplement, not completely replace experiential learning in the clinical environment.

Vyas et al. (2010) developed a simulation to supplement IPPEs. Fourth year student pharmacists at a satellite campus participated in a 6-week high fidelity patient simulation series incorporating three scenarios: asthma exacerbation, acute decompensated heart failure, and infective endocarditis. Following each simulation students completed a post-simulation quiz to evaluate students' knowledge, skills, and attitudes compared to a control group on the main campus. The control group completed identical curriculum, with the exception of the simulation exercises. Long-term retention was evaluated with an identical assessment administered 3-months later. All knowledge-based quiz items at completion of series demonstrated significant improvement compared to pre-simulation quiz ($P < 0.001$). Overall, students felt more confident making clinical recommendations (76%, $P = 0.01$) and identifying the physiologic effects of medications on the human body (70%, $P = 0.01$) following the simulation experience.

Results of a 2012 survey found that 21% of hospital practice sites that responded did not allow APPE students to prepare compounded sterile preparations (CSPs) (Wuller and Kwasiborski, 2012). This finding represents a potential gap in experiential education. The incorporation of sterile compounding simulation exercises into the curriculum may bridge this gap. Cretton-Scott et al. (2015) incorporated a sterile-technique module into an IPPE for third-year student pharmacists. Students performed a modified media fill challenge test for low-risk level CSPs and prepared an antibiotic injection solution. The CSP was analyzed for accuracy by Liquid Chromatography Mass Spectrometry (LCMS) or High Pressure Liquid Chromatography (HPLC) in 2012 and 2013, respectively. CSP analysis showed that 84% in 2012 and 71% in 2013 were within 10% of the desired concentration. While additional research is needed, it can be deduced from these and similar examples that simulation may be an appropriate model to implement as a complement to clinical practice sites and reduce the burden created by expanding programs.

Implementation of SBE

Simulation Framework and Facilitation

The framework of healthcare simulation generally consists of three distinct components: (1) pre-briefing; (2) simulation scenario; and (3) debriefing. Facilitation occurs throughout the SBE exercise. This section will explore the purpose of each component in simulation education.

Pre-Briefing

Pre-briefing, or briefing, occurs prior to the simulation scenario and serves as an orientation session for participants. Components of the pre-briefing may vary, but in general should include: (1) setting ground rules; (2) defining learner expectations; (3) ensuring psychological safety; (4) establishing a fiction contract; (5) providing a technology review or orientation to the simulation environment; and (6) a case lead-in. Pre-briefing helps guide the learners by setting the stage for the simulation exercise.

Simulation Scenario

An important component of SBE is choosing appropriate scenarios. Prior to developing and implementing SBE, considerable thought must be applied to the curriculum design process. Essential elements for curriculum development include systematic and scientific approaches when constructing learning experiences (Rosen et al., 2008). Effective instructional design should also be intentional (Branch, 2009). Educational theory provides the systematic framework when developing curriculum so the effects of design may be collected and analyzed. The use of systematic approaches to curriculum design, such as Kern's six step approach (Kern et al., 1998) will enhance the curriculum including the simulation teaching and learning experience. Additional consideration for scenario development and implementation are summarized in **Table 3**.

Table 3 Considerations for simulation scenario development and implementation

Description	*Comments*
Develop learning objectives	Objectives should be SMART: specific, measureable, achievable, realistic, and timely (INACSL Standards Committee, 2016b)
Develop a script for standardization	Rigidly scripted scenarios may decrease fidelity; Minimal scripted scenarios may be difficult to control or standardize
Create a scenario flow chart	Outlines progression of scenario and aids facilitator and simulation technician
Document list of equipment and supplies	Aids in staging or resetting the scenario
Rehearse the scenario	Provides opportunity to evaluate the scenario and identify opportunities for improvement

(Alinier, 2011; INACSL Standards Committee, 2016a; Motola et al., 2013)

Table 4 Seven essential elements of debriefing in healthcare simulation

Ensuring psychological safety
Establishing basic assumptions of the learner or learners
Establishing of ground rules
Establishing a shared mental model
Addressing learning objectives
Utilizing open-ended questions
Utilizing silence

(Sawyer et al., 2016)

Debriefing

Debriefing and feedback are critical components of the learning process with healthcare simulation (Issenberg et al., 2005). These terms are often used synonymously in the healthcare simulation literature (Sawyer et al., 2016), but important distinctions exists. Feedback may be described as a passive form of learning, by providing information for, or an evaluation of performance. Debriefing has been described as an active learning methodology, where faculty and students reflect on experiences to close performance gaps and enhance the learning process (Dreifuerst, 2009; Raemer et al., 2011; Rudolph et al., 2008) and is recognized as a critical component of SBE (Cheng et al., 2015a). The value of debriefing in SBE originates from its connection to elements of experiential learning and reflective practice. It is important to recognize that reflection on one's practice is an essential component of the experiential learning process (Rudolph et al., 2008; INACSL Standards Committee, 2016c).

While debriefing is generally conducted at the end of or following a scenario debriefing may occur during a simulation scenario, in the form of a "time-out" to explore immediate actions or frames or to assist learners that may be struggling (Motola et al., 2013). Debriefing during a simulation is an example of reflection-in-action, whereas debriefing following a simulation illustrates reflection-on-action. Numerous debriefing strategies are described in the literature (Cheng et al., 2015b, 2016; Raemer et al., 2011; Sawyer et al., 2016; Rudolph et al., 2007). Sawyer et al. (2016) describes seven essential elements for debriefing in healthcare simulation. These elements are listed in **Table 4**.

Barriers to Simulation Implementation

Many barriers exist for designing and implementing SBE. Barriers include, but are not limited to: time, resources, logistics, and faculty development. As with any project, allocating an appropriate amount of time is essential to its success. Resource allocation, including competition for said resources, may present an additional barrier. Budgetary restrictions may limit the quantity or quality of simulation resources available. If simulation resources are shared with other colleges, schools, or departments then competition for those resources may be an issue.

Due to the cost of purchasing, maintaining, and running patient simulations, it is critical to determine the educational value compared to other educational methods. Ray et al. (2012) compared pharmacy students' knowledge retention and comfort level with a simulation using a patient simulator and a written patient case. Performance improved for both the simulation and written case groups compared to the pre-test and post-test results. When comparing results from the post-test and retention test, the simulation group scores remained the same and there was a small, but not significant decrease in the written case group. Participation in simulation may improve retention of knowledge by pharmacy students compared to written cases but more research is needed to draw a conclusion.

Logistical barriers can prove particularly challenging as they involve coordinating schedules for learners, faculty, and staff. Successfully navigating logistical barriers includes respectful, meaningful, and efficient use of time and resources. Additionally, faculty development is a potential barrier that should not be marginalized. The skill of blending simulation technology with clinical cases takes time and experience. Furthermore, effective facilitation of debriefing for reflective practice is a new concept for many faculties. Fortunately, debriefing is a skill that simulation educators may learn through specific training and experience (Cheng

et al., 2015a). Training programs are currently offered by manufacturers of simulators, at professional conferences, through academic institutions, and simulation centers. Debriefing assessment tools are available to evaluate debriefing practices and afford feedback, or debriefing, for the debriefer (Arora et al., 2018; DASH, 2011).

Simulation Modalities

Various types of simulation are used in health professions training. Features of the simulation methodology employed include the degree of fidelity and technology as well as which skills are to be trained or assessed. This section will discuss the relationship between fidelity, technology, and various types of simulation methods. When determining the appropriate methodology to employ, consultation with other faculty accompanied by a thorough examination and alignment of a simulator's capabilities with learning objectives is essential.

Fidelity vs. Technology

Distinguishing between fidelity and technology is an important consideration in SBE as they are often used interchangeably. In general, fidelity describes the degree to which the simulation replicates the real event and/or environment, or the level of realism of a simulation exercise (Lopreiato et al., 2016). In contrast, technology describes the equipment and devices utilized for training within a simulation (Lopreiato et al.). A high-fidelity simulation should be interpreted as more realistic compared to a low-fidelity simulation. Based on these definitions, one must realize that while fidelity and technology are essential components of a simulation, they are distinct from one another. The fidelity of a simulation scenario depends not only on the technology utilized, but the environment, equipment, and supplies as well. It is essential to consider both simulation technology and fidelity when developing a simulation exercise and specifically consider how technology will impact fidelity.

Skoy et al. (2013) compared the impact of low-fidelity and high-fidelity simulation on student pharmacists' injection technique using a cross-over study design. The described low-fidelity and high-fidelity simulations incorporated an injection pad and a partial task trainer injection arm, respectively. The primary outcome was to ensure the ability to properly administer both intramuscular and subcutaneous injections to a peer. All students demonstrated competency with the injection administration. The results of this study indicated that students' ability to administer injections through either route of administration was not significantly impacted by one level of simulator fidelity over the other.

Standardized Patients

Standardized patients (SPs) are individuals trained to portray a patient with a specific condition in a realistic, standardized, and repeatable way. SPs may be referred to as a simulated patient, simulated participant, confederate, or embedded participant. SPs portray many roles within SBE, including patients, caregivers, family members, and healthcare providers (Meakim et al., 2013; Lopreiato et al., 2016). Standardized patients are advantageous when teaching communication and interpersonal skills (Maran and Glavin, 2003). Disadvantages of SPs include time and resource allocation for training as well as limitations on training procedures that may harm the SP.

Patient Simulators

Patient simulators afford learners the opportunity to practice skills from basic assessment to advanced clinical skills. The technology of patient simulators (a.k.a. human patient simulator, manikin, or mannequin) continues to grow (Maran and Glavin, 2003). Today, features of high technology simulators are advanced and include breathing (normal and complicated), ophthalmic changes (pupillary dilation and constriction, eyelid opening and closing), cardiovascular (heart and Korotkoff sounds, pulses with variable intensity, and electrocardiogram rhythm monitoring), intravenous (IV) access, seizures, moving limbs, and bowel sounds. Communication through the patient simulator is often possible via pre-recorded or instructor narrated options. Some patient simulators may be paired with a compatible computer program to control these features (Laerdal, 2018).

For the purpose of this chapter, the term "patient simulator" will designate a full-body human patient simulator. Partial-body patient simulators will be referred to as "partial-task trainers." A description of partial-task trainers is provided below.

Partial-Task Trainers

Partial-task trainers, or task trainers, are a type of patient simulator, but rather than represent a whole patient, they are generally intended to represent a specific part of a human body for training a distinct task. Partial-task trainers include limbs, body parts, or other structures. These models may be integrated into training to facilitate learning of technical, procedural, or psychomotor skills (Bradley, 2006). Task trainers are available for teaching skills such as (1) injection technique; (2) assessment of vital signs; and (3) auscultation of body sounds. Partial-task trainers are not inherently low-technology. For instance, partial-task trainers for educating and assessment of cardiopulmonary resuscitation (CPR) may incorporate high-technology to measure rate and depth of chest compressions as well as accuracy of breaths administered during a Basic Life Saving (BLS) simulation. While generally considered

low-fidelity due to their nature and function, these simulation models are useful for high-volume simulation training, such as basic assessment skills involving vital signs. Partial-task trainers may be paired with other simulation methods such as standardized patients in hybrid simulations.

Computerized Models

Computerized simulation models include virtual reality and augmented reality. Virtual reality refers to the recreation of environments or objects as a complex, computer-generated image (Bradley, 2006). Virtual reality simulations require the use of a computer or computerized technology such as wearable goggles. Computerized models have recently grown to include: (1) virtual cleanrooms (Patel et al., 2011); (2) virtual patients for communication, patient assessment, and documentation training (Hussainy et al., 2012; Taglieri et al., 2017); and (3) electronic health records (Kirwin et al., 2013).

Hybrid Simulations

Hybrid simulations incorporate two or more simulation modalities. Hybrid simulations may be beneficial when more than one skill is being trained or assessed. An example of a hybrid simulation would include pairing an SP with a partial task trainer for assessing communication skills and accuracy of blood pressure measurement. Assessment of both skills would be difficult if employing only one of these modalities.

Simulated Learning Environment

A simulated learning environment is the physical area or location where simulation-based education and learning exercises occur. Development and utilization of a realistic environment may enhance the fidelity of simulation. A high-fidelity simulated environment allows for both profession specific and interprofessional education (IPE). Simulated environments will generally contain another form of simulation, such as SPs or patient simulators, and equipment and supplies appropriate for the fidelity of the simulation.

Current Uses of Simulation-Based Education for Teaching Clinical Skills

This chapter has alluded to significant changes to the practice and profession of pharmacy over the past few decades. The progression of pharmacy practice incorporates new skills beyond the traditional dispensing role of a pharmacist to the provision of clinical services. This section will describe examples of simulation training for a variety of skills for student pharmacists and practicing pharmacists, including: (1) clinical skills; (2) professional attitudes; (3) patient counseling and communication; (4) patient safety; and (5) IPE.

Clinical Skills

The emergence of pharmacist-delivered patient-centered care has generated new expectations of pharmacists in ensuring continuity of care as members of an interprofessional team. Accompanying roles of the pharmacist have progressed into more clinical services from medication reconciliation to disease state management. With this expanding role, student pharmacists should become more familiar with the different needs and expectations in both inpatient and outpatient settings. Serag-Bolos et al. (2017a) incorporated simulation to assess the knowledge and attitudes of third-year student pharmacists toward institutional pharmacy practice, specifically transitions of care. Students learned concepts of medication reconciliation, medication errors, and communication in an interprofessional team while using electronic medication records as the basis of their patient cases. Students reviewed their cases prior to the simulation and participated in an open discussion afterwards. By the end of the simulation, student pharmacists showed an increased ability of doing hospital pharmacy practice and felt more prepared for their fourth year rotations.

One of the earliest examples of SBE in pharmacy education was for teaching blood pressure assessment. Seybert and Barton (2007) assessed students' skills to accurately assess blood pressure on a patient simulator. Student satisfaction with the teaching method was also measured. Didactic lectures were used in conjunction with patient simulators for the training. Students practiced on the patient simulator at two time points prior to the final skills assessment. The ability of the students to measure blood pressure accurately, as assessed by a rubric, increased with each session. Vital sign assessment using simulation was also described by Tokunaga et al. (2010).

Pharmacy simulations focused on cardiovascular life support and resuscitation have been described in several studies. Mieure et al. (2010) described the design and implementation of an Advanced Cardiovascular Life Support (ACLS) workshop incorporating a patient simulator with didactic lecture and a calculation exercise. Participants reported an enhanced learning experience with the simulation exercise, but mean score on knowledge-based questions was only 25%. Bingham et al. (2015) assessed the long-term retention of knowledge and skills following prior ACLS training with a patient simulator. Teams were evaluated within 120 days of previous training. In this study, teams that included participants with prior simulation training demonstrated numerical, but not

significant, superiority in ACLS knowledge and skill retention compared to those without previous training. Maxwell et al. (2016) evaluated the impact of an ACLS simulation on pharmacy student knowledge and confidence. Both knowledge and confidence scores improved significantly post-simulation, but scores were not significantly correlated. In a related study, Davis et al. (2013) compared the improvement in ACLS knowledge, confidence, and satisfaction between high-fidelity simulation and lecture. This was a parallel, cross-over study between two groups. The sequencing of teaching and learning methods, lecture vs. simulation, differentiated the groups. The greatest improvement in test scores from baseline was observed in the group where lecture preceded the simulation. Overall, there was not a significant difference in improving knowledge of ACLS. Simulation participation was associated with higher self-confidence in ACLS skills and learning satisfaction. While these studies incorporated student pharmacists in their design, Eng et al. (2014) assessed the impact of high-fidelity simulation on pharmacy residents. A review of their institutions cardiopulmonary arrest algorithm, applicable medications, and calculations preceded participation in three simulated scenarios with patient simulators. Six-months after the initial training and three-weeks prior to the high-fidelity patient simulator enhanced training, pharmacy residents completed pre-simulation knowledge, competency, and confidence assessments. Post-assessments were completed three weeks following the simulation training with high-fidelity patient simulation. Post-simulation knowledge scores, competency evaluations, and confidences scores improved significantly.

Professional Attitudes and Behaviors

Simulation has also been used in healthcare education to assess attitudes and behaviors such as empathy and professionalism. Perdue et al. (2017) measured the effects of a simulation on medical, nursing, and pharmacy students' beliefs about adherence and concordance following a polypharmacy simulation. During the simulation portion of the curriculum, participants were provided a seven-day regimen of four simulated medications. Following the simulation, the majority of participants found it harder to take the medications than they expected, a decreased confidence in their ability to take their medications correctly, and an increase attitude toward the importance of concordance.

Blaszczyk et al. (2017) assessed the effects of a simulation exercise on student empathy toward polypharmacy. Participants were provided a one-week supply of eight prescriptions simulated with jellybeans and instructions for administration. Students completed a pre-and post-questionnaire to assess difficulty managing the medication regimen. Statistical analysis indicated a significant increase in empathy ($P < 0.001$) from pre- to post-simulation questionnaire responses. There was also a statistically significant change in students' perception that the simulated medication regimen was difficult post-simulation.

Simulation has also been utilized to assess attitudes and empathy of student pharmacists toward geriatric patients. Chen et al. (2011, 2015) incorporated an aging and geriatric medication game where students role-played older adults during simulated scenarios. They implemented a game, which encompassed the disabilities, limitations, and barriers in healthcare of the senior population. The simulation incorporated different workstations, including two physician's offices, a pharmacy, a laboratory testing area, and specific activities to reflect real-life settings of the older population. Students completed surveys on cognitive and affective qualities and empathy. Overall, the results from the instruments showed an increase in student empathy as well as attitudes toward geriatric patients and the challenges they face.

Zagar and Baggarly (2010) evaluated student perceptions about medication management difficulties in patients with low-vision. Students wore low-vision simulation goggles and engaged in medication management tasks such as reading prescription labels and patient information leaflets, distinguishing physical characteristics of medications, and measuring doses of liquid and injectable medications. These exercises created an opportunity for students to experience and subsequently recognize challenges faced by patients with low-vision.

Skoy et al. (2016) employed an auditory hallucination simulation to assess student empathy for patients with mental illness. Participants listened to an audio recording while completing several stations that required various skills. Participants completed the Kiersma-Chen Empathy Scale (KCES), a 15-item empathy tool for health professions students, immediately following the simulation (Kiersma et al., 2013). Empathy increased significantly ($P < 0.05$) on 13 of the survey items.

Patient Counseling and Communication Skills

Pharmacists have long been considered one of the most accessible healthcare professionals and are often a primary point of information and presentation of health-related issues. Pharmacists must be prepared and willing to respond to a variety of patient inquiries including knowledge of pharmacotherapy, skills related to medication administration, and use of ancillary devices. Salter et al. (2014) conducted a study using simulated patients to evaluate community pharmacists manage patients with anaphylaxis. Specifically their preparedness to treat acute anaphylaxis and their willingness to engage patients to discuss their anaphylaxis was measured. This study indicated pharmacists had a reasonable knowledge of anaphylaxis symptoms and emergency care, but had poor epinephrine auto-injector technique. Additionally, pharmacists rarely discussed action plans in case of anaphylaxis with the simulated patients.

Dolovich et al. (2007) evaluated pharmacists' ability to facilitate an asthma action plan with a simulated patient following an asthma education program versus pharmacists in a control group. The program included didactic material and progressed to self-directed learning and role-playing with simulated patients. There was a statistically significant difference in the ability to facilitate an appropriate asthma plan for pharmacists who experienced the simulation intervention compared to the control group (44.8% and 29.3% respectively, $P = 0.004$). Pharmacists in the intervention group also demonstrated better overall communication skills

compared to the control group (Dolovich et al., 2007). In a related study, Schneider et al. (2009) used simulated patients to examine assessment and counseling practices by community pharmacists in relation to over-the-counter asthma reliever medications. Of note, pharmacies included were unaware of the study. The study found that in the simulated patient visits, some form of assessment was performed 84% of the time but counseling was only provided 24% of the time. These studies indicate opportunities to improve processes and the delivery of care related to asthma in the community pharmacy setting.

Simulation has also been utilized to assess patient counseling related to emergency contraception (EC). Access to EC without a prescription has become more readily available over the past decade. This has created an opportunity for pharmacists to provide patient education regarding appropriate use. Ragland et al. (2015) described the impact of counseling by student pharmacists in a retail setting on customer knowledge of EC and customer satisfaction with counseling. Participants completed a pre-test prior to a counseling session with a student pharmacist, which was followed by an identical post-test to assess for changes in knowledge and a follow-up test via telephone 1–3 months post-counseling session. This study showed an increased score on both the post-test and follow-up test compared to pre-test scores indicating knowledge was improved and retained.

Glasier et al. (2010) conducted a study using mystery shoppers to evaluate the quality of service provided by community pharmacies and measure the information provided to patients in regard to EC. Their research indicated that patient consultation regarding EC was generally good, but less than half provided education about contraception following EC use.

Patient Safety and Medication Errors

Medication errors have been ranked as the eighth leading cause of death in the United States (Aspden et al., 2006). Medication errors, also referred to as preventable adverse drug events, are linked to additional healthcare costs and harm to the patient (Samp et al., 2014). Given the magnitude of this safety issue and the pharmacist's role as the medication expert, it may be inferred that pharmacy education should measure a student's ability to identify medication errors.

While systems have been developed and implemented to report and analyze incidents and trends in patient safety, under-reporting jeopardizes the validity of these analyses. Estimates suggest that only 10%–20% of errors are actually reported (Griffin and Resar, 2009). Simulation allows individuals to work individually and as a healthcare team to identify and resolve potential and existing threats to patient safety. Hamman et al. (2009) implemented in situ simulation in a labor and delivery ward and found the training was helpful in identifying and resolving latent environmental threats to patient safety. SBT could be beneficial in making personnel more aware of what and how to report patient safety incidents.

Daupin et al. (2016) designed a medication errors room for an interprofessional simulation including medical, nursing, and pharmacy staffs. The primary objective was to assess staffs' ability to identify errors associated with the medication-use system. Simulated situations covered an array of medication errors. Overall, 67.5% of the errors were detected. The rate of correct responses was lower at some stations, including: (1) y-site compatibility; (2) hand hygiene practices; and (3) use of personal protective equipment when administering hazardous drugs. Participants also identified errors that the researchers had not planned. The majority of participants felt the simulation was effective for identifying errors and relevant to their practice.

Atayee et al. (2016) developed a simulation for first-professional year student pharmacists to improve their ability to identify medication errors. The simulation focused on the top 100 prescription medications and students reviewed prescriptions individually and in teams. The number or correctly checked prescriptions was evaluated at two time points. In this particular study, there was no significant change in individual student scores between the two assessments, but group scores significantly increased from, 79.1% to 98.6%, *P*-value = < 0.001.

A study by Warholak et al. (2011) evaluated medication error identification rates by pharmacy, medical, and nursing students. Participants evaluated three prescriptions for accuracy and indicated the type of error, if found. Student pharmacists identified the medication errors at a significantly higher rate than the other student groups ($P < 0.001$) and more frequently identified the type of error correctly.

Interprofessional Education

Since the publication of, *To Err is Human* and *Crossing the Quality Chasm*, by the Institute of Medicine (Institute of Medicine, 2000, 2001), there has been a growing demand for a transformation of healthcare education through the expansion of IPE opportunities to create a collaborative approach to delivering patient care (Institute of Medicine, 2000, 2001; Interprofessional Education Collaborative (IPEC), 2011; World Health Organization (WHO), 2010). These reports recognized that healthcare providers could no longer operate in disciplinary silos and expect to optimize patient care. They identified simulation training as a potential strategy and mechanism to improve patient safety (Institute of Medicine, 2000, 2001). A number of organizations, including the World Health Organization, the Interprofessional Education Collaborative (IPEC), and the International Nursing Association for Clinical Simulation and Learning (INASCL) have published guidelines and frameworks to aid in creating and implementing interprofessional learning opportunities (World Health Organization (WHO), 2010; Interprofessional Education Collaborative (IPEC), 2011; Decker et al., 2015).

While students in healthcare schools may be provided with a description of other professionals' roles within the healthcare team they may not have the opportunity to experience and apply interprofessional teamwork skills during their education. Patient simulation may be utilized for teaching and promoting interprofessional communication and teamwork to improve patient safety.

Ragucci et al. (2016) evaluated the interprofessional team disclosure of a medical error to a simulated patient. Students from up to four different disciplines (medicine, pharmacy, nursing, and physician assistant) participated in team simulated interprofessional rounds. This article focused primarily on the pharmacy students but all disciplines participated. The patient had a medical condition (i.e., gastrointestinal bleed) due to a medication error. Teams were expected to identify and communicate the error with the patient. The results of the study are limited because pharmacy students participated in a workshop whereas the other students did not. Interprofessional simulations such as this may improve knowledge of interprofessional roles and expertise which may in turn may improve patient safety.

Vyas et al. (2012) developed a patient simulation experience, utilizing five patient cases in a hospital emergency department, using both standardized patients and high-fidelity simulators. The scenarios integrated specific patient safety issues, but varied between the cases. The pharmacy student on each team was expected to ensure the appropriateness of the patient's drug therapy. Over 90% of participants agreed or strongly agreed that the simulation had increased understanding of importance of interprofessional communication and understanding roles of other healthcare professionals. Interestingly, while students' reported the simulation had increased their ability to recognize and respond to patient safety issues, they did not report feeling more confident reacting to patient safety issues after the simulation.

The Team Strategies and Tools to Enhance Performance Patient Safety (TeamSTEPPS) communication training program, developed by the Agency for Healthcare Quality and Research (AHRQ) is designed to improve communication and teamwork skills and has been used by multiple professions (Agency for Healthcare Research and Quality (AHRQ), 2012; Robertson et al., 2010). Brock et al. (2013) described the impact of an IPE team communication simulation focusing on student attitudes, knowledge, and skills. Fourth-year medicine, third-year nursing, and second-year pharmacy students participated in a TeamSTEPPS module, which included didactic and simulation training in practice areas of adult acute, pediatric, and obstetrics. Pre- and post-assessments measured changes in attitudes, beliefs and opportunities around team communication. Significant differences were found for several attitudinal measures, including team communication, motivation, utility of training and self-efficacy as well as changes in TeamSTEPPS skills such as team structure, situation monitoring, mutual support, and communication.

IPE simulation was also described by Bordley et al. (2018) to enhance recognition of latent patient safety issues in the Intensive Care Unit (ICU). Medical interns, nurses, and pharmacists in the ICU participated in a rounding simulation incorporating the review of a simulated electronic health record. Cases contained five days of patient data and embedded patient safety events. This exercise demonstrates an additional opportunity for evaluating the performance of interprofessional teams.

Discussion

Due to the evolving nature of the profession of pharmacy there has been an increase in demand for clinically competent pharmacists. Incorporation of simulation into pharmacy curriculum provides the opportunity for pharmacy students to actively engage through innovative simulated experiences, which they otherwise might not have been exposed to during experiential education.

Simulation framework includes pre-briefing, stimulation scenario, and debriefing. Facilitators should aim to have specific objectives prior to designing scenarios as well as to provide reliable and valid methods of assessment. Barriers to successful implementation of simulated experiences include, but are not limited to, budgetary restrictions, logistics, and faculty development.

A variety of simulation modalities can be used in training healthcare professions. Simulation exercises should incorporate a degree of fidelity (i.e., realism of event or environment) and technology (i.e., equipment and devices) to facilitate a robust training opportunities. Simulation exercises may include the use of standardized patients, patient stimulators, partial-task trainers, computerized models, and hybrid stimulations.

Simulation exercises have been incorporated across training medical, nursing, and pharmacy students mapped to a variety of skills and skill sets. Several studies have demonstrated students' appreciation of these processes as a means to increase confidence and clinical skills via integration of simulated scenarios in clinical education. The use of simulation in pharmacy education continues to experience dynamic growth. In conjunction with this growth, evaluation of these modalities—including comparative efficacy studies—is necessary to establish best practices for enhancing learning through these approaches.

Glossary

Debriefing: A formal, collaborative, reflective process facilitated or guided by a facilitator within or following a simulation activity (Fanning and Gaba, 2007; Lopreiato et al., 2016).
Facilitator: An individual who is involved in the implementation and/or delivery of simulation activities (Lopreiato et al., 2016).
Feedback: The relaying of information back to a learner (Lopreiato et al., 2016).
Fidelity: The realism of the simulation scenario, e.g., high-fidelity and low-fidelity (Lopreiato et al., 2016).
Frame: The perspectives through which individuals interpret new information and experiences for the purpose of decision-making (Lopreiato et al., 2016).

Healthcare Simulation: A technique that creates a situation or environment to allow persons to experience a representation of a real healthcare event for the purpose of practice, learning, evaluation, testing, or to gain an understanding of systems or human actions (Lopreiato et al., 2016).
Interprofessional Education (IPE): When students from two or more professions learn about, from, and with each other to enable effective collaboration and improve health outcomes (World Health Organization (WHO), 2010).
Medication Error: A medication error is any preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is in the control of the healthcare professional, patient, or consumer. Such events may be related to professional practice, healthcare products, procedures, and systems, including prescribing, order communication, product labeling, packaging, and nomenclature, compounding, dispensing, distribution, administration, education, monitoring, and use (National Coordinating Council for Medication Error Reporting and Prevention, 2018).

Pharmacist Workforce Issues

Manuel J. Carvajal, Ioana Popovici, Nova Southeastern University, Fort Lauderdale, FL, United States

Introduction

When one thinks of pharmacy, several concepts come to mind. Medications, kinetics, drug metabolism, and delivery mechanisms are some of them. Only after a while does the image of a pharmacist appear; yet the pharmacists are a vital component of the healthcare system. Without pharmacists medications would be used haphazardly, patients would not be counseled effectively, and drug-discovery and drug-utilization scientific advancement would be virtually nonexistent.

Pharmacists' functions and practices are as diverse as their culture and skills. These in turn are shaped by social, economic, political, and administrative structures conditioned by idiosyncrasies and national/regional pride carved by historical developments. Despite the differences, however, a common denominator binds them: the responsibility bestowed upon them to provide pharmaceutical care for effective and safe drug treatment and therapy.

The purpose of this chapter is to analyze pharmacist workforce issues that emerge in response to this responsibility. The issues are imbedded into the worldwide presence and composition of pharmacists and an analysis of the demand for their professional skills. The issues are by no means exhaustive, but are intended to highlight the complexities of studying the global pharmacist workforce and the circumstances that bring practitioners together or set them apart.

Overview of the Global Pharmacist Workforce

According to the International Pharmaceutical Federation (2017), which periodically provides reliable information on the global pharmacist workforce, approximately 2.82 million pharmacists practiced their profession in 2017 in 74 countries and territories comprising 76% of the world's population. Practicing pharmacists represented less than 70% of licensed/registered pharmacists identified in the survey; no explanation was given for the inactivity of the remaining pharmacists, but one might venture to identify separation from the labor force (i.e., retirement, child and elderly care) and working in nonpharmacy venues as important reasons. About 75% of practitioners worked in community pharmacies, 13% worked in hospital pharmacies, and 12% worked in industry, wholesaling, research and development, academia, and regulatory activities.

Community pharmacy practice constitutes the heart and soul of the profession and the most visible resource for patients (Health Care Intelligence Pty Ltd., 2003; Peter Bacon and Associates, 1999). Most community pharmacists spend a substantial portion of their time dispensing medications, counseling patients, compounding, and engaging in pharmacovigilance activities. In a growing number of countries their jobs encompass identification, resolution, and prevention of drug therapy problems through the evaluation of medication profiles, provision of patient education, and assessment of drug adherence patterns; administration of disease management programs (i.e., diabetes, hypertension); and measurement of clinical parameters (i.e., blood pressure, blood sugar, and body mass index). In addition, community pharmacy administrators normally supervise and coordinate the services rendered by the pharmacy, manage the acquisition of drugs and related products, and address human resource issues.

Hospital pharmacists also have a broad range of functions. Since the pharmacy is responsible for the safe and effective use of medications administered to patients during their hospital stay, the pharmacist's role is critical. McCarthy and Schafermeyer (2007)

have identified three major types of activities conducted by hospital pharmacists: drug product distribution, patient care or clinical services, and administrative duties. Distributive responsibilities are associated with medicines and include order entry and verification, checking medication carts, supervision of technicians, and preparation of sterile products. Patient care or clinical services include overseeing drug therapy quality, monitoring patient progress, looking for cost-effective therapy alternatives, providing education to discharged patients, managing adverse drug reaction programs, responding to drug information inquiries, and communicating with other healthcare providers for therapy coordination. Besides dealing with personnel issues, administrative responsibilities include managing the hospital's medication budget and serving as the pharmacy representative on multidisciplinary hospital committees. Practitioners' participation in these activities is influenced by hospital size; in larger institutions the responsibility may be shared by various persons, while in smaller institutions one pharmacist may carry out all activities. The functions also are influenced by the structure of the healthcare system, the hospital-ambulatory care balance, and accessibility to hospitals by the population.

Availability of Pharmacists

The International Pharmaceutical Federation (2017) has reported that in 2017 the worldwide pharmacists' median density was 5.09 per 10,000 population. Regionally, density varied from 8.28 in Europe to 4.96 in the Western Pacific, 4.67 in the Americas, 4.28 in the Eastern Mediterranean, 2.31 in Southeast Asia, and 0.61 in Africa. It also varied by countries' median income level: 7.61 for high income countries, 4.91 for upper-middle income countries, 3.80 for lower-middle income countries, and 0.60 for low income countries. (Bates et al., 2016) have found a positive association among pharmacist density, gross national income, and health spending per capita. In many low income countries, where shortages of pharmacists prevail, pharmacists prefer practicing in urban areas where they can earn more income, thus resulting in even greater pharmacist shortages in rural areas (Goel et al., 1996; Simpson and Wilkinson, 2002; Smith, 2004).

The global composition by type of practice setting also varies by world region and country income level (International Pharmaceutical Federation, 2017). The largest percentages of community pharmacists are recorded in Southeast Asia (81.1%), Europe (78.5%), the Western Pacific (75.0%), and the Americas (68.0%), with only 39.1% in the Eastern Mediterranean and 37.4% in Africa. The largest percentages of hospital pharmacists are found in Africa (29.1%) and the Americas (25.6%), followed by the Eastern Mediterranean (14.1%), the Western Pacific (11.9%), Southeast Asia (9.2%), and Europe (8.9%). The Eastern Mediterranean and Africa report larger percentages of pharmacists working in settings other than community or hospital (46.8% and 33.4%, respectively) than the other regions.

Variation patterns in practice setting by country income group are not clear cut. In low income countries, community pharmacists account for 39.2% of the workforce; this fraction increases to 79.1% in lower-middle income countries and 84.7% in upper-middle income countries, but declines to 67.6% in high income countries. Such discontinuity is not surprising given the changing role of pharmacists in more developed countries. The proportion of hospital pharmacists drops from 29.2% in low income countries to 9.3% in lower-middle income countries and 4.4% in upper-middle income countries, but increases to 21.5% in high income countries. The incidence of pharmacists practicing in settings other than community or hospital is greater in low income countries (31.6%) than in high income (11.9%), lower-middle income (11.6%), and upper-middle income countries (10.9%).

These erratic patterns in practice setting composition call for a further probe into separate density variations of community and hospital practitioners. Again, the information is provided by the International Pharmaceutical Federation (2017). Europe reports the highest density of community pharmacists (6.26 per 10,000 population), followed by the Western Pacific (4.55), the Americas (3.26), Europe (3.06), the Eastern Mediterranean (2.78), Southeast Asia (1.73), and Africa (1.04); the global median density is 4.22 community pharmacists per 10,000 population. The density of community pharmacists by country income group is as follows: 5.66 for high income countries, 3.58 for upper-middle income countries, 3.29 for lower-middle income countries, and 0.92 for low income countries.

Hospital pharmacists exhibit a different regional pattern. With a global median density of 4.52 hospital pharmacists per 100,000 population, the Western Pacific shows the highest density (10.45), followed by the Eastern Mediterranean (6.57), the Americas (5.04), Europe (4.08), Southeast Asia (3.51), and Africa (1.80). High income countries exhibit by far the greatest density (10.05) followed by lower-middle income countries (3.24), upper-middle income countries (2.54), and low income countries (0.69).

Education Trends

Increasing the worldwide presence of pharmacists requires improving professional training capabilities. This translates into more pharmacy schools with more students in lower income countries. The number of pharmacy schools throughout the world in 2017 was estimated to be 0.46 institutions, with an average of 28.3 graduates, per 1,000,000 population, which was equivalent to 63.3 graduates per pharmacy school per year (International Pharmaceutical Federation, 2017). While the number of schools may be sufficient to meet population needs in most high income countries (Arora et al., 2015; Knapp et al., 2010; Taylor et al., 2013), low income countries, especially in Africa, lack adequate pharmacy programs or are unable to accommodate enough candidates. For example, according to a World Health Organization (2011) report, only 11% of applicants in Nigeria are admitted into the Bachelor of Pharmacy programs despite a widespread shortage of pharmacists and a density below 1 practitioner per 10,000 population.

In most high income countries pharmacy education has moved away from a basic natural-sciences focus to include clinical, healthcare, economic, social, and administrative components. The Doctor of Pharmacy (Pharm.D.) degree, with an expanded

curriculum and more years of training, has replaced traditional baccalaureate degrees in the United States, the United Kingdom, Australia, Canada, New Zealand, and several European countries (Jamshed et al., 2007). Although, some low and middle income countries have tried to adopt pharmacy education models from high income countries, formal assessments of need and adaptation success of the new programs are lacking (Babar et al., 2013).

Recently Australia, Canada, Ireland, the United Kingdom, and the United States have experienced massive expansions in institutions and enrollment (Hawthorne and Anderson, 2009; Health Care Intelligence Pty Ltd., 2003; Jesson et al., 2001; Peter Bacon and Associates, 1999), and there is concern that the growth may have detrimental effects on the labor market's ability to accommodate the absorption of newly graduates in the short run and the sustainability of the profession in the long run (Covvey et al., 2015; Walton et al., 2010). In the United Kingdom and the United States some regions are experiencing a surplus of pharmacists, which has motivated some practitioners to seek additional professional training (McCarthy and Weber, 2013) and led to the recognition of advanced practice beyond what is expected from general practitioners (International Pharmaceutical Federation, 2015).

Another trend worth mentioning has been a move toward an international pharmacy education market and migration from lower income to higher income countries. India, for example, educates its pharmacists with the aim of meeting international standards; its graduates are equipped to sit for competency examinations that allow them to work in the United States (Ghilzai and Dutta, 2007). In response to political and economic problems, African community pharmacists have migrated to higher income countries. Historically, South Africa and Zimbabwe have been responsible for the education and training of pharmacists in the Southern African region; their pharmacy schools prepare graduates to practice overseas, especially in English-speaking countries (Katerere and Matowe, 2003). This practitioners flow aggravates the shortages experienced by lower income countries.

The Role of Pharmacists

The World Health Organization (1997) and the International Pharmaceutical Federation have developed the concept of "the seven-star pharmacist." The seven-star pharmacist is defined as a key member of the healthcare team responsible for providing pharmaceutical care and fulfilling the roles of caregiver, decision maker, communicator, manager, life-long learner, teacher, and leader. According to this view, a well-rounded pharmacist interacts with patients as an integral part of the healthcare team, ensures safe and cost-effective use of healthcare resources, facilitates communication between patients and physicians or other healthcare providers, assumes a leadership role in the healthcare system, participates in learning activities along his/her career, and helps train future generations of pharmacists. Recently these roles have been expanded to include comprehensive, patient-centered, and outcomes-oriented health care. Pharmacy throughout the world is becoming an increasingly clinical, patient-facing profession, and pharmacists are being endowed with expanding responsibilities and accountabilities for pharmaceutical care in clinical and domestic environments (International Pharmaceutical Federation, 2015).

Beyond the traditional roles of dispensing, counseling, compounding, and pharmacovigilance, several advanced services are provided (International Pharmaceutical Federation, 2017). These include drug utilization review, reported by 68% of countries; management programs for chronic diseases, reported by 47% of countries; and measurement of clinical parameters, reported by 62% of countries. Yet in rural areas of low income nations, pharmacists are the only healthcare professionals available, and it is not uncommon for them to assume the roles of other healthcare professionals for the sake of patients.

Preventive health care and cost reduction have become increasingly important as patients worldwide assume more responsibility for their health. Because of their expertise, accessibility, and close interaction with patients, community pharmacists are in a unique position to expand preventive care services and improve population health. This is especially true for vulnerable and isolated groups such as families with low income or living in remote areas. Pharmacists help directly by offering preventive care services (i.e., immunization and screening) and indirectly by providing education and referrals to primary care for follow-up, testing, and treatment (Kelling et al., 2016). In the United States, for example, the proportion of pharmacists rendering immunization services increased from 15% in 2004 to 53% in 2014; in 2014 almost one-half of chain pharmacists reported offering health screening services (Gaither et al., 2015). Several studies suggest that pharmacist-delivered preventive care is both safe and cost effective (Ayorinde et al., 2013; Edwards et al., 2012; Higginbotham et al., 2012; Otsuka et al., 2013).

Medication therapy management is another area in which community pharmacists recently have expanded their functions. Medication management provided by pharmacists improves drug adherence and clinical outcomes (Fox et al., 2009; Isetts et al., 2006; Robinson et al., 2010; Welch et al., 2009) and reduces healthcare costs, especially for chronic-disease patients (Isetts et al., 2008; Wittayanukorn et al., 2013). In the United States the proportion of pharmacists providing medication therapy management services jumped from 13% in 2004 to 60% in 2014 (Gaither et al., 2015); furthermore, pharmacists' evolving role has expanded to include drug reconciliation, which improves patient outcomes and reduces healthcare costs by lowering the incidence of adverse medication events (Delate et al., 2008; Israel et al., 2013; Schnipper et al., 2006).

Hospital pharmacists' roles are rapidly evolving, too. According to the International Pharmaceutical Federation (2017), the most widely rendered services are providing medications and support to emergency departments (96% of countries), reporting drug-adverse reaction events (95% of countries), and participating in therapeutic committees (95% of countries). Hospital pharmacists also provide services to improve responsible utilization of medications, including implementation of quality assurance strategies to reduce medication errors and antimicrobial drug stewardship programs to promote adequate use of antibiotics. In 88% of countries, hospital pharmacists' roles include drug consultation to other healthcare professionals.

Having access to patients' shared healthcare records is a prerequisite for improving pharmaceutical care in hospitals; in about four-fifths of the countries surveyed, hospital pharmacists have access to these records. Unfortunately, hospital pharmacists' roles have not evolved as fast in other areas. Only 31% of countries report that hospital pharmacists provide services related to pharmacogenomics testing, and a handful of countries report pharmacists engaging in collaborative or independent prescribing. Hospital pharmacists are allowed to provide immunization services in only 26% of countries.

While pharmacists' roles have expanded in higher income countries, pharmacy practice models elsewhere experience an absence of standard practice guidelines, scarcity of pharmacists, and no separation between prescribing and dispensing (Azhar et al., 2009). The main obstacle to expanding pharmacists' roles in lower income countries is a ubiquitous workforce shortage. In some countries like Malaysia, prescribing and dispensing are not separate practices. Separation is desirable because it prevents exploitation of the sick, controls drug expenditure growth, and encourages appropriate prescription of medications, but it has not occurred in Malaysia due to the shortage of pharmacists (Tiong et al., 2016). Consequently, both physicians and pharmacists have the legal right and responsibility to dispense medications. Something similar happens in China; due to the shortage of pharmacists, hospitals are the main outlet for the distribution of medications. In 2009 Chinese hospitals accounted for about three-quarters of total medication sales (Huang, 2007; Sun et al., 2008).

Diversity in the Pharmacist Workforce

Workforce diversity produces good results; men and women, practitioners from different ethnic groups, younger and older, as well as society as a whole, gain when the workforce becomes more heterogeneous and its distribution resembles the composition of the population being served (Ash, 2008; Otto and Gurbey, 2006). Diversity fosters variety in perceiving issues, analyzing alternative courses of action, and creating divergent processes, thus broadening the range of options to deal with problems and conflicts. It also promotes programming and implementation choices that may not be available otherwise. Three sources of pharmacist workforce diversity are apparent: gender, ethnic group, and age.

Differences between men and women transcend physical appearance and biological functions. According to Maier (1999), when men strive for success they engage in competition to win; women are more interested in attaining balance in life. Men's purpose in communication is to find solutions, gain status, and attain independence, while women's main motivation is to establish links and search for intimacy. He also points out that men's leadership image is framed within a hierarchical setting, while for women the concept of authority has a more personal nature, determined by competence and expertise. This dissimilarity of views has a profound impact on the reactions by male and female pharmacists to social, economic, and administrative stimuli.

Social structures throughout the world assign household and childcare responsibilities disproportionately to women. Women are expected to work more than men at home, so many end up not working, or working fewer hours, in the labor market (Carvajal and Hardigan, 2008; Cunningham, 2008; Fogli and Veldkamp, 2007; Mott, 2000; Poeschl et al., 2006; Quesenberry et al., 2006); this often leads to lower wages and salaries, fewer promotions, and less accessibility to managerial positions (Ahituv and Tienda, 2004; Blasius and Pae, 2005; Rad et al., 2016; Report of the ASHP Task Force on Pharmacy's Changing Demographics, 2007). These conditions also increase the potential for discrimination by employers and unequal treatment by managers who may believe that female pharmacists are less productive at work than male pharmacists because of their domestic commitments. The essence of gender discrimination and unequal treatment lies in the systematic, overt or covert preference by employers and managers to hire men when faced with a choice between equally qualified male and female candidates. Gender discrimination sets a higher performance goal for women than men, and women who are able to accomplish those goals and end up being hired (or promoted) frequently perform better than their male peers.

Recently the global pharmacist workforce has experienced a substantial influx of women. In the U.S. almost two-thirds of graduating students are women (American Association of Colleges of Pharmacy, 2016), and 84% of female pharmacists were practicing in 2014 (Gaither et al., 2015). Similar trends are observed in other countries (Brown et al., 2006; Gardner and Stowe, 2007; Health Care Intelligence Pty Ltd., 2003). Although male pharmacists outnumber female pharmacists in African and Eastern Mediterranean countries, globally women account for 59% of practicing pharmacists (International Pharmaceutical Federation, 2017). Female practitioners tend to be younger than male practitioners, which suggests a continued gender restructuring of the pharmacist workforce in the near future, as retiring older pharmacists are replaced by younger female pharmacists (Health Care Intelligence Pty Ltd., 2003).

Another form of workforce diversity pertains to ethnic classifications. Race and physical appearance play a major role in segregation, but the concept of ethnicity is more comprehensive as it includes language, religion, heritage, cultural identity, and other symbolic representations that people use to differentiate between themselves and others (Bissell et al., 2003). When the characteristics that set groups apart weigh more heavily than the commonalities bringing them together, competition for political control and access to economic resources often ensues and leads to dominance of some groups over others. The latter are frequently called minorities. Ethnic classifications within countries and regions are vast and complex; it is difficult to establish generalizations. Unlike differences by gender and age groupings, which are observable virtually everywhere, ethnic distinctions and comparisons, as well as relations among ethnic groups, are characterized by unique conditions forged by the specific geographic setting, historical development, and cultural context of each country or region. Consequently, lessons learned from ethnic interaction in one location may not be applicable to other locations.

Probes into ethnic composition and interaction are important because of patient and economic outcomes. Several studies suggest that minority patients receive better quality care and are more satisfied when healthcare services are provided by ethnically similar

practitioners; ethnic resemblance is conducive to improving communication and generating trust (Collins et al., 2002; LaVeist and Nuru-Jeter, 2002; Vanderpool, 2005). Minority healthcare providers are more likely than their non-minority counterparts to practice in medically underserved areas (Baldwin, 2003; Smedley et al., 2004; Weeks and Wallace, 2006).

Ethnic identification also has economic repercussions because the choice of cultural self-identity is closely related to the acceptance of, and acculturation into, the professional and social norms of the dominant group. Insofar as different ethnic groups have different beliefs and values that govern attitudes and expectations, they normally are expected to behave differently. A cultural self-identity may or may not be used by a minority person to distance himself/herself from a minority group to improve his/her chances of being accepted into the dominant group. Acculturation brings forth some degree of acceptance by the mainstream, which usually opens up economic opportunities, but it bears an implicit cost; by adopting the cultural norms of the dominant group, practitioners may alienate themselves from their own ethnic communities (Bodenhorn and Ruebeck, 2003). An effective ethnic acculturation into the mainstream depends not only on minority practitioners' actions, but also on the dominant group's receptiveness and willingness to accept minorities.

Last, but not less important, are age-group workforce diversity patterns. Younger-versus-older pharmacist comparisons possess an important perspective, namely, the role that work plays in people's lives. Younger pharmacists often express an interest in working more hours; they want to pay off loans, form families, and build estates. At the other end, many older pharmacists choose to remain active in the workplace on a part-time basis, frequently reducing the number of hours or days of work to engage in activities consistent with retirement. The conditions experienced by them may be of little or no concern to younger pharmacists. Some common motivating factors for older pharmacists to seek employment while in retirement include earning additional income, avoid depletion of savings, fight boredom, validation of personal worth, and coping with unanticipated care of dependents (Teeter, 2004). Understanding the similarities and differences in motivation to work underlying the various stages of pharmacists' work lifecycles improves communication, increases satisfaction, and raises productivity (Carvajal and Armayor, 2015b).

Generational differences affect pharmacists' behavior beyond their motivation to work (Carvajal and Armayor, 2015a). In many societies older workers exhibit a work ethic characterized by clearly defined professional goals, long hours of work, and commitment to their employers; they consider work a very important part of their lives and frequently define themselves in terms of what they do. Younger workers tend to hold different values; they prefer autonomy and flexible work schedules, are more interested in family and friends than in material success, are oriented toward technological innovation, place emphasis on personal growth and creativity, are more open toward diversity, and view organizations with cynicism and contempt (Jovic et al., 2006; Kennedy, 2003; Shields and Shields, 2003; Smola and Sutton, 2002; Southard and Lewis, 2004; Washburn, 2000). Conflicts inevitably arise between the different sets of values. Many older practitioners view their younger peers' attempts to balance work and leisure as an erosion of work ethics and lack of commitment, while younger practitioners criticize their older counterparts as being too competitive, overly cautious, and loyal to their jobs beyond reason.

Pharmacists aged 30–45 years comprise the largest segment of the global workforce, and male pharmacists outnumber female pharmacists over 50 years old (Cohen et al., 2000; Hawthorne and Anderson, 2009; Health Care Intelligence Pty Ltd., 2003; Mott et al., 2006; Peter Bacon and Associates, 1999). In the United States and other higher income countries, workforce participation by older pharmacists is expected to remain at unprecedented high levels (Knapp and Cultice, 2007), although a substantial portion may continue to work only part time (Carvajal and Popovici, 2016). Managing an age-diverse workforce is not easy; employers trying to maintain safety standards and patient satisfaction while finding suitable replacements for turnover employees, especially those who retire, often are challenged by the interaction of workers of all ages whose diversity of values, attitudes, opinions, expectations, and behavior may bring conflict to the workplace and jeopardize operations.

Demand for Pharmacist Services

Employment opportunities reflect the labor demand for pharmacists. They are set by business firms and government in response to people's demand for goods and services sold in pharmacies and other places where pharmacists practice their profession (i.e., universities, research laboratories). Thus, the demand for pharmacists is a derived demand influenced by employer-established job requirements (i.e., qualifications, skills, experience, and productivity) subject to social expectations and regulations, such as licensure and continuing education (Gabriel and Schmitz, 2007; Sørensen, 2007). If there were no demand for pharmacists-produced goods and services, there would be no demand for pharmacists; by the same token, the demand for pharmacists grows when more people demand more services. Understanding this labor demand structure requires knowledge of the ongoing relationships between the organizational environments and the motives for providing pharmacist-related services within the constraints limiting the ways in which they are allowed to function.

Labor Demand Curves

A labor demand curve depicts the number of pharmacist hours one or more organization(s) is (are) willing and able to hire at different wage rates in a given location and at a given time. Movements along the same curve occur because of wage-rate changes. When the wage rate increases, pharmacist's hours become more expensive for employers and organizations respond by hiring less labor; when the wage rate declines, organizations respond by hiring more labor. Thus, pharmacists' demand curves are normally negatively sloping, indicating that the wage rate and the number of pharmacist hours hired by employers vary inversely with each other.

Displacements of the curve to the right or left occur due to changes other than the wage rate. When pharmacist labor demand curves move to the right, labor demand is said to increase; organizations are willing and able to hire more pharmacist hours at the same wage rate. Conversely, when labor demand curves move to the left, pharmacist labor demand is said to decline; organizations are willing and able to hire fewer pharmacist hours at the same wage rate. These displacements explain why two organizations or groups of organizations, or the same organization or group at different times, may hire different amounts of pharmacist hours while paying the same wage rate.

The global demand for pharmacists has risen in recent decades and is likely to continue rising, thus pushing the demand curve to the right (Okunade, 2006). Several factors account for this push, including changes in population size and composition, increases in national and personal incomes, the rising prevalence of chronic disorders, the development of new pharmaceutical products and technological innovation, and the evolving roles of pharmacists.

Changes in Population Size and Composition

More people demand more pharmacist services. According to the United Nations (2017), the world population in 2017 consisted of approximately 7.6 billion persons, and was expected to increase to 8.6 billion in 2030 and 9.8 billion in 2050. This amounts to a 29% growth over a 33-year period. Most of the recent and projected expansion can be attributed to a steady rise of the elderly age group due to increases in life expectancy. Abubakar et al. (2015) have estimated that worldwide life expectancy has increased from 46.5 years in the 1950s to 65.3 years in 1990 and 71.5 years in 2013. The global population 60 years and older is expanding faster than any other age group. In 2017, at an estimated 962 million persons, they accounted for 13% of the total; they are expected to increase, at approximately 2.5% annually, to 1.4 billion persons in 2030 and 2.1 billion persons in 2050 (United Nations, 2017). Europe is the region with the greatest percentage of elderly population (about 25%), while Africa records the lowest percentage.

In the United States medications are used more frequently than in any other country; over 80% of adults take some form of medication and around 50% take at least one prescription drug (Kaufman et al., 2002). Individuals 65 years or older consume twice as many prescription medications as the rest of the population; they also purchase 40% of all nonprescription drugs, almost three times their share of the total population. More than five out of every six persons in this age bracket suffer from at least one chronic condition (i.e., cancer, heart disease, Alzheimer's disease) that requires continuous treatment, and over one-half take three or more prescription drugs (Manassee and Speedie, 2007; Report of the ASHP Task Force on Pharmacy's Changing Demographics, 2007). These indicators account for an increase of 44% in the number of new prescriptions generated through physician offices and hospital visits during 2005–30. As long as the population continues to grow and the elderly percentage increases, the demand for pharmacist services will continue to rise.

Increases in National and Personal Incomes

Prescription drugs are normal goods (e.g., their demand changes in the same direction, but less than proportionately, with income). The worldwide secular rise in national and personal incomes is another reason to expect increases in prescription drug use and the demand for pharmacist labor. Vandegrift and Datta (2006) and Suraratdecha (1996) have reported a strong, positive effect of real per capita income on per capita prescription drug spending in the United States. Their findings suggest that private, out-of-pocket pharmaceutical spending is procyclical, namely, people spend more on medications during periods of economic expansion and spend less in recessions.

Other studies, however, show that public-health expenditures are countercyclical or acyclical in more developed countries, but procyclical in developing countries (Chen et al., 2013; Lane, 2003). In a study of financial crises in Argentina, Indonesia, Thailand, and the Russian Federation, The World Bank has identified procyclical drops in health spending; both per capita out-of-pocket and public-health expenditures declined substantially during the crises in each country, and it took several years to achieve precrisis levels of expenditure (Gottret et al., 2009; Thomas et al., 2013). In another study, Del Granado et al. (2013) have concluded that public expenditure on healthcare is acyclical in more developed countries and procyclical in developing countries, and a World Health Organization report examining healthcare system responses to 2008–13 crises in Europe has found that several countries restricted drug benefits, introducing or increasing user charges for prescription drugs (Thomson et al., 2014).

Rising Prevalence of Various Disorders

Another development leading to increasing medication use, and consequently greater demand for pharmacist services, is the rising prevalence of chronic disorders. One of these disorders, obesity, is associated with hypertension, Type II diabetes, cardiovascular diseases, and cancer (Must et al., 1999). According to the World Health Organization (2017), the obesity worldwide prevalence has trebled in the last 40 years, and one-third of the population is currently obese or overweight; countries in the Middle East, North Africa, Central America, the Pacific Islands, and the Caribbean report obesity and overweight rates above 40% (Ng et al., 2014a). The rise in the prevalence of obesity over the last decades is associated with a 75% increase in prescription drug spending (Sturm 2002; Vandegrift and Datta, 2006).

The global prevalence of diabetes has risen from 4.7% in 1980 to 8.5% in 2014 (Ng et al., 2014a); the fastest increases are reported by low- and middle-income countries (Mathers and Loncar, 2006). Cancer is another chronic disease, and it becomes more

prevalent as life expectancy continues to rise; approximately 14.1 million new cases are reported globally every year (Stewart and Wild, 2014). Smoking also is associated with multiple health issues and risks (i.e., cancer, cardiovascular diseases, Alzheimer's disease); smoking increases average medication costs by 28%–30% (Sturm, 2002). While the incidence of global smoking has declined due to widespread smoking cessation campaigns, the number of cigarette smokers has increased between 1980 and 2012 because of population growth (Ng et al., 2014b).

Development of New Pharmaceutical Products and Technological Innovation

Advances in medical technology allow a greater array of health problems to be treated more aggressively, along with the development of pharmaceuticals designed to treat conditions previously considered untreatable. Both trends increase longevity and quality of life. About one-third of countries report that pharmacists provide technological innovation services (International Pharmaceutical Federation, 2017).

A rapidly evolving field is pharmacogenomics testing, a form of precision medicine that explores how genes affect the human body's response to medications. Blood or saliva tests are conducted to assess whether a medication is effective for specific individuals, optimal dosage, and potential adverse effects. The US Food and Drug Administration includes pharmacogenomics information on the labels of about 200 drugs.

Europe lags behind the United States in the use of pharmacogenomics testing, but this situation may change in the near future as a new consortium aims to make pharmacogenomics testing a routine part of clinical practice (Just et al., 2017). The Ubiquitous Pharmacogenomics Consortium (U-PGx) is a collaborative effort of experts from ten European countries seeking to make effective treatment optimization accessible for every European citizen. It is conducting a study funded by the European Commission of the European Union to implement preemptive pharmacogenomics testing at seven healthcare systems across the continent by 2020. Testing already is being conducted routinely for a limited number of health disorders, and the accelerated expansion of pharmacogenomics-related treatment is expected to include testing in managing asthma, cancer, depression, and other conditions.

While hospital pharmacists' role in pharmacogenomics testing is clear, its application is expected to pervade community pharmacies as well. There are already several laboratories in the United States working directly with pharmacists to offer testing in community pharmacies, and the trend is expected to rise. With greater contributions by pharmacists, demand curves will likely shift to the right.

Another innovation affecting the demand for pharmacist services is the emergence of mail/Internet-ordered distribution of prescription drugs, which is becoming increasingly popular in higher income countries whose physical infrastructure can support this practice. In the United States Internet/online pharmacies started operating in the 1990s. Websites such as Drugstore.com provide prescription-drug services using Internet-based platforms to fill prescriptions that are delivered to patients by mail. This practice has flourished over the last 20 years, and today mail-order and Internet pharmacies account for approximately 20% of total retail medicine sales. They are used mostly by patients with chronic disorders who take drugs on a continuous basis (IMS Institute for Health Informatics, 2011). About 30% of chronic-disease prescriptions in the United States are filled by mail, replacing a substantial portion of the local retail-pharmacy medication distribution system and shifting to the left the demand curve for pharmacists. The mail-order and Internet pharmacies business is likely to continue expanding for two reasons: they are price competitive and they are appealing to younger patients, who feel comfortable purchasing goods and services online.

Other Considerations

The demand for pharmacist labor is projected to grow in the near future based on four basic forecasts: a global ageing population requiring more health care, especially because of the rising prevalence of various disorders; a wealthier population that can afford more and better healthcare services; advances in medical technology that continue to reduce both morbidity and mortality and improve patients' quality of life; and diversification in the roles that pharmacists play to make patients' lives better. These additional roles were addressed in the previous section of this chapter–drug utilization review, disease management programs, measuring clinical parameters, rendering immunization services, providing education and referral to primary care providers, monitoring medication adherence and therapeutic response to drugs, medication reconciliation, informatics, and collaborative team-based care, among others (Avalere Health, 2014; International Pharmaceutical Federation, 2017).

In some countries competition in the community pharmacy marketplace has led to the coexistence of chain and individually-owned pharmacies. Philipsen (2014) argues that whenever chain pharmacies are allowed to exist (e.g., the Baltic States, Belgium, Ireland, the Netherlands, Poland, the United Kingdom, and the United States), the average price of medications drops. The shift from independent to chain pharmacies also increases the demand for practitioners; chain pharmacies need more staff because their employees work fewer hours, thus requiring more practitioners to serve each store. In addition, whenever permitted to do so, chain pharmacies commonly expand hours of operation, which further raises the demand for pharmacists.

Conclusions

The issues reviewed in this chapter reveal the intricate nature of worldwide pharmacist workforce analysis. Despite obvious social, economic, and political differences across continents, practitioners and researchers address multiple common concerns: the

expanding roles of pharmacists, the demand for pharmacists' services, the emergence of new products and therapies, and the changing needs of populations being served, to name a few. Regardless of cultural setting, availability of resources, or technological infrastructure, these issues affect the way pharmacists practice their profession. It is important to understand that pharmacists' mission, to provide pharmaceutical care for effective and safe drug treatment and therapy, constitutes a common bond that transcends language, practice site, and other specifics, and unites practitioners and researchers into a clearly identified profession and an essential component of healthcare-providing teams.

Pharmacometrics and its Application in Clinical Practice

Muhammad Usman, Huma Rasheed, University of Veterinary and Animal Sciences, Lahore, Pakistan

Background

Ensuring the five rights of the medication use, that the right patient receives the right drug in the right dose at the right time and by the right route is classically included in the clinical decision making (CDM) goals of the pharmacist (Reynolds and Rupp, 2017). Once the choice of drug has been made, the process of the decision making shifts the selection of dosage regimen, which is governed by the pharmacokinetics of the drugs and the intended therapeutic goals. Variations in the patient's physiological conditions by factors like age, ethnicity, gender, and presence of other conditions like concomitant drugs or a disease state can alter the pharmacokinetics [i.e., absorption, distribution, metabolism, and elimination (ADME)] of the drug and hence can affect the amount and the rate at which the drug is available to the target site in the body. Identification of the factors that affect these key pharmacokinetic parameters and provision of an easy to use mathematical equation are crucial aids in CDM for selecting an individualized/optimized dosage regimen for the patient. This optimization of the dosage regimen is targeted at ensuring the safety and efficacy of medicine by keeping the drug levels in its therapeutic window (i.e., within the minimum effective and toxic concentrations).

The pharmacokinetics of drugs may be influenced by a variety of pathophysiological conditions, which can alter the renal and hepatic functions of the patients and ultimately affecting the drug activity. Patients with augmented renal or hepatic clearance (as in case of increased cardiac output in early state of severe sepsis) are at increased risk of subtherapeutic plasma concentrations which may result in therapeutic failure. On the other hand, patients with decreased renal or hepatic clearance (which can occur in case of end stage-organ dysfunction) are at risk of drug accumulation and toxicity (Taccone et al., 2011; Varghese et al., 2011). This problem becomes more pronounced in case of narrow therapeutic index drugs as slight change in dose can lead to either toxicity or therapeutic failure.

In addition to other factors, age is also an important factor for drug clearance because renal and hepatic functions decrease progressively with increasing age (Verhave et al., 2005). Therefore, the kidney and liver status must be considered for maintaining plasma concentrations of drugs at the required level in order to achieve therapeutic success on one side and also to ensure safety and cost effectiveness on the other side. Ethnicity can also be linked with modified pharmacokinetics of drugs as the distribution of cytochrome P450 (CYP450) isoenzymes is varied among people of different ethnic origins. For example, the occurrence of warfarin toxicity prevails more in white as compared to black individuals due to poor metabolism through CYP2C9 enzyme. Similarly, the risk of angioedema associated with angiotensin converting enzyme (ACE) inhibitors is high in black Africans (McDowell et al., 2006). Genetic variation among individuals for the metabolism of warfarin has also made it a target for pharmacogenetics research. In 2007, the US Food and Drug Administration (FDA) advised a lower initial dose of warfarin in patients with certain genetic variability (Laurence, 2009). Therefore, individualized dosage regimen is necessary for safe and effective administration of

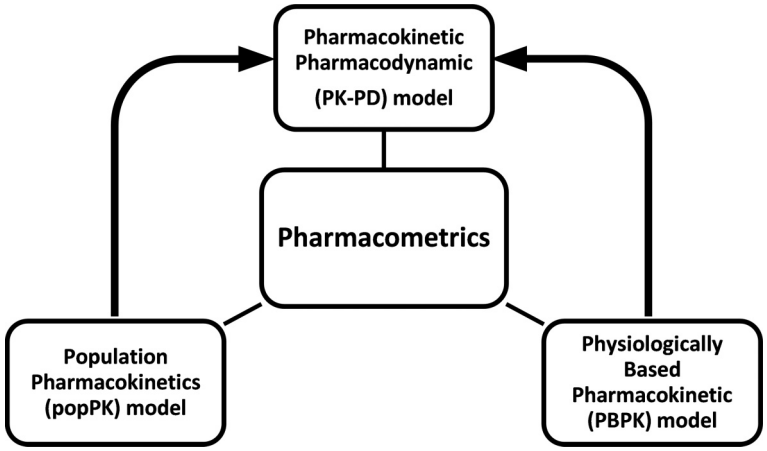

Figure 1 Components of pharmacometrics.

drugs. The selection of rational dosage regimen for individual patient is also inevitable for antibiotics, because subtherapeutic levels of antibiotics can cause development of resistance by pathogenic bacteria.

Pharmacokinetic modeling approaches such as physiologically based pharmacokinetic (PBPK), population pharmacokinetics (popPK), and pharmacokinetic/pharmacodynamic (PK-PD) can help in provision of critical information needed for the CDM regarding dosage regimen. As stated earlier, the information includes identification of physiological or genetic factors which have influence on pharmacokinetic parameters and derivation of the mathematical expression through which the drug dosage can be calculated. The advancement in the field of pharmacometrics is a key tool to establish this relationship and can be useful for tailored dosing through simulation of different dosage regimens.

Introduction to Pharmacometrics

The development in the field of pharmacokinetics accelerated greatly due to the availability of computer applications and advancement in the field of bioanalysis. The complex calculations of pharmacokinetic parameters are simplified by different software programs which allow rapid pharmacokinetic modeling and quick solutions to complex equations. Moreover, these software are also used for designing experimental studies, statistical analysis of data, graphical interpretation of results, dosing simulations, and prediction of drug effects (Shargel and Yu, 2015). The term "pharmacometrics" was first used in 1982 by *Journal of Pharmacokinetics and Biopharmaceutics* and can be briefly described as the science that deals with the use of computer programs to work with mathematical and statistical models in order to characterize, understand, and predict the pharmacokinetic, pharmacodynamic, and biomarker outcome behavior of drugs (Ene and Ette, 2007). This is a relatively new bridging science that describes the PK-PD behavior of drugs by the application of quantitative models representing pharmacology, physiology, and disease progression in relation to the effects and possibility of adverse drug reactions in patients (Barrett et al., 2008). The Division of Pharmacometrics has become an important part of regulatory affairs for decision making and establishing the product labels in new drug applications (NDAs) in US FDA (Gobburu, 2010). The modeling approaches in pharmacometrics are shown in Fig. 1.

The commonly used software available for pharmacokinetic modeling and simulation are listed below:

- NONMEM® 7.4 by ICON
- Phoenix WinNonlin NLME™ by CERTARA
- Simcyp® by CERTARA
- PK-Sim® by BAYER, Germany

Physiologically Based Pharmacokinetics

Pathophysiological changes due to chronic diseases could have significant effects on the pharmacokinetics of drugs, requiring the need for modification in drug therapy (Boucher et al., 2006). It is essential to state that most patients with chronic diseases are mostly suffering from multiple comorbidities. The development of drug-disease models due to the advancements in the field of PBPK modeling as well as the quantitative understanding of disease-related physiological changes, can be helpful in predicting the pharmacokinetic impact of these changes (Sayama et al., 2014). The major advantage of PBPK model is that it can be extrapolated to other populations and conditions (Tsamandouras et al., 2015). Therefore, a PBPK model that is developed for healthy individual with normal physiology can be modified according to the pathophysiology of a disease.

The developed PBPK model after incorporation of diseased condition, can be extended to a wide variety of drugs and can also be extrapolated from adult patients to special populations such as children and elderly (Rasool et al., 2015). Furthermore, the pharmacokinetics of drugs can also be altered due to incorporation of artificial organs to patients with organ failure such as extracorporeal membrane oxygenation (ECMO), which provides cardiac and pulmonary support to critically ill patients with cardiorespiratory failure. The PBPK models are also flexible to include the artificial organ as additional compartment and can be utilized to predict the change in pharmacokinetics of drugs for ultimate application to dose optimization (Watt et al., 2018).

Population Pharmacokinetics

Population pharmacokinetics is the study of variability among individuals with respect to drug concentrations after the administration of clinically relevant dosage regimens (Aarons, 1991). The selection of dosage regimen is most important for safe and effective use of drugs in a target patient population or more specifically in an individual patient (Joel and Owen, 2014). Population pharmacokinetic models are utilized for the construction of dosing strategies and play an important role for safe use of drugs (Ette and Williams, 2004). A sufficient number of samples are required to perform the traditional pharmacokinetic analysis whether the analysis is simple calculation of pharmacokinetic parameters through nonlinear regression or estimation of noncompartmental parameters on an individual subject basis. The population pharmacokinetic modeling approach extends the traditional individual subject model by addition of models that take into account the sources and magnitude of interindividual variability in model parameters and also the intraindividual variability within an individual (Joel and Owen, 2014). The pharmacometrics model parameters are of two types:

- Fixed effect parameters
  Fixed effect parameters are the model elements that take a particular or a scalar value. In a pharmacokinetic model, these represent the average population parameters such as clearance and volume of distribution (Kiang et al., 2012).
- Random effect parameters
  Random effect parameters are related to population models and include the interindividual variability on specific pharmacokinetic parameters as well as the errors that are related to the sampling and bioanalytical techniques.

Nonlinear Mixed Effect Modeling

The development of Nonlinear Mixed Effect Modeling (NONMEM®) software has tremendously enhanced the ability to analyze sparse data, to pool and analyze data from different studies and experimental conditions, and also to simulate new dosage regimens and conditions of drug use. The ability to analyze sparse data was a strong motivational factor for the development of NONMEM® approach, because the patients for whom dose selection is critical are frequently the ones from whom data collection is difficult. With the development of NONMEM® software in 1980s (Sheiner and Beal, 1980), population pharmacokinetic analysis has become extremely useful not only for the development of new drugs (Stone et al., 2010), but also for the improvement of already approved drugs (Zandvliet et al., 2008). Although other modeling software are also available, NONMEM® is still considered as gold standard in pharmacometrics (Keizer et al., 2013).

Use of NONMEM® for Population Pharmacokinetic Modeling

The major components of this system are NONMEM® the engine, subroutines for the PREdiction of Population Pharmacokinetic parameters (PREDPP) and NonMem TRANSlator (NM-TRAN). The estimation of parameters is governed by NONMEM® through FORTRAN subroutines. Multiple prewritten subroutines are available in PREDPP library for most of the common pharmacokinetic models. However, these subroutines can be customized according to specific needs of the modeler (Joel and Owen, 2014). The NM-TRANS provides the language used by modelers for model specification and interaction with the system (Beal et al., 1989–2011). The basic steps for the development of popPK model are described below (Joel and Owen, 2014). The schematic diagram for popPK modeling is presented in Fig. 2.

Analysis Planning

Data analysis planning (DAP) is a very important step in any kind of data analysis and modeling. In pharmacometrics, it is critical to complete this step before the start of actual modeling process in order to increase the credibility of the model to the reviewers. A good DAP provides a detailed information about analysis procedures and results interpretation and it should enable two independent modelers to come to the same conclusion after following the plan.

Dataset Creation

The construction of a dataset should be done before the actual modeling work. A pharmacometrics dataset is a complex set of information arranged in a format that is compatible with the software. The dataset usually requires the information of

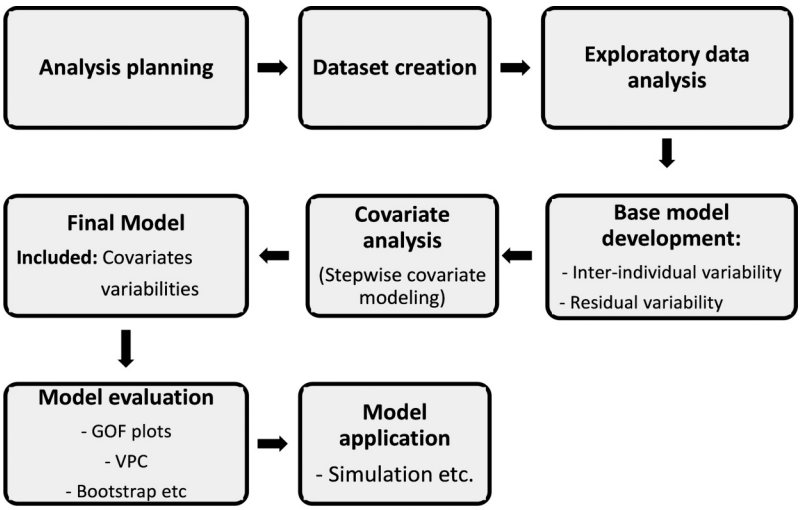

Figure 2 Schematic plan for population pharmacokinetic modeling.

dosing events, plasma concentration-time data, and patients' demographics (e.g., age, body weight, height, gender, etc.). Different data management packages can be used for generating data files which include spreadsheets, text editors, or programming languages such as SAS (Statistical Analysis Software) or R (R development Core Team 2013). A quality control review of the dataset with focus on individual fields and a structure of dataset should be performed when the dataset is not created by the modeler.

Exploratory Data Analysis (EDA)

Prior to running the initial model, an exploratory review of the data should be performed with the help of graphical and tabular summaries in order to explore the relation between the information available and the models to be evaluated. These summaries may also help in identifying extreme values in datasets, obvious trends in data, and outliers required for exclusion. The large complicated datasets can be analyzed by different scatterplots, boxplots, and frequency distributions of population related, dose related, and concentration related data to get the understanding of the available information in the data.

Development of Base Model

After getting the complete information of the dataset to be used for population pharmacokinetic modeling, model fitting may be started with a simplest model in order to portray the overall nature of the data, then proceeding to more complex model as long as more variability is explained and more information is gained. Therefore, the base model can be defined as the model that can appropriately describe the basic pharmacokinetic characteristics including between subject variability estimation on limited parameters and residual variability by using the simplest error model. Usually, a base model does not contain the influence of any covariate on pharmacokinetic parameters. However, the covariates with highly significant influence are necessary to obtain a base model. Several model diagnostic plots can be used to interpret the results of model fit. A table file is generated by NONMEM® after the successful run which includes the values of dependent variable (DV), population predictions (PRED), individual predictions (IPRED), residuals (RES), and weighted residuals (WRES) in addition to requested values. DV is the value of observed concentration included in the dataset. PRED is the model-predicted concentration of population corresponding to DV. The IPRED is the predicted concentration calculated once the effect of individual-specific random effects is taken into account. The RES is the difference between DV and PRED and is calculated as:

$$RES = DV - PRED \tag{1}$$

If the value of RES is positive, it indicates the points where the population concentrations are underpredicted (DV > PRED) and negative values represent the points of overestimation of PRED (PRED > DV). The WRES is the weighted difference between DV and PRED (Hooker et al., 2007). This can be calculated as:

$$WRES = \frac{DV - PRED}{\text{Residual error}} \tag{2}$$

Hooker et al. in 2007 (Hooker et al., 2007) illustrated that WRES are calculated by First Order (FO) approximation even if First Order Conditional Estimation (FOCE) method was used for estimation purpose which can lead to misguided diagnostic plots. They introduced conditional weighted residual (CWRES) which is calculated by using FOCE method and is a more appropriate model

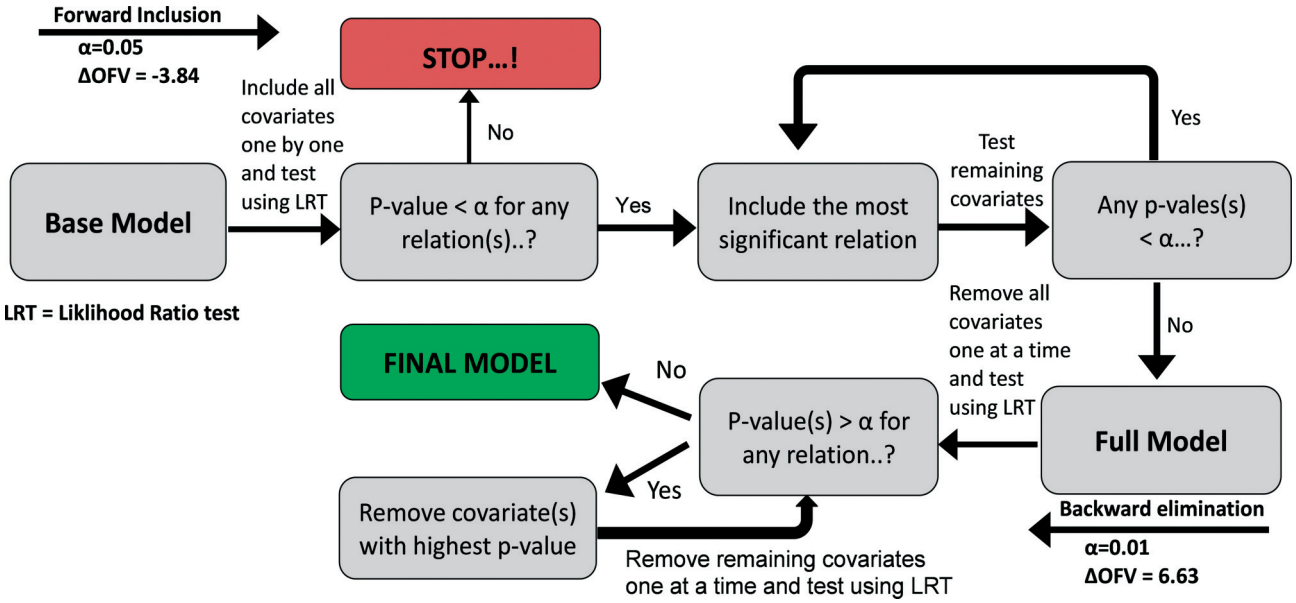

Figure 3 Stepwise covariate modeling—a forward inclusion process followed by a backward elimination process. Source: Adapted from NONMEM Workshop held in Köln, Germany on 11–12 Oct. 2014. Courtesy Dr. Ahmed Abbas Suleiman.

diagnostic for model performance. Moreover, CWRES can also be calculated by FO method combined with a post hoc step. The value of CWRES should be equally distributed around a mean 0 and are expected between −3 to +3, higher values indicate worse fitting points (Joel and Owen, 2014).

Covariate Analysis

Many methods describe the process for the evaluation of between-subject and within-subject variability with respect to patient-related factors. A covariate can be described as a patient specific variable that can influence the pharmacokinetics or pharmacodynamics of drugs and can be categorized as continuous covariates (age, weight, height, etc.), dichotomous covariates (e.g., gender), or polychotomous covariates (race, smoking habit, etc.) (Bonate, 2011). The influence of a covariate on the improvement of a model can be measured by several ways. The most desirable tool for decision making is the statistical measure of improvement in model. The addition of the influence of a covariate to the model must decrease the objective function value (OFV = −2 × log of likelihood; −2LL) to a significant level. The selection of the covariates in final model can be made by stepwise covariate modeling (scm) on the basis of forward inclusion process and backward elimination process. During forward inclusion, all the covariates are added one by one and a covariate is included to the model if a significant ($P < 0.05$) drop in OFV (≥3.84) is observed between two nested models after inclusion of that covariate. The importance of included covariates should be reassessed by backward elimination process by using a stricter criterion ($P < 0.01$) in which a covariate is removed if a significant increase in objective function value (ΔOFV ≥ 6.63) is not observed after elimination of that covariate. The resulting model can be considered as the final model. Fig. 3 illustrates the scm.

Model Evaluation

Model evaluation is the assessment of its predictive performance or the determination of model deficiencies on substantive conclusions (Yano et al., 2001). The FDA guidance for population pharmacokinetics describe several methods for model validation which include internal and external validation, assessment of predictive performance, objective function evaluation, goodness of fit plots, bootstrapping, visual predictive checks, etc. (Food and Drug Administration, 1999).

Internal validation

Internal validation procedure should be planned carefully and should be described in DAP. For internal validation, a randomly selected portion of dataset (validation dataset) is set aside and model development should be performed with remainder dataset. After the development of final model, it should be used for the prediction of observations in the validation dataset in order to observe whether the model is appropriate for the characterization of data (Sheiner, 1982).

External validation

In external validation procedures, the developed model is validated against the validation dataset similarly as in internal validation. The difference is the source of validation dataset which is obtained from a study independent of the study used for model development.

Predictive performance assessment

The predictive performance of models can be assessed by using easy statistics by comparing the observed values in a validation dataset to the model predicted values in order to assess the bias and precision of the model (Sheiner and Beal, 1981). This can be performed by calculating the prediction error (PE) as follow:

$$PE_j = pred_j - obs_j \tag{3}$$

where $pred_j$ is the predicted value and obs_j is observed value of jth individual. The positive and negative values of PE indicate the overprediction and underprediction by the model, respectively. The overall bias in the model can be predicted by calculating the mean prediction error (MPE) in which the mean of PE are calculated as:

$$MPE = \frac{\sum(PE)}{N} \tag{4}$$

where N is the total number of observation. Similar to PE, MPE is also either positive or negative indicating, overprediction or underprediction respectively. The positive or negative signs from the PE can be removed by calculating absolute prediction error (APE) as;

$$APE_j = |PE_j| \tag{5}$$

For expression of these statistics in percentage units, it should be mentioned whether the percentage is calculated relative to observed value or predicted value. Eq. (6) shows the calculation of mean absolute prediction error (MAPE).

$$MAPE = \frac{1}{N}\sum_{j=1}^{N}\left[\left(\frac{|pred_j - obs_j|}{obs_j}\right)\times 100\right] \tag{6}$$

A prior criteria (e.g., $<\pm$10% for MPE and $<$25% for MAPE) must be mentioned in the analysis plan in order to assess the model validity.

Goodness of fit plots

Goodness of fit (GOF) plots are the analysis of the different scatterplots based on their graphical nature or by use of metrics in order to demonstrate the validity of a model. The most common parameters used in diagnostic plots include DV, PRED, IPRED, RES, WRES, and CWRES. The commonly used diagnostic plots described in literature are as follow:

- DV versus PRED
- DV versus IPRED
- CWRES versus PRED
- CWRES versus Time after Dose

Bootstrap analysis

Internal validation of a model by using a validation dataset, where a portion of dataset is kept aside, may prove ineffective when only limited data is available for modeling (Parke et al., 1999). Bootstrap is another technique used for internal validation of the model with the advantage of using the entire dataset. It involves creation of multiple new datasets of the same size as an original dataset, with different combinations of the subjects, by intensive and effective resampling from original dataset and fitting the model to each dataset in order to assess the accuracy of parameter estimation in a wider population (Parke and Charles, 2000). A large number of datasets are generated by repeating this process for many hundreds or thousands of times (at least 500 times) (Joel and Owen, 2014). The FDA proposed at least 200 replicates (Food and Drug Administration, 1999). The summary statistics (median, mean, maximum, minimum, and 95% confidence interval based on 2.5th and 97.5th percentile of distribution) are calculated for each parameter across the bootstrap estimates and compared with the final parameter estimates of the original model in a tabulated form (Joel and Owen, 2014). The convergence criteria for acceptability of bootstrap should also be specified in the analysis plan (e.g., 945 samples successfully minimized out of 1000 samples indicates 94.5% rate of convergence). In addition to the comparison of bootstrap and final model parameter estimates, a predefined convergence criterion should also be met for the acceptance of bootstrap results (Joel and Owen, 2014).

Visual predictive checks

Karlsson and Savic in 2007 proposed the visual predictive check (VPC) procedures for model evaluation. The theory behind this technique is that if the model is a correct description of data, then the simulations performed on the basis of developed model will produce a very similar simulated data as the original data used for the model development (Karlsson and Savic, 2007). This means that the plasma concentrations of a patient are simulated for hundreds or thousands (usually 1000) of times and then compared with the original observations. Typically, the results of VPC are presented graphically where the median and the 5th and 95th percentile (90% CI) of the simulation are shown in a graph with the observed data. If the observed data are within the simulated percentile, the predictive power of the model can be considered as good (Post et al., 2008).

Table 1 Advantages of NONMEM

1.	Data originated from patients in clinical settings
2.	Involves diverse demography and patient profile variation
3.	Accounts for concomitant drug and disease
4.	Noninterventional
5.	Sparse data including TDM
6.	Ideal for neonates, children, and geriatrics
7.	Useful for understanding pharmacokinetics of orphan drug
8.	Provides a clinically applicable expression for dose correction
9.	Devoid of ethical issues related with interventional studies and clinical trials

Model Application

A normal extension of a developed model is its use for simulation to get the answers of various questions regarding study design conditions. The simulation conditions are used to find the effect of these conditions on study outcomes which are further used for subsequent decision-making regarding clinical aspects (i.e., dose optimization) or regulatory affairs (i.e., drug approval) (Joel and Owen, 2014). The scope of this chapter is restricted to the role of pharmacometrics in CDM, discussed in the following section.

Advantages of NONMEM

Table 1 shows the key advantages of pharmacometrics over the conventional PK data originated from clinical trials.

Role of Pharmacometrics in Clinical Decision Making

The role of pharmacometrics in CDM is pivotal. It can also be used in dose optimization for individual patients and for prevention of adverse drug reactions and drug interactions through pharmacokinetic modeling. In modern practice, computerized decision-making systems known as clinical decision support systems (CDSS) are used for ensuring incorporation of critical information on clinical decisions (Sim et al., 2001). Fig. 4 describes how the patient data can be modeled using popPK to identify risk factors and then feeding this information to the CDSS can enhance the achievement of intended kinetic profiles avoiding therapeutic failure and

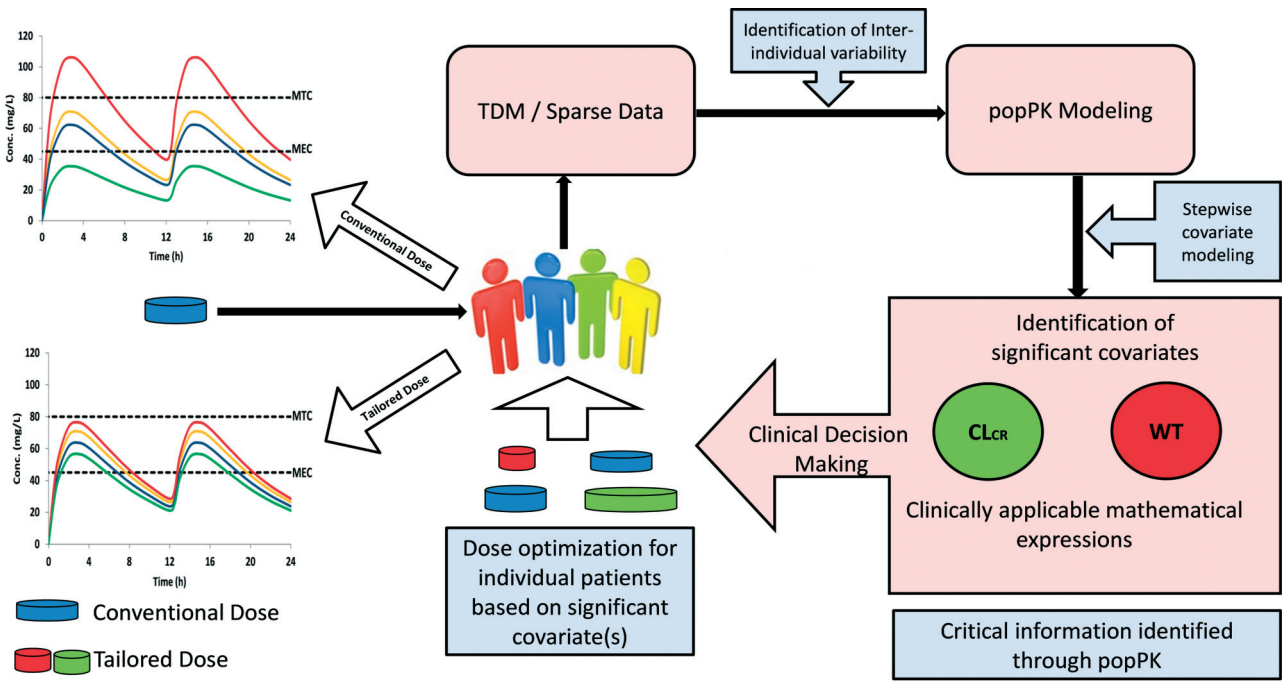

Figure 4 Schematic flow showing patient data using conventional dosing (*solid blue line*) and its application to produce information for use in clinical decision-making systems and the expected outcome.

toxicity. CDSS are used for prescription alerts on the dose adjustment for the potentially toxic medicines like anticancer drugs in case of renal impairment (Krens and Damhof, 2016).

Dose Optimization

The term "precision medicine," as described by the US FDA, is an innovative approach for the prevention and treatment of diseases by taking into account the variability among individuals based on genetic makeup, lifestyle, and environment (US Food and Drug Administration). Hence, it can be used for tailoring the dose for individual patients in order to ensure the administration of right drug to right patient in right dose. With the advancements in the field of bioinformatics along with the availability of large scale biologic databases, patient characterizations methods, and computational techniques for mathematical and statistical analysis of big data has led to the application of precision medicine to the clinical settings (Collins and Varmus, 2015). Antimicrobial agents are good candidates for dose optimization through modeling and simulation technique (Zhao et al., 2014) in order to enhance the therapeutic success on one hand and also to prevent the incidents of therapeutics failure and development of antimicrobial resistance on the other hand. Dose optimization is also necessary to reduce the "financial toxicity" to the patients and caregivers (Nair and Kong, 2018).

The lack of guidance documents and information tools regarding the selection of dosage regimen for antimicrobial agents is a big challenge being faced by antimicrobial stewardship programs. The appropriate dosage regimen can be evaluated by taking into account the patient demographics, susceptibility of pathogenic microbes, and pharmacokinetic—pharmacodynamic targets for antimicrobial agents. This unmet need was addressed by development of an educational mobile application consisting of Monte Carlo simulation algorithm integrating the patients' demographics, pathogenic susceptibility, and assessment of PK-PD target attainment for 35 antimicrobial agents against 29 infection categories. Population pharmacokinetic models were developed, evaluated, and refined for each antimicrobial agent. The susceptibility breakpoints for the pathogenic microorganism were defined based on guideline of US FDA, Clinical Laboratory Standards Institute (CLSI), and European Committee of Antimicrobial Susceptibility Testing (EUCAST). These information were incorporated to one interface, enabling the clinicians to select the antimicrobial agent of interest, target pathogen and infection type in order to obtain the percentage probability of target attainment (PTA%) for each dosage regimen based on patient's characteristics. Such algorithm can be helpful for the clinicians in selection of optimized dosage regimens of antimicrobial agents through the lens of PK-PD (Bulik et al., 2017). The commonly used PK-PD indices include the percentage of time above MIC of pathogenic bacteria (%$T >$ MIC), the ratio of maximum plasma concentration to MIC of bacteria (C_{max}/MIC), the ratio of minimum plasma concentration of the drug to MIC (C_{min}/MIC), and the ratio of area under the serum concentration time curve to MIC (AUC/MIC). The most commonly used PK-PD index is the %$T >$ MIC as this is attributed to the antibacterial possessing time dependent antibacterial activity (Zhou et al., 2011).

Clinical settings with small number of patients and drugs with complex pharmacokinetics hinder the conduct of clinical trials for dose optimization. The model-based simulation approach has played tremendous role in CDM for designing the tailoring dosage regimens based on the pathophysiological conditions of the patients, particularly in vulnerable populations such as children and elderly.

Sample popPK Profiles of Critical Medicines

Drugs with narrow therapeutic indices and the antibiotics of WATCH and RESERVE group (World Health of Organization, 2017) are of critical interest to pharmacists for their application in CDM because of their potential to produce toxicity and antimicrobial resistance in case of subtherapeutic doses, respectively. Some examples of these medicines are discussed below for sharing the information needed for dose optimization.

Vancomycin

Vancomycin is included in WHO's WATCH group antibiotics and the emerging resistant of MRSA to vancomycin is a huge concern globally. Inappropriate dosing of antibiotics can lead to subtherapeutic drug levels resulting in development of antibiotic resistant. Vancomycin is widely used in neonates, critically ill patients, and other vulnerable groups and therefore had been studied for dose optimization using popPK modeling.

An easy-to-use chart was developed for clinicians in order to adapt the schedule for dosing of vancomycin in pediatric cancer patients (Guilhaumou et al., 2016). A method for dose adjustment of vancomycin based on renal status in ICU neonates has also been reported (Li et al., 2018). Application of modeling and simulation-based dosing compared to mg/kg dosing in children with malignant hematological disease reduced the variability in AUC and Css/min values, resulting in improved therapeutic outcomes (Zhao et al., 2014). A higher dose of vancomycin was also recommended to achieve therapeutic concentration in patients during high-volume hemofiltration (Escobar et al., 2014). An important finding for vancomycin is that unlike renal clearance in adults, the body weight of neonates is identified as the significant covariate determining the pharmacokinetics of vancomycin (Anderson et al., 2007; Lo et al., 2010; Zhao et al., 2014). Similarly, dose optimization for vancomycin has been reported in different clinical conditions such as in trauma patients (Medellin-Garibay et al., 2016), postoperative neurosurgical patients (Li et al., 2016), and patients undergoing hemodialysis (Gunning et al., 2016).

Patient case studies have also been reported for individualized dose optimization after taking into account all the significant covariates affecting the clearance of vancomycin in Chinese patients (Lin et al., 2016).

Case study 1

A 69-year-old female patient developed high grade fever, neck stiffness, and headache 2 days after undergoing acoustic neuroma surgery. She was diagnosed with postcraniotomy meningitis (PCM) based on the presence of *Staphylococcus capitis* in cerebrospinal fluid (CSF) and blood cultures. Administration of vancomycin every 12 h was recommended to combat the infection. The clearance of creatinine for the patient was 40.6 mL/min and her body weight was 65 kg. The pharmacist simulated the vancomycin trough concentration by using the developed popPK model and taking into account the demographics of the patient based on significant covariates. The estimated trough concentrations were 8.5, 12.8, 17.0, 21.3, and 25.5 mg/L, respectively for the dose of 500, 750, 1000, 1250, and 1500 mg vancomycin administered every 12 h through i.v. infusion. The target trough concentration range (TTCR) was selected as 15–20 mg/L keeping in view the severity of the infection. Therefore, a dosage regimen of 1000 mg vancomycin every 12 h was administered to the patient. After 2 days, the blood samples were collected 5 min before the drug administration in order to observe the trough concentration, which was 15.7 mg/L. The body temperature of the patient returned to normal and the reports for her CSF and blood culture were negative after 10 days of treatment with recommended dose of vancomycin.

Case study 2

A 62-year-old male patient developed high fever, neck stiffness, and headache 3 days after undergoing glioma operation. He was diagnosed with PCM due to the presence of *Staphylococcus capitis* in cerebrospinal fluid (CSF) and blood cultures. Administration of vancomycin and meropenem every 12 h was recommended for the treatment of the infection. The creatinine clearance of the patient was 45.7 mL/min and his body weight was 68 kg. The pharmacist simulated the vancomycin trough concentration by using the developed popPK model and taking into account the demographics of patient based on significant covariates. The estimated trough concentrations were 7.8, 11.7, 15.7, 19.6, and 23.5 mg/L for the dose of 500, 750, 1000, 1250, and 1500 mg vancomycin administered every 12 h through i.v. infusion, respectively. A 1000 mg dose every 12 h was selected to maintain the target trough concentration range (TTCR) between 15 and 20 mg/L keeping in view the severity of infection. The TDM report revealed the trough concentration as 26 mg/L, which was above the required trough level. Given the possible risk associated with this high trough level, the pharmacist estimated the concentration once again by incorporating all the significant covariates in popPK model. The Bayesian method was used to acquire the TDM results in order to lower the trough concentration levels of vancomycin for ensuring patient's safety. The new predicted trough concentrations were 18.1, 23.3, 28.5, 33.7, and 38.9 mg/L, respectively for 500, 750, 1000, 1250, and 1500 mg of vancomycin as an i.v. infusion every 12 h. Based on this prediction, 500 mg of dose was selected to be administered every 12 h. This time the trough concentration from TDM record was observed as 19.6 mg/L. The body temperature of the patient returned to normal after 8 days of treatment with simulation-based recommended dose of vancomycin and meropenem.

Valproic acid

Valproic acid, an antiepileptic drug, is being used for the treatment of both partial and generalized seizures. A number of popPK models have been developed for identification of significant covariates on pharmacokinetics of valproic acid among which body weight, dose, coadministered drugs, age, and gender proved to be significant covariates for valproic acid clearance while weight and dose significantly influenced volume of distribution (Methaneethorn, 2018). Lin et al. have developed a popPK model in Chinese population and have used their model for individualized dosing of patients in their affiliated hospital (Lin et al., 2015). They reported a case as follows:

Case study 3

A 23-year-old male patient suffering from complex partial secondarily generalized seizures had been receiving carbamazepine 300 mg TID, clonazepam 1 mg TID, and valproic acid 500 mg BID. However, he was still having seizures 1–2 times daily. In popPK model, carbamazepine was a significant covariate for clearance of valproic acid. Thus, the level of valproic acid may not be reaching to the minimum effective concentration when coadministered with carbamazepine. The trough concentration of valproic acid was estimated using the established popPK model by taking into account the demographics of patient medication information. The predicted trough concentrations with dose of 250, 500, 750, 1000, and 1250 mg BID were 27.57, 45.83, 61.49, 75.61, and 88.61 mg/mL, respectively. A 500 mg BID dose of valproic acid may not be sufficient to achieve the target concentration within the therapeutic window (50–100 mg/mL), while 750 mg BID will likely achieve the target despite coadministration with carbamazepine. Therefore, 750 mg BID dose was selected for this patient with continued administration of other medications. The TDM report, after 3 months of continuous treatment with simulation-based dose selection, showed the trough concentration of valproic acid as 60 mg/mL. The frequencies of seizures decreased gradually, and the patient had no seizures attack for approximately 2 months in addition to normal liver function.

Meropenem

Meropenem, a potent carbapenem, is effective against a variety of bacteria including gram positive and gram negative anaerobes, Enterobacteriaceae, and Pseudomonas species. In popPK studies of meropenem, CL_{CR} is the most consistent covariate for meropenem clearance (Kees et al., 2016; Ulldemolins et al., 2015; Usman et al., 2017). In a popPK model of meropenem, different dosage regimens of meropenem, based on dose and dosage intervals, were simulated keeping in view the renal status of the patients. The most appropriate dosage regimens were defined and tailored dosage regimens were recommended for patients with different renal status (Usman et al., 2017).

Phenobarbital

The TDM data of 53 neonates was obtained and used for the development of popPK model by using NONMEM® software. The effect of different covariates was observed on clearance and volume of distribution of phenobarbital. The birth weight and postnatal age (PNA) were the most significant covariates for phenobarbital clearance. The dose optimization of phenobarbital based on PNA and birth weight was recommended for term and preterm neonates (Voller et al., 2017).

Prevention of Drug Interactions

Drug interaction is a primary cause of adverse drug reactions and is a significant challenge in current clinical practice. The extraction of pharmacovigilance data and pharmacokinetic modeling are computational tools for integration of drug interaction knowledge and generation of drug interaction hypothesis (Zhang et al., 2018). The major areas where pharmacometrics has a vital role is drug interaction research where the numerous patient databases such as electronic medical records, electronic health records, and spontaneous reporting systems are being maintained for epidemiological studies and post marketing surveillance by different hospitals, regulatory agencies, and research organizations. Drug-drug interactions (DDIs) are being identified and prioritized through the development of computational models based on data obtained from research communities and hospitals (Harpaz et al., 2012).

The pharmacokinetic DDIs are also being predicted by the use of modeling approaches like stepwise covariate modeling in popPK and PBPK. A popPK-based simulation study recommended a dose reduction or increase in dosage interval of vancomycin when coadministered with frusemide (Medellin-Garibay et al., 2016). In another study, the coadministration of spironolactone decreased while amoxicillin-clavulanic acid increased the clearance of vancomycin (Marques-Minana et al., 2010). The interaction of carbamazepine, phenobarbital, and phenytoin with clearance of valproic acid was identified and this information was used for designing the individualized dosing regimens for valproic acid as described in case study 2 above (Lin et al., 2015).

Conclusion

Pharmacometrics is a novel science that quantifies the interaction between drugs and patients by interlinking the biology, physiology, and pharmacology with disease condition through mathematical models. The data and information collected from different sources are linked together quantitatively. The quantitative answers are required for the questions raised during clinical use regarding safety, efficacy, and dosage regimen or more specifically to design individualized dosage regimen of pharmaceutical products. Pharmacometric analysis can provide arguably better insight than any other available tool to answer these questions when utilized by trained clinician or researcher. Nonlinear mixed effect models (NONMEM) have been commonly used for the population-based pharmacometric analysis. Furthermore, the US FDA considers modeling technique utilizing NONMEM software as a gold standard. The analysis of sparse data is a unique feature of NONMEM, offering a valuable advantage for patients from whom sample collection is difficult including neonates and other critically ill pediatric and geriatric patients. These vulnerable patient groups are also the ones for whom the appropriate dose selection is critical. The development of PK model and establishment of relationships between the PK parameters and patient's demographics can enable the clinicians to devise the appropriate dosage regimen for individual patients ensuring the safe and effective treatment of underlying clinical conditions.

Dynamic Relationship Between Education, Regulation, and Practice: Case Studies and Examples

Michael J. Rouse[*], **Lina R. Bader**[†], [*]Accreditation Council for Pharmacy Education (ACPE), Chicago, IL, USA; [†]International Pharmaceutical Federation (FIP), The Hague, Netherlands

Introduction

This chapter presents eight case studies that provide a more detailed description of a conceptual framework which describes the dynamic relationship between education, regulation and practice. The conceptual framework describes that in any professional arena, there is a dynamic relationship between three interrelated professional sectors: practice, education, and regulation (International Pharmaceutical Federation (FIP), 2008, 2014) (**Fig. 1**).

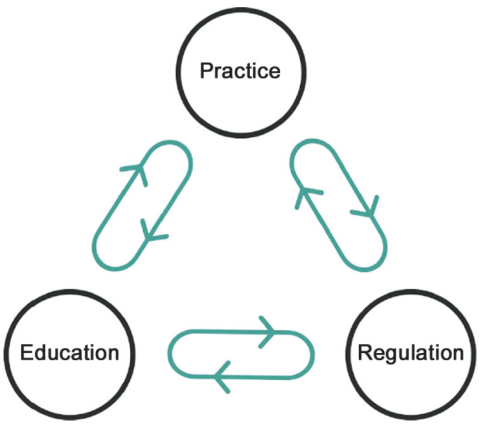

Figure 1 A conceptual framework depicting the dynamic relationships between practice, regulation, and education. *Source: Adapted with permission from International Pharmaceutical Federation, 2014.*

The framework was first developed by author Rouse in the early 2000s as a result of his work with the Accreditation Council for Pharmacy Education (ACPE), the U.S. national accreditation agency for pharmacy education. The framework was first published in the Global Framework for Quality Assurance of Pharmacy Education (Version 1), which was adopted in 2008 by the International Pharmaceutical Federation (FIP)—the global leadership body for the pharmaceutical workforce worldwide (International Pharmaceutical Federation (FIP), 2008, 14).

Between 2013 and 2014, the framework was validated and used in a country-level study in Jordan. Preliminary research resulted in the identification of eight major challenges facing the professional arena in Jordan. National stakeholders used the framework to map each of the challenges to the primary sector-to-sector disconnect that they perceived to explain it (Bader et al., 2017). Between 2017 and 2018, the authors collected country and regional case studies using the tool for publication in the Encyclopedia. The purpose of this was to further utilize the tool's descriptive and prescriptive purposes in other countries around the world and to help national stakeholders reflect on successful developments and assess any existing challenges. An initial scoping survey was distributed to the authors' contacts around the world. The scoping survey served to identify preliminary case studies that were evaluated by the authors for inclusion in the chapter. A total of 10 initial submissions spanning 10 countries were received. In-depth case study templates were then sent to these country contacts and reminders were distributed. From this scoping survey, seven full case studies were received and included in the chapter; these case studies span the following countries and regions: Brazil, Europe (with specific examples from Spain), Japan, Nigeria, Oman, Romania, and Taiwan. With the exception of South East Asia, all World Health Organization (WHO) regions are represented in this study. One additional case study from the United States was then purposively identified to provide an example of a country where a structure had been established to promote and facilitate active and ongoing communication, interaction and collaboration between the practice, education, and regulation sectors within the profession, thereby illustrating how the conceptual framework can and should work in a country. The case studies describe varying issues that touch on different sectors—demonstrating the usability of the whole conceptual framework.

This chapter reports on these case studies. Each case study is accompanied by a descriptive, contextual background on education, regulation, and practice in the country or region and an analysis of the dynamic sectoral relationship(s) reported by the case study authors. Drivers and barriers to advancement, lessons learned, and implications for future planning are also discussed. The chapter authors carefully reviewed the case studies, edited them, and returned them back to their original authors for validation. The authors of the case studies are acknowledged at the end of the chapter.

Case Studies

Using the conceptual framework, Fig. 2 provides an illustrative summary of the case studies and where the dynamic relationship(s) reported in each case study lies.

Brazil

Background

Education and training of pharmacists

Entry for students to pharmacy school occurs via an entrance examination or a national test for high school students (National High School Examination—ENEM). Pharmacy graduation requires a minimum study load of 4000 h distributed over 5 years. After graduation, pharmacists must register with the Regional Council of Pharmacy of their state to obtain a professional registration, and

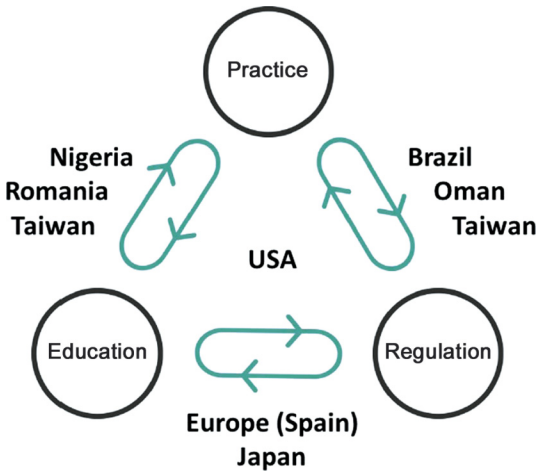

Figure 2 Summary of the dynamic relationships reported by the eight case studies.

they enter the labor market to practice in their area of interest. The pharmacists are not evaluated again to verify the maintenance or improvement of their professional competencies. Two types of postgraduate programs exist in Brazil: one at higher education institutions, with an academic purpose (postgraduate programs, *sensu stricto*), and the other aimed at professional qualifications (postgraduate programs, *sensu lato*), including residencies.

Regulation of Practice

Pharmacy practice is regulated through legislation by the Brazilian Government, regulations of the agency for control of health products and services (Brazilian Health Regulatory Agency, ANVISA), and Federal and Regional Council Resolutions. These laws provide for the education/training of pharmacists, registration, and professional responsibilities in the various areas and rules/procedures for the functioning of the Councils and establishment of pharmaceutical practice.

Oversight and Quality Assurance of Education

Higher education is regulated by the Conselho Federal de Farmácia (CFF, Brazilian Federal Council of Pharmacy) Resolutions and the Brazilian Ministry of Education legislation. Specialization courses and Master's-level, doctoral and post-doctoral programs exist, and they are subject to authorization requirements and accreditation provided through legislation of the Ministry of Education. Residency programs were created by Federal Law in 2005.

Pharmacy Practice

Pharmacy practice is structured along the following axes: health-care provision, management, and technology/innovation. Health-care provision is the set of actions and services offered to the individual, family, and community, conducted through the promotion, protection, and recovery of health, along with disease prevention. Management encompasses technical, political, and social processes and the ability to integrate resources and actions to achieve results. Technology practice is the organized use of scientific knowledge in the research, development, production, quality assurance, and provision of goods and services; whereas, health innovation is related to the introduction or improvement of processes, products, strategies, or services, with positive repercussions on individual and collective health. In Brazil, the main challenge is related to clinical pharmacy, because it is not yet consolidated to the same extent as in other countries.

The Relationship Between Practice and Regulation

The pharmacy profession in Brazil has undergone continual transformations over the last two centuries and has excelled in many fields of activity due to the ability of the profession to renew and adapt to the market. In some areas of practice, the regulatory sector stands out as a positive driver for change in the practice sector, particularly in clinical pharmacy and professional education (Fig. 3). The Federal Council of Pharmacy (CFF) is a member of the Brazilian executive branch, with full autonomy, officially in charge of professional regulation and pharmacy licensing, including pharmacists and companies that perform activities related to the pharmacy. Therefore, important professional legislation is published by the CFF, while other regulations derived from the Brazilian government and the agency responsible for control of health products and services (ANVISA).

Particularly in clinical pharmacy, some of this legislation broadened the scope of the profession. For example, the publication of Federal Law 13.021 innovated by transforming pharmacies and drugstores into health units and by authorizing the administration of vaccines in these establishments. The impact of this law has brought about the need for change in many other resolutions, which will probably expand pharmacists' health-care services. Published CFF legislation has also contributed to the expansion of the scope of the profession, for example, CFF Resolution 585/2013 (Conselho Federal de Farmácia (CFF), 2013d), which establishes the clinical attributions (rights and responsibilities) of the pharmaceutical profession, and CFF Resolution 586/2013 (Conselho Federal de Farmácia (CFF), 2013e), which regulates pharmacist prescribing.

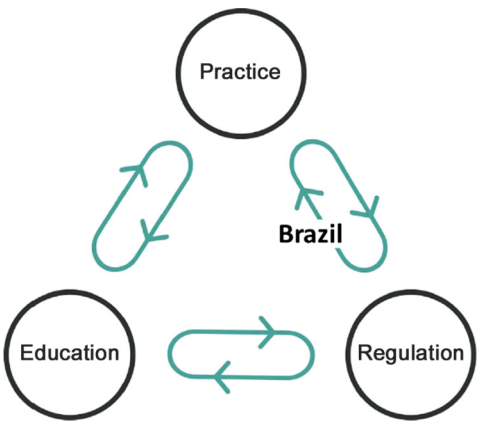

Figure 3 The regulatory sector is a positive driver for practice change in Brazil.

Legislation enacted in education was also a factor that contributed to change of the professional training model and to meeting the demands generated by the updating of the professional practice resolutions. The new curriculum guidelines published in 2017 (Ministério da Educação (MS), 2017) represent a major advance for the professional training of pharmacists and reshaped the training of pharmacists based on three axes: health care, technology, and innovation in health and health management. Notably, 50% of the course workload is now targeted for health care. The CFF also published important resolutions in the area of education, such as CFF Resolution 581 (Conselho Federal de Farmácia (CFF), 2013b), which established the title of professional pharmaceutical specialist, without academic characterization, and CFF Resolution 582 (Conselho Federal de Farmácia (CFF), 2013c), which regulates the recognition of courses for professional pharmaceutical specialization.

However, in the field of esthetic health (National Center for Biotechnology Information (NCBI), 2018), resolutions were passed to regulate procedures already performed by pharmacists in practice. This situation is also common to other health professions, which have also broadened their scope to encompass esthetic health, for example, nursing, dentistry, and biomedicine. Accordingly, the CFF published three resolutions. In 2013, esthetic health was recognized as within the pharmacist's scope of practice, through Resolution 573 (Conselho Federal de Farmácia (CFF), 2013a). This resolution regulates the duties of the pharmacist in the practice of esthetic health and technical responsibility for the establishment that performs related activities. The publication of this resolution also consolidates an important market activity. Additionally, CFF Resolution 616 (Conselho Federal de Farmácia (CFF), 2015) emerged, which defines the technical requirements for the pharmacist's practice in esthetic health and expands the number of techniques and therapeutic resources used by the pharmacist in esthetic health establishments. This resolution was amended by CFF Resolution 645 (Conselho Federal de Farmácia (CFF), 2017).

Although the regulatory sector stands out as a positive driver in specific areas of the profession, it is possible to observe the dynamics and synergies among the practice sectors, regulation, and education in Brazil. The professional practice advances strongly supported in the elaboration of guidelines of clinical practice and in the systematization of the continuing education of pharmacists. In the field of education of new pharmacists, advances have been made in the unification of the two national entities for pharmaceutical education. There is a long way to go with respect to teacher development to design and delivery a competency-based educational program, as well as the use active teaching-learning methods. Despite these challenges, in the field of education, there is a national perception of what is the way forward in educational processes.

Drivers for Advancement

Four important drivers exist in Brazil for this practice:

1. state policies and health legislation;
2. the social needs of individuals and clients;
3. the marketplace and social division of labor; and
4. the internal processes of regulation and professional ideology

Barriers to Advancement

- Legislators and government technocrats: they are sensitive to lobbying and the lobbying of interest groups, including the pharmaceutical market. They are also sensitive to public opinion, and their decisions directly interfere with the laws that regulate the profession.
- Archaic and contradictory legislation: these are complex and sometimes raise conflicts between the allocation of pharmaceutical professionals and other health professionals.
- Health legislation: it is fairly dated and incomplete. The updating of professional legislation and terminology occurred mainly in the scope of professional practice (Brazilian Federal Council of Pharmacy). However, in the areas of health regulation (Health Surveillance) and health (Department of Pharmaceutical Assistance)—both within the Ministry of Health—progress is slow; for example, the misalignment between terms and techniques that have evolved over the years.
- Owners of pharmacies and drugstores do not value the pharmacist in the pharmacy.
- Some pharmacists who do not want to improve or be part of the change.
- Conflicts and legal disputes between professions: The Brazilian Federal Medical Council has filed several injunctions against the Brazilian Federal Council of Pharmacy. Until now, court decisions have been favorable to pharmacists. Other professional councils (Nutrition, Nursing, and Biomedicine), on a smaller scale, took legal action to prevent the expansion of pharmacy professional practice. To the same extent, they have not been successful with legal proceedings, although some demands are still under judicial review.

Important Lessons Learned

- A need exists to build a national professional initiative of Brazilian pharmacists in the coming years. These advances require an essential foundation of technical knowledge and important social and political strategies, which involve different areas. The first step is to build national unity in the pharmacy professional domain and prepare a strategic plan; specifically, the need to strengthen the "Fórum de Valorização da Profissão Farmacêutica" (Forum for Valuing the Pharmaceutical Profession). This Forum was established in 2014 and aims to identify strategic priorities for the development of the profession, as well as to integrate different sectors of society, such as councils, federations, labor unions, to achieve this.

- An evaluation of clinical services impact in Brazil is necessary. Research is highly important to the implementation of the services or products in practice. "Implementation science and sustainability" will comprise an important discussion within the next few years.

Implications and Future Planning

This case study allows reflection on the development of the pharmaceutical profession in various aspects. It also identifies breakthroughs, gaps, and challenges that still need to be overcome. The way forward is to consolidate the importance of pharmacists in Brazilian society; highlighting this for the population. In addition, stimulating research in the area as well as the dissemination of the results will contribute to the relevance of professional development. Finally, another important point is the need to encourage the continuous training of pharmaceutical professionals, in order to achieve excellence in practice.

Europe (With Specific Examples From Spain)

Background

Education and training of pharmacists

In Spain, as well as in all the European Union countries, the requirements are as follows:

1. 4 years of full-time theoretical and practical training at a university or at a higher institute of a level recognized as equivalent, or under the supervision of a university.
2. during or at the end of the theoretical and practical training, a 6-month traineeship in a pharmacy that is open to the public or in a hospital under the supervision of that hospital's pharmaceutical department.

Most countries have adopted a 5-year course, which in accordance with the European Higher Education Area Framework of Qualifications (European Commission, 2018) has a Master's level (Ministerio de Educación Cultura y Deporte, 2015).

Regulation of Practice

Regulation in Europe is according to European Directives 2005/36/CE and 2013/55/UE (European Parliament and Council, 2005, 2013), and Pharmacists can be established in any of the European Union countries in accordance with the principle of free movement of people. In general, community pharmacies are private health-care establishments of public interest, subject to the health-care planning established by the national or regional authorities.

Oversight and Quality Assurance of Education

In each country, there are national and regional agencies of accreditation. In Spain, for example, the agency is The National Agency for Evaluation of Quality and Accreditation (ANECA) (The National Agency for Evaluation of Quality and Accreditation (ANECA)). ANECA is a state foundation for the evaluation, certification, and accreditation of courses, programs, teachers, and institutions. There are recognized agencies in many "autonomic" (regional) communities that work in collaboration with the national agency, ANECA. Both national and autonomic agencies are recognized by the European Association for Quality Assurance in Higher Education (ENQA) (European Association for Quality Assurance in Higher Education (ENQA)). These agencies follow the directives of the European Higher Education Area (EHEA) member states.

Pharmacy Practice

According to European Directives 2005/36/CE and 2013/55/UE, the roles of pharmacists are as follows:

1. preparation of the pharmaceutical form of medicinal products
2. manufacture and testing of medicinal products
3. testing of medicinal products in a laboratory for the testing of medicinal products
4. storage, preservation, and distribution of medicinal products at the wholesale stage
5. supply, preparation, testing, storage, distribution, and dispensing of safe and efficacious medicinal products of the required quality in pharmacies open to the public
6. preparation, testing, storage, and dispensing of safe and efficacious medicinal products of the required quality in hospitals
7. provision of information and advice on medicinal products as such, including on their appropriate use
8. reporting of adverse reactions of pharmaceutical products to the competent authorities
9. personalized support for patients who administer their medication; and
10. contribution to local or national public health campaigns.

In Spain, the primary practice sectors are community pharmacy (regulated; i.e., restricted to pharmacists), distribution, hospital (regulated), pharmaceutical industry, other industries (including food, dietetics, and cosmetics), biological and chemical analysis, and others including public organizations and health administration services.

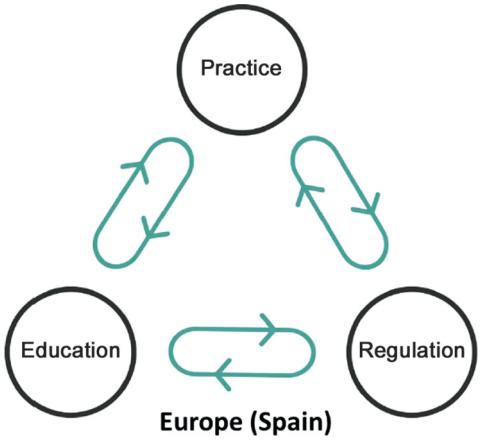

Figure 4 The beneficial effects of regulation on education in the case of Spain, Europe.

The Main Challenges Facing Pharmacy Practice in General

The economics and organization of health-care systems, with community and hospital pharmacists playing an increasingly important role in health-care systems: dispensing alone is no longer a sustainable economic retail model; to compete, pharmacies need to promote and expand their service offerings, get closer to consumers, and reduce economic and logistical inefficiencies. Pharmacogenomics may be one of the services to be incorporated soon, as the use of genetic testing offerings is becoming available within retail pharmacy settings, or it will be done by other professionals.

Advances in the pharmaceutical and biotechnology industries, with a move from small molecule medicines to therapies of biomedical origin: this has increased the growth of the specialty market, which will require special handling, administration, or monitoring.

The Relationship Between Regulation and Education

In this case study, we analyze the beneficial effects of "soft regulations," such as the European Directives (ED) and the EHEA's agreements on the changes in pharmacy education using, as an example, the case of Spain. See Fig. 4 for an illustrative description of the relationship between regulation and education reported in this case study.

Directives and EHEA are soft regulations, as they can be implemented in the different countries in accordance with their own laws. The result, however, has been that they have been adopted by most of the countries with little changes. Implementation is going on, although with a considerable delay. For example, in Spain, ED 2013/55/UE was incorporated into Spanish law as Royal Decree 581/2017 (Agencia Estatal Boletin Oficial del Estado, 2017).

The European Directives established the conditions for the activity in pharmacy and other health care professions, indicating the core elements and the education and training needed. As noted, countries are free to take these recommendations or not, but the result has been that at least for pharmacy programs, all faculties in Europe include the recommendations in their study plans. Harmonization is now the key word and there are many successful initiatives such as the European Community Pharmacy Blueprint. Professional chambers and professional associations are negotiating a new model for pharmacy based on competences (Consejo General de Colegios Oficiales de Farmaceuticos et al., 2018). Furthermore, in cases such as Spain and other Latin countries, the professional organizations are in the process of debating with the governments in order to prepare the profession for these principles. The abolishment of barriers together with easier recognition has significantly increased professional mobility. Currently, the implementation of a professional card is in process.

Starting with the so-called Bologna Process, universities and countries all around Europe agreed to increase the compatibility and comparability of their higher education systems, while at the same time respecting their diversity. The result has been the development of the European Higher Education Area (EHEA), based on institutional autonomy, academic freedom, equal opportunities, and democratic principles that will facilitate mobility, increase employability, and strengthen Europe's attractiveness and competitiveness.

The variability in Europe regarding degrees is high; however, two initiatives have reduced the problem considerably. The first is the adoption of the European Credit Transfer and Accumulation System (ECTS) (European Commission), which eliminates the ambiguity of the years of duration by introducing the estimated student workload. The second is the European Framework of Qualifications (EFQ) (European Commission, 2018), which establishes up to seven levels according with knowledge, skills, and responsibilities, and allows each country to find the equivalence. For example, the Spanish system (MECES) (Ministerio de Educación Cultura y Deporte, 2015) establishes four levels, and the degree in pharmacy MECES Level 3 (Master's degree) corresponds to Level 7 of the EQF. Another tool that helps recognition is the Diploma Supplement, which explains the degrees in more detail (European Commission et al.).

Finally, as a result of the increasing harmonization and to guarantee the quality of the studies, in all countries the accreditation processes have been implemented following the recommendation of the European Agency, ENQA.

Drivers for Advancement

The main drivers for the change in Spain have been the recognition of studies and professionals and the European mobility programs, such as Erasmus. The globalization in all fields goes in parallel with mobility and it requires recognition. This is especially true for health professionals, who clearly are a global workforce.

Barriers to Advancement

First, the main barrier is the lack of flexibility in the management of the changes, second, the lack of resources in some cases, and hird, the low level of recognition of the efforts made by educational professionals for their career promotion.

Important Lessons Learned

A "soft regulation" shared by the different actors can promote big changes in education.

Implications and Future Planning

- Implementation of competences and learning outcomes in all degrees: This is necessary in order to facilitate the rapid changes in the profession and to increase recognition. This applies both academically (as it is easier to recognize previous study based on achievement of competences rather than on content) and socially, especially in Spain, where the role of pharmacists is under-recognized. In this regard, the Pharmine and PHAR-QA projects have establish a framework of competences for use in community pharmacy (Pharmine; Pharmine).
- Recognition of specialties is needed in Europe: Pharmacy, like medicine, has the possibility for specialty curricula development, otherwise recognition would decrease. In the case of hospital pharmacy and, in general, in the development and recognition of pharmacy specialties, a good example is the Common Training Framework for Hospital Pharmacy (European Association of Hospital Pharmacists), a first step to the recognition of this specialty in Europe.

Japan

Background

Education and training of pharmacists

The Japanese School Education Act was revised in 2004, and the new 6-year initial pharmacy education program was implemented in 2006 (Ministry of Education Culture Sports Science and Technology, 2004). This substantial reform indicated that becoming a pharmacist requires not only sufficient practical training but also specialization and a demonstrated sense of humanity (Inui et al., 2016). Since this model core curriculum was implemented; however, several problems have been described (Inui et al., 2016). The model core curriculum was, therefore, revised, and the revised model core curriculum was implemented in 2015 (Inui et al., 2016). The basic policy of the revised model core curriculum was to foster "Professional Competencies for Pharmacists," which were stipulated as follows: (1) professionalism, (2) patient-oriented attitude, (3) communication skills, (4) interprofessional collaboration, (5) basic sciences, (6) medication therapy management, (7) community health and medical care, (8) research competency, (9) lifelong learning, and (10) education and training (Inui et al., 2016). In addition, the revised model core curriculum includes pharmacy practice training for 22 weeks (11 weeks in hospital and 11 weeks in community settings) and establishes some new criteria that prevent differences in practical training content by facilities, etc. (Ministry of Education Culture Sports Science and Technology, 2015).

Regulation of Practice

The systems currently in place in Japan issue various credentials to pharmacists (Yasuhara, 2016; International Pharmaceutical Federation (FIP), 2015; Araki, 2016):

- Certified pharmacists for pharmacy practical training (in hospital or in pharmacy) for students in a 6-year initial pharmacy education program
- Certified pharmacists through a continuing education program
- Certified pharmacists through related "specialty" societies such as the Japanese Society of Pharmaceutical Health Care and Sciences, the Japanese Society of Clinical Pharmacology and Therapeutics, the Japanese Society for Emergency Medicine, and the Japanese Society of Chemotherapy. Other certified pharmacists include "sports pharmacists," who play a role in helping to prevent doping in athletes; and
- Specialized pharmacists certified by the Japanese Society of Hospital Pharmacists in fields, such as oncology, infection control, psychiatry, HIV infection, pregnancy, and lactation.

Recently, the types of certified or specialized pharmacists were also increasing; some of these relate to the medical fee. These medical added fees can be calculated in cases where certified pharmacists or specialized pharmacists contribute to drug management, etc. (Araki, 2016).

Oversight and Quality Assurance of Education

The establishment of all universities or colleges is controlled by set standards of the Ministry of Education, Culture, Sports, Science and Technology (MEXT) (Ministry of Education Culture Sports Science and Technology, 2002). These standards differ between public or private, department and junior university. In accredited universities and colleges, self-assessment was in place since 1991, and it was mandated since 2004. The Japan Institution for Higher Education Evaluation (JIHEE) was founded in 2004, and has been authorized by MEXT as a certified evaluation and accreditation agency for universities and junior colleges, etc. (Ministry of Education Culture Sports Science and Technology, 2002; Japan Institution for Higher Education Evaluation, 2004). All universities or colleges must be evaluated on a 7-year cycle. The evaluation results are indicated by "conformity," "nonconformity," and "hold" and are publically disclosed. Universities or colleges that were evaluated as "nonconformity" and "hold" are required by MEXT to demonstrate improvement.

Pharmacy Practice

The nature of pharmacy practice is dispensing, instruction on dosage, and administration for patients, medication therapy management (prescription analysis, prescription proposal, and therapeutic drug monitoring), and home medical care in the community (Mochizuki, 2014). The main challenge is community health medical care in Japan (Saito, 2016; Tamiya, 2016).

The Relationship Between Regulation (Accreditation) and Education

In 2004, the Japanese School Education Act was revised, and the new 6-year initial pharmacy education program was implemented in 2006 (Inui et al., 2016; Ministry of Education Culture Sports Science and Technology, 2004). This substantial reform indicated that becoming a pharmacist requires not only sufficient practical training but also specialization and a demonstrated sense of humanity. The 6-year initial pharmacy education program was created based on the following policies (Inui et al., 2016):

- Training pharmacists suitable for current social and health-care needs;
- Students being the center of learning, and hence how they should achieve their goals must be clearly explained;
- Assessing whether students reach their educational goal;
- The balance between basic scientific and clinical subjects is maintained; and
- Practical professional training is comprehensive.

In these various changes, to assure quality of pharmacy education, the Japan Accreditation Board for Pharmaceutical Education established the Third-Party Pharmaceutical Education Evaluation in 2008 (Japan Accreditation Board for Pharmaceutical Education, 2018). This organization, which is the first to specifically evaluate colleges or universities of pharmacy in Japan, has been evaluating all such institutions with a 6-year initial pharmacy education program since 2012. The purposes of the evaluation are to ensure the quality of education programs, to promote their improvement, and to provide support for actively obtaining public understanding and cooperation (Hirata, 2015; Japan Accreditation Board for Pharmaceutical Education, 2018).

Evaluations are performed on the students and structure of each education program, and as of March 2018, 48 of the 74 universities have been evaluated. The evaluation has eight areas that comprise 57 standards and 176 viewpoints (Hirata, 2015; Japan Accreditation Board for Pharmaceutical Education, 2018). All evaluated universities or colleges would have self-assessed against the standards for the first time to check if their curricula, methods of evaluation of students' outcomes, and systems, etc. are appropriate. Each university or college of pharmacy, therefore, would have identified their problems, and the problems must be improved by the deadline set by Third-party Pharmaceutical Education Evaluation. Third-party Pharmaceutical Education Evaluation may serve to assure the quality of Japanese pharmacy education; however, since evaluation of graduates is not included in this system, most universities and colleges of pharmacy are not evaluating graduates (Hirata, 2015; Japan Accreditation Board for Pharmaceutical Education, 2018). The outcomes of pharmacy education are reflected by the quality and competence of graduates; therefore, the assessment system should include evaluation of the graduates in the near future. Regulation in the form of accreditation, therefore, drives changes in education (**Fig. 5**).

Drivers for Advancement

Third-party Pharmaceutical Education Evaluation: This organization, which is the first system to specifically evaluate colleges or universities of pharmacy in Japan, has been evaluating all such facilities with a 6-year initial pharmacy education program (Hirata, 2015; Japan Accreditation Board for Pharmaceutical Education, 2018). Assessments are performed on the students and the structure of each education program, and, the first cycle of assessment of all universities will be finished by 2019. Assessments will restart in 2020, and this audit will improve eight items that comprise 19 standards and 53 viewpoints; accordingly, assessment in the second cycle will be more in-depth than in the first cycle (Japan Accreditation Board for Pharmaceutical Education, 2018). All universities or colleges of pharmacy will self-assess against the evaluation items again. The QA of Japanese pharmacy education might be improved as a result in the future. On the other hand, it has already been decided that new universities and colleges of pharmacy will be established after 2018 (Ministry of Education Culture Sports Science and Technology, 2018). Universities and colleges of pharmacy, therefore, will require QA of pharmacy education more than now and will have to work on QA by themselves.

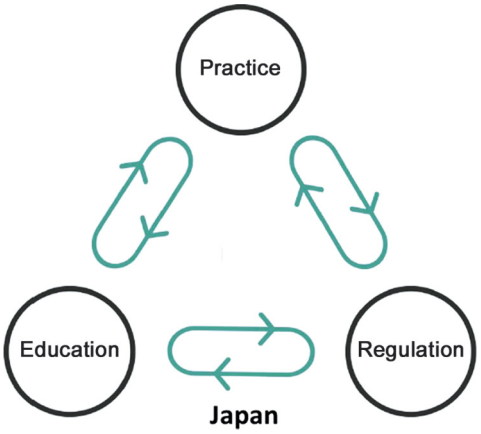

Figure 5 The relationship between regulation, in the form of accreditation, and education in Japan.

Barriers to Advancement

Universities and colleges of pharmacy depend on the Third-Party Pharmaceutical Education Evaluation.

Standards for the establishment of universities in Japan were revised and were deregulated since 1991 (Ministry of Education Culture Sports Science and Technology, 1991). The number of colleges and universities of pharmacy was rapidly increased from 46 (2002) to 74 (2017) (Ministry of Education Culture Sports Science and Technology; Japan Pharmaceutical Association). As a result, faculty members spend a lot of time on basic education of students in many private colleges or universities of pharmacy and also spend a lot of time responding to the education reforms in all colleges and universities of pharmacy (Koyama and Kodama, 2014; Ozawa, 2012; Wada and Yoshimura, 2015). For these reasons, universities or colleges of pharmacy might not have a clear vision about QA and the need for good internal QA systems, and might depend too much on assessment (QA) by the Third-party Pharmaceutical Education Evaluation, which has its limitations.

There is no nationally adopted list of educational outcomes (competencies) for graduates for pharmacy degree programs, as exists in some other countries. Such a list could provide valuable guidance to colleges and universities and provide a standardized point-of-reference for the evaluation of graduates.

Important Lessons Learned

When quality is evaluated, evaluation criteria and standards are most important for appropriate evaluation; therefore, if something is missing from the evaluation criteria and standards, appropriate evaluation cannot be performed. Moreover, the university or college itself must constantly evaluate the outcomes of the education for assurance of quality.

Implications and Future Planning

The university or college itself must also evaluate the outcomes of the education program, including the evaluation of graduates. Appropriate evaluation criteria and standards must be in place to ensure effective evaluation.

Nigeria

Background

Education and training of pharmacists

Educational requirements for registration as a pharmacist in Nigeria are either a 5-year Bachelor of Pharmacy or a 6-year Doctor of Pharmacy undergraduate degree covering the basic sciences, pharmacy, and biomedical sciences. A 1-year mandatory internship training follows under a registered pharmacist in an accredited institution.

Foreign pharmacy graduates (FPG) must be from institutions recognized by the Pharmacists Council of Nigeria (PCN) and satisfy the following requirements: (1) at least 4 years of undergraduate pharmacy education; (2) degree content should be equivalent to the Nigerian program; and (3) the graduate must participate in a 5-week FPG Orientation Program (FPGOP) that tests knowledge of pharmacy, educates on the laws and ethics of pharmacy practice in Nigeria and on tropical diseases and medicines.

With success in the FPGOP, applicants can enter the mandatory 1-year internship program, which is waived for those with evidence of registration in their country of study.

All pharmacists must pass a Pre-Registration Examination (PEP) set by the PCN and participate in the Mandatory Continuing Professional Development (MCPD) program.

Regulation of Practice

Practice regulation falls under the "4P components": the practitioner, practice, premises, and the product. The PCN regulates the practitioner, the practice, and the premises, while the National Agency for Food Drug Administration and Control (NAFDAC) regulates the product.

The PCN uses its prescription of training curricula, graduate induction/oath taking, provisional registration, internship, full registration, annual licensure, and MCPD to regulate the practitioner based on the Pharmacy and Drug Laws, e.g., the PCN publication—"A Four-Part Compendium of Minimum Standards for the Assurance of Pharmaceutical Care in Nigeria." PCN uses its instruments of inspection, approval, registration, and annual licensure to regulate the premises.

NAFDAC controls the registration, manufacture, importations, export, advertisement sale, and distribution of drug products. Routine monitoring is conducted to ensure compliance to preset standards.

Oversight and Quality Assurance of Education

The PCN regulates pharmacy education in conjunction with the National Universities Commission (NUC). Benchmark standard requirements are stipulated by the PCN to the NUC as packaged minimum academic standards.

Pharmacy Practice

The primary pharmacy practice sectors in Nigeria include the community, hospital, and industrial sectors, as well as pharmacy administration/regulation, academia, publishing, research, and the emerging public health pharmacy sector. The community and hospital pharmacy sectors have witnessed significant improvement in practice following the concerted attention clinical pharmacy education has received in line with global trends.

The main challenge confronting pharmacy practice in Nigeria is the disconnect between the training received in pharmacy school and what is practical in the work environment that the pharmacist meets upon graduation. Key components of this environment include competition with medical colleagues and lay businessmen in the control of drug distribution activities, poor remuneration, hitherto weak regulatory activities, poor understanding of pharmacists' role in patient care by the public, and the low pharmacists to patient ratio resulting in increased workload.

The Relationship Between Education and Practice

Pharmacy education in Nigeria has served as a positive driver for change in practice (Fig. 6). Its impact can be viewed from two perspectives—the roles played by pharmacy regulators and the universities (formal sector), and the contributions of implementing partners in public health programs supported with donor funds (informal sector).

The formal sector witnessed a gradual shift from the traditional product-centered practice to patient-focused practice over the past 25 years with the promotion of clinical pharmacy education. The shift started in 1992 with the Pharmacists Board of Nigeria (PCN's predecessor) approving two separate delegations (each consisting of Deans of pharmacy faculties and the PCN Registrar) to the United States and the United Kingdom to understudy clinical pharmacy education and practice. The objective was to determine applicability to Nigerian pharmacy education. In 2002, PCN approved the Pharmaceutical Society of Nigeria's proposal to officially adopt the Doctor of Pharmacy degree (PharmD) program in Nigeria, which had commenced in 2001 in the University of Benin.

Today, all faculties of pharmacy in Nigeria offer clinical pharmacy courses and their undergraduate students participate in clinical clerkships in hospitals for hands-on experience as part of their training. The knowledge so gained enables pharmacists to be more proactive in providing pharmaceutical care as well as collaborating with other health professionals in medication management, as opposed to only serving as a medication dispensing point in the clinical care process. The second pharmacists' summit in Nigeria held in 2012 made a landmark recommendation that the PharmD degree should be the minimum registrable qualification for the profession by 2023, and that all accredited pharmacy schools in Nigeria should commence admission of students for the PharmD degree program from 2016/2017 academic year.

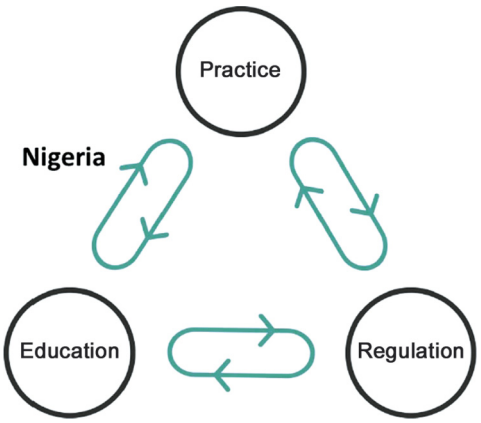

Figure 6 Education as a positive driver for practice changes in Nigeria.

A major catalyst that facilitated the achievement of PCN and Nigerian universities' drive for a patient-focused pharmacy practice is the contributions of United States Government (USG) funded Implementing Partners programme. Notable among the partners is Howard University Pharmaceutical Care and Continuing Education Centre (HU-PACE), which was given the dual mandate under two USG funded projects (GHAIN and SIDHAS) to promote quality care for the patients by strengthening the pharmacy systems, and enhancing the pharmacists' capacity to provide pharmaceutical care in all supported hospital and community pharmacies. Since 2004, HU-PACE has been setting up structures and processes for providing, documenting, and monitoring pharmaceutical care implementation across Nigeria through some of the following activities:

- Conducting didactic pharmaceutical care training/retraining in Human Immunodeficiency Virus/Acquired Immunodeficiency Syndrome/Tuberculosis (HIV/AIDS/TB) for 2151 Pharmacists between 2004 and July 2017. Trainings are usually followed by onsite, hands-on mentoring in the hospitals to institutionalize the eight elements of Pharmacy Best Practice and by Skill Certification workshops for community pharmacists (Oqua et al., 2013);
- Developing and rolling out various pharmaceutical care tools to support the provision and documentation of pharmaceutical care services by pharmacists;
- Providing support to PCN to develop pharmaceutical care modules on HIV/AIDS for its MCPD program and to the National Pharmacovigilance Centre (NPC) in NAFDAC to develop adverse drug reaction (ADR) screening and reporting forms;
- Setting up structures for support of confidential counseling, as well as processes for routine assessment and interventions for ADR manifestations and medication adherence problems, and patients and prescription screening for medication errors;
- Enlisting community pharmacists into the national HIV and TB case findings and providing a continuum of care in the community including anti-retroviral therapy refills for HIV-positive clients discharged from public hospitals; and
- Setting up new, and strengthening existing Drug and Therapeutic Committees/Pharmacovigilance Committees to demand and use pharmaceutical care data for clinical decision making in supported hospitals.

Drivers for Advancement

In addition to named factors above, drivers for the impact pharmacy education has had on patient-centered pharmacy practice include the following:

- The global paradigm shift toward patient-centered pharmacy practice with the resultant realignment of pharmacy education in Nigeria;
- Consistency in PCN's support for pharmacy education that shifted its focus over the years;
- The platform provided by USG funded HIV/AIDS/TB projects in Nigeria, which has helped to strengthen the pharmacy system and the pharmacists' capacity to provide pharmaceutical care; and
- The preexisting yearning of Nigerian pharmacists who have consistently complained of being over educated and underutilized.

Barriers to Advancement

Barriers to the advancement of this relationship include the following:

- Poor remuneration has caused many pharmacists to seek fulfilment in other sectors, with some exporting their services to other countries (brain drain);
- Ongoing inter-professional friction with other medical colleagues, who see the increasing patient-centered role of pharmacists as an encroachment into their areas of clinical practice; and
- Inadequate or complete absence of pharmacists in many hospitals, especially in privately owned hospitals, to provide pharmaceutical care.

Important Lessons Learned

The positive impact pharmacy education has had on practice has shown clearly that:

- Concerted collaborative efforts of key stakeholders in pharmacy education (PCN, PSN, academia, and NGOs) are instrumental in achieving the pharmacy practice that meets the needs of the people; and
- When pharmaceutical care is practiced at the community and hospital levels, it has the potential to increase public understanding of pharmacists' roles in safeguarding their health, bring recognition to the pharmacy profession, create demands for pharmaceutical care, and ultimately fetch greater benefits to the profession, the health-care system and the entire citizenry.

Implications and Future Planning

The case has demonstrated clearly that forward planning is critical to the achievement of any desired goal. The next steps for further improvement in pharmaceutical care in Nigeria include the following:

- Implementation of more synergistic activities that promote pharmacy practice by the key stakeholders (PCN, PSN, Academia, and NGOs) such as joint use of data collection and reporting formats, use of project-based training materials as part of the national professional continuing education program; and

- Improved data collection on pharmaceutical care practice in Nigeria and dissemination to increase public awareness of its benefits, thereby creating demand for the practice.

Oman

Background

Education and training of pharmacists

In Oman, pharmacists and assistant pharmacists are the two pharmacy practitioners who can practice the pharmacy profession. Pharmacists should complete a Bachelor's degree in pharmacy or equivalent, e.g., PharmD. Assistant pharmacists should obtain a Diploma in Pharmacy (minimum 2 years) and work under pharmacists' supervision. They are equated to pharmacy technicians in some developed countries, except they have had comprehensive academic courses in pharmacology and pharmacy practice (Higher College of Technology, 2016). Pharmacists are required to complete a Master's degree in clinical pharmacy to practice in inpatient settings.

Pharmacists and assistant pharmacists should fulfil the pharmacy licensing conditions to practice in the country; this includes:

1. completing a Bachelor's degree or equivalent for pharmacists, or diploma in pharmacy for assistant pharmacists;
2. passing the licensing exam;
3. completing the training hours for Oman graduates

Overseas applicants must be registered with the pharmacy council or association in the country of origin and have at least 3 years of practice experience (Directorate General of Pharmaceutical Affairs and Drug Control (DGPA&DC)).

Regulation of Practice

The Directorate General of Pharmaceutical Affairs and Drug Control (DGPA & DC) under the Ministry of Health (MOH) governs pharmacy practice. It is the main regulatory organization responsible for pharmaceutical law and its implementation. One of its responsible duties is licensing and inspection of pharmaceutical establishments and for registration and licensure of pharmacy staff. There is no independent regulatory pharmacy council or pharmaceutical association in Oman.

The Department of Pharmaceutical Care under the Directorate General of Medical Supplies (DGMS) is responsible for identifying and facilitating the training and support of the pharmacy workforce for better delivery of pharmaceutical care and services.

Oversight and Quality Assurance of Education

The Ministry of Higher Education and MOH license pharmacy academic degrees in the country. The Oman Academic Accreditation Authority regulates the quality of higher education in Oman (Oman Academic Accreditation Authority, 2018). The Bachelor of Pharmacy degree program provided by Oman Medical College is affiliated with West Virginia University in the United States (Oman Medical College (OMC), 2015). The provision of pharmacy education is limited in the country, as no school of pharmacy provides postgraduate degrees.

Pharmacy Practice

The services provided by community pharmacies are traditional services, i.e., product-oriented rather than patient-centered. Clinical pharmacy services are limited and usually associated with a hospital setting, where staff are clinically trained and supported by clinical pharmacists. With no clinical pharmacists working in the primary health-care sector or private community pharmacies, clinical pharmacy services are very limited and highly dependent on individual initiatives (Al-Abdullatif, 2014). The concept of pharmaceutical care, therefore, is not fully and effectively developed, and the clinical pharmacy services can vary between different health sectors.

The challenge faced is the lack of a national policy and/or guideline on good pharmacy practice that can maintain a standard in the quality of pharmacy services between the two pharmacy sectors. Thus, the main challenge is the suboptimal standard of pharmacy practice in the primary health-care sector.

The Relationship Between Practice and Regulation

The case study describes how effective enforcement of regulation positively impacted practice in one sector in Oman while lack of effective enforcement in another sector was a barrier to advancing practice (Fig. 7).

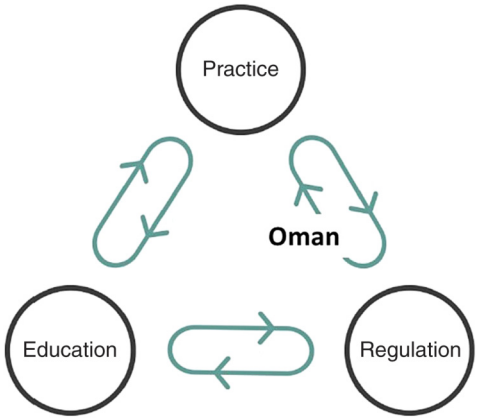

Figure 7 The effect of enforcement of regulation on the advancement of practice in Oman.

The administration of pharmacy practice varies significantly in Oman. The Ministry of Health (MOH) regulates both the public and the private (community) health sectors, but variation in the clinical practice between the two sectors is observed. Using semi-structured interviews carried out in a PhD candidate's qualitative study, community pharmacy staff were asked about their dispensing practice and role in patient care (Al Juma, 2017). The study identified that most of the community pharmacy staff adhere only to MOH regulations when practicing pharmacy. One community pharmacist stated: "Here, almost we are following the Ministry rules only, almost we are not violating and that is actually good only for customers and for the community." Furthermore, a variation in perceptions and practice was observed among the community pharmacy staff; some explained that they would refuse to supply prescription-only-medicine (POM) without a prescription while others agreed to supply without a prescription, especially for chronic medications. The difference in approach was perceived to be influenced by the profit motive *versus* the professional obligation. Some pharmacists suggested that enforcement of the law is required. A community pharmacist explained: "First of all, the pharmacist should feel the importance and commitment to it, and this will only come either by enforcing the law or by feeling a good conscience, to take into account every simple (sic) thing in their profession."

The Oman Pharmacy Law was updated in 2015; however, the prohibition of supplying POMs without a prescription has recently been added to the draft version of the good pharmacy practice (GPP) bylaw. Moreover, the bylaw does not clearly stipulate the minimum international standards for medicine labeling (GSD; **g**eneric name, **s**trength of medicine, individual **d**osage instructions) or counseling (International Pharmaceutical Federation (FIP), 2001; International Pharmaceutical Federation (FIP), 2012). Labeling of medicines and patient's counseling are standard procedures to be performed in most of hospitals' pharmacies in the country, but they are lacking in community pharmacies. Consequently, no integrated labeling system is available in most of the private sector pharmacies. The observed current practice is handwritten dosage instructions on the box itself using abbreviations, for example, the Latin number is used to indicate dose and frequency, i.e., "II–II" is the instruction to take two tablets, twice daily.

People acknowledge pharmacists' expertise in medicines, although some people observed a variation of the pharmacy staff who are working in the community compared to those working in a hospital setting. People indicated that most community pharmacies supply the medicines without providing adequate counseling: "I cannot trust the pharmacist, he may issue a medicine without explaining the benefits and side effects." A member of the public, who had a positive experience with a community pharmacy in an overseas country, questioned the competency of local community pharmacy staff to provide health advice, which raised concern of patient safety: "In [Country X] they will ask you: Is it for you? How old are you? What is your weight? and will explain for you how much dosage, within how many hours, and so on, but here they just give it to you without asking. The pharmacy here is like a shop to buy from, and not a place to be treated" (Al Juma, 2017).

Drivers for Advancement

- Under the national health strategy "Health Vision 2050," there are plans to privatize some of the health-care services to overcome the challenges of demand (Ministry of Health, 2014). There is a national need to standardize and close the gap between the two sectors with regard to patient care and the quality of pharmaceutical care services provided.
- Identify and recognize the importance of the pharmacy profession in optimizing medicine use and patient education in hospitals
- Stress the need to develop a national strategy to improve the clinical role of the pharmacy profession in the private sector for safe and effective involvement in patient care and medicine use.

Barriers to Advancement

- The good pharmacy practice law lacks the elements related to the clinical role of the pharmacy profession and patient care. There is, therefore, no clear minimum national standard established for activities related to either labeling of dispensed medicines or provision of effective medication therapy management.

- The absence of a clear implementation strategy of pharmacy law and inefficient enforcement of regulation are barriers for the advancement of pharmacy practice to comply with the international standards of GPP.
- The absence of an independent body to monitor compliance of pharmacy staff to the Law and to provide professional support to reduce variation in practice between both sectors or among the overseas pharmacy workforce.

Important Lessons Learned

- Weakness of regulation (scope of regulation and/or effective enforcement) is a threat for advancement of the pharmacy profession in the country.
- Absence of a clear professional strategy or guidelines results in incapacity of the profession to meet international standards.
- Individual initiatives and efforts can improve practice, but they are not sustainable if the system does not support this advancement.
- Adherence to some regulation was observed after enforcement by sending reminding circulars, regular inspection, and requests to maintain documented evidence. Since the MOH has not identified labeling and therapy management as a requirement to meet the GPP standards, this will not be adhered to by the community pharmacies.

Implications and Future Planning

- Set clear national minimum standards of GPP related to the clinical role of the pharmacy profession, including medicine labeling, patient counseling, and supply of POM. Identify a mechanism or key indicators for GPP implementation, assessment, and monitoring in community pharmacy.
- Develop a clear professional strategy to support the implementation of Oman national health policy and set a framework/roadmap for the pharmacy profession in the new health vision of the country.
- Enhance the governing role of the Oman Pharmaceutical Society to act as an independent body responsible for practice and training in the pharmacy profession.

Romania

Background

Education and training of pharmacists

Pharmacists during the period 1998 through 2002, before Romania joined the European Union, could register through the professional association, the College of Pharmacists, if they possessed a pharmacist diploma (degree) delivered by a Higher Education Institution accredited in Romania or abroad (if recognized according to the law). In this period, pharmacy education was organized in a 5-year curriculum that included all disciplines required by the European standards (but not specific training on contraception and family planning) as well as a period of 4 months of in-service training. Diplomas were delivered after the validation of each individual's program, and a graduation exam that included both a theoretical component as well as the defence of a degree thesis.

Regulation of Practice

The practice of pharmacy was regulated in this period by Law 81/1997 and was based on a free practice authorization delivered by the Ministry of Health, with the concurrence of the College of Pharmacists. All practicing pharmacists were enrolled in the College of Pharmacists, whose role was to defend and promote the rights and interests of its members, as well as to ensure that professional obligations, the norms, and code of ethics (Deontology code) were respected. The College was also involved in the creation of new pharmacies, warehouses or laboratories, as well as the continuing education of practitioners. The practice in pharmacies was regulated by norms approved by the Ministry of Health.

Oversight and Quality Assurance of Education

Higher education institutions delivering pharmacist diplomas had to have a pharmacy program accredited by the National Council of Academic Evaluation and Accreditation, based on the quality of the curriculum, the faculty, and on teaching facilities and resources.

Pharmacy Practice

At that time, pharmacy practice was mostly in the private sector, with the exception of hospital pharmacies, as they were just beginning. The practice sectors included: public pharmacies, pharmacies in polyclinics, in diagnostic and treatment centers open to the public, hospital pharmacies, warehouses, and units for the synthesis and production of pharmaceutical products. The main challenges at that time were related to the rapid growth in the number of public pharmacies. This led to a high demand for pharmacists in the labor market, to an increase of industrial preparations available and by consequence the need for more time available for pharmacists to interact with their patients. This was coupled with the increasing recognition of their role

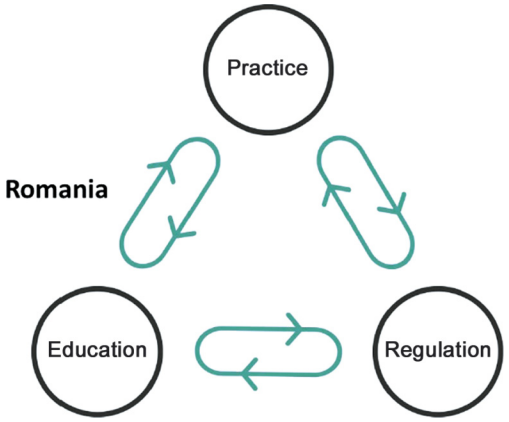

Figure 8 The relationship between education and practice in Romania.

in primary health care and increasing need for continuing education in this respect, especially for the pharmacists who graduated prior to 1989.

The Relationship Between Education and Practice

Demonstrating a dynamic relationship between education and practice (Fig. 8), this case study refers to the segment of pharmacy practice in Romania that was a part of the partnership begun in 1998 with a focus on expanding primary health care in the pharmacy curriculum and continued with the TrainPharm Project (1999–2002).

The role of the pharmacist in Romania was under transformation since the change in the political system in 1989 served as a motivator for reform in the health-care system. As in many other countries, pharmacists were educated with an emphasis on preparing and dispensing medicines. As the health-care system reformed, the training of health-care professionals shifted toward the improvement of primary health care (PHC) delivery including family planning. Pharmacists were placed in a position to strengthen their service and expand the scope of their practice. Universities wanted to mount more formal continuing education programs for practitioners to provide them with updated information and skills enhancement.

Recognizing the potential of pharmacists to make a significant contribution to women's health services, the United States Agency for International Development (USAID) in Romania entered into a cooperative agreement with Howard University's Pharmacists and Continuing Education (PACE) Centre for 1 year (1999–2000) to support USAID/Romania's Strategic Objective *"Improved Welfare of Women and Children in Romania."* The initiative had a primary emphasis on Women's Health Services—Reproductive Health and Family Planning. The TrainPharm Project was designed to support this objective through the provision of training and skills enhancement for pharmacists, who would be enabled to increase their contribution and expand their roles in primary health care delivery to women and their families. Pharmacists gained knowledge and skills related to shifting their practice from primarily drug manufacturing and distribution to a more patient-care centered focus within the health-care system. Additional project goals in Phase I were to:

- assist the University of Medicine and Pharmacy in Cluj (UMF-Cluj) to develop, organize, and conduct a training process for 300 pharmacist practitioners from three judets (counties), Cluj, Constanta, and Iasi
- assist UMF-Cluj with the development of a sustainable capacity to plan, implement, and evaluate continuing education (CE) services for pharmacists.

In the second phase (2000–02), the training was conducted in target counties using the methods and model of instruction from the first phase of the TrainPharm Project but with improvements based on feedback, evaluations, and lessons learned in the first phase. This phase of the TrainPharm Project was structured to increase the cadre of pharmacist practitioners who were better prepared to participate in health reform in general and assure wider access of women and couples to reproductive health services. Due to practitioner's interest, the second phase, initially planned for seven judets, accommodated pharmacists in nine judets: Alba, Botoşani, Călăraşi, Dolj, Ialomiţa, Sălaj, Suveava, Tulcea, and Vâlcea. Project results yielded training of 1026 pharmacists representing over 500 pharmacies in 30% of the judets of Romania. As a result of training, a technical expert assessed the effectiveness of the workshops that revealed the following:

- A high level of participant satisfaction with the training
- Measurable growth in pharmacists' knowledge of family planning methods and their professional role in primary health-care delivery
- Acceptance of an interactive training method
- Change in the pharmacists' method of practice to incorporate skills acquired in patient interaction and education

Drivers for Advancement

A key driver toward advancement of the relationship of education and practice change was the international partnership between UMF-CLUJ & HU-PACE as supported by funding of the local USAID Mission. The international partnership exhibited many successful principles:

- Shared mission, goals, and measurable outcomes
- Positive relationship characterized by respect, congeniality, commitment, and mutual trust
- Roles, responsibilities, and processes identified with agreement of all partners
- Mutual benefit, with sharing of credit for joint accomplishments, but highly focused on the trainees' needs and attainments
- An evolving partnership that built upon the strengths of each partner
- Balanced, clear, and open communication
- Key personnel remained committed over time

Barriers to Advancement

Barriers to this relationship included distance between educator and practitioner, inability to accommodate all of the pharmacists who wished to be participants in the training so that they could change their practice appropriately, as well as the need to produce some material in English for later translation and use.

Important Lessons Learned

The main lessons learnt from this case were as follows:

- mutuality of vision, goals, and understanding is essential to the ease of forward planning
- a wide inclusion of practitioners helps to generate a high level of interest in change
- the engagement of practitioners from several geographic practice settings and cultural (e.g., urban/rural) perspectives contributed greatly in effecting change. These lessons also serve as a basis for the evaluation of future planning and practice change efforts. Furthermore, it assists a diffusion of the ideas and practices into those areas where actual training could not take place.

Implications and Future Planning

The implications of this case include recognition of the importance of maintaining clear communication between the relevant component participants, e.g., university, practitioners, and resource agency. In this case, an outcome of the TrainPharm Project was the expansion of the internal drug information system to permit practitioners to enact evidenced-based changes. For this reason, among others, the first drug information center in Romania was established at the University of Medicine and Pharmacy in Cluj. This site was designed to be a resource for physicians as well as pharmacists and continues to this day. Its role was expanded to research and educational purposes in the field of pharmacovigilance.

Taiwan

Background

Education and training of pharmacists

Taiwan has nine schools of pharmacy. With the progression of the Doctor of Pharmacy (PharmD) degree program, the number of years of study required for graduation and the conduct of the licensure examination became complicated. Some schools kept the traditional 4-year curriculum; some added Chinese herbal medicine and adopted a 5-year curriculum; and some adopted a 6-year PharmD program. Regardless of the number of years of study, students need to complete at least 132 credits of coursework and 640 h of hospital internship in order to graduate from the school of pharmacy. Before 2015, students who graduated from a school of pharmacy could take the licensure exam. The rules changed, however, and after 2015, the licensure exam became a two-stage exam—the basic exam and the clinical exam. Those who do not pass the first stage cannot take the second stage. The licensure exam is governed and managed by the Ministry of Examination. Pharmacists need to take 120 continuing education (CE) hours in 5 years to renew their practice license.

Regulation of Practice

The Ministry of Examination has a committee to determine the rules and contents of licensure examination. The Taiwan Food and Drug Administration (TFDA) sets the rules for pharmacy practice; however, pharmacist workforce issues are regulated by the Department of Medical Affairs under the Ministry of Health and Welfare. The Taiwan Pharmacist Association (TPA) is the contact organization for the government to discuss any issues related to pharmacy practice.

Oversight and Quality Assurance of Education

The Department of Higher Education in the Ministry of Education organizes a committee from professors of the nine schools of pharmacy to decide the requirements of pharmacy education and graduation. In 2005, the Higher Education Evaluation and Accreditation Council of Taiwan was established to conduct accreditation on the university level, including medical universities. Pharmacy education is included under the university level and Taiwan does not have the school or programmatic level of pharmacy accreditation. The Pharmaceutical Society of Taiwan is the contact organization for issues about pharmacy education.

Pharmacy Practice

In the health sector, pharmacists can practice in hospital or community pharmacies, or pharmacies in primary care clinics. Prescription dispensing is the major task; however, many clinical and drug use quality management services were conducted in hospital pharmacy. Starting in 2010, TPA in collaboration with the National Health Insurance Administration (NHIA) started a pharmacist home care program for high users of medical resources; this started the direct patient care services conducted by community pharmacists. Thereafter, TPA received research funding from TFDA and the Nursing and Health Care Administration to develop more services for patients at home, in long-term care facilities, or in community pharmacies. The challenges are that pharmacists do not receive competent training on direct patient care while at pharmacy school; therefore, they are not used to being responsible for interventions or documentation, do not have confidence in communication with physicians, and even do not have the concept of the patient care process.

The Relationships Between Education/Practice and Practice/Regulation

In this case study, two relationships are reported by Taiwan: education and practice and practice and regulation (Fig. 9).

Regulation has been a positive driver for innovation and changed the practice by community pharmacists. In 2007, the Pharmacist Law added a new responsibility of pharmacists to provide pharmaceutical care related activities. At that time, the concept of pharmaceutical care was to conduct clinical services in the hospital setting. However, in 2009, when TPA requested the Ministry of Health to create new roles for pharmacists to practice in the long-term care environment, the NHIA responded that a group of high users of medical resources might need help from pharmacists. Physicians and nurses tried to manage those high users but in vain. NHIA provided a budget and drafted a plan for pharmacists to manage the high users, with the goals to decrease their number of outpatient department (OPD) visits and reduce outpatient health-care expenditure. The author was invited by TPA in late 2009 to lead the training, qualification, implementation, monitoring, and presentation of outcomes to the NHIA in 2010.

The first year pilot study had very positive outcomes. Later, the project expanded from eight cities to the total 24 cities in Taiwan, and the budget was increased four times higher in 2011. In addition, from 2011 to 2015, TPA applied funding from TFDA to conduct more trainings and developed standard operating procedures (SOPs) for different kinds of services that can be conducted in community pharmacies, such as cognitive services, adherence counseling services, and the PharmaCloud drug integration service (Yan and Lu, 2016). The NHIA created the PharmaCloud system, putting all prescription information for every citizen for the past 3 months into the system; physicians and pharmacists can access the information via the Internet with the patient's agreement. In 2014, TPA also applied for funding from the Health Promotion Administration (HPA) to conduct a Diabetes Management Program. From 2010 to 2018, the NHIA project continued.

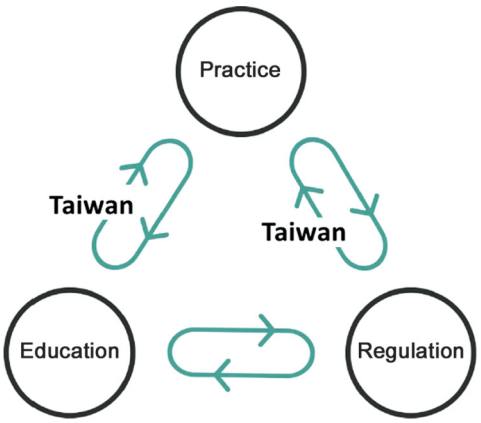

Figure 9 The relationship between practice and education, and practice and regulation in Taiwan.

Practice and pharmacists' education did not go hand-in-hand. The pharmaceutical care process taught and practiced by community pharmacists includes assessment of patient information and medication used, development and implementation of a care plan, and follow-up evaluation.[2] The author also created an AABBCC coding and documentation system for drug therapy problems identified (AA code), resolution recommended to the physician or patient (BB code), and follow-up of the changes of prescription or patient behavior (CC code).[3] The computer system for documentation was developed using the same philosophy. The above-mentioned NHIA home care services can only be conducted by community pharmacists due to the claiming process, and most of the other projects were conducted mainly by community pharmacists. With the total annual budget for projects of nearly (New Taiwan Dollar) NT$80 million, not many hospital pharmacists can take it up because the claiming process needs to go through contracted community pharmacies and some are specifically designed for community pharmacists. Clinically oriented teachers in the schools of pharmacy mostly have experience in hospital practice, using SOAP format (**s**ubjective, **o**bjective, **a**ssessment, and **p**lan) to take care of patients in the acute environment. They were, therefore, not involved in the training and practice in the TPA projects. They still teach the patient care process using SOAP format and ignore the practices developed in the community pharmacy sector for the holistic care of patients (Cipolle et al., 2012; Joint Commission of Pharmacy Practitioners (JCPP), 2014; Tarn and Li, 2017).

Graduates from schools of pharmacy still do not have the competency to conduct patient-centered care for patients with chronic diseases, illustrating a disconnect between education and practice. Community pharmacists need to take 31 Credit CE hours and pass the written exam developed by TPA, practice on five real patient cases, and then pass the oral test in order to get the certificate to join all the home pharmaceutical projects. Every 4 years, they need 48 CE hours and other requirements (proof of taking care of at least 15 patients, etc.) to continue their qualification; however, those CE courses did not invite faculty members from pharmacy schools to teach. It is hoped that the new PharmD program in the schools of pharmacy may change the Education–Practice relationship.

Drivers for Advancement

- Due to the needs of complex patients, the leaders of the TPA believe pharmaceutical care is the future. They persuaded the NHIA, TFDA, and HPA to provide funding for pharmacists to help those patients identified with multiple chronic diseases, polypharmacy, and poor adherence.
- The longevity of members of the population and the move in the health-care environment pushing toward long-term care that is more community-based practice, and not hospital services.
- The waste of medications, and the fact that drug expenditure accounts for ±25% of total health-care expenditure in NHIA, contributes to the need of having pharmacists improve the rational and safe use of medications.

Barriers to Advancement

- Community pharmacists were not trained to conduct patient-centered care.
- Few knowledge-based drug or decision-support information resources could be accessed in the community pharmacy.
- More professional services should be developed and receive remuneration so that more efficient hospital pharmacists can be attracted to conduct ambulatory care practice.
- Taiwan does not have pharmacy technician training programs to assist pharmacists to practice at a higher level.
- The schools of pharmacy is still debating having a 4, 5, or 6-year education and are missing on competency requirements.
- Only candidates with a PhD degree can be recruited as a professor to teach in pharmacy schools, and they are not familiar with professional practice.

Important Lessons Learned

- Schools of pharmacy are research-oriented institutions and not a place to prepare professionals who can improve patient health through the provision of pharmaceutical care.
- Pharmacists are used as "technicians," and there is not a plan to create a technician workforce.
- The professors who teach clinical pharmacy mainly focus on hospital practice and ignore community practice, and the patient care process does not follow the model promoted by the Joint Commission of Pharmacy Practitioners (Joint Commission of Pharmacy Practitioners (JCPP), 2014).
- The future for pharmacists will be direct patient care, holistic care, and not only disease management for those in need.
- Schools of pharmacy need to change how they recruit faculty members and focus more on professional practice, not only publications on basic or applied sciences.

Implications and Future Planning

Recently, NHIA asked TPA to propose pharmacist services that can add to the physician home visit for those who cannot go to clinics or hospital for medical care. Four more services, in addition to home pharmaceutical care, were developed and proposed with remuneration. Another TPA campaign requested a budget from NHIA to reimburse clinical services conducted by hospital pharmacists, especially in the intensive care unit. Although this would be difficult, it is a message sent to the government that pharmacists have value and can do more in the patient care environment. Achieving good collaboration between hospital and community pharmacists will be the major task for TPA to revise future professional practice.

USA

Background

The final case study provides an example of a country, the United States of America, where a structure has been established to promote and facilitate dynamic relationships between the practice, education, and regulation sectors of the profession, which has been the focus of this chapter. The Joint Commission of Pharmacy Practitioners (JCPP) was established in 1977 and now comprises practitioner member organizations and liaison member organizations from pharmacy education, regulation, and accreditation. (Joint Commission of Pharmacy Practitioners, 2018) Through JCPP, active and ongoing interaction, communication, and collaboration have been achieved within the profession, resulting in several notable advances for the profession, which have ultimately served the best interests of patients.

Education and training of pharmacists

To optimize pharmacy practice and the role of pharmacists within the health-care system requires that pharmacists are educated to meet society's care expectations for today and the future. In 2004, with the final graduates of Bachelor of Science degree programs, the transition to a single accredited entry-level degree—the Doctor of Pharmacy (PharmD) degree program—was completed.

The PharmD degree is a 4-year professional degree program completed after a minimum of 2 years of prerequisite undergraduate coursework. Some US colleges and schools of pharmacy require completion of a baccalaureate (BS) degree prior to admission to their PharmD program. Accordingly, a PharmD degree typically takes between 6 and 8 years to complete. The PharmD curriculum consists of didactic and experiential education that meets the accreditation standards of the Accreditation Council for Pharmacy Education (ACPE). In 2016, ACPE released new degree program standards that incorporated or expanded expectations for patient-centered care, working in interprofessional teams, evidence-based practice, quality improvement, public health, and transforming activities of pharmacists. Successful completion of both the didactic and experiential pharmacy curriculum prepares students to apply for pharmacist licensure. Post-graduate education and training of pharmacists support pharmacists' ability to enhance skills, knowledge, and abilities to advance patient care. All pharmacists are required by state regulations to complete a number of hours of approved or accredited continuing education (National Association of Board of Pharmacy, 2017). Many pharmacists complete post-graduate training programs and achieve other credentials, including certificate training programs, 1 or 2-year residency programs, fellowship programs, specialty certifications for pharmacists (12 different specialties), and interdisciplinary certifications.

Regulation of Practice

Pharmacist licensure and relicensure, as well as scope of practice, are governed at the state level by individual boards of pharmacy. Licensure indicates that state requirements to practice pharmacy have been met. US candidates for licensure in all states must have graduated an ACPE-accredited pharmacy degree program and pass the North American Pharmacist Licensure Examination (NAPLEX). This competency-based examination applies knowledge gained in pharmacy education to real-life practice situations. All states also require a law examination incorporating both federal and state laws. Foreign pharmacy graduates are required to achieve Foreign Pharmacy Graduate Equivalency Certification (FPGEC), which includes among other requirements an evaluation of the graduate's curriculum, assessment of competence in the English language, and passing of the Foreign Pharmacy Graduate Equivalency Examination (FPGEE) before being eligible to sit for the NAPLEX. Additional details can be obtained from the NABP website (National Association of Board of Pharmacy, 2018)

The federal Food and Drug Administration (FDA) regulates pharmaceutical manufacturing. However, states are the primary regulator of pharmacies. Every state has laws and regulations guiding pharmacy standards and requirements, addressing issues such as required licenses for each facility and for the credentialed pharmacists and other employees who work there. Virtually every state also has requirements for storage, recordkeeping, prescription requirements, labeling, and patient safety among others. The annual NABP Surveys of Pharmacy Law provide a comprehensive summary of state requirements for pharmacy practice and facilities (National Association of Board of Pharmacy, 2017). The practice of pharmacy as governed under state sovereignty is influenced by state legislators and advocacy at the local level.

Oversight (State and Federal) and Quality Assurance (Accreditation) of Education

ACPE provides public recognition that a professional degree program leading to the Doctor of Pharmacy degree is judged to meet established qualifications and educational standards through initial and subsequent periodic evaluations. Accreditation is of educational programs and is different from licensure, which applies to individuals. A directory of programs accredited by ACPE is published and maintained on ACPE's website (Accreditation Council for Pharmacy Education, 2018). The directory includes the accreditation history of the program, the term of accreditation, scheduled monitoring, and any special certification status of the program, such as Probation. ACPE accreditation does not imply or infer that all Doctor of Pharmacy programs are equivalent beyond meeting the expectations of the accreditation standards. Accreditation standards include both quantitative and qualitative parameters.

A professional program is evaluated on the extent to which it accomplishes its stated mission and goals and is consistent with the concept that pharmacy is a unique, personal service profession in the health science field. ACPE is an independent, autonomous, not-for-profit agency, which is recognized by the US Department of Education (USDE) for the accreditation and preaccreditation,

within the United States, of professional degree programs in pharmacy leading to the degree of Doctor of Pharmacy, including those programs offered via distance education.

Pharmacy Practice

Since 1977, the Joint Commission of Pharmacy Practitioners (JCPP) has served as a forum for US pharmacy on matters of common interest and concern to US-based, national organizations of pharmacy practitioners and invited liaison members on professional, educational, legislative, and regulatory issues through analysis, interpretation, communication, and exchange of views on relevant issues. JCPP is where the cross-section of pharmacy organizations occurs. These organizations are focused on achieving the JCPP Vision for Pharmacists' Practice (adopted in 2013): *Patients achieve optimal health and medication outcomes with pharmacists as essential and accountable providers within patient-centered, team-based health care.*

Where able, the Joint Commission has issued position statements to communicate its position on contemporary issues impacting the profession and health-care system. Representatives to the Joint Commission consist of the chief elected and executive officials of the member organizations. During the history of the Commission, this process has allowed participating organizations to adopt identical positions on several major issues. These identical positions are significant because practitioner organizations of the Commission represent pharmacy practitioners from the community and institutional environments, the two largest practice sectors. Where appropriate and feasible, organizations collaborate on cross-profession issues, as well as interprofessional issues working with medicine, nursing, public health, etc.

In 2014, JCPP developed and adopted the *Pharmacists' Patient Care Process* (Joint Commission of Pharmacy Practitioners, 2014). The goal of high quality, cost-effective, and accessible health care for patients is achieved through team-based patient-centered care. Pharmacists are essential members of the health care team. As a result of the profession's evolution, the importance of, and need for, a consistent process of care in the delivery of patient care services has been recognized by the profession. This led JCPP to the development of the patient care process document.

The Relationship Between Practice, Education, and Regulation (Fig. 10)

Obtaining authority, recognition, and coverage for pharmacists' patient care services is a critical element of JCPP's Vision for Pharmacy Practice and has driven collaboration among the various sectors of the profession and health care. Advancements in pharmacist education, credentialing, and certification have positioned pharmacists with the ability to assume greater roles on patients' health-care teams (Council on Credentialing in Pharmacy, 2014). Innovations in practice have supported the advancement of pharmacist education to where expanded pharmacist-provided patient care services have been integrated within school and college accreditation standards and post-graduate continuing education. This has also influenced pharmacy practice laws, regulations and policies on the national, state, and local levels that empower pharmacists to assume expanded roles in patient care. Examples of where this has occurred are medication therapy management (American Pharmacists Association, 2008; Bluml 2005; Cipolle et al., 2012; McInnis et al., 2012) pharmacy-based immunizations, and collaborative practice activities. Several collaborations have been formed by JCPP member organizations and other stakeholders, within and outside of the profession to advance progress toward JCPP's vision. Collaborations within health information (pharmacy-HIT collaborative), quality (PQA—pharmacy quality alliance), and the Patient Access to Pharmacists' Care Coalition (PAPCC) support pharmacists' efforts to attain recognition for and coverage of their quality patient care services.

- Patient Access to Pharmacists' Patient Care Services: https://pharmacistscare.org/
- Pharmacy Health Information Technology Collaborative: www.pharmacyhit.org
- Pharmacy Quality Alliance (PQA): https://www.pqaalliance.org/

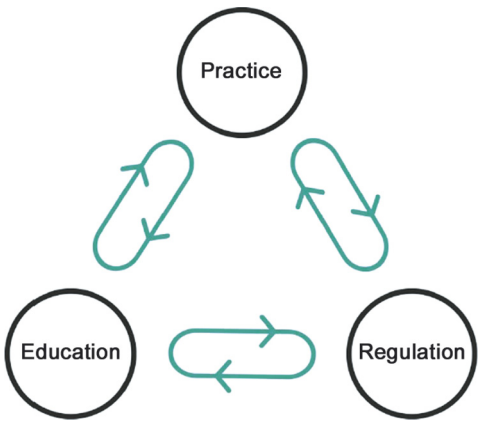

Figure 10 The relationship between practice, education and regulation in the USA.

Drivers for Advancement

- Increased need for improved medication use and outcomes.
- Pharmacists' unique training and expertise.
- Health-care provider shortages and gaps in healthcare service access.
- Collaborative practice agreements and expanding authority.
- Health information technology provides tools that support pharmacist integration in team-based care.
- Collaboration, coordination, and communication among health-care providers.

Barriers to Advancement

- Inconsistency across states and other jurisdictions regarding the practice authority of pharmacists.
- Lack of recognition by other health-care providers, payers, the public and other decision makers regarding pharmacists' delivery of meaningful patient care services.
- Lack of coverage for pharmacists' patient care services and a business model supporting the provision of patient care services.
- Reimbursement of pharmaceutical products has tightened and increased pressure on provider provision of medication use and management services.
- Manpower issues.
- Pharmacist well-being.
- Lack of read/write access to patients' health records.

Important Lessons Learned

- Keep patient needs and desire as the focal point
- Use consistent and understood terminology for describing patient care services provided by pharmacists
- Pharmacists must demonstrate their value
- Pharmacists must document their services
- Educate decision makers regarding pharmacists' education, training, and skillsets and alignment with other health-care team members
- Obtain multidirectional access to patients' health records

- Dayani Galato, PhD Brasilia University, Brasília, Brazil.
- Josélia Cintya Quintão Pena Frade, MSc, Brazilian Federal Council of Pharmacy, Brasília, Brazil.
- Tarcísio José Palhano, BPharm, Brazilian Federal Council of Pharmacy, Brasília, Brazil.
- Wellington Barros da Silva, PhD, Federal University of Sergipe, Aracajú, Brazil.
- Walter Jorge da Silva, MSc, Brazilian Federal Council of Pharmacy, Brasília, Brazil.

Europe (with specific examples from Spain) case study author:

- Antonio Sánchez Pozo, PhD in Pharmacy; Full Professor, University of Granada, Granada, Spain.

Japan case study authors:

- Kayoko Takeda Mamiya, PhD; Lecturer, Hokkaido University of Science, Sapporo, Japan
  The case study author would also like to thank:
- Professor Nahoko Kurosawa, Hokkaido University of Science and Professor Kazumasa Hirata, Osaka University Graduate School and School of Pharmaceutical Sciences, for their valuable comments.

Nigeria case study authors:

- Rosalyn C. King, PharmD, MPH, FNPhA; Founder and Projects Director (ret.), Howard University PACE Center, Washington, DC, USA.
- Dorothy Oqua, PhD, FPCPharm, FPSN; Country Director, Howard University Global Initiative Nigeria, Abuja, Nigeria.

- Onuche I. Omeh, B. Pharm, PharmD, Associate Director for Clinical Pharmacy Services, Howard University Global Initiative Nigeria, Abuja, Nigeria.

Oman case study author:

- Muna A. Al-Juma MPharm, MSc, PhD, ARPharmS; Lecturer in Pharmacy Practice, Graduation Project Coordinator, Department of Pharmacy, Higher College of Technology, Muscat, Sultanate of Oman.

Romania case study authors:

- Rosalyn C. King, PharmD, MPH, FNPhA; Founder and Projects Director (ret.), Howard University PACE Center, Washington, DC, USA.
- Prof. Dr. Felicia Loghin, PhD; Scientific Vice Rector, University of Medicine and Pharmacy, Cluj-Napoca, Romania.

Taiwan case study author:

- Yen-Huei (Tony) Tarn, PhD; Associate Professor, School of Pharmacy, Kaohsiung Medical University, Kaohsiung City, Taiwan.

USA case study author:

- Mitchel C. Rothholz, RPh, MBA; Chief Strategy Officer, American Pharmacists Association, Washington, DC, USA; and Secretary, Joint Commission of Pharmacy Practitioners, Washington, DC, USA.
