Typically passive surveillance, or passive reporting, of AEs by drug companies, health professionals, and patients are utilized in most countries around the world to capture AEs related to various health products, including prescription drugs (Pal, 2011). While product companies are mandated to report serious harms that occur during clinical trials or postmarketing surveillance, reporting by health professionals and consumers remains low. Unfortunately, we know that passive surveillance captures less than 1% of all ARs that occur (Wiktorowicz, 2010). While health professionals are mandated in their standards of practice to report all ARs identified in their practice, barriers such as time constraints and lack of confidence in completing AR reports prevent much of it from occurring (Wiktorowicz, 2010).

The issue of underreporting in passive surveillance AR reporting systems is further intensified when considering NHPs (Barnes, 2003). Many patients do not disclose CAM or NHP use to their conventional health professionals, such as physicians and pharmacists, and in return these health professionals often do not question about such use (Wiktorowicz, 2010; Pal, 2011; Morgan, 2012; Morgan et al., 2012). This reduces the likelihood that a patient will disclose an AE related to such products to their health professional. In addition, many individuals perceive NHPs to be safe since they are considered natural and therefore do not relate experienced AEs to a NHP itself (Raynor et al., 2011). It has been found that health care providers report NHP-related AEs to regulatory agencies, even when identified, less than drug-related AEs (Pal, 2011). Pharmacists, however, have been found to report AEs to regulatory bodies more than any other health care provider (van Grootheest et al., 2004); pharmacists likely do and should play an important role in reporting NHP AEs as well.

The Pharmacy SONAR research initiative across Canada aimed to identify rates of AEs associated with NHP use by implementing active surveillance strategies into community pharmacies (Vohra et al., 2012; Necyk et al., 2014). Active surveillance "seeks to

ascertain completely the number of adverse events via a continuous pre-organized process" (ICH, 2004). Different active surveillance approaches, such as electronic databases that track specific medical conditions or drug utilization, as well as strategies built into health clinics, have been found to markedly improve the frequency and quality of AE reports (Walley and Mantgani, 1997; Al-Tajir and Kelly, 2005; Talabi et al., 2009; NDB, 2013). Few active surveillance programs have been implemented for NHP-specific AEs. Pharmacy SONAR led such an aim, and the results were astonishing. When pharmacy staff systematically screened all individuals who visited the pharmacy about NHP AEs, the rates of such events identified were 3000 times greater than what had been captured by Health Canada through passive surveillance during the same time period (Vohra et al., 2012; Necyk et al., 2014). The SONAR protocol has been further applied to various specialty clinics, including mental health outpatient clinics, to identify NHP AE rates in individuals living with various chronic diseases (Necyk et al., 2016).

It is important for pharmacists to build active screening around NHP use and related AEs into their patient histories and discussions. This is especially true now that pharmacies are leading the sales of many NHPs and becoming a preferred source of information for individuals taking such products. All AEs related to NHP use should be reported to the respective regulatory agency in order to collect accurate safety data on such products. Since many NHPs do not require the premarketing clinical trials that prescription drugs do, monitoring and reporting of AEs is even more critical to improve patient safety.

Finding and Interpreting Evidence Surrounding Complementary and Alternative Medicine

Evidence-Based Medicine and CAM

Pharmacists are trained in evidence-based medicine, utilizing the most up-to-date and high-quality research to inform their practice decisions. This essential skill can become difficult to apply to CAM where much of the evidence pharmacists are accustomed to is lacking (Ung and Harnett, 2017). High-quality evidence surrounding CAM is lacking for various reasons, such as a lack of research funding dedicated to CAM to carry out the same premarketing clinical trials that pharmaceutical companies are able to do (Veziari et al., 2017). NHPs also do not require the same evidence base prior to marketing compared to pharmaceutical drugs, and in some countries, do not require any evidence at all, therefore, the need to conduct such research is not as urgent (Government of Canada, 2016; European Medicines Agency, 2018). Majority of studies exploring NHP efficacy and safety are observational in nature, and/or consist of small sample sizes that hinder the integrity and generalizability of the study results (Aickin, 2010). While randomized controlled trials (RCTs) are considered the gold standard level of evidence to be sought while assessing causality, it may be difficult to implement a placebo-controlled RCT for certain CAM treatments (i.e., acupuncture and chiropractic) (Aickin, 2010). While sham treatment procedures can be used in such a design, we must consider that part of the treatment effect that may be present when utilizing CAM lies within the placebo effect and the patient–provider relationship itself (Veziari et al., 2017; Spencer et al., 2018). It is also important to consider that this idea of situating RCTs at the top of the evidence pyramid is very much a Western medical concept. Countries and medical systems that follow more traditional belief systems do not necessarily hold this level of evidence to the same standard and, instead, value traditions and generations of treatments handed down through word of mouth and scripture (Aickin, 2010; Veziari et al., 2017). Pharmacists should practice evidence-based patient care, while simultaneously appreciating that the values and belief systems of such therapies may pose a challenge in this pursuit. Regardless, interpreting available evidence on CAM should be held to the same rigor as conventional treatments, assessing the validity, risk of bias, generalizability of the results while considering some of these nuances that may exist. In the same manner, evidence should be taken into consideration individually, alongside patient values and goals.

It has been reported that up to 80% of the public report using the Internet to gain health advice; many Internet sources are inaccurate and could lead to further patient harm (Williams, 2013). Given how accessible pharmacists that work in community settings are to the public, providing accurate education around CAM is an important public health initiative.

Resources for Locating Evidence on CAM Practices and Procedures

Pharmacists may need to identify up-to-date literature on various CAM treatments and procedures, such as chiropractic, massage therapy, and acupuncture, in order to provide integrative treatment plans or to educate the public. While extensive primary literature can be accessed through databases such as PubMed (NLM, 2018) and MEDLINE (Medline, 2018), not all health professionals have access to such resources. *BMC Complementary and Alternative Medicine* is the partnered journal for the International Society for Complementary Medicine Research and provides open access to all published articles within this journal (ISCMR, 2016; BMC, 2018). The United States' National Institute of Health (NIH) houses a National Centre for Complementary and Alternative Health that provides well-summarized descriptions and evidence on various CAM treatments, including scientific literature summaries on the effectiveness and safety considerations (NCCIH, 2017b). This resource is free to the public and all health professionals (NCCIH, 2017b). Also, out of the United States, Maryland Center for Integrative Medicine created Cochrane Complementary Medicine, an organization that aims to improve and disseminate quality systematic reviews related to CAM for widespread public use; this resource is also available at no cost to health professionals and the public and is beneficial since systematic reviews summarize and interpret available clinical trials in the literature (CCM, 2018).

Resources for Locating Evidence on CAM Products

A number of user-friendly databases and resources exist that summarize the most up-to-date evidence for thousands of NHPs. Free, comprehensive, and credible resources that are available to health professionals and the public include NIH's National Centre for Complementary and Alternative Health (NCCIH, 2017b) and American Botanical Council's HerbMed (HerbMed, 2018). An enhanced, more exhaustive version of HerbMed is also available at an additional cost through subscribing (HerbMed, 2018).

Pharmacists commonly report using the Natural Medicines Comprehensive Database (NCMD) to access such information, a database to which a subscription and associated cost is required (Ogbogu and Necyk, 2016; NMCD, 2018). Evidence and functions from both NCMD and Natural Standard have now been combined into the comprehensive database, Natural Medicines (TRC, 2018). The Natural Medicines team, which includes contributors from over 50 institutions, systematically collect data around mechanism of action, dosage, effectiveness, safety, and interactions on an extensive list of NHPs (TRC, 2018). Data are critically appraised and reported based on the relevance, validity, and quality of data available, and updated regularly; such a feature is exceptionally useful for pharmacists who are constrained by time pressures in their work environment (TRC, 2018). Natural Medicines provides practical information that is of interest and use to health professionals (TRC, 2018).

When accessing primary literature related to NHPs, tools utilized to critically appraise RCTs and observational studies such as the Cochrane Risk of Bias Tool (CRBT, 2018), STROBE checklists (STROBE, 2009), and the tools provided within JAMAevidence User's Guide to the Medical Literature: A Manual for Evidence-Based Clinical Practice (JAMAevidence, 2018) also apply and can be very useful. Specific tools for evaluating RCTs related to NHPs have been developed as well (Jurgens et al., 2009).

Where no evidence exists on particular NHPs or CAM treatments, it is important to have a discussion with the patient around the fact that a lack of evidence does not inherently indicate safety and that such products should only be used with caution and close monitoring for effect and toxicity. In the same manner, it is important to relay the message that a lack of available evidence also does not guarantee a lack of efficacy. It may be appropriate to engage in a benefit-risk discussion with the consumer to present alternative therapies, CAM, or conventional, which do have a solid evidence base backing them. Further discussion on how to communicate with individuals around CAM will follow in the next section.

Communicating with Patients about Complementary and Alternative Medicine Use

Before in-depth discussions can take place around CAM treatment options, patients must actually disclose such use or interest in use to their health professionals. Less than half of patients actually disclose NHP use to their physician for reasons including fear of judgment, immediate dismissal of concerns, and fear that their physician knowing may lead to halted access to NHPs on the market (Walji et al., 2010). Interestingly, the single greatest factor that led to disclosure of such use was the physician actually inquiring about NHP use (Busse et al., 2005); however, it has still been found that only 24% of pharmacists ask their patients about CAM use (Tiralongo et al., 2010). Pharmacists should always strive to collect a best possible medication history (BPMH) from all their clients in order to provide accurate, timely, and optimal care to each individual; BPMH guidelines clearly state the need to inquire about CAM use in addition to prescription and OTC drugs (OCP, 2007). CAM inquiries should be adopted as standard practice for all health professionals, but especially pharmacists since NHP use may significantly impact drug therapy.

When CAM use is disclosed or inquired into, it is appropriate for health professionals to engage in a shared decision-making care model when discussing CAM treatments with patients (Elwyn et al., 2012). Shared decision-making is defined as "an approach where clinicians and patients share the best available evidence when faced with the task of making decisions, and where patients are supported to consider options, to achieve informed preferences" (Elwyn et al., 2010). Often with CAM, health professionals assume that there is not enough evidence to support such treatment and may not actually take the time to search available databases and literature to support such a blanket recommendation. It is important to remember that we do not have to agree with our patients' choices to effectively communicate with them around that choice (Verhoef et al., 2008). If a client is considering CAM and taking the time to ask for advice, it is important to reciprocate with a fair search for available evidence in order to engage in an accurate discussion around the evidence. Listening to your patient and engaging in shared decision-making can go a long way in building a strong therapeutic relationship. It is through these actions and refraining from judgment that pharmacists can promote appropriate and safe use of CAM and prevent AEs related to specific products and interactions with other medications. Such an approach aligns with the WHO Traditional Medicine Strategy that advocates to "promote therapeutically sound use of appropriate traditional medicine by practitioners and consumers" (WHO, 2013b).

Conclusion

CAM use is prevalent and increasing each year worldwide. It is important for pharmacists and other health professionals to be aware of the regulations, safety considerations, and evidence behind such use in order to engage in shared decision-making models with their patients and to promote patient safety. Effective communication and adequate knowledge around CAM is pertinent to building strong therapeutic relationships with patients, as many individuals consider pharmacists frontline to providing accurate education around CAM use, especially NHPs. A variety of evidence-based resources and databases are available to pharmacists to gain additional expertise and information around CAM efficacy and safety.

Prevention and Management of Substance Misuse and Addiction in Pharmacy Practice

Beth A. Sproule, Maria Zhang, Centre for Addiction and Mental Health (CAMH) & Leslie Dan Faculty of Pharmacy, University of Toronto, Ont., Canada

Introduction

The health burden of substance misuse and addiction are major causes of disability and premature loss of life globally (Peacock et al., 2018). Pharmacists play a key role in optimizing pharmacotherapy in the management of alcohol, nicotine, and opioid use disorders, as well as in the prevention, monitoring, detection, and treatment of medication use disorders that arise during the therapeutic use of pharmaceutical products, for example, opioids, benzodiazepines, and medical cannabinoids. Health professionals report frequently identifying addiction to medications among patients, including those with long-term pain, mental health problems, sleep disorders, and other substance use disorders, but also report that these addictions are often not addressed (Hagemeier et al., 2016). The prevalence of use of these substances is extremely high (Peacock et al., 2018); therefore, pharmacists can expect to be presented with opportunities to help people prevent or manage substance use disorders as part of everyday practice. The primary role of pharmacists in clinical practice is to prevent, identify, and resolve drug-related problems. With this unique knowledge, skills, and responsibilities, the profession needs to take a lead role and actively engage in being part of the solution to the clinical problem of substance misuse and addiction.

Terminology in the addictions field can be confusing. Certain terms can go in and out of favor and there are often no standardized definitions. The term "addiction" has a long history, is generally understood, and is used interchangeably with terms such as dependency or habit. However, it is important to recognize that addiction is more than the development of physical dependence (i.e., tolerance to a substance or the presence of a withdrawal syndrome when use is reduced). Addiction has features reflecting difficulties in controlling use, continuing use despite knowing it is causing harm, and use of the substance taking priority over other aspects of life. It may or may not include physical dependence (American Psychiatric Association, 2013). As understanding the nature of addiction has progressed, so has the acceptance of addiction being a health problem, rather than a moral or criminal issue. However, there remains a pervasive pejorative attitude toward addiction (van Boekel et al., 2013). The term is not used in diagnostic classification systems, instead it is referred to as dependence syndromes or substance use disorders. Likewise, the term "substance abuse" is no longer preferred since it implies the problem lies solely with the person (unlike other health conditions), rather than the reinforcing properties of the substance itself (Broyles et al., 2014). Therefore, terms such as use or misuse are being used, where misuse reflects use that is associated with greater risk of harm.

Although there is a limited repertoire of pharmacotherapy options for substance use disorders, focused research continues to expand the field. It is accepted in many jurisdictions that pharmacotherapy is primary in the treatment of opioid use disorder (e.g., methadone, buprenorphine), with psychosocial interventions having an important supporting role. For all other substance use disorders at this time, psychosocial interventions are primary, with adjunctive pharmacotherapy options available for some. These include medications for alcohol use disorder (e.g., acamprosate, naltrexone, disulfiram) and smoking cessation (e.g., varenicline, bupropion), as well as medications to manage withdrawal symptoms (e.g., benzodiazepines for alcohol and sedative-hypnotic withdrawal symptoms, nicotine replacement therapy for nicotine withdrawal symptoms). Pharmacists have important roles in the provision of methadone and buprenorphine services in several countries. Likewise, pharmacists have broadly embraced providing some level of service to assist with smoking cessation. These roles could be expanded both in availability and scope, as well as pharmacists could take on a more proactive role in supporting pharmacotherapy for alcohol dependence. In specialty settings for medically assisted management of withdrawal syndromes, pharmacists are involved in the development of protocols, help monitor and adjust withdrawal treatment, monitor and treat general medical needs, and assist in providing patient education on substances. Pharmacists have also provided urine drug testing consultation services to assist providers with interpreting complex results. The patient-centered, clinically focused pharmaceutical care practice model provides an excellent

framework for pharmacists to provide assessments, develop care plans, conduct follow-up evaluations, and work collaboratively with other members of the health-care team.

Several pharmaceutical products have psychotropic properties that are experienced as reinforcing, either by producing pleasurable effects or relieving negative states. Some people may use these medications specifically for these effects, or they may be exposed to them for therapeutic reasons. Pharmacists are at the interface of the supply of these medications and the health-care system. Depending on the jurisdiction, these include both prescription medications (e.g., opioids, benzodiazepines, stimulants, cannabinoids) and nonprescription products (e.g., low-dose codeine products, dextromethorphan, dimenhydrinate). This has resulted in the need for pharmacists to know how to recognize and manage complex patients who may be using medications for therapeutic purposes and developing an addiction to them. The expansion of prescription monitoring programs providing real-time information to pharmacists at point of care can be a significant help clinically in identifying problems, for example, the presence of multiple prescribers or drug–drug interactions. In addition, pharmacists have traditionally played a role in preventing the diversion of prescription medication through their training to detect forged or altered prescriptions. Unfortunately, health-care providers often find it easier to dichotomize people into either "legitimate patients" (assuming that if the patient has an identifiable indication, then they are not at risk of addiction) or "abusers" (assuming there is no therapeutic need). This may do a disservice to everyone. It is likely that most people fall somewhere in between these extremes. Patients may not be monitored for a developing problem, and those labeled as abusers may not have their health problem treated adequately. Pharmacists may be the health-care provider most frequently in contact with these patients. They must be familiar with factors that increase the risk of addiction, have the skills to identify the emergence of addiction, and not miss opportunities for engagement in treatment. In addition, the profession should take on public health stewardship roles for these medications, including, for example, limiting quantities to reduce unused leftover medication, actively promoting safe storage, and accepting returns of unused medication for proper disposal.

There are barriers to pharmacists fully engaging in practice in the area of addictions. These broadly include the presence of pervasive stigma and a lack of robust education on the scientific basis of addiction and clinical management. Taken together, these contribute to pharmacists avoiding the topic with patients, to not treating patients with respect and compassion, and to a lack of confidence in the ability to help (Hagemeier et al., 2016; Matheson et al., 2016).

Stigma refers to negative attitudes (prejudice) and negative behaviors (discrimination) toward people using substances. Negative attitudes may stem from long-standing beliefs and judgments that this is a self-inflicted problem and people are weak for allowing this to happen. As our understanding of the neurobiology of addiction improves, it is clear that exposure to these psychoactive substances causes neurobiological changes that contribute to compulsive use, that the acute rewarding effects are only part of the picture, and brain functions related to learning and memory are key contributors. Some people are more vulnerable than others, based on genetics as well as life experiences and stressors, including other psychiatric comorbidities (Volkow and Boyle, 2018).

There is a recognition that negative attitudes persist in part due to the language used in this field, which reinforces ideas that people are unworthy or "bad." This has led to recommendations for the use of alternative language and a message that "words matter." For example, rather than call someone an "addict" or "abuser," use first person language and say he/she suffers from addiction or a substance use disorder. They are more than their addiction. Do not refer to people as "clean" when they are successful in stopping harmful substance use—the implication is that they were "dirty" before. It is better to indicate they are in recovery. These words can have an impact on the person's self-perception, their willingness to seek help and on their clinical outcomes (Broyles et al., 2014).

Substance use disorders are generally not covered in most undergraduate pharmacy training programs, nor are they a focus of continuing education programs, despite the prevalence of these disorders. Pharmacists who report having education in the area are more likely to interact and feel more confident in their interactions with patients (Lafferty et al., 2006). Education must include the scientific basis of addictions, the evidence-base for pharmacotherapy and other treatment approaches, the development of good communication skills with other health-care team members, and the use of motivational conversations to help guide patients toward behavior change.

Of course, pharmacists are also susceptible to developing substance use disorders, and several aspects of the profession may actually increase the risk (Merlo et al., 2012). Most notably, access can be a key issue in the development and maintenance of an addiction to prescription drugs, in particular. Mechanisms for obtaining drugs from the pharmacy include taking expired drugs awaiting disposal or keeping patients' returned unused medications, changing inventory records to steal drugs, or forging prescriptions. This may be exacerbated by the pharmacist's perception that they are drug experts and can manage their use. Contributory factors may also be stressful work environments and reluctance to seek treatment due to potential professional consequences. Recognition of the problem and confidential access to assessments, treatment, and monitoring are important. A unique challenge in long-term recovery may be the return to a work environment that includes exposure and handling medications, which could serve as triggers for resuming use. In this case, pharmacists may need to seek out professional opportunities that do not involve dispensing, for example, drug information, medication reviews, or other clinical roles.

The follow sections focus specifically on pharmacy practice issues related to opioids, benzodiazepines, alcohol, and nicotine.

Opioids

Opioid medications including, morphine, hydromorphone, hydrocodone, oxycodone and fentanyl, have a significant role to play in the management of acute pain and cancer-related pain (World Health Organization, 2017). For many in developing countries

around the world, appropriate access to opioids for pain relief is often lacking. The vast proportion of all opioids used globally are accessed and consumed by a small subset of the population, particularly by those in North America. Concurrently, there is a need for improved quantity and quality of pharmacological and nonpharmacological options for pain management, particularly for chronic noncancer pain, across the world. However, with access to opioids comes exposure to opioids. All opioids have an inherent risk of misuse because of their ability to activate key reward pathways in the brain. For some people, an opioid addiction or use disorder may occur as a result of a complex interaction between genetic predisposition, concurrent psychiatric conditions, and/or psychosocial factors such as a history of trauma. Individuals who have a current or past history of substance use are likely at highest risk of developing problematic opioid use. As a preventative measure, pharmacists can proactively assess patients' risk prior to dispensing an opioid medication, particularly in a primary care setting. For example, the Opioid Risk Tool is a validated self-report questionnaire that stratifies opioid-naïve patients with pain to an estimated low, moderate, or high level of risk for developing problematic opioid use (Webster and Webster, 2005). This tool stratifies risk based on the patient's age, sex, personal and family history of psychiatric illness, and/or substance use. Clinicians can utilize the score to established individualized monitoring parameters to balance rational access to opioid medications while minimizing risk of iatrogenic opioid-related harms such as opioid addiction, or at least ensuring earlier detection of it (Webster and Webster, 2005). While the Opioid Risk Tool has sufficient sensitivity and specificity, it is worth noting that individuals stratified as being of lower risk can still develop an opioid use disorder, and those who are at high risk could still be provided access to opioids, depending on the indication (e.g., severe acute pain), within a more robust monitoring program.

To decrease acute and long-term harms associated with prescription opioids, pharmacists can recommend or initiate opioid stewardship strategies that promote safe and rational access to opioids. For example, depending on relative scopes of practice, pharmacists may wish to independently, or recommend to prescribers, reduce the quantity of opioids dispensed at a single time. In the context of acute pain, this could mean dispensing three to seven days' worth of medication instead of providing one month's supply of opioids. Similarly, for cancer-related pain management, consider dispensing one month's worth of medication at a time, rather than 3 months' worth. This supports the health and safety of the patient, their family, and their community as it minimizes the risk of overdose and/or diversion. Other examples of opioid stewardship include encouraging safe storage of medications and employment of a 'take-back' program of unused medications, with a particular focus on opioids and other narcotic or controlled substances.

In jurisdictions where access to codeine can be obtained without a prescription (frequently at low doses per dosage form), pharmacists may have an even more crucial role to play with respect to ensuring rational access to opioids and monitoring for effectiveness and safety. While codeine may be considered a "weak" opioid, problematic use does occur with its exposure. In fact, likely because of its relative low potency and lower risk in overdose, and thus the increased access or prescription of it relative to other opioids, codeine poses a significant public health issue that is frequently under recognized (Nielsen and Van Hout, 2017). Furthermore, medical complications can arise from its use and overuse as it is frequently combined with other analgesics that may produce gastric bleeding (when combined with nonsteroidal anti-inflammatory drugs) or hepatotoxicity (when combined with acetaminophen).

For all medications with abuse liability, including opioids, pharmacists should regularly monitor for requests for early refills, multiple prescriptions from different health-care providers, altering the medication's dosage form (e.g., chewing and swallowing tablet as opposed to ingesting it whole), and/or acquiring them from nonmedical sources. While these signs are not diagnostic of an opioid addiction or use disorder, they can be signals that a patient is having poorly managed physical or mental pain and/or problematic opioid use. When these signs are observed, wherever possible, pharmacists should take a patient-centred approach to care by providing an objective assessment of the behavior to appropriately triage and refer, where needed. This contrasts a paternalistic approach, which may be punitive, judgmental or stigmatizing. One way to prioritize the patient's health and well-being and maintain a therapeutic alliance is to ask "how" and "why" questions related to the behavior, as opposed to the individual. For example, asking the patient about why they think their opioid use has increased over a short period of time, or how much time per week they spend acquiring new prescriptions from various practitioners.

More formally, as with other substance use disorders, opioid use disorder (or addiction) is characterized by impaired control, social impairment, risky use, and physical dependence (i.e., tolerance and/or withdrawal) (American Psychiatric Association, 2013). For individuals who are using opioids under medical supervision, a diagnosis of opioid use disorder or addiction cannot be made based on the presence of physical dependence via withdrawal symptoms or tolerance (decrease in effects with continued use at the same dose) (American Psychiatric Association, 2013). Both are expected with regular use of opioids, regardless of reason for use. Opioid withdrawal is characterized by signs and symptoms such as sweating, increased pupil size, runny nose or tearing, gastrointestinal upset, tremor, and anxiety or irritability (American Psychiatric Association, 2013).

Pharmacists can support all patients receiving opioid therapy by distinguishing between physical dependence and an opioid use disorder or addiction. Fear of developing an opioid use disorder may prevent some individuals who have an appropriate indication for opioid therapy from using it, even with an appropriate monitoring plan in place. The risk of iatrogenic complications associated with opioid use needs to be balanced with under treatment of syndromes such as acute pain, which may then progress to chronic pain.

In individuals who develop a moderate to severe opioid use disorder to nonprescription or prescription opioids, and/or illicit opioids such as heroin, opioid agonist treatment with methadone or buprenorphine should be initiated as soon as possible and for as long as the treatment is beneficial for the patient. While adjunct psychosocial support is preferred, it should not be a stipulation of accessing pharmacological treatment given its strong evidence base. Given the high rates of relapse associated with abstinence based

therapy, simply managing an individual's acute opioid withdrawal symptoms does not equate treatment of the opioid use disorder. In fact, solely offering or promoting "detoxification" from opioids may elevate an individuals' risk of death when relapse to opioid use occurs in the context of decreased tolerance (Sordo et al., 2017).

Methadone and buprenorphine are considered first-line medications to treat opioid use disorders. Based on their evidence in reducing mortality, improving treatment retention, reducing spread of blood-borne illnesses, and decreased rates of illicit opioid use, both forms of opioid agonist treatment are considered essential medications by the World Health Organization. In fact, other than nicotine replacement therapy, methadone and buprenorphine are the only medications on the list of essential "medicines for disorders due to psychoactive substance use" (World Health Organization, 2017).

Methadone is a synthetic, long-acting, full agonist at key opioid receptors. Over decades of research and use, there is extensive clinical and epidemiological evidence supporting its role in improving individuals' physical and mental health, social functioning, and quality of life. Through once daily oral ingestion of methadone, once an effective individualized dose is achieved, methadone diminishes the effects of other opioids, and its long half-life breaks the cycle of negative reinforcement by preventing the onset of opioid withdrawal symptoms. For pregnant women with an opioid use disorder, methadone protects both the mother and the developing fetus from obstetrical and fetal complications associated with unpredictable yet frequent changes in opioid concentration (Terplan et al., 2018).

Buprenorphine is a relatively newer treatment for opioid addiction. It is a partial mu-receptor agonist that is frequently formulated with naloxone, an opioid antagonist, to minimize misuse via injection or insufflation. Due to safety benefits conferred by its mechanism of action as a partial-agonist, buprenorphine can be quickly titrated to a stable dose, and is preferred in individuals who might be at risk of experiencing adverse effects with methadone, a full opioid agonist. This would include individuals who have prolonged QTc intervals, baseline respiratory illness, severe constipation, and/or concurrently taking central nervous system depressant medications or substances. Anecdotally, buprenorphine is also considered to have less of an association with stigma. As such, buprenorphine may be used first when initiating pharmacotherapy for treatment-naïve individuals with an opioid addiction. Due to its partial mu-receptor agonist action, individuals should be in at least moderate opioid withdrawal before the first buprenorphine dose to prevent the risk of precipitated withdrawal. One frequently used scale to help in this assessment in clinical practice is the Clinical Opiate Withdrawal Scale (COWS) (Wesson and Ling, 2003).

Both methadone and buprenorphine treatment typically occur as part of a structured dispensing process. Specifically, patients usually present to a health clinic or pharmacy for daily observed doses, particularly during treatment initiation. While this structure likely minimizes the risk of diversion and supports closer monitoring of opioid agonist treatment effectiveness and safety, mandating individuals to present for daily doses can be viewed as stigmatizing, onerous on patients, and deter their motivation to participate in treatment. Wherever possible, arrangements should be made to promote easier access to methadone and buprenorphine, for example, for the patient to receive dosing at a nearby pharmacy or clinic of their choice as opposed to one that is physically geographically challenging to get to. Additionally, like any other patient, all patients with an opioid use disorder presenting to the clinic or pharmacy should be treated with respect. This is particularly important for patients with an opioid use disorder as they often have been stigmatized by their family, community, and by other health-care professionals who have written them off as "drug-seeking" or "weak" for not being able to "deal with their habit." Witnessed or observed doses can be particularly contentious as it may be perceived as mistrust between the medical community and the individual; the clinician may have to ask to look underneath the patient's tongue to check of dissolution of buprenorphine tablets, for example. To emphasize respect and empathy, individuals should be offered a seat in a private area to take their methadone or buprenorphine dose, while still being witnessed by a pharmacist or health-care provider (Isaac and Sproule, 2009).

As mentioned previously, the length of opioid agonist treatment depends on the patient and their goals of therapy. In general, longer durations of treatment are associated with better outcomes for patients (Barrio, 2017). It provides patients with an opportunity to build resilience and address contributing factors to their substance use disorder, including trauma or concurrent psychiatric illness. If or when patients wish to taper off of opioid agonist treatment, longer, flexible, and individualized tapers lead to better patient outcomes as compared to short tapers (Sordo et al., 2017).

Regardless of what individuals choose with respect to treatment for their opioid use disorder, harm reduction strategies should be offered in conjunction with pharmacological and nonpharmacological resources. Naloxone is a pure opioid antagonist that is indicated for use in emergency situations to temporarily reverse the potentially fatal effects of an opioid overdose. Evidence has shown that take-home naloxone kits decrease overdose mortality with minimal adverse effects (McDonald and Strang, 2016). In some jurisdictions where pharmacists can provide take-home naloxone kits pursuant to a prescription, or more independently via a medical directive, or without a prescription at all, pharmacists can provide crucial information related to opioid overdose prevention, along with how to respond to an opioid overdose. Take-home naloxone kits should also be recommended to caregivers of, and individuals who are taking opioids for pain management as they are at risk of experiencing an opioid overdose or poisoning as well, particularly if they are on other central nervous system depressants or using high doses of morphine or equivalent. Other harm reduction strategies are discussed in further depth later in the chapter.

Sedative–Hypnotics

Sedatives (drugs that tend to calm or soothe) and hypnotics (drugs that produce sleep) are widely used in clinical practice. They are also frequently used on a long-term basis with little evidence to support this practice. These medications include, for example,

benzodiazepines (e.g., lorazepam, alprazolam, diazepam), "z-drugs" (e.g., zopiclone, zolpidem), and barbiturates. The use of barbiturates for sedation has largely been replaced by benzodiazepines due to their better safety profile. By comparison, benzodiazepines are safer in overdose, have a less severe withdrawal syndrome, and have a lower abuse liability. Benzodiazepines are used therapeutically for sleep disorders, anxiety and mood disorders, alcohol withdrawal, and for aggressive behaviors in psychosis. They also have muscle relaxant and anticonvulsant properties. Although safer than older sedative-hypnotics, benzodiazepines can cause cognitive and coordination problems, psychomotor impairment, physical dependence, and addiction (Lader, 2011). They are frequently prescribed for patients at increased risk of adverse effects, including those with substance use disorders, or taking other CNS depressant medications (e.g., opioids) (Kroll et al., 2016; O'Brien et al., 2017). They are recommended primarily as adjunctive therapy short-term early in treatment to help acute symptoms while the primary treatments (both pharmacological and nonpharmacological) reach their full effect.

The question remains, why is long-term use so prevalent? Do they continue to be effective, or is it due to the development of physical dependence or addiction? Regular use at therapeutic doses can produce physical dependence. It may be that the emergence of withdrawal symptoms drives continued use. Patients may interpret symptoms experienced at the end of dosing intervals, with missed doses, or when their dose is decreased as proof that the medication is still needed. Although not all patients experience symptoms when discontinuing long-term benzodiazepine use, many people report anxiety, insomnia, restlessness, agitation, and irritability. Less frequently symptoms could include nausea, lethargy, blurred vision, aches and pains, and ataxia (Busto et al., 1986). Rarely serious symptoms are experienced such as seizures, psychosis, and tinnitus (Lader, 2011). The more serious symptoms, particularly withdrawal seizures, are more likely after abrupt discontinuation of high doses. Overall, it is recommended that benzodiazepines should not be abruptly discontinued, but tapered slowly, often over several months (Pottie et al., 2018). In practice, pharmacists should be continually evaluating long-term benzodiazepine use, communicating with patients and prescribers, balancing the risks and perceived benefits, and encouraging initiation of a taper. When managing a taper, it is important to let patients know what to expect, particularly that withdrawal symptoms are temporary.

Beyond physical dependence, some people develop an addiction to sedative-hypnotics. There are recreational drug users that use high doses of these drugs. They are often used by individuals who use other substances (Busto et al., 1996). For example, those with a past history of alcohol dependence are also more likely to become dependent on benzodiazepines. They are also one of the most common drugs to test positive in urine drug screens of patients on opioid agonist therapy (Heikman et al., 2016). They may be part of a polysubstance use pattern, or used when drugs of choice are not available. There are no pharmacotherapy options for the treatment of sedative-hypnotic addiction. Tapering strategies are used to manage withdrawal symptoms, and nonpharmacological therapies are the mainstay. In cases of multiple substance use, tapering may be initiated in inpatient medically assisted withdrawal settings; however, longer-term tapering may still be required. Pharmacists have a role in the development, implementation, and monitoring of tapering regimens, especially in a multidisciplinary environment.

Alcohol

Worldwide, almost one in five of the adult population engage in heavy episodic alcohol drinking (Peacock et al., 2018). In general, countries that have greater economic wealth have more people consuming alcohol and fewer abstainers. Approximately 5% of the global burden of disease and injury have been attributed to alcohol consumption (Global Burden of Disease Collaborators, 2018). All levels of government have instituted policies to help reduce the harmful use of alcohol.

In clinical practice, pharmacists have the opportunity to respond to several common clinical presentations of alcohol dependence. These presentations include patients experiencing alcohol withdrawal symptoms, those seeking help to reduce or stop drinking alcohol, and those experiencing medical complications due to alcohol use.

Alcohol withdrawal symptoms are common among those drinking more than 40 standard drinks per week on a regular basis (Butt et al., 2011). Although not needed for all patients, the goals of pharmacotherapy for alcohol withdrawal are to prevent the life-threatening symptoms (seizures, delirium tremens), reduce other symptoms such as autonomic hyperactivity, anxiety, and nausea/vomiting. Benzodiazepines are very effective in treating withdrawal symptoms due to cross tolerance with alcohol (Amato et al., 2010). Protocols where benzodiazepines are administered using a "symptom" triggered approach, particularly with an initial dosing load that matches the patient's level of tolerance have been shown to be effective (Devenyi and Harrison, 1985; Soravia et al., 2018). The Clinical Institute Withdrawal Assessment for Alcohol (CIWA-Ar) is a validated, commonly used scale to guide medication needs (Sullivan et al., 1989). In addition, routine administration of thiamine helps to prevent Wernicke's encephalopathy, the symptoms of which could be missed during withdrawal (Chandrakumar et al., 2018).

For those seeking help to maintain abstinence and prevent relapse, acamprosate and naltrexone are options for adjunctive treatment that are thought to work by helping with cravings and reducing rewarding effects. They have very different mechanisms of action and unique features that help guide decision-making with patients. Disulfiram is an older medication that produces an aversive reaction when alcohol is consumed. The efficacy of this medication has not been well established in clinical trials; however, it may be helpful for some patients. Pharmacists can make two key contributions in the treatment of alcohol dependence. One is to advocate for the use of these medications when appropriate—they are not as widely used as they may be indicated, particularly in primary care settings. The other is to work with patients to promote adherence. Nonadherence is common and has been linked to poorer outcomes. Regular interactions and exploring ambivalence using techniques such as motivational interviewing may be helpful. Psychosocial interventions are key in the treatment of alcohol dependence. Approaches such as cognitive-behavioral

therapy focus on dysfunctional beliefs toward alcohol use and help to modify this. Options include individual or group therapy, family therapy (in outpatient or residential settings), and self-help groups (Ray et al., 2018).

Patients also seek health care for the medical complications of alcohol use, whether or not the attribution to alcohol has been made or acknowledged. These complications can be quite varied and include, but are not limited to, liver disease (fatty liver, hepatitis, and cirrhosis), esophageal varices, Wernicke's encephalopathy, Korsakoff's dementia, peripheral neuropathy, sleep disorders, hemorrhagic stroke, cardiomyopathy, arrhythmias, and impotence (Butt et al., 2011). Clinical assessments for these conditions must include a determination of the contribution of alcohol consumption to the clinical picture.

Many countries have instituted low-risk drinking guidelines. These are comprised of daily, weekly, and/or per episode recommended consumption limits, generally in the range of 2–3 drinks per day for men, and 1-2 drinks per day for women, with drink sizes ranging from 8 to 14 g of alcohol (Butt et al., 2011). A clinically useful definition of problem drinking includes regularly drinking above the guidelines and developing a social or physical problem as a result, without meeting the threshold for a diagnosis of alcohol dependence. In practice, people may not recognize their alcohol consumption is risky, if the patterns appear normal based on their peer group, for example. Reframing this within the context of what is "normal" or less risky may be helpful. The four-item screening test for alcohol problems (the CAGE) is a simple, validated clinical tool (King, 1986). The questions are Have you ever felt you ought to ***C***ut down on your drinking?; Have people ***A***nnoyed you by criticizing your drinking?; Have you ever felt bad or ***G***uilty about your drinking?; Have you ever had a drink first thing in the morning to steady your nerves or to get rid of a hangover (***E***ye opener)? A "yes" response to two or more of these questions is suggestive of alcohol problems requiring further evaluation.

Routine screening and brief interventions (SBIs) in primary care or emergency department settings have a good evidence base for reducing alcohol-related harms (Wamsley et al., 2018). Research from several countries in pharmacy settings indicate that patients across the spectrum of alcohol use support involvement of pharmacists in reducing alcohol use and endorse the appropriateness of pharmacists to serve in this public health role (Dhital, 2010, Sheridan, 2012, Hattingh, 2016, Mackridge 2016, Fitzgerald 2015). Pharmacists are also express willingness to take on this further scope of practice, with some evidence for effectiveness (Fitzgerald, 2009, Horsfield, 2012, Khan, 2013). SBI in pharmacy settings often included used of the AUDIT C and a recent drinking history, followed by provision of feedback and advice. The service may also include providing referrals for further assessment and treatment (also known as SBIRT). People identified with higher risk are referred to their general practitioner or to specialized alcohol services. Factors influencing the success of the brief intervention approach include pharmacist attitudes (e.g., perception that alcohol is a sensitive topic) and lack of confidence and training in brief motivational discussions (Horsfield, 2012, Brown, 2014). It has been shown that pharmacists can be trained to deliver the service and those with more a positive attitude provide more brief interventions (Dhital, 2013).

Smoking Cessation

It has been estimated that approximately 15% of the adult population smoke tobacco daily (Peacock et al., 2018). Tobacco smoking has the highest burden of disease among substances (Peacock et al., 2018). The many health risks for people who smoke include cardiovascular diseases, several types of cancer, respiratory diseases, erectile dysfunction in men, and menstrual and pregnancy problems for women such as premature delivery and low birth weight babies. Successful interventions exist, both pharmacological and nonpharmacological, with combinations recommended. Nicotine replacement therapy (NRT), bupropion, and varenicline are the three first-line pharmacotherapy options recommended, with varenicline having the largest effect (Cahill et al., 2013). The choice of agent is based on patient preference and the clinical situation.

Nicotine replacement therapy is generally a safe choice since a regular smoker is already exposed to nicotine; however, the pharmacological nicotine products eliminate the risk of exposure to the harmful constituents in tobacco. Therefore, it is a better way to deliver nicotine to manage nicotine withdrawal symptoms. The nicotine patch in particular helps provide a more even exposure to nicotine with gradual reduction, avoiding the extreme peak and trough nicotine levels associated with smoking cigarettes. Combining nicotine patch treatment with other forms of NRT is reasonable with titrating the nicotine dose early in therapy, to provide options for faster onset products to help at times of severe craving, or based on patient preference to provide flexibility in choosing different products for different situations. Sometimes NRT can be used to help reduce smoking as a harm reduction approach. Earlier concerns regarding cardiovascular adverse events from smoking while on NRT have been dismissed. NRT, varenicline, and bupropion are all considered safe treatment options in patients with cardiovascular disease. (Benowitz et al., 2018) There has also been concern over neuropsychiatric adverse effects such as suicidality and aggression, but it is unlikely to occur, particularly in those without psychiatric disorders. For those with psychiatric disorders, it is less clear and they may have a small increased risk requiring close monitoring (Anthenelli et al., 2016). All three first-line agents are efficacious in patients with psychiatric disorders. This is important because this population has a higher rate of smoking than the general population (Lawrence et al., 2009). Other clinical factors can be considered in recommending an agent, for example, if the patient is at increased risk for seizures, then bupropion is not a good option. Likewise, varenicline may be less desirable in someone with poor renal function. Other comorbidities and concomitant medications must also be considered.

Although successful interventions exist, there is a need for more health-care practitioners to provide smoking cessation interventions. When surveyed, pharmacists see themselves as having a role in providing cessation support to their patients (Ashley et al., 2007). Pharmacists are generally very accessible health professionals and often a primary source of contact for smokers seeking advice on quitting smoking. In addition, community pharmacists are able to simultaneously provide both smoking cessation

interventions and NRT to smokers who want to quit. In some jurisdictions, pharmacists can initiate varenicline and bupropion. Increasing the utilization of pharmacists in smoking cessation activities may have a positive impact on reducing smoking rates at the population level.

All health-care providers, including pharmacists, should document the smoking status of patients and clearly advise those that smoke to quit. Patients should also be assessed for their interest in stopping smoking. A readiness to quit assessment can be as simple as asking the patient to indicate both their desire and confidence in quitting on a 10-point scale. Those willing to begin treatment should be offered assistance. Although any level of intervention can be helpful, the more intensive the intervention the patient receives (i.e., session length, number of sessions) the more it is effective (Stead et al., 2015). Patients can be offered a variety of supports, for example, self-help print or Internet-based resources, and individual or group sessions, in combination with pharmacotherapy. Motivational interviewing approaches to guide and encourage patients can be effective (Lindson-Hawley et al., 2015). Patients should have regular follow-up and support as needed.

When pharmacists are working with patients to initiate pharmacotherapy, there are several key additional considerations to take into account, in addition to usual factors weighed when making recommendations to prescribers (e.g., drug interactions, renal function, past responses), particularly when independently initiating varenicline or bupropion. When assuming responsibility for treatment with these agents, it is important to consider how well-known the patient is in order to be confident that it will be possible to provide adequate monitoring and follow-up, or that there is confidence that the patient will be in contact if an adverse effect develops. A risk evaluation is part of the clinical decision-making process. A comprehensive history and good clinical documentation is essential.

Evaluations of pharmacist-led smoking cessation services have included interventions ranging from providing minimal education to pharmacy personnel to providing comprehensive three- to four-month structured pharmacist-led programs. These programs have taken place in community pharmacies and, hospital settings, in person or by telephone, with prescriptive authority or not, and in groups or individual sessions. In general, these studies provide support for pharmacists delivering effective smoking cessation interventions in a variety of settings (Mdege, 2014, Dobrinas et al., 2014).

Harm Reduction

Harm reduction is often described as health or social initiatives aimed to reduce negative consequences of alcohol or drug use, without requiring individuals reduce or abstain from drug use (Thomas, 2005). Harm reduction does not equal approval of drug use. Instead, it is pragmatic and accepts that drug consumption does occur within a society and that individuals act autonomously in making decisions about drug use (Thomas, 2005).

Social initiatives aimed to reduce drug-related harms may include decriminalization or legalization of substance possession or consumption such that individuals who use drugs are less likely to receive a criminal record, and therefore, the downstream negative consequences that carries (Thomas, 2005). Alternatively, opioid-related mortality can decrease with relatively smaller changes in legislation. This includes improving access to take-home naloxone kits by delisting it as a prescription drug, or by offering protection for individuals who require or seek emergency help during an overdose to reduce fear of police and to encourage activation of emergency first responders (Health Canada, 2018).

With respect to reduction of other health-related harms, there is a vast amount of literature highlighting the cost-effectiveness of connecting individuals using substances to biopsychosocial support and treatment, as opposed to the criminal justice system.

To apply harm reduction principles, pharmacists must first ascertain whether or not their patient uses alcohol and/or other substances. While this may initially be a challenging question to ask given the shame that society frequently casts on individuals with drug use, pharmacists who incorporate this within their standard assessment simultaneously collect richer information about the patient and destigmatize drug and substance use. As much as possible, this information should be collected in a private area and kept confidential. Considering the profound impact of words, pharmacists should be mindful of what they say and how they say it. Using patronizing language such as "I don't think you use drugs, but I have to ask, are you using anything else other than alcohol?" is presumptive and closes the door to a more meaningful conversation about substance use. Instead, open the dialogue by stating "Many people use drugs or substances. These may impact their health or some of the medications they're on" to provide context for the question, and to build trust and engagement. This can be followed by, "Are you using anything other than alcohol?."

While abstinence is the only way to prevent negative consequences associated with drug use, for individuals who cannot or do not wish to abstain from substance use, pharmacists can apply recommendations from guidelines that promote lower-risk substance use. For example, in the context of alcohol use, while total abstinence is preferred, avoiding alcohol use in certain situations such as prior to, or during driving, can significantly reduce rates of motor vehicle accidents. By avoiding binge drinking and keeping alcohol use to a maximum of a few drinks per day, and having alcohol-free days during a week, patients can significantly reduce acute and long-term complications of alcohol use including cirrhosis, and a whole host of cancers (Global Burden of Disease Collaborators, 2018). To reduce the psychoactive effects of cannabis, pharmacists may advise individuals who wish to continue using cannabis to use strains of lower delta-9-tetrahydrocannabinol (THC) potency. Individuals may also reduce their exposure to carcinogenic chemicals by vaping, instead of smoking. Similar to alcohol use, individuals who use cannabis should be advised to avoid driving for several hours after cannabis use and to avoid using it with other central nervous system depressants (Fischer et al., 2017).

In the context of injection drug use, evidence-based harm reduction strategies decrease rates of blood-borne illnesses by making drug consumption supplies readily and freely available (e.g., needles and sterile water for injection) and by taking back used supplies. Other initiatives include improved access to legally sanctioned supervised drug consumption sites where individuals use drugs with the supervision of health-care providers who can respond quickly to any medical or psychiatric complications from drug consumption and connect individuals with harm reduction supplies or substance use disorder treatment. In particular, supervised injection sites have demonstrated lower rates of overdose mortality for people living within its vicinity, as well as reduced rates of ambulance calls to treat overdoses, reduced rates of cutaneous injection-related infections, and reduced rates of Human Immunodeficiency Virus (HIV) infection. Importantly, the presence of supervised injection sites has not been demonstrated to increase drug use or trafficking in nearby areas (Potier et al., 2014).

Given the relative ease of access to pharmacies, and therefore pharmacists, public, and preventative health initiatives promoting harm reduction could integrate well within pharmacy practice. One frequently cited example in the literature is pharmacists' involvement in reducing the harms associated with injection drug use, namely, transmission of HIV and Hepatitis C Virus (HCV). In some jurisdictions, pharmacists may be informally, and perhaps unconsciously, involved in reducing harms of injection drug use through selling needles to decrease transmission of blood-borne illnesses. However, legal restrictions may impede a pharmacist's ability to support these initiatives. For example, some jurisdictions prohibit pharmacists from distributing or selling sterile needles without a prescription and/or confirmation that the patient has a qualifying illness such as insulin-dependent diabetes. Other barriers to implementing harm reduction strategies may include lack of remuneration for services and/or supplies and insufficient education and training about substance use and harm reduction (Watson and Hughes, 2012). Simultaneously, pharmacists may consciously or unconsciously hold stigmatizing views on individuals who use drugs, which may present as fear of attracting the "wrong clientele" to their practice setting, or overlook the applicability of harm reduction to their current patients (Watson and Hughes, 2012).

As a key point of contact, pharmacists also play an important role in referring patients, and their caregivers, to other health-care provider and community resources. Pharmacists should be aware of local public health centers that provide harm reduction supplies, addiction treatment centers and supervised injection sites, where available.

Conclusion

The health burden of substance misuse and addiction are major causes of disability and premature loss of life globally. Pharmacists play a key role in optimizing pharmacotherapy in the management of alcohol, nicotine, and opioid use disorders. Pharmacists also have an important role in the prevention, monitoring, detection, and treatment of medication use disorders that arise during the therapeutic use of pharmaceutical products, for example, opioids, benzodiazepines, and medical cannabinoids. In addition, some pharmacists have been involved in screening and brief intervention activities and providing harm reduction services. There are barriers to pharmacists fully engaging in practice in the area of addictions, including the presence of pervasive stigma and a lack of robust education on the scientific basis of addiction and clinical management. Progress has been made in overcoming these hurdles. The prevalence of use of substances is extremely high; therefore, pharmacists can expect to be presented with opportunities to help people prevent or manage substance use disorders as part of everyday practice. With unique knowledge, skills, and responsibilities, the profession of pharmacy needs to take a lead role and actively engage in being part of the solution to the clinical problem of substance misuse and addiction.

Self-Care/Over-the-Counter Drugs/Minor Ailments in Pharmacy Practice

Nardine Nakhla, School of Pharmacy, University of Waterloo, Waterloo, ON, Canada

Introduction

This chapter introduces the concept of self-care and explores its universal value to healthcare.

The current self-care marketplace, including legislative and regulatory influences, and characteristics common to today's self-care consumers, are described. The expanding role of pharmacists in encouraging safe and effective self-care practices is reviewed, with consideration given to variation between countries. An introduction to the Pharmacists' Patient Care Process, as well as its application to self-care encounters is discussed. Interviewing frameworks and documentation considerations pertaining to self-care are also explored. Other tools to aid pharmacists in self-care recommendations are presented, including those to facilitate the provision of culturally competent care. Throughout this chapter, the term nonprescription replaces over-the-counter (OTC), reflecting formal usage in pharmacy practice—however, in other publications and common parlance, these designations are often used interchangeably. This chapter concludes with a discussion of thoughts on the future of self-care, as it relates to pharmacy.

Self-Care

The History and Evolving Definition

Self-care has been common practice among centuries of human history. There is no single definition of self-care that is universally accepted in the literature, as definitions vary depending on the setting in which the term is used and stakeholders' perspectives (Ausili et al., 2014; Godfrey et al., 2011; Health Canada, 2002; Soller and Mann, 2014). The World Self-Medication Industry (WSMI) defines self-care as "a life-long habit and culture. It is the action individuals take for themselves and their families to stay healthy and take care of minor and long term conditions, based on their knowledge and the information available, and working in collaboration with health and social care professionals where necessary" (WSMI, 2017).

All health-related activity can be described as a continuum (Self Care Forum), with purely self-initiated activities (e.g., preventative healthy lifestyle choices) on one end to fully managed care (e.g., major trauma) on the other (Self Care Forum). Treatment of minor ailments and self-management of long-term conditions are found towards the middle of this scale. Patient and caregiver engagement, understanding and support is essential across the continuum, as Dzau et al. (2017, pp.5) suggest it is associated with patient "health and wellbeing, as well as system efficiency, quality, and overall performance."

In summary, self-care is characterized by individuals who take proactive roles for themselves, on behalf of and with others in order to develop, protect, maintain, and improve their physical and psychological health (Self Care Forum) and involves three core elements: self-care maintenance, self-care monitoring, and self-care management (Riegel et al., 2017; WSMI, 2017).

The Seven Pillars of Self-Care

The International Self-Care Foundation (ISF) holistically illustrates the entire range of self-care activities and many possible entry points for self-care in their seven pillars framework (Fig. 1). It is known that unhealthy behaviors—smoking, excessive alcohol consumption, poor diet and insufficient exercise—tend to 'cluster' together in individuals and particular parts of a population (Nakhla, 2018). Interestingly, healthy behaviors in the seven pillars also cluster together. This implies that if a person is motivated towards one self-care aspect (e.g., smoking cessation), they may also be more strongly disposed towards undertaking other healthy behaviors (e.g., losing weight) (ISF, 2017). Clinicians can use this approach to better understand patients' self-care practices and to tailor specific interventions aimed at improving one or more of the domains (Nakhla, 2018).

It should be emphasized that while the seven pillars framework is designed to describe the entire range of self-care activities, individual circumstances, and country conditions mean that self-care practices vary considerably around the world. Self-care practices in resource-poor countries are inevitably somewhat different to those of richer countries, for example.

Minor Ailments

Minor ailments (also known as common ailments, common conditions, minor illnesses, self-limiting conditions, self-treatable conditions, and ambulatory conditions) are defined as "common or self-limiting or uncomplicated conditions which can be diagnosed and managed without medical intervention" (Paudyal et al., 2013). These conditions represent an important aspect of self-care, given that the public is more apt to self-treat such ailments (Nakhla, 2018). The most prevalent problems cited in the literature can be categorized into four therapeutic areas: pain disorders (e.g., headaches, musculoskeletal), respiratory issues (e.g., coughs, colds), skin conditions (e.g., acne) and gastrointestinal disturbances (e.g., indigestion) (Fielding et al., 2015; Rutter, 2015; Self Care Forum, 2018; Taylor and Joubert, 2016).

When people feel ill, a complex process is initiated to determine how best to return to health. This includes an assessment of symptom severity and the impact on day-to-day life, all within the context of their present health, social circumstances, finances, and other forces (Nakhla, 2018) Several paths could be followed: do nothing (wait-and-see approach), use a nondrug measure, take medication, or seek professional medical care (Taylor, 2013). In the United States (US), a recent survey found that 93% of adults prefer to treat minor ailments with nonprescription medications before seeking professional care (Consumer Healthcare Products Association, 2010). In the United Kingdom (UK), 87% of people report self-treating minor ailments often, with 42% saying they do

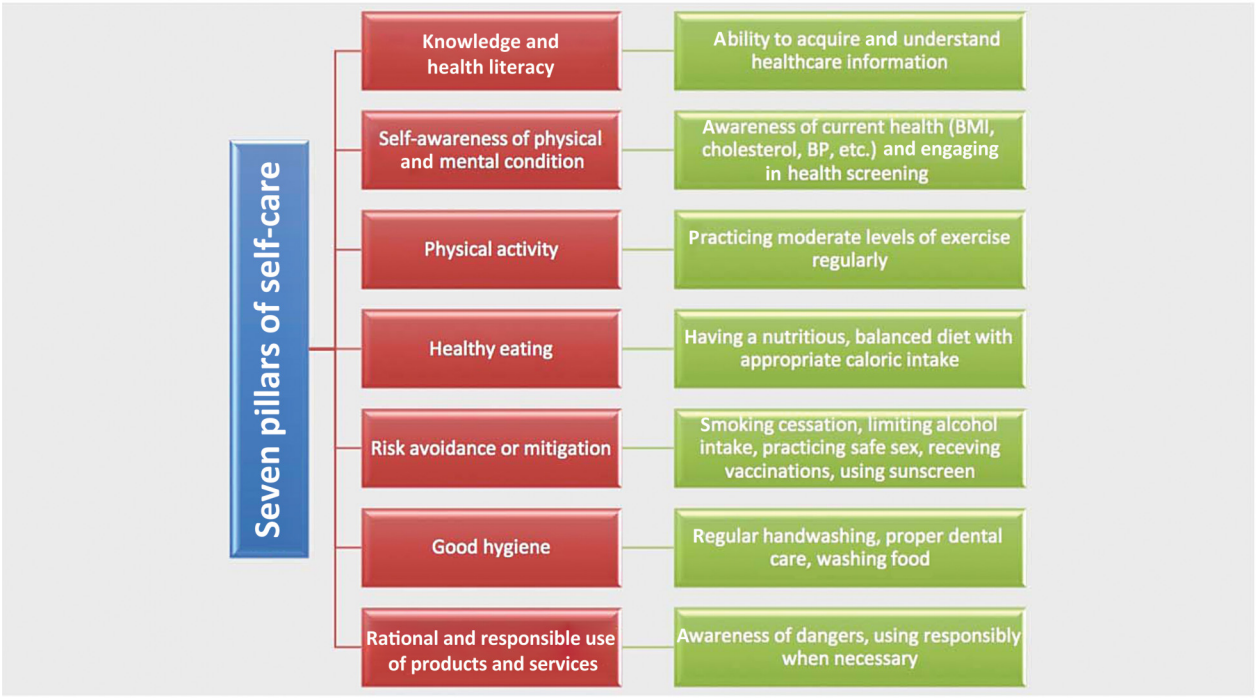

Figure 1 The seven pillars of self-care. *Source: Adapted from ISF, 2017. The seven pillars of self-care. International Self-Care Foundation (ISF). Available from: http://isfglobal.org/practise-self-care/the-seven-pillars-of-self-care/; Webber, D., Guo, Z., Mann, S., 2013. Self-Care in Health: We can define it, but should we also measure it? SelfCare, 4, 101–206.*

it all the time (Department of Health (UK), 2005). Despite this, minor ailments consultations in general practice cost an alarming £2 billion annually (Paudyal et al., 2013) and take up, on average, an hour a day for every general practitioner (GP) (Self Care Forum). As such, minor ailment consultations still present a major burden on higher cost healthcare settings; uncertainty about the services and treatments available from pharmacies exists with patients and HCPs, therefore, effective strategies are required to raise awareness regarding conditions that can be effectively managed by pharmacists and to assist patients in changing these health-seeking behaviors (Fielding et al., 2015).

It is imperative to note that although discussions of self-care and minor illness often go hand in hand, they are not the same. As alluded to above, self-care refers to the broad approach taken for the specific ailment, be it minor or otherwise (Taylor, 2013). For example, a person who rests and drinks warm fluids when they have a cold is engaging in self-care for a minor ailment, whereas a person who elevates their feet to alleviate swelling in heart failure is practicing self-care for a more serious, chronic condition (Taylor, 2013). A minor ailment, on the other hand, is the target illness itself when considered common, self-limiting or uncomplicated (Paudyal et al., 2013). Recognition is growing that promotion of self-care is considered a crucial factor for chronically ill patients' care (Ausili et al., 2014).

Understanding Today's Self-Care Landscape

Consumers today are increasingly driven and empowered to manage their health using self-care. According to a 2014 survey by the National Council on Patient Information and Education (NCPIE) and Pfizer Consumer Healthcare, most individuals agree that nonprescription products are an important tool to better manage one's health and to address health issues quickly (NCPIE, 2014). Furthermore, a 2013 survey showed that almost 98% of primary care physicians, nurse practitioners, and pharmacists recommend nonprescription medicines to their patients, with 84% of consumers saying they trust their HCP's recommendations (CHPA, 2013).

Self-Medication

Self-medication is a key component of self-care and is defined as the selection and use of medications – legally classified as drugs specifically designed and labeled for use without medical supervision and approved as safe and effective if used as directed for such use—by individuals to treat self-recognized illnesses or symptoms (Brown et al., 2013; Rutter, 2015; WSMI, 2017). Self-care medications are often called 'nonprescription' or 'OTC' and are available without a prescription. In some countries, nonprescription products are also available in other retail outlets (e.g., supermarkets, gas stations) and are commonly self-selected

by the public. Three general categories of products are available for self-medication: (1) Nonprescription medications, (2) dietary supplements, and (3) complementary and alternative medicines (CAMs). This chapter will focus on nonprescription medications.

While the common practice of self-medication has been around long before pills came into existence, there has been steep growth in self-medication practices globally as both HCPs and consumers recognize the value and cost savings that nonprescription products offer. US data show that 81% of US adults use nonprescription products as a first response to minor ailments, and off-the-shelf availability of these medicines provides symptomatic relief for an estimated sixty million people who otherwise would not seek treatment (CHPA, 2017b). However, choosing nonprescription products continues to be overwhelming for many consumers given the multitude of choices available, not only within each therapeutic class, but between brand, generic and private labels (Sclar et al., 1996).

Facilitated Self-Medication

"Facilitated self-medication" occurs when consumers seek assistance at the point of product purchase. In community pharmacies, pharmacy students/interns or pharmacists are often responsible for this facilitation. Limited research has revealed that recommendations provided by pharmacy staff influence consumer-purchasing decisions (Rutter, 2015). For example, in studies by Nichol et al. (1992) and Sclar et al. (1996), 25.4% and 42.6% of consumers, respectively, altered their nonprescription purchasing decision when proactively approached by pharmacy students. In the study by Sclar et al. (1996, pp.180), these changes reduced product expenditures by an average of US $1.53 per customer (attributable to movement from brand to lower-priced generic or private label equivalents). A notable number of consumers, 13.4% (Nichol et al., 1992) and 8% (Sclar et al., 1996), made no purchase after consultation, which resulted in cost savings and avoidance of errors in self-medication. Furthermore, 1.3% (Nichol et al., 1992) and 4.3% (Sclar et al., 1996) of consumers were referred to a physician after features warranting further medical assessment were identified. This emphasizes the role of pharmacists and pharmacy staff in self-care and highlights an opportunity for ensuring safe and effective self-medication practices. It also accentuates the consumer need for pharmacy consultation and additional product information in order to "optimize both the therapeutic appropriateness of, and pharmaceutical expenditures for, nonprescription medication" (Sclar et al., 1996).

Self-Care Market

Nonprescription medicines are a trusted first line of treatment to alleviate symptoms, with more than two-thirds of consumers preferring to use a nonprescription medication instead of a prescription agent when available (CHPA, 2013). Studies show that certain populations may be more inclined to use nonprescription products—90% of pregnant women, for example, have been reported to use them (Smedberg et al., 2016). Approximately 50% of Polish patients use nonprescription medications for the first time without consulting a pharmacist or physician (Piecuch et al., 2017).

In the US, retail sales of OTC medications and dietary supplements exceeded US$34 billion in 2016, representing a 10-fold increase since 1974 (CHPA, 2017a). In Canada, domestic retail sales of consumer health products have also increased rapidly over the last decade, valuing CAD$5.6 billion in 2014 (CHP Canada, 2017). The global self-care marketplace continues to expand, with well over 100,000 nonprescription products available in the US alone.

Impetus for Continued Growth

Two main trends that have contributed greatly to the expanding self-care market are (1) growing consumerism, and (2) increased healthcare costs and demands.

Various social and health trends have also altered individuals' outlook on health and the way in which they perceive their own health status. Increased access to almost instantaneous, limitless health information via the Internet and mobile, coupled with improved educational levels and subsequent health literacy, has caused a shift towards informed, empowered consumers wishing to become more active in their healthcare. Self-care products provide individuals with the opportunity to take more responsibility for, and become more involved in, their health. The spike in digital health technology has also engaged patients by supporting more personalized and tailored health care (Dzau et al., 2017). For example, mobile phone applications that monitor daily habits, weight fluctuations, steps taken, and calories burned (e.g., MyFitnessPal) are trending (Sarasohn-Kahn, 2013).

Changing demographics worldwide, including a greater number of older adults living longer and with more complex chronic conditions and medication regimens, the provision of medical care is becoming increasingly expensive. In some countries, wait-times, and access to family physicians are concerning. The increasing incidence of noncommunicable diseases, including potentially preventable conditions (e.g., heart disease, diabetes), is also associated with significant disease burden and costs. These rising healthcare costs have led to global healthcare reform, which has included encouraging the public to use effective and cost-efficient self-care. In many countries, self-care has been integrated into public health policy, with the main impetus to divert people from the formal healthcare systems to save resources. These efforts have successfully increased the self-management of conditions by patients, with approximately 80% of all care in the UK now being self-care (Self Care Forum), resulting in a self-care market with immense revenue potential. Also fueling this growth is prescription-to-nonprescription switches (Porteous et al., 2006) (see section, 'Regulatory and Legal Considerations').

The Benefits of Self-Care and Self-Medication

Self-care products play an increasingly important role in the healthcare of millions as they offer symptom relief and disease prevention while providing convenience and affordability to patients. As documented by Brown et al. (2013, pp.113) and several other researchers, "the added convenience of OTC medicines is the primary reason why consumers prefer these products to prescription medicines for the treatment of common health conditions, such as headache, heartburn, and allergies." This accessibility eliminates the stress and inconvenience of GP visits, saving time and money, and reducing lost work productivity. For example, a 2004 European Union study estimated over 16 billion in annual savings from shifting 5% of professional care to self-medication (AESGP, 2012). In the US, every dollar spent on nonprescription medicines saves the healthcare system US $6–7 in avoided costs.

Utilizing self-care can enhance patients' self-care confidence by improving their skill set and empowering them to care for certain conditions on their own, such that GPs are only visited when necessary (Bell et al., 2016). This gives the public greater control over their own health and encourages healthy behaviors that help prevent future illnesses. With other HCPs, namely pharmacists, guiding patients in the self-management of ailments, GPs are able to focus on caring for higher risk patients and managing long-term conditions (Self Care Forum). Canadian industry data shows that if only 16% of Canadians who see the doctor for mild symptoms practiced self-care instead, an additional 500,000 Canadians could have access to a family doctor (Willemsen and Harrington, 2012).

Furthermore, increased personal responsibility around healthcare has been shown to improve people's health and wellbeing (Self Care Forum). In particular, self-care management has been shown to enhance disease-state control, reduce overall health distress, and improve mental health when incorporated into therapy (Marks et al., 2005). For example, Ausili et al. (2017) showed that diabetics engaging in self-care have improved metabolic control, reduced cardiovascular risk, fewer disease-related complications, and enhanced quality of life. Other self-care initiatives with demonstrated success include, but are not limited to, the prevention of cardiovascular disease with lifestyle modifications (e.g., diet and exercise), the use of nicotine replacement therapy for smoking cessation, and the treatment of lice infestations with nonprescription medications.

In summary, empowering people to manage their health conditions through self-care, such that a physician is only consulted when needed, may improve wellness, increase life expectancy, reduce costs and demands on the healthcare system, allowing for scarce resources to be redeployed in priority areas. Note however, that while available literature on self-care is encouraging, significant correlations between self-care practices and outcome measures (e.g., general health status, quality of life, healthcare costs) have been underreported and additional studies are needed (Ausili et al., 2014).

The Pharmacist's Role in Self-Care and Minor Ailments

Pharmacists have a crucial role to play in self-care and minor ailment management as they are one of the most accessible HCPs worldwide (Nichol et al., 1992) and are among the best trained to advise patients on the selection and manner of use of nonprescription medications (Schimmelfing et al., 2017). In fact, supporting self-care is recognized as being a core activity of the profession in many countries (European Commission, 2013). Based on their knowledge, assessment skills, experience, location, and availability, pharmacists are ideally placed to assist a patient in their self-care journey to ensure safe and effective therapies are recommended to optimize health outcomes.

Pharmacists provide valuable information to ensure patients receive treatments that are appropriate for a given condition. Education specifically designed for the patient's level of understating is central to self-care monitoring (Wilde and Garvin, 2007). After the initial diagnosis of a condition, the pharmacist is responsible for educating the patient on identifying signs and symptoms of recurrence and ways to effectively self-treat these recurrences, as well as identifying circumstances when it would be more appropriate to consult a physician or emergency medical care (e.g., if symptom severity increases or alarm features develop). When patients understand the symptoms that correspond with their disease, they can learn to recognize these symptoms early on and can more effectively self-manage their disease and prevent complications (Wilde and Garvin, 2007).

Based on these functions and findings, the World Health Organization (WHO) describes pharmacists as being communicators, drug suppliers, collaborators, and health promoters in self-care and self-medication (WHO Consultative Group on the Role of the Pharmacist and World Health Organization, 1998). As communicators, pharmacists initiate dialogue with patients, formulate questions to gather pertinent information, and provide objective education on therapies using a variety of modalities based on patient-specific factors. As drug suppliers, pharmacists provide access to nonprescription medications and ensure products are from reputable sources and are of good quality. As collaborators, pharmacists establish relationships with patients, other HCPs, and various stakeholder groups to facilitate continuity of care, ensure resources and expertise are used to their full potential, and improve outcomes through shared decision-making and interdisciplinary care. Finally, as health promoters, pharmacists screen patients in the community to identify those at risk of health problems, advise patients on disease prevention and other health-related practices, and participate in campaigns to raise awareness of public health issues. Additional roles for pharmacists in self-care and self-medication include managing minor ailments and ensuring safe and appropriate self-medication practices, as described below.

Managing Minor Ailments in the Community

Estimates out of the UK suggest that 15%–40% of emergency department (ED) visits and 20% of GP consultations, respectively, are for minor ailments that could be managed in community pharmacies—a reportedly underutilized resource (Richardson et al., 2018). Results from a cohort study by Watson et al. (2015) suggest that patients with minor ailments presenting in community pharmacies have similar health outcomes to those in GP and EDs, but costs are substantially lower for pharmacy-managed consultations. The authors concluded that "the substantially lower costs associated with pharmacy management of these ailments, combined with similar health outcomes across settings, suggest there is an urgent need to identify effective interventions to promote the use of community pharmacies for the management of minor ailments. These interventions should be evidence-based and underpinned by behavior change theory to maximize their effectiveness and reproducibility" (2015, pp.13).

Thus, shifting care for certain conditions from physicians to other HCPs can help to alleviate the increasing burden on the healthcare system by reducing costs and resource utilization (Bell et al., 2016). Therefore, pharmacists play a vital role in helping consumers manage minor ailments without costly and time-consuming physician visits.

Facilitating Safe and Appropriate Self-Care and Self-Medication

Inappropriate use of nonprescription products can increase morbidity, mortality and related healthcare costs. One reason for this is that these medications have the potential to interact with prescription products, causing adverse events, especially in vulnerable patient populations (e.g., older adults, immunocompromised individuals). The increased risk of adverse outcomes secondary to self-medication in these groups may be related to the presence of multiple disease states, higher prescription drug use, and/or impairments in activities of daily living. Other vulnerable patient populations include infants, children, and women who are pregnant or lactating. Pharmacists should ensure patients understand that self-care products are not without safety concerns and emphasize the importance of using these products as directed (Nakhla, 2018).

The abuse and addiction potential of some nonprescription medications is also a growing concern (Cooper, 2013) and will be discussed further in Regulatory and Legal Considerations. Pharmacists can play a pivotal role in deterring misuse and abuse by informing related policy regulations, and interventions. However, essential to this is the need for additional research to more fully "quantify the scale of abuse, evaluate interventions and capture individual experiences" (Cooper, 2013, pp. 103–104).

Other inappropriate self-medication practices can be harmful from a public health perspective and require prompt action (Annadurai et al., 2017). For example, an increasing incidence of self-medication with antimicrobials has contributed to one of the greatest global health threats ever—antimicrobial resistance (Alhomoud et al., 2017; Annadurai et al., 2017; Ayalew, 2017; Wang et al., 2016; Zoorob et al., 2016). Pharmacists have a responsibility to advocate for appropriate self-care and raise awareness of the potential negative consequences of inappropriate practices. This may include participating in community antimicrobial stewardship efforts or other public health initiatives.

Another important role for pharmacists in self-care and self-medication is ensuring symptoms perceived to be minor are not the result of an undetected, more serious condition (European Commission, 2013). This requires that pharmacists exercise enhanced clinical judgment, with particular attention to the presence of alarm features, previous treatment attempts, and behaviors suggesting avoidance of care. Accurately identifying the need for further medical assessment is crucial for avoiding delays in the treatment of more serious ailments.Last but not least, collaboration with other HCPs is a key step in implementing system-wide improvements to facilitate the delivery of safe and effective self-care and to reduce healthcare costs.

Pharmacists' Patient Care Process in Self-Care

Advising patients on self-care activities is an important component of pharmaceutical care and carries great professional responsibility (Nakhla, 2016). A contemporary, consistent and comprehensive model, the Pharmacists' Patient Care Process (PPCP) was developed by the Joint Commission of Pharmacy Practitioners (JCPP) (JCPP, 2014). The PPCP was built on previous approaches to care and was designed to achieve the JCPP Vision for Pharmacists' Practice (JCPP, 2013), which states "patients achieve optimal health and medication outcomes with pharmacists as essential and accountable providers within patient-centered, team-based healthcare."

The PCPP provides a systematic five-step approach for the delivery of pharmacists' patient care services in any setting, however, the intensity of each step may vary depending on the service provided in that particular setting. By using principles of evidence-based practice to *Collect*, *Assess*, *Plan*, *Implement*, and *Follow-Up*, in addition to continual collaboration, documentation, and communication, this standardized process helps pharmacists provide consistent services to patients. The following section will provide a comprehensive overview of the PPCP, outlining each step within the process, the multiple components of each step, and ways of implementing the steps with a focus on self-care encounters.

PPCP: The Core

As shown in Fig. 2, the PPCP features a patient-centered core.

The patient-centered care approach depends first and foremost on the pharmacist having an established relationship with the patient—one that supports engagement and effective interactions throughout the process (JCPP, 2014). Several strategies can be

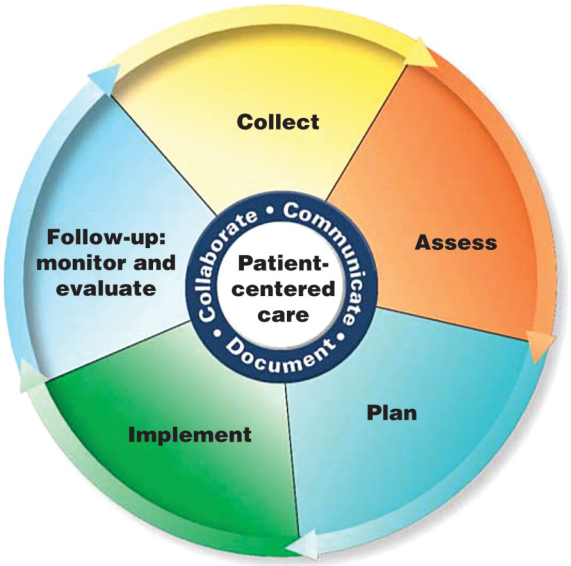

Figure 2 PPCP components. *Source: JCPP, 2014. The pharmacists' patient care process. Joint Commission of Pharmacy Practitioners. Available from: https://jcpp.net/patient-care-process/.*

used to encourage patient-centered self-care encounters including, but not limited to, active listening, empathy, ensuring patients are well-informed, and involving patients in their care.

Collaboration and communication occur most often with patients and/or caregivers in the context of self-care encounters, although other HCPs may be contacted for referral. An informed or shared decision-making model, based on information exchange and mutual expression of preferences between a professional (e.g., pharmacist) and a patient, is desirable when selecting nonprescription medication in a pharmacy, as such a model respects patient empowerment in self-medication and results from patient-centered care (Murray et al., 2006; Piecuch et al., 2017).

It is essential that self-care encounters be documented, as it demonstrates the pharmacist's "contributions to care, ensures continuity of care, provides legal evidence for professional liability, and contributes to billing and reimbursement needs" (Divine and McIntosh, 2018). Documentation can be completed on paper or in a computer system, so long as it is timely and legible. Documentation by pharmacists may include, but is not limited to, medication action plans, notes on interventions or referrals, and follow-up information. Some pharmacists may choose to use an established method of documenting, such as a *SOAP* note, which organizes information into *s*ubjective and *o*bjective data gathered, the pharmacist's *a*ssessment, and the recommended care *p*lan. Such an approach may help to ensure documentation is complete, organized and presented in a manner that is familiar to other HCPs.

PPCP: The Five Steps

Self-care encounters in pharmacies typically occur via two paths. In one, a patient or caregiver will initiate the interaction by contacting or approaching the pharmacist with their concern. In the second path, the pharmacist or pharmacy staff initiate the interaction and offer assistance after observing the patient or caregiver in the nonprescription aisle (Lauster and Srivastava, 2014; Nichol et al., 1992). Reports from various countries indicate that when advice is received, the process is initiated almost exclusively by patients (Sclar et al., 1996). Regardless of the path, the pharmacist must build rapport with the patient in order to establish engagement and effective communication, and complete the five PPCP steps to determine the most appropriate recommendation(s).

Collect

> "The pharmacist assures the collection of the necessary subjective and objective information about the patient in order to understand the relevant medical/medication history and clinical status of the patient" JCPP (2014).

Collecting appropriate information is key to understanding the patient's health status. This may include:

- *Medication history*: (current and past medications)
  - Prescription
  - Nonprescription
  - Dietary supplements
  - CAM

- *Relevant health data*:
  - Medical history
  - Health and wellness information
  - Biometric test results
  - Physical assessment findings
- *Patient-centered factors:*
  - Lifestyle habits
  - Preferences and beliefs
  - Health and functional goals
  - Socioeconomic factors

Professional clinical judgment should be exercised when determining which factors are pertinent to collect in each specific self-care situation. For these encounters, most information collected will be in the form of subjective data gathered from the patient or caregiver during the patient interview. There may or may not be a need to collect objective information—unbiased data that can be collected through direct observation and measurement—from medical and pharmacy records, diagnostic studies and laboratory tests, and physical assessment (Herrier et al., 2015). It may be appropriate to perform physical assessment for certain consults but not for others as some patients may not be able to explain what their condition looks like, but may be able to show it. For self-care interactions, it is important to determine why the patient is seeking help or looking for a nonprescription product and then ask the patient to explain the condition, symptom, or problem she/he wishes to treat. Throughout the interview, the pharmacist must use open-ended questions and carefully listen to and consider the patient's response, needs, wants, habits, preferences and beliefs to ensure the process remains patient-centered.

Assess

> "The pharmacist assesses the information collected and analyzes the clinical effects of the patient's therapy in the context of the patient's overall health goals in order to identify and prioritize problems and achieve optimal care" JCPP (2014).

This step includes:

- *Medication assessment*:
  - Appropriateness; effectiveness; safety; adherence
- *Patient history and risk assessment:*
  - Health and functional status; risk factors; health data; cultural factors; health literacy; access to medications or other aspects of care
- *Preventive care assessment:*
  - Immunization status; Preventive care needs; Other services, where appropriate

For self-care encounters, this step may or may not encompass all components listed above, and involves differentiating the patient's signs/symptoms to correctly identify the problem(s), its severity, urgency and most probable cause.

Medication assessment

In contrast to a comprehensive medication review involving the analysis of each medication the patient is currently taking (JCPP, 2014), a self-care encounter generally includes a more targeted medication review (Divine and McIntosh, 2018). For example, a focused medication review in self-care may include assessing the cause of a patient's chief complaint as potentially medication-related (e.g., was a patient presenting with vulvovaginal candidiasis recently started on a medication known to increase the risk of this type of infection, such as canagliflozin?). The pharmacist's role in these situations is to identify and prioritize medication-related problems and make subsequent modifications to the patient's care plan. While all are possible, the most likely medication-related problem in a self-care encounter is "needs additional drug therapy," as patients are presenting with the intent to purchase a product to treat a disorder and may require a nonprescription medication for resolution (Divine and McIntosh, 2018). It is also essential to consider the risks and potential benefits associated with each medication, including an assessment of whether current self-care therapies are working for the patient in the way they were intended to.

Patient history and risk assessment

Analyzing key information (e.g., health and functional status) in this category may alter a pharmacist's assessment and plan. For example, if it is determined that a patient seeking self-care for recurrent aphthous ulcers has human immunodeficiency virus, the assessment would be an exclusion for self-treatment as the patient requires further medical evaluation and treatment beyond self-care.

Preventive care assessment

For self-care encounters, the pharmacist often focuses the preventive care assessment on the presenting chief complaint. For example, if a patient presents with diaper dermatitis, the pharmacist may assess the need for future diaper dermatitis prevention and recommend a preventive plan that includes a barrier product.

Appropriateness for self-treatment assessment

For self-care encounters, patient-specific data should also be assessed to identify exclusions for self-treatment. To establish that the patient is an appropriate self-care candidate, ask if the patient (1) has any severe symptoms, (2) has any symptoms that persist or return repeatedly, or (3) is self-treating to avoid medical care. A patient meeting any of these three criteria is not an appropriate self-care candidate and should be referred to primary care providers for nonurgent issues or to emergency services for urgent issues (Buring et al., 2007), since most conditions that can be safely self-treated are characterized as having no severe symptoms and no symptoms that are persistent, or repeatedly return without an identifiable cause. Additionally, patients should not self-treat in an attempt to avoid evaluation and treatment by a HCP. Divine and McIntosh (2018) list additional exclusions for self-treatment, including:

- Patient-specific factors that preclude treatment with nonprescription medications
- Health status or history that precludes self-treatment, even if a nonprescription medication is indicated for the disorder
- Nonprescription medications are not indicated for the disorder
- Previous treatment with nonprescription medications was ineffective after an adequate trial

It is the responsibility of the pharmacist to be knowledgeable in exclusion criteria for self-treatment for presenting disorders or symptoms as well as gathering appropriate information that may result in this assessment (Divine and McIntosh, 2018).

Plan

> "The pharmacist develops an individualized patient-centered care plan, in collaboration with other health care professionals and the patient or caregiver that is evidence-based and cost-effective" JCPP (2014).

In a self-care encounter, information that has been gathered, assessed, and analyzed thus far will culminate in one of four general recommendations:

- Refer to another HCP (for treatment and/or further evaluation)
- Recommend self-care until another HCP can be consulted
- Recommend self-care
- Do nothing/watch-and-wait approach

If self-care is deemed appropriate, the pharmacist can provide the patient with a suitable plan. This plan may not include any pharmacologic recommendations but rather nonpharmacologic measures. If referring and recommending self-care measures, it is imperative to emphasize that the referral is the primary recommendation and explicitly states the repercussions of ignoring this advice.

This plan should be developed in collaboration with other HCPs and the patient or caregiver, and should be individualized, evidence-based, safe, cost-effective, and patient-centered. Four key areas that should be addressed within the created care plan include:

Medication-related problems

For self-care encounters, this usually results in the pharmacist recommending a safe and cost-effective self-care product to resolve the "needs additional drug therapy" problem (Divine and McIntosh, 2018).

To ensure patient-centrality and an individualized approach, it is crucial to involve the patient in the decision-making process for product selection or discontinuation and tailor therapy to meet the patient's preferences and beliefs. For example, provide the patient with a choice of products, dosage forms and regimens, costs, and flavors if possible, and consider their past medication experiences.

Goals of therapy

Goals of therapy serve as endpoints to measure outcomes and should contain three components: (1) clinical parameters (signs and symptoms) and/or laboratory values which are observable, measurable, and realistic; (2) a desired value or observable change in the parameter; and (3) a specific time frame in which the goal is to be met. For self-care encounters, the clinical parameter is likely to focus on resolution of the presenting sign or symptom, such as "alleviate the discomfort associated with primary dysmenorrhea" when an NSAID is recommended. Alternatively, the clinical parameter may be a preventive measure, such as suggesting oral rehydration solution to prevent progression of dehydration from mild to severe.

Establishing the patient's goals of therapy and formulating realistic timelines for achieving clinical outcomes in the context of their overall health goals and access to care is imperative (JCPP, 2014) and establishes clear expectations. For example, "curing" a cold is not possible but symptomatic relief is.

Patient engagement

Known as a "blockbuster drug of the century" (Chen et al., 2016), patient engagement in healthcare has the potential to achieve the "triple aim" of improved health outcomes, better patient care and lower costs (Chen et al., 2016). Every self-care encounter requires the pharmacist to engage the patient through education, empowerment, and self-management (JCPP, 2014). Education should encompass the presenting illness, pharmacologic and nonpharmacologic options, as well as when to seek medical attention. Empowerment results from engaging the patient in goal setting and aligning expectations.

Care continuity

The plan should include the continuity of care, involving follow-up, referral, and transitions of care to another HCP, if necessary.

Implement

> "The pharmacist implements the care plan in collaboration with other health care professionals and the patient or caregiver" JCPP (2014).

Included in this step is execution of the developed plan, in which the pharmacist:

- Addresses *medication- and health-related problems*
  - Engages in preventive care strategies, including vaccine administration
- *Initiates, modifies, discontinues, or administers medication therapy* (as authorized)
- *Provides education and self-management training* to the patient or caregiver
- *Contributes to coordination of care*, including referral or transition of patient to another HCP
- *Schedules follow-up care* as needed to achieve goals of therapy

The pharmacist should share the goals of therapy that were established and the subsequent self-care strategies. It is important to explain what the therapies are, how they will help, and what the patient should do as follow-up. The pharmacist should then educate on how to take the medication and the duration of therapy; addressing common adverse effects and ways of managing them is also important. Clear articulation, in patient-friendly language, of what the patient should expect from treatment, as well as an understanding of follow-up and monitoring parameters (including signs that the condition might be worsening and when to seek the advice of a physician) are imperative. Where applicable, the education should also include lifestyle modifications, nonpharmacologic therapies, as well as future prevention measures. In some instances, no medications will be indicated, and only wellness and preventative measures will be suggested.

Follow-Up: Monitor and Evaluate

> "The pharmacist monitors and evaluates the effectiveness of the care plan and modifies the plan in collaboration with other health care professionals and the patient or caregiver as needed" JCPP (2014).

The final step of the PPCP is ongoing monitoring and evaluation of:

- *Medication appropriateness, effectiveness, safety, and patient adherence* (through available health data, biometric test results, and patient feedback)
- *Clinical endpoints* contributing to the patient's overall health
- *Outcomes of care*, including progress toward or the achievement of goals of therapy

It is imperative to evaluate the self-care plan outcomes and adjust when results are not optimal. From a patient safety perspective, this step should include the documentation and reporting of any adverse drug events to appropriate personnel, followed by appropriate adjustments to therapy to avoid additional adverse outcomes. Changes to care plans should also be documented and communicated to the patient's entire healthcare team to ensure patient safety, effective follow-up, and continuity of care.

Patients should be provided with an appropriate follow-up plan, including timing and triggers, which would warrant a pharmacist or physician visit. Encourage patients to call or return if symptoms fail to resolve. While follow-up may not be possible in some self-care encounters due to the patient being unfamiliar to the pharmacy or workload/time restrictions, there are times when follow-up is vital to ensure patient safety. Pharmacists should use professional judgment in determining which cases require follow-up.

Tools and Mnemonics for PPCP Efficiency

A systematic approach to determining patients' self-care needs results in consistent and comprehensive patient assessment, optimizing therapeutic outcomes. Several tools have been developed (Bates et al., 2002; Buring et al., 2007; Margolis et al., 2016; Maguire, 2015; McCallian and Cheigh, 2002) to assist pharmacists in standardizing their approach to information gathering, patient assessment and triage. It is important to note that these tools and mnemonics are NOT meant to replace the

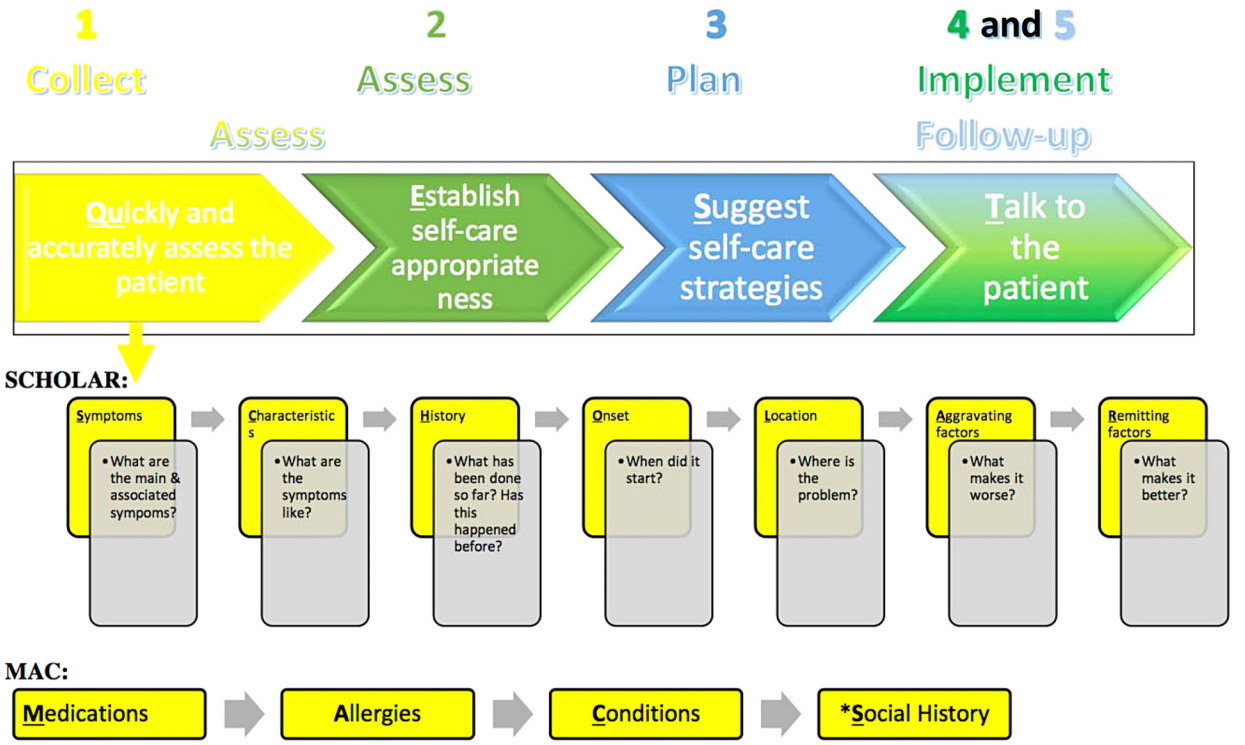

Figure 3 Tools and mnemonics for PPCP efficiency. *S for social history is not part of the original published algorithm, but was added by the author to ensure pharmacists also consider lifestyle factors such as physical activity, diet, smoking, alcohol intake, caffeine consumption, etc. *Source: Adapted from JCPP, 2014. The pharmacists' patient care process. Joint Commission of Pharmacy Practitioners. Available from: https://jcpp.net/patient-care-process/; Divine, H., McIntosh, T., 2018. Pharmacists' Patient Care Process in Self-Care. In: Krinsky, D. L., Ferreri, S. P., Hemstreet, B. A., Hume, A. L., Newton, G. D., Rollins, C. J., Tietze, K. J. (eds.). Handbook of Nonprescription Drugs, nineteenth ed. American Pharmacists Association, Washington, DC.)*

PPCP in self-care encounters, but rather to assist in streamlining the process by highlighting the key areas most relevant for self-care, improving efficiency.

One useful tool, QuEST, was designed specifically for self-care encounters (Leibowitz and Ginsburg, 2002). Each letter in the acronym QuEST represents an ordered step in the pharmacists' problem-solving process:

1. *Qu*ickly and accurately assess the patient (using SCHOLAR-MAC).
2. *E*stablish that the patient is an appropriate self-care candidate.
3. *S*uggest appropriate self-care strategies.
4. *T*alk with the patient about various aspects of those strategies.

Note: each letter in SCHOLAR represents subjective information about the patient's current chief complaint. MAC was added to QuEST/SCHOLAR to capture information on an individual's medications, allergies, and medical conditions (Fig. 3).

Evidence shows that the use of a structured interviewing framework, along with adequate training, improves user confidence, ensures elicitation of a comprehensive patient history and assessment, and results in appropriate recommendations for management of self-care concerns (Buring et al., 2007; Curley et al., 2016).

Developing Cultural Competency for Self-Care

With increasing globalization, countries have become more culturally diverse. HCPs including pharmacists have an obligation to provide care that is equitable for all patients, irrespective of culture. This requires that HCPs recognize their own cultural beliefs and biases, and continually pursue efforts to become more culturally competent. A failure to do so may have negative implications on patient satisfaction and health outcomes. Cultural competency, as it relates to self-care, will be explored here, including strategies pharmacists can employ to facilitate the delivery of culturally sensitive care.

Rationale for Improving Cultural Competency in Healthcare

Countries have become more culturally diverse over time. A major reason for this has been the rapid growth in international migration—since 2000, the number of international migrants worldwide has increased by an average of 2.3% annually, reaching a

total of US$244 million in 2015 (United Nations, 2016). Populations have also become more diverse in terms of gender expression, socioeconomic status, sexual orientation, and religious affiliation (Sias and Jacobson, 2018). As such, HCPs, including pharmacists, are encountering increasingly heterogeneous patient populations.

Health disparities exist in culturally diverse populations and may be attributed to differences in determinants of health, such as education, living conditions, and access to health services (CDC, 2015). The prevalence of diabetes, for example, is higher among Hispanics and those with lower education levels, than non-Hispanic Whites and those with higher education levels (Sias and Jacobson, 2018). To successfully care for a diverse patient population and resolve existing disparities, HCPs must be culturally competent. This idea is supported by several studies that demonstrate cultural competency in healthcare care not only enhances patient satisfaction (Govere and Govere, 2016), but may improve health outcomes as well (Truong et al., 2014).

Important Considerations for Working Across Cultures

An essential component of cultural competency is recognizing patients' unique experiences and understanding how those experiences influence interactions with the healthcare system. A patient's language abilities and health literacy are also important considerations for pharmacists providing crosscultural care.

Beliefs of Different Population Groups

To provide care recommendations that are culturally respectful and acceptable, a basic understanding of cultural values, beliefs, and practices is necessary. For example, in African and Asian cultures, CAMs are often preferred approaches to self-care, and being aware of this will help pharmacists to make recommendations that are more acceptable to patients (Sias and Jacobson, 2018). A comprehensive review of cultural values, beliefs, and practices in the context of healthcare is beyond the scope of this discussion, and culture-specific resources should be consulted for more detail.

Communication

Establishing effective communication may be one of the greatest challenges in providing crosscultural care. Language barriers may hinder pharmacists' ability to accurately assess a patient and provide recommendations that are easily understandable. Furthermore, when language barriers exist, nonprescription drug labels are inadequate for ensuring safe and effective use of these products. Nonverbal communication may also cause difficulties, as specific body language and gestures have different meanings across cultures. Low health literacy is also common in minority groups—pharmacists should never assume that patients fully comprehend recommendations, even when potential language barriers are overcome (Sias and Jacobson, 2018). Strategies for mitigating communication barriers and low health literacy are described in "Providing Culturally Competent Care" below.

Providing Culturally Competent Care

Recognizing Personal Beliefs and Biases

An important step in providing culturally competent care is recognizing personal cultural beliefs and biases. During each encounter, pharmacists should treat patients as unique individuals and avoid stereotyping. In doing so, pharmacists recognize that each patient has distinct values and beliefs, and acknowledge that not all persons within a group behave in the same manner. Pharmacists should also be cautious when making generalizations, however, knowledge of typical health-related practices may facilitate more successful crosscultural encounters (Sias and Jacobson, 2018).

Several cultural competency models have been developed (Campinha-Bacote, 2002; Cross, 1988; Purnell, 2002) and can aid pharmacists in identifying where on the continuum they fall and what to strive for. The Cultural Competence Continuum model has been summarized in **Fig. 4**, however, an in-depth review of this model, and others, is beyond the scope of this discussion.

Strategies for Gathering and Assessing Patient Information

The following strategies may be employed by pharmacists during crosscultural encounters to assist in information gathering and assessment (Sias and Jacobson, 2018):

- Open-ended questioning to encourage disclosure
- Patient mirroring and inclusive language to build trust and rapport
- Models such as LEARN to facilitate cross-cultural communication (**Fig. 5**)
- Kleinman's patient explanatory model to elicit beliefs about illness (**Fig. 6**)
- Language assistance tools to overcome language barriers, including interpreters and translation apps for smartphones

Note: using family members as interpreters should be avoided where possible, as patients may feel uncomfortable disclosing information and such practices may place undue burden on family members (Sias and Jacobson, 2018). Unrelated interpreters—preferably ones with training in medical language translation—should be used to uphold patient privacy and reduce the risk of misinterpretations (Sias and Jacobson, 2018).

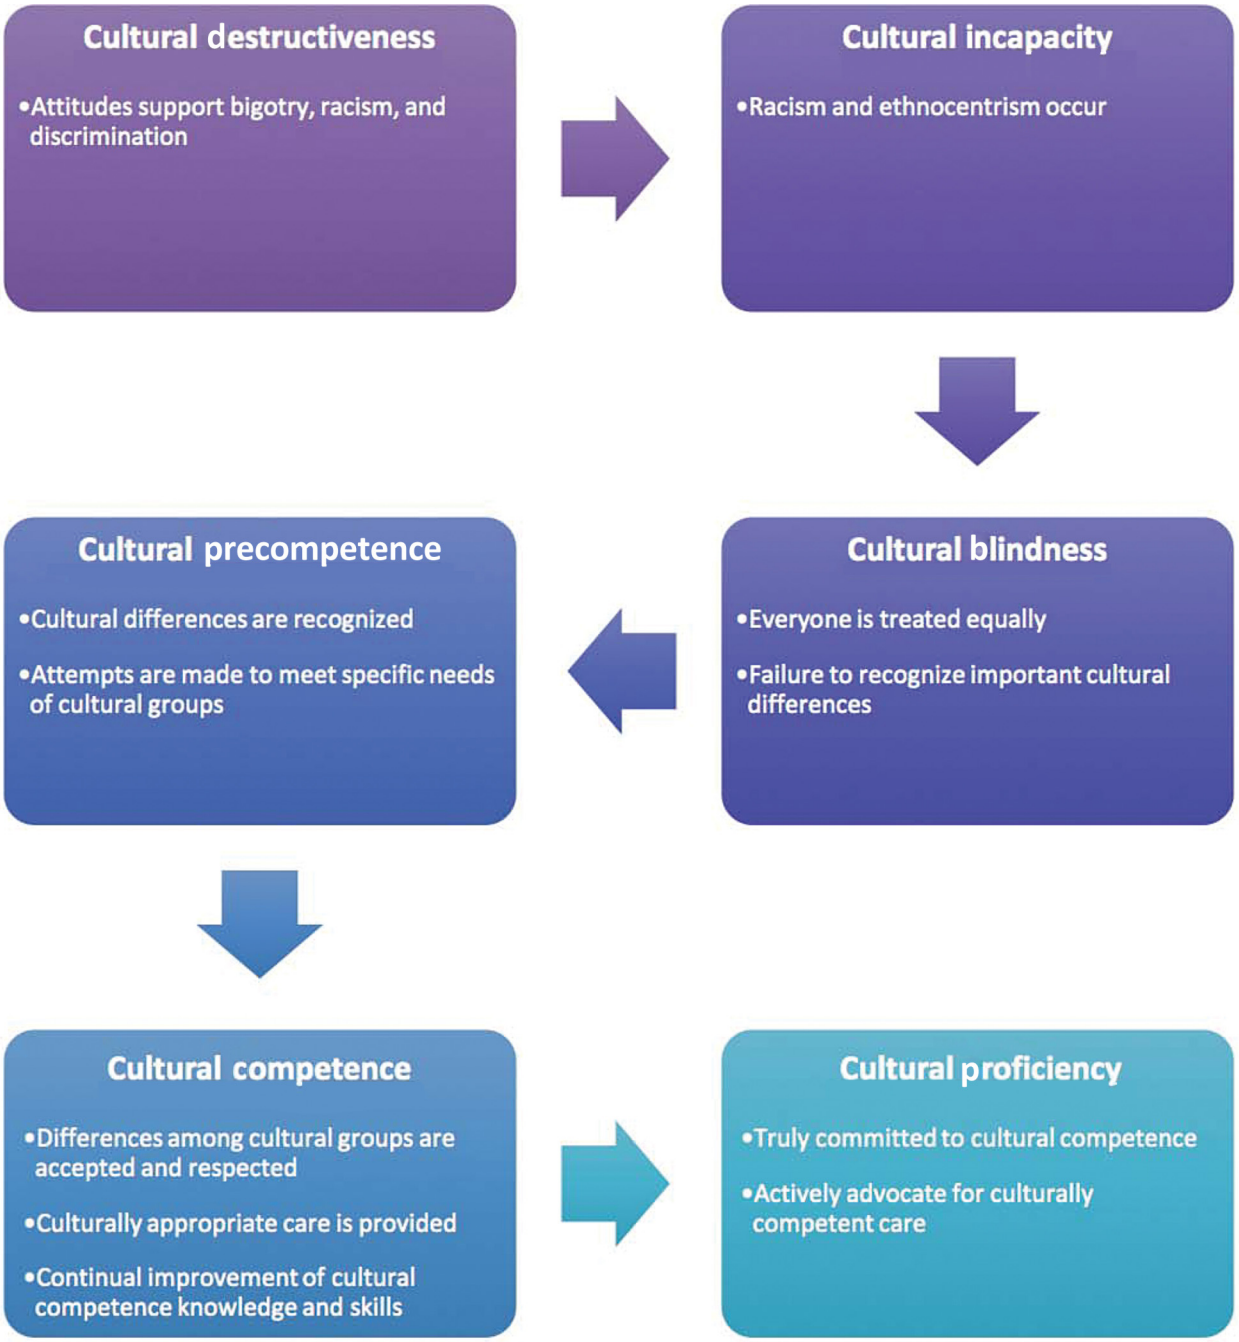

Figure 4 Summary of cross' cultural competence continuum model. *Source: Cross, T., 1988. Cultural competence continuum. Exploring Cultural Aspects of Self-Care. In: Krinsky, D. L., Ferreri, S. P., Hemstreet, B. A., Hume, A. L., Newton, G. D., Rollins, C. J., Tietze, K. J. (eds.) Handbook of Nonprescription Drugs, nineteenth ed. American Pharmacists Association, Washington, DC.*

Developing and Articulating a Self-Care Plan

In developing a care plan, it is essential that pharmacists consider patient values and beliefs to increase the likelihood their recommendation will be followed. No matter how clinically sound a pharmacist's care plan is, if the patient does not follow the recommendation, it has failed (Nakhla, 2018).

Ethical dilemmas may arise when patient values and beliefs do not align with the safest and most effective care plan. In an ideal situation, the pharmacist and patient will be able to negotiate a care plan that is mutually acceptable to both parties. In some situations, pharmacists may have to accept the use of safe, but less effective treatment modalities out of respect for patient autonomy. If a pharmacist does not feel comfortable or competent in providing such care, patients should be referred elsewhere.

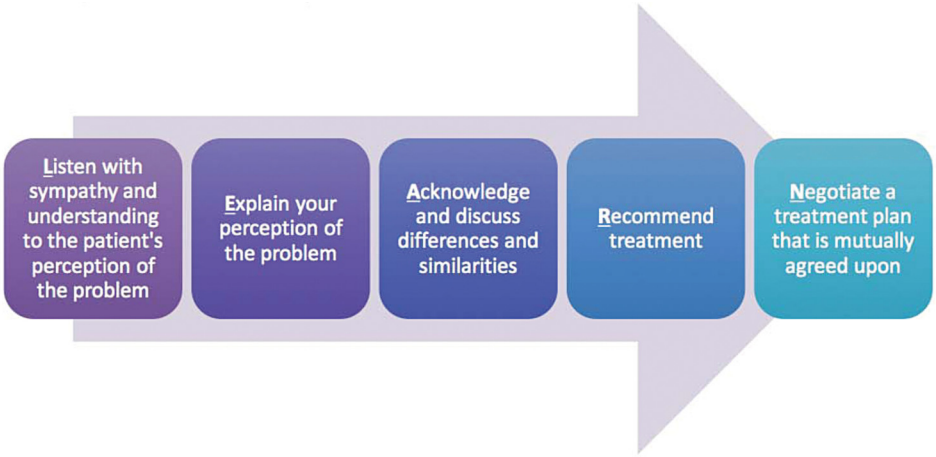

Figure 5 The LEARN model for cross-cultural communication. *Source: Sias, J. J., Jacobson, A. N., 2018. Exploring Cultural Aspects of Self-Care. In: Krinsky, D. L., Ferreri, S. P., Hemstreet, B. Figure 6 Example questions from Kleinman's Patient Explanatory model. *Source: Kleinman, A., 1989. The Illness Narratives: Suffering, Healing, and The Human Condition. Basic Books, New York.*

When discussing care plans, it is important to ensure information is communicated effectively. This may include using interpreters or translation services, and providing educational materials in a patient's native language or as pictograms. The teach-back method—where patients repeat back, in their own words, information provided—is an effective means of ensuring clarity and understanding (Sias and Jacobson, 2018).

Regulatory and Legal Considerations

The definition of self-care is highly dynamic and reflects ever-changing legislative and regulatory activities worldwide. Legislation and regulations surrounding nonprescription drugs vary from country to country and consequently, the availability and accessibility of these products also varies. However, there are some global commonalities in the self-care framework—trends in nonprescription drug regulation, approval, safety, and liability will be discussed here. Key differences in the regulation of nonprescription products will also be considered, however, country-specific resources should be consulted for more detail. Although beyond the scope of this discussion, it should be noted that natural products, dietary supplements, homeopathic products, and point-of-care testing devices also play an important role in shaping self-care, with varying regulatory practices worldwide.

Regulatory Considerations for Nonprescription Drugs

The regulation of nonprescription products is complex—excessive regulation may restrict access and a patient's ability to engage in self-care, whereas insufficient regulation may compromise drug quality and patient safety. Historically, countries have struggled to differentiate between prescription and nonprescription products from a regulatory standpoint. However, more recent initiatives reflect key differences between drug classes. These differences and their resulting impact on regulations have been described by the World Self-Medication Industry (WSMI, 2007), and include:

1. Nonprescription products commonly have a longer history of international experience than prescription products. As such, nonprescription products may not be subjected to the same degree of regulation at the time of market authorization or with ongoing use.
2. Nonprescription products are not often protected by intellectual property patents on the basic molecule, like with prescription products. Therefore, several countries offer data protection or market exclusivity for new indications on existing self-care products.
3. Nonprescription products can be obtained without direct intervention by a HCP. As such, most countries have specific regulations surrounding the labeling and advertising of nonprescription products to facilitate appropriate selection and use by consumers.
4. In several countries, there is pricing freedom for nonprescription products, but not prescription products. Consequently, regulations surrounding nonprescription drug pricing controls have been eliminated, reducing the administrative burden for regulators in these countries.

In many countries, including New Zealand and Singapore, nonprescription drugs are further classified as over-the-counter (OTC) or behind-the-counter (BTC) products—the latter requiring intervention by a pharmacy staff member, typically a pharmacist, for sale (Field, 2005). In Poland, the majority of nonprescription products are available BTC (Piecuch and Kozlowska-Wojciechowska, 2013). Unsurprisingly, BTC products are subjected to greater regulatory control than over-the-counter products, but are less heavily regulated than prescription products. Classifying drugs as BTC has potentially significant implications on product surveillance and cost. As such, countries like the US have opted to continue using a two-tiered system, with drugs being classified as prescription or nonprescription only. The UK and Canada, however, use a three- and four-tiered system, respectively. In the UK, classification categories include prescription only medicine (POM), pharmacy (P), or general sales list (GSL; available in any retail outlet), with P and GSL products being available without a prescription (Paudyal et al., 2013). In Canada, drug products are classified as Schedule I (prescription-only), II (BTC), III (OTC), or U (unscheduled; available in any retail outlet), with II, III, and U products being available without a prescription.

Although specific regulations for nonprescription drugs differ between countries, the underlying goals are same—ensure the quality, safety and efficacy of products, improve public health, and encourage competition in the nonprescription sector. With appropriate regulation of nonprescription products, patients can be empowered to engage in self-care without potential compromises in safety.

Approval of Nonprescription Drugs

In most countries, there is a formal means of approving nonprescription products. In the US and India, these activities are governed by the Food and Drug Administration (FDA) and Central Drugs Standard Control Organization, respectively (Mulaje et al., 2011). Products generally obtain nonprescription status by one of two ways: (1) they are classified as nonprescription with initial market authorization, or (2) they become nonprescription after initial approval as a prescription product. Note that in many countries, drug scheduling decisions are made following recommendations of an independent committee, such as the Advisory Committee on Medicines Scheduling in Australia (Therapeutic Goods Administration, 2011a).

Regardless of the route to nonprescription status, approval requires that the safety, efficacy, pharmacokinetics, pharmacodynamics, and indications of a drug be well established and documented (WHO, 2000). For novel drugs, initial evidence of safety and efficacy is primarily from animal studies. To be given nonprescription status with initial authorization, many countries require that clinical trials reflect the self-care paradigm and that postmarketing surveillance be undertaken to monitor long-term safety and efficacy in humans (WHO, 2000). Several countries have adopted an accelerated approval process for prescription drugs seeking nonprescription status, as safety and efficacy were established with initial authorization (WSMI, 2007). In the case of prior market authorization, approval decisions focus more on evaluating a drug's suitability for self-care, rather than reassessing safety and efficacy data.

In assessing the appropriateness of a drug for self-care, regulatory and/or advisory bodies commonly review the product's approved indications, efficacy, side effects, dosage form, and route of administration. Additionally, the feasibility of implementing potential safeguards, such as restricting package size or improving labeling, is often evaluated. An analysis of the pros and cons of granting nonprescription status is also commonly performed. Characteristics that suggest a drug may be suitable for self-care are outlined in **Table 1**.

Despite assessing similar information, countries have drawn varying conclusions regarding the appropriateness of specific drugs for self-care. The Ingredients Directory (AESGP, 2016), published by the Association of European Self-Medication Industry, lists drugs that have nonprescription status somewhere in the world and highlights differences in classification among 39 countries. This

Table 1 Characteristics of drugs suitable for self-care

Clinical:

- Used for conditions or symptoms that are readily recognizable and/or self-limiting
- Provides reliable relief of symptoms
- Has a wide safety margin, even if used incorrectly
- Low potential for dependence and abuse
- Adverse effects are minimal and/or well-characterized
- Low risk of masking a serious underlying disease
- Pharmacokinetic properties unlikely to be affected by other common drugs or food

Administration:

- Oral or topical preparation
- Technical expertise is not required for administration

Safety:

- Appropriate treatment duration has been defined
- Package size reflects recommended treatment duration and reduces risk of misuse
- Available in child-resistant packaging

Source: WHO, 2000. Guidelines for the regulatory assessment of medicinal products for use in self-medication. World Health Organization, Geneva. Available from: http://www.who.int/iris/handle/10665/66154.

publication underlines that, even for well-established drugs, nonprescription status is not universal, contributing to an inconsistent self-care environment worldwide (AESGP, 2016).

A Note on Prescription-to-Nonprescription Switches

Prescription-to-nonprescription switches are currently the most common means by which products obtain nonprescription status. These switches are thought to be motivated by three factors: (1) the desire to extend product viability by pharmaceutical companies, (2) attempts to contain costs by healthcare payers; and (3) an increasing interest in self-care from the public (Cohen et al., 2005). Examples of prescription drugs that have transitioned to nonprescription status in the US, the UK, France, or the Netherlands are provided in **Table 2**. The UK has led the way in prescription-to-nonprescription transitions, with 22 switches between 2000 and 2013 (Cohen et al., 2013). Fewer switches have been approved in the US, perhaps owing to the lack of a BTC regulatory class and the consequential struggle to mitigate safety concerns (Cohen et al., 2005).

Prescription-to-nonprescription switches will continue to play a significant role in expanding the global nonprescription market, with an increasing focus on drugs for health promotion and disease prevention (Cohen et al., 2005). With this brings cost savings for public and private payers and patients through lower drug costs, reduced physician visits, and increased productivity. However, public and private payers have shown a tendency to remove switched drugs from their formularies and increase copayments for prescription drugs in the same class, increasing out-of-pocket expenses for patients (Cohen et al., 2005). Thus, while prescription-to-nonprescription switches have been argued to increase accessibility, the shift of financial burden to other HCPs (particularly pharmacists) and consumers may create a new barrier to care for some patients.

Another consideration for an expanding nonprescription market is the role of pharmacists. Pharmacists will be increasingly responsible for helping inform patients' self-diagnosis of ailments, selection of products, and monitoring of therapy. For example, it

will be mandatory for pharmacists to assess a patient's erectile dysfunction symptoms, comorbid conditions, and other medications prior to dispensing Sildenafil without a prescription in the UK—a recent prescription-to-nonprescription switch (Medicines and Healthcare Products Regulatory Agency (MHRA), 2017).

Ensuring Nonprescription Drug Safety

At the center of regulatory controls for nonprescription drugs is patient safety, irrespective of the country. Not only is this reflected in formal approval processes for market authorization, as described previously, it is also reflected in regulations for the labeling, packaging, advertising, and postmarketing surveillance of approved nonprescription products.

Labeling, Packaging, and Advertising

Although labeling, packaging and advertising regulations vary by country, overarching themes exist. For example, most, if not all, countries require that information necessary for the correct and unsupervised use of nonprescription drugs be included on the product label or package insert (WSMI, 2007). This generally includes the product name, intended use, active and nonmedicinal ingredients, directions for use, common side effects and drug interactions, contraindications, storage requirements, lot number and expiry date, and the name and location of the manufacturer or distributor (WSMI, 2007). Furthermore, regulations require that information be provided in easily understandable and patient-friendly language (WHO, 2000). Additional labeling requirements are country-specific—for example, the FDA in the US has regulations pertaining to the placement of information included and font size (Rumore, 2018).

For packaging, regulations are typically aimed at reducing the risk of accidental drug exposure by children, facilitating recognition of product tampering, and deterring the misuse of nonprescription drugs (WHO, 2000). In Australia, for example, the Therapeutic Goods Administration requires that nonprescription products be sold in child-resistant packaging if the quantity marketed is likely to cause significant harm in a child weighing 11 kg (Therapeutic Goods Administration, 2008). Similar mandates for child-resistant packaging are found in the UK, Canada, and the US.

Regulations pertaining to drug advertising ensure information communicated to consumers is truthful and not misleading (WSMI, 2007). This is important, as misinformation regarding the use of nonprescription products can have significant implications on patient safety and wellbeing. In the Netherlands, Australia, and the UK drug advertising is monitored by a self-regulatory body that acts on behalf of the government (WSMI, 2007). In Argentina, Mexico, and Japan drug advertising is overseen by both government and self-regulatory bodies (WSMI, 2007).

Adverse Drug Reaction Reporting

Several countries have systems in place for reporting adverse reactions related to nonprescription drug use, allowing for ongoing monitoring of drug safety. In most countries, reporting can be completed by anyone, including healthcare professionals, consumers, and manufacturers. In the US and Canada, it is mandatory to report serious adverse reactions (e.g., death, birth defects, etc.) related to nonprescription drug use. Reporting of nonserious adverse reactions is also encouraged, but may not be mandatory. Routine analysis of information reported may lead to product recalls, safety alerts, revision of contraindications, and advisory statements, with the intention being to maintain safe nonprescription drug use (Therapeutic Goods Administration, 2011b).

Safety Concerns Related to Nonprescription Drugs

Despite best regulatory efforts, ongoing safety concerns related to nonprescription drug use exist worldwide and will be discussed in this section.

Substandard and falsified products

A substandard product is one that fails to meet quality standards and/or specifications (WHO, 2017a). With falsified products, the identity, composition or source is deliberately misrepresented. These products may contain the wrong active ingredient (AI), no AI, or the wrong amount of the correct AI (WHO, 2017a). Additionally, substandard and falsified products commonly contain unknown impurities as they are often compounded in unsanitary conditions, by unqualified personnel.

The growing risk of substandard and falsified medications may be related to increased internet connectivity, as those responsible for manufacturing and distributing such products have gained access to a global market. Consequences related to the use of substandard and falsified medications can be far reaching, from the failure to prevent or cure disease to serious patient harm or death (WHO, 2017b). Furthermore, patients may lose faith in drug regulatory authorities, manufacturers, and the healthcare system when concerns of product safety and efficacy arise (WHO, 2017b).

In 2013, the WHO launched the Global Surveillance and Monitoring System (GSMS) to encourage reporting of substandard and falsified medications. As of 2017, over 1500 products had been reported. **Fig. 7** shows countries in which substandard and falsified medications have been discovered and reported, highlighting that this is a global problem.

Abuse of nonprescription medications

Nonprescription drug use and abuse includes using these products for reasons other than those intended, and exceeding recommended dosages (Conca and Worthen, 2012). Factors that may contribute to inappropriate nonprescription drug use include public perception that these medications are without safety concerns, and the ease of procurement (Conca and Worthen, 2012). Rates of

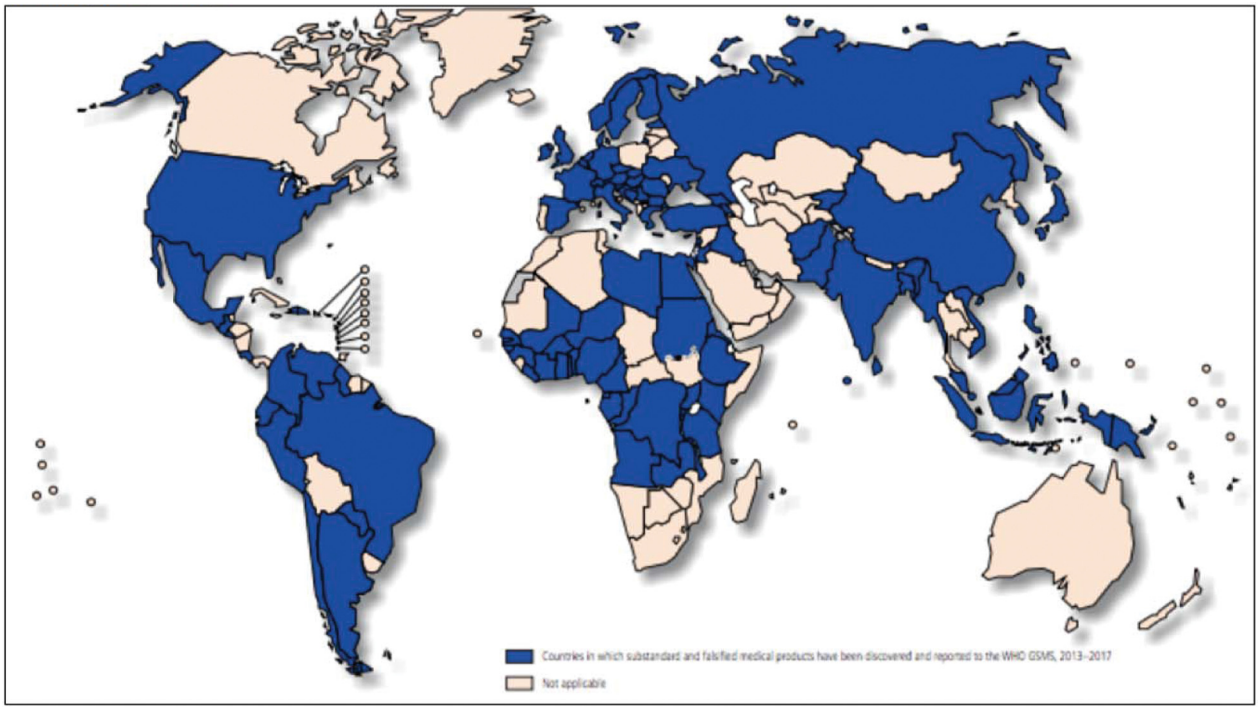

Figure 7 Countries in which substandard and falsified medical products have been discovered and reported to the GSMS, 2013–17. *Source: WHO, 2017a. Substandard and falsified medical products. World Health Organization, Geneva. Available from: http://www.who.int/mediacentre/factsheets/fs275/en/; WHO, 2017b. WHO Global Surveillance and Monitoring System for substandard and falsified medical products. World Health Organization, Geneva.*

nonprescription drug abuse have increased over time. In the US, for example, dextromethorphan abuse increased 15-fold from 1999 to 2004 among adolescents aged 9–17 (Levine, 2007). Nonprescription drug abuse can occur in all patient population, however, those with mental health issues, pain disorders, and diseases of aging may be more susceptible (Conca and Worthen, 2012). Although abused products vary worldwide, a 2013 systematic review identified codeine products, laxatives, sedating antihistamines, cough products, and decongestants as the most commonly abused drug classes worldwide (Cooper, 2013). With an ever-expanding nonprescription drug market, initiatives to improve the detection of abuse will be paramount to ensure patient safety—pharmacists will have a prominent role in such initiatives.

Legal Considerations for Nonprescription Drugs

Liability in the context of nonprescription drug therapy varies greatly with jurisdiction, however, general commonalities exist. First, manufacturers are held liable for the *quality* and *safety* of drugs they produce and distribute. Historically, most legal proceedings related to nonprescription products have been against manufacturers due to defective drugs. However, an increasing number of pharmacists and pharmacies are finding themselves in litigation for advice provided on nonprescription products. Such cases are complex, as a pharmacist's duty to counsel patients on the safe use and risks of drugs available for self-selection is debated. In countries where certain nonprescription products are kept BTC, expectations for pharmacists are clearer—those who fail to provide appropriate intervention for such medications may be ruled negligent in legal proceedings. Pharmacists and pharmacies may also be found liable if harm occurs following the provision of inaccurate information on nonprescription drug use or the sale of expired or recalled products. With increasing responsibility in direct patient care, including prescribing authority in some jurisdictions, the liability of pharmacists is evolving. Pharmacists are encouraged to regularly consult legal resources to stay up-to-date on professional obligations in their jurisdiction.

Pharmacist-Led Minor Ailment Services (PMAS)

Pharmacists have a long history of helping patients manage minor ailments—traditionally, this has involved making nonprescription medication recommendations, facilitating lifestyle changes, and referring patients to other HCPs when needed. Canadian estimates show 10%–30% of physician consultations are for minor ailments (Taylor and Joubert, 2016). In recent years, several countries have introduced pharmacy-led minor ailment services (PMAS) in hopes of reducing the burden of minor ailments on these high-cost settings (e.g., GP offices, emergency departments) by transitioning minor ailment care to community pharmacies (Paudyal et al., 2013). PMAS grant pharmacists the option of selecting medications traditionally under control of prescribers for minor

ailment treatment. A 2013 report (Ontario Pharmacists Association, 2013) estimated that introducing a program involving nine minor ailments could save CAD$12.3 million over 5 years in Ontario, Canada alone. Realizing this cost-saving potential, several countries have implemented PMAS, with no reported compromises in patient safety or quality of care.

PMAS regulations differ from country to country and even from jurisdictions within the same country. For example, pharmacists in Saskatchewan, Canada are limited to selecting from a set formulary of medications for a specified condition and must follow a detailed protocol. Pharmacists with prescriptive authority in Alberta, Canada have more autonomy as they can prescribe most medications and are not limited to specific ailments. There is no overarching national initiative and government reimbursement of the service also varies by province (Taylor and Joubert, 2016). In the UK, PMAS allow pharmacists to supply any nonprescription agent (P drugs and GSL products) in addition to POM through locally agreed protocols or by supplementary and independent prescribing (Fielding et al., 2015).

A recent systematic review has supported PMAS as an effective and cost-effective strategy for managing patients (Watson et al., 2014). Furthermore, research shows GPs are generally in favor of diverting the care of minor ailments to other areas, including community pharmacies, to allow for a greater focus on complex cases (Paudyal et al., 2013) but some are concerned with the ethics behind pharmacists diagnosing then prescribing an agent (Taylor and Joubert, 2016). Mounting evidence shows the public response to PMAS has been positive, with patients seeking pharmacist help judiciously.

The success of PMAS has emphasized the value of pharmacists as care providers and encourages further expansion of pharmacists' scope of practice and pharmacy-based services. Such initiatives may further reduce strain on healthcare systems and facilitate sustainability.

The Future

With a growing and aging population and subsequent rising healthcare costs, stakeholders worldwide have been challenged to identify opportunities for cost-savings. Research shows that encouraging pharmacist-guided self-care is an effective means of reducing healthcare costs, without compromising quality of care (Nakhla, 2018). As such, many countries have implemented formal programs, including pharmacy-based minor ailment schemes (PMAS), to promote and facilitate community-based care. Essential to the success of these programs, is identifying opportunities for increasing public awareness of pharmacists' expertise in self-care, and improving patient engagement (van Eikenhorst et al., 2017). Strategies may include becoming more active in health promotion campaigns, such as those targeting drug safety, or displaying signs in nonprescription aisles to encourage consumers to seek pharmacists' advice prior to product purchase (Covington, 2002, pp.519).

As self-care becomes more prevalent, additional clinical tools will be required to ensure pharmacist-led care is not only evidence-based and outcomes-focused, but also efficient and consistent (Boyce, 2017). Curley et al. (2016) recently explored developing and utilizing guidelines/protocols for minor ailment management in community pharmacies. These tools facilitate the accurate assessment of patients, including identifying when referral to another healthcare professional (HCP) is warranted, and the urgency of this, and when patients can be safely treated in the pharmacy setting. Such community pharmacy triage services (CPTS) have already emerged in a number of countries (Curley et al., 2016). Tools to better identify potential drug interactions will also be needed, as current interaction surveillance systems are not often applied to self-medications (Indermitte et al., 2007). Lastly, improving pharmacy efficiency will be critical to ensuring pharmacists have sufficient time to respond to the growing demand for self-care consults.

Increasing awareness of the importance of health and wellness has motivated patients to play a greater role in their care. This, coupled with prescription-to-nonprescription switches and advances in technology, products and devices, has contributed to an expanding self-care market worldwide. Amid this ever-growing self-care movement has been the need for an accessible and knowledgeable HCP to facilitate safe and effective self-medication practices. Pharmacists, as community-based medication experts and gatekeepers, have taken on this role. Through thorough assessment, evidence-based recommendations, effective communication, and active collaboration with patients and other HCPs, pharmacists can empower patients to engage in self-care safely and effectively. Life-long learning to stay current is paramount, if pharmacists wish to remain preeminent self-care advisors and nonprescription drug therapy managers in a rapidly changing self-care environment (Covington, 2002).

Glossary

Culture the ideas, customs, attitudes, and behaviors of a particular nation, people, or social group (Oxford Dictionary, 2017)
Cultural competency in healthcare "the ability to provide care to patients with diverse values, beliefs and behaviors, including tailoring delivery to meet patients' social, cultural, and linguistic needs" (Betancourt et al., 2002)
Complementary and alternative medicines (CAMs) treatments that are usually less well-studied and are used in addition to (complementary) or instead of (alternative) standard treatments—examples include herbal preparations, acupuncture, magnetic therapy, and spiritual healing (NCI, 2015)
Generalizations documented or self-described behaviors or characteristics of groups or cultures that are often used as a starting point for understanding these populations (Sias and Jacobson, 2018)

Health literacy degree to which individuals have the capacity to obtain, process, and understand basic health information needed to make appropriate health decisions (US Department of Health and Human Services, 2000)
Medication-related problems the term replacing 'drug therapy problems' in the PPCP (JCPP, 2014) which includes unnecessary drug therapy; needs additional drug therapy; ineffective drug; dosage too low; adverse drug reaction; dosage too high; and adherence(Cipolle et al., 2012).
Minor ailment "common or self-limiting or uncomplicated condition which can be diagnosed and managed without medication intervention" (Paudyal et al., 2013)
Nonprescription medications (aka over-the-counter medicines) drugs which are available for sale without a medical prescription (Oxford Dictionary, 2017)
Patient-centered care providing care that is respectful of and responsive to individual patient preferences, needs, and values, and ensuring that patient values guide all clinical decisions (Institute of Medicine (US), 2001).
Pharmaceutical care a philosophy of practice in which the patient is the primary beneficiary of the pharmacist's actions (Hepler and Strand, 1990).
Self-care confidence the ability to perform a specific self-care-related task and persist in performing that action or behavior, despite barriers or challenges (Riegel et al., 2012); "not an element of self-care but a factor that strongly influences self-care maintenance, self-care monitoring, and self-care management" (Ausili et al., 2017)
Self-care maintenance behaviors (e.g., making healthy lifestyle choices, engaging in physical activity) used to preserve health, maintain physical and emotional stability, improve well-being, or avoid disease and complications (Ausili et al., 2017; Riegel et al., 2012).
Self-care management autonomous or consultative process of responding with appropriate behaviors (e.g., responsible treatment implementation, adherence to medication therapies, implementing lifestyle modifications, collaborating with HCPs in shared decision-making) to health changes and problems to avoid an exacerbation (Ausili et al., 2017; Ausili et al., 2014)
Self-medication the selection and use of medications by individuals to treat self-recognized illness or symptoms (Rutter, 2015).
Self-care monitoring process of routine, vigilant body monitoring or surveillance, including symptom recognition and interpretation as well as self-surveillance of signs and symptoms for deterioration or improvement (Ausili et al., 2017); it serves as the link between self-care maintenance and self-care management(Riegel et al., 2012)
Stereotypes widely held, but fixed and oversimplified, images or ideas of particular types of people or things (Oxford Dictionary, 2017).

Extemporaneous Compounding in Pharmacy Practice

David Dubins, Andreea Laschuk, Certina Ho, University of Toronto, Toronto, ON, Canada

Introduction

This chapter will familiarize the reader with basic principles involved in nonsterile compounding. As regulations pertaining to compounding, vary regionally, the emphasis will be on the basic pharmaceutics and practical scientific principles relating to compounding, rather than local policies regarding regulatory requirements. The reader is referred to seek their regional guidance for country-specific details regarding pharmacy setup and compounding requirements. Any recommendations or suggestions made in this chapter are intended to supplement, and not supersede or contravene these guidances. As regulations change, the compounder is always responsible for consulting the latest compounding guidances.

After reading this chapter, the learner will:

1. contextualize the importance of compounding and its applicability to patient care;
2. understand the roles and responsibilities within a pharmacy pertaining to compounding, including the pharmacy technician and compounding pharmacist;
3. garner a workflow for the general setup of a compounding pharmacy, in terms of layout, equipment, and record keeping;
4. have a basic framework for compounding common liquid, semisolid, and solid formulations; and
5. recognize that compounding is a high-risk process in pharmacy practice and it warrants special attention with respect to patient safety.

As sterile compounding carries an added risk of sepsis, stroke, and death, with regional-specific requirements for setup, monitoring, and testing, sterile compounding will not be discussed in this chapter. The learner is referred to their local pharmaceutical college and pharmacy regulatory authorities for training, recommendations, and guidance regarding sterile compounding.

Compounding in Community Pharmacy

In the pharmaceutical field, compounding refers to the creation of a medication through the addition, mixing, alteration, or removal of ingredients to provide customized medications to patients. It may involve the modification of an existing manufactured drug product or the preparation of a compound using raw ingredients (Feldschuh, 2008). The most common reason to compound medications is to mask unpleasant tastes, change the formulation of the medication and to provide patients with doses, not commercially available. All of these common barriers position compounding in community pharmacy to improve patient care by incorporating individual patient preference in the administration of medications. Compounding can also eliminate the administration of unnecessary ingredients, which is relevant with increasing intolerances and awareness of allergies. There is a growing patient population base that is allergic to preservatives, dyes, or binders that can be commonly found in manufactured medications. Compounding can also allow the patient to receive multiple medications in one formulation to increase compliance. Veterinary compounding can also allow for treatment of pets, farm animals, and even zoo animals (Bednarczyk et al., 2009; Connolly et al., 2018) (**Table 1**).

Table 1 Reason to compound medications

- Requirement of different dosage form (liquid instead of tablet, ointment instead of cream)
- Manufactured medication has been discontinued (reason not related to safety concern)
- Dose required not available as a manufactured product
- Alternate route of administration required
- Patient has allergy/intolerance/sensitivity to ingredient(s) in manufactured product
- Patient compliance will be improved with compounding (palatability for pediatric formulations, viscous suspension for palliative (or any) patients who have trouble in swallowing tablet formulations)

Source: Feldschuh, M., 2008. Compounding in community pharmacy. Aust. Prescr., 31 (2), 30–31.

Nonsterile Compounding

Compounding in the retail pharmacy setting is usually nonsterile compounding. Nonsterile compounding involves creating a medication in a clean environment but does not require the environment to be completely free from all microorganisms. This type of compounding is used for medications that will be taken orally, such as capsules, liquids, oral disintegrating tablets (ODTs), lozenges, or lollipops to name a few. It is also used for medications that are to be administered topically, such as creams, ointments, gels, toothpastes, sprays, and deodorants. Compared to medications that are injected into the body or put into the eyes, oral, and topical preparations have a much lower risk of causing infections (Connolly et al., 2018).

Before starting any compound, the USP 795 Guidance Document provides helpful guidance on the following questions that need to be answered (Okeke, 2014; USP, 2007):

1. Are the active ingredients already available in a manufactured product of the same formulation and dose?
2. Is a referenced formula available?
3. Is the beyond-use date (BUD) and relevant stability data available?
4. Does pharmacy staff have the dedicated space for compounding and is this space clean and free from clutter?
5. Are the appropriate equipments, ingredients, and materials readily available to make the compound in question?
6. Are the pharmacy personnel trained and competent to perform compounding for the preparation?
7. Can pharmacy personnel compound the preparation uninterrupted?
8. Should the compounded preparation be referred to another pharmacy with appropriate facilities, equipment and expertise?

Overcoming Errors in Compounding Pharmacy

Although dispensing errors in community pharmacies are generally low, ranging from 0.26% to 1.6% (Ashcroft et al., 2005; Boyle et al., 2011; Flynn et al., 2003), as the volume of compounded prescriptions increases, there are common dispensing errors that pharmacy staff should be mindful of. The following table depicts the multiple categories of possible dispensing errors to consider (**Table 2**).

In order to overcome these potential errors while compounding, the pharmacy staff must have designated roles, responsibilities, training, and procedures in place. In general, the following should be considered in pharmacy practice with respect to nonsterile compounding prescription preparation (Christ et al., 2017):

- Design labeling and packaging of compounding ingredients or chemicals in order to minimize the risk of identification and/or selection confusion.
- Adopt or apply a unique identification number or identifier for each ingredient in compounding formulas.
- Incorporate automated identification of compounding ingredients or chemicals (e.g., barcode scanning).
- Verify each ingredient and its measured amount of a compounded prescription through an independent double check process.
- Have written policies and procedures, or checklists for the preparation of compounded products that are based on professional standards of practice and guidelines for training and orientation of pharmacy staff.

Table 2 Categories of dispensing errors in compounding pharmacy

• Medication dispensed to the incorrect patient
• Incorrect medication is dispensed to the patient
• Dispensing the incorrect strength or concentration of the medication
• Dispensing the incorrect dose or frequency of the medication
• The wrong quantity is dispensed
• Incorrect dosage form or formulation dispensed
• Medication is dispensed with an incorrect route of administration
• Medication is dispensed with an incorrect duration of treatment
• Medication is expired or will expire during the regimen length
• Failure to dispense
• Dispensing an incorrectly compounded medication
• Dispensing a compounded prescription with omitted medication or dose
• Labeling error on dispensed medication (incorrect patient name, drug name, drug strength, quantity, instructions, dosage form, expiry date, omission of warnings, incorrect pharmacy information, etc.)
• Errors during compounding (wrong ingredients, wrong weights incorporated, inappropriate compounding techniques used, using expired products)
• Contamination during compounding (utensils, active pharmaceutical ingredient, surface contaminants)
• Improper storage of ingredients or compounded preparations prior to dispensing
• Errors during third-party billing of compounded prescriptions

Source: Cheung, K., Bouvyl, M., De Smet, P., 2009. Medication errors: the importance of safe dispensing. Br. J. Clin. Pharm., 67 (6), 676–680; Gudeman, J., Jozwiakowski, M., Chollet, J., Randell, M., 2013. Potential risks of pharmacy compounding. Drugs R&D, 13 (1), 1–8; Ho, C., Hung, P., Lee, G., Kadija, M., 2010. Community pharmacy incident reporting: a new tool for community pharmacies in Canada. Healthc. Quarter., 13 (Special Issue), 16–24.

Nonsterile Basic Pharmacy

Although roles and responsibilities can vary from pharmacy to pharmacy, in a typical compounding pharmacy, the owner or manager assigns a designated compounding lead that is responsible for developing, organizing, and supervising all activities related to nonsterile pharmacy compounding. The compounding lead can share the responsibilities or assign them to a pharmacist or pharmacy technician. Just like regular pharmacy dispensing, compounding requires a strict standard of operations. Personnel need additional training, as common compounded preparation errors include calculation, unit of measure, calibration, and mixing errors. Appropriate measures need to be taken to ensure the safety of personnel during the preparation of each compounded prescription. Typically, the pharmacy manager or compounding lead is responsible for developing the policies and procedures, regularly reviewing them to ensure they are updated. The current recommendations are to review procedural documents every 2–3 years to ensure that they reflect any regulatory changes (National Association of Pharmacy Regulatory Authorities, 2016).

As a part of the initial compounding pharmacy setup, the facilities and the equipments used to compound must meet requirements and need to be calibrated or certified according to manufacturers' specifications or standards (whichever is more stringent) (National Association of Pharmacy Regulatory Authorities, 2016).

The compounding lead should also ensure that the available resources reflect recognized scientific literature to determine stability and to establish beyond use dates (BUD) for each non-sterile preparation. Any master formulation records that are developed are regularly reviewed and updated. The formulas utilized in compounding should either be gathered from reputable compounding or evidence-based drug information resources, or can be formulated by the compounding pharmacist or pharmacy technician. Stability data needs to be readily available to make educated considerations when designing a compound. If any formula is designed or formulated in-house, the compounded preparation should be sent for testing to a contract laboratory for stability analysis. The act of preparations, weighing, measuring, and formulations can be delegated if the pharmacy technician or assistant has received the appropriate training on compounding techniques and procedures (National Association of Pharmacy Regulatory Authorities, 2016).

Since compounding is considered as one of the high-risk processes in community pharmacy practice (Boucher et al., 2018), all steps in the process should be independently double-checked by pharmacy professionals to ensure errors are prevented and processes are maintained (Bednarczyk et al., 2009; Gudeman et al., 2013). The significance of independent double checks and strict compliance to standardized procedures to confirm accuracy and quality of compounded preparations can be illustrated by the incident below (Kawano and Ho, 2012).

> *A pharmacist intended to compound an oral suspension of clonidine (using clonidine powder) for a 15-year-old male. The pharmacist incorrectly compounded the clonidine suspension (due to mixing up during calculations/conversions among grams, milligrams, and micrograms) resulting in a preparation 1,000 times more concentrated than prescribed. Before the error was discovered, the patient was admitted to hospital multiple times.*
>
> Evans et al. (2011)

A miscalculation could lead to dispensing a preparation 1000 times more concentrated than the intended prescription, resulting in harm to patients. On the other hand, an incorrect conversion could also result in a compounded preparation, many times less concentrated than prescribed, rendering a suboptimal therapy to patients.

Physical Layout

General

Pharmacy compounding must be performed in a designated space that allows room for equipment and materials in a fashion that will prevent errors among ingredients, containers, or in the processing of the compounded prescription (National Association of Pharmacy Regulatory Authorities, 2016).

Layout

The design should prevent the opportunity for cross contamination between products. The active ingredients should be stored in a way that would prevent recognition error or confusion between sound-alike and look-alike ingredients. Some techniques could include storing ingredients based on typical formulations in which they would be compounded, ultimately separating oral, topical, and other formulation ingredients (e.g., Diclofenac, Baclofen, Gabapentin, Lidocaine, and similar active pharmaceutical ingredients (APIs) being stored in a cabinet of items used in topical pain preparations along with vehicles). This type of structure would prevent the inadvertent use of a topical API in an oral formulation. A haunting incident occurred in Toronto, Canada in 2016 leading to the death of an 8-year-old patient who was dispensed a compounded suspension of baclofen 150 mg/mL instead of a tryptophan suspension of equal concentrations. This incident resulted in pharmacy practice changes throughout the country (Christ et al., 2017). The compounding pharmacy layout must be easily cleanable including any fixtures that collect dust. The areas utilized for nonsterile compounding must be maintained in clean, orderly, and sanitary conditions.

Lighting

The lighting must be optimized, with fixtures located in such a way as to provide a well-lit area to facilitate the compounding process and to allow verification at all stages of compounding. Personnel need to be cognizant of light labile ingredients and store them appropriately.

Heating, Ventilation, and Air Conditioning System

Measures need to be in place to ensure that heating, ventilation, and air conditioning are controlled. Appropriate temperature and humidity is required to be maintained as chemicals, components, and compounds are subject to degradation. Proper ventilation is required to prevent contamination of products during compounding, ensuring the quality and purity of stored products. Heating, ventilation, and air conditioning systems need to be in place to ensure staff safety and comfort during compounding as well. For items requiring refrigeration, a separate refrigerator in the compounding room is recommended.

Water Supply

Potable water is required for hand and equipment washing. The compounding lab should have a reasonable stainless steel sink and faucet that is ideally accessible to all compounding areas. Distilled water is required for use in compounding nonsterile drug preparations when formulations indicate the inclusion of water. The facility plumbing system is required to be free of any defects that could contribute to possible contamination in compounded preparations.

Work Surfaces

Furniture and work surfaces need to be constructed of smooth, nonporous material that is impermeable and easy to clean. This material must be resilient to repeated cleaning and disinfecting and must be resistant to damage from cleaning or disinfecting products.

Furniture, Walls, and Flooring

All furniture, floor, and wall surfaces must be designed and placed to facilitate cleaning and disinfecting.

Basic Equipment

The equipment chosen must be appropriate to the type of preparations that are to be compounded. The designated apparatus or instruments should only be used for compounding activities. The equipment must be comprised of material that can be easily cleaned and disinfected and will not react with any of the ingredients used in compounding. Table 3 is not exhaustive of all compounding lab equipment but may serve as a list to consider when a compounding pharmacy is to be set up.

Introduction to Common Extemporaneous Formulation Types

This section will introduce the reader to the basic-building blocks of pharmaceutical compounding.

Compounded nonsterile preparations include, but are not limited to the following types of medications:

- Oral liquids (solutions, suspensions, and emulsions)
- Ointments and creams
- Other topical products (lotions, powders, emulsions, and gels)
- Suppositories
- Lillipops, troches, lip balms, mouthwashes
- Sachets and oral powders
- Capsules and tablets

Liquids

Oral liquids are useful in delivering medication to specific patient demographics. Pediatric patients (5 years and younger) are typically unable to swallow solid-fixed dosage forms like tablets, caplets, or capsules. Another issue that arises in the pediatric population is the frequent inability to use fixed doses, as weight or surface area based dosing is the gold standard. Thus, compounded

Table 3 Basic compounding equipment

Glassware	*Beakers flasks graduated cylinders watch glass*
Hot plate and accessories	Hot plate, beaker holder, extension clamp, thermometers, stir bars, stirring rods
Mortar and pestles	Various sizes, porcelain or flint glass
Ointment slab and paper	Ointment paper, glass or marble slab
pH products	pH paper, pH meter
Scoops, spoons, and spatulas	Measuring spoons, mini metal spatulas, mixing spatulas, stainless steel spatulas
Digital scale and accessories	Electronic scale, weighing paper, weighing boats, calibration weights
Dispensing containers	Glass bottles, plastic bottles, drop containers, plastic or glass droppers, spray bottles, ointment jars of various sizes, lotion pump dispensers, sealable tubes, Topi-CLICKS(R)
Molds	Lozenges/troches, lollipops, suppositories, triturate (oral disintegrating tablet [ODT])
Personal protective equipment	Latex or nitrile gloves, N95 masks, gowns, safety glasses (eye protection)
	Lab coat
	Hair cover
	Other protective wear (as appropriate)

liquid preparations are particularly useful in the pediatric population to ensure appropriate dosing ranges are maintained, as the dose can be varied by the volume of compound administered.

Suspensions

Typically, community pharmacies compound using available fixed dose medications, pulverize them, and then suspend the drug in a palatable, flavored vehicle to promote administration and compliance. Carboxymethylcellulose or methylcellulose suspensions and simple syrup are commonly used vehicles for suspending medications (Nahata and Allen, 2008).

Best practices recommend utilizing the pure, raw API when compounding liquid medications. Manufactured oral medications in the tablet form contain excipients that may not be soluble when suspended. These ingredients include disintegrants, diluents, coatings, glidants, lubricants, and colorants (Troy and Beringer, 2005). Although the drug may be soluble in the vehicle, the excipients may not be, ultimately yielding an unappealing, unusable product.

When compounding liquid formulations using tablet or capsule manufactured drugs, it is important to avoid using controlled release formulations (slow-release, controlled-release, delayed-release) or enteric-coated formulations. If coated is the only option, the coating may need to be dissolved or very finely ground to unbind the active ingredient. See section, *Product Example Formulations and Calculations*, for example: sample formula for Baclofen 5 mg/mL Oral Suspension (60 mL) (Sick Kids Pharmacy, 2007).

Emulsions

An emulsion is a two-phase system where one liquid is dispersed in the form of small globules throughout other liquid. The dispersed liquid is known as the internal phase and the dispersion material is known as the internal or continuous phase. A typical emulsion is an oil-in-water emulsion where oil is the dispersed phase in an aqueous solution as the continuous phase. These mixtures require emulsifying agents to promote homogeneous mixing.

Emulsions serve a couple of purposes in compounding for oral use. The absorption and penetration of some medications are easily controlled if they are incorporated into an emulsion formulation. Emulsions are widely used in compounding pharmacy when certain medicinal ingredients have an unpleasant taste. Emulsions can create a more palatable product to be administered orally as is commonly used when masking oil-in-water administration of drugs. The aqueous phase can be formulated to contain appropriate sweetening and flavorant to mask the oil and drug mixture. For example, in an oil-in-water emulsion, the API may be readily soluble in the oil phase. After administration, the oil droplet that contains the medication will be absorbed using normal absorption mechanisms of oils. Typical emulsifying agents in oral mixtures include acacia, gelatin, and lecithin. The ideal emulsifying agent is stable, compatible with the other ingredients, colorless, odorless, tasteless, nontoxic, and will not interfere with the delivery of the API (**Tables 4 and 5**).

Emulsions have been used ubiquitously in the formulation of dermatological products like creams and lotions. External emulsions like lotions and creams serve to provide an external medication delivery vehicle of a drug that has low aqueous solubility.

A compounding pharmacist may rely on hand homogenizers and electric mixtures when preparing emulsions.

Table 4 Natural emulsifying agents

Class	*Example*	*Emulsion type; route of administration*
Finely divided solid	Bentonite	o/w and w/o; topical
	Aluminum hydroxide	o/w; oral
Phospholipid	Purified lecithin	o/w; oral
Polysaccharide	Acacia	o/w; oral
	Methylcellulose	o/w; oral

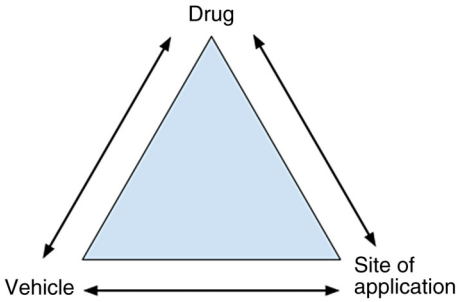

Figure 1 With topical the drug, base, and application sites affect each other, which can affect release of the drug from the base, and ultimately the potency of the formulation.

Ointments

Semisolid-dosage forms are intended to be applied on the skin or other topical surfaces of the body (e.g., eyes, fingernails, and lesions), for the purpose of:

1. providing lubrication (emollients);
2. bringing into contact with the drugs for skin, that are required in healing skin disorders;
3. acting as protective coverings to prevent contact of the skin surface with chemicals, solutions, and organic solvents.

The preparations include primarily ointments/creams (salves), cerates, jellies, pastes, plasters, and poultices. Ointments are of such a consistency that they may be readily applied to the skin by spreading. The viscosity of an ointment should allow it to soften, but not necessarily melt when applied to the body. Creams and jellies generally have a lower viscosity than ointments whereas cerates, pastes, plaster, and poultices generally have a higher viscosity (Dubins et al., 2017).

When semisolid preparations are applied to local areas of the skin, the vehicle often has a more pronounced initial effect than the APIs. The effect produced is often due to a synergistic effect between the APIs (e.g., antibiotic agent, keratolytic agent, antipyretic agent, antiseptic) and the base itself. The base usually has a more general action on the skin, providing occlusion to water loss from the skin, emollient and lubricating action, or a drying action. In turn, the base also will affect the properties of the tissue on which it is directly applied, which can also affect absorption of the API. The relationship between vehicle, API, and site of application is extremely contextually dependent. Drug absorption through thicker skin (e.g., knees and elbows) will be slower and more susceptible to mechanical removal by rubbing against clothing than drug absorption through intertriginous areas (e.g., armpits and groin). Fig. 1 illustrates the interrelationships between API, vehicle, and properties of the skin. For instance, an occlusive vehicle can hydrate the skin, making it more porous and therefore, more permeable to the API. These interrelationships are not always predictable, and are sometimes not completely understood until clinical testing.

Ointments in the pharmaceutical sense are one phase—having one component (e.g., oily ointment or hydrophilic ointment). This can give ointments a translucent appearance (e.g., Petrolatum USP), although depending on the identity of the ointment and the API incorporated, an ointment need not be translucent (e.g., Hydrophilic Ointment USP is opaque white).

Preparation by Fusion

If any components of an ointment are solid, fusion is required to compound the ointment. Ointment preparation is easily accomplished by fusion, provided the vehicle melts easily and is thermostable within bench-top heating temperatures (<200°C), and the API is reasonably thermally resistant to degradation at the temperatures and duration they are exposed to heat during compounding. The principle of fusion is simple. It involves melting all of the intended excipients in a ceramic dish, over a hot plate (and preferably a water bath to control the temperature and protect the excipients from burning). The excipients can be added to the ceramic dish in reverse order of melting point, in order to minimize exposure of each excipient to high-temperatures. A thermometer may be used to monitor the temperature to ensure that the mixture is above the melting point of the highest excipient, but in general, most excipients melt quite readily and are qualitatively homogeneous liquids when melted properly. It is important not to overheat the melted mass, or the excipients may burn, degrade, or separate. The mixture should be continually stirred with a glass rod while melting.

Once the mixture is melted, the API is added at this point, again to minimize exposure of the API to heat unnecessarily. The API can be added directly as a powder, or tituated through a wire mesh screen to reduce the particle size. Once incorporated, the mixture should be removed from heat and stirred continuously while congealing to ensure the API is evenly distributed throughout the vehicle. Some API powders will disperse and not dissolve in the ointment; this can result in separation or caking of the API powder in the vehicle, which precludes an elegant, homogenous ointment. After the mixture congeals, it can be removed and packed into an ointment jar.

Fusion may also be used to prepare solid formulations (e.g., suppositories, lip balms, etc.), and the same method is followed (Fig. 2).

Preparation by Mechanical Incorporation

Mechanical incorporation is often used on the pharmacy bench if a ready-made ointment is purchased through a compounding retailer, and especially if an API is heat-sensitive. Mechanical incorporation involves directly mixing the API into the vehicle in a

Figure 2 A steam bath is set up to limit direct exposure to heat from the hot plate. A ceramic dish is set on top of the steam bath to melt components of the formulation.

controlled way, ensuring even distribution of the API. If the API is a course or lumpy powder, it can be pulverized or passed through a handheld sieve using a spatula to reduce the particle size. Two common techniques for mechanically incorporating an API into a base are first *levigation* and then *geometric dilution*.

Levigation

Whether or not a drug is compatible with a vehicle (e.g., a hydrophobic drug is to be incorporated into a hydrophobic base), most APIs are available as white or off-white dry powders. It is difficult to disperse a dry powder evenly throughout a semisolid vehicle. Air can entrap between powder particles, and ointments by nature have very high-surface tensions, making wetting the surface of the particles a lengthy task. In order to facilitate the drug being dispersed into the vehicle, a minimal amount of liquid *compatible in hydrophilicity* with the vehicle may be mixed with the powder, in order to wet the powder granules, and reduce particle size. This process is known as *levigating* the powder. The following procedure is used for levigation:

1. The API powder is weighed, and transferred to the middle of a glass slab or wax paper compounding pad using a spatula.
2. A levigating agent is selected that is compatible with the ointment vehicle. For a hydrophobic ointment, mineral oil (heavy) USP may be used in many cases. For a hydrophilic ointment, Glycerine USP may be used. If the vehicle is not very viscous, then the vehicle itself can be used to levigate the API.
3. The levigating agent is added drop by drop to the powder and carefully mixed, until a homogenous, toothpaste-like consistency is obtained. Mixing should be controlled and contained so that the API remains in a small mound at the center of the glass slab or pad. A thin, diffuse layer of API will dry out quickly, and will be difficult to recover in its entirety. The total volume of levigating agent added should be quantitatively minor compared to the overall batch weight of the ointment (**Figs. 3 and 4**).

Geometric dilution

Once the API is levigated and at the center of the glass tile or wax pad, the next task is mixing the API with the intended amount of vehicle, to produce the correct overall concentration in the ointment. Many topical ointments are highly potent (e.g., progesterone or hydrocortisone), and the challenge is incorporating a small amount of API evenly in a large amount of vehicle. For example, a 0.1% Hydrocortisone Ointment, batch size 30 g would only require 30 mg of drug. If drug and vehicle are mixed together all at once, the API can "get lost" in the vehicle, resulting in uneven ointment potency. A more efficient way of mixing a small amount of API in a comparatively large amount of vehicle is by *geometric dilution*. The principle of geometric dilution is that it is more efficient to mix equal parts of mixtures (half/half). The following procedure is used for geometric dilution:

1. The total amount of vehicle required for the formulation is prepared and weighed.
2. The API powder required for the formulation is added to the center of a marble or glass tile.

Figure 3 A few drops of a levigating agent is added to the component to be dispersed in the ointment vehicle.

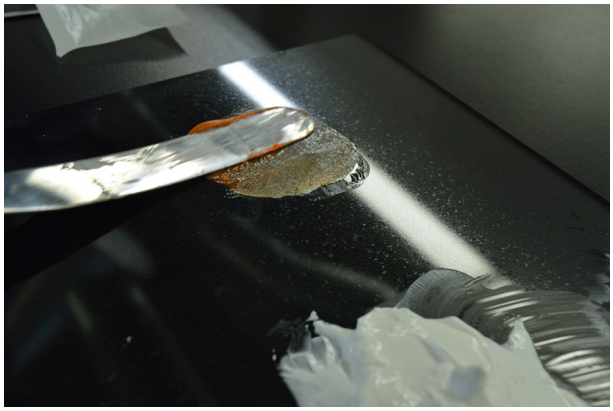

Figure 4 Using a spatula, the powder is reduced to a fine paste by mixing with the levigating agent.

3. The API powder is levigated with a levigating agent (if required), or reduced in particle size mechanically with a handheld sieve (if required).
4. An amount of vehicle approximately equal to the amount of API powder on the compounding pad is added to the pad, directly beside the API.
5. A spatula (hard rubber, plastic, or stainless steel) is used to evenly mix the equal amounts of API powder and vehicle. Mixing is performed in a controlled but thorough way, in order to prevent the ointment mixture from spreading out on the compounding pad. Continue mixing until the mixture is uniform.
6. Once the moieties are mixed, steps (4) to (5) are repeated (this time adding an amount of vehicle approximately equal to the amount of mixed API powder + vehicle, then mixing until uniform), until the entire amount of vehicle has been incorporated into the mixture.

The ointment is then ready to be recovered, packed, and labeled, using an ointment jar appropriate for the volume of ointment prepared (Fig. 5).

Ointment Jar/Container Selection

Since ointments tend to be very viscous, it can be difficult to pack a thick ointment into an ointment jar. The first consideration for packing an ointment is to choose an appropriate ointment jar size (one where the ointment jar is full, allowing for a bit of space at the top). As with other formulation packaging, jar size is important for various reasons:

- a patient shouldn't have to reach deeply into the jar to recover the ointment;
- an ointment jar that appears to be less than half full has the perception of being empty or underfilled;
- the amount of air in the ointment jar should be minimized;
- if the jar is overfilled, it will stick to the lid and appear pharmaceutically inelegant.

An ointment tube may also be considered, if the compounding pharmacy has a tube end-sealer (Fig. 6).

Figure 5 The vehicle is mixed in equal proportions sequentially to the levigated powder, to ensure even mixing.

Figure 6 From left to right: lip balm tube, ointment jar, foam dispenser, pump dispenser, armpit applicator.

Ointment Jar Packing

Once a jar size is selected, the compounded ointment is transferred to the ointment jar using a spatula, by adding a small amount of vehicle to the tip of the spatula, and plunging the spatula directly downwards into the mouth of the ointment jar. Then, the ointment is scraped onto the inside ridge of the ointment jar by removing it at a 45-degree angle while gently pressing down. This action reduces the amount of air entrapped at the bottom of the ointment jar. The jar is rotated slightly each time a new amount of ointment is transferred from the compounding pad (Fig. 7).

Figure 7 The ointment is packed by scraping it off the spatula on the inside of the ointment jar lid, while pressing downward. The ointment jar is rotated slightly for each new transfer of ointment.

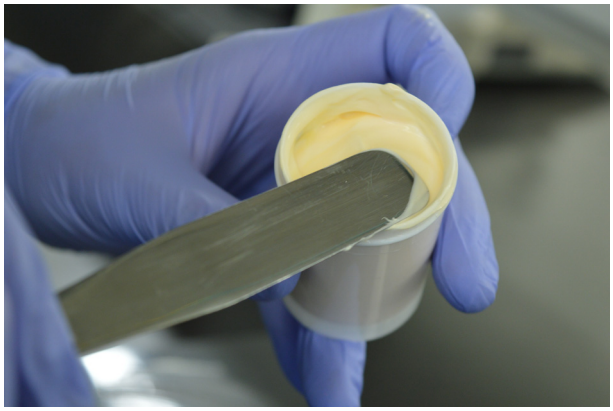

Figure 8 The ointment jar is rotated as a spatula is used to smooth out the surface of the ointment.

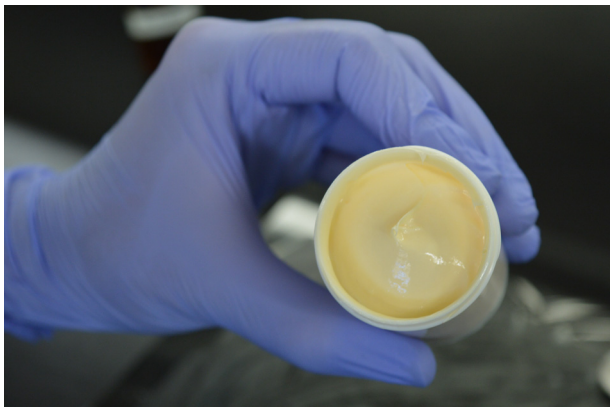

Figure 9 The ointment is finished with a clean looking cone-shaped spiral.

If the ointment jar becomes too full before all of the ointment is transferred, consider the following actions:

- Plunging the spatula up and down quickly, but gently in the middle of the ointment jar. This will work any entrapped air pockets upwards, freeing up more room for ointment.
- Selecting a larger ointment jar.

In the past, ointment jars were typically made of glass. Generations of pharmacists were taught not to bang the ointment jar body against the counter in concern of cracking the glass. Although modern ointment jars are hard white plastic, plunging the ointment is preferred to banging the jar body against the counter, as it is a more effective measure of mechanically removing entrapped air.

After the entire compounded vehicle is transferred to the ointment jar, the top of the ointment should be smoothed out with a spatula into a single spiral peak, providing a pharmaceutically elegant looking product. This is obtained by carefully placing the tip of the spatula on the surface of the ointment, angled upward, toward the middle of the jar, then rotating the base of the jar (**Figs. 8 and 9**).

Finally, the sides of the ointment jar should be wiped clean of any ointment, and the lid should be capped tightly. The packed full ointment jar should not result in any ointment sticking to the lid. The jar is then appropriately labeled. See section, Product Example Formulations and Calculations, for a hydrocarbon ointment example: White Ointment USP XXII: (hydrocarbon ointment) (Troy and Beringer, 2005).

Creams: O/W, W/O

A cream is a mixture of two otherwise immiscible phases: a hydrophobic phase and a hydrophilic phase, and usually a surfactant or emulsifying agent to keep the cream from separating. For this reason, since one phase is dispersed in the other, the refractive index between the continuous and dispersed phases imparts a milky, opaque color to creams, scattering light as it travels through.

The method of preparing creams by the fusion process is slightly more complicated. In this case, both the aqueous phase and the oil phase are heated separately, to somewhere between 60–80°C. As a general rule, the oil phase should be heated to at least 5°C above the melting point of the highest melting waxy ingredient. The water phase is heated to 5°C *above* the temperature of the oil phase to prevent premature solidification prior to mixing and emulsification. Melting points can be obtained through literature values, or the compounder can simply observe when the last solid disappears during the melting process, and heat the mixture an

additional 5°C. Water-soluble excipients are dissolved in the heated aqueous phase with stirring, while nonvolatile oil-soluble ingredients are dissolved in the heated oil phase. Generally, the internal (dispersed) phase is gradually added to the external (continuous) phase and vigorously mixed. An electric hand blender may be used to facilitate mixing. Multiple excellent creams have been produced by combining the reverse order, and the method of preparation may vary from one formula to the other.

If the hydrophilic phase of a cream contains water, then a preservative should be considered. The following formulation is an example of a common O/W emulsion (discrete oil-based phase suspended in a water-based continuous phase). An O/W emulsion will be less oily, and more washable than a W/O emulsion (Dubins et al., 2017). See section, Product Example Formulations and Calculations for O/W cream example: Hydrophilic Ointment USP (USP, 2007), and a W/O cream example: adapted from Cold Cream USP XVIII (Singh, 2010).

Poloxamer Gel Cream

Gels can offer a unique vehicle for topical (especially ocular), or systemic delivery. Gel properties can be custom tailored to the formulation. Compatibility may be an issue, as the biochemical properties of the API can alter the integrity of the gel. Temperature is also a very important control, particularly in the vicinity of the gel-sol transition temperature of the vehicle. Preparation of a gel vehicle is therefore extremely formulation dependent, since some gelling agents undergo this transition backwards, gelling with increasing temperature. One such gel cream is poloxamer/lecithin isopropyl palmitate vehicle (also called PLO/LIPS cream). Poloxamer creams are extremely versatile. The poloxamer moiety, purchasable at different concentrations under the name "pluronic gel", constitutes the aqueous component of the cream. Interestingly, this gel sets at and above room temperature, into a stiff jelly-like consistency. The gel also "rings" when tapped, reverberating the vibrations against the walls of its container. When chilled, the gel reverts back to a free-flowing solution (an interesting phenomenon called reverse thermal gelling). Poloxamer gels have wide-ranging applications from teeth-bleaching to artificial skin. Pluronic gel may be purchased, or compounded at the desired concentration using the protocol provided in section, Product Example Formulations and Calculations (Poloxamer 20%/LIPS gel cream [Dubins et al., 2017]).

Carbomer and Cellulose-Based Gels

Carbomers (also called Carbopols) are one of the most common thickening agents for water phases. Their properties in aqueous solutions depend both on temperature and pH. At low pH, the gel is more liquid, so adjustment to neutral pH may be required depending on the formulation (Sultana et al., 2006). The pH of the vehicle may be adjusted with sodium or potassium hydroxide for aqueous solutions. If alcohol gels are required, triethanolamine can be used to adjust pH to neutrality (https://pharmlabs.unc.edu/labs/gels/agents.htm). At lower concentrations, these same agents can be used as suspending agents, which are more free-flowing than their gelled form. Carbopol can also be combined with methylcellulose to form stiffer gels. Working with gelling agents can be difficult, as they can be difficult to solubilize, and readily clump together when added to water in a single pour, floating on the surface. One way to accomplish this task (the "hot" method) is by heating one third of the required vehicle just below boiling (80–90°C), then slowly adding the gelling agent while stirring vigorously with a large magnetic stir bar or glass rod. Once the powder is dispersed, the remainder of required vehicle is added as cold water, and then the mixture is refrigerated overnight. See section, Product Example Formulations and Calculations for an example: 2% Methylcellulose Gel (Dubins et al., 2017).

Another method (the "cold" method) is performed, by adding the powder to the required amount of vehicle in a large beaker, and then using an electric-hand blender to disperse and solubilize the particles. As with any aqueous solution, a preservative should be added to prevent bacterial growth. See section, Product Example Formulations and Calculations for an example: 1% Carbomer Gel (cold method).

Preparations Using Molds (Solids)

The compounding pharmacist or pharmacy technician has unique opportunities to help design and prepare custom formulations by shape and type, in order to best meet the needs of patients. Using a mold, whether by pouring in a vehicle that solidifies, or compressing a powder, offers the ultimate flexibility. Mold preparations have found their way into pediatrics (lollipops, suppositories, gummy bears), adult medicines (rectal rockets, troches, vaginal suppositories, and lip balms, rapid-dissolving tablets), and veterinary medicines as well.

Whereas, most pharmaceutical preparations are prepared by weight (% w/w), preparations involving mold filling are performed by volume. This results in the need to either calibrate the mold in order to plan for the correct dose, or formulate in such a way that the *volume* of the APIs in the formulation is taken into account. Molds offer the ultimate flexibility in creating a useful and potentially innovative shape and appearance. This can help with administering the drug (e.g., the shape of a suppository is tapered to facilitate insertion), or can improve the organoleptic properties of the drug (e.g., adding colorants and flavorants to a lollipop formulation). See section, Product Example Formulations and Calculations, for calculations pertaining to formulations using molds.

Suppositories

A suppository is a plug of medication that is intended to be inserted in an orifice other than the mouth (e.g., rectum, vagina, urethra) that melts or dissolves at body temperature. They can be formulated for local or systemic drug delivery. Table 6 lists some common uses for suppository formulations, intended for local and systemic drug delivery.

The ideal suppository vehicle should be compatible with the drug intended for delivery (i.e., not degrade or interact with the drug), have a melting temperature in the vicinity of body temperature (or dissolve in body fluids), and not interfere with drug release

Table 6 Suppository formulation examples for local and systemic drug delivery

Local delivery	*Rectal:* • Constipation (glycerin, bisacodyl) • Antipruritic (lactic acid) • Vasoconstrictor (phenylephrine) • Local anesthetic (lidocaine) • Steroid (hydrocortisone) *Vaginal:* • Antifungal (clotrimazole) • Antibiotic (metronidazole) • Fertility agent (progesterone) *Urethral:* • Erectile dysfunction (alprostadil)
Systemic delivery	*Rectal:* • NSAIDs (diclofenac, indomethacin) • Antipyretic (acetaminophen) • Antiemetic (prochlorperazine, chlorpromazine, dimenhydrinate, ondansetron) • Opioid analgesia (oxymorphone HCl)

or absorption. Generally speaking, absorption occurs across a topical surface, but because the vehicle melts or dissolves, the thermodynamic activity of the drug in the vehicle helps drive diffusion. Consequently if systemic absorption of the drug is intended, a vehicle should be selected that is *opposite* in hydrophilicity to the drug. In other words, a hydrophilic vehicle should be selected for a hydrophobic drug, and conversely, a hydrophobic vehicle should be selected for a hydrophilic drug. Table 7 illustrates examples of the major types of suppository vehicles: oleaginous, hydrophilic, and water-dispersible.

Suppository compounding equipment

Although in an industrial context, suppositories are made by compressing the vehicle/drug mixture into a mold, in a compounding context, fusion molding is required (melting the required ingredients, mixing, pouring into the mold, and cooling to solidify). Various mold types are available. The first suppositories were cocoa butter, and were formed by hand-rolling, a practice no longer used (Allen, 2014). Subsequently, large aluminum molds were used, consisting of plates that could be separated to expose the formed suppositories lengthwise. This facilitated removal of the dosage form from the mold. Lubrication of the mold (e.g., with mineral oil) was required, particularly with hydrophilic vehicles, in order to recover the suppositories without breaking them.

Table 7 Common suppository vehicles

Base type	*Advantages*	*Disadvantages*	*Examples*
Oleaginous	• Easy to prepare • Self-preserving • Better for inflammation/irritation (emollient) • Most common • Self-lubricating (facilitates insertion)	• May leak out of orifice upon melting • Poor systemic absorption of hydrophobic drugs • Unfavorable polymorphs of cocoa butter may form with overheating or rapid cooling	• Cocoa butter • Hydrogenated vegetable oils (e.g., Theobroma oil) • Synthetic triglycerides (Witepsol H-15)
Hydrophilic	• Melts at 37°C • Melts more slowly than oleaginous vehicles • Well-suited to rectal/vaginal/prolonged release • Chemically stable, nonirritating • Miscible with water/mucous secretions	• Not self-preserving (will require a preservative if formulation contains water) • Hygroscopic (may cause pain in orifice) • Not self-lubricating (wet before insertion) • Poor/sensitive mechanical properties (brittle) • Glycerinated gelatin requires mold lubrication prior to casting	• Glycerinated gelatin • Hydrogels (polyvinyl alcohol, hydroxyethyl methacrylate, polyacrylic acid, polyethylene) • Polyethylene Glycol (macrogols)—high-molecular weight, or mixtures
Water dispersible	• Can make an oleaginous base more hydrophilic	• Surfactants can irritate the orifice lining (e.g., the anal mucosa) • This can result in expulsion of the dosage form, and/or have a laxative effect	• W/O emulsions • Polyoxyl 40 stearate (surfactant) • Oleaginous vehicles with surfactant

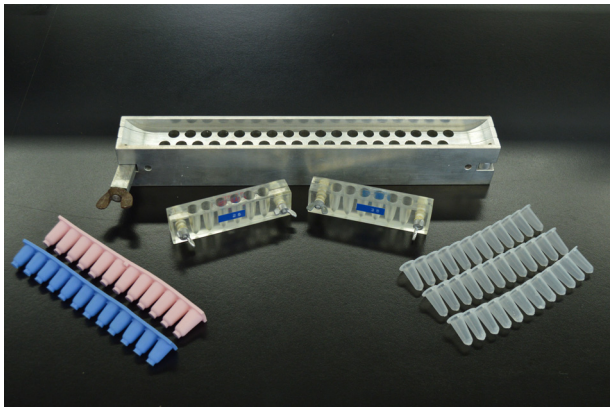

Figure 10 Various suppository molds. Left: silicone molds, center: aluminum and acrylic molds, right: plastic shells.

Contemporary compounding sees less of this style mold in favor of disposable rubber, plastic, or silicon suppository strips. Heat-shrink suppository shells can be purchased that also function as the dispensing package, leaving removal of the suppository as a task for the patient.

At the very minimum, the compounding pharmacist or pharmacy technician would require the following equipment for making suppositories:

- hot plate
- pyrex beaker (for a steam bath)
- large ceramic dish
- stirring rod
- suppository mold (Fig. 10)
- suppository mold stand, or suitable bracket to keep the mold from tipping over (Fig. 10)
- metal spatula or microspatula
- Personal protective equipment: laboratory glasses, lab coat, and oven mitts.

See section, Product Example Formulations and Calculations, for a suppository vehicle example: Polyethylene Glycol Suppository Vehicle

Rectal Rockets

As their interesting name suggests, rectal rockets have a unique rocket-like shape, allowing them to be partially inserted before bedtime, to apply medication topically overnight on both sides of the anal sphincter. This is particularly useful in treating anal fissures and prolapsed hemorrhoids. A radial slit runs longitudinally down the rectal rocket body, to allow for the passage of gas without the concern of ejecting the dosage form. See section, Product Example Formulations and Calculations, for a training formulation (Rectal Rocket Vehicle Example) from the University of Toronto, which could be used as a vehicle for rectal rockets, although any suppository vehicle may be considered in conjunction with the physicochemical properties of the drug, and the intended delivery (local or systemic).

Lollipops

Pediatrics offers a particular challenge for drug delivery, as poor organoleptic or aesthetic qualities of the formulation will likely result in poor patient adherence. Lollipops are a preferred pediatric formulation, particularly when local drug delivery is required to the oral mucosa, teeth, gums, or throat. Depending on the vehicle selected, the drug requires a high resistance to thermal degradation. Temperature monitoring is important, particularly with sucrose-based vehicles.

Lollipops can be formulated with many classes of drugs, including those intended for systemic effects. Table 8 lists some common uses for lollipop formulations.

See section, Product Example Formulations and Calculations, for an example training formula at the University of Toronto, which uses silica gel as a stiffener (optional), to accelerate solidification. The formulation requires ample mixing while incorporating ingredients and while pouring. The flavorant should be selected with the preferences of the patient in mind (Dubins et al., 2017).

Troches

Troches (pronounced tr-oh-keys) are another interesting term for oral lozenges. The shape of the troche will depend on the mold. Two major types of vehicles for troches are gelatin based, and higher molecular weight polythene glycols. In fact, the lollipop vehicle above could also be used to formulate troches. However, a gelatin-based training formulation from the University of Toronto is provided here as another example. Selection of vehicle may depend on the physicochemical properties of the drugs, and potential drug-excipient interactions. Troches are appropriate for pediatric (but not infant) or adult formulations, and share the same

Table 8 Common uses for lollipop formulations

Local delivery	Dental/buccal pain (lidocaine, tetracaine, benzocaine)
	Excessive bleeding (tranexamic acid)
	Oral thrush (ketoconazole)
Systemic delivery	Systemic pain (fentanyl)
	Cough suppressant (dextromethorphan)
	Antipyretic/analgesic (acetaminophen)
	Conscious sedation (ketamine)

advantages and indications. Troche molds can be smaller than lollipops, and thus a higher number of doses can be administered in a troche case compared with a lollipop. An example troche mold is provided in Fig. 17. See section, Product Example Formulations and Calculations, for an example training formula.

Lip Balms

Lip balms or lip salves are fantastic for delivering medication locally to the topical surface of the lips, and can also be applied to other areas of the body (e.g., lesions, hives, sores, insect bites, or even as sunscreen). Anesthetics (e.g., lidocaine, prilocaine) or steroids (e.g., hydrocortisone) can be incorporated to relieve pain or inflammation. A hydrophobic formulation would be occlusive, and thus hydrating to the lips. Almond or orange oil could be substituted for lemon oil, depending on the fragrance preference of the patient. See section, Product Example Formulations and Calculations, for a training formula at the University of Toronto, an example lip balm vehicle (Petrolatum/Beeswax).

Capsules

Capsule sizes run counter-intuitively backwards, with larger numbers having smaller internal volumes. Table 9 presents the most common capsule sizes for humans. Veterinary capsules can be much larger, depending on the animal, and strength required. One of the parameters used to perform capsule filling calculations is the capsule fill weight. The fill weight of an excipient or API is the mass that would occupy a capsule of a given size if it were completely filled with that ingredient alone. Capsule fill weight tables are available for common pharmaceutical excipients (Allen, 2014), and also by powder density (Troy and Beringer, 2005). However, these values are easily calculated if the tapped powder density of the excipient(s) and API(s) are known (or determined). If the fill weight of an excipient or API is not known, it may be determined by completely filling 5 capsules with that excipient or API alone, weighing, and then calculating the average filled weight (not including the weight of the empty capsule bodies).

Having the flexibility to compound capsules allows a pharmacist or pharmacy technician to produce a non-standard dose of a drug, or compound an oral drug in the event of a shortage. Capsules are filled by volume, and consequently the calculations are normalized by the fill volumes of the capsule, which vary depending on capsule size and powder density. The overall assumption

Table 9 Capsule size volumes, and tapped powder densities of common pharmaceutical powders

Capsule size	*Capsule volume*[a] *(mL)*	*Tapped powder densities of selected common pharmaceutical powders (g/mL)*
000	1.40	Acetaminophen: 0.343[b] (bulk)
00	0.95	Aspirin: 0.743[a]
0	0.68	Avicel PH-101: 0.338[c]
1	0.50	Avicel PH-102: 0.350[c]
2	0.37	Avicel PH-105: 0.46[d]
3	0.30	Corn starch: 0.441[c]
4	0.21	Dibasic calcium phosphate anhydrous: 1.43[d]
5	0.13	Ibuprofen 110: 0.453[b] (bulk)
		Lactose: 0.713[c]
		PEG 4000: 0.571[c]
		Povidone K-30: 0.434[c]
		Quinine sulfate: 0.464[a]
		Sodium bicarbonate: 1.021[a]
		Sodium carboxymethylcellulose: 0.489[c]
		Sorbitol: 0.73[d]
		Stearic Acid:0.59[d] (bulk)

[a]Troy and Beringer (2005)
[b]Jallo et al. (2012)
[c]Rahman et al. (2017)
[d]Hancock et al. (2003)

made is that powder volumes are indeed additive despite excipients having different densities. See section, Product Example Formulations and Calculations, for example capsule filling calculations.

Hand Filling

Once the capsule blend is compounded, hand filling the capsule may be performed for small batch sizes (e.g., 10 or less capsules). This technique is slower and more manual, but does not require any specialized equipment. In order to facilitate hand-filling, compressible powders like Avicels and cornstarch are useful as diluents, since they will compress well into the capsule body without falling out. Hand filling may be accomplished using the following protocol.

1. Scale up the batch to allow for extra powder (e.g., by a factor of five).
2. Mix the powder formulation and mix by inverting repeatedly in a closed bag (e.g., 2 min of continuous inversions).
3. Add the mixed powder contents to the center of a marble or glass slab.
4. Smooth the surface of the powder so that it is a thick even layer in height, equivalent to approximately half the length of the capsule body.
5. Remove the cap from the capsule body.
6. Gently push and rotate the capsule body down into the powder bed. Perform this motion repeatedly until the capsule body is filled.
7. Replace the capsule cap by firmly pressing it onto the capsule body until it snaps shut.
8. Dust and weigh the final capsules, and weigh each capsule.
9. Weigh five empty capsules, and calculate the average empty capsule weight.
10. Each capsule should be within 90%–110% of the theoretical mass per capsule + average empty capsule weight. Capsules can be opened and adjusted (powder blend added or removed with a microspatula) if they are outside these limits.

Capsule Machine Filling

Capsule filling machines enable the compounder to make large batches of capsules without having to individually fill them. Various commercial products are available, each with specific instructions. Some machines have the capacity to remove capsule lids with one single motion, and replace the lids after they are filled. The batch weight is calculated as the total mass per capsule multiplied by the number of capsules to be compounded. A card is used to move and press the powder down into the capsule bodies, and a tamper is used to compress the powder so that the entire batch can be loaded. No losses are anticipated provided the capsule machine is used correctly.

Oral Disintegrating Tablets (Molds and Baked Versions)

An ODT is a solid dosage form that disintegrates and dissolves in the mouth (either on or beneath the tongues or in the buccal cavity) without water within a minute or less. These tablets are distinguished from conventional sublingual tablets, lozenges, and buccal tablets which require more than 1 min to dissolve in the mouth. ODT can be used to administer a medication to a patient that has difficulty swallowing other oral formulations (elderly, palliative, bedridden, stroke patients). This formulation is also an option for patients that refuse to swallow medications such as pediatric, geriatric, and psychiatric patients. It is the choice of formulation for patients that have a high risk of choking from oral drugs (Nagar et al., 2011). It may also be useful for vomiting patients since absorption occurs through the oral mucosa, and one example that is widely used is ondansetron wafer for vomiting pediatric patients, avoiding the need for i.v. therapy.

In general, when an ODT medication is administered, water must quickly enter the tablet to facilitate rapid disintegration and dissolution. When deciding if this formulation is appropriate based on patient characteristics it is important to consider other characteristics. The API must not be bitter and have a small to moderate molecular weight. It must be readily soluble in water and saliva and have the ability to penetrate the oral mucosal tissue (Nagar et al., 2011). ODT formulations are hygroscopic and must be handled very carefully. Specific packaging is required prior to dispensing ODT tablets. Drugs, which are usually formulated as ODT include antiepileptics, antibacterials, PDE-5 inhibitors used in erectile dysfunction, analgesics, sedatives, and anxiolytics.

Typical excipients used in ODT formulations include at least one disintegrant, a diluent, a lubricant, sweeteners, and flavorant. Table 10 details common excipients and their role in ODT compounds.

This custom formulation types can be created in the compounding lab but an oven is usually required for basic ODT compounds. Tablet triturate molds are recommended to facilitate easy compounding. Compounding distributors generally formulate rapid-dissolving tablet bases that can be mixed with the active ingredient. Trituration is not done in these cases as temperatures of 105–110°C for 10–15 min establish bonding, ultimately resulting in a homogenous solid disintegrating tablet. The heat enables tablet shrinking and ease of removal from the mould. This type of formulation is beyond the scope of this introductory chapter but was included to provide background for consideration.

Flavorants

Flavorants are a critical component of oral, buccal, and sublingual formulations, as they play an important role in masking unpleasant flavors of drugs, excipients, and their combination. Surfactants, preservatives, and certain vehicles can impart bitter or sour tastes to oral preparations. To make matters more complicated, taste can be very subjective. The perceived flavor of a formulation can vary greatly based on the patient's preferences, and importantly, the patient's expectations. Particularly in pediatrics,

Table 10 Excipients for oral disintegrating tablets

Excipient type	*Example*	*Function*
Binders	Hydroxypropylcellulose	Maintain the integrity of the dosage form prior to administration
Colors	Amaranth	Enhances the appearance and organoleptic properties
	Red iron oxide	
Fillers	Mannitol	Maintains the bulk of the dosage form
	Sorbitol	
	Xylitol	
	Calcium carbonate	
Flavors	Flavoring oils as per patient preference, fruit essences	Improve palatability, enhance patient adherence
Lubricants	Stearic acid	Reduce friction and wear between the mechanical moving parts of the punching machine and tablet parts
	Talc	
	Polyethylene glycol	
	Colloidal silicon dioxide	
Superdisintegrants	Microcrystalline cellulose	Increase rate of disintegration
	Sodium starch glycolate	
	Carboxymethylcellulose	
Surface active agents	Sodium doecylsulfate	Reduce interfacial tension and enhance solubilization
	Sodium lauryl sulfate	
	Fatty acid esters (Tweens)	
	Sorbitan fatty acid esters (Spans)	
	Polyoxyethylene stearates	
Sweeteners	Aspartame	Taste masking properties and improve patient adherence
	Dextrose	
	Fructose	
	Mannitol	
	Sorbitol	
	Xylitol	

Source: Nagar, P., Singh, K., Chauhan, I., Verma, M., Yasir, M., Khan, A., Sharma, R., Gupta, N., 2011. Orally disintegrating tablets: formulation, preparation techniques and evaluation. J. Appl. Pharm. Sci., 1 (04), 35–45.

the success of administering an oral formulation can hinge on its appearance and flavor. Color, consistency, smell, and mouthfeel all play a part in the intricate organoleptic experience that is lumped under "taste." The perceived sensory experience of a taking a drug can also have direct consequences on its efficacy, which formulators can manipulate to an extent (Sharma and Sharma, 1988).

An ideal flavorants masks any unpleasant tastes or aftertastes of the preparation, is compatible/miscible with the preparation, does not affect the stability of the drug or excipients, is only required in small quantities, and is favorable to the patient. There is a cultural aspect of flavoring that should be taken into account by the formulator. For instance, bubble gum is a very popular North American flavorant for pediatric syrups, and yet has far less appeal in European and Asian countries. A colorant used with a flavorant can impact the patient's perception of the flavor, even if the coloring agent has no flavor on its own. In recent years, the use of coloring agents has become less popular for pediatrics due to parental concerns about food dyes. Patients may express other requirements, such as a formulation that is sugar-free, gluten-free, or casein-free. Thus, the decision to use a flavorant and colorant should be made in consultation with the patient (patient's parents, if applicable). A private taste test can also be arranged to ensure the optimal flavorants are selected, at the optimal concentrations.

The amount of flavorant used will vary depending on the API, the flavor selected, and the flavorant vehicle. As a very approximate guideline, water-based flavorants are typically used at 1–3% w/v of the formulation. However, at the upper end of this range, adding too much flavorant can affect the stiffness of solid formulations (e.g., PEG/Sorbitol lollipops). Water-based flavorants are best used in aqueous or anhydrous hydrophilic or amphiphilic vehicles. Oil-based flavorants tend to be more potent, and are used in concentrations an order of magnitude lower (0.1–0.3% w/v). They are best used in vehicles that are hydrophobic (e.g., wax-based preparations like lip balms). Mixing an oil-based flavorant into a hydrophilic vehicle (or vice versa) will result in poor mixing and phase separation of the flavorant.

Veterinary preparations have different flavor requirements than preparations for human use. Beef, chicken, tuna, cheese, and liver flavors are commonly used for dogs, cats, and other animals. Table 11 provides some suggestions regarding common drug classes and flavors to help mask the taste of some drug classes, and tastes. Table 12 provides recommendations regarding sweeteners.

Formulation Stability

Beyond Use Dates: A Guideline

A BUD is provided to inform the patient when to stop taking a compounded preparation. Over time, particularly in aqueous preparations, microorganisms will grow. In addition, even at room temperature, drugs and excipients are expected to degrade. Coming up with a reliable estimate for a BUD would depend not only on the APIs and excipients, but also the container, the label,

Table 11 Flavorant table: suggestions

Drug class	*Masking flavorant*
Antibiotics	Fruit flavors (cherry, pineapple, orange, banana–pineapple, strawberry–vanilla), coconut–custard
Antihistamines	Fruit flavors (apricot, cherry, grape, lime, peach–range, raspberry), honey, root beer, cinnamon
Barbiturates	Fruit flavors (banana–pineapple, orange, peach–orange, lime, grenadine–strawberry, banana–vanilla), root beer
Decongestants and expectorants	Fruit flavors (coconut–custard, custard–mint–strawberry, grenadine–peach, strawberry–lemon, orange, tangerine, pineapple, raspberry), coriander, maple, butterscotch
Electrolyte and geriatric solutions	Fruit flavors (cherry, grape, lemon–lime, raspberry, lime, strawberry), root beer
Masking general flavors	*Masking flavorant*
Salty	Cinnamon, raspberry, orange, maple, butterscotch, glycyrrhiza (licorice)
Sweet	Berry flavors, vanilla
Bitter	Chocolate–mint, glycyrrhiza (licorice), cherry, raspberry, walnut, tutti-frutti
Sour/acid	Fruit flavors, citrus, cherry
Oily	Wintergreen, peppermint oil, lemon, anise oil
Metallic	Mint, marshmallow

Source: Medisca, Suggested Flavoring Reference Chart: Suggested Flavorings to Mask Tastes & Drug Classes. Available from: https://www.medisca.com/Files/ReferenceCharts/Suggested%20Flavoring%20Reference%20Chart%20-%20MUS%20&%20MCA.pdf; Sharma, A.V., Sharma, P.V., 1988. Flavouring agents in pharmaceutical formulations. Ancient Sci. Life, 8 (1), 38

the storage conditions (temperature and humidity), exposure to sunlight, and a whole host of other factors that are not easily predicted. Even under perfect storage conditions, the patient repeatedly opens the drug-containing vessel, potentially introducing and promoting microbial growth. Stability testing is employed by pharmaceutical manufacturers in order to estimate a conservative expiry date to protect the patient. The compounding pharmacist or pharmacy technician does not have these capabilities or resources, and so guidelines for setting BUDs can be suggested, which are dependent on the regulatory body, and change from time to time. In the absence of specific drug formulation stability information, USP 795 and the National Association of Pharmacy Regulatory Authorities provide some recommendations, summarized in **Table 13**, for nonsterile compounded drug preparations. These recommendations are currently in review at the time of writing this chapter. The pharmacist and/or pharmacy technician is responsible for ensuring they have consulted and are following the most recently accepted guidance for estimating the BUD in their regulatory jurisdiction(s).

Preparations should be packaged in tight, light-resistant containers and stored at controlled room temperature or colder, depending on the nature of the formulation (Kawano and Ho, 2012). In addition, the BUD should be not later than the expiration data of any component (Connolly et al., 2018).

Preservatives

Particularly when compounds contain water, antimicrobial and antifungal preservatives are essential for protecting the formulation. Different strategies may be used, which depend on physicochemical properties of the drug and formulation. For instance, some preservatives only work above or below certain pH values. Benzoic acid, for instance, has little antimicrobial activity above pH 8

Table 12 Sweetener chart (approved sweeteners vary by country and local regulations)

Sweetener	*Relative sweetness (relative to 10% sucrose solution)*	*Class*
Acesulfame potassium	180–200	High-intensity sweetener
Aspartame	180–350	High-intensity sweetener
Neotame	7,000–13,000	High-intensity sweetener
Saccharin	300	High-intensity sweetener
Sucralose	600	High-intensity sweetener
Glucose	0.5	Monosaccharide
Fructose	1.5–1.8	Monosaccharide
Maltose	0.4	Disaccharide
Mannitol	0.5–0.72	Sugar alcohol
Sorbitol	0.6	Sugar alcohol
Xylitol	1	Sugar alcohol
Stevia	30	Stevia plant extract
Sucrose	1	Disaccharide

Table 13 Beyond Use Dates (BUD guidelines vary by country and local regulations)

Non-sterile preparation	*Beyond-use date (BUD)*
Non-aqueous formulations (such as ointments, suppositories, fixed oils, waxes, and others *where no water is contained*). (USP 795 proposed revisions, March 30 2018: any preparation other than solid dosage forms that have a reduced water activity, Aw of ≤0.6.).	Not later than 25% of the time remaining until the product's expiration date or 6 months (180 days, with Day 1 as the day of compounding), whichever is earlier. Stored at controlled room temperature.
Solid dosage forms, where USP or NF substance is the source of the active ingredient.	Not later than 6 months (180 days, with Day 1 as the day of compounding). Stored at controlled room temperature.
Water-containing oral formulations (nonpreserved—USP795 proposed revisions, March 30, 2018).	Not later than 14 days (with Day 1 as the day of compounding) when stored at controlled cold temperatures (2–8°C, or 36–46°F).
Water-containing topical/dermal, mucosal liquid and semi-solid formulations (and preserved aqueous dosage forms—USP795 proposed revisions, March 30, 2018).	Not later than 30 days (with Day 1 as the day of compounding).

Guidance Document for Pharmacy Compounding of Non-Sterile Preparations: Companion to the Model Standards for Pharmacy Compounding of Non-Sterile Preparations. National Association of Pharmacy Regulatory Authorities (NAPRA), Ottawa, Ontario; USP, 2007. January 1, last update, Hydrophilic Ointment [Homepage of US Pharmacopeia].

(Rowe et al., 2009). Sometimes, multiple strategies may be used together. Occasionally, some excipients have antimicrobial activity at opportune concentrations in solutions (e.g., Glycerine at 20% or sucrose above 70%). Ultimately the patient should be considered, particularly in consultation with the parents in the event that the patient is a child or infant. Some preservatives have become less popular in pediatric populations, for example, parabens in pediatrics. Benzyl alcohol is not recommended for use with infants (Rowe et al., 2009). It is the responsibility of the pharmacist or pharmacy technician to research and select the appropriate preservative for the formulation, and if there is more than one phase (e.g., a cream) that the selected preservative not partition into the oil phase, leaving the aqueous phase vulnerable. Nonionic surfactants interfere with many preservatives (e.g., parabens) by enclosing them in micelles (micellization) and thus preventing their activities in solution.

Table 14 is a summary of some typical preservatives used in compounding preparations, and their working ranges.

Product Example Formulations and Calculations

This section focuses on how to prepare the common classes of liquid, semisolid, and solid preparations. An emphasis is made on proper technique. Formulas are provided as examples. It is up to the discretion of the formulator to select the most appropriate vehicle and formulation for a particular drug.

Sample formula for Baclofen 5 mg/mL oral suspension (60 mL) (Sick Kids Pharmacy, 2007)

Baclofen 20 mg tablet	15 tablets
Glycerin USP	2 mL
Simple syrup	q.s. to 60 mL

1. Crush tablets to a fine powder (ideally the powder is sifted to ensure finely ground).
2. Wet powder with glycerin and levigate to form a fine paste (can add some simple syrup as well).
3. Gradually add simple syrup in small amounts, levigating well after each addition until a liquid is formed.
4. Transfer to a graduated cylinder.
5. Use additional simple syrup to rinse the remaining drug from mortar and add to the graduated cylinder.
6. Continue up to the final volume stir well.
7. Transfer to glass amber bottle and label accordingly.

This suspension needs to be refrigerated, and shaken well prior to dose administration.

Hydrocarbon Ointment Example: White Ointment USP XXII: (Hydrocarbon Ointment) (Troy and Beringer, 2005)

White wax	5 g
White petrolatum	95 g
To make	100 g

Table 14 Common preservatives used in compounding nonsterile preparations

Antimicrobial agents	*Active against*	*Typical uses in nonsterile preparations*
Ethanol (10%–20% by volume)	Bacteria (not spores)	Oral, transdermal
Benzalkonium chloride 0.01%–0.02% (pH 4–10)	Bacteria, yeast, fungi	Topical, ophthalmic, nasal (not otic or oral)
Benzethonium chloride 0.01%–0.02% (pH 4–10)	Bacteria	Topical, ophthalmic, otic (not oral)
Benzoic acid 0.01%–0.5% (<0.15% for oral) (pH 2.5–4.5)	Bacteria (not spores), molds, yeasts, fungi	Oral, topical, vaginal
Benzyl alcohol 1%–3% (pH < 5)	Bacteria, fungi	Oral, topical, ophthalmic, aerosol sprays
Boric acid 0.03%–1% (also, sodium borate) some safety concerns in pediatrics/neonates	Bacteria, yeast	Ophthalmic, topical (not oral), cosmetics (also emulsifier)
Bronopol 0.01%–0.1% (pH 4–6, light sensitive)	Bacteria	Topicals, cosmetics. High affinity for polar solvents.
Butylene glycol 8% (antimicrobial) 17% (antifungal)	Bacteria, fungi	Topical creams, ointments, lotions, transdermal patches
Butylparaben 0.006%–0.05% (oral), 0.02%–0.4% (topical) (pH 4–8)	Yeast, mold, bacteria	Oral, topical, cosmetics
Certrimide 0.005% (pH > = 7)	Bacteria (not spores), fungi, some viruses	Oral, topical. Not for use with magnesium stearate.
Chlorhexidine 0.01%–0.05% (pH 5–7, light sensitive)	Bacteria, molds, yeasts, fungi	Ophthalmic (also antiseptic at higher concentrations)
Chlorobutanol 0.5% (pH 3.0–5.5)	Bacteria, fungi	Ophthalmic, nonaqueous liquids (incompatible with plastic vials)
Chlorocresol 0.05%–0.2%	Bacteria, spores, molds, yeasts	Ophthalmic, topical, emulsions, cosmetics (shampoos)
Chloroxylenol 0.1%–0.8% (broad pH) (higher: antiseptic, disinfectant)	Bacteria (not spores), fungi, yeast	Topicals (creams, ointments), cosmetics (not oral or ophthalmic)
Cresol 0.15%–0.3% (pH < 9)	Bacteria (not spores), yeasts and molds	Topical, wound disinfection
Edetic acid (EDTA) 0.01%–0.1% copreservative	Bacteria, yeasts, fungi	Topical solutions, oral, otic, rectal, cosmetics (also chelating agent, antioxidant)
Ehylparaben 0.1%–0.25% (pH 4–8)	Yeasts, molds bacteria	Oral, topical
Glycerin 20%–30% also a sweetener, plasticizer, humectant, emollient	Bacteria, molds	Oral, ophthalmic, topical, inhalations, nasal, suspensions, otic, rectal, vaginal, transdermal
Hexitidine (up to 0.1%)	Bacteria, fungi, yeasts	Solutions (e.g. mouthwash) (incompatible with strong acids and oxidizing agents)
Imidurea 0.03%–0.5% (pH 3–9), synergistic with parabens	Bacteria, fungi	Cosmetics, topicals
Methylparaben 0.015%–0.2% (pH 4–8)	Yeasts, molds, bacteria	Inhalation solutions, nasal, oral solutions and suspensions, rectal, topical, vaginal, cosmetics
Phenol 0.1%–0.5% (acidic pH, light sensitive)	Bacteria, fungi, viruses	Topical, cosmetics (not oral) (incompatible with gelatin)
Phenoxyethanol 0.5%–1.0% (copreservative, wide pH)	Bacteria	Topicals, cosmetics, vaccines, wound disinfection
Phenylethyl alcohol 0.25%–0.5% (pH <5, copreservative), 1% (topical)	Bacteria (not spores)	Nasal, ophthalmic, otic
Potassium benzoate 0.03%–0.1% (pH < 4.5)	Bacteria	Beverages, food products where low sodium desired
Potassium sorbate 0.05%–0.2% (pH < 6) (also: sorbic acid) • Used as a co-preservative • Incompatible with bases, oxidizing agents, reducing agents	Fungi, bacteria	Topicals, nasal sprays, oral capsules, solutions, suspensions, syrups • Compatible with nonionic surfactants
Propionic Acid (5%–10%) (also: sodium propionate—higher solubility)	Fungi, molds	Oral, topical
Propylene glycol (solutions and semisolids: 15%–30%, oral solutions: 10%–25%, topicals: 5%–80%)	Bacteria, molds	Topical, oral, dental, ophthalmic, otic, rectal, vaginal, aerosol solutions. Excellent general solvent/cosolvent, plasticizer, flavor vehicle, humectant.
Propylparaben 0.005%–0.02%, used together with methylparaben. Topicals: as high as 0.6%. (pH 4–8) (also: propylparaben sodium—higher solubility)	Yeasts, molds, bacteria, fungi	Oral solutions and suspensions, topical, nasal, inhaled solutions, rectal, vaginal, cosmetics (not ophthalmic).
Sodium benzoate 0.02%–0.5% (pH 2.5–4.5) avoid with neonates	Bacteria (not spores), molds yeasts	Oral capsules solutions and tablets, topicals, rectal, cosmetics
Sodium metabisulfite 0.01%–1.0% (neutral to acidic pH) (also: potassium metabisulfite) avoid sulfites with asthmatics	Bacteria	Oral, topical, inhalations, ophthalmic, rectal, topical, vaginal (also acts as antioxidant)—avoid sulfites with asthmatics
Sodium sulfite 0.1% avoid sulfites with asthmatics	Fungi	Topical creams and emulsions, oral syrups and suspensions, otic, inhalations, topicals, ophthalmic, cosmetics

Source: Rowe, R.C., Sheskey, P.J., Quinn, M.E., 2009, Handbook of Pharmaceutical Excipients, sixth ed., Pharmaceutical Press, London; Troy, D., Beringer, P., 2005. Remington: The Science and Practice of Pharmacy, twenty-first ed., Lippincott Williams & Wilkins, Baltimore, MD, Philadelphia.

1. Set up a steam bath by filling a 250 mL beaker approximately one-third full with water. Set the beaker on a hot plate. Set the hot plate on high.
2. Set a large ceramic dish on the beaker. Melt the white wax in the ceramic dish.
3. Add the white petrolatum, warming until liquefied.
4. Remove the ceramic dish from the steam bath.
5. Stir until the mixture congeals, and allow it to cool.

White petrolatum USP is a purified mixture of semi-solid hydrocarbons from petrolatum and is decolorized. It may contain a stabilizer. Synonyms: white soft paraffin, white petroleum jelly, Vaseline, White Ointment USP.

Yellow-soft paraffin is often used in eye ointments, as it is not bleached and probably does not contain a stabilizer. Hydrocarbon ointments are the most occlusive, meaning that they form a physical barrier on the skin that is somewhat impermeable to water. This prevents water leaving the surface of the skin, and therefore a hydrocarbon base has the strongest hydrating effect on the skin.

Hydrophilic Ointment Example: Polyethylene Glycol Ointment

Carbowax PEG 3350 (formerly polyethylene glycol 4000)	40 g
PEG 400 (also known as PEG-8)	60 g
To make	100 g

1. Set up a steam bath by filling a 250 mL beaker approximately one-third full with water. Set the beaker on a hot plate. Set the hot plate on high. Bring the water to a boil, and reduce heat to a rolling boil.
2. Set a large ceramic dish on the steam bath. Melt the PEG 3350 in the ceramic dish.
3. Add the PEG 400, and mix until uniform.
4. Remove the ceramic dish from the steam bath.
5. Stir until the mixture congeals, and allow it to cool.

O/W cream example: hydrophilic ointment USP (USP, 2007)

		Alternate formulas for a softer base	
Methylparaben (methyl *p*-hydroxy benzoate)	0.025 g	0.025 g	0.025 g
Propylparaben (*n*-Propyl *p*-hydroxy benzoate)	0.015 g	0.015 g	0.015 g
Sodium dodecyl sulfate	1 g	1 g	1 g
Propylene glycol	12 g	24 g	20 g
Stearyl alcohol	25 g	19 g	25 g
White petrolatum	25 g	19 g	17 g
Purified water	37 g	37 g	37 g
To make	100 g	100 g	100 g

1. Set up a steam bath by filling a 250 mL beaker approximately one-third full with water. Set the beaker on a hot plate. Set the hot plate on high. Bring the water to a boil, and reduce heat to a rolling boil.
2. Set a large ceramic dish on the steam bath. Melt the stearyl alcohol and white petrolatum together in the ceramic dish.
3. Dissolve the other ingredients in a second beaker, warmed to ~75°C.
4. Discontinue heating. Add the water to the melted oil phase with agitation.
5. Allow to cool, and stir until congealed.

Notes:

- The parabens are used as preservatives. Water-containing ointments should have a preservative.
- Stearyl alcohol functions as an adjuvant emulsifier and makes the cream smoother.
- Propylene glycol (a humectant) thickens the water phase (suspending agent) and lessens evaporation. It is typically also used in humidors for the same reason.

The following formulation is an example of a common W/O emulsion (an aqueous phase suspended in a continuous oil phase). An oily cream results in a hydrophobic drug partitioning into the continuous (oil) phase. Together with their occlusive action on the skin, oily creams tend to result in relatively higher transdermal delivery of a hydrophobic drug than their hydrophilic counterparts (O/W creams) (Dubins et al., 2017).

W/O Cream Example: Adapted from Cold Cream USP XVIII (Singh, 2010)

Cetyl esters wax (Spermaceti)	12.5 g
Beeswax or white wax (granulated)	12 g
Mineral oil (heavy)	56 g
Sodium tetraborate	0.5 g
Purified water	19 g
to make:	100 g

1. Set up a steam bath by filling a 250 mL beaker approximately one-third, full with water. Set the beaker on a hot plate. Set the hot plate on high. Bring the water to a boil, and reduce heat to a rolling boil.
2. Set a large ceramic dish on the steam bath. Melt the cetyl esters wax and white wax together in the ceramic dish.
3. Once the waxes are melted, add the mineral oil to the large ceramic dish.
4. Continue heating until the temperature of the mixture reaches 70°C; maintain at 70°C for 5 min.
5. In a separate beaker, dissolve the sodium tetraborate in the purified water, warmed to 70°C.
6. Slowly add the warmed aqueous phase to the melted oil mixture, while continuously mixing with a stirring rod.
7. Remove from heat. While the mixture is cooling, *use a hand blender* to emulsify the two phases. Run the hand blender on the lower speed until the mixture appears milky.
8. *Stir rapidly and continuously* until the mixture has congealed. Otherwise, the phases will separate (the emulsion will break).

Notes:

- The aqueous (internal) phase is preheated before it is combined with the oily (external) phase, so that it does not cause congealing.
- Nivea Cream and Pond's Cold Cream are commercial examples of W/O emulsions.
- Sodium tetraborate is a detergent, and acts as an emulsifier along with the cetyl esters wax. However, this vehicle requires a lot of mechanical agitation to produce a homogenous vehicle.

Poloxamer 20%/LIPS Gel Cream (Dubins et al., 2017)

Poloxamer 20% (PLO 20%)

Poloxamer 407 (Pluronic F127)	20 g
Potassium sorbate	0.3 g
Purified water (chilled)	q.s. to 100 mL

1. Transfer poloxamer 407 to an amber 220 mL graduated prescription bottle.
   a. Note: Pluronic F127 powder is a respiratory irritant. Wear an N95 mask when dealing with poloxamer 407 powder.
2. Weigh 0.3 g of potassium sorbate and place in the same bottle.
3. Cap the amber bottle and gently mix the pluronic F127 and potassium sorbate together so that it is adequately blended.
4. Open the cap, and while gently agitating, slowly add cold purified water (5–10°C) to approximately 100 mL (use the graduated markings on the amber bottle).
5. Gently agitate the mixture, label, and place in a refrigerator.
   a. The PLO will disperse and dissolve in the fridge in 1–2 days.
6. More water is added up to the designated volume.

Notes: pluronic F-127 is a nonionic surfactant, MW 12,500, which forms gels of tailorable strength and gelling temperature, depending on the concentration and excipients used.

The lecithin isopropyl palmitate (also called LIPS) is made up primarily of soy lecithin granules, which are yellow and sticky. The following protocol is for preparing LIPS vehicle, the second precursor for the poloxamer/lecithin isopropyl palmitate cream. Ready-made LIPS may also be purchased at the desired concentration (e.g., under brand names such as Lipmax).

Lecithin/Isopropyl Palmitate (LIPS)

Lecithin	22.7 g
Sorbic acid	0.45 g
Isopropyl palmitate	22.7 g (26.6 mL)

1. Transfer lecithin into a 100 mL amber prescription bottle.
2. Add sorbic acid to the bottle.
3. Add isopropyl palmitate to the bottle. Store at room temperature.
4. The lecithin beads will dissolve at room temperature over 1–2 days.

Once both precursors are sourced or prepared, the drug is dispersed in one of the components. Usually, a hydrophobic drug would be levigated with a suitable hydrophobic levigating agent, then dispersed in the LIPS solution, whereas a hydrophilic drug would be levigated with an appropriate hydrophilic levigating agent, then dispersed in the poloxamer solution. Then, at room temperature, the two are combined in a ratio of one-part LIPS to three-parts poloxamer gel, forming an O/W emulsion. Particle size may be reduced by vigorously triturating in a mortar with a pestle, or extrusion through the small bore opening of a syringe (without needle tip).

In the following example, a 2% salicylic acid cream is prepared in PLO/LIPS vehicle.

1. In a glass mortar, combine 0.8 g salicylic acid in an equal quantity (0.8 g) of 95% ethanol, and mix with a pestle until smooth.
2. Shake the LIPS solution prior to using.
3. Add 8.8 mL of the LIPS solution, and continue mixing until smooth.
4. Add 28.8 g of PLO 20% (about 29 mL), and triturate until a smooth gel/cream is made.

Gel formation happens as the mixture equilibrates to room temperature. The lecithin gives the mixture an opaque light beige color. The pestle should be able to stand upright in the mortar when the gel is finished.

2% Methylcellulose Gel (Hot Method) (Dubins et al., 2017)

Methylcellulose USP (1000 cps)	4.0 g
Propylparaben	0.02 g
Methylparaben	0.1 g
Purified water	196 mL

1. Add about 70 mL of purified water to a large beaker. Heat the water to just below boiling (~90°C).
2. Sprinkle in methylcellulose while vigorously stirring with a magnetic stir bar or glass rod.
3. Add parabens.
4. Remove beaker from heat. Carefully add the remainder of the purified water as chilled water, with stirring. Bring it up to 200 mL volume mark.
5. Refrigerate overnight.

Notes: at lower concentrations (e.g., 0.5%), methylcellulose solution is an excellent suspending agent, which thickens/imparts viscosity to a liquid formulation.

1% Carbomer Gel (Cold Method)

Carbomer 940	2.0 g
Propylparaben	0.02 g
Methylparaben	0.1 g
1N Sodium Hydroxide	(Required number of drops)
Purified Water	200 mL

1. Add the purified water to a large beaker.
2. Using a plastic dropper, adjust the pH of the water with 1N sodium hydroxide. Test with a digital pH meter or pH paper, until pH 7 is attained.
3. Add the propylparaben, and methylparaben.
4. Slowly sprinkle in the carbomer 940 while blending with a hand blender, until solubilized.

Notes: for a stiffer gel, increase the pH of the solution by titrating up with 1N sodium hydroxide (ANFCC Ltd., 2018).

Mold Preparation Calculations

The calculations involved in formulating each mold type share a common theme - filling by volume. There are different methods to accomplish this. Once the principles of mold filling are understood, they are inevitably applicable to new mold types. A good understanding of these principles will unleash the power of the pharmacist, together with the prescriber, to improve patient compliance and efficacy.

Mold Calibration

In order to formulate a product with the correct dose, the first step in formulating using a mold is to calibrate it with the intended vehicle. For a very approximate filling weight, the mold can be weighed empty, tarred, and then filled with water. This will provide an approximate figure for how much vehicle to prepare, for calibrating the mold with the intended vehicle. Some molds come "precalibrated" to a specific base. However, it is worthwhile calibrating the mold even given this information, since the provided value may have been performed using a different vehicle. When preparing the placebo vehicle for calibration, prepare more vehicles (e.g., double) than required by the number of units intended to compound, since most vehicles for molds are viscous, and will stick to the sides of the glassware when pouring.

In order to calibrate the mold, prepare the empty vehicle, filling all units in the mold completely. Cool the mold, recover the units, and calculate the average weight of one unit. This is the calibrated unit weight (m_{placebo}). We will begin our discussion on the various methods to determine the amount of vehicle required using suppositories as they are more common in compounding, although these methods are applicable to other mold preparations as well.

Density Factor/Displacement Factor Method

Once the mold is calibrated with the intended vehicle, the volume of the drug must be taken into account, in order to formulate the correct strength. A popular way of accounting for the volume of the drug is by using a published or calculated *displacement factor*, or *density factor* (DF) for the drug in the specific vehicle. The mass of vehicle required for the formulation will be *less* than the amount required for calibrating with empty vehicle, because we now have to make room for the drug. The following formula is used:

$$(1)\ m_{\text{vehicle}} = m_{\text{placebo}} - \left(m_{\text{drug}}/\text{DF}_{\text{drug}}\ \text{in vehicle}\right)$$

This formula can be used for a single unit (e.g., one suppository), but is more often used when planning the entire batch. This method requires an accurate estimate of the displacement factor and correct calculations, or compounding will result in an incorrect potency (Kalmár et al., 2014).

Example: a 100 mg suppository strength of a drug is required. A formulator calibrates a suppository mold with PEG vehicle, finding that the average unit weight is 1.203 g (=m_{placebo}). The drug is known to have a displacement factor of 1.1 in PEG vehicle. The formulator plans to compound 24 suppositories (scaling up to account for losses from glassware and breakage upon ejection). One suppository will have the following:

$$m_{\text{drug}} = \text{formulation strength} = 100\ \text{mg}$$

$$m_{\text{vehicle}} = m_{\text{placebo}} - \left(m_{\text{drug}}/\text{DF}\right) = 1.203\ \text{g} - (0.100\ \text{g}/1.1) = 1.203\ \text{g} - 0.091\ \text{g} = 1.112\ \text{g}$$

The formulator would then scale up the batch for a *planned* 24 units:

$$m_{\text{drug,batch}} = 100\ \text{mg} \times 24\ \text{units} = 2.400\ \text{g drug}$$

$$m_{\text{vehicle,batch}} = 1.112\ \text{g} \times 24\ \text{units} = 26.688\ \text{g vehicle}$$

Calibrated Batch Volume Method

This method involves remelting placebo units in a small vessel and marking the volume occupied. The medicated units are made in the same vessel and brought up to volume with melted vehicle, thus resulting in the correct concentration of drug in the vehicle.

1. First calibrate the mold with an excess amount of empty vehicle (no API).
2. Cast and recover each perfectly formed unit (let the number of recovered perfectly formed units be $n_{\text{recovered}}$).
3. Measure and record placebo weights, then calculate the average placebo weight for one unit (=m_{placebo}).
4. Remelt the perfectly formed units in a small beaker (Beaker A).
5. Mark the meniscus on the side of the beaker with a wax pencil or marker. This volume mark is precisely the batch volume required to compound $n_{\text{recovered}}$-medicated units.
6. Pour off about half the melted vehicle into a second beaker (Beaker B).
7. Add the total amount of API required for the number of units melted to Beaker A (=formulation strength $\times n_{\text{recovered}}$).
8. Mix the API in Beaker A until evenly dispersed or dissolved in the vehicle.
9. Bring up the volume of Beaker A to the marked line, using the poured-off melted vehicle from Beaker B.
10. Mix Beaker A, then pour the API-vehicle mixture from Beaker B into the mold.
11. Cool and recover the medicated units.
12. Weigh the medicated units and then calculate the final average medicated weight (=$m_{\text{medicated}}$).

This method does not require using a density factor. However, once performed, the density factor of the API in the vehicle may be calculated using the following formula, and used for subsequent compounding: (Allen, 2014)

$$(2)\ \text{DF} = \text{Dose}/\left(m_{\text{placebo}} - m_{\text{medicated}} + \text{Dose}\right)$$

where Dose is the mass of active ingredient in one unit, $m_{placebo}$ is the mass of one placebo unit, and $m_{medicated}$ is the mass of one medicated unit. Note that if the dose is quantitatively minor compared to $m_{placebo}$ and $m_{vehicle}$, this formula will give erratic estimates for DF, and the displacement factor method need not be used (e.g., if the drug occupies less than 1% of the formulation by weight). The calibrated beaker can be retained to make future batches of the same formulation, or the calculated displacement factor method may be used if the strength or batch size changes.

There are a few limitations to using the Calibrated Batch Volume method. Since the vehicle is melted twice, excipients sensitive to degradation may be less resilient and more prone to degradation. In addition, the liquid/solid transition upon cooling must be reversible. This is not the case for all vehicles, as some formulations require the evaporation of water, and remelting the solidified vehicle could result in burning (e.g., a hard candy lollipop base). Alternately, the following modified step can rectify this problem:

6. Pour out and discard the entire melted vehicle from Beaker 1. Prepare an excess of fresh vehicle in a second beaker (Beaker 2).

When the total unit weight is quantitatively small, it may also be imprecise to find a small enough container to calibrate by volume, making this method impractical for physically small units, or when only a few units are required.

Double-Casting Method

The double-casting method is another clever way of accounting for the volume contribution of the API without using displacement factors. It is similar to the Calibrated Batch Volume method:

1. A portion of melted base *less than required* for a placebo batch is mixed with the correct amount of drug for the batch, thus underfilling the mold cavities with a mixture of API and vehicle.
2. Empty vehicle is then used to "top up" each cavity.
3. The units are recovered, cooled, and remelted for proper mixing.
4. A second round of casting is performed with the remelted mixture, so that the medicated units are uniform in terms of potency.
5. The medicated units are cooled and recovered.

The vehicle and drug are exposed to heat twice when this method is used, which may be a concern for thermo-sensitive APIs. As with the Calibrated Batch Volume method, solidification of the vehicle must be thermoreversible, which may not be practical with some formulations. This method precludes the calculation of a displacement factor, or estimation of the placebo unit weight ($m_{placebo}$), since placebo units are never formulated and weighed.

Disregarding the Volume Contribution of a Drug or Excipient

As mentioned above, if the drug occupies a negligible proportion of the formulation, then subtracting off a density-factor corrected mass from $m_{vehicle}$ will not result in a meaningful correction. Many guidance set compounding tolerance limits for the theoretically calculated weight and volume. For example, USP 795 states that compounded preparations are to be prepared to ensure that each preparation shall contain not less than 90.0% and not more than 110.0% of the theoretically calculated weight or volume per unit of the preparation (The United States Pharmacopeial Convention, 2013). Thus, if a formulation requires a very small amount of drug (e.g., 0.1% hydrocortisone, micronized), then the volume contribution may simply be disregarded. The mold preparation would be performed by:

1. First calibrate the mold with an excess of empty vehicle (fill the mold with water for a quick estimate)
2. Recover the well-formed units and determine the average placebo unit weight ($m_{placebo}$)
3. Calculate the amount of vehicle required for the medicated batch, aiming to compound *more* than required (usually double) to account for losses on glassware and broken units:

$$m_{vehicle,batch} = m_{placebo} \times \#\,\text{units required}$$

$$m_{drug,batch} = \text{strength required} \times \#\,\text{units required}$$

4. Compound the medicated batch using the calculations in Step 3.

Suppository vehicle example—polyethylene glycol (PEG) suppository vehicle

The following example traces through how to compound placebo rectal suppositories using a hydrophilic vehicle. A method above should be chosen (e.g., density factor method, calibrated batch volume method, double pour method) in order to cast medicated suppositories, depending on the vehicle and API required.

Ingredient	*Weight percent (% w/w)*	*Mass for 12 × 2.1 g suppositories*
Polyethylene glycol 3350	58.8	20.58 g
Polyethylene glycol 400 (liquid)	39.2	13.72 g
Silica gel, micronized (stiffener)	2.0	0.7 g

Figure 11 The suppository mold cavities are intentionally overfilled to account for contraction upon cooling.

1. Fill a 600 mL Pyrex beaker approximately one-third, of the way with water. Set beaker on a hot plate on high heat. Set a large porcelain dish on top of the beaker.
2. When the water starts to boil, set the hot plate to medium heat. Add the PEG 3350. Stir with a stirring rod until it melts completely clear.
3. Add the PEG 400 and silica gel, and mix until homogeneous. At this point, APIs would be added and thoroughly stirred. Calculation of the correct amount of API should be performed using one of the methods described in the mold calibration section.
4. Using an oven mitt, pour the melted vehicle while stirring into the suppository mold, in a slow, steady stream. Overfill each mold cavity so that there is a thick, continuous bead of mixture overflowing on top of the mold without spilling over the sides. Overfilling the mold cavity compensates for base contraction upon cooling.
5. The mold may be cooled at room temperature, or transferred to a refrigerator to accelerate solidification (1–2 h).
6. Remove the excess vehicle using a metal spatula, by scraping it firmly across the top of the mold. The spatula may be heated by briefly touching it to the hot plate.
7. Smooth out any pits or imperfections on top of the suppository with a gently heated spatula.
8. The suppositories may be dispensed in the mold cavity for the patient to remove prior to use. Alternately, eject the suppositories from the molds by gently pressing directly upwards from the bottom of the mold cavity, until the suppository pulls free from the walls of the mold. Lift the suppository out of the mold. Be careful not to push too hard, or the mold walls will deform the suppository shape. Individually wrap the suppositories in tinfoil.
9. Store the finished suppositories at 5°C.

Notes: Excipients are melted in reverse order of their melting point. Micronized silica gel is used in this formulation as a stiffener (Figs. 11–13).

Figure 12 The suppository mold is scraped across the top with a gently warmed spatula to remove the excess vehicle.

Figure 13 The top of each suppository is smoothed to correct minor imperfections.

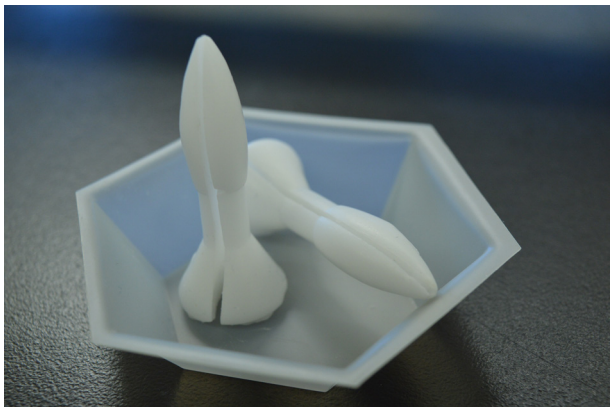

Figure 14 The rectal rocket is uniquely shaped to flank the topical surfaces of the rectum and sphincter. A slit allows the patient to flatulate without concern of ejection.

Rectal Rocket Vehicle Example (Oleaginous)

Ingredients	*Weight percent (% w/w)*	*Mass for ~2 × 6.6 g rectal rockets*
Witepsol 15	63.0	12.6 g
White wax (granulated)	20.0	4.0 g
Stearic Acid	10.0	2.0 g
Almond Oil	5.0	1.0 g
Silica Gel	2.0	0.4 g

The vehicle is prepared by fusion, using the same technique described as rectal suppositories, also over-filling the rectal rocket mold, and scraping excess vehicle across the top before recovering (Fig. 14).

Lollipop Vehicle Example: Sorbitol/PEG 3350

Ingredients	*Weight percent (% w/w)*	*Mass for ~6 × 9 g Lollipops*
Sorbitol (powder) NF	64.7	58.23 g
Polyethylene glycol 3350	32.3	29.07 g
Silica gel, micronized	2.0	1.80 g
Flavorant (water based)	1.0	0.90 g
Colorant (water based)	(Trace)	1–2 drops (optional)

1. Prepare the lollipop mold by lightly lubricating with a fine layer of mineral oil. Insert lollipop sticks into the mold cavity, ensuring the sticks penetrate the center of the lollipop circle.

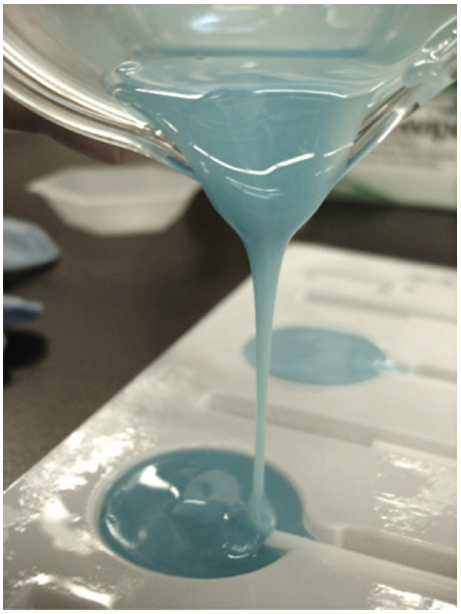

Figure 15 The lollipop molds are filled to ensure the lollipop sticks are completely submerged in vehicle.

2. Fill a 600 mL Pyrex beaker approximately one-third of the way with water. Set beaker on a hot plate on medium heat. Set a large porcelain dish on top of the beaker. Set up a thermometer inside the beaker to monitor formulation temperature.
3. Add the PEG 3350 to the beaker and stir with a glass rod until completely melted.
4. Add the Sorbitol powder. Mix continuously while maintaining a temperature of ~100–110°C, to form a smooth homogenous liquid-like dispersion. The mixture will be opaque, but should not be gritty. If the mixture is overheated, it will separate into two phases. If this occurs, cool the mixture while stirring until the solution thickens and becomes a single phase again, without solidifying.
5. Add the micronized silica gel and flavorant. Stir until homogenous.
6. Remove the beaker from the hot plate. Continue stirring until the vehicle thickens to a white glue-like consistency, and appears uniform.
7. Carefully pour the melted mixture into the mold, while stirring. Fill the entire cavity flush with the top of the mold, being sure to cover the top of the lollipop stick. Rotate the stick in the mold to ensure it is submerged in the mixture (Fig. 15).
8. The mold may be transferred to the refrigerator to accelerate cooling, or may cool slowly at room temperature. It will take 1–2 h for the formulation to completely solidify. Do not attempt to remove the lollipops while not completely solidified, or they will deform upon ejection.
9. Carefully remove the lollipops by pressing gently upwards from the center of the lollipop cavity from the bottom of the mold. Recover and weigh the lollipops to obtain the calibrated weight. Tare the balance with a lollipop stick so the weight of the lollipop stick is not included.
10. Medicated lollipop weights can be formulated using the same technique, adding the API(s) to step 5 to reduce exposure to heat. Calculation of the correct amount of API and vehicle should be performed using one of the methods described in the mold calibration section. The recovered lollipops can be stored in an amber plastic prescription vial (e.g., 60 dram, see Fig. 16), with a suitable-sized hole drilled in the cap to suspend it when capped.

Troche Vehicle Example—Glycerin/Gelatin/Acacia

Ingredients	*Weight percent (% w/w)*	*Mass for ~30 × 0.8 g Troches*
Glycerin USP (softener, preservative)	46.0	46.0 g
Gelatin (225 Bloom or equivalent)	20.0	10.0 g
Purified water	23.4	11.7 g
70% Sorbitol solution (sweetener)	8	4.0 g
Acacia NF (thickener)	1.5	0.75 g
Stevia powder (sweetener)	0.2	0.1 g
Silica gel, micronized (stiffener)	0.9	0.45 g
Flavorant (water-based)	(Trace)	1–2 drops
Colorant (water-based)	(Trace)	1–2 drops (optional)

Figure 16 Various sizes of amber plastic prescription vials. The amber color helps protect the products from light.

1. Consider lubricating the troche mold with a light coating of mineral oil. This step is not required for this formulation, as it is self-lubricating.
2. Using a glass mortar and pestle, gently triturate the silica gel, stevia powder, and acacia to a fine powder. Trituration should be performed lightly with a quick circular motion, allowing the weight of the pestle to reduce the particle size against the mortar. The pestle should not be pounded against the mortar, as this can damage the mortar or pestle.
3. Add purified water, glycerin, and 70% sorbitol solution to a 150 mL Pyrex beaker. Stir with a stirring rod until clear.
4. Set the beaker on a hot plate, set to high heat. Set up a thermometer in the beaker, to monitor formulation temperature. Stir continuously until the mixture reaches 80°C, and is clear.
5. Carefully remove the beaker from the hot plate. Add the gelatin. Mix with a stirring rod until the gelatin dissolves. The mixture will not appear completely transparent. The consistency should be smooth. Use periodic heating on the hot plate to keep the mixture from solidifying.
6. Add the powders from step 2 into the gelatin mixture. Stir with a stirring rod until evenly dispersed, and uniform.
7. Add the colorant and flavorant into the gelatin mixture, mixing thoroughly with a stirring rod.
8. Pour the mixture into the troche mold; ensuring each cavity is completely filled. If the mixture solidifies before or while pouring, gently reheat and mix until pourable.
9. A metal spatula, warmed on the hot plate, may be used to scrape excess vehicle from the top of the troche mold to ensure units solidify independently, to allow for easy separation when cooled.
10. Some troche molds double as the dispensing package, and are designed with a built-in lid. Allow the troches to cool at room temperature with the lid open. Recover and weigh the troches. Turn each unit upside-down in the troche mold to dispense.
11. For the medicated troches, API(s) would be added to step 2, to minimize exposure to heat. Calculation of the correct amount of API and vehicle should be performed using one of the methods described in the mold calibration section (Figs. 17–19).

This vehicle could also be used to compound gelatin-based gummy bears (making ~12 × 3.8 g gummy bears). Gummy bear molds should be slightly overfilled to have a rounded top. The gummy bear molds are *not* scraped across the top to remove excess

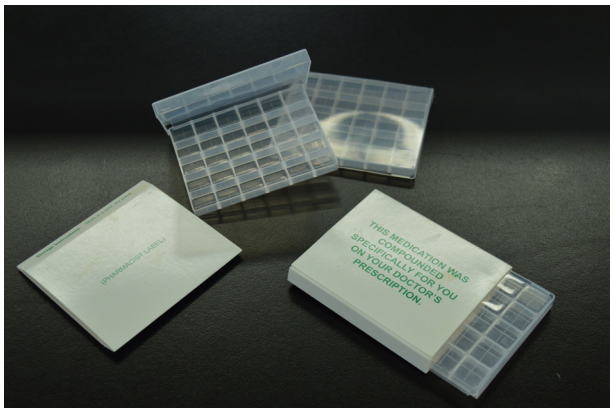

Figure 17 Plastic troche molds, with package sleeve.

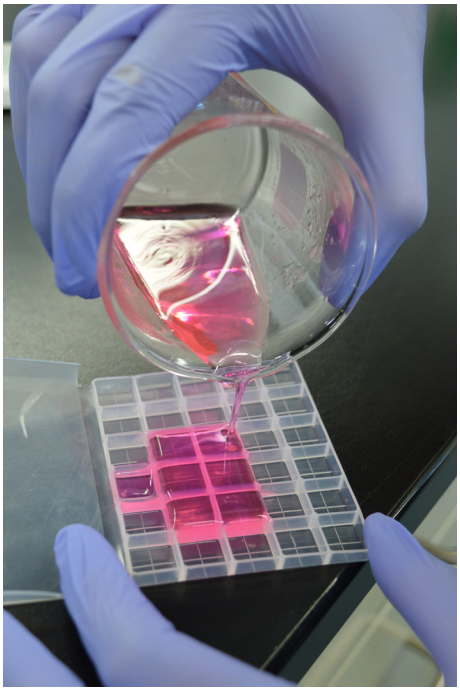

Figure 18 Troches are poured at the mold center then spread outward.

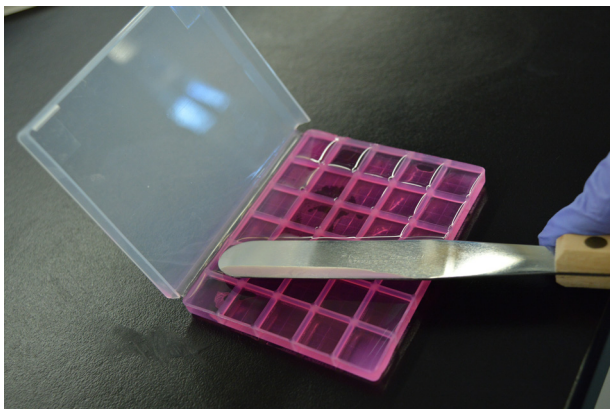

Figure 19 Troches are finished by scraping the vehicle across the top, to ensure each unit is forms separately.

vehicle, or the formulation will be too thin for successful removal. An attempt should therefore made to be consistent when overfilling (without spilling over the borders of the mold cavity, in order to minimize variations in weight. Pouring is best accomplished when the vehicle is cooled close to its melting point, so it is more viscous when poured. Calibration of the mold is required to obtain the correct desired strength.

Lip Balm Vehicle Example—Petrolatum/Beeswax

Ingredients	*Weight percent (% w/w)*	*Mass for ~3 × 4.2 g sticks*
White petrolatum	48.9	12.23 g
Beeswax	20.2	5.05 g
Polyethylene glycol 400	18.6	4.65 g
Lemon oil (fragrance/emollient)	12.3	3.08 g

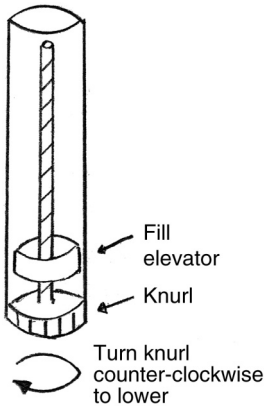

Figure 20 Lip balm casing. Rotate knurl counter-clockwise to lower fill elevator.

1. Set up a steam bath on a hot plate by filling a 250 mL beaker approximately one-third of the way with tap water, and placing it on a hotplate set to high. Set a small ceramic dish on top of the beaker.
2. Remove the caps from the lip balm casings. Verify that each casing has a fill elevator inside. Ensure the elevator is at the lowest-most position by twisting the bottom ring (called the "knurl") counter-clockwise completely, with the knurl facing towards you. Weigh and record the mass of each casing without the cap (Fig. 20).
3. Add the beeswax, petrolatum, and lemon oil to the ceramic dish. Heat the mixture with stirring, until completely melted and homogenous. Do not overheat the mixture.
4. Use polyethylene glycol 400 to levigate the API(s), and transfer the remainder to the ceramic dish. For the calibration procedure, add all of the polyethylene glycol to the ceramic dish. Mix uniformly.
5. Remove the ceramic dish from the steam bath and blot the bottom of the dish to remove any condensate. Carefully pour the melted vehicle into the lip balm casings, completely filling them to the top, without overfilling. The vehicle will contract slightly as it cools.
6. Allow the formulations to cool. Weigh the filled casings to determine formulation weight.

Capsule Filling Calculations

For example, a 100 mg acetaminophen script is to be filled in size 1 capsule. Magnesium stearate (1% by volume) is to be added as a powder glidant to facilitate capsule filling, and lactose powder is to be used as a diluent, occupying the remainder of the capsule volume. The following formulation is desired:

	Tapped density (g/mL)	*Fill weight (mg)*	*Fill volume (%)*	*Mass per capsule*
Acetaminophen	0.343	?	?	100 mg
Magnesium stearate	0.286	143.0	1	?
Lactose (diluent)	0.713	356.5	?	?

Tapped density is used to calculate the fill weights of each ingredient. The tapped density of magnesium stearate is not available, so the formulator completely packs 5 capsules with magnesium stearate, and determines that the average fill weight for magnesium stearate is 143 mg. This corresponds to a tapped density of 0.286 g/mL (=143 mg/0.5 mL per size 1 capsule). The remaining fill weights for a size 1 capsule (volume = 0.50 mL) can now be calculated:

$$\text{Acetaminophen fill weight} : 0.343\,\text{g/mL} \times 0.5\,\text{mL} = 0.1715\,\text{g}$$

$$\text{Lactose fill weight} : 0.713\,\text{g/mL} \times 0.5\,\text{mL} = 0.3565\,\text{g}$$

	Tapped density (g/mL)	*Fill weight (mg)*	*Fill volume (%)*	*Mass per capsule*
Acetaminophen	0.343	171.5	?	100 mg
Magnesium stearate	0.286	143.0	1	?
Lactose (diluent)	0.713	356.5	?	?

Once the fill weights are calculated (or obtained from tables), the percentage of fill volumes can be calculated for each powder. This is the theoretical ratio of volume occupied by each powder in the capsule.

$$\text{Acetaminophen}(\%)\ \text{fill volume} = \text{strength}/\text{fill weight} = 100\ \text{mg}/171.5\ \text{mg} = 58.3\%\ \text{fill volume}.$$

$$\text{Magnesium stearate}(\%)\ \text{filled volume} = 1\%\ (\text{design parameter})$$

$$\text{Lactose}(\%)\ \text{fill volume} = 100\% - (\text{sum of all other}(\%)\ \text{fill volumes}) = 100\% - (58.3\% + 1\%) = 40.7\%$$

	Tapped density (g/mL)	*Fill weight (mg)*	*Fill volume (%)*	*Mass per capsule*
Acetaminophen	0.343	171.5	58.3	100 mg
Magnesium stearate	0.286 (measured)	143.0	1	?
Lactose (diluent)	0.713	356.5	40.7	?

Finally, the theoretical mass per capsule can be calculated as the fill weight x %fill volume for each powder:

$$\text{Magnesium stearate mass per capsule} = \text{fill weight} \times \%\text{fill volume} = 143.0\ \text{mg} \times 1\% = 1.430\ \text{mg}$$

$$\text{Lactose mass per capsule} = 356.5\ \text{mg} \times 40.7\% = 145.1\ \text{mg}$$

	Tapped density (g/mL)	*Fill weight (mg)*	*Fill volume (%)*	*Mass per capsule*
Acetaminophen	0.343	171.5	58.3	100 mg
Magnesium stearate	0.286	143.0	1	1.430 mg
Lactose (diluent)	0.713	356.5	40.7	145.1 mg
Total			100	246.5 mg

The theoretical weight of the filled capsule (not including the capsule body) should be 246.5 mg (=100 mg + 1.430 mg + 145.1 mg). The entire batch may now be prepared by multiplying the mass per capsule of each ingredient by the number of capsules to compound. For instance, if a batch of 50 capsules is to be compounded, the following would be required:

	Mass per capsule (mg)	*Batch mass (to prepare 50 capsules)*
Acetaminophen	100	100 mg × 50 capsules = 5.00 g
Magnesium stearate	1.430	1.430 mg × 50 capsules = 71.5 mg
Lactose (diluent)	145.1	145.1 mg × 50 capsules = 7.255 g
Total	246.5	12.325 g

The batch may now be compounded and be hand filled, or filled using a capsule machine. Capsules are QC'd against their theoretical capsule weight, which is defined as a pass if they are within 10%. For this formulation, a pass would be defined if the measured capsule weight was within (0.9 × 246.5 mg to 1.1 × 246.5 mg =(221.8–271.1 mg), also taking into account the weight of the capsule body by measuring and adding the average empty capsule weight onto those limits (The United States Pharmacopeial Convention, 2013).

Capsuling a Nonstandard Dose: Interesting Example of Dose Taper

It is commonplace in a community pharmacy to encounter the need to formulate a drug taper. The active ingredient may not necessarily be available for purchase as a pure raw ingredient and other capsuling methods are required in this case.

For example, patients that are discontinuing long-term selective serotonin reuptake inhibitors (SSRIs) may require a gradual dose taper. A slow wean is recommended in order to avoid discontinuation reactions like dizziness, insomnia, nausea, vomiting, irritability, and hyperhidrosis (Eli Lilly, 2016). Manufactured formulations of duloxetine exist as 30 and 60 mg strengths. A patient that has been on long-term duloxetine at a dose of 30mg daily would require a steady dose taper to prevent discontinuation symptoms. If switching to a longer acting SSRI like fluoxetine is not an option then compounding a gradual tapered strength is the only option (Attfield et al., 2016). There are no defined SSRI taper guidelines, so it is pertinent for the physician and pharmacist to work closely with the patient in managing their taper schedule. A general guideline is reduced the dose by about 15%–20% each week. This unspecified guideline is established through collaboration with the prescriber, typically on a case-by-case basis. The taper schedule for this patient may look as follows:

- Week 1 of taper: 25 mg capsules daily ×7 days
- Week 2 of taper: 20 mg capsules daily ×7 days
- Week 3 of taper: 15 mg capsules daily ×7 days

- Week 4 of taper: 10 mg capsules daily ×7 days
- Week 5 of taper: 5 mg capsules daily ×7 days and then discontinue

This taper schedule may need to be re-evaluated during the first week if discontinuation symptoms occur. A 10% dose reduction weekly may be more appropriate is sensitive patients. A simple way to proceed with compounding this particular prescription would be to tackle one week at a time. The first week taper schedule is discussed below as an example.

Total amount of duloxetine required for the week

$$25\,\text{mg} \times 7 = 175\,\text{mg}$$

The number of standard capsules required making up this content

$$175\,\text{mg} \times 1\,\text{cap}/60\,\text{mg} = 2.9167\,\text{capsules}$$

The commercially available duloxetine capsules are coated pellets. It is not recommended to crush the contents of the capsules and add fillers in this case. As the enteric coating leads to dissolution resistance until pH >5.5 in the gastrointestinal tract, it is important to maintain this coating. The contents of 3 × 60 mg commercially available capsules should be emptied in a small non-static measuring container.

$$\text{Weight of } 3 \times 60\,\text{mg capsules} = 1.377\,\text{g}$$

$$\text{The theoretical weight of } 2.9167\,\text{capsules} = 2.9167/3 \times 1.377\,\text{g} = 1.33875\,\text{g}$$

Each compounded capsule should have 25 mg of duloxetine, which amounts to

$$1.33875\,\text{g}/7\,\text{capsules} = 0.19125\,\text{g}(191\,\text{mg})$$

This particular weight is the weight of pellets that will be poured into an empty capsule amounting to 25 mg of duloxetine. There is no filler required as the contents of the weigh boat can be placed directly into the empty capsules by hand and sealed immediately after. A recommended quality assurance check after the 7 capsules have been sealed is to weigh the batch and calculate the average capsule weight.

Assume:

$$\text{Weight of 7 empty \# 3 gelatin capsules} = 336\,\text{mg}$$

$$\text{Weight of 7 capsules containing duloxetine pellets} = 1.673\,\text{g}$$

$$\text{Therefore, the weighted duloxetine pellets} = 1.673 - 0.336 = 1.337\,\text{g}$$

Conclusions

Compounding can be a rewarding service provided in community pharmacies, as it can allow for customization in patient treatment, ultimately improving health outcomes. This service is an integral part of pharmacy practice and can be essential in patient care. The compounding of quality preparations requires access to appropriate updated reliable resources and reference materials. Typically these materials include reputable textbooks, relevant research articles, and usually telephone access to a compounding resource center that can provide appropriate aids in formulations and stability data. Depending on the location of practice, government regulation determines the breadth of resources that are required to be kept in the facility for staff to access. From a business aspect, compounding can strengthen the practitioner–patient–pharmacist relationship, ultimately enabling the provision of individualized, safe and effective patient-centered care.

Global Health and Pharmacy Practice

Albert Wertheimer, Leanne Lai, College of Pharmacy, Nova Southeastern University, Ft. Lauderdale, FL, United States

Background and Introduction

Global health refers to population health in a global construct. Its principal goals are to improve health status and achieve equity for people in all countries around the world.

Health status is the aggregate product of a nation's wealth, traditions, the climate, priorities, and the degree of democracy. For example, it was in the very late 1890s when Germany popularized the concept of the nation-state. In order to have a strong army for the country, it meant maintaining the health of the population, so that young men called to service would be healthy and fit for battle. In some other countries, maintenance of health was for its own sake. Some medical conditions exist only among certain occupational groups such as farmers being injured by tractor accidents, or construction workers who may fall or have something dropped on them, or office workers whose sedentary activities could lead to obesity, emboli, and lack of exercise. Some conditions such as heat stroke are normally seen only in tropical and very warm climates, whereas frostbite is most usually seen in very northern or extreme southern areas (White et al., 2003).

Pandemics such as bird flu, SARS among many others do not discriminate or respect political borders. They may begin in one area but soon are spread by the traveling public or bird migratory patterns. The strains of the annual seasonal flu immunizations are determined by the strains found in Asia and used all over the world shortly afterwards.

For the last 50 years, a United Nations agency, the World Health Organization (WHO) headquartered in Geneva, Switzerland, has been responsible for global health matters. WHO collects disease statistics and shares them with member nations in an effort to gain an early clue of a likely spreading condition. The WHO is hampered by a few rather serious shortcomings: the reported numbers are accurate and the organization can only recommend or suggest health policies to member countries. If a country depends on foreign tourists for income, it may elect to downplay the incidence of some prevalent local disease so as not to scare away potential visitors. The WHO can make recommendations but no member country can be compelled to follow its policies or guidelines. Here, some of the poorest countries may not have the resources to battle a problem, whereas others have wide-scale corruption and vaccination materials may be diverted or sold.

Yet, in spite of all of these flaws, the WHO has served well as a monitoring and coordination center. The recent Ebola outbreak was tracked by the WHO which reported on new cases in countries, giving health planners valuable information about disease progress by areas, and what resources and precautions would be required in what locations (Learning to Live Together, in press).

While we all live on one planet sharing air, water, and space, there are massive differences in health status, life expectancy, and illness rates in different countries and continents. There are probably at least 50 different variables that determine a person's health status in a region or country. Even gender differences play a role, as do age, ethnicity, housing quality, etc. People who walk barefoot should be expected to have greater health problems, especially if they live in areas where parasites, worms, and amoebic species are present. A pharmacist must understand what types of health problems might be encountered in different practice sites in differing regions. Most pharmacists in North America or Western Europe, for example, have probably never encountered a case of thrush,

Chagas disease, leishmaniosis, or Yellow fever. Pharmacists in South Saharan Africa deal with malaria, dengue fever, and river blindness (AHR, in press).

Industrial Development

Third World Environment: Developing Countries

As the aging population grows bigger over time, many developing countries' health care system do not have the capacity to meet its demand. According to the United Nation, life expectancy globally will "rise from 71 years in 2010–15 to 77 years in 2045–50" (UNDESAPD, 2017). This means that the topic of care for aging population must be addressed more seriously. "The number of older persons in the world is projected to be 1.4 billion in 2030 and 2.1 billion in 2050, and could rise to 3.1 billion in 2100" (UN, 2018). Specifically "by 2050, the projected 434 million people aged 80 or over will account for 21% of the global population over age 60" (UNDESAPD, 2015). This population often suffers from limited access to health care due to many barriers, such as the lack of availability, accessibility, affordability, and acceptability (Odonnell, 2007). Improvement of health care system in developing countries is essential to maintain its demand in the years to come.

China, one of the developing countries with the biggest population in the world, has deaths from multiple diseases, such as cardiovascular disease, cancer, chronic respiratory diseases, and diabetes (WHO, 2016a). Providing education to the population can prevent most of these diseases. WHO is one of the largest health organizations in the world with its mission "to promote health and to prevent and control major chronic diseases and their risk factor" (WHO, 2016b). One of WHO's core functions is to prevent and manage chronic disease (WHO, 2016b). Prevention is the key for developing countries to improve health care as the aging population increases. As the population of the world is shifting from younger toward older, so is the causes of death shifting from acute disease to more of chronic disease. The top death rate in low-income economies in 2015, according to WHO, are respiratory, stroke, heart disease, and HIV. Developing countries are "now living long enough to die of diseases that typically hit in old age" (Tavernise, 2017). These chronic diseases require specific health care systems to support their needs. As aging population increases the need for prevention also increases. Developing countries' health care faces many problems, but prevention is the key for chronic disease control and to improve the quality of life.

Prevention can be divided into three categories: "primary, secondary, and tertiary" (IWH, 2015). Primary prevention can be done through legislation, such as banning a control substance, educate patient on disease state, or immunization against certain disease. Primary prevention is one of the keys to prevent disease in aging population. This is a great challenge for developing countries, many of which emphasize on managing diseases and often ignore patient education. Preventative measures can be taken in the example of tobacco usage. Tobacco usage in the developing countries "are seeing a sharp rise in number of people smoking" (Parry, 2017) compares to the decline in the developed countries. The increase in usage rate can be prevented through primary prevention of education.

Secondary prevention includes "regular exam and screening tests to detect disease in its earliest stages" (IWH, 2015). Secondary prevention can directly improve the treatment success rate of many chronic diseases. The aging population can benefit from screening because early treatment is one of the few ways to prevent the disease or diagnose it in early stage. This is especially important in chronic diseases because screening can raise awareness for patients to be more careful with certain lifestyle. For example, diabetes, patient can be diagnosed as prediabetic. This does not require treatment but more of a lifestyle modification. This crucial step will lower the overall cost of health care, as insulin or any other medications for chronic disease is rather expensive. The average "Indian family earns an income of only US$ 28 per month" while insulin can cost up to US$ 15 for a "month supply of 40-unit human insulin" (Anderson, 2015). This cost can be challenging for patients and health care system in developing country to handle.

Tertiary prevention can be used to "soften the impact of an ongoing illness or injury that has lasting effects" (IWH, 2015). This step is one of the possible ways to help elderly patients to cope with their new lifestyle. This is one of the most important steps of prevention, as relapse or rehospitalization can be costly to the overall health care system.

Prevention is the key to a better health care system for the developing countries. It is possible for a developing country to lower the cost of health care yet still have a good quality of patient care. The overall population of the world is growing, so is the elderly population. This population is expected to grow even more according to the researchers at WHO. This can be detrimental to the health care system that is already weak in the developing countries. Major changes in implementation of prevention can help decrease the pressure that is pressing on the health care system.

First World Environment

By first world, we are referring to the most highly developed, industrialized nations, such as those seen in North America, Western Europe, Australia, New Zealand, Japan, Taiwan, Israel, Brazil, Argentina, and South Africa, as a few examples. Life is basically different in these countries. Residents have access to convenient, affordable medical care especially preventive services such as pediatric immunizations and nearly all babies are born in hospitals under the supervision of skilled experts. Denizens of such areas have indoor plumbing and running safe water supplies. One might say that life is easy in such areas, but that may not be entirely true, as a different set of lifestyle diseases are seen in these populations. While one might not have to walk 2 km to fetch water, city people sit at an office desk all day without participating in sufficient levels of physical exercise; they breathe in the

pollution from factories and automobile exhaust. They work and live in cities with high levels of particulate matter in the air causing asthma, COPD, allergies, and their work leads to chronic low back pain, emboli, and the pressure of work may lead to depression, hypertension, and related diseases.

Workers at industrial factories, such as chemical, iron and steel, electronics, and a host of other industries are faced with exposure to heavy metals and other toxic substances along with repetitive motion disorders such as carpel tunnel disorders found in secretaries and keyboardists. Due to often long commuting times and competition at work, these persons often eat commercially prepared foods containing preservatives, color enhancers, high levels of salt, and other chemicals, not to mention the leaching of substances from tin cans and elasticizers from plastic containers (ILO, 2010).

As the ownership of automobiles is so large, many people walk or exercise very little. This leads directly and indirectly to a series of lifestyle diseases as type II diabetes, hypertension, heart failure, gout, obesity, and the need for hip and knee prosthetics, GERD, among many others. In these areas, food is abundant, plentiful, and relatively cheap. People snack sometimes all evening while watching television, night after night.

On a related topic, professional medical care services are readily available in most areas and especially in large urban areas where there are high concentrations of all of medical specialists and tertiary care hospitals. The availability of these resources leads to greater use to a point where some say that there is overt overmedicalization, where someone with a cough may be referred from their primary care physician to an ear, nose, and throat specialist, who may order an MRI or other imagining along with laboratory tests. Some false positives may lead to unwarranted biopsies and surgeries, and at a minimum, time away from work, additional expenditures and perhaps adverse events related to the drug therapy, which requires further diagnosis and treatment.

Persons in such affluent areas spend money on esthetic interventions, such as wrinkle removal, removal of varicose veins, plastic surgery of the breasts and nose, laser treatments of the eyes to negate the need for spectacles, bariatric surgery, liposuction, hair transplants, and a host of recent antiaging treatments. As one might expect, each of these treatments results in some small fraction of adverse events requiring medical or even hospital attention.

Store-prepared or catered-takeout meals often contain high quantities of sodium and/or sugar and frequently include little or no fresh fruits or vegetables. Some cancers are seen at higher incidence levels in industrialized countries in certain neighborhoods near factories expelling toxic pollutants, or near previous industrial dump sites. Stress, which causes elevated catecholamine levels, may increase other CNS disorders.

Affluent living standards may result in persons hiring others to handle routine tasks as cutting the lawn, shoveling snow, painting the house, or other landscaping tasks (PEW, 2018).

Age

Age is an important determinant of health status. Babies and small children are affected by numerous bacterial and viral infections. Many are upper respiratory with the typical colds, coughs, runny noses along with ear infections, diarrhea, falls with scraped skin, playground accidents with bumps and bruises. We witness falls from bicycles and skateboards, broken bones from sporting accidents.

Adolescents are sometimes afflicted by acne and skin disorders, injuries from automobile crashes due to inexperience, eating disorders, and other problems due to risky behaviors such as sexually transmitted diseases and substance abuse.

There is a period from the early 30s into the 50s when most persons are fundamentally healthy for their age peer group. Beginning sometime in the 50s we see most people of this age group using eyeglasses in order to read, with the use of hearing aids not seen as much until the population is in their 70s. Now we find the major burden of chronic conditions, such as congestive heart failure, type II diabetes, hypertension, gastritis, inflammatory diseases, arteriosclerosis, various cancers, eye cataracts, prostate enlargement, dyslipidemias, among many others.

Recently, one cannot avoid seeing "memory care" institutions. The conditions of dementia and Alzheimer's disease are contributing to a huge number of nursing home admissions, and it is predicted that these conditions will be responsible for the greatest number of long-term care patients in institutions. They are expected to exceed the number of stroke and Parkinson's disease patients presently residing in nursing care facilities. The bones of the elderly are less flexible and strong than those found in younger persons, leading to broken femurs from falls. Declines in sensory prowess continue gradually with poor vision or challenged hearing and memory leading to morbidities. Moreover, it is speculated that a weaker immune response may permit the growth of cancer cells. Such weaker immune systems are found in many elderly persons.

Gender

Factors, such as age, sex, race, and ethnicities, can influence the prevalence of diseases in the population. Sex characteristics and gender have proven to impact the development and severity of certain diseases that manifest differently in men and women. The incidence of many health conditions and diseases among males and females varies throughout the world and this is most likely due to the physiologic differences that lie in gender. According to the National Institute of Health (NIH), sex and gender can influence the development, presentation, progression, and management of certain diseases and can have different impacts on the overall health of an individual. Some of these diseases are further discussed.

Alcohol Use

According to the Global Information System on Alcohol and Health (GISAH), about 3.3 million people die each year from inappropriate alcohol consumption. The excessive use of alcohol around the world has been linked to 100% of fetal alcohol syndrome cases, 22% of suicides, 15% of traffic injuries, 25% of pancreatitis, 10% of colorectal cancer, 8% of breast cancer, and 8% of heart disease (WHO, 2014a). In the year 2010, the consumption of alcohol reported by people around the world was equivalent to 6.2 L of alcohol per individual of 15 years or older. The pattern of alcohol consumption varied from one country to another, that is, the countries with the highest incomes reporting the highest consumption of alcohol per capita. Interestingly, WHO reports that females tend to abstain from consuming alcohol more often than men. As a result, there are marked differences in alcohol-related death in men and women. In the year 2012, alcohol claimed the lives of 7.6% of men globally and 4% of women (WHO, 2014b). In 2010, the total alcohol consumption among male around the world was 21.2 L while for female it was 8.9 L. The proportion of current drinkers reported in that same year among individuals 15 years and older in the world was 47.7 males and 28.9 females (WHO, 2018a). In the United States, the 2015 National Survey on Drug Use and Health (NSDUH) reported that 9.8 million men (8.4%) and 5.3 million women (4.2%) of 18 years and older had an alcohol use disorder (NIAAA, 2017). As a result, the WHO has proposed to reduce the harmful use of alcohol in the world by 10% by the year 2020 (WHO, 2014b).

Cancer

Cancer can affect all persons regardless of their gender, race, or ethnicity. Nonetheless, the prevalence of cancer varies among individuals and variations in individual characteristics may be the reason why. These differences can be attributed to genetics, hormones, environmental factors, etc. Therefore, the risk of developing cancer among men and women varies significantly, and the types of cancers men and women develop can be quite different (NIH, 2018). In 2012, breast cancer claimed the lives of 521,900 women in the world, and as a result it was categorized as the most common type of cancer in women. Nonetheless, when examining the prevalence of cancer in developed countries, it was noticed that lung cancer deaths exceeded those of breast cancer. Meanwhile, lung cancer seems to be the number one cancer seen in men worldwide killing 1,241,600 men around the globe in 2012. Although, in developed countries, the number of prostrate cancer cases was higher (ACS, 2015). In the United States, the three most common cancers in men are prostate cancer (95.5), lung cancer (68.1), and colorectal cancer (44.0) (CDC, 2015a). Meanwhile, the most common cancers in women are breast cancer (123.9), lung cancer (50.8), and colorectal cancer (33.7) (CDC, 2015b). According to statistics published by the Center for Disease Control (CDC), the rate of new cancer cases for all cancer types was 472.3 for males (471.2–473.3) and 413.6 for females (412.6–414.5) of all races and ethnicities for the year 2014 (CDC, 2015c).

Depression

Depression is said to be one of the leading causes of disability around the world, as it can affect an individual's personal, professional, and social life. It is one of those diseases influenced by gender since according to many studies it is most prevalent among women than men. Physicians often fail to diagnose patients with depression due to stigma or due to the fact that it can be potentiated and eclipsed by other diseases, such as cancer, Alzheimer's disease, autoimmune conditions, etc. (NIH, in press). According to data from the National Health and Nutrition Examination Survey, from 2009 to 2012, 7.6% of Americans 12 years of age and older suffered from depression. Of these, 20.4% of were men while 36.1 were women (CDC, 2014). World statistics also reveal that depression is more common in women (5.1%) than in men (3.6%). According to WHO region estimates for 2015, age was also a factor contributing to this prevalence with more 7.5 % of females and more than 5.5% males from 55–47 years suffering from depression (WHO, 2017a).

Cardiovascular Risk

Cardiovascular disease continues to be the leading cause of death among men and women. However, gender is one of the factors associated with differences in prevalence of this disease, its presentation and progression (NIH, 2014). Paying attention to the risk factors and managing them appropriately in men and women can have a huge impact on morbidity and mortality. Well-known risk factors for cardiovascular disease are smoking, diabetes, high cholesterol, and obesity among others (NIH, 2005). Nonetheless, there are specific risk factors that make women more prone to suffer from such complications. For instance, some estrogen receptors have been associated with heart function and cardiovascular disease, there exist differences in the way men and women age with regards to the cardiovascular system, sex hormones play crucial roles in maintaining blood pressure, pregnancy can affect the heart in different ways, etc. (NIH, 2014). According to the CDC, heart disease claimed the lives of 321,000 men in 2013 killing 1 in every 4 men in the nation (CDC, 2017a). Meanwhile, in the same year 289,758 women died. This represented 1 in every 4 female deaths (CDC, 2017b). Russian Federation, Ukraine, Romania, Hungary, Cuba, Brazil, Czech Republic, Argentina, Mexico, and the United States are the ten top countries in the world with the highest number deaths due to heart disease, stroke, and high blood pressure. The following table summarizes the death rates among men and women between the ages of 35–74 years in these countries (AHA, 2018).

Countries	*Men (death rate per 100,000)*	*Women (death rate per 100,000)*
Russian Federation	1173	466
Ukraine	1067	454
Romania	657	312
Hungary	524	218
Cuba	359	209
Brazil	347	205
Czech Republic	347	142
Argentina	305	139
Mexico	261	137
United States	235	117

Obesity

The prevalence of obesity in the word has increased more than 2 times from the 1980s until today. It continues to be one of the leading causes of preventable morbidity and mortality in the United States and in the world. The World Obesity Federation reported in 2014, about 15% of men and 15% of women in the European Union were classified as obese (World Obesity, 2016). In most countries, obesity is more prevalent among women than men. Countries such as Korea, Italy, Spain, and England saw an increase in such gender inequality regarding to obesity between 2010and 2014 and reports show that less educated men and women were more likely to be obese than those with higher educational levels. Nonetheless, in the United States the rate of obesity has increased the most among educated individuals (OECD, 2017). In 2014, 10.8% of males and 14.9% of females of 18 years or older were classified as obese worldwide (WHO, 2018c). In the United States, data from the National Health and Nutrition Examination Survey from 2011 to 2014 revealed that rates of obesity were higher among women (38.3%) compare to men (34.3%). Interestingly, the prevalence of the disease was similar among men and women in terms of age with men between the ages of 40 and 59 (38.3) having a higher prevalence of obesity compared to men 20–39 years of age (30.3%). Meanwhile, women between the ages of 40–59 years of age showed a higher prevalence of obesity of 42.1% and those between the ages of 20 and 39 showed a prevalence of 34.4% (CDC, 2015d).

Alzheimer's Disease

According to CDC, Alzheimer's disease is the most common form of dementia. It is a progressive disease that limits a person's ability to live a normal life and to perform day-to-day activities individually. The risk of developing Alzheimer's disease varies among men and women (ALZ, 2016). According to a study included in the World's Alzheimer's Report in 2015, a significant difference in disease prevalence was observed between men and women in certain geographical areas, such as East Asia, South Asia, the Caribbean, Latin America, and Western Europe. In such places, the prevalence of Alzheimer's was 14%–32% lower in men (ALZ, 2015).

In the United States, men 65 years old have a 9.1% risk of developing the disease while women have a 17.2% risk. At age 75, men have a 10.2% risk and women have an 18.5% risk. Finally, at age 85, men present with a risk of 12.1% while women present with a risk of 20.3%.

Occupation

Occupational work-related illnesses have become one of the social matters that is alarming and need to be addressed. According to Global Estimates of Occupational Accidents and Work-related Illness, the three most concerning work-related illness are circulatory disease, malignant neoplasms, and communicable disease; which respectively accounted for 35, 29, and 10% of total work-related mortality (WSHI, 2014).

Depending on an individual's lifestyle, occupation, or social economic status, these factors can precipitate different work-related illness. For instance, occupational injuries and respiratory diseases occur more often in industrialization countries (MacLeod, 2016). Agriculture has adapted to the advancement of technology where machinery is utilized for every step of the process. This development introduces crucial threat to the health of many. Industrial chemical wastes and pollutants provoke global warning that cause disturbances to the ecosystem, in addition, elicit precipitation to serious respiratory infection. According to WHO's recent study in 2011, respiratory disease was one of the top three occupational diseases globally, specifically in the low, middle, and even high income (WSHI, 2014). Second, recent data suggests that there is a different disease pattern between developed and developing countries. Developed countries in Western Pacific region are most likely to contract malignant neoplasms while developing countries in South-East Asia region are more likely affected by circulatory diseases (WSHI, 2014). For malignant neoplasms, an estimates of total 204,215 cases in Western Pacific region while there were only 94,834 cases in South-East Asia (WSHI, 2014). Respectively, there were a total of 110,399 cases of circulatory diseases in Western Pacific region compares to 223,872 cases in

South-East Asia region (WSHI, 2014). Given the supported data from the study, there seems to a correlation between occupational-related illness and environmental/personal factors, such as: occupation, lifestyle, country regions, etc.

Since work-related mortality has become a more concerning social matter globally, WHO's new project—a global plan that has different directions but ultimately accomplish a mission—to control the escalation in number of workers affected by these work-related illnesses (WHO, 2013; WHO, 2007). WHO emphasizes on the implementation of workers' health policy by enhancing protection and communication at the workplace about health and work safety (WHO, 2013; WHO, 2007). Fundamentally, an improvement in the occupational health services translates to a reduction in occupational-related diseases.

Climate

Global warming is becoming a major threat to the health of many. According to CDC, there has been a steady rise in temperature since 1991. Pattern of extreme temperature, such as: heat waves, winter storms contribute to 10% of earth surface in 2012 compare to 0.1% back in 1981 (WHO, 2017b). This is partially due to the rise in consumption of fossil fuel, which cause a release of high concentration of carbon dioxide. Carbon dioxide traps and keeps the heat in the atmosphere, hence a rise in temperature. Variation in temperature affects many aspect of life, including: ecosystem, crops, water supplies, etc. which can further precipitate into serious health issues.

The change in climate has a big impact on human health. A rise in temperature translates to flooding, water contamination, abnormal migration pattern, etc. According to WHO, the changes in pattern of the environment evidently show a correlation between a shift in climate and serious health-related diseases, such as vector-borne diseases, airborne diseases, and waterborne diseases. First, vector-borne disease is account for 17% of all infectious disease globally; malaria and dengue seize more than 3 billion cases alone (WHO, 2017b). There has been much research which shows an extension during summer months due to a rise in temperature can result in a prolong season for vector-borne diseases and opportunity for these diseases to migrate further to the north region (Climatenexus, 2017). Specifically, suitable climax conditions allow for optimal survival and reproduction for these vectors. WHO estimated that there were 212 million cases of malaria worldwide in 2015, and Africa is accounted for 90% of the cases (WHO, 2017c). Second, the frequent heat waves have recently put a tremendous crisis on the water source. A decline of water supply, water sanitation places underdeveloped countries at a much higher rate at contracting these infectious diseases (WHO, 2014c). Cholera affected more than 42 countries along in 2015, cultivated approximately 172,454 cases (WHO, 2016c). Likewise, the incidences of Lyme disease were also significantly high during 2015. It was one of the sixth most common national notifiable diseases (CDC, 2017c). There were a total of 38,069 confirmed cases reported to CDC with additional notes of expansion evidence in term of geographic distribution (CDC, 2017c). Third, global warning accelerates the melting glacier process, which gives rise to a sea level. The combination of both torrid heat and a rise in sea level place a major role in the migration of bird species. A recent study shows that if ruddy turnstones—a bird species reaches Delaware Bay several weeks earlier than its normal migratory schedule, then the influenza infection rate increased significantly (Erickson, 2012). According to CDC, there is an increase in influenza-related death since 2011 (CDC, 2018). The outcome of the study and the data provided from CDC suggest a correlation between influenza infection rate and migration of bird species.

WHO situates an emphasize on fossil fuels consumption, which plays a major role in the contribution toward global warming (WHO, 2014d). A reduction of pollutants and greenhouse gas distribution can suggest a positive health impact (WHO, 2018b). Additionally, a source of safe water is also important in risk reduction in the transmission rate of certain diseases (Beard, 2014). A program called WASH FIT, Water and Sanitation for Health Facility Improvement Tool was developed by WHO and UNICEF; this program aims to educate on the importance of safe water management and its impact on health globally (Beard, 2014).

Lifestyle

Lifestyles are frequently interwoven with income, wealth, and social class. Simply stated, lifestyle is a way an individual or group lives. Impoverished persons are unlikely to travel long distances to famous ski resorts, resulting in few ski accidents among that demographic, and many more such ski accidents among the wealthy/leisure classes. Conversely, fewer wealthy persons have automobiles fall on them and crush arms, hands, or legs. When the oil in their cars must be changed, they take the car to a service establishment where a professional completes that task. If one in a lower social class notes the need for an automobile oil change, they do it themselves to save the money, but unfortunately some are ill-prepared for the task in front of them.

The indigent have little risk of contracting Norwalk virus GI problems commonly acquired on cruise boats, simply because they do not take cruises. Lifestyle is often partially determined by peer groups. Persons in young suburban communities ride bicycles more often than inner city dwellers who may not have a secure storage area for the bicycle and who may fear its "disappearance." We see the impact of peer pressure on lifestyles in so many ways. When you are landing at an airport, you notice a swimming pool in the backyard of a house. But look more carefully next time you are on a flight. Rarely will you see a single, isolated pool. There will be clusters of pools adjacent to each other in neighborhoods. The same is true in those young suburban communities with bicycle riders. It starts with one person riding a bicycle to the grocery store or train station, and shortly thereafter, there will be many bikes parked at these places. Lifestyle is also partially dictated by environment. Persons in senior communities may be more willing to use a

hearing aid when they see that hearing aid use is the usual situation or what is considered normal in that community. This is due to humans' need and desire to conform and possibly a little peer pressure involved as well.

Lifestyles dictate the probability of certain medical issues. Husband and wife violinists are more likely to have a child, a violin-playing offspring. Sumo wrestler parents are more likely to have a sumo wrestler child than a violin-playing child. Lifestyle is also partially determined by social class. Usually, one's neighbors are in the same social class. We get ideas for home decorations, clothing, hobbies, etc. from our neighbors and through this process, the likes and preferences of an area where there is a single social class become close to the others. Illnesses of that social class population are determined by their habits and behaviors. For example, families that take trips to exotic places are more probably to return with amoebic or parasitic diseases than a family that stays closer to home-playing badminton or horseshoes in their backyards.

Lifestyles, social class, income, and occupation type influence the use of health care services in a large way. Consider the outdoor construction worker who can tolerate cold or hot weather extremes, minor cuts, scratches, bruises, sprained muscles, and other problems. As this person is paid on an hourly basis, he or she will be reluctant to miss time from paid work to visit a physician's office, costing 3 h or more plus the doctor's fee or insurance copayment. That person might be expected to depend on their community pharmacist for advice and recommendations. The consultation is free, less time consuming, and any recommended over-the-counter (OTC) drugs are generally not terribly expensive. The highly paid executive who gets a paper cut in a finger might go to a leading surgeon or dermatologist specialist physician since they are salaried and will not lose any pay for the time away at the physician's office. Moreover, they usually have very complete, robust health insurance with a minimal personal expense to them. Fewer of this latter group will be consulting the pharmacist for professional services or OTC product recommendations.

In warm climates, people go to the beach, go swimming, diving, boating, and partake in other water sports leading to the obvious potential health problems, such as drowning, fish bites, infections from polluted water, bug bites, etc. In other areas, people have ski and snowboard accidents, heart attacks after shoveling snow, falls on the ice, and car accidents on slippery pavement. It should not take long for a pharmacist to determine which, if any, areas he or she may want to study in greater depth based on all of these factors describing the residents in close proximity to their pharmacy employment location.

Discussion

There should no longer be any doubt in the minds of readers of this chapter that global health is complex and that it is not an example of "one size fits all." If we as pharmacists truly desire to participate in the health team, we must be proactive and identify unmet health needs and then prepare ourselves to be able to satisfy those currently unmet needs. Unfortunately, we cannot wait for someone else to identify such gaps, as their groups will claim that area for itself. We cannot, similarly, develop a common global health course for pharmacy students since global health, as abundantly pointed out in this chapter is defined differently in different geographic areas and even differently within smaller boundaries, such as neighborhood wealth, social class, age, population density, proportion of families with young children, etc.

The alternative is unattractive, for us to stand behind the counters of our shops and sell pills to people. That scenario makes us more as merchants/shop owners rather than as health care professionals. For the student or coworker who has been in practice for some number of years, the path ahead could not be clearer. We need to learn from local health authorities what are the most pressing health problems in that community. Let's say that it is an alarming increase of the incidence of hepatitis C. Then, we need to explore the age group and location of patients. When we learn that it is most common in 50 years and older persons who participate in international travel, we now have a target. We can suggest testing to our patients in this sociodemographic and/or we can prepare educational materials in print and distribute them. We could also write a health column for the local newspaper, or have a local weekly television show where the pharmacist can educate and promote healthy behaviors.

Pharmacists have missed many opportunities for expanded professional services scope in the past. Let us hope this time will be different. The community pharmacist is the ideal person to assist communities with their global health needs.

Pharmacy Practice in the UK

Oksana Pyzik, UCL School of Pharmacy, London, United Kingdom

Introduction

What is Pharmacy Practice?

Modern pharmacy practice incorporates not only elements of clinical pharmacy and the legal and ethical aspects of professional practice, but also addresses the psychological drivers of patient behavior and the wider social determinants of health. As such, pharmacists require a blend of clinical skills, scientific knowledge, and communication and coaching skills to assess and respond to patients' pharmaceutical and health needs.

Good Pharmacy Practice (GPP) is defined by the International Pharmaceutical Federation (FIP) as "*the practice of pharmacy that responds to the needs of the people who use the pharmacists' services to provide optimal, evidence-based care.*"

GPP is organized around four major roles for pharmacists

1. Prepare, obtain, store, secure, distribute, administer, dispense, and dispose of medical products.
2. Provide effective medication therapy management.
3. Maintain and improve professional performance.
4. Contribute to improve effectiveness of the healthcare system and public health.

Pharmacy practice research explores GPP and encompasses topics such as social pharmacy, behavioral medicine, medicines' use, medicines' safety, health economics, pharmacoepidemiology, and pharmacovigilance.

As a field of research, pharmacy practice is relatively new and reflects the profession's evolving priorities and new applications to healthcare delivery. The changing landscape of pharmacy practice, as with all healthcare professions, has been driven by technology, as well as by political, economic, and social factors. In response, modern pharmacy has undergone an identity shift from a medicines' supply-focused profession to a patient-centered profession. While the transition is far from complete, and has been fraught with outward interprofessional tensions and, at times, an inward "identity crisis," the role of the pharmacist continues to evolve beyond the dispensary to make better use of pharmacists' extensive and expensively acquired skills.

The Face of Pharmacy in the UK

The United Kingdom of Great Britain and Northern Ireland (England, Scotland, Wales, and Northern Ireland) has a population of approximately 66 million people. In the UK, 1.8 million people visit a pharmacy each day, and on average a person will visit a pharmacy more than 14 times over a year. Unlike many other countries, approximately 89.2% of the population can reach a pharmacy within a 20-minute walk, making pharmacies highly accessible and central to communities (Todd et al., 2014). In urban areas, it is 98.3% of the population, while for rural areas it is much lower at 18.9% of the population. However, a study (Todd et al., 2014) showed that the areas of highest deprivation have the greatest access, with 99.8% of the population within a 20-min walk of a pharmacy. Contrary to the inverse care law, which states that "the availability of good medical care tends to vary inversely with the need for it in the population served," there is good evidence to demonstrate a positive pharmacy care law in the community pharmacy context (Todd et al., 2014).

As a result, in future, pharmacies may be at the forefront of public health strategies aimed at reducing health inequalities, as pharmacy density is highest in the regions with the most underserved populations. Overall, in the UK, access to medicines is good, as the National Health Service (NHS) funds over 90% of the prescriptions dispensed; thus the cost barrier around medicine use is significantly reduced. Approximately 10% community pharmacies are open for 100 h a week, and many are open longer than GP surgeries, again improving access to out-of-hours care. There are approximately 50,650 pharmacists and 13,000 community pharmacies, with approximately 70% working in the community sector, 20% in hospital pharmacy, and 6% in primary care (FIP, 2015). Pharmacy is the third largest healthcare profession after medicine and nursing in the UK. In addition, some pharmacists visit patients in care homes and in their own homes, and are increasingly taking on more specialized roles on advisory boards and at the health authority level.

Patients visit the pharmacy more than any other health facility to access medicines and healthcare advice, yet the opportunistic interventions delivered are often not remunerated and go unrecognized. In the 1980s the "Ask Your Pharmacist" campaign was launched to raise awareness around the role of the pharmacist and to address the issue of underutilization of the pharmacists' skill set. Other public health campaigns such as "Change 4 Life" and "Smoke Free" actively refer the public to pharmacists for smoking cessation services in their televised and printed adverts. Despite such efforts, it is probable that the scope of pharmacy is still not clearly understood by the general population and even by some healthcare professionals today. Although some improvements have been made, pharmacy leaders must continue to adapt to meet modern consumer needs and unite the profession around the future of pharmacy.

Pharmacists are the experts in medicines and their use in disease management. They play a crucial role in supporting medicine adherence as part of a shared decision-making process, as well as in improving cost-effective measures aimed at reducing medicine waste. The pharmacist's central aim is to use their pharmaceutical expertise to enhance patient care. In addition to supporting patients with their prescribed medicines, pharmacists also help patients to manage minor and common ailments and prescribe over-the-counter medicinal products. Pharmacists can also train as independent prescribers (see pg 15 for Nonmedical Prescribing).

Many pharmacies across the UK are now commissioned to provide public health services, and increasingly, the role of the pharmacist in public health is being recognized. For example, the quality payment scheme, a form of remuneration made to

pharmacies based on contractors fulfilling certain quality criteria, is now linked with Healthy Living Pharmacies (HLPs) (see pg 13 for Healthy Living Pharmacy). With the advent of HLPs, pharmacists are increasingly taking on roles such as health coaching to support patients with weight loss, smoking cessation, and encourage healthy lifestyles to reduce the growing burden of noncommunicable diseases.

However, pharmacists' role in public health is not limited to the community sector with hospital pharmacists also providing smoking cessation and nicotine replacement therapy in secondary care. Despite these advances across both sectors, the 2016 Royal Public Health Society "Building Capacity: Realising the potential of community pharmacy assets for improving the public's health," highlights a lack of awareness among commissioners, and the public has persisted and hindered service uptake.

In the community setting, pharmacists have further clinical roles in delivering services such as cardiovascular screening, substance misuse and needle exchange programs, travel clinics, flu vaccines, medicines' use reviews, new medicines' service, and others (see pg 16 for Pharmacy Services). Pharmacists also assist patients in their journey through the health care system, for example, by signposting to relevant patient support groups as well as refer patients to clinics, general practitioners and accident emergency units where appropriate. A key role of the pharmacist is to differentiate between the minor ailments that can be treated with over the counter products and more serious conditions that require specialist care or immediate attention in the case of a medical emergency.

A Brief History of Pharmacy

Pharmacy is one of the oldest professions in the world, with origins dating back to antiquity when the role of healer was equal parts priest, pharmacist, and physician, and their medical art was practiced in temples. Moving into the first century AD, pharmacy evolved into a scientific field, and by the eighth century, the first privately owned drug stores were established by the Arabs in what is modern day Baghdad. The Arab influence spread across Europe, and many of the pharmaceutical teachings from the East were treated as authoritative up until the seventeenth century.

The legal separation of pharmacy from medicine in Europe can be traced back to the Edict of Palermo 1231 AD, which distinguished the differing roles and responsibilities, as well as regulations for practice. However, in the UK, medicalization of the apothecary, and ultimately the evolution of pharmacy, occurred over the twelfth to the twentieth century.

In England, as well as in most European countries, apothecaries developed from the Pepperers and Spicers, and traded in spicery, which included crude drugs and prepared medicines. Pharmacists and physicians have a shared history as apothecaries, and as such diagnosed patients and prescribed medicines that they sold and dispensed. Apothecaries became a distinct occupational group from the Pepperers and Spicers in the thirteenth century, and the Society of Apothecaries, the first organization of pharmacists in the Anglo-Saxon world, was formed in 1617.

However, another group, the chemists and druggists, not only dispensed medicines, but also manufactured, packaged, and wholesaled drugs. The Apothecaries Act of 1815 further defined the separation of roles, with apothecaries evolved into general practitioners. The business of sale and supply of medicines was left to pharmacists (Harding and Taylor, 2016).

Finally, the modern history of pharmacy has been shaped during years of great social change, leading up to the establishment of the welfare state in 1911, and later the establishment of the NHS in 1948. Prior to the NHS, dispensing prescriptions accounted for less than 10% of income generated, whereas by 2011, 88% of the revenue of independent pharmacies came from the NHS, and approximately 96% of work flow in the community pharmacy centered around dispensing and supply of medicines. As the volume of NHS prescriptions increased over time and dispensing became the main form of revenue for the pharmacy, pharmacists retreated further and further behind the dispensary and away from patients. However, with the introduction of remuneration for enhanced service delivery, such flu vaccines and cardiovascular screening the future of pharmacy are changing (Harding and Taylor, 2016).

How Pharmacy Became a Profession in the UK?

The professionalization of pharmacy in the UK began with the foundation of the Pharmaceutical Society of Great Britain in 1841, today known as the Royal Pharmaceutical Society. In 1842 the Society set up its own School of Pharmacy within its Bloomsbury Square headquarters marking the beginning of organized pharmacy education in the UK. In 2012 this original School of Pharmacy, merged with University College London (UCL), and is now known as the UCL School of Pharmacy.

The Pharmaceutical Society set registration examinations and established the first register of "pharmaceutical chemists" under the Pharmacy Act of 1852 (Harding and Taylor, 2016). The Society acted as both the professional body and regulator until 2010. Following the split, a newly formed body, the General Pharmaceutical Council, took on full regulatory function, and the Royal Pharmaceutical Society evolved into the professional leadership body (see pg 23 General Pharmaceutical Council, and Royal Pharmaceutical Society).

In addition to the establishment of the professional body, both the transformation of pharmacy education and the introduction of a register further formalized pharmacy as a profession. Other factors such as the emergence of retail chains and mass manufacture of medicines have also challenged and shaped modern pharmacy practice. Although the single largest historical factor in creating a volume-driven dispensing model was the shift away from extemporaneous preparation of products in the pharmacy to the wholesaler, and finally to the domination of the manufacturer producing original packs (Harding and Taylor, 2016).

In the UK, multiple chain community pharmacies first entered the market in the 1880s. The first limited company was established by an unqualified druggist, Jesse Boot. By 1883 Jesse Boot owned 33 branches and by 1897, 126 pharmacy chains. Today Boots is by far the largest retail chemist chain in the UK, if not the world. In 2014 Boots merged with Walgreens to form the Walgreen Boots Alliance Inc. comprising manufacture, wholesale, distribution businesses, and retail pharmacies. In the 2016 fiscal year, total sales reached $117.35 billion. The merger with one of the largest American pharmacy chains signifies further entrenchment of the monopoly model in Britain and raises the issue of professionalism versus commercialism.

Healthcare Landscape

Origins and Values of the National Health Service

The NHS was established on July 5th, 1948 by the Minister of Health, Aneurin Bevan, based on the ethos that quality healthcare should be available to all, regardless of wealth. The vision of the NHS is underpinned by three core principles:

- that it meets the needs of everyone
- that it be free at the point of delivery
- that it be based on clinical need, not ability to pay

These principles have guided the development of the NHS and remain at its core despite the many reforms in systems and structure over time. The NHS is free at point of use for all UK residents; however, in England, there is a prescription charge (currently £8.60 per item), as well as charges for optical and dental services. Under devolution, Wales was the first part of the UK to make prescriptions free in 2007, Northern Ireland followed in 2010, and Scotland in 2011.

The prescription fee only applies to England and was introduced in 1952; however, many groups are exempt from payment including patients over the age of 60, children under the age of 16, full-time students aged 16, 17, or 18, pregnant women, patients on low income, prisoners on release, and patients with a medical exemption certificate.

The NHS employs more than 1.5 million people, putting it in the top five of the world's largest workforces, together with the US Department of Defence, McDonalds, Walmart, and the Chinese People's Liberation Army. The NHS in Scotland, Wales, and Northern Ireland employs 161, 415; 84,000; and 66,000 people, respectively. However, a 2015 report by the King's Fund "Workforce Planning in the NHS" reveals severe shortages in the healthcare workforce, which could jeopardize quality of care (Addicott, 2015).

This pressure on the healthcare workforce has resulted in innovative ways of working such as incorporating skill mix and a team approach to managing health. For example, due to the GP shortage, pharmacists work alongside GPs in surgeries resolving problems with medicines, leading on high-risk prescribing, managing patients' long-term conditions, and liaising with local pharmacies (see pg 14 for Primary Care Pharmacy—GP and Pharmacist Partnerships).

NHS Reform and Structure

In the UK, healthcare is primarily accessed via the NHS. The Department of Health (DH) is a department of the UK government responsible for strategic leadership for both health and social care matters and for the NHS in England. The ministerial department, comprising 23 agencies and public bodies, develops policies and guidelines to improve the quality of healthcare. Across Northern Ireland, Scotland, and Wales, the responsibility for healthcare is devolved to the Northern Ireland Assembly, the Scottish Government, and the Welsh Assembly Government, respectively. The Chief Pharmaceutical Officer for each region is responsible for providing specialist advice on medicines and pharmaceutical issues to the Department of Health and for the development of policy relating to medicine optimization and pharmacy.

The NHS is funded directly through public taxation and is managed by the Department of Health. The Secretary of State for Health heads the department and is accountable to Government on all health-related issues. In 2013 the NHS underwent structural reform, and The Health and Social Care Act 2012 transferred full statutory responsibility for pricing from the Department of Health to NHS England and NHS Improvement jointly. Prior to this, all NHS planning and delivery was done by the Department of Health, Strategic Health Authorities, and Primary Care Trusts.

NHS Performance Ranking

The Commonwealth Fund study (Schneider et al., 2017) rated the NHS as the best overall healthcare system compared to 10 other countries including Australia, Canada, France, Germany, Netherlands, New Zealand, Norway, Sweden, Switzerland, and the USA. This study evaluated the NHS as the best healthcare system with regards to equity, safe care, coordinated care, and preventative care measures, but it was ranked 10th for healthcare outcomes despite the UK having the fastest reduction in deaths amenable to health care in the past decade, see **Table 1** and **Fig. 1**.

Table 1 Healthcare system performance rankings

	AUS	*CAN*	*FRA*	*GER*	*NETH*	*NZ*	*NOR*	*SWE*	*SWIZ*	*UK*	*US*
Overall ranking	**2**	**9**	**10**	**8**	**3**	**4**	**4**	**6**	**6**	**1**	**11**

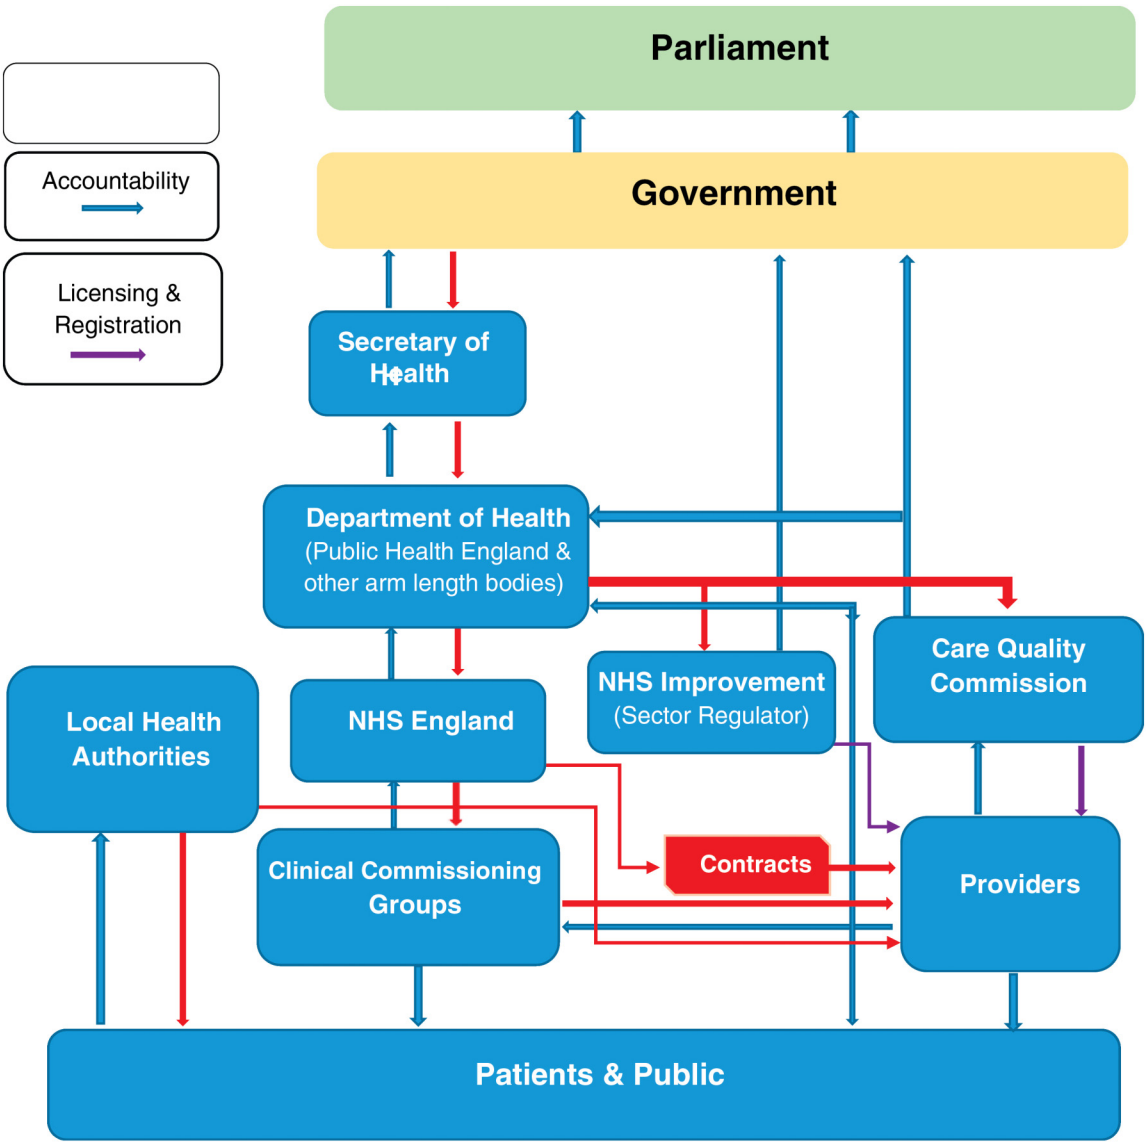

Figure 1 Basic NHS structure and funding.

NHS England

NHS England is an independent body, at an arm's length to the government, and was established in 2013 to set the direction and priorities of the NHS. It acts as the commissioner for primary care services to pharmacists, dentists, GPs, and other specialized services such as military health. NHS England oversees approximately £100 billion of the total NHS budget and works to ensure

efficient use of allocated funds via clinical commissioning groups (CCGs). NHS England is responsible for the direct commissioning of services outside the remit of CCGs, with a focus on specialized services.

NHS Improvement

NHS Improvement was created in 2016 to oversee NHS foundation trusts and independent providers delivering NHS funded care. It is an umbrella organization that brings together monitoring groups such as the monitoring, NHS Trust Development Authority, Patient Safety, the National Reporting and Learning System, the Advancing Change team, and the Intensive Support teams with the overall aim of improving quality of care.

Clinical Commissioning Groups

Clinical Commissioning Groups (CCGs) replaced primary care trusts on April 1, 2013 and are clinically led statutory NHS bodies. These bodies are responsible for commissioning healthcare services by region and comprise GPs and other clinicians. CCGs are responsible for 60% of the NHS budget and largely commission secondary care services, as well as GP services. The secondary services commissioned are:

- Planned hospital care
- Rehabilitative care
- Urgent and emergency care
- Most community health services
- Mental health services
- Learning disability services

CCGs can commission any service provider that meets NHS quality standards and budget, such as private sector providers, NHS hospitals, and charities.

Fig. 1 illustrates the basic NHS structure around funding, licensing, and accountability between government and the arm's-length bodies and other groups that work within the umbrella structure.

Fig. 2 further illustrates the NHS structure in relation to Public Health England, Regulatory Groups, healthcare professionals, and their duty to the general public.

NHS Sectors

Primary Care

The NHS is divided into three main sectors: primary care, secondary care, and tertiary care. Primary care is the largest sector of the NHS and is the backbone of patient care. It is mainly provided by general practitioners, community pharmacists, opticians, and dentists. Most primary care is delivered via a local practice where a patient will be registered for treatment by a number of healthcare professionals. In this sector, community pharmacists are key to medicines' supply and provide healthcare advice. However, pharmacists are increasingly working in an integrated model of general practice alongside GPs and taking on a greater clinical role.

Secondary Care

Secondary care is organized into different levels and types of services for patients known as "Trusts," mainly comprising hospitals, and together deliver a comprehensive service for patients. A wider variety of healthcare professionals work in secondary care including doctors, nurses, pharmacists, radiographers, physiotherapists, and dietitians. Patients enter secondary care through referral via the primary care systems, although in urgent cases patients may access secondary care through the accident and emergency department.

The Urgent Treatment Centres (UTCs) are open 12 h a day, seven days a week, and are integrated with local urgent care services. These centers will be rolled out for patients who do not need hospital accident and emergency care but require treatment by clinicians with access to diagnostic facilities, for example, X-ray machine. By 2018 approximately 150 designated UTCs will be available via GP referral.

Tertiary Care

Tertiary care includes more specialized medical centers, for example, specialist centers in pediatric cardiac surgery or cancer care.

Pharmacists and pharmacy technicians work in all three areas providing advice, guidance, and the supply of medicines and medical devices and appliances.

In rural areas of the UK where patients live over a mile from a pharmacy, patients may obtain medicines from a dispensing doctor as part of their NHS service. GPs often employ a pharmacy technician to provide support with dispensing services.

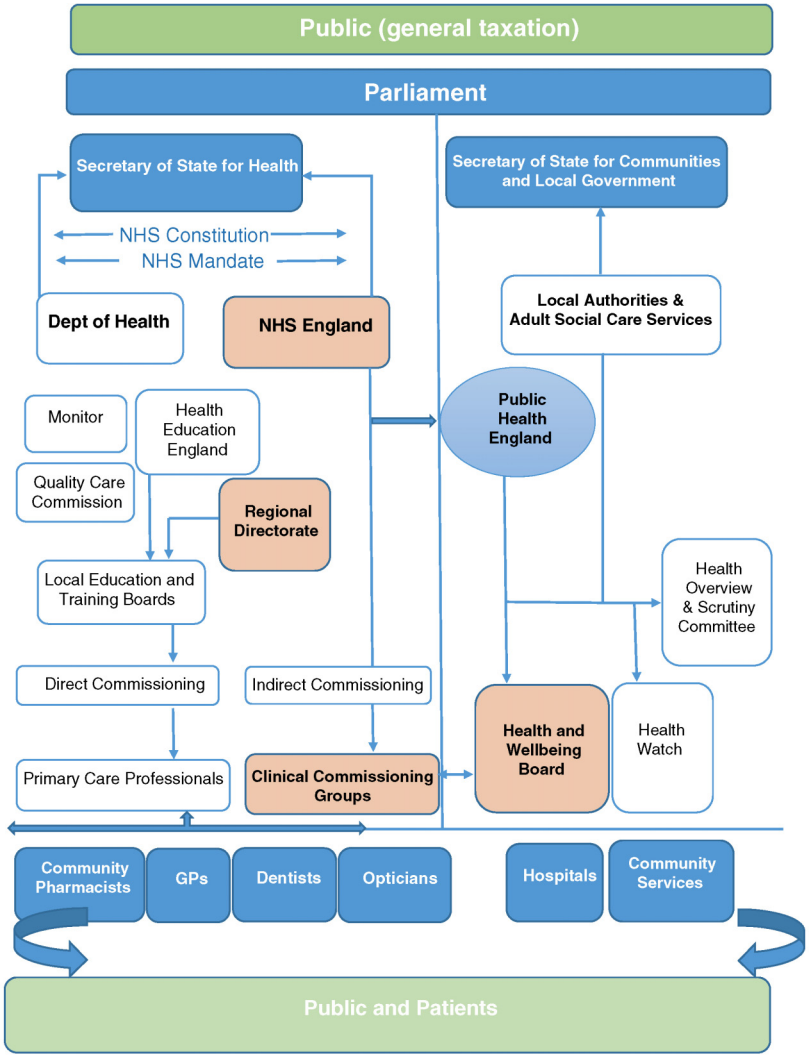

Figure 2 NHS structure (PSNC, 2017).

Private healthcare is structured in a similar way, as patients can access private care in the community through GPs and other healthcare professionals. These practitioners may provide solely private services or joint NHS and private services. Private secondary care is provided in private hospitals and treatment centers in a similar way to the NHS (Fig. 3).

NHS Budget for Medicines

As a provider of universal health coverage, the NHS is an expensive healthcare system to sustain. To reduce cost in the UK, certain medicines have been placed on the blacklist and are not available on an NHS prescription but can be purchased privately. The blacklist was introduced in 1984 in an attempt to economize; however, over time drug costs continue to rise due to improved diagnostics, an ageing population, and patient demand. Over the past decade, the number of prescriptions written has increased by 30%, and the cost of general practitioner prescriptions has risen by over 50% in real terms, driving up NHS expenditure on drugs and thus straining the budget (Harding and Taylor, 2016).

As part of a wider effort to reduce the NHS budget for medicines, a drive toward self-medication with the support of community pharmacists was introduced in the 1990s through a series of legislative changes. The European directive 92/26/CEE stated that medicines should be classified as prescription-only medicine (POM) only if they are frequently taken inappropriately, dangerous without medical supervision, or normally injected. Thus it was argued that medicines with a proven safety and a low-toxicity profile could be used to treat minor ailments. This deregulation process started slowly in the UK, but with the support of the Royal Pharmaceutical Society (RPS) and to some extent the Royal College of General Practitioners, it now has the widest range of over-the-counter medicines available in the world (Fig. 4).

Figure 3 Context of the RPS professional standards. *Adapted from RPS Report 2014.*

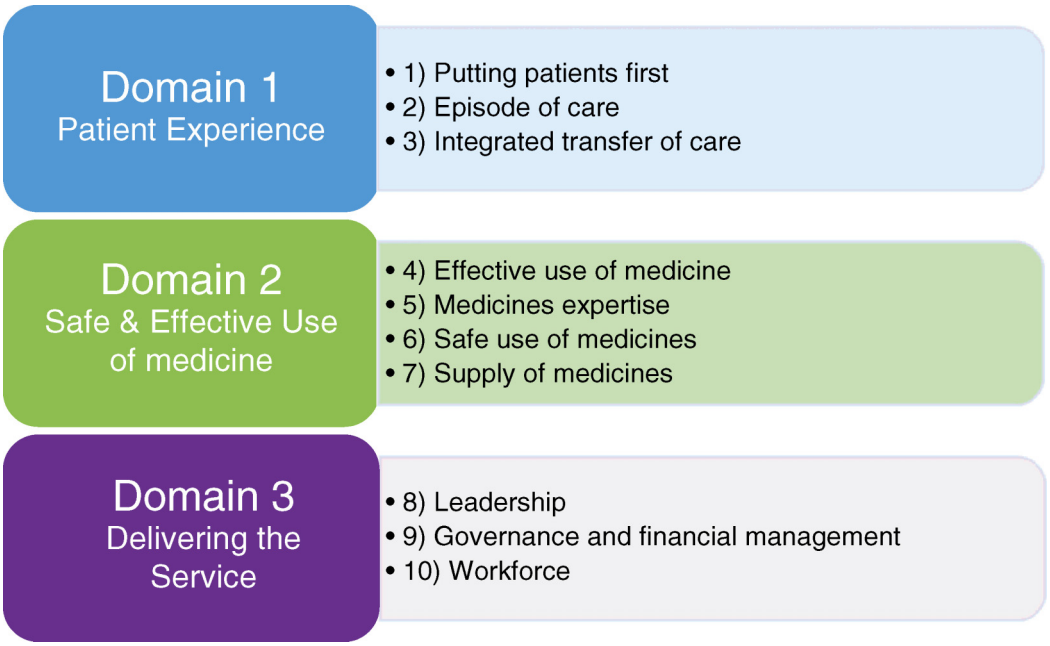

Figure 4 The RPS 10 standards for pharmacy services. *Adapted from RPS Report 2014.*

This move toward deregulation of medicines has further reduced the cost to the NHS as over-the-counter (OTC) medicines are purchased out-of-pocket. In the UK, the first POMs to be deregulated to P status was loperamide and ibuprofen in 1983. The deregulation of 1% hydrocortisone cream saved patients in the UK £2 million pounds in 1987 alone (Harding and Taylor, 2016). Since then, over 80 POM to Pharmacy medicine (P) switches and 50 P to General Sale List (GSL) have been reclassified. In recent years, the rate of deregulation of GSL medicines has increased with most P medicines now available at all retail outlets. The extension of medicines available as OTC and the pharmacists role in advising patients on their use have come under criticism following the *"Which?"* report that exposed up to 43% of all patient consultations in community pharmacies were unsatisfactory and potentially dangerous (Royal Pharmaceutical Society and General Pharmaceutical Council, 2013).

However, the RPS Minor Ailment Study showed that patients receiving treatment in a community pharmacy for the management of one of four minor illnesses had similar outcomes compared to patients managed by GPs. The study also found that patient satisfaction was high and the pharmacy service was significantly more cost-effective than alternative providers (Watson, 2013).

As more medicines continue to become available OTC, pharmacists have a wider advisory role to play in supporting patient self-care for common conditions and minor ailments. It is estimated that minor ailments cost the NHS £2 billion annually in GP visits. A further 8% of Emergency Department consultations involve minor ailments, and this translates up to a cost of £136 million to the NHS annually (Watson, 2013).

Beyond supporting patient self-care, pharmacists help to improve cost-effective medicines use and support in quality, prescribing at a strategic and practice level. In the UK, pharmacists work with interdisciplinary teams to develop drug formularies and appraise the available evidence for inclusion. In the community setting, pharmacists monitor and review repeat prescriptions, which make up 80% of all prescriptions. Repeat dispensing is an essential service under the pharmacy contractual framework. It is a process that allows a patient to collect repeated supplies of their medicines without the need for a prescriber to hand sign prescriptions on each occasion. The prescriptions are then available for dispensing for up until one year or until the next patient review. The repeat dispensing service is most suitable for patients on stable and/or multiple therapies, with chronic conditions, and patients who can appropriately self-manage seasonal conditions. The pharmacist must ascertain the patients' need for a repeat supply, and as such, pharmacists are well placed to make prescribing recommendations and improve prescription quality (Rees et al., 2014).

Pharmacy Regulation in the UK

General Pharmaceutical Council

Pharmacy in the UK is regulated by the General Pharmaceutical Council (GPhC) whose main function is to safeguard patients by upholding standards and public trust in pharmacy. However, in Northern Ireland, the Pharmaceutical Society acts both as the professional body and the regulator.

The GPhC was established in 2010 to set the standards for conduct, ethics, proficiency, education and training, and continuing professional development. Prior to 2010, the Royal Pharmaceutical Society acted as both the regulator and the professional body. Following the demerger, the GPhC is now responsible for the register of pharmacists, pharmacy technicians, and pharmacy premises and monitors pharmacy professionals' fitness to practice requirements. In addition, the GPhC approves qualifications for pharmacists and pharmacy technicians and accredits education and training providers.

Medicines and Healthcare Products Regulatory Agency

The Medicines and Healthcare Products Regulatory Agency (MHRA) is an executive agency of the Department of Health. The agency works to ensure that medicines, medical devices, and blood components for transfusion meet quality standards and issue market authorization for the sale of medicines. In addition, the MHRA influences UK and EU international public health regulatory framework.

Pharmacy Leadership

Royal Pharmaceutical Society

There are a number of general organizations that support and represent pharmacy and pharmacists, such as the RPS. The RPS is the professional leadership and membership body whose aim is to promote pharmacy and support its members to improve the health of the public across England, Scotland, and Wales.

In Northern Ireland, the regulatory and professional leadership functions of the pharmacy profession in Northern Ireland are currently performed by one organization only, the Pharmaceutical Society of Northern Ireland.

General Pharmacy Organizations in the UK

Organization	*Function*
Association of Pharmacy Technicians UK (APTUK)	APTUK is the professional leadership body of registered Pharmacy technicians.
Centre for Pharmacy Postgraduate Education (CPPE), Wales Centre for Pharmacy Professional Education (WCPPE), NHS Education Scotland (NES)	CPPE and the Welsh and Scottish equivalents function as a provider of continuing professional development courses and resources linked to national priorities, which are centrally funded. CPPE also provides postgraduate education.
National Pharmacists' Association (NPA)	Trade association for community pharmacists.

(*Continued*)

Organization	*Function*
Pharmacists' Defence Association (PDA)	The Pharmacists' Defence Association supports the needs of individual pharmacists and provides indemnity insurance. It defends pharmacists in conflict and is a lobbying organization.
Pharmacists Support	Independent charity providing support to pharmacists and their families.
Royal Pharmaceutical Society (RPS)	Professional membership and leadership body in the UK.
RPS Local	The RPS local is the regional branch of RPS members including pharmacy employers, pharmacy education providers, and pharmacists.
British Oncology Pharmacy Association (BOPA)	BOPA is a registered charity and works to promote excellence in the pharmaceutical care of patients with cancer.
UK Clinical Pharmacy Association (UK CPA)	Promotes excellence in clinical practice, leadership, medicines management, and specialist clinical areas.
Pharmacy Voice	It is an association of trade bodies representing community pharmacy contractors. The umbrella organization includes National Pharmacy Association, Company Chemists' Association, and Association of Independent Multiples.

Community Pharmacy

In the UK, the community pharmacist is one of the main providers of medicines and healthcare advice in primary care. Community pharmacists are based in pharmacies either on the high street, grocery stores, or as part of a GP practice. The business model includes independent pharmacies, as well as small chain or large multiple chain pharmacies. Over the years, the number of independent pharmacies in the UK has begun to decline as large multiples have come to dominate the market. Multiples have the necessary economies of scale and resources to invest in infrastructure. In some cases, they are also able to achieve supply chain efficiency with the vertical integration of wholesale operations. These large multiples are achieving more than double the net retail profit margins in their pharmacy operations (Anscombe and Thomas, 2012).

Use of Technology in Community Pharmacy

Summary Care Record

While hospital pharmacists in the UK have had access to summary care records (SCR) for some time, in the community setting, the introduction of the SCR is relatively new. The SCR is a "centrally held electronic record containing key clinical information including a patient's medication, known allergies and any adverse reactions to medication." Over 96% of the population has an SCR that can be reviewed by healthcare professionals 24 h a day, seven days a week. Until recently, community pharmacies did not have access to the SCR. Following a proof of concept pilot launched in April 2014 across 140 pharmacies, SCR access was granted to all pharmacies across the UK. At this stage, pharmacists have "read" only access to the SCR and cannot add notes "write access" to document side effects or other serious problems patients may experience with their medicines and health.

Currently, over 93% of community pharmacies have access to the SCR, and over 24,000 pharmacy professionals have completed the SCR eLearning training. In the 2017–18 financial year, community pharmacies received funding through the Quality Payments Scheme if they were able to demonstrate that they are using the SCR to aid patient counseling and queries where necessary. Pharmacy staff must ask patients for their explicit verbal consent before accessing a patient's SCR.

The privileges gained by community pharmacy, such as SCR "read" access, signifies a further move toward the integration of pharmacists within the primary healthcare team and in particular with GPs. In future, if "write" access is permitted, it will further enhance the scope of pharmacy practice, but this may have legal ramifications.

Community Pharmacy Services

The NHS community pharmacy contract for England and Wales outlines all the NHS services to be provided by pharmacists. There are four service domains: optimizing the use of medicines, public health services, supporting people to live independently, and supporting self-care.

The scope of service provision is expanding, and over 90% of pharmacies in the UK have a private consultation room; however, in community pharmacy, dispensing remains a core part of daily practice.

There are two levels of pharmacy services delivered at the community level:

1. Essential Services
    a. Dispensing appliances
    b. Dispensing medicines
    c. Disposal of unwanted medicines
    d. Public health and promotion of healthy lifestyles

e. Repeat dispensing
f. Managed repeats
g. Signposting
h. Support for self-care

2. Advanced Services

a. Appliance Use Review
b. Flu Vaccination Service
c. Medicines Use Review (MUR)
d. New Medicines Service (NMS)
e. NHS Urgent Medicine Supply Advanced Service (NUMAS)
f. Stoma Appliance Customisation (SAC)

Locally commissioned services in community pharmacies can be contracted by local authorities in response to the needs of the regional population.

Medicines' Use Review

The MUR is one of the most significant innovations in community pharmacy in delivering medicines' optimization and improving patient knowledge and medicines' adherence. In 2015 3.2 million Medicine Use Reviews (MURs) were carried out by 10,916 community pharmacies (Pharmacy Voice, 2017).

In England and Wales, it is an advanced service funded by the NHS and is both a diagnostic and educational intervention (Blenkinsopp et al., 2012). As part of the consultation, the pharmacist explores the patient's understanding of how their medicines should be used and why they haveprescribed it. The pharmacist identifies any problems and provides feedback to the prescriber where necessary. Thus the MUR complements the work of the GPs and fosters interprofessional collaboration between pharmacists and GPs.

To deliver the MUR service, the pharmacy and pharmacist must undergo accreditation and meet certain criteria such as competency assessment, and the premises must have a consultation area that meets NHS standards of privacy. In 2011, national targets groups for selection of MUR were introduced for patients taking high-risk drugs, patients with respiratory disease, and patients recently discharged from hospital. MURs should be conducted on an annual basis, and at the time of publication, the remuneration rate per MUR conducted equates to £28.

In Scotland, a similar service, the Chronic Medication Service (CMS), is part of the core community pharmacy contract. It is more comprehensive than the MUR service and includes a full pharmaceutical care assessment, plan, and implementation. The CMS allows for repeat prescribing of long-term medication, and all data storage is electronic, thereby facilitating communication between the pharmacist and GP.

There is good evidence to show that MURs improve prescribing outcomes, for example in the reduction of polypharmacy, and as such, GPs have accepted most pharmacist recommendations and interventions in the UK (Blenkinsopp et al., 2012).

New Medicine Service

The New Medicine Service (NMS) was added to the Community Pharmacy Contractual Framework as an advanced service in 2011, and since then more than 90% of pharmacies in England have provided this service to patients. The service provides support for people who have been prescribed a new medicine for a long-term condition with the aim of the patient-centered identification of problems with treatment and providing support if needed. The intervention consists of two consultations with the patient: 7–14 days after presentation of new medicine prescription and 14–21 days thereafter. A randomized control trial demonstrated that the NMS significantly increased the proportion of patients reporting adherence to their new medicine by 10.2%–70.7%, compared with normal practice, 60.5% (Elliott et al., 2016).

The NMS aims to:

- improve patient adherence and health outcomes;
- increase patient engagement with their condition and medicines;
- support patients in making decisions about their treatment and self-management;
- reduce medicine wastage;
- reduce hospital admissions due to adverse events from medicines;
- lead to increased reporting of adverse reactions via the Yellow Card scheme, thereby supporting improved pharmacovigilance;
- receive positive assessment from patients;
- support the development of outcome and/or quality measures for community pharmacy.

At time of publication, the remuneration rate per NMS equates to £25. Some limitations of the service include insufficient integration, underdeveloped relationships between pharmacist and GP, and in some cases, unwillingness by pharmacists to implement the service (Elliott et al., 2016).

The Role of Pharmacy in Health Promotion

Healthy living pharmacy

In efforts to further public health interventions in a community pharmacy setting, the "Healthy Living Pharmacy" was piloted in 2009. The vision for the scheme was born out of a government 2008 White Paper, "Pharmacy in England: building on strengths, delivering the future." Among the recommendations made in the White Paper, a call for community pharmacy to play a greater role in prevention and early detection of disease and management of chronic conditions was outlined. In addition, it encouraged pharmacy to take greater clinical responsibility for patients such as prescribing and, in turn, broaden the role of pharmacies beyond dispensing volume-driven activities.

Health Living Pharmacy (HLP) framework is a tiered commissioning framework designed to improve the health and well-being of the local population and reduce health inequalities via public health services delivered in community pharmacies. Furthermore, the framework aims to develop a pharmacy as a community hub for healthy living and develop the pharmacy workforce as a skilled team to promote behavior change and thereby improve health and well-being. Central to the HLP concept is further engagement with the local community, GPs and other health professionals, social care and public health professionals, and local authorities. There are three levels of service delivery within the HLP framework:

- Level 1: Promotion—Promoting health, well-being, and self-care (in July 2016, Level 1 changed from a commissioner-led process to a profession-led self-assessment process)
- Level 2: Prevention—Providing services (commissioner-led)
- Level 3: Protection—Providing treatment (commissioner-led)

In the UK, the healthy living pharmacy framework has been developed to support pharmacies to provide a wider array of public health services tailored to local need. This includes offering accessible and effective interventions around smoking cessation, weight loss, sexual health, alcohol, and other harm reduction services. Pharmacy Voice have identified that 60% of patients using HLPs would have otherwise visited a GP for health improvement advice and 20% would not have changed their lifestyle (Holden, 2015).

To be awarded HLP status, pharmacies must demonstrate the suitability of their premises, systems and resources, and a commitment to a healthy living ethos illustrated by a proactive approach to self-care and healthy lifestyles in their community. Each HLP must have at least one "Health Champion" trained and accredited to provide health and well-being advice to customers. By January 2016, 2100 pharmacies were accredited as HLPs, and 3500 pharmacy staff qualified as Health Champions (Public Health England, 2016).

Around 70% of people who visit pharmacies do not regularly access other healthcare services, thus HLPs can provide health and well-being support to people in their community that may be outside the reach of other resources. Improved choice and access to early interventions on issues such as common ailments, optimal medicines use, and lifestyle could improve outcomes in the longer term and therefore positively impact cost of care in the future. (Holden, 2015)

Primary Care Pharmacy—Pharmacist and General Practitioner Partnerships

From the 1990s onwards, pharmacists began working more closely with the general practice based primary healthcare team. As pressures and demands on GPs have increased over time, clinical pharmacists have begun to work as part of the general practice team to resolve day-to-day medicine issues and treat patients directly.

In this integrated model of care, clinical pharmacists provide health checks, counsel patients on complex medicine regimens, and manage patient's chronic and long-term conditions. In addition, pharmacists have advised on GP formularies and take responsibility for anticoagulant and *Helicobacter pylori* assessment clinics. The role of the clinical pharmacist in GP practices helps to improve the quality of prescribing and care. Furthermore, the integrated model allows for GPs to focus on diagnosing and treating patients with complex conditions. According to the Pharmacy Voice, 92% of GPs would like more support from community pharmacy teams to help their patients take their medicines correctly. Following the successful pilot in 2015 that placed 490 clinical pharmacists in 650 GP practices, a further £100 million has been invested to support an extra 1500 clinical pharmacists to work in general practice by 2020.

To support this transformation, a new Pharmacy Integration Fund was established with a budget of £42 million secured for 2016–18. The fund will drive the greater use of pharmacists and pharmacy technicians in a variety of settings such as general practices, care homes, urgent care settings, and further support the development of clinical pharmacy. Further development of digital integration between settings is required.

Out of Hours Services

NHS is a free-to-call single nonemergency phone number and medical helpful that operates in England and Scotland. The equivalent in Wales is NHS Direct Wales, which was rolled out in 2016. It is a 24 h a day service and triages urgent but nonlife threatening health issues. Audits of the calls have shown that a high number of queries are linked to medicines use and as such pharmacists are employed to give direct online healthcare advice (Rees et al., 2014).

Patient Group Directions

An alternative strategy to improve patients' access to medicines is the use of Patient Group Directions (PGD). PGDs allow for medicines to be accessed without a prescription and is supplied by a pharmacist or other healthcare professional, usually in planned circumstances. PGDs require significant resources and time to implement and should be developed by a multidisciplinary group of healthcare professionals as well as the prescribing advisory boards. The legal definition of a PGD is "A written instruction for the sale, supply, and/or administration of named medicines in an identified clinical situation. It applies to groups of patients who may not be individually identified before presenting for treatment" (MHRA, 2017).

The PGD allows the supply of prepacked licensed POMs only to patients who meet the inclusion criteria. The DH has enforced that the PGD should only be used for short courses of standard treatment of, for example, sildenafil for erectile dysfunction and orlistat for weight loss. While emergency hormonal contraception is not a POM, it is also available under the PGD and in certain instances is free of charge.

NonMedical Prescribing

In the UK, improved access to medicines has been a significant driver of the legislative changes enabling pharmacist prescribing. Making better use of pharmacist's skills and pharmaceutical expertise, as well as the specializations of other healthcare professionals, was the focus of the two Crown Reports. The 1999 Crown Report critically changed the landscape of prescribing with the recommendation that pharmacists, nurses, midwives, physiotherapists, podiatrists, optometrists, and radiographers should gain prescribing privileges. To qualify as a nonmedical prescriber, additional assessments and accreditation is required. Nurses were the first to become nonmedical prescribers, followed by pharmacists in 2003. By this time, about 24% of pharmacists worldwide had already incorporated "some form" of prescribing into pharmacy practice. In the UK, the legal framework emerged at a later stage to support the work that clinical pharmacists were already undertaking (Baqir et al., 2012).

Supplementary Prescribing

In the supplementary prescribing model, a diagnosis must first be made by either a doctor or dentist, and a clinical management plan (CMP) must be agreed in collaboration with the independent prescriber and the patient. The patient must give their consent to the transfer of care to a supplementary prescriber. The extent of the allowances for prescribing dictated by the CMP is largely determined by the therapeutic area expertise of the supplementary prescriber, and the relationship with the doctor. Most importantly, the CMP sets out the terms of agreement between the independent and nonmedical prescriber and can vary in specificity and detail. There are few restrictions around what nonmedical prescribers can prescribe to patients, and in May 2005, certain controlled drugs and unlicensed medicines were added to the list of medicines that can be prescribed by supplementary prescribers (Rees et al., 2014).

Now that pharmacists can become independent prescribers (IP) in the UK, supplementary prescribing is less common, although important in creating the foundation and framework for independent prescribing.

Independent Prescribing

The IP regulations came into effect in 2006 and allowed pharmacists to prescribe autonomously for any condition within their clinical competence (Harding and Taylor, 2016). The independent prescriber is responsible for the assessment of patients with undiagnosed or diagnosed conditions, and accountable for clinical management decisions, including prescribing. At time of publication, an IP may be a specially trained nurse, optometrist, physiotherapist, therapeutic radiographer, podiatrist, or pharmacist. Nurse and pharmacist-independent prescribers can also prescribe unlicensed medicines and controlled drugs apart from three types of controlled drugs for the treatment of addiction.

To qualify as an IP, the pharmacist must have practiced for a minimum of 2 years and complete a GPhC accredited programe that is typically run over a period of 6 months. In addition, there are conversion courses available to allow supplementary prescribers to qualify as independent prescribers.

There is a single competency framework for all prescribers including doctors, see **Table 2** for a summary table of the prescribing competency framework. In the table, there are ten competencies split into two domains, the consultation and prescribing governance. However, it does not list individual outcomes for each competency area.

IP pharmacists may also run their own clinics or prescribe in wards such as intensive care or medical administration units. However, currently there is a vast variation (2.5%–71%) in the rates of prescribing pharmacists as a proportion of hospital pharmacists.

Pharmacy education is also changing to reflect the extended role of the pharmacist and prescribing competencies will become core components to the pharmacy undergraduate curriculum. In future, a multifactorial prescribing model will be more likely to encompass activities such as the Medicines Use Review, New Medicines Service, Chronic Medicines Service, and repeat dispensing (Harding and Taylor, 2016).

Table 2 Prescribing competency framework

Consultation	*Prescribing Governance*
1. Asses the patient	7. Prescribe safely
2. Consider the options	8. Prescribe professionally
3. Reach a shared decision	9. Improve prescribing practice
4. Prescribe	10. Prescribe as part of a team
5. Provide information	
6. Monitor and review	

Hospital Pharmacy

In the UK, hospital pharmacy is the second largest employer of pharmacists, in both NHS and private hospitals. In general, the hospital pharmacist's role is not only more specialized than in the community setting, but also includes similar functions such as the purchase, preparation, dispensing, and supply of all the medicines. Beyond the supply of medicines, hospital pharmacists play a key role in providing clinical and pharmaceutical expertise to patients and healthcare professionals alike. The pharmacy department works closely with other healthcare professionals and advises staff on the safe and effective use of medicines with regard to dose, formulation, administration, and drug monitoring.

In the UK, hospital pharmacists also provide medicine information services such as writing medication-related guidelines and developing hospital formularies. The medicines information team also supports healthcare professionals and patients on all aspects of medicines and have access to a wide range of reference material to respond to queries.

While clinical pharmacy is not practiced in a uniform manner across the UK, most hospital pharmacists will speak to patients during ward rounds to improve patient understanding and adherence to their medicines and conduct medicine reconciliation (i.e., taking a medication history from patients and resolving any discrepancies.) NICE has recommended that pharmacists complete this as soon as possible after patient admission to hospital. A 2009 report from the General Medical Council highlighted that 8.9% of orders across UK hospitals contained a prescription error. Furthermore, the evidence suggests that pharmacists take more accurate drug histories than medical staff, and so pharmacists have been identified as central clinical staff in improving prescription quality (Harding and Taylor, 2016).

The 2016 Carter Report, which was launched to review efficiency improvement in hospitals, recommended that the pharmacy workforce drives outcomes and achieves optimal value from the £6.7 billion it spends on medicines per year. Overall, the NHS is expected to deliver efficiencies of 2%–3% per year with a 10%–15% real terms cost reduction target by April 2021.

As part of this strategy to heighten operational productivity and performance, recommendations have been made for pharmacists and pharmacy technicians to spend more time delivering clinical patient facing activities such as medicine optimization. Furthermore, the Carter Report has emphasized skill mix and enhanced efficiency to build in medicine optimization as part of daily practice with the aim of reducing unwarranted variation in productivity and efficiency.

According to the Royal College of Physicians, in the UK, there has been a cumulative rise of 37% in patient visits to hospital over the past 10 years (Harding and Taylor, 2016). To accommodate this significant rise in patient numbers and the complexity of admission services, recommendations have been made for seven days a week service. However, there is still widespread variability in pharmacy departments' delivery outside of the standard working hours, particularly on weekends, and this presents as a significant challenge for hospital pharmacy. In response, NHS trusts have launched hospital transformation programs (HTTP) to prepare clinical pharmacy staff for seven-day healthcare service delivery and deploy clinical pharmacists onto wards to ensure optimal use of medicines.

Hospital Pharmacy Standards

The regulations around the use of medicines in hospital settings are intricate, and hospitals are required to register with the Care Quality Commission (CQC) in England. The CQC's role is to ensure that hospitals, care homes, and dental and general practices provide people with safe, effective, and high-quality care.

In the wake of the Francis Report 2013, which exposed serious neglect of patients in the Mid Staffordshire NHS Foundation Trust, the issues of patient safety, quality of care, and leadership are at the forefront of public and policy debate. As a result, the organizational culture of the NHS has responded with an emphasis on value-based recruitment for all staff. Values such as empathy and compassion are screened for from point of university entry across most UK pharmacy universities, and in the workplace pharmacists must demonstrate empathy and compassion.

In addition, the Royal Pharmaceutical Society is reviewing the current set of Professional Standards for Hospital Pharmacy Services to improve patient safety for 2017. These standards serve as a broad framework to support pharmacy departments in improving the quality of service delivery. It also outlines future pharmacy services and pharmacy roles designed to reduce incidents of avoidable harm within organizations. The standards are aimed at giving patients a clear picture of what to expect from their pharmaceutical care. There are currently 10 standards for pharmacy services divided into three domains: Patient Experience, Safe and Effective Use of Medicine, and Delivering the Service (see Table 2, p. 24).

Use of Technology in Hospital Pharmacy

In continental Europe and the US, the use of pharmacy-based automated dispensing machines for original pack selection became commonplace in the 1980s. However, robotic dispensing and automation was adopted more gradually in the UK due to a traditional mixed dispensing profile. Although the use of robotics in dispensing is now common, it was not until the European Community Directive 92/97 became law in 1999 that the automated system became viable in UK hospital pharmacies. (Goundrey-Smith, 2008)

In addition to the use of robots, electronic prescribing (EP) is a further safety measure that is used in hospital settings. While there is variation in the definition of EP from country to country, the NHS Connecting for Health has defined EP as the "utilisation of electronic systems to facilitate and enhance the communication of a prescription or medicine order, aiding the choice, administration and supply of a medicine through knowledge and decision support and providing a robust audit trail for the entire medicines use process" (Ahmed et al., 2016).

With the drive toward a "paperless NHS" by 2020, there has been significant investment in digital infrastructure; however, currently, the overall uptake is still low in comparison to other European countries. A new report from Digital Health Intelligence concludes that at the current rate of implementation, NHS hospitals will not become paperless before 2027.

The EP hospital system includes a range of different functions, and is more complex than the systems used in Primary care. EPs may be implemented in a wide range of organizational contexts and are accessed by different healthcare professionals at different stages of care.

Healthcare Organizations and Pharmacy Groups

National Institute for Health and Care Excellence

The National Institute for Health and Care Excellence (NICE) is an Executive Non Departmental Public Body (ENDPB) and, while accountable to the DH, operates independently of the government. The primary responsibility of NICE is to provide evidence-based guidance on health and social care to help practitioners deliver the best quality of care. The guideline recommendations are targeted toward individual health and social care professionals, but should be used alongside professional judgment and after discussion with service users.

It was originally established in 1999 as a special health authority to review efficacy and cost-effectiveness of medicines. It publishes recommendations around medicine use by prescribers. Over time, the NICE has evolved to include added functions, for example, health technology appraisals and guidelines around quality standards.

NICE publishes quality standards and guidelines on the following:

- Health technologies
- Health promotion
- Clinical Practice
- New and existing medicines and treatment.
- Treatment and care of people with specialist diseases and conditions.

While NICE guidance is specific to England, certain NICE services are shared with Wales and Northern Ireland. The devolved administrators from each country are consulted with in the development of their own NICE guidance that is relevant to their local context. In Scotland, it is the Scottish Intercollegiate Guidelines Network (SIGN) that develops evidence-based guidelines. The guidelines are developed by a committee of unbiased experts with at least two lay members who have an illness that the guideline pertains to, or have personal experience using the relevant healthcare service as a patient or carer.

A 2016 Medication Error report from the World Health Organization identified discrepancies in discharge medication following hospitalization in 43%–60% of items leading to a 77% error rate in transfer from secondary to primary care. In an attempt to reduce error at point of patient transfer, NICE recommends that medicines' discharge information should be shared with the community pharmacy. Some electronic tools help facilitate this process, for example, the Refer-to-Pharmacy tool allows bedside referral of inpatients to their community pharmacist for a post-discharge medicine adherence consultation, or to update a patient's pharmacy record with medication changes.

NICE has developed guidelines around medicines' optimization and adherence and is used by both hospital and community pharmacists for the most up-to-date diagnostic, treatment, counseling, and referral information.

Health Education England

Health Education England (HEE) is part of the NHS and is a national leadership body responsible for ensuring that education, training, and workforce development drives the highest quality public health and patient outcomes.

Pharmacy and pharmacists come under the remit of HEE, which is an executive nondepartmental public body sponsored by the Department of Health. As the national leadership organization for education and training, HEE is responsible for workforce planning and development. This body is further divided at the local level with Local Education and Training Boards (LETB) developing the NHS workforce locally.

In Scotland, the equivalent body and special health board responsible for developing and delivering education and training is NHS Education for Scotland.

Currently in the UK, the pharmacy degree is a 4-year Masters of Pharmacy (MPharm) program, which is classed as an "undergraduate masters program" under the Bologna agreement for educational equivalence across Europe. To qualify as a pharmacist, graduates complete a one-year preregistration training program and pass the General Pharmaceutical Council registration exam.

Public Health England

Public Health England (PHE) is an executive agency of the Department of Health that was introduced in the 2013 reform of the NHS, replacing the Health Protection Agency and the National Treatment Agency for Substance Misuse as well as 70 other health bodies. PHE has operational autonomy to advise and support the government, the NHS, and local authorities with professional independence. Public Health England works closely with public health professionals in Wales, Scotland, and Northern Ireland, and strives to improve the public's health and well-being, build capacity and capability of the public health system, and protect the public from threats and emergencies (Public Health England, 2016).

Pharmaceutical Services Negotiating Committee

The Pharmaceutical Services Negotiating Committee (PSNC) is recognized by the Secretary of State for Health as the representative negotiating body representing community pharmacy contractors on NHS matters in England. It was established in 1976 and works to promote and support community pharmacies by lobbying parliamentarians and policy makers. The PSNC primarily negotiates the terms and conditions of the NHS community pharmacy contractual framework and agrees the distribution of funds. In England, 11,600 pharmacies with an NHS contract fund PSNC through levies paid to their Local Pharmaceutical Committee. Across the UK, the PSNC works closely with its sister body Community Pharmacy Wales (CPW) which represents community pharmacy contractors in Wales. The PSNC also negotiates the remuneration that community pharmacy contractors receive for NHS dispensing services and other pharmaceutical services such as MURs, and promote further opportunities for service development. The remuneration is a financial reward for pharmaceutical service provision and is paid as fees and allowances, and the cost is charged to NHS England.

Future of Pharmacy

The Department of Health cuts to the pharmacy budget in 2015 and 2016 have already resulted in a growing number of independent pharmacy closures. However, in October 2017 it was announced that Lloyds Pharmacy, a major multiple chain, will cease trading in 190 branches across the UK due to commercial unviability (Torjesen, 2017). Up until now, the multiples have had a stronghold on pharmacy despite the often-challenging market conditions in the UK. As a result, there may be a rapid rise in the number of Internet Pharmacies, and with early signs, albeit not confirmed, that the corporate megalith Amazon may be entering the pharmacy business in the American market, it may not be too long before the UK follows.

Pharmacy will have to continue branching out beyond medicine supply and undergo a rebranding as a neighborhood health and well-being hub. This is already happening with the expansion of the Health Living Pharmacy model across the UK; however, more aggressive marketing measures may be required for public buy-in. Key to its success will be strong pharmacy partnerships across a broader range of local leaders and groups, ranging from charities to patient support groups.

Furthermore, as the global burden of noncommunicable diseases continues to grow, pharmacists are key healthcare workers in supporting personalized care for people with chronic conditions. The "Pharmacy First" services may be accessed by a variety of routes ranging from online to face-to-face, and the community pharmacy will serve as a triage center referring urgent cases to the GP or to the hospital. Community pharmacy staff will be able to book people directly into other services and fast-track them if necessary. Also with access to patient medical files via the SCR, pharmacists are better equipped now more than ever to give comprehensive healthcare advice. The next step for pharmacy will be to gain "write" privileges to record and update pharmacy-led interventions, building on the evidence base around the value of pharmacy.

In some ways, pharmacy is returning to its roots prior to the establishment of the NHS, with pharmacists positioned in a heightened patient facing role, and selling a broader range of services. However, as the scope of pharmacy service provision is widened, the remuneration must follow for future sustainability. As lessons of recent history show, pharmacy must adapt to technological, social, and political change at a faster pace to avoid further loss of self-determination as a profession. Perhaps most importantly, in order for pharmacy to thrive in a highly competitive and service provider saturated market place, the profession will have to demonstrate added value directly to the public and use each patient interaction as an opportunity to do so.

Pharmacy Practice in Western Europe

Lilian M. Azzopardi, Department of Pharmacy, Faculty of Medicine and Surgery, University of Malta, Msida, Malta

The Backdrop

Pharmacy in Western Europe has changed dramatically from the time of monastic pharmacy in the middle ages and the first apothecaries in Spain, Italy, and France to the present patient-centered pharmacy practice. Nowadays, in community pharmacy, the pharmacist is practicing independently, albeit in collaboration with other health care professionals, to provide primary care services to society. Documents, such as the Nuovo Ricettario from Florence, attesting to standardization of substances used as medicines, were the precursors of pharmacopoeias and pharmaceutical regulatory sciences, including the practice of pharmacovigilance. The evolvement of the concept of clinical pharmacy and later pharmaceutical care in the 1960s led to advances in pharmacy practice first in hospital pharmacy and subsequently in community pharmacy. The elaboration of pharmacy practice research is the foundation for the present evidence-based pharmacist interventions in health care. The concept of clinical pharmacy may actually trace its roots to Europe, at the time of the Knights of the Order of St. John of Jerusalem, who were a military-religious hospitaller order. There is evidence that the pharmacist participated in ward rounds with physicians to discuss the treatment to be given to patients in the Sacra Infermeria in Malta, at the time a state-of-the-art hospital established in 1574, which was run by the Knights.

This overview of pharmacy practice in Western Europe is analyzed by approaching advancements in the professional practice in community and hospital pharmacy with the impact of the concepts of clinical pharmacy, pharmaceutical care, and pharmacovigilance, as drivers of change. The influence of education and practice research on shaping these advancements is considered.

It is difficult to establish a geographical definition of Western Europe, because it is not a formal region, as is the European Union. There have been major transformations in the region post-World War II to date. Europe consists of a number of countries in terms of economic forces, political influences, and military successes. This geographical and nation-state, not to mention languages situation, makes the region unique in terms of an attempt of convergence of systems for countries within the European Union while there are also other significant models for the other countries, which are European although not members of the European Union. A broad outlook that goes beyond the geopolitical definition is adopted in this chapter where the outlook is embracing the advancements and innovations in pharmacy practice within Europe.

Data from the PHARMINE study undertaken by the European Association of Faculties of Pharmacy (EAFP) among 25 EU member states in 2008, established that there were 419,353 pharmacists working in these countries (Atkinson and Rombaut, 2011). Patterns of practice for pharmacists reported in the PHARMINE study are similar to the data presented in the 2017 report by the International Pharmaceutical Federation (FIP) "Pharmacy at a glance" where principal areas of practice for pharmacists in Europe identified are: 78.5% in community pharmacy, 8.9% in hospital pharmacy, and 12.6% in other areas. In terms of pharmacists density per population, the European median is 8.28 pharmacists per 10,000 population. The number of pharmacists per population is highest in Europe when compared to the figures for other regions: western Pacific region, 4.96; Pan American region, 4.67; eastern Mediterranean region, 4.28; southeast Asian region, 2.31; and African region, 0.61 (International Pharmaceutical Federation, 2017). According to 2012 data, the range of pharmacists density per 10,000 population varies from 5.25 in Norway to 24.82 in Malta (**Table 1**) (International Pharmaceutical Federation, 2015). There could be a geographical trend in that: the higher density (12–25) of pharmacists is seen in the southwest Mediterranean countries (France, Portugal, Spain, Italy, and Malta) and the lower density (5–6) is seen in the Nordic countries of Norway and Finland.

Table 1 Pharmacists density per 10,000 population in European countries

Countries	*Pharmacists per 10,000 population*
Austria	6.93
Belgium	11.63
Croatia	7.17
Czech Republic	7.62
Finland	5.80
France	11.57
Germany	9.58
Hungary	5.70
Ireland	10.46
Italy	13.47
Malta	**24.82**
Norway	**5.25**
Portugal	12.56
Spain	13.74
Switzerland	8.45
United Kingdom	8.08

International Pharmaceutical Federation (FIP), 2015. Global pharmacy workforce intelligence: Trends report. The Hague, The Netherlands: International Pharmaceutical Federation.

Forces of Change

Over the past 50 years, there have been multiple changes in European countries that have impacted on the evolvement of pharmacy practice models. A significant impact was the transition from compounding of medicines in community pharmacies to the industrial manufacture of medicines (Higby, 1996).

A consequence of the industrialization of the manufacture of medicines was a change in the practice of community pharmacy: the dimensioning of the community pharmacist as a caregiver rather than as a producer of the medications (Azzopardi, 2000). The community pharmacist has a tradition of playing a central role in the social network of the community being served, and this role also encompassed accessibility to medications. The introduction of medicines that were produced within a pharmaceutical industry under a trade name presented a challenge to accessibility of medicines. Governments intervened in some countries to oversee that medicines were available to different social strata. Industrialization from a broader perspective was seen as a driving force for national economic growth. Governments in Europe, through different approaches, were addressing disease from various angles including access to medicines. Poverty was central to access to health care and in some instances ensuring equitable access to medicines was considered a key performance indicator in the successful redistribution of wealth (Szreter, 2004). Health care models were developed across European countries post-World War II. The introduction in the United Kingdom of the National Health Service in 1948 was seen as an innovative social service model targeting national coverage of health care, including pharmaceutical services (Lopes et al., 2010). Europe retained a characteristic trait of variability in health services delivery. This diversity in its health services structure is very relevant when reflecting on how the economic driving force of industrialization impacted on the models of pharmacy practice. Switzerland is an example highlighting this variability that transcends to a national level. In Switzerland, the national health system relies on regional laws and regulations adopted by the 26 different cantons (Simonet, 2009). The evolvement in health care systems in European countries is an on-going strategy, which needs to take into account the continuous reshaping of the region, starting in the 1990s with the reunification of Germany and expansion of the European Union (Ridic et al., 2012). The impact of Brexit on the National Health Service in the United Kingdom and an influence of Brexit on health care systems in other countries may be a driving force for future transformations impacting on pharmacy practice.

Forces of change taking place in other regions outside Europe, especially in the United States, impacted on the evolvement of pharmacy practice in Europe. In the United States, with a backdrop of economical prosperity and an expanding repertoire of industrially manufactured medications, leaders of hospital pharmacy from the American Society of Hospital Pharmacists instigated a survey on the status of pharmacy practice in hospitals. In the report of the findings of the survey, the authors take forward this initiative by presenting innovative clinical pharmacy services that pharmacists could develop in hospitals where the focus moves toward the patients (Francke et al., 1964). The survey and the resulting publication sowed the seeds for the germination of the philosophy of clinical pharmacy in the United States, which at the time was envisioned to be affiliated with institutional care settings (Higby, 2014). The philosophy of clinical pharmacy practice took longer to germinate in Europe (Gums, 2013). An explanation for this delay is that in addition to change resistance inherent to human nature, pharmacy leaders in Europe were engrossed in developing health system models of accessibility and delivery of medicines as a priority to convincing European governments of the benefits of clinical pharmacy services.

Medicines regulatory sciences, particularly aspects of quality assurance started to become formalized. The thalidomide disaster brought to light in 1961, is seen as the driving force to the evolvement of pharmacovigilance, as a patient-safety strategy, which relies

on the remodeling of pharmacy practice (Routledge, 1998). Pharmacovigilance, which broadened the description of pharmacy practice beyond community and hospital settings, is seen as a pharmaceutical science reflecting a practice that looks at safety in whichever platform of care a pharmacist is performing.

Community Pharmacy

In Europe, community pharmacy is represented by a median of 3.06 community pharmacies and 6.26 community pharmacists per 10,000 inhabitants (International Pharmaceutical Federation, 2017). The Pharmaceutical Group of the European Union (PGEU) is an international nonprofit organization that represents community pharmacists in Europe and plays an advocacy role at the European Union level to advance community pharmacy practice as a contributor to health systems and society well-being. Community pharmacy practice in Europe may be described as having a common trend of transforming the practice to focus on public health, patient care, and quality services, albeit with terms of diversity in the regulation of the profession (Anderson, 2007).

Regulation of community pharmacy practice in Europe is influenced by different ways of ensuring accessibility and sustainability, such as an exclusive ownership of pharmacies by pharmacists, pharmacies run by chains, control of establishment of new pharmacies based on distance and/or population, and exclusive rights to sell non-prescription medicines (Chave, 2014). The European Commission is in support of liberalization, but European court cases have ruled that restrictions at national levels are justified and lawful, as the restrictions are in the interest of protecting delivery of quality health care (Lluch and Kanavos, 2009). Liberalization or deregulation of distribution of community pharmacies in Europe may not necessarily lead to increasing access to medicines in rural areas, where the service is perhaps lacking. Quality and expansion of pharmacy services, particularly beyond dispensing of prescription-only medicines, may be challenged if opening of pharmacies is not controlled (Vogler et al., 2014).

The legal frameworks governing community pharmacies highlight requirements related to premises, dispensing of medications, storage of medicines, and some description of professional services. Patcheva et al. (2012) describe legal requirements in Germany, Slovenia, Croatia, and the Republic of Macedonia. Quality systems for community pharmacy practice and the relevance of adopting key performance indicators of professional services to identify areas of improvement were established (Azzopardi, 2000; Azzopardi et al., 2003; Halsall et al., 2008; Mark, 2008; Vo et al., 2017). The strengths of quality systems for community pharmacy practice serve to identify the professional intervention of the pharmacist as it impacts on patient care and promotion of health. Accessibility to medicines by requiring a pharmacist to manage a community pharmacy does not present a legal restriction on accessibility to medicines (Community Pharmacy Section, International Pharmaceutical Federation, 2005).

Community pharmacists are active players in the primary care setting to support patients in the selection of non-prescription medicines and identifying signs or symptoms requiring referral. The elaboration of protocols to support a standardized approach by community pharmacists is a means of measuring the intervention of the community pharmacist in patient care while promoting evidence-based practice (Vella et al., 2009). Community pharmacists are empowering patients in choosing non-prescription medicines rationally based on scientific evidence (Galea et al., 2014).

The need for the formal establishment of cognitive pharmaceutical services that should be remunerated and recognized as contributing to health outcomes is acknowledged as strengthening the community pharmacy model. As the concept of pharmaceutical care, coined by Hepler and Strand in 1990 gained ground in Europe, non-remuneration for pharmaceutical care services provided by community pharmacists was identified as a barrier to the implementation of professional services focusing on pharmacotherapy management and patient monitoring (Van Mil et al., 2001). The concept of pharmaceutical care within community pharmacy practice led to the development of pharmacy practice research aimed at demonstrating value of the cognitive services provided by community pharmacists in monitoring patient adherence to treatment, in undertaking medicines use reviews, and in patient counseling. The Pharmaceutical Care Network Europe was established in 1994 to stimulate pharmaceutical care and pharmacy-related outcomes research in Europe. The network serves as a collaborating platform for pharmacists interested in developing community pharmacy practice research.

The barrier of the need for reimbursement for professional pharmacy services has been overcome in a number of countries. Reimbursement by health insurances for cognitive pharmacy services including pharmaceutical care services and disease management was started in Germany in 2003 (Eickhoff and Schulz, 2006). In the United Kingdom, the Medicines Use Review (MUR) community pharmacy service was introduced in 2005 (van den Berg and Donyai, 2010). In Switzerland, the provision of pharmaceutical services by community pharmacists is reimbursed by health care insurers (Schneider et al., 2009). The Swiss Polymedication Check, which is a pharmacist-led medication review implemented in Switzerland and reimbursed by health care insurers, was shown to identify drug-related problems related to adherence by the patient to treatment and improved patient knowledge about the medicines (Messerli et al., 2016). In Italy, medicines use review for patients with asthma (I-MUR) was launched as the first nationally reimbursed cognitive pharmaceutical service (Manfrin et al., 2017). The positive results and validated protocols from the countries where pharmacists are reimbursed for cognitive services serve as tools for the development of such services in other countries (Swieckowski et al., 2017).

Consumer satisfaction studies of community pharmacy services indicate a good degree of satisfaction for the services received related to conventional professional pharmacy services (Wirth et al., 2011). The consumer perception regarding extended professional services provides information about priority areas to be considered for innovative community pharmacy services. The participation of the pharmacist in interdisciplinary collaboration in the management of chronic conditions and the provision of diagnostic testing was reported by consumers as key areas of evolvement (Vella et al., 2015). The incorporation of point-of-care

testing within a cognitive service provided by community pharmacists is feasible and contributes to improved management of drug therapy (Geerts et al., 2013). The introduction of a community pharmacist-led anticoagulation management service was shown to be sustainable and contribute to the improvement of management of patients on warfarin (Mifsud et al., 2014). Application of point-of-care testing of urine analysis for microalbuminuria in diabetic patients may be incorporated within diabetic patient monitoring services (Ungaro et al., 2015). Topics described in Scotland as requiring prioritization in community pharmacy services development included appropriate supply of non-prescription medicines, patient counseling for prescribed medication, pharmaceutical care to promote medication adherence, responding to minor symptoms, and pharmaceutical care of vulnerable patients (Newlands et al., 2017).

The development of new services within community pharmacy practice may be examined through the application of risk management intervention (Pereira Guerreiro et al., 2012). Studies on the risks in prescribing by pharmacists, for example, antibacterial drugs as perceived by physicians are an indication of the need for community pharmacists to disseminate the positive contribution of pharmacist prescribing in enhancing patient safety and timely access to medicines (Attard Pizzuto et al., 2016). Pharmacist prescribing was developed in the United Kingdom since 2003, first through supplementary and later through independent prescribing (Baqir et al., 2012). Professional services evolved for the past 14 years in different forms and aspects. There is room for further development of the service within the community pharmacy context even in the United Kingdom (Stewart et al., 2011).

Community pharmacy practice has come a long way since its apparent threat of deprofessionalization with the industrialization of production of medicines. Transformation is ongoing and is seen by community pharmacists as a means to contribute significantly to patient care and to social health care models. The drive of transformation is evolving and there are many challenges coming along in the future.

Hospital Pharmacy

European data stands at 4.08 hospital pharmacists and 0.94 hospital pharmacies per 100,000 population. There is a wide variation of percentage of pharmacists holding a principle employment as a hospital pharmacist on a national level in Europe. The United Kingdom and Malta top the list where 19.8% and 19.2% of the total pharmacists population are practicing in a hospital setting. Bulgaria and Greece represent the other end of the spectrum with 1.6% and 2.3%, respectively (Atkinson and Rombaut, 2011). Hospital pharmacy practice consists of: (1) administrative services related to procurement and distribution of medicinal products, medicines preparation, such as compounding and intravenous admixtures, and quality assurance; (2) clinical services related to drug information, therapeutic drug monitoring, direct-patient services, and patient safety. The European Association of Hospital Pharmacy represents national associations in Europe of hospital pharmacists and promotes networking between hospital pharmacists to promote continuous improvement of hospital pharmacy services.

Hospitals in Western Europe tend to procure medicines directly from the manufacturing industry, whereas hospitals in Eastern Europe in general go through wholesale dealers (Frontini et al., 2012a). Challenges particularly relevant to small hospitals and islands, with regards to procurement of medicines include accessibility, drug shortages, and pricing. The centralized distribution model requires a large operational structure in the hospital pharmacy that includes non-pharmacists to handle stock distribution and management. Hospital administrators are looking into models that provide the best efficiency and clinical outcome from the pharmacist manpower. This is leading to circumstances where the number of pharmacists contributing to administrative pharmacy services is being reduced or some of the services are being subcontracted or outsourced. The production of sterile and non-sterile medicines in hospital pharmacies in Europe has decreased over the past 17 years (Frontini et al., 2012b).

In the 1967 issue of the journal Drug Intelligence published in the United States, Don E. Francke refers to the emerging role of the hospital pharmacist as a member of the health care team contributing to the patient care area (Francke, 1967). The contribution of the emerging clinical pharmacists was identified as reducing medication errors, monitoring adverse effects, and contributing to unit dose dispensing and pharmacist participation in intravenous admixtures preparation (Francke, 1969). Anthony Serracino-Inglott, a pharmacist from Malta who was following a residency and a postgraduate doctor of pharmacy degree at the Cincinnati General Hospital was working with Don Francke and his team between 1969 and 1972. He worked on improving intravenous administration of drugs by the patients' bedside (Kramer et al., 1971). Serracino-Inglott went back to Malta after completing his doctoral studies and was instrumental in developing clinical pharmacy services at the acute and rehabilitation hospitals in Malta and in giving the strategic shift of pharmacy education in Malta toward a patient-centered approach. Graham Calder, the first Regional Director of Pharmacy Service in Great Britain, Birmingham Region, participated in the ASHP-AACP workshop on clinical pharmaceutical practice and education held in Kansas City, United States in 1971 (Calder, 1971). Calder reflects on the experience as enlightening and in fact he was another European pioneer who witnessed clinical pharmacy beginnings in the United States and went on to contribute to the spread of clinical pharmacy models in the United Kingdom. These encounters may well explain the highly clinical pharmacy-oriented services in the hospitals in Malta and the United Kingdom. In the United Kingdom, the movement of clinical pharmacy practice in the hospitals spread throughout the country, and in 1981, the UK Clinical Pharmacy Association was established.

The clinical services in hospitals in Europe are expanding. For example, in a rehabilitation hospital in Malta, 61% of the pharmacist time is dedicated to clinical activities, 27% to administrative services, and 12% to other activities (Wirth et al., 2009). In Malta, a number of studies have shown the impact of clinical pharmacy services in the acute hospital setting within particular specialties, including cardiology (Agius Decelis et al., 2015), psychiatry (Bugeja et al., 2015), and rheumatology (Grech et al., 2013).

Standardization of clinical pharmacy practice in the hospital contributes to quality of patient care (Mamo et al., 2013). The development of Medication Assessment Tools as evidence-based instruments intended to support clinical pharmacy services in ensuring appropriateness of drug therapy was started by the research group led by Professor Steve A. Hudson from the University of Strathcylde, Scotland (McAnaw et al., 2003). Innovatively developed Medication Assessment Tools were implemented in Maltese hospitals for stroke (Gauci et al., 2017a), atrial fibrillation (Gauci et al., 2017b), and rheumatology (Grech et al., 2016). Pharmacist contribution to patient care includes the contribution of the pharmacist in rational drug therapy selection based on predictor models, such as prediction of analgesic consumption postcesarean (Buhagiar et al., 2011) use of antibacterial agents in peripheral arterial disease (Zammit et al., 2011; Vella et al., 2016) and pharmacogenetic testing (Wirth et al., 2016).

The evolvement of clinical pharmacy services in hospitals in Italy followed a different pattern of development. Hospital pharmacists initially carved a unique contribution related to the strengthening of clinical pharmacology and epidemiological studies. This was an indirect excellent contribution for Italian pharmacists to participate in the generation of scientific data that contributes to improved pharmacotherapy selection and access to therapy (Adami et al., 2012). One of the early centers that spearheaded this scientific development of pharmacy practice was the Mario Negri Institute, founded by Silvio Garattini in 1963 to undertake clinical research related to cancer chemotherapy, transplants, rare diseases management, and clinical trials. The perspective in Italy was that by bringing to the forefront the value of pharmacokinetic studies, pharmacoepidemiology studies, and clinical trials data, the pharmacist contributed to innovation in drug therapy (Garattini, 2006). In 1998, the Mediterranean Institute for Transplant and Highly Specialized Therapy (ISMETT) was developed in Palermo in collaboration with the University of Pittsburgh Medical Center Health System (Johnson et al., 2007). ISMETT was one of the earlier models of hospital pharmacy services with a major focus on clinical pharmacy services that was developed in Italy. Hospitals in Italy are developing clinical pharmacy services, such as the one by Francesco Cattel at the San Giovanni Battista Hospital in Torino (Uomo et al., 2012).

Clinical pharmacy practice in hospital settings in Europe is developing at different rates and in varying extents across the region. Reflections on the status of the pharmaceutical services in the hospital settings and identification of processes that will enhance the evolvement of the clinical services are steps taken up by countries, which are identifying appropriate approaches for a successful start up in extending clinical pharmacy interventions (Pawlowska et al., 2016). Services focusing on specific areas of clinical pharmacy include (1) medication reconciliation at admission—Ireland (Byrne et al., 2017); (2) integrated medicines management during patients' hospital stay—Sweden and Norway (Horvei Andersen et al., 2014), Germany (Lenssen et al., 2016), and the Czech Republic (Rychlickova et al., 2016); and (3) medication reconciliation at discharge—France (Van Hollebeke et al., 2016). The development process in some instances is directed to specific specialties, for example, cardiology—Northern Cyprus (Al-Baghdadi et al., 2017). In a number of instances, the service development starts off from pharmacy practice research projects many of which are a result of collaboration between faculties of pharmacy and practice settings.

Pharmacovigilance

The thalidomide tragedy in the 1960s and the shift of focus in community and hospital practice from product to the patient contributed to the notion of evidence-based medicine. Evidence-based medicine is a broad concept where the evidence is covering aspects of rational selection of the drug, including pharmacoeconomic aspects, as well as aspects of patient safety. The notion of "evidence" is sometimes questioned as to how much knowledge and clarity one can ascertain to achieve evidence (Lilja et al., 2008). The weakness of evidence provided to prescribers and pharmacists led to the inability to empower health care professionals to realize the risk-benefit attributes of the drugs in the individual patients. Some drugs, which were withdrawn in the late 1990s, such as Terfenadine, Astemizole, and Cisapride could perhaps be still useful medication for some patients if present pharmacovigilance processes were in place in pharmacy practice settings (Raine et al., 2012). The rapid developments which have taken place in the area of pharmacovigilance over the past years may be considered as an answer from pharmaceutical regulators and stakeholders to the lack of transparency and the limitations of the "evidence" notion.

The European Pharmacovigilance Research Group (EPRG) was established in 1993 with the support of the European Commission, actually before the foundation of the European Medicines Agency (Anon, 1993). The EPRG was coordinated by Sir Michael Rawlins, who today chairs the Medicines and Healthcare Products Regulatory Agency of the United Kingdom. The European Commission took the lead to review the processes of medicines safety monitoring and this led to the EU directive specific to the process of pharmacovigilance, which came into effect in 2012 (Borg et al., 2015). The practice of pharmacovigilance is driven by the European Medicines Agency through the national medicines agencies of the EU member states. There is an element of reliance on the pharmaceutical industry to design and put forward risk management plans through safety specifications elaboration and the development of risk minimization plans and risk management plans (Wiktorowicz et al., 2012). Such an approach is a characteristic to the European process of pharmacovigilance in contrast to the United States. The pharmacovigilance directive encourages prescribers, as well as patients to communicate signals, which contribute to the compilation of real-time data on medicine use. The impact of pharmacovigilance on pharmacy practice is the greater transparency and solid evidence that is generated which empowers prescribers, pharmacists, and patients to make an informed decision as to the risk-benefit of the drug therapy.

Pharmacovigilance processes are generating complex data from different sources (health care professionals, patients, marketing authorization holders). This concoction of data highlights the need for the participation of experts who can analyze this data and interpret the benefit-risk ratio with a macro- and micro-level of patient-safety perspective (Anelli et al., 2017). Pharmacists can contribute to the comprehensiveness of following pharmaceutical regulatory processes while keeping the patient safety perspective.

Pharmacy practice expanded to include pharmacovigilance activity when it is undertaken at the patients' bedside or when the pharmacist is fulfilling this contribution in a regulatory position.

The proactive approach taken in the 2012 EU directive has reduced the strict definition between pre- and post-authorization data (Hidalgo-Simon and Arlett, 2012). There is an apparent trend to favour even more such an approach and to shift pharmacovigilance processes earlier in a medicine life cycle with suggestions to consider replacing stages of clinical trials with pharmacovigilance (EU Commission Conference Report, 2015). The substitution of a part of the extensive preregistration processes with a robust pharmacovigilance activity is especially relevant with respect to orphan drugs and rare diseases where access to medications may be limited. Health care professionals and patients should have the opportunity for informed access taking into consideration that the data is limited for the specific medicinal product. The success of this model relies on good practice by health care professionals, and hence the positioning of the activity of pharmacovigilance at the center of pharmacy practice models becomes unquestionable. The challenges are not limited to how far the proactive approach for identifying unwanted effects should extend. The increasing use of advanced therapies, such as biological agents, including the advent of biosimilars and stem cell technology, pose questions in terms of applicability of the pharmacovigilance current process primarily due to the differences in the manufacturing process (Cilia et al., 2017). Advanced therapies may indicate the need for specially designed pharmacovigilance methodology and pharmacists should participate in this design using their experience in pharmacy practice scenarios.

Pharmacy Education: The Motor for Pharmacy Practice

The European Association of Faculties of Pharmacy (EAFP) was established in 1992 when a group of academics met at the Faculty of Pharmacy Paris-Sud, France. In 1994, EAFP Secretary General Professor Pierre Bourlioux prepared a report on curricula mapping in European schools of pharmacy. The report showed that chemistry was the major component of pharmacy courses covering 25%–46% of the programs. Topics of biological sciences (physiology, biochemistry, and anatomy) contributed to 12%–32% and medical sciences (pharmacology, pharmacy practice, clinical pharmacy) contributed to 11%–30% of the curriculum. In the 2011 PHARMINE study, medical sciences (28%) were the major area constituting a pharmacy course followed by chemistry (24%) (Atkinson and Rombaut, 2011). Over the period of 17 years, there was a shift in pharmacy education in Europe toward the clinical sciences supporting the trends identified in the practice of pharmacy in the areas of community and hospital pharmacy. European pharmacy schools present an element of variability in terms of curriculum distribution across the subject areas (Atkinson, 2014). The data for individual schools of pharmacy show that some curricula are still more chemistry-oriented than others. There is a tendency that the medical sciences content is allocated toward the end of the program rather than as an integrated feature of the curriculum. Nunes-da-Cunha et al. (2016) compared the extent of patient focus in pharmacy curricula in Europe with the curriculum in the United States. In the United States, the Accreditation Council for Pharmacy Education (ACPE) establishes standards for pharmacy education that focus strongly on patient-centered care. The data from the Nunes-da-Cunha et al. study indicate that in the United States, 51% of the course content is patient-centered. In Europe, the range varies from Malta (54.2%) and The Netherlands (50.3%) to Macedonia (21.1%) and Greece (19.7%).

Pharmacy education in the European Union is described through an EU directive that was established in 1985. The directive relates to subject areas included in courses leading to a degree in pharmacy. The 2005 EU directive provides for mutual recognition of professional qualifications within member states. The EU directive stipulates a duration of studies of at least 5 years and highlights the requirement of at least 6 months traineeship in a community or hospital pharmacy. Yet the directives aiming at homogeneity in the pharmacy curriculum in the European Union allow for heterogeneity in the framework adopted for the pharmacy courses. Some programs are offered as integrated 5-year courses leading to a Master-level degree. Other programs adopt the Bologna Convention consisting of a two-cycle program, the first cycle is of 3 or 4 years leading to a Bachelor degree, which constitutes an academic scientific degree; and the second cycle is of 1 or 2 years, respectively, that leads to a Master-level degree in pharmacy. Variability also exists in the extent of experiential learning or internships offered in the program. Some programs in Europe provide internships in pharmaceutical industry and pharmaceutical regulatory settings in addition to the community and hospital practice.

Heterogeneity, which is contributing to functional pharmacists mobility in the European Union, provides for flexibility and opportunities for fine-tuning of pharmacy education toward specific national needs. At the same time, pharmacy educators are aware of the forces of change and transformations taking place in pharmacy practice, which inevitably have to be taken into consideration in the shaping of a contemporary pharmacy education program. EAFP has an advocacy role to liaise with stakeholders from the hospital, community, industrial, and international partners in pharmacy education. EAFP provides a network among educators and stakeholders to reflect on the needs and expectations of society from pharmacy schools. There are a number of dilemmas that are faced when navigating shifts in pharmacy programs to reflect a move toward patient-centered course content. It is painful to identify course content that is no longer relevant. It takes hard work, diplomacy, and leadership to support academic staff to reorient their discipline to embrace a patient-centered approach while maintaining the characteristics of a science-based approach. During the 2017 EAFP Annual Conference in Helsinki, a stakeholders' roundtable discussion was organized to identify consensus areas of needs that pharmacy educators should address. The four areas identified were: (1) maintaining a science-practice curriculum, (2) adopting teaching methods that maintain student involvement, (3) supporting students to become team members, and (4) sowing the seed of curiosity to instill the quest for lifelong learning. Transcribing intelligently fundamental sciences into medical sciences remains a challenge facing tomorrow's evolvement of pharmacy education to satisfy the needs of pharmacy practice integrating clinical pharmacy and pharmaceutical care.

Postgraduate education acts as a catalyst of change by supporting pharmacists in career development and providing them with leadership skills. Innovative perspectives nurture pioneering teams that will steer advanced pharmacy practice models to meet the transformations necessary to navigate the forces of change. There are a number of specialized Masters programs offered by faculties of pharmacy, which present opportunities for further education to pharmacists. Specialized Masters, which are relevant to pharmacy practice are offered in areas of clinical pharmacy, community pharmacy, hospital pharmacy, pharmacovigilance, and pharmacoeconomics. Programs, which incorporate aspects of experiential reflections are valuable in empowering the graduates with a practice analytical skill that makes them proactive toward enlightening and remodeling pharmacy practice.

There are countries in Europe where a specialization in hospital pharmacy is required to be followed before pharmacists are engaged as hospital pharmacists. The programs for the specialization vary in duration (2–4 years postgraduate) and in content (administrative vs. technical and clinical). Many programs focus on the administrative processes linked to hospital pharmacy. The European Association of Hospital Pharmacy is working on a project to achieve a common framework for hospital specialization so as to ensure recognition of the specialization between countries signatories to the common framework.

The emerging trends of a patient-centered education at the undergraduate level and the increased needs for patient focus in the pharmacy practice settings are a force to entice pharmacy educators to take the lead and guide the profession to move towards homogenized skills for patient-centered pharmacy practice. The increasing clinical pharmacy services required to provide the professional services, which are unique for the community pharmacist and the distinctive contribution of pharmacists to pharmacovigilance, indicate that clinical pharmacy aspects are not exceptional to hospital pharmacy settings. The situations where patients are discharged from hospital to community care earlier compared to previous years and patients in the community are using complex medication, such as self-administering biological agents for the management of rheumatoid arthritis, inferr an aspect of shared care between the hospital and community pharmacy practice scenarios. The developments of professional doctorates in pharmacy, which focus on a patient-centered approach, are a means of providing level 8 doctoral study for pharmacists. Professional doctorate programs are postgraduate courses, which rely on three pillars (1) enriching the graduate with advanced clinical skills; (2) providing the opportunity to develop reflective and analytical skills through experiential learning at pharmacy practice rotations in areas of hospital pharmacy, community pharmacy, and pharmacovigilance; and (3) undertaking advanced pharmacy practice research. A doctorate in pharmacy program, which encompasses practice and a research component was launched in 2014 leading to a Doctorate in Pharmacy degree is offered by the Department of Pharmacy at the University of Malta in collaboration with the College of Pharmacy of the University of Illinois at Chicago, United States. Pharmacists following the program experience the perspectives of health-systems and the implementation of clinical services for European and US models. The program has an international audience and currently pharmacists from 16 countries have embarked on the course. This strengthens the dynamics of learning where students share their pharmacy practice experience from different countries. Graduates from this program are taking the lead to pioneer innovation in pharmacy practice services when they return to the home countries.

Pharmacy Practice Research: Pioneering the Transformations

The European Society of Clinical Pharmacy (ESCP) was founded in 1979 with the intention of supporting quality and innovation in clinical pharmacy. During ESCP conferences, scenario analysis workshops are organized to identify driving forces of change for clinical pharmacy and the profile for the pharmacist as a "care manager" was described (Leufkens et al., 1997). Experimentation to create a profile, which provides an additive contribution to positive patient care outcomes and not a meager mirror of a physician or the nurse, is essential. A care manager profile for the pharmacy practice professional prepares a pathway for acceptability of such a role by the pharmacy profession and other players (health care professionals, administrators, patients), and for engaging economic support. The care profile is not a static status which, once achieved, the profession can rejoice and sit on its laurels, as it needs a continuously dynamically changing status. The profession requires drivers to ensure that the quest to establish an advanced practitioner profile fits the upcoming requirements of society. Pharmacy practice research is a resourceful tool to ensure sustainability. Research is pivotal to testing, refining, and implementing innovative pharmaceutical service developments. Audit and quality system checks, incorporated within a practice research, complement to the advancement of pharmacy practice models. The next step forward in pharmacy practice research is the direct application to practice of the outcomes and deliverables of scientific-driven studies.

An innovative characteristic to the pharmacy course, introduced in the 1970s by the Department of Pharmacy of the University of Malta, is a pharmacy practice project, which pharmacy students undertake over a period of 3 years as part of their studies. The project is developed as a study unit within the course and is intended to provide development of skills in pharmacy practice research and at the same time students are encouraged to immerse in projects that lead innovation of pharmacy practice interventions. This experience in introducing pharmacy research at the undergraduate level has now been introduced by a number of pharmacy schools in Europe.

Managing the Forces of Change

Pharmacy practice has evolved rapidly in the past 50 years when compared to the practice during the last thousand years. New advanced therapies, such as the biologicals combined with fast developments in information technology, which led to restructuring of data

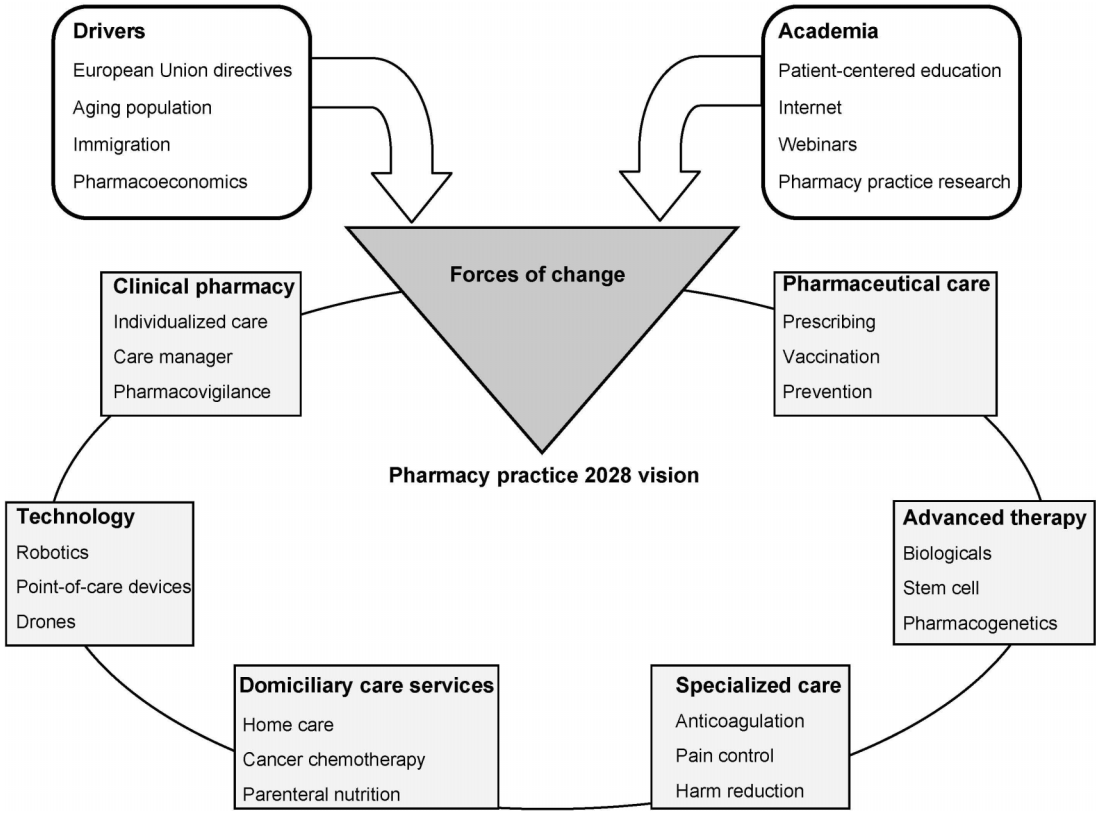

Fig. 1 Pharmacy practice 2028 vision.

storage and retrieval, drug information systems, and big data influence significantly decision-making. The political changes in Europe, led to dropping of barriers between countries, had their effect on health care and consequently on pharmacy practice especially with regards to accessibility to medicines. Political considerations influenced the harmonization of regulatory sciences, which in Europe led to the establishment of the European Medicines Agency. The European Medicines Agency served as a significant force resulting in advancements in pharmacy practice. Reimbursement schedules, the aging of the population, cultural, and social influences, such as immigration, and, not least, the accomplishments of many pharmacists will have an impact on the profession in the next years.

Fast-forward to 2028, forces of changes that can be predicted include metamorphosing concepts of clinical pharmacy and pharmaceutical care, technology, domiciliary services, specialized care, and advanced therapies (Fig. 1). The concept of clinical pharmacy is moving to individualized care where pharmacists need to intervene, as the care manager, to holistically manage a patient. Pharmaceutical care services are expanding beyond traditional aspects to include vaccination, prescribing, patient empowerment, and disease prevention. Pharmacy practice will need to catch up with technology where robotics are incorporated in service developments changing the landscape of the operations of pharmacy practice models, point-of-care devices for biological parameters monitoring are expanding and relying on information technology for real-time data transfer, and drones may be the upcoming tool to be considered in health system delivery. The need for domiciliary services to cater for patients receiving drugs that were previously looked at as hospital items, such as parenteral nutrition, cancer pharmacotherapy, palliative therapy, and medical oxygen therapy, is on the increase. With the expansion of drug therapy, patient management is truly becoming highly specialized for diabetes, anticoagulation, harm reduction, drug misuse, and pain control to name a few examples. The introduction of advanced therapies, such as biologicals, stem cells, and the application of pharmacogenetics to guide therapy form an element of the forces of change in pharmacy practice.

Multiple factors which range from geopolitical forces in the European Union, including the much needed revisiting of directives related to health that are aligned with contemporary scenarios, social factors, such as an aging population, delay in parenthood, smaller families, immigration, and financial factors including pharmacoeconomic aspects are driving forces of change. Academia, through education and research, is a fundamental structure that needs to be on the lookout to support the profession to steer through the forces of change and recognize the contemporary drivers. Patient-centered orientation in pharmacy and striking the optimum balance between the science and practice skills are the challenges academia is handling. Taking up the opportunities presented by technology to alter classic methods of teaching to incorporate distance learning, online learning, hybrid models, and webinars gets academia closer to today's students and pharmacists who are open to further academic opportunities. Liaising with pharmacy practice sites to support pharmacy practice research provides the impetus for the profession to test the waters into new models of pharmacy practice for the vision 2028.

Pharmacy Practice in Australia and New Zealand

Arjun Poudel, Esther T.L. Lau, Gregory J. Kyle, Lisa M. Nissen, Queensland University of Technology, Brisbane, QLD, Australia

History of Pharmacy Practice in Australia and New Zealand

Australia: The development of pharmacy practice in Australia followed the English tradition from the time of the First Fleet (Hattingh et al., 2013). There was no recognized role for pharmacists, and they competed with doctors, grocers, and retailers for professional recognition. The first pharmacist of Australia was John Tawell who started his chemist shop business in 1820 (Hattingh et al., 2013). A medical board certified him to work as an apothecary and to compound and dispense medicines (Hattingh et al., 2013). The pharmacy practice was casual and did not require qualifications, and activity was unregulated. It was not until the late 19th century that the first major legislative controls to regulate pharmacy practice were introduced (Hattingh et al., 2013). In 1901, the six colonies or states of Australia had a licensing system for selling poison, and groups of druggists and chemists established an organized pharmaceutical society colonially to protect the public from untrained quacks (Hattingh et al., 2013; PSA, 2017b). These colonial societies were modeled on the Royal Pharmaceutical Society (Pharmaceutical Society of Great Britain) and exerted a powerful force on the establishment of pharmacies and pharmacy practice in Australia. These societies developed the first written standards in pharmacy education, ethics, and qualifications, and influenced the development of pharmacy legislation in each state. It is assumed that they also maintained the first pharmacy schools in Australia. Through pharmacy registering authorities, state and territory legislation regulated the profession all over Australia until the pharmacy board was established. This authority was also responsible for registering pharmacists in each jurisdiction, until later when national registration was implemented under a Pharmacy Board of Australia (PBA) (Hattingh et al., 2013). The Pharmacy Act 1956 also introduced restrictions on titles to own pharmacies and rights to practice as a pharmacist. The enforcement of the legislation was later assigned to the pharmacy boards.

A significant contribution in developing pharmacy practice in Australia was made by three-core professional organization, namely, the Pharmaceutical Society of Australia (PSA), the Society of Hospital Pharmacists of Australia (SHPA), and the Pharmacy Guild of Australia (PGA). PSA is the national professional pharmacy organization representing Australia's pharmacists working in all sectors and across all locations. Their main aim is to improve pharmacy practice via an extensive program of education and professional development activities across Australia (PSA, 2017a). SHPA is the national professional organization representing pharmacists, interns, students, and technicians practicing in public and private hospitals and other health services in Australia. PGA is a national employers' organization that represents and promotes the value of the role of community pharmacy in Australian health care system (The Pharmacy Guild of Australia, 2017).

New Zealand: Pharmacy practice in New Zealand was also significantly influenced by the British model. Alexander Eccles was the first pharmacist in New Zealand, who opened the pharmacies in Napier and Hastings (Otago, 2013). The New Zealand Pharmacy Act (1880) introduced the registration of pharmacists, which was superseded by the Pharmacy Act (1939) (Mclintock, 1966). The Pharmacy Act (1939) gave power to the Board of Pharmaceutical Society of New Zealand to oversee regulation and advertising of medicines, and prohibited pharmacist from specified methods of selling drugs. To practice as a pharmacist, membership of the society was compulsory (Analyst, 1940).

The Pharmacy Board of New Zealand is composed of registered pharmacists acting as proprietors, pharmacists (members) of pharmaceutical society, and a barrister assigned by the Ministry of Health. The pharmacy board controls the training, registration, disciplining, and examinations of pharmacists, and appoints a board of examiners and a disciplinary committee. A board of examiners consists of six members where three are nominated by pharmacy board, two by the approved schools, and one by the

Ministry of Education. All pharmacies must be under the provision of the Pharmacy Act (1970), the Poison Act (1960), and the Dangerous Drugs Act (1927). Pharmacists are restricted for retail sale of a huge number of drugs and poisons. The Pharmaceutical Society of New Zealand is a professional, membership-based association representing pharmacists and technicians in New Zealand. They provide training, education, ethics, and status of pharmacists for continuing the professional development (Benrimoj and Frommer, 2004). The Pharmacy Council of New Zealand (PCNZ) was established under Health Practitioners Competence Assurance Act 2003 (HPCAA), which is responsible for the registration of pharmacist and promotion of good pharmacy practice (Pharmacy Council of New Zealand, 2017). In addition to the legal issues that need to be considered when making decisions about patient's clinical management and care, pharmacy practice also involves wide range of decisions about professional and business responsibilities and obligations. The existing legislations and acts ensure that the specified standards of pharmacy practice are met.

Health Care System and Funding

A good health system is one that delivers quality services to all people, when and where they need them (Health Systems, 2017). Health systems in Australia and New Zealand aim to offer universal coverage and publicly funded access to essential health services. Australia and New Zealand have implemented national medicine policies that aim to provide equitable access to cost-effective and safe medicines. Australia's National Medicines Policy is a well-established endorsed framework that aims to improve positive health outcomes for all Australians, focusing mainly on easy access and wise use of medicines (Policy, 2017). "Medicines New Zealand," New Zealand's medicines policy, was launched in 2007 with the aim to promote quality, effective, and optimal use of medicines (Francis, 2014). Although each country has adopted a different approach, both are globally recognized for their execution of national medicines policies (Babar and Vitry, 2014).

Australia: The health care system of Australia is a multifaceted web of both public and private health service providers, participants, settings, and supporting mechanisms (Benrimoj and Frommer, 2004). The responsibility for health care is shared between Australia's Federal, State and Territory, and local governments. Each has roles in funding, policy developments, regulation, and timely delivery of health care service. Some responsibility of funding and regulating the health system between the commonwealth and the state and territory governments are as follows (Biggs, 2013).

Commonwealth government is mostly responsible for

- Medicare, the national scheme, which provides free or subsidized access to clinically relevant medical, diagnostic, and allied health services;
- Pharmaceutical Benefits Scheme (PBS), which subsidizes universal access to thousands of prescription medicines;
- purchasing of vaccines for the national immunization program;
- medical research grants;
- subsidizing for aged care services, such as residential care;
- health professionals education; and
- therapeutic goods and medical devices regulation.

States and territories are mainly responsible for

- management and administration of public hospitals;
- preventive services delivery such as immunization programs, cancer screening;
- ambulance and emergency services;
- community and mental health services funding and management; and
- public dental clinics.

Health care services are provided by a variety of public and private organizations and health care professionals who can be employed by either or both sectors. Examples of services include public health and preventive services in the community, primary health care, emergency health services, hospital-based treatment in public and private hospitals, and rehabilitation and palliative care. Public sector health services are operated by all levels of government, which include public hospitals, visits to outpatient clinics, and general practitioners (GPs). Private sector health service providers comprise private hospitals, community pharmacies, medical practices, and a mix of public and private services (Benrimoj and Frommer, 2004; Remuneration and Regulation of Community Pharmacy, 2016). Private health insurance and out-of-pocket payments by patients mostly fund the activity of private hospitals, which is successively subsidized by the government of Australia by 30% reductions on member contributions to private health insurance (Pharmacy Guild of Australia, 2010). Local governments deliver community-based health and home care services. They also facilitate public health and health promotional programs such as nutrition awareness and weight loss programs, immunization services, and smoking cessation.

In 2015–16, health expenditure in Australia accounted for 10.3% of gross domestic product (GDP) (Australian Institute of Health and Welfare, 2017). Health care expenditures are funded through taxes, a Medicare levy, and private health insurance financing. Australia introduced Medicare in 1984, which is a universal public health insurance scheme funded by the Australian Government, with copayments by users when services are not "bulk-billed." Bulk billing is a payment option under the Medicare system where a GP bills Medicare directly for the services provided to patients, so patients have no out-of-pocket expenses. Medicare provides free treatment to Australians, permanent residents, and some overseas visitors in public hospitals, subsidization of wide

range of prescription medicines costs under PBS, and payments for professional health services itemized in the Medicare Benefits Schedule (MBS). Medicare mostly covers subsidized or free treatment by medical practitioners, optometrists and also dentists in specific circumstances, and allied health professionals. Private health insurance covers fully or partly the cost of health care as a private patient. It is available as hospital cover or ancillary or extras cover (general treatment cover). Hospital cover helps the cost of some or all in-hospital treatment including hospital accommodation and fees of a doctor as a private patient. General treatment cover pays the cost of nonmedical health services such as dental treatment, optometry, chiropractic ambulance, and physiotherapy (Moles and Stehlik, 2015; Public and Private Healthcare, 2016). Similarly, private health hospital cover insures patients against some or all of the additional costs of being a private patient in either a public or private hospital. Medicare will cover 75% of the MBS fee for associated medical costs (Private Health Insurance Ombudsman, 2015).

The key components of Australia's health system related to medicines are the PBS Schedule and Repatriation Schedule of Pharmaceutical Benefits Scheme (RPBS). These aim to facilitate timely, affordable, and reliable access to wide range of life-saving pharmaceuticals with government subsidized price. The Australian Government negotiates medicine price with the supplier to subsidize medicines that are necessary to maintain the health of the community. This is achieved by carefully assessing the therapeutic benefits and costs of medicines, including comparisons with other treatments where appropriate. PBS and RPBS are an integral part of Australian Government's broader National Medicines Policy that aims to deliver medication and other necessary services to achieve optimal health outcomes (Hattingh et al., 2013; The Pharmaceutical Benefits Scheme, 2016). Both PBS and RPBS are governed by Medicare Australia. Eligible people to receive this fund for health must be a citizen of Australia, or those who hold permanent resident visa, or those with verified relationship with Australian citizen such as on spousal visas, as well as certain foreign visitors covered by reciprocal health care agreement (Hattingh et al., 2013; Moles and Stehlik, 2015). The PBS was started in 1948 that includes "life saving and disease preventing medicines" available free of charge for Australian community (Moles and Stehlik, 2015; The Pharmaceutical Benefits Scheme, 2016). It is regulated by the National Health Regulations, governed under the National Health Act 1953 (Commonwealth). The pharmaceutical manufacturer makes an application for a PBS listing, which is assessed by Pharmaceutical Benefits Advisory Committee (PBAC). The PBAC examines the efficacy, safety, and cost-effectiveness of the proposed listing. They also make recommendation of medicines to the Federal Minister for Health about its availability as pharmaceutical benefits, maximum quantity, number of repeats available for each item, and recommend restrictions in some cases. To perform its function, PBAC has two subcommittees: Economics Subcommittee and the Drugs Utilization Subcommittee. The former committee advises on cost-effective policies and evaluations of cost-effective aspects of major submissions, and the latter committee monitors the patterns and trends of medicines used within the PBS. To improve transparency of the PBS listing process, "public summary documents" are published to make aware and inform the stakeholders about the rationale of specific recommendations and enhance the understanding of overall listing process (Hattingh et al., 2013). The RPBS established in 1919 is subsidized by the Department of Veterans' Affairs (DVA), under the Veterans Entitlements Act 1986, which provides pharmaceutical benefits to veterans having DVA card and to the eligible dependents (Hattingh et al., 2013; The Pharmaceutical Benefits Scheme, 2016).

For Australia's Aboriginal and Torres Strait Islander people with existing, or at risk of having chronic diseases, the closing the gap (CTG) PBS copayment program was established to reduce the cost for PBS medicines. If a prescriber believes that patient did not take prescribed medicines and experienced setbacks in the management of chronic disease or are unlikely to adhere to medicines regimen without support through the program, then they endorse prescription with CTG to allow the pharmacist that dispensing of the prescription should be done with copayment relief. CTG prescription for medicines listed on the PBS schedule draws a lower or nil patient copayment, that is, general patients with CTG prescription will pay the present concessional rate for every PBS medicine and concessional patients with CTG prescription will not be charged the patient copayment for any PBS item (Moles and Stehlik, 2015).

New Zealand: The New Zealand health care system includes a complex network of organizations and people. The health care system is funded primarily by the central government through the Ministry of Health. New Zealand has universal health coverage system which is publicly funded predominantly and services are provided via public, private, and nongovernmental sectors (Health Systems in Transition, 2014). There are 20 District Health Boards (DHBs) responsible for planning, funding, and delivering most publicly funded health services in their districts. DHBs arrange funding for primary care, hospital services, public health services, aged care services, and services provided by other nongovernment health providers. Public hospitals are owned and funded by DHBs, and the hospital care is provided free of charge to patients. Private hospitals offer elective services on contract to DHBs and on a private basis. Since 2002, primary health organizations (PHOs), a local structure designed to establish networks of GPs and other primary health providers, started providing primary health care services. The 36 PHOs deliver comprehensive primary health care in the community where children below 6 years of age pay no fees (Health Systems in Transition, 2014). PHO is funded on the basis of their enrolled population where most patients pay additional fees for service. However, significant additional government funding has later reduced the fees for most patients and has increased the consultation rates.

Uses of pharmaceuticals in New Zealand are governed by the New Zealand Medicines and Medical Device Safety Authority (Medsafe) and the Pharmaceutical Management Agency (PHARMAC). Medsafe administers the Medicines Act and Regulations ensuring that medicines used in New Zealand are safe and effective. PHARMAC on the other hand decides subsidy levels on medications approved by Medsafe. PHARMAC is responsible for managing the New Zealand Pharmaceutical Schedule and negotiates the purchase of drugs from suppliers, successfully controlling supply-side expenditure (Health Systems in Transition, 2014).

The Pharmaceutical Schedule includes a list of subsidized medicines, appliances, and other relevant products that can be prescribed by general practitioners, nurses, dentists, and midwives. Although patients have to make small copayments, concession procedures ensure that they are affordable. Copayments for most prescriptions is NZ$5 per item. PHARMAC is the only procurer of publicly subsidized medicines, and is successful in negotiating costs and controlling supply-side expenditure. It decides which medicines to fund, sets subsidy levels and conditions, and ensures that expenditures are within the allocated budget (Health Systems in Transition, 2014).

New Zealand has slightly higher health expenditures as a percentage of GDP than the Organization for Economic Cooperation and Development (OECD) average. Health expenditure as a percentage of GDP rose from 6.8% in 1990 to 10.1% in 2010 to 11% in 2014 (Health Systems in Transition, 2014). Health expenditures are funded through taxes, private health insurance financing, and by those receiving the services (direct payment). In addition to the funding from Ministry of Health and DHBs, Accident Compensation Corporation (ACC) is the other major public funder that provides comprehensive, no-fault personal injury cover for all New Zealand residents and visitors injured in New Zealand (Statistics New Zealand, 2010). They are funded through employer, employee, and car-licensing levies. They also provided funding for hospitals that has incurred accident-related care costs and pays care-related expenses to private health insurances or providers for approved treatment. This scheme has been highly successful in New Zealand (Health Systems in Transition, 2014).

The health care landscape around the world is changing and facing similar challenges to those seen in Australia and New Zealand such as the ageing population, the increasing prevalence of chronic diseases, increasing cost of medicines, new technologies and products, and the rising costs for human resources and other workforce issues (Pharmacy Guild of Australia, 2010). Future affordability of services and equitable health care is a challenge. The traditional approaches and models of health care service delivery require transformation. Some countries have recognized that the prominent ways to tackle this problem is to start with cost-effective implementation of primary health care. One approach would be to involve pharmacist to deliver public health interventions as pharmacists have been identified as having an increasingly important role in the primary care team (Duckett and Breadon, 2013; Page and Somers, 2015; Pharmacy Action Plan, 2016).

Practice Standards and Guidelines

Professional practice standards (PPS) and guidelines related to pharmacy practice provide the framework to maintain and improve the quality of pharmaceutical services, forming an essential aspect in regulating the profession (Hattingh et al., 2013).

Australia: In Australia, practice standard and guidelines are developed by major pharmacy organizations such as the PSA, the SHPA, and the PGA. The PSA's Code of Ethics and PPS articulate the expected standards of professional behavior of pharmacists in Australia. A number of practice guidelines are also developed by the PBA. PBA endorses the PPS. Pharmacists are advised to ensure that, in addition to complying with the code of conduct for registered health practitioners, they be guided by the code(s) of ethics relevant to their practice (Pharmacy Board of Australia, 2014). The PPS lies within a broader hierarchy of guidance underpinning and supporting the practice of pharmacists as shown in **Fig. 1**. Commonwealth, State and Territory Legislation forms the foundation on

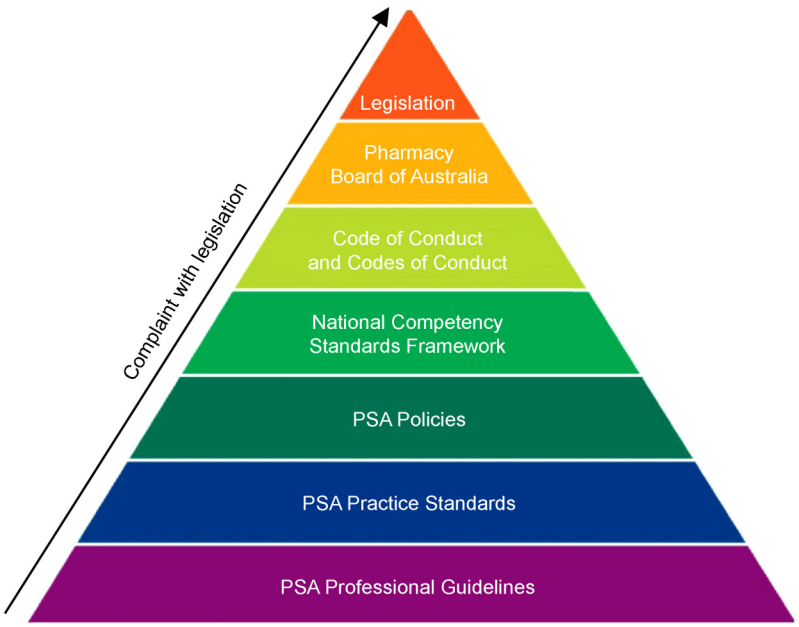

Fig. 1 Hierarchy of guidance and regulation of pharmacy practice in Australia.

which pharmacy practice is based. It is portrayed at the top of the pyramid (Fig. 1) depicting the various hierarchies of guidance and regulation. PPS reinforces the professional practice of all pharmacists in Australia, regardless of the role, scope, level, or location of practice. It encompasses both professional services such as dispensing and counseling, and selected specialty standards such as specialized medicine information services (Hattingh et al., 2013).

Practice in accordance with the PPS must not be interpreted as permitting a breach of the law, or discouraging compliance with legal requirements. At all times, the pharmacist must comply with legal obligations. The PBA is the registering authority of pharmacists in Australia. The board develops standards, codes, and guidelines for the pharmacy profession and also involves in approving accreditation standards and accredited courses of study. These guidelines and standards articulate the values of the pharmacy profession and expected standards of ethical behavior of pharmacists toward individuals and community (PSA, 2017a). The competency standards describe the skills, attitudes, and other attributes (including values and beliefs) attained by an individual based on knowledge and experience that enable the individual to practice effectively as a pharmacist (PSA, 2016). Professional practice and quality standards ensure that professional services deliver optimal health outcomes. Finally, practice guidelines support pharmacists and their staff in the implementation of quality professional services. These guidance and framework support pharmacists to practice professionally and ethically so that expected standards are met, and health and well-being of patients are improved. A collaborative forum to progress tasks and initiatives associated with the national competency standards for pharmacists was established in 2011 known as Advanced Pharmacy Practice Framework Steering Committee. This later in 2014 transitioned into the Pharmacy Practitioner Development Committee (PPDC) which focuses on the development of pharmacist practitioners through consideration of competencies and scopes of practice (Advanced Pharmacy Practice, 2017). PPDC mainly focuses on issues around pharmacist prescribing, implementation of an advanced pharmacy practice recognition model, strategies relating to competencies, and scopes of practice in the context of overall pharmacist practitioner development.

New Zealand: In New Zealand, regulation of the pharmacy profession is achieved through the Health Practitioners Competence Assurance Act 2003 (HPCAA) which dictates that clinical, cultural, and ethical competencies must be integrated into the learning objectives of pharmacy programs. The Pharmaceutical Society of New Zealand (PSNZ), PCNZ, and NZ Hospital Pharmacist' Association (NZHPA) develop and implement PPS and guidelines for pharmacists. The PCNZ is established under the HPCCA with a duty to protect the public and promote good professional practice by pharmacists. It achieves this through a range of roles including review and promotion of the competence of pharmacists, prescribing the qualifications required for scopes of practice within the profession, and accrediting and monitoring educational institutions and the programs of study they provide (Australian Pharmacy Council, 2012). The Health and Disability Services—Pharmacy Services Standard is the basis for relating good practice and promoting constant advancement in the quality of pharmacy services (New Zealand Standard, 2010). The Pharmacy Services Standard aims to provide safe and appropriate services which complies with the legislation, timely services which are planned and delivered in an appropriate manner, and clean and safe environment to provide service to the consumers. This standard defines the quality and safety requirements for the provision of community and hospital-based pharmacy services and clinical pharmacy services not provided from a pharmacy.

Pharmacists around the world are facing new challenges related to an increasingly complex health care system and their roles are changing significantly. Therefore, it is important that pharmacists follow defined practice standards and guidelines to protect themselves against potential litigation, and to respond to the specific needs of individuals and the community (Hattingh et al., 2013). Pharmacy practice standards and guidelines, therefore, aim to achieve consistency in service delivery and maintain continuous quality improvements so that the risks of misadventures are minimized.

Pharmacy Education

Formerly, pharmacist training in Australia and New Zealand was based on an internship system. From early 1960s, this has continuously advanced into a high standard university program producing qualified pharmacists with advanced clinical skills (Hattingh et al., 2013; Marriott et al., 2008; Otago, 2013). Individuals are eligible for registration as pharmacist when they complete their program of study accredited by the Australian Pharmacy Council (APC) and approved by the PBA or the PCNZ and registered on the Board or Council's website (Australian Pharmacy Council, 2012). Accredited programs are offered either as an undergraduate degree or postgraduate entry with bachelor's degree being the minimum requirements for registration.

Australia: The duration of pharmacy program that is eligible for accreditation should be consistent with the "volume of learning" descriptor of the Australian Qualifications Framework (Australian Pharmacy Council, 2012). University program of study exposes students to real pharmacy practice through placement programs, thus enabling them to provide patient-focused services (Hattingh et al., 2013). These placements form a significant element of several pharmacy programs and are obligatory requirement for accreditation of the program by the APC (Hattingh et al., 2013). Currently, the APC is the designated independent accreditation agency for Australian pharmacy under the National Registration and Accreditation Scheme (Hattingh et al., 2013). Graduates after completing their qualification from an approved Masters or Bachelors programs are required to complete a 12-month internship to get registration with PBA or PCNZ (Australian Pharmacy Council, 2012; Hattingh et al., 2013). This internship contains supervised practice, with an approved preceptor, continuous assessment, and participating in education program proposed by an Intern Training Program (ITP) provider approved by the APC (Australian Pharmacy Council, 2012; Hattingh et al., 2013). The ITP providers include some universities, the Pharmacy Guild of Australia/New Zealand, and the Pharmaceutical Society of Australia/New Zealand. The final requirement of all intern pharmacists to achieve a registration as a pharmacist is to undertake examinations

that are designed to test their level of competency (Australian Pharmacy Council, 2012). In December 2016, there were total of 30,368 registered pharmacists in Australia, which comprises 27,452 as general registration, 1777 as provisional registration, 1132 as nonpracticing registration, and 7 as limited registration (Pharmacy Board of Australia, 2017). A 2016–20 Action Plan of New Zealand Ministry of Health reported that there are about 3500 registered pharmacist across New Zealand (Pharmacy Action Plan, 2016).

In Australia, pharmacy education has experienced major structural changes over the past decade because of the substantial increase in the number of pharmacy schools and the number of pharmacists entering the workforce (Marriott et al., 2008). In 1997, there were 6 universities offering 6 undergraduate degrees, and in 2015 there are 18 universities offering 24 pharmacy degrees (Marriott et al., 2008; Pauline et al., 2004). The increasing number of pharmacy schools may be due to the large shortfall in the pharmacy workforce to meet the demand particularly in the regional and rural areas all over Australia (Marriott et al., 2008). None of the pharmacy school offers doctor of pharmacy (PharmD) degree in Australia; however, in addition to the research degrees like research masters or PhD degrees, many universities offer a range of postgraduate programs such as doctor of clinical pharmacy, master of clinical pharmacy, graduate diploma, or graduate certificate (Marriott et al., 2008). Majority of students directly enter into the pharmacy program from secondary school where their results from the previous study are the key selection criterion (Marriott et al., 2008; Pauline et al., 2004). The selection criteria may vary in different Australian school of pharmacy. Large number of students enter the undergraduate program following their secondary school final examination, but other modes of admission include transfer from another degree or completion of fast track course depending on the specific requirements of the universities (Marriott et al., 2008; Pauline et al., 2004). There are significant number of international students throughout the Australian school of pharmacy who are admitted following their completion of secondary education from their country of origin (Marriott et al., 2008; Pauline et al., 2004).

New Zealand: In New Zealand, there are two schools of pharmacy, the University of Otago and the University of Auckland (Pauline et al., 2004). The School of Pharmacy at the University of Otago celebrated its 50th jubilee in 2013, a milestone representing 50 years of pharmacy education (Otago, 2013). Initially, pharmacy was located in the Department of Pharmacology and Pharmacy within the Faculty of Medicine (Otago, 2013). In 1970, pharmacy became an independent department after moving into the Faculty of Science. Admission into pharmacy at the University of Otago is competitive and is based on the student's grades obtained from their previous course (Pauline et al., 2004). Students from the Maori and Pacific communities are favorably selected due to their high health needs and shortages of pharmacists from these communities (Pauline et al., 2004). At the University of Auckland, the School of Pharmacy was established in the year 2000 and most students get entrance directly into the pharmacy after their completion of secondary school. The entry is limited and competitive, and is based on the academic merit and an interview. Both universities in the New Zealand offer the postgraduate programs to continue developing the knowledge and skills of pharmacy.

Community Pharmacy

The part of the health care system that people have the most regular contact and the easiest access are often the community pharmacies. Community pharmacies offer an accessible, safe, and efficient professional primary health care service nationwide (Pharmacy Guild of Australia, 2010). Community pharmacists are the health professionals most assessable to the public. As the first point of contact between the general public and the health care system, pharmacists provide early intervention, prevention, health promotion, and overall management of health. Conventionally, the main providers of medicines for the population of Australia have been pharmacists and pharmacies. In the community, pharmacy is increasingly becoming a vital source of comprehensive health care services. However, pharmacy in Australia and New Zealand are changing. Pharmacy practice in community settings not only covers medicines supply but also information and services delivery to support quality use of medicines. Although the main purpose of community pharmacy is still the supply of medicines, it has been extended to the provision of professional advice via involvement in the primary health care services in consultation with GPs and other health professionals (Pharmacy Guild of Australia, 2010).

Australia: In Australia, the National Health Act 1953 and the Australian Community Pharmacy Authority (ACPA), an independent statutory authority established under section 99J of the Act, regulate the community pharmacy practice. Regulation includes pharmacist registration, standard courses to become a pharmacist, and setting and ownership of pharmacies. There are more than 5300 pharmacies in Australia that are located throughout the remote, rural, metropolitan, and suburban region. Of all health care providers, community pharmacies are often the most frequently accessed; the average Australian visits a pharmacy 14 times a year; about 300 million individual patient visits each year (Community Pharmacy, 2014). Approximately 3.9 million Australians ask health-related advice with their pharmacist each year. Among these 79% reported that they were happy with the advice and that the advice met their needs fully (Australian Bureau of Statistics, 2009). Availability of a pharmacist to provide the service through a community pharmacy has helped achieve current government's objective to reduce the number of unnecessary visits to a GP and the subsequent costs involved (Community Pharmacy, 2014).

The Pharmacy Guild of Australia negotiates a funding agreement with the Commonwealth government every 5 years. The Guild is committed to supporting and maintain the community pharmacy model as the most appropriate and efficient system of delivering medicines, medication management, and related services to the Australian public (The Pharmacy Guild of Australia, 2017). The present agreement, the Sixth Community Pharmacy Agreement (6CPA) 2015–20, permits pharmacy to collect practice incentive payments in six major areas: (1) dose administration aids, (2) clinical interventions, (3) primary health care as well as screening, risk assessment, and some chronic condition follow-up, (4) working with at least two other nonpharmacist health care professional,

(5) community services support along with needle exchange and opioid substitution dispensing, and (6) staged supply of medications especially for benzodiazepines, analgesics, and antidepressants (Moles and Stehlik, 2015). The other services that are reimbursed through this agreement are MedsChecks, Home Medicines Reviews (HMR), and the Residential Medication Management Reviews (RMMR). The MedsChecks services emphasize on self-management and education that is conducted in pharmacy. It is an in-pharmacy, consumer-centered service that aims to improve quality use of medicines by educating patients about the use of medicines, interactions involved, and any difficulties experienced with their medicines. On the other hand, HMRs are conducted often in stages and take much more time. HMR is a comprehensive clinical review of patient's medicines in their home by an accredited pharmacist on referral from the patient's GP. Nonaccredited pharmacist can still conduct the review however; they are not paid by MBS but by patients directly out of their own pocket. The pharmacist interviews the patient and records into a comprehensive report. This report contains findings and recommendations for consideration by doctors, patient, and other health care professionals (Moles and Stehlik, 2015). Similarly, a RMMR is a service provided to permanent resident of an Australian Government-funded aged care facility to assist consumers and their carers to better manage their medicines (Community Pharmacy Agreement, 2015).

New Zealand: In New Zealand, the Medicines Act 1981 regulates medicines, related products, and medical devices. The District Health Boards (DHB) manages health services such as the operating of hospitals, community pharmacies, and providing other community services. Service agreements have been made between DHBs and community pharmacies in different regions known as Community Pharmacy Service Agreements (Remuneration and Regulation of Community Pharmacy, 2016). Within these agreements, community pharmacies get remunerated for dispensing pharmaceuticals listed in the pharmaceutical management agency's (PHARMAC) New Zealand Pharmaceutical Schedule. Of more than 3500 practicing pharmacist in New Zealand, about 75% work in community pharmacies. There are around 1000 community pharmacies providing a range of services with over 1.3 million patients visit each year (Pharmacy Action Plan, 2016).

Cognitive pharmacy services delivered by community pharmacies in New Zealand include the adherence support service, that is, "Medicines Use Review" and the medication review service, that is, "Medicines Therapy Assessment" that are provided by accredited pharmacists (Campbell et al., 2017). These services unfortunately have difficulty gaining consistent funding by individual DHBs. Services such as "Community Pharmacy Anticoagulation Management Service" that provides safe reliable anticoagulant care with a consistently high level of anticoagulant control is funded only in few DHB areas. However, a newer model of service in community pharmacy, "Pharmacy Long-Term Conditions Service," that helps identify and register eligible patients to encourage better medicine adherence has better funding via a monthly fee per registered service user (Campbell et al., 2017).

Hospital Pharmacy

Pharmacists play an integral role in delivering health care services in hospital settings (Mak et al., 2012). Hospital clinical pharmacy services is a specialty field of pharmacy that has extended further from the traditional roles of compounding and dispensing medications, to more cognitive clinical aspects focusing more on patient-centered care. Throughout the medication-management process, hospital pharmacists assist in optimizing medication-related outcomes for patients (Ng and Harrison, 2010). Hospital pharmacists make up 18% and 13% of the pharmacist workforce in Australia and New Zealand, respectively (Pauline et al., 2004; Pharmacy Action Plan, 2016). Every year in Australia, about 10% of pharmacy graduates obtain intern training in a hospital sector, whereas others are employed in hospital pharmacy after they get registered (Moles and Stehlik, 2015). In contrast to other countries, Australia had no defined residency training program for pharmacists who desire to work in hospital setting until 2016 (Moles and Stehlik, 2015). Recently in 2017, SHPA initiated the first and only structured, formalized, supported, and accredited national pharmacy residency program in Australia.

With the changing needs and demands of modern health care, the practice of clinical pharmacy continues to evolve. Expansion of pharmacists' roles was facilitated by better understanding of drug-related morbidity and mortality which could be prevented by pharmaceutical services. Clinical pharmacy services are provided in all hospitals in New Zealand and Australia where a pharmacist routinely participates in both multidisciplinary and specialty ward rounds, with the explicit aim of reviewing and optimizing medications (Ng and Harrison, 2010; Pauline et al., 2004). A hospital pharmacy survey conducted in Australia reported that pharmacists will usually spend almost half of their time offering clinical services, providing training and education, and drug information (O'leary and Allinson, 2009). Similarly, in manufacturing, acquiring, and dispensing medicines, pharmacists spent 38% of their time and 15% time in medicines management and implementing hospital-wide activities like institutional drug policy management. Pharmacists who are involved in clinical services activities like reviewing prescription, recommendations of therapy (initiation, substitution or cessation of treatments, dose changes) have been reported to increase efficacy of treatment, symptom control, and reducing adverse reactions (Tan et al., 2014). With continuing input of pharmacists, a few hospitals have established electronic prescribing or medicines reconciliation systems (Pauline et al., 2004). During hospital ward visits and at discharge from hospitals, various types of clinical interventions are carried out by pharmacists that are documented for monitoring purposes and to detect recurring issues.

In large public hospitals, the majority of pharmacist work in multidisciplinary team and some specialize in a particular clinical department such as surgery, mental health, oncology, geriatrics, and pediatrics, whereas in smaller hospitals, one pharmacist may be involved in several departments (Moles and Stehlik, 2015; Pauline et al., 2004). Few newer roles for pharmacy graduates in hospital setting are in antimicrobial stewardship, medical admission pairing, emergency department, and surgical preadmission clinics. This

versatile role of hospital pharmacists is, however, underutilized to its full potential. There are reports arguing that although hospital pharmacist work in a team to improve care, patient information is not always transmitted to other sectors in a timely manner (Mak et al., 2012). In addition, unlike promoted in social media and advertised elsewhere that pharmacy services would be available 24 h a day and 7 days a week, most hospitals are providing the services only during routine business hours and an overnight on-call service (Moles and Stehlik, 2015).

The Way Forward: Expanded and Extended Role for Pharmacists

Traditionally, the pharmacist's role in health care was focused more on dispensing medications in accordance with a prescription. Their role has expanded over time to include more coordinated, cost-effective, and direct patient care such as medication management, medication reconciliation, continued supply of medicines, patient education and counseling, and preventive care. The evolving health care setting provides opportunity for pharmacists to become a part of a coordinated team that provides health care to their local community to better utilize scope of health professionals to increase accessibility to health care. The World Health Organization (WHO) and the International Pharmaceutical Federation (FIP) have recognized an expanded role for pharmacists for the purpose of improving patient care and drug therapy outcomes. A small number of expanded roles of pharmacists are explained in below sections as examples.

Integrating Pharmacy into the Broader Health Care Environment

Optimizing health professional's skills and knowledge into a robust integrated health care team will address the health care needs and ensures equitable health outcomes for all (An Integrated Health Care Framework for Pharmacists and Doctors, 2016). In many countries, the pharmacy profession has expanded considerably in professional service delivery and is recognized as an essential profession in the multidisciplinary provision of health care. Australia lags behind other comparable countries in terms of pharmacy integration across the health system, and in addressing the need for a more coordinated and collaborative approach to patient care (Remuneration and Regulation of Community Pharmacy, 2016). The uptake of models of care, such as e-health approaches, transitional care arrangements, and collaborative care models, that assists integration of pharmacists into wider health care environments is slow.

There are several reasons behind the slow integration of pharmacy into the broader health care environment in Australia. First, health policy development and implementation have occurred in isolation, both within and across jurisdictions. The PBS and community pharmacy have been treated separately from the MBS, and other areas of health policy, including hospitals, population health, private health insurance, e-health, and broader workforce. Second, instead of focusing on overall patient health outcomes, the remuneration and delivery of primary health care services were focused on individual health providers and practitioners. Third, efforts to enrich the access, effectiveness and harmonization via the health service delivery interventions were seen as threats rather than opportunities to deliver more cost-effective health outcomes. Fourth, digital health enablement in relation to the development of collaborative tools and take-up of eHealth has been slow (Remuneration and Regulation of Community Pharmacy, 2016) However, an integrated approach to health service delivery has been adopted recently by government and health care providers with greater focus on transitional care and referral pathways. Hence, in order for pharmacist to reach its full potential as health care providers, integration with the broader health care environment is very essential.

New Zealand, however, has recognized an enhanced role of pharmacists and has developed new models of integrated, person-centered practice known as Integrated Health Care Framework, where pharmacists and doctors could work together as part of the wider health care team. This framework also addresses existing collaboration and integration in current practice across New Zealand, and includes methods for enhancing these (An Integrated Health Care Framework for Pharmacists and Doctors, 2016). The framework highlights the significance of connecting the pharmacist with all members of a person's care team, including doctors, nurses, and the nonmedical prescribers. This framework also focuses on the clinical partnership between pharmacists and doctors for achieving an enhanced patient medication journey. The successful implementation of this strategy of pharmacist and doctors working together in a collaborative health care environment would support the current governments "One Team" Health Strategy of Ministry of Health, New Zealand. "One Team" is a better integrated and cohesive system that positions people and their families at the center of care so that health and disability workforce are utilized in most effective and flexible way (An Integrated Health Care Framework for Pharmacists and Doctors, 2016).

Pharmacists in General Practice (the Practice Pharmacist)

Integrating pharmacists into a general practice multidisciplinary team was explored in Australia which has gained professional commendation from pharmacy and medical organizations (The Pharmaceutical Society of Australia, 2008; The Society of Hospital Pharmacists of Australia, 2008). They define practice pharmacist as "a pharmacist who delivers professional services from or within a general practice medical center with a coordinated, collaborative and integrated approach with an overall goal to improve the quality use of medicines of the practice population" (Freeman et al., 2014). The concept of the practice pharmacist is supported by PSA, the Consumers Health Forum of Australia and United General Practice Australia. PSA provides members with a total package of continuous professional development trainings, practice support tools, and relevant external resources to support those who wish to explore the career pathway as General Practice Pharmacist.

The major role of a practice pharmacist would be to support GPs to minimize the risks associated with medicines and optimize patient outcomes through the quality use of medicines. This role has been broadly classified into three different levels: *patient level* that includes activities such as comprehensive medication review, medication reconciliation, therapeutic drug monitoring, and adverse drug reaction review; *clinician level* that included activities such as drug information, education, training for students, and registrars; *practice level* that includes activities such as clinical prescribing review and feedback, public health initiatives, pharmacovigilance, and medication recall (Famiyeh and McCarthy, 2017).

Integrating pharmacists into general practice enables pharmacists to work closely with GPs and their patients in delivering quality patient care. It would reduce fragmentation of care and medication misadventure by utilizing pharmacist's complementary skills and distinctive knowledge within the practice (Famiyeh and McCarthy, 2017). The general practice pharmacist can advise GPs on medication selection, conduct medication reviews, and provide prescribing advice to minimize harms associated with medications. Working collaboratively with pharmacist within the practice, GPs would be able to better care for patients and minimize the health care costs associated with adverse drug events and medication noncompliance.

Pharmacist Prescribing

Pharmacists are advancing their skills and knowledge in evidence-based practice and patient care. Traditional role of pharmacists has rapidly evolved which is enabling them to undertake further roles with a focus on patient care. Pharmacist prescribing is one of these expanded roles which is recognized in many countries and across several care settings such as community, clinics, and hospitals (Famiyeh and McCarthy, 2017). The primary aims of prescribing pharmacist is to optimize pharmacists' skills to safely increase patient access to health care services, and facilitate a team-based approach to care (Famiyeh and McCarthy, 2017). There are different pharmacist prescribing models across countries and between jurisdictions within a country. Pharmacist in Australia, New Zealand, the United States, Canada, and the United Kingdom undertake prescribing that ranges from shared prescribing with GPs in collaborative environment, to prescribing from selected formularies (Bourne et al., 2016). Studies from Australia report that a collaborative doctor–pharmacist prescribing model had a positive outlook and a high satisfaction level with pharmacist prescriber consultations (Hale et al., 2013, 2016). Similar to the Allied Health Prescribing Training program that aims to introduce models of care featuring allied health prescribing, a part of Queensland Health initiative is launched at the Queensland University of Technology that includes pharmacist prescribing across a range of areas. Prescribing rights to pharmacist in the United Kingdom, the United States, and Canada are broadly classified into two categories: independent prescribing and dependent prescribing. In independent prescribing, a pharmacist can clinically assess patient and diagnose the condition prior to prescribing, without any supervision by other health care professional. On the other hand, in dependent prescribing, the authority to prescribe is delegated to a pharmacist by an independent prescriber, usually a medical practitioner (Famiyeh and McCarthy, 2017).

In Australia, a number of health professionals have prescribing rights within their scope of practice. These include dentists, optometrists, podiatrists, nurse practitioners, and midwives. Pharmacists can only prescribe a limited range of medications listed under Schedules 2 (S2) and 3 (S3) of the Standard for the Uniform Scheduling of Medicines and Poisons (SUSMP) (Hoti et al., 2011a). S2: *Pharmacy medicines* and S3: *Pharmacist-only medicines* are sometimes called "over-the-counter" medicines. These medications are used for the management of minor illnesses and for conditions that can be easily recognized by the consumer and do not require medical diagnosis or management (Hoti et al., 2011b). It has been reported that with appropriate training and support, pharmacists are in a position to prescribe medications and deliver comparable outcomes to usual medical care prescribing by doctors in Australia (Weeks et al., 2014). Patients also had a high satisfaction level with pharmacist prescriber consultations and were willing to engage in a collaborative doctor–pharmacist prescribing models (Hale et al., 2016). Despite evidences supporting an expanded prescribing role for pharmacist (Hale et al., 2016; Hanes and Bajorek, 2005; Hoti et al., 2011b; Weeks et al., 2014), the uptake in Australia is lagging behind compared to those in the United Kingdom, the United States, Canada, and New Zealand.

In New Zealand, a regulation was passed in 2013 that allows pharmacist with appropriate postgraduate qualifications and clinical experience to register as pharmacist prescribers. A pharmacist prescriber is defined as "a pharmacist who is registered with the Pharmacy Council of New Zealand and who has completed the prescribed qualification for registration in the Pharmacist Prescriber Scope of Practice and who works in a collaborative health team environment" (Pharmacy Action Plan, 2016). Pharmacist prescribers are involved in managing patient's medications working collaboratively with primary diagnostician. They prescribe within the limits of their professional expertise and competence and following ethical codes of practice. Pharmacist prescribers, as part of the collaborative health team, provide individualized medicines management services to people across a range of primary and secondary health care settings (Pharmacy Action Plan, 2016).

Pharmacist Vaccinating

Community pharmacist possess the ability and skills to enhance the health care system of a nation by offering an expanded range of health services and assisting the government to achieve cost-effective use of the health budget (Community Pharmacy, 2014). The pharmacist-expanded service has been demonstrated by a successful pharmacist vaccination pilot in Queensland—Australia's first ever pharmacist vaccination project (Nissen et al., 2015). The pilot started with vaccinations for influenza which were later expanded to include pertussis and measles vaccinations because of overwhelmingly positive response and uptake of this service in community pharmacies. The pilot demonstrated that an appropriately trained pharmacist can deliver immunizations safely and effectively in the

community setting (Nissen et al., 2015). This also shows that pharmacists are in a position to deliver vaccination services for many other diseases that currently have suboptimal immunization rates. Also, since vaccination falls within the scope of pharmacist practice as defined by the PBA, universities might aim to train their undergraduates with this skill and provide a pharmacist vaccination workforce in the near future (Nissen et al., 2015).

Conclusions

Pharmacists as the medicines experts are slowly being better utilized and integrated into different practice settings. This is a slow, but positive start to having this unique set of knowledge and skills recognized, accepted, and used to its potential. Nevertheless, there are still many more areas and practice settings where the skills of pharmacists could be better leveraged, which would reduce the burden of disease on society to generate savings in health care spending, and improve quality of life and health outcomes for patients. Ultimately, extended and expanded pharmacy practice will improve patient access to required health care services in a timely manner.

Pharmacy Practice in China

Yu Fang, Caijun Yang, Jie Chang, Minghuan Jiang, Weihua Dong, Kangkang Yan, Tingting Wu, Zongjie Li, Xi'an Jiaotong University, Xi'an, China

China

China is a large, geographically and culturally diverse nation comprising approximately 20% of the world's population. With a rapidly developing economy, China is moving quickly towards meeting international standards for pharmacy; however, given the diversity of the country there are enormous variations in the meaning and practice of pharmacy. In China, pharmacists have

traditionally been trained for work in manufacturing, production, and research. Recently, however, there has been more interest in developing pharmacists for clinical and patient-focused roles than in the past. Pharmacy practice in the country is quickly evolving. Pharmacy practice in China must also be respectful of the long-standing use of traditional, complementary and alternative medicines and healing systems that are used throughout the country. As a result it is difficult to represent all facets of pharmacy in China within a single article; here, we provide you with the highlights of current and emerging trends in diverse sectors of the profession as a way of supporting greater understanding of the evolution of pharmacy in the country.

Pharmacy Education

Pharmacy Education in China

With continuous development of the Chinese economy and society, and ongoing reforms in the medical and health system in China, the demand for pharmacy and pharmaceutical care services in China is increasing (Yu et al., 2016). Over the years, while there has been growth in the number of pharmacies and pharmacists, there have been concerns that the quality of care and services provided to the public may not be to the same level as in other countries, and that new graduates may not have sufficient capacity to practice what they have learned in a patient-focused, clinical manner (Xinhui et al., 2006). In part to address this need, new pharmacy "undergraduate talent training programs" have been developed. These programs were designed to produce high quality graduates with strong technical skills who can function at international standards for pharmacy practice, and who can help address the needs of a rapidly modernizing healthcare system in 21st century China (Lianrong, 2003).

Historically, pharmacy education in China has been focused on training individuals to work in research and drug manufacturing environments, rather than in clinical or healthcare settings. The role of a clinical pharmacist (one who advises, prescribers, educates patients, and monitors drug therapy to ensure it is safe and effective) in China is relatively new, while the role of industrial and research pharmacists is long established. This has started to change with the increasing recognition that pharmaceutical knowledge and skill that is relevant to the manufacturing industry can also be of service in a clinical, patient-centered setting as well. This shift is challenging, however; with few role models, mentors, or trained clinician-faculty members in China, it is difficult to reorient pharmacy education towards clinical practice in a rapid way. In order to meet the needs of the 21st century, China's healthcare and educational systems are both changing rapidly. As part of this change, there is increasing recognition of the need for strong experiential and practical teaching and training in the pharmacy program as a way of modeling for and mentoring young students into clinically oriented practitioners.

Reforming the Pharmacy Education System in China

Pharmacy education in China is evolving to meet the needs of a changing healthcare system, one that recognizes that the traditional pharmaceutical expertise and knowledge of pharmacists is necessary to ensure best possible care for patients. Currently, there is a significant lack of standardization in pharmacy education and programs across China; in fact it is challenging to even accurately count the number of "pharmacy" programs and "pharmacist" graduates given the lack of standardization in terminology or educational outcomes (Ming et al., 2010). To this end, the following key initiatives are being discussed in Chinese pharmacy education (Xiangkui et al., 2008; Ming et al., 2010):

1. Establish a new pharmacy education model (aligned with international standards and outcomes), one in which students are more better able to apply scientific and theoretical knowledge to real world clinical problems. Such education can also help develop critical thinking and lifelong learning skills, as well as build employment readiness. In most pharmacy education programs today, there is strong emphasis on the technical and scientific knowledge base, with less emphasis on clinical application and skills. As the curriculum evolves, a greater patient-care focus will build on this scientific base and allow for more effective clinical application of pharmaceutical knowledge (Xiangkui et al., 2008; Ming et al., 2010).
2. Create a scholarly campus, and build a university culture, similar to international standards. Situating pharmacy education as an academic and scientific discipline within a university will increase its quality and rigor. Pharmacy programs must be associated with high quality library and information centers to promote scientific literacy among graduates. In the past, training of pharmacists varied considerably within the country and was not necessarily linked to a high quality or accredited university campus (Xiangkui et al., 2008); going forward, ensuring that those who graduate as pharmacists are educated within a scholarly university campus environment will enhance the quality of the profession.
3. Strengthen the network of practical training placements off campus and within the school to provide students with greater options for specialization, accessibility to diverse role models and mentors, and to generate more of high quality career options (particularly clinical or patient-care focused pathways) for students to consider (Yong and Yi, 2012).
4. Establish rules and regulations for practical teaching to ensure some measure of standardization in the processes and outcomes across the country. Currently, there are too many diverse educational practices with few standard requirements; standardization and measurement of outcomes (similar to accreditation systems used in other countries) will help improve the quality of educational programs and their graduates (Ming et al., 2010; Yong and Yi, 2012; Ying et al., 2012).

There is much potential in the pharmacy education system in China. As interest grows in the potential role of pharmacists in patient-focused clinical settings, there will be a need to build upon the historic strengths of pharmacy education, and ensure they can

be applied to a clinical context. The profession's historic roots in manufacturing and research ensure a strong scientific foundation, but further work is required to ensure this translates into application in clinical settings. It will be essential to work towards standardization of the pharmacy curriculum, as has been done in many other countries. Clear standards and expectations, along with measurement, reporting, and accreditation, will ensure academic programs are rigorous and that graduates of these programs are ready for the important work they will do as pharmacists. While standardization of educational processes does not preclude specialization or concentration in certain fields, it does ensure that baseline competencies are the same for all graduates, regardless of place of graduation.

Pharmacovigilance

The Concept of Pharmacovigilance (PV)

Pharmacovigilance refers to the science and action associated with adverse event detection, monitoring, assessment, identification, prevention and treatment, or management of drug safety incidents (Lijuan et al., 2006). Given the size of China's population, the diverse array of prescription, non-prescription, traditional, and complementary/alternative medical products used in the country, pharmacovigilance is of enormous importance to healthcare system, and in particular the need to develop sentinel early-warning and detection systems when adverse events occur and threaten to spread nationwide (Xin and Rong, 2009; Liting et al., 2014). In particular there is an important potential role for pharmacists in pharmacovigilance work given their central role in all aspects of the medication life cycle, from research to production to distribution and post-marketing surveillance (Liting et al., 2014). In China, the term "pharmacovigilance" was first proposed in the symposium on "First Pharmacovigilance and Drug Epidemiology" held in Shanghai in September 2004 (Lijuan et al., 2006). Prior to this, pharmacovigilance work in China was carried out mainly in the form of ADR monitoring (Lijuan et al., 2006). China began formal ADR monitoring pilot work in 1988; in 1989, the Ministry of Health Adverse Drug Reaction Monitoring Center was established and in 1998, China joined the WHO International Drug Surveillance Cooperation Program. In 1999, the Ministry of Health Adverse Drug Reaction Monitoring Center was merged with the State Drug Administration and Evaluation Center and renamed as "National Adverse Drug Reaction Monitoring Center" (Lijuan et al., 2006). Since then, pharmacovigilance has been widely seen as central to ensuring the safety and reliability of the medication system in the country (Liting et al., 2014).

The Organizational System for Pharmacovigilance in China

At present, the Chinese pharmacovigilance administrative supervision system is divided into four administrative levels: national (countrywide), provincial, county, and municipal (local) (State Food and Drug Administration, 2016). At each level, Food and Drug Administrations exist; while their work at each level is not fully standardized or prescribed, within each provincial center, there is coordination to ensure national pharmacovigilance objectives are achieved.

The current strength of pharmacovigilance staff across all levels is nearly 3,000 people, more than 1,000 of whom are full-time staff (EB/OL, in press) (**Fig. 1**). Their academic qualifications/credentials may vary considerably based on geographical location, role, and responsibility (EB/OL, in press). A priority for pharmacovigilance in China has been to ensure that all parts of the country are covered; as the map highlights, every province, region, and major municipality in the country has personnel in place to monitor the medication system to ensure it is safe and reliable (Ya et al., 2016).

In the continuous improvement of the organizational system, the technical management of monitoring department has gradually become standardized, and the National Center and Beijing, Liaoning, Jiangsu, Sichuan, Hunan, Zhejiang along with other provincial centers have passed international ISO9001 quality management system certification. Such international quality accreditation is essential to ensure that Chinese pharmacovigilance systems are capable of providing robust monitoring and surveillance of medication safety across the country. It is anticipated that in the future more centers will achieve such accreditation, which would further strengthen the system (Ya et al., 2016).

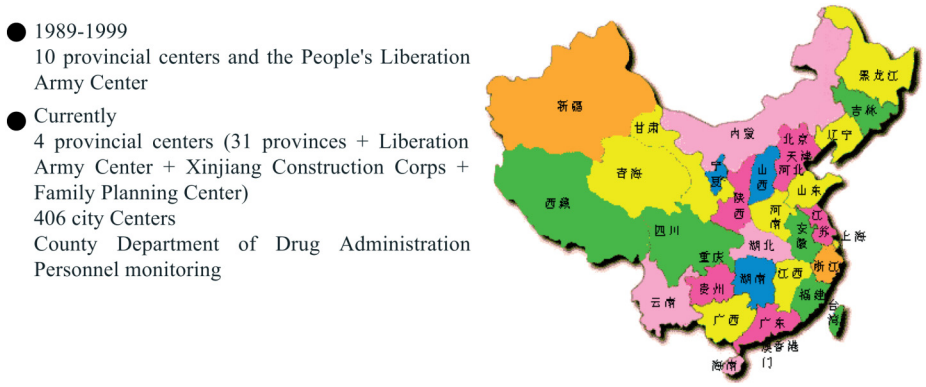

Figure 1 China Adverse Drug Reaction Monitoring Agency

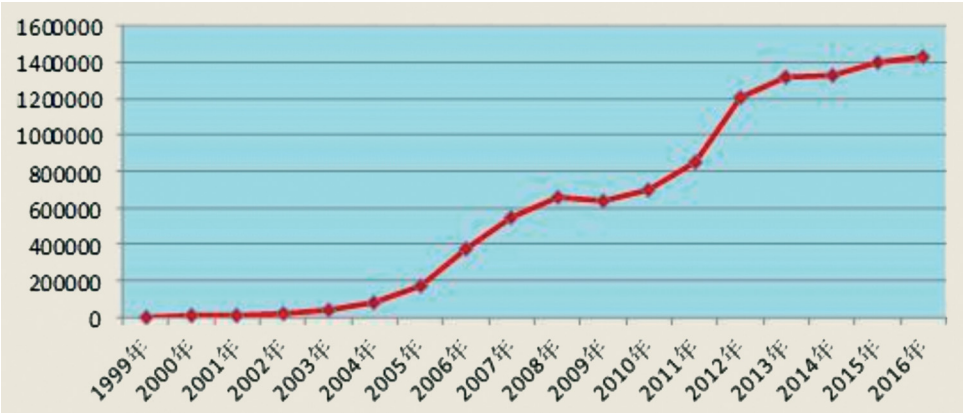

Figure 2 The growth trend of the national drug adverse reaction/events report in China from 1999 to 2016 (EB/OL, in press)

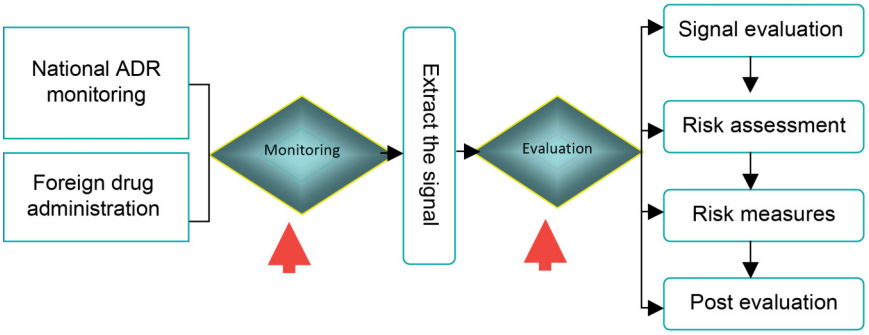

Figure 3 Signal mining and evaluation process

The Number of Reports Continues to Climb

From 1999 to 2016, the national ADR monitoring network received nearly 10.75 million reports of "adverse drug reactions / incident reports" (Fig. 4). In part, this increase may reflect better administrative structures to collect and analyze reports, as well as increased awareness about adverse drug reaction reporting amongst health care professionals (Liting et al., 2014). This increase in data is also important in helping China monitor its medication system more effectively. Yet, concerns persist that despite the increase, underreporting (particularly in some sectors such as manufacturing) continues to be a problem (Liting et al., 2014; EB/OL, in press). There exists significant opportunities for pharmacists (in industry, research, manufacturing, production and in clinical practice) to become better trained and more involved in reporting to reduce prevalence of under-reporting of adverse drug reactions (EB/OL, in press) (Fig. 2).

Risk Management Systems Continue to Improve

Signal mining and evaluation

At present, drug safety is established through daily monitoring of incident reports, weekly summaries, quarterly evaluations, and an annual evaluation. Through this process the National Adverse Drug Reaction System seeks to identify risk signals in China, while simultaneously monitoring other international pharmacovigilance data sources for comparison. While this monitoring system is aligned with international practices, it is important to note that the system is only as effective as the incident reports received; under-reporting, particularly by pharmacists, can undermine the quality of the system (EB/OL, in press). Further, there is a growing role for pharmacists who are trained to actually participate in the evaluation and risk assessment process, given their pharmaceutical knowledge and skills (Fig. 3).

Handling emergency events

With the goal of balancing harm reduction in as best as possible evidence-informed manner, mindful of time pressures and urgency, emergency events in drug safety may follow a different investigation and evaluation process than the traditional signal-mining approach. Given the large number of traditional, complementary, and alternative medications used in China, as well as the large number of pharmaceutical manufacturers involved in production of medications in the country, it is a challenge to identify emergency events in a timely manner without over-reacting. Pharmacovigilance staff must be careful in considering a

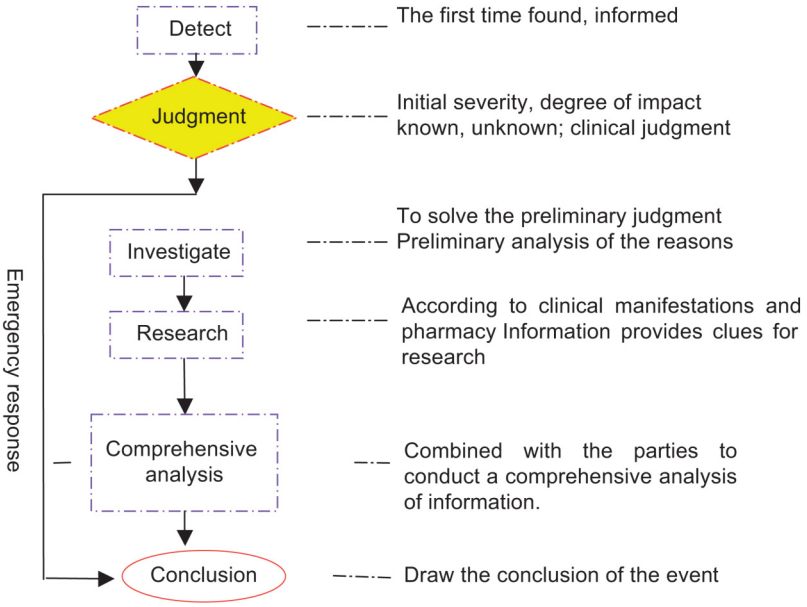

Figure 4 Emergency events treatment scheme

single or a few incidents of risk or harm; prematurely removing a product from the marketplace may cause greater harm than good in some cases, while conversely waiting too long for confirmation of risk/harm by additional cases can be problematic. To facilitate evidence informed decision-making, an emergency response treatment scheme has been developed to help support data analysis, interpretation, and decision-making. Again there is a growing opportunity for pharmacists to be involved, in both reporting and in evaluation and assessment (Fig. 4).

Risk warning

A national Early Warning Information Sharing Platform has been developed with the objective of providing support to decision-makers in flagging potential risks as problems that require immediate action. In a large and diverse country like China, there is always a challenge in balancing how information is transmitted and shared amongst stakeholders. Isolated or incomplete information about potential risk can lead to panic or stampede, while withholding of information can lead to gossip and innuendo. Developing a more systematic process for risk warning to different stakeholders, especially during emergency events, continues to be a work in progress. The current process is outlined in Fig. 5.

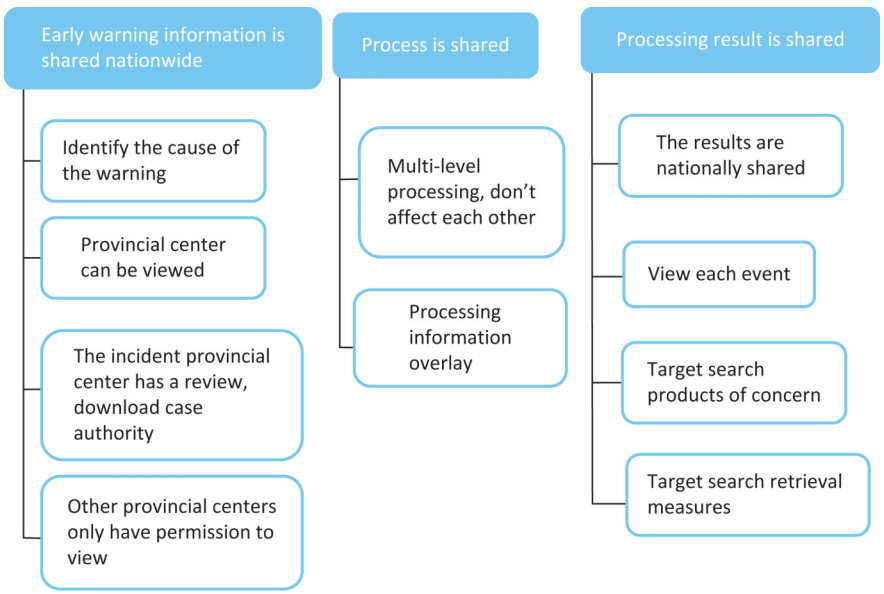

Figure 5 Early warning information sharing platform

Challenges and Opportunities for Pharmacovigilance in China

Reliability of the monitoring system needs to be strengthened

While the pharmacovigilance system in China is rapidly improving, several elements require strengthening (Liting et al., 2014; EB/OL, in press; Ya et al., 2016): (1) accountabilities and requirements of pharmaceutical production enterprises (manufacturers) must be clearer and legislated as currently there is likely significant underreporting by this group; (2) requirements for reporting of medication safety issues and risks by health professionals (including pharmacists) needs to be implemented; (3) systematic risk management systems in health institutions (including hospital pharmacy departments) need to be set up and developed; (4) pharmacovigilance monitoring institutions with qualified professionals (including pharmacists) must be expanded nationwide; and (5) penalties for non-performance in drug safety need to be established and enforced.

Case report quality to be improved

At present, the number of ADR reports in China is growing rapidly, but the quality of ADR reporting is uneven (Liting et al., 2014; Ya et al., 2016). Key issues to address include (Liting et al., 2014; Ya et al., 2016): (1) Participation of all parts of the country and the health system in reporting as currently reporting is generally limited to large urban centers; (2) all health professionals (especially pharmacists) must be trained in accurate reporting and documentation; (3) documentation standards regarding timeliness of reporting, quality, and authenticity need to be established; and (4) audit evaluations for quality need to be systematized and implemented.

At present, most ADR reports come from medical institutions such as hospitals; less than 7% of all reports come from the manufacturers, who currently have no regulated requirement to report. As a result, there is a likeliness of significant underreporting, which may undermine the entire pharmacovigilance system. Manufacturers need to be trained, incentivized, and ultimately held accountable to ensure they are working in accordance with laws and regulations to improve the overall reporting and monitoring system.

Risk Warning Capability Needs to be Strengthened

Early detection of risk is crucial to prevent harm. However, technical evaluation of risk to support evidence-informed decision-making requires further development. Currently, risk assessment and risk management standards can be somewhat non-specific, and this introduces potential of error or bias in decision-making (Yongfang et al., 2013). Prematurely withdrawing a medication due to early signal risks can, of course, produce other harms for patients who are now left without a medication that works for them. Conversely, waiting too long for additional evidence of harm may increase risk for patients. Technical guidance and decision support systems for risk warning need to be strengthened and better aligned with international standards to provide decision makers with confidence in their judgments. This is of course complicated in China due to the size of the country and population, and the diverse array of traditional, complementary and alternative medications used across each province and region (Yongfang et al., 2013; Ya et al., 2016). Further research and development in this area, customized to China's unique needs, is required.

The Future for Chinese Pharmacovigilance

Complete pharmacovigilance should include all aspects of drug safety and related factors, but at this stage China is still mainly focused on the post-marketing drug monitoring and ADR monitoring stages. In the long run, a comprehensive pharmacovigilance system needs to evolve, aligned with international standards, that begins with early stages of new drug development and continues to post-marketing surveillance along the entire life cycle of the drug (Lu et al., 2017). Further, pharmacovigilance activities need to extend to the traditional, complementary, and alternative medical products that are widely used across the country and that currently may not be reported as frequently as they should be.

Revise Laws and Regulations, and Strengthen the Duties of All Parties

Laws and regulations to enforce pharmacovigilance across the entire drug life cycle are required to reinforce the responsibilities of researchers, drug manufacturers, hospitals, health professionals, and ultimately patients to report on adverse drug reactions and other problems with medications. Currently, without laws and regulations, reporting by drug manufacturers is uneven and quite low; more robust reporting at the early stages of drug development and manufacturing would prevent problems at the post-marketing level from ever appearing. Legal requirements for individuals and institutions (including manufacturers) are an important way of strengthening the system.

Establish Inspection Mechanisms and Implement Corporate Responsibility

A major problem in the current system is the lack of consistency in accountability of pharmaceutical manufacturers. While some producers of drugs do take their reporting requirements seriously, many do not. Once laws and regulations on monitoring and reporting are in place, they must be supported by inspection and audit mechanisms by arms-length agencies, such as the National Adverse Drug Reaction Centre to reinforce corporate responsibilities. This is crucial to ensuring pharmacovigilance across the drug life cycle.

Promote Development of the Chinese Hospital Pharmacovigilance System (CHPS)

The Chinese Hospital Pharmacovigilance System (CHPS) is a potentially powerful information system for collecting and monitoring data related to medication use and safety in hospitals across the country. This system uses information technology to support and facilitate reporting by medical institutions, and to accelerate and improve monitoring of risks, signals, and trends. As of 2017, 62 hospitals had signed a cooperation agreement with CHPS, and 14 had implemented it (Lu et al., 2017). Though a very small number, it represents an important start on a technologically-enabled system for reporting and monitoring that could be a model for future developments in the country.

Strengthen Safety Education, Promote Information Feedback

In many countries, patients are encouraged to participate in ADR reporting, along with non-physician health professionals. Further work is currently underway to improve safety education for patients, and to provide mechanisms for non-physicians to report ADRs; in addition, there is a need to develop mechanisms to alert both patients and non-physician health professionals about the latest information on specific drug safety or risk issues. Within China, there is a particular interest in the role of journalists and media to eliminate rumors and panic regarding drug safety; further training of this group is needed, as are standards of practice, to ensure accurate and timely reporting of important public safety data (Lu et al., 2017).

Pharmacoeconomics in China

The size and complexity of the healthcare system in China means that the costs of medicines are substantial but difficult to actually calculate (Bae, 2015). Ensuring best possible value for pharmaceutical expenditures is crucial for the sustainability of the system (Reeder, 1995). Compared to other countries, the development of pharmacoeconomics in China has been slow, beginning only in 1990. However, since that time, there has been growing recognition of the importance of pharmacoeconomics within pharmacy and the healthcare system. Today, of the 100 more ISPOR (International Society for Pharmaceutical and Outcomes Research) regional chapters worldwide, seven are from China, highlighting its growing importance in the country (Walley and Haycox, 1997; Shi et al., 2014).

Guidelines for Pharmacoeconomic Evaluations in China

Although the development of pharmacoeconomics in China has been slow compared to developed countries, around 300 PE (pharmacoeconomic) articles from Chinese researchers are now published annually (Doherty et al., 2004). However, the research quality of the studies is uneven. Until recently, there was a lack of uniform standards in PE research across the country (Ramesh et al., 2014; Ma et al., 2016). To standardize research procedures and improve the quality of PE studies in China, the first edition of China Guidelines for Pharmacoeconomic Evaluations was published in 2011 (Hu, 2013). This guideline summarized essential items of PE studies, illustrated requirements and provided examples for each item. The guideline was updated in 2015 and a manual was added, which explained details on how to carry out PE studies by using specific examples (Ramesh et al., 2014). This updated guideline mainly included two sections: PE guidelines (introduction, instructions, executive summary, main texts, references, and appendix) and guidance manual. The PE guidelines were composed of 10 chapters, each corresponding to a step in the PE process itself: (1) Study question; (2) Study design; (3) Cost; (4) Health outcomes; (5) Evaluation techniques; (6) Modeling analysis; (7) Variability and uncertainty; (8) Equity; (9) Generalizability; (10) Budget impact analysis. **Table 1** highlights the Chinese approach to pharmacoeconomic evaluation, including criteria for study design, outcome indicators, evaluation techniques, and modeling methods used.

Potential Applications of Pharmacoeconomics in China

In general, pharmacoeconomics is not currently widely used in the public or private sector in China (Hu, 2013); it is most widely used by international pharmaceutical companies located in the country who sell their products to jurisdictions where PE is compulsory or more highly valued (Tian et al., 2012; International Society for Pharmacoeconomics and Outcomes Research, in press a; ISPOR, in press). Compared to international pharmaceutical companies, domestic pharmaceutical companies have a fewer pharmacoeconomic professionals, and they are not active in carrying out PE studies on their pharmaceutical products as the PE evidence is not currently a mandatory part of the drug approval or medicare reimbursement systems in China (International Society for Pharmacoeconomics and Outcomes Research, in press b; Ahmad et al., 2013).

The rate of health insurance coverage for Chinese populations has been rising in recent years (Letizia, 1995). The selection of drug lists for reimbursement is currently based mainly on clinical outcomes and benefit (Murray et al., 2000; Angevine and Berven, 2014); economic outcomes and budget impacts are not fully taken into consideration by decision makers. In China, pharmacoeconomics has not been used to guide selection of the hospital formulary. To promote rational use of medicine, reduce wastage of health resources, and to ensure a sustainable health system for the future pharmacoeconomics is now being discussed as a factor in developing hospital formularies, though practical implementation still is behind other countries (Hodgson, 1994; Shi et al., 2014).

Table 1 Ten chapters included in main texts of China Guidelines for Pharmacoeconomic Evaluations

Chapter	*Guideline*	*Recommended information*
1	Study question	1. Include study background (disease epidemiology and economic burden), interventions (conventional or standard treatment), perspective (society, payer, employer, healthcare provider, or patient), populations (inclusion and exclusion criteria), and objectives 2. Subgroup analysis to examine the stability of results
2	Study design	1. Select the study types (prospective, retrospective cohort, mix design, or secondary literature research) to determine data sources 2. Describe the rationale of study assumptions 3. Sample size and time horizon
3	Cost	1. Include cost identification, cost measurement, discounting, and uncertainty analysis 2. Cost identification should comply with the study perspective, including direct medical cost, direct non-medical cost, and indirect medical cost 3. Discounting rate for 0%–8% annually
4	Health outcomes	1. Include effectiveness, utility, and benefit 2. Final endpoints are preferred over intermediate endpoints 3. Generic utility values for healthy populations, and disease-specific utility values for patients 4. The recommended measurement of utility values: standard gamble, time trade-off, visual analogue scale, EuroQol-5 dimensions, short-form six-dimensions, health utilities index, and quality of well-being 5. The measurement of benefit outcomes: direct, indirect, and intangible benefits
5	Evaluation techniques	1. Decide the types of evaluations (cost analysis, cost-minimization analysis, cost-effectiveness analysis, cost-utility analysis, and cost-benefit analysis), while cost-effectiveness and cost-utility analyses are the preferred types 2. The incremental cost-effectiveness ratio (ICER) should be reported
6	Modeling analysis	1. Demonstrate the rationale of model structure, assumptions, and data sources in decision-analytic modeling (decision tree and/or Markov models) 2. Use econometric models to estimate medical cost and its influential factors, and internal estimates of ICER
7	Variability and uncertainty	1. Due to the uncertainty of variables, sensitivity analysis (one-way, multi-way, and probabilistic sensitivity analyses) and scenario analysis should be conducted 2. Due to the heterogeneity of patients, stratified analysis could be used for sub-group studies
8	Equity	Discuss the equity of study results for different age, gender, race, geographical, or social groups
9	Generalization	Describe the generalization or transferability of results for other regions, countries, or another medical environment
10	Budget impact analysis	Not compulsory analysis for pharmacoeconomic evaluation, but supplementary evidence for payers' decision making

In summary, while there is great and growing expertise in pharmacoeconomic models and methods in China, practical application and use of decision-making support has not been as widespread as in other countries (Jo, 2014; Sher and Punglia, 2014; Yee and Gary Chan, 2015; Nimdet et al., 2015). This is changing, and with new government standards in place (Academy of Managed Care Pharmacy, in press; National Institute for Health and Care Excellence, 2013; Rodrigues et al., 2014; Zhang et al., 2017; Zhao et al., 2017), pharmacoeconomic research is poised to grow significantly in the years ahead, beginning in the hospital sector (van Nooten et al., 2012; Jing et al., 2017) and spreading from there to the industry (Suh et al., 2002) and the private sector (Trask, 2011).

Social and Administrative Pharmacy In China, the terms "pharmaceutical administration" and "social and administrative pharmacy" are used; both are defined as the branches of pharmacy that use the theories and research methods of social science to study medication-related activities in diverse settings (Wengong et al., 2001).

The Development of Social and Administrative Pharmacy in China

In China, social and administrative pharmacy is focused on three main areas: commercial pharmacy, pharmaceutical administration, and social/societal aspects of pharmacy (Ying, 2006).

Commercial Pharmacy

Commercial (or "retail") pharmacy is a growing sector of the profession (Chao, 2011; Shimin, 2014). The economic, financial, and business aspects of commercial pharmacy are important to the viability and sustainability of the profession. Understanding how pharmacies work as commercial entities or businesses, and applying experiences from other business to improve the operations and success of pharmacies is a central part of this branch of social and administrative pharmacy. Social sciences disciplines ranging from economics to finance and accounting to information technology inform much of the work in this area, all aimed at understanding and improving the financial performance of the profession.

Pharmaceutical Administration

Pharmacies are complex entities and require sophisticated administration to ensure they function effectively. Whether in the commercial, hospital, or industrial sector, understanding of topics related to administrative laws, human resources management, legal and auditing practices, etc. are crucial for success (Ming et al., 2008a). Because pharmacies must work with specialty products–pharmaceuticals–additional standards and reporting requirements exist over traditional businesses, so pharmaceutical administration has emerged as a specialty area of social and administrative pharmacy in China. Given that some pharmacies employ hundreds of people, the importance of effective administration is clear. Social sciences such as marketing, psychology, sociology, management and law are all part of pharmaceutical administration and applied to the study of pharmacies in diverse settings.

Societal/Social Pharmacy

One of the fastest growing areas of research interest is societal/social pharmacy, which studies the ways in which medications, pharmacists, and pharmacies interact with and influence communities and societies (Ming et al., 2008b). Since the 1960s, with the development of clinical pharmacy, the societal role of the pharmacist has changed tremendously and redefined the pharmacist's interactions with patients, other healthcare professionals, and other stakeholders (Yu et al., 2010; Fang et al., 2013a). Social science disciplines such as sociology, psychology, and anthropology all are important in societal/social pharmacy, as are a diverse array of qualitative and quantitative research methods. Current issues explored in China include the pharmacists' role in preventing substance abuse, interprofessional collaboration, and the best way to encourage medication adherence (Yang et al., 2008; China Food and Drug Administration, 2015; Wiysonge et al., 2016).

Social and Administrative Pharmacy in China

The Development and Definition of the Discipline

In China, social and administrative pharmacy is a young discipline, and only became formally recognized in 2012 (Liu et al., 2011). In 1988, Professor Wu Peng in West China University of Medical Science first introduced the concept of pharmaceutical administration to China (State Council of People's Republic of China, 2015). In 1993, she published the first version of a reference text titled "Pharmaceutical Administration." In this version, she clearly defined the objective and research content of this discipline. Later, in 2002, Professor Yang Shimin in Xi'an Medical University also gave a formal definition of pharmaceutical administration. Professor Wu and Yang are regarded as the founders of this field in China (Chao, 2011).

Faculty

In 1988, during the early days of this discipline, there were only nine teachers in all colleges in the whole of China (Shimin, 2014). After years of development, the number of faculty in this area increased gradually. By 2007, there were 276 teachers in this discipline in 108 universities and colleges (Shimin, 2014). Some of these teachers were part-time professionals, as they came from hospitals, manufacturing units, and governmental organizations (for example, State Food and Drug Administrations) (Shimin, 2014). Compared with other disciplines, the number of teachers in pharmaceutical administration in China is still very small, and this has limited the growth and expansion of social and administrative pharmacy in the country (Ming et al., 2008a; Shimin, 2014).

Curriculum

Currently, pharmacy education in China is not quite standardized. Pharmacy students receive different levels of exposure to social administrative pharmacy theories, models, and methods depending upon the school they attend (Ming et al., 2008b; Shimin, 2014). In most programs, there is only one required social administrative pharmacy course: pharmaceutical administration and regulations, which highlights the laws and regulations governing the field (Shimin, 2014). Some programs have expanded curriculum offerings in areas such as management, economics, psychology, etc (Ming et al., 2008a; Shimin, 2014). As of 2007, the curriculum for pharmaceutical administration in China was classified into four categories : management, economics, laws and ethics, methodologies, and others (Ming et al., 2008a) (**Table 2**).

Unfortunately, the teaching of social and administrative pharmacy (both undergraduate and graduate) is quite unstandardized in China (Ming et al., 2008a; Shimin, 2014). In some cases pharmacists are not actually involved in teaching of the content (Ming et al., 2008a; Shimin, 2014). While the proliferation of different courses and programs may encourage innovation, the lack of standards in education has slowed down general progress in the field. As a result, social and administrative pharmacy education, research, and practice are still relatively immature in China compared to other parts of the world, though progress is being made, especially in graduate education.

PhD Graduate Student Education

The training of doctoral students began in year 2000 at Shenyang Pharmaceutical University. Since then several universities have established doctoral education programs in the hope of building capacity in China for pharmaceutical administration and social administrative pharmacy teaching and research (Ming et al., 2008a; Ming et al., 2008b; Shimin, 2014) (**Table 3**).

Table 2 Curriculum for pharmaceutical administration in China in 2007 (Ming et al., 2008a)

Category	*Topics covered*
Management	• Pharmaceutical management (including pharmaceutical administration, Chinese medicine administration) • Pharmaceutical administration and regulation • Hospital pharmacy management • Medical business administration • Medicine administration • Drug quality management practice
Economics	• Pharmaceutical marketing • Pharmacoeconomics • International pharmaceutical trade • Others (including medical economy, pharmaceutical e-commerce, medical market survey, and forecasting)
Laws and ethics	• Pharmaceutical laws and regulations • International drug regulations • Pharmaceutical intellectual property • Pharmacological ethics
Methodology and others	• Pharmaceutical administration research methods • Medical and pharmaceutical policy

Table 3 The number of PhD candidates and PhD graduates in the social and administrative pharmacy and pharmaceutical administration

	Number of PhD		*Number of PhD candidates*	
	Major of pharmaceutical administration	*Major of social and administrative pharmacy*	*Major of pharmaceutical administration*	*Major of social and administrative pharmacy*
2006	4	/	18	24
2007	8	3	29	27
2008	9		32	39
2009	7	15	32	47
2010	3	4	42	43

Professional Society

In July 1986, the 17th general council of the Chinese Pharmaceutical Society established the Pharmaceutical Administration Society. Since then, an annual academic conference has been held every year with focus on one specific topic. The topics discussed during the last 7 years are given in Table 4. More and more researchers, government officials, and professionals working in hospitals and pharmaceutical companies are involved in this conference. The participants increased from nearly 30 in the beginning to more than 200 in recent years, and the submissions also have seen a substantial increase in quantity and quality. All this points to an increasing role and influence of social and administrative pharmacy in China in the years to come.

Public Health Pharmacy in China

In China, the role of commercial (community or retail) pharmacies in providing healthcare services is growing (Yu et al., 2010). As in many other countries (Fang et al., 2013a), China's community pharmacies are private for-profit enterprise that historically have been

Table 4 Topics of the annual academic conferences of Pharmaceutical Administration Society in China from 2011 to 2017

Year	*Topic*
2011	Medical and pharmaceutical science development - new healthcare policy and medicine administration
2012	The development of 12th 5-year medical and pharmaceutical science
2013	The safety of medical and pharmaceutical products
2014	Strengthening the construction of pharmaceutical administration disciplines and promoting the healthy development of medicine
2015	Promoting legal system construction and administrating medicines according to law
2016	Focusing on the 13th 5-year plan and promoting healthy development of pharmaceutical administration
2017	Practicing the concept of healthy China and promoting the sustainable development of pharmaceutical administration

more focused on large-volume dispensing and sales rather than clinical services; by the end of 2015, there were over 450,000 community pharmacies nationwide (Wiysonge et al., 2016). As a result, there has been interest in the potential for public health pharmacy in China, despite the fact that currently most pharmacies are only involved in dispensing/drug distribution activities.

Legislation and National Policies

For public health pharmacy to flourish, it is essential that the pharmacy workforce is trained, competent, and meets professional standards for practice. To this end, new regulations and legislation are being developed in China to ensure all pharmacies have the human resource required to provide public health services.

Legal Requirement for Community Pharmacy

According to the Drug Administration Law (2015), a community pharmacy must: (1) be staffed with legally qualified pharmaceutical professionals, (2) meet specified standards for business operations, including, equipment, warehouses and hygienic environment required for drug distribution, etc., and (3) have systems in place to demonstrate quality control over the drugs to be dispensed (Wiysonge et al., 2016). According to the National 12th Five-Year Plan of Drug Safety (2012) issued by State Council of China (State Council of People's Republic of China, 2015), all newly opened community pharmacies must now be staffed by a licensed pharmacist. Further, all the owners or main administrators of community pharmacies must be certified and licensed pharmacists, and a licensed pharmacist must be on duty to supervise the rational use of medicines at community pharmacies during the operational hours (Yang et al., 2008; China Food and Drug Administration, 2015).

Standards to Ensure the Quality of Pharmacy Services

To enhance the quality of pharmacy services provided at community pharmacies, changes have been made to regulations and legislation (Liu et al., 2011; The State Council of People's Republic of China, 2012; State Council of People's Republic of China, 2015; National People's Congress, 2015). The Regulations for the Implementation of the Drug Administration Law (2016) of the People's Republic of China outlines the medication classification system in China (http://www.gov.cn/gongbao/content/2012/content_2068275.htm). Medicines are classified as prescription-only medicines (POMs) and over-the-counter medicines (OTCs); OTC medicines are further sub-categorized into two classes according to the safety level (http://www.gov.cn/gongbao/content/2012/content_2068275.htm).

In 2003, China Nonprescription Medicines Association (CNMA) developed the Chinese version of "Guidelines for Good Pharmacy Practice (GPP)" based on "GPP in Developing Countries" developed by the International Pharmaceutical Federation (FIP) (China Food and Drug Administration, 2016). This was further refined (http://www.sda.gov.cn/WS01/CL0053/159780.html) as "Guideline for licensed pharmacist practice" in 2015 (State Council, 2016). Recommended practices on several aspects, including prescription review, medication guidance, drug treatment management, and health education, are presented in detail in these guidelines (Yang, 2005; Fang et al., 2013b; http://www.cqlp.org/info/link.aspx?id=2557&page=1).

Emerging Roles of Pharmacists in "Healthy China"

In October 2016, China adopted "Healthy China 2030" plan as a national strategy for a healthy China in the next 15 years (Fang et al., 2013b; http://www.cqlp.org/info/link.aspx?id=2557&page=1). In this strategy, public health is given high priority (Top leadership of the Communist Party, 2016; Certification Center for Licensed Pharmacist of China Food and Drug Administration, 2017a). Strengthening health education has been highlighted as a key strategy (Badcott, 2011). It is planned that by 2030, all areas of China will have public health programs to support wellness, including: promoting balanced diets, tightening tobacco and alcoholic control, promoting smoking cessation, enhancing capacity to identify and intervene in common mental health disorders, and reducing unsafe sexual behavior and drug abuse/misuse (Carter and Slack, 2010).

In some developed countries, such as the United Kingdom and Australia, community pharmacists are already involved in delivery of such public health services (http://www.cqlp.org/info/link.aspx?id=2557&page=1; (Badcott, 2011; Top leadership of the Communist Party, 2016; Certification Center for Licensed Pharmacist of China Food and Drug Administration, 2017a). However, in China this is still only a "potential" rather than a reality. By August 2017, the number of licensed pharmacists practicing at community pharmacies in China had reached 343,402, accounting for 88% of total number of licensed pharmacists in the country (Carter and Slack, 2010). The variable quality of the workforce of licensed pharmacists in China has been identified by the Central Government as a key priority for meeting Healthy China 2030 objectives; in the years ahead, this may lead to greater training and support for pharmacists to implement the strategy (Deeks et al., 2014; Maher et al., 2015).

Education, Professional Qualification, Examination, and Training in Public Health

Higher education in pharmacy in China was initially and even currently is designed to train professionals for work in industry or research (Certification Center for Licensed Pharmacist of China Food and Drug Administration, 2017b). Clinical pharmacy education was introduced in China in recent years and is still at a nascent stage (Certification Center for Licensed Pharmacist of China Food and Drug Administration, 2017b). According to our best knowledge, public health courses seldom appear in the curriculum for pharmacy students, and public health knowledge is currently not included in the content of the National License Examination for pharmacists (http://www.gov.cn/zhengce/content/2016-03/11/content_5052267.htm). Public health has

emerged as a key priority for China in the years ahead, and as of 2017, the national Government has recognized that qualified pharmacists have a role to play in achieving the Healthy China 2030 objectives (http://www.gov.cn/zhengce/content/2016-03/11/content_5052267.htm; http://www.sph.umn.edu/academics/dual-joint-degrees/pharmacy/). Going forward, more work will be needed to train new pharmacists, upskill those currently in practice, and ensure community pharmacists are better integrated in the overall healthcare system (Ryan et al., 2008; Hu et al., 2014).

Future of Pharmacy

Throughout this chapter, we have highlighted the "potential" of pharmacy in China, and how recent recognition of the skills of pharmacists may, in the years ahead, lead to greater roles and responsibilities for pharmacists in different areas.

Hospital Pharmacy

As the complexity of care increases in China, there will be greater need for pharmacotherapy specialists to support cost-effective clinical practice (Xiang and Tan, 2016). This will result in a significant change in the function, organization, and structure of hospital pharmacies throughout China, as pharmacists become more prominent as medication experts. Traditionally, in a large general hospital of 1000 beds, pharmacy staff always accounted for about 8% of medical staff (= 45–50 persons) (Lee et al., 2013a). As the need for pharmacotherapy specialists increases, the staff will likely be subdivided into clinical pharmacists and dispensing pharmacists. The clinical pharmacist will mainly be responsible for clinical services (including therapeutic drug monitoring, adverse drug reaction monitoring, clinical recommendations and guidance to prescribers). The dispensing pharmacist group will mainly be responsible for the receipt and preparation of medicines, handling of drug accounts, prescription input and preparation of packaging materials. At the current time, the role of the regulated pharmacy technician (as it exists in other countries) has not been fully discussed in China.

Technology

As in other countries, automated dispensing systems are now being used in China to manage the labor- and time-intensive activities of drug distribution, thereby freeing pharmacists' time for more valuable clinical services. Hospital Information Systems (HIS) are being constructed now that will support robotic and automated dispensing systems (Lee et al., 2013a,b). This will also lead to better control over inventory, prevent drug loss, and ultimately save money in the healthcare system (Lv, 2016). This may also support greater research in pharmacovigilance and pharmacoeconomics to further improve the quality, safety, and effectiveness of the system.

Administrative Systems

Hospitals in China are currently moving towards establishment of a "master pharmacist" system, similar to the Chief Pharmacist in many other countries (Hammett et al., 2014). The master pharmacist will take responsibility for all aspects of the hospital's drug use process and has supervisory duties to ensure drug safety. This will require pharmacists to receive additional management education and training, and in some cases may lead to management specialization by some pharmacists and clinical specialization by others. Hospital pharmacists will therefore likely require additional training or credentials as they progress through their careers, and will have increasingly important roles to play in both departmental and hospital-wide administration.

Community Pharmacy

Community pharmacy will continue to evolve in China as pharmacists become more involved in medication management and public health activities.

Community Pharmacy in the Future

In the future, community pharmacies in China will likely conform to one of the following formats:

Standard pharmacy format: Similar to Japan's prescription drug dispensing pharmacy, the standard community pharmacy format will focus on providing high quality prescription and OTC pharmaceutical products, and basic but important education to patients about these products (Yang et al., 2015). The business model will be volume-focused with a strong emphasis on efficient, technologically sophisticated dispensing systems supervised by trained personnel.

Community convenience store format: This type of pharmacy will focus mainly on OTC (rather than prescription) products as well as a variety of day-to-day consumer items found in convenience stores. OTC product sales will likely account for less than 60% of all sales, and the business model will be volume-focused while providing some basic education and public health services (Wen et al., 2009).

Clinic pharmacy format: Such pharmacy clinics will have a doctor co-located with the pharmacy to ensure patients have immediate access to their medications and that prescribers have access to pharmacists to provide them with guidance and advice.

Clinical services such as medication management and medication review will be provided. In this format, medically complex patients with higher or chronic healthcare needs will be served; the business model is more patient-focused with the goal of minimizing drug therapy problems and optimizing healthcare (Min et al., 2009).

Online pharmacies: The main target customers of these pharmacies will be those patients who value speed, efficiency, and low cost, and who are comfortable with technology. Online pharmacies can also provide add-on services related to medication counseling, public health, or general health education, as the pharmacist's time will be freed up from technical dispensing activities due to technology though a pricing/economic model for this still needs to be developed.

Staffing and Management

The qualifications and professional skills of community pharmacists will gradually converge with hospital pharmacy staff, unlike the current situation where the two groups have major differences in academic qualifications (Xiao-ping, 2006). A minimum of an undergraduate degree will be required to be a pharmacist in any setting, and mobility between hospital and community sectors will start to increase. Graduate degrees and specializations (such as administrative pharmacy, or pharmacotherapy specialist) are also envisioned in the future as the pharmacist's role continues to expand.

Technology

More automated and robotics technologies will be introduced into community pharmacy, and this will free up the pharmacist's time to engage in public health and patient counseling activities. As logistics management of drug procurement, storage, and distribution becomes more automated, this will help to improve operational- and cost-effectiveness in community pharmacy. Technology will also facilitate group purchasing to further reduce costs of medication. A new specialty in community pharmacy logistics will evolve, similar to the administrative pharmacy role in hospital.

Summary

China is a large, diverse, and rapidly developing country. The profession and practice of pharmacy in China faces unique challenges due to the scale of the country, the plethora of traditional, complementary, alternative, and allopathic medications used, and (until recently) the lack of standardization in pharmacy education, community pharmacy practice, and understanding of the role and responsibility of pharmacists. As the country moves toward greater standardization in pharmacy practices based on international standards, there are many new opportunities for pharmacists, in areas such as pharmacovigilance, pharmacoeconomics, public health, and in social-administrative pharmacy research. A critical first step is to reform the Chinese pharmacy education system. Historically, pharmacy education has focused on research, manufacturing, production, and industrial pharmacy. The scientific foundations of the pharmacy curriculum are a useful starting point for evolution toward a more clinical, patient-focused curriculum, one that includes more social, administrative, and clinical components. As the curriculum evolves, more graduates with diverse and important skills will be produced, and these individuals will help shape the future of the profession in China.

Pharmacy Practice in India

Parthasarathi Gurumurthy*, Arun K.P.†, *JSS College of Pharmacy, Karnataka, India; †JSS College of Pharmacy, Ooty, India

Introduction

In India, "Pharmacy Practice" is defined as a subdiscipline of "Pharmacy" that involves the development of the professional roles of the pharmacists (Whalley et al., 2008). Across the world, the primary function and the purpose of pharmacy is to ensure timely access to the medicines to the individuals in society. This purpose is continuously evolving with the advancements in the health care system, and must adapt to changing societal needs (Brodie, 1981). Aligned with international standards, the pharmacists of India are expected to provide an array of professional services along with the traditional role of dispensing. The substantial variations in pharmacy practice existing across the length and breadth of the country are a result of India's diversity in cultures, languages, rural versus urban health care settings, disease burdens, policies, and local regulations. A consistent and standardized delivery of pharmaceutical care services across the country is therefore a significant ongoing challenge.

Realizing the need to adopt international pharmacy practice standards, pharmacy educators in India have introduced new degree programs such as the Masters in Pharmacy Practice and Pharm D which primarily focuses on training the pharmacists in patient care rather than pharmaceutical analysis or formulation. These programs introduced has produced only few hundreds of graduates specialized in the field of pharmacy practice. As a result, there is scant limited evidence of successful outcomes of pharmaceutical care services in India, though this will evolve in the years ahead as more graduates are produced and pharmaceutical care becomes more prevalent across the country.

Health Status of India

Incredible India

India, comprising about 2.4% of the Earth's land area is ranked as the second most populated country, accounting for more than 16% of the world's population (http://factsanddetails.com/india/Nature_Science_Animals/sub7_9a/entry-4264.html). There are 29 states and 7 union territories in India with 22 major languages, 13 written scripts, and over 720 dialects. On an average, every 1000 km distance in India results in a new/different language and culture across the country. Genetically, India has two divergent populations, the Ancestral North Indians (ANI) and Ancestral South Indians (ASI). The former population is genetically related to

Central Asians, Middle Easterners, Caucasians and Europeans and the second group, the ASI are not closely related to any other ethnic groups outside the subcontinent.

Key Indicators of Health

Life expectancy at birth and infant mortality rate have improved considerably over time in India, but are still lower than that of many developing countries. The comprehensive report on "Disease Burden Trends in the States of India 1990 to 2016" revealed that the estimated life expectancy at birth in 1990 of 59.7 years and 58.3 years for males and females respectively has significantly increased to 70.3 years and 66.9 years in 2016 (ICMR, 2017). However, this indicator showed huge variation among the individual states ranging from 66.8 to 78.7 years for females and 63.6–73.8 years for males. According to the official sources of the Indian government (http://niti.gov.in/content/infant-mortality-rate-imr-1000-live-births) the infant mortality was reduced by 50% from 2000 to 2016 with the figures of 68–34 per 1000 live births. But there is a disparity between the rural and urban areas with the figures of 38 and 23 per live births respectively. Such statistics highlight the need for a strong health care system—one that includes pharmacists as experts in medication use and management.

Disease Burden and Epidemiological Transition

In the last three decades, India has undergone a major epidemiological transition as the disease patterns and mortality have shifted from communicable, maternal, neonatal, and nutritional diseases (CMNNDs) to noncommunicable diseases (NCDs) and injuries. India reported 33% of the total DALYs (Disability Adjusted Life Years) from CMNNDs, 55% from NCDs, and 12% from injuries in 2016, those were 61%, 30%, and 9% of DALYs, respectively in 1990 (ICMR, 2017).

The epidemiological transition ratio (ETR) is defined as the ratio of DALYs caused by CMNNDs to NCDs and injuries. A ratio of greater than one indicates a higher burden of CMNNDs than NCDs and injuries and vise versa. Most of the Indian states had epidemiological transition ratio (ETR) of more than one in 1990 and all the states scored ETR of less than one in 2016 which is another indicator which reveals the paradigm shift in the disease pattern in the country. But, once again, there is a wide variation of ETR among individual states, ranging from 0.16 in Kerala to 0.74 in Bihar (ICMR, 2017).

Similarly, the proportion of all deaths in India due to CMNNDs reduced from 53.6% to 27.5% between 1990 and 2016, those due to NCDs increased from 37.9% to 61.8%, and those due to injuries changed from 8.5% to 10.7% in the same period, showing an alarming death rate due to NCDs that was over two times that of CMNNDs in 2016. The categories of CMNNDs caused the highest proportion of death were diarrhea, lower respiratory infections, and other common infectious diseases including HIV/AIDS and tuberculosis and neonatal disorders. Among NCDs, cardiovascular diseases were the leading cause of death, followed by chronic respiratory diseases, cancers, diabetes, and urogenital disorders (ICMR, 2017).

Ischemic heart disease (IHD) was the leading cause of YLL (Years of Life Lost) in the all the states across India except in the North–East states where stroke was the leading cause of YLLs. Across all the states, IHD caused a much greater proportion of total YLL among males than females, accounting for 14% of premature mortality in males compared to 10% in females. Road injuries also caused a higher proportion of YLL among males than females. Diarrheal diseases and lower respiratory infections were responsible for a higher proportion of YLL in females. The years lived with disability (YLD) had also increased in India from 17% to 33% between 1990 and 2016 (ICMR, 2017).

Thus, all these indices viz. DALYs, ETR ratio, death rate, YLL, and YLD have revealed the striking health status and inequalities between the states of India, rural and urban population and genders. This unique health profile in India warrants customized health care strategies, policies and guidelines for different states, geographical regions and populations of the country. It also highlights the importance of a well trained cadre of pharmacists to support better health outcomes and the need for a national pharmaceutical care system/infrastructure to improve the health of all Indians.

The Health Care System in India

The Health Survey and Development Committee (Bhore Committee) Report, 1946, is one of the landmark reports in India, from which the current health policy and systems have evolved (Ma and Sood, 2008). This report recommended a three tiered health-care system for providing preventive and curative health care in rural and urban areas in order to ensure that access to primary care is independent of individual socioeconomic conditions. But, over the period of postindependence, the lack of capacity of public health systems to provide access to quality care resulted in the simultaneous evolution of the private health-care system (Peters et al., 2003). Though the first national population program was announced in 1951, it took almost three decades for the release of the first National Health Policy of India (NHP) in 1983, which had a focus on providing primary health care to all by 2000. Twenty years later, NHP 2002 included an objective of decentralizing health services to the general public through the private sector and increasing public expenditure on overall health care, and also emphasized the use of nonallopathic form of medicines (Chokshi et al., 2016).

In the federalized system, the governance and operations of the health system in India have been shared by both the union and state governments where the national health programs are implemented by the former and adopted by the later. Further, the federal ministry provides technical assistance to the state governments in preventing and controlling the spread of seasonal disease

outbreaks and epidemics (Chokshi et al., 2016). However, the Indian Constitution identifies health care (including public health, hospitals, and sanitation services) as a state (rather than federal) responsibility. Areas such as family welfare, population control, medical education, prevention of food adulteration and quality control in manufacture of drugs are governed jointly by both federal and the state governments.

India has mixed health-care system including both public and private health-care service providers (Sheikh et al., 2015). Private health care is mostly established in the more prosperous urban regions while the rural areas are supported mostly by the public health-care system. However, the public–private dichotomy in health care services is skewed toward the urban population who constitute about 28% but have access to 66% of total hospital beds in the country while the rest of the 72% population in the rural areas are left only with 34% of beds (Ghosh, 2014).

Public Health Care System

The public health care system in India has three-tiers viz. subcenter (SC), primary health center (PHC), and community health center (CHC) established based on the population size of 5000, 30,000 and 120,000. respectively (Chokshi et al., 2016). SC is the connecting point between the PHC and the community. Each SC is required to be staffed by at least one male or female auxiliary nurse midwife (ANM)/health worker. These SCs are assigned with the tasks to bring about behavioral changes and provide services with respect to maternal and child health, family welfare, nutrition, immunization, diarrhea control, and control of communicable diseases. PHC are committed to provide integrated curative and preventive health care and maintained by the state Governments. PHCs also act as a referral unit for 5–6 SCs in the surrounding area and have 4–6 beds for inpatients. CHCs are also established and maintained by the state Government with about 30 beds apart from an operating theater, X-ray, labor room, and laboratory facilities which serve as a referral center for PHCs within the region. In 2016, there were about 722 district hospitals, 4833 CHCs, 24,049 PHCs, and 148,366 SCs in the country (Ma and Sood, 2008). An existing health care facility such as a district hospital, subdivisional hospital or CHC shall be declared a fully operational "first referral unit" (FRU), if it is equipped to provide 24 × 7 services for emergency obstetric and newborn care, apart from all other emergency care services and a blood storage facility.

Private Health Care System

Private health care is chiefly concentrated in urban India and is oriented only toward curative care. According to the WHO, health care expenditure in India averages $75 per capita and mostly comes from the private spending of households; out-of-pocket expenses (private spending) cover about 75% of costs and the remaining 25% is covered by public system spending (http://www.who.int/whosis/whostat/EN_WHS09_Table7.pdf).

The average cost for hospitalization in private health care was about four times greater (INR 5636 vs. INR 21,726 for rural population) than the expenditure at the country's public health care set up, according to a report published in 2016 (http://mospi.nic.in/sites/default/files/publication_reports/nss_rep574.pdf). About 72% and 79% of ailments were treated in the private sector in rural and urban areas respectively (http://mospi.nic.in/sites/default/files/publication_reports/nss_rep574.pdf). The report also revealed that in the treatment of in-patients at both rural and urban areas, the private institutions dominated with the share of 58% and 68% respectively. About 72% and 68% of total medical expenditure was spent by the rural and urban population for purchasing "medicines" for nonhospitalized treatment. It was also reported that about 86% and 82% of population from rural and urban areas were not covered by any health insurance schemes (http://mospi.nic.in/sites/default/files/publication_reports/nss_rep574.pdf).

The government through its health protection scheme cover only about 12% and 13% urban and rural population respectively, mostly for the people of unorganized sectors, Employee's State Insurance (ESI) Corporation for organized sectors, Central Government Health Scheme (CGHS) for government employees and other state insurance plans. In spite of creating awareness and marketing of private health insurance schemes, only 12% of the urban population had any level of arrangement for medical insurance from private insurance players, and the share of private insurance for all others is negligible (http://mospi.nic.in/sites/default/files/publication_reports/nss_rep574.pdf).

Inequality in Access to Health Care Systems

There are three important determinants of inequities responsible for persistent and widening differences in health outcomes across India; historical inequities, socio-economic inequities, and inequities in provision and access to health services (Baru et al., 2010). Availability, accessibility, and affordability of health services are the key factors influencing equity in health care services in India. Though there has been an expansion in both public and private health care sectors during the postindependence period, by and large such expansion has been inadequate and unable to ensure universal access to quality health care throughout the country. The inequities pertaining to distribution of public facilities and human resources between rural and urban and inter states are well documented (Duggal, 2005). Differences in infrastructure, human resources, supplies, and spatial distribution lead to uneven availability of preventive and curative interventions by public health services across the states of India. The evidence shows that people who are socially marginalized have limited access to preventive and curative health services (Govender and Kekana, 2007; Gupta and Dasgupta, 2007; Hart, 2000; Mahal et al., 2002; Peters et al., 2002).

Medication Use Problems

The disparities observed in the health status and health care systems are associated with various medication use problems in India. The factors that contribute to medication use include but are not limited to are:; multiple health care systems, illiteracy, poverty, limited access to independent, unbiased drug information, irrational fixed dose combinations, and the sale of prescription drugs without prescription by community pharmacies (Parthasarathi et al., 2002). However, few initiatives have been implemented at central, state, and local levels to address these issues. The Delhi Society for Promoting Rational Use of Drugs (DSPURD), and the Tamil Nadu Medical Services Corporation Limited (TNMSC), were the two earliest initiatives in the country toward ensuring access to quality medicines (DSPRUD, In press; Mohanta and Manna, 2015). TNMSC revolutionized the procurement procedure as the pooled procurement of medicinal products required for the state's health care facilities directly from the manufacturers, establishing the warehouses at every district with ICT enabled management and modern storage facilities including cold storage.

The central government has taken initiatives by developing guidelines, policies, procedures, and regulations for combating microbial resistance to antibiotics, medicinal product's price control, and establishment of community pharmacies exclusively to sell generic medicines (Mohanta and Manna, 2015). Recently, about 343 fixed dose combinations (FDCs) have been recommended for prohibition of sale by the subcommittee of the Drugs Technical Advisory Board (DTAB) as these combinations are deemed to be irrational (https://economictimes.indiatimes.com/industry/healthcare/biotech/pharmaceuticals/panel-recommends-ban-on-343-fixed-dose-combination-medicines/articleshow/65142395.cms). The decisions of the central government on compulsory licensing for anticancer medicines made those formulations as affordable ones (Mohanta and Manna, 2015). However, the rapid emergence of technology driven online pharmacies may in the future contribute to new medication related problems and their safety as central government control and oversight of such practices may be difficult.

The safe use of medicines is advocated by the Pharmacovigilance Program of India (PvPI) functioning under the National Coordination Centre (NCC) of Indian Pharmacopoeia Commission (IPC). There are about 250 adverse drug reactions (ADRs) monitoring centers across the country reporting ADRs to national center. NCC has also adopted various strategies for enhancing the patient safety which includes, capacity building for ADR monitoring, surveillance, and collaborations with other national health programs to enhance ADRs reporting and to ensure PvPI as a vital knowledge database for the regulators of India (Kalaiselvan et al., 2016).

A very few drug and poison information centers established by various educational institutions and professional associations are functioning in the country. As per the literature (Malik, 2010), not more than 25 such centers are providing information to the health care professionals of the institution where the center is established and to the general public. Though a few centers facilitated the access to their service by toll free numbers, mobile applications, compared to the number of health care setups and the massive population requiring these services, the existing numbers of drugs and poison information centers are significantly less. The country needs many more such centers and professionals as full time drug information specialists offering unbiased, evidence based information for better patient care.

The Pharmacy Profession in India

Pharmacy, the third largest health care profession in India, has a workforce of about one million registered pharmacists in India distributed in four major domains; 55% in community pharmacy, 20% in hospitals, 10% in industry and regulatory roles, and about 2% in academia (Sahu et al., 2016).

Industry

The Indian pharmaceutical industry which was almost nonexistent in the early 1970s has grown today to be one of the largest in the world, with the approximate value of about US$ 8 billion (Shah, 2012). Globally, the Indian pharmaceutical industry ranks 4th in terms of volume and 13th in terms of value and ensures the availability of essential drugs to the majority of the Indian population at affordable prices (Shah, 2012). The highest numbers of USFDA approved manufacturing plants outside US are in India and about 85% of the formulations manufactured are sold within the country (Shah, 2012). From the mere volume of INR 100 million during independence in the year 1947, the Indian pharmaceutical market had a value of INR 10 billion in March 2018 (https://www.springer.com/cda/content/document/cda_downloaddocument/9783790828757-c2.pdf?SGWID=0-0-45-1353130-p174515562; http://pharmabiz.com/NewsDetails.aspx?aid=108358&sid=1). As per the white paper report (http://ficci.in/spdocument/22944/india-pharma-2018-ficci.pdf) published by the Federation of Indian Chambers of Commerce and Industry (FICCI) in February 2018, the Indian pharmaceutical industry not only contributes to the local market but holds a significant share of the global market as well. 50%–60% of vaccine demand is supplied by Indian pharmaceutical industries; about 40% and 20% of the generics dispensed at US and UK respectively are from India. 60% of global ARV drugs and 30% of annual UNICEF requirements are supplied by Indian pharmaceutical market players. It is also projected that India will become one of the top three pharma markets by 2030.

Table 1 Various pharmacy programs offered in India

Sl. No.	*Name of the program*	*Number of years*	*Number of colleges*[a]	*Number of approved intake**
1.	D.Pharm.	2	1194	70,541
2.	B.Pharm.	4	1272	97,494
3.	M.Pharm. (12 specializations approved)	2	733	23,126
4.	Pharm.D.	6	237	7,110
5.	Pharm.D. (post baccalaureate)	3	111	1,110
6.	B.Pharm. (Practice)	2	24	960

[a]As on June 2018, according to the official website of PCI (http://www.pci.nic.in/home.html)

Education

Pharmaceutical Sciences

The first pharmacy college in Asia was started at Goa, India in the year 1842 by the Portuguese (http://www.ipapharma.org/news/career%20booklet.pdf). An institute for training compounders in pharmacy was established at Madras (now Chennai) in 1899 followed by the commencement of a similar program by the state medical faculty of Bengal in 1928. These were considered the earliest pharmacy institutes in the country and in the Asian continent (Tharappel et al., 2014). However, the department/college of pharmacy established in 1932 at Banaras Hindu University (BHU) by Professor. M.L. Schrof, fondly known as "Father of Pharmacy Education in India" offered a formal undergraduate degree program, Bachelor of Science (B.Sc.) in Pharmaceutical Chemistry This created the momentum in structured pharmacy education and paved the way for introducing a 3 year Bachelor of Pharmacy (B. Pharm.) program in 1937 at BHU (Basak and Sath, 2008) and the other Universities. Andhra University (1937), Madras University (1938), Bombay University (1943), Punjab University (1944), and L.M. College (1947) continued the legacy of university-based pharmacy education.

In 1948, the Pharmacy Act was enacted to regulate the pharmacy profession in the country (The Pharmacy Act, 1948). The Pharmacy Council of India (PCI), the body which regulates pharmacy education and the profession was established in 1949 and the first Education Regulations (ER) were framed in 1953, which was further amended in 1972, 1981, and 1991 (Sachan et al., 2012). All these four ERs refer to Diploma in Pharmacy (D.Pharm.) program. At present the regulations, curriculum for the other pharmacy programs, B Pharm, M Pharm, Pharm D are made available by PCI and are common to every institution imparting pharmacy education in the country.

Pharmacy programs are offered at three-tiers in India: D. Pharm., B.Pharm., Doctor of Pharmacy (Pharm.D.). The details of programs approved by PCI are summarized in **Table 1** and the scope, salient features of all such programs are discussed here.

- *D.Pharm.:* D.Pharm. is the minimum qualification to become a "Registered Pharmacist" in India. This program comprised of 1500 h of teaching with a share of 57% and 43% of didactic teaching and laboratory work spread over 2 years followed by 500 h of onsite training in dispensing of drugs. The curriculum is introductory in nature and thus trains pharmacists for dispensing and the sale of medicines either in hospital or in community pharmacies rather than providing any professional or pharmaceutical care services. D.Pharm. qualified pharmacists constitute the majority of the workforce among registered pharmacists in the country.
- *B.Pharm.:* The curriculum of B.Pharm. program in India is traditionally focused on the industrial aspects of the pharmacy profession rather than clinical practice concepts. The B.Pharm. graduates are groomed as the work force for pharmaceutical industry in the areas of pharmaceutical sales and marketing, manufacturing, quality control. B.Pharm graduates play a very small role in community pharmacy practice.
- *M.Pharm.:* This 2 years postgraduate program after B.Pharm enables the aspirants to choose their study in 12 specializations approved by PCI. The program is structured to have 1 year of education and training with theory and practical 1 year dedicated for research work leading to submission of a dissertation. It is noteworthy that among these 12 specializations, all except "Pharmacy Practice" are industry focused.

Thus, from inception the higher education in pharmacy both at undergraduate and post graduate levels in India focused on the needs of industry rather than pharmacy practice (i.e., pharmaceutical care or patient care). This structure therefore has limited the potential impact of pharmacists on the real and growing health care needs of the Indian population.

Pharmacy Practice Education

- *Pharm.D.:* The Pharm.D. program in India typically consist of two phases; theory and practical courses in the first 5 years (Phase I) followed by a 6th year internship (Phase II) consisting of "Introductory Pharmacy Practice Experiences" (IPPE) and "Advanced Pharmacy Practice Experiences" (APPE). The subjects included in phase I are logically sequenced and advance year on year with basic biomedical, pharmaceutical sciences and administrative pharmacy subjects in the first 3 years to build the foundation followed by intensive teaching of pharmacy practice subjects in the last 2 years. The 5th year also comprises a clerkship training in hospital wards and community pharmacy for a minimum period of 500 h (20 h per week dedicated for a minimum of 25 weeks in

an academic year) and 6 months' research work done in a group with not more than 4 students, leading to submission of a dissertation. The overall hours of teaching and training in Pharm.D. program have 29% didactic teaching, 16% practical in laboratories, and 55% of clinical and community pharmacy training.

- *Pharm.D. (PB).* : This is a 3 year program after B.Pharm. in which the students join directly the 4th year of the Pharm.D. program and pursue the same program along with the regular Pharm.D. students.
- *B.Pharm. (Practice).*: The curriculum of this 2 year bridging program for practicing pharmacists with D.Pharm. qualification includes the subjects of pharmacy practice to equip them to provide professional pharmaceutical care services. The practicing pharmacists pursue this program as a week-end (part-time) course with at least 10 contact hours per week.

More details about these programs are available from the respective regulations available from the official website of Pharmacy Council of India (http://www.pci.nic.in/home.html).

Evolution of Pharmacy Practice Education

The evolution of pharmacy practice education and inception of the Pharm.D. program were not knee-jerk reactions by the regulators or ill-conceived ones as criticized by a few professionals (http://www.pharmabiz.com/NewsDetails.aspx?aid=75997&sid=1), but rather a well-planned response with the vision of matching global standards of pharmacy education. This argument is substantiated by comparing the historical perspective of pharmacy practice and Pharm.D. to international standards. For example, in 1992, the Pharm.D. degree was approved as a professional degree in Pharmacy by the American Association of Colleges of Pharmacy (AACP) (Buttaro, 1992) and in 1997 the Accreditation Council for Pharmacy Education (ACPE) mandated all colleges of pharmacy to convert their degree programs to Pharm.D. by refusing accreditation for Bachelor of Science programs effective from the year 2000 (Carter, 2016). In the same decade, parallel processes occurred in Indian pharmacy education with the introduction of the first specialization in "Pharmacy Practice" at Masters degree (M.Pharm.) level in 1997 at JSS Colleges of Pharmacy Mysore and Ooty through a joint Indo–Australian program of cooperation (Nyfort-Hansen and May, 1998). This program was associated with the introduction of clinical pharmacy services at a private teaching tertiary hospital and a district headquarters secondary care public hospital respectively.

This was achieved through the planning and efforts initiated in the year 1992 by the JSS Colleges of Pharmacy, Mysuru and Ooty with the assistance of Frank May and his colleagues at Repatriation General Hospital (RGH), in Adelaide, Australia. Under a Memorandum of Understanding (MoU) in 1995, four faculty members of JSS Colleges of Pharmacy including the first author of this chapter, were trained in Australia and acquired a graduate diploma in clinical pharmacy from the University of South Australia (Berg, 2001). Thus, the M. Pharm program in the specialty of "Pharmacy Practice" started by these two colleges with trained faculty members, supported by clinical pharmacists from RGH, served as a reference and model sites for the entire country to offer similar educational programs and training (Nyfort-Hansen and May, 1998).

The "Mysore Declaration on Clinical Pharmacy Practice and Education in India" presented in a national meeting on "Hospital and Clinical Pharmacy" held at Mysore in the late 1999 was another milestone in the journey of pharmacy practice education in India. This declaration discussed the standards for the practice of clinical pharmacy in India including but not limited to: Training and facilities, Syllabus, Patient-focused teaching, Hospital infrastructure requirements, Resources, Interested and committed management, Inspection and approval of institutions (Berg, 2001). Two decades later in 2018, about 60 pharmacy colleges are offering M. Pharm program in Pharmacy Practice/Clinical Pharmacy/Hospital and Clinical Pharmacy specializations (http://www.pci.nic.in/home.html). The shifting of pharmacy education away from the traditional industry-focused stream to new postgraduate options in pharmacy practice can be seen as a pivotal development for the pharmacy profession in India.

After gaining experience for about a decade in the education and training requirements of the pharmacy practice curriculum, the Indian pharmacy fraternity decided to introduce the Pharm.D. degree, a 6-year professional doctorate program to train the professionals specialized in pharmacy practice and clinical pharmacy services. PCI introduced this new program:

1. Abolishing the existing B.Pharm. program and introducing a new Pharm.D. program
2. Upgrading the existing B.Pharm. program with additional years of study on clinical pharmacy curriculum
3. Introducing Pharm.D. program in parallel to B.Pharm. program and recognizing both as registrable qualifications for practicing the profession in the country

The decision of choosing the third option is well supported by data indicating that the Indian pharmaceuticals market has increased from US$ 6 billion in 2005 to US$ 36.7 billion in 2016, with a compound annual growth rate (CAGR) of 17.90% between the period 2005–16 (Parthasarathi et al., 2002). It is also forecasted that by the year 2020, on the basis of incremental growth, India is likely to be the top three pharmaceutical markets by incremental growth and sixth largest market in absolute size in the world (Parthasarathi et al., 2002). It is estimated that India's cost of production in the pharmaceutical sector is up to 60% lower than that of US and almost 50% compared to Europe, which gives India a competitive edge in pricing pharmaceuticals for the global market (https://www.ibef.org/download/Pharmaceutical-January-2017-D.PDF) These statistics reveal the growth of the Indian pharmaceutical industry and also the professional scope for B.Pharm. graduates with high demands for B. Pharm graduates trained in industrial perspectives.

On the other hand, the growth of the health care industry has also been massive, representing one of the largest sectors in India in terms of both revenue and employment in the period between 2008 and 2020. The total size of the Indian health care industry which

was about US$ 100 billion in 2015 will touch almost the three times the figure of US$ 280 billion by 2020 with CAGR of 16.5%, reports revealed (http://www.india-opportunities.es/archivos/publicaciones/Healthcare-January-2016.pdf). The majority of the secondary, tertiary and quaternary health care institutions are established by the private sector especially in urban centers and is poised to grow to US$ 280 billion by 2020 (http://www.india-opportunities.es/archivos/publicaciones/Healthcare-January-2016.pdf). Further, it is estimated that from 2009 to 2015, about 3043 clinical trials were carried out in India which also opened a huge market for employment for Pharm.D. graduates with about 1000 companies in the specialized sector of the industry known as Contract Research and Manufacturing Services (CRAMS)(http://www.india-opportunities.es/archivos/publicaciones/Healthcare-January-2016.pdf). Thus the decision of policy makers to introduce the Pharm.D. in India in parallel to the B.Pharm. program has served India well.

There has been debate about abolishing the Diploma in Pharmacy (D.Pharm.) as a registration qualification, and to mandate B. Pharm. as the minimum qualification for practicing the profession of pharmacy in India (http://www.pharmabiz.com/ArticleDetails.aspx?aid=109315&sid=1). This has proven controversial for two reasons: firstly, the proportion of B.Pharm. graduates choosing community pharmacy as their career is negligible and even if it is chosen, they are limited only to urban areas but not in rural. Secondly, upgrading the qualification of practicing D.Pharm. qualified pharmacists to degree would be time-consuming as they constitute about 75% of all pharmacists, with the community and hospital sectors sharing 55% and 20%, respectively (https://www.fip.org/files/fip/HR/final%20report/Part1.pdf). Further, such a major step toward shifting the professional standards of a country like India requires strong policy decisions and enormous resources by both central and state Governments.

However, PCI has introduced a bridging program called B. Pharm (Practice) through its regulation, "Bachelor of Pharmacy (Practice) Regulations, 2014" (**Table 1**; http://www.pci.nic.in/home.html). Pharmacists from community and hospital settings with a minimum of 4 years' professional practice experience can join this program to upgrade their qualification to degree which will be registered as an additional qualification. The success of this effort by the PCI should be assessed in due course as it would be premature at this time to make an assessment of outcomes. However, until professional benefits and career advancement with increased remuneration are realized, motivating D.Pharm. qualified pharmacists to pursue B.Pharm. (Practice) is likely to be a big challenge.

Having introduced the B.Pharm. (Practice) program to equip the practicing community and hospital pharmacists to provide pharmaceutical care services, PCI also redefined the roles of pharmacists in the country through its "Pharmacy Practice Regulations, 2015" (http://www.pci.nic.in/home.html) which is another milestone in the professional practice standards of pharmacy in India. Now practicing pharmacists with any qualification in either community or hospital who desire to offer any of the professional pharmaceutical care services listed in the regulation are encouraged to pursue B.Pharm. (Practice) to attain the required knowledge and skills. This regulation also paved the way for the pharmacists with degree qualification, both B.Pharm./Pharm.D. to focus their career either in community settings or in hospitals.

Thus, it is evident that the pharmacy profession and practice standards in India is evolving and progressing very systematically at a slow and steady pace. It is anticipated that by 2030, the professional practice standards shall reach international bench marks.

Practice

Historically the patient care role of the pharmacy profession in India was not developed to the same extent as roles in industry. The primary focus of pharmacy education toward industrial aspects for more than 70 years is one of the prime reasons for this. In addition, the pharmacists registered and licensed to practice in both community and hospital pharmacies were dominated by D. Pharm. holders who lacked the knowledge and skills needed to provide pharmaceutical care services on par with international standards.

Community Pharmacy Practice

As per the regulations of India governing the sales and distributions of drugs, each community pharmacy must have a registered pharmacist with a minimum qualification of D.Pharm. However, a significant number of community pharmacies are owned by nonpharmacists, in which registered pharmacists are employees and this sometimes leads to handling and sale of drugs by unqualified personnel. Though the minimum space requirement for establishing a community pharmacy is 10 m^2, the majority have about 20 m^2 but rarely more than 50 m^2 (Berg, 2001). In general, these retail outlets are open for about 13 h daily between 9.00 am and 10 pm and a few in urban areas are open 24 × 7 (http://www.pci.nic.in/home.html). As there are no regulations curtailing the number of pharmacies or the minimum distance between two pharmacies, community pharmacies are often concentrated in areas close to hospitals, market areas and bus stations, and urban regions. It is also common for many hospitals to have their own dispensaries through which drugs are sold to ambulatory patients and others. By default, about 99% of community pharmacies stock the formulations distributed by pharmaceutical industries either directly or through wholesalers and dispense them to the end users rather than making any extemporaneous preparations (http://www.pci.nic.in/home.html). These pharmacies stock a wide variety of products including prescription drugs, nonprescription medicines, food products such as health drinks, cosmetic products, surgical supplies, and certain medical devices, etc. depending on the location, market trends, and product demand.

Community pharmacists are paid only for the medication costs and receive no payment for pharmaceutical care services even if provided, and so there is a lack of incentive and motivation to provide professional services. The majority of patients meet their own health care expenses including purchase of drugs, unlike in the western world where many are covered by national health systems or private health insurance companies. However, the pharmacy practice regulations, 2015 of India has given provision to charge

patients for professional services if patients are willing to pay for these. The interaction between community pharmacists and prescribers are often limited to prescription clarification and permission to change brands of drugs during prescription filling.

Community pharmacists, known as retail pharmacists in India, are traditionally perceived by the public and physicians as traders of medicines rather than as professionals with the potential to provide professional services (Basak and Sathyanarayana, 2009). However, the efforts of the PCI and professional associations in the country including the Indian Pharmaceutical Association (IPA) in training them to offer pharmaceutical care services have had positive outcomes in certain areas. A distinctive example is the publication of "Good Pharmacy Practice Training Manual" by the collaborative efforts between the Drug Controller General of India (DCGI), IPA and WHO. This is used by IPA as a manual to conduct training programs for community pharmacists on various professional roles and activities (GPP, 2005). As the majority of the community pharmacy outlets are owned by individuals rather than companies, bringing these pharmacists in for training programs is a great challenge as every individual needs to be motivated toward this. Apart from the professional bodies/associations, the pharmacy colleges with pharmacy practice departments and or Pharm.D. programs also use their workforce, the faculty and students to conduct continuing pharmacy education (CPE) programs to update and upgrade the knowledge and skills of community pharmacists toward providing pharmaceutical care services.

A success story of a community pharmacy in the southern part of the country is motivational for new graduates to take up community pharmacy as their career choice. Two M.Pharm. (Pharmacy Practice) graduates established a community pharmacy in the year 2001 with many innovations at that time viz. larger premises, fully air conditioned, an exclusive space marked for patient counseling, along with pharmaceutical care/ health screening services such as measuring BP, blood sugar, BMI, medication counseling, all provided at free or subsidized cost. This novel practice attracted a huge number of patients to the community outlet, and due to this over-whelming response from patients, and their strategic plan, today the pharmacy stands as a private limited company having about 59 retail outlets across 18 cities in the state of Tamil Nadu with more than 700,000 customers registered in their database (http://thulasipharmacy.com/about.php). This reveals the potential benefits of professional services being offered at community pharmacies, and a role for these pharmacists to contribute to improving the health of the Indian population.

Pharmacists partnering with National TB Program

India accounts for about 20% of the global incidence of TB and has the highest burden in the world, adding nearly 2 million new cases annually. The indirect cost to society toward tuberculosis control is about US$ 3 billion. The Indian government has introduced the Revised National Tuberculosis Control Program (RNTCP) that includes the Directly Observed Treatment, Short Course (DOTS). Under this scheme, the full course of anti-TB drugs is given to patients. The community pharmacists in Mumbai were involved for the first time in the TB Fact Card Project, which was focused on creating awareness of TB and monitoring of medication adherence. The success of this project encouraged the stakeholders to involve about 350 community pharmacists in Mumbai and other parts of Maharashtra in the DOTS TB Pharmacists project in which the community pharmacists act as DOT providers (Nyfort-Hansen and May, 1998). The success of the Maharashtra model has led to a scale-up of this project to the entire country and it is reported that nearly 75,000 pharmacies across 4 states and 12 districts are engaged as DOTS providers to the patients near to their home (https://www.fip.org/files/fip/news/DOTS_TB_projectIndia.pdf).

Mission of combating HIV/AIDS in India

According to the UNAIDS gap report 2016, about 2.1 million people live with HIV and nearly about 86,000 were infected in the year 2015; of those about 43% were on antiretroviral drugs (UNAIDS, 2016). By recognizing the significant role of pharmacists in medication adherence and management, WHO and International Pharmaceutical Federation (FIP) jointly made a declaration on the role of pharmacists in combating HIV/AIDS pandemic (FIP and WHO, 1997). Consequently, as part of the countrywide initiative, IPA released a guiding principles document that was used for training the trainers and in-service pharmacists with the objectives of:

- Motivating pharmacists to disseminate information to the community on protection against HIV/AIDS;
- Explaining the safe use of disposable needles and condoms;
- Informing the HIV/AIDS patients about proper usage of drugs, diet, and lifestyle changes;
- Encouraging and counseling the kith and kin of the AIDS patients;
- Offering moral support to the HIV/AIDS patients to lead a normal life.

The contents of the training included pathophysiology, mode of transmission and therapeutics of AIDS, role of pharmacists in prevention of HIV/AIDS, safe use of blood and blood products, diagnostic screening tests and hazards of injectable drug use. Accordingly, about 400 pharmacists in New Delhi, 250 from Mysore and 25 from Kolkata were trained through this scheme in the year 2004 and IPA included the same in its regular training module as well (ICIUM, 2004).

Other initiatives by educational institutions in community pharmacy

Apart from these two nationwide initiatives to use the community pharmacy workforce for health care schemes, the other initiatives were limited to institutions and resulted in a few publications. Many of these studies were student projects, dissertations of M. Pharm., and or Pharm.D. programs. Few of such studies carried out were impact of patient counseling/education by community pharmacists on the quality of life of hypertensive patients (Carvalho and Nagavi, 2007), diabetes patients (Adepu et al., 2007; Kumar

et al., 2006), management of asthma (Van Sickle, 2006), self-medication (Manju et al., 2016), management of anticoagulants (Lakshmi et al., 2013), etc.

As the above case studies indicate, there is significant unmet potential for clinical pharmacists in the community to help address health care needs and disparities in India. The findings of these pilot studies should be extended to a larger section of community pharmacists in order to create a nationwide impact, but unfortunately in the majority of instances, after the study is completed, the community pharmacists do not show any interest to continue such services. Many times, the research in community pharmacy is limited to assessing the knowledge, attitude and perception (KAP) of community pharmacists on various professional activities and or assessing the KAP of patients/consumers on various services of community pharmacists. There is considerable scope for community pharmacists to extend professional services as they remain as the first contact point for the patients.

Hospital and Clinical Pharmacy Practice

Hospital pharmacy practice

The pharmacy practice standards in hospitals vary depending on the type of hospital viz. public vs. private/corporate, primary, secondary, tertiary care, and super specialty. The spectrum of drugs used also differs between the different types of hospitals.

Public Hospitals: As the drugs are dispensed free of cost at public hospitals, the generic formulations are made available rather than the branded ones. The procurement of these drugs and other surgical supplies are done through a centralized purchase procedure against a public tender, often for the entire state. The list of drugs to be procured are decided based on the essential drug list of WHO by the physician group who are in the administrative arm of government and thus the involvement of pharmacists in the process of centralized purchase procedure is very minimal.

The drugs purchased centrally are then sent to warehouses at district levels in which the pharmacists are in-charge of stock storage including cold storage and distribution to other health care facilities of the district. Once these stocks are received from the warehouse by the hospitals they are stored in the central store of the hospital from where they are distributed to the ambulatory pharmacy commonly known as the outpatient pharmacy in India. Once again here the central stores and ambulatory pharmacies are manned by registered pharmacists. In case of a PHC, the drugs received from the warehouse are stored directly in the ambulatory pharmacy of the PHC by the pharmacist. Interestingly, drug distribution into the wards for inpatients is not done by pharmacists but depends on nursing staff raising orders as per the medication orders written in the patients' case record. Thus, in the public health care system, the pharmacists are maintaining the stock of medications, inventory management and distributing them to various end-users rather than participating in the decision making process of drug procurement or in clinical medication management services.

Private Hospitals: Unlike the public hospitals, private hospitals tend to stock both branded and generic medications and depending on the size of the hospital, the responsibilities of the pharmacists vary. The number of pharmacists appointed also varies depending on the type of private health care system, viz. nursing home, small hospital, and large hospital. But, even in private settings, the hospital pharmacists do not have any role in dispensing drugs to inpatients. It is not a common practice to have a hospital formulary in India, and so the procurement of drugs in private hospitals is done based on demand and supply.

Thus, in both public and private health care settings, hospital pharmacists are involved only in drug procurement, inventory management and distribution. There is unrealized potential for pharmacists to be involved in pharmaceutical care and medication management services to improve patient health care outcomes.

Clinical pharmacy practice

The advent of the Pharm.D. program in the country has resulted in many remarkable changes with respect to the standards of pharmacy practice especially in the area of clinical pharmacy services, but only in selected private health care organizations. The large hospitals managed by corporations are very much concerned about the quality of health care services provided to their patients, who are ultimately customers. During this process, they strive to get the national and international accreditations for the quality aspects of various services offered by them. The quality standards of these accreditation procedures have a component of clinical pharmacy services with a set of quality indicators such as medication errors, drug-related problems, adverse drug reactions etc. In order to achieve the quality standards, hospitals aspiring to get accreditation establish a clinical pharmacy department, appoint clinical pharmacists and entrust the responsibilities on them.

Pharm.D. and M.Pharm. (Pharmacy Practice) graduates find placements in such hospitals, often with the responsibility to establish the clinical pharmacy department for the first time and become the chief of such clinical pharmacy divisions. In the hospitals where the clinical pharmacy department is established and clinical pharmacists are appointed, the quality use of medicines is achieved by various clinical pharmacy services viz.

- Constitution of a Pharmacy and Therapeutics Committee
- Establishment of drugs and poison information services
- Medication reconciliation
- Patient chart review
- Addressing drug-related problems
- Unit dose dispensing system
- Dose division for pediatrics

- Intravenous admixture services
- Educational services to Medical Doctors, Nurses, and other paramedical staff
- Therapeutic drug monitoring services
- Drug utilization evaluation (DUE)
- Preparing standard treatment guidelines for the institution, region
- Antibiotic stewardship programs
- ADR monitoring and reporting
- Chemotherapy preparations
- Total parenteral nutrition
- Patient education and counseling

As per the needs of the hospital, any of the services mentioned above are provided by the clinical pharmacist or a team of clinical pharmacists. These clinical pharmacists also act as student preceptors if it is a teaching hospital or providing internship training to Pharm.D. students.

Pharmacy practice and industry

A contract research organization (CRO) supports the development of pharmaceutical or biological products and medical devices on a contractual basis. The services include but are not limited to drug development, product development, process development, bio-analytical method development, preclinical studies, any phase of clinical trials apart from clinical trial management and pharmacovigilance services. India is emerging as a leading destination for CROs for various reasons such as the acceptance of intellectual property rights and international guidelines, presence of a huge population with diverse disease conditions, availability of larger hospitals with a huge patient load, educated and accessible human resources, and low operational costs.

It is estimated that the Indian CRO market will reach the heights of US$ 1973.82 million in 2023 from US$ 1000 million in 2016, at a CAGR of ~12.00%. Further, the market share by end users in the year 2017 was found to be about 22% by clinical trials and 18% by post marketing surveillance (India CRO, In Press). These two areas in which the Pharmacy Practice/Pharm.D. graduates have career opportunities constitutes about 40% of the CRO's market and is expected to expand further in future. Thus, the Pharmacy Practice/Pharm.D. graduates do not need to confine their career options to hospitals or community practice as they have wider employment opportunities in the industrial sector as well. Currently CROs absorb a higher proportion of Pharm.D. graduates than the hospital sector (India CRO, In Press).

Pharmacy practice research

Pharmacy practice research has a low profile compared to pharmaceutical sciences research, which may reflect funding limitations from research grants. Pharmacy practice research examines the impact of pharmacy practice services on patient and health care system outcomes. Though it has a wide scope to include clinical, economical, humanistic, and behavioral changes as study outcomes, in practice there is a paucity of evidence on the quality of services delivered by pharmacists, patient outcomes, and cost-effectiveness. This lack of evidence is due to the fact that by and large pharmacy practice research is carried out as part of the academic requirement to acquire a post graduate or Ph.D. degree rather than multicenter or nationwide studies to develop pharmacy practice services in a more systematic way. Carrying out such large scale studies is both an opportunity and challenge for researchers in the pharmacy practice area. Therefore, development of a professional evidence base and strategically integrating the same with practice is the first priority and will require the profession to build up research capacity in pharmacy practice.

Future Directions

Pharmacy education and practice continue to evolve in India, albeit at a slow pace due to the size, complexity, diversity, and economic realities of the country. Several key priorities have emerged:

Education

- Though the curriculum of Pharm.D. and M.Pharm. (Pharmacy Practice) are the same throughout the country, the quality of education and training provided by institutions has disparity in many aspects. Robust quality assurance mechanisms through national or international accreditation processes will help to minimize this difference if implemented in the future. Introducing a national licensure examination is a good idea to bring in uniformity in training the students.
- The pharmacy colleges need to adopt more student centric learning experiences so as to improve not only the clinical skills of the graduating students but also their soft skills to render a holistic development of the graduates.
- Novel pedagogies and assessment tools, such as OSCE/OSPE should be introduced throughout the country which is currently available only in a couple of institutions.
- As more graduates join hospitals/community settings, there is a growing opportunity for them to act as independent preceptors for future students.

Practice

- After a few years, pharmacists with higher qualifications may choose community pharmacy as their career choice as there is scope for practicing the profession and providing pharmaceutical care services.
- If the health expenditure pattern shifts from out-of-pocket to third party insurance, the possibilities of "professional services reimbursement" may improve that will further encourage many pharmacists to choose community pharmacy as their career.
- Similarly, if accreditation procedures are mandated for all large hospitals including public hospitals to ensure the quality of services provided, appointments of clinical pharmacists in those organizations will open up more and more opportunities for pharmacists.
- The ever increasing scope for CROs in India is promising for future pharmacy practice graduates including Pharm.D.

Research

- Generating robust evidence for successful implementation of pharmacy practice services is needed to obtain more funding from different agencies, and above all to convince the regulators to implement new regulations and guidelines pertaining to the profession of pharmacy.
- Apart from academic research, independent research by universities, professional bodies and associations is needed to generate reliable high quality data in pharmacy practice that can guide policy making and decision making.

Summary

Though pharmacy education and a regulated pharmacy profession have existed in India for more than 75 years, pharmacy practice education and professional/clinical practice are relatively young. In response to a paradigm shift across the globe with respect to the focus of pharmacy education and training, India strategically approached this change and took a balanced decision of retaining the B.Pharm. program to cater for the needs of the pharmaceutical industry while also introducing the Pharm.D. to strengthen pharmacy practice in the country. The experiences gained from the M.Pharm. (Pharmacy Practice) program helped institutions to more adopt the Pharm.D. program. Pharm.D. graduates are able to find jobs in CROs, academia and hospitals, as well as a small number who pursue higher studies. At present the community pharmacy and hospital pharmacy environment is not in a position to welcome revolutionary changes in practice standards as the majority of the workforce are D. Pharm qualified pharmacists who were not trained to provide professional services. However, PCI has already taken steps to bridge the gap in the knowledge and training of D.Pharm. holders through the introduction of B.Pharm. (Practice) program, and encouraged incumbents (through the pharmacy practice regulations 2015) to offer various pharmaceutical care clinical services for a professional fee, if the patient agrees. Pharmacy practice research needs to be carried out nationwide to create strong evidence in order to support policy changes by government and regulators.

Pharmacy Practice in the Gulf States

Kerry Wilbur*, Maguy Saffouh El Hajj†, Nadir Kheir‡, *University of British Columbia, Vancouver, British Columbia, Canada; †College of Pharmacy, Qatar University, Doha, Qatar; ‡The University of Auckland, Auckland, New Zealand

Introduction

For nearly a decade, we sat on the admission committee of a pharmacy training degree program in a Gulf State country. Applicants' country of origin peppered the map of the wider Middle East and North Africa region: Egypt, Jordan, Palestine, Yemen, Sudan, Somalia, Eritrea, Tunisia to name a few. When asked to describe their motivations for joining the pharmacy program, many applicants offered candid revelations in their written personal statements:

> My father experienced a major drug-drug interaction that nearly took his life. Thankfully, he recovered but he suffered and his hospital stay was prolonged.
>
> My main purpose for entering pharmacy major is to prevent medication errors because I have lost one of my best friends due to a medication error.
>
> I come from a place in the world where having a proper healthcare service is an advantage that is not available to all. Considering the suffering experiences in my community, I applied to study pharmacy with the objective of making healthcare more accessible to patients.
>
> Seeing people with amputated limbs because of suboptimal diabetes care and treatment raised a crucial question in my mind, "who is responsible for these patients?"

Shortcomings in medication-related health care exerted a profound and deeply personal toll on these young individuals, so much so that each made career decisions to address and defeat them. The World Health Organization (WHO) continues to endorse a prominent position for pharmacists in health-care systems. Outlined roles include those of *decision-makers*, *communicators*, *leaders*, *managers*, *life-long learners*, and *teachers*. First and foremost, however, is the duty as a *caregiver*, described as the provision of clinical, analytical, technological, or regulatory services that must be of the highest quality. These students determined that their families, their friends, their communities deserved better care and to contribute by becoming a pharmacist.

This chapter outlines the pharmacy practice landscape into which such young pioneers enter and where they and other colleagues will continue to lead in the future.

A Geographic and Cultural Orientation to the Gulf States

The "Gulf States" are considered to represent the seven Arab countries bordering the Persian Gulf, namely, Bahrain, Iraq, Kuwait, Oman, Qatar, Saudi Arabia, and United Arab Emirates (UAE).

The estimated regional population is 90 million and ranges from 1.4 million in Bahrain (also the smallest country in square kilometers) to 36.5 million in Iraq. Historically, low population density has been accounted for by geography (extreme aridity and limited freshwater supplies); however, in recent modern times, rapid economic growth in oil and gas sectors has led to widespread migration to develop and support local infrastructures. Indeed, significant proportions of enumerated residents are expatriate workers who inevitably contribute to cultural diversification at their destination. Meanwhile, the local population structure is generally young (just over half is under 25 years of age) and technologically savvy. Such demographic elements assuredly converge to impact health-care delivery and consumption in these settings.

With the exception of Iraq, all are members of a separate group of nations, the Gulf Cooperation Council (the GCC, formed in 1981) and are governed by monarchies (constitutional or otherwise). However, this formation of contemporary states has not annulled their shared history and traditions or common languages, beliefs, and values.

Defining a culture is a complex and nuanced enterprise. One of the most notable frameworks for characterizing national values is Hofstede's cultural dimensions model (Hofstede, 2003). Through comprehensive workplace study in over 60 countries, he arrived at six features, whereby a country's collective society exhibit different behaviors or preferences along these values: *power distance*, *individualism vs collectivism*, *masculinity vs femininity*, *uncertainty avoidance*, *long-term vs short-term normative orientations*, and *indulgence vs restraint*.

Cultural dimension profiles among the Gulf State countries are largely consistent. For example, society members accept and expect unequal distribution of power (high *power distance*); interdependency exists among members (low *individualism*); tolerance for ambiguity is low (high *uncertainty avoidance*); and focus tends to be on present and past over preparation for the future (*short-term orientation*).

Other models exist for characterizing cultures but most cover similar or overlapping concepts. It is important to recognize that a national (or even regional) cultural profile cannot represent the predisposition of every individual member. This is especially true for countries with heterogeneous resident populations, such as those of the Gulf State nations. Despite such caveats, these frameworks are useful guides to understanding how governments and professionals approach health-care regulation and delivery and in turn, how it may be received by patients and families and therefore have resulting implications on health care and pharmacy practice in the region.

Pharmacy Practice in the Gulf States

Health care in Gulf State countries is available through both private and public systems. Public medical services are often free or significantly subsidized. Pharmacy practice within the Gulf States is typically governed by a national Ministry of Health (MOH) or equivalent. In addition to health-care infrastructures and delivery in their country, these bodies and its subdepartments are responsible for the regulation of drug pricing, medication access, safety monitoring, pharmacy ownership, and pharmacist licensure.

Saudi Arabia has the largest domestic drug market and purchases approximately two-thirds of all medications sold elsewhere in the region (Almemman and Aljedai, 2016). Patented drug brands dominate the supply and generic substitution by community pharmacists is uncommon, due in part to regulations, but also patient rejection of perceived inferior product. Many therapies that might require prescriptions in other jurisdictions may be self-selected by patient for purchase at community pharmacies. Most countries more strictly regulate pharmacist dispensing of antibiotics, opioids, and controlled drugs. The patient safety threats of counterfeit medication in these developing countries are also recognized and a number have outlined strategies to combat infiltration into their jurisdictions.

Electronic health records are typically only available within inpatient care settings (for example, hospitals and not in community pharmacies), but variability exists. This poses difficulties for continuity of care across public and private settings and is confounded by both residents and expatriates importing medication for personal use from other countries.

Technical medication preparation functions such as compounding and prescription assembly are also still largely conducted by pharmacists. In community settings, in particular, it may be difficult for patients to differentiate between pharmacist and non-pharmacist staff.

Expanding scopes of outpatient pharmacy practice in Gulf State countries face additional hurdles. While over 75 pharmacy degree training programs now exist, the region still relies heavily on expatriate professionals and will continue to do so for the foreseeable future (Kheir et al., 2008). As an example, Saudi Arabia annually graduates the most pharmacists (~1000), but at a rate projected to take to 2035 to completely "nationalize" its pharmacy workforce (Almemman and Aljedai, 2016). As such, uniform knowledge and skill-set remains elusive. It is additionally difficult to attract and retain pharmacists to outpatient practices in the region (particularly community pharmacy or nongovernmental operations) as competitive pay and professional atmosphere are generally lacking. Indeed, the pervading public attitude toward pharmacists' roles is as "dispensers" or "businessmen," impressions which may be reinforced when motivated pharmacists chose other workplace settings. Most Gulf State countries do have pharmaceutical societies who strive to engage pharmacists and promote their roles to society.

Despite the extrinsic and intrinsic challenges to contemporary patient care in these landscapes, the past decade has in fact marked an important period of pharmacy practice advancement in Gulf State countries, which will undoubtedly continue, fueled by the vision and commitment of its young leaders.

Bahrain

Bahrain is the smallest among the Gulf State nations and may also be considered the most developing in its pharmacy practice. In 2015, Bahrain became the last country in the region to offer pharmacy degree training domestically (a 4-year Bachelor of Science in Pharmacy at the University of Bahrain). The total pharmacist workforce is currently an estimated 550 (as many as 65% in noninpatient settings), and practice development is supported by the Bahraini Pharmacist Society, established in 1996 ("Bahrain Pharmacists Society," www.baphso.org).

The public health-care service for the 1.425 million population is based upon a series of over 25 health centers and 6 government hospitals. The largest is Salmaniya Medical Complex that hosts a number of specialized outpatient clinics and is the main center for acute care. This complement of public institutions does not include at least an additional 16 private hospitals and health units (WHO, 2007, 2017). Community pharmacies (chain or otherwise) are pervasive (145 were registered in 2014) and many are open to provide services 24 h a day (Otoom et al., 2010).

Iraq

Iraq is located in the North of the Arabian Peninsula with a population of 38 million distributed across 18 governates (World Population Prospects 2017). Health-care services are provided without charge through public hospitals and primary clinics controlled by the MOH. However, years of conflict and imposed embargoes have left many facilities deficient in medications and medical supplies and lacking in information technology. Personnel staffing is also problematic, as health professionals have also left the country during this extended time period resulting in profound workforce shortages. For example, as per 2009 data, there were just over 5300 pharmacists practicing in the public sector (Ibrahim and Wayyes, 2016). As a result, pharmacy service hours are typically truncated (7 h, from 0800 to 1500 h) and functions are largely distribution in nature. Pharmacists in the public sector may work as managers in hospital pharmacies dispensing medications to ambulatory patients or as internal hospital personnel responsible for distributing drugs to the wards. There are reports of small number of pharmacists performing direct patient care on wards of major public hospitals (Al-Jumaili et al., 2013).

In contrast, the private health system in Iraq has been expanding to account for public sector shortcomings includes 96 private hospitals, 12,000 physician clinics and 6140 community pharmacies distributed throughout the country (Ibrahim and Wayyes, 2016). However, the private sector requires cash (out-of-pocket) payment as no private health insurance exists in the country.

Iraq has a long tradition in pharmacy services. The first apothecary in history is believed to have been established in Baghdad in 754 AD (Hamarneh, 1962; Ibrahim and Wayyes, 2016). Community pharmacies are privately owned by licensed pharmacists, but there are no chain pharmacies in the country. The MOH is responsible for community pharmacy regulation and monitoring. Pharmacist presence at the pharmacy is mandatory, and consequently, operating hours depend on the pharmacist's license. Part-time license is usually given to pharmacists working in the public sector meaning the community pharmacy may open after 1600 hours. Full-time license is issued to pharmacists who are retired or resigned from the public sector (Al-Jumaili et al., 2013). The majority of medications are designated as over-the-counter (OTC) and may be self-selected by patients. Unlike other countries in the region, community pharmacists in Iraq can make generic substitution to prescribed brand name medications; however, this practice is discouraged by physicians concerned with product integrity (Ibrahim and Wayyes, 2016). Medication shortages and absent quality control in pharmaceutical industry have undoubtedly left the country vulnerable to the counterfeit drug market influencing generic and brand therapy alike. Community pharmacists in few settings offer weight, blood glucose, and blood pressure monitoring services in addition to medication- and disease-related advice (Ibrahim and Wayyes, 2016). Such scope of pharmacist practice is in part associated with the political and economic situations preventing patients from visiting their physicians when community pharmacies meanwhile are easily accessible and are freely available (Basheti et al., 2014).

In terms of formal pharmacy education, the first college of pharmacy was opened at Baghdad University in 1936. Nearly 20 now exist in the country offering 5-year Bachelor of Pharmacy degree and some Masters and Doctoral programs. Unfortunately, many qualified academics have left the country, and colleges have consequently begun recruiting its own novice alumni (Kheir et al., 2008; Ibrahim and Wayyes, 2016). Doctor of Pharmacy degree training is not available (Al-lela et al., 2012). However, The Iraqi Council for Medical Specialties approved a professional degree in 2011 under the name of the "Iraqi Board in Clinical Pharmacy," permitting pharmacists a chance to provide advance patient care activities (Basheti et al., 2014).

Kuwait

The health care for Kuwait's population (~4 million) is predominantly provided by the public sector through primary, secondary, and tertiary care facilities. Primary care is delivered by over 70 health centers distributed in the country's six governates each of which also possess a general hospital (Awad et al., 2006; "Annual Health Report 2013", https://www.moh.gov.kw/en/Ministry-Statistics).

Medication is dispensed freely to Kuwaiti nationals and expatriate residents when obtained from pharmacies in public hospitals and clinics if prescribed by a hospital physician. However, certain therapies (typically high cost drugs) are no longer provided freely to expatriates, but they may be accessed if the individual wishes to pay out-of-pocket for the prescription. The MOH regulates the standards of private care where many hospitals and clinics also have their own pharmacies (WHO, 2006, 2012).

Almost two-thirds of pharmacists in Kuwait work in the government (public) sector. Only Kuwaiti nationals are granted pharmacy license for ownership and operation from the MOH (Szadkowska and Sochacki, 2015). Community pharmacists are acknowledged as the most accessible primary care provider in the country, but study indicates the public trusts medication-related information from physicians foremost. Less than one-quarter surveyed thought pharmacists had a suitable balance between dual health-care provider and business owner roles (Awad et al., 2017). Perhaps ironically, Kuwaiti law restricts a pharmacist to ownership of a single pharmacy (Szadkowska and Sochacki, 2015). Patient attitudes toward community pharmacies are more akin to a supermarket where product is purchased (Awad et al., 2017). However, only pharmacists or medical factories are

permitted to "warehouse" medicines for resale and so in fact medication is actually not available in supermarkets or shops, unlike in countries elsewhere.

Most drugs are available from community pharmacies as OTC and may be self-selected resulting in little routine interaction between the pharmacist and the patient. Prescriptions are however necessary for antimicrobials, corticosteroids, opioids, and certain psychoactive drugs. The law mandates labeling for all medications dispensed in both private and public sectors, but workplace conditions (patient volume, patient willingness to wait) may preclude routine adherence. Community pharmacies are not obligated by law to maintain patient medication records and most therefore do not (Matowe et al., 2003).

Clinical pharmacy services have not yet take root in most public and private hospitals in Kuwait (Kheir et al., 2013). In these settings, pharmacists fulfill mainly technical functions with minimal ward-based direct patient care. However, pharmacists in at least one large governmental hospital report participation in multidisciplinary rounds, development of pharmaceutical care plans, as well as committee work on guideline development and medication safety protocols (Lemay et al., 2018). While most inpatients will have first prescription of discharge medication filled directly at hospital pharmacies, opportunities for pharmacist interaction are unfortunately limited due to workload and environment (crowding of small available space) (Katoue et al., 2014).

Domestic pharmacist training is available at the national higher education institution, Kuwait University where approximately 60 students (male and female) are annually admitted (Kheir et al., 2008). Survey has found these gradates more likely to initiate clinical services in hospitals than pharmacists from overseas programs (Lemay et al., 2018). The Kuwait Pharmaceutical Society was established in 1974 representing one of the oldest professional associations in the Gulf State region. While continuing education is not a current requirement for pharmacist licensure, the government has outlined in its Kuwait Vision 2035 intention to enhance competencies and improve the performance of the country's health-care workers with training programs, in addition to expansion in health services and infrastructure ("New Kuwait" www.newkuwait.gov.kw.en),

Oman

The Sultanate of Oman has a population of almost 2.5 million and is administratively divided into 11 Governorates ("WHO 2010," www.who.int). The current status of health care stands in sharp contrast to the state of affairs up to 1970, when only two hospitals existed in the country. In keeping with decentralization policy, the Omani MOH was tasked with the delivery of comprehensive health care through a network of hospitals, health centers, and mobile units. Three public hospitals are now joined by over 1000 private clinics and 13 private hospitals and health centers. In the 1990s, the first computerized drug information service and a national poison center were established. In 2000, the MOH established the Directorate of Rational Drug Use, a body dedicated to overseeing rational prescribing and use of medications.

Two governmental bodies under the MOH regulate and oversee pharmacy practice and services in Oman. These are the Directorate General of Medical Supplies (DGMS) and the Directorate General of Pharmaceutical Affairs and Drug Control (DGPA & DC). Together they are responsible for drug registration, pricing, and quality assurance, as well as the country's Pharmacovigilance and Drug Information Department. The DGMS oversees the procurement, storage, and distribution of medicines, surgical, and laboratory consumables to all hospitals under the MOH and provides technical supervision of pharmacy services, including standardization of hospital pharmacy practices, continuing education, and training of pharmacy personnel. The DGPA & DC is the MOH's arm for licensing community pharmacies, pharmacists, and assistant pharmacists/pharmacy technicians. Approximately 2500 pharmacists and 2200 pharmacy technicians and assistants are working in Oman ("Directorate General of Pharmaceutical Affairs and Drug Control", https://www.moh.gov.om).

The country has approximately 674 community pharmacies. Community pharmacies in Oman sell both OTC and prescription medicines in addition to other health and lifestyle products. Except for few medications classified as prescription medicines (such as antibiotics, drugs acting on the central nervous system, drug-containing hormones), most of the medicines in the country require no prescription stocked and are dispensed or self-selected as OTC products. Several large chain pharmacies own the majority of the private pharmacy business in the country, and most of these also function as agents of giant pharmaceutical drug companies ("Ministry of Health, Sultanate of Oman," https://www.moh.gov.om/en/web/statistics/annual-reports)

Pharmacy practice governance is well organized in terms of laws outlining the physical requirements of community pharmacies, licensure of pharmacists, sale and documentation of controlled drugs, and other such aspects. However, like in other neighboring countries, there are virtually no regulations governing the "advanced practice." In the absence of regulations allowing provision of any cognitive services (such as medication review and pharmaceutical care services), community pharmacists perform basic pharmacy tasks of dispensing. For example, there are very little routine patient-centered services, such as medication counseling or simple patient assessment. When a cross-section of the Omani public was surveyed, over half considered pharmacists as "venders" or "dispensers" and did not expect them to have abilities to treat minor ailments (Jose et al., 2015). Community pharmacists in Oman, also like in other countries in the region, neither keep patient medication records in the pharmacy nor do they utilize computer-based programs to thoroughly review prescriptions for drug interactions (Paravattil et al, 2017). The minority of community pharmacies are web-enabled for seeking drug-related information (Al-Farsi et al., 2014). All of these short-comings mean that an opportunity to utilize a large network of accessible pharmacies and pharmacists is lost.

An estimated one-third of the pharmacy workforce has been "nationalized" and is much higher in government than in the private sector ("Oman Health Vision 2050," www.moh.gov.om/en/healthvision2050/). Replacing expatriates with Omani pharmacists in the community pharmacy sector is a huge undertaking considering some of the realities of practice. Remuneration of pharmacists working in the private sector had traditionally been significantly lower than those in the public. As a result, Omani pharmacy

graduates express greater interest in joining large government hospitals where they have more chance to provide advanced pharmacy services for which they have been trained therefore slowing of pharmacy practice development in ambulatory and private sectors. Meanwhile, the private sector remains primarily profit-oriented market and very few cognitive pharmacy services have emerged.

Unsurprisingly, there is a progressive scope of clinical pharmacy practice in the major tertiary hospitals where young and motivated Omanis seek employment ("Sultanate of Oman Ministry of Health," www.moh.gov.om/documents/). Clinical pharmacists are increasingly accepted members of the medical team and specialized clinical care (e.g., anticoagulation, cystic fibrosis clinics) are being formed. The government sponsors Omani nationals' education in overseas baccalaureate, masters, and doctoral degree training programs and are the pharmacists performing the majority of such advanced practice roles.

In 2014, the MOH released a long-term plan for the country's health-care sector focusing on disease prevention, strengthening primary health care, and initiating health promotion activities (Al-Riyami, 2012). Health Vision 2050 also aims at increasing specialized services, emphasizing principles of patient-centered care, equity in health-care provision, accessibility to services, and information sharing.

Qatar

The State of Qatar has a population of approximately 2.7 million people. The development of oil and gas reserves and parallel infrastructure and modernization projects have led to an influx of workers posing pressure on existing health-care services; approximately 80% of the country is made up of expatriates ("Ministry of Development and Planning," www.mdps.gov.qa/en/statistics1).

The Ministry of Public Health (MOPH) is the central government authority responsible for health laws, policies, standards, as well as facility and practitioner registration, certification, accreditation (Bener and Mazroei, 2010). The main public health-care provider is Hamad Medical Corporation, a MOPH-run organization encompassing a number of national public-sector hospitals, associated-pharmacies, and medication warehouses (Kheir, 2016). Government hospitals provide free (for Qataris) and subsidized (for non-Qataris) health care and pharmaceutical services and products. The country launched its first version of a National Health Strategy in 2011 outlining a comprehensive program of reforms to advance patient-centered health services throughout its facilities aligned with the Qatar National Vision 2030 ("National Health Strategy Qatar," www.nhsq.info).

Community pharmacy services are featured in this strategy that advocates a pharmacy network supported by appropriate policy and processes for enhanced efficiency and access in order to decrease patient reliance on hospitals for filling prescriptions.

Over 500 private community pharmacies are licensed in Qatar including 19 "chain" pharmacy groups (pharmacies in these bodies number from as few as 3 to as many as 50). According to Qatar law, community pharmacies must be owned by Qatar nationals, but may be managed and run by registered pharmacists (usually expatriate pharmacists). Pharmacies sell OTC and prescription medication, as well as cosmetics, mother-and-baby products, patient-support items, and diagnostic tests. Except for a few classes of medications requiring prescription (antibiotics, steroids, hormones, and drugs acting on the central nervous system), all other medications are available as OTC (Kheir, 2016).

Services provided by community pharmacies are still largely "traditional" without extended roles or cognitive services. Notable of the many contributing factors is the absence of regulations mandating maintenance of patient records within community pharmacies to ensure the provision of seamless care across repeated patient visits. Community pharmacy in the country has not yet made the necessary strides to position itself as a prominent source for public health and primary health care. The limited role is reflected in pharmacists' high levels of professional dissatisfaction (El Hajj et al., 2011). However, it is expected the next iteration of the country's health plan (Public Health Strategy 2017–2022) will help redefine the scope of community pharmacy practice in the country through new requirements for pharmacist continuing professional development and supporting roles of pharmacy technicians, automation, and information-technology systems (Kheir and Fahey, 2011). These initiatives will also encompass practice of over 160 pharmacists who are employed at two dozen public primary health-care centers who dispense prescriptions, provide patient counseling, and education. Conversely, pharmacy services delivered from government-run hospitals include traditional roles (medication dispensing), as well as advanced practice whereby ward-based pharmacists provide care and assume responsibilities in specialized clinics (such as heart failure and anticoagulation). Similar expanded roles of de-centralized pharmacist care in private hospital settings are lacking (Kheir et al., 2013).

Several initiatives are slowly driving the practice change in Qatar. While there is no autonomous association or society representing pharmacists, the country's only College of Pharmacy assumes promotional roles for the profession and has been one of the few providers of continuing professional development nationally (Kheir et al., 2011; Wilbur, 2010). Government health-care facilities have increasingly directed new staff recruitment from this Canadian-accredited program and pharmacists with advanced degrees in clinical pharmacy from elsewhere. As of 2016, all health-care providers in Qatar (including pharmacists and pharmacy technicians) must participate in a point-based and accredited continuing professional development system for registration and licensure renewal. Best practices are also being fostered within health-care facilities whereby international accreditation is underway throughout the country. The MOPH additionally plans modernization of the national pharmacy regulatory framework through eventual creation of a national drug information unit and a pharmacovigilance center.

In June 2017, a coalition of Middle East countries abruptly imposed widespread sanctions against Qatar. The country's inability to conduct trade with a major partner such as Saudi Arabia has depleted reserves and restricted regional import of many commercial goods and medical supplies, including drugs (Tharoor, 2017). Qatar has been compelled to accelerate development and diversification of its domestic supply chains, but the long-term effects of the dispute on health delivery, research, and pharmacy practice initiatives requiring GCC-wide coordination are unknown.

Saudi Arabia

Patient care delivery in the Kingdom of Saudi Arabia is distributed across facilities under the Ministry of Health (MOH) and other government sectors, such as the Ministry of Interior, the Ministry of Defense & Aviation, or the Saudi Arabian Oil Company (Alrasheedy et al., 2017). As of 2014, there were 270 public hospitals and 2251 primary health-care clinics in the country. While the majority of care is provided free through government services, the private health-care industry is also robust (141 private hospitals and 2412 polyclinics in operation), and patients may access services at private facilities paying out-of-pocket or through insurance. Tens of thousands of pharmacists (primarily expatriate or "non-Saudi national") are employed throughout the country, mostly working in the government settings (Almemman and Aljedai, 2016; Alrasheedy et al., 2017). Established in 1988, the Saudi Pharmaceutical Society is the primary group representing pharmacists in Saudi Arabia.

There are over 7300 community pharmacies in Saudi Arabia staffed by an estimated 12,500 pharmacists (Alaqeel and Abanmy, 2015). These include independent and chain stores located throughout communities, some of which may be linked with private health-care clinics. All community pharmacies are privately owned by a Saudi-licensed pharmacist (as dictated by law) and regulated by the MOH. Government requirements include the division of inventory within the pharmacy (OTC products, prescription medications, pharmaceutical preparations, cosmetics) and special permission to stock and dispense-controlled substances (and fulfillment of the associated security requirements).

All professional operations in a community pharmacy must be performed by a licensed pharmacist. Unless designated as an OTC, therapy must not be dispensed without a prescription. However, unlike in countries such as the United States, United Kingdom, or Australia, nearly every drug is considered an OTC (Khan, 2014). Medications obtained from a community pharmacy must be dispensed in their original packages and include the package insert/patient information leaflet. The intact outer package must show the medication name, manufacturer, active ingredients, dosage form, strength, storage condition, and price. Unfortunately, there are unintended implications of such laws that adversely affect the consumer. For example, patients with strength or dexterity issues would not be able to receive therapy in a modified container. Patients with cognitive impairments or multiple medications could not receive blister-packaging of their drug regimen. Powder-based treatments (such as antibiotics) are not reconstituted by the pharmacists prior to dispensing leading to high risk for preparation and dosing error by patients at home.

Other patient safety-related aspects of community practice draw attention from authorities. In Saudi Arabia, it is common for prescription-only medication to be supplied by community pharmacies without the necessary prescription. Examples include antibiotics, oral contraception, and therapy for chronic disease (such as drugs used to treat cardiovascular conditions or diabetes). Community pharmacists may then serve as the only point of contact for patients before initiating prescription drug therapy. While wide patient access to such a public health resource can be beneficial, there may be pharmacist skill or contextual factors that prevent adequate counseling. For example, the patient themselves may not the one presenting to the pharmacy for the prescription (this may be a driver or other member of the household). When studies are conducted to understand this phenomenon, pharmacists identify influencing patient factors such as age, emotional state, and financial means. They may feel unwilling or uncomfortable to challenge patients asking for the drug by name. Self-confidence in diagnosing and selecting the appropriate medication, especially antimicrobial therapy, are also cited as reasons to dispense treatments without the necessary prescription (Bahnassi, 2016a; Bahnassi, 2016b; Kashour et al., 2016; Al-Rukban et al., 2012). Many pharmacists do not find this practice problematic, but regulators conversely have concerns that perceived abilities may not match objectively documented knowledge of skills. Yet another cited reason is unintentional violation of the law; pharmacists are not always familiar with the medication prescription status. Others accurately concede that "if we don't sell it, someone else will" (Al-Mohamadi et al., 2013). Government resources to monitor and enforce legislation are lacking and are believed to have exacerbated these practices. In the capital of Riyadh, as an example, less than a dozen health directorate inspectors are responsible for thousands of community pharmacies.

Current conditions for pharmacy practice and advanced pharmacist roles are generally considered superior in in-patient settings (Al-jedai et al., 2016). Pharmacists are permitted to make medication changes and dosage adjustments in a number of institutions. Specialized pharmacy services are established in a number of the tertiary- and secondary-care hospitals, including pharmacist-run clinics for cardiology, anticoagulation, oncology, pain, and solid-organ transplant. As these care models are new to the country, the MOH is proceeding conservatively and often in collaboration with external international agencies and societies to guide planning and execution. Such clinics are also often staffed by "consultant clinical pharmacists" who have completed their education and postgraduate training abroad (e.g., Europe or the United States).

Indeed, Saudi Arabia visibly invests in advanced and international training of its pharmacists. Saudi-national pharmacy graduates are often supported to continue professional development overseas and return to the country to assume leadership positions in patient-care settings, government, and academia. Many such pharmacists are responsible for devising and implementing the 2010–2020 strategic plan for the MOH National Pharmacy Practice Programs. Eighty projects are intended to advance the MOH mandate to "*provide the best pharmaceutical and clinical care [using] high quality, modern technology, [at] the most reasonably-priced cost for patients*" and covers more than 7000 community pharmacies, 2200 primary care centers, and 400 hospital pharmacies across both public and private sectors (Alomi, 2015).

United Arab Emirates

The United Arab Emirates consists of seven emirates: Abu Dhabi (the capital), Dubai, Fujairah, Umm Al-Quwain, Ras Al-Khaimah, Ajman, and Sharjah. An affluent country of over 9 million, approximately 3.6% of its Gross Domestic Product (GDP) is allocated to

health-care spending (Blair and Sharif, 2012). Health-care services are offered free of charge to UAE citizens. For expatriates, health insurance is mandatory but usually provided by the employer. The MOH regulates and monitors health-care and pharmacy services in concert with the Health Authority of Abu Dhabi (HAAD) and the Dubai Health Authority (DHA) in these respective emirates. The MOH alone monitors services in the other parts of the country. Service quality is generally felt to have improved with the advent of the two additional semi-decentralized regulatory bodies, but is also coupled with some shortcomings in functions and task delegation among them (Hassan et al., 2017; Rayes et al., 2015; Sadek et al., 2016).

There are an estimated 1500 community pharmacies in the UAE (independent and chains) and all are privately owned. Nonpharmacists are permitted to own community pharmacies, but they must be operated by pharmacists. Pharmacies are open throughout the week for an average of 13 hours daily. Inventories include cosmetics and baby products in addition to medications and medical supplies (Rayes et al., 2015). The majority of medications in UAE community pharmacies are OTC and can be sold without a prescription. Exceptions include narcotics, psychotropic therapies (including antipsychotics, antidepressants, and benzodiazepines), and other substances considered "controlled," such as isotretinoin, misoprostol, dextromethorphan, octreotide, pimecrolimus, hormone therapy (Yeboah and Yeboah, 2014). The UAE has an expanding pharmaceutical industry regulated by the MOH (Hassan et al., 2017). The HAAD is in particular support of the local generic drug market and has developed policy for generic-only prescribing. While physicians persist in prescribing brand name products, in this emirate, pharmacists have the right substitute with generic alternatives (Hassan et al., 2017; Rayes et al., 2015).

Although many community pharmacies are staffed by two or more pharmacists, over two-thirds of pharmacies dispense less than 100 prescriptions at day (Hasan et al., 2012; Rayes et al., 2015; Sadek et al., 2016). Community pharmacists are additionally responsible for monitoring controlled substances, maintaining inventories, and interacting with insurance companies for medication approvals (Dameh, 2009). Professional roles are often limited to drug dispensing and basic counseling (drug dosing and administration). While it is expected that community pharmacists would offer patient counseling and advice regarding appropriate and rational use of medications, several barriers hinder provision of advanced pharmacy services in the UAE, including the lack of access to information resources and electronic medical records at community pharmacies, physician trust in the pharmacist skills, patient demand for these services, and the business image of the pharmacists in the country (Hasan et al., 2012). High pharmacist turnover associated with excessive workload, long hours, and professional dissatisfaction serves to exacerbate these circumstances (Hasan et al., 2012).

Conditions and scope of practice in the hospital sector may be considered more favorable to pharmacists. Pharmacists review medication orders, fill prescriptions, and provide basic counseling to patients at in-patient or outpatient pharmacies inside government or private hospitals. However, some institutions possess "smart pharmacies," where medications are dispensed by a robot and therefore freeing pharmacist time to interact with patients. Clinical pharmacists provide pharmaceutical care in direct patient-care settings at several hospitals and a few have developed one-year Pharmacy Practice Residency (PGY-1) accredited programs.

Domestic pharmacy training in the UAE was first provided to female students in 1992 by the Dubai Women's College. Seven colleges now offer undergraduate pharmacy education with some offering a Masters or PharmD degrees. Despite the presence of these colleges, the majority of licensed pharmacists are expatriates who obtained their degrees elsewhere (e.g., Egypt, India, Jordan, Philippines) (Rayes et al., 2015). Pharmacist licensure issued by MOH (or if applicable, HAAD or DHA) is required for practice in UAE. In certain emirates, evidence of continuing education is mandatory for renewal. The "Emirates Pharmacy Society" is a national association promoting the profession and providing continuing education opportunities (Rayes et al., 2015).

Increasing immigration to the UAE has placed added demand on its health-care system. As a result, the government has increased services and pledged health-care excellence in its 2021 Vision by achieving public and private hospital international accreditation. Additional public health and safety initiatives by the MOH include establishing national pharmacovigilance centers for monitoring of drug products and adverse drug reactions as well as medication error reporting from clinics, hospitals, and community pharmacies (Hassan et al., 2017).

Conclusion

Pharmacy practice in the Gulf States is a true study in contrast. The region is home to what is widely considered the "cradle of civilization" (modern day Iraq) and the source of some of the earliest documented records of pharmacists and formularies. Unfortunately, continued evolution from the long tradition in pharmacy here is stagnant, in part due to enduring political and national instability. Conversely, the governments of younger and newly oil-and-gas affluent states are investing heavily in health-care infrastructure and its professional workforce. Considering both ends of this spectrum (and in between), the region still faces challenges to reach and maintain standards of contemporary pharmacy practice, not least of which include: few available competency-based pharmacy educational opportunities and the reliance on expatriate pharmacists with heterogeneous and product-centered training; low public expectations of basic pharmacist roles; restrictive policies and resistance to expanded scopes of community practice; and preferred professional atmosphere of inpatient settings by new graduates.

Such clear and consistent accounts of barriers to advancing pharmacy practice in Gulf State nations offer ideal insight on directed approaches to move the profession forward. Momentum from emerging successes in the delivery of pharmacist care for specific populations (e.g., perinatal care, diabetes, and cardiovascular disease) within primary care settings can be further exploited as a strategy to extend nondispensing pharmaceutical services to other outpatient settings, perhaps initially at a small number of

"concept" or "model" community pharmacies where trained pharmacy technicians could instead assume most product-oriented tasks. Increased visibility of pharmacists engaged in health and therapeutic-oriented dialogue with patients (e.g., medication counseling and monitoring, OTC self-selection) over time is necessary to iteratively shift public opinion of pharmacy roles and expectations for their services. Ongoing development and quality assurance of domestic education programs and health-care environments (e.g., international accreditation initiatives) and government sponsorship for advanced professional development opportunities overseas will continue to build capacity of those exposed to contemporary pharmacy paradigms and their execution. Subsequent support for these advanced trained locals to assume positions of influence in government and policy decision making will be critical to implementing the changes required to facilitate the fundamentals of pharmaceutical care and patient safety. These include a commitment to web-enabling community pharmacies and mandating a shared electronic health and medication profile accessible across public and private and inpatient and outpatient settings, as well as review of community pharmacist reimbursement schemes. Similarly advocating for pharmacist members as stakeholders in the design plan and implementation of health-care infrastructure projects and national health programming initiatives would enable incorporation of perspectives that could have wide and long-term impact on how pharmaceutical care is delivered.

The future of pharmacy practice in the Gulf State will rely on these and other young motivated pharmacists, longstanding residents, and nationals alike, to push for change, innovate, and capitalize on new opportunities afforded by national expansion projects to contribute to enhancing cultures of patient-centered care and prominence of pharmacist roles there within.

Pharmacy: A Business, A Profession, Both, or Neither?

Meagen Rosenthal, Yiran Rong, University of Mississippi, Oxford, MS, United States

Pharmacy, like many health care providers, has undergone significant change over time. Some of these changes, such as the ability to provide immunizations, have been quickly adopted (Baroy et al., 2016). While other changes, such as completing medication reviews and medication therapy management (MTM), have been more slowly integrated (Stafford et al., 2017). These changes, and whether or not they have been taken into pharmacy practice, have prompted much discussion, and soul searching, amongst pharmacists and pharmacy educators. For some this soul searching has been geared toward understanding systemic reasons behind pharmacists' lack of change (Roberts et al., 2006, 2008). Others have focused on pharmacists as being the barrier to change (Rosenthal et al., 2010, 2016). Still others have focused on pharmacists' lack of integration into the health care system (Harding, 1997). Some have also pointed out the lack of professionalism of students as future pharmacists (Brown and Ferrill, 2009). While still others have pointed out that within pharmacy practice there is no consensus on how pharmacy defines professionalism (Wilson et al., 2010).

These final two points bring to light a long-standing debate within pharmacy that can be ultimately related back to the first three observations. In particular, this debate focuses on whether or not pharmacy can be considered to be a profession in the same way that medicine or law have been. Some have suggested that there is a disconnect between the true mission of the "profession" of pharmacy, and seemingly contrary images of pharmacy as a "business." *As such, the primary objective of this article is to examine the following question: Is pharmacy a profession, a business, both, or neither?* To begin to address this question, a brief recap of the history of pharmacy will be provided. Then a review of past sociological literature defining and describing professions will be outlined. This will be followed by a discussion of the threats to pharmacy being considered a profession, and conclude with a discussion of the future of pharmacy.

Please note that the following discussion may be uncomfortable. This article will revisit discussions of pharmacy that many people feel are better left in the past. However, ignoring this past and its influence on how members of the group have been, and continuing to be socialized, impacts how the practice of pharmacy does, or does not, move forward. Therefore, *the secondary objective of this article is to build a case for why carefully considering the possible answers to the question posed in the primary objective is important for pharmacy and its future.*

A Brief History of Pharmacy

Since ancient times people from various civilizations have utilized "remedies" from the natural world to address human illness. While understandings around the origins of illness, and the abilities of plants, animals, and minerals to treat it have changed over time, there have always been men and women tasked with returning health (Please note that the following overview of the history of

pharmacy is meant to be cursory, if the reader is interested in getting more detailed information please see Kremer and Urdang's History of Pharmacy (1976) (Sonnerdecker, 1976).). Examining the texts and histories left by various civilizations, it is often difficult to draw firm distinctions between those who would now be considered physicians and pharmacists (Sonnerdecker, 1976). In fact, in many rural areas, the physician and the pharmacist was often the same person (Sonnerdecker, 1976). It was not until the 11th or 12th century, depending on which European country is being considered, that pharmacy as a practice distinct from medicine began to flourish (Sonnerdecker, 1976).

However, this separation did not eliminate all of the problems for pharmacists. While physicians and pharmacists continued to vie for influence, a battle also began between the druggists, chemists, apothecaries, who would later be more formally known as pharmacists, and the "spicers" (Sonnerdecker, 1976). Spicers (épicier) were importers and wholesalers of bulk spices and drug products from the orient, but lacked formal training in the preparation of medications (Sonnerdecker, 1976). Eventually, pharmacists were able to gain formal control of the creation, and distribution of medicines as prescribed by a physician, through the delegation of the authority to inspect and regulate the quality of drug products (Sonnerdecker, 1976). However, this authority is a relatively recent development, not being granted in Britain until the 1930s. (Sonnerdecker, 1976)

As time passed, the position of pharmacists was further codified through the development of associations, societies, and colleges and schools of pharmacy. In the United Kingdom, the Royal Pharmaceutical Society was founded in 1842. In the United States, the American Pharmacists Association (APhA) became the country's first national pharmaceutical organization in 1852. The development of these associations took place alongside that of the legal regulation of pharmacy (Sonnerdecker, 1976). This licensure process began in the Territory of New Orleans in 1808, and spread to the rest of the country thereafter (Sonnerdecker, 1976).

As technological and manufacturing abilities advanced in the 20th century, pharmacists transitioned from being the makers and distributors of drug products to primarily the distributors (McCormack, 1956). This role was further cemented in the United States through the code of ethics promoted by the APhA from 1922–69, and the 1951 Durham-Humphrey amendment to the Food, Drug, and Cosmetic Act (Hepler and Linda, 1990). As such, pharmacists began to stake out a greater place in the provision of health care directly to the population. The Nuffield Report from the UK proposed and led to the extension of pharmacists' role to include, "advice to patients on minor ailments, keeping patient medication records, offering domiciliary services, advice to general practitioners and providing diagnostic testing, such as measurements of blood pressure, blood glucose and cholesterol levels" (Harding, 1997, p. 549). This shift from the creation of medicines to dispensing them marks the initial questioning of whether or not pharmacy could be considered a profession as group members sought to legitimize their role in patient care.

Definitions of Professions

Sociological Definitions

Much of the discussion about pharmacy as a profession began in sociology, which during the early 1950s was particularly interested in characterizing occupations to understand power differences between them (Newton and Paulshock, 1982). In particular, these early scholars were looking to answer very grand questions about human nature, and understand how people could have justified participation in the atrocities of the Second World War. While the following discussion should not be considered an exhaustive examination of the sociology of professions, it does provide guidance to meet the objectives of this article (see Further Reading).

According to some scholars there were two main schools of thought on the nature of professions, the "Harvard School" and the "Chicago School" (Newton and Paulshock, 1982). To the Harvard School, a professional occupation was characterized by a high degree of social importance, a complex knowledge base requiring extensive training, and a high degree of uncertainty, responsibility, and resultant stress (Newton and Paulshock, 1982). The "Chicago School," saw professions as a "semi-mythic construct"(Newton and Paulshock, 1982). In practice, this meant that members of the profession actively persuaded society to accept their "professional" status, as a means of obtaining social and economic advantages, by keeping aspects of their practices secret from the general population (Newton and Paulshock, 1982).

Using the example of physicians, it is possible to see their professional status from both the Harvard School (HS) and Chicago School (CS) perspectives. Physicians possess a great deal of social importance as is evidenced by their continued placement at the top of lists of most prestigious and/or trusted professions each year (HS/CS) (McCarthy, 2016, Butterfield, 2017). Furthermore, becoming a physician requires tremendous and lengthy training (an estimated average of 14 years post high school; Emanuel and Fuchs, 2012) (HS), and failing to apply this knowledge appropriately can result in injury or even death, leading to a high degree of stress (HS) (Rabatin et al., 2015). Physician groups have also self-advocated and amassed a great deal of power in the process. For example, during the development of Canada's single payer medical system, the Canadian Medical Association fought vigorously to maintain their previously independent status, and to this day work as state contractors not employees (CS) (Simpson, 2012).

Following the HS perspective, the first definition of professions suggests that they are occupations with specific training that provide a skilled service or advice for a definite fee (Denzin and Mettlin, 1968). The authors of this definition also state occupations that transform into professions, " . . . develop special codes of ethics, engage in formalized recruitment patterns, establish formal institutions to transmit . . . [and] develop social organizations to insure the perpetuation of the profession . . . " (Denzin and Mettlin, 1968;p. 376). Through this process occupations gain control over a particular, "social object" (Denzin and Mettlin, 1968). For example, the social object of medicine is generally considered to be the process of identifying and treating the causes of illness. The authors also state that occupations are professions if they, " . . . claim a mandate to define what is proper conduct of others toward the matters concerned with their work" (Denzin and Mettlin, 1968, p. 380). One example of this kind of mandate is medical

associations' objections to independent pharmacist prescribing (Pojskic et al., 2014). As a part of physicians' social object, the treatment of illness through the prescription of particular medications is being co-opted by pharmacists.

A second definition of professions outlines five characteristics, four of which could also be interpreted as being part of the Harvard school's perspective. The first characteristics is that a profession, "has an exclusive technical expertise based on systematic knowledge", which can only be obtained through formal training (Ladinsky, 1971, p. 25). Second, a profession has exclusive and publicly recognized control over its field of work, or social object (Ladinsky, 1971). Third, a profession has strict training standards and a code of ethics (Ladinsky, 1971). Fourth, a profession is characterized by the service idea meaning that, "technically competent work is exercised with devotion to clients' interests more than to personal or commercial interests" (Ladinsky, 1971, p. 25).

The fifth characteristic of this second definition deviates from the Harvard school into the Chicago school, as it advocates for a profession having self-control, meaning that it has the latitude to make decisions about how it approaches its work (Ladinsky, 1971). This self-control is also mentioned in the first definition through the statement, " . . . finally [professions] take on the characteristics of self-governing, autonomous institutions" (Denzin and Mettlin, 1968, p. 376). Self-determination affords the profession the ability to advocate for itself by determining how much of its knowledge is shared with the public and in so doing amass greater influence.

A third definition of professions also offers five characteristics that are similar to the previous definitions. More specifically, according to these authors, professions possess a systematic body of knowledge and theory, they have authority recognized by their clients and broad community sanction for this authority, they have a regulative code of ethics, and a professional culture sustained by associations (Anderson, 1977). These characteristics are further enshrined, and expanded upon, through definitions of professionalism applied to pharmacy students:

> "Traits of a professional include: knowledge and skills; a commitment to self-improvement and life-long learning; a service-minded orientation; pride in the profession and a dedication to advance its value to society; create a conventional relationship with those served; alertness, creativity, initiative, and innovation; conscientiousness, integrity, and trustworthiness; flexibility and punctuality; accountability for his/her performance; ethically sound decision making and moral behavior; leadership" (Popovich et al., 2011, p. 2).

Reading across these definitions, professions are characterized in the following ways: They have control over exclusive knowledge; requiring specific training, they develop a code of ethics and professional organizations to enforce that code; they obtain the social authority to provide this knowledge to both potential members of the profession and the public; and they recruit professional members who possess altruistic motivations. While some would argue that pharmacy meets these criteria, others have argued that pharmacy fails to meet the "ideal type" of this criteria (Anderson, 1977). In fact, some have argued that the only claim that can be made with respect to pharmacy is that it is an incomplete or "quasi-profession" (Denzin and Mettlin, 1968).

Threats to the "Pharmacy Profession"

Arguments for why pharmacy does not meet the ideal-type criteria often focus on "threats" to professional status. An examination of these threats suggests three themes, those that come from within pharmacy (internal threats), those that come simultaneously from within and outside of pharmacy (intermediate threats), and those that come from outside of pharmacy (external threats).

Internal Threats

Internal threats are those that stem from how pharmacy self-organizes and come from four primary areas: recruitment, training, fragmentation within the profession, and perspectives on the product of pharmacy.

Recruitment

As a profession develops, recruitment is key in how that profession distinguishes itself from all other occupational groups. Consider the "spicers" of France, who once functioned as parallel importers of drug products to pharmacists (Sonnerdecker, 1976). As pharmacists received the designated training, and consequent authority by governments, they supplanted spicers as the sole providers of prescribed medications (Sonnerdecker, 1976). This was accomplished by pharmacists advocating for legal changes making it unlawful for any other group to import and distribute drugs (Sonnerdecker, 1976). Therefore, to be called a pharmacist one needed not only the legal status, but also special training that distinguished them from mere importers.

Recruitment is also integral to the maintenance of the professional status. If a medical student was asked, "Why have you chosen to pursue a medical degree?" It would come as no surprise to receive a clichéd reply such as, "I really just want to help people." Medicine has reinforced its authority over the social objective of identifying and treating the causes of illness through the recruitment of *only* those people expressly interested in selflessly returning the public to health. However, it has been argued that pharmacy recruits future members who lack commitment to such, " . . . humanitarian and people-oriented endeavors" (Denzin and Mettlin, 1968).

For example, in a speech delivered in 1976, the speaker pointed to a number of "regrettable surveys," showing that students saw pharmacy as more of a business than a science or a profession (Anderson, 1977). That is, students from this time saw pharmacy as an entrepreneurial pathway, rather than a calling. While emphasis on the business aspect of pharmacy has waned since that time, more recent surveys of pharmacy students continue to suggest that many of them have entered the profession with little idea of what it

means to be a pharmacist (Noble et al., 2014). Some authors have posited that part of the reason for pharmacy's inability to recruit truly committed and altruistic candidates is that, unlike medicine where the social object is clear, pharmacy has failed to identify its core values (Denzin and Mettlin, 1968, Anderson, 1977).

Furthermore, each year it is possible for faculty at schools of pharmacy to identify a handful of students leaving for programs such as medicine or dentistry. In fact, the pull of medicine is so powerful that even completely trained pharmacists have left established practices to pursue medical degrees (Austin et al., 2007). An examination of the experiences of some of these pharmacists turned doctors revealed that pharmacy imposed too many limitations, such as having to defer to others to make final decisions about patient care (Austin et al., 2007)— limitations that were not present in medicine (Austin et al., 2007). While it could be argued that these few people chose poorly in coming to pharmacy in the first place, the perception of the power differential around these health care fields becomes obvious when imagining a reverse flow of students. How would a medical student leaving their program to attend pharmacy school be looked upon by fellow students and faculty?

Training

Another internal barrier of pharmacy is pharmacists' training. Early commentaries on this topic focused on the impact of courses like math, chemistry, and biology, which " . . . project a model of the pharmacist as a disinterested scientist, a man who understands, 'the principles upon which the methods of pharmacy depend'" (McCormack, 1956, p. 309). These authors go on to argue that if students trained in this way are provided opportunities to employ this scientific aptitude they, " . . . may find it satisfying enough to dismiss the publics' attitude" (McCormack, 1956, p. 309). That is, this training may generate good scientists but not good patient care providers. Along the same lines, other authors have suggested that the additional training in physical sciences, " . . . is usually at the level of such complexity . . . that it would only benefit, in a practical sense, the future graduate student" (Shaw, 1971, p. 540).

This focus in pharmacy training is an artifact of a time when pharmacists compounded of prescribed medications (Sonnerdecker, 1976). As this is no longer the case, the focus of pharmacist training has shifted to more clinically oriented services (Anon, 2015). It may be argued that this shift was accelerated by the advent of the "pharmaceutical care model" (Hepler and Linda, 1990). Pharmaceutical care is defined as, "the responsible provision of drug therapy for the purpose of achieving definite outcomes that improve a patient's quality of life" (Hepler and Linda, 1990, p. 539). Furthermore, it is intended to be patient centered in nature (Hepler and Linda, 1990).

Although the transition to this model of education is largely complete, it has fallen short. A paper published shortly after the proposal of the pharmaceutical care model found that most pharmacist respondents were not engaged in the active provision of clinical care (Schommer and Cable, 1996). Rather these respondents were engaged in information gathering and acting as a drug information resources (Schommer and Cable, 1996). More recently, reports suggest that pharmacists continue to miss opportunities to provide MTM services to patients who qualify (AmerisourceBergen, 2016, Stafford et al., 2017). This lack of uptake is compounded by traditional models of community pharmacy practice wherein, " . . . a pharmacist may spend a long period of time explaining the difference between several products [to a patient]", but neglect to charge a fee for that knowledge (Shaw, 1971, p. 540). In so doing, the patient is left with the perception that the pharmacist's consultation, and knowledge, is only relevant to the product or products under investigation, rather than to the patient's health more generally.

As such, students, especially in the community pharmacy setting are not exposed to examples of these clinical services in practice. Consequently, newly graduated pharmacists are left disillusioned. One study asking pharmacists to define their role found that in as little as 6 months' postgraduate new pharmacists said that pharmaceutical care was not a reality for their practice settings (Rosenthal et al., 2011). This lack of example may also contribute to students relatively lower rate of anticipated initiative in providing MTM services upon graduation (Urmie et al., 2007).

The reasons for this stalling out of the implementation of pharmaceutical care are complicated. As one commentator lamented the people at fault include, " . . . some educators who have failed to instill the professional ethic, chain executives and independent pharmacy owners who have degraded the profession, and employee pharmacists . . . who have allowed themselves to become professionally subservient" (Provost, 1979, p. 147). Today, pharmacy students are graduating with more clinical knowledge than ever before, but do they have what is needed to integrate that knowledge into a system that is not prepared for these new modes of practice? Perhaps, the next evolution of pharmacy training needs to be a focus on how to integrate the training students receive in pharmaceutical care into their practices. Or how to work effectively on large and diverse health care teams. Moreover, this new approach to the training of pharmacists may also impact pharmacy student recruitment. Over time, as these "new" kinds of pharmacists get into practice, the publics' interaction with and perception of pharmacists would also change attracting different kinds of applicants to the profession.

Fragmentation

The third internal barrier is fragmentation. It might be argued that the process of fragmentation started with, " . . . the new growth and professionalization of hospital pharmacy, the creation of clinical pharmacy programs, and the desire by the medical establishment for more of these" (Ladinsky, 1971, p. 29). As a result, a distinction grew between hospital/ambulatory care pharmacists and community pharmacists, or clinical and nonclinical pharmacy practices. Looking at the online resources for pharmacy students trying to decide which kind of practice to pursue, hospital pharmacy is often described as the practice wherein one would have the greatest opportunity to apply the extensive clinical knowledge they obtained in school (Hassan, 2013, Phelps, 2016). However, community pharmacy practices, particularly in the United States, often lack access to patient medical records and the resources needed to engage effectively in more complex patient care activities (Phelps, 2016, Hassan, 2013). Further distinctions are also made

within hospital pharmacy as some staff pharmacists' primary practice is reviewing and verifying orders, while clinical pharmacists' primary practice is outside of the dispensary interacting more directly with other clinicians and potentially patients (Phelps, 2016).

At one point in time, it was argued that a "monolithic community pharmacy orientation" focused on business aspects of pharmacy practice dominated pharmacy school curricula (Anderson, 1977), however, this is no longer the case. Moreover, there have been increasing efforts to further solidify pharmacists' clinical status through the expansion of both entry level doctor of pharmacy (PharmD) programs around the world, and increased emphasis on completing residency training to qualify for direct patient care roles (Murphy et al., 2006, Popovich et al., 2011, Anon, 2011). Even jurisdictions like Alberta, Canada, where legislation was passed granting independent prescribing authority without additional training have opted to transition to an entry PharmD program (Yuksel et al., 2008). As a result, it is a growing perception that there is a substantive difference between those pharmacists who graduated with bachelor's degrees and those who obtained PharmDs, as well as between those who did or did not complete a residency.

Some have argued that hospital pharmacists, and perhaps by extension clinical pharmacists, " . . . have demonstrated a personal and collective 'sense of mission' that is essential to a professional psyche" (Anderson, 1977). In particular, authors have stated that these pharmacists have honed in on the talents and abilities they bring to patient care that other members of the hospital care team do not possess or provide (Anderson, 1977). As such, hospital and community pharmacy practices are treated as distinct entities. Does this distinction make the development of a coherent vision around what constitutes pharmacy as a profession more difficult?

Perspective on the Product of Pharmacy

The final internal barrier is pharmacists' perspective on what constitutes the product, or social object, of pharmacy. According to some commentators' pharmacists in the community setting view, " . . . the drug as a product to be sold rather than as an object to direct a service toward" (Denzin and Mettlin, 1968, p. 378). By making the social object of pharmacy a physical product that can be seen and touched pharmacists are forced to advertise for a "profit" rather than a "fee" (Denzin and Mettlin, 1968). As one commentator describes: "We are paid not for our knowledge and service but for the products we dispense" (Anderson, 1977). The consequence of this perspective is that, " . . . pharmacists [compete] with each other, not on the basis of training and knowledge but on the basis of marketing" (Denzin and Mettlin, 1968, p. 378).

One possible solution to pharmacy's problem of identifying the incorrect social object would be to disconnect pharmacists from the physical drug. Efforts in this direction may be observed in pharmacist-run academic detailing programs, wherein pharmacists become drug knowledge repositories used to help improve drug decision-making (China et al., 2017). The popularity of this approach evidenced in the proliferation of these programs across Canada, as well as a growing set of research suggesting these programs yield improvements in evidence-based decision-making. (Jin et al., 2012)

Others have chosen to maintain the direct connection between pharmacists and the physical drugs, but have reimagined the social object of pharmacy as being the, " . . . symbolic transformation of a drug into a medicine" (Harding, 1997, p. 554). According to the authors this symbolic transformation has a long history of being under the purview of pharmacists who once created the physical "medicines" (Harding, 1997). Despite no longer being responsible for the physical creation of medicines, these authors maintain that a symbolic change is still taking place as the drug passes from the hands of the pharmacist to the patient (Harding, 1997). These authors go on to suggest that pharmacists' success in reprofessionalization depends upon their ability to promote, "... their knowledge and skills as mystical to the public they serve" (Harding, 1997, p. 555). An approach to professionalization also advocated for by the Chicago School. (Newton and Paulshock, 1982).

These are just three of the many differing perspectives on the social object of pharmacy. Similar to the fragmentation discussed, these multiple perspectives further complicate not only how pharmacists see themselves, but also how they are seen by nonmembers (Schommer and Gaither, 2014). As is often touted by pharmacists and pharmacy educators, pharmacists are medication experts, but a question remains as to which definition of this term impacts current and future pharmacists' practice?

Intermediate Threats

Intermediate level threats stem from what has been described as the commercialization of community pharmacy. It has always been the case for some commentators that pharmacy could not be considered a profession because of the conflicting goals of businesses and the altruistic treatment of patients by true professionals (McCormack, 1956). More specifically, how could a business owner, interested in staying in business, be trusted not to sell an unneeded product or service to a patient. In fact, one study suggested that pharmacy owners were much more likely to recommend a patient purchase a product (Harding, 1997). This concern may have been accelerated by the move away from single owner, relatively small operations to large corporations, which now employ the majority of community pharmacists (Ladinsky, 1971). Herein, the pharmacist serves two masters: the patients who need medical aid and the owners and shareholders of the corporations, who are primarily interested in profits (Ladinsky, 1971). In fact, there have been a number of recent examples of when this relationship has tipped too far in the direction of profits from instances of pharmacies supporting "pill mills" and helping to precipitate the opioid epidemic, to others accepting kickbacks from drug wholesalers to stock their drugs versus others (Anon 2017a, Sochoka, 2015, Bisgood, 2017, McLean, 2016).

Unlike physicians who have established business models wherein they act as independent contractors and the exchange of money is kept out of the public eye(Simpson, 2012), community pharmacy practice's connection to commercial endeavors is much more obvious. As one author suggested, "Even in the most exclusive prescription pharmacies, the pharmacist still uses a cash register" (Denzin and Mettlin, 1968, p. 380). Some jurisdictions, especially European countries, have addressed the concern of

nonpharmacists influencing pharmacy by limiting ownership of pharmacies to pharmacists (Gross and Volmer, 2016). However, in other countries, such as the United Kingdom, the United States, and Canada, few such restrictions exist (Gross and Volmer, 2016).

Interestingly, some research has suggested that the pressure on nonpharmacy owners may not be as great as once suspected. One study, which surveyed 646 pharmacy managers from across Canada, found that while pharmacist respondents were oriented toward their professional role, managers working in chain pharmacy settings were less oriented toward their business role than managers working in independent pharmacy settings (Perepelkin and Dobson, 2010). These findings were also supported by a study examining pharmacists clinical intervention in patients requesting assistance with OTC products, wherein nonowner pharmacists were less likely to recommend a product when their clinical judgment suggested that it was not needed (Kennedy and Moody, 2000). As such, it would seem that pharmacists who are not owners are freer from business constraints, and may be more able to focus purely on the care of patients. While more research into these findings is needed before firm conclusions can be drawn, this correlation may represent an unacknowledged opportunity for the advancement of pharmacy practice toward more clinical service provision.

External Threats

External threats are those that emanate from outside of pharmacy. The literature suggests these threats come from two main areas. The first are those attempting to curtail the role of pharmacy within health care. The second are those that act and make decisions with little understanding of the potential role of pharmacists in health care. In the following sections, players attempting to curtail the role of pharmacists in patient care will be exemplified by physician groups, and those acting with little knowledge of pharmacists' role will be exemplified by both patients and policy makers.

Physicians

At this point it is likely no surprise that medicine represents an external threat, especially given that the definition of "professions" was predicated on observations made of medicine. Medicine is the archetypal profession in health care. While an extensive discussion on how medicine was able to obtain this status is beyond the scope of this work, populations around the world have always placed high value on "healers," with insights into the human body, to decode illnesses and return health (Sonnerdecker, 1976). So physicians have been afforded broad social support in their role, as outlined by the Harvard School's definition of professions (Newton and Paulshock, 1982). However, physicians have also been careful to maintain a degree of mystery around their work, as outlined by the Chicago School's definition (Newton and Paulshock, 1982). Pharmacy, and many other health care professionals, exist in the long shadow cast by medicine (Ladinsky, 1971). Therefore, any attempt by groups, like pharmacy, to claim part of physicians' social object is a serious threat to their power.

As pharmacy has taken on a greater, more recognized, role in patient care, its understanding of itself has also changed. Arguably, this started with pharmacists increasing involvement in the detection and remedying of medication errors, which became more prominent as medication prescribing increased (Stewart and Cluff, 1972). More specifically, academic pharmacists began staking a new role by showing pharmacists' review of prescriptions could decrease medication errors (Folli et al., 1987). While this role was initially resisted by physicians, over time it became appreciated (Ranelli and Biss, 2000). However, with each "new" pharmacist role, they have had to start over with physicians showing their value to patient care. For example, in a study examining pharmacists' integration onto family medicine teams, physicians appeared to initially underestimate the contributions of pharmacists, but changed their minds as the study continued (Farrell et al., 2010).

Even as the body of evidence demonstrating pharmacists value in the active management of patients with chronic health conditions has increased, pharmacists continue to face resistance (Wubben and Vivian, 2008, Morgado et al., 2011). One relatively recent, and highly contentious, example is granting pharmacists the ability to prescribe medications. As far back as 1971, a report from the Commission on Pharmaceutical Services suggested that ultimately pharmacists should be given the ability to, and responsibility for, prescribing medications and monitoring patient outcomes (Yuksel et al., 2008). However, each time a change is proposed, or made, to legislation around pharmacist prescribing organizations like the American Medical Association (AMA), it comes out with resolutions like the one from 2012 opposing these changes (Pullen, 2012). Statements like these are particularly important because organizations like the AMA in the United States represent important and powerful government lobbies. For instance, a report from Kaiser Health News found that in 2010 the AMA spent more than $22 million supporting laws important to their members, which was more than another health lobby that year (Vaida, 2011). As such, physicians have the ability to seriously slow down, if not curtail, the expansion of pharmacists' scopes of practice.

Patients

Listing patients as an external threat may seem surprising given that pharmacists are often ranked by the public as being amongst the most trusted health care providers (Riffkin, 2014). However, there is some indication that patients' perceptions of pharmacists have shifted over time. In studies conducted in the mid to late 1970s, patients stated that they most often received drug information from friends or neighbors (Anderson, 1977). In fact, when asked to order their top sources of health information pharmacists were listed last after physicians and the media (Anderson, 1977).

It is also unclear if the current positive perception of pharmacists is based on patients' evaluations of the care they are provided or some other factor. As one commentator said when considering the proliferation of chain pharmacies, "Independents have watched with envy as the chains, recognizing that *convenience* is primary in consumer choice of pharmacy, secure the best urban shopping

center locations" (emphasis added) (Provost, 1979). This sentiment was reinforced in a study developing a pharmacy rating system wherein patient participants stated their choice of pharmacy depended on convenience, accessibility, and getting prescriptions filled quickly (Warholak et al., 2017). While patients pointed to instances wherein pharmacists had identified things like potential drug–drug interactions, they did not seem to equate this to part of pharmacists regular duties (Warholak et al., 2017). Rather, patients spoke as if the pharmacists had gone out of their way in identifying the problem (Warholak et al., 2017).

Another study wherein groups of pharmacists and patients were identified and compared over time found a mismatch between the conceptualization of pharmacists' role in the two groups (Schommer and Gaither, 2014). Pharmacists perceived great time pressures, which meant that they often neglected to provide medication advice, despite believing it to be an important part of their role (Schommer and Gaither, 2014). Consequently, patients did not seek medication advice from pharmacists, and rather relied on physicians to fill this role (Schommer and Gaither, 2014). The authors suggest that this results in a reenforcing cycle wherein pharmacists do not provide advice, so patients do not seek advice and vice versa (Schommer and Gaither, 2014).

Others have speculated that patients' misperceptions may stem from the nature of community pharmacy practice and the relationship it fosters between patients and the pharmacy. For example, even if your doctor's office houses several doctors, you will likely have your own "personal physician" who you will see every time you visit (Shaw, 1971). However, this is not generally the case in community pharmacy, where anyone on duty can be substituted in, and the personal relationship between patients and pharmacists is largely absent (Shaw, 1971). Moreover, the commercialization of pharmacy practice, with its resultant drive for efficiency and interchangability, may further compound this lack of relationship between pharmacists and patients (Provost, 1979). As such, patients are driven further away from seeing pharmacists as resources for medication information and chronic disease management assistance.

At the same time as the nature of community pharmacy practice is teaching patients to see a very narrow version of the care that pharmacists can provide, patients themselves are also changing. Some have referred to this as the "revolt of the patient," which has been driven by both media messages encouraging patients to demand their rights and an increase in patient knowledge and access to information (Traulsen and Bissel, 2004). Part of this shift is related to the availability of information online, and through democratization of internet access (Ahmed et al., 2006).

Another part of this shift, in places like the United States and New Zealand, has been the direct-to-consumer advertising of health products such as drugs (Guessous and Dash, 2015). The underlying assumption of these advertisements is that health care providers are no longer able to keep up with new medical developments, so patients must also keep abreast of medical research developments pertinent to them. Research suggests this advertising has resulted in increased prescribing, although it is difficult to determine whether or not this increase has rectified medication underuse, or resulted in medication over or misuse (Guessous and Dash, 2015). Even though direct-to-consumer advertising is illegal in most other jurisdictions, patients from around the world are exposed to them through the globalization of media products. As a consequence, it has been argued that patients today are fundamentally different from those in the past, regardless of whether or not this "revolt" has taken complete hold of the population (Traulsen and Bissel, 2004). If it is indeed the case that the patients do not completely understand the role and skills of pharmacists, this new attitude may make "reeducating" patients even more difficult.

Policy and Policy Makers

The final external threat to the perception of pharmacy as a profession comes from policy and policy makers. On the one hand, pharmacists' scope of practice has benefited greatly from policy changes (Gray et al., 2007, Yuksel et al., 2008, Richardson and Pollock, 2010). In the United States, this started with the expansion of Medicare Part D, which not only extended medication coverage to elderly patients under Medicare, but also introduced pharmacists' medication therapy management for eligible patients as a reimbursed service (Touchette et al., 2006, Gray et al., 2007). There is also growing momentum in the United States to get pharmacists provider status, which will enable them to seek reimbursement for patient care from the Centers for Medicare and Medicaid Services (Menigham, 2017). In the United Kingdom and parts of Canada, policy makers have developed legislation to enable pharmacists to independently prescribe medication to patients (Yuksel et al., 2008, Baqir et al., 2012). On the other hand, it is important to consider just how long some of these changes took, or are taking. For example, the process of developing pharmacist prescribing in Alberta, Canada started in 2001, before it was finally rolled out in 2008 (Yuksel et al., 2008). Pharmacist provider status has been a topic of discussion for many years in the United States and has only very recently risen again to the attention of federal policy makers (Harper, 2015).

There are numerous reasons for these delays. As outlined in a previous section, more powerful groups like physicians may present objections to perceived encroachments on their social object (Pullen, 2012). Depending upon the situation, the group of objectors, and their reach, legislators may have no choice but to reject policy changes. As one commentator stated, " . . . technically sound does not equal politically viable" (Harper, 2015). Politicians' primary objective is to remain in a position for long enough to do what they think is the most good for their constituents. This can mean sacrificing good and sound legislation in the interest of passing something less good, and less sound that also has a better chance of success, and keeping them in office. (Harper, 2015)

As such it is important to consider the constraints under which policy makers are working in their particular political environment. While Canada, the United States, and the United Kingdom have dramatically different health care systems, they all struggle with the cost of providing health care to their populations. Consequently, governments in each of these countries are looking for ways to reduce health care expenditures. Like many other groups, pharmacists have taken advantage of the need to reduce costs through demonstration projects showing the cost-effectiveness of pharmaceutical care in comparison to more traditional physician-provided care (Vegter et al., 2014, Truong et al., 2015).

However, it is also possible for occupational groups traditionally considered to be less powerful than pharmacy to make similar efforts. For example, there is an increasing body of evidence promoting an expanded scope of practice for pharmacy technicians (Elliot et al., 2014, Markovic et al., 2017). Tasks that are considered low status for pharmacy, such as taking medication histories, represent upskilling for pharmacy technicians (Traulsen and Bissel, 2004). Moreover, pharmacy technicians also seem to be interested in taking on more of these types of roles from pharmacists (Boughen et al., 2017). Importantly, from the perspective of policy makers, pharmacy technicians also cost the health care system less money. Therefore, it is possible, with a concerted effort and the right political moment, for pharmacy technicians to usurp many traditional pharmacy roles. The question remains as to whether or not pharmacists will be prepared to move into new and rising practice opportunities if this happens.

What Does This All Mean?

Using the sociologically derived definitions of professions and previous analyses of pharmacy as a profession a number of threats were identified. These threats are internal (i.e., recruitment, training, fragmentation, perception of the product of pharmacy), intermediate (i.e., influence of business), and external (i.e., physicians, patients, and policy and policy makers) to pharmacy. Each of these threats also plays some part in the kinds of people who become pharmacists (recruitment), how they understand and practice pharmacy (training, fragmentation, and perception of product), their primary focus as community pharmacists (business vs. health care), and how those outside of pharmacy see and influence it (physicians, patients, and policy makers). Taken together, it might seem obvious to conclude that pharmacy is not a true profession, and that perhaps community pharmacy, in particular, is a business. However, taking such a stance overlooks important details about the broader discussion of professions.

Unlike pharmacy, medicine has been discussed as having a singular and agreed upon social object, recruiting only those who purport altruistic intentions for becoming a physician, and not advertising for a profit (Denzin and Mettlin, 1968, Ladinsky, 1971, Anderson, 1977). But there is also another side of medicine that is rarely discussed. As one author laments the "medical-industrial complex" in the United States, encourages overuse, fragmentation, overemphasis on technology, and cherry picking of the healthiest, and therefore cheapest, patient populations (Relman, 1980). While few health care systems are as profit driven as that in the United States, this discussion brings into relief physicians' interest in being well compensated for their work.

Fascinatingly, there has been little questioning of physicians' potential business aspirations, despite the fact that physicians make most of the decisions about the medical needs of patients (Relman, 1980). Therefore, is it reasonable to assume that all recommended care is always, and solely, in the patient's best medical interest? Evidence examining the traditional fee-for-service funding model for physicians suggests that it is a major driver of increased health care costs and may incentivize increasing the volume services whether appropriate or not (Schroeder and Frist, 2013). It is also important to note that this is not a discussion that is unique to one country, place, or time. Physicians in Canada have also struggled against integration into the larger single payer system in the country (Simpson, 2012) and resisted tax reforms that may impact their revenues (Reddekopp and Hansen, 2017).

Moreover, the bureaucratization of health care to address costs has led others to question whether or not medicine can still be considered a profession, as they can make fewer and fewer decisions completely unencumbered (Abbasi, 2009, Galton, 2016). However, at no point have these discussions invalidated physicians' continued claim to professional status. As such, perhaps the question should no longer be whether or not pharmacy is a profession, business, both, or neither? Formally "clear" distinctions between professions and nonprofessions are permeable, and definitions are more complicated. As such, the more important question is how can pharmacy be a profession and a business, while placing patient needs at its center?

Rethinking the Mix: Can You Have Your Cake and Eat It Too?

One possible approach for pharmacy to be both a profession and a successful business might be through the combination of relationship marketing with patient-centered care and through the establishment of fiduciary relationships. Relationship marketing is most easily understood as the, "activities aimed at developing long-term, cost-effective links between an organization and its customers for the mutual benefit of both parties" (Bentley and Rosenthal, 2016, p. 417). To accomplish this long-term and mutually beneficial relationship, organizations must demonstrate four values. The first value is having a holistic approach to marketing, wherein the entire organization understands the importance of the customer in its success (Bentley and Rosenthal, 2016). The second value is recognizing and fostering long-term collaborations with not only customers, but also suppliers and other health care providers (Bentley and Rosenthal, 2016). The third value is fostering a culture wherein all collaborators are actively involved in the success of the collaboration (Bentley and Rosenthal, 2016). The fourth value is reinforcing the second and third values by focusing on relationships and service rather than rigid adherence to policy (Bentley and Rosenthal, 2016).

These values fit well with the underlying principles of patient-centered care. At its most basic level, patient-centered care accounts for the specific health needs and desired outcomes of each individual patient (Anon 2017b). It accomplishes this objective through the development of a relationship with the patient wherein their needs and concerns are sought out to understand their world view, so that common ground can be established to enhance health and maintain the relationship into the future (Stewart, 2001). Through patient-centered relationships all health care providers have a shared understanding of that patient's needs and desires. Therefore, developing a truly collaborative approach for helping patients to successfully manage their conditions is more straightforward and mutually beneficial for the health care team.

Both relationship marketing and patient-centered care are predicated on the idea of a fiducial obligation between the pharmacist and the patient. As was outlined in each of the definitions of professions, professionals possess a knowledge that the average person does not. The average person must, therefore, have faith that the professional will apply that knowledge fairly and honestly, as they lack the ability to assess whether they received the best health care (Zlatic, 2014). Taken together, these ideas demand a different underlying assumption to be made about the nature of business profits. Rather than thinking about maximizing profits solely through sales, at the expense of relationship development, the focus is on creating a sustained customer base through relationship building. For example, the previously described practice of pharmacy owners/managers recommending patients' purchase products they may not require would be replaced by that of staff pharmacists erring on the side of not selling the product in the interest of generating and maintaining patient trust.

Research suggests this approach has significant benefits to patients who avoid the stress and anxiety of finding new providers, and will in turn reward pharmacies with their continued business (Bentley and Rosenthal, 2016). Furthermore, there is a growing sense that patients will continue to rethink their relationship with health providers like pharmacists. Millennials are now the largest living generation in the United States according to the census bureau (Fry, 2016). This is important because literature from the business world suggests that this group, perhaps more than in generations past, is particularly interested in doing good within their communities, not just the bottom line (Case, 2014). Millennials are also interested in engaging with companies that exude a sense of authenticity and allow them to align and participate with the company (Jubenville, 2016). Relationship marketing, patient-centered care, and the fiduciary relationships, when well practiced align with the demands of not just patients falling into the Millennial generation, but arguably others as well.

Next Steps

Like most such proposals, successfully reworking the current practice of pharmacy to not only address pharmacists' own self-perceptions, as well as that of outsiders, but also developing a new business model is totally overwhelming, and seems unrealistic. As was outlined in the beginning of this article, pharmacy has a long history, struggling greatly with how it defines itself. Furthermore, while it has made many great strides in clarifying its role in patient care, as the overview of the threats to pharmacy suggested, there remain a number of outstanding issues, crossing the spectrum from internal to external, that need to be addressed. Practicing pharmacists, pharmacy educators, current and future pharmacy students, and patients must come together to decide how to best overcome these threats. Once potential approaches to overcoming these threats have been developed, carefully constructed and theoretically driven implementation programs are needed to test whether or not these programs are practical. Implementation science, or knowledge translation, offers a number of theoretical models that might be utilized in this capacity (Nilsen, 2015).

Conclusion

We began this article with two objectives:

1. To examine the following question: Is pharmacy a profession, a business, both, or neither?
2. To build a case for why carefully considering the possible answers to the question posed in the primary objective is important for pharmacy and its future.

While we were unable to wrap up this discussion with a neat and clean conclusion, the process of examining the components of the first objective have reinforced the case for the second. Pharmacy does not need to define itself as a profession to the exclusion of also seeing itself as a business. There is a way that it can be both of those things. If pharmacy chooses to move in this direction then the next steps it takes are crucial. What does a sustainable and scalable patient-centered, relationship marketing driven, business model look like? How do we train future pharmacists to meet the needs of this new model? And how can we help current pharmacists rethink their roles to take advantage of these news opportunities?

Glossary

1. Spicers were a group of spice importers that competed for status with pharmacists in the 13th century France.
2. *Social objects* are ideas, or objects, that gain additional meanings when they are integrated into self-perception of professions.

Health Scenario in the Philippines

The Philippines is located in Southeast Asia with the land area of approximately 300,000 square kilometers (Philippine Statistical Authority, 2017). As of 2017, the population of the Philippines was 104,921,600 with the density of 337 persons per square km, (Philippine Statistical Authority, 2017; Philippine Statistical Authority, 2016) which is projected to reach 142 million by 2045. With rapidly changing demographics, the population aged 65 years and over may quadruple in size to 16 million by 2045 (Philippine Statistics Authority, 2016). The country witnessed economic growth of 6.7% GDP in 2017 and an annual average growth rate of 6% over the past 5 years (Bangko Sentral ng Pilipinas, 2017). The projected average life expectancy at birth will increase from 70.38 years (male: 67.61; female: 73.14) from 2010 to 2015 to 75.68 years (male: 73.01; female: 78.34) from 2035 to 2040 (Philippine Statistical Authority, 2017; Department of Health, 2012). Furthermore, there is a steady decline in the total fertility rate of three births per woman as of 2017 (Department of Health, 2012; Philippine Statistics Authority and ICF, 2018a). The maternal mortality rate has also decreased to 114 per 10,000 live births in 2010 (Pinlac et al., 2015) due to the improved quality of maternity healthcare services by healthcare professionals (93%) and the symbiotic public–private partnership (Philippine Statistics Authority, 2018a; The Philippine Star, 2018) for healthcare services.

In 2016, 6 out of 10 leading causes of death were NCD in etiology. Most of the NCD mortality cases, such as ischemic heart disease, cancer, diabetes, and others shown in **Table 1**, are considered to be lifestyle-related (Philippine Statistics Authority, 2018b). Alarmingly, an increasing prevalence of obesity among children and adolescents are risk factors for NCDs. Behavioral risk factors, such as an unhealthy diet, smoking, alcohol consumption and a sedentary lifestyle also promote NCDs (Department of Health, 2012; Pinlac et al., 2015). The increased consumption of items such as saturated oils, fast food and sugar coupled with a decreased intake of carbohydrates, fruits and vegetables also contribute to the development of NCDs (Ulep et al., 2013). **Table 1** also highlights infectious diseases as one of the leading causes of morbidity (Philippine Statistics Authority, 2018b). Despite campaigning by the Department of Health (DOH) and funding agencies, tuberculosis still remains a leading cause of mortality and morbidity in the country (Department of Health, 2012). Though HIV cases are less than 1% (Department of Health, 2012), cumulative data from 1984 to 2017 implies that there were 60,207 confirmed HIV cases (94% male; 6% female) reported to HARP. There is an average of 32 people who have been newly diagnosed with HIV per day from January to October 2018 alone (Department of Health Epidemiology Bureau, 2018). Tropical endemic diseases such as malaria, schistosomiasis and filariasis occur with other emerging and re-emerging infectious diseases (Department of Health, 2012).

Table 1 Top 10 leading causes of death, Philippines: 2016 (Philippine Statistics Authority, 2018b)

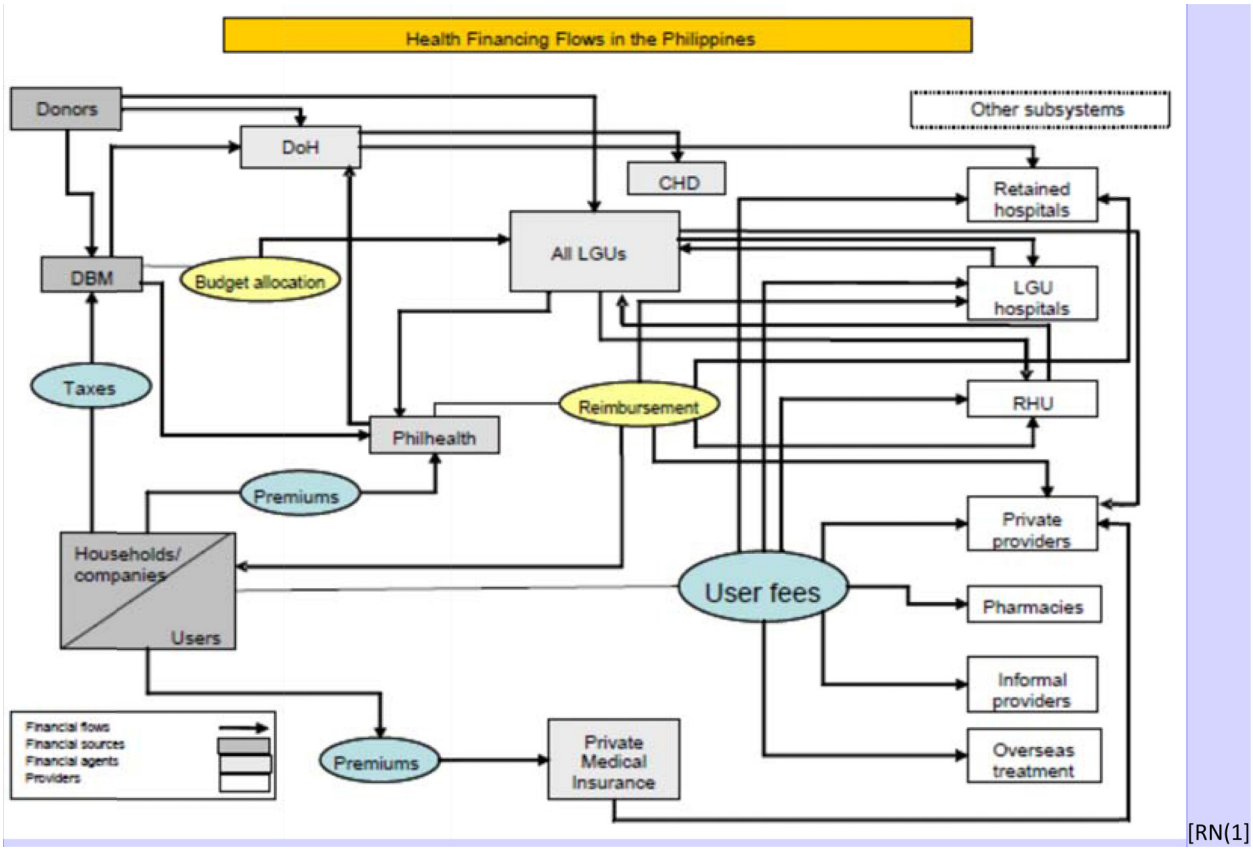
Leading causes	*Number*	*%*
All causes of death	582,183	100.0
Ischemic heart diseases	74,134	12.7
Neoplasms	60,470	10.4
Pneumonia	57,809	9.9
Cerebrovascular diseases	56,938	9.8
Hypertensive diseases	33,452	5.7
Diabetes mellitus	33,295	5.7
Other heart diseases	28,641	4.9
Respiratory tuberculosis	24,462	4.2
Chronic lower respiratory infections	24,365	4.2
Remainder of diseases of the genitourinary system	19,759	3.4
Other causes of death	168,858	29.0

Philippine Healthcare System: At a Glance

Health Financial Schemes and Expenditures

The Philippines has four main sources of health financing: insurance (government and private), national and local government, donors and household fees or out-of-pocket payment as shown in Fig. 1 (Department of Health, 2012; Crisostomo, 2018).

In 2018, almost 93% of financing was covered by the Philippine Health Insurance Corporation (PHIC or PhilHealth), (Department of Health, 2010), which initiated single-payer premium-based health financing in the country (Department of Health, 2012). PhilHealth has limited hospital insurance coverage including medicines, (Department of Health, 2010) resulting in a high level of out-of-pocket payments (Department of Health, 2010; Lavado et al., 2011) in private (48%) and public facilities (51%) (Department of Health, 2012). Other health insurance types such as the Government Service Insurance System, Social



[RN(1]

Figure 1 Health financing flow in the Philippines (Crisostomo, 2018).

Security System or private insurance provided coverage for 24% of the population (Philippine Statistics Authority and ICF, 2018b). Donations from philanthropist, non-government organizations and charity organizations are also some of the major sources of health financing (Philippine Statistics Authority, 2018c).

Healthcare Delivery System

The health scheme in the Philippines has a dual system composed of the public and private sector. The public sector is financed by the government through a tax-based budgeting system, which was decentralized from national to local government units in 1991. The DOH supervises national, regional and specialty hospitals, whilst the Department of National Defense manages military hospitals. The private sector covers half of the health system that is largely market-orientated and paid through user fees at the point of service (Department of Health, 2005b). There are 476 government hospitals, 960 private hospitals, 322 government infirmaries, 312 private infirmaries, 2,598 rural health units and 20,241 village (*barangay*) health stations that are in place for delivery of health services in the country (Medina, 2017). In 2018, the government hospital bed to population ratio was 1:1,121 (88,394 beds) with a target to reach 1:800 (142,500 beds) by 2020 (Antiporda, 2018).

Access to medicines: Filipinos access their medicines mostly in urban or rural private retail pharmacies. Some may purchase medicines in hospital pharmacies, especially for inpatients but prices are usually higher. When medicines are not available or out-of-stock in public hospitals, patients buy medicines at nearby drugstores (Dayrit et al., 2018). Drug retailers are classified into drugstores (chain and independent pharmacy), Botika ng Barangay (BnB), Botika ng Bayan (BNB), Chinese retailers, and retailers of non-prescription drugs. The most common type of retailer was the drugstores (73%), which are mostly found in urban areas, followed by BnB (24%) (Reyes et al., 2011). In 2018, the DOH relaunched BNB to reduce out-of-pocket expenditures for the underprivileged and to increase accessibility of essential medicines in rural areas of the country (Philippine Information Agency, 2018).

Pharmaceutical care: Pharmacy in the country has evolved over the years from a product-focused to a patient-orientated profession (Marin-Calero et al., 2004). Dispensing is the most commonly performed activity in the hospital (Agaceta et al., 2013) and community, alongside management, optimizing patient care and managing public health. Studies conducted by Salenga et al. in 2009 revealed that 36.4% of pharmacists were perceived to be competent in delivering public health services due to their positioning in practice, expertise and education, even though there was a low uptake of pharmacists in public health (Salenga, 2009; Capper and Sands, 2006). Ocampo et al. mentioned that barriers to the implementation of pharmaceutical care in the Philippines include lack of support of physicians and other healthcare professionals, time consuming completion of documentation, lack of economic incentives and inadequate space for pharmacist-patient encounters (Agaceta et al., 2014).

In recent years, community pharmacists have been providing patient care services in the form of medication counseling, blood pressure and glucose monitoring, medication adherence monitoring, provision of daily dose packs (Ball and Salenga, 2017), smoking cessation (Ware, n.d.) and lifestyle modification counseling. The pharmacist also has an expanded role in the Antimicrobial Stewardship Program to provide rational interventions on antimicrobial prescriptions, dose adjustments and education (Department of Health, 2016). Furthermore, public health pharmacists ensure access and availability of essential drugs through village pharmacies (Casis et al., 2011) and contribute in health education, disease prevention and health promotion to achieve optimal public health outcomes (American Public Health Association, 2006).

Human Resources

A recent FIP report on pharmacy workforce revealed that the Philippines have a pharmacist density of 5.8 per 10,000 population compared to Thailand (5.45), Indonesia (2.10) and Malaysia (4.99) (FIP, 2018). The majority of pharmacists work in community pharmacy (77%), hospital pharmacy (15%) and in industrial pharmacy (7%) (Lorenzo and Cruz, 2001). As per 2011 census, there were 101,181 pharmacy technicians or assistants (1 pharmacy assistant in 1000 population), suggesting twice as many pharmacy assistants/technicians (in all sectors) as there were pharmacists (World Health Organization, 2011). However, there is an increasing trend of pharmacists and pharmacy assistants migrating to other countries, (Philippine Overseas Employment Administration, 2016) especially to the USA (Loquias and Robles, 2012) and the Middle East (Casco, 2013).

Pharmacy Education

The University of Santo Tomas (UST) Faculty of Pharmacy was the first to offer the bachelor's degree in pharmacy in the Philippines in 1871 by virtue of the Modification of the Moret Decree. During the Spanish regime, the course duration was 6 years, which was then reduced to 4 years during the American colonization (University of Santo Tomas, 2016). The University of the Philippines College of Pharmacy started as a 3-year Graduate in Pharmacy (PhG) course in 1911 and commenced a 4-year Bachelor of Science in Pharmacy (BSP) course in 1913 (University of the Philippine College of Pharmacy, 2017). A minimum 5-year curriculum was implemented in 1954 (Carson, 1961) and was again reduced to 4-years in 1984 with the integration of some subjects. From then on, pharmacy schools have flourished from north to south in the Philippines. Pharmacy graduates were regulated by the Professional Regulation Commission Board of Pharmacy (PRC BOP) and must fulfill the 4-year BS Pharmacy

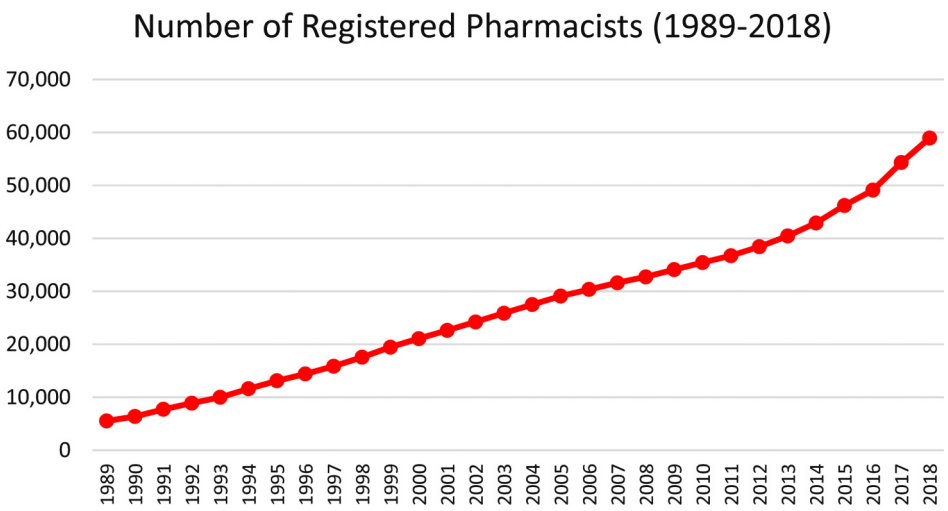


Figure 2 Number of registered pharmacists from 1989–2018. *Source: Professional Regulation Commission and Philippine Statistics Agency; data compiled by authors.*

degree and 960 h supervised internship (community, hospital and manufacturing) to be able to take the Pharmacy Licensure Examination (Professional Regulation Commission, n.d.; CMO, 2006). There are more than 60,000 registered licensed pharmacists in the country (Fig. 2).

Private higher education institutions offering courses in pharmacy must have the Commission on Higher Education (CHED) license to operate, and at least 192 total units of core courses (30 units), professional courses (90) and mandatory general education courses (21) (CMO, 2006). The cost of pharmacy education ranges from Php 20,000 (USD400) to Php 65,000 (USD1250) per semester in private institutions and is 40% to 75% lower in government institutions (Professional Regulation Commission, n.d.). Different universities and colleges offer additional undergraduate programs such as BS in Industrial Pharmacy (recently known as BS Pharmaceutical Science) (UP College of Pharmacy, 2017), a 5-year BS Pharmacy major in Clinical Pharmacy (University of the Immaculate Conception, 2014; Centro Escolar University, 2015; University of Santo Tomas, 2016a; University of Santo Tomas, 2016b) and a 6-year Doctor of Pharmacy (PharmD). Several universities offer a 2-year post-baccalaureate program for PharmD (Centro Escolar University, 2015; University of Santo Tomas, 2016b) and a 2-year mixed mode postgraduate program (coursework and research) Master of Science in Pharmacy and a 3-year mixed mode PhD in Pharmacy with research specializations.

There have been some drastic changes in pharmacy education in the country with an increasing trend of universities offering BS Pharmacy. In 2018, overall 101 universities and colleges registered in CHED for BS Pharmacy, 95% being private institutions and 5% SCU's (Commission on Higher Education, 2018). The Philippine Association of Colleges of Pharmacy, founded in 1975 with 40 pharmacy schools, is preparing for the new Charter Management Organizations (CMOs) on pharmacy education and curriculum, which is in line with the Outcome-Based Education (OBE) integrating the Philippine Practice Standards for Pharmacists (PhilPSP) (Philippine Association of Colleges of Pharmacy, 2017). Pharmacy universities are also preparing for the national reform in basic education known as K plus 12. An upcoming student is required to undergo kindergarten, 6 years of elementary, 4 years of junior high school and 2 years of Senior High school (Marcelo, 2014). This target to prepare students for tertiary education, skills, entrepreneurship and global employment (Arcangel, 2014). By 2021–22, higher education institutions (HEIs) will be affected through a reduction of courses being offered and faculty workload especially for general education lecturers as some subjects are transferred to senior high school curriculum (Acosta and Acosts, 2016).

Continuing professional development: RA 10912, also known as the continuing professional development (CPD) Act of 2016 mandated measures to continuously improve the competence of professionals in the Philippines. Pharmacists are required to obtain 45-credit units within a 3-year compliance period for the renewal of their license. These credits can be obtained through professional, academic, or self-directed learning units (Dayrit et al., 2018; Continuing Professional Development, 2016). There were 59 CPD providers in the country from 2008 to 2018 as approved by PRC BOP (Professional Regulation Commission, in press).

Regulations, Policies, and Standards

A recent reform in the country's pharmacy law was the approval of RA10198 or the Philippine Pharmacy Act of 2016; the act regulates and modernizes the practice of pharmacy in the Philippines, repealing the RA5921 or Pharmacy Law of 1987. RA10918 highlights the following major changes: (1) the expanded role of pharmacists in immunization (2) professionalization of the pharmacy workforce by upgrading pharmacy assistants to NC III, and (3) stringent rules for evaluation of pharmacy personnel and pharmacy licensing (Sambalud, 2017; Asia Pacific Institute for Medication Management, 2017). Furthermore, provisions of mutual

Table 2 Classification and characteristics of hospitals in the Philippines (World Health Organization, 2012a)

General hospitals	Most hospitals at all levels provide services for all kinds of illnesses, diseases, injuries or deformities. They have emergency and outpatient services, primary care services, family medicine, pediatrics, internal medicine, obstetrics-gynecology, surgery including diagnostic and laboratory services, imaging facility and pharmacy.
Level 1 general hospitals	Level 1 hospitals include isolation facilities, maternity, dental clinics, first level X-ray, secondary clinical laboratories with consulting pathologists, blood stations and pharmacy.
Level 2 general hospitals	Level 2 hospitals include level 1 services and departmentalized clinical services, respiratory units, intensive care units (ICU), neonatal intensive care units (NICU), high risk pregnancy units (HRPU), tertiary clinical laboratories, and second level X-ray
Level 3 general hospitals	Level 3 hospitals include level 2 services and teaching/training, physical medicine and rehabilitation, ambulatory surgery, dialysis, tertiary laboratories, blood banks and third level X-ray
Specialty hospitals	A tertiary hospital specializes in the treatment of patients suffering from a particular condition requiring a range of treatment (e.g. Philippine Orthopedic Center, National Center for Mental Health); patients suffering from disease of a particular organ or groups of organ (e.g., Lung Center of the Philippines, Philippine Heart Center); or patients belonging to a particular group such as children, women, or the elderly (National Children's Hospital, Dr. Jose Fabella Memorial Medical Center). Tertiary care facilities located all over the country serve as referral hospitals in the different regions of the country and provide an anticipated range of tertiary services.

recognitions, empowerment of pharmacist's responsibilities, eradication of "ghost pharmacists," board specializations and regulation of antibiotics (Philippine Pharmacist Association, 2016) shall be the future direction of pharmacy in the Philippines.

Accredited organizations: The Philippine Pharmacists Association (PPhA), founded on August 29, 1920, is the accredited professional organization of the PRC for licensed Filipino pharmacists. PPhA has 83 regional and local chapters, 10 affiliate organizations and the membership of about 15,000 pharmacists (Philippine Pharmacist Association, 2017a; Philippine Pharmacist Association, 2017b).

Core Pharmacy Practices

Hospital and Clinical Pharmacy

Hospitals are licensed by DOH (Food and Drug Administration, 1995) and accredited by PhilHealth. There are 1257 PhilHealth accredited hospitals in the country (Philippine Health Insurance Corporation, 2018). Hospitals are classified into three levels as shown in **Table 2** (World Health Organization, 2012a). Level 1 hospitals constitute almost 65% of the accredited hospitals, Level 2 hospitals comprise 26%, and Level 3 hospitals consist of 9%. Currently, five hospitals are accredited by the Joint Commission International (JCI) (Joint Commission International, 2015); 3 by Accreditation Canada (Accreditation Canada, 2019).

Hospital Pharmacy Services

Dispensing: Most hospitals dispense to both inpatients and outpatients. Some hospitals have an outsourced outpatient pharmacy (MedExpress Drugstore, 2018) so that the pharmacists can focus their services to inpatients. Most hospital pharmacists are assigned to the dispensing area to fill and prepare the prescribed medicines of the patient (Sarriff et al., 2011). Pharmacists in JCI-accredited hospitals, such as Asian Hospital and Medical Center (Joint Commission International, 2015), are required to review drug orders for appropriateness before dispensing as stated in the hospital pharmacy practice standards (PPhA Committee, 2015; Philippine Society of Hospital, 2016). Hospital pharmacists in Makati Medical Center (Makati Medical Center, 2017) and Manila Doctors Hospital (Manila Doctors Hospital, 2018) are also involved in dispensing investigational drugs.

Drug distribution system: Hospitals in the Philippines have centralized pharmacies that cater to the hospital wards and units. There are also floor stocks and emergency carts available in different wards to provide immediate access to certain medicines in case of emergency and for use during specific medical procedures. Some hospitals in the Philippines, such as Manila Doctors Hospital (Manila Doctors Hospital, 2018), also provide unit dose dispensing to their patients to aid the nursing staff in drug administration by preventing potential medication errors and minimizing returns and spoilage of prescribed medications (Gutlay et al., 2017).

Compounding: Extemporaneous compounding is common in hospitals. Pharmacists in The Medical City (Philippine Society of Hospital Pharmacists, 2016) receive requests for paper tabs for pediatric patients and other extemporaneous compounding that are not commercially available such as dermatological and topical preparations. Sterile preparations such as total parenteral nutrition, intravenous admixtures and chemotherapeutic agents can be compounded in some hospitals like Makati Medical Center (Makati Medical Center, 2017) and Manila Doctors Hospital (Manila Doctors Hospital, 2018).

Clinical Pharmacy Services

Clinical pharmacy in the Philippines is still developing as more healthcare institutions are realizing the need for the pharmacist to be involved in the healthcare team. Dr. Siopin L. Co is recognized as the dean of hospital pharmacy in the Philippines because of her various contributions in hospital pharmacy practice in the Philippines, especially in the field of clinical pharmacy. During her term as president of the Philippine Society of Hospital Pharmacists (PSHP) in the 1980s, she was known as an advocate of clinical

pharmacy and incorporated training in necessary skills in drug therapy management and pharmaceutical care in continuing professional development (CPD) programs for hospital pharmacists (Philippine Society of Hospital Pharmacists, 2016).

Clinical pharmacy services are usually provided in hospitals rather than in the community setting in the Philippines. Physicians and nurses expect pharmacists to be drug therapy experts and recognize that collaboration with pharmacists improve patient outcomes (Ramones et al., 2015). The hospital pharmacist can readily interact with other healthcare professionals such as doctors and nurses and with the patient in a hospital setting. They can easily access patient medical charts to retrieve necessary patient information. The hospital pharmacist is also in a better position to educate other healthcare professionals and patients on medicines and as a result, can also be involved in policymaking committees within the hospital (World Health Organization, 1994). Pharmacists from private hospitals have a higher level of perceived importance in performing patient care activities than those of government hospitals (Agaceta et al., 2013).

Medication reconciliation: Medication reconciliation is performed in the hospitals with international accreditation (Joint Commission International, 2015; Accreditation Canada, 2019), such as The Medical City (The Medical City, 2018) as this is the requirement in medication management. The outpatient pharmacy of St. Luke's Medical Center provides medication reconciliation as a value-added service to its clients (Samaniego, 2013).

Review of drug orders: Pharmacists should review drug orders before dispensing as stated in the Minimum Standards for Hospital Pharmacy Practice and PhilPSP (PPhA Committee, 2015; Philippine Society of Hospital Pharmacy, 2016). Similar to medication reconciliation, a review of drug orders is performed among hospitals with international accreditation (Joint Commission International, 2015; Accreditation Canada, 2019). In Makati Medical Center (Makati Medical Center, 2017) and The Medical City (The Medical City, 2018), the clinical pharmacist identifies drug therapy-related problems such as inappropriate drug dosing, potential adverse drug reactions and drug interactions, therapeutic duplication and contraindications, and discusses the recommendation or intervention with the doctor, nurse or patient.

Patient counseling: In The Medical City, the clinical pharmacist counsels the patient upon discharge (The Medical City, 2018). In the Philippine General Hospital, pharmacy interns were rotated to perform patient medication counseling services in OPD pharmacy and main pharmacy (Ching et al., 2016).

ADR monitoring: The FDA encourages healthcare professionals such as pharmacists as well as patients to report suspected ADRs (Food and Drug Administration Advisory on Reporting of Suspected Adverse Drug Reactions, 2016) using the Suspected Adverse Reaction Form (Food and Drug Administration, 2012). In 2008, there were only 1167 ADR reports, which is very low in relation to the Philippine population (MeTA Philippines, 2010). Even though hospital pharmacists have a low encounter with potential ADRs compared to doctors and nurses, pharmacists are still encouraged to report potential ADRs (Carandang et al., 2015).

Antimicrobial stewardship program: The DOH drafted the Manual of Procedures for Implementing Antimicrobial Stewardship Programs (AMS) in Hospitals in 2016. The clinical pharmacist plays an active role in the implementation of the AMS program in the hospital, therefore encouraging the adaption of clinical pharmacy services in the Philippines (Department of Health, 2016).

Barriers to clinical pharmacy services: A major barrier cited by pharmacists in implementing these services is the lack of support from physicians and other healthcare professionals. These healthcare professionals perceived pharmacists to be dispensers of medicines, based on their traditional role and not as active participants in the healthcare team. Pharmacists also identified having a lower salary and a lack of proper remuneration and financial incentives as a hindrance to implementing clinical pharmacy services. The workload of the pharmacist can also result in insufficient time to perform reviews of drug orders and provide patient counseling. Another barrier, especially in community pharmacy, is that patients often do not demand clinical services from the pharmacist because they are often pressed for time when they purchase their medicines from the drugstore (Agaceta et al., 2014).

Community Pharmacy

Community pharmacy is more popularly known as a drugstore or "botika" in the Philippines. These drugstores are classified as pharmaceutical outlets, which are licensed by the FDA (Food and Drug Administration, 2014). Based on the FIP Pharmacy Workforce Intelligence–Global Trends Report in 2016–there were 60,029 pharmacists in the Philippines, of these 77% were practicing in a drugstore (FIP, 2018; Lorenzo and Cruz, 2001). In the study on emerging roles of pharmacists in the Asia Pacific Region, it was found that almost 54% of pharmacists worked in a community pharmacy (Faller et al., 2017). Even though most pharmacists worked in the community setting, there was still a shortage of pharmacists in community pharmacy practice due to the increased number of drugstores as well as the fast turnover of pharmacists. Most independent drugstores do not have problems in hiring pharmacists because the business owner is usually a pharmacist. However, drugstores are losing pharmacists due to immigration for work overseas or due to local transfer to a higher paying job such as in business process outsourcing and regulatory affairs, or to government hospitals or clinical research (Loquias and Robles, 2012).

Community Pharmacy Services

Dispensing: Most of the duties of a community pharmacist involve dispensing of medicines to patients or clients (Ramos et al., 2017). The FDA requires that a registered pharmacist is present during the business operations of a drugstore (Food and Drug Administration, 2014). Based on the Philippine Pharmacy Act of 2016, only a registered and licensed pharmacist shall dispense prescription drugs and pharmacist-only over-the-counter medicines in a drugstore. Any prescription drug filled and prepared by the pharmacy assistant or pharmacy technician should be supervised by a pharmacist (Philippine Pharmacy Act, 2016; Implementing Rules and Regulations of Pharmacy Act, 2016). A community pharmacist should also implement good dispensing practices (World

Health Organization, 2012b), which include medication review, maintenance of patient medication record and labeling of dispensed medicines. A community pharmacist often has many different roles, such as being the owner, storekeeper, cashier, purchase officer, and manager of the drugstore. This multitasking can lead to a lack of or limited involvement of the pharmacist in the patient care functions such as medication review, patient profiling and patient counseling (Ramos et al., 2017).

Patient counseling: A community pharmacist faces hindrance in conducting patient counseling. Pharmacy students observed a lack of pharmaceutical care regimen during their community pharmacy internship (Carrido et al., 2016). As a pharmacist has multiple roles in a drugstore, it limits his time for patient counseling (Ramos et al., 2017). Other factors to consider include the lack of involvement and competence of the pharmacist in-patient counseling (Erku et al., 2017). Orientation of the pharmacist and support personnel in pharmaceutical care can help in improving patient counseling services (Faller and Velasco, 2015). Patients and caregivers may also reject patient counseling because they think that it will take up too much of their time. Value-added services such as screening of the vital signs of the patient can be provided to improve patient/client flow in the drugstore (Faller and Velasco, 2015; Faller et al., 2019).

Immunization services: The Philippine Pharmacy Act of 2016 stated the need for the involvement of the community pharmacist in providing immunization services for routine adult vaccination (Philippine Pharmacy Act, 2016; Implementing Rules and Regulations of Pharmacy Act, 2016). Community pharmacists are currently involved as advocates for vaccination but not as providers of immunization services (Echano et al., 2016). Training programs for pharmacists in immunization and vaccination will also be helpful in implementing immunization services (Echano et al., 2016).

Conclusion

Pharmacists have a critical role in UHC as they provide appropriate medication management. Evolution from a product-oriented service to patient-focused care in pharmacy practice is being recognized in the Philippines. Most pharmacists in hospital and community practice are assigned to traditional dispensing and inventory management functions. The clinical role of the pharmacist is being observed but is not being carried out consistently in the community and hospital settings. Factors that contribute to the barriers in implementing the clinical role of the pharmacist include lack of support from other healthcare professionals and upper management, lack of infrastructure, lack of clinical competency and training and fast turnover of pharmacists in the Philippines. The practice standards for pharmacists have emphasized the clinical functions of the pharmacist. Changes in the pharmacy curriculum will provide the necessary knowledge and skills to the pharmacist to provide pharmaceutical care services in the future.

Glossary

Accredited professional organization (APO) the duly integrated and accredited professional organization of registered and licensed pharmacists.
Botika ng Barangay (Village Pharmacies) (BnB) refers to a drug outlet managed by a legitimate community organization (CO)/Non-Government organizations (NGO) and/or the Local Government Unit (LGU), with a trained operator and a supervising pharmacist.
Botika ng Bayan (BNB) refers to a variant of Botika ng Barangay government-supported private drug franchise (PITC Pharma Inc) selling generic products with a trained operator and supervising pharmacist.
Clinical pharmacy an area of pharmacy concerned with the science and practice of rational medication use.
Continuing professional development (CPD) the development of advanced knowledge, skills, and ethical values in a post-licensure specialized or in an inter- or multidisciplinary field of study for assimilation into professional practice, self-directed research, and/or lifelong learning.
Dispensing the sum of processes performed by a pharmacist in reading, validating, and interpreting prescriptions; preparing; packaging; labeling; record keeping; dose calculations; and counseling or giving information, in relation to the sale or transfer of pharmaceutical products, with or without a prescription or medication order.
Medication reconciliation the process of creating the most accurate list possible of all medications a patient is taking—including drug name, dosage, frequency, and route— and comparing that list against the physician's admission, transfer, and/or discharge orders with the goal of providing correct medications to the patient at all transition points within the hospital.
Medicines drugs in their appropriate dosage forms, with assured quality, safety and efficacy for humans or animals, or both.
Pharmaceutical outlets entities licensed by appropriate government agencies, which are involved in compounding and/or dispensing and selling of pharmaceutical products directly to patients or end-users.
Pharmacovigilance The science and activities relating to the detection, assessment, understanding and prevention of adverse effects or any other drug-related problem.
Philippine Practice Standards for Pharmacists Refer to the established national framework for quality standards and guidelines for the practice of pharmacy that respond to the needs of the people who require the pharmacists' services to provide optimal, evidence-based care as formulated by the integrated APO and approved by the Professional Regulatory Board of Pharmacy.
Retailer any establishment that sells or offers to sell any health product directly to the general public.

Pharmacy Practice in Primary and Secondary Care Settings Within the UK: An In-Depth Analysis

Yousaf Ahmad*, **Ash Soni**†, *Care UK Healthcare, London, United Kingdom; †Royal Pharmaceutical Society, London, United Kingdom

General Overview of Pharmacy Practice Within the UK Healthcare System

This chapter will discuss and provide an in-depth analysis of the current practices of pharmacy services within primary and secondary care settings within the United Kingdom. It will describe the major services offered by pharmacy professionals in each sector; in addition, it will further illustrate the different roles and responsibilities the pharmacists have within the United Kingdom.

In addition, this chapter will hypothesize on potential future roles of the pharmacy services within the coming decade, especially in relation to the changing healthcare landscape in the United Kingdom. There will be a short analysis of current and emerging healthcare models within the United Kingdom, with a focus on pharmacy provision coupled with a review of challenges and hurdles that may be evident. The chapter will also provide some short case studies that further depict the broad range of service provision of pharmacy professional across all UK healthcare platforms.

History of Pharmacy and Clinical Practice Across the UK Heathcare System

Pharmacy within the United Kingdom has existed in one form or another for hundreds of years. Within the last half a century, pharmacists and their teams have become the cornerstone of healthcare services irrespective of the setting they are seen. The term

pharmaceutical care has largely been used to describe the historical and habitual practice of pharmacy professionals and has been most aptly coined by Hepler and Strand (1990):

> 'Pharmaceutical care is the responsible provision of drug therapy for the purpose of achieving definite outcomes that improve a patient's quality of life. These outcomes are: curing a disease, elimination or reduction of a patients' symptomatology, arresting or slowing down a disease process, or preventing a disease or symptomatology'

This has clearly focused the importance of pharmacists to ensure that medications given, prescribed, or administered to patients are safe, effective, and evidence drive. Medication is the most frequent intervention within healthcare systems worldwide. Achieving the best possible evidence of medication for the quality of life of patients should be the primary aim of all health professionals involved in the medication process.

Primary Care Description Focusing on General Practice and Community Pharmacy

Community Pharmacists are the traditional role seen by many people across the globe and within the UK. A community pharmacist is typically a professional who dispenses prescriptions written by a doctor, although this has changed dramatically within the UK. In recent years, community pharmacists have been developing clinical services in addition to the traditional dispensing role to allow better integration and team working with the rest of the National Health Services (NHS) within the United Kingdom. From medicine reviews, through to blood pressure and glucose testing, community pharmacy in the United Kingdom offers a number of enhanced services pertinent to the needs of the population (Community Pharmacy Scotland, 2019).

Community pharmacies are situated in high street locations, in neighborhood centers, in supermarkets, and in the heart of the most communities (Pharmaceutical Services Negotiating Committee, 2018). Many are open long hours when other healthcare professionals are unavailable. There are several different types and sizes of community pharmacies, ranging from the large chains with shops on every high street or in edge of town supermarkets, to small individually owned pharmacies in small communities, in the suburbs, and often in deprived areas or rural settings.

Within general practice, pharmacists work as part of the general practice team to improve value and outcomes from medicines and consult with and treat patients directly (NHS England). This includes providing extra help to manage long-term conditions, advice for those on multiple medicines, and better access to health checks. The role is pivotal to improving the quality of care and ensuring patient safety remains at the fore front of clinical care. They will also assist with communication across a patient's care pathway, manage medicines shortages by suggesting suitable alternatives where appropriate, and mentor newer pharmacists (Jankovic, 2016).

Having pharmacists in GP practices means that GPs can focus their skills where they are most needed, for example on diagnosing and treating patients with more complex conditions. This helps GPs to manage the demands on their time. This is a typical example of how pharmacy professionals are evolving from their traditional roles of medicine supply and public advice, to now being key professionals with extended roles for the delivery of exceptional patient care.

Secondary Care Description Focusing on Hospital Practice

Pharmacists working within secondary care, mostly within hospital settings, are often termed as hospital or clinical pharmacists, these nomenclatures are often used interchangeably. Although this reference to "clinical" is now less so been associated solely with secondary care, it is still largely reserved for pharmacists who work more in depth or on a 1-2-1 basis with patients. The term clinical pharmacist was first coined in the 1970s (Miller, 1981) and has developed in the hospital setting as a cornerstone of how pharmacy is practiced in secondary care (Walker and Whittlesea, 2011).

A hospital (or clinical) pharmacist is a source of knowledge, information, and relevant application of healthcare to patients, nurses, medical staff, and anyone in contact with hospital services. He or she can inform patients on all aspects of their medicines, including recommending types, as well as administration routes and dosages, which are all very dependent on the individual's needs. Hospital pharmacists can suggest whether tablet, injections, creams, or inhaler may be the best form of medication and frequently liaise with medical staff concerning their patients. Pharmacists in this setting tend to work very closely with healthcare professionals to ensure patients receive medication at the most optimal level. They assess the effectiveness of all medicines using biomarkers such as blood counts, drug assay, renal, and hepatic function and hematological markers.

Within hospital pharmacy, there are a number of differing roles and practices within the wider pharmacy teams, both for pharmacists and equally for pharmacy technicians, certainly in comparison to primary care roles within community and GP pharmacy. Main pharmacy practice subtypes in hospital include:

- Manufacturing
- Aseptic (sterile) production
- Medicine information
- Regulatory
- Clinical effectiveness
- Specialist clinical expert/hospital clinical pharmacist

- Radiopharmacy
- Education and training/teacher practitioner
- Leadership/management or executive

Primary Care

Current Primary Care Platforms and Service Offerings

Community Pharmacy

Community pharmacists work at the front line of healthcare in cities, towns, and villages across the United Kingdom since the 1800s. They work from their own pharmacies or out of local healthcare centers and doctor's surgeries (Royal Pharmaceutical Society, 2018).

Community pharmacists are easily accessible with over 11,600 community pharmacies in England located where people live, shop, and work. The make up of these pharmacies vary from sole/independent contractors through to small-, middle-, and large-sized multiples. As indicated by PSNC (2019):

- 89% of the population in England has access to a community pharmacy within a 20-min walk;
- Over 99% of those in areas of highest deprivation are within a 20-min walk of a community pharmacy; and
- As the accessibility of community pharmacies is greatest in areas of higher deprivation, they may have an important role to play in reducing inequalities

Community pharmacy and the pharmacists working in this setting help to deliver healthcare service providing a convenient and less formal environment for those who cannot easily access or do not choose to access other kinds of health service. The services offered by community pharmacy are categorized into essential, enhanced (or advanced), and locally commissioned, all dependent on the contractual framework in place within the United Kingdom (NHS Community Pharmacy services—a summary, 2015) (**Table 1**).

Pharmacy owners (contractors) must provide all essential services, but they can choose whether they wish to provide enhanced (advanced) service. Furthermore, they can decide with local commissioners regarding the additional service offerings all dependent on population needs.

The General Pharmaceutical Council (2018, p6) has clearly stipulated the core principles and standards that all community pharmacies registered within the United Kingdom should comply with. The five key principles that are overarching across the standards are:

- Principle 1: The governance arrangements safeguard the health, safety, and wellbeing of patients and the public.
- Principle 2: Staffs are empowered and competent to safeguard the health, safety, and well-being of patients and the public.
- Principle 3: The environment and condition of the premises from which pharmacy services are provided, and any associated premises, safeguard the health, safety, and well-being of patients and the public.
- Principle 4: The way in which pharmacy services, including the management of medicines and medical devices, are delivered safeguards the health, safety, and well-being of patients and the public.
- Principle 5: The equipment and facilities used in the provision of pharmacy services safeguard the health, safety, and well-being of patients and the public.

Pharmacy owners are responsible for ensuring the safe and effective provision of pharmacy services at or from a registered pharmacy. They are accountable for making sure that the overarching principles and standards for registered pharmacies are met and that staff are aware of them. Community pharmacy has developed multifold over the last two decades form a supply and manufacturer of medicines through to a clinical provider of care in their own right. All pharmacies now have a private

Table 1 Examples of service offering within community pharmacy

Essential	*Enhanced (or advanced)*	*Locally commissioned*
Dispensing	Medicines Use Review (MUR) & Prescription Intervention Service	Minor ailments management
Repeat dispensing	Flu Vaccination Service	Palliative Care
Disposal of unwanted medicines	New Medicines Service (NMS)	Care Home services
Promotion of Healthy Lifestyles (Public health)	NHS Urgent Medicine Supply Advanced Service (NUMAS)	Gluten Free food supply
Signposting patients to other healthcare providers	Stoma Appliance	Out of Hours services
Support for self-care	Appliance review service	Supplementary or Independent Prescribing
Clinical governance/Signposting		

consultation area specifically for confidential or sensitive discussions (NHS Community Pharmacy Services—a summary, 2015) and community pharmacists are beginning to have access to records that are most often only seen in general practice. This is allowing pharmacists to care for the patients and public in a holistic manner by understanding a complete medical picture of the individual in front of them. Allowing the future of community pharmacy to evolve rapidly to current service provisions such as the management and monitoring of long-term conditions, for example asthma and diabetes, as well as delivering flu vaccinations, and conducting medicines reviews.

Pharmacists and General Practice

The evolution of pharmacists working in general practice has occurred in last 10 years within the United Kingdom, granted in various forms and guises. As indicated by the General Practice Forward View (2016), there has been over £100 million to support an extra 1500 clinical pharmacists to work in general practice in England by 2020, resulting in a large expansion of the general practice pharmacy workforce. There are a number of reasons behind this central investment, namely due to the potential benefit, a pharmacist can add into the management of patients within a practice (Stone and Williams, 2015). Focusing on all aspects of medicines, from application and administration through to prescribing and interactions, pharmacists working in general practice have a number of key roles and responsibilities. Some of these include:

- Providing expertise in clinical medicines review and address public health and social needs of patients in GP practices
- Reducing inappropriate poly-pharmacy and wasteful prescribing through clinical medication review
- Increasing quality and safety of prescribing through mechanisms such as audit and PDSA cycles
- Managing practice formularies to improve the quality, safety, and cost-effectiveness of prescribing
- Acting as a source of medicines information for all of the practice team and patients
- Working within the practice-based team to undertake medication reviews particularly in high risk groups such as frail elderly, renal impairment, hepatic impairment– substance misuse, patients on high risk medicines, and revolving door hospital admissions
- Improving prescribing practice through educational support for all prescribers within the practice
- Leading on where changes in evidence require changes in prescribing across patient population, e.g., where a drug is withdrawn or indications change
- Liaising with colleagues in community pharmacy to align support for medicines adherence
- Implementing drug withdrawals and alerts, e.g., MHRA aimed at improving medicines safety
- Supporting improvements in clinical care through practice-based audit and implementing change
- Prescribing advice to prescribers in practice, e.g., temporary nonavailability of drugs
- Ensuring patient safety when they are transferred between care providers through reconciliation of prescribed medicines

There is a clear assertion that having pharmacists in GP practices means that GPs can focus their skills where they are most needed, for example on diagnosing and treating patients with more complex conditions. This helps GPs to manage the demands on their time.

Scotland, England, Wales, Northern Ireland Variance

Health and the provision of services across the major parts of the United Kingdom vary, as they are devolved to the individual government bodies within each county making up the United Kingdom. Thus, the NHS services and pharmacy-specific provision offered in Scotland does vary from that offered in England, Wales, and Northern Ireland (NI). One of the key differences is around how healthcare and in particular pharmacy services are funded and the types of services being offered. For example, community pharmacy services in Scotland and Wales provide a number of additional services such as a universal wide Minor Ailments service, providing acute and minor aliment care to the patients that need it more, in addition to a number of key patient directed initiatives such as Pharmacy First, which allows patients free advice and treatment of certain conditions (NHSGGC, 2019). Compared to England where this is not currently a common practice, equally variations in General Practice pharmacy provision are evident as in Scotland, there have been pharmacists working in General Practice for over 10 years now, compared to England and Wales, whereas this is still a relatively new phenomenon. In Northern Ireland, the Marking it Better Through Pharmacy in the Community—A 5-year strategy (2014, 2017) seeks to provide a clear direction for the delivery of pharmacy services in the community, which place the individual at the center and aim to optimize their health and well-being at all times. It sees the increased utilization of pharmacists' clinical skills in the delivery of services in the community and greater collaboration of pharmacists with other health and social care professionals to demonstrably contribute to the improvement of the health of the population, thus also bringing Northern Ireland in line with the strategies for the other main counties within the United Kingdom.

As with any part of the United Kingdom, each representative healthcare commissioner or government body has the core guiding principle of making sure that the NHS provides safe, high-quality patient care, and services within primary care and to ensure that the NHS lives within its means.

Challenges Facing Primary Care Pharmacy Within the UK

The challenges facing Primary Care within the UK are real and tangible, coupled with pressures facing not only pharmaceutical services but also the wider practitioners within the primary care sector. Analysis of 30 million patient contacts from 177 general practice found that patient consultations grew by more than 15% between 2010/11 and 2014/15 (Understanding pressures in General Practice, 2016). Specifically, for pharmacy, there is a growing consensus that this health care resource is accessed regularly, approximately 84% of adults visit a pharmacy at least once a year- 78% for health-related reasons. Three-quarters of people have visited a pharmacy in the last 6 months (Department of Health, 2019). This puts pressure on demand, capacity, funding, and appropriate utilization of resource. Some of the key challenges (Department of Health, 2014) can be summarized as:

- Sustainability and Transformation—There is a requirement to ensure Pharmacy within the primary care sector works at transforming itself at a similar pace as other areas. To ensure, it remains efficient operationally and can integrated seamlessly with other healthcare professions.
- Integration and Technology—Integrating community pharmacy into the wider NHS to make better use of their clinical skills by providing NHS mail, Summary Care Record, Skype for Business and the Electronic Prescription Service (EPS) prescription tracker. Local pharmacists and their teams will be able to access relevant clinical information quickly and communicate more easily with patients and other health professionals. Primary care offerings are so varied that systems and processes that exist are so acutely different, that practitioners are unable to share information about patient care between themselves safely and efficiently.
- Financial—Ensure capital and government funding remains in place, and continues to support pharmacy services
- Training and Competence—Working a developing core competency framework and definitions of appropriate training that allow all pharmacy professionals to work to a defined standard across primary care service provisions
- Population changes—An ageing population that lives longer can put a lot of demand on primary care services but also significantly challenges clinicians as patients will ultimately have more complex health needs, ranging from comorbidities through to polypharmacy-related issue
- Quality—There is no clear consensus on what quality and good care looks like within Primary Care; there is a real need to define and standardize the quality of care provided by all sectors of pharmacy and health within primary care

Networks, Classification, and Interaction of Pharmacists

There is a consensus that pharmacist working across primary care, either in Community Pharmacy or General Practice, must be able to communicate effectively and efficiently with each other. Currently, there is a lack of clear and structured communication between pharmacy professionals. There remains great support individually for pharmacists working in either General Practice or Community pharmacy through trade bodies, unions, professional bodies, and commercial entities in the United Kingdom, but a distinct lack of uniformed voice across the wider Primary Care sector. There is an underutilization of communication and technology advances within pharmacy in this sector to ensure a more collaborative approach to pharmacy delivery. Digitizing all aspects of medicines and pharmacy has an enormous potential to improve patient care, increase safety, and make the system in the NHS more efficient. As the world changes at a rate not seen since the industrial revolution, pharmacy has been slow to adjust. There remains a reliance on inefficient, paper-based processes, which slow operational delivery of pharmacy services down, increase the potential for errors, and cost money.

Case Studies

Case Study 1 Mr Pharmacist in General Practice

Mr Pharmacist had worked for 20 years in community pharmacy, but recently moved into GP Medical Centre. He was to use his experience to develop a range of new services within his practice, including:

- Introduced a new repeat medication policy, ensuring more patients have a medicines review, and reducing prescription queries.
- Provides daily telephone consultations for patients with medicines-related questions.
- Runs medication review clinics for people on multiple medicines, which include Quality and Outcomes Framework reviews for patients with long-term conditions.
- Provides a care home's prescription management service for 300 residents.
- Helps the practice fully achieve its annual medicines optimization incentive payments, including improving prescribing of antibiotics and blood thinning agents

Mr Pharmacist is part of a team at Westbourne Medical Centre and works alongside GPs, a community pharmacist, a pharmacy technician, a nurse practitioner, a practice business manager, clinical governance and quality manager, and a receptionist. They are all part of a high performing, integrated, multidisciplinary team dealing with complexity in primary care, centered on clinical pharmacy helping to contribute to team capability within the GP surgery allowing "the unit to deliver care."

Impact

They record all pharmacist activities that directly relate to patients (telephone consultations, face-to-face consultations for patients with polypharmacy, prescription queries, clinical tasks from clinicians, and medicines reconciliations post-hospital discharge) using a template on the practice software.

The team uses metrics to assess all changes in general practice giving them relevant, objective, and easy to collect data. The practice collectively agreed an average time needed to perform regular activities, which otherwise would have been done by a GP, and have estimated that one post saves GPs 80 h a month, excluding indirect patient activities, the equivalent to two working weeks a month across the practice.

Lessons Learnt

The biggest success to date has been seen via two neighboring practicers who have also employed a pharmacist. The benefit to patients is clear—accessibility to health, information, and education on appropriate medicine use and concise medicine advice. In addition to understanding the enhanced roles, pharmacist and their teams can play in General Practice.

Case Study 2 Pharmacy First Scheme in Community Pharmacy

Pharmacy teams in rural part of the United Kingdom have helped more than 8000 patients during the first 5 months of a "Pharmacy First" scheme, which brought together three services to make accessing prescription medicines more convenient for patients and help reduce pressure on out-of-hours services. Patients were not only happy with the service they received, but said that they would also recommend it to others. This Pharmacy First scheme, delivered in a community pharmacy, included a minor ailments service delivered via a PGD, a winter ailments service, and an emergency supply scheme. The services, funded by a central government fund, and the key findings are outlined showed:

The Emergency Supply service saw participating pharmacy teams supply 769 different medicines to patients who had run out of their regular medicine, with the most requested item being salbutamol/Ventolin inhalers. When asked what they would have done if the service had not been available at their local pharmacy, 53% of patients stated that they would have accessed out-of-hours GP services instead. Devon LPC also reported local pharmacies received twice the national average of referrals from NHS 111.

The Pharmacy First scheme also gave patients a more accessible route to medicines for typical winter illnesses as 45% of patients reported that they would have used urgent care centers or visited their GP without the Winter Ailments service. This service was the most well used, accounting for 40% of the total interventions made, with pain relief/antipyretic oral solutions being the medicine type most often supplied.

The Minor Ailments via Patient Group Direction (PGD) service was similarly successful at providing patients with an alternative method of medicine supply. The most popular condition presented to pharmacies was bacterial conjunctivitis, accounting for 56% of all PGD interventions (Devon Local Pharmaceutical Committee, 2015)

Impact

The Pharmacy First services have saved over 4800 appointments with doctors: 3790 appointments in General Practice, 1818 of out of hours GP appointments, and 210 Accident and Emergency appointments.

Lessons Learnt

Community Pharmacy has a vital role to play in Primary Care currently and in the future. There is a clear underutilization of pharmacy services within the community and it can be further developed with the appropriate infrastructure to help it achieve such benefits as seen in this case study.

Secondary Care pharmacy services in the United Kingdom

Current Secondary Care Platforms and Service Offerings

Pharmacy provision is Secondary Care occurs in most parts within a hospital environment. Pharmacy services are delivered in hospitals through teams working in the dispensary, procurement and distribution, clinical trials, clinical pharmacy, ward-based pharmacy, medicines information, aseptic services, education and training services, nonsterile manufacturing, and quality control. Pharmacists work on a rotational or permanent basis in one or more of these departments. The size and activity of each department depend on the type of hospital and the geographical area. Hospital pharmacists are recognized for their expertise in many specialties. Some of these include anti-infectives, cardiology, HIV, mental health, care of the elderly, oncology, pediatrics, palliative care, and renal pharmacy. They have a direct involvement in patient care and influence treatment choices by being involved in decision-making at the point of prescribing (Rodden, 2000) (**Table 2**).

Newly recruited basic grade pharmacists rotate through the various sections of the typical hospital pharmacy department, gaining experience of the different specialties. There is no longer a single career structure for hospital pharmacy. Instead, there is a myriad of possibilities. Importantly, specialization in one area does not bar pharmacists from posts in other areas. Pharmacists are graded in a banding structure, which is based on experience, expertise, and professional education. As a pharmacist progresses through the band, experience and seniority structure, this is complemented with relevant salary increases, as well as changes to the responsibilities and professional practices. Notably, within the hospital sector, there are opportunities to study for a clinical diploma or Masters qualification in relevant fields and a strong commitment to continuing professional development.

Clinical pharmacy forms a large part of hospital pharmacy work. Clinical pharmacists are part of the healthcare team on the ward, working with medical and nursing staff and the various therapy professions. Within the team, they are seen as the experts on drugs and their advice is sought by the other members. Clinical pharmacists work closely with both prescribers and patients. They often attend consultant ward rounds where they can influence prescribing, as well as prescribing themselves if an independent prescribing qualification is attained. A typical working day of a hospital pharmacist can vary significantly in role and day-to-day responsibilities, with a focus on the provision of clinical care most commonly at the heart of their daily duties (**Fig. 1**).

Table 2 Structure and examples of a pharmacist workforce within a typical hospital pharmacy department

Banding	*Title(s)*	*Years qualified*	*Expectation of learning*	*Examples of some typical duties*
Band 5	Pre-registration Pharmacist	0	Completion of undergrad and pharmacy degree	Shadowing pharmacists within clinical settings, dispensing, and learning technical skills
Band 6	Basic Grade Pharmacist, Hospital Clinical Pharmacist	1–2	Passing the General Pharmaceutical Council exam	Working on a ward, in a dispensary, checking, rotations through specialist areas such as aseptic, medicines information and clinical areas
Band 7	Hospital Clinical Pharmacist, Senior Clinical Pharmacist	2–4	Starting and completion of postgraduate diploma in clinical pharmacy	Autonomous clinical work on wards and departments, mentoring band 6, further exposure to clinical settings, conduct audits
Band 8a	Specialist Clinical Pharmacist	4–8	Completion of Masters within Clinical Pharmacy, starting and completion of Independent Prescribing qualification	Working on a specialized ward, attendance on ward round, conducting an outpatient clinic, teaching students, Quality improvement projects
Band 8b/c	Lead Clinical Pharmacist, Principal Pharmacist, Consultant Pharmacist, Head of Department or service	8-12	Further postgraduate degree in related discipline or clinical specialty, project management qualification, recognized leadership program	Managing a group of senior pharmacists, delivering on strategy and performance, attendance at meetings, shaping policy
Band 8d/Band 9	Head of Pharmacy, Director of Pharmacy, Chief Pharmacist	12+	Master of Business Administration, or additional leadership/management qualification	Leading the pharmacy service offering within hospital, Executive representation of pharmacy at platforms/meetings, strategizing and vision setting

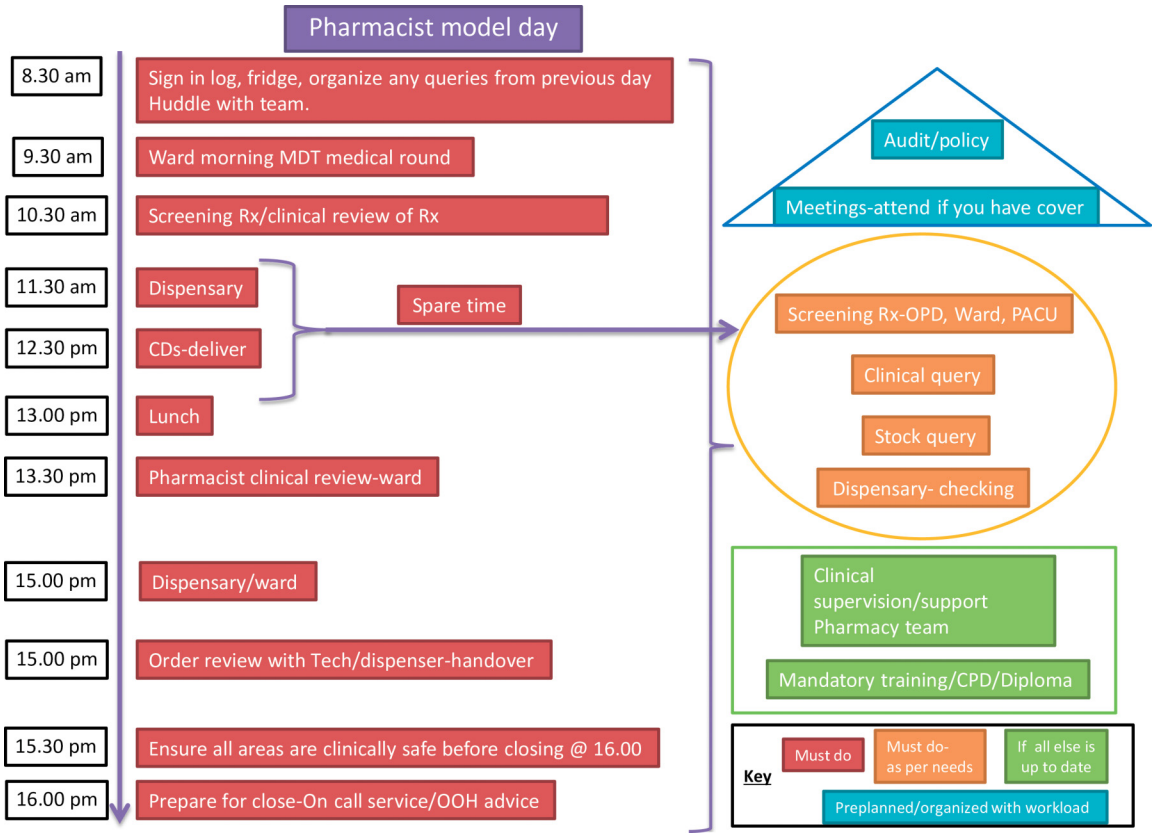

Figure 1 Typical day of a band 6/7 pharmacist.

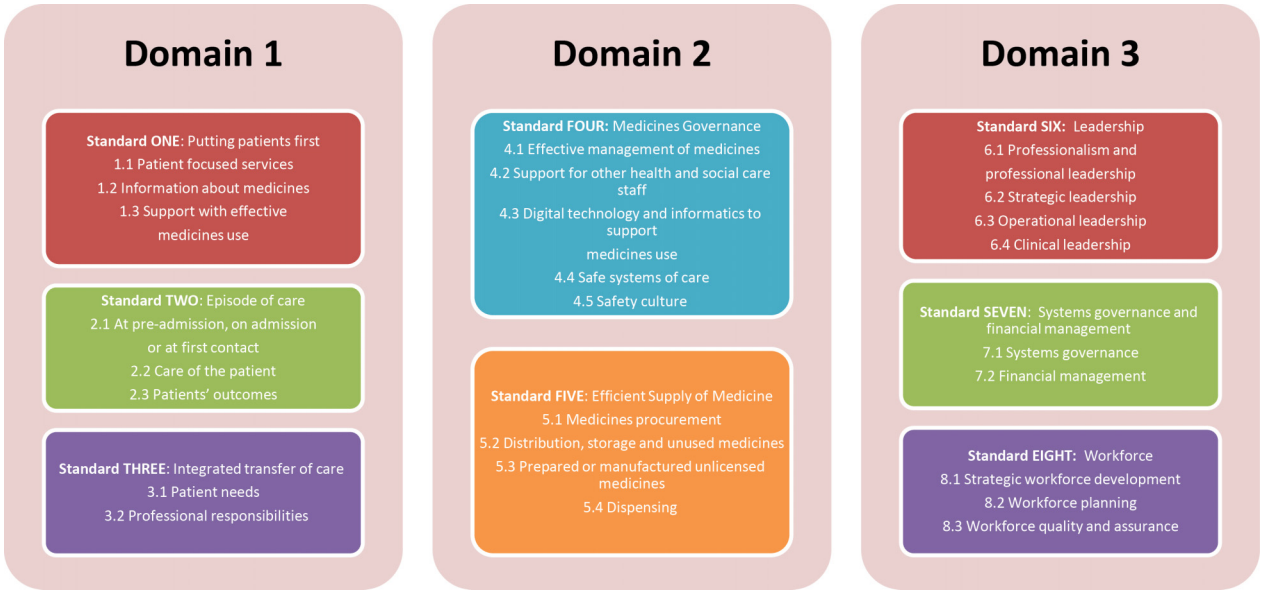

Figure 2 Eight overarching standards grouped into three domains (Royal Pharmaceutical Society, 2017).

Within the past 5 years, there has been great effort made at standardizing and recognizing the core elements of hospital pharmacy. The Royal Pharmaceutical Society (2017) created a revised version of Hospital standards, which heralds the first publication of key standards in relation to practice within this sector. The professional standards describe quality pharmacy services and key examples of excellence in this field. The standards provide a broad framework that will support pharmacists and their teams to continually improve services, shape future services and roles, and deliver high-quality patient care across all settings and sectors (Royal Pharmaceutical Society, 2017).

The professional standards support professional practice and encourage a culture of openness, transparency, and candor that puts patients first by encouraging professionalism. These standards help patients experience a consistent quality of service within and across healthcare providers that will protect them from incidents of avoidable harm and help them to get the best outcomes from their medicines (Fig. 2).

Scotland, England, Wales, Northern Ireland Variance

Within Secondary Care, the variance in practice of pharmacist and pharmacy teams is very minimal across the counties of Scotland, England, Wales and Northern Ireland. The differences that may exist would be reconciled to: variations in job roles and titles, slight salary fluctuations, and a contrast of clinical duties, but frequently their day-to-day practices would largely be very similar. The hospital sector traditionally within the United Kingdom has developed in a uniformed manner, allowing a clear understanding of pharmacists working in Secondary Care.

Origins of Clinical Practice Within Secondary Care

The role of pharmacists working in the Secondary Care sector in the NHS has evolved rapidly since the evolution of healthcare in the 1940s. Growing from what was originally a supply service to becoming a clinical orientated practice in hospitals, and with a range of new roles in clinical specialties, pharmacists are now recognized as a valuable part of the multidisciplinary clinical team (Jankovic, 2019).

Pharmacists were quite often only seen as the departments they worked in and rarely on a ward or taking to patients, compared to the current climate where pharmacists are routinely based in clinical environments such as wards and outpatient departments. Pharmacists were quite often only seen within the pharmacy departments they worked in and rarely visible on a ward or talking to patients. This is distinctly different to the current climate where pharmacists are routinely based in clinical settings, including wards, accidents and emergency departments, and outpatient areas. It can be acknowledged, this has come about due to the transformative difference in how the NHS is being delivered with a focus on ensuring that patients see the right health care professional in a timely manner for their care needs.

Current Pharmacists Roles Within Clinical Practice and Professional Development

Providing the best care to patients requires hospital pharmacists to build on the knowledge acquired during the 5 years of pharmacist training and to develop this knowledge further throughout their careers. The hospital sector provides excellent

development opportunities and some NHS departments provide financial support for postgraduate qualifications. Newly registered hospital pharmacists are encouraged to advance their practice by studying for postgraduate certificates or diplomas in clinical pharmacy or pharmacy practice. Exposure to different practices at this point in their career develops their knowledge, skills, and experience in order to decide on a specific area of practice in which to specialize. Clinically specific, secondary care pharmacists' role includes:

- Oncology clinical pharmacist
- Renal pharmacist
- Palliative care pharmacist
- Clinical effectiveness pharmacist
- Wound care pharmacist
- Cardiology pharmacist
- Pharmacoeconomics pharmacist
- Principal pharmacist
- Lead clinical pharmacist
- Pain management pharmacist

At all stages of a hospital pharmacist's development, training opportunities are provided, including in-house training from within the pharmacy department or hospital, regionally or nationally organized study days, courses, or conferences covering specific topics and specialty and management training. This ensures that pharmacists working in this sector are aptly trained and experienced to provide the level of specialized care needed.

Case Studies

Case Study 1 Ms Clinical Pharmacist in a hospital setting specializing in Renal Transplant and Urology

My daily routine involves: applying my expert knowledge to advise on dose adjustments for medicines in renal (kidney) impairment, pharmacokinetic interactions, drug administration and management of adverse drug reactions (side effects). In renal and transplantation the drug regimens are highly complex and a failure to manage them correctly could have catastrophic consequences, so the pharmacist is an important and respected member of the multidisciplinary team. I am also an independent prescriber and run a medication review clinic for transplant patients. Being able to suggest changes to make it easier for patients to manage their condition is very rewarding. Other roles that I have include writing guidelines, financial management of drug budgets and teaching and training undergraduates and junior pharmacists.

Impact

I am able to directly influence and shape the care patients get from the medicine patients receive. I am able to understand and evaluate the effects medicines are having on patients and appropriate correct and prescribing.

Lesson Learnt

An appropriate trained and experienced hospital pharmacist has a number of roles within the care of patients, and is able to effectively communicate and demonstrate the impact to the quality of care being delivered.

Case Study 2 Utilization of Technology and Informatics in Hospital Pharmacy (NHS England, 2016a,b)

The clinical informatics team at a NHS Hospital was created when the trust introduced an electronic patient record (EPR). The electronic prescribing (ePx) component of the system was implemented by the pharmacy department with the assistance of a multidisciplinary project team. Over the last decade, the system has been continually developed and is now digitally mature. Key to their ongoing informatics development is the department investment in a permanent pharmacy informatics team. The pharmacist-managed team of pharmacy technicians led the initial implementation being involved in process mapping, process design, system build, and user engagement. They also designed the testing, training, and governance processes to ensure safe successful implementation and compliance with information standards for clinical systems.

Experience, through continuity of the team, has been an important factor in ongoing improvement. This has been developed through the trust supporting the pharmacy informatics team to undertake informatics qualification, for example, informatics degrees, system architecture courses. With a wider understanding of the technical and operational aspects of developing and maintaining an EPR, the team has improved in troubleshooting, rule creation, report writing, interface development an example utilizing all of these being the development of an EPR-generated and automated community pharmacy referral process (Clinical Handover).

Another key to success is ensuring the pharmacy informatics teams are represented on key hospital groups and committees. Representation at these has been essential to ensure that informatics is developed according to hospital priorities and to ensure that informatics and its opportunities are embedded into new hospital developments with the engagement of key stakeholders.

Impact

The team have subsequently developed the system in close collaboration with the hospitals IT services. They have provided leadership on several system upgrades, for example, JAC upgrades and creation of a network version of the Trust's chemotherapy ePx system. They have also led on the uptake of new EPR functions. An example of this being the development of clinical pharmacy prioritization tools, which provide a supplement to traditional decision support models. The skills gained during this have benefited medicines optimization and wider applications of the EPR such as laboratory services.

Lessons Learnt

This department is one of several hospitals nationally that have focused on developing and implementing a best practice model to prioritize patients. This has enabled them to target and provide patients with a structured 7-days a week clinical pharmacy service. Electronic prescribing systems have the added value of providing intelligence of prescribing activity that occurs during the patient pathway in hospitals.

Case Study 3 Medicine Reconciliation

The hospital department have developed a Medicines Reconciliation checklist that is used for all nonelective adult hospital admissions. It is designed to be used by a pharmacist, technician, or preregistration student who has an underpinning knowledge of the medicines reconciliation process (any new member of the team is competency assessed on completing the activity by senior pharmacist or technician).

Each statement in the checklist is designed to act as a prompt so that the right information is elicited in a logical manner such that the best possible drug history is established. The final prompt is to ensure the patient's prescription chart reflects reality and any anomalies are resolved, so the drug history can be considered as clinically checked.

Impact

The checklist is designed to provide the hospital and pharmacy department with the assurance that an effective process has been followed in order to achieve medicines reconciliation. They carry out occasional audits of it; sometimes, we have incidents reported where the process has not been followed. If the checklist is used and the SOP is followed, invariably the drug history is correct.

Lessons Learnt

Medicines reconciliation is a process that helps to minimize significant medicine-related harm. More importantly, this case highlights the role that each health care professional can have at completing an accurate medicine reconciliation process.

Integration Model and Healthcare Redesign—What Does This Mean for Pharmacists?

Current and Future Landscape of Healthcare Delivery Within the United Kingdom

Healthcare in the United Kingdom is complex and variant. As mentioned, there are key sectors where healthcare and pharmacy services are delivered. New treatments for a growing and aging population mean that pressures on the service are greater than they have ever been. But treatment outcomes are far better—and public satisfaction higher compared to 10 or 20 years ago. Medicines are the single biggest intervention for the prevention and treatment of ill health, the overall medicines cost in the NHS in 2017/18 was £18.2 billion, an increase of 4.6 per cent from £17.4 billion in 2016/17, and an increase of 28.4% from £13.0 billion in 2010/11 (NHS Digital, 2019).

Medicine and pharmacy services are situated in every major clinical service within the United Kingdom. The future of healthcare delivery in the United Kingdom will need to transform to ensure sustainability; quality and capacity can be maintained. Patients, diseases states, medicine regimens, and patient pathways continue to evolve and develop as medicine research improves. Consensus of challenge of the future of healthcare delivery includes:

- legacy technology and commercial arrangements
- complex organizational and delivery structures
- a risk-averse culture
- limited resources to invest
- a critical need to build and maintain public trust

Current Government Policy and Strategy on Pharmacy Services Within the United Kingdom

There are multiple key pharmacy strategies across the United Kingdom, which detail the benefits of pharmacists with vision setting of what pharmacists can achieve in the delivery of health care across all platforms.

In Scotland, Achieving Excellence in Pharmaceutical Care (2017, p3) lists two key priorities for pharmacy:

1. Improving NHS pharmaceutical care
    a. Improvements to NHS pharmaceutical care services across Scotland
    b. Delivering safer use of medicines for the people of Scotland
2. Enabling NHS pharmaceutical care transformation
    a. Ensuring capability and capacity by further developing the pharmacy workforce
    b. Developing a digitally enabled infrastructure
    c. Planning and delivery requirements for sustainable NHS pharmaceutical care services

In England, the Pharmacy Integration Fund Strategy (2016) and Integrating NHS Pharmacy and Medicines Optimisation into Sustainability & Transformation Partnerships and Integrated Care Systems (NHS England, 2019a,b,c) describe a clear drive for the greater use of pharmacists and pharmacy technicians in new, integrated local care models. The initiatives provide opportunities for pharmacy teams to spend more time delivering safe and effective clinical services and health improvement for their patients; work in a variety of NHS settings as part of an integrated local primary care team; and to be supported by improved technology.

The priorities and visions for the future of NHS pharmaceutical care that are set out in these strategies, indicate how pharmacists and pharmacy teams can be integrated within a modern digitally enabled health and social care system and have the potential to open up new and rewarding career pathways for pharmacists and pharmacy technicians in increasingly clinical roles.

Current and Future Patient Demographics Within the UK National Health Service

It is widely accepted that the population in the United Kingdom is living longer; therefore, the challenges, demands, and changes required to provide adequate on-going health care are vast. Patients living longer can result in more complex care, through the development of comorbidities and the relevant polypharmacy that originates from this. Pharmacists and pharmacy services need to transform appropriately to cope with the change of patients and populations.

Pharmacist Utilization Analysis and Discussion Within the Health Systems Across the United Kingdom

Making the best use of a pharmacist can be difficult; there remains a distinct lack of utilizing pharmacists and their teams optimally within health systems across the United Kingdom. The NHS is using the clinical skills of pharmacists and pharmacy technicians to review people's medicines in GP surgeries, hospitals, care homes, and urgent care, working as part of the wider healthcare team, but currently there is limited research in how pharmacists are utilized appropriately.

Examples and Realization of Integrated Primary and Secondary Care Services

The integration strategy of health systems in the United Kingdom has resulted in the formation of a number of innovative pharmacist roles. Some of these include:

- Pharmacist in Telehealth—working at providing pharmaceutical care through telephony health
- Secondary Care Pharmacists working in Primary Care—pharmacists providing specialist care within the community via clinics
- Evolution of GP Pharmacists—identifying patient groups for pharmacists to care for autonomously, development of prescribing clinics and managing repeat prescriptions
- Pharmacist within the Care home setting—polypharmacy reviews of elderly patients
- Community Pharmacists developing long-term condition management clinics—where pharmacists within the community run disease-specific medicine management.

Emerging and Innovative Roles Currently and Within the Next 10–20 Years

Description of a Potential Healthcare Landscape Within the Next 10 Years

The healthcare landscape of the next 10 years is complex and constantly changing as indicated. The core principles that will help to describe and shape what the next 10 years will look like (NHS England, 2019a,b,c) are:

- Further joined-up and coordinated care
- Breaking down traditional barriers between care institutions, teams, and funding streams so as to support the increasing number of people with long-term health conditions, rather than viewing each encounter with the health service as a single, unconnected "episode" of care;
- Proactive in the services provision—with a focus on preventative care than cure
- Technological advances—how does innovation in technology can help to seamlessly integrate and transform care
- Workforce changes—ensuring appropriately trained staff are available and apt to be utilized

The recently published plan focuses on building an NHS fit for the future by enabling every patient to get the best start in life, continually helping communities to live well and helping people to age well.

Potential Examples of Pharmacist Roles

Many of the current strategies and government policies mentioned, recognize the potential for pharmacy, highlighting that there should be far greater use of pharmacists in the prevention of ill-health, support of self-care for minor ailments and long-term conditions, and as part of more integrated local care models. Subsequently, there are multiple roles that are emerging for the future. In Primary Care, the further evolution of General Practice Pharmacists continues, and the future will bring more patient ownership and self-governance of practice. Within Community Pharmacy, there is a real potential that this group of pharmacy

professionals are being shaped to become the cornerstone of health care within the community, a stronger focus of developing clinical skills of community pharmacists, in addition for this sector to be at the forefront of preventative health care and wider public health agenda. Within Secondary Care, there is a consensus that pharmacists working in this setting must start to care for patients out with the typical hospitals setting. Thus, the future will see a more portfolio approach to pharmaceutical care, where pharmacist's potentially will work routinely across care boundaries. Technological advances in automation, telehealth, informatics, and pharmacogenomics will herald new clinical settings and opportunities for pharmacists and pharmacy teams, and the traditional descriptors of primary and secondary care will potentially no longer be sufficient to illustrate where pharmacists will typically practice.

Obstacles and Hurdles and How is This Reached and What is Needed to Make This a Reality

There are some obstacles and hurdles facing pharmacy reach its true potential. Some include:

- Finance—the lack of assurance of funding within some sectors such as community pharmacy will destabilize the progress made, compared to other settings such as general practice, where much government funding has been given recently
- Sustainability—how best to ensure the on-going continuation of any potential new service model is not clear, in addition to fully implementing processes to cover the work done in the past by pharmacists in new and emerging roles
- Workforce—both undergraduate and postgraduate training of pharmacists will need to be developed to appropriately educate pharmacists to a competence that will allow them to deliver pharmaceutical care in other settings and in more specialized arenas.
- Reaching the potential and making it a reality—Traditionally, pharmacy services have been poorly represented in executive levels of health systems; the ability to influence key stakeholders will inevitably pose the biggest hurdle in making the future practice of pharmacy a reality

Role of Regulation, Professional, Academia, and Unionized Bodies

Regulatory, professional, and unionized bodies, coupled with academia, all have distinct roles in ensuring the continuation of pharmacy services within the traditional settings of care, but more importantly at ensuring the future landscape of care, have appropriately pharmacists and pharmacy services embedded in. Regulatory and professional bodies must ensure the regulation and representation of pharmacy is adequately explained and voiced at the most senior platforms within the United Kingdom. Unionized bodies must be able to change their stance in protecting the changing workforce, as the parameter of care will inevitably be different. Equally as important, the academia structures are vital to train, educate, and develop the future of the profession. The pharmacist and pharmacy team of the future are far removed from the typical primary and sector care descriptors; thus, they require a different skillset and knowledge base to be ready to practice.

Conclusion

Pharmacists and pharmacy services, teams, and departments in the United Kingdom have varied and challenging roles. Within primary and secondary care, we have pharmacists that have a number of patient facing roles, which have direct impact on the quality and provision of care offered within the wider health systems. Pharmacists in these sectors dispense, manufacture, prescribe, and advise on the most optimal use of medicines. The pharmacy professionals within each sector are quite unique in their practice and knowledge base, but as the future of heath care in the United Kingdom is being formed, we see more of a need for a collegiate pharmacist that has a unified competence base to care for patients adequately. The typical sectors of pharmacy in the future will be widely different in the future, and thus pharmacy in the United Kingdom in the next 10 years will look markedly different to that of now.

Pharmacy Practice in Portugal

Filipa Alves da Costa*, Ema Paulino†, Helena Farinha‡, *Instituto Universitário Egas Moniz, Monte da Caparica, Portugal; †Farmácia Nuno Álvares, Almada, Portugal; ‡Centro Hospitalar de Lisboa Ocidental, EPE, Lisboa, Portugal

Introduction

As in most countries worldwide, the focus of pharmacy in Portugal has shifted from a drug-oriented to a person-oriented practice. Historically, patients would go to a pharmacy and see the pharmacist spending most of his time in the laboratory, preparing ointments, syrups, and even suppositories. The existing space for the pharmacist to talk to medication users was practically nonexistent. In fact such a space was not even needed because no great interaction occurred, apart from informing how to use the magisterial or official preparation. By the 1980s and 1990s, there was refurbishing of many premises, increasing the public and consultation areas. At this time, aspirins and other over the counter medication appeared on the shelves behind the counter, although much of the space was still left for antique vases because many pharmacists still appreciated the relationship between pharmacy and art. More recently, a specific separate space within the public area was created so that people living with a disease could have their biomarkers measured, and this space was also used to counsel people on more sensitive matters that would require

discretion. Today, pharmacists have witnessed and supported the most recent investments, focusing on a second separate and larger space where vaccines could be administered, and also the acquisition of cars with the required legal conditions of strict humidity and temperature control for domiciliary delivery of medication.

What is Pharmacy Practice?

There are various definitions of the term Pharmacy practice. The World Health Organization (WHO), early in 2006, mentioned pharmacy practice as a natural evolution of the profession, moving away from medicines supply into patient care, profoundly influenced by the emergence of pharmaceutical care (World Health Organization, 2006). This practice change may be considered a landmark because the practitioner starts to be held responsible for patient outcomes (Hepler and Strand, 1990).

The International Pharmaceutical Federation (FIP) described Good Pharmacy Practice (GPP) and it proposed to be defined as "*the practice of pharmacy that responds to the needs of the people who use the pharmacists" services to provide optimal, evidence-based care*' (International Pharmaceutical Federation, 2011). The adoption of GPP both in the community and in the hospital setting contributed enormously to the practice model we have today in most developed countries.

More recently, a conceptual model for pharmacy practice has been proposed, where apart from the concepts of professional activities comprised into the above definition, broader roles of the pharmacist are considered, including the involvement in health policy (Scahill et al., 2017).

This chapter will adopt this broader model, aiming to provide a more comprehensive overview of how the pharmacist profession has evolved in Portugal, for which aspects of clinical pharmacy and pharmaceutical care have had an enormous contribution, but also wider disciplines including public health, without forgetting the contribution of pharmacy advocacy organizations to promote greater outreach of pharmacists' most traditional activities.

The Face of Pharmacy in Portugal

The pharmaceutical profession emerged in Portugal in the 13th century, with the establishment of the first apothecaries. Currently, there are approximately 14,500 practicing pharmacists, with 79% of them being female and 68% less than 45 years old (Ordem dos Farmacêuticos, 2018). This demographic profile reflects the substantial increase in the number of pharmacists in the country in the last two decades, as a result of the number of faculties of pharmacy having tripled, from three in the late 1980s to nine in 2018. Since 2011, more than 700 new pharmacists start practicing each year, which places the pharmacist density in Portugal at 1.4 pharmacists per 1,000 inhabitants.

As a result of their scientifically based education, pharmacists carry out their activity in several areas, with community pharmacy (59%), hospital pharmacy (9%), and clinical biology (5%) as the most predominant. However, pharmacists have been taking up new roles in other areas such as the pharmaceutical industry (5%), wholesale distribution (4%), research (1%), medical devices, and health technology assessment (Ordem dos Farmacêuticos, 2018).

Pharmacists in Portugal currently work in the more than 2900 existing community pharmacies—which operate with an average of 3 pharmacists/pharmacy, one of the highest ratios in the European Union (PGEU, 2016)—more than 200 hospitals, 400 clinical biology laboratories, 120 pharmaceutical industry companies, and 25 wholesale distribution warehouses.

Pharmacists are a highly trusted professional, with community pharmacies being the first place Portuguese citizens' visit when they have a minor health problem (CESOP, 2018). A recent survey further showed that 96% of the population is satisfied or very satisfied with the service received, highlighting aspects such as professional competence (95%), quality of services (95%), counseling appropriateness (92%), operating hours (90%), and location (89%). The overwhelming majority of respondents were also favorable to the development of new services by pharmacists (CESOP, 2018).

A study commissioned by the Portuguese Pharmaceutical Society in 2015 aimed at evaluating the social and economic value of public health interventions conducted by pharmacists in Portuguese pharmacies documented more than 120 million pharmaceutical interventions per year, covering 4.2 million users, which contributes to the improvement in citizens' quality of life of 8.3% and to an economic value of 879.6 million euros (Félix et al., 2016). Each individual pharmaceutical intervention represented an economic value of €7.30.

Moreover, the authors noted that potential savings of more than 144.8 million euros, if pharmacists could be given the opportunity to fully exercise according to their scope of expertise, in services covering adherence enabling strategies, renewal of chronic prescriptions, and provision of travellers' advice.

Overview of the Portuguese Health-Care System

Origins and Values of the Portuguese National Health Service

All Portuguese citizens have access to a National Health Service (PNHS), publicly funded by taxes, and free of charge at the point of delivery. The PNHS was created in 1979 and embedded into the constitution, to ensure all citizens have the right to preserve their heath, regardless of their socioeconomic status.

The creation of this service had an enormous impact and resulted in the improvement of various health indicators, namely, infant and maternal mortality. Portugal is now ranked as one of the best performing health systems in the world (Félix et al., 2016).

The PNHS is based on two pillars; it is universal, meaning it is accessible to all the population; it is of high quality, as it provides highly effective care. However, it is not comprehensive because not all treatment options are available within the PNHS. The choices made on what gets included are based on the state's budget, which in the Portuguese case, as in most countries, is somehow limited. The funnel of Dunning criteria are used to prioritize, and health technology assessment is used to select the most cost-effective options. Because of limited funds, in some cases, restrictions may be imposed to beneficiaries of a given treatment (e.g., only those having a BMI ≥35 are entitled to a paid bariatric surgery) or to the level of co-payment applied. Co-payments exist in the form of access fees, which are intended to promote a judicious use of healthcare (i.e., unplanned care has a higher fee than planned care) but are also applicable to medicines financing. To establish the different levels of co-payment for medicines, various criteria exist, including the prevalence of the disease, its severity, and the pharmacotherapeutic class demonstration of efficacy. These range from 15% to those considered borderline in terms of efficacy, a level normally applied when there is some uncertainty, to 100%, where the remainder is paid by the patient out-of-pocket. In all co-payment forms, however, the principles of solidarity apply, that is, those socially disadvantaged are awarded exemption of access fees or higher co-payment levels by the PNHS.

The Portuguese Health-Care System

Although the Beveridge principles prevail, in the recent decades, alternative models of care provision have emerged. Currently, care may be received in private, public services and also in mixed models of service provision. As a citizen, the citizen by birth or residency is entitled to benefit from the public facilities, which fit into the PNHS, and may then also choose to contract an insurance (which may be voluntarily made by the individual or the employer). This organization implies the person may choose to use one or the other, or even both depending on perceived needs, severity of the situation, or simply commodity. However, it may also be seen as a way of creating inequality because most of the uninsured will not be able to pay for care provided in private facilities.

PNHS Sectors

All these services are organized in three levels of care provision summarized below.

- Primary care is aimed primarily at disease prevention (including vaccination and screening) and management of chronic conditions. These are located at the heart of communities and organized in different formats. Primary care in Portugal is delivered by a mix of public and private providers, including primary care units integrated within the NHS, private sector clinics (both profit and non-profit), and groups of professionals in private offices (OECD, 2018). In the public sector, there are five regional health administrations, subsequently divided into Primary Health Care Clusters (ACES). These are public health services distributed throughout the country (n = 55 in 2018), with administrative autonomy, intended to provide proximity and tailored care to the population covered (which may range between 50 and 200 thousand inhabitants). The family units, hierarchically under the former, are the most recently developed structure, characterized by the use of technology, multidisciplinary work, where professionals are paid according to their performance, as dictated by contracted indicators periodically established and assessed. There are currently 532 family units in Portugal (ACSS, 2018). Under this model, each family is assigned a healthcare team, comprising a minimum of one GP, one nurse, and one administrative assistant. Other healthcare professionals may also be available in some of these structures, namely, psychologists, dentists, nutritionists, and even some additional medical specialties, but more seldom. PNHS GPs act as gatekeepers and refer patients for specialist care. There are other structures within primary care, not detailed here because they are more specific and less common.
- Secondary care is basically organized as hospital units or hospital centers and traditionally, their main goal has been to treat acute conditions or exacerbations of chronic conditions requiring surgical interventions or hospital admission. However, this has substantially changed in the past decade, with an increase in outpatient consultations and day surgeries which have, in conjunction with the bolstering of the long-term care network, led to a decrease in the total number of inpatient hospital beds and a shift of costs where currently the highest proportion of hospital costs (roughly 70%) is attributable to outpatient appointments (OECD, 2017).
  In 2018, there are 225 hospitals, of which 107 are public and 118 are private (ACSS, 2018). These include units from public administrative sector, public entrepreneurial entities, and institutions under a private–public partnership. A recent measure adopted in Portugal was the system of free access and circulation of NHS users, through which since 2016 any citizen may choose in agreement with his/her family physician the hospital to be monitored for the required medical specialty. Hospital care is currently also paid by performance according to contracted indicators, which may include clinical outcomes, such as mortality, or process indicators enabling evaluation of the quality of care, such as readmission rate, waiting time, or referrals to tertiary care (ACSS, 2018).
- Tertiary care is aimed at providing specialized care to people requiring temporary or permanent recovery services. Within tertiary care, the National Network for Continuous Integrated Care was created as part of public services enabling access to any citizen. This network covers care provided to adults, children, mental health patients, and those staying at home but requiring assistance (domiciliary care). In each of these levels, there are units for long term, intermediate and short-term stay. In March 2018, the total number of vacancies available within this network was 14,700, a number much lower than the necessary for an aging population.

PNHS Budget for Medicines

Health expenditure in Portugal was 7.5% in 1995, and since 2004 surpassed 9%, remaining quite steady since then (Simões et al., 2017) and in line with the EU average. The most recent published data points to the same value of 9.0% (OECD, 2018). There have been periods of lower investment in health, namely, during the 2008/2011 economic recession, when many cost-containment measures were imposed. In general terms, one can say that even though the value spent on health as a percentage of the GDP is apparently in line with the EU context, if we look at the public sources of spending as a percentage of the total health expenditure, Portugal has one of the lowest values in the EU (64.8% in 2014). In fact, although the Portuguese health-care system functions quite well, the proportion of out-of-pocket (OPP) payments made by our citizens is probably one of the lowest in the world. In 2014, the OOP payments as a percentage of the total health expenditure reached 26.8%. Health expenditure per capita was reported to be 2066€ in 2017, a value below the 2773€ for the EU28. In addition, Portugal was the country with the second greatest reduction in costs between 2011 and 2017, only surpassed by Greece (OECD, 2018).

Regarding pharmaceutical expenditure, following the Memorandum of Understanding signed after the economic recession, a target of 1.25% of the GDP was set for 2012 and 1% for 2013. In 2014, 1.23% of GPD was achieved (Simões et al., 2017). During this period, Portugal was portrayed as the country with the second highest reduction on pharmaceutical expenditure, mostly achieved through price reduction (OECD, 2016). However, it has later been shown that the reduction in costs for pharmaceuticals was only for the period 2008–12 (−0.7%), immediately followed by an increase in 2012–16 (0.8%) (OECD, 2018). Breaking down to setting, we can observe that the reduction of costs was mainly achieved through measures applicable to the ambulatory setting. In fact, for the period 2009–16, the reduction for retail was 5.4%, contrasting with an increase in hospital pharmaceuticals of 0.7% (OECD, 2018).

Portuguese authorities set several policies to control pharmaceutical expenditure. These start at the moment of market introduction, where the price is set based on a clinical evaluation complemented by economic considerations, i.e., the price of existing medicines and international prices considering at least three reference countries (Spain, France, Italy, and Slovenia established for 2019; Portaria n.° 326-A/2018, December 14th which modifies Portaria n.° 314-A/2018, December 7th). Internal reference pricing applies, through which INN prescription is mandatory and pharmacies will have to dispense one of the five cheapest products within the same active ingredient, form and dosage (reference pricing), except if the patient chooses otherwise, in which case he would have to pay the price difference. Promotion of generic substitution is also a popular measure to contain costs and the current target set is for 60% of the PNHS market (European Commission, 2016).

From 2014 onward, pharmaceutical expenditure has been monitored so that the introduction of innovative medicines is possible. The ambulatory market has been increasing 0.5% per year and hospital consumption increased 8% in 2016. In 2016, the value spent on ambulatory and hospital care on medicines was about even (1190 and 1107 million €, respectively). Again, as in care provision in general, the proportion of OOP payment applied to medicines may be considered quite high, although decreasing from 2011 to 2016, and perhaps an aspect worth improving in the country's functioning (World Health Organization, 2018). Medicines supplied in hospitals under the PNHS are fully reimbursed, but in ambulatory care, reimbursement varies from 15% to 100% depending on the pharmacotherapeutic subgroup and on eventual population exemptions. The average spent per capita on pharmaceuticals in Portugal was reported to be 297 €, a much lower value than the 402 € reported as the EU average (OECD, 2016).

There are specific areas where a budget is allocated per patient treated (within the NHS). For example, for Hepatitis C, the agreed price per patient treated in 2019 is 6922€. For HIV, the agreed price for treatment in ambulatory care (as long as registered under the national database) is 5997€ per year per equivalent patient. There are other areas for which a price is set, which will not be detailed, namely, pulmonary hypertension, multiple sclerosis, oncology (six types of cancer), paramyloidosis, and lysosomal diseases (ACSS, 2018).

Pharmacy Regulation in Portugal

Pharmacy Education

Education in Portugal is regulated by the Ministry of Education, and this applies to basic, high school, and university education, regardless of the professional area pursued at a later stage. As such, the education of pharmacists occurs at university and requires a 5-year degree, according to the Bologna declaration, which results in a Master's degree. This degree may be obtained in any of the existing nine faculties of pharmacy in Portugal, four of which public and five of which private. The quality of education in these establishments is supervised by the Ministry of Education, and there is limited input from the Profession. However, following recent developments of quality assurance systems, namely, those in the European area, the Portuguese Government decided to create an Agency for Assessment and Accreditation of Higher Education ("Agência de Avaliação e Acreditação do Ensino Superior"-A3ES), by Decree-Law no. 369/2007 (November 5th), with the purpose of promoting and ensuring the quality of higher education. The Agency is a foundation under private law, established for an indeterminate period of time, with legal status and deemed of public utility. The Agency takes independent decisions but in accordance to guidelines set by the Governmental structures. The assessment and accreditation regime to be developed by the Agency is defined in Law no. 38/2007 (August 16th). A3ES conducted a national evaluation on the pharmaceutical sciences degrees in all the schools of pharmacy across the country during 2016/2017. This evaluation comprised the quality of teaching, considering the syllabus and the curricular units, the laboratory facilities, the physical structure of the institutions and the qualification of the teaching staff, just to name a few. The standards are established according to the European Union. The jury created to evaluate all schools of

pharmacy included one president who selected a panel of 3–5 members of internationally reputed and distinguished professors and one student representative (Portuguese). A report was then issued in 2018 for each individual faculty stating whether the degrees were approved, given conditional approval for a time frame while pending further information or action, or totally failed in the evaluation. Following this evaluation, some of the existing degrees had a curricular change imposed.

Portuguese Pharmaceutical Society (PPS)

Once the Master in Pharmaceutical Sciences is awarded, the master may register with the Portuguese Pharmaceutical Society, which issues the professional license and is then responsible for establishing the standards for pharmacy practice.

The Portuguese Pharmaceutical Society is the professional public association that represents the Portuguese pharmacists and regulates the pharmaceutical profession in Portugal.

As a collective body governed by public law, the Society maintains the traditional designation of Lusitanian Pharmaceutical Society, of which it is a legitimate continuator, presenting the following statutory duties:

1. Collaborate in the definition and execution of health policy in cooperation with the State;
2. To defend the dignity of the pharmaceutical profession;
3. To promote and defend the interests of the pharmaceutical profession.

In order to carry out these functions, the Society exercises its mission in the social, scientific, cultural, deontological, professional, and economic fields of pharmaceutical activity.

This institution is also responsible for the accreditation of continuous professional development (CPD) courses provided by various independent entities, through its Council for Quality Accreditation (CQA). Since 2004, pharmacists in Portugal have compulsory CPD cycles of five years, following which a minimum number of CPD credits must be obtained to keep their license to practice (Aranda da Silva et al., 2004). The activities included in the portfolio awarding pharmacists credits are proof of practice, attending educational courses, participating in research activities, and contributing to training or education of pharmacists (supervision of internships is included).

The PPS is also the body responsible for awarding specialization degrees in the different areas of the profession, including in Clinical Analysis and Human Genetics, Hospital Pharmacy, Community Pharmacy, Pharmaceutical Industry, and Regulatory Affairs.

The CQA has also been actively involved in the development of accreditation norms for the emerging new services in pharmacy practice. The regulation for administration of vaccines was the first to be developed and was extremely important to standardize education and practice and to ensure high-quality service provision.

Another body within the PPS is the National Council for Quality (NCQ), which focuses on the development of good pharmacy practice norms for various areas of the profession. Two recently developed norms worth mentioning are the "Multicompartment Aids Service Provision Norms" and the "Medication Review Service Norms."

Medicines and Health-Care Products Regulatory Agency (INFARMED)

Medicines and Health-Care Products Regulatory Agency (INFARMED) is responsible for evaluating, authorizing, and regulating medicines, medical devices, and health products in Portugal. The main goal of INFARMED is therefore to protect public health by ensuring all medicines available are effective, safe, and meet high-quality standards. INFARMED also has a role in the evaluation of medicines, even if centrally approved, in terms of pharmacotherapy and pharmacoeconomic studies, and ultimately decides on the level of reimbursement, which will obviously impact on accessibility. Also as a contribution to the responsible use of medicines, INFARMED is responsible for providing up-to-date and reliable information to consumers and to health-care professionals, which is achieved by various publications, among which the Therapeutic Handbook and the National Formulary of Medicines are of particular importance. Still in the context of medicines use, INFARMED is particularly concerned about the constant monitoring of adverse drug reactions, through its National Pharmacovigilance System. This agency is also responsible for licensing and auditing pharmaceutical activity and pharmacy premises.

Sectorial Associations

Associations Representing Community Pharmacy Owners

There are two professional associations representing the interests of community pharmacy owners in Portugal, the *Associação Nacional das Farmácias* (National Association of Pharmacies, ANF) and the *Associação de Farmácias de Portugal* (Association of Pharmacies of Portugal, AFP), to which membership is voluntary.

The National Association of Pharmacies (ANF) was founded in October 1975, following the extinction of *Grémio das Farmácias*. It represents the majority of pharmacies in Portugal, totaling around 2800 associates, approximately 95% of the total number of community pharmacies in the country. Its mission is "to make pharmacies the most valued primary health-care network by the Portuguese citizens." To achieve this goal, throughout the years, it has developed companies, structures and projects which cover areas of impact on pharmacies, namely political, professional (education and pharmaceutical services), business, and financial. In order to ensure a close relationship between the executive structure and its associates, it has a decentralized structure, consisting of

groups of 50 pharmacies (circles). These are represented locally and in General Assemblies by circle, zone, and regional delegates, directly elected by the members.

The Association of Pharmacies of Portugal (AFP) was established by a group of six pharmacies in 1991 and has grown to represent more than 150 pharmacies in 2018. Its mission is to ensure that community pharmacists are recognized as medicine experts and valued as important members of the public health provider's network. For this purpose, it provides logistic support to the handling of prescriptions, provides continuing education opportunities, supports pharmacies in legal matters, and establishes protocols with several entities for the benefit of pharmacy owners and pharmacy teams.

For both organizations, one of the main activities is the relationship with the government and health-related public administration structures, in order to ensure that pharmaceutical legislation and regulation, as well as its operationalization, take into account both the specificities and the actual and potential added-value community pharmacies can bring to the health of the population.

Associations Representing Hospital Pharmacists

The *Associação Portuguesa de Farmacêuticos Hospitalares* (APFH) is an association of hospital pharmacist associates that perform their activity in Pharmaceutical Services of public and private Health-Care Units. According to their statutes, the APFH aims to:

- Promote the technical-scientific and deontological enhancement of its associates;
- Stimulate the improvement of practice conditions, as well as the social promotion of the Hospital Pharmacists' role;
- Represent Hospital Pharmacists near all other entities, such as regulatory bodies, both at the statutory and administrative levels;
- Encourage the realization of studies of technical and scientific nature and promote their dissemination within associates;
- Organize or sponsor the organization of courses, congresses, seminars, or similar activities, related to the subject of hospital pharmacy.

Community Pharmacy

The Development of Pharmacy Services

The development of pharmacy services in Portugal can be traced back to almost 20 years ago. Starting in 1999, the National Association of Pharmacies (ANF) developed a strategy, methods, and tools for the implementation of pharmacy-based disease management programs. When they were developed, these were set for asthma and COPD, diabetes, and hypertension, the latter subsequently broadened to include hyperlipidemia. In 1997, as a natural result of the St Vincent Declaration, a National Protocol for Diabetes was implemented (Primeiro Protocolo da Diabetes, 1998). The second protocol marked an important change, as it foresaw two levels of care, the second being the provision of pharmaceutical care (Segundo Protocolo da Diabetes, 2003). At this stage, remuneration of the diabetes program was successfully negotiated with the government (Costa et al., 2006), which was maintained when the Third agreement was signed (Terceiro Protocolo da Diabetes, 2008). The value set was 15 €/month/patient, where the Government would cover 75%. By April 2005, there were over 2500 patients integrated in these programs, followed-up in 328 pharmacies distributed nationwide. An evaluation of this program undertaken in 2007 using a retrospective intervention cohort suggested the program was effective in 21% of the patients to reach glycemic control (Martins et al., 2008).

The health gains shown by this service would hopefully inform the decision to also remunerate other pharmacist-led interventions. However, that has not happened and at the end of the mandate, the agreement was not renewed, that is, the program lost remuneration in 2010 (Protocolo de Colaboração entre Ministério da Saúde Ordem dos Farmacêuticos Associação Nacional de Farmácias Associação de Farmácias de Portugal. 2008).

Concurrently, the Dadér programme promoting patients' planned pharmacotherapeutic follow-up started its implementation in some pharmacies in 2001 (Santos et al., 2005). Although they had different approaches, both programs aimed to promote pharmaceutical care as part of the pharmacist's role.

In the year 2007, several legislative changes impacted the practice of pharmacy in Portugal. Pharmacy ownership was opened to nonpharmacists, nonprescription medicines were allowed to be sold outside pharmacies, and the sale over the Internet of pharmaceutical products was permitted, among other measures. In addition, pharmaceutical care provision was finally legislated (Portaria 1429/2007). This legislative piece established a total of eight services that could be provided by pharmacies, including four new services: home support, administration of first aid assistance, administration of vaccines not included in the National Vaccination Plan, and administration of medicines (e.g., intramuscular or subcutaneous routes). Four already existing services were also legally established in this decree or augmented in their scope: the utilization of auxiliary means of therapeutic and diagnostic (i.e., any service that may be used as a screening activity, e.g., cardiovascular risk, eye check, but also the possibility to utilize the expertise of other health-care professions to this end); provision of pharmaceutical care; engagement in health information campaigns, and collaboration in health education programs.

Some of these new services implied pharmacists' accreditation, or foresaw the possibility of subcontracting other health-care professionals, namely, nurses to provide them. The services for which pharmacist accreditation is compulsory include the administration of vaccines and the administration of injectable medicines.

This decree was updated in 2018, further expanding the scope of practice of community pharmacists to include medication adherence interventions, provision of multicompartment aids dispensing service, educational interventions targeted at using

medical devices, and medication reconciliation; health literacy promoting interventions, including health prevention campaigns and healthy lifestyle promotion; point of care testing for HIV, HBV, and HCV including referral to appropriate hospital care for reactive cases. In addition to these, other services to be provided by allied health-care professionals and made available at the pharmacy premises were also included, namely, nutrition service; simple nursing services, including wound treatment and care provision for ostomized patients; and the prevention and treatment for diabetic foot.

In 2016, a new dispatch has been published focusing on health reforms in general, while stating that community pharmacies need to be valued as providers of care, and therefore announcing the intention to test the delegation of the dispensing of specific medicines, which until this date were restricted to hospital use, namely, oral oncology and infectious diseases medicines (HIV and Hepatitis C) (Despacho n° 199/2016). A pilot for the dispensing of HIV medicines in community pharmacies has started in 2016 and is still ongoing, with preliminary results showing high patients' satisfaction rates.

The Role of Pharmacy in Health Promotion

The role of pharmacists in health promotion has a long history worldwide. Portugal is no exception and arguably is a good example of how pharmacists can go beyond their most traditional roles and visibly contribute to public health.

Needle Exchange Program

This program was initiated in 1993 as a response to the sudden period of drug use expansion lived in Portugal. The program resulted from a partnership established between the National Commission Against Aids and the National Association of Pharmacies, with the main aim of minimizing risks associated with the use of injectable drugs. The idea of this program was very innovative and controversial for which the role of Prof. Odette Ferreira was essential, recognizing the inability to stop the use of drugs, while recognizing that something could be done to prevent disease dissemination. The motto of the program was "do not use a second-hand needle." To achieve this, drug users would deliver their used needle in a pharmacy or in a street van and receive a new one in return. This initiative resulted in needles no longer being on the pavement and also that there was no need to share needles.

Later developments of the program based on needs assessments extended the scope of the program to also include condoms, citric acid, distilled water, and a metal recipient. This year, the 25-year anniversary of this successful program was promoted, where some of the key achievements were recognized publicly by the Health Directorate:

- A total of 56 million needles were exchanged;
- Over 30 million condoms distributed;
- In 2018, the lowest value of notifications was reached, with 18 new cases among 1064 total cases infected by this means.

This program is internationally recognized for its contribution to minimize HIV, HCV, and HBV infections. Portuguese pharmacies have been recognized for their 25 years contribution against HIV and other blood–borne diseases through their engagement in the needle exchange program. In 2016, the government recognized that the contribution of pharmacists resulted in a net benefit of 3.01€ per needle exchanged, originating overall system savings of over 2 million euros in a 5-year period, hence originating a reimbursement system which values at 2.40€ each package of 2 needles exchanged (Borges et al., 2016).

Opioid Substitution

This program also had an important role in fighting drug endemics. However, its scope is quite different as it aims to "cure addiction to opiates." The program exists in two main formats, where the first corresponds to the low-level provision and is available at the health-care center. In this phase, the intention is to provide methadone free of charge at specific moments so that opioid consumption using other substances and administration routes is progressively diminished. The second level, named high-demand level, is available in pharmacies and requires the individual to be free of drugs to be entitled to receive one daily dose of liquid methadone. To ensure this, there is no parallel drug consumption, and frequent analyses are made. The program is currently inactive in Portugal since 2014, mostly due to lack of funding, with no date anticipated for its revival.

Collection of Unused Medicines

Since 1999, a program for collecting unused medicines was created, which aims to promote adequate disposal of contaminated material, preserving the environment, while also contributing to improve responsible medication use. This is achieved by having a container available on the public area of the pharmacy, where people are encouraged to deliver the expired medication, but also those medicines they will not be using anymore, preventing, e.g., subsequent reutilization of unfinished courses of antibiotics. This program in 2015 was expanded to also collect veterinary medication.

Early Detection of Various Chronic Conditions

The community pharmacist has a privileged position in the center of communities, and being available through wide pharmacy operating hours, places him in an ideal situation to actively contribute to early detection programs. The fact that he is often the first health-care professional citizens seek when encountering a minor health problem, which may eventually hide a more important problem, also contributes to this role in disease prevention. Point of care testing is a regular service provided by all pharmacies throughout the country.

Table 1 Summary of most relevant or recent early detection initiatives in Portuguese community pharmacies

Disease	*Detection method used*	*Number of involved individuals*	*Number of referrals*	*Confirmed diagnosis*	*References*
Diabetes	Findrisk	7007	24.0%	Not available	Jacinto et al. (2016)
		1539	3.7%	Not available	Mendes et al. (2018)
	Glycemia measurements	7719	23.9%	Not available	Horta et al. (2010)
Cardiovascular risk	Blood pressure and total cholesterol measurements	12,930	21.0%	50.0%	Santos et al. (2011)
	SCORE	945	378	Not available	Brito et al. (2018)
Atrial Fibrillation	Pulse palpation and Kardia Alive Cor	2573 (internationally) 998 (Portugal)	23.7%	1.4%	Lobban et al. (2018) Cunha et al. (2017)
COPD	Spirometries	1266	31.1%	6.6%	Mendes et al. (2018)
Asthma and allergic rhinitis (uncontrolled)	Control of Allergic Rhinitis and Asthma Test (CARAT)	224	87% potentially to be referred	Not available	Lourenço et al. (2014)
Allergic rhinitis	Allergy Diary (MASK-rhinitis)	23,000 (internationally)			Bosnic-Anticevich et al. (2018)
Colorectal cancer	Presence of hidden blood in faeces	1143	5.7%	60.4% have been subject to a colonoscopy	Rosa et al. (2018)
HIV	Saliva swab	589	0.7%	Not available	Madeira et al. (2014)

The scope of services available varies, where glycemia, weigh, and blood pressure are almost universal (>95%); cholesterol measurement is also very common (>90%), and then other services are still progressively being implemented, namely, full lipid profile, HbA1c, INR, etc., some of which are estimated to exist in 5%–10% of the pharmacies.

Point of care testing may be provided as an isolated or continuous service, as a way to monitor medication effectiveness and safety and also as a means to detect some specific diseases early on, mostly when preventable, asymptomatic and those with improved prognosis when detected early. But early detection programs may also make use of symptom evaluation, isolated or in combination with biomarkers measurement.

In Portugal, the first "early detection" initiatives focused on people at risk for diabetes and a few years later on cardiovascular risk. In both these initiatives, pharmacists made use of symptom assessment and biomarker measurement. More recently, pharmacies started using standardized questionnaires to asses risk, such as the Findrisk instrument (Jacinto et al., 2016).

More recently, some of the innovative areas where community pharmacists have been engaged and even recognized internationally include the detection of COPD based on spirometries, or atrial fibrillation based on the use of portable mobile devices.

For all these services, the procedure is very similar. The pharmacist invites the person to participate, as part of a campaign that offers this assessment free of charge, or as part of a sustained service available at the pharmacy, in which case the patient usually pays out-of-pocket. Whenever results suggest a possible undiagnosed disease, there is a referral to the physician. In the process, pharmacists also strive to obtain medical confirmation in an effort to estimate their contribution to better patient care. This last flow of information is still suboptimal and for which technology-based direct communication is being tested, as described in Section Use of Technology in Community Pharmacy.

Table 1 presents a noncomprehensive summary of early detection initiatives developed in Portugal and presented at the Portuguese Pharmaceutical Society Congress in 2017, the National Association of Pharmacies Congress in 2018, the International Pharmaceutical Congress from 2016 to 2018, and/or published in Pubmed indexed journals the last 5 years.

Colorectal Cancer Screening

In Portugal, colorectal cancer is the most prevalent malignant tumor (14.5%), with about 7000 new cases diagnosed every year (GLOBOCAN, 2012). Many of the deaths caused by cancer could be prevented through measures such as reducing exposure to risk factors and promoting early diagnosis through systematic screenings. Early detection is key to survival, as colon cancer patients diagnosed early (stage I) have a 5-year survival rate of 92%, whereas if diagnosis is delayed and colon cancer is not detected until stage IV, the 5-year survival rate drops to 11% (American Cancer Society, 2014). Current national legislation establishes that all patients aged 50–74 be screened every 2 years for colorectal cancer (Despacho n.° 8254/2017). However, the enactment of this legislation has been unequal in the national territory. Therefore, the national association representing patients, Europacolon Portugal, has been working with a group of community pharmacies for the past 5 years in order to make screenings available free of charge to patients within the recommended age group. Screening is made by asking patients to collect stool samples and bringing them to the pharmacy. Pharmacies then send the samples to a clinical biology laboratory to test for the presence of blood. The results are subsequently sent to the pharmacy and delivered to the patient along with counseling based on the result. If the test is positive, the patient is referred to the physician for follow-up, namely, to perform a colonoscopy and eventually confirm a diagnosis and initiate treatment.

In 2018, 131 pharmacies participated in the awareness campaign and screened a total of 1143 individuals. Of these, 12.6% (n = 143) had a positive result in the screening and were referred to the physician.

HIV and Hepatitis Screening

New legislation that allows pharmacies to deliver point-of-care tests for HIV, Hepatitis C, and Hepatitis B without the need for a prescription has been published in March 2018 (Despacho n.° 2522/2018). With this measure, the Government aims to improve accessibility within the context of the early detection of HIV and viral hepatitis infections as a complementary means to the diagnosis already made in primary health care, hospital care, counseling and detection centers, pneumological diagnostic centers, and community-based organizations.

Several stakeholders were involved in the subsequent regulation and implementation of this service, including the Portuguese Pharmaceutical Society (to ensure pharmacists' competence to deliver the service) and the associations representing community pharmacy owners (to ensure pharmacies' readiness for execution).

In October 2018, the first 22 pharmacies launched the service in the municipality of Cascais. This municipality was chosen to introduce the service due to its involvement in the "Fast-Track Cities" initiative. The Fast-Track Cities is a global partnership, which was launched on World AIDS Day 2014 in Paris, where mayors from 27 cities in over 50 countries convened to sign a Declaration committing to accelerate and scale-up their local AIDS responses. Within this initiative in Cascais, the screening tests are made available free-of-charge to patients. Tests are also provided in an anonymous and confidential manner. However, if the test is reactive, the pharmacist is prepared to refer the patient to the appropriate level of care for follow-up.

This service is now projected to be rolled-out to other regions of the country.

The Role of the Pharmacist in Medicines Management

Many of the pharmacy-based initiatives have traditionally arisen from the National Association of Pharmacies, as mentioned in Section, "The Development of Pharmacy Services." However, in elderly care, the contribution of Universities has been profuse, through the development of various interventions focusing on medication use in this specific setting (Advinha et al., 2014; Costa et al., 2016a,b; Silva et al., 2015). Also, in the hospital setting, various studies, mostly focusing on potentially inappropriate medication and potential prescribing omissions, have been led by academia (Borges et al., 2012; Correia et al., 2014; Costa-Dias et al., 2014).

Medication review practices are normally encompassed by advanced services provision but may be developed in different moments in time. According to the Pharmaceutical Group of the European Union (PGEU), all pharmacies provide simple medication reviews (level 1), i.e., review of pharmacotherapeutic records (PGEU, 2017). This may be executed in the back office by periodically evaluating population subgroups (e.g., elderly; polypharmacy). Intermediate medication review (level 2a) includes contact with the patient to obtain additional information and may occur at each dispensing moment, as long as a standardized procedure is used. In a recent study, MR level 2a was reported as the most common MR in Portugal, although estimated to have a low implementation rate (Soares et al., 2019).

Current Scope of Practice in Community Pharmacy

The scope of practice of Portuguese community pharmacists is quite broad in European terms. Previously published work suggests Portugal to be the European country with more services available (Martins et al., 2015). This works refers to Portugal as only not being able to prescribe, a competency currently only existing in the United Kingdom in the European context.

When you contact a community pharmacist, you may expect to receive standardized counseling and information to ensure the responsible use of medicines, generic substitution, home delivery of medicines, various programs contributing to public health (e.g., needle exchange and others mentioned in Section The Role of Pharmacy in Health Promotion) in all the pharmacies throughout the country. Of course, you may also expect to be able to acquire medication (prescription, nonprescription, and pharmacy-only lists), medical devices, cosmetics, and veterinary products. In most of the pharmacies, you may also have access to intermediate level services, including assessment of inhalation technique, adherence and support monitoring (including the use of multicompartment aids, new medicines service, and other enabling strategies), smoking cessation, health screening, point of care testing, and immunization services. To a lower extent, advanced services such as pharmaceutical care, medication review, and administration of injectable medicines may also be found. The services currently not within the scope of practice of Portuguese community pharmacists include prescription renewal, prescribing, dose adaption, and personalized medicine. As mentioned earlier, opioid substitution is currently unavailable (although within the scope of practice). This implies that although the range of services available is wide, the implementation of such services is not homogeneous. In fact, some of the longer existing services, namely, pharmaceutical care, perhaps because they have a higher degree of differentiation, have been reported to have suboptimal implementation, although slowly increasing in the last decade (Costa et al., 2017; Hughes et al., 2010).

However, it is interesting to point out that some new services have had quite a good uptake by pharmacies, one of them being the immunization service. Since the publication of the legislation in 2007, more than 3000 pharmacists have been accredited by the Portuguese Pharmaceutical Society to deliver the service, and more than 2300 pharmacies have the service available, which represents almost 80% of the total number of pharmacies (International Pharmaceutical Federation, 2016).

Use of Technology in Community Pharmacy

Pharmacies in Portugal have long been early-adopters of technology. The process for implementing a pharmacy-specific software was conceptualized at the 1st Congress of the National Association of Pharmacies in 1981, and the first pharmacy started operating with a computer in 1987, after which there was a national roll-out (Machado and Martins, 2015). It is widely acknowledged that many Portuguese citizens saw their first computer in a pharmacy, and the same can be said about robots, since dispensing robots have been installed since 2002, with a total of over 200 robots operating in pharmacies throughout the country.

Several projects have been initiated that make use of technology. One of these projects is a mobile application, named "Farmácias Portuguesas." This app offers pharmacy-related services and personal management of some health data, including (1) a plan for medicines intake for the user or his family member, with a pill reminder; (2) information about health that allows the user to access useful and adequate information on medicines and effective use of these medicines; and (3) a personal area with a record of the user's point-of-care measurements, in which the results of the tests made at the pharmacy can be transmitted automatically by the pharmacy software to the user's mobile phone (Pinto et al., 2016).

Moreover, as previously mentioned, since 2007, pharmacies have the possibility to deliver medication requested over the Internet at the citizens' homes, provided the pharmacy is previously registered with the regulatory agency to provide the service (Portaria n° 1428/2007). For this purpose, interested pharmacies have launched Internet websites, which are either individually developed or make use of the platform made available by ANF.

Since November 2015, a paperless prescription process has been rolled-out, with over 95% of all PNHS prescriptions now dispensed within this system. The paperless prescription process involves the issuing of a dispensing code that the user can see either in an email, via an SMS text message or on the Health Data Platform. Once issued, the patient then uses the code number to obtain the medicines by showing his or her citizen card or other means of identification at the pharmacy. Besides decreasing the bureaucratic burden, due to the fact that there is instant confirmation of the reimbursement status, further benefits for the health system would include facilitated transfer of information between the dispensing pharmacist and the prescriber. However, until now, this has not materialized, given that the pharmacist still does not have access to the patient health record.

Whilst this access is being assessed by the National Data Protection Agency, the Health Ministry, and ANF initiated a pilot project in July 2017, intended to facilitate this communication exchange and collaboration between community pharmacists and physicians. The communication between pharmacies and primary care centers, or pharmacies and hospital care, is done via their respective computer systems. The list of predefined therapeutic notes is included in the software systems, and pharmacists can select and send the intended message to the prescribing physician. The physician may then provide feedback (useful/not useful) about the therapeutic note sent. The objective of this pilot is to better understand the needs of communication between the two stakeholders, and its results will allow drawing the next stages of development of this tool.

Currently, Portuguese pharmacies are preparing themselves for the implementation of the Falsified Medicines Directive (Directive 2011/62/EU), bearing in mind that all stakeholders must be ready to meet their obligations on February 9, 2019, in terms of the safety features within the medicines' packages, and the authenticity verification against a central database.

Transformation of Community Pharmacies Into Care Centers

For the past three decades, community pharmacies in Portugal have invested in competent human resources and adequate infrastructures to provide optimal care to citizens. Many of the advances have been initiated by pharmacists and their representative structures, very often within a gray legislative framework. To this end, pharmacies have offered an increasingly comprehensive portfolio of services and initiatives in order to respond to consumers' different needs, as depicted in the previous subchapters.

The publication of the pharmaceutical services legislation in 2007, subsequently updated in 2018, allowed pharmacies to further increase their intervention scope and, within this context, work in multidisciplinary teams in order to provide integrated health solutions that allow for better preventive care and management of the burden of disease.

In fact, many of the most prevalent diseases require a team approach, as is the case, for instance, of diabetes. Apart from adequate pharmacological interventions, a good nutrition plan, feet monitoring, and self-management techniques are essential for disease control and prevention of complications. This is why an increasing number of pharmacies have been integrating other health-care professionals such as nutritionists, nurses, and podiatrists in their teams.

Pharmacies are thus not focusing only on access to medicines and to services that enhance their correct use but also on access to other services that increase medicines effectiveness and safety. This requires a shift in approach every time a pharmacist receives a prescription. Instead of interpreting that prescription as a request for a specific medication, the pharmacist must interpret that prescription as an intention to control a disease or a symptom—which in that case, means that the patient will probably need much more than just the medicine to achieve the envisioned goal.

This new approach is especially relevant considering that throughout the country, there are many regions where pharmacies are the last health-care resource available. And, in other regions, are the ones with the most convenient opening hours. This, coupled with the competency of its human resources, makes pharmacies a much-needed health resource in the community.

In addition, pharmacies have been recognized globally as a gateway to care (International Pharmaceutical Federation, 2017), and this is also the case in Portugal. Pharmacies and pharmacists are well used access points for citizens seeking medicines, but also advice for common minor ailments, in addition to services involved in and related to prescriptions and medicines use. Considering the constrains in accessing other health-care resources in Portugal, pharmacists are being recognized as a trustworthy source of

information and advice, as well as in the process of personal empowerment for people who increasingly want to enact shared decision making in what relates to their health-care needs (CESOP, 2018).

Hospital Pharmacy

Hospital Pharmacy Standards

There are two main overarching international societies used by Portuguese hospital pharmacists to set their standards. These are the European Association of Hospital Pharmacists (EAHP) and the International Pharmaceutical Federation (FIP). To a lower extent, the European Society of Clinical Pharmacy (ESCP) and the American College of Hospital Pharmacy (ACHP) are also looked up to establish good practice standards.

The two first mentioned are particularly important in the context of establishing hospital pharmacy standards and these have been used to benchmark good practices and motivate pharmacists to constantly improve their practices. The Revised FIP Basel Statements on the future of hospital pharmacy, approved in 2014 as a revision of the initial 2008 version, constitute an important part of the process of alignment of Portuguese hospital pharmacy with international good practice standards (International Pharmaceutical Federation, 2009; International Pharmaceutical Federation, 2015)

The European Statements of Hospital Pharmacy, issued by the EAHP in 2014, are a set of statements to be ranked using a four-point agreement Likert scale, clustered into six main domains that characterize the areas of activity for hospital pharmacy (Preece, 2014). When initially launched, a baseline assessment of most European countries was made but then the use of such statements for national continuous improvement was left to member states. In 2017, the PPS carried out a survey using these standards, sent to all hospitals, in an effort to characterize hospital pharmacy in Portugal. Responses were obtained from 37 hospital pharmacies, providing a quite good picture of the national reality. For each of the six sections, we highlight the statement where higher agreement (green) and lower agreement (red) were reached, together with three statements we believe characterize quite well the domain (**Table 2**).

Table 2 State of implementation of selected EAHP statements in Portugal

	Totally agree (%)	*Partially agree (%)*	*Partially disagree (%)*	*Totally disagree*
Section 1: Introductory statements and governance				
At least one of the pharmacists in our team is a member of the Commission for Pharmacy and Therapeutics	94.6	2.7	0.0	2.7
At least one of the pharmacists has an active role in the antimicrobial resistance commission of the hospital	69.4	16.7	8.3	5.6
The pharmacists in our hospital are involved in the supervision of all steps of the process of medication use	40.5	56.8	2.7	0
The pharmacists in our hospital routinely work as part of the multidisciplinary team	40.5	51.4	0	8.1
Our hospital is able to prioritize the hospital Pharmacy activities according to agreed criteria (i.e., approved activity plan).	13.9	69.4	16.7	0
Section 2: Selection, Acquisition, and Distribution				
Our hospital has transparent processes implemented on drug purchasing	81.1	18.9	0.0	0
The pharmacists in our hospital take responsibility for all the logistic associated with medicines and health products, including experimental medicines	70.3	29.7	0	0
The pharmacists in our hospital coordinate the development, maintenance, and utilization of a drug formulary system	64.9	32.4	2.7	0
The acquisition of medicines not included in the Drug Formulary is made through a solid process	61.1	25.0	11.1	2.8
The pharmacists in our hospital have been involved in the development of a policy to handle medication brought in by patients	51.4	18.9	13.5	16.2
Section 3: Production and Preparation				
Before producing or preparing a medicine in the Pharmacy, the hospital Pharmacist determines if the medicine is available in the market	91.9	8.1	0	0
When medication require production or preparation, they are produced by hospital Pharmacy or externalized under the responsibility of the Pharmacist	94.6	2.7	2.7	0
Pharmacists in our hospital evaluate risks to determine safe practices demands before initiating a pharmaceutical preparation	86.5	8.1	0	2.7

(*Continued*)

Table 2 State of implementation of selected EAHP statements in Portugal (*cont.*)

	Totally agree (%)	*Partially agree (%)*	*Partially disagree (%)*	*Totally disagree*
Pharmacists in our hospital ensure the implementation of a quality management system for pharmaceutical preparations	66.7	30.6	0	2.8
The pharmacists in our hospital were involved in the development of written procedures that ensure that staff involved in the medicines preparation and reconstitution have received adequate training	45.7	34.3	8.6	11.4
Section 4: Clinical Pharmacy Services				
All the prescriptions in our hospital are reviewed and validated as soon as possible by a pharmacist	70.3	24.3	2.7	2.7
Pharmacists in our hospital are an integral part of multidisciplinary shared decision and collaboration, namely, through counseling, implementation, and monitoring of therapy	37.8	45.9	0	16.2
Pharmacists in our hospital have access to patients' medical record	62.2	18.9	2.7	16.2
Pharmacists in our hospital provide other health-care professionals all the necessary and relevant information to ensure the responsible use of medicines and health products	54.1	40.5	5.4	0
Pharmacists in our hospital optimize all medicines during admission	2.7	29.7	24.3	43.2
Section 5: Patient Safety and Quality Assurance				
The pharmacists in our hospital ensure that medicines are adequately packaged and labeled so that they are administered safely	91.4	8.6	0	0
The pharmacists in our hospital report drug adverse reactions to the National Pharmacovigilance System	61.1	33.3	2.8	2.8
The pharmacists in our hospital were involved in the development of quality assurance strategies for drug utilization processes that enable the identification of errors and priorities for quality improvement	47.2	47.2	2.8	2.8
Our hospital has procedures in place to adequately identify high-risk medicines and minimize the errors associated with the processes of acquisition, prescription, preparation, dispensing, administration, and monitoring	40.5	54.1	2.7	2.7
The pharmacists in our hospital ensure the adequate registry of all allergies and other relevant drug-related information in the patient's medical record	3.1	28.1	18.8	50.0
Section 6: Research and Education				
Pharmacists in our hospital may demonstrate their competencies through the activities they develop	61.1	36.1	2.8	0
Pharmacists in our hospital actively participate in all phases of clinical trials for experimental drug research	63.9	22.2	0	13.9
Pharmacists in our hospital participate in relevant education opportunities throughout their career	45.9	37.8	10.8	5.4
Pharmacists in our hospital regularly publish scientific papers on hospital pharmacy practice	5.6	36.1	25.0	33.3

Data made available by the Portuguese Pharmaceutical Society, 2018 (full report per request)

The Role of the Hospital Pharmacist

Hospital pharmacy has changed dramatically in the last 50 years. Parallel to the scientific and technological development, the growth and diversity of functions and responsibilities took place and new opportunities were included. Hospital pharmacists went from a product-oriented (medicine) practice to a practice focused on patient care.

In this sense, the current concept of hospital pharmacy focuses on the existence of two major areas: logistics and clinical area. The first involves all the activities of a more mechanical nature that function as support to activities of clinical nature. It integrates management and organization, acquisition and stock management, storage and conservation, repackaging, compounding, and distribution. The clinical area is constituted by all the activities related to hospital pharmacist's intervention in the patient medicines process, including clinical pharmacy/ pharmaceutical care (e.g., medicines selection and medicines information, pharmacovigilance, clinical pharmacokinetics, nutritional therapy, therapeutic review and management, medication reconciliation, pharmaceutical consulting, clinical trials). Thus, hospital pharmacy is not only product or patient-oriented pharmacy but also a combination of both.

In this activity "core" redefinition, where contemporary basilar practices are incorporated along with the promotion of advanced pharmacy practices, including a greater emphasis on multidisciplinary care and direct interaction with the patient, maintaining efficient support services remains a prerequisite for the development of sustained clinical activities that provide greater patient value

and optimal value through practice sustained by excellence. To this end, the commitment to continuous training, experience and awareness is a minimum requirement.

The national dispatch Number 14215/2013, November 11th and the Recognition of Qualifications, as well as the consequent harmonization among member states (9/10/2013), represented the long-desired opportunity for the revision of the hospital pharmacist's professional framework in the Portuguese national health system (NHS), in its various aspects. The recent publication of the Pharmaceutical Career diploma (Decree Law n° 108 and 109/2017, August 30th) embodies an important step for hospital pharmacist's professional identification since it corresponds to the spectrum of pharmaceutical interventions and reflects the high degree of training (pre- and postgraduate) and specialization required. We hope it will be soon complemented by the regulation of the precareer training period (a four-year pharmaceutical internship), which is a postgraduate training, leading to the specialty in hospital pharmacy (titled both by the Pharmaceutical Society and Ministry of Health).

In Portugal, hospital pharmacists have conferred responsibilities such as medicines/other technologies selection, acquisition, storage, and distribution, the implementation and monitoring of the drug policy defined by the Pharmacy and Therapeutics Commission and the management of the experimental medicines circuit. Other already mentioned functions/activities and functional areas are also recognized and have progressively increased, in accordance to today's patient needs and demands. All has been increasingly "hooded" by quality management systems and ethics, focusing on patient-centered care ("the exercise of the pharmaceutical activity has as essential objective the person of the patient/citizen"; art 72°, Pharmaceutical Society Statutes).

The implementation of quality management systems (QMS) in Portugal had a significant increase after the publication of the dispatch n. ° 25811/2006, November 24th, by the office of the Minister of Health. It was then established the Hospital Medicine Program (HMP) and created a Working Group to draw up an intervention program within the scope of hospital medicine, sustained in projects with quantified measurable targets and monitoring mechanisms. The hospital pharmacy landscape assessment at that time advised to the implementation of a specific support program through funding measures included in HMP. This intention of valuing hospital pharmacy was strengthened by the results obtained within the 1st National Survey conducted, which identified areas that needed priority intervention. By order of the Health Secretary of State, in 2008 a vertical funding program for the measures included in the HMP was created. The HMP was based on three main projects of action: (1) Good Practices in the field of medicines, (2) Therapeutic Plan Integrated Circuit and (3) Pharmacy and Therapeutics Committees.

A key objective of the HMP was the implementation of quality policies based on good practices particularly in the existence of quality assurance programs and definition of standards and procedures of the developed activities. At the time, some strategic points were identified considering which the working group presented proposals regarding the implementation of a quality policy through a certification process (Management/Procurement and Logistics, Distribution, Pharmacokinetics, and Clinical Pharmacy) and the certification development promotion of the activities related to hospital medicine. Several pharmacy services, by their own funding or through HMP funding, achieved certification of its activities in various functional areas (organization and management, drug procurement, reception and storage, compounding, distribution, information, nutritional therapy, pharmacovigilance, pharmacokinetics, pharmacotherapeutic monitoring, and other activities of clinical pharmacy, clinical trials, research, and teaching), or part of them. The concern for quality and safety focus has had an important growth since then and implementation of methodologies for evaluation and certification by competent bodies are a purpose for continuous improvement.

Hospital pharmacists have made efforts to improve the Quality programs through their participation in risk management, patient safety protocols, therapeutic reconciliation (improved care transitions), counseling on discharge and follow up, pharmaceutical consulting among others, all of which are quality improvement initiatives to promote patient safety, improved medicines use and risk management procedures (patients, professionals, and organization).

Today, on the one hand, we are experiencing a period of constant technological advances, social and political changes, and economic constraints but, on the other hand, we are aware of the global economic impact of health care, which has been conditioned by the aging population and increasing demand for health care, the incorporation of new, more complex and costly technologies, and the allocation of resources by a growing number of providers and consumers. In this context of declining birth rates, increased life expectancy, technological growth, and a consequent increase in care costs, the challenge lies in allocate and use resources efficiently and equitably, on the basis of an accessible, universal, egalitarian, and regulated health service. Hospital pharmacists have continuously contributed to the responsible use of economic and financial resources related to the quality of care delivered to the population. The path taken by hospital pharmacists and hospital pharmacies, at different rates, with greater or lesser difficulties, has been traced in the sense of safe practices, therapeutic monitoring and pharmacovigilance, optimization of drug use, pharmaceutical care, teaching, and research. Some have already achieved it in large, others have been pursuing the common goal. In addition, the articulation with other pharmacist specialties (clinical analyzes and human genetics) and other health-care professionals has itself an enormous potential for optimization of care with an impact on the rationalization of the use of available resources.

Currently, hospital pharmacy services are required to be governed by defined objectives, committed to their mission, vision, and values; they demand planning and organization and are based on minimum standards of performance and quality. Certainly, the pharmacists activity is framed by both plates of a scale: one of the plates there is the professional and deontological context, legally conferred by the statute of the Pharmaceutical Society, also mirrored into the Pharmaceutical Career and the other plate, regards to the Good Practices, which are based on scientific evidence and rendered by the Hospital Pharmacy College and Societies such as the EAHP and FIP.

Hospital pharmacists within the health-care team play an important role in patient care due to their interventions in improving the better use of medicines, medical devices, and other health technologies. The commitment to efficient and safe use of

pharmacotherapy is demonstrated by their intervention in medicines management, technical commissions, medicines information and monitoring, in the prevention, detection, and resolution of drug-related problems (interactions, adverse drug reactions, medication errors), pharmacotherapeutic follow-up, therapeutic reconciliation, active pharmacovigilance and spontaneous notification, therapeutic counseling and health education, evaluation of drug use, and other activities.

Hospital pharmacists may influence the correct use of medicines at three different stages:

- Before prescription (drug information, drug-related policies formularies clinical trials),
- During prescription (counseling activity; influence on prescription; monitor, detect, and prevent medication-related problems—*untreated indications, improper drug selection, subtherapeutic dosage,* medication *failure to receive, medication overdosage, adverse drug reactions, drug interactions, medication use without indication*; therapeutic drug monitoring, etc) and
- After the prescription (counseling, preparation of personalized formulation, drug use evaluation, outcome research, pharmacoeconomic studies, etc).

Hospital pharmacists' present responsibility/challenge is to promote the responsible use of medicines, in its broadest sense, providing integrated pharmaceutical assistance in a multidisciplinary complex environment, and measuring performance using principles continuous quality improvement (limit/minimize nonconformity and error, reporting adverse events, identifying opportunities for improvement, and promoting the care process optimization).

The Portuguese health-care system continues to evolve; hospital pharmacists participate more actively than ever in direct patient care. The direct interaction with the patient, in the context of hospitalization and outpatients, has resulted the development of a set of initiatives, including the Pharmaceutical Consultation and the Home Hospitalization project.

Medication errors are a major cause of morbidity and mortality (Aspden et al., 2006) and are common in care transitions as a result of gaps in communication and information transfer between health-care providers and between them and their patients. They occur when patients are discharged, admitted, or transferred to health services. According to Rozich and Resar (2001), 60% of all medication errors occur in such care interfaces, thus constituting a problem of quality and patient safety. The literature shows that between 10% and 70% of drug histories contain at least one error; up to 1/3 of these errors have the potential to cause harm to the patient; more than 50% of medication errors occur in the transition between care; patients with one or more drugs missing from the discharge are 2.3 times more likely to be readmitted to the hospital than those who have the correct drug information; and 85% of discrepancies are due to failures in the collection process of patient medication information (DGS STANDARD N°018/2016).

Medication reconciliation (MR) then emerges as a process designed to limit medication errors and discrepancies in care transitions (Gleason et al., 2004), and "evidence shows that the process has the potential to identify many drug discrepancies and reduce possible damage" (Lehnbom et al., 2014). It is a multidisciplinary, patient-centered process; it differs from the usual process of reviewing medication by incorporating other information, such as nonprescription medicines, natural products and dietary supplements, as well as by using other sources of information (e.g., list of medication delivered by the patient and/or caregivers; the medicines delivered by the patient; information available in computerized systems).

The Hospital Garcia de Orta, EPE in Almada developed a pilot project with the integration of the pharmacist into a new entity providing care, the Home Hospitalization Unit. Home hospitalization promotes dehospitalization and prevention of rehospitalization and is distinguished from the health and social support responses at home already implemented in the NHS, insofar as it affects the acute phase of the disease and/or exacerbation chronic disease. After an experimental phase and the home stay of more than 100 patients, the first national Home Hospitalization Unit reveals itself as an alternative care model to conventional hospital admission. The pharmacist's intervention in this unit reflects the relevance of its integration since the project's genesis and meets the requirements outlined in the National Plan for Patient Safety 2015–20 that dictates the implementation of therapeutic reconciliation in the transition of care. Patient's safety was the focus of the pharmaceutical intervention, through which all medication omissions and incorrect doses were detected and rectified. Pharmaceutical intervention also emphasized storage of medication, identification and collection of expired drugs, and further enhanced adherence to prescribed treatment (Brito et al., 2017). This is a recent practice in Portugal, but international experience has shown several advantages, such as reducing the risk of complications, such as falls, pressure ulcers, disorientation or confusion, reduction of hospital readmissions, and reduction of infection rate hospital. It also has the potential to contribute to improving access to hospital health care and to improved bed management available for the treatment of acute patients in the NHS.

The complexity of the pathologies and pharmacological and nonpharmacological therapies of patients is inter- and intravariable, so patients with acute and/or complex needs may benefit from more targeted pharmaceutical care integrated within the multidisciplinary team (chronic and complex therapies; technological development/alternatives; polypharmacy, presence of comorbidities, aging, risk of interactions and adverse drug reactions, etc.). Therefore, in addition to the process of medication reconciliation of hospital in-patients, this process can also benefit patients with chronic pathology in outpatient follow-up, reason why targeted pharmaceutical consultations (PC) have been developed in areas such as oncology, geriatrics, renal transplantation, and HIV. There, medication reconciliation is performed, as well as the evaluation of drug interactions, therapeutic simplification, allergies, among others. These PCs have been developed in some centers; we emphasize the PC that present as a process a predefined schedule, referral by physician, prior definition of referral criteria, report issuance, and its documentation in the clinical process (e.g., Centro Hospitalar de Lisboa Ocidental, EPE). PC allows the prevention/correction of drug-related problems, detection and resolution of interactions, simplification of the therapeutic regimen, optimization of responsible use, increased safety, promotion of adherence, health education, and multidisciplinary integration. Nevertheless, in addition to the PC value recognized by patients and the multidisciplinary team, the measurement of clinical outputs is essential for the effective evaluation of its impact.

Trends in the development and use of medicines are one of the key factors that are and will shape the profession in the coming years; others are related with the national and global economy status and health-care reform. These factors will demand that hospital pharmacists continue to move toward team leadership of drug therapy management, aiming patient care improvement and institutional sustainability.

Use of Technology in Hospital Pharmacy

The increasing changes to hospital pharmacy practice have resulted from expanded roles, changes in patients' expectations, introduction of new/renewed pharmacy practice models, and development of new technologies in the drug-use process.

Information and communication technology (ICT) can enable the storage of organized patient records, enable the electronic prescribing, dispensing and administration of medicines, automate the handling of medicines in the supply chain, and provide tools for monitoring the efficacy and safety of medicines in use. Therefore, it can improve patient safety, allow professionals to provide higher quality care, and help patients make proper use of their medicines. Here are some examples.

Electronic prescribing (CPC healthcare-Glintt; ST+I; etc): This has been shown to reduce medication errors, and it has a major impact on patient safety. However, the effect on error reduction is dependent on system design, that's why hospital pharmacists must be involved in the design, specification of parameters, and evaluation of ICT within the medicines processes (European statement 1.7).

Barcode medicine identification: This has been used with electronic prescription systems in some hospitals (e.g., Cascais Hospital) and has been shown to reduce medicine administration errors, as well as improve the extensiveness of the medication history. It seems to have a major impact on pharmacy workflow.

Automated dispensing: Pharmacy robots have been shown to reduce the incidence of dispensing errors, improve the speed and efficiency of the dispensing process, and optimize use of space in the pharmacy (e.g., Kardex—automated storage and retrieval solution for unit dose preparation; Consis—drug dispensing system that improves space and facilitates picking)/wards (e.g., Pyxis—automated medication dispensing system that supports decentralized medication management).

Mobile technology: Sophisticated apps have been developed for disease monitoring (e.g., medication adherence support and health education). These apps will have a larger impact on pharmacy practice in future.

Adherence monitoring: Various technologies for adherence monitoring are now available, such as "smart" packaging, where a microchip-containing tablet blister pack is able to monitor when doses are popped out (not necessarily taken) and prompt the patient to record side-effect monitoring information for the medicine in question. These data can then be transmitted to a mobile telephone or tablet device. Due to cots these are not fully implemented.

Telecare: It involves the use of digital communications technology (audio and visual) to provide health-care consultations and services to patients remotely at home. Their use for pharmacist consultations of long-distance outpatients is not yet fully implemented.

Pharmacists must be involved in ICT development since they are important players in the patient medication circuit, intervening on it early, when perceiving the patient need for a specific medicine, during, by monitoring medicine use and in the end, when evaluating medicines utilization. Additionally, pharmacists must ensure that they harness technologies in a way that will support and help their professional aspirations.

Future of Pharmacy

Rethinking the Segregation Between Public and Private

Since the very inception of the Portuguese National Health System, there has been an interaction between the public and private sectors. Although a recent doctoral thesis by the former Portuguese Minister of Health identified that in the last 30 years, the private sector in the health system has contributed to improve efficiency through health-care competition and cooperation, a more rational use of resources, sharing of responsibilities and increased productivity (Fernandes, 2015), the growth of the private sector has been subject to much discussion and sometimes criticism by some of the parties with a seat in the Parliament.

However, data have shown that overall, the private participation in the Portuguese health system, in the period of study (1983–2013), had an important role in the increase of equity in access, through increased supply and geographical coverage, reduction of access barriers, reducing of waiting lists, and also by better coordination between public and private sectors converted on a global improvement of health outcomes (Fernandes, 2015).

The debate about the public and private mix has been highlighted in the discussions leading up to an update of the "*Lei de Bases da Saúde*," which is the law that establishes the general framework of the national health system, namely, the National Health Service. In the new text, which is significantly different from the one that had been included in previous iterations of the document, it is stated that "the Government (. . .) intends to reduce the recourse to the private sector to what is strictly necessary."

This further amplifies the segregation between both sectors, which has been detrimental to community pharmacies in particular, given their private status.

However, pharmacists should remain optimistic considering the most recent Government Program for Portugal, in which the role of pharmacists and the integration of community pharmacies in the health-care system as part of the primary health-care

network are emphasized. Legislation that has been published subsequently, as highlighted in previous chapters, has reaffirmed this position.

This follows international trends, including from the World Health Organization, which in its Global Conference on Primary Health Care 2018, invited pharmacists to participate and present their contributions. Indeed, forty years after the milestone Alma-Ata Declaration, country representatives have again gathered in Kazakhstan, this time in Astana, and endorsed the Declaration of Astana, which renews political focus on strengthening primary health care from governments, nongovernmental organizations, professional organizations, academia, and others. The declaration states that the success of primary health care will be driven by knowledge and capacity building, human resources for health, technology, and financing. For this purpose, all health-care professionals have a role to play, irrespective of where they work.

Pharmacists' Integration into the PNHS

It is often stated that pharmacies are an untapped resource to improve health systems' efficiency (International Pharmaceutical Federation, 2012). The same can be said for pharmacists as providers of care. Facing the enormous challenges related to the demographic changes and subsequent burden of disease, countries cannot afford to waste pharmacist knowledge and expertise.

As the OECD/EC report pointed out, access to care will remain a challenge in future years, and a workforce strategy should be in place to ensure that citizens receive the services they need when they need them (OECD, 2017).

However, the integration of pharmacies in health-care systems is limited and most of the time only valued within the context of the medicines dispensing process.

Internationally, this has started to change, with more and more pharmacists and pharmacies being remunerated for services they provide (International Pharmaceutical Federation Pharmacy at a Glance, 2017).

Portuguese pharmacists are available and ready to take on further roles and have greater intervention in care areas, in conjunction with other health professionals acting at different levels of care.

With a forward-thinking vision, pharmacists have been preparing themselves for the various challenges of the present and the future in health care, with the aim of fully addressing the needs of citizens, health professionals with whom they work, the National Health Service, and the country in general.

To this end, processes already initiated such as ensuring access to the health data platform, extending the services to be provided in community pharmacies, hospitals and clinical biology labs, and the regulation of the pharmaceutical career in the National Health Service are fundamental.

Based on the value generated, a new remuneration model should be established that recognizes and aligns agreed-upon incentives and health gains.

EDITOR BIOGRAPHIES

Editor-In-Chief

Zaheer-Ud-Din Babar

Zaheer-Ud-Din Babar is Professor in Medicines and Healthcare and the Director of Centre of Pharmaceutical Policy and Practice Research at the University of Huddersfield, United Kingdom. He has worked as an academic in Pakistan, Malaysia, New Zealand, and in the United Kingdom, and understands the health systems and pharmacy globally. He is known for his work in pharmaceutical policy and practice, including quality use of medicines, clinical pharmacy practice, access to medicines, and issues related to pharmacoeconomics. Previously, he was the Head of Pharmacy Practice at the University of Auckland and received Vice Chancellor's Research Excellence Award from the University. He has published in high impact journals, such as *PLoS Medicine* and *Lancet* and has acted as a consultant for World Health Organization, Royal Pharmaceutical Society, Health Action International, International Union Against Tuberculosis and Lung Disease, World Bank, International Pharmaceutical Federation (FIP), and for the Pharmaceutical Management Agency of New Zealand.

His other work includes *Economic Evaluation of Pharmacy Services*, *Pharmaceutical Prices in the 21st Century*, *Pharmaceutical Policies in Countries With Developing Healthcare Systems*, and *Pharmacy Practice Research Methods*. Published by Elsevier and Adis/Springer, the books are used in curriculum design, policy development, and for referral all around the globe. Professor Babar is also the Editor-in-Chief of *BMC Journal of Pharmaceutical Policy and Practice* and can be contacted at z.babar@hud.ac.uk.

Section Editors

Zubin Austin

Zubin Austin BScPhm MBA MISc PhD FCAHS is Professor and Koffler Chair in Management at the Leslie Dan Faculty of Pharmacy and the Institute for Health Policy, Management, and Evaluation—Faculty of Medicine at the University of Toronto. His research focuses on the professional and personal development of the health workforce. He has published over 160 peer-reviewed manuscripts and authored four reference texts. In 2017, he was installed as a Fellow of the Canadian Academy of the Health Sciences, the highest award for health services researchers in Canada. He is the only faculty member of University of Toronto to have ever received both the President's Teaching Award for excellence in education and the President's Research Impact Award for the societal significance of his work. He has also been named undergraduate Professor of the Year by students on 18 separate occasions.

Ahmed Awaisu

Dr. Ahmed Awaisu is an Associate Professor of Clinical Pharmacy and Practice in the College of Pharmacy at Qatar University. He received his Bachelor of Pharmacy degree from Ahmadu Bello University Zaria, Nigeria in 1999, his masters and PhD degrees in Clinical Pharmacy from Universiti Sains Malaysia (USM) in 2004 and 2009, respectively. He is also a licensed pharmacist and has practiced in the hospital setting since 1999. Dr. Awaisu has a unique privilege of past academic experiences in international pharmacy degree programs. He has made substantial and tremendous contributions that impact teaching and learning, research, curriculum design, as well as professional development of students and healthcare practitioners in Qatar and other countries. He received the Qatar University Merit Award for Outstanding Faculty for 2016–17 Academic Year. He is a member of the American College of Clinical Pharmacy (ACCP), and the International Society for Pharmacoeconomics and Outcomes Research (ISPOR), among others.

Professor Awaisu has extensive experience in the conduct of pharmacy practice and clinical research involving various types of study designs including case-control and cohort studies, quantitative surveys, mixed-methods designs, randomized control trials, and systematic reviews mostly on diabetes, cardiovascular diseases, tobacco dependence, and other chronic diseases. He has published over 100 peer-reviewed articles in internationally reputable pharmacy and healthcare journals and 10 book chapters related to the field of pharmacy. He has successfully supervised several postgraduate and undergraduate research projects, including MSc and PhD.

His research interest includes pharmacy practice especially pharmacists' expanded scope of practice, outcome-based research, pharmacoepidemiology and medication safety, and health promotion. Dr. Ahmed Awaisu has conducted training sessions and workshops on research methodology and biostatistics, drugs in sports, developing cognitive pharmacy services, and responding to symptoms in pharmacy practice. He presents regularly at continuing professional development programs for healthcare professionals in Qatar and other countries.

Timothy Chen

Professor Timothy Chen is a registered pharmacist and Professor of Medication Management, School of Pharmacy, The University of Sydney, Australia. Tim is nationally and internationally renowned for his research in medication management review and strategies to reduce medication related harm. Tim's research directly informed the Australian Government funded Home Medicines Review programme (MBS Item 903). Tim is an experienced educator and health services researcher, with experience in both community pharmacy and hospital pharmacy practice. Tim leads a productive research team (>160 peer-reviewed papers) and has completed main supervision of 15 PhDs, amongst other postgraduates. Tim has delivered >70 invited presentations at conferences and meetings across the globe. Tim has received university and national awards (Australian Government) for teaching, is an International Pharmaceutical Federation (FIP) Fellow (2016), and is President of the Social and Administrative Pharmacy Section, FIP.

Louise Curley

Louise Curley is a pharmacist and Senior Lecturer in Pharmacy practice at the School of Pharmacy. Louise's area of research focuses on the effects of recreational drug use in humans. She began her research as an undergraduate by investigating the subjective and electrophysiological effects of the Party Pill drugs using electroencephalography (EEG) and graduated with a PhD in pharmacy in 2012. Her thesis investigated the effects of the main constituents of "Party Pills" benzylpiperazine (BZP) and trifluromethylphenylpiperazine (TFMPP) on executive functioning and reward using functional magnetic resonance imaging (fMRI). Currently, her focus is developing new fMRI paradigms to investigate different aspects of risk, specifically by comparing populations of dependent versus non-dependent participants. Louise also has an interest in pharmacy practice research including innovative methods of teaching undergraduate students using different technologies and evaluating the effects of these innovations. She has recently been awarded the Butland Teaching Award: Innovation in Teaching.

Danijela Gnjidic

Dr. Danijela Gnjidic (BSc PhD MPH) is an NHMRC Dementia Leadership Fellow and Senior Lecturer at the School of Pharmacy, Faculty of Medicine and Health, University of Sydney. Her research expertise is in clinical and geriatric pharmacology, clinical studies on polypharmacy, high risk prescribing, and deprescribing in older people, pharmacoepidemiology, and the quality use of medicines. Danijela's academic track record includes 115 publications, 3-book chapters, with over 2500 citations on Scopus and $4M in research funding. Danijela was awarded the Australasian Society of Clinical and Experimental Pharmacologists and Toxicologists (ASCEPT) Denis Wade Johnson & Johnson New Investigator Award in 2012. Internationally, Danijela's contribution to the filed was recognized with the 2018 American Society of Clinical Pharmacology and Therapeutics William B. Abrams award in Geriatric Clinical Pharmacology. Danijela is an Associate Editor of the *Journal of Alzheimer's Disease* and Academic Editor of the *PloS One Journal*.

Arijana Meštrović

Dr. sc Arijana Meštrović, MPharm, FFIP has been working as a community pharmacist and she was responsible for education, services, and competency development in the biggest pharmacy chain in Croatia. She is now independent consultant and educator in Pharma Expert international agency, providing lectures and workshops in CPD programs for pharmacists, pharmacy technicians, medical representatives, implementing new services in pharmacy chains, and teaching Social Pharmacy and Pharmaceutical Care at universities in Croatia and Cyprus as Assistant Professor. Her Doctor's degree is in biomedical sciences—competency development in pharmacy. Arijana serves as member of the International Services Program Advisory Group the Accreditation Council for Pharmacy Education (ACPE, USA), member of PCNE (Pharmaceutical Care Network of Europe), ExCo member of FIP (Pharmaceutical International Federation) Academic section, and WHO international expert consultant in Pharmaceutical care field. She used to serve as Co-Chair of the FIP World Congress Programme Committee, Expert Member of the Board of Pharmacy Practice at FIP. In Croatia, she is a leader in Croatian Pharmaceutical Society and Croatian Chamber of Pharmacist as a Lecturer and Co-author of New services model in community pharmacy practice. Arijana is dedicated to promoting competency-based education in CPD cycle, so her teaching usually addresses all components of competencies—knowledge, experience, and motivation. In collaboration with ACPE International Services, she has founded and implemented SMART Pharmacy CPD model for pharmacists in more than 12 countries all over the world. She was invited speaker and consultant in more than 40 countries.

Kath Ryan

Kath is Professor of Social Pharmacy at the University of Reading, and Visiting Professor at Bournemouth University, United Kingdom. She has 45 years of experience as a pharmacist in the pharmaceutical industry, community practice, and academia. She has held posts at the University of Otago, New Zealand; Bournemouth University, United Kingdom; La Trobe University, Melbourne, Australia; and the University of Reading, United Kingdom. She also has experience in academic nursing and midwifery. Her research interests include extended roles for pharmacists, especially in general practice; application of the behavioral sciences to pharmacy practice; personal experiences of health and illness; and public and patient involvement, engagement and participation in research, and the education of health professionals. She has expertise in quantitative, qualitative, and mixed methods research. She also has an interest in infant feeding,

particularly breastfeeding research, promotion and support, from lay, professional, and academic perspectives. She has been a health advisor to La Leche League International and La Leche League New Zealand. Kath has been on Scientific Committees for the International Social Pharmacy Workshops and the Australasian Pharmaceutical Sciences Association. She has consulted for the National Institutes of Health, USA; Canadian Forces; Health Technology Assessment, NHS UK; and the NZ Ministry of Health.

Kath has over 100 publications in peer-reviewed journals and several book chapters and reports. She produced two multimedia, online resources for Health Talk: women's experiences of breastfeeding in the United Kingdom, and people's experiences of ageing in Australia. She was a Founding Co-Director of Health Talk Australia.

FOREWORD

This first edition of the Encyclopedia of Pharmacy Practice and Clinical Pharmacy is one-of-a-kind and the most comprehensive amalgamation of an inclusive range of topics relevant to the pharmacy profession brought together to ensure safe and effective provision of pharmaceutical care across the world. Professor Zaheer Babar is a Professor in Medicines and Healthcare at the University of Huddersfield and also a global expert in pharmacy practice and pharmaceutical policy. He has united over hundreds of researchers and practitioners from across the world in a collaborative endeavor to provide a unique insight into current best practice and strategies for the future for the profession of pharmacy and its practice.

As patient care becomes more complex with advances in medicines and new developments in practice, including pharmacogenomics and pharmacoeconomics, there is an ever-evolving demand for practice and policy to keep pace. This encyclopedia contains 180 chapters, from all fields of pharmacy practice and clinical pharmacy, providing an in-depth coverage of modern approaches to the practice of pharmacy and highlighting the directions that will enable advancement to continue.

This encyclopedia includes definitions, concepts, theories, and applications of clinical pharmacy and pharmacy practice, providing background knowledge of the area that will provide valuable information for students of pharmacy practice. By providing relevant and topical summaries on a broad range of subjects, this book is also an excellent resource for those seeking information beyond their specific areas of expertise. In addition, the information contained in this book and its communication is of importance to a range of stakeholders, such as physicians and other healthcare professionals, health regulatory authorities, and the pharmaceutical and health industry, in addition to patients and their caregivers.

This encyclopedia also provides an excellent insight into pharmacy practice research and methods, as well as pharmacovigilance, pharmacoeconomics, social and administrative pharmacy, public health pharmacy, pharmaceutical systems research, the future of pharmacy, and new interventional models of pharmaceutical care. In addition, new treatments, algorithms, standard treatment guidelines, and pharmacotherapies regarding diseases and disorders are also covered.

The six key strands around which this encyclopedia is arranged pay testament to the complex and broad nature of the topic and are key topics of interest in pharmacy today and drivers of change for the future, for the benefit of public health across the world.

1. Pharmacy practice
2. Pharmacy practice research methods
3. Clinical pharmacy education, professional standards, and workforce
4. Clinical pharmacy and pharmacotherapy
5. Pharmacoepidemiology and pharmacovigilance
6. Socio-behavioral and administrative pharmacy

Topics range from the education and training of pharmacists, technicians and assistants to counterfeit medicines, pharmaceutical pricing policies, and implementation of change. As pharmacy practice evolves to meet the ever-more-complex health and medicines needs of patients, practitioners need an understanding of the social, political, and economic contexts across the world, noting particular highlights and challenges in developing countries to reach high standards. While it is acknowledged that there are differences between countries in terms of legislation, regulations, and guidelines (as detailed in individual chapters), the vision for the profession must be for a world in which everyone can access safe, effective, and affordable medicines and pharmaceutical care. The chapters include many examples of innovation and best practice in delivering health

services for the future, embracing additional roles beyond the supply of medicines in a robust manner underpinned by scientific and evidenced practice. Quantitative, qualitative, and mixed methods of pharmacy practice research are presented alongside expanded and evolving roles for pharmacists and where technology may take us. More quality research and coordinating efforts will bring a range of theoretical concepts and an evidence-based practice to the forefront of our activities, to focus a global workforce to meet the challenges of this exciting new era for pharmacy practice. This timely volume exemplifies the willingness and ability of the profession to work collaboratively on global issues, representing an unprecedented opportunity to shape the future of pharmacy practice.

With ever-increasing demands on healthcare systems, alongside growing financial pressures, it is essential that we work collaboratively with other pharmacists and the wider public health workforce who have the expertise, opportunity, and capacity to support and inform development.

In this context, this encyclopedia is an important resource with far-reaching impact on global healthcare community, and I hope this will be well liked by students, researchers, and academics.

Professor Barbara Conway
Department of Pharmacy, University of Huddersfield, Queensgate, Huddersfield, United Kingdom

March 2019

PREFACE

Encyclopedia of Pharmacy Practice and Clinical Pharmacy

This encyclopedia has 180 chapters in total and it covers all domains of pharmacy practice and clinical pharmacy, including pharmacy practice research, socio-administrative and behavioral pharmacy, pharmacy education, pharmacoepidemiology, and the pharmacotherapy. One main question being asked is the need for this work. *What encyclopedia of pharmacy practice and clinical pharmacy adds to the current body of literature and what it means for global pharmacy community?* The answer to that is, though there were a number of books available on pharmacotherapy, however, current landscape lacks material comprehensively covering aspects, such as pharmacy practice, pharmacy practice research, social pharmacy, pharmacoepidemiology, pharmacy education, and the linking of clinical pharmacy with the health system. This encyclopedia aims to provide a collection of chapters on the above-mentioned areas. It also developed, synthesized knowledge, and provided policy guidance in the areas where there were gaps in the literature. For example, filling the gaps and including chapters on health systems, pharmaceutical policy, evidence and impact in pharmacy practice research, and on pharmacy education.

Here is a brief summary of what is being covered in its three volumes: Volume 1, 2, and 3.

Volume 1 includes chapters on pharmacy practice and pharmacy practice research. The pharmacy practice section starts with the historical evolution of pharmacy practice, medicines management, expanded roles of pharmacists, cognitive pharmacy services, community, and ambulatory pharmacy practice, ethics and regulation, and the new models of pharmaceutical care. There are also chapters on prescribing standards, practices, and competencies, interpersonal communication, evidence-based medicine, models on patient counseling, innovative pharmacy services, technology in pharmacy practice, and the pharmacist's role in substance misuse. The case studies chapters include pharmacy practice in high, low, and middle-income countries; United Kingdom, Western Europe, Australia, New Zealand, China, India, Gulf States, Philippines, and Portugal.

It is vital to understand and discuss the quality of evidence in pharmacy practice research, for example, how the evidence is produced and how it could impact on health outcomes. This is a niche section in the encyclopedia covering chapters on quantitative and qualitative methods in pharmacy practice research, quality of qualitative research, philosophical perspective and theories applied in pharmacy practice research, meta-synthesis, mixed methods research, discrete choice experiments, and the use of network meta-analysis in pharmacy practice. There are also chapters on evolution and definition of practice research, evidence, impact, and gaps in pharmacy practice research in low- and middle- and high-income countries.

Volume 2 covers pharmacovigilance, pharmacoepidemiology, and the socio-behavioral and administrative aspects of pharmacy and medicines use. The knowledge regarding pharmacoepidemiology and pharmacovigilance significantly impacts on medicines safety. The chapters included are on definitions, principles, and application of pharmacoepidemiology, descriptive and drug utilization studies, case-control and cohort studies, methodological challenges in epidemiological studies, data sources, and the issues related to medicines safety and comparative effectiveness research.

The socio-administrative and behavioral pharmacy section covers two broad aspects, namely, social pharmacy and pharmacy administration. Social pharmacy section covers concepts, development, and theories related to social pharmacy, public and patient engagement, sociology for pharmacists, implementation of change in pharmacy practice, and the social perspectives in addiction. There are also chapters on medicines adherence, compliance, and concordance, medication narratives, investigating medicines use among elderly

from a sociological perspective, changing nature of pharmacy as a profession, the impact of culture and religion on medicine use, and the issues related to disease mongering.

The understanding of health system is vital when promoting access and the use of medicines, hence in this context understanding administrative aspects of pharmacy are crucial. This section explores the dynamics between public policy, pharmaceutical policy, pharmacy practice, health systems, and patient-health outcomes. It covers a range of pharmaceutical policy and health system issues including access to biosimilars, access to high-cost medicines, counterfeit medicines, factors influencing pharmaceutical policy implementation, funding mechanisms for community pharmacy services, generic drug policies, national medicine policies, essential medicines list, pharmaceutical company sponsored medication assistance programs, and the pharmaceutical pricing policies.

Volume 3 covers clinical pharmacy education and pharmacotherapy. Pharmacy education training and the workforce have a great impact on global health. There are 25 chapters or more on pharmacists' training, and certification exploring the relationship between education, regulation, and practice. This is one of the largest collection of chapters covering pharmacy education and regulation at the global level. This includes chapters on pharmacist workforce, competency standards for clinical pharmacists, quality assurance in the pharmacy education, developing and evaluating clinical skills, continuing professional development, experiential education, inter-professional learning, leadership in pharmacy education, and the needs-based education. There are also case studies chapters on clinical pharmacy professional standards in the United States of America, Canada, the European Union, and in the low- and middle-income countries.

The pharmacotherapy section covers over 70 chapters discussing standard treatment guidelines, pharmacist's role in the central nervous system, infectious diseases, cardiovascular disorders, skin and endocrine disorders, musculoskeletal disorders, neurology, gastrointestinal disorders, and the respiratory disorders. The other key chapters include clinical pharmacy concepts, history, and development, clinical governance principles, pharmacokinetics, therapeutic guidelines, end of life care, palliative care, long-term care, fundamentals of pharmaceutical care planning, health outcomes and quality of life, the role of the pharmacist in the military and prisons, and the pharmacotherapy and deprescribing.

It has been a challenging task to complete this encyclopedia within a short span of 2 years. However, I am very thankful to the support of my section editors, reviewers, and hundreds of authors from all over of the world to come together and to contribute to this exciting project.

I hope you will like this effort and it will serve its purpose.

What is Social Pharmacy?

Claire Anderson*, **Kath Ryan**†, *University of Nottingham, Nottingham, UK; †University of Reading, Reading, UK

Introduction

The practice of pharmacy, and consequently, the pharmacy curriculum and the focus of research in many countries have changed considerably over the last 20 years in response to a rapidly changing economic, political, and social environment. The cost of providing health care continues to escalate, with a greater range of health technologies available to an ever-increasing aging population. The costs of medicines continue to rise and there is heightened awareness of patient safety issues and the occurrence of errors and adverse events. People are increasingly knowledgeable about the medicines they take and many will have already consulted the Internet to find out more information by the time they seek professional help. Some people will also demand more information about their health and well-being and not blindly trust the advice of health professionals. If pharmacists are technically excellent and also communicate in a patient-centered manner, patients will not only be better informed but will also be more satisfied with their care. In a UK study, only 16% of patients prescribed a new medicine took it as prescribed, experienced no problems and received as much information as they needed. Ten days after starting a medicine, almost one-third of patients were already nonadherent. Pharmacists need to have skills to support people in their medicines taking and to advise prescribers about safe and rational prescribing (Elliott et al.).

In many countries, there has been a blurring of roles between health-care professionals leading to increased competition, for example, in the United Kingdom, Canada, and New Zealand accredited pharmacists are able to prescribe medicines and in the UK pharmacists are being trained as advanced practitioners alongside other health-care professionals like physiotherapists, nurses, and paramedics in areas like urgent and emergency care. The pharmacy profession has had to face up to key technological developments, in particular the development of original pack dispensing, robotics and artificial intelligence but also the evolving role of the pharmacy technician which has meant that community pharmacy has lost one of the components that sustained its professional status, compounding and to an increasing extent dispensing. In the United Kingdom, for example, technicians can now dispense and perform the final check for dispensed medicines. This leaves pharmacists free to provide patient facing clinical and public health services such as medicines use reviews, smoking cessation services, immunization and diagnostic testing, and case finding. These patients facing roles mean that pharmacists need to have excellent communication and consultation skills as well as an understanding of people's health beliefs and their concerns about taking medicines.

As a result of these developments, the pharmacy curricula in many countries have evolved from being dominated by the physical and biological sciences meeting the needs of drug discovery, development and control only, to including clinical, social, psychological, and administrative and practice elements. The basic sciences of pharmaceutical chemistry, pharmaceutics, pharmacognosy, and pharmacology, with their heavy reliance on the teaching of the drug entity, its chemical nature, its derivation from plant and animal sources, its action within the body and formulation, have become more integrated with a greater emphasis on subjects based around the clinical and social needs of patients and a knowledge of medicines and diseases. If a pharmacist understands something about patient behavior regarding health and illness and taking medicines he or she will be better equipped to support people in their decisions to make changes to their behaviors and to adhere to their medicines.

The idea of social pharmacy has developed as a term to embody and express these changes. It can be argued that social pharmacy, like social medicine, is a multidisciplinary hybrid, drawing on the theories and methodologies of the social and behavioral sciences. Social pharmacy like pharmacy itself is a hybrid discipline, drawing on the theories and methodologies of the social and behavioral sciences, including sociology, social psychology, psychology, political sciences, critical studies, educational studies, communications, economics, history, and anthropology.

Defining Social Pharmacy

The development of social pharmacy as a discipline has been internationally diverse and it has been defined in many ways. We asked some international colleagues to define it: the first said, social pharmacy is the application of sociological epistemologies,

frameworks and approaches to pharmacy phenomena. The second, the term is derived from social medicine and means the application of social and behavioral sciences to the medication use process and the patients who use medicines. It also has come to include epidemiology and other public health sciences. The third said, it addresses the fact that only medicines that are taken work, and we need to try to uncover and support the implementation of safe, effective and acceptable drug treatments. The fourth said, social pharmacy is the application of the social and behavioral sciences to pharmacy practice.

Johnson and Wertheimer (1979) proposed a general definition for what they then called "behavioral pharmacy": the field concerned with the development of behavioral science knowledge and techniques relevant to the understanding of drug use, drug effects, drug selection and prescribing, behavioral-therapy adjuncts and alternatives to drug therapies, the professional behavior and well-being of pharmacy practitioners, and the application of this knowledge and these techniques to prevention, diagnosis, treatment, and rehabilitation.

Nettleton et al. (1994) argued that social pharmacy (perhaps like social medicine) is a multidisciplinary hybrid, drawing on the theories and methodologies of the social and behavioral sciences. As such, it can be conceived of as part of a socio-environmental, or bio-psycho-social approach to understanding health and illness as distinct from the biomedical approach. One of the chief contrasts between these two approaches is that the former emphasizes the social and psychological determinants of health, whereas the biomedical approach has been criticized for its overly reductive approach. Harding and Taylor (1993) stated that social pharmacy cannot be equated to the sociology of pharmacy but that it explores the ...

> "... hitherto neglected social domain in which pharmacy is practised from the practitioner's social perspective."

This differs considerably from the definition by Sørensen et al. (2003) who stated that *"social pharmacy is the interdisciplinary discipline that enables the pharmacy profession to act, take part in and take responsibility for drug matters at a societal level"*. These authors appeared to see social pharmacy more broadly from a societal perspective rather than from the perspective of pharmacy as a profession.

More recently low- to middle-income countries have made significant contributions to the discussions surrounding social pharmacy (Babar and Jamshed, 2008; Hassali et al., 2011).

In addition to the lack of unified terminology, the discipline of social pharmacy has lacked consensus and a common understanding of what the research area covers (Almarsdottir et al., 2014). This is quite obvious when studying the definitions that have been put forward and from the lack of literature about what constitutes the field of social pharmacy.

Traulsen and Herborg (2016) beautifully captured the essence of the discipline when they wrote their introduction to a special issue on Social Pharmacy of the open access journal *Pharmacy*:

> "Social Pharmacy is the multidisciplinary field of education and research that focuses on the role, provision, regulation and use of medicines in society. The scope is broad, covering the social, psycho-social, economic, and organizational aspects of medicines. It analyzes policy decisions made on the local, national, international and global levels concerning medicines. It spans a variety of themes, including medicine distribution and use; economics and financing; decision-making; health behaviour; health knowledge, health beliefs, health literacy; health and pharmaceutical policy; pharmacoinformatics; ethics; and pharmacoepidemiology and pharmacovigilance."

Social pharmacy combines pharmacy with theories and methods from the social sciences, psychology, and humanities. Social pharmacy research encompasses the behavior and perspectives of people, patients, governments, local health authorities, third-party payers, health-care professionals, and the pharmaceutical industry. A central theme is people's perspectives on using medicines.

Sørensen et al. (2003) describe the remit of social pharmacy as studying

> " . . . the drug/medicine sector ... from the social scientific and humanistic perspectives. Topics relevant to Social Pharmacy consist of all the social factors that influence medicine use, such as medicine and health-related beliefs, attitudes, rules, relationships, and processes."

Scahill et al. (2017) in an attempt to define pharmacy and its practice argue for a global model of pharmaceutical practice in which social pharmacy is but one of four parts that include social and administrative sciences, community pharmacy, clinical pharmacy, and pharmaceutical sciences.

If we turn to medicine for some help with the definition, Horton (2013) while writing about social medicine quoted Ryle who said *"Whereas public health confined itself to housing, safe water, and sanitation, social medicine included "the whole of the economic, nutritional, occupational, educational, and psychological opportunity or experience of the individual or the community"* and concluded that it unites the clinical with the public. Porter (2006) defined social medicine as including topics such as the social and economic structure of health-care provision, health policy, and clinical holism, through to evolving concepts of the field, such as concerns with doctor/patient relations in culturally diverse societies. She says that the evolution of social medicine as an academic subject has been internationally diverse and a coherent definition of the discipline has remained elusive. So in attempting to define social pharmacy and borrowing Horton's definition of social medicine, that it unites the clinical with the public, it can be said that social pharmacy unites pharmacy policy and clinical pharmacy with the people who take medicines and use pharmacy services.

Concepts and nomenclature other than social pharmacy are used within the literature such as pharmacy practice and pharmaceutical policy. Social pharmacy research is well developed as an academic discipline in the Nordic countries, the United Kingdom, and the United States. In the United Kingdom, there is some overlap with what is often called pharmacy

Table 1 Overview of social pharmacy section of Encyclopedia of pharmacy practice and clinical pharmacy

Section	*Contents*
People's behaviors and perspectives	Culture, literacy adherence, stigma, addiction, aging populations
Organization	WDGs, gender, community pharmacy operations and management, public perceptions of pharmacy services, professional boundaries
Policies	Medicines and pricing policies, counterfeit medicines, access to medicines, funding pharmacy services, corporatization
Marketing	Marketing professional services, pharmaceutical industry marketing
Research and theory	Health inequalities, human factors, medication narratives, pharmaceuticalization, public and patient involvement, sociology

practice and policy and in North America pharmacy practice is also known as a research discipline, primarily carried out by clinical and/or hospital pharmacists. In North America, the term pharmacy administration is also used for social and administrative aspects of pharmacy but in the past two decades this label may also refer to pharmaceutical outcomes, pharmacoepidemiology, and policy analysis.

The International Social Pharmacy Workshop (ISPW) has long been a focus for the development of the research networks within the discipline. The focus of the workshop has at least until recently been on research directed toward pharmaceutical policy, access to medicines, medicine use and pharmacoepidemiology, pharmacoeconomics, organizational behavior, and individual pharmacist practice. *Research in Social and Administrative Pharmacy (RSAP)*, the major social pharmacy journal, includes a number of topics of interest such as outcomes evaluation of drug products, programs, or services; pharmacoepidemiology; medication adherence; disease management; medication use policy; drug marketing; evaluation of educational paradigms that could impact practice and/or patient behavior; and other topics related to public health in the context of pharmacy or medication use.

Social Pharmacy

Table 1 shows an overview of this section of the Encyclopedia of pharmacy practice and clinical pharmacy.

Horizon Scanning

Social pharmacy should maintain its cross-disciplinarity working together with scholars from associated social behavioral science disciplines to develop new understandings and theories. Social pharmacy has too often focused on psychology and behavior change to the detriment of other social science disciplines. It should be wider in its focus not just looking in a prescriptive way at the pharmacy profession and the way services are delivered but also cover broader societal and patient issues. So, if we say social pharmacy unites pharmacy policy and clinical pharmacy with the people who take medicines and use pharmacy services, how then do we develop the field?

We should meet people in their world, rather than bringing them into ours, using patient's own language and engaging with their understanding of medicines in their lives. Are patients really at the center of all we do? Do we have a holistic view of patients? Or does the system mitigate against that? Do we need to develop more user-friendly medicines and medicine regimens that fit into patients' lives rather than the other way around?

Social pharmacists need to align the development of the field with global challenges as exemplified by the Sustainable Development Goals. This includes climate change and health, security, migration, global inequalities in access to medicines, workforce issues, shifting modes of delivery of health care, for example impending focus on primary health care, increasing use of technology, the advent of artificial intelligence and the various agendas for medicines' design and development.

Social pharmacy should maintain an important place in the pharmacy curriculum, with the aim of educating well-rounded individuals who are critical thinkers and do not accept everything at face value. Pharmacy is an art form based on scientific knowledge and its application to the human condition. As such, rigid adherence to standard operating procedures at the cost of professional judgment and tailored patient encounters should be a thing of the past.

Conclusions

No more intellectual endeavor should be wasted trying to come up with a definitive definition of social pharmacy as it is now an established discipline. Social pharmacy needs the flexibility to continue to evolve as a distinct field within the broad and ever changing healthcare environment. We need to strengthen the application of theory as we develop new knowledge about the practice of pharmacy for the benefit of patients.

Access to Biosimilars

Humaira Azhar Khan, University of Bradford, Bradford, UK

Historical Background

Historically, biological medicines have been used to effectively treat a number of acute and chronic diseases, such as HIV/AIDS, cancer, inflammatory, and autoimmune diseases and more recently, Ebola and the ZIKA virus. Statistics for cancer alone indicate that it is still one of the leading causes of death worldwide. The number of new cancer cases is expected to rise to 22 million within the next two decades (NIH Factsheets - Cancer, 2017), which warrant the development of new therapeutic strategies and interventions.

The increasing demand for new therapies has led scientists and pharmaceutical companies to explore the field of "biologics"—which are extracted from or semi-synthesized from biological sources. They include blood components, vaccines, allergenics, gene therapies, recombinant therapeutic protein, tissues, and living cells. One textbook definition of biologics is as follows:

> By definition biologics are proteins and/or derivatives thereof that modulate the immune system, downregulate the inflammatory response or support tumor-specific defense. Biologics—also known as 'biologicals' or 'recombinant therapeutics'—do not represent one homogeneous group of drugs. Monoclonal antibodies, fusion proteins (along with other proteins, toxins, and radionucleotides) and recombinant proteins, growth factors, anti- and proangiogenic factors, and expression vectors generating proteins in situ may all be included as members of this class of pharmaceuticals (Boehncke and Radeke, 2007).

The European Medicines Agency (EMA) and World Health Organization (WHO) exclude vaccines, plasma-derived products, and their recombinant analogs from consideration as biosimilars due to their complexity and variable biological and functional characteristics. The EMA guideline states that "due to complexity and the likelihood that they cannot be thoroughly characterized at the molecular level, vaccines must be considered on a case-by-case basis" (EMA, 2017).

Historically, the term "biologics" was first coined in the United States more than a hundred years ago in connection with national health-care legislation and the control of vaccine synthesis (Schwerin et al., 2013). Currently, biologics comprise a growing portion of the pharmaceutical market. Biologics have had and continue to have a profound impact on a number of medical disciplines, including rheumatology and oncology, and have allowed for an increase in therapeutic options for the treatment of several diseases, where existing therapies proved ineffective (Oo and Kalbag, 2016). On the contrary, however, the emergence of biologics has led to several regulatory and pharma-economic concerns, as biological therapies bring with them a high cost in comparison to their conventional counterparts. Moreover, preclinical and clinical research prerequisites to the synthesis of biologics are costly as they require a strictly controlled environment and advanced technological parameters

(Bradford and Gary, 2014; Chow, 2014). For example, the monoclonal antibody, Trastuzumab, which targets HER2-overexpressing breast cancers, although an effective therapy, is not a cost-effective intervention. Compared to the average wholesale price of other cancer therapies, monoclonal therapies are expensive, and clarification is needed about whether such expensive therapies offer value for money (Neyt et al., 2006).

Although several biologics are under scientific research or at clinical trial phase, few have found their way to market as successful treatments for disease. Biologics are important therapeutic medicinal products; however, health-care costs for biologics are unsustainable for the average consumer. Consequently, biologics are either not available or have limited availability in several countries due to their high price and lack of accessibility by most consumers (Bradford and Gary, 2014; Francois and Pascal, 2015). Thus, a number of issues, including the increasing price of new biologicals, continuing pressure on health-care budgets, as well as patent expiration, have opened the door for new alternatives like "biosimilars" to emerge. As the patents for individual originator medicines expire, biosimilar medicines can be introduced to provide additional options for patients and the health-care system.

The EMA approved its first biosimilar for marketing authorization in 2006 and since has approved the highest number of biosimilars worldwide (EMA, 2017). On the other hand, the U.S Food and Drug Administration (FDA) has approved 11 biosimilar products, including five in 2017 (Biosimilars Action Plan, 2018). Biosimilars are now expected to make up an increasing share of the biologicals market, where more than 200 new biotechnology products are in the pipeline (phase II to registered), all of which could be future targets for biosimilars (EMA, 2017).

Biosimilar Clinical Features

Biosimilar medicines must possess certain specific clinical features for them to meet the strict criteria of the approval process as outlined by bodies such as the EMA and Food and Drug Administration (FDA). These are as follows:

1. Biosimilars must possess physical, chemical, and biological properties *highly similar* to the originator molecule, hence the term, "biosimilar." There may be minor differences from the reference medicine, but these must be clinically insignificant in terms of the drugs' safety and efficacy.
2. Biosimilars must possess *no clinically significant differences* from the reference drug as demonstrated through extensive and rigorous clinical studies to support their approval.
3. *Variability of biosimilar kept within strict limits*. Variability for a biosimilar should not affect the drug's efficacy, mechanism of action, or safety where the range of variability should be the same as that allowed between batches of the reference medicine. This is achieved through robust manufacturing processes to ensure that all batches of the medicine are of proven quality.
4. Same *strict standards of quality, safety, and efficacy*. Biosimilars must follow the same strict guidelines for quality, safety, and efficacy as any other medicine approved for use. For the finished medicine, both biosimilar and reference medicine must have the same dosage and route of administration. Some variations with regard to differences in the formulation of the medicine (e.g., excipients), presentation (e.g., powder to be reconstituted versus solution ready for injection), and administration device (e.g., type of delivery pen) are permitted (EMA, 2017).

Approval Process and Impact

To ensure biosimilars do not possess differences in safety, potency, and efficacy in comparison to their respective originator, products require stringent analytical studies to demonstrate their "biosimilarity" as outlined by the respective regulatory bodies (Surya and Karen, 2015). In 2003, the EMA introduced an adapted pathway for biosimilars, termed, "similar biological medicinal products." The basis of this pathway is to ensure a thorough demonstration of "similarity" to the existing approved drug through rigorous preclinical and clinical testing (Bui et al., 2015). In the United States, the Patient Protection and Affordable Care Act of 2010 created a shortened approval pathway for biologicals shown to be similar to, or interchangeable with, an FDA-licensed reference biological (FDA, 2018). These guidelines have evolved to help developers conform to strict regulatory requirements but also to keep pace with their increasing demand.

Development and Approval of Biosimilars in the EU

The EU approved its first biosimilar in 2006 where a robust regulatory framework ensured that all biosimilars conformed to the same stringent regulatory guidelines and requirements. The EMA has paved way for developers to adhere to these strict regulatory guidelines as a route for the introduction of a number of other biosimilars. These guidelines have been developed to keep up with the increasing pace of drug development and advances in biotechnology (EMA, 2017).

All medicines using biotechnology and those for specific clinical indications must go through a "centralized procedure" as outlined by the EMA. Data collected from the prospective drug go through a regulatory pathway that includes the EMA's scientific committee on Human Medicines and Safety, EU experts on biologics (Biologics Working Party), and specialists in biosimilars

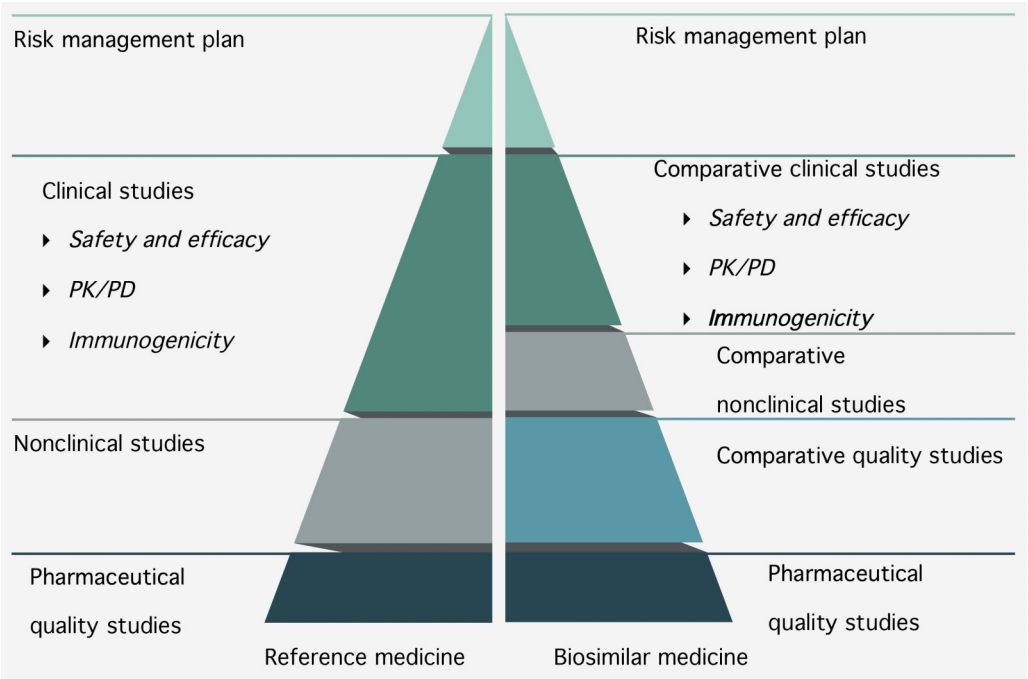

Figure 1 Comparison of data requirements for approval of a biosimilar versus the reference medicine (Biosimilars in the EU, 2017).

(Biosimilar Working Party). Analysists monitor the "positive benefit–risk balance" for the medicine as demonstrated through a series of nonclinical and clinical data for the drug of interest. Additionally, comparability (by means of safety, efficacy, and immunogenicity data) studies must also demonstrate the "biosimilarity" of the biologic to its originator where any possible impact on safety and efficacy is compared. Once reviewed by the EMA, results are sent to the European Commission which ultimately grants an E.U-wide marketing authorization. Fig. 1 illustrates the data requirements for approval of a biosimilar versus the reference medicine (EMA, 2017).

Development and Approval of Biosimilars in the United States

To date, the FDA approved has approved 11 biologics, including five in 2017 (Biosimilars Action Plan, 2018), where the FDA plays a pivotal role in the approval process and transition of biologics to market. In order to meet with the increasing demand for innovative therapeutic drugs that are more accessible to patients, the U.S Congress passed the Biologics Price Competition and Innovation Act (BPCI Act) in 2009. The purpose of the act was to establish an abbreviated pathway for biosimilar approval (Biosimilars Action Plan, 2018), thereby striking a balance between access and innovation of biosimilars and a pathway of entry to biosimilars once the period of exclusivity for originator compounds lapsed. The FDA may not approve an application for a biosimilar until 12 years after the date on which the originator product was first licensed. This bears some similarity to the pathway adopted through amendments made to the Hatch-Waxman Act (the Drug Price Competition and Patent Term Restoration Act—Hatch-Waxman Act—was introduced in 1984 to encourage the manufacture of generic drugs and established the regulatory pathways for these compounds), to strike a balance between innovation and availability of follow-on biologics and small molecule drugs. The new framework under the BPCI Act allowed for a pathway that would encourage the approval of new biosimilar products thus keeping up with market competition and providing access to patients.

A recent Biosimilars Action Plan, as introduced by the FDA (2018), recognized the critical role of the FDA in facilitating increased access to biosimilars. In doing so, they are taking several crucial steps including, developing, and implementing new FDA tools to improve the review process and increase public awareness on the process, creating resources and development tools for sponsors of biosimilars, including more information about approved biological products, establishing a new Office of Therapeutic Biologics and Biosimilars that will facilitate coordination of the processes, developing a FDA's Biosimilar Education and Outreach Campaign, that will provide much needed awareness about biosimilars to health-care professionals and other stakeholders (Biosimilars Action Plan, 2018). Several other strategic steps will also be taken as a part of BAP to promote and increase the efficiency biosimilar development and approval, increase scientific and regulatory clarity for biosimilar development, innovation and competition, and ensuring equitable access to safe and effective biosimilar medicines (Biosimilars Action Plan, 2018).

Impact of Biosimilars in the Global Market

The National Institute of Health and Care Excellence (NICE), WHO, FDA, EMA, and regulatory authorities of other respective countries are now receptive to the advantages of biosimilars and their cost-effectiveness in health care. Their common objective is to ensure equitable access of biosimilars to patients and to develop efficient and safe treatments similar to their originator products but at significantly reduced prices (Blackstone and Fuhr, 2010; Bradford and Gary, 2014; Francois and Pascal, 2015; Haustein, 2012).

In addition to cost-effectiveness of a biosimilar in comparison to its originator, other key factors are also important to their underlying rationale of replacing already approved medicines. These include their role in improving health-care professional and patient experience through value-added services and improved delivery devices; evidence-based research on product safety and efficacy, especially, when used to replace a patients' existing therapy and creating valuable engagement with strategic stakeholders in the market.

Biosimilars have the potential to provide reduced health care economic burden, which may allow ease of access to other biological therapies and may result in the development of innovative drugs in the future. Leading regulatory organizations such as the EMA, FDA, and WHO have issued and revised guidelines for the development and approval of biosimilars ensuring their equitable uptake across the global arena (CHMP, 2014, FDA, 2015b; WHO, 2009). Biosimilar products, as lower-cost alternatives of biological products, have the potential to provide savings for health-care systems, especially in countries where affordability of drugs is an issue (Christian et al., 2017). Due to the increasing impact of biosimilars in the global health-care system, "biosimilarity" is currently an area of discussion among clinical researchers, policy makers, and physicians (Christian et al., 2017; Dörner and Kay, 2015). Moreover, continuing development of biosimilar medicines creates increased choice for patients and clinicians, increased commercial competition, and enhanced value propositions for individual medicines. **Tables 1 and 2** highlight FDA- and EMA-approved biosimilars and follow-on biologicals, respectively, their scope of use and respective approval years.

Global Market Scope and Accessibility of Biosimilars

Detailed information regarding growth drivers, patterns of growth, opportunities, and barriers to growth has helped inform and educate key market players, researchers, and health-care professionals on biosimilar development (Tsiftsoglou et al., 2013).

Global Biosimilars Market: Regional Outlook

The global biosimilars market is expected to reach US$10.90 billion by 2021 up from US$3.39 billion in 2016, at a Compound Annual Growth Rate (CAGR) of 26.3%. The majority of biosimilars have been registered and commercialized in Europe (Francois and Pascal, 2015). Moreover, Europe is expected to lead the global biosimilars market and account for a large share of the global economic market over the next few years. This high growth can be attributed to the presence of several biosimilar drugs including AccofilBemfola, Abasaglar, and Omnitrope and other new products in the pipeline (EMA, 2014). The EMA approved four additional biosimilars in 2016, including three biosimilars in two new product classes: a biosimilar of Amgen's Enbrel (etanercept) and two biosimilars of Sanofi's Clexane (enoxaparin sodium) (Royzman and Seigelr, 2018). Moreover, growing pressure to overcome increasing health-care costs, patent expiry, and increased incidence of chronic diseases, such as cancer, diabetes, and rheumatoid arthritis, has led to Europe being market leaders in biosimilar growth.

European dominance is followed by Asia, North America, and the Rest of the World (RoW) where the Asian market is projected to grow substantially over the next few years due to their developing economies and progressive growth rate in the future markets (Rumore et al., 2016). In contrast, however, strict regulatory policies in North America are predicted to lower growth in this region.

Key players in the biosimilars global market include Pfizer Inc. (US), Sandoz International GmbH (Germany), Teva Pharmaceuticals Industries Ltd. (Israel), Amgen Inc. (US), Biocon Ltd. (India), Dr. Reddy's Laboratories Ltd. (India), F. Hoffmann-La Roche Ltd. (Switzerland), Celltrion, Inc. (South Korea), and Samsung Bioepis (South Korea) ("Market Report for Biosimilars" www.marketsandmarkets.com).

Global Biosimilar Market Drivers to Accessing Biosimilar Medicines

One of the major market drivers for biosimilars is their low cost compared to their reference biologicals. In addition, the increasing incidence of chronic diseases is predicted to substantially push growth in the future. The increasing level of competition owing to the growing participation of key players in Biosimilar innovation and development, is predicted to encourage market growth in the coming years (Tsiftsoglou et al., 2013).

The global market scope of biosimilars is expected to increase substantially over the next few years, and the factors influencing this growth are the accessibility of new innovative technology, market competition, patent expiry, cost-effectiveness, and an increasing demand due to the prevalence of chronic diseases (Tsiftsoglou et al., 2013). Although biosimilar development is growing

globally, defining which countries are "all in" depends upon a number of criteria that define their respective efforts and progression. These include, conducting expensive and extensive preclinical studies, clinical trials accompanied by initial scale up and process optimization, product manufacturing capacity, approval of applications, number of approved products, whether biosimilars in a given country are manufactured there or imported, product revenue, extent of discounts on biosimilars relative to reference biological, and the extent of government and industry involvement and funding (Rader, 2017).

Another key factor driving the increase in biosimilar demand and production is the imminent patent expiry of currently administered biological drugs. This cluster of patent expiry termed as the "patent cliff," awaits top biologics in the global market and warrants development of new biosimilars (Ghia et al., 2015). Biosimilars seem like a lucrative option as with patent expiry, large pharmaceutical companies are seeing the end of holding exclusivity on biologic drug treatments losing billions in revenue. Moreover, global sales of biologics are rising at a rate of 5.5% per year paving way for other drug manufacturers to gain entry into the ever competitive global biosimilar market. The estimated expiration of patents for biologicals is highlighted in **Table 3**.

Another crucial driver for biosimilar research and development is global market competition. An example of the stiff competition in the biosimilar market can be observed with Humira (Adalimumab). Humira (Scheinfeld, 2003), used to treat rheumatoid and psoriatic arthritis, ankylosing spondylitis, Crohn's disease, ulcerative colitis, chronic psoriasis, hidradenitis supurativa, and juvenile idiopathic arthritis, is owned by AbbVie. From 2012 to its patent expiry in 2016, Humira was listed as one of the top selling pharmaceutical compounds and boasted $16 million in global sales (Philippidis, 2016). In 2014, India manufactured and brought its first Adalimumab biosimilar to market. Subsequently, another Indian drug manufacturer, Torrent Pharmaceuticals, has launched a second biosimilar ("Torrent launches world's second biosimilar of generic auto-immune drug", Business Standard, 11th January 2016 include full date of publication). Moreover, another pharmaceutical company, Amgen, similarly filed an application for their

Table 3 Estimated expiry year of the patents of biological products

Expiry year	*Patent products*	*Drug*	*Indication*
2013	Avonex	Interferon beta-1a	Cytokine used to treat multiple sclerosis
	Byetta	Glucagon-like peptide-1	Hormone used against diabetes mellitus
	Epogen	Epoetin alpha	Artificial protein to produce red blood cells
2014	Remicade	Infliximab	Monoclonal antibody to treat autoimmune diseases
	Novolog	Insulin aspart	Fast acting insulin used against diabetes mellitus
2015	Lantus	Insulin glargine	Artificial hormone used against diabetes mellitus
	Herceptin	Trastuzumab	Monoclonal antibody used against breast cancer
	Neulastra	Pegfilgrastim	Recombinant human granulocyte colony-stimulating factor that simulates white blood cells
	Synagis	Palivizumab	Monoclonal antibody used to prevent respiratory syncytial virus infection
2016	Humira	Adalimumab	Monoclonal antibody used to treat rheumatoid arthritis
	Aranesp	Drabepoetin alfa	Synthetic erythropoietin used to treat anemia
	Enbrel	Etanercept	Protein used to target tumor necrosis factor
	Rituxan	Rituximab	Monoclonal antibody used to treat leukemia and lymphoma
2017	Avastin	Bevacizumab	Monoclonal antibody that is an angiogenesis inhibitor
	Pegasys	Pegylated interferon alfa-2a	Proteins used to treat viral infections including hepatitis C and HIV

own version of the drug and is in the process of fighting two of AbbVie's patents. If successful, Amgen will own a significant portion of the US biosimilar market.

Similarly, in Europe, Etanercept (trade name Enbrel), a biopharmaceutical that treats autoimmune diseases such as rheumatoid arthritis, juvenile rheumatoid arthritis and psoriatic arthritis, plaque psoriasis, and ankylosing spondylitis, by acting as a tumor necrosis factor (TNF) inhibitor, reaches its patent expiry in 2016, opening the market to biosimilar competitors. In January 2015, Samsung and Biogen's joint venture "Samsung Bioepis" successfully submitted Benepali, a biosimilar version of the drug, for review to the European Medicines Agency (EMA). It was approved in 2016, opening the door to further competition.

Another important factor pushing the development and distribution of new biosimilars is their low cost compared to the comparator biologic. In the EU, the average cost savings from opting to use a biosimilar versus a branded drug is roughly 35%, as compared to the Federal Trade Commission's projected 10%–30% discount in the US market. It is relatively easier to bring new biosimilars to market in Europe compared to the United States, as the FDA has a set of processes in place to determine interchangeability on any given biosimilar. The EMA recently updated their guidelines so substitution policies are done on a country-by-country basis. Once such approval processes have been revised and implemented, the increased competition could result in further discounts.

A report by Bloomberg Intelligence highlighted that biosimilars pose a threat to over US$190 billion in global pharmaceutical sales over the next decade, where companies such as Amgen, Merck, Samsung Bioepis, and Novartis could have their own follow-on biologics for drugs such as Humira, Enbrel, and Remicade. The success of biosimilars could thus influence the sustainability of the pharmaceutical industry in the next decade. The major competitors will be the big pharmaceutical companies that are interested in increasing their profit through high prices; therefore, discounted prices of biosimilars compared to originators are likely to be less than desirable (Pasina et al., 2016).

Economic Implications of Biosimilars

Cost-efficacy studies are crucial to compare the costs and outcomes of a biosimilar with those of a relevant comparator. These economic evaluations help guide the introduction of safe and cost-effective medicines (Drummond et al., 2005) and are used by scientists and industry to set up future biosimilar research and development plans. This methodology of evidence-based decision-making in health care is an effective tool as it fits within the criteria of cost-effectiveness.

In the United States, health-care spending is increasing largely due to the high cost of biological medicines. Biological medicines are the standard care for several debilitating chronic diseases such as cancer, diabetes, multiple sclerosis, and rheumatoid arthritis (Khraishi et al., 2016). While their significance in treating these diseases continues to increase, accessibility to these sometimes lifesaving medicines is denied because health systems cannot manage their high cost. In this context, biosimilars would play an important role in improving access and affordability of medicines (Singh and Bagnato, 2015).

Biological medicines are the most rapidly growing segment of health care in the United States constituting more than US $100 billion in annual spending and expected to exceed US$250 billion by 2019 (Biosimilars Council, 2017). However, as these drugs lose their patents, biosimilar medicines will grow rapidly and provide significant savings in health care. Increased market competition from biosimilars can help lower the cost of expensive drugs. Research has shown that 60% of Americans would be receptive to accepting a biosimilar drug if it would be cheaper (Moriarty, 2018). The US can, therefore, really benefit from biosimilars.

One of the biggest advantages of biosimilars in comparison to their reference medicines is their low market price and subsequent low cost for the health-care system. The low cost of biosimilars is partly due to a tailored development program that avoids repetitive nonclinical and clinical studies, which have already been carried out on reference medicines and also due to market competition (Rader, 2017).

Several stakeholders can benefit from the advent of new biosimilars, such as, patients, hospitals and care facilities, taxpayers, employers, insurers, and state and federal governments. Equitable and improved access to more affordable biosimilar medicines will, in turn, improve patient quality of life and reduce financial pressures on regional, national, and global levels (IMS Health, 2016). Increasing access to biosimilars will also help drive down the cost of originator brand biologics and allow access to biosimilar medications of proven efficacy for many patients who are unable to access the high-priced brand biologics for their treatment. For example, many rheumatoid arthritis patients in countries such as Japan, the United States, and the Europe do not have access to medicines for their treatment (NCBI Resources, "Biologic Monotherapy in the Treatment of Rheumatoid Arthritis," 2015). However, in countries where biosimilar alternatives have been introduced, patient access has increased by 100% due to their lower cost (IMS Health, 2016).

The "high out-of-pocket" treatment cost for patients is acknowledged as a barrier to the use of biologics in the neoadjuvant or adjuvant interventional therapies. Moreover, issues related to treatment costs, drug funding, and reimbursement have led to a significant impact on the management of cancer, quality of life, and long-term survival rates. Out-of-pocket expenses to patients have contributed to personal financial distress and/or a lack of realistic access of treatment options, thereby increasing the demand for low cost but equally effective alternatives (Cherny et al., 2016). Access to the market for biosimilars for diseases, such as cancer, diabetes, and rheumatoid arthritis, would also be economically beneficial as it is believed that biosimilars would be around 10%–40% less expensive than their reference biological products, which would be sufficient ground for adoption of biosimilars in hospital settings as replacement therapy for specific biological reference products (Rumore et al., 2016).

Table 4 Biological reference products with market price reduced as a result of biosimilar products

Biologics innovators	*Price reduction (%)*	*Country*
Erythropoietin	33	Germany
Infliximab	70	Norway

Biosimilars have also been reported to positively influence the reduction in market price of some biological reference products (Table 4) as competition among biosimilars and reference biologics drives down the market price of innovator biologics leading to improved patient access.

The Biologics Price Competition and Innovation Act, which is included in the Patient Protection and Affordable Care Act, creates an approval pathway for biosimilar and interchangeable biological products and is also responsible for providing affordable access to biological products and biosimilars (Rumore et al., 2016). Price control regulations of biosimilars help monitor biosimilar costs, increasing their affordability, and patient access. An independent analysis in 2014 predicted that the availability of biosimilars would result in a US$44.2 billion reduction in biologic spending between 2014 and 2024, or approximately 4% of total biologic spending over the period (Surya and Karen, 2015).

Access to Biosimilars in the EU vs US

It is important to note that there are significant differences between availability and hence access to biosimilars between Europe and the United States. Biosimilars have been widely used across Europe and are being approved by the EMA to ease their market access, which in turn leads to cost savings in pharmacotherapy related to biologics (Remuzat et al., 2017).

In the first 9 years since the passage of the BPCIA (2009) in [2009] in the US, the FDA approved 11 biosimilars (five of which were approved in 2017), with 60+ more in the pipeline, compared to approximately 35 biosimilars approved in the EU [over the same time period] (Biosimilars Council, 2017). Moreover, patient use of biosimilars in the EU has shown no difference in health outcomes to their originator biologicals for treatment indicating a similar profile of safety, quality, and efficacy in their administration. By 2020, the expected cumulative savings for biosimilars are expected to range from Euros 11.8 to 33.4 billion, which is equivalent of savings of 5.2%–14.6% of the estimated expenditures in 8 European countries. The majority of these savings will be observed in France, Germany, and the United Kingdom, while the lowest will be observed in Sweden due to the country's regulatory procedures for biosimilar approval (Haustein, 2012). It is important to note that considerable differences are and will be observed between the overall savings in different countries and between different classes of drugs.

Although there are several similarities between approval and regulatory processes in the United States and the EU, there is no EU-wide legislation for "interchangeable" biologics in Europe, and each biosimilar medicine is evaluated on a case-by-case basis. Equitable access to biosimilars in the EU and the United States is crucial to reduce global health inequalities and improve health outcomes and economies in the health-care sector (Hirsch and Lyman, 2014). Global biosimilar acceptance and availability will ensure a sustained supply of important, lifesaving medications for patients once biologicals have reached their patent expiry dates.

The WHO Prequalification of Medicines Program ensures that medicines purchased by international procurement agencies (e.g., UNICEF) for the purpose of distribution in low-income countries meet acceptable standards of quality, safety, and efficacy. The Lancet Commission on Essential Medicines recommends that the prequalification program should expand the range of essential medicines, including biosimilars. The incentive for governments to embrace biosimilars is to reduce health care economic burden, which in turn should increase access and improve population health-care outcomes (Lancet, 2017). WHO prequalification will hopefully increase competition in the biosimilar market to further reduce costs and increase access to these medicines in low-income countries (Babar, 2018).

Barriers to Access to Biosimilars

Over the past decade, the subject of biosimilar access and affordability has become increasingly significant. Different regulatory and evolutionary pathways play a pivotal role in determining the uptake of biosimilars in the global market. The role of biosimilars in providing access to more affordable medications and increasing competition has come into greater focus. Despite their evolution and growth in the global market, the development of biosimilars continues to be an expensive and time-consuming process, as they need to meet several stringent technical, manufacturing, and analytical challenges. In addition to this, biosimilars also face several regulatory, clinical, and commercialization challenges (Bui et al., 2015; Rathore, 2009). Biosimilar developers will need to continuously adapt to the regulatory criteria that will continue to evolve as biosimilars increase their market share. Thus, there are concerns and doubts regarding the ability of biosimilars to be commercially successful, especially in developed countries where

biosimilars must go through stringent and evolving regulatory processes (Konara et al., 2016). To this end, there are several barriers to access to biosimilars in the ever competitive global market. Pending expiry dates of patents for originator biologicals between 2012 and 2019, coupled with intellectual property rights, opens opportunities for biosimilars to compete in the market, but there are ***barriers*** to their access in health care.

High Expenditure for Development of Biosimilars

Although biosimilars are considered to be low-cost substitutions for pricy biologics, they must comply with the same quality, safety, and efficacy as their reference biologics. Manufacturing of biosimilars, therefore, requires complicated procedures compared to their small molecule reference compounds involving creating structures similar to the reference molecule. This is turn leads to several challenges for manufacturers who have to deal with failure rates and operational costs. Small molecule generics are synthesized using the same Active Pharmaceutical Ingredient (API) as originator molecules and are therefore chemically identical to these molecules and their manufacture involves only one-fifth of in-process tests to meet Good Manufacturing Practice compared to a biological which requires 50–250 tests comprising of complex quality assessment and stringent environmental control (Bui et al., 2015; Surya and Karen, 2015). Minor changes in manufacturing procedure may lead to significant variations of the cellular systems used for biologic production, and may affect stability, and biology of the end product. Manufacturing large molecule biosimilars is, therefore, a complex and expensive process where the end product must be similar to the original molecule in terms of its structure, mechanism of action, and biological activity (EMA, 2017). Furthermore, drug regulatory authorities require that there should be no clinically significant difference between the biosimilar and the reference drug in terms of safety and potency which again warrants the development of validated analytical studies to demonstrate biosimilarity. The development of biosimilars also involves expensive clinical studies that are conducted by using the relevant study populations and endpoints to demonstrate similarity between the proposed biosimilar and originator products in terms of their safety, immunogenicity, and efficacy profiles (CHMP, 2014; FDA, 2015b; WHO, 2009). It must be noted, however, that with standardizing the manufacturing process and the technology required, production costs have been significantly reduced.

It is important to note that before establishment of stringent guidelines and policies by the EMA, several copies of biologicals were sold in unregulated markets. To this end, products in lesser and unregulated international markets are generally classified as "biogenerics." Such products are generally not manufactured in compliance with Good Manufacturing Practice (GMP) standards and lack detailed analytical studies and comparative clinical trials. Now, however, these markets are targeting regulatory processes, procedures, and adopting strategies to comply with the guidelines of regulated markets.

Regulatory Pathways, Legislation of Biosimilars, and Entry to Market

Although the European market accounts for 80% of global spending on biosimilars, access across Europe varies greatly due to different national and local guidelines, funding, and approaches to health-care management Generics and Biosimilars Initiative (GaBI Online, 2017). Data collated from 46 European countries [2017] showed discrepancies in access to biologicals where 22% were not reimbursed for a biological for rheumatoid arthritis (GaBI Online, 2017), thus creating severe restrictions to their access. Non-EU states tend to have stricter eligibility criteria for access to biologicals leading to further barriers to equitable access. EU prescribing practices and regulatory pathways thus needs to be revised and standardized to ensure harmonious treatment strategies across the EU.

Similarly, in the United States, despite advances in biosimilar research and development, regulatory processes have not kept up with this increased development. This has been further complicated as a result of litigation between drug companies leading to a knock on effect on lowering market competition and hence biosimilar pricing. As in the EU, a clearer more cohesive regulatory pathway to FDA approval is required to improve access to biosimilars in the United States.

Requirement for Distinguishing Nomenclature for Generic and Originator Brands

Specific nomenclature is required to distinguish biosimilars from their originator reference compounds and from each other to ensure accurate prescribing and avoid confusion (Dörner and Kay, 2015). To achieve this goal, it would be more appropriate to use the brand name, the International Nonproprietary Names (INNs) plus the brand name, or some other unique identifier (Corrado et al., 2017). Alternatively, WHO has proposed a 4-digit code for a biologic qualifier that could be used to distinguish originators from biosimilars (WHO, 2012).

The European Commission issued the Directive 2012/52/EU, which requires the use of brand names "to ensure clear identification of biological medicinal products (EC, 2012)," a requirement that also applies to biosimilars. In addition, the batch number is required to be notified to the respective regulatory authority to ensure proper traceability because there is a risk of product drift (unintentional changes during manufacturing of biosimilars from the original product or previous batch of biosimilar). The US FDA regulations have created confusion regarding nomenclature for biosimilars (Rumore et al., 2016). According to these regulations nonproprietary (generic) names of biosimilars should contain a unique suffix identifier (e.g., filgrastim-sndz). This may cause confusion among prescribers, pharmacists, and patients and may also result in patent litigation that adversely influences the delay in biosimilars entering the US market (e.g., filgrastim-sndz vs. filgrastim) (Rumore et al., 2016).

The International Non-proprietary Name (INN) is the official generic name given to a pharmaceutical's active ingredient by the World Health Organization. Thus, irrespective of country, products with the same active ingredients share the same INN. This system also applies to biosimilars approved in the EU and elsewhere. Consistencies in scientific properties, efficacy, and patient safety to the reference compounds necessitate biosimilars possessing the same INN as the original drug. Moreover, WHO INN experts believe this INN system should not be altered as different INNs for biosimilars would disregard important scientific knowledge and safety information for health-care professionals who prescribe the medications. INNs assigned to biosimilars already used and circulated in the EU, Japan, and other strictly regulated markets match those of their respective reference compounds. With a different INN, a prescriber would legitimately conclude that the active ingredients in the biosimilar are different to the original reference compound—this in turn would cause confusion in terms of drug dosage, formulation, and package size. In addition to this, different INNs for two highly similar products with the same chemical properties, patient safety profiles, and efficacy would result in unnecessary burden on physicians and pharmacists when making important treatment decisions (WHO, 2012).

Biobetters and Next-Generation Biologics

Although biosimilars have been a success story since their approval in 2006, they face competition from "biobetters." The performance of biosimilars has also been affected by the fact that competition is limited to the first-generation reference products. The term "biobetter" refers to a recombinant protein drug that is in the same class as an existing biopharmaceutical but is not identical, and it is an improved version of the original and produces its effects on the target for a longer period of time. Biobetters build on the success of existing, approved biologics but are considered less of a commercial risk than developing a brand new class of biologics. Moreover, biobetters are being developed using protein or glyco-engineering, which reduces the risk of immunogenicity, makes the drug safer and more effective, and requires lower dosing (Dolinar and Reilly, 2014). Being new drugs, biobetters will possess 12 years of market protection in the United States and have lower research and development costs. Companies interested in the development of biobetter drugs are Novo Nordisk, Merck & Co, Roche Group, Biogen Idec, Amgen, Sanofi-Aventis, Eli Lilly, and GlaxoSmithKline.

The market entry of biobetters and next-generation biologics is thus an important consideration in evaluating the impact of biosimilars and their potential savings for the health-care system. This difference between the biosimilars and biobetters has a significant regulatory impact because unlike biosimilars, biobetters will be registered as innovator drugs. Similarly next-generation biologics have alterations in their molecules to improve their immune function, half-life, or capability of triggering other mechanisms of action (Beck, 2011). If biosimilars gain a substantial share of sales from their referenced products (of a previous generation), their share of overall patient treatments may be limited if physicians and patients prefer biobetters or the next generation of biological products (Grabowski et al., 2014).

Prescriber and Patient Concern's

Uhlig and Goll (2017) reviewed evidence from the administration of biosimilars and concluded that, for biosimilars to be used more widely, both prescribers and patients needed to have more confidence in their benefits and characteristics (Uhlig and Goll, 2017). Their statistical survey carried out via the European Crohn's and Colitis Organization (ECCO) indicated a high level of awareness of biosimilar attributes and warranted support for switching from infliximab to its biosimilar. The authors, however, also highlighted that in order for biosimilars to be adopted widely, both prescribers and patients need to be fully aware of their benefits and attributes. In total, 61% of responders highlighted their lack of confidence in using biosimilars due to a lack of awareness and education in their use (Uhlig and Goll, 2017). Moreover, a recent survey carried out in the United States and Europe highlighted that 47% of respondents thought the agents were sufficiently safe and effective to prescribe, whereas 43% said they required more information on biosimilars (Uhlig and Goll, 2017).

Patients also show concerns with regard to the fact that the low cost of biosimilars compared to their originator counterparts may bias prescribers and health insurers in prescribing them without patient consent and objectively assessing quality. The UK National Rheumatoid Arthritis Society has welcomed the entry of biosimilars into the market but has also highlighted the importance of prescribing biosimilars on the basis of their clinical attributes and not merely as cost-saving alternatives (Corrado et al., 2017).

There is a definite need for health-care professionals to have comprehensive and objective information on the key characteristics of biosimilars before their introduction into clinical practice. Limited literature is available on the opinions of health-care professionals with regard to biosimilars and their use, including US their biosimilarity, interchangeability, risk management, and switchability. Pharmacists and other health-care professionals must, therefore, remain vigilant and ensure they gain regular, continued knowledge and awareness of biosimilars to provide safe and optimal use of biologic products and biosimilars in their clinical practice (Adé et al., 2017). Moreover, a clear specific nomenclature and full transparency of labelling may be helpful in increasing the confidence of both physicians and patients. Health-care professionals and patients can truly benefit from widening their understanding of biosimilars by keeping up with evidence-based informative research that is being carried out on emerging biosimilars (Adé et al., 2017; Rumore et al., 2016). Patients also need to receive clear, concise, and informative information on biosimilars from their health-care professionals to feel included, engaged, and informed about the choices and options available to them.

Patent Litigation Barriers to Patient Access

Another important factor affecting biosimilar entry into the global market is a complex and multistep process called the biosimilar "patent dance." Along with creating the approval pathway for biosimilars, the Biologics Price Competition and Innovation Act (BPCIA) also created a mechanism by which patent disputes between brand companies can be resolved. Original biologic manufacturers have been using the patent dance litigation to keep competition from biosimilar manufacturers at bay. The "litigation backlog" created by brand companies, however, has resulted in the FDA approving only six biosimilars for use in the United States with only three marketed to patients (Chemistry World, "Biosimilars Battleground," May 15, 2017). In June 2017, the Supreme Court issued a unanimous ruling that under Federal law, biosimilar applicants can opt out of this patent dance giving them more control to choose how and when to resolve patent disputes with a brand company (Supreme Court of the United States, "SANDOZ INC. v. AMGEN INC", 2017)

Conclusion

Although biosimilars are effective alternatives to their reference medicines, there are still several challenges to access and use by health-care professionals. Equitable access to biosimilars in the global market is crucial to reduce global health inequalities and improve health outcomes and the economy in the health-care sector. Moreover, pharmacists, physicians, and patients should be knowledgeable about the specifics and issues associated with the administration of biosimilars as they are key players in the implementation of biosimilars in the global market. Biosimilars also face competition from next-generation biologicals and biobetters as they offer an improved version of existing originators and are considered less of a commercial risk than developing a new brand of biologic. It, therefore, remains to be seen how competition will evolve for the more complex biological products with patent expirations as well as biosimilars and biobetters on the horizon in the European and US markets.

In conclusion, based on clinical evidence and scientific studies, although biosimilars provide an attractive cost-effective option to the global market, more steps need to be taken to ensure health-care professionals are knowledgeable and confident in prescribing biosimilar drugs. Additionally, steps need to be taken to ensure a globally uniform regulatory and approval process so that access is equitable and timely.

Glossary

Biological A product derived from a living organism (from animal products or other biological sources) that is used in the diagnosis, prevention, or treatment of diseases. Examples of biological medicines include recombinant proteins, allergy shots, vaccines, and hematopoietic growth factors.
Biosimilarity Demonstration of high similarity to a reference biological medicine in terms of chemical structure, biological activity and efficacy, safety and immunogenicity profile, mainly based on comprehensive comparability studies.
Biotechnology Technology that relies on biological systems, living organisms, or components from living organisms (such as genes or enzymes) to make a specific product. A medicine obtained by biotechnology often has been produced by inserting a gene into cells so that they can produce the desired protein.
Clinical study or trial Study with the objective of determining how a (new) medicine is handled by, and affects, humans. Clinical studies or trials are conducted in healthy volunteers or in patients. Clinical studies routinely involve the use of a control group of patients that is given an inactive substance (placebo) that looks like the test product. Pivotal clinical studies involving a larger group of patients provide evidence on whether the medicine can be considered both safe and effective in a real clinical setting.
Comparability Head-to-head comparison of a biosimilar with its reference medicine to rule out any significant differences between them in terms of structure and function. This scientific principle is routinely used when a change is introduced to the manufacturing process of medicines made by biotechnology, to ensure that the change does not alter safety and efficacy.
Compound annual growth rate (CAGR) The compound annual growth rate (CAGR) is the year-over-year growth rate of an investment over a specified period of time.
EMA (European Medicines Agency) The European Medicines Agency. EMA is responsible for evaluating marketing applications for medicinal products to be approved in the European Union.
Extrapolation Extension of the efficacy and safety data from a therapeutic indication for which the biosimilar has been clinically tested to another therapeutic indication approved for the reference medicine.
Generics A generic drug is the same as a brand name drug in dosage, safety, strength, how it is taken, quality, performance, and intended use. A generic drug product must contain the identical amounts of the same active ingredient(s) as the brand name product. Drug products evaluated as "therapeutically equivalent" can be expected to have equal effect and no difference when substituted for the brand name product.
INN International nonproprietary name, a unique name that identifies active substances. The list of INNs, which is globally recognized and public property, is maintained by WHO.

Interchangeability Refers to the possibility of exchanging one medicine for another medicine that is expected to have the same clinical effect.
Originator medicinal product A medicine that has been developed and produced by an originator company and that has been approved by the national regulatory authorities or the European Commission on the basis of a full registration dossier.
Patent A patent is a legal mechanism granted by a State (national government), which allows the discoverer of a medicine the exclusive right to make and sell the product for a set period of time to recover the development costs, in exchange for public disclosure of their invention. Typically, however, a patent application must include one or more claims defining the invention, which must be new, nonobvious, and useful or industrially applicable.
Reference medicine A biological medicine approved in the EU, which is chosen by a company developing a biosimilar as a reference for the head-to-head comparison of quality, safety, and efficacy.
Specifications Acceptance limits for important quality standards, which an active substance or a finished medicine must meet.
US Food and Drug administration (FDA) The federal agency responsible for evaluating marketing applications and/or otherwise regulating the US marketing of medicinal products, medical devices, food, and cosmetics to be approved in the United States. This agency is responsible for approving all medicines before they are made available to doctors and patients in the United States.
Vaccine A biological preparation that is used to establish or improve immunity to a particular disease.

High-Cost Medicines: Access, Affordability, and Prices

Syed Shahzad Hasan*,†, Chia Siang Kow‡, Zaheer-Ud-Din Babar*, *University of Huddersfield, West Yorkshire, United Kingdom; †University of Newcastle, Callaghan, NSW, Australia; ‡Bukit Kuda Health Clinic, Ministry of Health, Malaysia

Introduction to the Concept of High-Cost Medicines

The concept of "high-cost medicine" has gained popularity in recent years. In general, the definition includes mostly new, specialized medicines for complex conditions such as cancers and inflammatory autoimmune diseases (Lu et al., 2008). These medicines include, but are not limited to, biological agents; they selectively target specific molecular sites and therefore are effective (Rader, 2008). In addition, some high-cost medicines are designed to treat rare diseases that affect only a handful of people; they are more commonly termed as orphan drugs. Access to high-cost medicines, regardless of public or private healthcare systems, is gaining attention (de Leon, 1989; Lu et al., 2004). By definition, high-cost medicines are much more expensive than conventional medicines, and therefore have limited patient access in most cases (Mayor, 2010). This in fact may negatively affect patient outcomes (Wong et al., 2010). The World Health Organization (WHO) Regional Office for Europe has defined a medicine as "high-cost" if the therapy for one patient exceeds €10,000 per year to be reimbursed by a public payer (World Health Organization, 2015).

Access to High-Cost Medicines in the European Region

Geographically, Europe is often divided into regions including Central Europe, Eastern Europe, Northern Europe, Southern Europe, and Western Europe. Although access to medicines at affordable prices is one of the key aims of the European Health Policy, it is far from being achieved, especially in the context where there are many life-saving high-cost medicines being introduced into the market (Zaprutko et al., 2017).

Access to High-Cost Disease-Modifying Therapies

Rheumatoid arthritis (RA) is one condition where the introduction of high-cost biologic disease-modifying antirheumatic drug (DMARDs) for the treatment of the disease has improved the control of the disease activity tremendously. According to clinical practice guidelines by the European League Against Rheumatism (EULAR), biologic DMARDs should be initiated in patients who are intolerant of or nonresponsive to conventional DMARDs, in the presence of adverse prognostic factors such as early joint damage (Smolen et al., 2014). Nonetheless, owing to high direct costs of biologic DMARDs in the context of limited healthcare budgets, patient access to reimbursed biologic DMARDs varies across the European region.

Kaló et al. (2017) examined the RA patient population having access to reimbursed biologic DMARDs according to European League Against Rheumatism (EULAR) criteria and national reimbursement criteria in 39 European countries (Kaló et al., 2017). By referring to published RA epidemiological data, they developed a population model to estimate the population size of the RA patient eligible for biologic DMARD treatment. This is according to clinical criteria defined in 2013 EULAR recommendations and national reimbursement criteria defined in a study of the 39 European countries. A composite eligibility score ranging from 1 to 5 was assigned to each country, with a higher score indicating less restrictive access to biologic DMARDs based on national reimbursement criteria and was subsequently categorized into low-access, moderate-access, and high-access clusters. In line with the developed model, 32% of RA patients in the European region were eligible for treatment with biologic DMARDs according to clinical criteria defined in 2013 EULAR recommendations. There were 86%, 68%, and 13% of the EULAR-defined patient populations eligible for biological DMARD treatment according to national reimbursement criteria in high-access, moderate-access, and low-access clusters. Only 59% of the EULAR-defined patient, on average, was eligible for biologic DMARD treatment. The findings highlighted that access to reimbursed biologic DMARDs varies across the European region, with RA patients in the majority of European countries having moderate access to the biologic agents (Putrik et al., 2014b; Smolen et al., 2014).

High priced biologic medicines have transformed the treatment of Crohn's disease (CD). Evidence from clinical trials has demonstrated the efficacy of biological drugs for the treatment of CD. The drugs such as infliximab, adalimumab, vedolizumab, and ustekinumab substantially improve disease remission rate, slow disease progression, and increase work participation and improve quality of life (Gulácsi, 2014). Since biologic drugs are more expensive than standard treatment, most countries have regulated the access to reimbursed biologic drug treatment (Péntek et al., 2017). Péntek et al. (2017) investigated access to biologic agents for the treatment of CD among 10 European countries (Czech Republic, France, Germany, Hungary, Latvia, Poland, Romania, Slovakia, Spain, and Sweden) (Péntek et al., 2017). The authors found that infliximab and adalimumab were reimbursed in all 10 countries, while vedolizumab was reimbursed in only five countries (France, Germany, Latvia, Slovakia, and Sweden). The availability score, which was developed by the researchers to examine the restrictiveness of clinical eligibility and administrative requirements to access biologics among patients with CD, was highest in Hungary, Poland, and Slovakia (most restrictive), but lowest in Germany and Sweden (least restrictive). Treatment with biologic drugs was most affordable in Sweden (26% of the gross domestic product per capita on average) and least affordable in the Eastern European countries such as Hungary (106% of the gross domestic product per capita on average) and Romania (198% of the gross domestic product per capita on average). Important barriers to access to the biologics cited by the gastroenterologists included limited availability and physicians' preferences. The observed inequalities in access to biologic drugs could be partly explained by differences in gross domestic product per capita in which the number of patients with CD on biologics per 100,000 population was positively correlated (0.91) with gross domestic product per capita (Péntek et al., 2017).

Access to High-Cost Anticancer Medicines

The list of high-cost anticancer drugs is growing, as are the challenges in providing equitable access to them for countries within European region. Patient access to 30 innovative anticancer drugs with the highest sales value among 13 European countries was analyzed in a 2015 report and presented in three perspectives.

These three perspectives include expenditure on innovative anticancer drugs, availability of innovative cancer drugs through reimbursement systems, and the waiting time for patients to gain access to the cancer drugs upon marketing approval (Poland, 2015). The highest and lowest expenditure on the 30 innovative anticancer drugs was recorded in Switzerland and Poland, respectively, in which the expenditure amounted to 94% and 24%, respectively, of the mean expenditure for the 13 investigated European countries. The expenditure incurred on innovative anticancer drugs was higher in highly developed European countries (Austria, France, Germany, Italy, Spain, Switzerland, the Netherlands, and the United Kingdom) than the other European countries (Hungary, Poland, Romania, Slovakia, and the Czech Republic), where the mean expenditure incurred in these highly developed countries was 15% higher than the mean expenditure incurred for all investigated European countries. The mean expenditure of the five countries (Hungary, Poland, Romania, Slovakia, and the Czech Republic) accounted for only 38% of expenditure for all other European countries.

Highest availability of anticancer drugs through the reimbursement system without restrictions was noted in the Netherlands (30), followed by Italy (26), and Switzerland (25). The country with the least availability of cancer drugs through the reimbursement system without restriction was Poland (2). In terms of the time elapsed (in quarters) until patients gain access to the included innovative anticancer drugs upon marketing approval, analysis was performed in two measures, namely, the mean time to the first sale and the mean time to achieve significant utilization level. The mean time to the first sale was the shortest in Switzerland (mean: 0.3 quarter after authorization by European Medicines Agency), followed by Germany (0.6), and the United Kingdom (0.6) (Poland, 2015).

Access to High-Cost Orphan Medicines

Alone marketing approval for certain pharmaceuticals does not ensure patient access, but there are some other factors which influence too and which include price, co-payments, and reimbursement policies. This is especially true for orphan drugs, in which usual cost-utility threshold values may not be applied during reimbursement decisions due to ethical considerations surrounding

the use of orphan drugs. Blankart et al. (2011) examined patient access to orphan drugs for the treatment of four rare diseases (pulmonary arterial hypertension, Fabry disease, hereditary angioedema, and chronic myeloid leukemia) in eight European countries (England, France, Germany, Hungary, Poland, Slovakia, Switzerland, and the Netherlands) (Blankart et al., 2011). Three indicators, the outcomes of technology appraisals, the extent of coverage provided by healthcare payers, and the price of the orphan drugs in each country, were used to determine the extent of patient access to these drugs. The authors noted that healthcare payers in five countries (France, Hungary, Poland, Slovakia, and the Netherlands) had issued recommendations for almost all orphan drugs included in the study, while only one drug (imatinib for the treatment of chronic myeloid leukemia) was appraised by the National Institute for Health and Care Excellence (NICE) in England. Germany had not assessed any of the included orphan drugs. Data were not available for Switzerland since Eidgenössische Arzneimittel Kommission (Federal Drug Commission) in the country did not publish its recommendations.

Every orphan drugs included in the study that had been appraised gained positive recommendations in the countries where they were analyzed. Exception was the agalsidase beta for the treatment of Fabry disease in Poland. The majority of the orphan drugs included in the study were being reimbursed in the countries analyzed, with slight variation in the extent of reimbursement owing to differences in co-payment regulations. It is worth noting that all of the orphan drugs included in this study were covered in Switzerland.

In Poland, for covered orphan drugs, no co-payment was needed from the patients. There were large differences in the prices of orphan drugs among the countries analyzed. When the prices were converted into USD, it was observed that Germany paid the most for the included orphan drugs. When the prices were adjusted for relative purchasing power parity, it was observed that the prices for the studied orphan drugs were highest in Slovakia and Poland. Although there were variations to patient access to orphan drugs among European countries, almost all studied orphan drugs were accessible to the patients in these countries (Blankart et al., 2011).

Access to High-Cost Medicines in the Asia-Pacific Region

Accessibility of high-cost medicines poses a major problem to the Asia-Pacific region, which comprises many low- and middle-income countries. Also, there are challenges related to low healthcare budgets and absence or minimal coverage of high-cost medicines under public health insurance schemes in this region (Mandal and Mandal, 2017). The prices of anticancer medicines are highly variable in the South-East Asian, Western Pacific, and Eastern Mediterranean regions (Salmasi et al., 2017).

Access to High-Cost Disease-Modifying Therapies in New Zealand and Malaysia

Increased understanding of the immune pathogenesis of RA has led to the introduction of biologic DMARDs. While the side-effect profile of biologic DMARDs restricted their use only for patients intolerant of or nonresponding to traditional DMARDs, recent findings suggest using these drugs as early as possible in the course of RA to avoid disabilities. However, the widespread use of biologic DMARDs is still limited due to their high-costs.

A study investigated patients' access to four biologic DMARDs (three tumor necrosis factor inhibitors and rituximab) in New Zealand, with comparisons performed between New Zealand and Australia as well as between New Zealand and 13 European countries (Kobelt et al., 2010). Patient access to biologic DMARDs was examined by estimating the proportion of patients treated with biologic DMARDs and the mean annual sales of biologic DMARDs per RA patient. The prevalence of RA was first used to estimate the proportion of patients treated in each of the included countries, to subsequently estimate the mean annual sales per RA patient (Kobelt et al., 2010). The study utilized two prevalence estimates to serve as sensitivity comparators: one estimate was an average of the Nordic region and the United Kingdom (upper prevalence estimate), while the other estimate was based on an average including all remaining European countries (lower prevalence estimate). The results of the analysis demonstrated very low utilization of biologic DMARDs for treatment of RA in New Zealand, where the estimated proportion of patients treated with biological DMARDs was the lowest when compared to the 13 European countries and Australia, in both upper and lower prevalence estimates. This was reflected in the mean annual sales per RA patient, where the figures were also trailing behind those of 13 European countries and Australia (Kobelt et al., 2010).

Like many middle-income countries, health systems in Malaysia operate on a multi-payer system, which includes public and private healthcare payers as well as out-of-pocket payment from individual patients. Due to over dependence on out-of-pocket spending, medicines are sometimes unaffordable. This is particularly true for patients who require long-term use of high priced disease-modifying therapy (DMT) for the management of chronic diseases such as multiple sclerosis (MS), where they frequently meet difficulties in obtaining continued access to these medicines (Kishore et al., 2015). Some of the first- and second-line disease-modifying therapies, which are commonly prescribed cost around MYR3200 to MYR6000 (USD695 to USD1390) per month, which exceeds the national mean monthly salary of about MYR2312 (USD522) (Vijayasingham et al., 2017). The situation is complicated by the fact that MS is considered one of the critical medical conditions by private health insurance providers in Malaysia. This restricts eligibility of patients to apply for new health insurance policies (Vijayasingham et al., 2017).

Vijayasingham et al. (2017) present case experiences of working individuals with MS in navigating access to high-cost DMTs through various public and private health care payers in Malaysia. All participants included had relatively high socioeconomic status were white-collar workers and the majority of them had received tertiary-level education. However, each of them

encountered challenges to sustainably finance continued access to DMTs. One patient, who gained access to DMT through the public healthcare system initially after having his or her socioeconomic background, thoroughly vetted only to be denied access later because of a salary increment. Furthermore, a patient had been forced to resign from his job after seeking reimbursement on DMTs from his employer. These experiences illustrate the challenges for Malaysia in the provision of access to high-cost medicines.

Access to High-Cost Anticancer Medicines in Australia

Anticancer drugs are often expensive, especially those that are newly developed, which contribute to the growing cost of cancer care. In Australia, patient access to expensive drugs often depends on listing of the drugs on the Pharmaceutical Benefits Scheme (PBS) for reimbursement. Nevertheless, to be eligible for listing, drugs must have favorable cost-effectiveness assessment, and this is not forthcoming for every new anticancer drug. It would pose many difficulties for patients to access new anticancer drugs that are not listed on the PBS (Karikios et al., 2014). Wilson and Cohen examined patients' access to newer anticancer drugs approved by the United States Food and Drug Administration (USFDA) between 2000 and 2009 among publicly insured beneficiaries in Australia (Wilson and Cohen, 2011). Three subdimensions of patient access were analyzed, namely market availability, insurer coverage and conditions of reimbursement, and patient out-of-pocket costs (Wilson and Cohen, 2011).

There were a total of 34 new chemical entities and biologics approved by USFDA for cancer treatment between 2000 and 2009. However, only 19 of these new anticancer drugs were granted marketing approval in Australia. In addition, only 12 of the 19 approved new anticancer drugs were listed on the PBS for reimbursement, while Medicare in United States covered 18 of the 19 approved new anticancer drugs. All 12 listed new anticancer drugs were designated as authority required items in Australia, where initiation requirements were assigned to six of the new drugs. Also, nine of these new anticancer drugs were subject to treatment continuation rule based on evidence of treatment response, and seven of these new drugs had step therapy requirements. All new anticancer drugs except bevacizumab had quantity limits (maximum quantity that can be marketed/prescribed/dispensed over a given period of time) placed on them (Wilson and Cohen, 2011). On average, the time elapsed between marketing approval and reimbursement was 23.8 months, ranging from 6 to 53 months, while in the United States, it was 16.3 months, ranging from 11 to 21 months. Generally, anticancer medicines were priced 24%–41% lower in Australia compared to the United States, and cost sharing per prescription was greater among the Medicare population in the United States than the publicly insured beneficiaries in Australia. The analysis suggested that although there was a higher number of new anticancer drugs available in the United States, the evidence-based approach to the reimbursement decision adopted by Australia had contributed to the reduced prices compared to the United States, which may positively influence the affordability of new anticancer drugs (Wilson and Cohen, 2011).

Access to High-Cost Medicines in Thailand

A well-designed and well-executed public access scheme has the potential to improve access to high-cost medicines. For instance, the Thai government implemented a multipronged strategy known as the high-cost medicines E2 access program (E2 Program), including different health insurance schemes to cover selected high-priced specialty medicines (Yoongthong et al., 2012). The scheme aims to address the challenges of increasing healthcare expenditures while enabling access to high-cost medicines.

Sruamsiri et al. (2016) assessed if the E2 Program has achieved its goals of improving access to high-cost specialty medicines. The utilization rate of the selected high-cost medicines (intravenous immunoglobulin, leuprorelin, liposomal amphotericin B, verteporfin, and botulinum A toxin) was used as a proxy measure for patient access to the medicines. It was observed that at baseline, about two-thirds of eligible patients received the selected high-cost medicines. The utilization rate of the selected high-cost medicines among eligible patients increased significantly immediately after the implementation of the E2 program [rate of increment = 9.8% (95% confidence interval (CI) = 6.8%–12.8%)]. The estimated rates of increment in the utilization of the selected high-cost medicines at 1 year and 2 years after the E2 program implementation were 12.7% (95% CI = 4.4%–21.0%) and 11.5% (95% CI = 0.3%–22.7%), respectively. In conclusion, the study demonstrated E2 access program as a successful means to facilitate patient access to high-cost specialty medicines (Sruamsiri et al., 2016).

Access to High-Cost Medicines in the American Region

Access to High-Cost Disease-Modifying Therapies in Brazil

High prices of new disease-modifying therapies play an important role in pushing countries toward fair and transparent pharmaceutical access schemes. For example, in Brazil, access to biologic drugs is achieved through the judicial system or via administrative means (Lopes et al., 2014). While the legal route provides easy access to these medicines, it may also encourage the financing of health technologies that may not have a concrete proof of efficacy and safety.

Lopes et al. (2014) conducted a descriptive cross-sectional study to examine the access and utilization profile of biologic medications for psoriasis treatment provided by the judicial system in Brazil (Lopes et al., 2014). A total of 190 lawsuits filed between 2004 and 2010 to obtain biologic drugs for psoriasis treatment were analyzed. It was observed that the Infliximab (57.4%)

had the highest request rate followed by efalizumab (21.6%), etanercept (16.3%), and adalimumab (4.7%). The authors noted that the prescription of a biologic medicine in the majority of the analyzed lawsuits was not explicitly justified, with the absence of information concerning patient's previous treatment, progression of the disease, supplementary examination, or clinical diagnoses. In fact, none of the analyzed prescriptions for biologic drugs fulfilled the legal prescribing requirements. In addition, it was also observed that the applicants were treated with biologic medicines for periods of more than 13 months, with some patients being treated for more than 49 months. Additionally, more than two-thirds (70.3%) of the patients did not undergo laboratory tests for drug therapy monitoring (Lopes et al., 2014).

Access to High-Cost Anticancer Medicines in Canada and the United States

In Canada, many patients depend on drug access programs to get access to high-cost anticancer drugs. These access programs are independently administered by the provincial governments, with each provincial government deciding on the arrangement and eligibility requirements for their programs (Morgan et al., 2014). Therefore, concerns have been raised regarding equitable access to these high-cost anticancer drugs among patients from different provinces (Morgan et al., 2014). Chafe et al. (2011) surveyed eight provincial drug program managers about top 10 highest expenditure intravenous and oral anticancer drugs (Chafe et al., 2011). They then compared the number of top 10 intravenous and oral drugs that each program had in common with programs in other provinces. Provinces were categorized as having "fair," "moderate," "substantial," and "perfect" agreement when there were five, six or seven, eight or nine, and ten drugs in common, respectively. Furthermore, the utilization rates per 100,000 population for the five intravenous and four oral anticancer drugs for which complete data were available were compared across the provincial programs (Chafe et al., 2011). For intravenous anticancer drugs, there were about seven drugs in common on average, indicating "moderate" to "substantial" agreement among the provinces in terms of the highest expenditure on intravenous anticancer drugs. In case of oral anticancer drugs, the results indicate "fair" to "moderate" agreement across the provincial programs. The authors also noted that the coefficient of variation of utilization rates for nine intravenous and oral anticancer drugs across the provincial programs ranged from 8.4% to 55.3%. The study demonstrated that there were important variations in Canadians' publicly funded access to anticancer drugs despite approval for public coverage (Chafe et al., 2011).

Trastuzumab, a recombinant humanized monoclonal antibody that selectively targets the human epidermal growth factor receptor 2 (HER2), was approved by USFDA as the targeted therapy for HER2-positive metastatic breast cancer and as adjuvant treatment for HER2-positive breast cancer. Ades et al. (2017) evaluated patient access to trastuzumab in the United States by determining whether its use was proportional to patients' needs between the years 2001 and 2013 and compared the results with European countries (Ades et al., 2017). Since HER2-positive breast cancer cases ranged from 15% to 20% of the new breast cancer cases, the authors considered both scenarios (15% and 20%) in their analyses (Ades et al., 2017). The study highlighted that there was insufficient access to trastuzumab for all patients in need in the United States after the approval of trastuzumab as adjuvant treatment of HER2-positive breast cancer in 2006 despite complete coverage earlier (Ades et al., 2017).

Access to High-Cost Orphan Medicines in the United States

The advent of the Orphan Drug Act in the United States in 1983 fostered the development of treatments for rare diseases affecting fewer than 200,000 individuals, also known as orphan drugs (Cohen and Awatin, 2017). Since the targeted population is limited, orphan drugs have relatively high unit costs. Therefore, regulatory approval by USFDA for more than 600 orphan products does not ensure a sufficient condition for reimbursement or patient access.

Cohen and Awatin (2017) examined patient access to orphan drugs by analyzing payer coverage of 138 orphan drugs approved between 2000 and 2016 in the United States (Cohen and Awatin, 2017). Payer coverage rate for a particular orphan drug was presented as the percentage of 20 leading commercial payers that cover the drug. The 20 payers were selected based on their numbers of covered lives and data accessibility. It was reported that the payer coverage rate was between 75% and 100% for 80% of the orphan drugs, with more than one-third (n = 46) of the orphan drugs achieving complete coverage.

Affordability of High-Cost Medicines

The wealth of a country, or more specifically the affordability in a health system, is an important determinant of the access to high-cost medicines. The affordable high-cost medicines could be crucial for those who are suffering from curable form of any disease but cannot afford high priced medicines. A number of studies within the published literature have demonstrated that affordability as measured by gross domestic product per capita correlates with patient access to high-cost medicines.

Affordability of Cancer Drugs

Goldstein et al. (2017) compared the patterns of affordability of cancer drugs in Australia, China, India, Israel, South Africa, the United Kingdom, and the United States. They found that anticancer medicines are significantly less affordable in India, China, and South Africa than in high-income countries, including the United States where prices are considerably higher (Goldstein et al., 2017). In 2008, Kos et al. compared the access to nine new targeted oncology drugs in eight selected European countries

(Austria, France, Germany, Italy, Slovenia, Sweden, Switzerland, the United Kingdom) (Kos et al., 2008). The utilization rate of bevacizumab, bortezomib, cetuximab, erlotinib, imatinib mesylate, and rituximab was much lower than the average utilization rate in the eight selected European countries (Kos et al., 2008).

The differences in utilization of oncology drugs in Slovenia compared to the selected European countries are attributed to factors such as purchasing power, incidence rate of the cancer types considered in the analysis, and the allocation of resources for health. Slovenia had the lowest gross domestic product per capita according to purchasing power compared to the other selected European countries. Due to the low gross domestic product per capita of Slovenia, the country had a lower rate of utilization of the targeted oncology drugs in most cases.

Affordability of Disease-Modifying Therapies

Putrik et al. (2014a) investigated three dimensions of patient access (availability, affordability, and acceptability) to biologic DMARDs among patients with RA in all European countries (n = 46) (Putrik et al., 2014a). One proxy variable was chosen for each dimension of patient access, namely, the number of reimbursed biologic DMARDs for the dimension of availability, average annual price of biologic DMARDs for the dimension of affordability, and average score on the barriers to access to treatment with biologic DMARDs for the dimension of acceptability (Putrik et al., 2014a). The researchers developed a simple scoring system to evaluate the level of patient access to biologic DMARDs across the countries. For each of the dimensions, a score ranging from 0 to 3 was given to a country based on either an absolute number of biologic DMARDs for the dimension of availability or on the position in the quartile distribution of the variable for the dimensions of affordability and acceptability. Upon analysis, the overall access score to biologic DMARDs was reported to vary between 0 and 9 (9 indicating the best patient access), and it was observed to correlate strongly and positively (correlation coefficient = 0.86) with gross domestic product per capita (Putrik et al., 2014a).

Similarly, Péntek et al. (2017) explored the associations between patient access to biologics for the treatment of Crohn's Disease (CD) (in terms of both the dimensions of availability and affordability) with gross domestic product per capita, among 10 selected European countries. Affordability was defined as the annual cost of treatment as a percentage of gross domestic product per capita. It was observed in the correlation analysis that both the availability score (correlation coefficient = -0.88) and the affordability (correlation coefficient = -0.75) of biologics were strongly and negatively correlated with gross domestic product per capita. The authors also concluded that the wealth of a country influenced patient access to biologics for the treatment of Crohn's Disease (Péntek et al., 2017).

Strategies to Improve Access to High-Cost Medicines

High-cost medicines pose both health and economic challenges for healthcare systems. Some of the major challenges include affordability, decision-making related to the evaluation of high-cost medicines for coverage, and reimbursement and the difficulties associated with defining value for money. Health technology assessment has also become the key health policy instrument for decision-making and managing the introduction and use of high-cost medications. With well-performed health technology assessment, patients' access to cost-effectiveness can be made possible. Nevertheless, there exist disparities in health technology assessment processes among countries as illustrated in a review within Europe (Akehurst et al., 2017). The review illustrates the differences that include availability of published guidelines to support submission, timelines for decisions, and the price negotiations as part of the decision-making process. There are also differences in the health technology assessment process; some countries emphasize on disease severity and drug efficacy, whereas others focus on cost-effectiveness (Akehurst et al., 2017).

As decision makers have a significant role to allocate funds for the purchase of valuable targeted therapies, managed entry agreement like value-based pricing is a good strategy to adopt. Value-based pricing or value-optimized pricing is essentially a pricing strategy that dictates prices according to the perceived value of a product or service to a customer as opposed to the cost of the product (Shapiro and Varian, 1998). Currently, almost all targeted therapies have adopted cost-plus pricing model or cost-based pricing model, which considers the total cost involved in developing the drug and adding some amount to ensure the ability of the manufacturer to make a profit (Department for Business Innovation and Skills, 2012). Value-based pricing is gaining traction because the prices can be determined solely by patient outcomes, which include a reduction in hospitalization and associated medical care. In this context, the drug can be priced much higher than its counterparts in other classes as it lowers overall medical costs, hence providing better value for money (Gilmore, 2017).

Conclusion

Healthcare systems are under significant pressure to provide sustained access to affordable high-cost medicines. Health technology assessment and value-based pricing have the potential to improve medicine pricing regulation and accessibility to high-cost medicines. Improvements in the decision-making processes in regions like Europe have played a central role in increasing acceptance to prioritize access to high-cost medicines.

List of Abbreviations

CD	Crohn's disease
DMARD	Disease-modifying antirheumatic drug
DMT	Disease-modifying therapy
EMA	European Medicines Agency
E2 program	High-cost medicines E2 access program
EULAR	European League Against Rheumatism
HER2	Human epidermal growth factor receptor 2
PBS	Pharmaceutical Benefits Scheme
RA	Rheumatoid arthritis
USFDA	United States Food and Drug Administration

Medication Adherence

Elizabeth J. Unni, Roseman University of Health Sciences, College of Pharmacy, South Jordan, UT, United States

The World Population Prospects report that the number of older persons has increased significantly in recent years and is projected to grow by 56% between 2015 and 2030 (United Nations, 2015). Studies over a period of years have shown that age is a powerful predictor of health and the incidence of chronic diseases (United Nations, 2015). Chronic diseases are defined as "diseases which have one or more of the following characteristics: they are permanent, leave residual disability, are caused by non-reversible pathological alteration, require special training for the patient for rehabilitation, or may be expected to require a long period of supervision, observation or care" (Dictionary of Health Services Management, 1982). Chronic diseases account for 60% of all deaths in the world and the World Health Organization reports that the prevalence of chronic diseases will increase by 57% by 2020 (World Health Organization, 2002). An increase in the prevalence of chronic diseases can be translated to an increase in the number of medicines taken by individuals for a long period of time, with some patients on lifelong medicines. With the advances in medicine, many of these chronic diseases can be controlled by medicines, if the medicines are prescribed optimally, and if they are taken by the patients as prescribed.

What Is Medication Adherence?

> "Not only be prepared to do what is right himself, but also to make the patient . . . cooperate"
>
> —Hippocrates

The World Health Organization defined medication adherence as the "degree to which the person's behavior corresponds with the agreed recommendations from a healthcare provider" (World Health Organization, 2003). The US National Library of Medicine defines medication adherence as the "voluntary cooperation of the patient in taking drugs or medicines as prescribed. This includes timing, dosage, and frequency" (Definitions & Translations, 2017). Meichenbaum and Turk defined medication adherence as the "active, voluntary, and collaborative involvement of the patient in a mutually acceptable course of behavior to produce a therapeutic result (Meichenbaum and Turk, 1987). As evidenced by all the definitions of medication adherence, it is apparent that the patient plays an active role in medication adherence. The patient has to take medicines as "agreed upon," "voluntarily," and with "collaborative involvement." These words define the ultimate drive for medication adherence. The term "medication adherence" is also called "medication compliance" and is defined as taking a medicine as prescribed by a physician. This definition takes a paternalistic attitude and puts the blame on the patient for not taking the medicine. For this reason, the word "compliance" is now replaced by "adherence," which displays more shared decision making between the patient and the provider.

For patients with chronic conditions, where the medicines have to be taken for a long period of time, the healthcare providers have to develop a collaborative relationship with patients, so that the patients take an active role in their treatment and agree to take the medicines as prescribed. To conclude, when patients do not take their medicines as prescribed based on agreed recommendations with the provider, it is called medication non-adherence.

How Common Is Medication Non-Adherence?

> "Noncompliance, the invisible epidemic"
>
> —Clepper

The World Health Organization reported that among patients with chronic diseases, in developed countries approximately 50% do not take medicines as prescribed and the adherence rate is even lower in developing countries (World Health Organization, 2003). The rate of non-adherence varies among diseases and populations and is reported anywhere between 10% and 92% (Grahame-Smith and Aronson, 2002). For example, non-adherence to cardiovascular medicines was 67.53% in Asia, 54.53% in Latin America, 48.48% in Eastern Europe, 47.44% in Western Europe, 46.45% in North America, and 35.02% in Middle East (Rodriguez et al., 2013). For type 2 diabetes, the prevalence varies between 36% and 93% and for asthma it is between 40% in the United States and 78% in Iceland (Cerveri et al., 1999; Cramer, 2004). African Americans are often found to be more non-adherent than Whites among the older people in the United States (Gerber et al., 2010). Another study conducted in a large integrated healthcare system in the United States found that older people and men were better adherent (Rolnick et al., 2013). Among older adults, the rate of non-adherence varies between 38% and 57% (Sackett and Snow, 1979). In the United Kingdom, one in five patients does not take all their medicines as prescribed (Hagan, 2015). Approximately 50%–90% of patients stop taking their medicines by the end of the first year of treatment. This is observed across various diseases such as hyperlipidemia, type 2 diabetes, obesity, hypertension, and depression. As can be seen, the prevalence of medication non-adherence is large enough to warrant attention from clinicians, researchers, payers, and health policy regulators.

Why Is Medication Adherence Important?

> "Drugs don't work if patients don't take them"
>
> —Former US Surgeon General Everett Coop

There are several and varied consequences of not taking medicines as prescribed, the most significant among them being the lack of optimal clinical benefits. If the prescription is optimal and based on a chronic care plan from the healthcare provider, not taking the medicine as prescribed can result in suboptimal clinical outcomes. On one hand, this can result in an increased medication dose, which can result in increased treatment cost and potential risk of adverse effects. On the other hand, non-adherence can result in exacerbations of the symptoms which can result in increased healthcare utilization such as emergency room and hospitalization visits, in addition to lost productivity for both patients and/or caregivers. Additionally, medication non-adherence can result in disease progression and overall lower quality of life. Literature has reported that medication non-adherence has resulted in approximately 125,000 deaths per year in the United States and is responsible for 33%–69% of the medication-related hospital admissions (McCarthy, 1998; Osterberg and Blaschke, 2005). In the European Union, approximately 190,000 people die every year as a result of medication non-adherence (Cordis, 2011). A study conducted among 493,609 older people in the United States demonstrated that patients with diabetes who were non-adherent to oral hypoglycemic agents, ACEIs/ ARBs, and statins were 44.6% more likely to be hospitalized for any cause, 32.8% more likely to visit the emergency room, and 22.6% more likely to die during the follow-up period (Yang et al., 2009). The same study also demonstrated that for each class of medicine, adherence resulted in an 11.8% reduction in all-cause hospitalizations, 9.7% reduction in emergency room visits, and 6% reduction in mortality.

What Is the Financial Impact of Medication Non-Adherence?

> "Medicine is most expensive when it's not taken at all"
>
> —John Lechleiter

In the United States, medication non-adherence is called the $289 billion problem, while in the United Kingdom, it is called the £500 million problem (New England Health Care Institute, 2009; Hagan, 2015). In Canada, the total annual cost due to medication non-adherence is estimated between $687 million and $1.633 billion dollars (Iskedjian et al., 2002). The World Health Organization reports that for every additional dollar spent on adhering to a prescribed medication, medical costs would be reduced by $7 for people with diabetes, $5.10 for people with high cholesterol, and $3.98 for people with high blood pressure (Sabatte and De Geest, 2003). In the United States, the total direct cost of non-adherence for patients diagnosed with diabetes, hypertension, and dyslipidemia is $105.8 billion or $453 per adult (Nasseh et al., 2012). A study conducted among 3260 diabetes patients showed that the total medical costs were $4000 when the adherence is greater than 80% compared to $9000 when the adherence is less than 20% (Ansell, 2008). Among older adults in the United States, non-adherence to medicines associated with diabetes, heart failure, and pulmonary disease costs between $49 and $840 per patient per month (Stuart et al., 2013). The United States Congressional Budget Office reported that a 1% increase in the number of prescriptions filled by older adults results in a 0.2% decrease in overall medical spending (Congressional Budget Office, 2012). As can be seen from the literature, medication non-adherence poses a heavy economic burden to the healthcare system.

Why Are Patients Non-Adherent With Their Medications?

> "Keep a watch . . . on the faults of the patients, which often make them lie about the taking of things prescribed . . . "
>
> —Hippocrates, Decorum

Table 1 Determinants of patient adherence

Categories of reasons for medication non-adherence as identified by the World Health Organization	*Factors that determine medication non-adherence under each category*
Social/economic factors	• Family support • Family/caregiver • Social support • Social stigma of a disease • Cost of drugs/treatment • Prescription coverage from insurance/employer • Socioeconomic status • Employment status
Therapy-related factors	• Adverse effects • Patient-friendliness of the regimen • Effectiveness of the drug (objective and perceived) • Duration of the treatment • Type of drug • Organized treatment (setting, treatment plan, psychotherapy, etc.)
Patient-related factors	• Age • Gender • Marital status • Education • Ethnicity • Housing • Cognitive function • Forgetfulness • Patient's knowledge of disease and treatment • Health beliefs to both drugs and illnesses • Psychological profile • Co-morbidities and patient history (such as non-adherence in the past, past treatment failure, etc.) • Alcohol or substance abuse • Patient related barriers (such as transportation)
Condition-related factors	• Presence (or absence) of disease symptoms • Severity of disease • Clinical improvement (feeling better or disappearance of symptoms) • Psychiatric disorders • Specific disease conditions • Duration of the disease
Health system-related factors	• Barriers to healthcare access • Poor drug supply • Prescription from a specialist • Receiving unclear, multiple and conflicting information about drug administration • Provider-patient communication and relationship • Lack of efficient follow-up with patients

(Modified from Kardas, P., Lewek, P., Matyjaszczyk, M., 2013. Determinants of patient adherence: a review of systematic reviews. Front. Pharmacol. 4, 91.)

Patients do not take their medicines for a multitude of reasons. The past four decades of research on medication adherence has identified the various reasons that contribute toward medication non-adherence. With the multitude of factors that influence medication adherence and to ensure that the blame for non-adherence is not completely placed on the patient, the World Health Organization organized the reasons for medication non-adherence into five categories: (1) Social/economic factors, (2) Therapy-related factors, (3) Patient-related factors, (4) Condition-related factors, and (5) Health system-related factors (World Health Organization, 2003). Kardas et al. (2013) conducted a review of systematic reviews to identify the various factors that can be included in each of the five categories defined by the World Health Organization report (Kardas et al., 2013). The team identified 771 individual factors that influence medication adherence and **Table 1** describes the results from this review.

Several studies have taken effort to determine the effect of the individual factors on medication adherence. However, there is no evidence as to the hierarchical nature of these factors. All these factors are important and vary depending on the patient, disease, and treatment. While some of these factors can have a direct and relatively easy intervention, certain others will need more coordinated care between the providers such as physicians, pharmacists, and nurses to improve medication adherence. For example, factors such as adverse effects or regimen complexity can be addressed effectively in a time-efficient way to improve adherence. Other factors,

such as affordability of medication or transportation issues, can also be addressed in a timely manner. However, factors that are related to beliefs of patients about the drug, disease, healthcare system, provider, etc. can be more difficult to be addressed and need more time and resources to be resolved.

Another important factor to keep in mind while addressing non-adherence is comorbidity and the way adherence varies across different disease conditions and treatments for the same patient. Also, the reasons for non-adherence can differ for the same patient across different disease conditions and across time. In other words, a patient can be adherent to one medication and be non-adherent with another medication. For example, while being adherent with asthma medicines due to the symptomatic nature of the disease, can be non-adherent with diabetes insulin injections due to fear of needles. Yeaw et al assessed persistence and adherence to drug therapy in six chronic conditions using a claims database and reported varying rates of adherence for the same patient (Yeaw et al., 2009). Thus, a healthcare provider's role is to understand the patient as a whole so that the factors that trigger non-adherence at various situations can be assessed and appropriate interventions can be implemented.

Lack of adequate communication between patients and healthcare providers, especially physicians, is a major factor that can lead to medication non-adherence. Studies have reported that either patients do not understand what they are expected to do or they misunderstand what they have been asked to do. This issue adds up when the patient does not have adequate health literacy, the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions (Ratzan and Parker, 2000). While 35% of adults do not have adequate health literacy in the United States, the rate of inadequate health literacy is 42% in England, and 47% in the European Union (Kutner et al., 2006; Department for Business Innovation and Skills, 2012; Sorensen et al., 2015). Additionally, recent studies have shown the moderator effect of health literacy in the relationship between patient beliefs and medication adherence (Unni and Shiyanbola, 2016). In other words, while the relationship between patient beliefs and medication adherence was strong in patients with adequate health literacy, it was almost non-existent in patients with inadequate health literacy. Thus, assessing patients' health literacy, then communicating and developing interventions based on their health literacy can be a step toward better medication adherence.

Efforts have been taken to simplify and understand the complex medication non-adherence behavior by developing various taxonomies. A recent effort by the "Ascertaining Barriers for Compliance (ABC) project by the European Consensus meeting on the taxonomy and terminology of patient compliance" mainly classified adherence on a treatment timeline as adherence happening at initiation, implementation, and discontinuation (Vrijens et al., 2012). Initiation is defined as the moment at which the patient takes the first dose of the prescribed medicine; implementation is the extent to which a patient's actual dosing corresponds with the prescribed dosing regimen; and discontinuation occurs when the patient stops taking the prescribed dosing regimen. Between the prescription initiation and discontinuation, steps have to be taken to promote and manage adherence and it includes patients, social support (including family and caregivers), providers, community, and healthcare settings. Persistence is the length of time between initiation and discontinuation; the time between discontinuation and end of prescribing time denotes the non-persistence to therapy (Vrijens et al., 2012). Non-adherence at initiation is often referred to as primary medication non-adherence. Primary medication non-adherence occurs when a new medication is prescribed for a patient, but the patient does not obtain the medication or an appropriate alternative within an acceptable period of time after it was prescribed (Adams and Stople, 2016). A recent literature review reported that primary medication non-adherence ranges from 1.94% to 75% with a non-weighted average of 20.3% (Adams and Stople, 2016). This rate is often higher at 28% for new prescriptions, especially for chronic diseases such as hypertension, hyperlipidemia, and diabetes (Fischer et al., 2010). While continuous efforts are in place to increase the adherence at the stages of implementation and discontinuation, it is imperative to keep an eye on the stage of initiation too.

An earlier classification of adherence was based on the reasons for non-adherence as intentional and unintentional non-adherence. When non-adherence happens due to missing or altering doses to suit one's needs, it is known as intentional non-adherence; when non-adherence happens due to forgetfulness or cost issues it is known as unintentional non-adherence (Cooper et al., 1982). Examples of intentional non-adherence include stopping medicines due to side effects, thinking medication is not effective, omitting medicines if not feeling well, altering dosing for convenience, stopping medicine to see if it is still needed, and being careless about taking medicines as prescribed. Examples of unintentional medication non-adherence include forgetfulness, trouble opening containers, trouble swallowing pills, trouble reading labels, inability to afford medicines, and running out of medicines (Vik et al., 2005). Wroe discussed how intentional non-adherence is an active process whereby the patient weighs the various pros and cons of taking medicines (as suggested by Donovan and Blake) and decides whether or not to adhere with the medicines (Wroe, 2002; Donovan and Blake, 1992). Horne et al., in their beliefs about medicines theoretical framework explained how patient's beliefs in the necessity of medicines and their concerns about their medicines can influence this value proposition in the mind of patients (Horne et al., 1999). When the necessity beliefs about medicines outweigh the concern beliefs about medicines, the patient will be adherent and when the reverse occurs, the patient will be non-adherent. The necessity beliefs are statements such as "My health, at present, depends on my medicines" and concern beliefs are statement such as "I sometimes worry about the long-term effects of medicines." These beliefs often arise from patients' experiences about both medicines and illnesses, either personal or what they have observed in other patients. Unintentional non-adherence, on the other hand, is a more passive process where the patient wants to take medicines but does not due to reasons such as forgetfulness.

Forgetfulness is one of the reasons that is commonly attributed to non-adherence and is considered as unintentional non-adherence. Approximately 24% of patients who are non-adherent report forgetfulness as the reason for non-adherence (Boston Consulting Group, 2003). A recent survey in the United Kingdom reported 65% of the patients reporting forgetfulness as the reason for non-adherence (Hagan, 2015). Several interventions such as pill boxes and reminders were developed to address this reason for non-adherence. However, some recent studies have cast doubt on the unintentional nature of forgetfulness (Unni and Farris, 2011;

Gadkari and McHorney, 2012). These studies have shown a significant relationship between concern beliefs about medicines and unintentional non-adherence, concluding the possibility of overestimation of forgetfulness as unintentional non-adherence. In a study of breast cancer patients, Atkins and Fallowfield commented that "based on the veracity of responses given by patients, there was a possibility that patients found it easier to report 'forgetting' to take tablets than the less socially desirable admission that they chose not to take them" (Atkins and Fallowfield, 2006). Thus, when patients without any evident cognitive issues report forgetfulness as the reason for non-adherence, asking them about their underlying concerns about medicines can be a proactive way to promote medication adherence.

What Are the Theoretical Models That Explain Medication Adherence?

> "Theories without facts may be barren, but facts without theories are meaningless"
>
> —Kenneth Boulding

Medication adherence is a complex phenomenon with several interwoven factors that determine adherence. The patient, the disease, the treatment, society, the environment, and the healthcare system (including the providers), all play a major role in defining medication adherence. Thus, understanding the theoretical models that explain medication adherence becomes significant. Several models have been developed to explain medication adherence. The most commonly used theoretical models for improving medication adherence are Social Cognitive Theory, Health Belief Model, Transtheoretical Model, and Common Sense Model of Self-Regulation. A brief summary of the frequently used models is provided below. Though the models were originally developed for explaining health behavior, not necessarily medication adherence, the model descriptions below will use medication adherence as the healthcare behavior.

Health Belief Model (HBM): The HBM (Rosenstock, 1990) is based on the value expectancy theory where a health behavior, such as adherence, will be based on the balance between the desire to get well (value) and the belief that taking medicines will help in getting well (expectancy). The various components of the model are; perceived susceptibility (patient's perception of their risk of contracting the condition), perceived severity of the condition, perceived benefits of taking the medicines, and perceived barriers in taking the medicines (such as cost). Patients often balance all these perceptions in their mind to determine whether they want to adhere with medicines. These perceptions are also influenced by the cues to action such as symptom exacerbation and other demographic and sociopsychological variables such as age, gender, personality, knowledge, etc.

Theory of Reasoned Action (TRA) and Theory of Planned Behavior (TPB): According to the TRA (Ajzen and Fishbein, 1980), the proximal determinant of a behavior such as adherence is the "intention to adherence." The intention in turn is determined by the attitude to the behavior (beliefs about the outcomes from the behavior) and subjective norm (how important is this behavior to significant people in the patient's life and the patient's motivation to comply with those people). The TPB (Fishbein and Ajzen, 1975) was a modification of the TRA which added perceived behavioral control (the patient thinks they can actually do the behavior) to the model as a determinant of both intention and behavior.

Self-Efficacy Theory: The Self-Efficacy Theory (Bandura, 1997) postulates that a patient's decision to adhere with the medicines will depend on the patient's beliefs in their ability to take the medicines as prescribed by the healthcare provider. These beliefs are further influenced by their previous experiences in adhering with medicines, the success of the previous experiences, urging by significant others in adhering, and how the patient infers outcomes from the adherence behavior.

Social Cognitive Theory (SCT): The SCT includes a range of theoretical concepts and serves as a framework for understanding and implementing both organization and individual approaches to behavior change (Bandura, 1998). The theory incorporates cognitive, emotional, and behavioral understanding of behavior change. The major constructs in the SCT are environment (factors physically external to the patient), situation (patient's perception of the environment), behavioral capability (knowledge and skill to perform a behavior), expectations (expected outcomes from a behavior), expectancies (value of the expected outcome), self-control (how well the patient can regulate his goal-directed behavior), observational learning (learning a behavior by watching the actions and outcomes from another person's behavior), reinforcements (responses to a behavior that will either facilitate or impede the reoccurrence of that behavior), self-efficacy (patient's confidence in performing a behavior), emotional coping responses (how a patient deals with emotional stimuli), and reciprocal determinism (the dynamic interaction between the patient, the behavior, and the environment in which the behavior is performed). The SCT explains the dynamics of individual behavior which is quite significant in medication adherence. Each construct in this theory is quite dynamic when it comes to medication adherence. Thus, understanding the desired behavioral outcome, which is medication adherence, and then identifying the various constructs from the theory that is relevant to the patient at each point of time in their life should be considered while communicating with the patients and developing interventions. For example, while behavioral capability is essential when diagnosed with a new condition, self-control may be important later in the diagnosis.

Transtheoretical Model (TTM): The TTM conceptualizes the process of intentional behavior change, or in this case, intentional medication adherence (Prochaska and Diclemente, 1983). The model defines the various stages of change, with each stage having a temporal dimension, and the processes of change. The first stage, pre-contemplation, is the stage when the patient is not ready to adhere with their medicines in the next six months. At this stage, patients are either uninformed or under-informed about the consequences of non-adherence, or did not have positive previous experiences with medication adherence. The second stage, contemplation, is the stage when the patient is getting ready to be adherent with their medicines in the next six months. In this

stage, they are aware of the pros and cons of being adherent with the medicines. In the third stage, preparation, the patient is ready to be adherent with their medicines in the immediate future (within a month). The fourth stage, action, is when the patient is actually taking the medicines for the past six months. The fifth and last stage, maintenance, is when the patient has been taking medicines for more than six months. The processes of change are the activities that patients use to progress through these stages. The various processes are: consciousness raising (increasing awareness to encourage medication adherence), dramatic relief (experiencing the negative emotions that go with the consequences of medication non-adherence), self-reevaluation (realizing that medication adherence will help in creating a better self-identity), environmental reevaluation (realizing the positive impact that adherence can create in the patient's proximal social and physical environment), self-liberation (making a firm commitment to be adherent), helping relationships (social support), counterconditioning (learning to be adherent with medicines), contingency management (giving either rewards for adherence or consequences for non-adherence), stimulus control (removing cues for unhealthy behavior such as non-adherence), and social liberation (change in social norms to support medication adherence).

Common-Sense Model of Self-Regulation (CSM): According to this model, patients use their "lay" beliefs about their illnesses to guide their decisions on coping with the illness, in this case, being adherent with medicines (Leventhal et al., 1980). The model describes various components of the illness representations, both cognitive and emotional: (1) identity—the label of the symptoms that the patient believes are related to the illness; (2) cause—personal ideas about the etiology of the illness; (3) timeline—how long the patient believes the illness will last; (4) consequences—beliefs about the expected effects and outcomes of the illness; (5) cure/control—expectations about the course and treatment efficacy; (6) illness coherence—understanding the meaning of the illness; and (7) emotional representation—emotional response to the illness such as worry, depression, anger, anxiety, and fear. Based on the illness representations, patients will decide to either take or not take the medicines.

Horne's Extended Self-Regulatory Model (ESRM): The ESRM is an extension of the Common Sense Model, wherein the cognitive and emotional responses to the treatment by patients were added to their illness perceptions to determine the adherence behavior of the patient (Horne and Weinman, 2002). Similar to patient's perceptions about their illness, they also have cognitive and emotional responses to treatment. The cognitive responses to treatment are often classified as necessity beliefs in treatment (perceptions of personal need for treatment) and concern beliefs in treatment (concerns about a range of potential adverse consequences). Thus, when there is a health threat in the form of symptoms, patients use their illness perceptions, beliefs about medicines, and their emotional responses to both medicines and illnesses to appraise the situation. Based on the appraisal, they will decide on the coping procedure, which is medication adherence.

Information-Motivation-Behavior Skills Model: The Information-Motivation-Behavior Skills Model has three major constructs to guide complex health behaviors such as medication adherence (Fisher and Fisher, 1992). This includes information (basic knowledge about the disease and the effective strategies including medicines for its management), motivation (personal attitudes toward adherence, perceived social support for adherence, and the perception of how others with this condition will behave), and behavioral skills (patient has the specific skills necessary to perform the adherence behavior). According to this model, information, motivation, and behavioral skills have a direct influence on the behavior, which is medication adherence in this case. Additionally, behavioral skills are also influenced by information and motivation.

How Is Medication Adherence Measured?

> "Every line is the perfect length if you don't measure it."
>
> —Marty Rubin

With the high rate of non-adherence and the various factors that lead to medication non-adherence, it is important to measure medication adherence. For clinicians, measuring adherence is important so that effective treatments are not discarded when the reason the treatment was not working was because of non-adherence. Additionally, knowing the level of adherence and the reasons for non-adherence can assist clinicians in implementing interventions to improve medication adherence. However, measuring medication adherence can be quite challenging, depending on the goal for measurement and the definition of medication adherence. With different definitions and measurements, comparing adherence across different studies, diseases, and populations is also difficult. Thus, the clinician and/or researcher should have a clear goal for the measurement so that appropriate measurements can be used.

The measurements are mainly divided into two categories: objective and subjective (Vik et al., 2004). Objective measures include measures such as direct biochemical measures, electronic monitoring, pill counts, and secondary database analysis. While some of these measures will objectively evaluate whether the patient actually consumed the medicines (such as direct biochemical measures and electronic monitoring), other measures, such as pill counts and secondary database analysis will measure whether the medicines were picked up by the patient either from the pharmacy or the pill bottle. The major disadvantages with the direct biochemical and electronic measures are the clinical intrusion, cost, and the difficulty in doing it in a regular clinical setting. Using pill counts and secondary database analyses are rather inexpensive and easy to use, however the clinician or researcher cannot determine whether the medicine was actually consumed or not. Additionally, while objective measures quantify the level of medication adherence, they cannot determine the reasons for non-adherence, making it difficult to implement appropriate interventions to improve adherence. The subjective measures on the other hand can overestimate adherence due to self-reporting bias, but can point to the reasons for non-adherence or barriers to adherence. Though overestimation of adherence can be an issue with subjective measures,

Table 2 List of adherence measurements

Type of measure	*Specific measure*	*How is it measured?*
Objective Measures		
Direct measures	Measurement of the drug or its metabolite concentration in body fluids	
Electronic monitoring	Medication Event Monitoring System	
Secondary database	Medication Possession Ratio (MPR)	Days' supply obtained/refill interval or fixed interval
	Proportion of Days Covered (PDC)	Days' supply obtained/number of days between the first fill of the medication during the measurement period and the end of the measurement period
	Continuous, Multiple Interval Measure of Medication Acquisition (CMA)	Cumulative days' supply obtained over a series of intervals/total days from the beginning to the end of the time period
	Continuous, Multiple Interval Measure of Medication Gaps (CMG)	Cumulative days without any medication over a series of intervals/total days from the beginning to the end of the time period
Pill counts	Pill counts	(Number of dosage units dispensed − number of dosage units remained)/(prescribed number of dosage unit per day × number of days between 2 visits)
Subjective Measures		
Patient diaries	Self-reported tool on how patients follow the drug regimen	
Patient interviews	Traditional interview	Clinicians interviewing patients to assess the level of adherence and the reasons for non-adherence
	Motivational interviewing	Interviewing techniques to assess the level of adherence, determine the reasons for non-adherence, and make interventions when non-adherence is identified
Self-reported questionnaires/scales	Morisky Medication Adherence Scale (8 items)	Classifies patients as low, medium, and high adherents
	Brief Medications Questionnaire (9 items)	Medication taking behavior and barriers to medication adherence
	Self-Efficacy for Appropriate Medication Use Scale (SEAMS, 13 items)	Self-efficacy in chronic disease management
	Medication Adherence Reasons Scale (MAR-Scale, 20 items)	One global item of medication adherence and 19 specific reasons for non-adherence in the past seven days
	Adherence Estimator (3 items)	Screening instrument for predicting medication non-adherence

interventions can be implemented to improve the adherence of patients who self-report as non-adherent. A list of the most commonly used adherence measures is described in **Table 2**.

Since every measure has its own advantages and disadvantages, defining the goal of the measurement can aid in selecting the appropriate measurement. For example, if the goal of the measurement is to quantify adherence after the implementation of a new treatment protocol, objective measures such as secondary database analysis can be adequate. However, if the goal of the measurement is to develop a tailored intervention program to improve adherence, a subjective measure can be more useful. If the clinician is trying to evaluate the level and reasons for non-adherence, a patient interview will be sufficient. However, if the goal is to understand how patients are taking medicines and what the barriers are in taking medicines, a self-reported questionnaire will be appropriate. Additionally, when needed, it is apt to use multiple measures such as a pill count followed by a self-reported questionnaire.

How Can Medication Adherence Be Improved?

> "Increasing the effectiveness of adherence interventions may have a far greater impact on the health of the population than any improvement in specific medical treatments"
>
> —Haynes et al.

Being a complex phenomenon with significant clinical consequences and enormous financial impact, several interventions are available to improve medication adherence. For a patient to be adherent with medications, especially the medicines for chronic conditions, the patient has to acquire new coping strategies including new behaviors, new routines, and learning to live with a chronic illness. Therefore, most patients will require some kind of intervention to improve their adherence with medicines. The World Health Organization recommends the use of multimodal, targeted, and tailored interventions for efficiency and effectiveness (World Health Organization, 2003). A comparative effectiveness review of the various interventions reported that interventions range from low-cost, low-intensity telephone, and mail interventions to intense interventions such as care coordination, case management, and care collaboration (Viswanathan et al., 2012). The often-reported interventions are: blister

Table 3 Interventions often used in improving medication adherence

Type of intervention	*Strategies used for each interventions*
Behavioral intervention—to change the patient's behavior toward treatment	• Cognitive behavioral interventions including telephone follow-ups and home visits • Medication management programs—providing planning and support such as discharge interventions • Employing prompts or cues for medication taking and linking patient's daily routines with medication taking
Educational interventions—to increase patient's knowledge and beliefs about medicines and illnesses	• Education programs about the disease or treatment • Self-management skills training • Managing side effects from the treatment
Integrated care interventions (case management)—collaboration within and between healthcare providers to improve adherence, especially in patients with complex health problems	• Collaboration between physicians, pharmacists, nurses, case managers, and payers • Often can reduce the risk of hospitalization and length of stay in hospitals
Self-management interventions—enabling the patient to manage symptoms, treatments, lifestyles, and psychosocial, cultural, and spiritual consequences of chronic diseases	• Goal-setting • Self-monitoring for symptoms, lifestyle, adherence, etc. • Access to own health records • Stimulus control and corrective feedback • Creating social support • Commitment enhancement, reinforcement, and relapse prevention • Support via technology such as telemedicine, web-based interventions, and cellphones/text messaging
Risk communication interventions—to address the patient's perceptions about the risk associated with taking the medicines as prescribed	• Decision aids—education tools that will present the risk information to enable the patient in shared clinical decision making • Often recommended to be used as part of a complex intervention
Packaging and daily reminders—to remind patients to take their medicines as prescribed	• Reminder phone calls • Text messages, pagers • Interactive Voice Responses (IVR) system • Video telephone calls • Pill boxes • Blister packaging

packaging; reminders; risk communication; case management; counseling using a software-based telephone; collaborative care by telephone or telephone and in-person; decision aids; face-to-face education with a pharmacist; education and behavioral support by telephone, mail, and/or video; education and social support; health coaching; pharmacist-led multi-component interventions; patient access to medical records; provider access to patient adherence data; self-management; shared clinical decision making; telemonitoring, and using a virtual clinic. While 50% of interventions were targeted at multiple agents (such as patients, caregivers, providers, and health system), 40% were targeted only the patient. Also, half of the interventions were delivered by a pharmacist, physician, or nurse, and also had some type of face-to-face interaction. **Table 3** provides a snapshot of the various interventions used to improve medication adherence.

Of the various interventions, the most consistent for the most improved medication adherence are educational interventions and case management approaches (Viswanathan et al., 2012). However, these approaches were not the best for hypertension, hyperlipidemia, myocardial infarction, and diabetes. Other interventions that are promising are reminders and a pharmacist-led multicomponent approach (Viswanathan et al., 2012). For clinical conditions such as depression and diabetes, collaborative care was the most effective (Viswanathan et al., 2012). Reducing out-of-pocket expenses can improve medication adherence at a moderate level, especially in cardiovascular conditions (Viswanathan et al., 2012). Evidence has shown that targeting interventions at patients and at the healthcare team can be more effective (DeBusk et al., 1994). Shared decision making between a patient and a non-physician clinician had better improvement in adherence, and the adherence lasted up to two years (Wilson et al., 2010). Similarly, patients given a decision aid to help them decide whether to take statins to lower the risk of cardiovascular diseases had better adherence than patients given the usual care. Incorporating patient preferences through shared decision making can have a positive impact in increasing medication adherence (Viswanathan et al., 2012).

A meta-analysis of the interventions to improve medication adherence reported a statistically significant moderate effect size of 0.301 for treatment versus control comparisons, 0.533 (statistically significant) for treatment group pre- vs. post-intervention comparison, and 0.011 (statistically insignificant) for control group pre- vs. post-intervention comparison. The effect size of adherence interventions was 0.211 for underrepresented racial/ethnic groups and 0.33 for older adults (Conn et al., 2016). An effect size of 0.2 or less is often considered as a small effect from the interventions, 0.5 and higher as a moderate effect and 0.8 and above as a strong effect. However, the translation of this improvement in medication adherence to clinical outcomes and quality

of life outcomes is not very evident. The meta-analysis reported that the face-to-face delivery of interventions was more effective, especially when the goal is to change the patient's knowledge, attitudes, or beliefs about medicines. Other effective interventions reported by the meta-analysis are behavior-based interventions such as employing prompts or cues for medication taking and linking the patient's daily routines with medication taking. The authors postulate that, as they are ongoing, behavior-based interventions are more successful compared to educational interventions, which happen less frequently. The unsuccessful interventions reported by the meta-analysis include asking patients to self-monitor their symptoms and medicine taking behaviors, teaching patients about managing side effects, giving patients' feedback about their adherence, goal-setting, and increased provider communication. Finally, the effectiveness of the interventions was not related to demographics such as age, gender, or racial/ethnic composition.

Who Are the Stakeholders in Improving Adherence?

"If you think about how healthcare is delivered, it's on an ad hoc basis. Someone comes into a hospital, someone comes into a pharmacy, someone comes into a doctor. But beyond those touchpoints, the patients are on their own. There's no real continuity of care."

—Christopher A. Viehbacher.

Patients are an important stakeholder in the world of medication adherence. They are the ones experiencing the illness, having their routines altered, being subjected to the side effects from the medicines, and having emotional responses to all these situations. Family and caregivers along with society also play an important role in adherence. Providing adequate social support and providing the right social and physical environment is equally important in improving medication adherence. Patient support groups and patient organizations can also work alongside patients to ensure that the voices of patients are heard. Physicians who work with patients from the moment of diagnosis play a significant role in medication adherence. Communication between the physician and patient, developing a trusted relationship, encouraging patients to be a part of the shared clinical decision making, and developing an integrated care network for the patient will all work toward improved medication adherence. Pharmacists, with their knowledge of medicines and developing medication management plan for optimized clinical outcomes, are also significant stakeholders. Additionally, due to their accessibility to patients and being the last point of contact before patients go home with medicines, pharmacists should counsel and encourage patients for improved medication adherence. Nurses with their clinician role, and opportunity to interact with patients before and after their physician appointment, can be in the ideal place to assess the levels of medication adherence and to determine the reasons for non-adherence, if non-adherence exists. They can also play a significant role in educating patients about their illness, medicines, side effects from medicines, and encouraging them to ask questions. Psychologists can also play a significant role in adherence improvement. Since medication adherence can be considered as a behavior that needs modification, psychologists can assist in developing tailored intervention programs for each patient depending on their social context, personality, and needs. Finally, pharmaceutical industries can play a significant role in the overall improvement of adherence. Developing drugs with fewer side effects, less complex regimens, and with easier administration can promote adherence. Additionally, offering patient assistance programs for those patients who cannot afford their medicines can also improve medication adherence.

What Are Some Practical Strategies to Improve Medication Adherence at the Patient Level?

"We have to be very careful not to blame the patients. A lot of the conversation [around patient engagement] has been, how do we get them to do stuff? To me, that's not engagement. "

—Victor Montori.

Consider medication non-adherence as a possibility with each patient. With the rate of non-adherence varying between 10% and 92% and with 50% and 90% of patients stopping medicines within the first year of treatment, even after a cardiovascular event, non-adherence should be in the mind of every provider. Even when the patient is adherent with one medicine, they may be non-adherent with another medicine. When a therapy is not working, thinking about non-adherence before changing the drug/dose can be the right step.

Communicate with the patient about non-adherence and document the level of adherence and reasons for non-adherence in their records. The physician or pharmacist can ask these questions directly, use a self-reported scale before the visit, or they can ask the patient to keep a diary, especially with new medicines and those with too many side effects/fear of side effects. Clinicians can use empathetic communication styles to allow patients to open up about their medicine taking habits. Once non-adherence is identified, clinicians should investigate the patient's reasons for non-adherence. A scale such as the Medication Adherence Reasons Scale can be a comprehensive tool to identify the reasons for non-adherence (Unni et al., 2014). While identifying the reasons, clinicians need to put themselves in patient's shoes and be receptive to the answers from them. If a patient is non-adherent due to lack of beliefs in the medicine (in spite of a clinician spending an hour explaining about the medicines), the clinician needs to remain empathic. The patient's environment with their families, colleagues, and friends, and their experiences all play a major role when they decide not to be adherent.

Identify a solution that is targeted and tailored for the patient based on their situation, beliefs, and experiences. Take input from patients in developing these solutions so that they are co-authors in the prescribed treatment regimen. If needed, include the patient's family and caregivers in the process as social support can increase medication adherence. Develop a system to communicate with patients in between clinic visits. This can encourage patients to ask questions and have their concerns taken care of by a healthcare professional. Additionally, this can also increase the self-efficacy of patients in following the treatment regimen as planned.

Develop an integrated care network of healthcare providers for each patient that can include the primary care physician, pharmacist, nurse, social worker, psychologist, and any specialist as needed. With increased communication and reinforcement from each provider about the illness, medicines, and the need for medication adherence, a safe environment can be created for patients to adhere with their medicines.

Conclusion

Medication adherence or non-adherence is a complex behavior. Non-adherence behavior is not black and white or right and wrong. A patient is making a decision based on many factors about initiating and continuing medicines. As a result, patients, especially when taking medicines for chronic conditions, need to be supported and not blamed. In other words, we need to reengineer the healthcare system to meet these challenges. The current system does not allow adequate time for providers to encourage communication with patients. Patients with complex conditions and low health literacy need more time with their providers. Also, adherence behavior is not static; it changes and evolves over time based on the needs and beliefs of the patient. For example, a forty-year-old woman diagnosed with high cholesterol may be non-adherent due to her busy schedule and strong "I can manage it with lifestyle change" attitude. However, the same patient in her fifties may have different beliefs and may be ready for adherence, but may also need coaching on the illness as well as the medicines. Moving into her sixties, with other comorbidities and retirement, her beliefs and adherence patterns can change again. Thus, healthcare practitioners have to develop a system to capture the beliefs and adherence patterns of patients over the years to better understand patients and assist them with adherence. In spite of the best prescription, the best discharge plan, and the best packaging, if a patient decides not to take their medicines, it is a waste of healthcare resources and a source of frustration to providers. Thus, every provider should consider their patients' adherence as the top priority in every visit and communication.

Aging Populations and Medicine Use: A Sociological Approach

Shubashini Gnanasan*, Mahmathi Karuppannan*, Maryam Farooqui†, *Universiti Teknologi MARA, Puncak Alam, Selangor, Malaysia; †Unaizah College of Pharmacy, Qassim University, Saudi Arabia

Background

The world's graying population is growing steadily. Declining fertility rates and significant improvements in life expectancy are the major causes of this phenomenon. Globally, life expectancy at birth has risen from 67.2 to 70.8 years between 2000–05 and 2010–15 (UN, 2017). It is projected to rise by 6 years (from 71 to 77 years) between 2010–15 and 2045–50.

In 2017, the number of people aged 60 or above was 962 million. This is expected to be more than double by 2050 and more than triple by 2100, rising from 2.1 billion in 2050 to 3.1 billion in 2100. The number of people aged 80 or over is expected to be triple by 2050, from 137 million in 2017 to 425 million in 2050. By 2100, it is expected to increase to 909 million, nearly seven times it's value in 2017 (UN, 2017). In spite of decline in fertility rates and higher life expectancy, the increasing number of older people in developed countries is also partly due to the improvements in curative medicine.

Longer life provides the opportunity to reconsider what the life of older people might consist of and people are rethinking ways to spend these extra years. A remarkable event occurred in Malaysia in May 2018: a 93-year-old became the seventh prime minister and is considered to be the oldest prime minister in the world. This sets an example of what an older person above the age of 80 years can achieve. The ability to carry on with these extra years of life; however, heavily depends on their health status and does not necessarily mean that older people are living healthy lives. People are living longer but with more disease.

Aging is commonly associated with an increased risk of multimorbidity. The increasing prevalence of medical conditions associated with old age is a major challenge. Although this is also prevalent in other age groups, it is much higher in older age groups, affecting 65% of people aged 65–84 years and 82% of people aged at least 85 years (Barnett et al., 2012).

In 2010, the Global Burden of Disease (GBD) estimated 23.1% of the total disease burden [574 million of the 2490 million disability-adjusted life years (DALYs)] is attributable to disorders in people aged 60 years and older (Prince et al., 2015), the leading causes being cardiovascular diseases, malignant neoplasms, chronic respiratory diseases, musculoskeletal diseases, mental and neurological disorders, infectious and parasitic diseases, unintentional injuries, diabetes mellitus, digestive diseases, respiratory infections, and sense organ diseases. Globally, in 2016, three disorders dominated mortality in this age group: ischemic heart disease, stroke, and chronic obstructive pulmonary disease (WHO).

The GBD in older people is projected to increase more or less in line with the increase in the older population, consistent with population aging being the most important driver of the chronic disease epidemic (Mathers and Loncar, 2006). The largest increases in disease burden will occur for those disorders that are strongly age-associated (dementia, stroke, COPD, and diabetes).

The number of people with dementia worldwide will increase sharply, driven by worldwide patterns of population aging; 44.4 million people had dementia in 2013, with numbers nearly doubling every 20 years to 75.6 million in 2030 and 135.5 million in 2050 (ADI). People with dementia have the highest multimorbidity. In Scotland, people with dementia have 4.6 additional chronic illnesses (Guthrie et al., 2012). In the United States (US) primary care, people with dementia on an average had four additional chronic medical disorders—82% had hypertension while 39% had diabetes mellitus—and were prescribed about five drugs (Schubert et al., 2006).

The Health of Older Adults

The health of older adults can be conceptualized in four categories on a population health continuum (Tkatch et al., 2016):

Healthy and Active

These older adults have no chronic health conditions or disease and therefore staying healthy and active is critical to them.

At Risk but Healthy

Older adults in an "at risk" but healthy group are managing a chronic condition (such as hypertension) and their focus is to stay healthy, prevent the progression of their condition, and prevent future chronic conditions.

Coping with Disease

Older adults who have multiple conditions or diseases and their focus is on slowing the progression of these conditions and/or reversing the damage.

Very Ill

Older adults who have severe medical episodes and are in need of constant or regular medical interventions.

Tkatch and team suggested a holistic perspective on health that includes a more objective construct such as physical functioning and the more subjective constructs of psychological well-being, social well-being, and self-rated successful aging to provide a more accurate health description and a comprehensive perspective on the quality of life of older adults (Tkatch et al., 2016).

Physical Functioning

Physical functioning relies primarily on objective determinants and outcomes as it relates to issues that result as a function of a combination of age, illness, and mobility. The objective measures of age and chronic illness are particularly relevant as physical decline occurs. For example, some physical limitations of older adults are characterized by the inability to walk a quarter of a mile, stand for 2 h, stoop, bend or kneel, and lift or carry something more than 10 pounds (equal to bags of groceries). Reduced physical functioning also includes activities of daily living (ADLs), for example, bathing, dressing, etc., and risk of a fall. Age, minority status, being female, lower education, depressive symptoms, and illnesses such as diabetes, arthritis, and heart failure are examples of the characteristics of those with physical decline. Outcomes of poor physical functioning include continued decline, falls, worse mental health, and increased mortality. Sensory impairment is another aspect of physical functioning limitations. For older adults, the decline of hearing and vision has a significant impact on their well-being and could increase risk of falls, depression, cognitive impairment, and loneliness (Tkatch et al., 2016).

Psychological Well-being

Psychological well-being is a multidimensional construct that personifies the human capacity to continue to grow, adapt to our environment, and evolve throughout the aging process. For older adults in particular, psychological well-being is characterized as the ability to deal with life situations, to have and maintain positive and close relationships, self-acceptance of both self and others, and autonomy. Predictors of high psychological well-being for older adults include social support, physical activity, spirituality, and higher socioeconomic status. Conversely, depression, stress, and anxiety are predictors of low psychological well-being. Outcomes of high psychological well-being include lower rates of cognitive decline, higher levels of resilience, and greater life satisfaction. Notably, high psychological well-being is a key factor in successful aging and reduced mortality rates for both physically healthy and unhealthy older adults (Tkatch et al., 2016).

Social Well-being

Social well-being has been defined as the relative ability to deal with social challenges and how well one functions in the social world. Social integration, social contribution, social coherence, social actualization, and social acceptance are the five major

components of social well-being. Social well-being has a significant impact on the health of older adults, with higher levels of social well-being related to lower levels of cortisol and inflammatory factors that contribute to a number of diseases including cardiovascular disease. Aging has an implication on one's social networks and social roles whereby some of these changes enhance one's social well-being and some detract from it.

Social relationships are an important indicator of quality of life, with those who have negative social relationships reporting worse quality of life independent of disease status. Close knit family ties have particular relevance for the well-being of older adults. Negative social factors that reduce the social well-being of older adults include loneliness and social isolation. Loneliness can result from a feeling a loss of meaning in life, lack of independence, and loss of loved ones. Social support is also a key influence on the social well-being of older adults. Among older adults, high levels of social support are associated with lower stress and better mental and physical well-being (Tkatch et al., 2016).

Medicine Use

Aging is often associated with a decline in organ function. Physiological changes that occur while aging affect pharmacokinetics (what the body does to a drug) and pharmacodynamics (what a drug does to the body). Changes that occur in absorption, distribution, metabolism, and elimination of drugs cause reduced volume of distribution for some drugs, slower drug metabolism, reduced renal clearance of many drugs, and slower gastric emptying. Additionally, sensitivity to drugs also increases and necessitates dose reduction of many medicines to avoid toxicity (Lucas, 2011).

Older people, however, consume more medications than any other age group. In the US, approximately 36% of patients aged 65 years or older are prescribed five or more drugs (Qato et al., 2016). Population-based studies conducted in the United Kingdom (UK) revealed that people aged more than 65 had a dramatic increase in the total amount of medication within 20 years (Gao et al., 2018). The type of medications commonly used by older people and seen to be increasing are statins, antiplatelets, NSAIDs, antihypertensives and proton pump inhibitors, particularly simvastatin, aspirin, lisinopril, and omeprazole (Qato et al., 2016). Additionally, multivitamin or mineral supplements, especially omega-3 fish oils, vitamin D, and coenzyme Q10; and calcium were the most commonly used supplements.

There has also been a global upsurge in the use of complementary and alternative medicine (CAM) among those aged 50 years and above (NIH, 2011). It has been claimed that CAM offers a safer approach to common health conditions for the elderly, strengthening their body's own defensive and healing abilities (Eliopoulos, 2006). CAM use among patients with several chronic conditions such as cancer, osteoarthritis, cardiovascular, and neurodegenerative disorders has been widely studied. For osteoarthritis patients, acupuncture and glucosamine together with conventional care has been reported to provide a safer option in improving mobility and reducing pain than conventional care alone (Maa et al., 2008). Biofeedback and mind body therapies have been reported to reduce systolic blood pressure among hypertensive patients (Greenhalgh et al., 2010; Oberg, 2009). Similarly, mindful therapies such as meditation, Tai chi, spiritual therapies, and prayer are reported to improve health-related quality of life of elderly patients with neurodegenerative diseases (Lavretsky, 2009). Integrating CAM into geriatric care might remove communication barriers among patients and their health care providers, improving cost-effective therapeutic options with fewer side effects. Furthermore, the holistic approach of CAM therapies might provide elderly patients a chance to take charge of their own health creating treatment options that reflect their own health and cultural believes. Geriatric care in old people's homes is another challenge faced by their caregivers. In this context, a number of CAM therapies such as Qi Gong, Tai chi, dancing, and yoga can be offered in groups and might help people to socialize, thereby reducing symptoms of depression and stress which are commonly seen among residents. Such rehabilitation techniques can assist old people to improve mobility and physical dependence which is commonly seen in many chronic conditions.

Polypharmacy

The top most issue related to medicine in older people is polypharmacy. Polypharmacy is associated with poorer clinical outcomes, increased risk of adverse drug reactions (ADRs), nonadherence, drug–drug interactions, and higher health care costs. The prevalence and incidence of polypharmacy are high among older adults (Morin et al., 2018). In the UK, the proportion of older people taking five or more medications increased four times from 12% to 49% between 1991 and 2011 (Gao et al., 2018). The most common definition of polypharmacy is the concomitant use of "five-or-more-medications" (Gnjidic et al., 2012). Many people can benefit from polypharmacy but the higher the number of medications the higher the risk of adverse events (Gnjidic et al., 2012) and nonadherence (Pasina et al., 2014). In Sweden, a nationwide cross-sectional study found that 16%–24% of all older adults (≥65 years) were exposed to medications whose risks overweigh the expected benefits (Morin et al., 2018).

Polypharmacy often reflects the magnitude of chronic multimorbidities. The number of medicines a patient takes strongly correlates with the number of chronic conditions the patient has (Morin et al., 2018). For each additional chronic disease, at least one additional drug was introduced. Additionally, the rise in polypharmacy was also due to older people being treated with preventive medicines to reduce the rate of mortality and morbidity, particularly in cardiovascular disease (Force et al., 2016) and stroke prevention (Alhusban and Fagan, 2011). Another cause of polypharmacy is the development of clinical practice guidelines focusing only on the management of a single disease and absence of guidance on how to tackle older patients with multimorbidity (Vitry and Zhang, 2008). If clinical guidelines are to be followed for all medical conditions, an older person might be expected to take

more than 10 medicines. This calls for development of combined guidelines for most common patterns of multimorbidity. On top of that, another possible reason for polypharmacy is a prescribing cascade (David et al., 2016). This occurs when a new medicine is started to treat an adverse effect of another medicine which has been misinterpreted as a new medical condition (Kalisch et al., 2011; Nguyen and Spinelli, 2016).

Polypharmacy is seen as a threat to patients but underutilization of medicine may also be hazardous. A study in Belgium observed a high prevalence of polypharmacy (58%), concurrent with a high prevalence of underuse (67%), and misuse (56%) among a cohort of community-dwelling patients aged 80 years and above (Wauters et al., 2016). The study found that underuse of medicines was associated with increased rates of mortality and hospitalization, after controlling for polypharmacy and misuse. Deprescribing is one means of possibly overcoming polypharmacy. It is the process of tapering or stopping drugs, aimed at minimizing polypharmacy and improving patient outcomes. Caution needs to be taken; however, when limiting the number of medicines prescribed, as when beneficial medicines are stopped patients are at risk of worsening medical conditions.

Nonadherence

Adherence is "*the extent to which a person's behavior—taking medication, following a diet, and/or executing lifestyle changes, corresponds with agreed recommendations from a health care provider*" (WHO, 2003). Adherence to medication has always been an issue, especially in older patients. Poor adherence could lead to decreased therapeutic benefits for the patient, frequent hospital visits and increased health care costs and even lead to death (Yap et al., 2016).

A study classified the reasons for nonadherence into patient factors, medication factors, health care provider factors, health care system factors, and socioeconomic factors (Yap et al., 2016). Some of the patient factors that might affect adherence to medications are education level, patient's mental state, physical health, behaviors and attitudes, knowledge and beliefs about medications, and past medical history. Medication factors which might influence adherence among older people are types of drug formulation, packaging, storage issues, drug regimen such as polypharmacy or complex dosing regimen, drug handling such as necessity to cut tablet or difficulty opening containers, presence of ADRs, drug–drug interactions, poor labeling instruction, and lack of immediate consequences of missed doses (Yap et al., 2016).

Health care provider–patient relationship is important in achieving the therapeutic goals of a treatment. Some of the health care provider factors that could hinder adherence in older people are poor communication between the provider and patient, lack of patient involvement, lack of confidence in health care providers, and lack of trust by the patients. Among the health care system, factors that could lead to nonadherence are lack of patient education and follow-up. Finally, lack of caregiver and increased caregiver burden are the socioeconomic factors associated with poor adherence (Yap et al., 2016). Similarly, a cross-sectional study conducted in Korea found that thorough explanation of medication and patients' satisfaction with counseling were the strongest predictors of higher adherence. Whereas, the use of multiple pharmacies, frequent dosing interval and low level of education were associated with poor adherence (Jin et al., 2016).

Adverse Drug Reactions

The number of medications that a patient takes is the strongest risk factor for harm (Steinman et al., 2014). Up to 6.5% of hospital admissions are due to ADRs and patients on multiple medications are more likely to suffer from an ADR (Pirmohamed et al., 2004). Among older adults, ADR prevalence rates are as high as 26% (Hamilton et al., 2011) and incidence of ADR rates are as high as 21%–22% (Lavan et al., 2018; O'Connor et al., 2016) have been reported. Additionally, it was found that 12% of patients aged 70 and above were admitted to hospital due to ADRs (Mannesse et al., 2000). The majority of ADRs in older people are Type A reactions involving commonly prescribed medications and are usually preventable (Davies and O'Mahony, 2015). The most common ADRs were acute kidney injury and electrolyte disturbance secondary to diuretics; falls secondary to benzodiazepines and opiates; orthostatic hypotension/symptomatic bradycardia secondary to anti-hypertensives; and upper gastrointestinal bleeding, gastritis and acute kidney injury secondary to nonsteroidal antiinflammatories (O'Connor et al., 2016). Factors such as changes in pharmacokinetics and pharmacodynamics could have contributed to ADRs; however, the main independent risk factor is the number of medications that older people take (Davies and O'Mahony, 2015).

A Sociological Approach toward Medicine Use

Sociology is the study of the relationship between the individual and society. It seeks to understand how an individual's thoughts, actions and behaviors are influenced by the society. Besides, it also seeks to understand how individuals actively structure their society through their own actions. Sociology deals with real-world issues (research on and with people) and these issues are forever bound to be in transition and change (Paul et al., 2001). The following quotation from Nettleton clearly illustrates the role of sociology in health and illness as well as health services.

Our birth may be mediated by technology and controlled by health professionals. The beliefs about health and illness held by our peers and by those with whom we live will shape our experiences of illness and understandings. Our contact with health professionals (dentists, doctors, pharmacists, opticians, health promoters, practice nurses, etc.) is likely to be a routine fact of our lives. Our self-identity may be shaped by our experiences of illness and our interactions with both formal and informal institutions of health care. Our attitudes toward our bodies will be

influenced by our socio-cultural context. We may come into contact with new technologies of health care, either through our own illness or through having children. We may have to face the ethical and moral dilemmas central to the blurring of the beginning and ending of life (Nettleton, 2013, p.1).

Health and illness are social phenomena. Morbidity and mortality might change according to social differences in social class, age, gender, and ethnicity. Within the context of aging, sociology is concerned about the lives of older people and the context of their existence, about how they live, the social forces that operate upon them, and how those individuals contribute to and change those social forces (Paul et al., 2001).

Being healthy or successfully aging depends on the degree of health independence, family, financial security, life adaptation, personal growth, friends' and relatives' relationships, emotional care from family and friends, satisfaction with life, regular social activities, high level of psychological and social well-being, learning new things, physical appearance, sense of humor and spirituality, leisure activity, happiness, and independence (Tobiasz-Adamczyk, 2015). The concept of healthy aging of older people; however, differs based on norms, traditions, religious beliefs, and the system of values.

For example, for older Japanese people the main components of successful aging were: remaining in good health, being able to take care of oneself, having family and friends, "good genes", being free of chronic diseases, satisfied with life, and adjusted to age-related changes. For older Australians, except for good genes, similar concepts to the Japanese were shared and other concepts that emerged were feeling good about oneself, being able to make choices about things that affect aging, staying involved with the world and people, being able to act according to ones' own inner standards and values, not feeling lonely or isolated, being able to cope with the challenges of later years, and being able to meet all of their needs (Tobiasz-Adamczyk, 2015).

As far as illness is concerned, it is socially patterned and an older person's social position as well as their individual health will have an important influence on their life experiences especially when it comes to medicine taking. Nettleton clearly illustrated that health care does not happen in isolation but is within a specific organizational context. For example, when an older person gets ill, he or she might visit a doctor, a pharmacist, a nurse or a traditional or complementary practitioner. These services might be funded or require direct payment from patients, which might have an implication on the provision of service and the use of such services by patients. The maintenance of health and the management of illness among the older population happen through interactions with health care workers and these interactions help to sustain their lives and the society that they live in. Being ill can be detrimental to older persons' lives and their relationships with other people and society (family, friends, colleagues, and health workers) and might impact on their ability to perform daily activities and how they choose to present themselves to others. An elderly person being ill will have an impact on the caregivers at the same time. This interactional element is one component of sociological analysis in relation to the understanding of health and illness.

Sociology deals with the nature of the social structure, the relationship between self and society and the historical development of society (Paul et al., 2001). Different kin-ship, religious, economic, political, and other institutions of a society frame a social structure. The power of individuals to operate independently from the constraints of the social structure is called agency. A deeper understanding through the exploration of the relationship between the social structure and agency provides a sociological approach for understanding medicine use in older adults.

Sociology of Aging

The evolution of the sociology of aging can be divided into three phases. The first phase perceived aging as a "role less roles", whereby older citizens withdrew from social roles and social interactions, in relation to diminishing biological, psychological, and social dimensions. The second phase replaced the concept of withdrawal by a new approach to aging, focusing on the continuation of activity in the older stage of life in order to develop a concept of successful aging. The third, and current, phase is focused on promoting older stages of life as active (activity theory), concentrated on the social participation of older citizens, physical activity, diet and other behaviors promoting health, and reducing the risk of disease (Tobiasz-Adamczyk, 2015). Structural functionalism, symbolic interactionism and conflict theory are three main theoretical frameworks that can be applied to the sociology of aging.

Functionalism

Talcott Parsons (1902–1979) is one of the founding fathers of sociology and theorized the relationship between patients and health professionals. Parsons was well known for introducing the concept of the "sick role". Sick role theory refers to the notion that an individual's response to illness is governed by a set of social expectations and responsibilities (Paul et al., 2001).

Parsons theorized that a person who experiences illness is deviating from normal social roles and responsibilities and is forced to rely on others. He argued that as long as individuals conformed to the conditions of the sick role then they were seen to be legitimately deviant. His famous four components of the sick role are:

1. Ill people are exempt from their normal social responsibilities such as work or domestic labor. This exemption requires some form of legitimation from doctors or those in medical authority.
2. They are not held responsible for their condition and cannot be expected to recover by an act of will.
3. Ill people must want to try to get well, if not, they can by accused of malingering.
4. Ill people are obliged to seek and cooperate with medical practitioners to help make themselves well again.

With regard to medicine taking, it can be assumed that pharmacists represent an important link by reinforcing the doctor's instructions through the supply of medicines and maintaining the ideology and values of the sick role (Van Der Geest and Whyte, 1989).

As conceived by Talcott Parsons, the functionalist perspective on health and medicine emphasizes that good health and effective medical care are essential for a society's ability to function. Poor medical care is likewise dysfunctional for society, as people who are ill face greater difficulty in becoming healthy and people who are healthy are more likely to become ill.

Parsons emphasized the importance of individuals' good health for society's health but his perspective has been criticized for several reasons. First, his idea of the sick role applies more to acute (short-term) illness than to chronic (long-term) illness. Although much of his discussion implies that a person temporarily enters a sick role and leaves it soon after following adequate medical care, older people with chronic illness can be locked into a sick role for a very long time or even permanently.

Although, the prominent theories of aging emphasize the involvement of older people in social activities and engagement in society, functionalists find that people with better resources who stay active in other roles adjust better to old age (Crosnoe and Elder, 2002). Older people, however, go through a period during which relationships can be affected due to retirement, decreased community involvement, and reduced social networks. Disengagement theory suggests that withdrawing from society and social relationships is a natural part of growing old. Older people are benefited because disengagement allows them to focus on the next era of their lives and society is benefited because it allows the next generation to take over societal roles, which supports societal stability. In this view, older adults become increasingly disengaged from society, have reduced social roles, and become socially isolated. Activity theory shows that older people who remain active are the happiest. This theory posits that society benefits from older people who continue to contribute and are accepted as valued members of society. From activity theory and the symbolic interactionist perspective, older people need to continue to be active, although their social roles may change. As opposed to being socially isolated, this view sees older people as continuing to be involved with others and often creating new networks. Critics of this theory point out that access to social opportunities and activity are not equally available to all and not all older people find fulfillment in the presence of others or in participating in activities.

Conflict Theory

Neither disengagement theory nor activity theory explain why the level or type of social interaction needs to change in old age. Critics of these theories say they fail to take into account the effects of social stratification and class on elderly people. Conflicts of interest and class divisions are key elements of conflict theory (Paul et al., 2002a). Research has found that individuals from the upper classes tend to have better health and be less likely to be dependent in their later years than are individuals from the lower classes. More affluent people typically have better or even greater access to health care, consistent access to food and medication, and can afford to have the help they need for necessary everyday activities than less affluent people. Conflict theorists also take a note of the age stratification that can be observed in society. Older people are often the victims of agism and unable to get jobs with the same income level as they had in their youth or are forced to live on a fixed income from social security or a pension. As a result, they are reduced in terms of social status. In general, conflict theorists see elders as victims of social stratification and capitalism.

Illness, diagnostics, and treatment are conceptualized as expressions of relations of power in society and unequal distribution of resources. The concept of professional dominance describes the superior power exercised by physicians in relation to other professions in the health services, a power that stems from the physician's legitimized right to define medical reality (Freidson, 1970). Freidson's conflict theory assumes that the doctor and the patient come from different social and cultural worlds.

Modernization theory suggests that the primary causes of elders losing power and influence in society are the result of industrialization and modernization (Cowgill and Homes, 1972). As the status of older people decreases, they are increasingly likely to experience social exclusion. Before industrialization, strong social norms bound the younger generation to care for their elders. As societies industrialize, however, the extended family is replaced by the nuclear family. As societies become increasingly individualistic, the norms regarding the care of older people change accordingly. Thus, the (voluntary) obligation of caring for an elderly family member is diminishing in both developed and developing nations. The presence of chronic illness, loss of a spouse and lack of income in the elderly can be seen as triple jeopardy. This theory suggests that as people age, family support, and care giving will eventually become a huge burden.

When asked about intergenerational relationships and family solidarity, parents usually rated their relationship as warmer and more cohesive than did their children (generational bias). The model of intergenerational solidarity in families identifies six dimensions of solidarity: affectual, associational, structural, consensual, functional, and normative. In addition, conflict, ambivalence in family relationships, and the role of stress have been used to provide a multidimensional theoretical explanation for the mistreatment of older people. Dependency, caused by health status and disability in older people associated with expected help, care and social support (like a "hospital at home"), triggers problems related to issues such as abusive behavior of carers (Tobiasz-Adamczyk, 2015).

The conflict approach also critiques the degree to which physicians try to control the practice of medicine and to define various social problems as medical conditions. On one hand, it is believed that physicians are the most qualified professionals to diagnose problems and determine treatment. On the other hand, it has also been recognized that physician's financial status will also improve if they succeed in characterizing social problems as medical problems and in monopolizing the treatment of these problems. This leads to the concept of medicalization. Once certain problems become "medicalized," possible social causes and the potential solutions are neglected.

Medicalization of Aging

Medicalization describes a process by which nonmedical problems become defined and treated as medical problems in terms of illness and disorders (Gabe et al., 2004). It can occur conceptually when medical vocabulary is used to define a problem, institutionally, when organizations adopt a medical approach to treating a problem in which they specialize, and at the level of practitioner–client interaction when a problem is defined as medical and medical treatment occurs (Conrad and Schneider, 1980). Medicalization causes an increase in the (1) consumption of pharmaceuticals, (2) use of new medical technologies, (3) frequency of visits to medical settings, (4) range and extent of medical services, (5) risk of iatrogenic disease, (6) influence of medicine in previously nonmedical domains, (7) level of health surveillance, and (8) media coverage of health and medical matters (Russel, 2009).

Pharmaceuticalization or the "translation or transformation of human conditions, capabilities and capacities into opportunities for pharmaceutical intervention," often works in tandem with medicalization but it has potential to reach beyond it (Williams et al., 2011). The pharmaceutical industry is crucial to the creation and definition of disease through its dominance in clinical research and scholarly knowledge, direct-to-consumer advertising and lobbying power. The pharmaceuticalization of old age occurs through various mechanisms, including conditions such as osteoporosis, expanding the terrain covered by cognitive enhancement, the creation of completely new pathologies such as erectile dysfunction and by transforming normal life experiences into "undesirable" but "manageable" states, for example the menopause (Twigg, 2015).

The increasing medicalization of society is often viewed negatively (Moynihan et al., 2002). For Marxists, medicalization is seen as catering to the interests of the ruling capitalist class, whereby people are made dependent on medicine which is categorized as a consumer good propagated by that class (Gabe et al., 2004). Nevertheless, medicalization can be positive if it means some form of treatment can be offered. Redefining a condition as appropriate for medical attention opens up opportunities for the alleviation of symptoms or a cure and also legitimates the condition. It also helps to reduce the stigma associated with a particular condition (Gabe et al., 2004).

The expansion of the role of pharmaceuticals in defining life's problems has also been alternatively viewed as a "culture of liberation," in which individuals liberate themselves from undesirable social or biological forces (Twigg, 2015). This ultimately leads to a "culture of perfectibility" where people have the freedom and responsibility to pursue solutions to health problems, including the spiritual, emotional, and physical dynamics of life (Twigg, 2015). The growing population of affluent older people leads to greater expectations of medical care, fueled both by greater consumerism and the promotion of new medical technologies by doctors and the pharmaceutical industry. Aging individuals are bombarded with messages about how to use pharmaceuticals to alleviate disease, to manage risk and to function well. It is a trend for older people to demand cures for wrinkles, baldness, yellow teeth, and relief from symptoms of the menopause and andropause. Growing treatment options, such as botulinum toxin for the treatment of wrinkles, minoxidil for male pattern baldness, tooth whitening treatments, and hormone replacement therapy for women, are some of the examples of medicalization in the aging population (Ebrahim, 2002). Since these new pharmaceutical interventions are changing the norms of old age, it could be empowering to some people to be expected to live up to new expectations of virility and youth, while some might feel guilty for not managing their old age in the 'right" way. Hence, pharmaceuticalization of old age may make pharmaceutical consumption a "personal health responsibility." This particular "pharmaceutical imagination" views the world from a certain race, class, gender, sexuality, and age perspective, which could be oppressive to those who are marginalized.

In favor of the medicalization theory, it is argued that although aging is a natural process, it does not mean that the diseases that accompany it are also natural and should be excluded from medical attention. The aging process varies from one individual to another and it could cover a wide range of conditions and needs, from the fit to the frail. Various trials have shown the benefits of treating older people rather than ignoring their health problems. For example, evidence from trials of blood pressure lowering and statins show that older people are no different from younger people in their response to treatment but, because of their higher levels of risk, they might gain greater benefits from effective treatments. The availability of effective treatments for cataracts, hearing impairments, angina, osteoarthritis, impotence, depression, and other conditions should be an opportunity for the older population to enjoy better health care (Ebrahim, 2002).

Medicalization can also be seen as risky when legitimate concerns exist about the risks of infection during hospitalization, overprescribing, inappropriate use of tranquillisers for restraint, and the hazards of pressure sores. It has also been argued that hazards associated with medical care exist at any age: poor standards of practice and medical injuries can be prevented (Rothschild et al., 2000). Based on the potential benefits of treatment, attempts to ration medical care on the grounds of chronological age are unethical, as medicalization of aging can mean greater access to health care for older people, which could translate to reductions in mortality and disability (Ebrahim, 2002).

Symbolic Interactionism

Interactionists believe that social life can only be understood by exploring the "real-life" situations that people experience and which they believe to be meaningful (Paul et al., 2002b). The interactionist approach emphasizes that health and illness are merely social constructions whereby various physical and mental conditions have little or no objective reality but will be considered as healthy or unhealthy conditions if they are defined as such by society (Buckser, 2009).

Theories within the symbolic interactionist perspective focus on how society is created through the day-to-day interaction of individuals, as well as the way people perceive themselves and others based on cultural symbols. It assumes that if people develop a sense of identity through their social interactions, their sense of self is dependent on those interactions.

With regard to aging, symbolic interactionists stress that the changes associated with old age have no inherent meaning; however, the attitudes displayed toward the elderly are rooted in society. The symbolic interactionist approach is commonly used to study interactions between patients and health care professionals.

Symbolic interactionist, Erving Goffman, extensively studied the behavior of staff and patients in mental institutions. He noted that a mental hospital was not intrinsically a therapeutic environment: it was custodial, centered on eradicating the self-image and self-respect of residents. He argued that to understand the behavior of residents, it was better to construe them as psychologically normal rather than mentally ill. He blamed their behavior on the lack of privacy and the level of surveillance that they experienced. Goffman noticed the various techniques used by residents to maintain their self-respect, for example, they appeared to be obsessive about trivial objects. He tried to make sense of their behavior from the point of view of the residents under the conditions in which they were forced to live. He explained that residents were typically not allowed to have any access to trivial things such as string, tin foil, and toilet paper. In these circumstances, any trivial item becomes a desirable possession, and they are the items that other residents would steal, thus, the only safe place is to put them in their pocket. Goffman felt that rather than being irrational, the resident's behavior appeared to be rational in the circumstances. He concluded that when one attempts to see behavior sympathetically from the point of view of the individual displaying that behavior, then the assumptions of the observer can be questioned and such behavior can be seen as rational (Goffman, 1968).

Goffman's theory encouraged many researchers to explain how the structure of institutions for the elderly affects service-provider/resident interactions. For example, elders often experience negative effects in institutionalized settings, such as being infantilized. Research showed that a marked improvement in elderly people's verbal responses were seen when a competent caregiver left and was replaced by a social worker who used a different approach with the residents. Residents seemed more alert and less cognitively impaired in their interactions with staff and visitors. The only explanation was the difference in the caregivers' communication styles, since both were competent and caring staff members. The first caregiver spoke to the residents in a slow, sing-song voice using a child-like vocabulary in her attempt to be nurturing and comforting, whilst the caregiver who replaced her spoke to the residents with the same adult speech patterns she used with staff. It was surprising when some residents who had previously spoken very little or who had seemed to show signs of dementia started speaking and interacting in more normal ways. This observation sparked the interest to investigate whether infantilization can alter the responses of elders to their caregivers and, in turn, increase the risk of residents being labeled as cognitively incompetent (Marson and Powell, 2014).

Other issues within the scope of symbolic interactionism include the study of health beliefs, labeling, the role of culture in defining health and illness, and stigma, as well as compliance and concordance model which are also related to the domain of pharmacy practice (Paul et al., 2002b).

Conclusion

This chapter addresses issues pertaining to medicine use in older people from a sociological perspective. The growing aging population poses various challenges to the health care system due to the projected increase in the GBD. To improve the quality of life of older people, a holistic approach that integrates physical functioning, psychological well-being, and social well-being is crucial. Polypharmacy, adverse drug reactions, and nonadherence are common drug-related problem amongst older people with multi-morbidity. Nevertheless, medicine use is a social phenomenon that deals with real-world issues which are continuously changing and evolving. Functionalism, symbolic interactionism, conflict theory, medicalization and pharmaceuticalization of aging are examples of sociological theories that can inform pharmacy practice beyond the biomedical perspective.

Who Are We?—The Evolving Professional Role and Identity of Pharmacists in the 21st Century

Jamie Kellar, Leslie Dan Faculty of Pharmacy, University of Toronto, ON, Canada

Introduction

Pharmacy is in the midst of significant professional transformation. The profession once responsible for compounding and dispensing medication is looking to reposition itself as clinicians within the health-care system (Adamcik et al., 1986). A crucial element to the success of this transformation will be the ability of the profession to clearly form a clinician identity or way of "being," which can be clearly internalized by pharmacists and subsequently role modeled to pharmacy trainees in both classroom and workplace environments. Identity formation is a crucial part of becoming a professional (Cruess et al., 2016a; Goldie, 2012). According to Irby, it involves "expanding one's knowledge, understanding, and skilled performance; through engagement with other members of the professional community and by deepening one's commitment to the values and aspirations of the profession" (Irby, 2011).

Also identity formation is not static. It is a dynamic process, which occurs over time, often relying on student immersion into a community of practice (Cruess et al., 2016a; Irby, 2011). Much work has been done in the area of professional identity formation in the health professions arena, specifically in medicine. Moreover, medical educators have gone so far as to propose that identity formation should be the foundation of all medical curricula (Cruess et al., 2016a). A paper by Monrouxe suggests that the goal of medical education is as much about the development of a professional identity, as it is about gaining knowledge and skills (Monrouxe, 2010).

This increased attention to professional identity formation as a mandate for medical education has led to a significant increase in research and publications over the last several years. Pharmacy, on the other hand, has been under-studied in this domain, which is surprising considering it is an ancient profession (Beales and Austin, 2006). One reason that might contribute to the lack of research in this area in pharmacy is the ongoing questioning of its professional status (Denzin and Mettlin, 1968; Dingwall and Wilson, 1995). On the one hand, if pharmacy is not a profession, then why would one study its identity or how it is formed?

On the other hand, the lack of research might be because pharmacy is a relatively small, allied health profession, thus not as attractive to sociologists, compared to doctors, who draw more interest, prestige, and funding (Dingwall and Wilson, 1995). Regardless of the reason, there currently exists a paucity of literature in the area of professional identity in pharmacy. This chapter

will provide an overview of the evolving professional role of the pharmacist over the last century. It will explore the aforementioned professional status debate surrounding pharmacy and will look at the work that has been done in the area of professional identity formation and professional socialization to date. In addition, it will explore some of the key conversations and accompanying research on professional identity formation currently taking place in medicine, which may inform future research directions and curriculum design in pharmacy. This chapter will also explore the construct of professional identity in both pharmacy education and pharmacy practice—as one's professional identity formation begins during the education process, but is enacted and continues to evolve in practice settings over the course of one's career.

What Is a Profession?

What defines a profession has been a topic of interest for sociologists for close to a century (Bader et al., 2017). No single definition exists, yet most would agree professionals are afforded significant status in society, thus, they are interesting to study. Much of the early academic work on professions was uncritical, focusing on the role that professions played in society and the traits, which would allow professions to be discriminated from other occupations (Dingwall and Wilson, 1995; Traulsen and Bissell, 2004). Over time, the line of thinking shifted to a more critical lens, with a focus on how professions competed for status, wealth, and power within the market (Dingwall and Wilson, 1995). A paper by Traulsen and Bissell reviews some key theories of professions and the impact on the pharmacist (Traulsen and Bissell, 2004). The table below highlights some key individuals and theories noted in their paper, as well as others noted in the works of Bader et al. and MacDonald (Bader et al., 2017; MacDonald, 1995; Traulsen and Bissell, 2004). A complete review of the sociology of professions is beyond the scope of this chapter; however, some key references in this area are listed at the end of the chapter for those with a specific interest in this area.

The Professionalization of Pharmacy

The History of Pharmacy

The notion of pharmacy as an invisible profession, lacking an identity, seems incomprehensible, given the ancient origins and elite standing it once held (Beales and Austin, 2006; Charters et al., 1927; Kronus, 1976a,b). In the introduction to the *Basic Material for a Pharmaceutical Curriculum*, Charters states:

> Pharmacy is an ancient and honourable profession. Its beginnings are lost in the mists of antiquity and its history replete with substantial accomplishments. Pharmacy is the mother of medicine and the original source of many forms of research (Charters et al., 1927; p. 1).

The practice of pharmacy dates back to ancient Egypt, where evidence of the first prescriptions and "recipe" books are documented (Kronus, 1976a). Over centuries, the profession evolved, alongside medicine, with a clear role, identity, and professional status. It has been said that before the turn of the 20th century, "druggists in North America were closer to the public ear than the doctor and were increasingly sought for advice in therapeutic matters" (Muzzin et al., 1993, p. 381). Similar stories exist in Europe and other parts of the world. As time passed, however, and medicine became more formalized, the role of the pharmacist changed and pharmacists began to lose professional ground. During this time, the status of pharmacy relative to medicine began its decline (Kronus, 1976a). Societal changes in industrialization and health-care organization provide some explanation for this shift. The professionalization of pharmacy is set within the historical constructs that govern various practice models at different periods of time (Bader et al., 2017). In the 19th century, manufacturing, compounding, and distributing medications were key activities of practice (Bader et al., 2017; Hepler, 1987). By the early 1900s, however, pharmacy practice was essentially restricted to compounding and dispensing medications (Adamcik et al., 1986; Denzin and Mettlin, 1968). Then, with the advent of industrialization and large-scale manufacturing of medicines, pharmacists soon lost their social purpose as both compounders and distributors, leaving dispensing functions as their predominant role (Buereki, 1999; Hepler, 1987). Both internally and externally, this was viewed as another downgrading of the professional status (Adamcik et al., 1986; Bader et al., 2017; Beales and Austin, 2006). Despite pharmacists having complete occupational control over the activity of dispensing medications, it has always been seen as a "lesser" activity. Hepler notes in a 1987 paper, that as early as 1858, William Proctor was noted to have said:

> If the preparation of medicines is taken from the apothecary and he becomes merely the dispenser of them, his business is shorn of half its dignity and importance, and he relapses into a simple shopkeeper (Hepler, 1987, p. 370).

Because of the loss of jurisdiction over the majority of their professional roles over time, pharmacists have been in continuous search of new responsibilities and functions. As such, their professional status has been constantly questioned by pharmacists themselves and by other professions and members of the public. The debate continues today, and the search for legitimacy as professionals is currently embedded in the construct of pharmacist clinicians and the pharmaceutical care paradigm. The continuous shifting in professional roles contributes to role ambiguity and impacts the process of identity formation.

Is Pharmacy Really a Profession?

In a public address in 1915, Abraham Flexner challenged the professional status of pharmacy. Flexner, the man associated with medical education reform, gave a keynote address at a social work conference during which he asked the following question "Is pharmacy a profession?" He answered his own question as follows:

> The pharmacist compounds the physician's prescription, for which task he requires a considerable degree of expertness, a knowledge of certain sciences—especially chemistry and a high degree of caution, since either the slightest error on the part of the physician, whether due to ignorance or to carelessness, may have very serious consequences. Recurring to our criteria, I should say that pharmacy has definiteness of purpose, possesses a communicable technique, and derives at least part of its essential material from science.
>
> On the other hand, the activity is not predominantly intellectual in character and the responsibility is not original or primary. The physician thinks, decides, and orders; the pharmacist obeys—obeys, of course, with discretion, intelligence, and skill—yet in the end obeys and does not originate. Pharmacy, therefore, is an arm added to the medical profession, a special and distinctly higher form of handicraft, not a profession (Flexner, 1915, p. 582).

Sociologist, Harold Wilensky, later echoed this sentiment in a landmark paper entitled *The Professionalization of Everyone?* (Wilensky, 1964). In this paper, Wilensky describes the struggles that numerous occupations embark on, to achieve the authority and recognition of established professions such as medicine and law, noting that very few will be successful in achieving such authority and status. Wilensky classifies pharmacy as a marginal profession, auxiliary to medicine. In spite of pharmacy's heroic attempts to expand their professional status, they remain in the shadow of medicine based on power structures that are reinforced by both formal and informal societal structures (Wilensky, 1964).

Medical sociologists Denzin and Mettlin further explored this notion of pharmacy as a marginal or quasi-profession in their 1968 paper entitled *Incomplete Professionalization: The Case of Pharmacy* (Denzin and Mettlin, 1968). In contrast to Wilensky, however, they focused their work completely on pharmacy, dismissing it as a profession (Bader et al., 2017; Denzin and Mettlin, 1968; Muzzin et al., 1993). This paper is important, as it has provided much of the framework within which pharmacy has been examined as a sociological phenomenon over the last 50 years, in spite of the numerous ways in which the theories of professions have evolved since its publication (Dingwall and Wilson, 1955). It has had significant impact, as it contributes to the perpetuation of the discourse of pharmacy as an inferior profession.

In this paper, Denzin and Mettlin argued that pharmacy is an example of an ancient occupation, which has failed to maintain its prestigious title and is now commonly labeled as a quasi-profession. In essence, pharmacy has achieved "incomplete professionalization." That is, pharmacists have taken on a number of characteristics of a profession (trait theory), but they failed to overcome the marginality associated with professions, which still contain elements of an occupation (Denzin and Mettlin, 1968). The authors noted that although pharmacy took on many professional elements, such as the development of formalized institutions to transmit knowledge, codes of ethics, professional organizations, and the ability to self-govern, they never actually reached full professional status (Denzin and Mettlin, 1968). In their opinion, pharmacy lost its ability to maintain its status in many domains. Specifically, pharmacy failed to abide by the requirement of a profession that "you do not advertise." Similarly, they noted that pharmacists have failed to recruit truly committed persons who commit their lives to the altruistic goals and values of the profession. They have likewise failed to engage in long-term activities, which ensure their control over the social object around which their activities are organized—the drug. Furthermore, they have failed to accumulate a systematic body of scientific knowledge which can only be learned by socialization in their own institutions, and which is needed for the enactment of their professional role. Finally, due to the proliferation of subspecialties within the profession, pharmacy has failed to hold together a cohesive social organization, which exercises strict control over its members and ensures its perpetuation through time (Denzin and Mettlin, 1968). Denzin and Mettlin felt that the business aspect of retail pharmacy kept the profession caught between two dominant value orientations: business versus profession (Denzin and Mettlin, 1968; Kronus, 1975). This is important as business and service professions are commonly conceptualized as relying on different core values to attract and motivate members (Friedson, 1970; Kronus, 1975). Business offers more to individuals who value financial reward, whereas professions offer more to those who value altruism as the reward (Friedson, 1970). This tension creates a potential conflict when selecting individuals into pharmacy schools, designing pharmacy curricula and ultimately impacts on how pharmacists form their professional identity.

As noted, the Denzin and Mettlin paper is one of the most detailed sociological accounts of the professional status of pharmacy; however, it may no longer sufficiently explain the professional role of the pharmacist, since sociological theories have changed, as has the work of the pharmacist. In 1995, Robert Dingwall and Eileen Wilson undertook a study to explore whether pharmacy was really an incomplete profession (Dingwall and Wilson, 1995). Their paper challenged Denzin and Mettlin's claim of incomplete professionalization and went on to present the results of an ethnographic case study of a neighborhood pharmacist's work. This was an initial attempt to develop new theories around the role of the pharmacist and the nature of medicines. Dingwall and Wilson argued that Denzin and Mettlin's dismissal of pharmacy's claim to full professional status rested on two main grounds. First, it was the failure of pharmacy to meet criteria of the trait theory of professions (i.e., advertising, failure to recruit altruistic people, loss of control over the drug, failure to develop a unique body of knowledge, and failure to maintain occupational cohesion). Second, it was the failure of pharmacists to gain control of the social object of their work—the drug (Dingwall and Wilson, 1995).

Dingwall and Wilson challenged these grounds by comparing pharmacists to doctors and lawyers, the gold standards when discussing established professional status (Wilensky, 1964). They noted that lawyers advertise on a large scale without compromising their professional status. In a similar vein, service orientation is not necessarily in tension with the desire to maximize income, as

most self-employed doctors and lawyers are also concerned with marketing their services and making a profit. They suggested the comment that pharmacy fails to recruit students of altruistic nature is difficult to substantiate, as there is no comparative data to support or refute this claim. Of final note, although pharmacists do not have complete control over the social object of their work, it is not clear as to what extent other professions actually control this either and there is no evidence to suggest controlling the social object is a requirement of being a profession. As an example, lawyers do not control the creation of the law, but they have considerable influence over its interpretation and use. Much the same can be said for pharmacists. They do not control all aspects of the drug, but they have significant influence over its use. These criticisms overall reflected the general weaknesses of a trait-based approach to understanding professions. Overall, a key problem that Denzin and Mettlin faced is ultimately their lack of data on the everyday work of a pharmacist. Their analysis was based predominantly on surveys, attitude studies, and occupational propaganda, which did not provide a complete picture of the work pharmacists do (Dingwall and Wilson, 1995). Dingwall and Wilson set out to improve upon Denzin and Mettlin's conclusions by developing a program of ethnographic study of the different organizational conditions under which pharmaceutical services are delivered to examine their general propositions about the status and meaning of the social object and its control (Dingwall and Wilson, 1995).

Dingwall and Wilson carried out a study of participant observation over a six-week period in an independent retail pharmacy in the Southern United States in 1992. Over the course of their study, they found that a significant dimension of the pharmacist's work was related to the control and use of information. They observed that it was not the drug itself that was the social object but rather the passage of information around the drug that constituted it as a social object. From here, Dingwall and Wilson identified three aspects related to the use of information by pharmacists: (1) their knowledge about patients; (2) the advice given to patients about the use of drugs; and (3) their understanding of drug interactions and other adverse effects (Dingwall and Wilson, 1995). Dingwall and Wilson noted that pharmacists use information about patients, obtained from consultations and information in pharmacy computer systems to assess the nature of the patients' conduct with respect to medication use. The pharmacist mobilizes data to facilitate appropriate medication use. Patient counseling involves the giving of information to patients and this was noted as a significant area of autonomy in pharmacy work, as much counseling is patient initiated. This is in contrast to work that suggests pharmacists are just mediators between physicians and patients.

Lay people recognize pharmacists as an independent and authoritative source of expertise. Finally, there are cases where pharmacists take the initiative around information giving and most of these are around drug interactions and allergies, which the physicians were unaware of or overlooked in the course of prescribing. This role is important—the pharmacist is looking into the future and warns of hazards to come. Therefore, Dingwall and Wilson challenged Denzin and Mettlin's notion that the social object of pharmacy is the drug. Dingwall suggested that the social object of pharmacy is "the symbolic transformation of the inert chemical into the drug, which is itself a focus of actions designed to restore or limit the impact of disordered human biology on the order of society and everyday life" (Dingwall and Wilson, 1995, p. 125). In this respect, pharmacy plays a distinctive part in health care in modern society. All this being said, Dingwall and Wilson did not conclude that pharmacy is a profession because they have a distinct social object, but clearly, they refute the notion that it is incomplete. They suggested maybe we are asking the wrong questions—maybe a better question is what kind of occupation is pharmacy? This line of inquiry might lead to a deeper understanding of the profession.

Other Work in Professionalization of Pharmacy

Other research that has looked at the professional work of pharmacy includes that done by Carol Kronus. She took a specific look at the dominant value-orientation concept associated with professional status. She used pharmacy practice to test the theoretical model that business is based on pecuniary and extrinsic values, while service professions are predicated on altruistic values (Kronus, 1975). Kronus compared pharmacists with business role orientations (retail pharmacists) versus those favoring a professional role orientation (hospital pharmacists). The results of this paper were compelling, as they did not support the aforementioned theory that community pharmacists were business oriented and thus less altruistic. In fact, Kronus found that pharmacists, regardless of role orientation, were equally motivated by service and income values (Kronus, 1975). In addition, after controlling for work setting, altruism actually predominated in the business setting (Kronus, 1975). This paper was the first of its kind to challenge the notion that pharmacists working in retail settings are merely "entrepreneurs" thus not professionally oriented. This noteworthy outcome further complicates current notions of pharmacists' professional identities, as there is still significant stigma associated with being a retail pharmacist due to the business element of the role.

Another theory that has been explored in the professionalization of pharmacy is the concept of reprofessionalization. According to Birenbaum, the effort to upgrade the status of pharmacy in the health-care delivery system can be viewed as reprofessionalization (Birenbaum, 1982). Birenbaum claims this movement in pharmacy was a reaction to developments in technology, social organization, the division of labor, and financing of health-care services and pharmaceuticals (Birenbaum, 1982). It involved upgrading pharmacy into a clinical profession (Adamcik et al., 1986; Birenbaum, 1982). The clinical pharmacy movement was looking to change the knowledge, skill, and motivation of pharmacists and convince outsiders that pharmacists should be able to consult with patients and physicians. Reprofessionalization in pharmacy practice has been encouraged by structural changes in the organization and delivery of pharmaceutical services. Reprofessionalization can be seen as a collective response to occupational displacement. Structural changes driving the reprofessionalization include (1) the decline of the community pharmacy, (2) automation, (3) development of physician extenders, namely physician assistants and nurse practitioners, (4) new patterns of recruitment into pharmacy schools, and (5) communication among pharmacists. Although this reprofessionalization sounds attractive, it is unclear

how successful it has been since the professional status of pharmacy is still being challenged, and the clinical role has not been fully realized by the profession.

Is a New Conceptual Framework the Future?

Building on the notion of "reprofessionalization" and the need for health-care providers to evolve their professions, Bader and colleagues proposed the application of a conceptual framework composed of three interrelated professional sectors to uncover challenges in the advancement of the profession of pharmacy: education, regulation, and practice (Bader et al., 2017). The authors suggested that no unified approach currently exists as to what constitutes professionalization—or the process of becoming a profession and a framework could help identify current challenges or gaps in the process (Bader et al., 2017). The study was conducted in Jordan and used the Jordanian pharmacy environment as a case example. The original framework used in the study was developed by Rouse in his work with the Accreditation Council for Pharmacy Education (ACPE). The framework has been used for quality improvement purposes and to support the development of the pharmacy profession. It depicts the dynamic nature between education, regulation, and practice. A slight tension between the three sectors is desired to drive change and advancement. It is important, however, that the separation between the three sectors does not get too wide, as this creates a disconnect, which might lead to dissatisfaction or frustration within the profession. A proper push-pull fit between these professional domains is crucial not only to maintaining the integrity of the profession but also to advancing it (Bader et al., 2017).

In the study, Bader et al. conducted semi-structured interviews and focus groups with 53 key pharmacy informants in Jordan. First, interviews were conducted to identify challenges facing pharmacy in Jordan. This was followed by focus groups in which the same participants validated the interview findings and mapped the challenges against the conceptual framework designed by Rouse (Bader et al., 2017). The study identified eight major challenges spanning education, regulation, and practice: graduate preparedness for practice, the quality assurance and accreditation of pharmacy education, pharmacy preregistration requirements, workforce development, workforce planning, pharmacist remuneration, pharmacy assistants, and PharmD-trained pharmacists. These challenges were mapped to the conceptual framework to identify the sectorial disconnects, which could help to explain each challenge and lead to the identification of potential solutions. The authors concluded that the challenges identified were complex and could often be tracked to all sectors of the framework. The use of the framework highlighted the importance of multisector engagement from across the professional sectors when looking to design and implement solutions, as without collaboration, the gaps between the sectors get too wide, which can negatively affect the professional advancement of pharmacy. The findings of this study are interesting and could be applicable beyond Jordan, thus further work in this domain is warranted.

What Is Professional Identity?

In its simplest form, an identity is who we are and who we are seen to be (Monrouxe, 2010). A professional identity, therefore, is who we are in the context of our chosen profession. Professional identities develop alongside our personal identities, incorporating experiences from our personal, private, public, and professional selves into a meaningful whole (Cruess et al., 2016a,b). According to Monrouxe, these identities are rooted in language and interaction and are not fixed but rather are dynamic and constantly transforming (Monrouxe, 2010). Currently, there exists no universal definition of professional identity. From a medical lens, Cruess and colleagues define a physician's professional identity as a "representation of self, achieved in stages over time, during which the characteristics, values, and norms of the medical profession are internalized, resulting in an individual thinking, acting, and feeling like a physician" (Cruess et al., 2016a; p. 8).

This definition, although specific to physicians, highlights the dynamic nature of identity and can be applied to other health professions as well. A professional identity is important, as it is thought to facilitate the internal regulation of professionals, as well enabling confidence to practice (Monrouxe, 2010).

Identity Theory

The concept of identity has been an area of interest within social sciences for decades, but is relatively new in health professions, particularly pharmacy. Numerous theories, from a broad range of paradigms exist, which can be used to understand professional identity (Monrouxe, 2010). A detailed explanation of all theories is beyond the scope of this chapter; however, some key theoretical underpinnings are presented here.

Identities are complex and can be conceptualized in a number of ways. In *Teaching Medical Professionalism*, Monrouxe explored professional identities from various perspectives including individual theories, interactional theories, and institutional theories (Monrouxe, 2016). Individual identity theory is focused around the notion that identity is situated within an individual, constructed in one's mind. In these models, identity encompasses the embodied individual and their psychological-cognitive worlds (Monrouxe, 2016). Erik Erikson is a key theorist in this paradigm. Using a psychoanalytic approach, he proposed eight stages (psychosocial crisis) in which we pass from infancy to adulthood (Erikson, 1968). In contrast, interactional theories are rooted in social constructionism. Meaning that from this perspective, professional identities are coconstructed through language, artefacts, and action and are continuously renegotiated. This paradigm encourages one to understand the impact of discourse and role modeling on the development of professional identities. Institutional identity theories encompass how identities are located or

formed through institutions, often organizations in which we work and learn. These theories explore how organizational culture impacts identity. Therefore, identities can be understood from various perspectives, which can all help inform how we form professional identities.

Professional Identity Formation

Now that we have developed an understanding of what professional identities are, we can begin to explore how they are formed. Not surprisingly, this is a complex process, with no step-by-step guide available for use. In addition, there is no consensus around a definition across professions. In the medical arena, Jarvis-Selinger and colleagues describe the process of professional identity formation "as an adaptive developmental process that happens simultaneously at two levels: (1) at the level of the individual, which involves the psychological development of the person and (2) at the collective level, which involves the socialization of the person into appropriate roles and forms of participation in the community's work" (Jarvis-Selinger et al., 2012, p. 1185). This definition implies that when thinking about identity formation, one must consider the role of both individual and interactional theories of identity. At the individual level, there are distinct stages that one moves through to become a professional. In medicine, practitioners move from medical student to clerk to resident to physician. Each of these stages is associated with a new identity; therefore, individuals must move through a process of constructing and abandoning identities as they transition (Jarvis-Selinger et al., 2012). This is complicated, thus it is essential that educators understand these transitions to help students navigate the process successfully. In addition, social interaction is another key component of identify formation. Individuals, enroute to becoming professionals, join communities of practice in which their identities are forming based on participation in the work of the community. This interaction provides opportunity for strong socialization into these professional communities of practice, including its ways of being and acting (Jarvis-Selinger et al., 2012).

In the pharmacy arena, the American Association of Colleges of Pharmacy (AACP) Taskforce on Professional Identity Formation defined the process as "a transformative process of identifying and internalizing the ways of being and relating within a professional role" (AACP, 2014). The council went on to identify 10 factors or traits that play a role in this transformation/socialization and they are as follows:

1. Knowledge and skills of a profession
2. Commitment to self-improvement of skills and knowledge
3. Service orientation
4. Pride in the profession
5. Covenantal relationship with the client
6. Creativity and innovation
7. Conscience and trustworthiness
8. Accountability for his/her work
9. Ethically sound decision making
10. Leadership

Overall, the definition proposed by AACP reflected the dynamic nature of professional identity formation and the importance of "being" a professional, as opposed to merely acting professionally. That said, the identification of factors (with no clear definitions) seemed to be an attempt to reduce the complexity of professional identity into a checklist exercise that can be implemented in curricula and observed for assessment purposes. The list of factors seemed to be better aligned with the notion of professionalism versus professional identity (Von Hoff, 2017). Professionalism is a term used to describe the behaviors of a professional, thus, "what one does" (Cruess et al., 2016a). Professional identity on the other hand is "what one is" and includes many dimensions beyond behaviors. Pharmacy might benefit from the work occurring in medicine, to further refine professional identity, and the process of formation in pharmacy education and practice. Overall, forming a professional identity is important, as it has been shown to provide a sense of worth, belonging, or purpose (Dawodu and Rutter, 2016); hence, further research in this area is needed to better understand it in the context of health professions, and specifically pharmacy.

Professional Identity—The Role of Higher Education

As previously noted, to be a professional requires one to construct an identity to fit into the desired professional world or community of practice. The role of professional education then, is to help students or novice practitioners to construct these identities (Ronfeldt and Grossman, 2008). During the educational process, students negotiate images of themselves as professionals, based on input and images reflected to them during their programs (Ronfeldt and Grossman, 2008). This is a complex process, as alongside professional identity formation, students must also negotiate their personal identity within the context of their developing professional role (Ronfeldt and Grossman, 2008; Von Hoff, 2017). Currently, there is pressure for universities to produce graduates who are 'work-ready'. What this actually means, is that universities need to generate students who display mastery of knowledge and skill; competency in applying such knowledge and skill in complex work environments; and professional temperaments that nurture

ethical and reflective practice (Trede et al., 2012). Going a step further into health professional education specifically, this means students must graduate with an understanding of their professional roles, clinical responsibilities, workplace culture and societal role. This is no small undertaking for universities and professional programs. It reinforces the need for professional faculties to have a clear understanding of the identities they want to foster in their learners and how they will do so through both the formal and informal curricula.

A recent literature review on the development of professional identities in the higher education literature illustrates that forming a professional identity is a multifaceted process that goes beyond technical skills and interpersonal skills alone (Trede et al., 2012). Identity development must also include professional judgment, self-reflection, and self-directed learning (Trede et al., 2012). This illustrates the importance of research in this area, specific to pharmacy, to better understand what is required to form patient-centered clinical identities. The ability to generate pharmacy specific data will enable informed curriculum design and professional training in the future. The transition from student to novice to expert is difficult and, if left to occur naturally, might lead to disillusionment and issues with retention in the profession (Ronfeldt and Grossman, 2008). In addition to the above, professional socialization processes during education and training are critically important to identity development, as is workplace placements (Trede et al., 2012). Therefore, there is little doubt that universities and professional programs play a significant role in identity formation, though how much is intentionally designed versus being left to chance is debatable. What is clear though is that numerous opportunities exist for professional education to contribute to the formation of professional identities.

Professional Identity—Pharmacy Education

There has been a significant philosophical shift in health professional education recently: a shift from teaching professionalism to supporting professional identity formation (Cruess et al., 2016a). The idea of professional identity, however, is not new. According to Cruess et al., Merton published one of the first studies of the sociology of medical education in 1957 (Cruess et al., 2016a). In this work, Merton stated that "medical education has a dual purpose: to shape the novice into the effective practitioner of medicine, to give him the best available knowledge and skills, and to provide him with a professional identity so that he comes to think, act, and feel like a physician" (Merton, 1957, p. 5). In addition, Cruess and colleagues stated that, "if medical education is to be reframed around the concept of professional identity formation, the definitions of identity, professional identity, and professional identity formation become foundational elements of any education program" (Cruess et al., 2016a, p. 7). This is of particular importance to all health professions, including pharmacy whose professional practice is currently undergoing significant change. Having clear definitions of the concepts of professional identity in pharmacy education is crucial, as they are the cornerstones of contemporary curriculum design and student socialization processes.

The formation of professional identities is important to enable students to transition from university life to work life (Noble et al., 2014a). It plays an important role in helping novice practitioners cope with uncertainty and build confidence, in addition to providing frameworks for professional work (Noble et al., 2014a). Currently, there is a paucity of literature on professional identity and professional identity formation in pharmacy education and practice (Dawodu and Rutter, 2016; Noble et al., 2014a). It is difficult to articulate the identity of contemporary pharmacists, which contributes to role ambiguity for both the profession and society. A commentary by Dawodu and Rutter argued that the change to mass production of medicines by the pharmaceutical industry has eroded the status that was once afforded to the profession (Dawodu and Rutter, 2016). Because of this change of function, pharmacists have been searching for new roles that go beyond the dispensing of medications.

> Current pharmacy leaders are advocating for the pharmacist as medication expert, a clinical role committed to maximizing the use of medications for individual patients, thus contributing to improving patients' health outcomes (Dawodu and Rutter, 2016, AFPC Educational Outcomes, 2017). This lack of identity creates problems in education and practice, as pharmacists do not have a clear sense of who they are and what they stand for. There is currently a lack of consensus to clearly articulate the professional identity of a pharmacist. Dawodu and Rutter state: Incoherent, confused and mixed messages conveyed by the profession (about what we are) are hindering professional socialisation and consequently the ability of future pharmacists and qualified pharmacists to gain a sense of true professional identity (Dawodu and Rutter, 2016, p. 2).

A thought-provoking piece by Morison and O'Boyle reinforced this professional identity crisis. It compared first-year nursing, medical, dental, and pharmacy students' perceptions of the professional identity of their respective discipline (Morison and O'Boyle, 2007). The results illustrated that medicine and nursing students had a strong belief and commitment to their professional identity at the outset of training and high intrinsic motivation to join their professional group. Pharmacy and dental students, on the other hand, were motivated in terms of less personal factors such as good working conditions and good salaries (Morison and O'Boyle, 2007). Pharmacy students actually struggled to identify roles that made their profession distinct. Also of note in this study was that nursing and medical students had clear ideas about what it means to belong to their profession but pharmacy and dental students struggled to describe this, resorting instead to explaining their identities by how they differed from medicine. Pharmacy and dental students had a stronger grasp of a doctor's role, than of their own respective future professional role. This is problematic as evidence suggests that pharmacy students enter working life without a strong sense of professional identity and hold negative opinions of the profession. Overall, this literature reinforces the need for pharmacy educators to revise curriculum to include clear attempts to facilitate 21st century pharmacist identity formation. There is a significant role for pharmacy educators to shape student views on what it is to be a pharmacist, and this should not be taken lightly.

Professional Identity—The Role of the Curriculum

If the goal of health professions education in the 21st century is professional identity formation, then the curriculum must support this process. This has major implications for curricular design such as the creation of new educational outcomes, methods to engage and support students through the process, development of educational activities that promote professional identity formation, methods to assess progress toward a professional identity, and faculty development (Cruess et al., 2016a). Currently, there is a lack of literature outlining how professional identity can be supported throughout the continuum of professional education; however, there are studies, including some specific to pharmacy, that explore various curricular activities and their impact on identity formation.

In professional education programs, some key factors influencing students' professional identity are (1) opportunities for imagination, (2) observation, (3) experimentation, and (4) evaluation (Noble et al., 2014a). Taking this into account, pharmacy curriculum then needs to include learning opportunities where connections are made for students between what is being taught and the implications for future practice, so they can imagine their future selves. In addition, curriculum needs to provide opportunities for students to observe role models in action and to experiment with being a professional themselves through activities that are authentic approximations of practice. Finally, there needs to be opportunities for students to evaluate their learning experiences (Noble et al., 2014a).

With these factors in mind, Noble and colleagues undertook an ethnographic study to examine the student experience of the formal pharmacy curriculum at a large research focused Australian university. The study used sociocultural learning theory as a theoretical framework to understand how the formal curriculum experience supports students' professional identity formation. The researchers examined a typical week for a pharmacy student in each year of study. All of the formal curricular experiences were examined, as it has been found that all aspects of professional education, not just the practice related aspects contribute to students' formation of their professional identities (Noble et al., 2014a). The study data were analyzed for themes based on an a priori framework for student professional identity formation (1) opportunities to imagine being a pharmacist; (2) observing what it might be like to be a pharmacist; (3) experimenting with being a pharmacist; and (4) evaluating the experience of being a pharmacist. Overall, there were significant opportunities for students to imagine being pharmacists in the curriculum; however, there were few observed instances where explicit connections between the content being presented and practice were made. This presented challenges to the students who indicated they struggled to establish meaning from the presented content.

During the study, students tended to observe academics and tutors in educator roles rather than enacting pharmacist roles, which meant students had to imagine for themselves what the pharmacist's role might be like or how the educator may actually practice. This is problematic, as for successful identity formation, expert role models are needed.

The key opportunities for students to experiment with their professional identities occurred during tutorials and laboratory practicums. Despite the intended patient-centeredness of these activities, there was an absence of patients and when the students role-played being patients they lacked authenticity. This approach encouraged information provision rather than patient engagement, and there was a focus on the assessment checklist. As such, students were not afforded opportunities to develop their own way of doing things. As a result, the observed ways that students engaged with the counseling and dispensing tutorials tended to mechanistic. Rather than presenting the curricular experience as an opportunity to experiment with provisional pharmacist identities, the direction toward assessment seemed to reinforce student identities and provided limited opportunities to experiment with being pharmacists.

Finally, students were rarely prompted to examine how their learning experiences related to their future pharmacist selves. In other words, they were not asked to consider what types of pharmacists they would like to be. In a number of instances, students were upset that they could not see how what they were learning related to their future roles.

This study begins to address an important gap in pharmacy practice and education research. Overall, from the perspective of professional identity formation, the curriculum may not be enabling students to construct strong patient-centered professional identities. This creates opportunities for pharmacy educators to consider how the curriculum promotes professional identity formation and redesign it with more emphasis on patient-centeredness, making connections to practice, pharmacist role modeling, and opportunities to experiment and a curriculum that supports feedback.

In addition to the above study, Noble and colleagues also used focus groups comprising 82 students representing each year of the 4-year curriculum at the same Australian university (Noble et al., 2014b). The study explored students' perceptions of their overall curricular experience and examined how these experiences influenced the construction of their professional identities. Overall, the authors found that the students struggled with professional identity formation. Many were entering the degree with little understanding of what being a pharmacist entailed and many did not actually desire to become a pharmacist. Many students saw pharmacy as a gateway to other professions, such as medicine, which contributed to a lack of a sense of professional identity (Noble et al., 2014b). Once in the curriculum, the role of the pharmacist became clearer, but it was very idealistic, and the students felt that it was not enacted. Students experienced a disconnect between the idealistic notion of pharmacy practice shared in the curriculum with the realities of practice experienced during experiential rotations and work placements. The struggle left the students feeling that the role of the pharmacist was constrained and limited. Overall, this study highlights the importance of support of professional identity formation immediately from the point of entry. Students need to be supported through the process of learning to "be" a pharmacist, particularly as they transition through different learning and practice environments. More research in this area is needed to further understand how to support students through the process.

Other Curricular Activities—Teaching Methods

To best support professional identity formation in the curriculum, evidence informed pedagogic strategies and teaching methodologies must be used. There is evidence to support the use of reflection/reflective writing, clinical and professional experiences, mentoring, learning communities, and interprofessional experiences (Holden et al., 2016). There are limited data specifically exploring teaching methodologies; however, there are some studies which have looked at the use of group work and problem-based learning (PBL) and their impact on professional identity formation. A brief review of these studies is provided.

As previously noted, professional identity formation is not static but rather constantly undergoing reformation. This relies significantly on social and relational factors between faculty, students, practice environments, and courses (Bridges, 2018). Group work is a common pedagogical strategy used in pharmacy education, which draws on social aspects of learning and is thought to be a means to develop collaboration, teamwork, leadership and as a way to enhance students' intellectual, personal, and professional development (Bridges, 2018). A recent study aimed to explore the potential of mutual learning through group work to contribute to not only academic knowledge and understanding but also to the development of students' professional values and selves. The study was conducted in the United Kingdom. Overall, the study found that the opportunity for group work and collaboration can positively influence development of students' professional outlook and values; however, careful management of group working is required to create a mutually supportive environment where students feel able to interact, share, and develop together.

Another study by Tan et al. (2016) looked specifically at problem-based learning and how it contributes to students' professional identity development. PBL originated in medical education but has expanded and is used in many other areas of professional education. It has been suggested as a useful strategy to support professional identity formation. For their study, Tan et al. applied a comprehensive professional identity framework (professional identity five-factor scale or PIFF) to PBL pedagogy at a polytechnic in Singapore that prepares students in a wide range of professions. The study aimed to gain insight into how PBL was incorporated into the dimensions of (1) knowledge about professional practices, (2) having the professional as a role model, (3) experience with the profession, (4) preference for a particular profession, and (5) professional self-efficacy (Tan et al., 2016). They obtained data from 709 students and 6 educator-practitioners. The students provided descriptions of significant influences that helped them understand what it meant to work in their chosen professions and the educator-practitioners provided information regarding their preferred teaching approaches that were influenced by their professional journeys. Overall, the authors found that from the student perspective PBL does not feature in the dimension "experience with the profession," but it did impact identity formation in the other four dimensions. From the educators-practitioners perspective, PBL was important in self-efficacy and preference for a particular profession but only in the context of aerospace engineering (Tan et al., 2016). For most educator-practitioners, however, PBL was not their preferred teaching approach to prepare students for work. Overall, the authors found that to comprehensively promote professional identity development, PBL has to include experience with the profession in some way and this can be challenging.

Other Curricular Work—Assessment Practices

Assessment is a central component to education, as emphasized in the age-old statement "assessment drives learning." Assessments are the mechanisms by which educators and professional stakeholders are assured learners have met educational outcomes and minimum standards for professional practice (Norcini and Shea, 2016). For students it offers guidance to areas of strength and weakness in their professional development. There is an abundance of literature on assessment practices in health professional education, specifically aimed at determining what students know and how well they perform (Norcini and Shea, 2016). In contrast, there is much less evidence to support the assessment of what a student "is" (Norcini and Shea, 2016). Debate exists as to how professional identity can be assessed and maybe more importantly, if it should be assessed? Significant challenges exist in the assessment of "being," particularly with respect to the lack of clear definitions of professional identity and how it is formed. Recent work by Cruess et al. proposed amending Miller's Pyramid to include professional identity formation (Cruess et al., 2016b). The author's proposed that a fifth level be added at the apex of the pyramid, to reflect the presence of a professional identity and that this level be named "is" (Cruess et al., 2016b). Recall, each level of Miller's pyramid is associated with structured methods of assessment. The levels are "Knows," "Knows how," "Shows How," "Does," and now potentially "Is". Amending Miller's pyramid will have significant teaching implications, as this new level will require changes in what is being taught to students, as well as the development of appropriate tools to assess identity formation. More work is needed in this area; however, it is important to consider assessment if professional identity formation is a mandate of health professions and more specifically, pharmacy education.

Professional Socialization—Pharmacy Education

Professional socialization is a term used frequently in health professional literature to describe social processes associated with becoming a professional. Similar to professional identity formation, there is no universal theory of socialization; hence, it is used in various ways in the literature and often vaguely (Hafferty, 2016). According to Fred Hafferty, "socialization fundamentally involves training for self-image and identity" (Hafferty, 2016). This implies that the underlying dimension of all socialization processes is personal transformation, not merely changing behaviors and attitudes to align with professional roles—identity transformation is not merely situational adjustment (Hafferty, 2016). The core element of socialization is adopting a collective sense of what it means to be an in-group member versus out-of-group member. The process of socialization is impacted by formal,

informal, and hidden curricula; hence, curricular design must be intentional to reinforce development of the type of health professionals we wish to produce.

Historically, learning how to be a pharmacist involved an apprenticeship model. An aspiring apothecary (pharmacist) would work alongside an established practitioner and learn the skills required to practice (Buereki, 1999). In this way, pharmacists were socialized to their role by a "master" of the profession (Buereki, 1999). Over time, pharmacists came together in formalized colleges and universities for education and training purposes. For example, the first schools of pharmacy in the United States, United Kingdom (UK), and Canada opened in 1821, 1842, and 1882, respectively. By the mid-1940s, baccalaureate degrees in pharmacy were standard. During this time, the pharmacy curriculum was heavily rooted in chemistry, preparing pharmacists to formulate and dispense medications. Over time, however, the basic science and chemistry focus of the curriculum shifted to be more rooted in biology with an emphasis on pharmacology by the 1960s. The 1970s saw the beginning of the clinical pharmacy era and the 1990s marked the birth of the pharmaceutical care era in pharmacy education (Buereki, 1999). With each curriculum shift over the last century, the role of the pharmacist is assumed to have evolved, moving away from that of dispensing and information gathering, toward clinical decision making and the pharmaceutical needs of the patient (Anderson, 2002; Frankel et al., 2014). The most recent significant curricular transition from Bachelor of Science in Pharmacy (BScPhm) programs to entry-level (undergraduate) Doctor of Pharmacy (PharmD) programs across North America, and Master of Pharmacy (MPharm) programs across the United Kingdom and other parts of Europe, is designed to emphasize the evolving roles of the pharmacist, specifically in the patient care domain (Austin and Ensom, 2008; Sosabowski and Gard, 2008; Waite et al., 2006). However, in spite of these changes to the degree designations and curricular content, there is no evidence to suggest that pharmacy educators themselves have internalized the new roles and identities they are expected to teach. Many pharmacy educators and mentors harbor pharmacist identity constructs of the past. Therefore, in spite of curricular changes, pharmacy education continues to socialize students to dispensing and scientist orientations. To be successful in constructing a new identity for pharmacists in the 21st century, new socialization processes must take root. A significant challenge to developing this new clinician identity in pharmacy education and training is the unwillingness of practicing pharmacists to accept increased professional responsibility and accountability for patient care (Frankel et al., 2014; Rosenthal et al., 2010).

The aforementioned challenges infer that additional work is needed to better understand pharmacy identity formation during formal and informal pharmacy education. As previously mentioned, literature suggests that practising pharmacists struggle to articulate a clinical pharmacist identity (Elvey et al., 2013; Frankel and Austin, 2013). This is problematic, as these practising pharmacists become teachers and mentors in the workplace to large numbers of pharmacy students during clinical rotations and work experiences. This practice exposure has significant impact on the pharmacy learner's developing professional identity and might inhibit growth of the clinician identity that was forming during in-class experiences.

A study from Australia specifically examined professional socialization in pharmacy education (Kritikos et al., 2003). The authors set out to explore pharmacy students' perception of their profession relative to 10 other health-care professions. The results revealed that pharmacy students perceived community and hospital pharmacists to be similar in power and status, but significantly lower in status than physicians, dentists, and physiotherapists. This study highlights the notion that pharmacy students' lack a clear identity during pharmacy school but have strong beliefs that they are professionally inferior to other health disciplines, namely, medicine. This is another area that the profession needs to tackle if pharmacists are to be viewed as equally contributing members of the health-care team.

Another paper by van Huyssteen and Bheekie examined professional identity development specifically in first-year students. The authors identified and described first-year pharmacy students' professional identity and explored whether it changed during the first semester "introduction to pharmacy" course.

For this study, the students wrote three sequential reflective reports in which they were expected to identify critical experiences since their enrolment. The authors analyzed student reports for themes. The early reports indicated that students had stereotypical views of pharmacists as medicine suppliers. Subsequent reports, however, showed a shift in perspective, as students articulated a more complex role for the pharmacist and formulated the pharmacists' value for society. The findings showed that students developed an increasing sense of belonging to the pharmacy profession as they moved through the introductory course. It would be interesting to repeat a similar study in subsequent years of the program, to determine if the professional identity of students changes. There is work to suggest that pharmacy students professional identity might shift and become more negative as they move through the program (Knapp and Knapp, 1968) suggesting that informal and hidden curriculum content might impact identity formation in a negative way and more strongly than formal curriculum content. Further work in this area is needed to better understand the evolution of professional identity formation throughout the pharmacy curriculum.

Additional work by Carol Kronus examined the impact of formal education in pharmacy on the formation of professional identity versus workplace impact (Kronus, 1976b). She was curious to know if the roles that pharmacists were socialized to during formal education remained consistent as pharmacists entered the workplace or if pharmacists were resocialized to, different role orientations as work commenced. Pharmacy practice is characterized by diverse values and work settings; however, the education and training process is quite standardized. As such, Kronus rightfully identifies pharmacy as being ideal to test two models of influence: (1) the professional model that posits that occupational members retain a stable identity established via their socialization experience during education versus and (2) the situation model, which emphasizes the resocializing pressures of the work situation (Kronus, 1976b). The results of this study indicate that professional identity formation in pharmacy is more strongly influenced by the work setting compared to the education setting. She suggests that the notion of long-lasting professional identity only works in situations where occupations have more power than other occupations, clients and governments, which is not the case

for pharmacy as it is considered a weak profession, particularly compared to medicine (Kronus, 1976a,b). This study is of particular importance when one begins to think of professional identity and the potential for experiential placements to impact professional socialization. It is very important for pharmacy educators and schools of pharmacy to select the sites for workplace placements very carefully—to ensure the sites are modeling the identity characteristics consistent with the formal, didactic education. Very little literature exists in pharmacy looking at the impact of experiential education and professional identity formation. This topic will be explored in more detail later in this chapter.

Development of professional behavior and attitudes in pharmacy students is an important professional outcome. In spite of this, there seems to be a lack of structure or clear framework in pharmacy curricula related to professional socialization of our pharmacy students (Kelley et al., 2009). A paper by Kelley and colleagues set out to determine if pharmacy educators have the right formula for successful professional socialization. The paper drew on literature in higher education that showed that student engagement leads to positive learning outcomes, as well as character development. With this in mind, Kelley and colleagues compared strategies used by undergraduate first-year experiences (FYE) programs to enhance student engagement with approaches used by professional doctoral programs to improve professionalism (Kelley et al., 2009). The study was conducted in six US universities with pharmacy schools. The study found that both FYE and professional programs used orientation programs, course work, and student codes of conduct to develop character or professionalism, respectively. The FYE programs included more reflective writing activities, peer mentoring, and diversity activities than professional schools. The study concluded that the undergraduate FYE is a useful framework for developing professional attitudes and behaviors in pharmacy students. The authors go on to recommend the following to pharmacy education: (1) incorporating professionalism development into program mission statements; (2) communicating the importance of developing professionalism to students; (3) offering activities aimed at professional development; and (4) engaging students fully in these activities.

Professional Identity and Experiential Learning

Experiential learning is a common component for most modern health professional education programs. Pharmacy is no exception, with many programs expanding the number of weeks students spend learning in workplace environments. With the movement to entry level of doctor of pharmacy programs across North America, students are required to complete experiential rotations after each year of professional study, with the entire fourth year of the program being experiential in nature. In many schools, students are spending upward of 40 weeks in experiential learning environments. This shift in experiential learning is important when it comes to professional identity formation, as students will incorporate these experiences into their developing identities. These rotations have the potential to enhance identity formation or potentially inhibit it. There are numerous definitions of experiential learning; however, a good one by Yardley and colleagues states that experiential learning involves "constructing knowledge and meaning from real life experience" (Yardley et al., 2012). The key to experiential learning is reflection. Similar to other areas, there is limited evidence regarding the impact of experiential learning in pharmacy on professional identity formation. A 2016 paper in the American Journal of Pharmaceutical Education (AJPE) examined the extent to which reflective essays written by graduating students revealed professional identity formation and self-authorship development (Johnson and Chauvin, 2016). After a six-week advanced pharmacy practice experience (APPE) in which the students were exposed to a model of self-authorship development they completed a culminating reflective essay on their rotation experiences and professional identity formation. The essays were then thematically analyzed. The results indicated that a relationship existed between self-authorship and pharmacist professional identity formation. This study suggests that purposeful structuring of experiential rotations can facilitate professional identity formation and is an opportunity for pharmacy educators to impact student growth and development in this domain. More work is needed to further understand how to structure rotations to maximize the potential for professional identity development in students.

Professional Identity—Pharmacy Practice

Currently, the profession of pharmacy is still considered to be in transition, still seeking out professional legitimacy as clinicians. The modern day paradigm of pharmacy practice is pharmaceutical care. Pharmaceutical care is a patient-centered philosophy, in which the focus of attention is optimizing medication outcomes for individual patients (Anderson, 2002; Cipolle et al., 2012). Increasingly, pharmacy curricula across the globe have been revised to incorporate a patient-centered approach as a foundation. Yet, in spite of the strong movement toward the pharmacist clinician, this identity is still not widely accepted by pharmacists themselves nor among other health-care providers. A recent paper by Elvey and colleagues examined how pharmacists in England perceive their professional identity. The study identified the presence of nine separate identities for pharmacists. Of the nine, the strongest identities were that of scientist and medicine maker (Elvey et al., 2013). The identity of clinical practitioner was overshadowed by those of businessperson, manager, and medicine supplier (Elvey et al., 2013). These multiple identities might reflect the continued role ambiguity, inadequate socialization processes during education and training, and lack of clear professional direction (Elvey et al., 2013). The study also reinforces a clear need to understand what should define a pharmacists' identity in the 21st century from the beginning of education and training and into the workplace. As noted, professional identity formation begins during ones' professional education; however, it continues to evolve as individuals begin to practice.

Further to the Elvey et al. study, a Canadian study by Pottie and colleagues explored pharmacist's identity development within multidisciplinary primary health-care teams (Pottie et al., 2009). The study analyzed narrative reports from 63 pharmacists over a 9-month integration period. The study found that pharmacists' integration into team-based primary health care provided both challenges and opportunities. Pharmacists' professional identities evolved in relation to valued role models, emerging practice-level opportunities, and their patient related contributions. Overall, setting, skills, perspectives, and mentorship factored into identity formation. This study is important as it suggests that pharmacists' professional identities require further transformation depending on practice type, thus reinforcing the transforming nature of identities over time.

The Future: Where are we Heading?

Pharmacy is in the midst of yet another professional transformation, to the role of clinician. Trends in pharmacy curricula across the globe suggest an increase in clinical therapeutics courses, pharmacy skills labs, and experiential rotations contrasted against a decrease in basic science courses and dispensing and compounding labs, with the intention of creating clinicians. If pharmacy is going to be truly successful in achieving clinician status; however, it must go beyond curricular content change and make professional identity formation an explicit curricular objective. This means that pharmacy educators must define the desired patient-centered pharmacist identity and purposefully design the curriculum to include teaching and assessment practices that will support the development of the desired identity. The formal curriculum will need to include significant time for reflection so learners can consciously factor patient-centered culture into their way of being. In addition, pharmacy will need to invest in significant faculty development. If the identity of the profession is going to change, it will require strong faculty leadership. Faculty members will need to be educated in professional identity formation and pedagogical practices that support it. In addition to core faculty, pharmacy will also need to work with pharmacist preceptors and role models to ensure they are supporting the formation of the clinician identity. Pharmacists who have responsibilities to mentor and assess students during rotations must provide positive clinical experiences for students. These individuals with teaching responsibilities should receive education and development similar to faculty members and their performance should be assessed regularly with validated tools. If not adequate, they should be remediated and/or removed from teaching. Finally, pharmacy would benefit significantly from more research in this area. The data available currently are sporadic, but the profession needs approaches that are more systematic.

Conclusions

Pharmacy has undergone significant professional transformations over the last century in both practice and education. These changes have impacted how pharmacists and pharmacy educators understand their professional identities. With the current movement in health professional education to make professional identity formation, the main goal of professional programs, pharmacy is well situated to develop a program of research in this area to inform curricular design and future educational reform.

Counterfeit Medicines: A Quick Review on Crime Against Humanity

Mohamed Izham B. Mohamed Ibrahim, Qatar University, Doha, Qatar

Introduction

People's lives and public health depend on effective and quality legitimate medicines. There are two types in the market: proprietary medicines and generic medicines (Liu and Lundin, 2016). Generic medicines are also known as nonproprietary medicines, while the proprietary medicines are brand-name medicines. The proprietary medicines is produced, marketed, or used under exclusive legal right of the inventor or manufacturer (Law Insider, 2018), while generic medicines are medicines that are no longer under patent protection and may be produced by any manufacturers.

People's healthcare is mainly in need of essential medicines for prevention and treatment of illness, slowing down the disease process, reducing suffering and rehabilitation. Unfortunately, individuals especially in the low- and middle-income countries (LMICs) lack access to effective and quality medicines (Leisinger et al., 2012); most of the reasons for mortality, morbidity, and disability could be prevented or treated with medicines, and individuals are not just neglected and deprived from getting these medicines but are exposed to illegitimate medicines such as counterfeit medicines (also referred to as fake, spurious, or falsified medicines; sometimes the abbreviation SSFFC (substandard/spurious/falsely labeled/falsified/counterfeit) is used.

Definition

The Australian Therapeutic Goods and Administration (TGA) defines counterfeit medicines as imitation goods which are packaged to look like genuine items (TGA, 2015). Products are considered counterfeit if they are falsely manufactured, packaged, or advertised. According to the US FDA (Food & Drug Administration), counterfeit medicine is fake medicine, sometimes called falsified pharmaceutical products or different other terms (US FDA, 2016). The MEDICRIME convention (Council of Europe, 2011: Article 4j) defines the term counterfeit as "a false representation as regards identity and/or source". According to the Pharmaceutical Security Institute (PSI), "counterfeit medicines are products deliberately and fraudulently produced and/or mislabeled with respect to identity and/or source to make it appear to be a genuine product" (PSI, 2018a). In 2017, the term "falsified" was accepted by the members at the Seventieth World Health Assembly as a more acceptable term and clearly understood for future work (WHO, 2017a, 2017c). Different organizations, stakeholders (from lay people to policymakers), and countries have defined the word "counterfeit medicines" differently and this can cause confusion. According to the new term, falsified medical products are defined as "medical products that deliberately/fraudulently misrepresent their identity, composition or source." This chapter will use the term "falsified medicines" throughout. The term "counterfeiting" is meant in its broadest sense of "falsification."

Falsified medicines may be comprised of incorrect ingredient, without active ingredient, with harmful substances, with active ingredient, but with the wrong amount or maybe the product is contaminated. They can have less or more than the required amount of active ingredients. They can also contain the correct amount of active ingredients, but have been manufactured in unhygienic and unsafe environments (PSI, 2018a). PSI reported cases where genuine medicines have been placed in counterfeited packaging to extend the expiry date.

Merck, one of the top multinational pharmaceutical companies defined counterfeiting as: "Unauthorized use of trademark, trade name, other identifying mark, imprint, or device, or any likeness thereof to adulterate, falsely purport, or represent that the product was manufactured or distributed by the identified manufacturer or distributor" (Merck, 2014).

It is important for authorities and researchers to differentiate falsified medicines from substandard medicines defined as "pharmaceutical products that do not meet their quality standards and specifications" (WHO, 2017a). These products are produced by legitimate companies that have limited technical capacity and appropriate facilities to ensure minimum quality standards to manufacture, supply, and distribute the medicines (WHO, 2017b).

Extent of the Problem

According to the World Health Organization (WHO, 2006), it is a worldwide issue, affecting every region and, especially the LMICs. All range of products can be affected, i.e., generic and originator brands; cheap and expensive; and different classes of medicines. Falsified medicines may harm the users with deteriorating patient health and disease conditions. They do not ensure quality, therapeutic efficacy, or safety. Moreover, they also have financial implications for caregivers, healthcare system resources, and healthcare delivery (Sanofi, 2013).

Even though many reports have mentioned the extent of the problem, the accurate prevalence rate is hard to estimate, partly due to non-well-documented reports. Thus, there is lack of reliable data, however, it is worth mentioning estimates provided by various studies and organizations. The volume of falsified medicines is also unclear. According to Cockburn et al. (2005), the prevalence of falsified medicines seems to be growing. Cockburn et al. (2005) and Newton et al. (2006) reported that in areas that are suffering from communicable diseases such as HIV-AIDs, tuberculosis, and malaria, the number of falsified medicines could be more than 50%. Nayyar et al. (2012) reviewed studies on the quality of five classes of anti-malarial medicines from seven countries in Southeast Asia. Thirty-five percent from 1437 samples of medicines failed chemical analysis, 46% of 919 failed packaging analysis, and 36% of 1260 were classified as falsified. Further findings from 21 countries in sub-Saharan Africa, reported that in 21 surveys of medicines from six classes, around 804 (35%) failed chemical analysis, 28 (36%) failed packaging analysis, and 78 (20%) were classified as falsified. The global falsified medicine trade, a billion-dollar industry, is thriving in Africa (Sambira, 2013).

The Pharmaceutical Security Institute has collected data on medicines falsifying worldwide for many years. According to the agency, between 2013 and 2017, total pharmaceutical crime incidents, which include falsifying, increased from 2193 cases (in 2013) to 3509 cases (in 2017). PSI tracked worldwide falsified medicine confiscations and the amounts seized. In 2017, 52% of cases were classified as commercial incidents (i.e., incidents involving the seizure of more than 1000 dosage units), 32% as non-commercial (i.e., incidents involving less than 1000 dosage units were classified as non-commercial), and 16% were unknown cases. Close to six hundred falsifying incidents involved either customs seizures or police/health inspector raids (PSI, 2018b). Mackey et al. (2015) studied the PSI Counterfeit Incident System database and found that in 417 (27.6%) reports, China was the source country of the incident.

According to a 2010 World Health Organization Fact Sheet—IMPACT (AIFA, 2011)—it is difficult to estimate the percentage of falsified medicines in circulation. WHO estimated around 1% of medicines in circulation in industrialized countries are falsified. Moreover, in many African countries, parts of Asia, Latin America, and countries in transition, a much higher percentage of the medicines on sale may be falsely labeled or falsified. The World Bank reported that up to 15% of all medicines sold in developing countries create a threat to patients (World Bank, 2014). In another report, INTERPOL estimated that 30% of medicines in Africa are either falsified or of inferior quality. The issue is more problematic in the poorest countries (INTERPOL, n.d.). INTERPOL's flagship pharmaceutical investigation, Operation Pangea, for example, seized 2.4 million fake and illicit pills in 2011 (INTERPOL, n.d.). During another Operation Pangea VIII in summer 2015 that involved 115 countries, approximately 21 million falsified medicines worth a total value of USD81 million were confiscated in a week (Lundin, 2015). The author further reported that the WorldWide Antimalarial Resistance Network revealed that 35% of all anti-malarial medication was falsified. The figures in Nigeria were as high as 64%. Other medications that are often falsified are those used for HIV/AIDS, TB, and Ebola (Lundin, 2015).

According to the European Union's custom authority, there is an upward trend in Intellectual Property-violating goods crossing the borders: one-tenth of the 43,500 cases of such goods in 2009 were medicines (EU Custom Authority, 2017). Uganda's National Drug Authority reported that cases of medicines failing to meet quality standards at the country's national laboratories have fallen by 15% since the early 2000s (Wilson, 2013). A drug quality project carried out by the Medicines Transparency Alliance (2015) in Uganda found that 55% of cefixime products, 23% of cefuroxime products, and 25% of erythromycin products were suspicious. According to a report by Sari (n.d.), in Indonesia, in terms of financial value, fake medicines constituted 25% of the country's $2 billion pharmaceutical market. Meanwhile, in terms of quantity of goods, the size of falsified pharmaceuticals was 3.8% (versus other products such as food, cosmetics, software, etc.) according to the Indonesian Anti-Counterfeiting Society (MIAP) in 2016. According to the Center for Medicine in the Public Interest in the USA, the global sales of falsified medicines could increase to USD75 billion in 2010, a 90% rise in five years (WHO, 2010).

Who and What Are Affected?

No product is immune from falsification. Both generic and branded (or originator) medicines are affected. Falsified medicines involve both lifesaving and lifestyle medicines (Blackstone et al., 2014). Falsification affects all countries, healthcare systems,

pharmaceutical supply chains, manufacturers of the original medicines, retailers, wholesalers, healthcare institutions, healthcare providers, regulatory agencies and officers, policymakers, publics, and patients.

Based on the PSI (2018c) data, when examining falsifying incidents only, medicines in the genitourinary, anti-infectives, and central nervous system (CNS) therapeutic categories were the most frequently targeted by individuals engaged in pharmaceutical falsifying. The PSI tabulated 1510 falsified incidence reports worldwide (from 2009 to 2011), mostly from health-related government agencies. Slightly more than half (51.3%) reported a falsified medicine without a recognized or verifiable subcategory. Despite the fact, practically all types of pharmaceutical products have been shown to be involved, the prevailing data suggests that anti-infectious agents, mainly antibiotics and antiparasitic agents, are the most falsified products in developing countries (Wondemagegnehu, 1995; Frankish, 2003; WHO, 1999; Pincock, 2003; Scutti, 2015; PSI, 2018b). Others are genitourinary (15%) and cardiovascular (12%) medicines (PSI, 2018b). Even though no one has a clear idea about the statistics, still, it is clear the falsified medicine problem is bigger than in the past and covers widely used medicines, such as anti-malarials, as well as high-demand medicines, and high-value medicines, such as those used to treat cardiovascular disease, cancer, and HIV/AIDS (Mackey et al., 2015).

Economy-wide falsifying undermines innovation, which is key to economic growth. The crime of falsifying medicines affects intellectual property rights. Intellectual property theft decreases incentives to create and innovate, consequently reducing economic output and employment. Falsification affects the income of pharmaceutical and biopharmaceutical industries, reducing the incentive to engage in research, development, and innovation. Besides posing health hazards to patients, including death, falsification wastes consumer income with spending on useless products. In China, about 0.20–0.30 million people die annually because of falsified and substandard pharmaceutical products (Morris and Philip, 2006). Additionally, and more importantly, 28% of the counterfeit reports (from 2009 to 2011) in the Counterfeit Incident System of Pharmaceutical Security Institute indicated China to be the source country of the falsified medicines (PSI, n.d.). The severity of the effects on patients and consumers depends on the contents in the falsified medicine. It can affect the legal medicine supply chain as the raw material and ingredients of the products can pass through the system including storage, transportation, and distribution activities. **Table 1** shows some cases of the effects of falsified medicines on people.

What Are the Roots of the Problem?

There are many diverse reasons for falsified medicines. Political, economic, social, and cultural factors of the country are part of the reason for the emergence and prevalence of falsified medicines. Due to increasing globalization, the problem of falsified medicines has expanded vastly, to both developed and developing countries (FIP, n.d.). Falsified medicine trade is probably linked to organized crime, terrorist groups, corruption, the narcotics trade, the business interests of unscrupulous politicians, and unregulated pharmaceutical companies (Moken, 2003; Carpenter, 2006). China and India are reported as the main countries of origin of falsified medicines, the two largest manufacturers and exporters (Delepierre et al., 2012). Russia, China, Brazil, Mexico, Pakistan, Southeast Asian, and Middle Eastern countries are also considered as chief operators in manufacturing and distributing falsified medicines (Clark, 2015; Shepherd, 2004). Dégardin et al. (2014) reported that areas like the middle-east and Switzerland are assumed to be major transit hubs of falsified medicines.

Trafficking in falsified medicines can be extremely profitable; detection of falsified medicines is difficult, and the penalties are relatively moderate. Eser et al. (2015) illustrated the illegitimate supply chain from the design of fake medicines through to the utilization level by willing and unwilling buyers. Among the reasons for this high prevalence were a weak or absent drug regulatory authority; absence of a legal mandate for licensing of manufacture/import of medicines; lack of regulation by exporters and within free trade zones; proliferation of small pharmaceutical industries; complex transactions involving many intermediaries; high demand for curative and preventive medicines and vaccines that exceed supply; high prices of medicines; and inefficient and insufficient cooperation among stakeholders (WHO, 1999).

In some countries, matters related to insurance coverage can be a factor for the use of falsified medicines. People who are underinsured or uninsured tend to access cheap medicines from unauthorized sources such as Internet and foreign pharmacies. The tendency for falsified medicines proliferation when medicines are expensive is high. Over 90% of Nigerians' income is below USD2 a day and they cannot afford good medicines (HAI Africa, 2008). Moreover, an earlier survey showed a low availability of essential medicines in the health facilities where only 46% of key medicines were found. Another study reviewing the efforts made by the Nigerian National Agency for Food and Drug Administration and Control (NAFDAC) to control the distribution of falsified medicines noted that the inability to close the unmonitored, unlicensed, unregulated, chaotic, open pharmaceutical market that forms the major medicine distribution centre patronized by many medicine outlets, has brought about a wider spread of falsified medicines without control (HAI Africa, 2008). Another reason for the spread of falsified medicines was the lack of punishment by the government of perpetrators.

The prevalence of falsified medicines also increases with the expansion of the Internet, consumer accessibility to the Internet, high information communication technology literacy rates, and lack of cybersecurity in a country. Communication and technology have an important role in health. According to the International Telecommunication Union (ITU, 2017a) Internet worldwide users were 16% in 2005 (world population of 6.5 billion) and increased to 47% in 2016 (world population of 7.3 billion). Generally, the statistics by ITU have shown a significant increased in all regions between 2005 and 2016 (ITU, 2017b). In developed countries, the proportion of households with Internet access at home is twice as high as in developing countries (84.4% vs. 42.9%) (ITU, 2017c). The proportion of individuals aged 16–74 in the EU-28 who order or buy goods or services over the Internet for private use continues

Table 1 Examples of counterfeit medicine and its effects on people

Country	*Medicines and class*	*Disease or health problem; indication*	*Case*	*Link and source*
Myanmar	Artesunate	Malaria	Artesunate given to the patient had only 20% of the active ingredient required to kill the parasites; patient died	Ossola (2015). http://www.newsweek.com/2015/09/25/fake-drug-industry-exploding-and-we-cant-do-anything-about-it-373088.html
Pakistan	TB agent	Tuberculosis	100 patients were hospitalized at a Lahore hospital in 2012 by triggering severe adverse reactions after taking poor-quality TB drug	Ossola (2015). http://www.newsweek.com/2015/09/25/fake-drug-industry-exploding-and-we-cant-do-anything-about-it-373088.html
India	Antibiotic	Infection post-surgery	In 2013, officials in India discovered that 8000 patients died over a five-year period in a remote Himalayan hospital because an antibiotic used to prevent infection after surgery had no active ingredient	Ossola (2015). http://www.newsweek.com/2015/09/25/fake-drug-industry-exploding-and-we-cant-do-anything-about-it-373088.html
Democratic Republic of Congo	Not mentioned	Not mentioned	A thousand people were hospitalized after taking a fake drug in 2014 and 2015. It turned out that the drugs contained an antipsychotic used to treat schizophrenia	Bichell (2017). https://www.npr.org/sections/goatsandsoda/2017/11/29/567229552/bad-drugs-are-a-major-global-problem-who-reports
Netherlands	Oseltamivir (Tamiflu)	Flu	Dutch Healthcare Inspectorate warned consumers in early 2006 not to buy Tamiflu through the Internet, after counterfeit capsules were found in the Netherlands containing lactose and vitamin C, and no active substance	WHO (2006). https://www.gphf.org/images/downloads/library/who_factsheet275.pdf
Nigeria	Not mentioned	Not mentioned	NAFDAC destroyed N80 million counterfeit and expired regulated products in Abuja	NAFDAC (2018a). http://www.nafdac.gov.ng/index.php/component/k2/item/390-nafdac-destroys-n80-million-counterfeit-and-expired-regulated-products
China	Anti-diabetic	Diabetes mellitus	A diabetes drug was pulled after samples showed the medicine, which killed two people in the western region of Xinjiang, was six times as potent as it should have been	Lewis (2009). https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2774384/
Cambodia	Traditional medicines	Pain relieve	The Cambodian Health Ministry has warned the public to avoid using two traditional Chinese medicine products, Tong Mai Dan and Zhuan Guwan. It is thought that both products are falsified and contain dexamethasone, a chemical product which could affect public health	Sotheary (2018). Warning on fake Chinese medicine. www.khmertimeskh.com
Cambodia	Not mentioned	Not mentioned	Police arrested a Vietnamese businesswoman after seizing five tones of whitening lotion and 125 packets of counterfeit medicines during a raid of her warehouse in Phnom Penh's Toul Kork district	Konkkea (2017). Woman held over fake cosmetics and medicine. http://www.khmertimeskh.com/news/38474/woman-held-over-fake-cosmetics-and-medicine/
Argentina	Iron-based preparation	Anemia	In 2004, fake medicines led to a trail of death in Argentina	WHO (2008). https://www.gphf.org/images/downloads/library/whoimpact2008_counterfeit_drugs_kill.pdf
Panama	Cold medicine (syrup)	Cold	In 2006, more than 100 patients were killed in Panama by medicines manufactured with counterfeit glycerin. The toxic syrup contained diethylene glycol	Bogdanich and Hooker (2007). http://www.nytimes.com/2007/05/06/world/americas/06poison.html

to rise: in 2016, it reached 55%, an increase of 11 percentage points compared with 2012 (Eurostat, 2018). The Internet is the biggest unregulated market in the world: a place where people can easily become the victims of dishonest online pharmacies (Sanofi, 2013). In industrialized and developing countries, the sale of pharmaceutical products online, from supplements to life-style to life-saving medicines, is a major source of falsified medicines that can endanger people's health. There are online pharmacies that are perfectly legal, having been created to simply ease the purchase of medicines, however, a large number of websites operates illegally, offering access to controlled medicines without a prescription, not to mention non-approved and falsified products. Organized crime is behind some of these structures, which function as a network while hiding their true identity and location. Internet sites that pose as legitimate pharmacies and serve as a clearinghouse of unapproved and dangerous falsified medicines those unsuspecting patients can buy, even without a prescription also present a significant threat to patient safety. Since it is relatively easy to create Internet presence for falsified medicines, there are currently thousands of these illegitimate sites (Merck, 2014). According to Legitscript (European Alliance for Access to Safe Medicines, 2015), of the 331,430 websites monitored that sell healthcare products, 94.3% are selling pharmaceutical products illegally. INTERPOL's Operation Pangea X in collaboration with 123 countries targeting the illicit online sale of medicines resulted in 3584 websites taken offline and suspension of more than 3000 online adverts for illicit pharmaceuticals (INTERPOL, 2017). All countries with access to Internet are targeted by unscrupulous traffickers who sell medicines at very attractive prices, whose contents are not guaranteed and which can cause serious damage to the health of those that take them (European Alliance for Access to Safe Medicines, 2015).

Perspectives on Falsified Medicines Use

Many parties are involved with pharmaceuticals and in the pharmaceutical sector. There are benefits and risks in dealing with pharmaceuticals. Public access to affordable and quality medicines is important, but there is a growing concern about the increased incidence of falsified medicines around the world. It affects public trust and confidence in the healthcare system, the medicines, and drug regulatory authorities. Thus, countries need strong and effective medicines policy and regulations throughout the medicines supply chain, i.e., from manufacturing, importation, and registration to utilization. There are countries that have reported progress in decreasing the supply and circulation of falsified medicines. In many parts of the world, barriers still exist. Many LMICs lack regulatory infrastructure, resources, trained personnel, quality assurance, and pharmacovigilance activity (Mohamed Ibrahim et al., 2016). Thus, the quality, safety, and use of medicines are not effectively monitored. The issue of falsified medicines is of concern from difference perspectives.

Policy Perspective

Due to the complexity and importance of the pharmaceutical markets, they require careful stewardship. A medicine policy document reflects the commitment of the government to ensure that efficacious, safe, and quality medicines are available, accessible, affordable, and used rationally (Management Sciences for Health, 2012). According to Hoebert et al. (2013), the number of National Medicine Policies (NMPs) worldwide has increased over the years especially in high income countries which have more NMP implementation plans and have an up-to-date NMP. A non-existence or weak NMP could expose a country to the incidence of falsified medicines and increase the prevalence of them in the country's pharmaceutical market. A clear and effective policy can ensure that all the pharmaceutical-related stakeholders in a country know their roles, rights, and obligations in relation to medicines, and that these are supported by monitoring and effective regulation (WHO, 2004). There are six dimensions that can be used to analyze a policy, i.e., "effectiveness," "unintended effects," and "equity" under the domain "*Effects*," and "cost," "acceptability" and "feasibility" under the domain "*Implementation*" (WHO, 2012). There is a relationship between policy and governance. A quality policy should cover aspects such as conviction, penalties, and requirements. Because of the extent of the falsified medicines problem around the world, it is important to have multilevel policies, i.e., at the national level (country-specific), regional (such as GCC, European Union), and international (such as WHO). Policies related to falsified medicines need to be evaluated against their objectives such as impact, e.g., problem containment and eradication, and cost-saving. It is important for policymakers to monitor the implementation of the relevant polices and then to evaluate them. For example, the European Union initiative on medicine falsifying-related policy development and implementation requires safety characteristics on medicines packages (i.e., for most prescription-only medicine) allowing to detect individual packages and confirm their authenticity.

Merck established a Public Policy statement in 2014 (Merck, 2014) and designed an Anti-Counterfeiting program to keep the legitimate medicine distribution system secure and safe. One aspect of the policy requires customers to purchase Merck medicines and vaccines directly from Merck or a Merck authorized distributor. This action could prevent falsified medicines from entering the pharmaceutical supply chain. In addition, part of Merck's commitment is to cooperate with government agencies, INTERPOL, other pharmaceutical industries, and to educate the public. Merck provides effective advocacy on high-priority anti-counterfeiting policy initiatives. In summary, there should be a zero tolerance policy.

Regulatory Perspective

The manufacture, distribution, and the sale of medicines in a country can be protected from falsified medicines if there is proper and strict regulation related to these aspects. Organized criminal enterprises that work for high profit, approximately 25 times higher

than legitimate medicines, with low risk business (Ness, n.d.). Countries with lax regulations will provide the opportunities for falsified medicines. Absences in nationwide and international-wide legislation and enforcement are mostly discussed and criticized at different international forums. There are countries that rely on a high percentage of imported medicines, and have a weak distribution network and supply chain. Some authorities are not able to accept their weaknesses and to be criticized or are willing to cover up the failure of the pharmacy authority to prevent falsified medicines entering the country. There are countries where medicines, especially prescription and controlled items, can easily be found in open market, street vendors, or sold without a prescription. Counterfeiters know the laws and their weaknesses. They also plan for falsified medicines to enter the legitimate supply chain and reach health institutions and patients. It is important to have a working and effective authority in place to control and regulate the whole pharmaceutical supply chain and protect it from the penetration of falsified medicines into the market. Unfortunately, many LMICs are underfunded and lack human and financial resources to evaluate the quality of medicines and control the problem. A 2014 report published by the Independent Joint Anti-Corruption Monitoring and Evaluation Committee (Ossola, 2015) found, for example, that government officials in Afghanistan and China received bribes to approve untested medicines. The size and effects of falsifying are so significant that they require effective and continuous action from governments, consumers, and businesses. It is critical to have more effective and strong enforcement to fight against falsifying, as well as increased cooperation between the stakeholders. For example, police, customs, drug regulatory authorities, international organizations, and private sector partners from some 100 countries participated in Operation Pangea VI in 2013, which saw the seizure of 9.8 million potentially dangerous medicines worth USD41 million and more than 13,700 illicit websites shut down (INTERPOL, 2014a). Unless laws are harmonized and unless there are no gaps in regulatory and enforcement schemes globally, criminals will exploit markets at their weakest points (INTERPOL, 2014a). Unlike many other African countries, Zimbabwe has strict medicine control laws. People caught selling falsified or unregistered medicines can face sentences of up to 20 years if convicted (Musvanhiri, 2017). Still, strict laws do not seem to be enough to stop the spread of falsified medicines. In China, people who are caught can be fined between RMB100 ($17) and RMB3000 ($507): they can also face the death penalty (Lewis, 2009). Recently the European Commission (2018), revealed that medicine falsification in 22 countries is punishable by imprisonment. The sentences range from one year in Greece, Finland, or Sweden up to 15 years in Austria, Slovenia, and Slovakia. Fines can range from Euro4300 in Lithuania to Euro1million in Spain.

The Council of Europe has long been concerned about the absence of harmonized international legislation, non-deterrent sanctions that were not proportionate to the harm caused to patients, and the involvement of criminal organizations which do not respect geopolitical borders (Mackay and Liang, 2011; Keitel, 2012). International cooperation is crucial. To crack the global networks of counterfeiters, authorities need to cooperate across borders. In mid-2013 several European countries joined forces to scan international shipments for an entire week in order to track down falsified medicines.

Social Perspective

What is the public perception about this matter? What do health professionals say about this problem? What are the reactions of other stakeholders? It is not easy for consumers in the pharmaceutical market to realize whether a pharmaceutical product is safe or not, or to recognize if a product is genuine or falsified. According to Liu and Lundin (2016), there are three crucial problems: first, related to the definition of good versus poor quality medicines; second, poor level of awareness regarding the extent of the problem; and third, low level of knowledge and skill in conducting proper research to identify the problem, investigate the quality of medicines, and to make proper documentation and reporting. Newton et al. (2009) and the Center for Economics and Business Research Ltd (2002) have provided study designs and data analysis procedures in relation to falsified medicines. Further, Newton et al. (2009) also encouraged the use of Medicine Quality Assessment Reporting Guidelines (MEDQUARG).

Public ignorance is a factor contributing to the availability of falsified medicines. Illiteracy is a problem in many parts of the world and it is difficult for some people to differentiate between genuine medicine products and fake medicines, especially when they want cheap and easy access to medicines (Chinwendu, 2008).

Sanofi conducted a study to help understand Asians' perceptions of falsified medicines and how buying habits help fuel the falsified medicine market worldwide (Sanofi Le Hub, 2015). The study was conducted in six countries—China, Indonesia, Malaysia, Philippines, Thailand, and Vietnam—and asked consumers whether they thought taking falsified medicines was a risky business. The results shed new light on the falsified medicine trade in Asia. Of those surveyed, 67% considered falsified medicines to be dangerous, and around 31% considered them potentially dangerous, though this level of recognition rose substantially in Indonesia to 86%. While understanding of the dangers of falsified medicines is generally widespread, of more concern is a lack of knowledge on the subject. Of those surveyed, 67% of Thais and more than half of Indonesians said they did not know how to tell the difference between a fake medicine and the real thing. Around 64% of Asian respondents thought that it is possible to be exposed to falsified medicines online. Online purchasing is particularly widespread in Asia, thus it is very essential to have preventive actions.

A study in Tanzania evaluating public awareness found that a significant number of respondents were able to differentiate between genuine and falsified anti-malarial medicines (Mhando et al. 2016). Respondents who had knowledge on health effects of falsified medicines were nearly three times more likely to distinguish genuine and falsified medicines than their counterparts. A study in Iran of pharmacists' professional attitudes and practices toward falsified medicines illustrated that pharmacists showed low knowledge and a poor practice level about falsified medicines but had high level of knowledge about preventing the spread of counterfeit medicines in the community (Shahverdi et al., 2012). Nagaraj et al. (2015) noted that medical practitioners had more knowledge regarding falsified medicines than medical storekeepers and dental practitioners. A study in Lebanon showed that

falsified medicines were found in 33% of the households visited and demonstrated awareness in both the public and pharmacists of the perceived risks these medicines pose to both individual and public health (Sholy, 2015).

There are several initiatives that could be taken to create and raise awareness and educate the public and healthcare professionals about falsified medicines, ranging from printed materials to providing a 24-hour anti-counterfeiting hotline.

Economic Perspective

Falsifying medicines is an illegal business in which criminal networks thrive. A study conducted by the OECD (2007) reported that falsified products are produced and consumed in almost all countries regardless of economic level. The study also indicated that Asia is the single largest producing region. Falsified medicines businesses take away from governments, genuine private businesses and communities legitimate jobs, profits and tax revenues (ICC, n.d.). Costs are incurred in combating the problem. For poor countries, limited resources have to be used to deal with detection, enforcement, and awareness programs. Falsified medicines take income from consumers by having them pay for products that have little or no medical value (Liang and Mackey, 2012). Genuine products can experience loss of sales potentially from loss of confidence in those products. Figures reported by the International Chamber of Commerce (ICC, n.d.) indicate that by 2022, the negative impacts of general falsifying and piracy are estimated to drain US$4.2 trillion from the global economy and affect 5.4 million legitimate jobs. Transnational organized crime networks involved in falsifying medicines and pharmaceutical products are so focused on making profits that they turn a blind eye to the health risks this presents to unsuspecting consumers (EUROPOL, 2015). According to the OECD report, more than US$250 billion in revenue is lost in falsifying products (OECD, 1998).

Falsified products infringe trademark and intellectual property (IP) rights of the originator company (Ness, n.d.). The goal of the IP is to create funds for future innovation in therapies and technologies. Pharmaceutical products are research and development (R&D) intense: R&D is time consuming and costly. Patents are designed to run for 12–15 years. The most recent analysis by the Tufts Center for the Study of Drug Development of the average cost to develop and gain marketing approval for a new medicine is estimated to be $2.558 billion (Tufts CSDD, 2016).

Based on the cost of the problem (e.g., USD75 billion in globally per year), the need for action is clear (INTERPOL, 2014b). The Council of Europe Convention noted that the administrative costs for investigation and prosecution, and physical and emotional harm to countless victims, are not known. The Council also noted increased long-term economic costs due to an increasing global disease burden (Council of Europe, 2015).

Medicine quality surveys can be expensive, mostly because of the costs of chemical analysis, and this has inhibited such work with the result that we have very little objective information. Given the large expense of clinical trials, the cost of medicines, and the enormous economic burden of life-threatening diseases, this lack of investment is a false economy. More investment in laboratory infrastructure and personnel training is needed. It has been argued that surveys with random selection of outlets are not necessary, too complicated, or too expensive, however, it has also been suggested that they are vital and that the additional expense in comparison to the chemical analysis cost is small (Newton et al., 2009).

In short, falsified medicines can affect a country significantly, especially LMICs, in terms of lost tax revenues, lost sales revenues, wasted money by individuals purchasing useless medicines, costs incurred to fight against falsified medicines including analyzing samples, and unnecessary healthcare costs due to problems caused by poor quality medicines.

Laboratory Analysis and Technology

One important aspect in dealing with falsified medicines is detection technologies and methods. It is unethical to use a wrong procedure or analysis and falsely ill repute a genuine medicine or falsely support non-quality medicine. Thus, authorities and researchers need to be familiar with the different methods of analysis to measure the quality of medicines in the medication supply chain. The main challenges for countries are lack of well-equipped laboratories, analytical know-how, competencies, resources, and managerial ability (Newton et al., 2009). The most important considerations in choosing the appropriate technology for detecting poor quality medicines are the testing site and the purpose for testing. Factors related to the testing site include whether there is a consistent electrical supply, competent staff, and whether the purpose of the testing is screening or confirmation.

According to Kovacs et al. (2014), there are at least 42 unique technologies to detect poor quality medicines. In another report, Newton et al. (2009) highlighted the common chemical analysis techniques for quality of medicines research. It is a challenging task to test for poor quality medicines because of the cost to carry out the test, facilities and skills required. Kovacs et al. (2014) considered 17 technologies as either portable or requiring only a basic laboratory.

Table 2 illustrates few examples of medicines and methods used for detecting poor quality medications.

The methods and technologies used should be able to evaluate if the packaging is fake, the chemical composition correct, the presence of unexpected active ingredients in the product, and if the product is substandard or falsified (Newton et al., 2009). The choice of the methods and technologies used by the drug regulatory authorities should be based on the availability of the instruments, knowledge and skill of the operator/technician, cost, and the advantages and disadvantages of the techniques.

Other Anti-Counterfeiting Technologies

Many anti-counterfeiting technologies are being utilized by pharmaceutical companies to ensure distribution of the authentic product from the manufacturing site to the pharmacy. These technologies must be non-clonable. Among the technologies used by

Table 2 Examples of method used for detecting poor quality medications

Method	*Medicine*	*Reference*
Thin-layer chromatographic-densitometric	Clotrimazole	Nyamweru et al. (2014)
Library of chemical color tests embedded on an inexpensive paper card	Anti-malarial	Weaver and Lieberman (2015)
Colorimetric assay	Both lumefantrine and artemether in Coartem® tablets	Green et al. (2015)
Colorimetric assay	Artemether, dihydroartemisinin, and artesunate tablets	Green et al. (2001)
Chemical and bioassay methods	Miltefosine	Kaur et al. (2015)
Detection reagent and micro-fluidic platform	Anti-malarial	Ho et al. (2015)
MiniLab® semi-quantitative TLC test	Anti-malarial	Visser et al. (2015)
Combination of Thin Layer Chromatography, High Performance Liquid Chromatography and Raman spectroscopy	Artemether/lumefantrine	Yemoa et al. (2017)
Combination of CD3+ tool with TruScan™ Portable Raman spectrometer and GPHF Minilab®	Anti-malarial (artemether-lumefantrine tablets and artesunate-amodiaquine tablets)	Batson et al. (2016)

pharmaceutical manufacturers are holograms, color-shifting inks, and embedded codes, images, and dyes. These anti-counterfeiting features allow pharmacists to identify suspicious medications as possible falsified products (Williams and McKnight, 2014).

Techniques based on interference pattern, encryption, spectroscopy, and chromatographic principles used by pharmaceutical industries to authenticate genuine products have curtailed the problem to a limited extent (Kumar and Baldi, 2016). Bansal et al. (2013) reviewed the different anti-counterfeiting authentication technologies that can be used in different ways, e.g., tamper-evident/tamper-resistant packing; product authentication; and track and trace technology.

Table 3 shows few examples of additional technologies.

Developing reliable detection and diagnostic technologies is crucial for national drug regulatory authorities and international organizations to detect falsified medicines and take action against the illegal enterprises involved. Countries, especially LMICs, need to establish good laboratories for monitoring, checking quality of all pharmaceuticals manufactured locally, and those imported or donated to these countries. It is important to acknowledge that having good technologies is not the only solution to the problem.

Table 3 Examples of anti-counterfeiting authentication technologies

Technology	*Description*	*Reference*
Counterfeiting Incident System (CIS)	Record falsifying pharmaceutical products worldwide; CIS incidents come from a variety of sources, including open media reports, PSI member company submissions, and public-private sector partnerships	PSI (2018c)
mHealth Technology	A company, Sproxil, developed a creative mobile solution, which comprises of text messaging and scratch-off labels. The company works closely with pharmaceutical companies to provide verification services of for their products; providing brand protection and product authentication	Sproxil (2015) and Goldstein (2011)
mPedigree Network	A verify-by-mobile system; printed barcodes and scratch-off stickers, developed in partnership with US tech giant Hewlett-Packard, help consumers check authenticity against a central database	Wall (2016)
Counterfeit Detection Device, Version 3 (CD-3)	The CD-3 tool contains a library of information about authentic medicines and the packaging they come in. It allows the user to compare authentic images of a product with the suspect product, instantaneously showing clear differences between suspect and authentic products that would not have been clear to the naked eye	Autor and Plaisier (2013)
TruScan	A handheld spectrometer being used at airports and border posts to analyze the chemical composition of medicines, helping to spot "bad medicines" in seconds	Sambira (2013)
Integrated mobile telephony-based consumer verification	Countries like Ghana, Nigeria, and Kenya have included it in their safety regulations	Sambira (2013)
Radio Frequency Identification (RFID) device	Track-and-trace system uses information stored and remotely retrieved on transponders to provide automatic identification. An RFID tag is a chip that can be used to provide serial numbers to confirm the identity of a product	Coustasse et al. (2010)
I-Checkit	An INTERPOL pilot project which assisted citizens in determining the authenticity of medicines and other products before making a purchase, by scanning a code on the item to check it against information provided by the manufacturer	INTERPOL (n.d.)
Rapid Alert System (RAS)	A web-based communications network involving focal persons and representatives of countries and areas in the Western Pacific Region, WHO and partner agencies. It alerts member countries and areas and relevant partner organizations, through their focal points and representatives in the network, about cases of counterfeit medicine	WHO-WPRO (2005)

Table 4 Summary of steps or strategies to fight against counterfeit medicines

Steps or strategies	*Aspect*
Educate the public, healthcare providers, and regulatory officers to increase their awareness	Education and training
Increase the knowledge, skills, and competencies to empower healthcare professionals to be effective partners in the fight against falsified medicines	Education and training
Increase training for regulatory officers and lab technicians in chemical analysis and forensic techniques	Education and training
Broadcast advertisements for fake medicine	Media
Involve media, e.g., TV channels and printed media to educate and create awareness	Media
Strengthen the law and regulation in relation to dealing with counterfeit/falsified medicines	Policy, law, and regulation
Apply tougher penalties for individuals involved in this crime	Policy, law, and regulation
Seizure of related assets that belong to the criminal	Policy, law, and regulation
Take action on healthcare providers who prescribe and dispense counterfeit/falsified medicines to their patients	Policy, law, and regulation
Strengthen the medicines registration and vendor licensing process	Policy, law, and regulation
Increase cyber security to protect the public and consumer from getting medicines through the Internet	Policy, law, and regulation
Initiate the use of technology to fight against counterfeit/falsified medicines, i.e., developing protection technologies on product packaging	Technology
Improving detection with the development of analytical methods with reliable techniques	Technology and analytical method
To have expert enforcement officials including police, prosecutors, customs, and judges	Human resource
Improve management of medicines supply chain	Management and practice
Improve government quality control and assurance activities	Management and practice
Having a good governance	Governance
Increase dedication of regional cooperation with other countries, i.e., harmonization regarding counterfeit/falsified medicines to make tracking and tracing more effective	Networking and cooperation

In summary, Table 4 lists the steps, approaches, and strategies that different stakeholders can carry out solely or in collaboration with partners.

Counterfeit Medicines in Pharmaceutical Supply Chain: Organization's Involvement and Country Case Studies

There are various government, non-governmental, for profit, and non-profit organizations that work against falsified medicines. Below are different local, regional, or international organizations, authorities, and associations. This list is not all-inclusive but enough to provide some idea about the initiatives of various, diverse organizations (Table 5).

No country is immune: falsified medicines can be found in developing and developed countries. Falsified medicines cases are more prevalent in LMICs due to many reasons discussed above. Table 6 presents example of cases.

Table 5 Organizations and their roles against counterfeit medicines

Organization	*Roles*	*Link*
International Chamber of Commerce (ICC)	Urges government action and resources to strengthen intellectual property rights enforcement, seeking significantly higher benchmarks for government performance against counterfeiting and piracy at the national, regional, multi-lateral, and international level	ICC (n.d.). https://iccwbo.org/global-issues-trends/innovation-ip/counterfeiting-piracy/
International Medical Products Anti-Counterfeiting Taskforce (IMPACT)	The launched by WHO in 2006 to respond to the increasing public health crisis of counterfeit drugs	WHO (2011). IMPACT International Medical Products Anti-counterfeiting Taskforce. The Handbook. Facts, Activities, Documents Developed by the Assembly and the Working Groups, 2006–2010. http://apps.who.int/medicinedocs/en/d/Js20967en/
International Federation of Pharmaceutical Manufacturers and Associations (IFPMA)	Represents the research-based pharmaceutical companies and associations across the globe; it collaborates with other organizations around the world and creates a global movement of people to fight against fake medicines and trying to limit the consequences of this criminal traffic	International Federation of Pharmaceutical Manufacturers and Associations. https://www.ifpma.org/

Table 5 Organizations and their roles against counterfeit medicines (*cont.*)

Organization	*Roles*	*Link*
National Agency for Food and Drug Administration and Control (NAFDAC)	The government agency in Nigeria that is fully empowered to regulate and control the importation, exportation, manufacture, advertisement, distribution, sale, and use of drugs to ensure that safe and quality drugs are available to the public	National Agency for Food and Drug Administration and Control. http://www.nafdac.gov.ng/
Medicines & Healthcare products Regulatory Agency (MHRA)	Regulates medicines, medical devices, and blood components for transfusion in the UK. The agency plays a leading role in protecting and improving public health and supports innovation through scientific research and development	Medicines & Healthcare products Regulatory Agency. https://www.gov.uk/government/organisations/medicines-and-healthcare-products-regulatory-agency
United States Food and Drug Authority (US FDA)	Responsible for protecting the public health by ensuring the safety, efficacy, and security of human and veterinary drugs, biological products, and medical devices; and by ensuring the safety of our nation's food supply, cosmetics, and products that emit radiation	US FDA. What we do. https://www.fda.gov/Drugs/ResourcesForYou/Consumers/BuyingUsingMedicineSafely/CounterfeitMedicine/default.htm

Australian Government. Department of Health. Who we are & what we do. https://www.tga.gov.au/who-we-are-what-we-do
World Health Organization (WHO)	A specialized agency of the United Nations that is concerned with international public health. Working through offices in more than 150 countries, WHO staff work side by side with governments and other partners to ensure the highest attainable level of health for all people	Burci (2013). American Society of International Law. https://www.asil.org/insights/volume/17/issue/2/public-health-and-%E2%80%9Ccounterfeit%E2%80%9D-medicines-role-world-health-organization
Organisation for Economic Co-operation and Development (OECD)	Uses its wealth of information on a broad range of topics to help governments foster prosperity and fight poverty through economic growth and financial stability. It helps ensure the environmental implications of economic and social development are taken into account	OECD. What we do and how. http://www.oecd.org/
International Pharmaceutical Federation (FIP)	Concerned with the continuing, even increasing, risk to public health represented by counterfeiting of medicines, particularly in countries where legislation governing the manufacture and distribution of medicines, or the enforcement of legislation, is ineffective	International Pharmaceutical Federation (FIP). FIP Statement of Policy on Counterfeit Medicines. http://www.fip.org/www/uploads/database_file.php?id=164&table_id
Centers for Disease Control and Prevention (CDC)	Works to protect America from health, safety and security threats, both foreign and in the US	Centers for Disease Control and Prevention (CDC). https://www.cdc.gov/about/organization/cio.htm
Management Sciences for Health (MSH)	Supports all levels of a country's regulatory infrastructure, from helping implement accredited drug seller initiatives in the private sector, to developing registration software to streamline access to medicines, to providing technical assistance to countries to draft national pharmaceutical policies; promotes the development of comprehensive pharmacovigilance systems and availability of drug information	Management Sciences for Health. https://www.msh.org/our-work/health-systems/pharmaceutical-management/policy-legislation-and-regulation
Médecins Sans Frontières (MSF)	A private, international, independent, medical humanitarian organization; provides assistance to populations in distress, to victims of natural or man-made disasters and to victims of armed conflict irrespective of race, religion, creed, or political convictions	Médecins Sans Frontières (MSF). MSF Charter. http://www.msf.org/en/about-msf
Pharmaceutical Security Institute (PSI)	Based on the need to face the challenge of counterfeit pharmaceuticals, in 2002, the Security Directors from fourteen major pharmaceutical companies established the Pharmaceutical Security Institute as a not-for-profit corporation based in the Washington, DC metropolitan area. PSI has developed improved systems to identify the extent of the problem and to assist in coordinating international inquiries	Pharmaceutical Security Institute (PSI). The Challenge of Counterfeit Pharmaceuticals. http://www.psi-inc.org/about.cfm
International Criminal Police Organization (INTERPOL)	Established in 1923 as the International Criminal Police Commission (ICPC). It is today heavily involved in the international enforcement of counterfeit medicines controls. Its mission is to facilitate cross-sector international action to identify, investigate, and prosecute the criminals behind falsification	INTERPOL. Pharmaceutical crime. https://www.interpol.int/Crime-areas/Pharmaceutical-crime/Pharmaceutical-crime

(*Continued*)

Table 5 Organizations and their roles against counterfeit medicines (*cont.*)

Organization	*Roles*	*Link*
Global Pharma Health Fund (GPHF)	A charitable organization initiated and funded exclusively by donations from Merck, Germany aims to improve healthcare and the work currently supporting the fight against counterfeit medicines proliferation using the GPHF-Minilab™	Global Pharma Health Fund. https://www.gphf.org/en/index.htm
International Institute of Research Against counterfeit medicines (IIRACM)	An independent international organization dedicated to fight against counterfeit medicines. This organization provides information, training, and prevention programs	International Institute of Research Against Counterfeit Medicines (IIRACM). http://www.iracm.com/en/
European Alliance for Access to Safe Medicines (EAASM)	An independent, pan-European initiative dedicated to protecting patient safety by ensuring access to safe and legitimate medicines.	European Alliance for Access to Safe Medicines (EAASM). http://www.eaasm.eu/index.php?cID=32&cType=news
The Siracusa International Institute for Criminal Justice and Human Rights	Organizer of the third meeting of experts to strengthen "The Fight against Counterfeit Drugs in Francophone Africa." The project currently involves eight African states: Burkina Faso, Cameroon, Central African Republic, Guinea, Ivory Coast, Mali, Senegal, and Chad and is intended for representatives of the Ministries of the Interior and of Health. The main objective of this project is to help strengthen the fight against counterfeiting while reaching a political consensus for the preparation, adoption, and implementation of a comprehensive, modern, and adequate national legislation	Siracusa International Institute for Criminal Justice and Human Rights. http://www.siracusainstitute.org/portal/2017/11/27/fight-counterfeit-drugs-francophone-africa-third-meeting-experts/
US Pharmacopeia (USP)	Helps build the safety net across the drug industry and healthcare system, establishing standards to ensure medicine is of the highest quality from the time it's manufactured until the moment someone takes it. USP not only provides standards for what goes into a medicine and how it's named and labeled, but also to ensure that once it's in the hands of a healthcare team, it's prepared and handled safely	USP. Healthcare Quality & Safety. http://www.usp.org/healthcare-quality-safety
The Center For Safe Internet Pharmacies (CSIP)	A nonprofit organization founded in 2011 by a diverse group of Internet service providers and technology companies to address the global problem of consumer access to illegitimate pharmaceuticals from illegal online pharmacies and other sources	Center For Safe Internet Pharmacies (CSIP) (2018). Who we are. https://safemedsonline.org/

Table 6 Examples of case studies of counterfeit medicines in the pharmaceutical supply chain

Year	*Country or areas*	*Case*	*Reference and source*
2000	Cambodia	Fake malaria medicines flooded the Cambodian market have killed dozens of people. The fake drugs—marketed as the powerful malaria medicines Mefloquine and Artesunate, but actually of no medicinal value—accounted for the deaths of at least 30 people	Pharmaceutical Security Institute (PSI) (n.d.). http://www.psi-inc.org/reports.pdf
2000	India	A large batch of out-of-date medicines illegally imported from abroad was burned in Uzbek. The medicines were illegally imported and smuggled into the country. They came by the Delhi-Tashkent route. Government tests showed the medicines were produced in India and did not have all the basic ingredients, making the medicines useless	Pharmaceutical Security Institute (PSI) (n.d.). http://www.psi-inc.org/reports.pdf
2003	India	New Delhi police seized 100 kg of spurious versions of nimesulide, ranitidine, and betadine made in Agra, Meerut, and Ghaziabad	Drug control (2013). http://www.drugscontrol.org/spurious_drugs.htm

Table 6 Examples of case studies of counterfeit medicines in the pharmaceutical supply chain (*cont.*)

Year	*Country or areas*	*Case*	*Reference and source*
2004	Hong Kong	Customs officers arrested nine people and confiscated nearly 18,000 bottles of counterfeit Chinese medicine from a fake-medicine syndicate. Customs also seized about 927 bottles of counterfeit ointment and 17,000 bottles of balm bearing two brand names. Local radio reported the estimated value to be $740,000	South China Morning Post (2004). http://www.scmp.com/article/483156/customs-arrest-nine-confiscate-18000-fake-medicine-bottles
2004	UK	In 2004, two lots of counterfeit Cialis (tadalafil) and one batch of Reductil (sibutramine) were withdrawn	Chaplin (2007). http://onlinelibrary.wiley.com/doi/10.1002/psb.106/pdf
2005	Kenya	A survey from 2005 revealed that 30% of medicines in Kenya were counterfeit, some containing nothing more than water and limestone	Kayaoglu (2016). http://www.euronews.com/2016/02/11/the-dangerous-and-illegal-trade-in-counterfeit-medicines
2006	South Korea	Police served a fresh arrest warrant on two foreigners on suspicion of smuggling and selling fake Viagra and other medicines without a license. The police and customs seized about 100,000 pills at Kansai International Airport and other places related to the suspects	The Partnership for SafeMedicines (2006). http://www.safemedicines.org/2006/06/2-foreigners-served-with-new-arrest-warrant-over-sale-of-fake-viagra.html
2009	Uganda	A raid conducted by INTERPOL and the WHO-supported group IMPACT (International Medical Products Anti-Counterfeiting Taskforce), discovered five tons of fake drugs in the central and eastern districts of the country	Sambira (2013). http://www.un.org/africarenewal/magazine/may-2013/counterfeit-drugs-raise-africa%E2%80%99s-temperature
2009	Egypt	Egyptian police authorities carried out a series of raids in strategic locations in collaboration with World Health Organization—IMPACT. A wide range of counterfeit medicines were identified, including lifestyle products and others intended for organ-transplant patients or serious diseases such as cancer, diabetes, heart disease, epilepsy, or schizophrenia	INTERPOL (2009). https://www.interpol.int/News-and-media/News/2009/N20090529
2011	Various (81) countries	2.4 million illicit and counterfeit pills confiscated with an estimated value of USD6.3 million. Almost 13,500 websites were shut down. Some 45,500 packages inspected by regulators and customs authorities, of which almost 8000 were seized	INTERPOL (2011). https://www.interpol.int/Crime-areas/Pharmaceutical-crime/Operations/Operation-Pangea
2012	Coast of Africa	A major sweep across 16 seaports on the east and west coasts of Africa in July 2012 allowed the World Customs Organization, an intergovernmental organization that advises customs administrations worldwide, to seize more than 82 million doses of illicit medicines estimated to be worth over $40 million. The fake drugs found during the raid included cough syrup, anti-parasitic and anti-malarial drugs, antibiotics and even contraceptives	Sambira (2013). http://www.un.org/africarenewal/magazine/may-2013/counterfeit-drugs-raise-africa%E2%80%99s-temperature
2012	USA	The US FDA found that some batches of counterfeit bevacizumab (Avastin) contained no active pharmaceutical ingredients at all. This drug was found to have traveled through Turkey, Switzerland, Denmark, the UK, and Canada before reaching the USA	Kollmorgen (2015). https://newrepublic.com/article/121589/counterfeit-medicine-global-problem
2013	The Philippines	In March 2013, Philippine authorities arrested five traffickers attempting to traffic 20 pallets of fake slimming pills, pain relief medication, and antibiotics which had been shipped to the Philippines from Singapore	INTERPOL (2014a,b). https://www.interpol.int/Crime-areas/Pharmaceutical-crime/Pharmaceutical-crime
2013	Russia	Russian authorities reported that they had dismantled a counterfeiting operation which had been ongoing for several years in Rostov. Fake medicines such as Herceptin, Meronem, Cefobit, Mantera, Sulperason were manufactured and distributed by an organized crime group. Russian authorities arrested seven suspects and carried out 23 raids in connection with this case	INTERPOL (2014a,b). https://www.interpol.int/Crime-areas/Pharmaceutical-crime/Pharmaceutical-crime

(*Continued*)

Table 6 Examples of case studies of counterfeit medicines in the pharmaceutical supply chain (*cont.*)

Year	*Country or areas*	*Case*	*Reference and source*
2013	India	Officials in India discovered that 8000 patients died over a five-year period in a remote Himalayan hospital because an antibiotic used to prevent infection after surgery had no active ingredient	Ossola (2015). http://www.newsweek.com/2015/09/25/fake-drug-industry-exploding-and-we-cant-do-anything-about-it-373088.html
2014	Cambodia	Anti-economic crimes department of the Cambodian Interior Ministry, looks through confiscated fake medicines in Phnom Penh, Cambodia, November 28, 2014. About five tons of counterfeit medicines were seized	Ossola (2015). http://www.newsweek.com/2015/09/25/fake-drug-industry-exploding-and-we-cant-do-anything-about-it-373088.html
2015	The Philippines	Hundreds of thousands of dollars' worth of illegal medicines were seized during 2015, with the majority of fake medicines imported from India, Pakistan, and China	Sanofi Le Hub (2015). https://lehub.sanofi.com/en/access-healthcare/counterfeit-medicines-in-asia/
2015	Democratic Republic of Congo	More than 1000 people were admitted to hospital in a remote area of Democratic Republic of Congo (DRC) in 2015 after suffering toxic effects from "falsified" or wrongly labeled drugs	MSF (2017). http://www.msf.org/en/article/democratic-republic-congo-alarming-consequences-poor-quality-medicines
2015	USA	The San Francisco Department of Public Health released an urgent warning concerning deadly fentanyl disguised as the low-level anti-anxiety medication Xanax. Three people died as a result of consuming the fentanyl-laced pills	The Partnership for SafeMedicines (2015). http://www.safemedicines.org/2015/10/nationwide-epidemic-of-counterfeit-pain-pills-containing-fentanyl-claims-lives-in-22-states.html
2016	Indonesia	In 2016 between May 30th and June 7th, the Indonesian Food and Drug Monitoring Agency seized more than a thousand packages of illegal and fake medicines worth $4.2 million. Thousands of counterfeit pills were seized in 64 factories and drug facilities all across Indonesia. A total of 214 websites selling illegal products were identified and closed	Sari (n.d.). http://integrity-asia.com/blog/2017/09/06/counterfeit-medicine-in-indonesia/
2016	Portugal	In the Operation PANGEA, 42% of 57 products analyzed by Infarmed's Laboratory were counterfeit medicines and/or illegal	European Commission (2011). Detention of counterfeit and pirated goods at EU borders in 2010—Frequently Asked Questions. http://europa.eu/rapid/press-release_MEMO-11-506_en.htm?locale=en
2017	Germany	Fake hepatitis C medicines were available on the German market in numerous instances. According to the Federal Institute for Drugs and Medical Devices (BfArM), various drugs for the treatment of chronic hepatitis C in adults were affected	Bayer (2000). https://www.bayer.com/en/news-about-counterfeit-drugs.aspx
2017	Democratic Republic of Congo (South Kivu)	Two versions of falsified cefixime products were identified and reported to the World Health Organization. Both products were presented in standard white plastic containers of 100 tablets. The label of both products displayed spelling mistakes. Assays indicated only 2.5% of cefixime in the first product and nil in the second product	NAFDAC (2018b). http://nafdac.gov.ng/index.php/world-sport/item/391-falsified-cefixime-products-circulating-in-the-democratic-republic-of-congo
2017	Panama	Panama's national customs authority seized 179,642 counterfeit drugs linked to money laundering and organized crime totaling USD808,202, as part of the international operation "Pangea X" conducted in 123 countries	Panama Today (2017). http://www.panamatoday.com/panama/counterfeit-drugs-linked-money-laundering-was-seized-panama-5333
2018	USA	According to the Department of Justice (DOJ) report, three residents from Florida pleaded guilty to counterfeit drug and illicit steroid charges and were sentenced to prison. United States Postal Inspectors discovered that large volumes of steroid and counterfeit drug ingredients were being shipped from China to locations in Southern Alabama and Northwest Florida	The Partnership for Safe Medicines, 2018. http://www.safemedicines.org/2018/02/counterfeit-drug-manufacturing-trio-from-florida-sentenced.html

Note: to be read in conjunction with Table 1.

Final Remarks

Patient safety is the utmost important aspect in healthcare. Falsified or counterfeit medicines are a real problem, especially in developing countries. They will continue to be a problem unless strategic actions are put in place. Even if the speed of policing increases, it will not enough to prevent falsifying and public harm. Multipronged approaches and strategies are required. Further research is needed to identify the best methods and cost-effective, dynamic and long-term anti-falsification approaches strategies. Product assay methods, regulation of the pharmaceutical supply chain, severe punishment for breaches, and public and professional education and awareness programs, are just a few effective tools to prevent this crime against humanity.

Acknowledgment

The author would like to thank Ms Abeer Abdullah for her assistance in searching for articles.

The Impact of Culture and Religion on Medicine Use

Fatima Suleman, Velisha Ann Perumal-Pillay, University of KwaZulu-Natal, Westville, South Africa

Introduction

The decisions an individual makes are influenced by many confounding factors and this is no less true for the factors that influence an individual to seek and accept medical interventions. Culture may be one such factor which influences the decision making process. Culture has various definitions including "the way people live which consists of a system of ideals, values, beliefs, knowledge and customs transmitted from generation to generation within a social group" (Jekayinfa, 2000). According to this definition culture is, in itself, influenced by various factors such as an individual's religion, spirituality, ethnicity, etc. This is due to the fact these aspects shape the ideals and beliefs of the individual.

Thus, health care does not merely involve the eradication of disease but also encompasses the holistic care of the patient which includes mental and social wellbeing (World Health Organization, 1946). The changing demographic landscape in health care systems worldwide necessitates research into how this diversity impacts on health care attitude, behavior, and knowledge. Spirituality has emerged as an important social concept in the health of patients (Anadarajah and Hight, 2001; Levin et al., 1997; Matthew et al., 1998), however, research indicates that it appears to be largely neglected (Anadarajah and Hight, 2001; Levin et al., 1997; Matthew et al., 1998) in the caring of patients. There is, also, a growing body of literature that emphasizes the importance of physician behaviors that consider the patient as a whole, beyond the person's disease (Cassell, 1991; Magyar-Russell et al., 2008).

Religion and spirituality form an important component of a patient's value system and may be a unique tool in providing motivation and helping a patient cope with life events (Koenig et al., 2001; Magyar-Russell et al., 2008; Pragament et al., 2005). In a review of the relationship between religion and health (Anadarajah and Hight, 2001; Levin et al., 1997; Matthew et al., 1998), a positive relationship between religious commitment and mental and physical health was found in up to 84% of studies that included a measure of religious commitment as part of the study (Anadarajah and Hight, 2001; Larson et al., 1992).

A multitude of variations attest to the fact that patients are, above all, human beings regardless of class, gender, age, or culture (Fainzang, 2005). Delving into cultural idiosyncrasy does not exclude the anthropological aim of highlighting the universality of certain human behaviors (Fainzang, 2005). Anthropology of medication consists in knowing and understanding not only the use of medications but what that use reveals about individuals and society (Fainzang, 2005).

Aside from the possible health benefits involved in the incorporation of religion and spirituality into health care there is also the autonomy of the patient to consider (Easterbrook and Maddern, 2008). The ideal of informed consent, that is, consent given by the patient based on knowing all the facts about the risks and the benefits of a particular treatment regimen as well as possible future repercussions of the treatment to medication or medication regimens, protects the ethical fabric of a health care system. Unlike other transactions, however, patients rely heavily upon the knowledge of the health care provider when making decisions regarding medicine and health. The incorporation of spiritual and emotional considerations may be a useful tool to increase a patient's adherence to medication and bring about holistic care of a patient.

Cultural beliefs play an important role in determining a patient's inclinations toward accepting treatment. Appreciation of cultural and religious practices could be vital in increasing patient compliance and more importantly cementing a relationship based on trust and mutual understanding, between health care professional and patient. This chapter therefore looks at the influence of culture on medicine use, using race, ethnicity, and religion as surrogate measures. The chapter also looks at this from the perspective of both patient and health care provider viewpoints.

Ethnicity and Medicine Use

Palacio et al. (2002) undertook a systematic review of published studies investigating potential associations between race and/or ethnicity and use of HIV-related medications, including antiretroviral medications and medications used for prophylaxis of opportunistic infections. The authors identified 28 reports, of which: (a) 26 studies published in 1991–2001 addressed antiretroviral use, spanning data collection periods from 1984 to 1999; (b) 11 studies published in 1994–2001 addressed prophylaxis for Pneumocystis carinii pneumonia (PCP), reporting on data collected from 1989 to 1998; and (c) three studies published from 1998 to 2001 addressed prophylaxis for other opportunistic infections, reporting on data collected from 1993 to 1998. Among the studies that addressed antiretroviral use, 14 found a negative association between nonwhite race and at least one measure of antiretroviral use, three studies found a positive association, and 16 studies found no association; 7 studies found mixed results across several measures of antiretroviral use. Only 4 of 11 studies found a negative association between race/ethnicity and PCP prophylaxis; the remainder found no association. Two out of three studies found a negative association between race/ethnicity and prophylaxis for other infections. Thus, it is evident from this review that there is a role between race and ethnicity and medicine use that could affect health outcomes.

Polacek et al. (2007) found that patients from minority racial/ethnic and cultural backgrounds that differ from the majority, are disadvantaged when it comes to advocating for their health care and they evaluate their treatment decision making much less favorably than whites. Many reasons have been suggested (Health Policy Brief, 2011; Morris et al., 2010) for different or disparate care and outcomes among racial/ethnic and cultural minorities. These range from personal factors related to socioeconomic position or geographic area (e.g., educational attainment, income, neighborhood) to health system factors (e.g., differential delivery of care, reduced hospital resources). Yet the authors found that few discussions about differences in receipt or quality of health care discuss the role of patient engagement by health care professionals or involvement in health care decision making, and how this involvement (or lack of) may contribute to differences in use of care and access to treatment (or even adherence to treatment).

Morgan et al. (2011) looked into prescription medicine use by people of different ethnic groups in Canada. The authors found variation in prescription medicine use by ethnicity. Patients who were of South Asian descent, or mixed ethnicity, were almost as likely to fill prescriptions for most types of medicines studied as women and men who identified themselves as white. In addition, South Asian men were more likely than white men to fill prescriptions for antibiotics and NSAIDs. Women of Chinese ethnicity were significantly less likely to fill prescriptions for antihypertensives, antibiotics, antidepressants, and respiratory drugs, and Chinese men for antidepressant drugs and statins.

A pilot study assessed the differences in attitudes toward medications between the different population groups in South Africa (Suleman et al., 2008). The study analyzed the attitudes of a sample of patients, collected from the Durban Metropolitan Area within the province of KwaZulu-Natal, South Africa, to determine the existence of variances based on demographic characteristics, medication knowledge, self-care orientation, medication use, and contact with health care workers (Suleman, 2008). The results of this study indicated, in accordance with a similar study conducted in Sweden (Isacson and Bingefors, 2002), that the population fell into two groups: those who considered drugs as beneficial, and those who considered drugs as something necessary but not always in the best interest of their health care (Isacson and Bingefors, 2002; Suleman et al., 2008). In the South African study, perceptions of medication improved with age and respondents who visited a health care worker in the last six months had a more positive attitude toward medicines (Suleman et al., 2008). In terms of race 64% of black people and 57% of colored (mixed-race) people believed medicines to be good while 53% of whites and 52% of Indians believed that medicines are necessary but not necessarily good for you (Suleman et al., 2008).

Ethnicity has been found to influence not just prescription and nonprescription medicines but also complementary and alternative medicine (CAM) use. Villa-Caballero et al. (2010) studied the effect of ethnicity as a predictor of the use of CAM among patients with diabetes in the United States. The authors reported that the prevalence of pharmacological and non-pharmacological CAM among 806 participants with diabetes was 81.9% and 80.3%, respectively. Overall, CAM prevalence was similar for Caucasians (94.2%), African Americans (95.5%), Hispanics (95.6%), and Native Americans (95.2%) and lower in Pacific Islanders/Other (83.9%) and Asians (87.8%). Pharmacologic CAM prevalence was positively associated with education (P = 0.001). Several significant ethnic differences were observed in specific forms of CAM use. Hispanics reported using frequently prickly pear (nopal) to complement their diabetes treatment while Caucasians more commonly used multivitamins. Similarly, a study by Schoenberg et al. (2004) showed that Hispanics had a higher CAM use (40%) than African Americans (20%), Native Americans (15%), and Caucasians (15%). CAM use was associated with ethnic and cultural background in all the groups studied. Other studies report lower prevalence of CAM use among African Americans compared to other ethnic groups (Eisenberg et al., 1998).

Research has also been conducted in terms of self-care assessments and ethnicity. Johnson et al. (2014) looked at differences in diabetes self-care activities by race/ethnicity and insulin use in the United States (US). From the sample observed, only 20% of adults had high levels of diabetes self-care, while 64% had moderate and 16% had low self-care. Racial/ethnic differences were apparent for every self-care activity among non-insulin users but only for glucose monitoring and foot checks among insulin users. Overall, American Indian/Alaska Natives had higher odds of glucose monitoring; Blacks had higher odds of foot checks; and Hispanics had higher odds of not smoking compared with non-Hispanic Whites. Non-insulin-using American Indian/Alaska Natives had higher odds of foot checks, and non-insulin-using Hispanics had higher odds of fruit/vegetable consumption.

Thus, ethnicity, in terms of the findings of these studies, can influence access to care and treatment, use of prevention measures, attitudes and perceptions of medicine use, including CAM, and thus ultimately health outcomes. Health care workers, especially

pharmacists, need to be aware of these differences and tailor counseling and advice, or other specific interventions, based on the different ethnic groups in the populations they serve and variations within those particular groups.

Religion and Medicine Use

Religious beliefs are likely to impact of health care as well. Devotion to religious values shapes how a group or an individual approaches health care and medicine use. The Amish population in the US, for example, have been known to consult their religious book (or Almanac) and choose to use home remedies in the first instance (Hostetler, 1995). Religious beliefs include trust in God for healing purposes, reliance on individuals within their community, a preference for natural remedies, motivation to reduce health care costs and sometimes, limited access to health care facilities. The Amish have their own healers in their community who tend to prescribe home remedies (Amish Burn Study Group, 2014; Trinkle, 2016). The Bishop is an important agent in the community, as s/he acts as an intermediary between the community members and what the Amish consider as the outside world. Therefore, the views of the Bishop in this faith carry much weight and can be a facilitator or barrier to access to care and medicine use. The Amish will only access health care services and facilities if they feel that their traditions, religion, and values are respected (Ember and Ember, 2003). Similarly, Baptist and Methodist congregations have weekly sermons that incorporate health and healing topics. The congregations are encouraged to rely on the power of prayer for curing the ailments (Dessio et al., 2004).

The most pressing issue with regard to establishing an interfaith friendly medical system is the dietary requirements of individual faiths. Seventh Day Adventists promote vegetarian diets, and abstention from alcohol and tobacco (Dessio et al., 2004). Jehovah Witnesses refuse blood transfusions, organ transplants, and vaccines. Medical literature has detailed the use of religiously forbidden products (for example, in the religions of Islam and Hinduism, etc.), such as gelatin capsules and surfactants (Adappa et al., 2003; Gatrad et al., 2005; Sattar et al., 2004a,b).

However, an extensive literature search only indicated one study that directly investigated the influence of patients' faith and concordance with porcine derived medicine (Sattar et al., 2004a). This study conducted in the United Kingdom provides a glimpse of a previously unexplored avenue. In the study of 50 Muslim patients and 18 Muslim general practitioners, it was found that only 26% of patients would take a medicine if they were unsure as to whether or not it was halal (In Islam food and drink which are forbidden are termed haram, while any food and drink that can be taken are termed halal) (Sattar et al., 2004a). A further 58% stated that they would stop taking a medicine if they found out it was haram (Sattar et al., 2004a). Medical necessity was shown to influence circumstances as 36% of patients and 44% of GPs believed it was acceptable to take a haram medicine for a major illness: for minor illnesses, however, only 8% of patients and 36% of GPs believed it was acceptable to take a haram medicine (Sattar et al., 2004b).

Followers of Judaism and Islam strictly forbid pork within the diet and these restrictions are outlined within the religious scriptures (Easterbrook and Maddern, 2008; Mynors et al., 2004; Shalom, 2005). Hinduism and Sikhism exalt vegetarianism and do not advocate the consumption of beef and pork (Easterbrook and Maddern, 2008; Mynors et al., 2004). Some problem excipients found in medications include gelatin (which is usually of animal origin), glycerol/glycerine (however most glycerol and glycerine used are now of vegetable origin), stearic acid and stearates, and lactose (milk-derived sugar) (Mynors et al., 2004). Although these avenues provide a critical view of possible patient reservations only one study provides a direct link between religious dietary requirements and patient compliance (Mynors et al., 2004).

As a follow on to the United Kingdom study, a postgraduate study was conducted in the eThekwini Municipality of KwaZulu-Natal, South Africa between May 2009 and May 2010 (Pillay, 2010). From the study participants, 35.5% of patients indicated that their specific religious, cultural, or personal belief system had specific dietary requirements. The most commonly prohibited items among those who did have specific dietary requirements was alcohol and porcine/pork (53%), and bovine/beef derived products (43%). 41.4% of patients indicated that they would not take a medication if it contained an ingredient which their specific dietary requirements did not allow; 75.1% agreed that they would take it for a serious illness (such as cancer) while 44.3% indicated that they would not take it for a minor illness (such as the flu). Most patients (63.3%) would take a medication which contained products that are not allowed according to their specific dietary requirements for a chronic condition and 36.2% would stop taking a medication if they found out that it contained prohibited products. 94.3% of patients had never been informed by a health care worker that a medication contained ingredients which may be in contravention of their specific dietary requirements. 93.1% of patients believed that physicians should talk to patients about spiritual faith in terms of a patient's health and medication regimens. 60.6% of the sample agreed that manufacturing companies should indicate the presence of ingredients that may not be allowed according to certain individuals dietary preferences and 48.0% indicated that they were more likely to accept treatment that suited their dietary preferences.

Very few patients (4.9%) were aware that medications contain constituents of bovine, porcine, dairy, or alcohol origin. 94.6% of patients could not identify any product, in a table of eight commonly used prescription and nonprescription items, which contained any ingredients that may not be permissible according to their specific dietary requirements. Religion was a significant factor ($P = 0.008$) when patients were required to indicate if it was difficult to take their medication exactly the way the doctor had told them. When questioned if they would take a medication containing an ingredient which their specific dietary requirement did not allow, only 10% of Muslim patients agreed while 100% of Christians and 64.5% of Hindus indicated that they would take it ($P = 0.000$). When asked if they would be willing to take a medication containing an ingredient that their specific dietary requirements did not allow for a serious illness (e.g., cancer) 37.4% of Muslims, 100% of Christians, and 88.4% of Hindus agreed

that they would take the medication. When asked if they would take it for a minor illness (e.g., the flu) 7.2% of Muslims, 100% of Christians, and 57.9% of Hindus agreed that they would take it ($P = 0.000$). In terms of chronic illness and the taking of a medication containing an ingredient which is not permissible, 18% of Muslim patients, 100% of Christian patients, and 72.3% of Hindu patients indicated that they would indeed take the medication ($P = 0.000$). All religious groups agreed that doctors should speak about spirituality with regard to health and treatment regimens (i.e., 90.6% of Muslim patients, 98.6% of Christian patients, and 89.3% of Hindu patients) ($P = 0.004$). 90.6% of Muslim and 91.7% of Hindu patients believed that manufacturers should indicate the presence of potentially problematic ingredients.

Religion, Medicine Use, and Health Professionals

Health professionals have an ethical obligation to receive informed consent from their patients to conduct treatment or perform a medical procedure but how informed are patients regarding the religious, cultural, and spiritual sacrifices entailed in making a specific treatment choice? Understanding cultural and religious practices could contribute to increasing patient compliance and building a relationship between health professional and patient based on trust and mutual understanding. Religious and spiritual factors also need to be taken into account when counseling a patient and therefore it is important for health professionals to understand patients' beliefs and practices. In addition, health professionals need to be aware of their own cultural influences and reflect on these when interacting with patients.

There are a large number of studies that indicate that most patients would like their physicians to include the spiritual and religious considerations during the illness experience (Armbruster et al., 2003; Daaleman and Nease, 1994; Ehman et al., 1999; King and Bushwick, 1994). Many physicians accept that patients' religion and spirituality can positively affect their health, however, most do not initiate enquiry into religious or spiritual background (Armbruster et al., 2003; Brooks and Chibnall, 2001; Chatters, 2000; Chibnall and Brooks, 2001; Daaleman and Frey, 1999; Ellis et al., 1999). Of 724 quantitative studies of religion and health published during the 20th century, 66% of studies found that a statistically significant relationship existed between religion and improved mental health, greater social support, and less substance abuse (Johnston et al., 2007). Religious patients relied on beliefs as coping mechanisms, while nonreligious professionals and patients did not, as they felt that religion had no role to play in managing and coping with illnesses which was due to psychological and physical factors (Johnston et al., 2007).

Religion and culture in these first world nations also became the basis for withholding medical services, with 14% of health professionals, specifically physicians, indicating that their personal religion and beliefs justified withholding information from their patients (Sloan, 2009). One such example is a study, conducted by Davidson et al. (2010) in Nevada, United States of America (USA), which found that religious pharmacists were more likely to refuse to dispense medical abortifacients and emergency contraceptives, while nonreligious pharmacists were more willing to dispense (Davidson et al., 2010). The primary intention of these health professionals was to honor their own beliefs rather than act in the best interest of the patient (Davidson et al., 2010).

A Dutch study surveyed 120 General Practitioners (GPs) regarding the extent to which the GPs respect the religious beliefs of their patients (Kuyck et al., 2000). The study found that only 16% of GPs enquired about the religious affiliation of their patient during registration at their practice, while 25% enquired during routine consultation (Kuyck et al., 2000). Religious beliefs became more important with situations that were considered a "major life event" such as abortion, terminal illness, and euthanasia (Kuyck et al., 2000). A study conducted in the USA, between 1976 and 1986, indicated increased enquiry about patient's religious affiliation in situations relating to terminal illness, with 69% of physicians indicating that they do enquire about religious beliefs. With respect to near death experiences, 68% of physicians enquire about religion, while 52% enquire about religion when dealing with abortion issues (Craigie et al., 1988). The Dutch study found that the propensity of a GP to enquire about religion was also dependent on their own religious upbringing (Kuyck et al., 2000). In this sample, GPs of Protestant upbringing were more likely to discuss religious beliefs with patients (Kuyck et al., 2000). In an evidence-based medicines study, conducted in Canada, it was found that contextual factors such as the religion and ethnicity of the physician did not significantly influence the physician's decision to prescribe a particular treatment (Tracy et al., 2005). However, there was a significant difference ($P = 0.005$) in the influence of religion on a female physician's decision to prescribe a certain treatment versus a male physician (Tracy et al., 2005). The authors suggested that female physicians were more likely to respond to contextual clues, and spend more time with patients, engaging in more communication that could be considered patient centered than their male colleagues.

In addition, a study conducted by Siegel et al. (2002) on a sample of 165 pediatricians and pediatric residents in the United States of America (USA) found that few pediatricians enquired about spirituality and religion despite believing it to play a role in patient healing. The majority of pediatric residents considered themselves to be religious/spiritual, and were more likely to pray with patients and initiate spiritual dialog. This group was also more likely to contact a religious leader or (spiritual/religious professional) on behalf of their patient.

A study of the awareness, attitudes, and knowledge of psychiatrists in addressing issues of faith (particularly dietary restrictions) was conducted in the south-west of England (2008) by Khokar et al. Results indicated that although the majority were aware of the presence of potentially forbidden excipients (different substances) in medications, more than half (53%) indicated that discussion should only take place if the patient indicated concern (Khokar et al., 2008). However, 55% indicated that information relating to the presence of "forbidden contents" may negatively influence a patient's future compliance to medication (Khokar et al., 2008). This is in contrast to Pillay (2010) who also included health professionals in a study on the influence of religion on medicine use in

the eThekwini District in South Africa. Almost all participants (93.7%) considered themselves to be part of a religion, with 43.4% indicating that they had personal beliefs independent of their religious beliefs. More than three quarters (78.9%) did not routinely enquire about a patient's religious affiliation; this number decreased to 65%, when asked about establishing their patient's religious beliefs in a health crisis or life threatening illness. Over three quarters (88.1%) indicated that they do not take a spiritual history from their patients. Almost two-thirds (64.8%) indicated that they were rarely asked to discuss religious and spiritual issues by a patient.

Doctors were more likely to agree that patients' religious belief positively affects their health, and that patients' and family religious beliefs were important to patients' care. They were also more likely than pharmacists to believe that a patient or patient's family would feel that a health care professional was imposing their religious views on them, if a health care professional engaged in religious discussions. Doctors were more inclined to believe that religious involvement reduces patient morbidity, and that health care professionals should acknowledge/support patients' religious beliefs.

Numerous reasons have been cited for physicians not initiating spiritual discussion. These include physician discomfort in relation to psychosocial and emotional interventions, lack of time, lack of training, and the applicability of spiritual and religious concepts within a patient encounter (Armbruster et al., 2003).

Understanding Culture and the Health System

Health care systems face many challenges with the diverse, multicultural populations of the world. The relationship between medicine use, religion, and culture is complex, has been under discussion for many years and requires investigation employing medical ethnographies. The early works by William Osler in early 20th century medicine viewed religion and medicine in opposition where medicine was scientific, objective, and neutral while religion was irrational and subjective. Science required religion to conform to the values of medicine (Bishop, 2009; Bishop and Trancik, 2013; Stahl, 2013; Trancik, 2013). The secular and scientific viewed medicine as the judge of religion demanding that religion prove it is an effective and efficient biopsychosocial therapy (Bishop, 2011). This view has evolved to the extent that today religion and medicine are seen as binary, and to the extent that religion may be perceived as an alternative form of medicine (Cohen, 2007) and some religious rituals are allowed in hospitals (Taylor, 2012). This indicates some tolerance of religion in the medical arena, however, this must still occur in a defined regulated space (Cohen, 2007).

Arthur Kleinman (1978) described medical systems as both social and cultural systems with meanings and behaviors attached to social relationships and institutional settings and believed that separating the cultural system from the social aspects of health care is not possible. Kleinman developed a model that viewed medical systems as cultural systems to better understand how culture mediates between the external and internal parameters of the medical system. He further stated that culture determines the content, effects, and changes of a medical system. Illness is viewed as a cultural idiom that links beliefs about the cause of the disease, symptoms experienced, patterns of illness behavior, treatment decisions, therapeutic practices, and the evaluation of the therapeutic outcome. A system of relationships exists between these components, governed by the same set of social rules, thus health, illness, and health care must be understood in relation to each other and cannot be dealt with in isolation as this may lead to a distorted understanding of how each function within a health care system and may lead to errors in cross-cultural comparisons. Both semantic network analysis (Good, 1977) and symbolic analyses support this (Ahern, 1975; Gould-Martin, 1975; Harwood, 1971; Ingham, 1970; Obeyesekere, 1976; Turner, 1967). Chinese culture employs cross-cultural medical models (Kleinman, 1975).

The concepts of gender, race, and ethnicity are important in multicultural health care systems. There exists a fair amount of overlap of and distinctions between race and ethnicity and how they relate to health. For example, race was initially associated with the biologic genetic makeup of a person but more recently has been closely associated with the social experiences of belonging to a particular social subgroup, while ethnicity has been associated with social background, shared traditions/cultures, or language and religion that are specific and passed through generations providing a sense of identity and belonging to a specific group. Ethnic inequalities in health and health care exist in some settings as a result of racism and socioeconomic position impacting on the racial/ethnic minority groups (Bhopal, 2007). A report on sex, illness, illness behavior, and the use of health services (Mechanic, 1978) showed that women reported illness more than men and this was related to how women responded to their illness and life situation. This difference was reduced when objective measures were used (more tangible symptom of the illness) implying women reported more subjective symptoms than men, specifically symptoms indicative of physical disease or psychosocial stress.

Culture is often the underlying cause of the burden of diseases borne by communities of color and despite years of research and efforts to reduce the degree of poorer health outcomes for communities of color the gap is widening (Institute of Medicine, 2001). This is due to the fact that the concept of "culture" is rarely defined or adequately measured.

There exists a lack of clarity of the impact of culture on health outcomes as a result of the poor understanding of this concept and the proxy of race is used for culture. When this single proxy variable was used in a multilinear regression, its contribution accounted for an insignificant proportion of variance and was left out of the analysis (Gregg and Saha, 2006) leaving a gap which was filled by socioeconomic status (Zambrana and Carter-Pokras, 2010). Such compounding of race and culture misinforms population science (Kagawa-Singer, 2006).

Scientifically, culture is a complex, dynamic, integrated conceptual framework that is unrelated to how it is operationalized in health behavior theories. If the concept of culture were more appropriately operationalized, results from studies with diverse populations would yield more scientifically valid findings relevant to that specific community. Steps to achieve this include (i) when culture is a factor of behavior then researchers must provide their definition of culture and identify the measures used

to operationalize it; (ii) develop models that capture the holistic influence of culture on health beliefs and behaviors; (iii) establish the cross-cultural equivalence and validity of measures; (iv) address the limitations of acculturation; (v) develop guidelines for the use of culture in population science to resolve confusion with racial/ethnic groups; and (vi) use more inductive and mixed method studies to identify unrecognized domains of cultural influence on health outcomes in diverse cultural communities (Kagawa-Singer, 2012). Thus, more community appropriate results from studies could assist with developing more effective strategies to reduce poorer health outcomes for communities of diverse cultures. Until that time, health care workers need to understand that these contextual factors experienced by patients and by themselves, will influence access to care, adherence to treatment, and health outcomes for patients. However, health care workers need to be careful to not assume that all people belonging to a religion or race group or ethnic group are homogenous. Each patient needs to be engaged on an individual basis and stereotyping should be avoided.

Conclusion

Culture is an important consideration in medicine use. It is a worldview that is embraced by individuals and communities and passed down to generations. Culture affects health care perceptions and attitudes as well as behavior, based on the values and beliefs of an individual. Culture also tends to evolve over time. Studies have indicated that treatment interventions are more effective when they are culturally accepted and recognized. Health care professionals need to recognize the influence of culture (and its many surrogate indicators), when dealing with patients, not just in terms of understanding their medical condition, but also to encourage adherence to medication treatment plans. In this increasing global world, and with the increased movement of populations across countries (as migrants), cultural sensitivity would need to be incorporated into training programs for health care professionals internationally, and strengthening of communication and systems between health providers and spiritual leaders is critical. Finally, more research is required around the impact of culture on health outcomes, and on interventions that can help to promote cultural sensitivity and therefore medication adherence in communities.

Key Lessons

Health professionals need to be aware of the influence of culture on patient's medication use and self-care activities and counsel or create interventions tailored to these ethnic groups.

Health professionals should engage in discussions with patients regarding the ingredients contained in medicines and its impact on patient's observance of religious rules to prevent disruption of treatment in the event of the patient finding out. This will build trust in patients. If alternatives exist, these should be offered.

Patients continue to express the need for transparency in labeling of medicines, which should be introduced by regulators as much as the food industry has introduced transparency in labeling for specific dietary requirements.

Health professionals should include a short religious enquiry as part of their initial consultation to establish any religious limitations regarding dietary requirements.

Health professionals should familiarize themselves with religious organizations in their area so they can consult them for advice and refer patients who require information.

Glossary

Culture The sum of attitudes, customs, and beliefs that distinguishes one group of people from another.
Halal Food and drink that is permissible in Islam of or being meat from animals slaughtered in the manner prescribed by Islamic Law.
Haram Food and drink that is prohibited as it is from meat from animals not slaughtered in the manner prescribed by Islamic law.

Disease Mongering: Corporate Greed and the Creation of Disease

Joel Lexchin[*,†,‡], [*]York University, Toronto, ON, Canada; [†]University Health Network - Toronto, ON, Canada; [‡]University of Toronto - Toronto, ON, Canada

Introduction

Pharmaceutical companies operate within a capitalist environment, and therefore, like all other for-profit organizations, are oriented to maximizing revenue and increasing the value of their shares. In simple terms, there are two ways of increasing revenue, raise prices or sell more products. While these are not mutually exclusive strategies, it is not always possible to combine them. Even in the unregulated US market where prices are higher than anywhere else in the world (Langreth et al., 2015), there is a pushback as witnessed by the controversy about the price of the EpiPen used for the treatment of serious allergic reactions that forced Mylan to halve the price (Skinner, 2017). Some US states are starting to take action to try and counter unconscionable price increases (Greene and Padula, 2017).

There are a number of ways that companies can achieve greater sales of their products. They can develop drugs that treat diseases where there were no previous therapies, they can market newer more effective treatments, or they can compete in an existing drug class. However, despite the tens of billions of dollars that companies spend each year on research and development (R&D) (PhRMA, 2016), only about 10% of new drugs are major therapeutic advances compared to existing medicines (Prescrire Editorial Staff, 2017). So-called "me too" drugs that represent the bulk of the output of R&D are less likely to generate the level of sales that companies aim for.

The other way to sell more drugs is to either find new diseases to treat, expand the definition of existing diseases, or set a new benchmark for when treatment should begin. Sometimes this may be entirely appropriate, as with HIV where the early approach to treatment using antiretroviral therapy was to wait until the CD4 level dropped below 500 cells/mm^3, to the current recommendation to start treatment once the diagnosis is made. Whereas this change was made in the interest of achieving a better health outcome, in most cases these changes are made for commercial reasons, that is, to increase revenue. In these circumstances, this approach is usually referred to as "disease mongering."

The term disease mongering appears to have been coined back in the early 1990s by the medical journalist Lynn Payer. Payer's thesis, as summarized in a review of her book by Ray Moynihan, was that "the boundaries of disease are fluid, and that there are too many vested interests trying to push those boundaries as wide as possible." Doctors, drug companies, test makers, medical writers, hospitals, courts, and insurance companies were all: "Trying to convince essentially well people that they are sick, or slightly sick people that they are very ill—is big business" (Moynihan, 2002a, 2002b). Payer's message was only picked up by a relatively small number of people. The notion of disease mongering achieved much wider publicity following the publication of an article by Moynihan in the 2006 April fool's issue of the *BMJ* about a made up disease called "motivational deficiency disorde" and the introduction of indolebant, a supposedly newly discovered treatment for this condition (Moynihan, 2006).

The release of the article coincided with a 3-day conference on the subject in Newcastle, Australia attended by about 150 national and international delegates and the papers presented at this conference were subsequently published in a special edition of *PLoS Medicine* (Public Library of Science, 2006). In their introduction to this special issue, Moynihan and Henry defined disease

mongering as "the selling of sickness that widens the boundaries of illness and grows the markets for those who sell and deliver treatments"; whether that is medicalizing aspects of ordinary life, turning mild problems into serious illnesses, or framing risk factors such as high cholesterol as diseases (Moynihan and Henry, 2006). While they acknowledged that for any "mongered" condition certain individuals with severe forms might benefit from industry-raised awareness, and some people might welcome their symptoms being branded a disease since it "legitimizes" what they experience, their overall conclusion was that disease mongering is dominated by marketers who are primarily interested in profit.

Disease mongering fundamentally corrupts the meaning of modern medicine by elevating commercial goals over the objective of serving the public interest in both health and economic terms. Disease mongering "carries the dangers of unnecessary labeling, poor treatment decisions, iatrogenic illness, and economic waste, as well as the opportunity costs that result when resources are diverted away from treating or preventing more serious disease. At a deeper level it may help to feed unhealthy obsessions with health, obscure or mystify sociological or political explanations for health problems, and focus undue attention on pharmacological, individualized, or privatized solutions. More tangibly and immediately, the costs of new drugs targeted at essentially healthy people are threatening the viability of publicly funded universal health insurance systems" (Moynihan et al., 2002).

The remainder of this article will first delve into the general techniques that companies use to expand or create definitions of disease and then it will use case examples of disease mongering to show how these techniques have been used in the past. Finally, the article will conclude by putting disease mongering into the context of how society deals with the boundary between health and illness.

Approaches to Disease Mongering

The message from the pharmaceutical industry collectively and from companies individually is that they are not disease mongering, rather they engage in appropriate marketing. At one conference, Harvey Bale, at the time the director general of the International Federation of Pharmaceutical Manufacturers and Associations, conceded that there were examples of unethical marketing but maintained that most promotion was ethical. The Association of the British Pharmaceutical Industry produced a pamphlet for journalists where it claimed that companies do not define diseases. Individual companies, such as GlaxoSmithKline, have denied that they engaged in disease mongering to sell more of its drug for restless leg syndrome (Moynihan et al., 2008). But a report from Reuters Business Insight makes the motivation behind the campaigns clear. The strategy is to "change the way that people [and doctors] think about common ailments and to make natural processes into medical conditions"; to see problems that were previously regarded as trivial or part of the human condition, such as baldness, short eyelashes, or skin wrinkles, as issues that are worthy of medical attention, and that in fact need medical attention (Moynihan and Cassels, 2005). Moreover, the message in disease mongering campaigns always follows the same pattern—pushing out the boundaries of diseases as far as possible, while at the same time restricting the treatment for these conditions to medications alone.

Disease mongering campaigns are directed both at consumers and at health care professionals who have the ability to prescribe, primarily doctors. While the methods described further are common in disease mongering campaigns, they are also widely used in promotion, in general.

Disease Mongering to Doctors

Obviously, expanding the definition of what requires pharmacological treatment is key to the success of disease mongering. Traditional methods of influencing doctors, such as journal advertisements and visits of sales representatives, while still important, are giving way to methods that use the direct control of knowledge and the means of transmitting that knowledge. This section focuses on three of those methods—key opinion leaders, ghost management of clinical research, and the use of clinical practice guidelines and continuing medical education.

Use of Key Opinion Leaders

In trying to get their message out to doctors, companies are cognizant of the reality that if they communicate directly with doctors, their message risks being perceived as having a commercial bias. As a result, the concept of using "key opinion leaders" (KOLs) as an "independent" source of information has significantly expanded. In the United States, a 2007 survey found that 16% of physicians, or about 141,000 received payments for serving as a speaker or being part of a speakers' bureau (Campbell et al., 2007). More recently, in just 5 months of 2013, companies made what appear to be speaker payments of US$400 or greater to 55,000 US doctors (Sismondo, 2015).

One way of judging the importance that pharmaceutical companies place on KOLs is the fact that roughly one-third of the marketing budget for pharmaceutical companies is spent on them (Millard, 2008; Elliott, 2010). This amounts to an average of about US$38 million on each product as it moves from clinical testing to launch (Cutting Edge Information, 2005). Companies are willing to spend this amount of money because of the return that they get. According to an internal Merck document, doctors who attended a lecture by a KOL on Vioxx (rofecoxib) wrote an additional US$623.55 worth of prescriptions for the drug over a 12-month period compared with doctors who did not attend. "After factoring in the extra cost of hiring a doctor to speak, Merck calculated that the 'return on investment' of the doctor-led discussion group was 3.66 times the investment, versus 1.96 times for a

meeting with a sales representative" (Hensley and Martinez, 2005). Whereas in 1998, in the United States, the number of talks by sales representatives and KOLs were about equal at just over 60,000 each annually; by 2004 there were almost twice as many talks by KOLs compared to sales representatives (Hensley and Martinez, 2005)—a reflection of the economic benefits of using KOLs instead of sales representatives. Anton Ehrhardt, the senior medical director for the Global Medical Affairs division of Millennium Pharmaceuticals, was quite open about the value of KOLs. "The 'dirty little secret' in this field . . . is that people working in pharma view the KOLs as sales agents" (Millard, 2008). According to Kimberly Elliott, a former drug company sales representative, her company "would routinely measure the return on our investment, by tracking prescriptions before and after their [KOLs'] presentations . . . If that speaker didn't make the impact the company was looking for, then you wouldn't invite them back" (Moynihan, 2008b).

Finally, KOLs are often used as guest editors for journal supplements where a series of articles favorable to a new drug are published. Previous work has shown that, in general, the quality of articles in paid journal supplements is inferior to that in the parent journal (Rochon et al., 1994).

Manipulating Clinical Research

Clinical trials form the basis for medical practice. Regulators such as the Food and Drug Administration (FDA) use them to decide whether or not to approve a new drug. Doctors may not read the original research, but that research is incorporated into continuing medical education (CME) talks, clinical guidelines, and review articles. Pharmaceutical companies fund the vast majority of clinical trials (Moses et al., 2005) but these trials also present an economic and ethical dilemma to drug companies. Trials using rigorous methodology, the appropriate population groups, and that are properly analyzed and published in a manner that accurately and completely presents their conclusions are the ideal. At the same time, companies can use trials with positive results in order to drive sales. Negative trials can have significant adverse effects on sales. Within 1 year of the publication of the Women's Health Initiative trial that found that the estrogen/progestin combination caused an increased risk of cardiovascular disease and breast cancer in postmenopausal women, prescriptions for Prempro, the most widely sold estrogen/progestin combination, had declined by 66% in the United States (Hersh et al., 2004).

There is, therefore, a strong temptation to deviate from the ideal for economic reasons. The result is trials that are often biased in some manner. The contention is not that every industry-funded trial is biased but the accumulating evidence provides strong grounds to believe that this type of behavior is common. The results of clinical research are comprehensively manipulated through the practice of ghost management that encompasses ghostwriting and guest authorship. Ghostwriting refers to the practice of an article being written by a person who is not listed as an author, usually an employee of a medical writing firm working for the product's manufacturer. Guest authorship refers to named authors, usually academic clinicians, who have not written the article or been directly involved in the study it describes, and who often have no access to study data. Sismondo describes a broader, integrated process of "ghost-management" consisting of the publication of clinical trial results to provide a positive body of evidence concerning the effects of a specific drug (Sismondo, 2007).

Ghost management takes place in the context of all clinical research, but is perhaps most pernicious when it comes to Phase IV or "seeding trials," trials that are conducted once the product is on the market. These are trials without a scientific design to test a specific research hypothesis whose main goal is to encourage physicians to use new drugs on a widespread basis. A fifth of drug trials published in the six highest impact general medical journals in 2011, including the *New England Journal of Medicine*, *Lancet*, and *PLoS Medicine*, had features that were suggestive of being designed for marketing purposes (Barbour et al., 2016).

When individual principal investigators have financial ties to the manufacturer of a study drug, then regardless of who funded the trial, a financial tie is significantly associated with a positive outcome in randomized controlled trials (Ahn et al., 2017). When a pharmaceutical company sponsors a drug study, both the results and conclusions of the study are more favorable to the product under examination than when sponsorship is undertaken by any other source (Lundh et al., 2017).

Controlling Clinical Practice Guidelines and Continuing Medical Education

With the exponential increase in medical information, doctors are finding it harder to sort out the wheat from the chaff and decide how to manage their patients. Many doctors are increasingly turning to clinical practice guidelines (CPG) to help them in preventing illness and diagnosing and treating it once it occurs (O'Malley et al., 2007). CPGs are print and/or electronic documents that, when rigorously done, involve "defining the primary clinical question the guidelines will address, surveying stakeholders (physicians, patients, policy makers) to identify priority areas, conducting an extensive systematic review of the scientific literature on the chosen topic . . . rating and synthesizing the evidence, convening a panel of experts to discuss the evidence and make clinical recommendations, submitting the recommendations for review to independent experts, and finally, publishing the guidelines and creating knowledge translation tools to push the information out to clinicians" (Collier, 2011).

Clinicians rely on CPGs for guidance when making treatment decisions for patients. Although CPGs should be based on a critical analysis of the best available scientific evidence, authors' recommendations in some guidelines have been based on lower levels of evidence or expert opinion (Tricoci et al., 2009). Therefore, recommendations may be vulnerable to biases (Bindslev et al., 2013), which are of particular concern since financial ties are common among guideline authors, committee members, and drug companies that manufacture medications recommended in guidelines (Abramson and Starfield, 2005; Norris et al., 2011). Just as financial conflicts of interest can influence the reporting of clinical trials, the same is true for CPGs. Cosgrove et al. evaluated the American Psychiatric Association's Practice Guideline for the Treatment of Patients with Major Depressive Disorder to determine the existence of financial and intellectual conflicts of interest and examine their possible effects. Financial ties to industry were disclosed by all

members of the guideline development committee. Fewer than half of the studies cited in support of the recommendations met criteria for high quality and 17.2% did not measure clinically relevant results. One-fifth of the references were not congruent with the recommendations (Cosgrove et al., 2013).

CME is complementary to clinical practice guidelines; it is also subject to commercial bias. Data from the United States suggest that, in 2014, support from the pharmaceutical industry accounted for approximately 25% of total income reported by CME providers (Accreditation Council for Continuing Medical Education (ACCME), 2014). Although industry representatives maintain that their funding of CME is motivated by the desire to provide up-to-date information to doctors, researchers independent from the pharmaceutical industry suggest that this financial support is used to advance sponsors' marketing interests (Relman, 2001; Rodwin, 2010; Steinbrook, 2010). Funding for CME is generally considered by researchers to be part of the marketing budget, dedicated to producing sales, and they include it when reporting promotional expenses (Gagnon and Lexchin, 2008; Kornfield et al., 2013). Fugh-Berman and Hogenmiller argue that even when CME activities have not received pharmaceutical industry funding, speakers who are funded by industry can still be used (Fugh-Berman and Hogenmiller, 2016).

In early 2004, mdBriefCase, a commercial CME provider that was approved for CME credit by the Canadian College of Family Physicians, distributed material regarding a case of a man who was supposedly suffering from andropause, a decrease in his level of testosterone. At that point there had not been any long-term randomized controlled trials showing the benefits of androgen replacement in men who met the description of the patient in this case. (There still have not been any convincing studies (Huo et al., 2016).) The doctor in charge of reviewing the case before it was distributed was on the advisory board for Solvay Pharma, the company that funded production of this material. The doctor's conflict of interest was not disclosed in the material. One of the questionnaires mentioned in the case, the Androgen Deficiency in Aging Males, was developed in part by Solvay. This potential commercial bias was also not disclosed. Finally, the therapy given to the patient in this case fits the description of the product that Solvay was currently promoting. Moynihan documents how one Australian provider of medical education allowed companies to have input into the selection of some seminar speakers despite the fact that these seminars were advertised to general practitioners with the claim that "all content is independent of industry influence" (Moynihan, 2008a).

Disease Mongering to Consumers

Company executives portray promotion to consumers as a way to empower them and enable them to act as partners with their doctors in deciding the best course of treatment. While there may be examples of this, for the most part what we are witnessing are campaigns that skew the understanding of the causes of illness and distort the knowledge of treatments, playing up the benefits, and minimizing the harms (Moynihan and Cassels, 2005). Three main methods that companies use that will be covered in this section are funding patient groups, direct-to-consumer advertising (DTCA), and the use of mass media.

Funding Patient Groups

Just as doctors are suspicious of messages coming from sales representatives, patients are likely to be skeptical about what drug companies say about the products that they produce. To get around this problem, companies are increasingly funding patient groups. Funding of groups is widespread, at least in the United States, as demonstrated by the results of recent surveys published in the *New England Journal of Medicine* (McCoy et al., 2017) and *JAMA Internal Medicine* (Rose et al., 2017). The former looked into the financing of 104 patient-advocacy organizations (PAOs) and found that 83% (86) reported receiving financial support from industry. Of the 59 that published the amount of donations, 23 (39%) reported receiving at least US$1 million annually from industry donations and in 11 of these 59 cases the donations made up at least 10% of their annual income. In the latter survey, a total of 165 of 245 PAOs (67.3%) reported receiving industry funding, with 19 of 160 PAOs (11.9%) receiving more than half of their funding from industry.

Information from other countries is not as detailed but funding of breast cancer groups in Canada is widespread (Batt, 2017). In Australia, in 2008, Pfizer spent A$135,000 to set up the Australian Lung Foundation in conjunction with the launch of its antismoking medication Champix (varenicline) a year earlier, and in 2009, GlaxoSmithKline spent A$1.3 million sponsoring 14 groups (Dunlevy, 2010). Nine out of 15 British patient organizations reported receiving corporate sponsorship that constituted a median of 11% of their revenue (Ball et al., 2006). Finally, in Finland, 71% (39) of 55 organizations said that they had received some form of financial support from pharmaceutical companies (Hemminki et al., 2010).

Although it is not possible to attribute a cause and effect relationship to the receipt of industry funding and the positions that patient organizations take, there are a number of documented cases where the latter have publicly supported industry. The president and CEO and the vice president of research and professional education of the Canadian Diabetes Association (now Diabetes Canada), which acknowledged receipt of unrestricted education grants funding from 11 companies, including Sanofi, the maker of insulin glargine (Lantus), wrote a letter to the *CMAJ* protesting the decision by the Canadian Coordinating Office for Health Technology Assessment, the national health technology assessment body, to recommend that provincial governments not fund Lantus (Howlett and Lillie, 2006). The British Multiple Sclerosis Trust wrote to the Daily Telegraph to criticize the negative funding decision of the National Institute for Health and Care Excellence regarding nabiximols and fampridine, two drugs the Trust characterized as "life-changing." Although the Trust did receive money from the companies marketing these products it did not disclose that fact in its letter (Arie and Mahony, 2014). In a more systematic review, Health Action International, a consumer-oriented non-governmental organization based in Amsterdam, examined the association between patient and consumer organizations' financial sponsorship from the pharmaceutical industry and their positions on the European Commission's proposal to allow

a limited form of DTCA. An association was observed between receiving sponsorship and support for an expanded role of the pharmaceutical industry as an information provider about its medicines to consumers (Perehudoff and Alves, 2011).

Direct to Consumer Advertising

Only the United States and New Zealand allow full DTCA, that is, mentioning the name of a drug along with its indication in a single advertisement. However, other countries such as Australia, Canada, and The Netherlands allow disease awareness ads where a condition is mentioned and then readers or viewers are advised to consult their doctor about a treatment for the condition. In addition, Canada also allows the mention of the name of a product without stating its indication although that indication can be implied. The pharmaceutical industry's viewpoint about DTCA is encapsulated in a statement from the Association of the British Pharmaceutical Industry (ABPI): "The public want more information about their medicines from a wide range of sources, a survey has shown. And the Association of the British Pharmaceutical Industry (ABPI) said today that the results indicated that information provided by the industry would be welcomed by patients" (abpi, 2003). In other words, patients want more information about the medicines that they are taking or are potentially going to take and pharmaceutical companies are in a position to provide that information and are willing to do so. In the United States, drug companies are currently spending about US$5.8 billion annually on DTCA (statistica, 2017).

Studies on the three main forms of DTCA—broadcast advertising, print advertising, and websites—have all found that the quality of information that they contain is seriously flawed. A review of DTCA ads airing on television between 2008 and 2010 concluded that of the 84 most emphasized claims, 55% of them were potentially misleading (Faerber and Kreling, 2013). An earlier analysis of television ads found that while 82% made some factual claims and 86% made rational arguments for product use, only a quarter described the causes of the condition, risk factors, or prevalence. More than half of the ads portrayed the product as a medical breakthrough (Frosch et al., 2007). Ads in magazines generally did not fare any better. In 67 unique drug ads that appeared in 1998 and 1999, two-thirds used emotional appeals and almost 90% described the benefits of the medication with vague, qualitative terms while only 13% used hard data. None of the ads mentioned cost (Woloshin et al., 2001). Ads for bleeding disorders in a patient-directed magazine devoted twice the amount of text to benefits as compared to risks/adverse effects, and the information about the latter was more difficult to read. Experts in the area found that only slightly more than one-third of the ads presented the claims fairly and accurately (Abel et al., 2008). DTCA websites were noted to offer benefits on the homepage 82% of the time, whereas risk information was two clicks away in 75% of the cases. While most websites had a direct link to benefit information in the main navigational button set on the homepage, only 8% of websites provided the same tool for risk information (Huh and Cude, 2004). Drug company-funded mental health websites were significantly more biased toward biogenetic causes of illness and medication than were sites that were financially independent of the industry (Read and Cain, 2013).

The accumulated evidence strongly suggests that DTCA indirectly changes prescribing behavior through its effect on motivating patients to request particular products from their doctors and that there are more negative than positive consequences from the effects of the medications that patients get. Kravitz et al. carried out a randomized controlled trial of the influence of patient requests for paroxetine using standardized patients who described symptoms of depression or of a less severe temporary condition, "adjustment disorder" that is due to life problems and does not require antidepressant treatment (Kravitz et al., 2005). If patients requested an advertised brand-name drug, they were equally likely to receive an antidepressant prescription whether they had symptoms of depression or "adjustment disorder."

US magazines, cable, and satellite television reach Canadian audiences with prescription drug advertising that is illegal under Canadian law. Researchers looked at three drugs that were being promoted on US media and compared prescribing rates in English-speaking Canada versus Québec, which is mainly francophone, and thus is less affected by US media. They found an effect on prescribing rates for one product, tegaserod, a drug that was later withdrawn from the market for safety reasons (Law and Soumerai, 2008). Among US men residing in the 75 designated market areas, regional exposure to televised direct-to-consumer advertising was associated with greater testosterone testing and receipt of new prescriptions for testosterone products without recent testing for androgen deficiency (Layton et al., 2017). Finally, DTCA may promote over-diagnosis of high cholesterol and over-treatment for populations where risks of statin use may outweigh potential benefits (Niederdeppe et al., 2013).

Use of Mass Media

The introduction of new medicines or the findings of medical research are almost invariably accompanied by press releases either directly from pharmaceutical companies or via public relations companies, advertising companies, or media and communication companies acting on their behalf. The objective is to generate public interest in the announcements by creating news value, obtaining editorial attention, and, in general, generating free publicity (van Nuland and Damen, 2010). The website of one Dutch communication company is quite clear about what the value of engagement is for the company marketing the product: "And there are more groups than just the prescriber that determine your market! We all want to work in a patient-oriented fashion, but there are more stakeholders. We know who they are, but where is the win/win? How do you get eyes on you and your product/service? Walking the tightropes intersecting rules, laws, ethics and still managing to get the market moving" (van Nuland and Damen, 2010).

The press releases that are generated are not neutral documents. One study looked at 235 from 10 pharmaceutical companies that were based on the results of original research. Twenty-one percent were not explicit about the source of original data, and almost one-third did not quantify study results. Moreover, almost half of the releases quoted a study author who was typically the lead

researcher, but although the authors usually commented on the benefits of the research only 10% described the limitations (Kuriya et al., 2008). The companies issuing the press releases are also relying on the fact that, at least in The Netherlands, print media and news websites often publish verbatim copies of press releases (van Nuland and Damen, 2010).

One particularly insidious form of disguised press release are video news releases (VNR) that are designed to look like independently produced news but are actually prepackaged promotions containing film footage typically created by public relations firms working for the corporation (Lenzer, 2006). According to a 2002 survey by a leading VNR producer, 88% of US television stations used VNRs from medical, pharmaceutical, and biotech corporations (Price, 2005). VNRs are regarded as particularly valuable as they can deliver a targeted message to the public in the disguise of real news and news reports are a major source of health information for people (Kaiser Family Foundation, 2005). In January 2006, a television station in Rochester, Minnesota, ran a 90 second story on an inhaled form of insulin that was taken entirely from a VNR prepared by Pfizer, the company marketing the product (Lenzer, 2006). VNRs have run in Australia for an estrogen patch for menopausal women (Media Watch, 2005) and a flu medication made by GSK (Moynihan and Sweet, 2000).

Although experts are often quoted in press releases or featured in news stories, their conflicts of interest are typically omitted. Moynihan and colleagues (Moynihan et al., 2000) reported that 50% of news stories about research on three medications cited at least one expert or study with a relevant financial conflict of interest, of which only 40% were reported. Another analysis of 104 comments in news stories about medical research found that there was a financial conflict of interest in 33 cases of which only one-third were actually mentioned in the news story. When there was a financial conflict, 93% of the comments were favorable to the research. In addition, 23 comments were provided by representatives of advocacy organizations. In six instances, the organization had received sponsorship from a commercial entity but none of those conflicts were reported (Wang et al., 2017). Similarly, of 306 news articles about medication research, 130 did not report that the research had received company funding (Hochman et al., 2008).

Examples of Disease Mongering Campaigns

This section uses documented examples of disease mongering campaigns in a number of areas to show concretely how the various tactics that were described are implemented in practice. This is not meant to be a comprehensive review of all of the industry efforts but rather a representative sample.

Erectile Dysfunction

There is no doubt that rofecoxib (Viagra) is effective in treating ED secondary to organic causes, but had Viagra been confined to use in these cases it would probably have been just a modest commercial success for Pfizer. In order to grow the market, Pfizer had to make Viagra the treatment of choice for a much wider population of men. The perceived prevalence of ED needed to be expanded. The impression had to be created that ED was of significant concern to many, perhaps even most men. The criterion of success for treating ED had to be redefined, and finally, Viagra had to be seen as an important treatment option for men with any degree of ED, including rare or transitory failures to achieve or maintain erections.

This process was started by widely and misleadingly promoting the results of the Massachusetts Male Aging Study (MMAS) (Feldman et al., 1994) to argue that 52% of the entire male population in the United States between the ages of 40 and 70 suffered from ED (Pfizer, 2004) despite using a possibly unrepresentative sample of men in the survey (Lexchin, 2006). Moreover, the MMAS results were at variance with those from a number of other studies. Out of 13 studies on the prevalence of ED that were published prior to June 1998, the MMAS results were the highest (Burls et al., 1998).

The Massachusetts study was also used to support the position that ED has a major psychological impact on men (Feldman et al., 1994) even though it may have been an outlier. In a Dutch study only one-third of all men and 20% of men over the age of 70 with significant ED had major concerns (Blanker et al., 2001). Furthermore, in these sexually active Dutch men, 17–28% had no normal erections, indicating that full erectile function is not essential for sexual functioning.

To make Viagra into a lifestyle drug, Pfizer needed to convince men that it was the first choice of therapy for any degree of ED whatever the genesis of the problem. Here is a sample of the Questions and Answers that used to appear on the "Common Questions" portion of the Viagra website:

> "Question: I don't have erectile dysfunction (ED) because the problem doesn't happen often. Does this mean that VIAGRA isn't for me?
> Answer: Even if it happens once in a while, it's still ED. Most men with ED have it just some of the time. VIAGRA has helped about 16 million men around the world with their ED. And VIAGRA helps treat ED whether it happens often or only once in a while" (Pfizer, 2004). Pfizer reinforced its message with direct-to-consumer magazine ads like one featuring a virile looking man around 40 saying "A lot of guys have occasional erection problems. I chose not to accept mine and asked about Viagra."

The initial television ads for Viagra used an aging Bob Dole (born 1923), a 1996 Republican presidential candidate. Pfizer refocused its advertising campaign to match the lifestyle message on its website and replaced Dole as a spokesman with then 39 year-old Rafael Palmeiro, a former Texas Ranger baseball player (St. John, 2003). Between 1999 and 2001 Pfizer spent over $303 million on direct-to-consumer advertising to get its message about Viagra to men (Findlay, 2000; IMS Health, 2001; Yuan and

Duckwitz, 2002). Besides the large promotion budget, Pfizer has also paid a number of doctors to act as "consultants" delivering public lectures and appearing in the mass media to expound on ED and Viagra (Deer, 1998).

Pfizer denied that it was targeting younger men or that it was positioning Viagra as a life-style drug. Mariann Caprino, a spokeswoman for the company, was quoted in the *New York Times*: "Have we gone out and given our advertising agency instructions to speak to this young population? No, we haven't" (St. John, 2003). But the message from the pictures on the website, in magazine ads, and from people like Rafael Palmiero was that everyone, whatever their age, at one time or another, can use a little enhancement, and any deviation from perfect erectile function meant a diagnosis of ED and treatment with Viagra.

Out of 70 websites dealing with ED, the 31 that were drug company funded were significantly more biased toward biological factors in general, and toward medication in particular, compared with the 39 websites that were not industry funded (Read and Mati, 2013).

Social Anxiety

Social phobia or social anxiety disorder is characterized by a significant level of fear in one or more social situations, causing considerable distress and impaired ability to function in at least some parts of daily life. A literature survey conducted in the early 2000s estimated that the lifetime prevalence was between 0.5% and 2.6% of the population, although one US study put it at 13.3% (Martin, 2003). In the late 1990s, SmithKline Beecham (SKB, now GlaxoSmithKline) received approval to market its antidepressant paroxetine (Paxil) for the treatment of social phobia. That prevalence figure quickly escalated to an estimated 10 million in the US, making it the third most common mental disorder after depression and alcoholism, although the US National Institute of Mental Health continued to put the figure at about 3.7% of the population (Vedantam, 2001).

The approval for the use of paroxetine to treat social phobia coincided with a campaign orchestrated by the public relations firm, Cohn & Wolfe on behalf of SKB. The company created a slogan "Imagine Being Allergic to People" and put up posters with pictures of a dejected looking man vacantly playing with a teacup with messages such as "You blush, sweat, shake – even find it hard to breathe . . . That's what social anxiety disorder feels like" (Koerner, 2002). The campaign used television shows such as "Ally McBeal" and magazines such as *Rolling Stone* to get the message across and, according to the *Washington Post*, media accounts of social anxiety rose from 50 stories in 1997 and 1998 to more than 1 billion references in 1999. About 96% of those media references had the message that "Paxil is the first and only FDA-approved medication for the treatment of social anxiety disorder" (Vedantam, 2001). A month after 9/11, SKB attempted to play on peoples' fears to further increase the sales of paroxetine. The company used an advertisement of a woman walking on a crowded street, her face strained, in a crowd otherwise blurred. The caption on the ad read "Millions suffer from chronic anxiety. Millions could be helped" (Mintzes, 2002).

The medical director of SKB denied that the company had a fiscal motive behind its campaign and said that "the reason we do all this is to enhance the lives of our patients. To be in it for financial reasons only would be short-sighted" (Rose, 1999). Paxil's product manager offered a different perspective. "Every marketer's dream is to find an unidentified or unknown market and develop it. That's what we were able to do with social anxiety disorder" (Goetzl, 2000).

The day that paroxetine was approved for treatment of social phobia, a patient group called Freedom From Fear released a telephone survey that claimed that people with the problem spent nearly 40 hours per week worrying. The survey mentioned neither SKB nor paroxetine, but the media contact listed was an account executive at Cohn & Wolfe (Koerner, 2002). In the United States, there was a coalition of nonprofit groups, the Anxiety Disorders Association of America (ADAA), partially funded by SKB, and in July 1999 as part of its effort, the ADAA held a press conference to publicize the findings of a study that purported to quantify the high economic cost of anxiety disorders. The study in question was underwritten by a group of drug manufacturers (Cottle, 1999). Jerilyn Ross, the founder of the ADAA denied that her organization had ever promoted any drug and maintained that her organization had even got into "fights" with SKB because the company wanted the ADAA to do things it was uncomfortable with (Vedantam, 2001). However, a 1996 ADAA brochure on social phobia that was supported by an educational grant from SKB, advocated the use of medication for the disorder and did not mention the high rate of relapse associated with drug therapy (Cottle, 1999).

Key opinion leaders who have served as paid consultants or scientific investigators for companies marketing treatments for social phobia discount any notion of conflict of interest (Vedantam, 2001). One of the people featured in a video on social phobia that was distributed by Cohn & Wolfe was Dr. Jack Gorman who would later give talks on SKB's behalf about paroxetine. Another prominent physician advocating for paroxetine was Dr. Michael Liebowitz, a consultant to many pharmaceutical companies. Dr. Leibowitz was on the advisory panel that updated and expanded the definition of social phobia that appeared in the Diagnostic and Statistical Manual III-R, the widely used manual of psychiatric diagnoses (Cottle, 1999). Along with Dr. Gorman, he was also the author of an article that maintained that social phobia was significantly underdiagnosed (Liebowitz et al., 1985).

Overactive Bladder

Overactive bladder (OAB) is the symptom complex of urinary urgency, frequency, and urge incontinence. Until 1996, it was more commonly known as incontinence or more formally as "detrusor instability." The renaming was done by two urologists, Dr. Alan Wein from the United States and Dr. Paul Abrams from the United Kingdom, with marketing in mind, although they maintained that Pharmacia was opposed to the name that they chose (Abrams and Wein, 2012). As Dr. Wein said, "detrusor instability sounded like it referred to a psychiatric condition, whereas the phrase overactive bladder was immediately recognizable" (Fiore et al., 2016).

These two doctors organized their first conference on OAB in London in 1997, sponsored by Pharmacia (now part of Pfizer), which started to market tolterodine (Detrol) for its treatment in 1998. A year later, there was a new definition of OAB written by the International Continence Society that expanded the number of people who met the criteria for OAB. The International Continence Society does not list its funding sources on its website (https://www.ics.org) but it does note that it offers Pfizer International Fellowships.

Drs. Wein and Abrams were two of the KOLs that Pharmacia set out to cultivate. A slideshow presented by Neil Wolf, group vice president at Pharmacia, is titled "Positioning DETROL (creating a disease)" (Wolf, 2002). One of the slides titled "Creating OAB KOLs" listed activities, including "advisory board, consultant meetings, significant Phase IV activity (postmarketing trials) leading to ICS definition of OAB changed rapidly and dramatically." Although Pharmacia may have been initially unhappy with the name change, this slide seems to indicate that it later enthusiastically supported that change. The expansion in the recognition of OAB was furthered in December 1997 with the publication of a 114-page supplement of the journal *Urology* that was paid for by an unrestricted educational grant from Pharmacia and guest edited by Drs. Wein and Abrams.

In the slideshow, one slide was titled "Broaden and Own the Understanding of the Market" while another one was titled "Converting a Niche Product into a Mass Market Opportunity." The contents of a third slide listed one of the critical success factors of the campaign as "Establish[ing] OAB as a serious medical condition with profound negative impact on people's quality of life." The latter was achieved in Canada when a new drug for OAB was launched with the manufacturer (Astellas) describing OAB as "a chronic, debilitating condition that can have a profound, negative impact on a patient's quality of life. Many patients with OAB are plagued by depression, experience a disruption in sleep, limit their social activity and experience a loss of control and decreased self-esteem" (Cassels, 2013). Neil Wolf denied creating a disease. His point of view was that "We created awareness of a condition so that people who suffered from the condition could recognize themselves and talk with their doctors" (Fiore et al., 2016). In The Netherlands, Astellas contributed to creating awareness through a website that offered a self-test with four questions. It was recommended that even in the case of mild complaints consumers print the results and take them to their general practitioner (van Nuland and Damen, 2010).

Industry-funded consultants continue to play a major role in the way that OAB is investigated. The majority of nonrandomized controlled trials, epidemiological studies, and randomized controlled trials are industry funded and the majority of authors in these types of studies report conflicts of interest (Tikkinen and Auvinen, 2012). KOLs have also played a major role in expanding the number of people who could potentially be treated for OAB. The initial 2001 survey, with Abrams and Wein as two of the six authors and funded by Pharmacia, that identified 17% of people of 40 years of age and over as having OAB based this figure on a positive answer to any of the three symptoms: frequency, urgency, or urge incontinence. There was no question about whether these symptoms interfered with people's lives or whether they were distressed by them (Milsom et al., 2001). A subsequent survey published in 2009, also funded by Pfizer, and published as a journal supplement with three of the six authors declaring being consultants for Pfizer and one a Pfizer employee upped the number of Americans with OAB to 42 million or 18.6% of the adult population 40 years or over (Onukwugha et al., 2009). The most recent survey, again funded by Pfizer with three authors having a financial relationship with the company and the other two employed by the company, concluded that in 2008 one in nine people in the world had OAB with direct annual costs approximating 2 trillion (Irwin et al., 2011). By contrast, a study in Finland done without the involvement of a pharmaceutical company found numbers approaching these levels only among people 60 years and older (Tikkinen et al., 2007).

The guidelines on the diagnosis and treatment of OAB issued by the American Urological Association (AUA) in 2012 and updated in 2014 were produced by a panel of 11 with 8 of those listing financial ties to companies that marketed treatments for OAB (Gormley et al., 2014). After the initial guidelines were released, the AUA put out a pocket guide for primary care doctors summarizing the recommendations, paid for by Astellas, that by that time was marketing two of the most widely prescribed drugs for OAB (Fiore et al., 2016).

Osteoporosis and Osteopenia

The definition of osteoporosis came out of a World Health Organization-sponsored Working Group that met in 1992. The group defined "normal" bone mineral density as that of a 30-year-old woman and somewhat arbitrarily proposed that osteoporosis should be diagnosed when bone mineral density dropped 2.5 standard deviations below normal and that when it was 1.0–2.5 standard deviations lower then the diagnosis of osteopenia should be applied (WHO Study Group, 1994; Alonso-Coello et al., 2008). However, the report made it clear that "The argument for treating or screening all women is poor" and "[t]he cost of preventive measures may possibly outstrip the savings made by preventing fractures" (WHO Study Group, 1994). Specifically, the group created the osteopenia category for public health researchers for epidemiological purposes and, according to two of the people who attended the meeting, they never intended that people would come to think of osteopenia as a disease in itself to be treated (Alonso-Coello et al., 2008; Spiegel, 2009). This message was repeated in a meta-analysis that looked at the ability of measurements of bone density in women to predict later fractures (Marshall et al., 1996).

However, this is not the message that Merck took away from the WHO report. In 1995, the company had just received approval to market alendronate (Fosamax) for the treatment of osteoporosis. Merck faced a challenge in selling its drug because the condition needed to be diagnosed in the first place. To overcome that barrier, Merck bought the exclusive rights to bone-testing technology from one company, gave a loan to another company to help develop a different machine for testing bone mineral density, and created a leasing program so that doctors could finance the purchase of a machine (Kellcher, 2005; Spiegel, 2009). According to a

former lobbyist for Merck, "Merck would tell you virtually every woman post-menopausal should go on Fosamax." Merck was looking at screening and potentially treating all 40 million postmenopausal women in the United States (Kellcher, 2005; Spiegel, 2009).

When Merck started its campaign in 1995, there were 750 bone-measuring devices in the United States and by 1999 there were between 8,000 and 10,000 (Kellcher, 2005; Spiegel, 2009). Merck also helped push the Bone Mass Measurement Act through the US Congress that allowed Medicare coverage for bone scans. As a result of the substantial increase in the number of machines and Medicare coverage, the number of claims for screening went from 77,000 in 1994 to over 1.5 million in 1999 (Spiegel, 2009). However, by the early 2000s, it was clear that a fracture prevention strategy based on bone mineral density was looking at the problem from the wrong perspective. Most of the fracture burden comes from uncommon events among people who do not have osteoporosis, rather than from common events in those with the diagnosis (Järvinen et al., 2015). This is especially true in women aged 50–59, where a bone mineral density score compatible with osteoporosis will miss 80% of the women in this age group who will actually have a fracture and the cost of preventing one fracture is US$156,400 (Sanders et al., 2006). Overall, 104–270 women would need to be treated for 3 years to prevent a single hip fracture (Alonso-Coello et al., 2008; Järvinen et al., 2015).

These were not the figures that Merck and the groups that it sponsored were putting out. Merck targeted ads and brochures directly at younger women, telling them that "menopause is the single most important cause of osteoporosis" (Kellcher, 2005). The US-based National Osteoporosis Foundation, which received money from drug companies, estimated that 10 million Americans had osteoporosis and that the disease was "a threat for an estimated 44 million Americans or 55 percent of people 50 years of age and older" (Kellcher, 2005). Osteoporosis Australia, which also received funding from companies making osteoporosis treatments, in the early 2000s "issued a press release recently urging people to take a one minute test for their risk of osteoporosis. According to the foundation, 'we call this disease a silent thief: if you're not vigilant, it can sneak up on you and snatch your quality of life and your long-term health.' An accompanying 10 point checklist suggests that merely being a menopausal woman was enough to justify a trip to the doctor to be tested for this disease" (Moynihan et al., 2002).

The consensus conference that came up with the definition of osteoporosis and osteopenia was funded by two drug companies—Sandoz Pharmaceuticals (now part of Novartis) and SmithKline Beecham (now GlaxoSmithKline)—and one foundation—Rorer Foundation—set up by a pharmaceutical company. Recognizing that doctors are much more favorable to company-sponsored consensus conferences as a source of information compared to journal advertising and sales representatives (Pitt and Nel, 2007), companies selling drugs for osteoporosis have also heavily backed these types of meetings. The conference that produced the consensus statement from the Scientific Advisory Board of the Osteoporosis Society of Canada on the prevention and management of osteoporosis was sponsored by nine pharmaceutical companies and the recommendations were published in a supplement to the *CMAJ* that was paid for by three companies (Green et al., 1997). All of the studies up to the end of 2007 looking at the treatment of people with osteoporosis were funded by pharmaceutical companies. These trials were subsequently reanalyzed to look for subgroups of women with osteopenia who would benefit from treatment. In three of four cases, drug company employees were part of the team conducting the reanalysis. In the other case, the reanalysis was conducted by a group that included investigators with financial ties to industry (Alonso-Coello et al., 2008).

Conclusion

Disease mongering represents a fundamental threat to how society draws the boundary between health and illness and how it responds to what to do in the face of illness. Disease mongering promotes a view of people not as healthy autonomous beings but as vulnerable individuals always at risk from a threat just around the corner. And the way to deal with that threat, if it even exists, is only through the consumption of pharmaceuticals. As Iona Heath eloquently puts it: "The rhetoric surrounding disease mongering suggests that it will promote health, but the effect is in fact the opposite. Much disease mongering relies on the pathologizing of normal biological or social variation and on the portrayal of the presence of risk factors for disease as a disease state in itself . . . Disease mongering exploits the deepest atavistic fears of suffering and death" (Heath, 2006).

What are the consequences of widening the boundaries of what is considered a treatable medical problem? One of them is how general practitioners balance the risk/benefit ratio of pharmacotherapy. No drug is without side effects, but side effects are more acceptable as the illness being treated becomes more serious. What degree of side effects are acceptable in treating someone who feels she is too shy? Compared to the other selective serotonin reuptake inhibitors, paroxetine causes significantly more sexual dysfunction (Montejo-González et al., 1997). As the number of people being treated for shyness rises, so will be the number with sexual problems. Other, even more serious consequences from disease mongering are not far behind, including iatrogenic illnesses, the waste of resources on drug therapy when other forms of treatment, or no treatment at all beyond reassurance are much more appropriate. "At a deeper level it may help to feed unhealthy obsessions with health, obscure or mystify sociological or political explanations for health problems, and focus undue attention on pharmacological, individualized, or privatized solutions" (Moynihan et al., 2002).

Many of the conditions that disease mongering focuses on have a direct or indirect social origin or are shaped by natural forces that are out of our control. Much of ED comes from type 2 diabetes that is a result of the way that corporations produce and market food. Concern about ED is also based on a societal definition of what it means to be a man. Social phobia seeks to homogenize how people relate to one another and does not recognize the wide spectrum of how individuals react in a social situation. In many cases,

what is defined as overactive bladder is simply the product of the natural ageing process. Osteoporosis and osteopenia are also largely secondary to other forces that promote obesity, smoking, and a sedentary lifestyle.

None of this should imply that we should ignore people who are genuinely suffering from one of these conditions and who might benefit from drug therapy, but in the vast majority of cases pharmacotherapy is not necessary. The first, and perhaps biggest, step in countering disease mongering is to adopt the recommendation put forward by Moynihan and colleagues and reject the definition of disease put forward by the corporations and their allies in the medical profession and patient movement (Moynihan et al., 2002). We need to forge a new way of looking at these problems based on independent unbiased sources of information and find ways of disseminating these points of view as widely as possible. The medical profession and patient groups also need to reject the offer of resources and perks, however tempting they may be in the face of the absence of alternatives and reestablish themselves as reliable and trusted sources of information about how to deal with problems that distress people. We need to reject the corporate construction of illness in favor of social construction (Moynihan et al., 2002). None of this will be easy but the alternative is to succumb to corporate greed.

Factors Influencing Pharmaceutical Policy Implementation

Andy Gray, University of KwaZulu-Natal, Durban, South Africa

Introduction

The concept of a National Medicines Policy (previously referred to as a National Drug Policy) is most commonly associated with the guidance provided by the World Health Organization (WHO) in two documents, issued in 1988 (World Health Organization, 1988) and in revised form in 2001 (World Health Organization, 2001). The first of these emphasized the role of political will in ensuring that such a document did not languish on policymakers' shelves but was actually implemented: "A vital requirement is that governments should exert the political will necessary to formulate and implement a drug policy. Lack of political will, even more than lack of resources, has been a decisive factor in the failure of some countries to ensure adequate provision of drugs and vaccines" (World Health Organization, 1988). However, political will is itself not sufficient to ensure implementation, or to explain why implementation has not delivered the desired results.

The Lancet Commission on Essential Medicines Policies reported that by 2015 a total of 95 countries had developed a National Medicines Policy (NMP) (Wirtz et al., 2017). This number now included the full range of low-income, middle-income and high-income countries. The proportion that were classified as low-income had declined from the peak in the early 2000s, as such countries improved their economic status. Even though more than half the countries in the world, however, had, at least at some point, developed an NMP, the Commission identified the need for even more attention to comprehensive essential medicines, or pharmaceutical policies, to ensure equitable access to affordable, quality essential medicines, and their quality use, as well as to the development of the medicines for presently unmet needs.

Despite a large literature, the limitations of the evidence base for the success or failure of NMP implementation cannot be ignored. For example, a review of the literature on the impact of NMPs on improving medicines use in developing countries identified a dearth of well-conducted studies with rigorous designs (Ratanawijitrasin et al., 2001).

Content, Process, Context, and Actors

A key consideration in identifying the factors influencing pharmaceutical policy implementation is that the process is profoundly political in nature, and is far from merely technocratic. The seminal publication in this regard, which has inspired an entire category of policy analysis, is that by Walt and Gilson in 1994 (Walt and Gilson, 1994). The Walt and Gilson model recognizes that it is not merely the content of a policy that determines how it is developed and implemented but also the context in which it occurs, the processes involved, and the actors involved in each of those processes. It is in the intersection of these elements that the true lessons can be drawn, for example understanding how the processes are influenced by the context at a particular point in time, and how those processes shape the ability of actors to engage with the policy development and implementation process. Critically, there is no simple dividing line between policy development and implementation. The two are inextricably linked. To ask what the factors are that influence pharmaceutical policy implementation is therefore to ask, at the same time, what the factors are that influenced its development.

A Stagist Viewpoint

The classical "stagist" approach to policy development encompasses the following steps (or stages):

- agenda setting;
- policy formulation; and
- policy implementation.

This neat, theoretical description of the process is temptingly simple, and can result in the expectation that implementation automatically follows "ticking the boxes".

The WHO guidance outlined the following steps in the development process (World Health Organization, 2001):

- Step 1: Organize the policy process
- Step 2: Identify the main problems
- Step 3: Make a detailed situation analysis
- Step 4: Set goals and objectives for a national drug policy
- Step 5: Draft the text of the policy
- Step 6: Circulate and revise the draft policy
- Step 7: Secure formal endorsement of the policy
- Step 8: Launch the national drug policy.

This does not imply, however, that a simple "cookbook" approach was advocated. The guidance contained many warnings of the need to consider the very different positions that could be taken by different stakeholders ("actors" in the Walt and Gilson sense): "The draft document should be widely circulated for comments, first within the ministry of health, then in other government ministries and departments, and finally to relevant institutions and organizations outside the government, including the private and academic sectors . . . Once this wide consultation is complete, the draft document should be revised in the light of the comments received, and finalized (p14)"

Specifically, the WHO offered detailed guidance on the need to manage opposition to the policy proactively, listing the following strategies (World Health Organization, 2001):

- "At an early stage, prepare the relevant legislative structure to enable the development and implementation of the national drug policy.
- Seize a window of political opportunity, such as a specific political change or developments in neighboring countries, to advance policy development or implementation.
- Start implementing the policy in relatively easy subject areas, in order to ensure initial high visibility and success, and support for the policy at the critical early stage.
- Adopt a flexible approach; be prepared to postpone an activity if more time is needed to prepare for it, to explain it and to build consensus for it.
- Have national experts and respected political figures publicly express support for the policy and vouch for its technical soundness. It is important that the public feels confident about the policy.
- Mobilize key groups in society to support the policy. Consumer organizations, trade unions, religious organizations and the media, for example, can be important in building such support.
- Anticipate shifts in opponents' positions, and identify strategies to involve them and to win their support. For example, the pharmaceutical industry may oppose drug pricing policies and the introduction of an essential drugs list, but will usually support strategies to strengthen drug regulation and improve drug quality assurance.
- Create constituencies that support the policy both inside and outside the government. This is crucial to the policy's long-term success and sustainability. (Box 1, pg 16)"

A more detailed, stepwise approach can be considered, as follows:

- Establish an implementation working group
- Prepare a draft NMP implementation plan
- Prepare a draft priority action plan
- Workshop the drafts with stakeholders, possibly by means of a multisector seminar
- Publish the NMP implementation plan and the priority action plan.

Nonetheless, failure to complete each and every step, in order, does not explain the shortcomings in NMP implementation that are responsible for the gaps in medicines access that still prevail.

The 2001 WHO guidance outlined the key content components of an NMP, as follows (World Health Organization, 2001):

- Selection of essential drugs
- Affordability
- Drug financing
- Supply systems

- Regulation and quality assurance
- Rational use
- Research
- Human resources
- Monitoring and evaluation

That structure has been followed by many NMPs across a range of countries and levels of development. They are not, however, the only components that are necessary. The 2017 Lancet Commission report focused on five areas of concern: "paying for a basket of essential medicines, making essential medicines affordable, assuring the quality and safety of medicines, promoting quality use of medicines, and developing missing essential medicines" (Wirtz et al., 2017). Some, but not all of these concerns, can be seen in the components proposed in 2001. As the challenges of ensuring equitable access to increasingly expensive medicines now affect every country, at every level of economic development, the need for new policy approaches is evident. Although by no means comprehensive, data from the World Health Survey point to persistent gaps in access to medicines (Wagner et al., 2011).

The Window of Opportunity

The concept of taking advantage of a moment of political opportunity—a "window"—is most commonly associated with the work of Reich (Reich, 1995). Based on an analysis of the pharmaceutical policy processes in Sri Lanka, Bangladesh, and the Philippines, Reich argued that "health sector reform is feasible at certain definable, and perhaps predictable, political moments, especially in the early periods of new regimes". This concept of manageable political timing was also mentioned by WHO—the 2001 guideline stated that "Very often an acute emergency or an important political change created a window of opportunity to start the policy formulation process" (World Health Organization, 2001). A subsequent description of the NMP development process in a WHO policy perspective underlined the concept, giving the example of South Africa's 1996 National Drug Policy: "Part of its success was due to the political "window of opportunity" immediately after the end of apartheid in 1994" (World Health Organization, 2003). That "window" may not always be represented by a change of regime; however, it can be created by an event, a crisis that affects or highlights access to medicines for an individual, a group of patients, or the population at large.

A particular example is provided by the responses to sudden changes in economic conditions, as represented by the financial crisis in Greece in 2008. Faced by severe fiscal contraction, the Greek government was forced to implement a range of cost-containment measures, which resulted in a dramatic reduction in public drug expenditure (Vandoros and Stargardt, 2013). Included in the package was the re-introduction of a positive list (in essence, an essential medicines list), as well as reductions in the margins charged by community pharmacies and wholesalers. Such changes would always have faced opposition from those with vested interests. In the face of the financial crisis and the austerity measures agreed with the International Monetary Fund, European Union and the European Central Bank, their implementation was possible, despite resistance. Greece was not alone in facing an economic crisis. A crisis can also be caused by the imposition of political sanctions. The impact of responses to such crises, however, may result in cost-savings but also deleterious effects on access to needed medicines. A review of 89 policies implemented in 11 countries that had faced either economic crises or sanctions showed that there was little evidence of improved access to medicines as a result of the implementation of such policies (Kheirandish et al., 2015). Italy has also been through a series of pharmaceutical policy reforms over more than a decade, which have responded to the need to implement cost-savings, while protecting access (Fattore and Jommi, 1998; Ghislandi et al., 2005).

The emergence of a new, highly effective but expensive group of medicines can pose a new crisis. While the global response to HIV has seen new financial resources and the emergence of measures to ensure faster access to cost-effective generics, the same cannot (yet) be said about the new direct acting agents for hepatitis C virus infection (Assefa et al., 2017).

On a more positive note, the substantial changes to China's health policy have created the demand for pharmaceutical policy reform, at least at the national level. Provincial and county-level implementation has lagged somewhat, again emphasizing the complexity of the implementation task even in highly structured and hierarchical systems (Tian et al., 2012; Xiao et al., 2013). Similar challenges are posed in all countries that are attempting to advance universal health coverage, especially where this implies the development of a new National Health Insurance system. Ghana provides an object lesson in this regard, where both positive and negative implications for medicines access and quality of use have been identified by key informants (Ashigbie et al., 2016). Across five sub-Saharan African countries, key data to allow for the monitoring of access to medicines as these countries implement health insurance reforms has been noted to be lacking (Carapinha et al., 2011). A systematic review identified a lack of published evidence on the ability of health insurance systems in low- and middle-income (LMIC) countries to use active pharmaceutical management strategies, such as selection, purchasing, and utilization management strategies (Faden et al., 2011).

Policy Coherence

Perhaps more compelling than crisis-engendered policy-making and implementation, the ideal of policy coherence can explain whether particular pharmaceutical policies are developed and effectively implemented.

A country which follows a careful, yet sustained, incremental approach to advancing equitable access to healthcare services can make substantial progress. Brazil's NMP was first issued in 1998, reviewed after 20 years of concerted effort and showed sustained improvements in access to medicines but also a vulnerability in the face of inadequate financing of the Unified Healthcare System (SUS) (De Vasconcelos et al., 2017). Access to affordable essential medicines still lags behind the standards enshrined in the Brazilian constitution (Bertoldi et al., 2012). In particular, Brazil has been noted for its use of public sector production to meet the need for specific, strategically important essential medicines (Figueiredo et al., 2017).

Among high-income countries, Australia has a coherent NMP, which has tackled the thorny problem of balancing health and industrial policy objectives (Morgan et al., 2008). Australia has seemingly managed to achieve relatively low prices for generic medicines, yet still enabled access to "breakthrough" patented medicines at globally competitive prices. Simultaneously, it has offered incentives for local innovation and capacity development. Sustaining that policy coherence in the face of ever-growing demands for newer, more expensive medicines will remain a challenge, even for the best-resourced health systems. Many low- and middle-income countries' NMPs contain a commitment to improving access through reducing prices yet at the same time aim to foster the development of a national pharmaceutical manufacturing capacity. Those objectives can be in conflict, and can be difficult to achieve when affordability is a key consideration.

Interconnected Systems

Although the WHO guidance on developing and implementing NMPs lists discrete areas of attention, such as the need to promote generic medicine use as a cost-saving measure, a key lesson from decades of implementation is that many of the elements are interconnected, and rely on the existence of a comprehensive system. For example, it has been shown that a key determinant of the success of pro-generic policies has been the existence of a functioning medicines regulatory authority (Kaplan et al., 2012).

Other areas of interconnectedness relate to the operation of the intellectual property system, and its ability to effectively assess the patentability of new inventions, but also to implement the flexibilities in the global system that are available (Wirtz et al., 2017).

Transparency

Over the years, both the World Bank and WHO have placed great emphasis on the need for good governance in the entire pharmaceutical system, for which country ownership is critical (Kohler et al., 2014). Although some assessments have identified progress in reducing vulnerability to corruption (Dalia et al., 2015), there are persistent challenges in some settings, particularly with regard to medicines regulatory practice (Vawda and Gray, 2017).

Opportunities for Engagement

Inherent in the Walt and Gilson emphasis on the role of "actors", and also in the WHO guidance about repeatedly engaging in the publication of draft policy documents and draft implementation plans, as well as multisector workshops, is the concept of creating opportunities for engagement.

Many policymakers rely on Brinkerhoff and Crosby's model as guidance (Brinkerhoff and Crosby, 2002). The model describes the following implementation tasks:

- Creating legitimacy
- Building constituencies
- Accumulating resources
- Modifying organizational structures
- Mobilizing resources and actions
- Monitoring impact.

The first two steps can be achieved through events that raise awareness by identifying champions and by creating new forums for discussion. This can be done though policy dialog workshops, public–private forums or the creation of task forces. Some of the techniques that can be employed are stakeholder analyses and political mapping.

A 20-year retrospective view of the South African NDP implementation process has pointed to the narrowing of the opportunities for engagement over time (Gray et al., 2017). While some of the formal opportunities for engagement (such as parliamentary hearings and the opportunities to comment on draft legislation) had been maintained, other consultative bodies (such as the National Health Consultative Forum) had lapsed. Much of the detailed debate was now occurring in the National Health Council technical committees, which were accessible only to senior bureaucrats and political office-bearers. An earlier analysis of the same policy process had emphasized the need for "learning by doing", a process which can only occur when the opportunities for engagement are deliberately sustained (Gray et al., 2002). Similarly, interviews with key stakeholders in Australia highlighted the need to ensure that "on stakeholder groups imperatives do not stifle those of other groups" (Lipworth et al., 2014). One possible reason for the differences in implementation of policies on dispensing practitioners seen

between Japan and Korea was attributed to the engagement of progressive civic groups in the latter country (Jeong, 2009). Despite this, the Korean reforms were the cause of unprecedented physician strikes, and perhaps unintended consequences in terms of access and cost (Kim et al., 2004).

It has been argued that pharmacists have a particular responsibility and opportunity to engage in the development and implementation of effective pharmaceutical policies (Morrow, 2015a; Morrow, 2015b).

A Focus on Data and Accountability

Globally there is an increasing focus on improved accountability, at both national and international levels. Civil society is increasingly holding governments to account for the outcomes of public policy. This is entirely consistent with the focus on monitoring and evaluation which has always been part of the WHO NMP concept but which has often been neglected during implementation. A greater focus on the development of rigorous policy analysis and impact assessments has been specifically advocated for in relation to pharmaceutical policies (Almarsdóttir and Traulsen, 2006).

Conclusion

Although the WHO documents that have guided the development and implementation of NMPs in many countries are now dated (World Health Organization, 2001), the penetration of this concept across countries of widely differing economic status and health systems design has been considerable (Wirtz et al., 2017).

The factors that could potentially affect the implementation of pharmaceutical policies are as varied as the national contexts and legislative and legal systems that pertain across the globe. There are some key concepts; however, that can guide policymakers and implementers. Both Walt and Gilson (1994) and Brinkerhoff and Crosby (2002) have drawn attention to the key roles of "actors"/"stakeholders" and the need for active and sustained engagement during both policy development and implementation.

No simplistic checklist of steps to be completed can suffice to guarantee success, but there are principles that can inform such steps. The window of opportunity that can enable an issue to become an issue, for a policy intervention to become feasible when previously it was not, can vary considerably. Crisis-engendered policymaking is possible, but pharmaceutical policy must always be coherent with broader health, economic and industrial development policies, and must seek to take into account the interconnectedness of many systems that determine access to and quality use of affordable, quality-assured essential medicines. Finally, there is a need for a greater focus than ever before on the data that are essential to enable accountability and a learning system that is able to take remedial action where necessary.

Funding Mechanisms for Community Pharmacy Service Provision

Shane Scahill, School of Pharmacy, University of Auckland, Auckland, New Zealand

Introduction

The focus of this chapter is on the comparison of a range of funding mechanisms for community pharmacy in high-income countries around the globe. It is reasonable to ask the question "why bother doing this type of comparative analysis?" and "what does it add for the policy-driven pharmacy sector and the academic literature?." Of course, these are two rather significant questions and ones that are not easily answered in a single sentence. Suffice to say, to survive, community pharmacy needs to drive a global "reprofessionalization" agenda based on extended clinical roles and professional leadership (Roberts et al., 2003; Ruston, 2001; Scahill et al., 2010). This has been talked about for some time, but to continue on in a sustainable manner, the community pharmacy sector needs to think carefully about how and what value it adds and in which ways this is going to be funded, depending on the type of market within which these pharmacies sit. Clearly this is easier said than done, but the sector as a whole will benefit from an analysis (summative enquiry) of this nature.

Being both a retail business and a health-care provider in most international markets (Scahill, 2010), the community pharmacy sector generally relies on a combination of funding from external third-party agencies (government or insurance fund) alongside

public free market spending by the patient/consumer, to make business viable in the long term. To this end, John Chave, in a commentary in the *Pharmaceutical Journal* comparing UK and European community pharmacy, highlights the importance of collectively demonstrating "value" in order to receive funding streams for community pharmacy; publicly funded or through private markets (Chave, 2014).

> *"Pharmacy stands or falls (in the UK and everywhere), on its ability to show it meets a public need worth paying for. There are plenty who argue that technological change, from Amazon-style distribution to mobile apps, challenges retail business and intellectual services. Pharmacy is both of those."*

This demonstration of public need must be ratified by the community at large and health funders and planners. Founded on this notion then, the chapter compares and contrasts the funding policies and associated politics for pharmacy services among selected high-income countries. What we don't often think about, nor even talk about, as pharmacy academics, practitioners, or thought-leaders within pharmacy professional bodies is where pharmaceutical policy sits within the wider political arena and from where funding arises and via what mechanisms and streams; and how these might vary around the world. Also, are there particular pharmaceutical systems we can learn from, for example? There is the need for greater consideration of the requirement for change in business models to deliver cognitive services in pharmacy that both government and the private paying public will be comfortable to remunerate. This chapter attempts to address this by drawing together individual countries "whole of health system" with facts and figures pertaining to the "pharmaceutical system" from a variety of high-income nations around the globe.

The focus of this Chapter is on the subsector of community pharmacy; the reason being 80% of the pharmacy workforce ends up in this sector and it is where most of pharmacy activity occurs (Hawthorne and Anderson, 2009). It is also an area where in some countries, public monies are invested into a service environment that also involves the conduct of retail-based business activities and so funding models are most important and may vary considerably country to country. However, before we can begin to compare funding mechanisms for community pharmacy services it is important to define what is meant by a "pharmaceutical system" and within this "community pharmacy services". A pharmaceutical system has been defined as: "all structures, people, resources, and their interactions within the broader health system that aim to ensure equitable and timely access to safe, effective, quality pharmaceutical products and related services that promote their appropriate and cost-effective use to improve health outcomes" (Hafner et al., 2017). This definition has been adopted for this analysis.

What this highlights is that when thinking about the funding of pharmaceutical services, it is difficult to unpack and disentangle in a systematic way (across countries) the various components when comparing pharmacy service provision within different high-income countries. For example, in large parts of Europe, dispensing remuneration is linked to the pricing of pharmaceuticals per se; whereas in New Zealand, it is not the case. As such, the pricing mechanism of pharmaceuticals cannot always be completely separated (or at least omitted) from the analysis of funding for community pharmacy services, which may include the provision of enhanced pharmaceutical care (also denoted cognitive pharmacy services) or even the counseling associated with a basic medication dispensing service. Community pharmacy services must be considered "as a whole" sitting within the overall pharmaceutical system, which is embedded within a country's overall health system. It is upon this framework that the cross-country analysis is undertaken. As such, this summation may include elements of pharmaceutical pricing, dispensing/counseling fees, regulatory facets, and payments for pharmaceutical care within some of the country portfolios (Fig. 1).

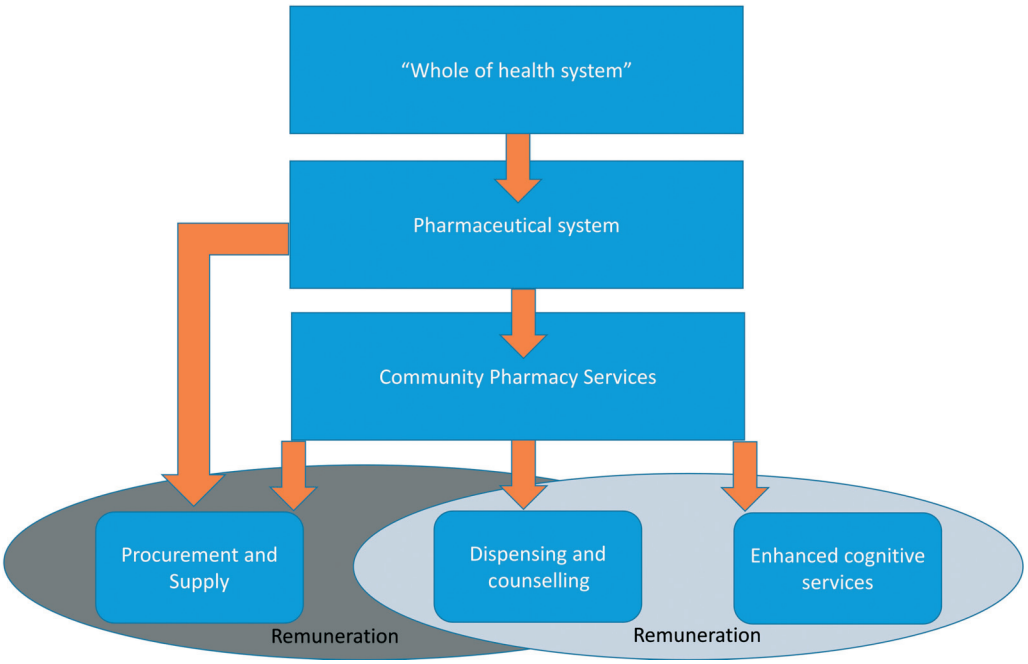

Figure 1 Community pharmacy services embedded within pharmaceutical and whole of systems funding.

What is apparent from the analysis is that the world is a diverse place, health systems are complex and different, and pharmacy has not escaped this. In fact, as individual countries' health systems become more and more alike due to migration and a degree of "sameness" in global health pressures (Crisp, 2017), pharmaceutical systems within the overall health systems appear to represent the diversity in these systems. Just as service provision is diverse, so are the funding models that drive business activity and clinical behavior in the dichotomy that is community (retail) pharmacy (Jacobs et al., 2011; Mossialos et al., 2015).

Looking to the literature for appropriate context, a systematic review has been , which identifies remunerated pharmacist clinical care programs worldwide (Houle et al., 2014). The review found remuneration for pharmacists' clinical care services to be highly variable, with very few programs reporting clinical outcomes. Sixty new remunerated programs (over and above their previous review) were included in their update from Canada, the United States, Europe, Australia, and New Zealand. These ranged in complexity from emergency contraceptive pill (ECP) counseling to full minor ailments programs, and comprehensive medication management reviews.

Their findings suggest that in North America, the average fee provided for a medication review is $68.86 (all figures are given in Canadian dollars), with $23.37 offered for a follow-up visit and $15.16 for prescription adaptations. Time-dependent fees were reimbursed at $93.60 per hour on average. Few programs evaluated uptake and outcomes of these services but, when available, indicated slow uptake but improved chronic disease markers and cost savings. They concluded that programs and pharmacists are encouraged to examine the time required to perform these activities and the outcomes achieved to ensure that fees are adequate to sustain these patient care activities. This sets the scene for the need to understand international funding systems. The analysis suggests that information is not as publicly available and transparent across all countries, as one might expect. The aim is to build on this work by searching the academic literature for the 2014–17 period.

This chapter represents a synthesis of global pharmacy funding policies based on publicly available "grey" policy literature and academic literature across a range of high-income countries. For an extensive analysis of pharmaceutical policy in developing countries, the reader is referred to a book edited by Prof Zaheer Babar titled "Pharmaceutical Policy in Countries with Developing Healthcare Systems" (Babar, 2017).

International "whole of health" Systems

The study of global health systems is fascinating in its own right, and there is a need to understand the wider system as pharmaceutical subsystems are embedded within overall health systems (**Fig. 1**). As Babar and Scahill highlight, pharmacist activity needs to be embedded in a strong, appropriately funded and well-developed pharmaceutical system (Babar and Scahill, 2009); otherwise, there is no point in embarking on clinical advancement in pharmacy. The pharmaceutical system needs to be supported by an overall health system, which is efficient and effective and transparent in its decision-making processes, especially with regard to access and affordability of high cost medicines (HCM) (Babar, 2018). This also must apply to the funding of community pharmacy activities, and it is wholly surprising how little information is publicly available on this topic. Personal communication with pharmaceutical policy leaders in some countries has been required to obtain even the most basic information.

When considering health system structure and function, New Zealand research provides a sound platform for understanding the different types of health-care funding models that influence policy making and the funding and delivery of services in a health system (Gauld, 2009). Gauld covers mechanisms of tax funding, social insurance, and private funding, as well as providing historical insights into health funding models in New Zealand, Great Britain, and the United States. This chapter uses Gauld's work as a platform to understanding the health systems of the countries for which community pharmacy funding is being analyzed while continuing to focus on pharmaceutical policy of countries not reviewed by Gauld (i.e., Sweden, Belgium, Spain, Germany, the Netherlands, and so forth). The aim is to explore differences and similarities between country structures, overall health systems, pharmaceutical systems, community pharmacy funding, and any relevant policy discourse within the community pharmacy sector of selected high-income countries.

Despite being high income, these countries have been selected to represent a diverse range of funding models. This type of comparative health policy analysis is informative as there is the perception by governments that shared challenges in health policy development and implementation exist, and useful insights can be gained by comparing and contrasting policies, and experience in enacting them. The indication is that there are significant global trends in how health policies are formulated and the result is that national health systems are becoming increasingly "alike" in high-income countries (Blank and Burau, 2018).

The glut of health reforms that have occurred in high-income countries since the 1990s has led to a degree of convergence of health systems where there appears to be a universal paradigm for health care financing, organization, and management that is irrespective of whether services are public or private and regardless of whether political ideologies are centrally driven or decentralized. An example supporting this thinking is how the social organization of medical work is increasingly similar across global health systems, leading to health systems sharing more common elements. Other ways in which health systems appear to be converging is through internationally recognized uses of a large number of complex medications (some essential, others high-cost), hospital quality standards being utilized across countries, and health care as a business while working within the parameters of being a publicly funded service.

Health policy is very much a political matter and is therefore dependent upon the political arena, which impacts on subsystems such as the pharmaceutical system (Birkland, 2016). This certainly applies to the funding of community pharmacy services as a subsector of pharmaceutical policy, particularly with respect to the discourse globally around remuneration for

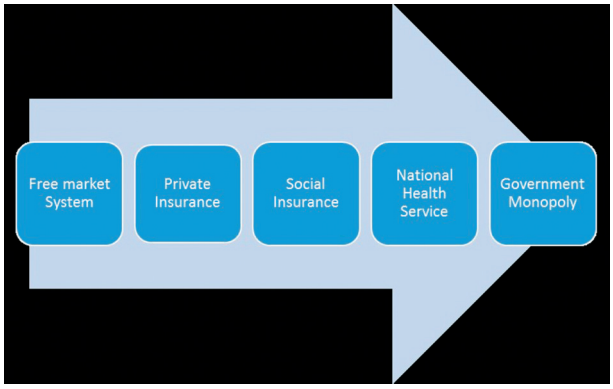

Figure 2 Funding continuum from free market to Government monopoly.

enhanced services. The political arena includes not only the formal political institutions such as legislatures, executives and courts but also regulatory agencies, semi-public bodies, and specialized committees and commissions (Blank and Burau, 2018). In addition to these formal practices, there are informal practices and structures that have evolved within the particular formal institutional frameworks, the institutional cultures. Although it is argued that no two political systems are the same, many share similar characteristics or typologies.

Having said this, and despite facing similar health-care challenges, there are distinct differences among the health systems reviewed in this chapter. This is recognized by the organization for Economic Cooperation and Development (OECD), which have developed a typology for the different types of health-care system using service provision and funding as the determinants (Mossialos et al., 2016; Thomson et al., 2012). The different types of health systems can sit anywhere on a continuum from a completely "free market" driven health system, with little or no government involvement through to the scenario of a Government monopoly involving fully tax supported provision of funded health services for all, i.e., little or no private sector (Fig. 2). However, in reality, the two extremes do not exist (at least in the context of high-income countries) with government involvement in health services varying along a continuum.

In high-income countries, three major models sit within the continuum outlined in Fig. 2. They all impact on the development and implementation of pharmaceutical policy and include privately funded health insurance (consumer sovereignty model), social insurance (Bismarck model), and National Health Service (Beveridge model). What we are considering here is the degree of access to care with financial risk protection (Kutzin, 2001). Total "free market" in the completely neoliberal sense and full Government monopoly in the communist sense sit at either end of the spectrum. Funding streams for health systems as a whole, and for pharmaceutical systems in particular, are determined by the classic funding models found within each of these types of system. Blank and Burau (2013) have suggested that the United Kingdom and New Zealand are located at the end closest to the National Health Service (Beveridge) model, whereas Australia and the United States, for example, are located more toward the private insurance (consumer sovereignty) model (Blank and Burau, 2018). This suggests that there is no set pattern of health system structure based on British Commonwealth status, with New Zealand and Australia having quite different health systems. Based on this, the analysis is not structured to compare pharmacy service funding in Commonwealth vs non-Commonwealth countries. What is of interest is whether there is broad alignment of funding mechanisms for community pharmacy services in countries that operate under Free market, Sovereignty, Beveridge, Bismarck, and Government monopoly funding models.

A sound overview of the different types of system is available (Lameire et al., 1999). Each of these systems is outlined in general terms in this section and then within the pharmaceutical analysis the reader will be reminded of the model under which the health system of that country falls.

Free Market

Purely free market health systems are generally found in developing nations where health services are largely funded "out of pocket" by the consumer and competition drives pricing and service provision. In a paper to the New Zealand Treasury in 2013, Professor Nick Mays (London School of Hygiene and Tropical Medicine) suggests that supplier competition for individual health-care services in neoliberal markets is not good (for chronic care management), causing fragmentation of care and lack of integration (Mays, 2013).

Sovereignty Model

Also known as "private insurance," this mechanism includes predominantly private funding through medicare/aid + managed care. In the United States, this predominantly involves private health care, and Australia appears to be heading more toward this direction than the Bismarck Model. This type of model is often denoted as "Private" (Kutzin, 2001; Lameire et al., 1999).

Beveridge Model

It includes nations such as the United Kingdom, New Zealand, Italy, Spain, Sweden, Denmark, Norway, Finland, and Canada. Funding occurs through national taxation, and infrastructure is provided through a National Health Service. This type of model is often denoted as "Public" (Kutzin, 2001; Lameire et al., 1999).

Bismarck Model

It includes France, Germany, Switzerland, Belgium, Holland, and Japan. This system is premium-funded through mandatory insurance and draws on a combination of private/public providers. This type of model is often denoted as "Mixed" (Kutzin, 2001; Lameire et al., 1999).

Government Monopoly

This form of funding sits with the communist/socialist model, whereby the only form of health care in place is a government funded structure without any private-sector health service delivery and no "insurance-based" model. All funding comes from one source, the government, and there is the suggestion that reforms in the Beveridge-type systems aim to increase choice and reduce waiting times. Bismarck models on the other hand have been directed toward cost control by restricting choice of provider (Or et al., 2010).

This chapter sets out to explore funding mechanisms associated with community pharmacy services and so the focus is on the primary health care sector as it relates to the pharmaceutical subsystem. This is important to bear in mind because in many countries (and particularly developing countries) hospital care (and medicines/pharmaceutical services) is provided free; however, community pharmacies are deemed to be in the "private sector" in many countries, and people are expected to pay "out of pocket" for their medicines. This analysis draws out those countries.

Funding the Value Proposition: Community Pharmacy in Context

This section provides context for the value proposition of community pharmacy and the rationale for funding enhanced services. The readiness for change by pharmacists embracing funded cognitive services is outlined in the country monographs as appropriate. There are commonalities and differences between government health policies in developed countries; many call for pharmacy to "reprofessionalize" through role extension into enhanced cognitive services. There are commonalities in the response of the pharmacy sector in different countries to these policies. This chapter highlights the commonalities and some of the differences in policy and response across countries with very different macro health funding policies and pharmaceutical systems. Interestingly, though, many of the professional issues seem to be the same. Funding is a lever and readiness for change and the acceptance of service implementation seems to have been something that has challenged the international community pharmacy sector in a profound way, for a long time.

Sustained funding is only going to come with the complete reprofessionalization of community pharmacy. This needs to be a collective and ongoing global agenda extending a relatively long history (Birenbaum, 1982; Edmunds and Calnan, 2001; Gilbert, 1998). The need to reprofessionalize suggests that community pharmacy has the roots of a profession but that its professionalism has been eroded in some way. There has been a growing sense of urgency both from within and external to the profession that community pharmacy needs to change (Edmunds and Calnan, 2001; Scahill et al., 2010). Professional pharmacy bodies are calling for this reprofessionalization and their expectations seem to align with health policy makers who have historically been shy address community pharmacy remuneration (Edmunds and Calnan, 2001; Scahill, 2008; Scahill et al., 2010).

An occupation such as pharmacy becomes a profession when it is granted autonomy, is recognized by society as possessing a technical knowledge base, has lengthy and superior education, and adopts a code of ethics with a commitment to common good (Birenbaum, 1982; Edmunds and Calnan, 2001; Holloway et al., 1986). Professional autonomy exists in the medical sphere when an occupation has economic, political, and clinical autonomy. There has been a view that pharmacy's professional development has been hindered, largely because of the control of the medical profession over clinical autonomy and therefore economic autonomy (Edmunds and Calnan, 2001). This functional role based on trait theory seems to suggest that community pharmacists have a number of the characteristics of professions including monopoly over practice, compounding, dispensing and advice, possess specialized knowledge, and have a service orientation toward health-related service provision. However, more modern professionalization theory suggests that time, place, identity, and market place also feed into the notion of professionalization. Community pharmacy has been guided by commercial interests, and pharmacists lack control over "medicines," which are the social object of the profession (Traulsen and Bissel, 2004).

A historical lens suggests that community pharmacy has had access to and control over a unique body of specialist knowledge around procurement, storage, and compounding of medicines and other remedies (Gilbert, 1998). Until the 20th century, community pharmacy sourced raw product, formulated dosage forms, and dispensed potions; the formulas for which were often controlled by pharmacy. Industrialization involving large-scale manufacturing of medicinal products resulted in pharmacy losing the source and compounding aspects of its role with the pharmaceutical industry making community pharmacy's role in the manufacture and production of medicines largely redundant (Bissell and Morgall Traulsen, 2005; Edmunds and Calnan, 2001;

Gilbert, 1998). With this comes the loss of deeply rooted functions, endangering the identity of the profession which must change to survive (Birenbaum, 1982). The simple act of dispensing medications on the order of a medical prescriber, and the associated financial transaction, has meant that the pharmacists have found themselves overtrained for what they do and underutilized for what they know (Gilbert, 1998). In some regards, a loss of function, social power, and status have resulted in a loss of identity for pharmacy (Adamcik et al., 1986; Bissell and Morgall Traulsen, 2005; Edmunds and Calnan, 2001).

Part of the response to this has been the drive for reprofessionalization, where there has been a gradual shift in focus away from the technical role of pure procurement, supply, and distribution of medications, toward disease and patient-oriented approaches to pharmaceutical decision making, and the adoption of more clinical roles (Adamcik et al., 1986; Bissell and Morgall Traulsen, 2005; Gilbert, 1998). It is the role expansion through these enhanced or cognitive clinical services that has received most attention in the literature. The need to reposition the pharmacy profession as medicines management experts through delivering cognitive services (Benrimoj and Roberts, 2005; Hopp et al., 2005, 2006; M. B. Roberts and Keith, 2002) has been one of the main drivers for the "reprofessionalization" of pharmacy (Bissell and Morgall Traulsen, 2005). This has been supported by professional pharmacy bodies and health policy makers (Edmunds and Calnan, 2001). The bottom line is that this requires significant funding to achieve.

Seven Directions of Future Focus that Influence Funding for Community Pharmacy

Critical review of the academic pharmacy practice literature and pharmacy-related health policy documents has resulted in the synthesis of seven themes, which were deemed to influence development and funding within the community pharmacy sector. These themes included (Scahill et al., 2010):

- A greater emphasis on integration and collaboration.
- A focus on the provision of quality primary health care.
- A focus on patient-oriented services vs selling a product.
- Looking after your patient...looking after your population.
- The provision of enhanced pharmaceutical services.
- Developing new models of pharmacy practice.
- A defined agenda and processes for change.

In summary, internationally, there is a diverse range of developed and underdeveloped community sectors. It is clear, however, that both policy makers and pharmacy professional leaders see the move to the provision of enhanced services as imperative. Internationally, significant barriers to this have been identified at the level of the individual pharmacist, suggesting a lack of readiness by community pharmacy to engage and deliver. The barriers and facilitators to change are considered in the context of the country profiles in this chapter. Pharmacy needs to become more autonomous and express its evidence-centered value proposition to gain the confidence of key stakeholders who will be funding services in the long term. Positioning for appropriate funding is key.

Funding of Medicines, Distribution and Enhanced Services: Country Monographs

This section outlines the individual country monographs and divides them (as far as possible) into Sovereignty, Beveridge, Bismarck, and "Other" health system models. Within a whole pharmaceutical system, components that require funding can be thought about (Fig. 3).

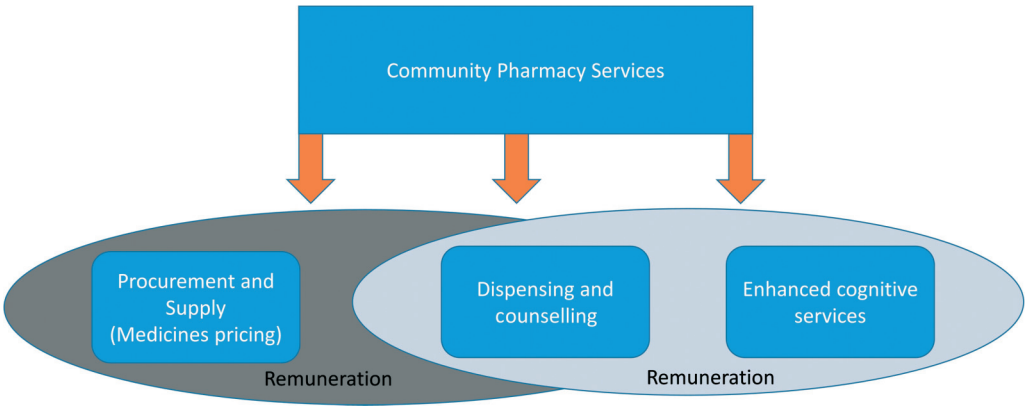

Figure 3 Remuneration schema for community pharmacy services; core and enhanced services.

Table 1 Country by funding models

Sovereignty like	*Beveridge*	*Bismarck*
USA	UK	France
Australia	Canada	Germany
South Africa	Spain	Belgium
	Sweden	Netherlands
	Denmark	
	New Zealand	

Central to pharmacy is the procurement and cost of the medicines that are being dispensed and cost, availability, access, and affordability can be considered. The fee for providing a dispensing and counselling service by the pharmacist is a second component to think about. Finally, funding for extra clinical services such as long-term conditions (LTC) programs and medication reviews which have been called for by policy makers are the most recent funding considerations for the sector (at least for this chapter). Funding of these activities is likely to vary considerably around the globe and this chapter aims to explore these similarities and differences in a structured way, and to report on the international situation (from selected countries) within a coherent framework that outlines historical development.

This section of the chapter is structured to group countries into the type of health system they have adopted, i.e., Sovereignty, Bismarck and Beveridge systems, rather than whether countries are British-Commonwealth or non-Commonwealth countries or European/non-European. The groupings are made up as follows (**Table 1**):

The overview provides comparison by funding model as opposed to geographical location of nations. This demonstrates how similar many of the Commonwealth nations are (except Australia/South Africa). In addition to this *funding model-based approach*, there have been regional analyses undertaken, e.g., of European nations, which demonstrates how different the pharmaceutical systems are despite being within the EU.

Beveridge Funding Model

United Kingdom (UK)

Policy Reform Relating to Funded Service Provision

The United Kingdom is dealt with as one country but of course there are pharmaceutical subsystems with differing activities in England, Scotland, Wales, and Northern Ireland. For the purposes of this chapter, they are considered "as one.' From an historical viewpoint, the United Kingdom has been a leader in pharmaceutical policy reform, especially regarding the community pharmacy context (Dept of Health (UK), 2000, 2003, 2008; Galbraith, 2007). The UK Department of Health has been prolific in its commissioning of consultation reports (Galbraith, 2007) and health policy relating to community pharmacy (Dept of Health (UK), 2000, 2003, 2008). There has been commitment to develop community pharmacy services and the early White Paper on Community Pharmacy (Dept of Health (UK), 2008) (citation or at least date) drew on what Galbraith described as the "attributes of a good pharmaceutical service." The UK Government was one of the first (of the Commonwealth countries at least) to attempt to define what constitutes an "effective" community pharmacy. At the time Commissioner Galbraith noted the potential contribution of community pharmacy and outlined a list of distinguishing features of a world class pharmacy; characteristics that pharmacies where meant to aspire to in order to achieve sustainable funding streams (**Panel 1**).

From a contractual viewpoint, Galbraith suggested there needed to be adequate incentives to drive changes in best practice at that time. The greatest shift in practice was the requirement to provide enhanced "cognitive" services in addition to the traditional supply and distribution roles community pharmacy has held and the focus of this chapter is on what the funding for this activity looks like some years following these policy drivers (**Panel 2**).

New models of practice were expected to enhance the patient experience, support well-being, and promote the safe use of medicines. Community pharmacy was expected to develop integrated "pharmaceutical care management" services with greater clinical focus, integration with other providers, and a quality focus. In the mid-2000s, the UK Government appeared to be happy enough to pay for these value-added clinical services. The positive climate, however, seems to have changed when in May 2017 an announcement meant that thousands of small community pharmacies were facing closure. The High Court upheld cuts equating to GBP320 million in NHS Government funding to the pharmacy sector (Robinson, 2017). Although cohorts of pharmacists in the United Kingdom were positive about implementing enhanced services, uptake and action was much slower than stakeholder expectation (Celino et al., 2004; Elvey et al., 2006). Some of the cited barriers included: lack of time (Bush et al., 2006; Ewen et al., 2006; Hall and Smith, 2006; Staton et al., 2006; Warchal et al., 2006); inadequate remuneration (Bush et al., 2006; Celino et al., 2004; Hall and Smith, 2006; Staton et al., 2006); patient expectations and knowledge (Ewen et al., 2006; Hall and Smith, 2006); lack of GP understanding (Celino et al., 2004); professional boundaries and turf protection (Adamcik et al., 1986; Gilbert, 1998; Nathan and Sutters, 1993); increased documentation and accreditation processes (Celino et al., 2004; Elvey et al., 2006); and lack of a common medical record (Warchal et al., 2006). Human factors such as pharmacist confidence (Elvey et al., 2006; Hall and Smith, 2006); an unwillingness to leave the comfort zone of the dispensary (Bush et al., 2006); a

Panel 1 Galbraith's (2007) view of future service provision by UK Pharmacy

Attributes of a good pharmaceutical service – what it might offer patients and consumers

- Accurate
- Knowledgeable
- Providing value for money
- Professional
- Supporting patients
- Convenient service
- Personal
- Informative
- Integrated
- Accessible
- Evaluation
- Full service

Potential contribution of pharmacy to various levels of patient care including promoting better health, prevention and early detection, long-term conditions/chronic care management, case management.

Distinguishing features of a 'world-class' pharmacy

- Primary source of health information and advice
- Helping people to stay healthy and to improve health where needed
- Routinely promoting self-care and being associated with key public health initiatives
- Providing new services to help people with acute conditions and long term conditions
- Skilled, knowledgeable, competent and considerate staff
- Part of a strong local network of health improvement services and local leaders for health in the community
- A wider information retailer of medicines but also broader health, wellbeing and social matters i.e. sustainable development

Panel 2 Contracted services for community pharmacy (UK)

Essential Services

- Dispensing and repeat dispensing
- Health promotion
- Healthy lifestyle advice
- Signposting to other services
- Support for health care
- Disposal of medicines

Accredited Advanced Services

- Medicines Use Review

Local Enhanced Services – commissioned by PCTs

- Smoking cessation
- Supervised methadone administration
- Patient group directions (ECP, NRT)
- Minor ailments

uniprofessional culture (Walker, 2000); and pharmacy's inexperience of the commissioning process (Bush et al., 2006) have been cited as barriers by stakeholders in the United Kingdom. It has not been made explicit that these factors have played a part in the reduction in funding over time for community pharmacy in the United Kingdom, or whether it is simply economic factors post the global financial crisis (GFC). This discourse is very important and what we do know is that pharmacists will be paid less this year by the UK Government than in the previous year, and it will be interesting to see whether this trend continues.

Current Service Funding Changes in the United Kingdom

Unlike the Australian Government which is significantly increasing funding to the community pharmacy sector. On October 20, 2016, the Government announced that funding for NHS contractors providing services under the community pharmacy contractual framework was to be:

- GBP2.687 billion in 2016
- GBP2.592 billion in 2017/2018

This represented a 4% reduction in funding in 2016/2017 and a further 3.4% reduction in 2017. As part of the package the Department of Health (DH) made changes to the way in which funding was distributed, introducing quality payments and a Pharmacy Access Scheme (PhAS) for isolated pharmacies (n = 1341). Pharmacy establishment payments will be phased out, and a range of dispensing fees have been amalgamated into a single activity fee. The Government has also recently announced a pharmacy urgent repeat medicines supply pilot along with plans to refer NHS#111 callers with minor ailments to pharmacies. It is unclear what the funding package for this will look like. There is also a Pharmacy Integration Fund available, which is expected to support closer working between pharmacy and other parts of the NHS (Jones and Baker, 2016).

Canada

In 2002, the Commission on the Future of Health Care in Canada, headed by former Saskatchewan Premier Roy Romanow, released a report on the nation's health-care system (Romanow, 2002). The Commission's findings and recommendations have taken a central place in the debate on the value and future of Canada's public health-care system. A key element identified in the Commission's report was the need to transform Canada's health-care system to focus squarely on primary health-care strategies. In October 2001, the Canadian Pharmacists' Association (CPA) produced a submission for the Romanow Commission on the Future of Health in Canada. The CPA submission outlined the challenges facing the Canadian community pharmacy sector and included a section on the development of new models of pharmacy practice. There was the recognition by the CPA of the need for the pharmacy profession to continue to evolve. The need for change within the profession, as well as within the wider health-care system in Canada, was highlighted (Canadian Pharmacists Association, 2001). The main recommendations regarding "re-professionalization" were:

- The profession of pharmacy must work with health-care administrators and other health-care providers to effectively define and structure new consultative practice models focusing on more direct patient care.
- The federal Government must recognize the value of pharmacists' services and remove fiscal barriers to access.
- The need for multidisciplinary educational programs to ensure that pharmacists have up-to-date knowledge and to foster collaboration and respect among the profession.

With respect to community pharmacy, the Romanow Commission highlighted that:

> There is a growing emphasis on medication management programs. This is likely to have a direct impact on the role of pharmacists and make it possible for them to play an increasingly important role as members of the healthcare team. (Romanow, 2002, p. 107)

In 2008, the CPA launched the Blueprint for pharmacy: Designing the Future Together (Canadian Pharmacists Association, 2008). The aim of the Blueprint was for pharmacists to provide optimal drug therapy outcomes for the peoples of Canada, through patient-centred care. A shift was required from dispensing and technical duties to a focus on services that would improve patient outcomes (Rosenthal et al., 2010). One study suggested that over 60% of Canadian pharmacists participating in a national survey (Jorgeson et al., 2011) felt it was time to begin taking on new responsibilities, and over 70% of pharmacists surveyed wanted to be performing expanded clinical duties within 5 years. The authors concluded that:

> . . . pharmacists responded positively to the proposed vision for the future of pharmacy and are eager to move away from the traditional dispensing role to an extended clinical role. (Jorgeson et al., 2011, p. 125)

Pharmacists surveyed in the United Kingdom also held similar views, however, these have not translated into action and implementation has been slower than stakeholder expectation. Some of the lack of responsiveness and progress has been attributed to the way pharmacists think and act (Bush et al., 2006; Hall and Smith, 2006; Walker, 2000). Rosenthal and colleagues imply that in Canada, pharmacists themselves might be the ultimate barrier to successful implementation due to their own psyche and culture (Rosenthal et al., 2010). Rosenthal and colleagues call for a cultural research agenda in much the same way as previous New Zealand commentary has (Rosenthal et al., 2010; Scahill et al., 2009a).

Alongside the work of Rosenthal, the engagement of pharmacists in patient-oriented health care in Canada has been largely driven by the efforts of Professor Ross Tsuyuki and his team at the University of Alberta (Tsuyuki and Schindel, 2004). The focus in Canada has been on the application of classic change management strategies in an attempt to provide a framework to engage the entire profession in a wholesale change management program (Kotter, 1995). The direction of change is on pharmacist practice as opposed to organizational level change. The eight steps of Kotter's change framework have been applied to the pharmacy context and a descriptive narrative of each step outlined as it relates to community pharmacy. It is expected that this systematic application of Kotter's work around change will provide an informed and robust platform for community pharmacy moving forward (Kotter, 1995; Tsuyuki and Schindel, 2004). Funding is required to achieve this!

Medicines Pricing and Core Dispensing Services in Canada

Medicines pricing in Canada has been well covered by Joel Lexchin in Professor Zaheer Babar's book in 2015 titled "Pharmaceutical Prices in the 21st Century" where he highlights that there is divided responsibility between Federal and Provincial Governments (Lexchin, 2015). Unlike other Commonwealth countries such as Australia and New Zealand, Canada does not have a set dispensing fee that is legislated by Central Government policy. As such the dispensing fee charged to the patient

varies significantly not just between, but within provinces. While private insurance pays for over one-third of all drug costs, the industry has very little influence in either setting prices or containing costs. Overall Canada has among the highest drug costs across developed countries, but a lack of drug insurance means that up to 35% of low income people without insurance do not fill their prescriptions (Lexchin, 2015). This funding issue is different from that required to enact clinical services but it adds to the wider discourse around medicines-related funding.

Funding Extended Clinical Services in Canadian Community Pharmacy

In February 2016, the Canadian Pharmacists Association published a review of Pharmacy services in Canada and Health and Economic Evidence (Canadian Pharmacists Association, 2016). The Canadian system is complex, as funding models for extended services vary considerably across provincial jurisdictions. Payment for pharmacy services—both expanded scope and core services—can happen through public payer compensation, insurer coverage, or out-of-pocket payment. There is significant variation across jurisdictions on public payer compensation—some pay for many services while others pay for none. This raises interesting questions about equality of medicines access across the various constituencies in Canada. In terms of renew/extended prescriptions for continuity of care and changes to dosage/formulation in Alberta, public remuneration is highest (CAD20/assessment; renewals, adaptations and discontinuations) and lowest in Saskatchewan (CAD6 to renew or alter dosage/missing information). For making therapeutic substitutions again public remuneration is highest in Alberta (CAD20/assessment) and lowest in Newfoundland and Labrador (CAD11.96-12) for provincial drug plan beneficiaries. For initiating prescription drug therapy, Pharmacists in Alberta receive CAD25/assessment from public funding. In many other provinces such as Manitoba, Saskatchewan, New Brunswick and Nova Scotia, the authority to initiate prescription drug therapy does not come with attached funding; however, this activity is able to be undertaken within a collaborative practice agreement with prescribers. Public funding for prescribing for minor ailments and smoking cessation also varies considerably across the Canadian provinces. For example, Saskatchewan provides CAD18 and Quebec provides CAD16 funding per minor ailment assessment, while funding is not provided in Manitoba, Prince Edward Island, or Newfoundland and Labrador for this service. All provinces provide public remuneration for influenza vaccination (except Quebec, where this service is not authorized except for demonstration purposes). Alberta provides the highest public payment (CAD20), and Manitoba provides the lowest (CAD7). Clearly there exists significant variation in public funding models for pharmacist services across Canada not only in terms of availability/access for patients but also in terms of reimbursement for pharmacist time. Some believe that this lack of compensation is an impediment to realizing the full potential of the expanded scope possible for pharmacists in Canada. As with the other jurisdictions, however, there is very limited evidence of cost–benefit of pharmacist activities for the overall health system (Canadian Pharmacists Association, 2016). This is an area that needs to be addressed globally so that pharmacists are ensured ongoing and sustained reimbursement (**Table 2**).

Research by the CPA highlights the following payer priorities for Community Pharmacy Services in Canada (**Panel 3**):

Funding pharmacy initiatives for future savings in the overall health-care system appears to be a policy discourse in Canada. The Conference Board of Canada suggests that Pharmacists are an integral part of the health care delivered to many Canadians and that they could play an even greater role in ensuring the sustainability of the healthcare system if the state can further capitalize on pharmacists' role as medication experts and expand the services they provide. The highlights of the Conference Board's report—*The value of expanded pharmacy services in Canada*—includes:

- Expanding three community pharmacy services (smoking cessation, advanced medication review and management for cardiovascular disease, and pneumococcal vaccination) could lead to cumulative savings between CAD2.5 billion and CAD25.7 billion over the next 20 years.
- Scaling up advanced medication review and management for cardiovascular disease could generate cost savings between CAD1.9 billion to CAD19.3 billion.
- Population health benefits of expanding these services include avoiding cases of chronic disease and premature deaths.

Obviously one of the significant impediments to funding is lack of evidence for cost-effectiveness and health outcomes. Commentary around the evidence for pharmacy service provision in Canada is outlined in **Table 3**.

Table 2 Publicly funded pharmacy services by province

Panel 3 Canadian Public payer priorities

- Achieving health system savings by reducing the costs associated with unnecessary doctor and emergency room visits
- Leveraging the core skill set of pharmacists with a focus on safety, adherence, compliance, and appropriate use
- Improving health outcomes
- Serving the high-needs/high-cost population
- Exploring approaches to better leverage the skill set of pharmacists, and services of community pharmacies, in primary care

Table 3 Health and economic impact of pharmacy services

Service	*Comments*
Tobacco cessation	There is good evidence for the use of community pharmacy for cessation interventions for smoking and chewing tobacco. A significant likelihood of quitting was established but very few studies were controlled. Most programs in the literature included remuneration. Candidate for scale-up consideration and modeling based on WHO focus on implementation of cessation interventions.
Influenza vaccinations	Activity increased dramatically over past few years in Canada but research is only starting to publish evaluation results. Lack impact assessment with research to date having focused on pharmacist and patient readiness. Appears to be data to support an increased uptake of vaccination but no cost-effectiveness data is available in the Canadian context.
Other vaccinations	There is some research showing the effectiveness and feasibility of administering other vaccines with some low-quality evidence, such as pneumococcal (pneumonia) and herpes zoster (shingles) vaccinations. The report suggests that there is potential to model the future impact of expanding pharmacist privileges (in those provinces where this service is not currently authorized) and providing remuneration (to increase implementation and uptake) and/or increasing access in those provinces where the authority exists for pneumococcal or herpes zoster vaccination in Canada.
Cardiovascular disease and related conditions—hypertension/dyslipidemia	Several studies report the significant improvement in blood pressure in patients managed by pharmacists in the community setting compared with usual care. Given the strength of the evidence for health benefits and some evidence of lower costs for community pharmacist intervention for the management of hypertension, it would be feasible and justifiable to model the scale-up of this therapeutic service. Several studies have been published to explore the impact of community pharmacist intervention for the control of dyslipidemia with variable but mostly positive results. Improvements in health outcomes have been realized in models where pharmacists collaborate with other health professionals to co-manage care of individuals with certain conditions.
Coronary heart disease and heart failure	Much of the evidence on community pharmacists in cardiovascular care is strongest for managing cardiovascular risk factors—specifically in managing hypertension and cholesterol. Impact of this downstream on events could be assessed. Although there is some evidence of pharmacist impact on heart failure in terms of reducing health system utilization, there is not enough evidence of scale-up interventions for the purpose of reducing cases of CHD or heart failure at this time.
Diabetes	Few studies are available in community pharmacy which assess impact on HBA1c and there are contradicting studies on the difference between pharmacy intervention and control. More evidence is required but the fact pharmacists have an impact on hypertension and hyperlipidemia plays into this. Hypertension and dyslipidemia interventions in community pharmacy should be considered priority service areas for high-risk populations, including patients with type 2 diabetes.
Asthma and COPD	Further research on the role and impact of community pharmacists and pharmacy on asthma and COPD management is required to make any conclusions on intervention effectiveness or cost-effectiveness. The evidence of effectiveness to date is not strong enough to warrant evaluation of potential scale-up at this time.
Mental Health	The amount of evidence for community pharmacy in Mental Health is too low in Canada. Some work has been undertaken in Australia.
Parkinson's Disease	Due to the paucity of evidence and the slow increase in the number of new studies over the past several years, community pharmacist services to address drug-related problems in Parkinson's disease may not be considered a good candidate for scale-up at this time.
Medication Review	A recent review of systematic reviews suggests promise in medication management interventions by pharmacists including medication reviews, and care services including care plan development and follow-up. Furthermore, there is evidence finding technology-assisted pharmacist interventions effective in reducing medication errors.
Minor ailments assessment and prescribing	Future research requires the examination of cost implications and other contextual barriers and facilitators to scale up. In the context of managing and prevention of diseases and risks, prescribing authority would be an important component of a community-pharmacist intervention for scale-up for any one or more ailments or conditions for which there is supportive evidence.

Source: Synthesized from the Canadian Pharmacists Association (2016)

New Zealand

As with the Canadian reforms, historically the focus on health policy and funding reform in New Zealand has been on primary care, mainly surrounding general practice. In the early days (the 1990s and early 2000s), the place of community pharmacy in the reforming health-care system was not explicitly stated compared with the United Kingdom, Australia, and Canada. New Zealand health policy makers expect primary care provider organizations to contribute to improving access, equity, quality, and service delivery through improving levels of integration and multidisciplinary team work. This started with the New Zealand Primary Health Care Strategy (NZPHCS) of the former Labour Government in the late 1980s and was carried forward by the National Government in their primary care initiative paper titled Better, Sooner, More Convenient Primary Health Care (BSMC) (Ministry of Health, 2001a, 2001b, 2006; Ryall, 2007). The 2017 Labour Government continues to focus on the improvement in youth health, mental health, particularly with respect to access to primary health care (Labour Government, 2017). There is no particular direction at this point in their policy with regard to pharmaceutical management and/or community pharmacy.

The NZPHCS expects community pharmacy to undertake counseling, and deliver education, and be integrated into service provision as part of the primary care team. This is in addition to the traditional source, dispense and distribution roles it has held over time. However, the NZPHCS was not explicit in how community pharmacy would contribute to health outcomes. One of the major thrusts of the National Government's BSMC strategy was the development of Integrated Family Health Care Centres (IFHC). These centres are expected to support the devolution of services from secondary to primary care including: specialist assessments, minor surgery, walk-in access, chronic care management, increased nursing and allied health services, as well as selected social services. Aside from outlining pharmacists as one of nine professional groups that could be co-located to an IFHC setting, and the implicit connections of "different islands of health care," there is nothing which specifically relates to future service provision by community pharmacy within BSMC.

By virtue of accessibility and skill set, community pharmacy is arguably in a strong position to triage and refer to general practice or deliver appropriate first contact primary care. Community pharmacy is an integral part of the primary healthcare system in New Zealand but has been an under achiever in terms of meeting the expectations of primary healthcare policy (Scahill et al., 2010). Pharmacists complete a 4-year degree and a 1-year preregistration internship training program in New Zealand. While pharmacists are highly trained, in many instances community pharmacists spend their time counting tablets in a dispensary. One study suggests that the interventions pharmacists make are predominantly bureaucratic, legal or stock related, with less than 20% being professional in nature (Bryant, 2006).

Working documents (under the broad umbrella of health policy) were developed for community pharmacy in the early-mid 2000s, but they were largely operational in nature. The District Health Board New Zealand (DHBNZ) National Framework for Pharmacist Services (District Health Boards New Zealand, 2006) was launched in 2006. The DHBNZ framework was squarely directed at individuals not organizations and provides service specifications rather than organizational level activities or outputs (4) (**Panel 4**).

Level A services involved providing education to patients when they collected their prescriptions. Level B services required focus on assisting patients to be more concordant with their medication regimens. The aim of Level B was to identify medicine-related problems and to formulate solutions and communicate these back to the general practice teams. Provision of Level C and D services required a much higher level of clinical training and more interaction with the prescriber. Issues with the medication regimen are addressed in addition to aspects of patient concordance. Patients who receive a level D review have chronic conditions, are on 10 or more medications, and have significant medication-related problems. Payment for the provision of these services was made through contractual discussions at the level of the Programme Manager—Pharmacy within District Health Boards. It was never clear where the funding was coming from to achieve this.

After wide consultation in 2007, the Medicines New Zealand (MedNZ) strategy was released (Ministry of Health, 2007). Prior to this, New Zealand health policy had not been explicit in signalling the role of community pharmacy within a wider health-care team

Panel 4 DHBNZ National Framework for Pharmacist Services (2006)

Existing Pharmacy Services

- Base dispensing services
- Methadone services for opioid dependence
- Monitored therapy medicine services (clozapine services)
- Aseptic pharmacy services – syringe driver services

New Pharmacist Services

Level A – Services: Information services

- Health education
- Medicines and clinical information support

Level B – D Services: Medicines Review Services

- Level B – Medicines Use Review and Adherence support
- Level C – Medicines Therapy Assessment
- Level D – Comprehensive Medicines Management

(Ministry of Health, 2001a, 2001b, 2006). The MedNZ document outlines opportunities where the optimal use of medicines in New Zealand could be improved. The framework was based on the tenets of: safety, efficacy, access, and optimal use of medicines in New Zealand. It was founded on sector involvement, system capability, efficient structures, and excellent systems, with knowledge transfer. The framework was underpinned by the principles of equity, effectiveness, trust, confidence, and affordability.

At this point, community pharmacy did not appear in the discourse around primary care collaboration, and there was little or no talk about funding for enhanced cognitive services (Scahill, 2011). The MedNZ document was implicit in its role of community pharmacy, rather than explicit and there was no signaling about funding for enhanced services. Subsequent to the launch of the MedNZ strategy document, some engagement with the community pharmacy sector occurred.

Barriers and Issues to Moving Forward with MedNZ

In August 2009, the Hon. Peter Dunne (Associate Minister of Health) hosted a health sector workshop on "realizing the potential of the pharmacy workforce to achieve optimal use of medicines" as a biannual review of the MedNZ strategy (Dunne, 2010). A summary of the issues and the response to these outlined by the Pharmaceutical Society of New Zealand included:

- The lack of connected primary care sector information technology.
- The lack of a consistent and appropriate funding model for pharmacist services.
- Deficiencies in the current medicines legislation.
- The sector doesn't maximize the potential of the GP-pharmacist professional working relationship so improved patient outcomes have yet to be maximized.
- The bureaucracy surrounding current prescribing and dispensing and service payments and its impact on pharmacists is not well understood.
- A lack of understanding of pharmacy activities by DHBs, lack of appreciation of the value of advanced pharmacist services and their benefits to patients and GPs, and the poorly defined role of pharmacists in the primary health-care team and within PHOs. (Pharmaceutical Society of New Zealand, 2010).

Significant value was expected for the New Zealand health-care sector through integration of community pharmacy mainly through the delivery of value-added enhanced pharmaceutical services yet the funding did not follow (Scahill, 2011; Scahill et al., 2010). The expectation is that general practice will have patients who are better informed about their medications and more likely to be concordant. It is then more likely that health targets set by health funders and planners will be achieved (Ministry of Health, 2006, 2007). Community pharmacy, however, should not be solely responsible for integration of their professional activities with general practice and some accountability lies with health funders and planners. Primary Health Organizations (PHOs) are meso-level community-based support organizations for the primary care sector in New Zealand. They sit within 21 geographically based District Health Boards (DHBs) that have health funding, planning, and service delivery responsibilities. PHOs are expected to support integration of health-care providers such as community pharmacy into the primary care sector. PHOs were expected to demonstrate that all of their providers and practitioners (doctors, nurses, pharmacists, other allied professionals) are in the position to influence PHO decision making, rather than one professional group such as GPs being dominant (Ministry of Health, 2001a). Although a minority of PHOs have taken a lead in developing relationships with community pharmacy and there are small pockets of activity around New Zealand, integration of community pharmacy representation into PHO governance structures has been slow. Involvement of community pharmacy in integrated primary care initiatives has also been tardy (Scahill, 2011; Scahill et al., 2010). The underlying problem is that PHOs had no budget or fiscal (or any other) accountability to incentivise community pharmacists to integrate their clinical services.

District Health Boards (DHBs) have significant responsibility for the development of integrated community pharmacy services. In much the same way as the PHOs, the DHBs have been relatively slow to engage with community pharmacy (Scahill et al., 2010). MedNZ calls for increased involvement of community pharmacy to ensure the optimal use of medicines, and DHBs were expected by the former National Government to fully support this strategy. In some DHBs, this occurred at the time through the formation of district wide advisory groups with project leaders being assigned to community pharmacy development portfolios. Involvement of community pharmacy in integrated care projects has flowed from this approach. This also requires full engagement by community pharmacy which has been equally tardy (Scahill et al., 2010).

The Community Pharmacy Services Agreement (July 2012)

The Community Pharmacy Services Agreement (CPSA) was introduced on the July 1, 2012, and represented the greatest shift in community pharmacy funding mechanisms in New Zealand since colonization in the 1840s (Technical Advisory Service (TAS), 2012). The CPSA reflects the Government's drive for a shift to a patient-centered pharmacy delivery model, which encourages integration between health professionals—doctors, nurses, and pharmacists. The CPSA is a contract between individual District Health Boards (DHB) and each individual pharmacy throughout New Zealand. The contract covers the provision of pharmacy services. Part C of the contract provides the Summary of Services to be Provided. Services that are funded are outlined in **Panel 5**.

Core pharmacy services

The New Zealand Government funds core pharmacy services to enable eligible patients where appropriate to access pharmaceuticals and advice services that are responsive to the health needs and priorities of these patients and the communities they live in. It is

Panel 5 Description of the services

Core Pharmacy services
Long Term Condition pharmacy services
Specific pharmacy services

- Class B Controlled Drug Services
- Aseptic Pharmacy Services
- Sterile Manufacturing Services
- Special Foods Services
- Pharmacy Clozapine Services
- Age-related residential care (ARRC) Pharmacy Services; and/or
- Community Pharmacy Anti-coagulation Management Services
- Extemporaneously Compounded Preparations Services;
- Named Patient Pharmaceutical Assessment (NPPA) Services A; and
- Named Patient Pharmaceutical Assessment (NPPA) Services B.
- Community residential care (CRC) Pharmacy Services
- Any other pharmacy services, if applicable

intended that these services will enhance the effectiveness of medicines usage by patients in the community. Core pharmacy services are expected to be part of an integrated community-based service that provides patients with the best quality and most cost-effective services, within the available funding. This is expected to occur through applying current pharmacy knowledge and skills to ensure a high standard of professional competence. Both patient and staff safety are paramount. Within this service, there is a requirement to dispense pharmaceuticals and provide advice and counseling while maintaining appropriate patient medical records. The dispensing process must include:

- Ensuring completeness of prescription information.
- Verification of appropriateness of prescribed pharmaceutical, suitability, dosage, possible interactions.
- Checking medication history for consistency of treatment, possible interactions, and evidence of noncompliance or misuse.

Pharmacists are contracted to provide essential professional advice and counseling and to take reasonable steps to ensure that patients have sufficient knowledge to enable optimal therapy. This process includes:

- Directions for the safe and effective use of the pharmaceutical;
- The expected outcomes of therapy;
- What to do if side effects occur;
- Storage requirements of the pharmaceutical; and
- Disposal of unused pharmaceuticals (needle exchange scheme for some pharmacies).

Long-term condition (LTC) pharmacy services

This service is provided to patients, with a diagnosed long-term condition, who have poor medicine adherence and who are assessed as having the capacity and willingness to receive additional support from a designated pharmacy. Patients must meet the LTC Access Criteria. Community Pharmacy is expected to be a key member of the multidisciplinary team linking with doctors and nurses in general practice but even wider than that. The CPSA contract calls for regular, proactive contact between the pharmacist and the LTC patient. The essential LTC services provided to each patient must include:

- Core pharmacy services outlined previously
- Medicines reconciliation services—collect and compare information from prescribers to make the most accurate list of medicines being taken
- Synchronization services—coordinating the quantities so prescription periods align
- Reminder services—about when the next supply of pharmaceuticals is to be collected
- Regular screening of compliance with and adherence to medicines regimes
- Regular engagement with multidisciplinary care team to provide information about progress in improving management of medications.

All of the LTC pharmacy services provided to each patient must be supported by appropriate documentation, which is available for inspection and audit.

Specific pharmacy services

There are many funded specific services and a brief summary is provided in Table 4.

Table 4 Service fee and handling multiplier

Service	*Service fee (NZD)*	*Handling multiplier*
Core Pharmacy Services	2.50	1.00
LTC Pharmacy Services	30/month and 43.32/month High Needs Adherence Management	1.00
Extemporaneously Compounded Preparations Services	0.00	7.95
Age-related residential care (ARRC) Pharmacy Services	0.00	5.30
Class B Controlled Drug Services (Methadone)	0.00	6.89
Aseptic Pharmacy Services	0.00	26.50
Sterile Manufacturing Services	0.00	26.50
Special Food Services	0.00	5.30
Pharmacy Clozapine Services	0.00	10.60
Named Patient Pharmaceutical Assessment (NPPA) Services A	0.00	5.30
Named Patient Pharmaceutical Assessment (NPPA) Services B	0.00	7.95
Community residential care (CRC) Pharmacy Services	0.00	5.30

Financial remuneration

The annual contracted remuneration package for each individual pharmacy is dependent on the mix of activities undertaken in terms of core, LTC, and specific services. This is a significant change from the previous contract whereby the bulk of medicines-related funding came from claims on dispensed items/scripts. The aim of this contract (the CPSA) is to spend less of the national budget on the dispensing and distribution of medicines and more (proportionately) on value-added clinical services that are expected to improve patient health outcomes. The provisions in the Consolidated Agreement (in July 2017) were the same for all DHBs, in the interests of maintaining one common agreement that governs funding arrangements with each community pharmacy services provider in New Zealand. This reduces complexity and ensures a degree of equity across the country.

The formula for reimbursement is complicated by the fact that the new funding system was implemented in stages. The figures provided in this section are from Stage 3 (July 1, 2013, to June 2014). There are a complicated set of equations, which underpin the funding calculations for Core Pharmacy Services, LTC Pharmacy Services, and Specific Pharmacy Services. In addition to handling and service fees, there was a transition payment made to pharmacies during the initial stages of the transition from the dispensing-based contract to the CPSA contract. This amount varied by pharmacy dependent on historic activities. Over this period, there was a transition pool of funds with a monthly transition payment, based on market share of initial items calculated from historical dispensing figures. Funders also acknowledged the need for quality management and a quality incentive payment is under development.

It is apparent from this analysis that pharmacy income in New Zealand has transitioned from one of dispensing fee payment and retailing to the inclusion of a remuneration structure that includes specific defined clinical activities, attached to a remuneration schedule. Individual pharmacy owners will understand the impact of this new business model on their own pharmacy business. To make the change in model sustainable and ensure that the sector was not disrupted too much financially, a transition payment was provided. This transition payment period has now ceased, and remuneration comes from core pharmacy/LTC and specific services alongside a quality incentive payment.

European Member States

In 2015, FIP collected data on remuneration models for community (and hospital) pharmacy across numerous countries. There was found to be large variations and a focus on product over cognitive (enhanced clinical) services (International Pharmaceutical Federation (FIP), 2015). The European countries under study in this chapter include the Netherlands, Germany, France, Spain, and the Scandinavian countries of Denmark and Sweden. Pharmacists remuneration for distribution (dispensing) in most European countries consists of the combination of a fixed fee per item and a certain percentage of the acquisition cost or the delivery price of the medicine (Dylst et al., 2012).

At the 3rd International Pharmaceutical Pricing and Reimbursement Policies Conference in Vienna, Austria, October 12–13, 2015; Vogler and colleagues presented the results of a survey comparing remuneration policies for wholesale and community pharmacies for 30 European countries (all 28 EU member states, Norway and Switzerland). They found that in 28 of the 30 countries surveyed, pharmacy remuneration was regulated or agreed upon between the pharmacy sector and funders for reimbursable medicines. In 16 of the 28 countries remuneration depended exclusively on the price of the dispensed medicine and was usually a regressive scheme. A performance-based fee for service remuneration was in place in Croatia, Ireland, the Netherlands, Slovenia, and the United Kingdom. Pharmacy remuneration that involves a remuneration framework that is both price-based and performance-based existed in only seven countries Belgium, Denmark, Finland, France, Germany, Norway, and Switzerland.

Spain

Spain is the fifth largest pharmaceutical market in the EU after the United Kingdom, Italy, Germany, and France in terms of market value at ex-factory prices. ISPOR—the Professional Society for Health Economics and Outcomes Research—Road Map for Spain (International Society of Pharmaceutical Outcomes Research (ISPOR), 2017a) highlights that there are three reimbursement categories for medicines in that country:

- 100% reimbursement for hospital pharmaceuticals.
- 90% reimbursement for pharmaceuticals for the management of chronic illness.
- 60% reimbursement for the majority of prescription only pharmaceuticals.

Medicines Availability

To gain entry to the Spanish market, medicines must obtain marketing authorization from the Spanish Medicinal Products and Medical Devices Agency (*Agencia Española de Medicamentos y Productos Sanitarios*) (AEMPS) or the European Medicines Agency (EMA). The product must be registered with the medicines registry within the AEMPS. The pharmaceutical company must have offered it to the national health authorities for inclusion in the reimbursed medicines public health system before marketing begins. Medicines can only be sold by pharmaceutical companies holding the appropriate marketing authorization and their local representatives, or by licensed wholesalers (Paz-Ares and Cocina, 2017). The distribution (technically "dispensing") of prescription medicines to patients is reserved by law to:

- Authorized retail pharmacies open to the public

Pharmacies in hospitals, health centers, and primary health-care facilities of the National Health Service and medicine deposits (first aid kits) (Paz-Ares and Cocina, 2017).

The drug distribution system is organized mainly through wholesalers, who distribute 85% of medicines. The main purchasing bodies are cooperatives of retail pharmacists accounting for 75% of supply and the other 25% is purchased by hospitals. Pharmacists need to complete a 5-year degree, not only to dispense medicines but also to own a pharmacy. There is a compulsory requirement to belong to the College of Pharmacists (Garcia-Armesto et al., 2010). In terms of site regulation, Spanish pharmacies are all independents, and chains are banned at this point. All pharmacies must be owned by pharmacists. Retail pharmacies must be in possession of an authorization granted by the appropriate authority in the autonomous region where the pharmacy is located (Paz-Ares and Cocina, 2017). This is issued according to a quota system based on geographic location and population. Both France and Spain are two of the countries in Europe with the strictest levels of regulation. It is more or less impossible to open new pharmacies and pharmacies have the right to sell nonprescription medicines.

It is very important to understand the drug pricing, procurement, and distribution system as funding of pharmacy services seem (in many countries) to be inextricably linked to this.

In 2014, the Spanish Government considered deregulating chain pharmacies, and this deregulation could likely have a direct effect on funding of pharmacy and the services provided. The notion of full deregulation and the relative instability of funding of the system as a whole would leave pharmacies in much of Europe exposed. In many countries in Europe (Spain included) when prices of medicines fall, then so does pharmacy remuneration.

Pharmaceutical services are defined as part of the Governments' common benefits package (European Observatory on Health Systems and Policies, 2017d). This package covers the products—medicines and/or other health products. This package also covers the actions ("the service") that ensures patients receive the right medicine(s), at the correct dose and duration for the lowest cost possible to individual patients, and the community they live within. Unlike other medical services in Spain that are provided free of charge, pharmaceutical services are co-financed by users. In this way, the base price of the pharmaceutical and wholesaler discounts become very important; this is what funding hinges on. Medicines dispensed in hospitals, however, don't attract a co-payment. For prescriptions funded by the Government pensioners and their beneficiaries are exempt from co-payments. Nonpensioners and their beneficiaries pay 40% of the retail price. The remaining 60% is billed to the regional health system in the area where the person lives. There are specific groups that are subsidized such as those with AIDS and chronic disease who are subjected to a 10% co-payment; capped at a fee/script. The average reimbursement price (back to the pharmacist) in 2016 was EUR10.99 for a script item.

There have been suggestions of the need to change the reimbursement system to accommodate cognitive (enhanced clinical) service delivery as well as dispensing, into the community pharmacy model in Spain. Community pharmacists considered remuneration as the most important facilitator for practice change while funders thought education and training was most important and remuneration did not feature (Gastelurrutia et al., 2009). At the time of writing, there was no publicly available information in policy documents on payment for cognitive (enhanced clinical) services to pharmacists in Spain.

Denmark

The Danish Ministry of Health is responsible for development of the overall framework for the pharmaceutical system. The Ministry is involved with the approval of pharmaceuticals and pharmacy sector and for making legislation concerning the reimbursement system as a whole and as it relates to pharmaceutical services. The Danish Medicines Agency decides the reimbursement status for each pharmaceutical product after a pharmaceutical company files an application for funding. Safety and efficacy considerations are

Table 5 Different types of primary care pharmacies in Denmark

Type	*Description*
Pharmacy	Must retail all types of pharmaceuticals and also have a suitable and adequate stock in relation to the demand at the place in question. And if the pharmacy is asked to do so, it is obliged to procure a medicine that is not in stock. A pharmacist must always be on duty at the pharmacy.
Supplementary pharmacy unit	Is a pharmacy owned by a pharmacist who also owns another pharmacy. The only difference between a pharmacy and a supplementary unit is the ownership and some technicalities concerning the equalization system among the pharmacies. There should be one or more pharmacists employed of which at least one must be on duty.
Branch pharmacy	Is attached to a pharmacy and is operated at the pharmacy's expense. The branch pharmacy has its own independent premises and professionally qualified staff. For each three pharmacies and/or pharmacy branches there should be at least one pharmacist employed. Branch pharmacies may retail the same products as the pharmacy and may also dispense prescription medicine.
Pharmacy outlet	Is also a unit attached to a pharmacy and operated at the cost of the pharmacy in independent premises. The pharmacy outlet has professionally qualified staff, but there is no requirement for having pharmacists employed. The pharmacy outlet may retail OTC drugs and other products that are also carried by pharmacies, but it may not dispense prescription medicine. However, it may hand out prescription medicine dispensed at the pharmacy (including branch pharmacies) to which the outlet is attached.
OTC outlet	Is in premises not belonging to the pharmacy—typically in another store. The outlet receives products from a specific pharmacy and is operated by a store manager, with whom the proprietor pharmacist has a contracted agreement. The store manager typically has no training within the pharmacy sector. OTC outlets are subject to the same rules as outlets of medicine in the nonpharmacy sector. This means that they may carry only a limited assortment. OTC outlets may also provide customers with prescription medicine and other pharmacy restricted medicine that has been dispensed at the pharmacy (including branch pharmacies) to which the outlet is attached.

Source: The Association of Danish Pharmacies

made and pharmacoeconomic criteria are applied if the company submits a voluntary economic dossier—this is not compulsory. Annual reimbursement policy is set as part of this process (Skrijelj and Strandberg-Larsen, 2017). In the primary care sector, medicines are distributed from the pharmaceutical industry to private pharmacies, retail shops, and web-based pharmacies by pharmaceutical wholesalers. Prices are set by the wholesalers fortnightly, with the reimbursement price being calculated based on the least expensive generic product. The amount of reimbursement a patient receives depends on their accumulated pharmaceutical expenses during a 12-month period (January to December) which ranges between 0% and 100% dependent on categories of expenditure threshold.

The pharmacy sector in Denmark is divided into different "Units" as outlined in **Table 5**.

As of February 20, 2017, the 214 proprietor pharmacists have ownership of 235 pharmacies (21 of the proprietor pharmacists own two pharmacies) and 190 branch pharmacies. The new flexible establishment regulation has resulted in 112 new branch pharmacies since July 1, 2015. Furthermore, there are 52 pharmacy outlets and approximately 550 OTC outlets and 250 delivery facilities. Delivery facilities do not stock medicine, but they receive addressed dispatches from one or several pharmacies and pass them on to the individual customer (Danish Association of Pharmacies, 2017).

All community pharmacies in Denmark are expected to provide advice about medicine use, dose dispensing, generic substitution, and the administration of individual reimbursement registers. Many pharmacies offer Body Mass Index assessment, blood sugar, blood pressure, and cholesterol measurements, smoking cessation counseling, and inhaler technique counselling. Extending services in clinical pharmacy is a priority for all Danish pharmacy organizations. Professional bodies use the competence of the pharmacist/pharmacy to take co-responsibility for the pharmaceutical treatment of the patient and for patient safety (European Observatory on Health Systems and Policies, 2017a).

In terms of payment for enhanced cognitive services, there is not a great deal of publicly available information but it would appear that there is an expectation that this occurs in Denmark.

Sweden

Sweden has a population of over 9 million, and national health coverage for all residents is provided by county councils (World Health Organization (WHO), 2017). As such, the Swedish system is highly decentralized, and there are levels including national government, county councils, and municipalities, which are responsible for health-care funding and delivery. Health services are mainly funded by taxes and patients pay a limited amount of the actual costs for medical service visits and treatment. In 2017, patients paid a maximum co-payment of SEK 2200 (EUR 232) per year, which is payable for out-patient pharmaceuticals included in the benefits scheme. The costs of the pharmaceuticals in the benefits scheme are largely paid for by a government grant (World Health Organization (WHO), 2017). Pricing and reimbursement of new pharmaceuticals in the out-patient setting in Sweden is decided by the Board of Pharmaceutical Benefits based on clinical evidence and health economic dossiers following the principles of Value Based Pricing.

Up until June 2009, Sweden's state-owned Apoteket Abs pharmacies had a monopoly in the market place (Wisell et al., 2016). The market was reregulated in 2009 by a centre-right government, and half of the 900 state-owned pharmacies were sold to private owners. Five large pharmacy chains now exist and there has been a 30% increase in the number of pharmacies from around 929 to over 1355 in Sweden (World Health Organization (WHO), 2017). Despite being a fully liberalized pharmacy sector (and therefore

market), the funding is still mostly public with additional co-payments from patients (Wisell et al., 2016). For pharmaceuticals to be reimbursed, they are included in the Pharmaceutical Benefits Scheme, which means they have been approved by the Dental and Pharmaceutical Benefits Board. This board sets the pharmacy purchase price and the pharmacy margin—a fixed national pharmacy retail price (Faulkner et al., 2017).

In terms of enhanced services, pharmaceutical care was introduced into the then state-owned pharmacies in 2002 and was provided by specially trained pharmacists (Montgomery et al., 2010). The service consisted of a scheduled initial counseling session of 30 min and shorter follow-up evaluation sessions that can be both planned and scheduled or "drop in." Patients are identified by a pharmacy team or they can self-identify their own needs and enrol. Despite searching, the author could not find any publicly available information on the funding directive for these services.

E-commerce has seen rapid growth in community pharmacy in Sweden with increase in the distribution of pharmaceuticals and related products by 70% in 2016, but from a relatively low base. By 2020, it is expected that up to 15% of all combined pharmacy revenue could come from e-commerce distribution channels in Sweden (World Health Organization (WHO), 2017).

As a finishing point, a special government commission of inquiry will review financing, reimbursement, and pricing of medicines in Sweden and the report for this review is due in December 2018. At that time, there will be a better understanding of funding levels for services in community pharmacy looking into the future.

Bismarck Funding Models

The countries analyzed in this section that fit into the Bismarck health systems model include the Netherlands, France, Germany, and Belgium.

Netherlands

The Netherlands Pharmaceutical Country profile was published by the Ministry of Health, Welfare and Sports in collaboration with the WHO (World Health Organisation and Ministry of Health Welfare and Sport, 2011). This report covers a broad remit in outlining pharmaceutical policy, medicines trade and production, financing, procurement and distribution, selection and rational use, and household level data/access. In 2009, the Netherlands spent 9.6% of its total government funded health budget on pharmaceuticals equating to EUR 5153 million or EUR 311.77 per individual. No one group receives medicines free of charge in the Netherlands. Most medicines are reimbursed through social health insurance or a private health insurance fund but, if not, then the patient pays the full or partial cost (if partly subsidized). There are no co-payments or fee requirements imposed for medicines at the point of delivery in the public system. There are pricing regulations for the private sector in the Netherlands. Retail medicine prices are publicly accessible and a maximum price is published in the government Gazette. Pharmacists receive discounts from wholesalers and these are reduced by a statutory clawback of 6.82% (max of EUR6.80/script in 2009). In addition, certain health insurers have preference lists of medications and often these include generic medicines which the pharmacist must supply. In terms of payment for enhanced services such as Pharmaceutical Care, a Special Report was undertaken by FIP in 2012 (Federation Internationale Pharmacists (FIP), 2012). There is significant discourse in this report related to remuneration fees and medicine pricing but also facts and figures relating to funding of the system.

Everyone who lives or works in the Netherlands is required to take out basic health insurance. This is a fixed sum payment for all over the age of 18, regardless of associated health risk. There is also an income-related contribution, which the employer deducts from wages and pays to the government. The statutory insured drug package was EUR220 per person in 2012. People can also take out additional policies for cover if they wish. Some individuals with chronic conditions receive a partial refund. In terms of drug reimbursement, the government decides which medicines are allowed to enter the market and which are included in the GVS (Drug Reimbursement System). A baseline limit is set twice per year based on average prices of a medicine in Belgium, Germany, France, and the United Kingdom. The GVS has been around since 1991. Prior to 2012, a dispensing fee was claimed by pharmacies, and a claw back was able to be claimed on the cost of the pharmaceutical from the wholesaler. Of course, remuneration for pharmacy services then depends on medicines pricing, and the cost of pharmaceuticals in Western Europe has steadily declined over the past 15 years. It is fair to assume that average pharmacy reimbursement has declined in the Netherlands. Revenues from dispensing fees were set centrally and remained virtually unchanged between 2006 and 2012. From January 1, 2012, there has been a treatment-related pricing in the pharmacy sector to reimburse the services provided by the pharmacy. There is no longer "central setting," but these are freely negotiable with the insurers (and have shown a decline of 4% for the average pharmacy). It would appear that ongoing sustainable funding for clinical services is a challenge for pharmacists in the Netherlands.

France

Pharmacy-based remuneration that is both medicines price-based and performance-based is found in France. This is also the case for Belgium, Denmark, Finland, Germany, Norway, and Switzerland. Outpatient pharmaceutical care is paid according to the official tariffs defined by the Economic Committee for Health Products (CEPs). Prices and payments are set for whole units and not broken packages. From 2000 to 2015, Pharmacists in France were remunerated via a fixed-sum component (EUR 0.53 per item) and a digressive sliding-scale margin. From 2015, there has been a move toward a fee-based system where in 2016 pharmacists were paid a

fixed sum of EUR 1, in exchange for a reduction in price-based margins. Since 2013, pharmacists have been paid EUR40/patient for consultations for asthmatic patients and patients on anticoagulant medications. A "pay for performance" scheme centered on the use of generic medicines was also instigated in 2013. There is a bonus available for pharmacists of up to EUR3000/year dependent on the proportion of generics dispensed, as well as the change from baseline. The mark-up in absolute terms paid for generic medicines is the same as for originator medicines, but the manufacturer rebates allowed for generics is much higher (50%) than that for branded medicines (2.5%) (European Observatory on Health Systems and Policies, 2017b). Again this discourse is centered on medicines distribution and pricing not clinical service provision.

The general conditions of the pharmaceutical reimbursement system in France are established by law and are implemented principally at a national level by governmental bodies. When marketing authorization is granted either by the EMEA or the French Medicine Agency (AFSSAPS), the pharmaceutical company has to apply for reimbursement on positive lists to obtain funding by the mandatory health insurance scheme (*assurance maladie obligatoire*). There are two lists: one for reimbursable medicines dispensed by retail pharmacies (*Liste des Spécialités remboursables aux Assurés Sociaux*) and one for hospital medicines (*Liste des Spécialités agréées aux collectivités*).

Germany

The pharmaceutical industry in Germany is among the most powerful in the developed world and so there has been a tension in the dichotomy between pharmaceutical policy driving quality and access through fair pricing and industry policy driving the economy in Germany. With a large workforce of over 5 million employees, the pharmaceutical industry also plays a key role in labour market policy being such a large and powerful part of the German economy (Döring and Paul, 2010; European Observatory on Health Systems and Policies, 2017c).

Germany's health-care system is a contribution-based social insurance system, which fits the Bismarck model. This model was outlined previously but what this essentially means is that health care is primarily funded by the public sector. The basic principles of social rights are used as the framework for ensuring social security in cases of illness, and these social right principles must be followed by both health insurance companies and the health service providers (Döring and Paul, 2010).

Of the EUR45.3 billion spent on medicines in 2010 in Germany, the majority (84%) was through community pharmacy (European Observatory on Health Systems and Policies, 2017c) and so this sector is not insignificant and plays a vital role in the procurement and distribution of pharmaceuticals. For dispensing prescription-only medicines, pharmacists in Germany are paid a flat rate payment (EUR8.35) plus a fixed margin of 3%. The retail price contains an additional 19% value added tax (VAT), also known as Umsatzsteuer in German. The margin is calculated from the manufacturer's price plus the relevant maximum margin for wholesalers (excluding VAT). For OTC and other nonprescription medicines, the German community pharmacies are free to determine the price.

Aside from procurement and distribution in German Community Pharmacy, cognitive pharmaceutical services have been available for almost one-quarter of a century (Eickhoff and Schulz, 2006). In 2003, a contract was established between representatives of community pharmacy owners and the largest of the nationwide German health insurance funds. This was the first time a nationwide contract had been successfully negotiated. One year later, a very interesting tri-lateral integrated care contract was signed, which brought together "family pharmacy" with "family physician"–family denoting the primary care focus and delivery. The majority of community pharmacies in Germany were registered to participate at that time.

Belgium

There appears to be relatively less publicly available information on Belgium when it comes to pharmaceutical services reimbursement. For example, ISPOR has not generated a Global Health Care Systems Roadmap for Belgium although 22 other European countries have profiles. In Belgium, there are approximately 4950 pharmacies servicing a population of around 11 million inhabitants. Most European nations spend around 10% GDP on health care; however, there is significant variability of pharmaceutical expenditure. Belgium is similar to France in that its pharmaceutical spend is toward the top end of European countries at 16.4% (le Polain et al., 2010). From the same data-set, Belgium also has the highest "out of pocket expenses" for medicines of 22% (among Austria, Belgium, France, the Netherlands, and Sweden). In Belgium, patients pay a co-insurance for pharmaceuticals (a % of the reimbursement basis), and there is an annual income-dependent ceiling for total out-of-pocket expenditure on health care.

Advanced pharmaceutical care in community pharmacy is in its infancy as a formalized process in Belgium. In October 2013, a New Medicines Service (NMS) was introduced to support one chronic illness—asthma management. This is the first initiative that puts this form of pharmaceutical care into practice in Belgium; and as far as the author is aware, it is the first to be evaluated (Fraeyman et al., 2017). Pharmacists register NMS interventions and are able to claim for this but it appears that details of reimbursement are not made publicly available on policy websites.

Sovereignty Funding Models

USA

The United States appears to be the most complicated of the pharmaceutical systems reviewed in this chapter. This is largely the result of the whole health-care system being rather complex (from a funding viewpoint) and quite different from most other systems

around the world. The literature describes the pharmacy system as a "supply chain" from supplier to market—the consumer being the patient. There does not appear to be a Government imposed price for medicines or the cost of dispensing and this is how health pricing is determined in a Sovereignty-based system. The United States is as close to "free-market" as any of the health systems analyzed in this chapter.

Joey Mattlingy (2012) suggests one of the most confusing markets for the consumer is located at the pharmacy counter in the United States (Mattingly, 2012). He adds that the rise of health-care costs has lawmakers and employers scrambling to find ways to provide access to care without going bankrupt. Numerous policies at different levels of government and in the private sector have further complicated this market, creating a system nearly impossible for the average person to navigate.

When thinking of the pharmaceutical system and its associated policies as a supply chain, there are four main touch points: pharmaceutical manufacturer, wholesaler, community pharmacy, and the consumer, but in the United States, there is a third party involved (the insurer) and they have pharmaceutical supply managers to monitor pricing. It is not an entirely free market with Congress establishing average sale prices (ASPs) as the primary basis for Medicare Part B Drug reimbursement (Murrin, 2015).

ISPOR in their global health-care systems roadmap (USA) state that Medicare, for Part B prescription drugs, pays the average sales price (ASP) plus 6% for drugs administered in the physician's office or clinic, whereas for Part D and Medicare Advantage Prescription Drug (MA-PD) plans, Medicare negotiates rebates and discounts with the pharmaceutical industry. Under the Medicaid program, the State (since Medicaid is managed by individual States) will pay pharmacies or managed care plans for medicines dispensed using rates based on wholesale acquisition cost (WAC) for branded medicines, and maximum allowable cost (MAC) for other brands and generics. WACs are set by manufacturers and are an estimate of the manufacturer's list price for wholesalers or other direct purchasers, not including discounts or rebates (International Society of Pharmaceutical Outcomes Research (ISPOR), 2017b).

Medicare Part B (Medical Insurance) generally does not cover most prescription medicines used at home but it does cover a limited number of outpatient prescription medicines under certain conditions. Generally, medicines covered under Part B are those that would not usually be self-administered, like those obtained from a doctor's office or hospital outpatient setting. Medications not covered under Part B may be covered under Medicare prescription medicines coverage (Part D). The official US Government site for Medicare outlines the following regarding Part B scheduled items (US Government, 2017a).

- **For covered Part B prescription medicines that patients obtain in a doctor's office or pharmacy**, they pay 20% of the Medicare-approved amount, and the Part B deductible applies. Patients must accept assignment for Part B medicines, so they should never be asked to pay more than the co-insurance or co-payment for the medication itself.
- **For covered Part B prescription drugs obtained in a hospital outpatient setting**, patients pay a co-payment. If patients are given medicines not covered under Part B in a hospital outpatient setting, they pay 100% for them, unless they have Part D or other prescription drug coverage; what is paid depends on whether the drug plan covers the drug, and whether the hospital is in the drug plan's network.

Each Medicare medicines plan has its own list of covered medicines (called a formulary). Many Medicare medicines plans place medications into different "tiers" on their formularies. Medications in each tier have a different cost. A medicine in a lower tier will generally cost less than a medicine in a higher tier. Sometimes, if prescribers think patients need a medicine that's on a higher tier, the patient or prescriber can ask the plan manager for an exceptionto obtain a lower copayment (US Government, 2017b). A Medicare medicines plan can make some changes to its formulary during the year, within guidelines set by Medicare. If the change involves a medicine the patient is currently taking, the plan must do one of these:

- Provide written notice to patients at least 60 days prior to the date the change becomes effective.
- At the time the patient requests a refill, provide written notice of the change and a 60-day supply of the medicine under the same plan rules as before the change.

Congress mandates the Office of Inspector General (OIG) to compare ASPs with average manufacturer prices (AMPs) and directs the Centers for Medicare & Medicaid Services (CMS) to substitute payment amounts for medications with ASPs that exceed AMPs by a threshold of 5%. To comply with its statutory mandate, OIG has completed over 30 quarterly pricing comparisons. In April 2013, CMS began substituting payment amounts in accordance with its published price substitution policy, which currently applies to only certain medication codes with complete AMP data that exceed the 5% threshold in two consecutive quarters or three of the previous four quarters.

In the United States, pharmacists have been called to actively participate in the new primary care era following a period of transformative legislation in the Affordable Care Act (ACA) alongside the broadening of health-care insurance coverage. A very high percentage of the US population (92%) live within 3 km of a pharmacy, and there are now over 67,000 pharmacies within the United States, suggesting access to pharmacy services is in fact very good. Part of the reform movement is to lever community pharmacy into helping meet two key goals of the ACA—expanding care to the insured and uninsured and providing greater access to care (Munger et al., 2016).

With the complexity already outlined regarding the US health system and changes in Medicare payment structures, Johnson and colleagues have highlighted the need for pharmacists to keep up with changes (such as the considerable policy changes over a dozen years ago) and the complexities of pharmaceutical reimbursement to help them improve the financial viability of their organizations (Fijalka et al., 2008; Johnson, 2006, 2008).

Community-based pharmacies in the United States began incorporating convenience clinics also known as "retail clinics" into their business models in 2000 (Munger et al., 2016). Retail clinics are medical clinics located in pharmacies, grocery stores, and large retailer outlets such as Target and Walmart (RAND Corporation, 2016). They provide just one primary care function: first-contact care although there has been criticism that these clinics have failed to meet expectations in transforming health-care systems (Hwang and Mehrotra, 2013). Again this highlights the complexity of the US health system, especially when we think about how pharmacy might impact health outcomes through colocation with physicians compared with when these clinics are also found in large retail stores.

Australia

Australia is perhaps the most difficult nation to categorise in terms of overall health system type. At the macrolevel of the "whole of system", Australia is perhaps closest to operating like the USA; in a sovereignty market. When one considers the pharmaceutical system (funded by the overarching system as a whole); however, it operates much more like a Bismarck system. Funding is through national insurance but there is significant linkage between Government, Pharmacy Guild and University Schools of Pharmacy.

Pharmacy Funding Policy Reform

A long-term strategic program of pharmacy practice research has produced a substantial evidence base to underpin proposed new community pharmacy services funded by the Australian Government (Anderson et al., 2008). Tripartite arrangements between Schools of Pharmacy, the Australian Government, and the Pharmacy Guild have supported this through the Community Pharmacy Agreement Research and Development Program. This has been used to inform the priorities of the Sixth Agreement (6CPA) (Commonwealth Government of Australia, 2005). The 6CPA took effect on July 1, 2015. It is a significant jump in investment in community pharmacy by the Australian Government of AUD2.4 billion over the 5-year period 2015–2020. This figure increases to AUD2.8 billion when including chemotherapeutic products and services. The Government will provide AUD825 million over 3 years, from 2017 to 2018 to community pharmacies. This is expected to support and improve the access to medicines by Australians. Over AUD600 million will be through the 6CPA agreement allowing pharmacists to deliver new services or expanded programs. This funding covers the evaluation of the following:

- Dose administration aids
- Staged supply
- MedsCheck
- Diabetes MedsCheck
- Home medicines review program
- Pharmacy trial program

The key features of the 6CPA include:

- A new Administration, Handling and Infrastructure (AHI) Fee, which replaces the previous pharmacy mark-up,
- Dispensing remuneration indexed to the Consumer Price Index,
- An increased investment in Community Pharmacy programs and services,
- A government commitment to extend the Location Rules until mid-2020, with an independent review to be conducted during the 6CPA to inform future arrangements. The rules relate to the establishment of a new pharmacy or the relocation of an existing pharmacy. The rules set out location-based criteria, which are intended to provide further stability of the community pharmacy network and patient access.

The tripartite arrangement in Australia signals a strong and long-term commitment by the Australian Government, the Pharmacy Guild, and the academic community to develop community pharmacy services and to evaluate service provision in a robust manner.

The tripartite agreement has resulted in a positive approach toward community pharmacy development, practice evaluation, and organizational research by all three parties (Anderson et al., 2008). The academic focus has been on identifying facilitators to the successful provision of extended services in Australian community pharmacy. This is a different focus to the barrier identification reported in other high-income countries. Seven facilitators to the implementation of cognitive clinical services in Australia have been identified (Roberts, 2005; Roberts et al., 2006). These include relationships with doctors, remuneration, communication and teamwork, pharmacy design, positive patient expectation, external support, and assistance with change management. The inverse of the first three facilitators reported by Roberts and colleagues were reported by New Zealand pharmacists as potential barriers in the Ten Year Vision study and this is discussed further in the section below (Scahill et al., 2009b).

The downstream benefits have been realized through development of sustainable research programs evaluating and supporting community pharmacy (Feletto et al., 2010a, 2010b, 2011; Roberts, 2005; Roberts et al., 2003, 2006). So, clearly, remuneration is one of the facilitators for pharmacy service uptake, and the following section outlines the current status of funding in Australia.

Administrative handling and infrastructure (AHI)

The Pharmacy Guild of Australia states that the AHI substantially delinks pharmacy remuneration from the price of medicines and is in recognition of the nonprofessional costs of delivering the Pharmaceutical Benefits Scheme (PBS) to patients on behalf of the

Panel 6 Continuing Community Pharmacy Programs in Australia (2015-2020)

- Medication Adherence Programs – Dosage administration aids (DAAs) and Staged Supply with periodic instalments of a full prescription period
- Medication Management Programs – Clinical Interventions, Home Medicines Reviews, Residential Medication Management Reviews and MedsCheck
- Rural Support Programs – Rural Pharmacy Workforce Program and the Rural Pharmacy Maintenance Allowance
- Aboriginal and Torres Strait Islander Program

Government. This does not occur in large parts of Europe and is a significant and positive move for the Australian Community Pharmacy sector. Compared to the existing mark-up structure, which would have continued to trend down over the 6CPA period due to falling PBS prices, the AHI provides an immediate overall increase compared with current mark-up and will increase each year during the 6CPA as a result of indexation. The trending down of remuneration with the mark-up structure and falling pharmaceutical prices is certainly what is happening in parts of Europe.

Importantly, the AHI Fee has been tiered such that the fee applicable to the most expensive medicines on the PBS will remain in line with the current mark-up (AUD72.43 maximum).

The value of this fee from 1 July 2017 was:

- Where the Approved Price to Pharmacist (wholesaler PBS list price) is up to AUD180.00: AUD3.94 per prescription
- Where the Approved Price to Pharmacist is between AUD180.00 and 2089.71: AUD3.49 plus 3.5% of the amount by which the price exceeds AUD180
- Where the Approved Price to Pharmacist is AUD2089.71 or above: AUD72.43

The "AHI Fee" is indexed annually on 1 July by the Consumer Price Index (CPI). From 1 July 2017, the dispensing fee will increase to AUD47.15 for ready-prepared prescriptions. As with the AHI Fee, it is indexed annually on 1 July by CPI. The Pharmacy Guild of Australia highlights that a remuneration review is to be conducted to inform possible pharmacy remuneration arrangements for the 7CPA (July 2020 onwards). The review will not be able to be used to change pharmacy remuneration during the 6CPA. What is clear though is that the Australian Government is prepared to negotiate suitable remuneration packages.

There has been an increase in the total funding allocated to community pharmacy programs in the 6CPA to focus on evidence-based, patient-focused services. This includes programs that benefit Aboriginal and Torres Strait Islanders, and people living in rural and remote areas. This is a significant change from previous agreements and represents a change in the focus of the Government toward the health of these peoples. There is a strong focus on diversity. The Pharmacy Guild of Australia notes that the Government has increased its funding for Programs by over 70% equating to AUD1.26 billion apportioned to the following:

- Continuing Community Pharmacy Programs (AUD613 million) (see **Panel 6**)
- Pharmacy Trial Program (AUD50 million)
- Additional funding to support new and expanded Programs (AUD600 million)

There are major steps forward in terms of funding and support for clinical programs. For the first time, pharmacies are directly remunerated for the provision of diabetes products under the National Diabetes Services Scheme (NDSS).

On the technology front, pharmacies will continue to be funded for electronic transfer of prescriptions and are encouraged to be more involved in e-health through the 6th Agreement and this is likely to be a significant aspect of future agreements.

In summary, in Australia, information is freely available, and the remuneration contract is supported by evidence of pharmacies' value proposition through years of well-funded collaborative research.

Other Systems

South Africa

In 1996, the South African Government released the South African National Drug Policy (NDP) (South African Government, 1996). The aim was to ensure an adequate and reliable supply of safe, cost-effective medicines of acceptable quality to all citizens of South Africa and the rational use of medicines by prescribers, dispensers, and consumers (Section 2, pg 3). The policy had a focus on health, economic, and national development objectives, and the WHO highlighted that the policy was expected to serve the health needs of South Africa by:

- Providing a clear description of the management of the pharmaceutical system,
- Steering key stakeholders with respect to what they can contribute in achieving policy aims,
- Systematic reduction of inefficiencies and waste through development of pharmaceutical infrastructure,
- Design through implementation of suitable programs for human resource development in health care related to pharmaceuticals (World Health Organisation (WHO), 2017).

The policy was a high level one that provides a platform for the development of a robust pharmaceutical system. There is a specific (special as per WHO) place for the pharmacist in this policy in ensuring the supply, distribution, and rational use of medicines. The

aim with respect to procurement and distribution was to promote cost-effectiveness in the public sector and to utilize private-sector facilities as appropriate. It was made clear that a system of joint responsibility between the government and the patient for the financing of medicines was what the government wanted. At this time, financing was related to the procurement and distribution of essential medicines which were provided free of charge at the point of service, at the primary care level. Further policy has been developed and on 19th January 2015 a national policy for the establishment and functioning of Pharmaceutical and Therapeutics committees in South Africa was generated by the Department of Health of the Republic of South Africa (Department of Health: Republic of South Africa, 2017).

A recent review of health-care systems and pharmacy practice in South Africa has been undertaken by Andy Gray at the University of KwaZulu-Natal in Durban (Gray et al., 2016). It is clear that there has been significant change and there is ongoing reform since the transition to democracy in 1994, when the system was fragmented and primary care services underdeveloped. There remains private-sector medical scheme reimbursement policies (health insurance) with no pharmaceutical surcharge for those who can afford to pay (Gray et al., 2016; Malangu, 2014).

In South Africa, there is almost complete separation of private and public sector provision of services. In the public sector, all services at the primary care level are free, and pharmacists in the public sector facilities are salaried. At this point, apart from a centralized dispensing service for chronic medicines (which is provided by large distance dispensing contractors but with some pick-ups being from private-sector community pharmacies), the private sector does not service public sector-dependent patients (Personal communication A Gray, 18th September 2017). Pharmacists in the private sector provide services predominantly to those who are members/beneficiaries of medical schemes (i.e., insured; approximately 8 million out of 55 million population).

In the private sector, pharmacists are reimbursed by means of a regulated maximum dispensing fee and the dispensing fee is not divorced from the price of the medicine (Gray and Suleman, 2015; Gray et al., 2017; Suleman and Gray, 2015), which is the same for most of the European countries investigated in this chapter. The current fee structure for dispensing in South Africa is outlined as below:

- where the single exit price of a medicine or scheduled substance is less than ZAR97.06, the dispensing fee shall not exceed ZAR9.25 plus 46% of the single exit price in respect of that medicine or scheduled substance;
- where the single exit price of a medicine or scheduled substance is greater than or equal to .06 but less than .88, the dispensing fee shall not exceed ZAR22.50 plus 33% of the single exit price in respect of that medicine or scheduled substance;
- where the single exit price of a medicine or scheduled substance is greater than or equal to .88 but less than .10, the dispensing fee shall not exceed ZAR69.00 plus 15% of the Single Exit Price in respect of that medicine or scheduled substance;
- where the single exit price of a medicine or scheduled substance is greater than or equal to ZAR906.10), the dispensing fee shall not exceed ZAR160.00 plus 5% of the Single Exit Price in respect of that medicine or scheduled substance (South African Department of Health, 2017).

The Single Exit Price (SEP) is the factory-gate price (which includes any logistics fee paid to wholesalers or distributors), is delinked from volumes, and cannot be discounted. It is paid by all private-sector purchasers (pharmacists, dispensing practitioners, hospitals). A maximum SEP increase is allowed each year.

South Africa is in the process of implementing universal health-care coverage through a National Health Insurance scheme (National Department of Health: Republic of South Africa, 2017). It is not clear at this point how cognitive (enhanced clinical) pharmaceutical services will fit into this scheme, which could take up to 15 years to fully implement. Having said this, pharmacists will need to play a central role in the move to a single financing approach; certainly specialist clinical pharmacists are suggested to be vital to this transition as it relates to medicines use (Gray et al., 2016).

Another interesting change in the South African pharmaceutical system is the Authorized Pharmacist Prescriber Qualification (South African Pharmacy Council, 2011). This is a postgraduate diploma in Pharmacy proposed by the South African Pharmacy Council, which dovetails with the National Human Resources Strategy for Health and the National Drug Policy. Pharmacists will treat patients with medicines listed in the Primary Healthcare Essential Medicines List (EML) according to standard treatment guidelines. There are, however, no publically available details regarding service remuneration at the time of writing.

Summary

This chapter explored the funding mechanisms of selected nations in the international community pharmacy sector. The focus is on developed countries—those high-income nations that have health system infrastructure in place and for which there is a strong and definable pharmaceutical subsystem. The chapter is framed by grouping nations with the same or similar "whole of health systems" model—rather than by geographic location or affiliation with such jurisdictions as the British Commonwealth. Community Pharmacy structures and funding have been framed in terms of levels including medicines pricing, dispensing/counseling fees, and payment for enhanced cognitive (clinical) services.

This analysis highlights several global issues for the community pharmacy sector when it comes to funding and remuneration. First, there appears to be a dearth of publicly available information on not only strategy but also payment mechanisms to community pharmacies for dispensing and enhanced services in many countries. Medicines "pricing" seems to be more freely available. Second, where information is available, there is often a relationship between medicines pricing and pharmacy services remuneration. There needs to be a substantial "delinking" of pharmacy remuneration from medicines price—mark-up structures

linked to price are tracking downward as pharmaceutical policy puts pressure on the pharmaceutical industry to reduce prices. Switching to generics is also causing a significant reduction. Third, although countries can be grouped into like "whole of health systems," the variation in pharmaceutical subsystems within these countries is more obvious and significant than the system as a whole. A strong overall system if required to strengthen the pharmaceutical system but there is much variation in the pharmaceutical systems of these developed nations.

Although pharmaceutical care was implemented a long time ago in parts of Europe, a number of countries are yet to gain appropriate direct (free from medicines pricing) funding for these professional services. In late 2018, Australia and Canada have the most advanced remuneration systems.

Abbreviations

ACA—Affordable Care Act
AEMPS—Agencia Española de Medicamentos y Productos Sanitarios (Spanish Medicinal Products and Medical Devices Agency)
AFSSAPS—Agence Française de Sécurité Sanitaire des Produits de Santé (French Agency)
AMP—Average Manufacturer Prices
ARRC—Age-related Residential Care
ASP—Average Sale Prices
BSMC—Better, Sooner, More Convenient Primary Health Care
CEPS—Economic Committee for Health Products
CMS—Centers for Medicare & Medicaid Services
6CPA—Sixth Community Pharmacy Agreement
CPA—Canadian Pharmacists Association
CPI—Consumer Price Index
CPSA—Community Pharmacy Services Agreement
CRC—Community Residential Care
DAA—Dose Administration Aids
DHBNZ—District Health Boards New Zealand
ECP—Emergency contraceptive pill
EMA—European Medicines Agency
EML—Essential Medicines List
FIP—Federation Internationale Pharmacists
GVS—Geneesmiddelenvergoedingssyteem (Dutch Drug Reimbursement system)
ISPOR—International Society of Pharmaceutical Outcomes Research
LTC—Long-term conditions programme
MA-PD—Medicare Advantage Prescription Drug
MedNZ—Medicines New Zealand
NDP—South African National Drug Policy
NDSS—National Diabetes Services Scheme
NMS—New Medicines Service
NZPHCS—New Zealand Primary Health Care Strategy
OECD—Organisation for Economic Cooperation and Development
OIG—Office of Inspector General
PhAS—Pharmacy Access Scheme
PHOs—Primary Health Organisations
SEP—Single Exit Price
VAT—Value Added Tax
WHO—World Health Organization

Generic Drug Policies

Helle Håkonsen[*,†], **Else-Lydia Toverud**[*], [*]School of Pharmacy, University of Oslo, Oslo, Norway; [†]Institute of Medicine, University of Gothenburg, Gothenburg, Sweden

Definitions of Generic Drugs

The definition of a "generic drug" varies across countries, based on differences in legal requirements in the generic drug approval process and if the definition includes the original drugs with expired patents. Several countries have an official country-level definition while others refer to definitions by the World Health Organization (WHO), the European Medicines Agency (EMA), or the US Food and Drug Administration (FDA) (Alfonso-Cristancho et al., 2015). Common for most definitions is that a generic drug is a medicinal product that can be manufactured and put on the market by companies, other than the company that invented it, because the original patent[1] has expired.

WHO's definition of generic drugs comprises all multi-source pharmaceutical products that are therapeutically equivalent and interchangeable, including original drugs for which the patents have expired. A multisource pharmaceutical product is a drug that can be purchased under any of several trademarks from different manufacturers or suppliers. After the patent has expired, an original drug, also denoted "single-source drug," becomes multi-source. The WHO definition is different from those of the EMA and the FDA, which do not include the original drug.

According to the EMA, which is responsible for the drug marketing authorization process in the European Union (EU), a generic drug is "a medicinal product that has the same qualitative and quantitative composition in active substances and the same pharmaceutical form as a reference drug,[2] and whose bioequivalence with the reference drug[2] has been demonstrated by appropriate bioavailability studies" (EMA, 2004). In the USA, the FDA's Center of Drug Evaluation and Research (CDER) is responsible for approval of generic drugs (FDA, 2018). Their definition of a generic drug is "a drug product that is comparable to a brand/reference listed drug product in dosage form, strength, route of administration, quality and performance characteristics, and intended use."

Bioequivalence is the main regulatory principle for generic drug approval in the EU and the USA. For two drugs to be approved as bioequivalent, they have to be pharmaceutically equivalent and their bioavailabilities (rate and extent of availability) at the site of drug action, after administration in the same molar dose under similar conditions, have to be similar to such a degree that their effects can be expected to be essentially the same (WHO, 2016). The term "pharmaceutical equivalence" requires that the two products have identical amounts of the same active ingredient in the same dosage form and route of administration, and meet the same standards of strength, quality, purity, and identity. Despite this, the active ingredients can be in different chemical forms (salt,

[1] Patents are described in "The Regulatory Process From Invention to Generic Competition" section.
[2] The reference drug is usually the original drug which was granted a marketing authorization by an authority on the basis of submitted quality, pre-clinical and clinical data (often referred to as the "brand-name drug"). Sometimes other generic drugs are used as reference drugs, for instance if the original drug has been withdrawn from the market.

ester, ether, isomer, mixture of isomers, complex or derivative of an active substance) unless they differ significantly in properties with regard to safety and/or efficacy (EMA, 2010; FDA, 2018).

The parameters used to measure bioavailability are the area under the plasma concentration–time curve (AUC) and the maximum plasma concentration (C_{max}). Average bioequivalence is established if the 90% confidence interval for the geometric mean of both the AUC and C_{max} for the generic drug is within 80% and 125% of the corresponding parameters of the drug used as reference (EMA, 2010; FDA, 2018). Measurement of these parameters is usually performed in 20–30 healthy volunteers (usually both women and men) under standardized conditions regarding food, exercise, other drug intake, smoking, and alcohol. The volunteers receive both the original (reference) and the generic (test) drug to be compared in a randomized order. If the plasma levels achieved for the two drugs are equal and the tissue distribution is equal, the original's formulation is irrelevant, and the drugs are pharmacodynamically alike.

In most countries outside the EU and the USA the legal requirements that generic drug manufacturers must follow to obtain approval for their products are less rigid. This is often reflected in the country-specific definitions, which may state that a generic drug needs to be "similar" to a reference drug. To be similar usually implies that the products contain the same active ingredient in the same amount, but that there is no hard evidence of bioequivalence or the products being manufactured under the same industry standards (Alfonso-Cristancho et al., 2015).

Naming of Generic Drugs

During the process of research and development, a new pharmaceutical substance is given a generic and "Internationally agreed Non-proprietary Name" (INN), in addition to the proprietary, or brand, name. The INN is the shortened scientific name based on the active ingredient. Names of pharmacologically related substances demonstrate their relationship by using a common "stem." The INN system was introduced by WHO in 1950 as an internationally recognized nomenclature for pharmaceutical substances. The INNs are available in the public domain, hence their designation as "non-proprietary." According to WHO, an international nomenclature for pharmaceutical substances is important for the clear identification, safe prescription and dispensing of drugs to patients, and for global communication and exchange of information among health professionals and scientists. By the use of common stems the physician, the pharmacist, or anyone dealing with pharmaceutical products can recognize that the substance belongs to a group of substances having similar pharmacological activity (WHO, 1997).

INNs are used by default as generic names in major national and regional pharmacopoeias, such as the British Pharmacopoeia and the European Pharmacopoeia. The use of INNs is normally required by national or, as in the case of the European Union, by international legislation.

Generic drugs can be either branded or unbranded products. Branded products are registered with a specific "invented" trade name while the unbranded drugs often go by their INN combined with the name of the company. Generally, most of the scientific literature uses INNs, whereas brand-names dominate the commercial information. The brand-name is designed by the pharmaceutical firm with the intention to promote brand loyalty and facilitate recognition among health professionals and patients.

The Regulatory Process From Invention to Generic Competition

Development of new drugs is a complex and resource intensive process including pre-clinical and clinical studies. It is estimated that the average cost of bringing a new drug to the market is about USD2.6 billion (2013 dollars) (DiMasi et al., 2016) and that one in six new drugs that enter clinical testing is eventually approved for marketing (DiMasi et al., 2010).

New original drugs are usually protected by patents, which are exclusive property rights that exist in the laws of sovereign states to prevent other than the innovative company from manufacturing, marketing, and selling generic versions of the drug. Patent rights are limited in duration, with the global standard being 20 years from when the application was submitted. In the area of drug development, early disclosure of inventions is seen as necessary, usually long before a resulting product is marketed. The pharmaceutical industry is, in most countries, regulated by government agencies requiring documentation of safety and efficacy, which adds time to the pre-marketing process. The time between patent submission and having the product ready for sale can therefore be longer than the sales period under patent. Of the 20 years with patent, the sales period may typically constitute 7–10 years. The legislation in some countries permits a patent holder to apply for an extension of the patent period to compensate for the loss of marketing time due to safety and efficacy regulation.

The period of market exclusivity is meant to compensate for the cost burden incurred by years of research and development. Once the patent of an original drug has expired, however, and there are no other intellectual property rights associated with the drug, other companies are allowed to start the manufacturing of generic equivalents and sell these on the market for a lower price. A lower price is anticipated for multiple reasons. Since generic drugs are bioequivalent to already approved products,[3] the manufacturers of

[3] Extensive reviews of bioequivalence data submitted to the FDA (from 1996 to 2007) have clearly demonstrated that generic drugs are pharmacologically equivalent to the original counterparts (Davit et al., 2009; Kesselheim et al., 2008). An assessment by Davit et al. showed that the average difference in absorption between the original and generic drug was 3.5% which is comparable to differences between two different batches of an original drug (Davit et al., 2009).

generic drugs do not have to repeat the pre-clinical and clinical studies that were required for the original drug and the costs associated with generic drugs are therefore less than for their original counterpart. Furthermore, the costs of manufacturing an original or a generic drug will probably not differ significantly, as they have to be manufactured under the same industry standards. In fact, it is not uncommon that the original drug and a generic equivalent are being manufactured in the same facilities. This becomes possible when innovative-based companies buy or develop their own generic department in order to pursue access to both the patent and the off-patent pharmaceutical market (Probyn, 2004). The generic manufacturers also benefit from the existence of an already prevailing market, which was developed by the previous patent holder, and can spend less economical resources on market establishment. In addition, multiple applications submitted by different manufacturers are often approved to market a single drug, creating a potential for lower prices due to competition in the market.

The Need for Generic Drug Policies

Along with rising drug expenditures, the role of economics in pharmaceutical policy has evolved drastically during the last decades. Generic drug policies, which refer to any regulation, measure or initiative, typically undertaken by the government authorities to promote the use of generic drugs, have been important in this context. The cost-saving potential for generic drugs has been attractive to health authorities worldwide as a means to tackle the long-term challenges of an ageing population, increased incidences of chronic diseases, and budgetary constraints compounded by the high cost of new drugs. The ultimate aim of generic drug policies is, however, not only to reduce drug costs but also to increase the access to and regulation of generic drugs and prevent drug shortages and supply disruption. The availability of low-priced generic drugs is especially important to increase the economical access to drug treatment in low- and middle-income countries, where the pharmaceutical market is regulated to a limited extent.

Although economic theory indicates that it should not be necessary to create policies for the generic drug market, there are several features of this market that makes regulation favorable from a payer's perspective. Due to patent protection, pharmaceutical companies may have some market power to be used in price setting, at least within certain therapeutic areas and for a certain period of time. The prices of patented drugs are therefore generally higher than what would have been the case in a market with several suppliers of the same product. In addition, the patent period allows the companies to provide physicians with brand-name specific information which may establish a brand-name loyalty that persists after the product's patent has expired (Lundin, 2000). This "first mover advantage," in combination with the fact that physicians are not economically responsible for their prescribing, makes it possible for brand-name manufacturers to maintain a high-price strategy after patent expiry, instead of engaging in price competition with generic suppliers. This phenomenon, known as the "generic competition paradox" (Kong, 2009), implies that the brand-name manufacturers may continue to target the market segment that remains loyal to the original product.

In many countries, a third party, in the form of a private or public insurer, is paying the main share of the drug costs. This significantly affects the demand elasticity and restricts prescribers' and patients' incentives for economically rational drug use. When individuals are exempted from the financial consequences of their consumption, the price sensitivity in the market falls and the demand is not reflected in the prices. Presuming that patient demand is initially responsive to the drug price, third party payment has an unquestionable positive effect on the access to drug therapy. There is, however, a negative effect known as "moral hazard" which implies that if a patient is shielded from the total costs of the drug therapy, he/she might choose differently than if he/she was fully exposed to the costs (Lundin, 2000). This might result in an undesirable increased utilization of drugs in general or an increased utilization of more expensive drugs than strictly necessary.

Regulatory authorities and third party payers have implemented various policies to directly or indirectly regulate availability and access to lower-priced generic drugs. There are in broad outline two main categories of such policies: supply side and demand side policies. These will be described in the next sections.

Supply Side Policies

Generic Drug Approval and Market Access

The most important competitive advantage for the suppliers of generic drugs is that they do not have to bear the costs of years of research and development. In addition, the substantial scientific evidence for the original drug from clinical trials as well as from real-life can be used to simplify the market authorization process for generic equivalents.

A simplified approval process for generic drugs was first introduced when the *Drug Price Competition and Patent Term Restoration Act* (known as the *Hatch-Waxman Act*) was passed in the USA in 1984. The Act included a statement that pre-clinical and clinical testing does not have to be repeated for generic equivalents of original drugs approved after 1962. Hence, it created an abbreviated pathway for approval of generic drugs. The first coherent set of bioequivalence standards was also presented in the Act. It was put in place to ensure that generic drugs would be less expensive than the original drug and thereby make it easier for generic drugs to enter the market and expand access to important drugs. In practice it means that pharmaceutical companies can submit an abbreviated new drug application (ANDA) to the FDA when they apply for market approval of a generic drug. In the application they must demonstrate that the generic drug contains the same active ingredient as the original drug (inactive ingredients, denoted

"excipients," may vary), is identical in strength, dosage form, and route of administration, is manufactured under the same strict standards as the original, and is sold in an appropriate container with the correct labeling. Generic drugs manufactured by the original companies, i.e., the previous patent holders, are exceptions from this. These so-called "authorized generics" are approved under the same new drug application (NDA) as the original drug and marketed and distributed by an authorized generic drug distributor with a generic drug product label. Authorized generics contain the same excipients as the original drug and do not differ in taste, color, size, or shape.

An abbreviated pathway similar to the one in the Hatch-Waxman Act was later included in the EU legislation by the generic market authorization application (generic MAA) described in the Directive 2004/27/EC of the European Parliament and of the Council. The generic MAA is applicable to generic equivalents to original drugs that have been approved for at least 10 years in an EU member state. If the generic drug is found to be bioequivalent to the original drug, the efficacy and safety data that formed the basis for approval of the original drug apply to the generic drug.

Another effort to increase market entry of generic drugs is to prioritize applications from companies that want to deliver generic drugs in markets where the availability of generic alternatives is scarce. In addition, it is possible to reward the company that brings the first generic alternative to the market with a time-limited market exclusivity. The shortcoming of this is, of course, that it holds other suppliers away from the market, possibly also in the long run.

The time spent to get a generic drug on the market can be reduced by permitting legal exemptions from the patent law, often referred to as Bolar provision.[4] The exemption allows other than the patent holder to use the technology of a patented drug to perform work that would assist in the marketing or regulatory approval of the generic product, while the original's patent is still in force. It includes permission for the generic manufacturer to set up and test the manufacturing and delivery capacity before entering a market, enabling marketing of a generic drug as soon as the patent expires. This legal exemption has been put in place worldwide but its nature and scope varies significantly from country to country.

Pricing and Reimbursement

Many countries, especially in Europe, have implemented price control on prescription drugs. Price control can be applied either on all prescription drugs or only on those that are included in a reimbursement scheme. A common pricing practice for generic drugs is to set the price in reference to the original drug, for instance, by giving generic drugs a price that is a certain percentage lower than the original drug—a policy called "generic drug linkage" or internal reference pricing. The policy design varies between countries with respect to the size and timing of the price reductions (e.g., immediately after patent expiry or when a generic market is established), and if the price of the original drug is subject to the same price reductions as the generic alternatives. In some countries, it has been decided that the first company to market a generic version must set a price at a certain percentage below the price of the original drug at the time of patent expiry and that subsequent market entry of other generics must be prices at or below this level (Vogler, 2012). Another approach is to incrementally reduce the price of a drug according to predefined rates, depending on sales volume (Dalen et al., 2011).

There are also pricing practices that do not directly restrict the companies' freedom to set drug prices but affect prices in a more indirect manner. The intention is to decrease the sales of more expensive drugs by encouraging patients to opt for more cost-effective drugs. Indirect price controls can also be denoted as "incentive-based" systems since they depend on how the different stakeholders behave in response to the incentives in the system. In such a system the stakeholders (i.e., patients in the role as consumers and pharmacists in the role as sellers) are rewarded (positive incentives) or punished (negative incentives) depending on whether they behave in accordance or deviation with how the makers of the system want them to behave.

A generic reference price system is a typical example of an incentive-based strategy. This strategy is based on the premise that drugs are generically interchangeable and can be clustered into "reference groups" of similar drugs. Each group is assigned a reference price, which is the reimbursement price for the drugs in that particular group.[5] For drugs that are more expensive than the reference price, the patient has to pay the cost above the reference price. The reference price is often set around or below the average price of the generic drugs, or at the lowest price in the cluster. A "not too low" reference price has been advised for a brief, initial period, to provide incentives for more generic suppliers to enter the market.

It is also possible for the third party payer to reimburse only one of a few drugs within a certain cluster, typically the least expensive drug in the group. This stimulates a price competition when new generic drugs enter the market because the companies compete to be the preferred supplier within the cluster. An undesired consequence, however, might be that some generic drug suppliers, whose products have not been selected for reimbursement, are forced out of the market, thereby reducing the generic competition. Another strategy is to offer patients low-cost generic drugs without co-payment. If generic drugs are available free of charge, the presumption is that patients' demand will shift away from expensive brand name drugs toward cheaper generics.

[4] Named after the case Roche Products versus Bolar Pharmaceutical in 1984, a court case in the USA related to the manufacturing of generic pharmaceuticals.

[5] Other levels of reference-based pricing exist where the reference groups constitute drugs that are analogues (chemically different) and drugs that are therapeutically similar and used to treat a particular condition. Most countries, however, have adopted the "generic" approach which has relatively small implications for patients' drug therapy but thereby also limited cost saving potential (Ioannides-Demos et al., 2002).

Tendering

Tendering is another way to encourage price competition in the pharmaceutical market. In the context of drugs, tendering can be explained as any formal and competitive procurement procedure through which tenders (offers) are requested, received, and evaluated for the procurement of drugs and where the contract is granted to the pharmaceutical company/importer who submits the most advantageous offer.

Tendering has traditionally been applied in the hospital sector, for separate hospitals or for groups of hospitals at a regional or national level. The latter is a form of tendering referred to as joint procurement. Joint procurement enhances the hospitals' purchasing power over the pharmaceutical companies by stimulating the companies to lower the prices of one or more drugs to obtain the exclusive right to distribute these to the hospitals.

More recently, several countries have made use of tendering also in the outpatient off-patent sector, effectuated by governmental authorities or private health insurance companies. WHO reports that even supranational initiatives have been suggested to make the procurement process more efficient and strengthen the supply management systems in countries which are facing financial challenges in the healthcare sector. In the WHO European Region report on improving access to drugs through public tendering, three main groups of tenders to be used for generic drugs are described: open tender, restricted tender, and competitive negotiation (WHO, 2016). An open tender implies that bids are invited from any supplier which fulfills the terms and conditions specified in the announcement. This is in contrast to a restricted tender where interested suppliers need to be approved in advance, for instance through a prequalification process that takes into account adherence to good manufacturing practices, past supplier performance, financial viability, and similar. Restricted tenders can also be conducted in a step-wise manner where the lowest price offered is published without announcing the name of the bidder before other qualified bidders are invited to submit lower offers. In a competitive negotiation, a preselected number of suppliers are invited to submit price offers, followed by negotiation to achieve a better price or particular arrangements.[6]

To win a tender can imply large delivery requirements that some suppliers have problems fulfilling because they are unable to keep up with manufacturing to meet the demand. To minimize the risk of supply disruptions and secure sustainability, the contracts can be divided between two or more companies.

Demand Side Policies

Generic Prescribing

An important way to try to control drug expenditures is to influence prescribing patterns. Generic prescribing, or prescribing by INN, implies that the prescriber writes the active ingredient name instead of the brand name on the prescription. This may be enforced as an indicative or mandatory prescribing practice. Generic prescribing is supposed to contribute to rational drug utilization and prevent prescribing and dispensing errors.

Since mandatory generic prescribing was introduced in the UK in 1968, many countries worldwide have little by little put in place a similar practice for either a selection of therapy groups or all groups where generic drugs are available. No matter if generic prescribing is indicatively or mandatorily enforced, important additional measures are to teach practicing physicians as well as medical students to prescribe by INN and implement prescribing software that supports such prescribing. From the 2000s onwards, more and more countries have installed electronic prescribing systems which can be designed with a default generic drug choice. This has been found to give an immediate and sustained increase in the proportion of generic drug prescriptions (Malhotra et al., 2016). Applied in hospitals, generic prescribing does not only stimulate generic drug use in the hospital, it also affects the use after discharge. If the hospital physicians prescribe generic drugs upon patient discharge, these drugs are quite likely to be dispensed at retail level and possibly also affect prescribing in primary care.

It is crucial to note, however, that generic prescribing in itself does not stimulate generic drug use unless pharmacists choose to dispense a generic drug. Therefore, incentives for pharmacists to sell less expensive drugs should also be implemented (described in next section).

Generic Substitution

Generic substitution is the practice where pharmacists substitute a prescribed drug with a generically equivalent drug. This kind of substitution is economically rational in situations where the prescribed drug is more expensive than the generic alternative that is available in the pharmacy. It also has positive effects beyond the economic argument because it makes it legal to switch to a different brand if the prescribed one is unavailable.

In countries with mature healthcare systems, the national drug authorities normally decide if a drug is substitutable with another drug based on generic interchangeability. In the same way as for generic prescribing, this policy may be indicative or mandatory. For generic substitution policies to be successful, it is of principal importance to have in place proper incentives for pharmacists to dispense generic drugs. This can for instance be in the form of a system that financially rewards the pharmacists for dispensing

[6] This method has for instance been used in the negotiation of reduced prices for antiretrovirals conducted by the United Nations Children's Fund (UNICEF) and the Clinton Foundation.

generic drugs, by extra dispensing fees or higher margins for generic drugs. Pharmacy-owners may be offered discounts by generic drug suppliers who want to enter the market or increase their market shares, something that may increase the pharmacy's profit. To prevent the entire discount from being retained at the retail level, and to ensure economic benefit to the patient and/or the third party payer, generic substitution can be combined with other policies, for instance generic reference pricing (described in "Pricing and Reimbursement" section). The opportunity to perform generic substitution is considered important for a successful outcome of a reference price system. If the pharmacist is not allowed to select the cheapest/reimbursable drug in a reference group, the consumer shift mechanisms will easily be undermined. On the other hand, a reference price system, which is combined with generic substitution, allows the pharmacist to retain some of the difference between the price of the drug and the reference price if they dispense a drug below the reference price. This makes, in many situations, an attractive financial incentive for pharmacists.

Financial incentives for pharmacists, however, are of limited value if patients do not accept the substitution. In most countries, patients are provided with an opportunity to refuse generic substitution and request a specific brand (often the brand specified on the prescription). The decisive point is whether patients are financially punished by having to pay an additional cost (a "brand premium") if they refuse substitution. In some countries, the patient has to pay the full price of the drug if they are unwilling to accept the generic drug that the pharmacist has to offer. In addition, the physician may also have the opportunity to exempt the patient from generic substitution and, possibly, the extra payment.

It is an evidence-based argument that policies that allow generic drug companies to set their own prices, while giving physicians and pharmacists incentives to prescribe and dispense the least expensive product, are more effective at reducing prices over time than direct regulation of prices (Wouters et al., 2017). Despite being rewarded with higher margins on generic drugs, pharmacy-owners are not necessarily collaborative when the aim is to bring down prices in the long-term (Håkonsen et al., 2009). It is therefore of importance to get the incentives right in both short and long perspectives, properly adjusted to the distribution power in the market, so that market actors do not sideline the strategies.

Targeted Information and Academic Detailing

Physicians play an important role in the uptake of generic drug use since they make the final decision of what to prescribe. They also have a more indirect role because their views on generic drugs may be reflected in the views of their patients. Patients generally prefer exactly the drug prescribed by their physician but tend to accept generic substitution if they perceive that the physician is positive toward generic drugs (Håkonsen and Toverud, 2012). Physicians might, however, be unaware that generic drugs are available and/or that they are sold at a lower price. They might also have scarce knowledge about the bioequivalence requirements for generic drugs and hold opinions that generic drugs are inferior to brand-name drugs. Particularly in countries with less mature healthcare systems, physicians are concerned about generic drug suppliers' trustworthiness (Toverud et al., 2015), sometimes with good reason.

To raise the acceptance of generic drugs among physicians, it is crucial to provide them with appropriate information, which will also prevent potential misconceptions and increase the extent of generic prescribing (if allowed). This can be achieved by targeted information campaigns or academic detailing involving meetings with clinical consultants (e.g., physicians and pharmacists) who give the physicians unbiased, evidence-based information about generic drugs. A follow-up measure is to combine this with feedback on their prescribing behavior. The feedback can include detailed information about the prescribing rates of generic and original drugs, the costs per defined daily dose of drugs prescribed in each category, the rate of reservation against a generic being dispensed and the potential savings if generic drugs are being consistently used.

Academic detailing can also be organized as sessions where physicians discuss their prescribing patterns, with or without the presence of pharmacists. So-called "pharmacotherapeutic discussion groups" or "quality circles for pharmacotherapy" give physicians the opportunity to exchange information and experiences which eventually can change their prescribing behavior. These sessions also have the potential of changing physicians' knowledge and perceptions of generic drugs and increase the proportion of generic drug prescriptions (Spiegel et al., 2012).

Finally, a principal measure to increase familiarity with generic drugs is to focus on INNs instead of brand names in health professional education systems. The education curricula should also make sure that students gain sufficient insight into the principles of generic equality and interchangeability.

Prescribing Budgets and Indicators

The abovementioned policies to stimulate generic prescribing are sometimes combined with financial incentives for physicians. For instance, physicians can be given a prescribing budget (or a quota) that puts restrictions on how much they can prescribe (Rashidian et al., 2015). If they choose to prescribe low-cost generic drugs instead of more expensive brands, their budget will cover more prescriptions and minimize the chances of running financially short during the budget year.

Another approach is to implement a pay-for-performance policy, whereby prescribers or their organizations are financially rewarded for their prescribing behavior (Rashidian et al., 2015). As a generic drug policy, this could take the form of additional payment for increased generic prescribing or reduced payment for prescriptions of expensive original drugs. As an indicator for rational prescribing, the percentage of prescriptions for certain generic drugs versus more expensive drugs within different drug classes can be monitored by the third party payer. In addition to increasing the share of generic dispensing, this facilitates the understanding and evaluation of the prescribing practices for the policy maker and forms the basis for prescriber feedback.

Public Information Campaigns

Although generic drugs are equivalent to the original drug, they may have other names, colors, and shapes because of the other excipients. Patients may have specific preferences for using a certain brand and be opposed to substitution to a drug they are unfamiliar with. For instance, patients who know their drugs by name and appearance might find it more demanding to keep track of their drugs if they are dispensed a different brand of generic. A review of studies from high-income countries showed that although generic substitution and generic drugs are well accepted by most patients, about one-third report negative experiences with generic drugs (Håkonsen and Toverud, 2012). Patients of higher age and/or low educational level seemed more likely to hold negative views toward generics while the results were inconclusive regarding variables such as sex and income.

There are many potential reasons why someone might hold negative attitudes toward generic drugs. It is a common notion that lower prices imply poorer quality and this applies to drugs as much as for other products. Studies show that patients make tradeoffs between price and perceived quality in relation to the seriousness and complexity of the condition they are treating when choosing among original drugs and generics (Al-Gedadi et al., 2008; Ganther and Kreling, 2000; Heikkilä et al., 2007). Particularly, when patients have to bear only a small share of the cost themselves, they tend to choose perceived quality over cost. Even in countries without public healthcare and limited access to private health insurance, patients tend to choose the most expensive brands, which they can afford within their budgets, in attempts to avoid counterfeit and substandard drugs. Although counterfeit and substandard drugs can be available under different names, brand-names as well as INNs, and be offered at any price, there is general skepticism toward the cheapest generics, especially if they are labeled with unknown names (Håkonsen and Toverud, 2011).

Lower prices, however, are a double-edged sword. Price differentials have also been shown to have considerable effects on peoples' decisions to opt for the cheapest alternatives (Dalen et al., 2011; Rizzo and Zeckhauser, 2009). Personal economic benefits, in terms of reduced co-payments or avoidance of an additional cost, are decisive factors in patients' acceptance of generic drugs regardless of income. In addition, patients' choices are influenced by knowledge, previous experience with the drug and information from friends, family, and media.

Hence, policies to improve the knowledge of and attitudes toward generic drugs in the general population are crucial supplements to the other presented generic drug policies. Information campaigns through mass media have resulted in public awareness of important health-related topics (e.g., more rational use of antibiotics, how to quit smoking, what to do in case of a heart-attack) and could be a useful channel for unbiased information about generic drugs. Physicians, pharmacists, and other healthcare personnel should also provide information, on the condition that they possess appropriate information themselves.

Evaluation of Generic Drug Policies

The objective of generic drug policies is to promote the use of generic drugs and thereby maximize health gain for the population by efficiently allocating limited resources. Price reduction and market share of generic drugs after patent expiry are commonly used indicators for the success of generic drug policies. It has been argued, however, that a methodological framework should also take into account the robustness of the generic market, which is operationalized as the availability of generic drugs and the time of generic entry. The main argument is that patients may already be switched to other therapeutic options that are still under patent protection if generic drugs are brought to market months after the original brand lost its exclusivity. In a framework by Kanavos (2014) the following five indicators are proposed to address the robustness of a generic market: (1) availability (whether a generic is available after loss of patent exclusivity); (2) time delay and speed of generic entry (i.e., how soon a generic enters the market); (3) number of generic competitors (i.e., is there a sufficient number of competitors to stimulate price competition; (4) generic volume share evolution (i.e., does generic volume increase its share relative to the originator brand); and (5) price developments (i.e., do prices decline significantly post-patent expiry, is the amplitude of price reduction following generic entry related to the price level at patent expiry, and is there a link between the magnitude of price reduction post-patent expiry and generic market share).

In the evaluation of generic drug policies and the robustness of the generic market, it is important to consider the possibility of price segmentation within a country. Particularly in low- and middle-income countries, drugs may have higher prices in private pharmacies targeting wealthier customers while lower prices are offered in public pharmacies (WHO, 2016). In some low- and middle-income countries the price level on selected drugs in the private sector is higher than in high-income countries. Therefore, studies should report prices in private versus public sectors in relation to international reference prices.

Multiple factors might attenuate the efficiency of generic drug policies related to health outcome and subsequent health expenditures. Drug non-adherence and medication errors might be unintended consequences of generic drug policies leading to lost opportunities to improve or maintain a patient's health status and increased costs of therapy. The costs can be divided into direct costs due to increases in drug use, physician visits, and/or hospitalization rates, health benefits forgone (human cost and opportunities lost), and indirect, productivity costs (personal and social economic burden). In total, the economic consequences of these problems might be substantial; potentially counterbalancing some of the savings gained. In the pursuit of short-term decreases in costs, there is a concern that the result could be increased long-term costs, e.g., costs due to increased morbidity and mortality resulting from suboptimal drug use. There are also other costs involved in implementing and managing the different policies including the development of a feasible regulatory framework, implementation of necessary changes in administrative and computer systems, and education of healthcare and administrative personnel. It is, therefore, important that savings are compatible with administrative costs in the short and long-term.

Global Considerations

In low-income countries, particularly, low-cost generic drugs have made medical treatment possible for large parts of the population. Despite this, it is estimated that about one-third of the world's population lacks sustainable access to essential drugs (WHO, 2008). Most of the generic drug policies described in this chapter are examples of policies implemented in mature healthcare systems in high-income countries. In less developed countries, where essential drugs are not always available or affordable to those who need them, pharmaceutical markets are relatively unregulated and free from pharmaceutical measures to enhance generic drug use. Prescribing guidelines and prescribing facilitators (such as electronic prescribing systems) are scarce and so are policies for drug pricing and maximum mark-ups. It is also a challenge that generic drugs manufactured in countries that do not have stringent regulatory authorities can create product-quality risks due to improper control routines and lack of bioequivalence requirements. Other challenges in the implementation of generic drug policies in low- and middle-income countries include legal barriers associated with regulatory and intellectual property policies (lack of harmonized regulatory provisions among stakeholders, data exclusivity, patent linkage, patent extensions) and financial barriers to the uptake of generic drugs (Kaplan et al., 2012). Low salaries for prescribers and dispensers, ownership of pharmacies by physicians, low mark-ups for the dispensing of generic drugs, or dispensing fees as a fixed percentage of price are examples of the latter (Kaplan et al., 2012). As described in "Generic substitution" section, proper incentives for pharmacists to dispense generic drugs are a prerequisite for a successful outcome, otherwise generic drugs would only be offered to the poorest patients.

To promote the use of quality assured generic drugs also in less mature healthcare systems, WHO has developed a guideline for low- and middle-income countries on how to implement effective pharmaceutical pricing policies (WHO, 2015). Besides policies to promote uptake of generics via an increased number of market authorizations and reduced timelines, the guideline focuses on policies to ensure quality and safety, including the monitoring of good manufacturing practice (GMP), publication of inspection reports, post-market surveys, sanctions for false quality claims, and documentation of bioequivalence.

Conclusion

Although the definition of a generic drug varies between countries, there is a universal understanding that generic drugs are medicinal products that can be manufactured and marketed by companies other than the innovator company after the original patent has expired. The ultimate aim of generic drug policies is to increase the global access to and regulation of generic drugs, reduce drug costs, and prevent drug shortages and supply disruption. The availability of low-priced generic drugs is important to increase economical access to drug treatment in low- and middle-income countries. Despite this, most of the existing policies, which are described in this chapter, remain unimplemented in the less mature healthcare systems.

Healthcare professionals, particularly physicians and pharmacists, have important roles in the uptake of generic drugs since they make the final decision on what to prescribe and dispense. They also have important roles in their encounter with patients whose confidence in generic drugs often depends on proper information from health professionals.

Glossary

Active substance: A substance that alone or in combination with one or other substances is considered to fulfill the intended activity of a drug.
Bioavailability: The rate and extent to which the active substance or active moiety is absorbed from a pharmaceutical form and becomes available at the site of action.
Bioequivalence: When two drugs contain the same amount of the same active substance(s) in the same dosage forms and the bioavailabilities of the two drugs after administration in the same molar dose are similar to such degree that their effects, with respect to both efficacy and safety, will be essentially the same.
Generic drug: A drug whose original patent has expired (various definitions are presented in the text).
Generic drug policy: Any regulation, measure or initiative, typically undertaken by the government authorities to promote the use of generic drugs.
Internationally agreed non-proprietary name: A unique public drug name, usually similar to the name of the active substance, that is globally recognized.
Market exclusivity: Exclusive marketing rights granted by the government authority upon approval of a drug. Can be granted if statutory requirements are met.
Multisource product: A drug that can be purchased under several trademarks from different manufacturers or suppliers.
Patent: Exclusive property rights to prevent other than the innovative company from manufacturing, marketing, and selling generic versions of the drug.
Pharmaceutical equivalence: When medicines contain the same amount of the same active substance(s) in the same dosage forms that meet the same or comparable standards.
Price control: When government authorities set the price of a drug and/or indirectly influence it.

Reference drug: A marketed drug used as comparator in the assessment of bioequivalence and market approval of generic drugs.
Third party payer: A public or private organization that pays or insures health or medical expenses on behalf of beneficiaries or recipients.

The Social Determinants of Health Inequalities: Implications for Research and Practice in Social Pharmacy

Paul Bissell, School of Human and Health Sciences, University of Huddersfield, Huddersfield, United Kingdom

Introduction

The causes and consequences of health inequalities (and their implications for research and practice) have not, it is fair to say, been a notable feature of the body of work that we refer to as social pharmacy. By contrast, the previous three decades have witnessed a burgeoning number of empirical studies, numerous reviews, and growing political awareness about the social determinants of health inequalities (Wilkinson and Pickett, 2009; Wilkinson and Pickett, 2018). The field of epidemiology and public health, focusing on health inequalities, has risen in prominence with a finding that an individual's social position (whether this is measured by social class, education, or deprivation) profoundly shapes their health outcomes. To illustrate this using deprivation as a marker of social position, the recent Global Burden of Disease study showed that males who lived in the most deprived areas of England in 2013 could expect to have a life expectancy which was 8.2 years shorter than those living in the least deprived areas (Newton et al., 2015). If we were to look at social class or education, we would also see wide differences in health outcomes (Wilkinson and Pickett, 2009). There are, of course, huge inequalities in health outcomes when we compare health outcomes within and between different countries. For those who want to know more about this literature, there are numerous reviews (Dorling, 2010; Graham, 2007; Wilkinson, 1996; Wilkinson and Pickett, 2009, 2018).

While the cumulative effects of a lifetime of disadvantage and poverty are well known and well researched, the focus of the debate in recent years around the causes of health inequalities has moved towards understanding the health consequences of living in an unequal society, as measured by levels of income (or wealth) inequality. For example, Richard Wilkinson and Kate Pickett argue that the greater the level of social inequality within a country, the more likely that the country is to experience a worsening of a range of health and social problems(Wilkinson and Pickett, 2009, 2018). Their proposition is that it is inequality, per se, as well as poverty, disadvantage, and education that impacts on health (through what are referred to as bio-psycho-social processes). This set of arguments has gained considerable traction among researchers, commentators and epidemiologists, and even amongst politicians. However, as indicated, health inequalities have not been a particular focus of concern within social pharmacy.

This lack of attention to the macro determinants of health and illness, I will argue, is a feature of the wider landscape of social pharmacy and pharmacy practice research, focused as it is on the micro-determinants and organizational features of health services, rather than looking up-stream towards those factors that shape health outcomes at the macro level (Bissell and Traulsen, 2005).

In this chapter, I will describe some of the key arguments that have led to focus on social inequality as a key determinant of health inequality, while also seeking to make clear the relevance of these arguments in the world of social pharmacy and pharmacy practice research.

The Historical Background

As noted earlier, contemporary social epidemiology has shown that unequal societies have worse health and well-being than those that are more equal (Wilkinson and Pickett, 2009). In some ways, this is not a new argument. From Friedrich Engels onwards, many commentators have shown how the external world impacts our bodies. It is not difficult to appreciate (at least historically) how the cumulative impact of lack—for example lower levels of income, education, lack of employment, a lack of high-quality housing, environmental pollution, etc.—impact both physical and mental well-being. For example, back in the 19th century in Europe, the massive social changes that accompanied industrialization and urbanization, gave rise to a set of living conditions that condemned

some sections of the population to short and dangerous lives, while at the same time enriching a small number of the population. The impact of these changes on health in England is vividly described here:

> "the rates of smallpox, typhus, typhoid fever, diphtheria and scarlet fever all increased: two cholera epidemics swept through the warrens of the Great Towns, a third was on its way . . . industrial capitalism gave rise to novel physical arrangements for working and dwelling (the factory, the company, the town) that created new patterns of economic exploitation (mass displacements from land, urban migration in unprecedented numbers, wage labour) . . . hazardous and fatiguing work, damp cold, and stifling living quarters, cheap gin and adulterated foods, demoralisation – the legacy of disease bequeathed by early capitalism stems from such an environment." (Susser et al., 1985)

It is easy to understand how the working conditions characterizing capitalism in the 18th and 19th century shaped broader health outcomes, given the massive transformations that were taking place at this time. However, bringing this up-to-date, researchers now argue that it is the pyscho-social experience of living in an unequal society (rather than simply the material impacts of poverty, poor housing, hazardous working conditions as described earlier) that fundamentally shapes health experiences and outcomes.

This chapter describes the evidence and 'causal mechanisms' with respect to this literature, focusing in particular on Wilkinson and Pickett's ground-breaking work "*The Spirit Level*" (published in 2009) and their second book "*The Inner Level*" (published in 2018). This is a compelling set of arguments and has relevance to all researchers working in the field of health and illness––and to pharmacy practice researchers. Michael Marmot put it starkly:

> "Health inequalities result from social inequalities. Action on health inequalities requires action across all the social determinants of health" (The Marmot Review, 2010 Executive summary).

Before setting out the evidence, it is worth making the point that much of the work in social epidemiology is focused on socio-economic aspects or classed aspects of inequality. It is of course recognized that inequalities arise from other axes of difference (gender, age, ethnicity, region, etc), and the intersections between these are hugely important to understanding health outcomes. However, for reasons of space and in order to make clear their core arguments, this study focuses on socio-economic aspects of inequality.

Core Debates and Arguments Within the Social Determinants of Health

The starting point for much writing on health inequalities goes back to seminal research from the 1980s. The Black Report, published in 1980 in the United Kingdom, noted that the causes of health inequalities should not be attributed (as was common within political parlance at the time) to failings in the National Health Service. With the benefits of hindsight, this is a good example of focusing on the proximal cause rather than the distal causes of health inequalities. Having a comprehensive health service, free at the point of use, politicians (and epidemiologists) initially found it hard to understand why health inequalities in terms of outcomes arose since treatment was available to all. The Black Report, although initially ignored by the incoming Conservative administration, focused its attention on many of the 'upstream' social factors that 'get under the skin' and shape outcomes–such as poor housing, diet, income, and education.

In other words, the argument was that if one wants to understand health outcomes, one not only need to understand failing in health service provision, but also to understand how a range of socio-economic factors that disadvantage individuals and populations, shaped these outcomes. As many readers will know, the Black Report adopted four broad types of explanation for health inequalities. These were (in shorthand) a materialist explanation, a cultural/behavioral explanation, an explanation framed around social selection/drift, and the artifact explanation. It is important to bear in mind that the types of explanations framing health inequalities were very much a feature of their time, but they still provide a solid framework that facilitates understanding. The "artifact" explanation, that the inequalities were a product of the data collection strategies, has largely been rejected. The social selection argument, for which there is some support, argued that people who experience poorer health in early life end up being poorly equipped in terms of skills for the jobs market, which then results in ill health. The evidence suggests that some conditions, such as schizophrenia, do result in downward social mobility but the numbers of individuals experiencing this is small and insufficient to account for the patterns we saw earlier.

By contrast, materialist and cultural/behavioral explanations were more avidly taken up and have provided the starting point for frameworks that identify the underpinning factors, and hence, what might be the best approaches to tackle health inequalities. But before teasing out the nature of these explanations, some general comments on the history of the epidemiology of inequalities in health are given.

Contemporary debates about the root causes of inequality have often involved making moral judgments about those who have the poorest health outcomes. For example, it was commonplace to hear that those who lived in 'squalor' in the 19th century were responsible for their poor health outcomes and political commentators repeat a similar pattern today. The health of the poorest is still often referred to as an outcome which reflects suboptimal and deficient decision making and today the term 'lifestyle decisions' is often pointed to when seeking to make sense of the health outcomes of the poorest in the UK population. Something of the same argument can be seen in discussions about the social determinants of health inequalities. Jenny Popay and others have referred to this as the 'lifestyle drift' argument, common within many health policies, where the behavioral choices impacting chronic diseases are held to be the core reason for poor health outcomes, denying the salience of material living conditions, or the wider social determinants. Popay et al. (2010) note:

"'lifestyle drift'—the tendency for policy to start off recognizing the need for action on upstream social determinants of health inequalities only to drift downstream to focus largely on individual lifestyle factors."

To move onto some of the key issues here, debates about the role of environmental factors versus the role of individual, behavioral and biological factors has most extensively been studied in countries that have passed through the "epidemiological transition," and some understanding of the epidemiological transition is important for pharmacy practice researchers who may not be familiar with this.

The epidemiological transition refers to the point in the development of a country when the epidemic diseases of poverty, such as water-borne and infectious diseases, cease to be the major causes of mortality and are replaced by the cancers, cardiovascular, and other degenerative conditions familiar in the developed world (Wilkinson, 1996), which require both a functioning health system and some level of self-management of life-style to effectively manage them. An easy way of understanding this is that once national income (usually described through per capita income) rises, there is a very clear and rapid increase in life expectancy. However, at a particular point or threshold (and this is typically seen above around $25,000 per capita), any further increase in national income per capita do not typically feed into higher levels of life expectancy. Prior to this point, increase in income per head, produces increase in life expectancy. For example, as per capita income increases, basic public health infrastructure (better nutrition, better sanitation, and education) all feed into increased life expectancy. Mortality patterns at this point prior to the epidemiological tradition, see high rates amongst the most vulnerable––infants, under-fives, and the elderly––these groups being most sensitive to basic public health measures and infrastructural developments. But once beyond a certain point (the epidemiological transition), the picture changes.

The key point to understand here is that social inequality in health is the level of inequality in a given society. Health in the richer, more affluent societies loses its linear relationship with national income per capita, but within a given country the familiar gradient from rich to poor is maintained, and the health and a range of social problems show a relationship with the extent of inequality and not with average income. What is entirely clear, is that if we look at a country like the United Kingdom, what is seen is wide and increasing levels of inequality, which have clear health consequences.

There is substantial evidence about both the size (and the increasing size) of the gap in incomes and health consequences of such inequality. In the recent years there have been debates about the strength of the relationship between social and health inequality.

Inequality, Health and Social Problems

One of the most impressive aspects of the work of Wilkinson and Pickett, in *The Spirit Level* is their construction of an Index of Health and Social Problems, which extends their perspective beyond inequality and its association with health, using a wide range of studies and national and international datasets. This index uses data on levels of trust, mental health, life expectancy, infant mortality, morbidity, obesity, educational performance, teenage births, homicide, and imprisonment rates and social mobility to argue that what appears to be the underpinning variable for *all of them* is income inequality. In other words, inequality is the *fundamental causative factor* not simply one of many variables (Wilkinson and Pickett, 2009).

It is this argument that represents a shift, and one reflected in the Marmot report that has implications for public health policy and research. *The Spirit Level* was widely criticized for its methodological underpinnings, including data selection methods, statistical techniques, but perhaps most importantly, its central argument––that inequality is bad for all of us and that addressing problems one-by-one and leaving the income gradient untouched, would have little impact on health and social problems. However, their work is extended in their most recent book *The Inner Level* (2018), and backed up by an independent review of the evidence (Rowlingson, 2011) that concluded that the evidence for these claims and the underlying explanatory framework was strong. Indeed, although authors may have been critical of their central claims, it is also the case that there have been attempts to support and extend their arguments (Bissell et al., 2016).

Moving on, what accounts for the impact of inequality on health. this study sets out Wilkinson and Pickett's explanations below, alongside those that have taken a different approach. The study starts with the neo-material explanation that is often counter-posed to that adopted by Wilkinson and Pickett (2009). An understanding of this is important to understand how their explanation deviates from this.

Neo-Material Explanations

Neo-material arguments for health inequalities, follow the Black Report's emphasis on the absence or presence of material resources and have an obvious salience. They are perhaps best understood through some straightforward explanations. Neo-materialist explanations for inequalities in health emphasize the *"combination of negative exposures and lack of resources held by individuals, along with systematic under-investment across a wide range of human, cultural and political-economic processes"* (Lynch, 2000, p. 1001). This is a fairly straightforward explanation to understand. What is being said here is that the cumulative, life-course exposures to negative circumstances (for example, repeated experiences of unemployment, under-employment, poor housing, exposure to pollution) along with a lack of resources (a regular income and other economic resources) to manage these negative exposures, are clearly and obviously detrimental to health in the long term. What is often added into this argument, is the consequence of a lack of investment

in a welfare state that might ameliorate the worst effects of these negative circumstances, particularly for the poorest populations. The neo-materialist explanation focuses on the practical, tangible economic resources and circumstances faced by individuals, and it is these, authors argue, that accounts for the majority of the inequalities in health.

In many ways, this is a straightforward argument since it emphasizes on some obvious strategies that people deploy in order to manage their health. For example, if there are delays in obtaining health care (long waiting times for a particular treatment), then it is an obvious point that those with resources can obtain faster treatments by skipping waiting lists and taking services of the private sector. Similarly, they may find it easier to purchase those goods and services that offer health benefits (gym membership, physiotherapy services, counseling, etc.) Of course at the same time, this argument also assumes that all population groups are equally oriented to health and the prevention of ill-health but we know that this may not be the case (Bissell et al., 2016).

On the other hand, however, it is difficult to see how ownership of some of the goods that the neo-materialists argue have an impact on health and well-being could do so by exclusively or primarily material pathways. For example, possession of more than one car is unlikely to have a direct positive effect on health particularly for those who personally own more than one car (Dorling, 2010). Indeed, it could be argued that the effect could be a negative one resulting in reduced incentives to walk or take exercise. In contrast, it could be argued that any health gain is more easily explained by the prestige or status attached to owning two cars (Marmot, 2004). This issue of status is at the heart of the psychosocial argument of the study discussed in the next section.

Psychosocial Explanations

Psychosocial explanations––associated with Marmot, Wilkinson and Pickett (2009), have always recognized that access to goods and services, for adequate health and safety at work and comprehensive health care are key social determinants. However, their argument picks up from a point largely over-looked by neo-materialists. The evidence demonstrates that when behavioral risk factors and these material determinants are controlled for studies, they typically only explain less than half of the gradient in mortality. In other words, there remains an excess of mortality not explained by material factors alone. In order to situate and explain this finding, the psychosocial explanation focuses on three areas: the damaging effects of stress in early life, lack of friends or social engagement, and the focus here, shaming or invidious social comparisons that aggravate the consequences of greater social inequality. This, it is argued, has a key impact on health across the life course and is not taken into account by those espousing neo-materialistic explanations.

Arguments around social status and the deleterious impacts of shaming social comparisons loom large in their account. Wilkinson and Pickett (2009, 2018) argue that what is central to the experience of living in an unequal society is a process of social status differentiation involving shaming evaluations of the self in relation to socially salient others, up and down the income ladder. This is crucial to grasp, and is a very different argument to that advanced by neo-materialists. What Wilkinson and Pickett (2009) are arguing is that humans are constantly weighing up, both consciously and unconsciously, their place in the social hierarchy and this involves making finely tuned assessments of one's status in relation to others. In order to feel shame or shame related discomfort, we need to be in a position to care about or value the opinions or views of another. Wilkinson draws extensively on the work of sociologist Thomas Scheff who viewed shame as *"**The** social emotion"* (p.79 emphasis in the original). According to Scheff, who was supported by a few other sociologists, humans are intensely evaluative beings and on a day-to-day level this means we are constantly monitoring threats of exclusion from the bonds and connections with others which are central to our lives. To understand this, Wilkinson and Pickett (2009) describe this in the following way:

> "Greater inequality seems to heighten people's social evaluation anxieties by increasing the importance of social status. Instead of accepting each other as equals on the basis of our common humanity as we might in more equal settings, getting the measure of each other becomes more important as status differences widen . . . If inequalities are bigger, so that some people seem to count for almost everything and others for practically nothing, where each one of us is placed becomes more important." (Wilkinson and Pickett 2009 p. 43–44).

Their argument, therefore, is that contemporary unequal societies present more opportunities for people to feel shame, both chronic and acute and there are limited resources, particularly for the poorest, to protect themselves from these shaming social comparisons (unlike those further up the social hierarchy). These comparisons are often a source of considerable anxiety especially amongst those with the least resources in society, and one of the impacts as individuals ruminate on and seek to manage these, is an increase in 'othering' (Peacock et al., 2014). Indeed, in the latter paper, I have sought (with others) to extend their ideas about shame in the context of inequality that emanate from Wilkinson and Pickett (2009) work. In particular, we have sought to incorporate what Andrew Sayer refers to as low level shame, or, drawing on the work of the sociologist Pierre Bourdieu, shame that might be part of the *habitus*. For example, we might think of the impacts of shaming social comparisons in terms of acute, high level actions, which result in burning shame. However, as Sayer argues, it is more likely that shaming social comparisons are woven into the fabric of daily lives and are experienced in rather more prosaic ways. For example, we argue in the above paper:

> "The most harmful shame in the context of depression is chronic rather than acute. This may be similar to what Sayer (2005: 153) has described as 'low level shame', characteristic of unequal societies and far more difficult to access than acute shame, forming not just a backdrop to life but a sense of being woven into everyday experiences, and experienced as part of the habitus. For the least advantaged this can mean repeated exposure to numerous minor and major incidences of disrespect, mis-recognition or symbolic violence, starting in childhood and running throughout the life-course" (Peacock et al., 2014, p. 392)

To be clear, Wilkinson and Pickett (2009) are arguing here for a very different sort of explanation than that of the neo-materialists; their point is that a society which focuses on hierarchy holds those at the top as the most successful, most valuable and worthy, which can have very deleterious health impacts for others. As Wilkinson and Pickett (2009) argue, living in these types of societies produces social stressors that enter the body through particular pathways and it is these stressors that have an impact on health and well-being. This study briefly outlines these pathways in the final section below.

The Biology of Stress- How Inequality Gets Inside the Body

There is a growing body of evidence, drawn from evolutionary psychology and from other disciplines, which has shown bodily responses, and in particular blunted and raised level of cortisol in the blood (Wilkinson and Pickett, 2009). In short, their argument is that the anxieties about social status (in an increasingly stratified and unequal society) find their way into the body through heightened awareness of others social position. Social comparison and shame, they argue, are fundamental to this process and there is a literature from evolutionary psychology that supports their position. Awareness of these inequalities, it is argued, is a process of ruminating and reflecting on these inequalities that produce blunted and raised cortisol level that further impact on the working of the immune system (Wilkinson and Pickett, 2009).

Conclusion and Relevance to Pharmacy Practice

Health inequalities and their social determinants form the framework in which pharmacists operate and provide services—dispensing medicines, prescribing, giving advice, and treatment. Understanding how the 'outside gets inside' provides important contextual information for pharmacists, even if they feel there is little they can directly do as practitioners to impact these wider determinants. Of course, one area where they can be involved and make an impact, is through advocacy work, alongside other health professionals and policy makers at the local and national level. This is certainly an area where other health professionals have been focusing their activities. This is no different for the profession of pharmacy.

The new evidence described in this study shows that inequality has an "independent" effect on health that cannot be tackled without narrowing the gap between rich and poor. Interventions at the level of providing information or trying to persuade individuals to change practice can impact, but only at the local level and will leave the wider social determinants unaffected. Indeed, there are currently many initiatives seeking to address health inequalities that prefer to focus on "nudging" individuals into making better choices. There is limited evidence these will have a positive impact.

However, by contract, placing inequality at the center of policy and practice opens up the possibility of both advocacy and auditing for public health practitioners, including pharmacists. This chapter has sought to extend knowledge about how these inequalities manifest themselves, and awareness of this can be brought to bear on specific issues advocacy may extend to challenging some of the approaches of government if there is no evidence base to sustain them.

What does this mean for pharmacy practice researchers and why is it important to know more about the social determinants of health inequalities? Too often, pharmacy practice researchers make assumptions about the lifestyles of the poor without an appreciation of the macro factors shaping health outcomes. It is important for pharmacy practice researchers to be aware of these factors (Bissell and Traulsen, 2005). Pharmacists can act as advocates for change at the level of the social determinants. This chapter encourages this transformation and wider awareness of the social determinants of health inequalities.

Managing Cultural Diversity in Pharmacy Practice in the United States

Barry A. Bleidt[1], Sociobehavioral and Administrative Pharmacy, College of Pharmacy Nova Southeastern University, Ft. Lauderdale, FL, United States

Nomenclature

Culturalkinetics—movement along the Cultural Competency Continuum as new patients or cultures are encountered

> *"America's health care system is neither healthy, caring, or a system"*
>
> Walther Cronkite

Challenges patients face in accessing the health-care system generally that originate in early experiences of life. These obstacles include difficulties with literacy level, numeracy comprehension, cultural estrangement, and problem-solving skills. It is a paradox being a patient, moving from everyday life into the mysterious realm of the sick role is an enormous change. As a person enters into the "patient world," numerous aspects of his or her existence change (Bleidt et al., 2018), some examples are as follows:

- You have to engage, and you may not understand who you are;
- You hear many strange and ominous sounding words, and phraseology may be difficult to understand;
- You enter the health-care culture; there are idiosyncratic ways of doing things and strange rules;
- You have to adapt to a distinct time perspective; tasks run on specific time with significant waits to then rush to do something or you are asked to wake up in order to take your medicines;
- You are enclosed in a small place with little room for an extended or larger family to visit;
- You have to don strange garb that makes you feel more vulnerable and makes you look unappealing and immodest;
- You are not sure what the expectations of you are, creating an uncomfortable situation.

Being a patient is complicated. You come into a realm that is very different from your daily routine. You have to remain in this strange realm during the length of treatment, which, in the case of a severe chronic condition, may be for the rest of your life. This new existence usually runs parallel with day-to-day life; thereby, making it more involved. This intricacy can be considerably exacerbated in a patient with numeracy or low health literacy (Bleidt et al., 2018).

As the population changes in the United States and worldwide, the pharmacy profession must adapt to these transformations of a motley society in order to serve our patients better. To manage diversity successfully in our practice settings, we must become more

[1] Dr. Bleidt does not believe in race as a subdivision of humankind. When asked, he identifies himself as a member of the human race. The concept of race was an artificial construct developed by British sociologists used to justify slavery and treating others with less dignity than deserved. This chapter reflects these views.

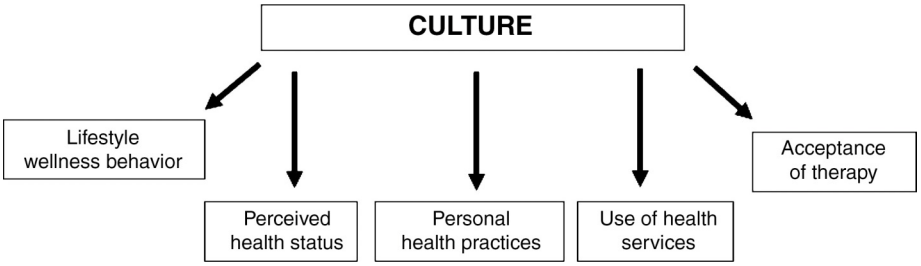

Figure 1 Influence of culture on a patient's health beliefs and health. *Source: Adapted from Bleidt, B., 1992. Understanding multicultural pharmaceutical education. In: B. Bleidt (Ed.), Multicultural Pharmaceutical Education. Pharmaceutical Products Press, New York, NY, pp. 141–150.*

familiar with the concepts of health (what is it), of culture (what does it entail), time (as a construct of culture), and of other social determinants of health. Health was defined as "a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity" by the World Health Organization (WHO, 1948, p. 1).

The culturally competent delivery of patient-centered care involves the recognition and understanding of cultural differences between pharmacists, as caregivers, (including pharmacy staff) and their patients. This process involves acquiring and utilizing specific tools and skills to gain mastery over these dissimilarities. A patient's cultural influences have an impact on his or her health-care choices and the ultimate outcome.

Introduction

In order to illustrate a key point, I often ask people "what is the most popular condiment in the United States?" Without fail, I receive the same answer—ketchup. This answer would be correct, if it were earlier than 1993. The sales and use of ketchup were surpassed by salsa in 1992. Thus, signaling a tremendous change in the taste buds of Americans and demonstrating the impact of cultural influences on society. Much has changed in the years since in society, in health care, and in food. Now, tortillas outsell burger and hotdog buns and tortilla chips are more popular than potato chips (Hirsch, 2013).

The 2001 Institute of Medicine (IOM) report, Crossing the Quality Chasm, described several components that need to be present to ensure high-quality care for all (IOM, 2001). Among these factors were that health care should be patient-centered, timely, and equitable. Fig. 1 illustrates the influence of culture on a patient's health beliefs and health. Health disparities among different groups are attributed to poorer overall health and decreased health outcomes.

In this chapter, culture will be defined, its role and influence as a social determinant of health will be explored, and the concepts of cultural awareness and cultural competency, which are the foundation of a patient-centered approach in pharmacy practice, will be examined. Managing cultural diversity in all practice settings, through a culturally competent awareness and approach, will lead to better outcomes and wellness. The chapter will also present the necessity for culturally competent services delivery, along with an exploration of what is involved in a practitioner's cultural integration journey.

What is Culture?

Culture is defined as "the totality of socially transmitted behavioral patterns, arts, beliefs, values, customs, life-ways, and all other products of human work and thought characteristics of a population of people that guide their worldview and decision-making" (Purnell and Paulanka, 2012, p. 2). In pharmacy, culture plays an essential role in patient–pharmacist communication. The health literacy and numeracy level of your patients are also strongly influenced by culture (Bleidt et al., 2018). "Even though culture is only one part of health literacy, it is a very important piece of the complicated topic of health literacy" (Office of Disease Prevention and Health Promotion, 2007).

In an individual patient, their culture is probably a significant determinant (AHRQ, 2015; Bleidt and Coleman, 2018) in:

- How they perceive illness overall
- How they interpret their current condition (serious or not)
- What the family's role will be in their care plan
- What their expectations are from the health-care system
- Why they may be distrustful of systems
- How medical or pharmaceutical decisions are made
- What their beliefs about medicines are
- How adherent they will be to their prescribed treatment(s)
- What the role of alternative therapy will be
- How traditional healing practices will impact care

Table 1 Health-care scenarios affected by culture

Cultural domain[a]	*Potential domain components*	*Pertinent health-care scenario*
Overview, inhabited localities, and topography	Heritage, residency, migration patterns, educational status, occupation	A group of people of a similar culture could live in areas where residents may not have easy access to fresh food or local grocers ("food deserts").
Communication	Language, dialects, cultural interaction patterns, temporal relationships, format for names	Colloquialisms may not be familiar to the health-care provider causing the provider to have difficulty perceiving common social cues from their patients.
Family roles and organization	Decision makers, matriarchal versus patriarchal priorities, alternative lifestyles	Family hierarchy of gender roles may dictate who receives patient counseling information or who the caregiver is for a patient.
Workforce issues	Conflicts in the workplace, professional autonomy	Immigration status may affect the patient's eligibility to receive employee health benefits.
Biocultural ecology	Client's physical, biological, and physiological variations	Specific ethnic groups may have an increased risk to be afflicted by a certain disease state, such a hypertension or cancer.
High-risk behaviors	Use of alcohol, tobacco, and other recreational drugs	It may be permissible to engage in promiscuous heterosexual encounters, but unacceptable to have a monogamous homosexual partner in certain cultures.
Pregnancy and childbearing practices	Sanctioned vs. unsanctioned fertility practices and practices related to pregnancy, birthing, and postpartum care, nursing/breastfeeding	Certain cultures may have no concept of the need for prenatal or postnatal care.
Death rituals	Death, euthanasia, burial practices, bereavement	Some cultures may require touching of remains although highly communicable disease could be present (e.g., Ebola). Others need to dispose of the body before sunset or within a certain timeframe (Winslow, 1920).
Health-care practitioners	Status, use and perceptions of traditional, magico-religious practitioners, and biomedical health-care professionals	Some cultures may consult advisors or healers prior to or instead of seeking treatment from health-care practitioners.
Health-care practices	Health-seeking behaviors, folklore practices, beliefs regarding blood transfusions, organ donation	A patient could employ alternative healing practices such as cupping or coining instead of or in addition to Western medicine modalities.
Spirituality	Religious practices, use of prayer, meaning of life, individual sources of strength, health-care practices related to these beliefs	A patient could require the presence of a spiritual advisor as a member of their health-care team or see their illness as part of God's plan.

[a]Cultural Domain headings expanded from: Purnell and Paulanka (2012).

Source: Bleidt, B., Coleman, C., 2018. Culturalkinetics: Cultural perspectives in public health. In: Introduction to Public Health: A Primer for Pharmacists, second ed. Jones and Bartlett Publishers, Sudbury, MA.

As ethnic diversity continues to expand, it becomes more important to understand that cultural considerations must be recognized as an integral factor in patient care to a greater extent than in past years. Cultural values and norms can be a determining factor in self-management of a disease, health-seeking behaviors, and cross-cultural communication with health-care practitioners. Health-care providers who fail to recognize that culture is the background for many of the decisions made relating to health will most likely encounter mistrust from the patient in addition to possible professional frustration from the lack of impactful patient outcomes due to patient nonadherence (Purnell and Paulanka, 2012). In **Table 1**, *Health-care scenarios affected by culture* contain material from the 12 domains of culture discussed by Purnell and Paulanka with an adapted situational aspect related to patient care in the Pertinent Health Care Scenario column from Bleidt and Coleman (2018).

Culturally Competent Care in Pharmacy Practice

Providing culturally competent care is a major contributor to reducing the more expansive concern of health disparities (U.S. Department of Health and Human Services, 2010). Disparities in health outcomes exist; they affect groups of patients who may experience more or larger obstacles to access or participate in the health-care system. These discrepancies in care, many of which will be discussed in more detail later, may be based on, among others (Surgeon General, 2014):

- Ethnicity
- Gender
- Gender identity
- Age
- Rurality
- Socioeconomic class

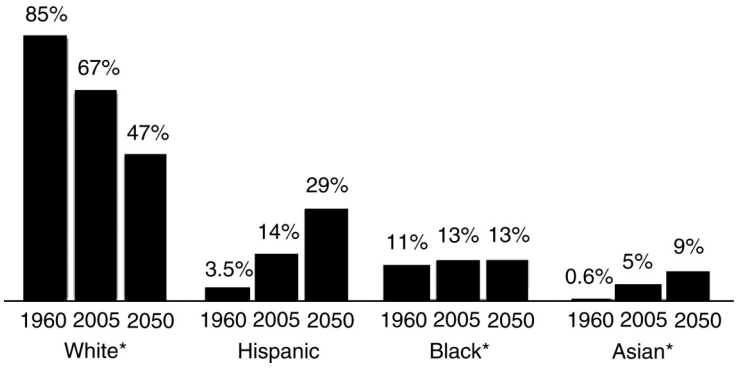

Figure 2 Population by ethnicity 1960, 2005, 2050. Note: All races modified and not Hispanic (*); American Indian/Alaska native not shown. *Source: From Passel, J.S., Cohn, D.V., 2008, February 11. U. S. population projections: 2005–2050. Washington, DC. Retrieved from http://pewhispanic.org/files/reports/85.pdf.*

- Religious beliefs
- Disability

There are other nuances to comprehending culture and its influences. The first is that each person is a member of numerous cultures. The dominant culture manifested may depend upon the circumstances. There may also be contradictory messages sent due to competing dominant cultures.

Second, some aspects of culture are more visibly obvious in an individual (such as ethnicity, gender, or religion), while other aspects may not be as readily apparent at all (such as religion, sexual orientation, or gender identity). Third is that there can be tremendous diversity within a defined culture. For example, Latino or Hispanic cultures are incredibly diverse, representing customs, beliefs, and values from different hemispheres and many countries. Fourth, some cultures to which a patient may identify may not be immediately recognizable as a distinct culture by a novice during his or her cultural-integration journey (Bleidt and Coleman, 2018). Examples of these cultures may include:

- Lifestyle (vegan, cross fit, couch potato); and
- Health professional (versus lay person);
- Generational (to which generation does a patient belong);
- Disability (psychological, mobility, emotional);
- Primary spoken language (e.g., English, French, Creole, Arabic, Spanish);
- Gender (transsexual, questioning).

Delivering culturally competent care that is respectful to a heterogeneous patient population is a very complex proposition. The complexity of this situation will multiply as both the United States and world populations become more diverse. Historically, the failure of the U.S. health-care system to recognize the influence of culture has had a negative impact on the health and well-being of the populace and has challenged how we value the individuality and autonomy of a patient.

The cultural composition of the U.S. population is evolving continuously and rapidly expanding. By 2050, the population is expected to increase to nearly 440 million people, showing an approximately 48% growth since 2005. Projections indicate that those who are now considered minorities will be a collective majority in 2050. Fig. 2 provides a graphical representation and ethnic breakdown of the U.S. population for the years 1960, 2005, and 2050 (Passel and Cohn, 2008, February 11).

The rapid growth and substantial changes projected over a 90-year timeframe provide a clear road map of how and why culture has become such a huge influence on health. Also of interest is that 20% of the 2050 population will include new immigrants to the United States.

The Need for Cultural Competence in Pharmacy Practice

To serve an increasingly diverse population better, it has been suggested that there is a need to increase the ethnic and gender diversity among health-care practitioners (National Academies, 2016). Much of this need is born from the fact that minority clinicians are notably more inclined to practice in minority and medically underserved areas than their nonminority colleagues (Smedley et al., 2004). Across the United States and other countries, there are many medically underserved communities and populations. Most reported health inequities and disparities can be found in these Medically Underserved Populations (MUPs) located within Medically Underserved Areas (MUAs) and also in places designated as "Health Professional Shortage Areas" (HPSAs) (Health Resources and Services Administration, 2016, July 1).

Medically Underserved Populations are comprised of clusters of people who face cultural, linguistic, literacy, and other obstacles to accessing health care. A *Medically Underserved Area* is defined as a region "designated by Health Resources Services Administration as having too few primary care providers, high infant mortality, high poverty or a high elderly population" (U.S. Department of Health and Human Services, 2018). MUAs can span an entire county, several adjoining counties, or multiple urban census tracts. HPSAs are

SNPhA is an educational service association of pharmacy students who are concerned about the profession of pharmacy, healthcare issues, and the poor minority representation in these areas.

The purpose of SNPhA is to plan, organize, coordinate, and execute programs geared toward the improvement of the health, educational, and social environment of minority communities.

Figure 3 SNPhA Mission Statement. *Source: Student National Pharmaceutical Association, 2018.*

locales that have shortages of primary medical, mental health, or dental providers. There areas cut across rural and urban settings, different types of populations, or a variety of medical facilities. The defining factor is that patients within a HPSA have difficulty accessing needed medical, dental, and mental health services due to a shortage of primary care clinicians (Health Resources and Services Administration, 2016, July 1).

Facilities having a greater diversity among health professionals have been shown to have an increase in patient satisfaction, more choices for the patient of clinicians, improved patient–pharmacist communication, and greater access to care for minorities (LaVeist and Pierre, 2014; Smedley et al., 2004; Williams et al., 2016). Pharmacy is privileged to feature a student professional society, Student National Pharmaceutical Association, whose mission is "to improve the health of the medically underserved and increase the number of minority pharmacists" (SNPhA, 2016). The SNPhA was formed by students in 1972 as an independent organization (SNPhA, 1972) to promote these interests among student pharmacists. SNPhA's Mission Statement is presented in Fig. 3; it explains the many clinical initiatives and activities undertaken and targeted at improving the health outcomes of medically underserved people.

SNPhA operates six (6) core patient outreach initiatives; among them are chronic kidney disease, HIV, AIDS, and diabetes. As part of its diligence, SNPhA measures and records the number of clinical events and patient interventions. In 2016, there were more than 108,000 patient encounters, primarily performed in MUAs showing that the student pharmacists in SNPhA have a significant impact on the health and wellness of the population they serve (SNPhA, 2018).

Cultural Competence

The delivery of effective and efficient pharmacy, patient-centered care necessitates a keen awareness of the similarities, nuances, and differences of the different cultures to which a patient identifies. Fig. 4 presents the stages involved in one's personal journey toward a proficient level of cultural integration (Bleidt, 1992). A practicing pharmacist can be at several different points along this continuum; his or her location depends on which culture(s) she or he is encountering at that point in time. This journey has no set starting gate, because learned techniques, practices, and skills gleaned from one cultural engagement advances the pharmacist along the continuum as new cultures are encountered. A pharmacist evolves toward a proficient mastery of cultural integration with each new and repeat cultural experience.

This continuum can be applicable to both organizations and individuals. The five demarcations along the continuum are meant as benchmarks to self-assess progress. Stage 1, *Cultural Insensitive*, can be considered as not being aware of cultural differences and their impact on health or not wanting to learn about diverse cultures. *Cultural Awareness* begins with a self-examination of one's own cultural background, what makes it unique, how it compares to the encountered culture, and what bearing these findings may have. In the *Cultural Sensitivity* stage, pharmacists build on the growing awareness and begin to develop a deeper cultural knowledge about others, but have not yet assimilated this knowledge into practice successfully. In the penultimate stage, *Cultural Competency*, the pharmacist becomes more proficient at identifying cultural influences and acquires a competent level of knowledge-based skills so that he or she is able to communicate more appropriately with patients of other cultures. The pharmacist is aware of valued norms and rules and the pharmacist–patient relationship is valued from the patient's perspective. In the last stage, *cultural integration*, the learned cultural knowledge and skills are easily placed into practice to serve the patient more efficiently and bring about better outcomes (Bleidt and Coleman, 2018).

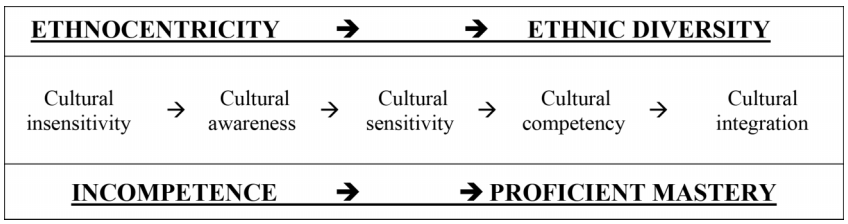

Figure 4 Journey toward cultural integration based upon the Cultural Competency Continuum. *Source: Adapted from Bleidt, B., 1992. Understanding multicultural pharmaceutical education. In: B. Bleidt (Ed.), Multicultural Pharmaceutical Education. Pharmaceutical Products Press, New York, NY, pp. 141–150; Bleidt, B., Coleman, C., 2018. Culturalkinetics: Cultural perspectives in public health. In: Introduction to Public Health: A Primer for Pharmacists, second ed. Jones and Bartlett Publishers, Sudbury, MA.*

A proficient, culturally integrated pharmacist has possession of sufficient skills, knowledge, abilities, and attitudes to deliver optimum patient-centered pharmacy care to a broad array of ethnic and cultural backgrounds. Organizations, facilities, or practitioners may be able to progress through the stages more rapidly due to greater support and resources; this progression makes patients feel more comfortable.

Culturalkinetics

The process of Culturalkinetics is "defined as the movement along the Cultural Competency Continuum as new patients or cultures are encountered" (Bleidt and Coleman, 2018). It involves understanding that other cultures may not share the same views or values as you do. This process starts with using established cultural baseline norms, being vigilant of the very small distinction between these norms and stereotyping. These models are used with each new encounter until sufficient data can be obtained from a cultural assessment of the patient. Then, the more relevant, individualized information is used in partnering with the patient on his or her care. With each patient encounter, more data can be gathered until a more complete understanding of who he or she is can be achieved.

The Culturalkinetics process, when applied correctly, results in better patient bonding. It is a continuous process of self-awareness and self-improvement. As more specific knowledge is gained about a culture or a patient, this information about cultural nuances and how they affect attitudes and health behaviors can be utilized. Through this process, one becomes more sensitive, understanding, and empathetic about cultural variances. Finally, cultural integration is reached when a practitioner is truly skillful in adapting and responding to those differences within appropriate contexts and circumstances.

The Golden Rule, "do unto others as you would have them do unto you," is derived from the Holy Bible; "as ye would that men should do to you, do ye also to them likewise" (Luke 6:31). It is a very common maxim relating to patient care, among other things. A much more patient-centered approach to care can be established using the Culturalkinetics process; this involves using the Platinum Rule, which states "do to others as they would have you do unto them" (Popper, 1966). This approach is more culturally competent, more sensitive to others, and more empathetic. This philosophy adjusts for the fact that different people want to be treated differently in similar circumstances. By accommodating the feelings of others, you are stating that you want to understand what they want, before initiating care.

Culturalkinetics utilizes a set of developed aptitudes needed to culturally assess a patient. According to Bleidt (1992), these skills include:

- identifying and empathizing with ethno-specific problems (such as bigotry, acculturation);
- respecting the person as an individual and his or her rights to be treated as a unique human being (autonomy);
- respecting those who appear to be different as equals (acceptance);
- being able to communicate at the patient's literacy level without appearing to be condescending;
- being an active, empathetic listener, and being courteous;
- appreciating, without prejudgment, contrasting value systems and beliefs that a patient may hold;
- being able to relate to the medically underserved;
- discovering something unique in a patient's background and using this connection to establish a rapport with them;
- using cross-cultural approaches to solve individual problems; and
- valuing cultural differences.

From the above list of essential skills, the behaviors and values most relevant to culturally competent organizational policies and processes can be embodied within standards and guidelines of the institution. Standards developed in this manner would, by definition, include an expanded definition of culture beyond race or ethnicity and a broader perspective on health, settings, and services provision. This philosophy is reflected in the 2016 National Center for Cultural Competence recommendations. To achieve cultural competence, an institution must:

- have a defined set of values and principles and demonstrate behaviors, attitudes, policies, and structures that enable them to work effectively cross-culturally;
- have the capacity to (1) value diversity, (2) conduct self-assessment, (3) manage dynamics of difference, (4) acquire and institutionalize cultural knowledge, and (5) adapt to diversity and the cultural contexts of the communities they serve; and
- incorporate the above in all aspects of policymaking, administration, practice, and service delivery and involve systematically consumers, key stakeholders, and communities (NCCC, 2016, para. 3).

Culturally and Linguistically Appropriate Services Standards

Public health is differentiated from health-care delivery in that it is concerned with issues that impact the health outcomes of populations in contrast to the health of an individual. A population can be defined as a small number of people within a community or as widespread as the people moving among different countries. Today, the burden, both financial and personal, of preventable, chronic diseases and the existence of world-wide communicable diseases substantially affect and challenge the public health and health-care systems. Winslow (1920), described Public Health as the "science and art of preventing disease, prolonging life and

promoting health through organized efforts and informed choices of society, organizations, public and private, communities and individuals" (Winslow, 1920, p. 30).

When public health issues arise that could affect health negatively, it is paramount to both identify and prioritize these concerns using a realistic framework that leads to positive action and solution. Dr. Silvia J. Rabionet, Associate Professor of Public Health at Nova Southeastern University College of Pharmacy, identified eight conditions that must be met for an issue to be defined as a public health problem (Bleidt and Coleman, 2018). These criteria are:

1. Does it affect the health and well-being of the population?
2. Is it widespread and increasing in scope and magnitude within a population or in a subgroup of a population?
3. Does it affect health-related and other societal resources (e.g., economic and social impacts)?
4. Does it challenge cultural norms and/or raise questions about core values?
5. Does its solution rest in collective measures and interventions based in disease prevention, health promotion, and education?
6. Does it require interprofessional collaboration?
7. Does it call for organized government intervention? and
8. Does it merit urgent action?

In the 1990s, the issues of health disparities and culturally ignorant care brought about many discussions and calls for action to find solutions to these now-better-defined public health problems. Activities undertaken to resolve the deficiency in culturally competent care in the past have included interprofessional teamwork, accrediting body guidelines, and governmental action, both regulatory and legislative. As a result of these factors, culturally competent care delivery has the criteria to be classified as a public health problem.

In response to the calls for action, the Office of Minority Health (OMH) released the National Standards for Culturally and Linguistically Appropriate Services in Health Care (CLAS Standards) in 1999. Since then, they have been the foundation for health-care organizations' endeavors to reduce health disparities, improve quality of care, and improve health equity (Office of Minority Health, 1999, 2001).

The relationship between the social determinants of health (SDH) and health was emphasized in the Introduction Section to the 1999 CLAS standards. The SDH include "those conditions in which individuals are born, grow, live, work, and age" (WHO, 2016), such as level of education, socioeconomic status, and the accessibility of health services.

Although the original 14 guidelines have been modified several times, the primary aim of these standards is unwavering: to facilitate health-care delivery for minority populations. These standards are targeted toward health-care organizations and the types of services that these organizations should provide in a culturally competent environment. Some of the particular services include:

- staff education in cultural and linguistic service delivery;
- language assistance provision including interpreters;
- strategic plan promotion, highlighting goals and policies in providing services to diverse populations; and
- collaborative partnerships development within the community.

OMH updated the CLAS Standards in 2012 to elucidate their meaning and expand their scope. In this revision, the former Standard 1 was designated as the Principal Standard, to "[p]rovide effective, equitable, understandable, respectful, and quality care and services that are responsive to diverse cultural health beliefs and practices, preferred languages, health literacy, and other communication needs" (OMH, 2013, p. 31). If the other 14 standards were successfully adopted and sustained, then the Principal Standard would be achieved. The remaining standards were divided into three categories. **Table 2** lists the standards for each of these categories.

The Joint Commission developed a document to reveal more clearly how their standards and performance elements match with the CLAS Standards. This crosswalk of CLAS Standards to Joint Commission Standards was developed for hospital accreditation and ambulatory care, among others. The latest version was released in 2014 (Joint Commission, 2014).

The principal goal of Western medicine is to provide optimal care for ALL patients. To realize this objective, health-care practitioners need to acknowledge and understand the existence of cultural variations and beliefs among their patients. The ethos of patient-centered care in pharmacy practice (pharmaceutical care or pharmacy care) is very compatible with delivering personalized care. This process considers how a patient's culture impacts her or his illness, as well as how the patient will accept the therapy. It is also cognizant of the relationship between the pharmacist and patient and how you communicate with them.

As the last century was ending, several agencies of the Federal Government began work on an ambitious project aspiring to decade-long targets designed to improve the health of the nation. Similar projects were being initiated in the European Union and other places. The U.S. Department of Health and Human Services (DHHS), in September 1990, released the first version of its strategy for improving the overall health of American citizens by the turn of the millennium (US DHHS, 1991). *Healthy People 2000*, National Health Promotion and Disease Prevention Objectives, set over 300 objectives that were proposed to be met in 10 years. Subsequently, *Healthy People 2010* and *Healthy People 2020* have been developed, approved, and implemented (US DHHS, 2000, 2010). A key target of *Healthy People 2000* was to decrease health disparities in America. *Healthy People 2010* took a step further and set a goal of eliminating health disparities. The current version, *Healthy People 2020*, went even further and set a goal to achieve health equity. These reports associate a patient's health with the broader social determinants of health espoused by the World Health Organization (WHO, 2016) and the United States (Secretary's Advisory Committee, 2010, July 6).

Table 2 National standards for Culturally and Linguistically Appropriate Services (CLAS) in health and health care

Principal Standard: Provide effective, equitable, understandable, respectful, and quality care and services that are responsive to diverse cultural health beliefs and practices, preferred languages, health literacy, and other communication needs.	
Theme 1: Governance, Leadership, and Workforce	1. Advance and sustain governance and leadership that promotes CLAS and health equity
	2. Recruit, promote, and support a diverse governance, leadership, and workforce
	3. Educate and train governance, leadership, and workforce in CLAS
Theme 2: Communication and Language Assistance	4. Offer communication and language assistance
	5. Inform individuals of the availability of language assistance
	6. Ensure the competence of individuals providing language assistance
	7. Provide easy-to-understand materials and signage
Theme 3: Engagement, Continuous Improvement, and Accountability	8. Infuse CLAS goals, policies, and management accountability throughout the organization's planning and operations
	9. Conduct organizational assessments
	10. Collect and maintain demographic data
	11. Conduct assessments of community health assets and needs
	12. Partner with the community
	13. Create conflict and grievance resolution processes
	14. Communicate the organization's progress in implementing and sustaining CLAS

Culture and Time

One major characteristic of unique cultures that seems to baffle one's understanding of it is the concept of time. Time has a unique significance within each culture. Having an appreciation of how a patient views time can be very beneficial to the pharmacist–patient relationship. In general, time can be viewed as mono-chronic (linear) or poly-chronic (multiway, nonlinear). A past, present, and future exist in the linear concept of time (Lewis, 2014).

Patients from Northern Europe and the US tend to be linear in how they experience time. In general, they view it as a priceless, continuous, limited commodity (Lewis, 2014); it can be lost (wasted), banked (saved), transferred (given), or used (spent). Linearly, time can also be described as spare (free) or overtime (bonus). In countries inhabited by linear-active people, time is money; it is both clock- and calendar-related (Helman, 2005). Behaviors are inclined to be based on the premise that the past is done and the present can be used to plan, so that time can be worked more efficiently in the immediate future.

Patients from Southern Europe and the Middle East tend to view time as nonlinear (Lewis, 2014). In general, patients from these regions may be more multiactive and manage their time differently from linear time followers. In these cultures, the best way to invest time is generally considered to be engaging and completing in a human transaction. They consider time to be less important than the closeness of the relationship and their interaction between parties; sometimes, these transactions are so important that the actual time of the meeting or appointment is irrelevant (Lewis, 2014). To people part of these cultures, time is considered as an event or as a commodity that can be shaped, allotted, or manipulated (Helman, 2005). To linear time followers, nonlinear time followers seem to pay very little attention to promptness or schedules.

In many Eastern cultures, time is generally seen as cyclic and is considered cosmological (Lewis, 2014). In cyclical time cultures, there is a limitless supply of time; therefore, it is not considered as a scarce commodity. As the sun rises and sets every day, seasons follow from one to the next, people age and die, but their children live on; these cultures view this as a form of timelessness (Lewis, 2014). A health-care professional from a mono-chronic culture may take a cyclic culture patient's action, or lack thereof, as either not understanding the severity of the medical situation or as being apathetic when dealing with his or her ailments. Neither assumption would be correct. A patient from a cyclic culture may be slow to follow-up on an appointment and only seek assistance when something is awry. After all, life begins at some points, ends at another, and the passage is slowly paced. Managing cultural diversity with cyclic-minded patients requires that a pharmacist comprehends that past and present decisions, must harmonize with the patient's future, and that medication may only be needed when the body "calls for it" (Helman, 2005).

There are other cultural concepts of time and with limited space allotted to this chapter, they will not be further discussed. For further information on this topic, one useful reference is *Cross-Cultural Concept of Time: Chronemics* from Communcaid, which can be found at the following URL: https://www.communicaid.com/cross-cultural-training/blog/chronemics-concept-of-time/. However, another example of a time perception cultural difference that really stands out involves the Malagasy culture, people from Madagascar. They envision their future as passing them from behind. The future becomes the past as it unfolds in front of them. That, which is visible, what is in front of them, is considered the past. Both the past and the present are observable and understood; "the future is totally unknown and therefore it is 'behind' or as some put it: 'none of us have eyes in the back of our head'" (Dahl, 1995). It is time that moves from behind and moves past you, you do not move through time.

Implications for Pharmacists and Pharmacy Practice

Pharmacists play many roles in delivering patient-centered pharmacy care. It is our responsibility to recognize that culture is not simply defined by ethnicity. It is a labyrinth that can only be navigated when factors such as customs, wellness values, health beliefs, language, gender identity, sexual orientation, among others are fully grasped (Bleidt, 1992).

An individual pharmacist's journey along the Cultural Competency Continuum can be made easier or more difficult by the organization or facility in which he or she practices. The following recommendations are presented to show what can be done to foster a more culturally-competent environment within practice sites. These suggestions are an excellent place to begin the ongoing voyage toward the proficient mastery of cultural integration (adapted from Brown and Nichols-English (1999)):

- Respect and value the differences and similarities in people and cultures;
- Establish an environment that is supportive to practicing multicultural, patient-centered, pharmacy care;
- Work to ensure that adequate resources are allocated to build a foundation for these purposes, such as staff and clinician training on an ongoing basis (including attendance at courses and workshops) and patient education materials;
- Help build an atmosphere where pharmacists and other practitioners are able to adapt their practice in response to changing patient demographics and differences in the population they are serving;
- Accept techniques, tactics, and approaches for dissimilar cultures; and
- Build better patient-care teams by reinforcing collaborative relationships with other health-care providers.

By identifying, acknowledging, and comprehending the factors that can lead to health disparities, pharmacists are able to make changes in their practice and service delivery in a more culturally competent manner to all their patients. By using the culturalkinetic process, the pharmacy environment can be made more welcoming for different groups and by incorporating health promotion and disease prevention initiatives, pharmacists will be able to enhance the overall health of local communities. Through minimizing or eliminating communication barriers, the quality of care improves (Vanderpool & Ad Hoc Committee on Ethnic Diversity and Cultural Competence, 2005).

Several national pharmacy organizations have adopted policies in support of culturally competent, patient-centered, pharmacy care. Acknowledged by the House of Delegates and Board of Directors of two of the most influential professional societies, these policies, which directly relate to cultural competence, for the American Pharmacists Association (APhA) are located in Appendix I and for the American Society of Health-System Pharmacists (ASHP) in Appendix II.

Wrap-Up

As presented throughout this chapter, there is a need for practicing pharmacists to understand that diversity and culture are not simply defined by a patient's ethnicity. Culture is a complex labyrinth that can only be solved when aspects such as customs, language, literacy level, values, health beliefs, religion, among others, irrespective of ethnicity, are understood. To be an excellent manager of diversity in pharmacy practice, one must first move forward sufficiently on the Cultural Competent Continuum and apply what has been learned to each patient encounter. Throughout this chapter, the process of Culturalkinetics and how to journey toward cultural integration were detailed to provide a template of a roadmap along this quest.

In the absence of culturally competent care, the dearth of understanding of the values, priorities, time, and fears of patients more than likely will lead to miscommunication between clinician and patient. Medical misadventures, poor diagnosis, and inadequate responses to medications and other treatments follow. Possessing the abilities, techniques, and skills to be able to interpret and comprehend patient-specific nuances are indispensable for those seeking pharmacy services.

Being culturally competent at the highest levels encompasses the abilities, attitudes, collective knowledge, and aptitudes of pharmacists to provide optimum services to a wide variety of ethnically and culturally diverse patients. This journey begins with developing the proficiencies to assemble and organize relevant cultural information. The first step is to ascertain if the patient needs a cultural assessment. Then, if the answer is yes, collect cultural information along with the other data that is needed to serve a patient well.

At the proficient mastery level of *cultural competency*, cultural integration, pharmacists consider individual differences in each patient worthy of recognition. These skills are becoming more valuable in an increasingly diverse society and more important as pharmacists encounter more patients who are immigrants or visitors from other countries. Pharmacists who use these abilities to help their patients also welcome people from other cultures not covered in this chapter, such as, to name a few:

- Disabled persons
- Lesbian, gay bisexual, transgender, intersex, and questioning (LGBTIQ) persons
- Speakers of English as a second language
- People from various religions
- People from different generations
- People from diverse geographical location (e.g., rural versus suburban or urban)
- People of all socioeconomic status

Many of the above-mentioned groups have been marginalized by the health-care system for too many decades.

One of the best philosophies for managing diversity in pharmacy practice is to follow the Platinum Rule, a more culturally competent variation of the Golden Rule (Popper, 1966). "Treat others the way they want to be treated." The Platinum Rule distinguishes among personal and cultural preferences and engages the patient as an autonomous being with the right to be treated as he or she feels is appropriate.

Acknowledgments

The author would like to acknowledge the tremendous assistance he received from two of his Advanced Pharmacy Practice Experience students, Rodolfo Sigler and Sean Murphy. They were instrumental in discovering resources and references on time conceptualization and finding cultural perspective points of view. I would also like to mention the contributions of a student worker, Doris Terry. She assisted in developing cultural reference points as well.

Appendix I American Pharmacist Association Cultural Competence Policies

APhA Policy: Cultural Competence (2005)

1. Recognizing the diverse patient population served by our profession and the impact of cultural diversity on patient safety and medication use outcomes, APhA encourages pharmacists to continually strive to achieve and develop cultural awareness, sensitivity, and cultural competence.
2. APhA shall facilitate access to resources that assist pharmacists and student pharmacists in achieving and maintaining cultural competence relevant to their practice.

(JAPhA NS45(5):554 September/October 2005) (reviewed 2006) (reviewed 2011) (reviewed 2016)

Cultural Health Beliefs and Medication Use (2006)

1. APhA supports culturally sensitive outreach efforts to increase mutual understanding of the risks and other issues of using prescription medications without a prescription order or using unapproved products.
2. APhA supports expanding culturally competent health care services in all communities.

(JAPhA NS46(5):561 September/October 2006) (Reviewed 2009) (Reviewed 2014)

Appendix II ASHP Cultural Competence Policies

1613 Cultural Competency

Source: Council on Education and Workforce Development

- To foster the ongoing development of cultural competency within the pharmacy workforce; further,
- To educate healthcare providers on the importance of providing culturally congruent care to achieve quality care and patient engagement.

This policy supersedes ASHP policy 1414.

Rationale

The United States is rapidly becoming a more diverse nation. Culture influences a patient's belief and behavior toward health and illness. Cultural competence can significantly affect clinical outcomes. Research has shown that overlooking cultural beliefs may lead to negative health consequences (Administration on Aging, 2018). According to the National Center for Cultural Competency, there are numerous examples of benefits derived from the impact of cultural competence on quality and effectiveness of care in relation to health outcomes and well-being (Goode et al., 2006). Further, pharmacists can contribute to providing "culturally congruent care," which can be described as "a process of effective interaction between the provider and client levels" of healthcare that encourages provider cultural competence while recognizing that "[p]atients and families bring their own values, perceptions, and expectations to healthcare encounters which also influence the creation or destruction of cultural congruence (Schim and Doorenbos, 2010)." The Report of the ASHP Ad Hoc Committee on Ethnic Diversity and Cultural Competence (ASHP, 2005) and the ASHP Statement on Racial and Ethnic Disparities in Health Care (ASHP, 2008) support ways to raise awareness of the importance of cultural competence in the provision of patient care so that optimal therapeutic outcomes are achieved in diverse populations.

Marketing of Pharmacy Services

Jason Perepelkin, College of Pharmacy & Nutrition, Edwards School of Business, Department of Management & Marketing, University of Saskatchewan, E-Wing Health Sciences, Saskatoon, SK, Canada

> Marketing pharmaceutical care [and other professional services] is not the responsibility of the few innovative pharmacists who try it first. Rather, it is the responsibility of everyone in the profession.
>
> Charles D. Hepler

Introduction

When one hears the word marketing different thoughts come up, such as the advertising of alcohol and tobacco, or those telemarketing calls that you find irritating, and how it can disrupt life, or how it leads to overconsumption. While we need to recognize that marketing can be and has been used in less than ideal ways, it has also been used to better society. For example, marketing is used in public education campaigns, such as the importance of getting the necessary vaccinations, to ways that tobacco harms the user and others around, or the dangers of consuming too much alcohol; this method is what is referred to as social marketing.

When people talk of marketing they have many misconceptions, such as it is just the promotion part; as an analogy, this is similar to the misconception many have that pharmacists simply count pills. According to Kotler (n.d.) marketing is defined as " . . . the science and art of exploring, creating, and delivering value to satisfy the needs of a target market." In layperson's terms, marketing is the process of determining the needs and/or wants of potential users/buyers and then providing products (goods and/or services) that meet or exceed expectations. Marketing occurs only when there is an exchange among two or more parties in which something of value is exchanged; for example, when a patient comes to your pharmacy to have a prescription filled, you provide the good (medications) and service (professional counselling) in exchange for payment (this can be out-of-pocket, government insurance, third-party insurance, etc.).

There are two ways to view marketing exchanges in your pharmacy: isolated, individual transactions where there is no expectation for future exchanges, commonly referred to as transactional marketing; or a series of transactions over time where a relationship is formed and is nurtured, and this is commonly referred to as relationship marketing. In most out-patient and community pharmacies relationship, marketing should be the goal as you want to form long-term relationships with your patients and therefore earn their loyalty; it is much more efficient and cheaper to retain customers than it is to continually try and attract new ones. Transactional marketing may be used in an in-patient setting where the patient has an acute illness and is less likely to interact, if at all, with the hospital pharmacist. For a more in-depth discussion on relationship marketing and its uses in pharmacy, see Doucette and McDonough (2002).

There are parallel characteristics between relationship marketing and pharmaceutical care:

Relationship Marketing		*Pharmaceutical Care*
Develop a relationship with customer	→	Establish therapeutic relationship
Collect and manage customer information	→	Assess and record patient needs
Individualize your services to customers	→	Create an individualized care plan
Involve front-line personnel	→	Delegate clerical tasks to free up time for professional duties
Emphasize long-term outcomes	→	Monitor impact on patient outcomes

Ultimately a patient seeks health care because of a known illness (acute or chronic), accident, or injury. Where they seek care depends on ones' previous experiences, family and friends, employers, etc. This is where pharmacists can play a greater role in having patients' and others they have formal or informal relationships with aware of what pharmacists can do to help treat or prevent a need for health care. In this chapter, you will learn about the basics of marketing and how it can be used to enhance practice.

NOTE: patient, consumer, client, and customer may be used in this chapter—ultimately, they all refer to the individual(s) that are the focus of a pharmacists' professional roles.

As highlighted by Holdford (2015), there are some issues in marketing community pharmacist services, including:

- Control of practice by non-pharmacists;
- Product (tangible good) orientation;
- Conflicting professional and business roles; and
- Poorly defined image of pharmacists among the general public.

Marketing to most is synonymous with promotion, but promotion is one of the "4 Ps"; that is, marketing consists of the marketing mix, or "4 Ps", of product, price, place, and promotion. Ultimately marketing is about getting the right goods and/or services, to the right people, at the right place, time, and price, using the right promotional methods.

With the ever-changing scope of pharmacy practice it is becoming increasingly necessary for pharmacists to promote professional services they can offer. Just because you have advanced education in cardiology and provide the most comprehensive patient care does not mean that people will seek out your services; you need to design your services with the patient in mind and then communicate the benefits of your service offering. "If you build it they will come" for the most part does not work in health care, especially when patients do not always know what is best for them, particularly in the more preventative, public health role many pharmacists assume that does not seek to treat a condition but prevent it. Added to this is that many outside of the profession ascribe to the old model of pharmacy, its distribution function, and tangible products.

It must be acknowledged that most patients do not want the products (goods and/or services) they receive; this is called negative demand, and many times a patient does not want to take the metformin or atorvastatin prescribed, those are negative products. Yes, they can improve one's health and reduce the likelihood of disease progression, but one does not typically want to take medication; however with good counseling they will see why they need to take the medication.

Pharmacists that can demonstrate their value are much more likely to succeed in practice. Marketing is a tool that pharmacists can use to demonstrate value by understanding their target market. A market is a group of people that share a need or want that can be satisfied through exchange relationships formed when using the tools of marketing. Target marketing focuses on the target market, which is the set of actual (current) and potential patients/customers for your product(s).

It is essential to avoid marketing myopia that occurs when an organization, like a community pharmacy, focuses on what they want to provide patients/customers instead of figuring out what the market (patients/customer) needs or wants (Levitt, 2004). When you focus on what you want to provide myopia (shortsightedness) may occur and as a result the target market is not having its needs and wants met.

Another factor to consider when examining your product offering and how you serve your target market is the concept of value and satisfaction. As many patients/customers cannot completely evaluate the service provided by a pharmacist they may look for other aspects that they can evaluate, such as the tone of voice of the pharmacist, the physical infrastructure of the pharmacy, the clothing worn by the pharmacy team, etc. If a patient/customer visits a pharmacy and expects the pharmacist to be friendly and the service delivered is above the expectation, then the patient/customer is highly satisfied; however, if because of previous interactions with the pharmacist the patient/customer expects a high level of service and it does not meet expectation, then satisfaction will be low.

Therefore, pharmacy as a profession should work to educate the general public on what pharmacists do and can do. There is still the common misconception of the "count, pour, lick, stick" image of pharmacists that primarily centers on the distribution functions of pharmacists and the role pharmacists played in the past. In most jurisdictions, however, where community pharmacies are businesses, most of the promotional efforts to enhance the image of pharmacists' center on the image of the pharmacist practicing for a specific employer, and not what pharmacists as a whole do and can do; for example, "your Company pharmacist can prescribe for . . . " instead of stating that "pharmacists can prescribe for . . . " As a result, it is up to individual pharmacists and professional advocacy organizations to educate the public on the role of pharmacists.

Marketing Research

Before undertaking a change in one's practice or wanting to promote a product offering, one must conduct marketing research so that what is offered to the market is what the market needs or wants; otherwise, one risks suffering from marketing myopia and not meeting the needs of the market. Marketing research involves the analysis of markets, current and/or potential, to determine what is currently offered, any opportunities and challenges, and to obtain the requisite information to make strategic decisions for marketing programs.

In collecting data there are two main forms to consider: primary data and secondary data. When conducting primary data research information is collected directly from the original source to solve a problem. Primary data are collected when there is no current, or sufficient, data to inform your decision making. Whereas secondary data are information that has already been collected for a purpose other than what you want information for, but it can be used to inform your decision. The benefit of primary data is

that you can ask very specific questions that require answers in order to make decisions; as a result, primary data are more expensive than secondary data. The benefit of secondary data is that the data has already been collected and therefore is cheaper than primary data; however, the downside is that because the data were collected for another purpose it may not adequately answer the questions you have. There is a good likelihood that you may have to obtain both primary and secondary data. Of note is that the patient database you have in your pharmacy is a rich source of data; it can allow you to see what medications are dispensed most often, how often patients have prescriptions filled (adherence), what conditions patients have, etc. and you can better target a specific segment of patients.

In obtaining secondary data you will want to understand how the data were collected; was it collected as part of a government census, were focus groups used, for what reason(s) was the data originally collected, etc.? Once you make the decision that primary data will need to be collected as there is no or insufficient existing secondary data, there are three broad methods of primary marketing research: survey; observation; and experiment.

Survey data collection involves gathering data, usually via a questionnaire, directly from respondents to obtain facts, opinions, and attitudes. If your organization does not have employees that are able to perform a survey you will likely want to hire a marketing research company to develop the survey questions and collect the data. Data may be collected via a telephone survey, through a mail self-administered survey, when interacting with patients at the pharmacy, or even a consumer intercept where consumers in the pharmacy are asked to fill out a questionnaire. There are other considerations to take into account when collecting data via survey, such as will there be an incentive to participate.

Observation primary data collection occurs by observing participants' actions without directly interacting with them. This can be done in person or could also be done by watching collected video. Observation can be useful when wanting to see the route customers take, once they have entered the store, to arrive at the pharmacy counter; this data can help in how you merchandise the route most often taken so that you can "encourage" other purchases. You may also want to understand whether a patient that drops off a new prescription stays in the store, and if so, what do they do, such as sit in the patient waiting area or wandering the store.

The final method of primary data collection is an experiment where you change one or more variables while observing the impact of the change on another variable. For example, you may want to see how workflow changes when you have pharmacists counsel patients when they drop off a new prescription, as opposed to when they pick up their medication; when conducting the experiment you may ask for feedback from patients and pharmacists on how they were affected by the changes and if the changes were generally positive or negative. Once that data is collected you can analyze it to inform your strategy.

In general, market research should: define the issue/problem; analyze the situation and choose a method of research; get problem-specific data, analyze and interpret data; and solve the problem/make recommendations. When conducting your marketing research, you should also include an environmental scan of the practice environment. The five factors in environmental scanning are: political and legal factors (e.g. regulations); technological factors (e.g. technical infrastructure in place); socio-cultural factors (e.g. demographics, culture, values, etc.); competitive factors (e.g. nearest competitors, speed, etc.); and economic factors (e.g. boom or recession, GDP, unemployment, third-party insurance, etc.).

One needs to consider the market that will be targeted with marketing efforts. A market is the set of actual and potential consumers of a product; these people share a need or want. For example, you may target patients who have been recently diagnosed with Type II diabetes for a program provided by a Certified Diabetes Educator pharmacist from your pharmacy; while those outside of your target market may find benefit, such as patients who have had Type II diabetes for a while, when targeting your marketing efforts you want to best communicate with your target market – those you recruit from outside your target market are a bonus! Some variables to consider in defining your target market include: the size and potential for growth of the target market; how "easy" is it to reach this target market; if the goal is profitability, is it going to be profitable; the nature of the market, such as highly competitive; and the nature of the organization (if you are a pharmacy that is a part of a discount retailer you are not going to try and charge a premium price as this will not match the nature of your organization).

The Marketing Mix

Marketing is about getting the right goods and/or services (products), to the right people (target market), at the right place, time and price, using the right promotion techniques. This can be achieved by using the marketing mix, or what is commonly referred to as the "4 Ps": product, price, place, and promotion (see **Table 1**). The 4Ps of Marketing were first introduced in 1967 by Philip Kotler in his book *Marketing Management* (Kotler and Keller, 2014). When the product is a service, there are three additional Ps: people, processes, and physical evidence (Kotler et al., 2002).

Another way to view the 4Ps is to remember that products provide consumer solutions, price represents consumer costs (financial and non-financial), place provides convenience, and promotion enables two-way communication.

Product

Many use the marketing term "product" in reference to a tangible item, however, products can be tangible and/or intangible items. If one remembers that in marketing a product can be anything satisfying a need or want, tangible and/or intangible, the application of marketing in pharmacy is better aligned.

Table 1 The Marketing Mix

Term	*Definition*
The 4Ps	
Products (service and/or good)	Provide customer/patient solutions to a need or want. For example, in a community pharmacy the products offered are a combination of goods, tangible items such as prescription medications, and services, intangible items such as tobacco cessation counselling. As well, a product can also mean an experience someone has, such as going to an amusement park, a community pharmacy, or a Cirque du Soleil show; however, for the purposes of this chapter a product will refer to a good and/or service.
Price	Represents consumer/patient costs, such as the financial cost to obtain a product (both for the patient and potentially other payers, such as insurance companies), but one needs to consider non-financial costs of obtaining a product, such as time and convenience.
Place	Provides convenience for the target market. For example, providing services at the community pharmacy may be convenient for pharmacists providing the service; however, it may be more advantageous to provide the service at a community center, or in the patient's home. Another example of place, primarily in regard to community pharmacies in the US, is drive thru pharmacies. While many within the profession view this as negative since drive thru windows are associated with fast food restaurants, it may be more convenient for the parent of an infant to pick up a prescription for amoxicillin to treat a bacterial ear ache at a drive thru window than taking the unwell infant into the pharmacy to pick up the prescription.
Promotion	Enables two-way communication where the provider/organization seeks to communicate, to the market, why the market should choose their organization over others. For example, the convenience of providing flu shots without an appointment versus at a public health clinic. As well, one must be aware of the regulations surrounding promotional efforts as there are restrictions for professionals, including pharmacists, in what is okay to include and what cannot be done, such as direct comparison between two competitors.
Additional 3Ps of services	
People	Are those such as the patient and the service provider, but also includes the customers waiting in line at the pharmacy, the other members of the pharmacy team, etc. For example, if you are counselling a patient on sildenafil, the likelihood of that patient retaining the information increases if it is just the pharmacist and the patient in a private counselling room, and not at the normal pick up counter where other pharmacy staff and customers are in close proximity.
Processes	Involve the policies and procedures that go into providing services to patients. For example, your pharmacy may find it cuts down on errors and costs by having a patient counselled when they drop off their prescription than when they pick it up. As well, many community pharmacies have protocols that the employer wants pharmacy team members to follow so that there is consistency among what a patient will expect among team members but also at other locations of the same pharmacy chain. While we cannot discuss them in this chapter, a good way of understanding the processes of your pharmacy is to create a service blueprint (see Holdford, 2015).
Physical Evidence	Is a key factor in marketing services since the intangible nature of services means that the patient cannot see, touch, or feel the service like they can when the product is a tangible item. As a result, patients will use the physical evidence to evaluate the service, pre- and post-consumption, such as the clothing worn by the pharmacist, how the pharmacy is organized, how easy is it to find parking, etc.

Consumer products can be divided into four types: convenience; shopping; specialty; and unsought. Convenience products are items that an individual buys frequently, immediately, and with little to no comparison and buying effort. These products tend to be priced low, mass advertising is used to be top of mind to consumers, and there are many purchase locations (i.e. there are little to no restrictions on where they can be sold). Examples of convenience products that are available through community pharmacy and other retailers are throat lozenges, regular strength pain relievers, adhesive bandages, etc.; many times these items are placed in locations where a consumer makes an impulse buy, such as beside the cash register or on the bunk-end of an aisle.

The next consumer product type, shopping products, are ones for which the consumer makes the effort to search out alternatives; they tend to be higher in price, bought infrequently, and there are limited locations in which a consumer can buy the product. Within a community pharmacy there are a limited number of shopping products, but an example would be blood glucose meters; some examples of shopping products not directly related to pharmacy are furniture, appliances, vehicles, etc. Specialty products are items that have unique characteristics that require the consumer to go to select few places to obtain the item and are likely to have one place to purchase the item within a given geographic area; these items tend to be higher in price and consumers are willing to expend considerable effort to obtain the specialty products. While there are few examples in pharmacy, specialty products that one can identify would be high priced, imported sports cars, a specific kind/brand of watch, etc.

The final type of consumer products are unsought products. For unsought products the consumer may not know about the product or has heard of it but does not normally think of buying it. Unsought products tend to require significant advertising and personal selling as they are new innovations or are products consumers do not want to think about. Within a community pharmacy examples of unsought products are pregnancy tests and emergency contraception; outside of pharmacy examples include life insurance and cemetery plots.

Products, in particular tangible products, tend to be part of a larger product offering by an organization. An item is simply a specific version of a product, such as cough suppressant for dry coughs. A product line is a group of closely related products such as all

formulations of cough suppressant. Product mix involves all product lines an organization sells, such as cough suppressant, oral pain relievers, first-aid products, etc.; organizations tend to have a portfolio of product mixes that are closely aligned.

The next product consideration is branding; this topic can be quite complex and to completely understand and appreciate branding one subsection of a chapter is not sufficient, but a general overview is provided. A brand is a name, term/slogan, sign, symbol, design or a combination that identifies the seller/maker of a product. Branding is about creating, maintaining, protecting and enhancing goods and services. Branding is defined as "the process involved in creating a unique name and image for a product in the consumers' mind, mainly through advertising campaigns with a consistent theme. Branding aims to establish a significant and differentiated presence in the market that attracts and retains loyal customers" (Business Dictionary, 2018).

There are some brands that are so strong that when one sees an image or even font style that most people would know what brand it is; for example, the big "M" is for McDonalds, the silhouette of a shaped bottle is recognized as Coca-Cola, or the image of an apple with a bite out of it is the Apple logo. Community pharmacies, especially chain pharmacies, have distinct brands and use branding to maintain and enhance the brand. Some aspects that represent a brand are the colors used for signage, the uniform that members of the pharmacy team wear, the labels on prescription vials, and others. Branding is even a consideration when developing the protocol pharmacy team members follow when a patient drops off a prescription. When an organization has multiple pharmacies the way a patient is greeted, the questions asked of them, the layout of the front store, etc. are used at all locations as it provides a recognizable way that an interaction will follow in any location. Ultimately the pharmacy wants to maintain brand loyalty, which represents commitment to a specific brand.

Two other aspects of branding to consider are brand awareness and brand recall. Brand awareness is the ability that someone can identify a particular product/brand by viewing the product/logo, packaging, or advertising campaign; for example, if shown the logo for a chain pharmacy and you are able to name the brand it implies brand awareness. Brand recall is the ability of someone, when prompted, to correctly name a brand from memory; for example, asking individuals what brand comes to mind when you say name the first community pharmacy you think of.

The ideal brand is one that is used in reference to all products in that category, a generalized brand/trademark. For example, many people will ask "where can I find a Band-Aid"; however, Band-Aid is a brand of adhesive bandages. Another familiar generalized brand is Q-tips, which is a brand of cotton swabs, not the name of all cotton swabs.

Products go through the four stages of a product lifecycle: introduction; growth; maturity; and decline. This is not to say that all products will experience a decline, but it does make one recognize that a product line or product mix should be maintained to have a diverse portfolio of products that will be in various stages. A brief, general overview of the product lifecycle is discussed below.

The initial stage is the introduction stage; during this time profits are below zero because of the costs involved in bringing the product to market and sales are just beginning. If it is a completely new product the adoption of the product is likely to be slow because you need to promote to your target market about the features of your product and its benefits. In health care consider the introduction stage that occurs for a new to the market branded pharmaceutical—efforts are immense to get the message out to the target market and encourage product trial (many times this may be done through samples of the medication given to physicians).

Next is the growth stage where sales rise quickly as do profits (sales and profits are used here, but it could be product adoption that is the goal of a non-profit organization). In this stage, if first to market or the leader in the category, one needs to constantly be monitoring how competitors are reacting to increase the chances that your product will survive long term; as well, in this stage sales continue to grow and profits peak and begin to decline as competitors enter the market.

In the maturity stage, sales reach peak and then begin to decline as more competitors enter the market; as well, profits decrease during this stage. As a result, if a product is doing well in the market an organization, to maintain market share, will have to invest in promotional efforts which also contribute to decreasing profits. The final stage is the decline stage when sales and profits fall rapidly. At this point one has to consider making improvements to products to stay in the market, especially if there are advancements made by competitors. Another reason for a product to fall out of favor is if it was part of a trend that is no longer relevant.

Two other product considerations are product differentiation and product positioning. Product differentiation occurs when a product is created and designed so that consumers perceive it as different from competitors. For example, product differentiation in some drug categories occurs when the drug is approved for a new indication when others in the category are not, or when a company combines two medications to create a combination drug that reduces the number of tablets a patient needs to remember to take. In product positioning, the organization works to create and maintain a certain persona in the consumers' mind; for example, when evaluating the pain reliever products on the market one may consider what the product is used for (body aches or headaches) and the price of the product (expensive versus inexpensive). Where an organization positions its products will depend on many factors, including the overall brand the organization maintains (e.g. low price, high value, prestige, etc.) and how it is relative to competitors in factors such as how fast it works, how long consumers can expect it to last, etc.

Price

Pricing is a crucial factor in marketing and is also one of the most challenging aspects to control. Each product will require a unique pricing strategy. Some examples of pricing strategy would be wanting to achieve a target profit or ROI (return on investment), building traffic in your pharmacy, achieving a specific market share, creating or maintaining an image, etc. While it is easy to recognize the financial price of a product, one must not forget about the other components of price, including time, energy, and

opportunity costs; it is important not to lose sight of price when offering a product in a non-profit environment as, just because there may be no financial costs to the patient, there are other costs to consider.

Some ways to determine a price are to create a cost-based pricing strategy where price to the consumer is set based on a desired profit margin. There is also demand-based pricing that comes into play when one, through market research, determines the price that the market is willing to pay for your product. Competition-based pricing occurs when prices are set above or below what the competition is charging. Another consideration is a break-even analysis, the point where net income is zero and any profit will come when sales are above the break-even point. When introducing a new product to the market a skimming strategy may be used where prices are set high to maximize profits while there is less competition; on the other end would be penetration pricing strategy where prices are set low to attract consumers and at the same time discourage potential competitors from entering the market.

Place

Place, or distribution, covers the activities that make a product available to consumers when they want to purchase them. In having a narrow view of place, many community pharmacists may only consider place to refer to the pharmacy itself; however, one should consider place in relation to what is best or ideal for the market. In some ways it may be more convenient for you to offer a medication assessment service in the counselling room of your pharmacy, but is that the most convenient place for your patients? For example, your target market is seniors not living in a nursing/care home who could benefit from a medication assessment. Given potential mobility issues, why not go to the patients by renting out a room at a retirement community center where you come to your patients?

In assessing market coverage, the three strategies are intensive, selective, or exclusive. In intensive market coverage the organization puts products in as many places as possible; this provides maximum exposure. The second strategy is selective in which only a select few locations would offer the product; for example, you may only have 4 of 10 community pharmacies in a city dispense vaccinations as intensive coverage would not be the best use of the organization's resources. The final strategy is exclusive market coverage where only one pharmacy in a geographical region offers the product; for example, only one of your pharmacies is given the license to conduct genetic screening to optimize medication use by patients.

Promotion

In its simplest form, promotion is communication that facilitates exchanges among two or more parties by influencing the audience to accept a product. As a reminder, while many examples in this chapter focus on the for-profit community pharmacy environment, all aspects of the marketing mix, including promotion, can be used within a non-profit environment.

The goal of promotion is to stimulate demand for your product(s). For example, a pharmacist at your pharmacy recently became a Certified Respiratory Educator and would like to offer spirometry testing to patients; since most patients would not know what spirometry is and why it would be good to get tested, there will be little to no demand if you do not promote the service. Whether your pharmacy is for- or non-profit promotion is required to inform many stakeholders, including patients, physicians, carers, etc.

Promotion is used to communicate effectively with the market leading to engagement. As a result your promotional strategy must align with the target market so that you are "speaking their language", otherwise you will simply be spending time and money on a flawed strategy. Objectives of promotion are numerous including creating awareness and stimulating demand for your product(s), retaining loyal customers, combating competitors' promotional efforts, reducing sales fluctuation, etc.

A common misconception is that promotion is really advertising; however, advertising is one of the four strategies that make up the promotion mix, which also includes sales promotion, public relations, and personal selling. Advertising is paid, non-personal communication that uses various types of media to communicate with the target market. Mediums used for advertising, with varying costs to consider, include television, direct mail, radio, online social media platforms, etc. Sales promotions are done when an organization promotes certain products, many times offering the products for a discounted price; for example, in winter months many pharmacies have sales promotions for vitamin D supplements.

Public relations are when an organization attempts to earn public understanding, acceptance, and trust in the organization or specific products offered by the organization. Publicity is any information about the organization or its products distributed through the media that is not directly paid for; when seeking publicity, the subject matter must be interesting, relevant, and newsworthy. For example, an organization may put out a media notice that a new professional service is being offered with the hope that media outlets will pick up the story and spread the message; publicity is also used by regulatory and advocacy organizations to inform the public of changes to regulations, increased scope-of-practice, etc. Some advantages to publicity are that it is free, more believable than advertising, and can reach those who may not see or pay attention to commercials; however, the disadvantages to consider include that the media may not pick up the story, they may alter the message, or it could be negative.

Personal selling is when an organization, or its employees, search for prospective customers, and can include face-to-face presentations, service after the sale, etc. Another promotional tool, that is the best form of promotion, is word-of-mouth advertising as it is the cheapest, most believable and most effective; word-of-mouth occurs when a satisfied customer sees value in the product and informs others in their social circle about the product.

Social media platforms are now a major medium for promotional messages. In using social media there are several ways to advertise to specific geographical areas, people of a select age range, people of specific genders, etc. There are some ethical issues that can arise when promoting a product using social media, such as advertising to people that do not realize the message they see is paid advertising. Furthermore, rules and regulations for promotional methods for pharmacists and pharmacies must be understood and followed. For example, most jurisdictions do not allow direct, head-to-head comparison advertising.

Products as a Service

A service is any activity or benefit that is offered to another that is intangible and does not result in the ownership of anything besides the knowledge gained through the service encounter. Services marketing is the component of marketing that focuses on the intangible components of a product. In considering the purchase of tangible products the majority of the time there is a service component to it. When the service is the main component of the transaction this is referred to as the core service, such as a medication review; whereas when the service is performed in support of the sale of a tangible product, it is referred to as supplementary service, such as the expected patient counselling provided when a medication is dispensed.

The goods–services continuum is the recognition that the vast majority of the time products contain components of both goods and services. On the mostly goods side of the equation there are products such as canned foods, whereas on the mostly services side of the equation there are products such as insurance, consulting, or teaching.

Physical evidence centers on where the service is provided. The environment in which the service is delivered can help distinguish your pharmacy from competitors. Depending on the physical evidence provided it may allow you to charge a premium price for your services, or it may reinforce the discount nature of the organization and therefore services are set to reflect the strategy and environment.

Process is the aspects that are involved in providing the service, the systems used. An organization will have its standard operating procedures that allow services to be provided in a relatively consistent manner. Understanding and defining the processes involved in service delivery will help to reduce confusion and promote a consistent service; essentially this lets everyone on the pharmacy team know who does what and when.

The final, obvious component is the people involved in service provision. The employees that interact with customers are the face of the organization and as a result customers evaluate the service based on how the employee(s) deliver it. The people providing the service are essentially the only component of a service that customers can see and interact with.

There are four characteristics of services: inseparability; intangibility; inconsistent; and non-inventoried. Inseparability is the result of the fact that services cannot be separated from providers; as a result the staff providing the service(s) are essential in the provision and quality of the service to patients. Intangibility occurs in the provision of services as they cannot be seen, tasted, felt, heard, or smelled before the service is provided; as a result, it makes it difficult to sample and evaluate a service, and even more so when the service is provided by a professional, such as a pharmacist. The inconsistent nature of service delivery means that the quality of services depends on who provides them and when, where, and how; therefore, you need to acknowledge that almost every time a service is offered it is going to be different and as a result services are difficult to standardize in terms of quality. The final characteristic of services is non-inventoried, meaning that services, unlike goods, cannot be stored for later sale or use; the fluctuating demand for some services can be a challenge to ensure services are provided when required, while at the same time preventing wasted resources by having a supply that exceeds demand. For example, you may provide influenza vaccinations without an appointment, but there will be greater demand at certain times of the day or even days of the week, and time of year so it is key to try and predict demand as best you can to have the optimal number of pharmacists on shift.

There are difficulties for those outside of a profession to adequately assess a professional service. When we examine qualities of a service there are non-search and search considerations (Nelson, 1970; Darby and Karni, 1973; Zeithaml, 1981). Search qualities are factors that one can identify and assess prior to choice and/or consumption; being able to evaluate the qualities ahead of time may be the result of reviews of the service provider (e.g. pharmacist) from past clients. Whereas non-search qualities are ones that cannot be evaluated prior to purchase/consumption. The non-search qualities are broken into experience qualities and credence qualities. Experience qualities are ones that can only be evaluated during or after a service has been provided. Whereas credence qualities can never be meaningfully evaluated even after use/consumption; these credence qualities relate to most aspects of professional services.

On one end of the spectrum of the ability to evaluate products are those high in search attributes, such as clothing, food, a motor vehicle, etc. In the middle, there are attributes high in experience qualities, such as a haircut, yard care, restaurant meals, etc. On the other end of the spectrum, are products hard to evaluate as they are high in credence attributes, such as pharmacy services, legal services, complex surgery, etc.

One method to help reduce fluctuations when providing professional services would be to develop service scripts. As outlined by Holdford (2015), service scripts describe a service performance in a written list of actions; that is, the steps that should be followed in a given circumstance. In the service script you should establish expected actions and responsibilities, standardize procedures, and base it on the best methods available. Service scripts can be developed for a variety of reasons, such as when there is a dispensing error, a patient complains about the cost of a prescription, a prescribing error, and the like. While service scripts attempt to standardize the actions taken during a particular encounter, as health care professionals pharmacists will still do what is right for the patient and use their professional expertise.

A strategy that may be linked with a service script, but can also be separate, is a service blueprint. Service blueprints are flowcharts/diagrams used to design service operations (Holdford, 2015). In the development of a service blueprint around interactions with patients, the point of view of the patient is taken into account; this can then give pharmacists a well-rounded perspective when designing a new service or changing current operations. Service blueprints concurrently illustrate the process, patient roles, service provider roles, and support service roles (Holdford, 2015). As an example, you could design a service blueprint for your current dispensing practices; in developing the blueprint you would consider the physical environment of the pharmacy, patient actions, contact employee (those directly serving patients) actions, and invisible processes that occur, such as interaction with insurance providers.

The final area to be examined in this chapter when providing a professional service is the service-profit chain that links a service organization's profits (if that is the goal of the organization) with employee and consumer satisfaction (Heskett et al., 1994). "The service-profit chain establishes relationships between profitability, customer loyalty, and employee satisfaction, loyalty, and productivity" (Heskett et al., 1994). The concept explains the connections that exist among the organization, employees, and consumers to manage a service experience.

The relationships among the organization, employees, and customers are connected in three ways: external marketing; internal marketing; and interactive marketing (Heskett et al., 1994). External marketing is the relationship that exists between the organization and its consumers; this relationship is the one that is developed and nurtured through various mechanisms discussed in this chapter including product design and promotional efforts. Internal marketing is the relationship that exists between the organization and its employees; this relationship is key as employees are the organization's direct link with customers. If employees do not feel they are a part of the decision-making process and are simply "told" what to do, not only will the relationship between the organization and its employees suffer but so will the relationship between the employees and customers. The relationship between employees and customers is the interactive marketing component of the service-profit chain; the interaction that occurs between employees and customers is directly linked with the contact between the organization and its employees.

The internal marketing environment is the direct link between the organization and its employees; the employees in this relationship are the internal customers. And just like you want to maintain a good relationship with external customers, so should you between the organization and its internal customers. If employees are treated like internal customers, the organization wants to make sure they are satisfied and are being heard. An organization should monitor the internal customers' satisfaction through methods such as surveys, exit interviews, anonymous feedback, etc. and use that information to continually evaluate ways to increase satisfaction.

Summary

An overview of marketing and its role in pharmacy practice was provided in this chapter. While the broad overview is a base from which to work, you are encouraged to examine the subject more deeply; the list of references provided is a good place to start. Marketing is a tool that can enhance pharmacy practice by better meeting the wants and needs of patients to optimize their health.

Medication Narratives

Karen C. Lloyd*, Kath Ryan*, Paul Bissell†, *University of Reading, Reading, United Kingdom; †University of Huddersfield, Huddersfield, United Kingdom

Medication narratives are stories told about medicines in people's everyday lives as they are embedded within broader stories of illness and health (Bissell et al., 2006; Ryan et al., 2007). They can be stories about taking medicines, experimenting with them, trying new medicines, stopping ones that are no longer needed or desired, and of resisting or refusing medicines. They can be stories about how people subjectively feel about their medicines, how they make sense of taking them, and the meanings ascribed to them in stories of living with illness or engaging in health-enhancing or risk-averting behaviors. They may also be stories of the social interactions with others—doctors, nurses, pharmacists, carers, family, and friends—as they engage with medicines in their everyday lives. Medication narratives, as stories about people's subjective experiences with medicines, particularly outside of the doctor's office or the pharmacy, provide a window into the lived experiences of health and illness.

Such stories are often referred to as offering a lay perspective on illness and medicines. In fact, Frank (2013) has argued that the biomedical model marginalizes those living with illness, and telling stories is one way that the voice of the experiencer of illness can be re-claimed. The concept of medication narratives works to center medication users' ways of representing their lives, drawing attention to how they offer something new, while also countering and complementing narratives created by doctors, nurses, pharmacists, midwives, and other health professionals about patients and their bodily experiences. The concept of medication narratives was originally developed by Bissell et al. (2006; see also Ryan et al., 2007) with the goal of catalyzing interest in utilizing narrative data—that is, stories told by people about their subjective experiences—to stimulate new ways of studying individual experiences of medication use in the field of pharmacy practice.

What are Narratives?

Not all speech acts or text, whether collected through research interviews, spoken in a public forum or in a YouTube video, or written in a diary or in an online blog, are necessarily narratives. Narratives attend to change and succession in a sequence, usually in time (Brockmeier, 1994; Bruner, 1990; Ricoeur, 1984). Narratives have a plot, with a beginning, a middle, often a turning point or narrative high, and an end that link together a series of events or experiences, involving the narrator or one or more other actors, often within a specific time frame. According to Riessman (2008, p. 3).

> In everyday oral storytelling, a speaker connects events into a sequence that is consequential for later action and for the meanings that the speaker wants listeners to take away from the story. Events perceived by the speaker as important are selected, organized, connected, and evaluated as meaningful for a particular audience.

French philosopher Paul Ricoeur (1984) described the construction of a story through a series of events in time as *emplotment*, a concept further elaborated on by Mattingly and Garro (2000). Narratives are not only about a series of events emplotted in a story but they are also about the emplotment of the narrative within the broader context of the teller's life history, told to make sense of and order lived experiences. Narrative gives external expression to internal representations of events, experiences, thoughts, and feelings (Squire et al., 2013).

Narratives are also performative, and they are engaged in the production of identities (Bruner, 1987; Riessman, 2008). Through narratives, people craft who they are and how they appear to others in social interaction. They are not told in a vacuum, but often are crafted for a specific audience, allowing the narrator to present a version of her or himself to others. This presentation of the self to

others through narrative may change over time and also may be crafted differently for different audiences (Squire et al., 2013). Lastly, narratives are rarely value neutral. They perform adherence to a set of values and tend to have a moral motive, a moral reason for being told, which often has to do with the values of the teller in her or his broader social and cultural milieu (Bissell et al., 2006; Riessman, 2008; Squire et al., 2013). They can be used to persuade others, to deceive, to mobilize for social and political change, and can be a source of social connection and entertainment (Riessman, 2008).

Narratives of Illness and Health
