Preface

Pharmaceutical dosage forms contain both pharmacologically active compounds and excipients added to aid the formulation and manufacture of the subsequent dosage form for administration to patients. Indeed, the properties of the final dosage form (i.e. its bioavailability and stability) are, for the most part, highly dependent on the excipients chosen, their concentration and interaction with both the active compound and each other. No longer can excipients be regarded simply as inert or inactive ingredients, and a detailed knowledge not only of the physical and chemical properties but also of the safety, handling and regulatory status of these materials is essential for formulators throughout the world. In addition, the growth of novel forms of delivery has resulted in an increase in the number of the excipients being used and suppliers of excipients have developed novel coprocessed excipient mixtures and new physical forms to improve their properties. Some excipient monographs in *Pharmaceutical Excipients* describe materials no longer in common use and a comment is included where this is the case. These monographs are retained in *Pharmaceutical Excipients* as a resource for users who may need to understand or reproduce the performance and properties of an old product. This database has been conceived as a systematic, comprehensive resource of information on all of these topics.

The first edition of *Pharmaceutical Excipients* was published in 1986 and contained 145 monographs. Subsequent editions have contained more monographs, as well as revised existing content. The data is available in print and online. This new edition contains over 400 new and revised excipient monographs with enhanced online features, compiled by over 170 experts in pharmaceutical formulation or excipient manufacture from around the world; the monographs have been reviewed and revised in the light of current knowledge. There has been a greater emphasis on including published data from primary sources although some data from laboratory projects included in previous editions have been retained where relevant. Variations in test methodology can have significant effects on the data generated (especially in the case of the compactability of an excipient), and thus cause confusion. As a consequence, the editors have been more selective in including data relating to the physical properties of an excipient. However, comparative data that show differences between either source or batch of a specific excipient have been retained as this was considered relevant to the behavior of a material in practice. Over the past few years, there has been an increased emphasis on the harmonization of excipients. For information on the current status for each excipient selected for harmonization, the reader is directed to the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website (www.edqm.eu), and also the General Information Chapter G10 in the JP. The Suppliers Directory (Appendix I) has also been updated with many more international suppliers included.

In a systematic and uniform manner, *Pharmaceutical Excipients* collects essential data on the physical properties of excipients such as: boiling point, bulk and tap density, compression characteristics, hygroscopicity, flowability, melting point, moisture content, moisture-absorption isotherms, particle size distribution, rheology, specific surface area, and solubility. Scanning electron microphotographs (SEMs) are also included for many of the excipients along with over 130 near-infrared (NIR) spectra specifically generated for this publication and over 150 infrared (IR) spectra. In addition, the current update includes around 150 Raman spectra. *Pharmaceutical Excipients* contains information from various international sources and personal observation and comments from monograph authors, steering committee members, and the editors.

All of the monographs in the digital and print edition are thoroughly cross-referenced and indexed so that excipients may be identified by either a chemical, a nonproprietary, or a trade name. Most monographs list related substances to help the formulator to develop a list of possible materials for use in a new dosage form or product. Related substances are not directly substitutable for each other but, in general, they are excipients that have been used for similar purposes in various dosage forms.

Pharmaceutical Excipients is a comprehensive, uniform guide to the uses, properties, and safety of pharmaceutical excipients, and is an essential reference source for those involved in the development, production, control, or regulation of pharmaceutical preparations. Since many pharmaceutical excipients are also used in other applications, *Pharmaceutical Excipients* will also be of value to persons with an interest in the formulation or production of confectionery, cosmetics, and food products.

About the Editors

Paul J Sheskey

BSc, RPh

Paul Sheskey has been involved in the *Handbook of Pharmaceutical Excipients* as an author and member of the Steering Committee since the third edition and as a co-editor since the fourth edition. He was formerly Principal Research Scientist at The Dow Chemical Company in Midland, Michigan, USA. Paul received his BSc degree in pharmacy from Ferris State University. Previously, he has worked as a research pharmacist in the area of solid dosage form development at the Perrigo Company and the Upjohn (Pfizer) Company. Paul has authored numerous journal articles in the area of pharmaceutical technology.

Walter G Cook

BSc, PhD

Walter Cook has been involved in the *Handbook of Pharmaceutical Excipients* as an author and member of the Steering Committee since the fourth edition. He is currently Head of Global Respiratory Scientific Affairs at Mylan Global Respiratory Group in Sandwich, Kent, UK. Previously, Walter has held positions in formulation research and development at companies including Pfizer, AstraZeneca, and Abbott Laboratories. He obtained a BSc in Pharmacy from the University of Strathclyde, UK and a PhD in Pharmaceutical Sciences from the University of Nottingham, UK.

Colin G Cable

Bsc, PhD, MRPharmS

Colin Cable has been involved in the *Handbook of Pharmaceutical Excipients* as an author and a Steering Committee member since 1992 during preparation of the second edition. He is currently Assistant Chief Scientist at the Royal Pharmaceutical Society and has had several posts within this organisation since 1990 including a joint RPS/hospital appointment between 2002 and 2008. In addition, his early career included positions as a hospital pharmacist and in the pharmaceutical industry. Colin obtained a BSc in Pharmacy from Heriot-Watt University, Edinburgh, UK and a PhD from the Department of Pharmaceutical Sciences, Strathclyde University, Glasgow, UK.

Acknowledgments

A publication containing so much detail could not be produced without the help of a large number of pharmaceutical scientists based world-wide. The voluntary support of over 170 authors has been acknowledged as in previous editions, but the current editors would like to thank them all personally for their contribution. Grateful thanks also go to the authors who have worked with us on the development of new chapter content introduced in this edition, and members of the International Steering Committee who advised the editors and publishers on all aspects of the *Pharmaceutical Excipients* project. Many authors and Steering Committee members have been involved in previous editions of this text. For others, this was their first edition although not, we hope, their last. We extend our thanks to all for their support. Thanks are also extended to Roger Jee, Kelly Palmer, and Tony Moffat at The School of Pharmacy, University of London for supplying the NIR spectra, to Pfizer PGRD, Sandwich, UK for supplying SEMs, and to excipient manufacturers and suppliers who provided helpful information on their products. IR and Raman spectra have been adapted with permission from Informa Healthcare.

Thanks are also gratefully extended to the editorial and production staff of the Pharmaceutical Press and American Pharmacists Association.

Paul J Sheskey, Walter Cook, Colin G Cable
April 2017

Notice to Readers

Pharmaceutical Excipients is a reference work containing a compilation of information on the uses and properties of pharmaceutical excipients, and the reader is assumed to possess the necessary knowledge to interpret the information that this resource contains. *Pharmaceutical Excipients* has no official status and there is no intent, implied or otherwise, that any of the information presented should constitute standards for the substances. The inclusion of an excipient, or a description of its use in a particular application, is not intended and should not be construed as an endorsement of that excipient or application. Similarly, reports of incompatibilities or adverse reactions to an excipient, in a particular application, may not necessarily prevent its use in other applications. Formulators should perform suitable experimental studies to satisfy themselves and regulatory bodies that a formulation is efficacious and safe to use.

While considerable efforts have been made to check the material in this publication, neither the publisher nor the authors accept any responsibility for errors or omissions. In particular, the inclusion of a supplier within the Suppliers Directory is not intended as an endorsement of that supplier or its products and, similarly, the unintentional omission of a supplier or product from the directory is not intended to reflect adversely on that supplier or its product. Additionally, the views expressed in the content by authors are not necessarily the views of their employers.

Although diligent effort was made to use the most recent compendial information, compendia are frequently revised and the reader is urged to consult current compendia, or supplements, for up-to-date information, particularly as efforts are currently in progress to harmonize standards for excipients.

Data presented for a particular excipient may not be representative of other batches or samples.

Relevant data and constructive criticism are welcome and may be used to assist in the preparation of any future editions or digital versions of the *Handbook*. The reader is asked to send any comments to the Editor, Handbook of Pharmaceutical Excipients, Royal Pharmaceutical Society, 66-68 East Smithfield, London E1W 1AW, UK, or Editor, Handbook of Pharmaceutical Excipients, American Pharmacists Association, 2215 Constitution Avenue, NW, Washington, DC 20037-2985, USA.

Disclaimer and Liability

Pharmaceutical Excipients is a reference text for trained healthcare professionals who bear the responsibility of interpreting the contents of this text, in light of professional knowledge and relevant circumstances. All use of the *Handbook of Pharmaceutical Excipients* is entirely at the reader's own risk and the reader is responsible for ensuring that the information being used is consistent with normal, generally accepted pharmaceutical practice. To the fullest extent permitted by law, the publisher assumes no responsibility for any aspect of healthcare administered with the aid of information gained from this text. The publisher and authors shall not be liable for any claims or losses, including but not limited to direct or indirect, incidental, consequential loss, damage, costs, or expenses and any claims from third parties whether in contract, negligence or other tortuous action arising out of or in connection with the use of the *Handbook of Pharmaceutical Excipients*.

A Guide to the *Handbook of Pharmaceutical Excipients*

Formulation considerations and related information

Pharmaceutical Excipients now includes chapter content, which explores the general considerations applied during the formulation of pharmaceutical dosage forms, in addition to emerging topic areas concerning excipient selection and use. *Pharmaceutical Excipients* contains the following chapters:

Functional Categories of Pharmaceutical Excipients
Pharmaceutical Excipients in Pediatric Formulations
The Selection of Excipients for Oral Solid Dosage Forms
Reactive Components in Pharmaceutical Excipients

Monographs

Detailed information on pharmaceutical excipients is presented in monographs, which are divided into 22 sections to enable the reader to find the information of interest easily. Although it was originally intended that each monograph contain only information about a single excipient, it rapidly became clear that some substances or groups of substances should be discussed together. This gave rise to such monographs as 'Coloring Agents' and 'Hydrocarbons'. In addition, some materials have more than one monograph depending on the physical characteristics of the material, e.g. Starch versus Pregelatinized Starch. Monographs are also included for coprocessed materials as these excipients provide additional functionality compared to a simple mixture of the component excipients. Regardless of the complexity of the monograph they are all divided into 22 sections as follows:

1 Nonproprietary Names
2 Synonyms
3 Chemical Name and CAS Registry Number
4 Empirical Formula and Molecular Weight
5 Structural Formula
6 Functional Category
7 Applications in Pharmaceutical Formulation or Technology
8 Description
9 Pharmacopeial Specifications
10 Typical Properties
11 Stability and Storage Conditions
12 Incompatibilities
13 Method of Manufacture
14 Safety
15 Handling Precautions
16 Regulatory Status
17 Related Substances
18 Comments
19 Specific References
20 General References
21 Authors
22 Date of Revision

Descriptions of the sections appear below with information from an example monograph if needed.

Section 1, Nonproprietary Names

Lists the excipient names used in the current British Pharmacopoeia, European Pharmacopeia, Japanese Pharmacopeia, and the United States Pharmacopeia/National Formulary.

Section 2, Synonyms

Lists other names for the excipient, including trade names used by suppliers (shown in italics). The inclusion of one supplier's trade name and the absence of others should in no way be interpreted as an endorsement of one supplier's product over the other. The large number of suppliers internationally makes it impossible to include all the trade names.

Section 3, Chemical Name and CAS Registry Number

Indicates the unique Chemical Abstract Services number for an excipient along with the chemical name, e.g., Acacia [9000-01-5].

Sections 4 and 5, Empirical Formula and Molecular Weight and Structural Formula

Are self-explanatory. Many excipients are not pure chemical substances, in which case their composition is described either here or in Section 8.

Section 6, Functional Category

Lists the function(s) that an excipient is generally thought to perform, e.g., diluent, emulsifying agent, etc. For the purpose of consistency, the functional categories used in the current edition of *Pharmaceutical Excipients* are regularly reviewed, in particular to take account of pharmacopeial developments; *see* Table I. For further discussion of functional categories *see Functional Categories of Pharmaceutical Excipients*.

Note that the terms specific to the type of stability issue addressed are used in place of the general term "stabilizing agent" or "stabilizer":

Physical stability
Antiadherent
Anticaking agent
Dispersing agent
Emulsion stabilizing agent
Foam stabilizing agent
Gelling agent
Humectant
Suspending agent
Viscosity-increasing agent

Microbiological stability
Antimicrobial preservative

Chemical stability
Acidulant
Air displacement
Alkalizing agent
Antioxidant
Buffering agent
Complexing agent
Opacifier

Section 7, Applications in Pharmaceutical Formulation or Technology

Describes the various applications of the excipient. Therapeutic applications and other uses (e.g. food or cosmetic applications) are included in Section 18, Comments.

Table I: Functional categories used in *Pharmaceutical Excipients*.

Functional category	Alternative term	Definition
Acidulant	Acidifying agent	Agent added to make a system more acid, decreasing the value of pH
Adsorbent	Adsorbing agent; sorbent; sorbing agent	Agent used to bind another component from within a formulation, acting as a carrier, reservoir or sequestrant
Aerosol propellant	Propellant	Agent used to provide an energy source within a formulation for generation of an aerosol on actuation of a valve
Air displacement	Gas flushing agent; sparging agent	Agent used to replace air in a product or pack with a gas phase of known composition
Alcohol denaturant	Bittering agent; denaturant	Agent added to make alcohol unfit to drink
Alkalizing agent		Agent added to make a system more alkaline, increasing the value of pH
Anionic surfactant	Detergent; surface active agent; wetting agent	Agent carrying an overall negative charge, added to reduce surface and interfacial tension
Antiadherent	Antiadhesive agent	Agent added to reduce the tendency of materials to remain attached to other surfaces
Anticaking agent	Flow aid; glidant	Agent added to reduce the tendency of materials to form non-redispersible masses
Antifoaming agent	Foam preventing agent	Agent added to reduce the stability of foams formed during processing or use of formulated products
Antimicrobial preservative	Disinfectant; preservative	Agent used to prevent spoilage due to microbial growth within a formulation
Antioxidant		Agent used to stabilize a system against oxidative degradation
Bioadhesive material	Mucoadhesive membrane	Agent used to promote adhesion to biomembranes
Biocompatible material		An agent that can be used in a parenteral implant product without producing an immune or imflammatory response
Biodegradable material		Used in products that can be degraded to nontoxic components while implanted over time
Buffering agent	Buffer	Agent used to stabilize pH within a defined range
Capsule shell material		Material used to form capsule bodies
Cationic surfactant	Detergent; surface active agent; wetting agent	Agent carrying an overall positive charge, added to reduce surface and interfacial tension
Coating agent	Enteric coating agent; film-coating agent; modified-release coating agent; sugar-coating agent	Agent used to produce a cosmetic or functional layer on the outer surface of a dosage form
Colorant	Color; colored lake; dye	An agent that imparts colour to a formulation
Complexing agent	Chelating agent; sequestering agent	Agent added to combine with another component, commonly to maintain or improve solubility or chemical stability
Cryoprotectant		Agent added to prevent cell damage during freeze-drying
Desiccant	Water-absorbing agent	Agent used to adsorb or absorb water
Direct compression excipient		Agent used to produce powder blends with flow and compaction properties suitable for tablet making without intermediate granulation steps
Dispersing agent		Agent added to prevent aggregation in liquid formulations
Dry powder inhaler carrier		Agent used in dry powder inhalation blends as a diluent providing suitable uniformity, flow and dispersion properties
Emollient		Agent added to topical formulations to promote softening of the skin
Emulsifying agent	Emulsifier	Agent added to promote mixing of immiscible phases
Emulsion stabilizing agent	Emulsion stabilizer	Agent added to improve stability against phase separation
Film-forming agent	Film-former; polymer film-former	A material which forms a thin film with some mechanical strength when applied to dosage form or other surfaces
Flavor enhancer	Flavor-enhancing agent	Agent added to enhance flavor
Flavoring agent	Flavor	Agent added to impart flavor to a product
Foam stabilizing agent	Foam stabilizer	Agent added to improve physical stability of foam
Gelling agent	Gel thickening agent	Agent added to produce a gel texture in a product
Glidant	Flow aid	Agent added to improve powder flow
Humectant	Moisture retention agent	Agent added to retain water within a product
Lubricant	Friction-reducing agent; lubricating agent	Agent added to reduce friction effects during processing or use
Lyophilization aid	Freeze-drying agent	Agent added to produce suitable physical properties in a freeze-dried product
Membrane-forming agent	Membrane former	A material which forms a thin film with defined permeability properties when applied to a surface or dosage form

Table cont.

Functional category	Alternative term	Definition
Microencapsulating agent	Encapsulating agent	Agent used to form microcapsules with desirable physical properties
Modified-release agent	Controlled-release agent; extended-release agent; release-modifying agent; sustained-release agent	Agent used to control the release rate of active ingredient from a dosage form
Nonionic surfactant	Detergent; surface active agent; wetting agent	Agent containing no ionisable functional groups added to reduce surface and interfacial tension
Ointment base		A nonaqueous vehicle for topical products
Oleaginous vehicle		An oil-based vehicle for topical products
Opacifier	Opacifying agent	Agent added to reduce light transmission in a product
Penetration enhancer	Penetration agent; penetration promoter; skin penetrant	Agent used to increase permeability of active ingredient through skin tissues
Pigment	Colored lake	An insoluble coloring agent
Plasticizing agent	Plasticizer	Agent added to promote flexibilty of films or coatings
Solubilizing agent	Solubilizer	Agent added to promote solubility of an active ingredient
Solvent	Cosolvent	Component used as the vehicle for dissolved ingredients
Stiffening agent		Agent added to increase stiffness of creams and ointments
Suppository base		Agent used as the carrier for other ingredients in suppository formulations
Suspending agent		Agent added to improve dispersion stability of solids in liquids
Sweetening agent	Sweetener	Agent used to produce a sweet taste
Tablet and capsule binder	Tablet binder	Agent used to promote granule formulation during tablet and/or capsule processing
Tablet and capsule diluent	Tablet and capsule filler; tablet diluent; tablet filler	Material used to produce appropriate dosage form size, performance and processing properties for tablets and/or capsules
Tablet and capsule disintegrant	Tablet disintegrant	Agent used to promote break-up of tablet and/or capsule formulations after ingestion
Tablet and capsule lubricant	Tablet lubricant	Agent added to reduce friction effects during tablet and/or capsule processing
Taste-masking agent		Agent added to improve and/or disguise taste
Tonicity agent		Agent added to alter osmotic potential of liquid formulations
Transdermal delivery component		Component used specifically in transdermal devices
Vaccine adjuvant		Agent added to activate antibody response in vaccines
Viscosity-increasing agent	Rheology modifier; thickening agent; viscosity-controlling agent	Agent added to increase the viscosity of liquid semi-solid products
Water-repelling agent	Water repellent	Agent used to make formulations hydrophobic products

Section 8, Description

Includes details of the physical appearance of the excipient, e.g., white or yellow flakes, etc.

Section 9, Pharmacopeial Specifications

Briefly presents the compendial standards for the excipient. Information included is obtained from the British Pharmacopoeia (BP), European Pharmacopeia (PhEur), Japanese Pharmacopeia (JP), and the United States Pharmacopeia/National Formulary (USP–NF). Information from the JP, PhEur, and USP–NF are included if the substance is in those compendia. If the excipient is not in the PhEur but is included in the BP, information is included from the BP. Pharmacopeias are continually updated with most now being produced as annual editions with supplements throughout the year. However, although efforts were made to include up-to-date information at the time of publication of this edition, the reader is advised to consult the most current pharmacopeias or supplements.

Where applicable harmonized monographs are indicated. Important to note for this edition of *Pharmaceutical Excipients* is the removal of the Heavy Metals tests from the European Pharmacopeia, and scheduled removal of the Heavy Metals from the USP–NF as of 01 January, 2018. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, the General Information Chapter G10 in the JP, and also *Reactive Components of Pharmaceutical Excipients*.

Section 10, Typical Properties

Describes the physical properties of the excipient which are not shown in Section 9. All data are for measurements made at 20°C unless otherwise indicated. Where the solubility of the excipient is described in words, the following terms describe the solubility ranges:

Very soluble	1 part in less than 1
Freely soluble	1 part in 1–10
Soluble	1 part in 10–30
Sparingly soluble	1 part in 30–100
Slightly soluble	1 part in 100–1000
Very slightly soluble	1 part in 1000–10 000
Practically insoluble or insoluble	1 part in more than 10 000

Near-infrared (NIR) reflectance spectra of samples as received (i.e. the samples were not dried or reduced in particle size) were measured using a FOSS NIRSystems 6500 spectrophotometer (FOSS NIRSystems Inc., Laurel, MD, USA) fitted with a Rapid Content Analyser against a ceramic standard supplied with the instrument. The instrument was controlled by Vision (version 2.22) software. Spectra were recorded over the wavelength range 1100–2498 nm (700 data points) and each saved spectrum was

the average of 32 scans. Solid powdered samples were measured in glass vials of approximately 20 mm diameter. Each sample was measured in triplicate and the mean spectrum taken. When more than one batch of a material was available, the mean of all the batches is presented. Liquid samples were measured by transflectance using a gold reflector (2 × 0.5 mm optical path-length, FOSS) placed in a 45 mm silica reflectance cell against air as the reference. Spectra are presented as plots of (a) $\log(1/R)$ *vs* wavelength (dashed line, scale on right-hand side) and (b) second-derivative $\log(1/R)$ *vs* wavelength (solid line, scale on left-hand side). R is the reflectance and $\log(1/R)$ represents the apparent absorbance. Second-derivative spectra were calculated from the $\log(1/R)$ values using an 11 point Savitzky-Golay filter with second-order polynomial smoothing. Note, peak positions and amplitudes in the second-derivative spectrum are very sensitive to the method used to calculate the second-derivative.

Infrared (IR) and Raman spectra have been adapted with permission from Informa Healthcare — *Pharmaceutical Excipients: Characterisation by IR, Raman, and NMR Spectroscopy* by David E Bugay and W Paul Findlay eds, Marcel Dekker, Vol 94, 1999. All samples conformed to the USP–NF for identity and purity, and were used as received. The IR spectra were acquired on a Nicolet model 740 Fourier transform (FT) IR spectrophotometer equipped with a water-cooled globar source, Ge/KBr beamsplitter, and a deuterated triglycine sulfate (DTGS) detector. Interferograms of 16K data points were collected at a spectral resolution of 2 cm^{-1}. The number of scans acquired for each sample varied so that a minimum signal-to-noise ratio of 5000:1 was achieved. For each data set, a phase angle was calculated and then a Happ-Genzel apodization function applied. The Fourier transform was performed and the phase was corrected on the real portion of the data using the calculated phase angle to produce the single-beam spectrum. Subsequent ratioing of the single beam spectrum to the reference spectrum produced a frequency domain IR spectrum. The intensity of the IR spectra have been normalized such that the most intense absorption band equals 1 intensity unit (absorbance or Kubelka-Munk (K-M) units) and all other band intensities are relative to that band. The Spectra-Tech Collector sampling accessory was used to acquire the DR IR spectra of the solid powdered excipients. Samples were diluted in KCl (~1–5% w/w sample to KCl), ratioed against a KCl background, and the resultant spectra displayed in K-M units. IR spectra of liquid and waxy solid samples were acquired as neat smears (capillary film) between two 25– x 2–mm KBr transmission windows. A single beam data file was used as the background file for subsequent ratioing.

Raman spectra were acquired on a Nicolet model 950 FT-Raman equipped with near-IR Nd:YAG excitation laser, CaF_2 beamsplitter, and a nitrogen-cooled germanium detector. Interferograms of 16K data points were collected at a spectral resolution of 2 cm^{-1}. Happ-Genzel apodization was applied to each spectrum and the spectrum was ratioed against a white light reference spectrum. The intensity of the Raman spectra have been normalized such that the most intense emission band equals 1 Raman intensity unit and all other band intensities are relative to that band.

Where practical, data typical of the excipient or comparative data representative of different grades or sources of a material are included, the data being obtained from either the primary or the manufacturers' literature. In previous editions of the *Handbook* a laboratory project was undertaken to determine data for a variety of excipients and in some instances this data has been retained. For a description of the specific methods used to generate the data readers should consult the appropriate previous edition(s) of the *Handbook*.

Section 11, Stability and Storage Conditions

Describes the conditions under which the bulk material as received from the supplier should be stored. In addition some monographs report on storage and stability of the dosage forms that contain the excipient.

Section 12, Incompatibilities

Describes the reported incompatibilities for the excipient either with other excipients or with active ingredients. If an incompatibility is not listed it does not mean it does not occur but simply that it has not been reported or is not well known. Every formulation should be tested for incompatibilities prior to use in a commercial product.

Section 13, Method of Manufacture

Describes the common methods of manufacture and additional processes that are used to give the excipient its physical characteristics. In some cases the possibility of impurities will be indicated in the method of manufacture.

Section 14, Safety

Describes briefly the types of formulations in which the excipient has been used and presents relevant data concerning possible hazards and adverse reactions that have been reported. Relevant animal toxicity data are also shown.

Section 15, Handling Precautions

Indicates possible hazards associated with handling the excipient and makes recommendations for suitable containment and protection methods. A familiarity with current good laboratory practice (GLP) and current good manufacturing practice (GMP) and standard chemical handling procedures is assumed.

Section 16, Regulatory Status

Describes the accepted uses in foods and licensed pharmaceuticals where known. However, the status of excipients varies from one nation to another, and appropriate regulatory bodies should be consulted for guidance.

Section 17, Related Substances

Lists excipients similar to the excipient discussed in the monograph. Where a full monograph for the related substance is not included in the publication, the relevant information will be included here.

Section 18, Comments

Includes additional information and observations relevant to the excipient. Where appropriate, the different grades of the excipient available are discussed. Also includes therapeutic applications and experimental studies. Comments are the opinion of the listed author(s) unless referenced or indicated otherwise.

Section 19, Specific References

Is a list of references cited within the monograph.

Section 20, General References

Lists references which have general information about this type of excipient or the types of dosage forms made with these excipients.

Section 21, Authors

Lists the current authors of the monograph. Authors of previous versions of the monograph are shown in previous printed editions of the text.

Section 22, Date of Revision

Indicates the date on which changes were last made to the text of the monograph.

Appendices

Pharmaceutical Excipients contains several appendices to aid the user.

Appendix I: Suppliers Directory

The suppliers directory lists suppliers by monograph and country, and additionally contains supplier address and contact information. The suppliers list for each excipient are revised alongside the monograph; as product lines are subject to frequent change, the current product availability may vary from the point of revision.

Appendix II: List of Monographs by Functional Category

To facilitate comparison of pharmaceutical excipients with similar functionality in formulations, the monographs are listed by functional category in appendix II.

Appendix III: List of Related Substances

The list of related substances directs the reader to information on pharmaceutical excipients not included in *Pharmaceutical Excipients* as a full monograph. The information can be found under section 17 of the monograph directed to.

Appendices IV-VI: List of Excipient 'E' Numbers; List of Excipient 'EINECS' Numbers; and List of Excipient 'CAS' Numbers

Appendices IV to VI allow the content to be searched by various identification numbers.

New Monographs

The following new monographs have been added to the *Handbook of Pharmaceutical Excipients* since the publication of the 7th print edition.

Ammonium Glycyrrhizate
Ammonium Phosphate
Ammonium Sulfate
Arginine
Asparagine
Beta Carotene
Calcium Polycarbophil
Cetrimonium Bromide
Cholestyramine Resin
Dextrose Anhydrous
Dimethyl-β-cyclodextrin
Edetate Calcium Disodium
Gellan Gum
Gluconolactone
Glyceryl Laurate
Glycyrrhizin
n-Hexane
Histidine
Hydrogen Peroxide
Hyroxyethyl-β-cyclodextrin
Magnesium Sulfate
Methylpyrrolidone
Niacinamide
Polacrilex Resin
Proline
Sodium Polystyrene Sulfonate
Tetrasodium Edetate
Trimethyl-β-cyclodextrin

Abbreviations

Some units, terms, and symbols are not included in this list as they are defined in the text. Common abbreviations have been omitted. The titles of journals are abbreviated according to the general style of the *Index Medicus*.

≈	approximately.
Ad	Addendum.
ADI	acceptable daily intake.
API	active pharmaceutical ingredient.
approx	approximately.
atm	atmosphere.
BAN	British Approved Name.
bp	boiling point.
BP	British Pharmacopoeia.
BS	British Standard (specification).
BSI	British Standards Institution.
cal	calorie(s).
CAS	Chemical Abstract Service.
CFC	chlorofluorocarbon.
cfu	colony-forming unit
cm	centimeter(s).
cm^2	square centimeter(s).
cm^3	cubic centimeter(s).
cmc	critical micelle concentration.
CNS	central nervous system.
cP	centipoise(s).
cSt	centistoke(s).
CTFA	Cosmetic, Toiletry, and Fragrance Association.
d	particle diameter (d_{10} at 10 percentile; d_{50} at 50 percentile; d_{90} at 90 percentile).
D&C	designation applied in USA to dyes permitted for use in drugs and cosmetics.
DoH	Department of Health (England).
DSC	differential scanning calorimetry.
EAFUS	Everything Added to Food US.
EC	European Community.
EC/SCF	European Commission Science Committee on Food.
e.g.	*exemplit gratia*, 'for example'.
EINECS	European Inventory of Existing Commercial Chemical Substances.
et al	*et alii*, 'and others'.
EPA TSCA	US Environmental Protection Agency Toxic Substance Control Act.
EU	European Union.
FAO	Food and Agriculture Organization of the United Nations.
FAO/WHO	Food and Agriculture Organization of the United Nations *and the* World Health Organization.
FCC	Food Chemicals Codex.
FDA	Food and Drug Administration of the USA.
FD&C	designation applied in USA to dyes permitted for use in foods, drugs, and cosmetics.
FFBE	Flat face beveled edge.
g	gram(s).
GMP	Good Manufacturing Practice.
GRAS	generally recognized as safe by the Food and Drug Administration of the USA.
HC	hydrocarbon.
HCFC	hydrochlorofluorocarbon.
HFC	hydrofluorocarbon.
HIV	human immunodeficiency virus.
HLB	hydrophilic–lipophilic balance.
HSE	Health and Safety Executive (UK).
IA	intra-articular.
ID	intradermal.
i.e.	*id est*, 'that is'.
IL	intralesional.
IM	intramuscular.
INN	International Nonproprietary Name.
IP	intraperitoneal.
IR	infrared.
IS	intrasynovial.
ISO	International Organization for Standardization.
IU	International Units.
IV	intravenous.
J	joule(s).
JECFA	Joint FAO/WHO Expert Committee on Food Additives.
JP	Japanese Pharmacopeia.
JPE	Japanese Pharmaceutical Excipients.
kcal	kilocalorie(s).
kg	kilogram(s).
kJ	kilojoule(s).
KM	Kubelka–Munk (K–M) units.
kPa	kilopascal(s).
L	liter(s).
LAL	*Limulus* amoebocyte lysate.
LC_{50}	a concentration in air lethal to 50% of the specified animals on inhalation.
LD_{50}	a dose lethal to 50% of the specified animals or microorganisms.
LD_{Lo}	lowest lethal dose for the specified animals or microorganisms.
m	meter(s).
m^2	square meter(s).
m^3	cubic meter(s).
M	molar.
max	maximum.
MCA	Medicines Control Agency (UK).
mg	milligram(s).
MIC	minimum inhibitory concentration.
min	minute(s) *or* minimum.
mL	milliliter(s).
mm	millimeter(s).
mM	millimolar.
mm^2	square millimeter(s).
mm^3	cubic millimeter(s).
mmHg	millimeter(s) of mercury.
mmol	millimole(s).
mN	millinewton(s).
mol	mole(s).
mp	melting point.
mPa	millipascal(s).
MPa	megapascal(s).
μg	microgram(s).
μm	micrometer(s).
N	newton(s) *or* normal (concentration).
NIR	near-infrared.
nm	nanometer(s).
o/w	oil-in-water.
o/w/o	oil-in-water-in-oil.
Pa	pascal(s).

pH	the negative logarithm of the hydrogen ion concentration.
PhEur	European Pharmacopeia.
pK_a	the negative logarithm of the dissociation constant.
PLGA	polylactide-*co*-glycolide.
pph	parts per hundred.
ppm	parts per million.
psia	pounds per square inch absolute.
R	reflectance.
RDA	recommended dietary allowance (USA).
rpm	revolutions per minute.
s	second(s).
SC	subcutaneous.
SEM	scanning electron microscopy *or* scanning electron microphotograph.
SI	Statutory Instrument *or* Système International d'Unites (International System of Units).
SLN	solid lipid nanoparticles.
TC_{Lo}	lowest toxic concentration for the specified animals or microorganisms.
TD_{Lo}	lowest toxic dose for the specified animals or microorganisms.
TPN	total parental nutrition.
TWA	time weighted average.
UK	United Kingdom.
US *or* USA	United States of America.
USAN	United States Adopted Name.
USDA	US Department of Agriculture.
USP	The United States Pharmacopeia.
USP–NF	The United States Pharmacopeia National Formulary.
UV	ultraviolet.
v/v	volume in volume.
v/w	volume in weight.
WHO	World Health Organization.
w/o	water-in-oil.
w/o/w	water-in-oil-in-water.
w/v	weight in volume.
w/w	weight in weight.

Units of Measurement

The information below shows imperial to SI unit conversions for the units of measurement most commonly used in this reference work. SI units are used throughout with, where appropriate, imperial units reported in parentheses.

Area

1 square inch (in^2) = 6.4516×10^{-4} square meter (m^2)
1 square foot (ft^2) = 9.29030×10^{-2} square meter (m^2)
1 square yard (yd^2) = 8.36127×10^{-1} square meter (m^2)

Density

1 pound per cubic foot (lb/ft^3) = 16.0185 kilograms per cubic meter (kg/m^3)

Energy

1 kilocalorie (kcal) = 4.1840×10^3 joules (J)

Force

1 dyne (dynes) = 1×10^{-5} newton (N)

Length

1 angstrom (Å) = 10^{-10} meter (m)
1 inch (in) = 2.54×10^{-2} meter (m)
1 foot (ft) = 3.048×10^{-1} meter (m)
1 yard (yd) = 9.144×10^{-1} meter (m)

Pressure

1 atmosphere (atm) = 0.101325 megapascal (MPa)
1 millimeter of mercury (mmHg) = 133.322 pascals (Pa)
1 pound per square inch (psi) = 6894.76 pascals (Pa)

Surface tension

1 dyne per centimeter (dyne/cm) = 1 millinewton per meter (mN/m)

Temperature

Celsius (°C) = (1.8 × °C) + 32 Fahrenheit (°F)
Fahrenheit (°F) = (0.556 × °F) –17.8 Celsius (°C)

Viscosity (dynamic)

1 centipoise (cP) = 1 millipascal second (mPa s)
1 poise (P) = 0.1 pascal second (Pa s)

Viscosity (kinematic)

1 centistoke (cSt) = 1 square millimeter per second (mm^2/s)

Volume

1 cubic inch (in^3) = 1.63871×10^{-5} cubic meter (m^3)
1 cubic foot (ft^3) = 2.83168×10^{-2} cubic meter (m^3)
1 cubic yard (yd^3) = 7.64555×10^{-1} cubic meter (m^3)
1 pint (UK) = 5.68261×10^{-4} cubic meter (m^3)
1 pint (US) = 4.73176×10^{-4} cubic meter (m^3)
1 gallon (UK) = 4.54609×10^{-3} cubic meter (m^3)
1 gallon (US) = 3.78541×10^{-3} cubic meter (m^3)

Formulation Considerations and Related Information

Functional Categories of Pharmaceutical Excipients

DJ Goldfarb, X He, CC Sun

Introduction

A drug product, active pharmaceutical ingredient (API) plus inactive ingredients (excipients), must be commercially manufacturable and the finished product must exhibit consistent quality and stability over a prescribed amount of time. The API concentration in a product may vary over a wide range, for example from less than 1% to more than 60%, depending on the dosage form and API potency. Regardless of the API loading, the remaining excipients in the drug product play a critical role in defining the quality and performance of the drug product.[1–3]

Considering the many possible dosage forms that may need to be developed, the diverse challenges presented by APIs, the large number of available excipients, and the availability of multiple grades of the chemically identical excipients, it is difficult for an individual formulation scientist to possess all the knowledge required to efficiently select suitable excipients for the formulation development task in hand. The matter is further complicated by the fact that the same excipient may be used to deliver several functions and the same grade of excipient may be manufactured by several suppliers. Moreover, a drug product must meet several, at times conflicting, requirements. For example, a tablet needs to be sufficiently strong for it to survive the stresses during manufacturing and handling. However, it may also need to disintegrate quickly to allow fast release of the API when administered. The former requirement would require the use of tablet binders to render the powder good tabletability, while the latter requirement would require the use of disintegrants. Without information to guide the selection of excipients based on functionality, the task of developing an optimized formulation can be daunting for anyone new to formulation development or to a particular type of drug product. An additional consideration is that the selected excipients need to be chemically and physically compatible with the API. When an incompatibility is observed or suspected, a chemically different excipient that delivers the same function to the product needs to be available and selected.

Considering these challenges in pharmaceutical formulation development and the requirements of Quality-by-Design,[3,4] categorization of excipients based on their intended functionality is important and helpful. Here, the definition of excipient functional category as 'the general purpose or utility of an excipient (function) in a formulation (e.g., diluent, lubricant, glidant)' is used.[5] Functions of excipients, based on past experience or research and widely accepted, are organized and presented in categories so that a formulator can easily access a short list of suitable excipients for further evaluation for use in a specific drug product. This would significantly reduce the amount of time and cost required for developing a high quality product. For functional categories used in *Pharmaceutical Excipients* and their definitions *see* Table I in A guide to the Handbook of Pharmaceutical Excipients.

Functionality related testing

It is important to monitor and control key quality attributes of excipients using functionality relevant tests to ensure that they meet the intended purpose. For this reason, both the United States Pharmacopeia-National Formulary (USP–NF) and European Pharmacopeia (PhEur) have included information on functionality of excipients in compendial texts. USP–NF General Chapter *<1059>: Excipient performance* provides a general description of each key functional category for many types of dosage forms; the mechanisms underlying each function; common physical and chemical properties; and a list of suggested tests that may be used to ensure consistent excipient performance.[6] PhEur chapter *5.15: Functionality-related characteristics of excipients* introduces the term 'functionality related characteristics' to stress the importance of assessing and controlling critical attributes of an excipient to ensure its intended functionality is met.[7] The approaches by USP–NF and PhEur towards excipient performance are somewhat different, with the former focusing more on intended use of the excipients while the latter more on material itself. USP–NF chapter *<1059>: Excipient performance* lists specific tests, which may be used to monitor excipient performance. It is a non-mandatory informational chapter and many of the suggested tests are missing from individual excipient monographs. In PhEur chapter *5.15: Functionality-related characteristics of excipients*, a 'functionality related characteristics' section has been added to individual excipient monographs; this section is also for information only. The Japanese Pharmacopeia (JP) has not yet addressed the topic of excipient functional performance. At present, there is no plan to harmonize the approach to excipient functional performance among the USP–NF, PhEur and JP. For information on harmonization see General Chapter 5.8 in PhEur, along with the '*State of Work*' document on the PhEur EDQM website, and also the General Information Chapter G9 in the JP.[8]

In an approach similar to USP–NF *<1059>: Excipient performance*, *Pharmaceutical Excipients* also categorizes excipients based on their functionality and links them to corresponding excipient monographs. A comparison of excipient functional categories between *Pharmaceutical Excipients* and USP–NF *<1059>: Excipient performance* is shown below, *see* Table I. The most pronounced difference is that USP–NF *<1059>: Excipient performance* categorizes excipient functional categories based on dosage form and route of administration.[5,6] For example, film forming agents used to coat tablets and capsules may have different requirements from those used in transdermal patch, as the former has to be able to coat and adhere to solids, whereas the latter needs to adhere to the skin. In *Pharmaceutical Excipients* there is no such distinction, i.e., the functional category represents the excipient functionality for any dosage form or route of administration.

Table I: A comparison of functional categories in *Pharmaceutical Excipients*[a] and USP–NF.[b]

***Pharmaceutical Excipients* Functional Category**	**USP 40–NF35 Functional Category[5,6]**
Acidulant	Oral Liquids: pH modifier (acidifying/alkalizing/buffering agent)
Adsorbent	Not included
Aerosol propellant	Aerosols: propellant
Air displacement	Air displacement[c]
Alcohol denaturant	Alcohol denaturant[c]

Table cont.

***Pharmaceutical Excipients* Functional Category**	**USP 40–NF35 Functional Category[5,6]**
Alkalizing agent	Oral liquids: pH modifier (acidifying/alkalizing/buffering agent)
Anionic surfactant	Oral liquids: wetting and/or solubilizing agent
Antiadherent	Not included
Anticaking agent	Tablets and capsules: glidant and/or anticaking agent
Antifoaming agent	Antifoaming agent[c]
Antimicrobial preservative	Oral liquids: antimicrobial preservative; ophthalmic preparations: antimicrobial preservative
Antioxidant	Oral liquids: antioxidant
Bioadhesive material	Related category: Transdermal & patches: adhesive
Biocompatible material	Not included
Biodegradable material	Not included
Buffering agent	Oral liquids: pH modifier (acidifying/alkalizing/buffering agent)
Capsule shell material	Tablets and capsules: capsule shell
Cationic surfactant	Oral liquids: wetting and/or solubilizing agent
Coating agent	Tablets and capsules: coating agent
Colorant	Tablets and capsules: coloring agent
Complexing agent	Oral liquids: chelating and/or complexing agents
Cryoprotectant	Not included
Desiccant	Desiccant[c]
Direct compression excipient	Tablets and capsules: diluent
Dispersing agent	Not included
Dry powder inhaler carrier	Dry powder inhalers: carrier
Emollient	Semisolids, topicals, suppositories: emollient
Emulsifying agent	Not included
Emulsion stabilizing agent	Not included
Film-forming agent	Tablets and capsules: film-forming agent; transdermal & patches: film-forming agent
Flavor enhancer	Tablets and capsules: flavor and fragrance
Flavoring agent	Tablets and capsules: flavor and fragrance
Foam stabilizing agent	Not included
Gelling agent	Not included
Glidant	Tablets and capsules: glidant and/or anticaking agent
Humectant	Humectant[c]
Lubricant	Tablets and capsules: lubricant
Lyophilization aid	Related categories: Parenterals: bulking agent; radiopharmaceuticals: colloid stabilizing agent
Membrane-forming agent	Not included
Microencapsulating agent	Not included
Modified-release agent	Tablets and capsules: release modifying agent
Nonionic surfactant	Oral liquids: wetting and/or solubilizing agent
Ointment base	Semisolids, topicals, suppositories: ointment base
Oleaginous vehicle	Not included
Opacifier	Not included
Penetration enhancer	Not included
Pigment	Related categories: Tablets and capsules: coloring agent
Plasticizing agent	Tablets and capsules: plasticizer
Solubilizing agent	Oral liquids: wetting and/or solubilizing agent
Solvent	Related categories: Parenterals: pharmaceutical water, also in oral liquids: wetting and/or solubilizing agent
Stiffening agent	Semisolids, topicals, suppositories: stiffening agent
Suppository base	Semisolids, topicals, suppositories: suppository base
Suspending agent	Semisolids, topicals, suppositories: suspending and/or viscosity-increasing agents
Sweetening agent	Oral liquids: sweetening agent
Tablet and capsule binder	Tablets and capsules: wet binder
Tablet and capsule diluent	Tablets and capsules: diluent
Tablet and capsule disintegrant	Tablets and capsules: disintegrant
Tablet and capsule lubricant	Tablets and capsules: lubricant
Taste-masking agent	Not included. Related categories: Tablets and capsules: flavor and fragrance, also oral liquids: sweetening agent
Tonicity agent	Parenterals: tonicity agent
Transdermal delivery component	Transdermals and patches: adhesive; film-forming agent
Vaccine adjuvant	Not included
Viscosity-increasing agent	Semisolids, topicals, suppositories: suspending and/or viscosity-increasing agents
Water-repelling agent	Not included

(a) For *Pharmaceutical Excipients* functional category definitions and alternative terms, *see* Table I in A guide to the Handbook of Pharmaceutical Excipients.
(b) The following USP–NF functional categories are not explicitly included in *Pharmaceutical Excipients*: dry powder inhalers: DPI capsule shells; ophthalmic preparations: polymers for ophthalmic use; parenterals: pharmaceutical water; radiopharmaceuticals: colloid stabilizing agent; radiopharmaceuticals: reducing agent; radiopharmaceuticals: transfer ligand; radiopharmaceuticals: free radical scavenger; tablet and capsules: polymer membrane.
(c) Additional USP–NF functional categories not listed in USP–NF <*1059*>.

Impact of excipient properties on functional performance

When excipients are the main components in the product, the properties of the product are dominated by excipients. However, when the excipients represent only a minor portion of the drug product (e.g., lubricants and disintegrants), their properties may still be important for attaining the desired pharmaceutical properties of the drug product. Therefore, batch-to-batch consistency of excipients can affect the consistency of the quality of drug products regardless of the drug loading.

The requirement of batch-to-batch consistency of excipients may be related to both chemical purity and physical attributes; that is, physico-chemical properties may impact the functional performance of an excipient. Examples of factors that may affect the batch-to-batch consistency include:[5,6]

- the amount of reactive components (e.g., peroxides, aldehydes and trace level of heavy metals), which may significantly affect the stability of a drug product: *see also* Reactive Components in Pharmaceutical Excipients;
- the molecular weight distribution of a polymer, which may affect critical properties such as viscosity;
- different grades of polymeric disintegrants, neutral or ionic, which may lead to very different disintegration performance of a tablet in the gastrointestinal tract;
- differences in particle size, morphology, and moisture content of chemically pure excipients, which may also lead to differences in performance during manufacturing and storage of various dosage forms, such as powders, tablets, semisolids, liquid suspensions, or solutions.

Different grades of chemically identical excipients can, therefore, have different functional purposes and may need to be categorized

accordingly; for example, the particle size distribution of lactose used as a carrier in an inhalation dosage form is usually smaller (for improved lung penetration) than lactose used as a filler in tablets manufactured using direct compression (in which powder flow and compaction properties are important functional properties). Such properties, which may be critical to the quality and the performance of the finished drug product, need to be monitored and controlled in accordance with their functionalities.

The selection of a particular excipient is based not only on the chemical compatibility, but also the intended manufacturing process, the final dosage form, and the unique functionalities of available grades of excipients. New types of excipients intended for unique functionalities have been developed by coprocessing or modifying the particulate properties of existing excipients. For example, bigger or more spherical particles exhibiting enhanced flowability may be more suitable for direct compression than finer grades of otherwise chemically identical excipients, provided powder segregation is not a problem. Where chemical compatibility is not an issue, this approach could be effective in addressing the difficulty in commercial introduction of chemically novel functional pharmaceutical excipients because of the high costs associated with establishing their safety profiles.

Quality risk management

As part of the drug product development process, the concentration and functional performance of the API and excipients, which impacts the drug product's Critical Quality Attributes (CQAs), must be documented in the ICH M4 Common Technical Document (CTD)[9] and be assessed during the Quality Risk Management (QRM) process. These are respectively described in the ICH guidance documents: *ICH guidance Q8 (R2), Pharmaceutical Development*,[10] and *ICH guidance Q9, Quality Risk Management*.[11] This evaluation is crucial to the development of a drug product, with the guidance documents highlighting the specific understanding of the impact of the API and excipients on the quality of final product.[10,11] Key to both guidance documents is the identification of the CQAs of the final drug product, and *ICH Q9* details the process for assessing the risks associated not only with the drug product manufacture but also with its components. The CTD should also include an evaluation of the compatibility of the API with the excipients, and requires that 'the excipients chosen, their concentration, and the characteristics that can influence the drug product performance (e.g., stability, bioavailability) or manufacturability should be discussed relative to the respective function of each excipient.'[10] Therefore, identification of the respective key excipient attributes, which impact the drug product CQAs, is an integral part of the drug product development and the QRM assessment conducted includes both the paper exercise and resultant development batch manufacture.

The Certificate of Analysis (CoA) for a given excipient lists specifications, but may not cover all the attributes relevant to the drug product CQAs. Additionally, the ranges may be too wide to be useful, even with compendial materials. While chemical attributes (e.g., purity) may be sufficiently explicit for the purposes of determining impact on the drug product CQA, physical attributes may be lacking. For example, a single sieve specification (e.g., 99% passing through a given mesh size) may be listed on the CoA, when a more detailed particle size distribution may be desired for properly assessing impact on drug product CQA. In the QRM process, the inherent risk related to the intended functionalities of excipients must be evaluated to reduce the risks of varying excipient attributes on the drug product CQAs. These risks are integrated into the process of developing a control strategy for the drug product under development. Such information may be obtained by measurements on multiple lots of excipients representing the whole range of variability, which may not be easily available otherwise. On the other hand, an overly tight specification based on certain physical attributes may risk rejection of excipients batches that are suitable for delivering desired CQAs to the drug product. It is advisable for the drug product manufacturer to discuss with excipient suppliers before setting tighter limits for an excipient specification.

Conclusion

By comparing the functional categorization in *Pharmaceutical Excipients* with that in the compendial literature and highlighting the impact of the excipient attributes in their respective functional roles on the drug product, consideration of the diversity of functionalities of excipients as well as the crucial role they play in the overall quality of the drug product dosage form is encouraged.

Pharmaceutical Excipients in Pediatric Formulations

L Contreras, A Cram, C English, J Heimlich

Introduction

Pharmaceutical excipients are included in formulations for both adult and pediatric patients for a variety of reasons, for example to provide a carrier for the active pharmaceutical ingredient, to improve drug product processability, to facilitate drug solubility or absorption, or to ensure formulation stability and physiological compatibility. While excipients were at one time considered to be 'inactive' ingredients, it is now understood that they can, in certain cases, have an impact on the safety, bioavailability and stability of the drug product as well as patient acceptability. Therefore the presence and quantity of excipients in the formulation need to be justified.

The introduction of the Pediatric Regulation in the European Union (EU) in 2006[1] had a significant influence on the development considerations of drug products for pediatric use. The Regulation outlines the requirements of the *Paediatric Investigation Plan* (PIP) aimed at ensuring necessary data are obtained through studies in children to support the authorisation of medicines for use in children. With regard to pediatric formulations, the PIP should include details of currently available presentations of the drug product and indicate where further formulation development activities are planned to provide an age appropriate dosage form for pediatric use. Within the US, the 2012 *Food and Drug Administration Safety and Innovation Act* (FDASIA)[2] strengthened the laws previously in place to improve the availability of pediatric drugs by making the *Best Pharmaceuticals for Children Act* (BPCA) and the *Pediatric Research Equity Act* (PREA) permanent. The FDASIA also outlined the requirements for the submission of a *Pediatric Study Plan* (PSP) to support earlier pediatric drug development. In support of both the PIP and the PSP, the applicant needs to provide a rationale for the chosen formulation for pediatric administration, along with a justification for the choice of excipients taking into consideration patient safety and the quality of excipients in each formulation.

As intended, the regulations in the EU and US have promoted an increase in the research and development of pediatric-specific dosage forms by both industry and academia, which includes investigation of both the dosage form and excipients to be used.[3,4]

At this time, only the EU and the US have pediatric specific regulation and guidance.

Pediatric Dosage Form Development

When a pediatric product is being developed, consideration needs to be made as to the route of administration and type of dosage form required, as discussed in the European Medicines Agency (EMA) *Guideline on Pharmaceutical Development of Medicines for Paediatric Use*.[5] There are a range of challenges related to pediatric dosage form development, with several reviews available.[6–8] Current regulations require 'age-appropriate' dosage forms, which indicate that a dosage form is required to meet the specific demands of the pediatric population in question including physiological requirements as well as administration challenges. There are many physiological differences between adult and pediatric patients that need to be addressed during the development of a dosage form for pediatric use, for example the pH and residence time in the gastrointestinal tract, and the activity of enzymes and transporters.

A very significant difference between pediatric and adult patients is in the ability to swallow different types of oral dosage forms, with younger children unable to swallow large, monolithic presentations (e.g. tablets and capsules). Multiparticulate dosage forms such as granules, pellets and minitablets, greatly facilitate the administration of solid oral dosage forms in younger children. Liquid oral dosage forms can also be taken by younger children and neonates, providing flexible dosing that can accommodate changes in dose based on adjustments for weight, body surface area, or patient age. The ease of swallowability and dose flexibility have led to a historical dependence on liquid dosage forms for pediatric patients, however they also have some significant drawbacks. Liquids (solutions or suspensions) can have issues with stability, concerns over transport (bulky containers, potential need for refrigeration), potential dosing errors (due to inadequate mixing of suspensions prior to administration), and significant difficulty in masking the unpleasant taste of an active ingredient. There are also concerns with oral powders for reconstitution related to the availability of potable water and appropriate reconstitution.[9] The administration of multiparticulate solid oral dosage forms can overcome some of the challenges associated with liquid presentations.

Development of a pediatric dosage form for oral use should include consideration of multiple dosage forms to address the needs of the pediatric population and the characteristics of the drug, for example a liquid dosage form (solution or suspension, ready made or for reconstitution), a monolithic solid dosage form (tablet or capsule), or a multiparticulate dosage form (for example pellets, granules or mini-tablets). The above considerations would need to be addressed for any dosage form, with age-appropriate delivery required across the target pediatric population, as well as more traditional concerns such as stability, bioperformance, and other factors generally considered for an oral dosage form.[10]

Parenteral dosage forms for children can be the same or similar to the adult dosage form, with the main concern being the availability of appropriate dose strengths and pack sizes to avoid dosing errors. Reasons for accidental misdosing include the requirements for complex dose calculations because of varying pediatric body weights or body surface areas, and complicated formulation dilution steps required to achieve the correct pediatric dose.[11] Factor of 10 errors or decimal place errors are common, especially when drugs are available in several concentrations and when pack sizes deliver multiples of the required pediatric dose.[12] In addition, the total acceptable fluid load for the pediatric patient age group as well as dose accuracy during administration need to be taken into account when developing the drug product. Neonates may only be able to accept very small volumes of medicines in order to avoid volume overload and to allow for the administration of essential fluid nutrition. On the other hand infusions must not be so concentrated that the appropriate dosing rates are not feasible by using standard pump equipment. Pediatric physiology and excipient acceptability should also be evaluated when designing parenteral products.

The Role of Excipients in Pediatric Dosage Forms

The role of excipients in pediatric dosage forms has been outlined in the EMA *Guideline on Pharmaceutical Development of Medicines for Paediatric Use*.[5] Consideration needs to be given to the

function of the excipient, the safety profile of the excipient with regard to the target age group, the exposure and the duration of use, the condition that is to be treated, patient acceptability, palatability and any known allergies and sensitisation concerns.

In order to develop an acceptable age appropriate formulation some excipients are more commonly used in dosage form development for the pediatric patient group. These include, amongst others, excipients to improve formulation palatability and provide taste-masking (e.g. sweeteners and flavouring agents), and excipients which facilitate formulation of oral solution and suspension products (e.g. solubilisers, preservatives, and suspending agents). Consequently, pediatric formulations may include a broader range of excipients than adult dosage forms, all of which should be justified.

Acceptable palatability is a key consideration when developing pediatric oral dosage forms as it directly impacts patient adherence. Taste-masking should be considered for all oral presentations, but this is challenging in oral liquid dosage forms, where the dissolved drug comes into direct contact with the taste receptors on the tongue. A range of excipients and technologies are available to the formulator to mask the unpleasant taste of drugs in different oral dosage forms. Examples include covering up unpleasant taste with flavours and sweeteners, complexation with ion-exchange-resins or cyclodextrins, and barrier approaches using polymer coatings or lipidic excipients.[13]

Dosage form stability and excipient compatibility studies are also an important aspect of formulation design; however requirements for pediatric dosage forms are largely the same as for adult preparations. When pediatric formulations are designed to be mixed with food or drink (e.g. multiparticulate or sprinkle dosage forms), stability and compatibility of the dosage form with the proposed food or drink needs to be confirmed. This is of particular importance for dosage forms with a functional film coat (for example providing taste-masking or modified release) where mixing with foodstuffs must not impact on dosage form performance prior to administration.

A key element in pediatric dosage form development is the choice of suitable excipient types and concentrations. In addition to ensuring the correct excipient is selected on the basis of its role, there are also biopharmaceutical, safety and regulatory considerations that need to be addressed for pediatric patients.

Biopharmaceutical Effect of Excipients

Physiology changes rapidly with age, impacting both pharmacokinetics and pharmacodynamic responses to drugs. For instance, the residence time of a dosage form in various portions of the gastrointestinal (GI) tract, the pH of the GI tract, the maturation of biliary excretions, and the presence and activity of different enzymes and transporters, can be significantly different in adults and in pediatric patients. Physiological changes can also vary significantly within the pediatric population (e.g. between neonates and older children).[7,8] For example, gastric pH and emptying can have a major impact on drug bioavailability through their effect on certain drugs (e.g. solubility, absorption, metabolism, stability) or pH sensitive dosage forms (e.g. enteric coated formulations).[14] Pediatric patients demonstrate a variable but age-related trend from birth well into infancy and childhood, with the greatest changes occurring during the neonate's first month. At birth, gastric pH is in the neutral range, between pH 6 and 8, but falls to between pH 1.5 and 3 within a day. Following this, up to 10 days from birth, gastric pH increases again to between 6 and 7, and remains in the neutral range for approximately 28 days. This is followed by a gradual reduction to adult capacity of pH 1 to 2 by the age of approximately 3 years. In addition, the rate of gastric emptying during the neonatal period is both variable and prolonged.[15]

Technologies and associated functional excipients, such as film coating of pediatric multiparticulate formulations (e.g. used for taste-masking purposes or gastric protection), also have the potential to alter drug bioavailability. For example, enteric coatings are commonly used to coat dosage forms either to protect the stomach from the drug, or protect the drug from the low pH typically seen in the stomach. However, the neutral pH conditions in the oral cavity can result in a loss of integrity of sensitive enteric coatings of tablet or granule formulations if the dosage form is not swallowed immediately, but kept in the mouth longer; this could be a consideration for pediatric administration. As another example, solid oral dosage forms may use barrier membrane systems based on a pH trigger (e.g. reverse enteric membranes). These systems have the advantage that they can achieve good taste-masking as they do not release drug under the neutral conditions of the mouth. Typical reverse enteric systems need to be in an acidic environment (the stomach) for a sufficient period of time in order to fully dissolve and release the drug. GI transit in the pediatric population can be very variable and age-dependent and similarly, there is also a risk that in certain pediatric age groups or disease states, the required acidic pH to cause complete dissolution of the film coat may not exist. All these factors need to be considered when assessing bioperformance risks associated with products containing these excipients.[15]

Other common excipients used in pediatric formulations may have unintended influence on the bioavailability of a drug. For example, they can affect absorption (e.g. surfactants or excipients that may affect transport transit proteins), *in vivo* solubility (e.g. co-solvents), or *in vivo* stability of the active substance.[16]

Excipients that accelerate transit through the small intestine (e.g. polyethylene glycol, sodium acid pyrophosphate, and poly-alcohols, such as mannitol and sorbitol) reduce gastrointestinal absorption of medicines primarily absorbed at this site (e.g. ranitidine, cimetidine). Diarrhoea has been reported for sorbitol-containing formulations as well as a decrease in maximum serum concentration (C_{max}) and total exposure (area under curve) for some drugs. In those cases, a relatively minor formulation change such as the use of a different sweetener in an oral formulation can have a significant effect on bioavailability of the drug.[17] The bioavailability of a drug may also be reduced when it forms a poorly soluble, non-absorbable complex with an excipient (e.g. tetracycline with calcium phosphate; amfetamine with sodium carboxymethylcellulose; or phenobarbital with polyethylene glycol 4000).[18,19]

Safety of Excipients

The justification of selecting excipients for pediatric dosage forms needs to take into account a range of safety-related factors, including patient age, route of administration, dose levels and frequency (e.g. acute or chronic dosing). The condition to be treated and the safety in the targeted age group at the proposed exposure levels also needs to be considered. The number and concentration of each excipient used in a formulation should be kept to the minimum necessary to achieve the required target product profile criteria such as product quality, stability, bioavailability and patient adherence. It should also be noted that previously authorized pediatric products may contain concentrations of excipients, which are now no longer recommended for use in children. Previous approval of an excipient in a pediatric drug formulation may not automatically qualify its safe use in another pediatric formulation, route or age group.

The EMA *Guideline on Pharmaceutical Development of Medicines for Paediatric Use*[5] contains guidance on the choice of excipients for pediatric products, along with suggested sources of information to assess the excipient safety. It also provides a hierarchical decision tree to guide the developer through the various sources of information already available to support the justification or to determine whether additional safety studies may be required.

The 'Acceptable daily intake' (ADI) established by the Joint FAO/WHO Expert Committee on Food Additives (JECFA) provides an acceptable mass of excipient per unit body weight per day (mg/kg/day) for the adult population. However ADI figures are commonly used for the risk assessment of excipients in pediatric

Table I: Examples of excipient-related adverse events in pediatric patients, patients with metabolic disorders, and hypersensitive patients.

Excipient	Route of administration	Adverse event
Neonates and infants <6 months of age		
Benzyl alcohol[30,31]	Oral, parenteral	Neurotoxicity, metabolic acidosis, gasping syndrome, risk of hyperbilirubinaemia in neonates.
Propylene glycol	Oral, parenteral[8,20,31]	Seizures, hyperosmolarity, neurotoxicity.
	Topical[18,30,31]	Skin irritation, contact dermatitis.
Polyethylene glycol[20]	Parenteral	Metabolic acidosis.
Polysorbate 20 & 80[20]	Parenteral	Liver and kidney failure.
Polysorbate 80[30]	Topical	E-Ferol syndrome—thrombocytopenia, renal dysfunction, hepatomegaly, cholestasis, ascites, hypotension, metabolic acidosis.Inhibition of p-glycoprotein with potential effects on the blood–brain barrier and drug–drug interactions.
Ethanol[30,31]	Oral, parenteral	CNS depression—muscle incoordination, visual impairment. Negative synergic effects on CNS when associated with propylene glycol. Chronic toxicity.
Propylparaben[30,31]	Oral	Hyperbilirubinemia in neonates. Hypersensitivity reactions. Agonistic activity at hormone receptors.
Patients with a metabolic disorder		
Aspartame[8]	Oral	Phenylketonuria (source of phenylalanine).
Fructose, sucrose[20]	Oral, parenteral	Hereditary fructose intolerance.
Sorbitol[20]	Oral	Hereditary fructose intolerance.
Lactose[8]	Oral	Lactose intolerance, galactosemia, diarrhoea.
Hypersensitive patients		
Azo dyes[8]	Oral	Allergenic potential, should not be used in children.
Parabens[20]	Oral, ocular, topical	Allergies, contact dermatitis.
Sulfites, bisulfites[30,31]	Oral, parenteral, topical	Rashes, abdominal upset. Hypersensitivity, paradoxical bronchospasm, wheezing, dyspnoea and chest tightness in asthmatic children.
Lanolin[20]	Topical	Contact dermatitis, urticaria.

formulations.[20] Precedence of use of excipients or excipient concentrations in commercially available drug products for adults may not be appropriate for use in pediatric patients, or for children of different ages. Excipients may also have different effects on developing organ systems, depending on the child's age and developmental stage. In addition, metabolic capacity is restricted in young children, especially during the first months of life. These factors can result in elevated toxicological risks in children compared to adults for some excipients.[21] As an example, propylene glycol is commonly used to solubilise drugs in oral, parenteral and topical formulations; in the body it is partially excreted by the kidneys unchanged and partially oxidized to lactic and pyruvic acid, entering the glycolic pathway and ultimately resulting in the production of carbon dioxide and water. The half-life of propylene glycol in adults is 5 hours compared to 16.9 hours in a neonate; adverse events reported in neonates include metabolic acidosis (due to lactic acid) and serum hyperosmolarity (due to propylene glycol accumulation) after intravenous administration and topical administration on burn wounds.[22] As such, the use in a product for pediatric use should be carefully considered and justified in line with current safety information and regulatory requirements.[23]

Specific hypersensitivities associated with certain excipients (e.g. azo-dyes, lanolin), as well as metabolic disorders (e.g. phenylketonuria) also need to be considered when selecting excipients; however this does not exclusively apply to the pediatric population.

Table I provides examples of reported adverse events with a number of excipients commonly used in pediatric formulations.

The STEP (Safety and Toxicity of Excipients for Paediatrics) database, jointly developed by the European Paediatric Formulation Initiative (EuPFI) and the US Pediatric Formulation Initiative (USPFI), collates preclinical and clinical safety and toxicity data for excipients commonly used in pediatric dosage forms. The STEP database is a useful repository for the formulator when assessing excipient safety for different pediatric age groups and routes of administration.[24–26]

Other sources of safety information on excipients include the EMA web page 'excipients labelling',[27] which contains a growing number of question and answer documents that have been generated following a decision by the European Commission (EC) to revise the guidance on excipients in the label and package leaflet of medicinal products for human use. The guidance documents with specific reference to pediatrics include; ethanol, propylene glycol, sodium methyl/propyl paraben and boric acid. In the US, the FDA Inactive Ingredient Database (IID) provides information on the quantities of excipients found in US approved drug products; such information can be useful to determine previous precedence of use. However, such information in isolation is not sufficient to justify the use of an excipient in a formulation.

Justification of Excipients - Regulatory Considerations

The EU Paediatric Regulation outlined the requirement for the submission and approval of a PIP. The PIP must be approved prior to the application for a Marketing Authorisation Application (MAA) for a new medicinal product in the EU, or following significant changes to an existing product already approved and on-patent such as a new indication, pharmaceutical form, or route of administration. Within the quality sections of the PIP, the applicant is expected to provide a justification for the pharmaceutical form for the intended pediatric population, which would include the excipient justification for review by the Paediatric Committee (PDCO).

The Formulation Working Group (FWG) supports the PDCO in the review process providing input on formulation aspects. In 2013, the EMA published a list of criteria for screening PIPs with regard to pediatric specific quality issues and referring them to the PDCO and the FWG for discussion. Included are aspects related to the age appropriateness of the formulation, considerations for administration (including palatability and the safety evaluations for the chosen excipients with respect to the target population), dosing, and duration of exposure.[28]

Following the review by the PDCO and the FWG, the choice of excipient may become the subject of 'key binding elements in the PIP decision', with a recommendation to replace or remove an excipient in the formulation, which would lead to the requirement to reformulate the drug product and has a high probability of affecting the overall development timeline for the product.[29]

Conclusion

The choice of suitable excipients is one of the key elements of pharmaceutical development for a pediatric medicinal product. When designing an age-appropriate pediatric formulation, excipients should be selected considering a number of different aspects outlined in this chapter.

The number and concentration of each excipient should be kept to the minimum necessary to achieve the required target product profile criteria, such as stability, bioavailability and patient compliance. Each excipient needs to be justified in terms of its function and quantity present in the dosage form, using a benefit-risk approach.

Where excipients with an identified risk cannot be avoided in the formulation of a particular pharmaceutical dosage form, the added value of the chosen pharmaceutical dosage form (and route of administration) should be balanced against the possible use of other pharmaceutical dosage forms and routes of administration that do not require the use of such excipients.

The Selection of Excipients for Oral Solid Dosage Forms

IL Smales, MG Rowland

Introduction

The preferred route of administration for most Active Pharmaceutical Ingredients (APIs) is orally due to ease of administration, improved patient adherence and reduced complexity required to manufacture oral solid dosage forms compared with alternative drug delivery systems. Factors which may preclude oral administration of APIs include poor bioavailability resulting from poor solubility and/or permeability, poor stability and degradation during gastric transit, as well as the therapeutic site and method of action. Examples of common oral solid dosage forms include tablets, capsules, beads, orally disintegrating tablets (ODTs) and lozenges, all of which involve compounding the required quantity of the API (the dose) with one or more excipients. The range of excipients available to the formulator is truly diverse; however, excipients are, in general, intended to be pharmacologically inert whilst conferring advantageous physical properties to the formulation, facilitating its ability to safely and reliably deliver the API to the therapeutic site of action. Excipients are only included within a formulation if there is suitable justification to do so. In general, the selection of an excipient is based on the dose, type of drug product, physicochemical properties, chemical compatibility with the API, route of delivery, administration frequency, interactions with other formulation components, method of manufacture, processability and the container or closure system.[1] This chapter aims to describe the scientific rationale behind the selection of common excipients used to manufacture oral solid dosage forms.

Excipients to enhance the flow of powders and granules

One of the most commonly identified critical quality attributes (CQAs) in the production of oral solid dosage forms is powder or granule flow. Modern tablet and capsule machines are designed to produce several hundred thousand units per hour and adequate flow of the final blend is essential to ensure that the resultant dosage form is consistent in terms of weight, composition and, for tablets, the degree of compaction it has received.

Flowability is not an inherent powder property but depends on four factors:

- Intrinsic properties such as particle size, density, shape and roughness.
- Bulk properties such as particle size distribution, cohesive and frictional interactions.
- External conditions such as temperature, humidity or state of compaction.
- Processing equipment design and settings, which affect the powder dynamics.

As such, it is impossible to adequately characterize flow using a single measurement technique. Although traditional, empirical tests such as compressibility or angle of repose may give a qualitative means of classifying or comparing powder behaviors, the data produced by more sophisticated techniques such as ring shear testing or powder rheometry enables a more complete characterization of powder flow and cohesion properties.[2]

APIs are often subjected to a particle size reduction process in order to ensure that the final dosage form meets the required standards of content uniformity and dissolution; thus they often contain a significant proportion of fine particles (e.g. with diameter <20 μm). These particles, by virtue of their high specific surface area, often exhibit high degrees of adhesion to other surfaces and cohesion to neighboring particles resulting in poor flow.[3] Certain morphologies of the API such as needle-shaped or acicular particles may also have a negative impact on flow due to mechanical locking. As a result, where the formulation contains a high percentage of API (e.g. $>10\%$) it may be possible to improve the overall blend flow by modifying either the particle shape or the particle size of the API present.

If the formulation composition is fixed, a preferred option for improving flow is to increase the particle size using a granulation process, which requires a degree of compactibility and moderately good flow for the purposes of roller compaction or the selection of an appropriate binder if wet granulation is adopted. If the formulation is open to modification, flow can be improved by switching excipient grades; many of the excipients used in solid dosage forms are marketed in a range of different particle size grades as shown in Table I. The benefits of increasing particle size must be weighed against the potential increased risk of API segregation from the other blend components, or the possible reduction in compactibility or dissolution rate. For example, one of the larger grades of microcrystalline cellulose (*Avicel PH-200*) has improved flow but has poorer compactibility than a smaller particle size grade (*Avicel PH-102*).[4]

The flow of both powders and granules can often be significantly improved by the addition of glidants, which are very finely divided powders that, by virtue of their small particle size (typically less than 50 nm), have a strong tendency to become adsorbed onto the surface of larger powder blend components. This process increases the minimal contact distance and reduces the contact area between the larger particles, resulting in the reduction of van der Waals forces and the tendency of powders to aggregate.[5,6] Additionally, glidants may increase flowability by absorbing moisture or rolling under stress.[5] Colloidal silica is one of the most effective glidants and is usually added at levels $<1\%$, but other materials such as maize starch or talc are often used in capsule formulations where compactibility is less crucial. A recently developed technique to improve flow known as 'nanocoating' involves comilling of colloidal silicon dioxide onto host pharmaceutical particles, prior to the addition of the remaining formulation components. This step has been shown to improve the flow of both APIs and active blends.[7]

Excipients to enhance the compaction of oral solid dosage forms

Compaction can be defined as the transformation of a powder or granules into a coherent dosage form of defined shape through the process of compression[8] and is the fundamental concept behind successful tablet production. A degree of compactibility is also important for capsule formulations, as successful capsule filling depends on the production of robust and uniform powder plugs at forces much lower than those used in tablet production.[9]

The compaction of a powder under pressure generally involves a number of processes:[8]

- Particle rearrangement

Table I: Examples of particle size grades of common solid dosage form excipients.

Excipient	Grade	Manufacturing method	Nominal particle size (μm)
Microcrystalline cellulose	*Avicel PH-101*	Spray Dried	50
	Avicel PH-102	Spray Dried	100
	Avicel PH-200	Spray Dried	180
α–Lactose monohydrate	*Fast Flo*	Spray Dried	120
	Tablettose 70	Spray Agglomeration	200
	Tablettose 80	Spray Agglomeration	180
	FlowLac	Spray Dried	190
Dibasic calcium phosphate anhydrous	*A-TAB*	Precipitation	180
Starch, pregelatinized	*Starch 1500*	Partial pre-gelatinisation	65
Corn starch and pregelatinized starch, coprocessed	*StarCap 1500*	Partial pre-gelatinisation & blending with corn starch	90
Mannitol	*Pearlitol 50 C*	Crystallization	50
	Pearlitol 200 SD	Spray Dried	180

- Elastic i.e. reversible deformation of particles
- Plastic i.e. irreversible deformation of particles
- Fragmentation of particles
- Formation of interparticle bonds

Theoretically, materials may compress by either plastic deformation or brittle fracture but, in practice, most excipients and drugs will compact via a combination of these mechanisms. Compacts prepared from the excipients most commonly used to formulate immediate release dosage forms can be ranked in order of tensile strength as follows:[10]

Highest

Microcrystalline cellulose

Spray-dried lactose

Dibasic calcium phosphate

Lactose

Mannitol

Lowest

A number of particle bonding mechanisms that may occur during compaction have been identified however, three tend to dominate where dry powders are involved:

- Solid bridges (e.g. due to melting)
- Distance attraction forces (intermolecular forces)
- Mechanical interlocking (between irregularly shaped particles)

Intermolecular forces act between surfaces separated by distances of 100–1000 Å and are the dominant bonding mechanism for plastically deforming materials.[8] If the surfaces of these particles become coated with the API or a lubricant, such as magnesium stearate, the bonding ability can be seriously compromised. However, during the compaction of brittle materials, fresh uncoated surfaces are exposed by particle breakage and for this reason it is generally preferable to formulate tablets using a blend of plastic and brittle materials in order to maintain tablet hardness despite changes in processing methods or API properties. Solid bridges are formed where a true contact is established between particles at the atomic level. These can occur as a result of sintering, melting, crystallization, chemical reaction or binder hardening. Mechanical interlocking can occur when particles become twisted or hooked together and thus depends on the shape and surface structure, becoming more significant where needle-shaped fibers or irregular particles are compressed.[9]

Microcrystalline cellulose (MCC) is partially depolymerized cellulose comprised of needle-like microcrystals agglomerated into porous particles. As a result of its peerless compactibility, low lubrication requirement and self-disintegrating properties, MCC has become perhaps the most popular excipient for tablet compaction in the modern pharmaceutical industry.[11,12] A range of grades is available that vary in their particle size, moisture content, and density and therefore their physical properties and applications. In order to avoid potential segregation issues in blends destined for direct compression, it is advisable to use a grade of a similar particle size to the API being formulated. MCC also exhibits a high degree of viscoelastic behavior, resulting in increased strain rate sensitivity; hence at higher tableting speeds there may be insufficient time for plastic deformation to occur and care is needed when scaling up formulations containing MCC from slow speed development presses to high speed rotary production machines.[12]

Lactose is widely used as a tablet excipient and is available in several grades with differing physical properties. Spray-dried lactose comprises mainly of α–lactose monohydrate microcrystals bound into spherical agglomerates by small amounts of amorphous lactose, and was specifically designed to exhibit the superior flow and compaction properties necessary for direct compression.[11]

Dibasic calcium phosphate dihydrate forms very hard but brittle compacts and is frequently used in tandem with plastic materials such as MCC; blends formed can therefore be used for both direct compression and granulation. It has a high bulk density, which can lead to segregation issues with some APIs, but an anhydrous form of lower density is available as well as granulated grades possessing superior flow.[13]

Mannitol and sorbitol both have good aqueous solubility, a pleasant cooling taste, and are widely used in the manufacture of chewable and sublingual tablets.[11] Although mannitol contributes little in the way of strength to a tablet, it does show a reduced tendency for brittle fracture making it suitable in direct compression applications.[10] Mannitol may also be an appropriate replacement for lactose, where the latter shows chemical incompatibility with the API. The hygroscopic nature of sorbitol may accelerate the degradation of moisture-sensitive compounds, and recrystallization of sorbitol upon ageing may also give rise to tablet hardening over time.

Pregelatinised starch is a form of starch which has been chemically and/or mechanically modified to rupture some of the starch granules; this process improves the compactibility, disintegration and flow. This material, however, is sensitive to the adverse effects of magnesium stearate on tablet hardness and dissolution; hence stearic acid may be a better choice of lubricant. At higher strain rates, starch deforms elastically which can increase the risk of tablet capping.[11]

In addition to the fillers mentioned above, low levels (<10%) of a high performance dry binder (e.g. polyethylene glycols or povidones) may be added to a formulation to increase compactibility either for tableting or as an aid to granulation by roller compaction, without significantly adding to the tablet weight.[14,15]

Various excipient grades are commercially available with a range of properties, and it is essential that the correct grade is identified as

early as possible; compaction issues such as tablet hardness or friability can often be alleviated simply by switching to a more appropriate grade of the same material.[10,13] In addition, apparently equivalent materials sourced from different manufacturers can also differ in their properties and it is therefore essential that excipients obtained from alternative suppliers are evaluated before any changes are adopted.[10,12]

It is also important that potential polymorphic changes during processes such as compaction or wet granulation are monitored as the properties of some excipients such as mannitol may change drastically as a result of polymorphic changes occurring during processes such as wet granulation.[16]

Excipients to enhance the lubrication of oral solid dosage forms

Most tablet formulations require the addition of a lubricant (generally added in powder form) to reduce friction at the interface between the powder or granule and the metal surfaces of the die wall during tablet formation and ejection. The addition of a lubricant can also prevent sticking of tablets to the punch face, reduce wear to tablet or capsule tooling, and improve flow and filling properties. Lubricants are often added to capsule blends to reduce adhesion to metal surfaces and reduce the force required to eject the formed capsule powder 'plug' into the capsule shell.[9] Lubricants are usually added at the end of the blending process, but where a dry granulation step is required, a proportion of the lubricant is added prior to granulation to prevent sticking to the rollers.

There are two basic mechanisms for the action of lubricants: either by the formation of a continuous 'liquid film', which separates the tablet and powder surfaces, or by means of 'boundary lubrication', where lubricant particles form a continuous or noncontinuous resistant layer on the metal surfaces or the powder or granules. Boundary lubrication is more common in pharmaceutical dosage forms.

A wide range of materials have found employment as lubricants in pharmaceutical formulation as shown in Table II.[17,18]

Table II: Classes of Materials used as Lubricants in Pharmaceutical Solid Dosage forms.

Chemical Class	Examples	Typical levels used
Metallic salts of fatty acids	Magnesium stearate; aluminium, calcium and sodium stearates	0.5–1.0%
Fatty acids, hydrocarbons and fatty alcohols	Stearic acid; palmitic acid; stearyl alcohol	2.5%
Fatty acid esters	Glyceryl behenate; glyceryl monostearate	2.0–4.0%
Polymers	Polyethylene glycols; polytetrafluoroethylene	1.0–4.0%
Others	Hydrogenated castor oil	0.5–2.0%
	Hydrogenated vegetable oil	0.5–2.0%
	Sodium stearyl fumarate	0.5–1.0%

Magnesium stearate, which works as a boundary lubricant, is the material most commonly used in both tablet and capsule formulations. Magnesium stearate possesses a number of appropriate physical properties including a small particle size, high surface area and melting point, and a low affinity for tooling and die surfaces, which result in low coefficients of friction and low shear stresses.[19] However, the hydrophobic nature of magnesium stearate, together with its low shear strength, mean that excessive blending may lead to the generation of a 'waterproofing' layer over powder particles, which can inhibit the wetting and dissolution of the eventual dosage form. This magnesium stearate layer also inhibits bond formation during tablet compression; hence overblending can also lead to reduced tablet strength. Special attention should therefore be given to the amount of blending experienced by formulations containing magnesium stearate, not only during blend preparation but also whilst the powder passes through the various hoppers, feed tubes and other surfaces of the processing equipment.

Other stearic acid salts have also been used, however these all have the same potential for adverse effects on tablet hardness and wettability.[17] Fatty acids, hydrocarbons, and fatty alcohols are less effective lubricants than magnesium stearate but do not carry the same risk of overlubrication. Stearic acid is the most commonly used material in this category and is typically added at levels of 2.5%. The hydrophilic nature of sodium stearyl fumarate means that even though it is a boundary lubricant, its use does not attract the same risk to wettability as that of magnesium stearate and it can be used as a replacement where dissolution or tablet hardness effects are a concern.[19] Glyceryl behenate, glyceryl stearate and hydrogenated vegetable oil are examples of liquid film lubricants which function by melting under pressure and are generally added at levels of 2.0–4.0%; of these, glyceryl behenate is the most commonly encountered. Other materials, such as colloidal silicon dioxide, starches, and talc, have also been shown to improve the lubrication of oral solid dosage forms.[18]

Excipients to enhance the disintegration of oral solid dosage forms

Disintegration, whereby a tablet or capsule breaks down into granules or aggregates is the first step in the dissolution of an immediate release formulation. The solubility and particle size of the API will naturally exert a large influence over drug dissolution, but excipients can also exert either a positive or negative effect by virtue of their solubility, wetting or wicking ability. Water soluble, hydrophilic excipients such as lactose or mannitol will naturally assist in wetting and dissolution. Conversely, dibasic calcium phosphate dihydrate, which is insoluble, nevertheless has a very low contact angle and will promote rapid fluid penetration into the dosage form.[11] MCC is also insoluble but has a very high intraparticle porosity, which promotes fluid penetration by means of capillary action; this and the disruption of hydrogen bonds as a result of wetting promote swelling and tablet disintegration.[12] Wetting can also be promoted by the inclusion of low levels (typically $\leq$1%) of solid surface active agents or surfactants at the blending stage. Careful attention should be paid to the regulatory acceptability of these materials and there is some evidence that sodium lauryl sulfate may hinder the dissolution from capsules in acidic media and reduce tablet hardness.[20]

To ensure effective disintegration of solid dosage forms in solution, it is usually necessary to add an excipient specifically designed to act as a disintegrant. Maize starch has a long history as a disintegrant due to its ability to promote water uptake but its prominence, particularly in tablets, has been largely superseded by the advent of the 'superdisintegrants'. These materials, which are generally added at levels up to approximately 8%, fall into one of three main types: modified starches such as sodium starch glycolate, crospovidones e.g. *Polyplasdone XL*, or modified celluloses such as croscarmellose sodium and low-substituted hydroxypropylcellulose (L-HPC). Superdisintegrants draw water into the tablet by capillary action then swell to force the tablet apart by exerting internal pressure.[21] This mode of action means that in the case of capsules, where the powder fill is only lightly compressed, it may be necessary to increase the level of disintegrant used.

The water uptake and swelling capacity of disintegrants containing ionisable materials have been shown to be reduced in acidic solution. However, crospovidone is nonionic and so its mode of action may be less affected by the pH of the dissolution medium.[22] The efficacy of a disintegrant should be assessed in the context of the complete formulation, as the solubility of other

excipients can have a large effect on disintegrant action, particularly at a lower or higher pH.

Wet and dry granulation processes may extend tablet disintegration times by increasing the disintegrant particle size; the modified cellulose types may be less susceptible to this effect, and dry granulation is likely to have a lesser effect than wet granulation.[23] Where a formulation requires granulation, it is sometimes necessary to incorporate disintegrants in both the intra- and extra-granular locations.[24] Some excipient manufacturers offer alternative grades of disintegrants that are recommended for granulated formulations.

Excipients to facilitate the granulation of oral solid dosage forms

Where the drug loading exceeds approximately 30%, or where the physicochemical properties of the API may be expected to significantly change the physicochemical properties of the formulation, it may be preferable to adopt a granulation process that renders the formulation less dependent on the API properties by:

- Improving the uniformity of API distribution.
- Improving the distribution of functional excipients e.g. disintegrants.
- Increasing density and flow.
- Reducing dust.

Techniques for granulation can be broadly divided into wet and dry methods. In wet granulation a binder solution is added, usually by spraying into the powder blend whilst mixing, either under low or high shear conditions. The wet mass is dried and then milled, prior to the addition of additional excipients such as lubricants. The water absorbing qualities of MCC make it particularly suitable for the wet granulation process, although some of its compactibility may be lost during the process, so it is common to combine it with a brittle fracturing excipient in order to maintain tablet hardness. The wetting and drying process may also compromise the efficacy of some disintegrants so care should be taken when making selections for which to use.

Binders are used in wet granulation to promote the agglomeration of powders into granules; they may also improve tablet hardness by enhancing both intragranular and extragranular forces. A wide variety of natural and synthetic polymers and sugars have been used in wet granulation as shown in Table III.[25]

Table III: Commonly used binders for wet granulation.

Natural Polymers	Acacia; alginic acid; gelatin; sodium alginate; starch.
Synthetic polymers	Carboxymethylcellulose sodium; ethylcellulose; hypromellose; methylcellulose; povidone.
Sugars	Dextrose; sucrose; sorbitol.

The natural polymers and sugars are generally added to the powder blend in the form of a solution or, in the case of starch, as a paste; the synthetic polymers may be added as a dry powder, a solution in water, or a hydroalcoholic solvent blend. Whilst the selection of a binder may be affected by experience and precedence, it should largely be determined through optimization studies using parameters such as granule and tablet friability, tablet tensile strength, dissolution and stability.

Dry granulation is usually achieved via the process of roller compaction, where the powder is compressed between two counter-rotating rollers; thus formulations designed for roller compaction must possess good compaction properties as well as sufficient flow to maintain a consistent process. The ribbons or flakes formed are then milled to the required size. Roller compaction is generally a faster process, and, because it avoids the wetting and drying steps involved in wet granulation, it is suitable for moisture and heat sensitive APIs or excipients.[25] As the forces involved in roller compaction are only slightly less than those involved in tablet compaction, the tensile strength of the final tablets will be reduced compared to tablets prepared from the original powder blend. Some of the compactibility of roller compacted granules may be improved by the addition of extra-granular MCC or a polymeric binder.[14,15] Tablet tensile strength may also be improved by the selection of smaller particle size grades of excipient (e.g. MCC), as the poor flow of these materials is ameliorated by the granulation process.[26]

Excipients to enhance the bioavailability of APIs within oral solid dosage forms

The physicochemical properties of both the API and the formulated medicine, including the *in vivo* solubility and permeability, will determine the pharmacokinetic parameters and the absolute bioavailability of the API. According to the biopharmaceutics classification system (BCS) as adopted by the FDA, APIs may be broadly divided into four main classes depending on their solubility and permeability as shown in Figure 1.[27] In this instance, the solubility refers to the solubility of the API in aqueous media over a pH range of 1 to 7.5 and the permeability relates to the permeability of the API through the intestinal wall.[27]

BCS Class II and Class IV compounds, which have low solubility, may be poorly bioavailable since the API does not readily dissolve in gastrointestinal (GI) fluid. In this case, the dissolution rate is the rate limiting step for systemic absorption, which may reduce the ability of the API to be therapeutically active, even at high doses.

A number of techniques may be used to improve the solubility of the API particles and the bioavailability, including particle size reduction, polymorph and salt selection, and surface chemistry modification.[28] Excipients may also be used to further enhance the solubility via a number of different mechanisms.

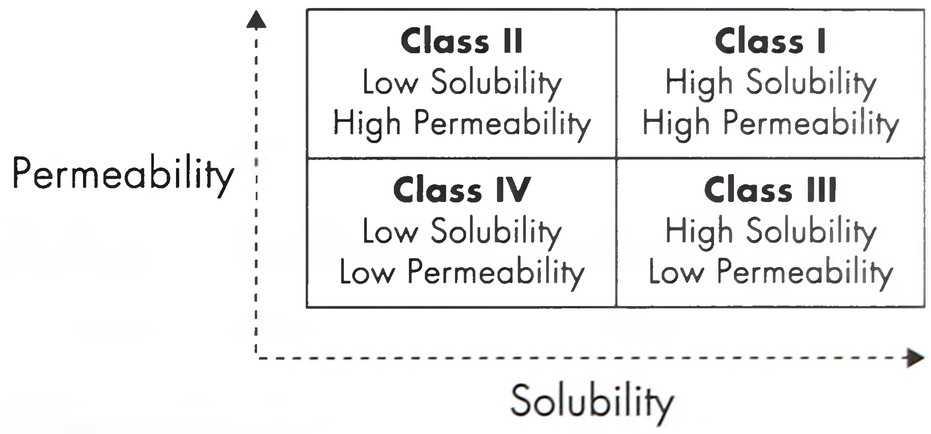

Figure 1: The biopharmaceutics classification system (BCS) as determined by the permeability and solubility of active pharmaceutical ingredients according to FDA guidance.[27]

Cyclodextrin Complexation

Cyclodextrins are cyclic oligosaccharides which are obtained from the enzymatic degradation of starch. The most commonly used are α, β and γ-cyclodextrins, which are cup shaped and consist of a ring of 6, 7 or 8 D-(+)-glucopyranose units respectively. The external surfaces of cyclodextrins consist of polar, hydrophilic, water soluble functional groups that impart water solubility. The internal cavity consists of apolar, hydrophobic groups that are able to complex to the API, and the cyclodextrin is chosen so that the diameter of the internal cavity matches the diameter of the API for complexation. Cyclodextrin–API complexes may be prepared by generating solutions which are subsequently spray-dried or freeze-dried to produce the complex as a solid powder. Substituted cyclodextrin complexes are commonly used in parenteral formulations. Cyclodextrin complexes may also be included in oral solid dosage forms, and as well as improving API solubility and bioavailability, they may also improve API stability, taste, odor and other physical properties.[29]

Solid dispersions

A pharmaceutical solid dispersion is defined as a mixture of an API with one or more hydrophilic carrier excipients in the solid state, in which the API is evenly distributed throughout the carrier and the release rate is governed by the carrier solubility in addition to other physical properties.[30] The excipients are selected according to their physical properties, including wettability, solubility, dissolution rate, melting point, compatibility with the API and the method of preparation. Excipients typically selected are more water soluble than the API, improving the solubility by dissolving quicker than the API and therefore improving the rate at which it is released into solution. This allows for the preparation of either immediate or modified release dosage forms depending on the physical properties of the excipients selected.

Various methods are available to prepare solid dispersions with common techniques employing either melting or solvent evaporation of a suspension or solution of the API and excipients to produce a uniform solid mixture.

In the case of melting, the API is mixed with a molten carrier, such as a sugar or polymer, and cooled to produce the solid dispersion. Examples of melt techniques used to produce solid dispersions include hot melt extrusion,[31] melt agglomeration, and injection molding.[32] The resulting structure may have a lower lattice energy than the pure API, and so is easier to disrupt, thus enhancing the kinetic solubility of the API by increasing the dissolution rate. Further processing such as milling may then be used to produce granules or particles suitable for the preparation of dosage forms if required. Melt techniques may therefore be used as a tool to further decrease the particle size of the API and thus enhance its solubility. Examples of crystalline excipients that have been used for melt processes include urea, mannitol and other simple sugars. Polymer excipients which are utilized include polyethylene glycols (PEGs), povidone (PVP), polyvinyl alcohol (PVA) and polymethacrylates, polyvinyl caprolactams, polyvinyl acetates, and natural polymers including cellulose derivatives such as ethylcellulose (EC), hydroxypropyl cellulose (HPC) and hypromellose (HPMC). In order to further increase the solubility of the API, surfactants such as sodium lauryl sulfate, inulin, polysorbates, stearoyl polyoxylglycerides or poloxamers may also be incorporated into the formulation.[33] Modified release formulations may also be prepared by using polymers such as poly(lactic-co-glycolic acid) (PLGA).

In the case of solvent evaporation, a solution of the API and the excipients is produced with a volatile solvent which is then removed to produce the solid dispersion. This typically results in the production of an amorphous solid solution, again with a lower lattice energy than that of the pure API, thus increasing its solubility. Depending on the method, solvent evaporation may be advantageous over high temperature methods of producing solid dispersions if the API is thermally labile. Two commonly used techniques to prepare solid dispersions via solvent evaporation are spray drying and lyophilization.

During spray drying, the API and excipients are atomized and exposed to a heated drying gas to evaporate the solvent; this leaves behind solid particles consisting of an amorphous dispersion of the API and excipients. Various carrier excipients may be used for spray drying in combination with poorly soluble APIs, including cellulose derivatives such as HPMC, HPMC acetate succinate, sodium carboxymethylcellulose, and MCC; vinyl polymers such as PVP and PVA; lipids such as stearoyl polyoxylglycerides and glyceryl dibehenate; polytheylene oxides (and derivatives) such as polyethylene glycols and poloxamers; and carbohydrates such as mannitol, lactose, acacia gum and inulin.

During lyophilization, a solution or suspension of the API and excipients is frozen and then dried under vacuum. Drying consists of both primary drying (sublimation of frozen water) followed by secondary drying (the removal of nonfrozen 'bound' water).[34] The most common application of lyophilization is to provide a stable dispersion of an API and excipients suitable for reconstitution and intravenous or subcutaneous injection. However, other uses include the preparation of solid dispersions for incorporation into tablets and capsules, and the preparation of wafers for buccal delivery and orally disintegrating tablets (ODTs).[35] Excipients are used within a lyophilized formulation to improve the physical properties and stability of the formulation,[36] for instance as bulking agents,

Table IV: Excipients commonly used for freeze-drying.

Bulking agent	Buffering agent	Solubilizing agent	Tonicity agent	Antimicrobial preservatives	Collapse temperature modifier
Sugars:	Buffers:	Complexing agents:	Sodium chloride	Benzyl alcohol	Dextran
Mannitol	Citric acid	Edetic acid (EDTA)	Sucrose	Phenol	Hydroxyethyl starch
Lactose	Sodium citrate	Alfadex	Mannitol	*m*-Cresol	*Ficoll*
Sucrose	Potassium citrate	Hydroxypropyl	Dextrose	Methyl paraben	Gelatin
Trehalose	Tartaric acid	betadex		Ethyl paraben	
Sorbitol	Sodium phosphate				
Glucose	Tris base				
Raffinose	Tris HCl				
	Tris acetate				
	Zinc chloride				
	Sodium acetate				
	Potassium acetate				
	Arginine				
Amino acids:	pH Adjusters:	Surfactants:			
Arginine	Hydrochloric acid	Polysorbate 80			
Glycine	Sodium hydroxide				
Histidine	Meglumine				
Polymers:		Co-solvents:			
Dextran		Tert-butyl alcohol			
Polyethylene glycol		Iso-propyl alcohol			
		Dichloromethane			
		Ethanol			
		Acetone			
		Glycerol			

buffering agents, solubilizing agents, tonicifying agents, antimicrobials and collapse temperature modifiers. *See* Table IV.[37]

Permeability enhancers

As well as poor solubility, a further factor that may prevent absorption of APIs is poor permeability. APIs may be poorly permeable if the molecule weight is very large (such as in the case of proteins and peptides) making the API too large to pass through the intercellular tight junctions in the intestinal wall. A further cause of poor permeability may be the presence of significant hydrogen bonding between API molecules, or if the API is highly hydrophobic.[38] No true permeability enhancers are included within oral solid dosage forms as excipients. Nevertheless, various different types of excipient may act as permeability enhancers by enhancing API transit through the intercellular tight junctions. Care must be taken if attempting to enhance permeability that the intestinal wall is not damaged.

Mechanisms by which excipients may improve permeability include membrane modulators, tight junction modulators, substrates of uptake transporters, carriers across membranes and inhibitors of efflux transporters as described by Hamman and Steenekamp.[39] Lipid excipients are a major class of permeability enhancers, which may also act to increase the solubility of hydrophobic APIs. Examples of lipid excipients include fatty acids, natural oils and fats, semisynthetic mono-, di- and triglycerides, semisynthetic polyethylene glycol (PEG) derivatives of glycerides and fatty acids, polyglyceryl fatty acid esters, cholesterols, phospholipids as well as ionic and nonionic surfactants.[40] The majority of lipid excipients are liquids at room temperatures and therefore for oral solid dosage forms may only be suitable for incorporation into soft or hard gelatin capsules. However, some solid lipids may be incorporated into tablets or powder in capsule (PIC) formulations. As well as promoting solubility and permeability, the incorporation of lipids may produce self-emulsifying drug delivery systems (SEDDS), promote supersaturation, increase gastrointestinal residence time, effect intestinal based efflux, and influence drug metabolism in the intestine.[41] Medium chain fatty acids such as capric acid, lauric acid, and their sodium salts, which are solid at room temperature, have been used as permeability enhancers although the biological mechanism by which they operate is still disputed.[42]

Surfactants

In order to further improve the bioavailability of an API within an oral solid dosage form a surfactant may also be included within the formulation. In the formulation of drug products, surfactants are commonly used as emulsifiers, solubilizers and wetting agents.[43] Surfactants may be broadly divided into anionic, cationic, amphoteric, and nonionic subgroups.

Anionic surfactants have a negative charge on the hydrophilic headgroup group which commonly consists of carboxylate, sulfate or sulfonate ions. Examples of the types of anions used include stearates, sulfosuccinates, lauryl sulfates, oleates and fumarates. Metal cations which are typically employed to balance the anionic charge include sodium, magnesium, calcium and zinc. Cationic surfactants have a positive charge on the hydrophilic headgroup and are generally considered to have a greater toxicity than anionic surfactants; therefore cationic surfactants are less commonly used. Examples of cationic surfactants include benzalkonium choride and cetrimide. Amphoteric surfactants have the ability to be positively charged, negatively charged, or neutral, depending on the pH of the media which they are in and are commonly found in cosmetics, but not oral solid dosage forms. Nonionic surfactants which may be used in oral solid dosage forms are numerous and include glycol and glycerol esters, sorbitan derivatives, polyoxyl esters, polyoxyl ethers, poloxamers, and natural emulsifiers (including phospholipids). Comprehensive lists may be found in the United States and European Pharmacopeias and are summarized by Marti-Mestres and Nielloud.[43]

Excipients used in Film Coating

Sometimes APIs are bitter in taste which may result in poor patient compliance when formulated within oral solid dosage forms. In addition, stability of the API may be compromised due to moisture ingress into the tablet core or exposure to light hence reducing shelf life. Film coating of tablets is therefore often performed in order to provide taste-masking of the formulation and to enhance stability.[44] Film coatings are also commonly used for decorative purposes in order to provide a color for the dosage form, thus providing a commercial image.

Typically, film coatings are applied by spraying an aqueous or organic solution of a polymer, a plasticizer (such as triacetin or polyethylene glycol) and if required an anti-tacking agent (such as talc) onto tablet cores which are then dried to remove the solvent. Various polymers are used for film coating, examples of which are shown in Table V.[44] For decorative film coats, hypromellose or polyvinyl alcohol are commonly used and globally acceptable pigments such as iron oxides or lakes may also be included to provide color to the tablets thus providing brand enhancement. In addition, the inclusion of certain polymers within a film coat may also be used to produce modified-release formulations.

It is advisable to ensure that dosage forms to be film coated do not contain excessive amounts of disintegrant (<5%) so that film defects or core erosion do not occur during the coating process. It is also advisable to keep lubricant levels below 2% in order to ensure suitable film adhesion to the core.

Modified release oral solid dosage forms

Modified-release formulations are used to modify the rate, place or time of drug release from a dosage form.

(a) Modifying the rate of drug release

Modified release products that affect the rate of drug release prolong drug absorption resulting in a longer time to maximum plasma concentration (t_{max}) and a lower maximum plasma concentration (C_{max}). This may allow for a reduction in the dosing

Table V: Polymers used for film coating oral solid dosage forms.

Water soluble polymers	Entero-soluble cationic polymers	Enteric, anionic polymers	Water insoluble polymers
Hydroxyethyl cellulose	Amino dimethyl methacrylate copolymer	Sodium alginate	Ethylcellulose
Hypromellose	Amino diethyl methacrylate copolymer	Shellac	Cellulose acetate
Carboxymethylcellulose sodium		Cellulose acetate phthalate	Poly (ethyl acrylate-co-methyl-methacrylate)
Povidone		Cellaburate	Ammonio methacrylates
Polyvinyl alcohol		Methacrylic acid copolymer (Types A, B and C)	Polyvinyl acetate
			Carboxymethylcellulose

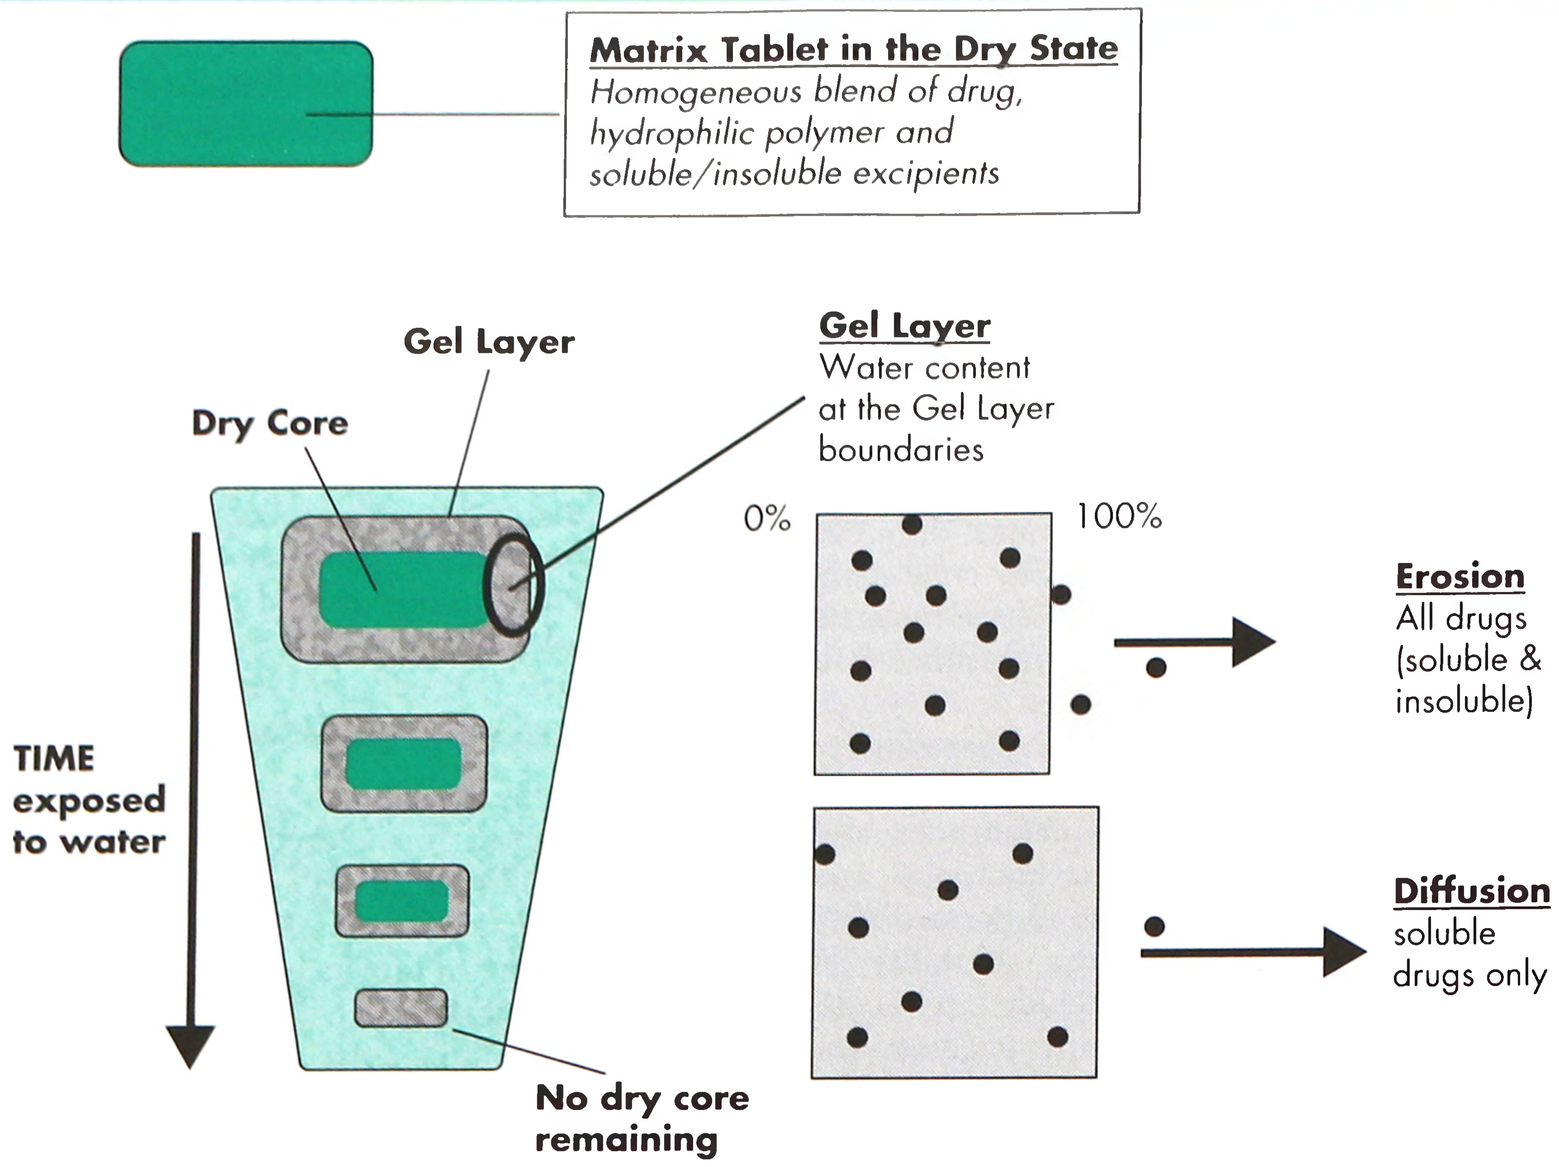

Figure 2: Hydration and drug release from a controlled release matrix tablet.

interval and may also potentially reduce the number of adverse events compared to an immediate release formulation.[10] Oral modified-release delivery systems that modify the rate of drug release can be broadly divided into 4 categories based on their mechanism of drug release:[45]

a(i) Dissolution-controlled release

Dissolution-controlled release of an API depends on modifying the rate at which either a polymer membrane or a polymer matrix dissolves in the dissolution fluid. A rate-controlling membrane is achieved by coating particles (often beads or pellets) with a relatively insoluble polymer, for example ethylcellulose or cellulose acetate using pan coating or, more commonly, an air suspension coating technique. API release is modified by the type of polymer and the thickness of the applied coat. Coated pellets are frequently tableted or filled into capsule shells. Ethylcellulose is available as a water-based coating system (e.g. *Surelease*, Colorcon, or *Aquacoat*, FMC Biopolymer) to reduce safety or environmental concerns around processing.

Dissolution-controlled release using a matrix involves the incorporation of the API into either a hydrophobic matrix or hydrophilic matrix. API release is controlled by the rate of penetration of the dissolution fluid into the matrix which is affected by the matrix composition and porosity. Excipients used to form a hydrophobic matrix include, for example, polyethylene, polypropylene, carnauba wax or ethylcellulose; examples for a hydrophilic matrix include hypromellose, methylcellulose, hydroxypropyl cellulose or sodium carboxymethylcellulose.

a(ii) Diffusion-controlled release

Diffusion-controlled release depends on controlling the partitioning of solubilised API molecules through a polymer; this polymer can either be applied as a coating around powder particles or, more frequently, it is dry blended with the powder and compressed using a conventional tablet press to form a continuous matrix tablet. As matrix tablets are relatively easy to develop and manufacture they are widely employed to modify the drug release rate from dosage forms, and are well understood as a result of several decades of research. On contact with the dissolution medium, the exterior surface of a matrix tablet forms a swollen gel layer which advances towards the interior of the tablet as hydration proceeds as shown in Figure 2. Whilst the release of soluble APIs is via diffusion through the polymer matrix, some release of both soluble and insoluble APIs can occur through erosion as the polymer chains in the outer surface begin to disentangle and the gel layer is slowly worn away. The importance of erosion can be determined comparing the dissolution profile of the API with the dissolution profile of the polymer alone.

Cellulose ethers are the most popular excipients used to formulate matrix tablets as they display good compactibility and swell rapidly on contact with aqueous media. In addition, they are available in a wide range of grades depending on their degree of substitution and viscosity, both of which have an effect on drug release.[45] Hypromellose (HPMC) is the most frequently encountered polymer used to formulate matrix tablets[46] but other materials include:

- Methylcellulose (MC)
- Ethylcellulose (EC)
- Hydroxyethyl cellulose (HEC)
- Hydroxypropyl cellulose (HPC)
- Carboxymethyl hydoxyethyl cellulose
- Hydoxyethylmethyl cellulose (HEMC)
- Cellulose acetate phthalate enteric coating

The characteristics of HPMC encourage the formation of a tight, strong gel compared to other cellulosics; as a result API release is slowed to a greater extent when using HPMC compared to using similar levels of methylcellulose, hydroxyethyl cellulose or carboxymethyl cellulose.[47]

The two grades of HPMC most frequently used for matrix tablets are HPMC 2208 (USP) & HPMC 2910 (USP). HPMC 2208 has a higher ratio of hydoxypropoxyl to methoxyl substitution, rendering it more hydrophilic and thus faster to establish the release-limiting gel barrier on the tablet surface. Rapid gel formation has a large effect on initial drug release i.e. the lag time during which release is uncontrolled and is of particular importance when formulating APIs of higher water solubility.[45]

HPMC 2208 and HPMC 2910 are available in a range of molecular weight grades (classified by their viscosity in aqueous solution) and those of higher viscosity will retard drug release to a greater extent. These materials are also both produced in small particle size grades recommended for the formulation of matrix tablets with modified drug release. Polymer particle size appears to have a greater effect on the release of water soluble drugs; smaller particles ensure a more rapid gel layer formation, which is crucial where the release of soluble API is of interest.[47]

Drug release from HPMC-based matrix tablets is controlled by:

- Drug solubility in water
- Drug concentration in the tablet
- Hydoxypropoxyl : methoxyl substitution ratio
- Polymer viscosity grade
- Polymer concentration
- Polymer particle size

Products of different viscosity can be blended to obtain an intermediate viscosity where fine tuning of drug release rate is required. In addition, other excipients may be added to the formulation to aid the compactibility and other physical properties as outlined previously in this chapter. Where granulation is required (e.g. to improve flow), roller compaction is generally the preferred process as the addition of any aqueous binder solution to a blend containing these polymers will initiate irreversible gel formation and processing may be more difficult.

a(iii) Ion Exchange Resins

Ion exchange resins are water insoluble materials containing either:

- Anionic groups such as amino or quaternary ammonium groups.
- Cationic groups such as carboxylic acids or sulfonic groups in repeating positions on the resin chain.

An API–resin complex is formed by prolonged exposure of an API to the resin, and exchange of the ionic form of the API with the resins ionic functional group. This complex can be made into a range of dosage forms including tablets or capsules.[48] Exchange with ions in the gastrointestinal fluid releases the API, and is dependent on the concentration and affinity of the gastrointestinal ions to exchange.[49,50] The API is bound at both internal and external exchange sites, therefore release rate is influenced by diffusion to and from the internally bound exchange sites.[49,50] The release of the API from weak anionic or cationic resins is also influenced by the pKa of the resin and pH at the site of action, as the API release will only occur when the API–resin complex is in its ionized state.[49,50] The release of API can be further modified by coating the API–resin complex with a semipermeable membrane providing a barrier to diffusion.[49,50]

a(iv) Osmotically controlled systems

Osmotically controlled systems consist of a semipermeable membrane surrounding an osmotic tablet core containing the API. At a rate depending on the surface area, thickness and composition of the membrane, fluid is drawn into the tablet core causing an increase in pressure which forces the API, as either a solution or a suspension, out of the dosage form via a delivery port drilled through the membrane layer. Some systems use a bilayer tablet core where a sweller layer is used beneath the API layer to ensure constant and complete release of the drug content as shown in Figure 3. The increase in volume of the sweller layer pushes the API layer through the delivery port.

The semipermeable membrane comprises a mixture of a water insoluble material with a water soluble polymer, for example, cellulose acetate with polyethylene glycol, typically applied to achieve a coat thickness up to 250 µm. A low molecular weight grade of polyethylene oxide (e.g. *Polyox N80*, Dow Chemical Company; molecular weight approximately 200 000) is blended with the API to form the API layer; the sweller layer uses a higher molecular weight grade of polyethylene oxide (e.g. *Polyox coagulant*, Dow Chemical Company; molecular weight approximately 5 000 000) combined with an osmogen, such as sodium chloride. API release rates from these systems generally show a good correlation between *in vitro* and *in vivo* profiles as it is relatively immune to gastrointestinal pH and motility and the fed/fasted state of the patient.

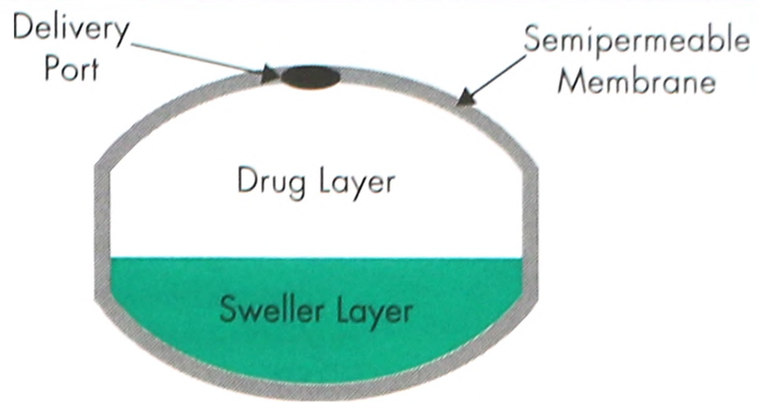

Figure 3: Schematic diagram of a bilayer osmotically controlled modified release dosage form.

b) Modifying the site of drug release

b(i) Gastroretentive systems

Variability in GI transit time can adversely affect the release profile of orally administered modified-release drug substances, particularly if the API has a narrow absorption window. A dosage form retained in the stomach whilst the API is released will ensure that a solution of the API regularly exits the stomach along with the gastric fluids and thus has the whole surface area of the small intestine for adsorption. In addition, it can offer enhanced drug therapy for local conditions affecting the stomach. Retention in the stomach can be achieved by formulating a low density or floating dosage form, based on a gel forming polymer (e.g hydroxypropylcellulose) or using a hydrophobic fatty material (e.g. stearates).

b(ii) Enteric coatings

Entero-soluble cationic polymers do not dissolve in the saliva of the patient but do dissolve in the acid media of the stomach, providing effective taste-masking but still ensuring rapid release of the API from the dosage form. Anionic polymers do not dissolve in either the saliva or the acid conditions of the stomach but do dissolve slowly in gastrointestinal (GI) fluid. This is known as enteric coating and may be used for modified-release formulations together with various insoluble polymers as described in Excipients for Capsule Formulation. *See also* Table V.

c) Modifying the time of drug release

c(i) Pulsatile Drug Delivery Systems

Some conditions require a dosage form which delivers its drug only after an initial delay or lag time has elapsed. This delay can be used to protect the drug from the acidic conditions of the stomach or to maximize drug delivery to the lower regions of the GI tract.[51] The onset of drug release can be time-controlled (i.e. as a result of changes in the delivery device itself) or site-controlled as a result of the biological environment within the GI tract (e.g. pH or enzymes).[52]

Delayed onset or pulsatile drug delivery is generally achieved using a drug reservoir based on a capsule or tablet which is coated with a polymeric barrier, which gradually dissolves or erodes or is ruptured as a result of swelling of the core. Core swelling is achieved through the use of effervescent excipients, for example, citric acid and sodium bicarbonate, or swellable materials such as cellulose ethers. In some devices water is drawn into the core through a semipermeable membrane via the action of an osmotically active material added to the formulation.[51]

The water-insoluble polymers used to form the barrier coat include cellulose acetate, ethyl cellulose, cellulose acetate phthalate or various types of methacrylic acid copolymers (e.g. *Eudragit RS* or *Eudragit RL*).[2] The pH-solubility of the methacrylic acid copolymers depends on their structure and composition – thus by careful choice, drug release can be targeted to specific regions of the

Table VI: Desirable Flow Parameters for Capsule Blends.[9]

	Very poor flow	Recommended Range	Very good flow
Flow parameter	Level powder bed not maintained Poor filling of cavities on tamping disc machines High fill weight variability	—	Water effect seen on tamping disc machines. Stable plug may not be formed on dosator machines
Compressibility Index	>35%	15–25% 5–35% may be suitable for dosator nozzle machines	<15%
Angle of repose	>30°	25–30°	<25°
Flow function coefficient (from ring shear testing)	<4	4–10	>10

GI tract. Lipids such as carnauba wax or beeswax have also been used to create the barrier coat.[51]

In the *Pulsincap* device, a nondisintegrating capsule body is closed with an insoluble plug which separates the capsule contents from the external medium. The plug swells on contact with the medium and, after a controlled lag time, is extruded from the shell thereby releasing the capsule contents. A range of polymers can be used to form this plug[53] as follows:

- Insoluble but permeable and swellable polymers e.g. polymethacrylates such as *Eudragit*.
- Erodible compressed polymers e.g. hypromellose, polyvinyl alcohol, polyvinyl acetate, polyethylene oxide.
- Congealed, melted polymers e.g. saturated polyglycolated glycerides, glyceryl monooleate.
- Enzymatically controlled erodible polymers e.g. pectin.

Drug delivery devices such as these can also be tailored to synchronize drug release with the circadian rhythms shown by many physiological functions (e.g. hormone secretion, gastric emptying and gastrointestinal blood transfusion) or the pathophysiology of several disease conditions (e.g. bronchial asthma, myocardial infarction, ulcer and hypertension).[51]

Excipients for Capsule Formulation

Despite the enduring popularity of the compressed tablet, there are several circumstances where a capsule may be more appropriate:

- It is necessary to mask the taste of an unpalatable drug.
- The formulation is not sufficiently compactible to form a robust tablet.
- The stability of the API or the excipients is adversely affected by the compaction process.
- The dosage form must be easy to swallow (important for specific patient groups).
- To prevent the patient from subdividing tablets.

In addition, a capsule shell presents a versatile canvas for product recognition and dose strength differentiation through the use of colored shells and/or printing.

The excipients used to formulate capsules are generally similar to those used for tablets. A survey conducted in 1994 found that various grades of lactose were the most commonly used excipient in capsule formulations registered in both the US and Europe; next in popularity were microcrystalline cellulose in the US but chiefly starch in Europe.[54] A coprocessed mixture of corn starch and pregelatinised starch has been designed for successful capsule production. It has good flow properties and a reduced level of very fine particles to minimize dust; it also yields capsules with good disintegration regardless of pH.[4]

The majority of modern capsule filling machines used within the pharmaceutical industry fall into one of two categories based on their mode of action: tamp-filling machines or dosator nozzle machines. In both cases, good flow is essential to ensure consistent plug production and filling.[9] However, powders designed for capsule filling using a dosator machine must also possess sufficient cohesivity to form a robust arch within the dosator nozzle as the powder plug is transferred to and dropped into the capsule shell.[9]

Glidants, such as colloidal silicon dioxide or talc, are commonly added to capsule formulations to improve flow and reduce the sticking propensity.[9]

Powders with very good flow are by definition not cohesive and may not form a plug of sufficient robustness to remain intact during the filling process; this is particularly important for dosator machines, where the formed powder plug must remain within the dosator tube without losing any powder as it moves to the filling station. In tamp-filling machines, powders with very good flow may also exhibit the 'water effect' in which the powder is displaced sideways rather than downwards by the descent of the pins into the powder bed.[9] Capsule blends should therefore be formulated to fall within a range of flow values, as described in Table VI.

As with tablet development, issues related to flow or plug formation may be resolved by selecting a more appropriate excipient grade. It is also important to remember that apparently equivalent material from different manufacturers may not behave in a similar fashion on a capsule machine.[55] Particle size has a large effect on capsule filling as shown in Table VII.

A hard gelatin capsule shell contains 13–16% moisture as a plasticizer and for this reason hygroscopic materials should not be considered for capsule filling as they will draw water from the shell, causing it to become brittle.

Cross Linking of Gelatin Capsule Shells

The gelatin forming a capsule shell is susceptible to a phenomenon known as crosslinking, which hinders dissolution by the formation of an insoluble, swellable hydrogel around the powder fill. Crosslinking can be induced by storage at elevated humidities and temperatures. Crosslinking has also been correlated to the presence of a wide range of compounds; the most important of these are aldehydes, including formaldehyde, which unfortunately may be present as a reactive component in many common excipients used in capsule formulations;[56] *see also* Reactive Components in Pharmaceutical Excipients. Where it is unavoidable to exclude the presence of a material known to be implicated in gelatin crosslinking, an alternative to gelatin capsules exists in the form of capsule shells made from other polymers such as hypromellose (HPMC). These capsules contain less water than their gelatin counterparts (approximately 5%) so are preferable where filling particularly hygroscopic materials; in addition, the water present in HPMC shells does not act as a plasticizer, so changes will not have the deleterious effects on capsule robustness to which gelatin capsules are prone.

General Conclusions

The range of excipients available to the formulator that may be used for the preparation of oral solid dosage forms is highly diverse. However, as a general rule, excipients are only selected if they aid

Table VII: Effect of particle size on capsule filling.[9]

Median particle size	Properties	Tamp filling machines	Dosator nozzle machines
>150 μm	Excellent flow	Weight uniformity may suffer due to 'splashing' of the blend as the pins descend into the powder bed. Fill wt. may be difficult to achieve as blend lacks compressibility	Generally do not form cohesive plugs – dosator not recommended
100–150 μm	Plug strength may be variable	Increase level of microcrystalline cellulose	
50–100 μm	Ideal plug formation but flow may need improving	Plug formation controlled via tamping force	
20–50 μm	Sticking & poor flow	May be fillable by optimizing levels of lubricant and glidant, or via granulation	
<20 μm	Excessive adhesion to metal parts & very poor flow	Not usually fillable – granulation necessary	

with processing of the formulation or enhance/control the ability of the formulation to deliver the API to the therapeutic site of action. By modifying the physicochemical properties of excipients such as particle size, morphology and surface chemistry (to name but a few) the functionality may be tailored to suit specific applications. Furthermore, APIs that were once considered to be unsuitable for development due to poor solubility and/or bioavailability may now be revisited as candidates. Care should always be taken that the excipients selected are both physically stable and chemically inert in order to ensure the robustness of the formulation and the safety of the patient.

Despite the present wealth of knowledge generated around excipients for oral solid dosage forms, there is still a large amount of research being conducted by both industry and academia. Areas include the development of coprocessed excipients using methods such as spray-drying, or the production of combination excipients, where two different excipients are chemically linked together. These methods may confer the advantages of both excipients within the same product. The role of quality by design (QbD) in the selection of excipients is also expected to become increasingly more prominent with the justification of excipient selection occurring earlier in the development process.

Over the years, awareness of the role of excipients in the performance of dosage forms has increased drawing attention from regulators, for example with the release of guidance around safety evaluations for novel excipients.[57] As globalization continues, it is expected that the number of excipient manufacturers in developing countries will increase. This will result in an increase in the volume of imports from and outsourcing of manufacturing operations to countries with less developed regulatory systems than areas such as the US, EU and Japan. As such it is expected that cGMP guidance from the regulators concerning excipient manufacture and supply will be modernised in order to ensure continued robustness and safety of the ingredients of all medicines.[58]

Reactive Components in Pharmaceutical Excipients

R Chen, BC Hancock

Introduction

Similar to the degradation an active pharmaceutical ingredient (API) may undergo on storage, an excipient may also undergo degradation over the duration of its shelf life. Excipient degradation products may interact with an API and thus may impact the stability, safety and bioavailability of the drug product. There are also residual components such as process aids and intermediates from the excipient manufacturing process that may be carried over to the finished products. These residual components do not usually change on storage or upon incorporation into a formulation, but they may react with the API and each other and thus may compromise the stability and performance of the drug product. Excipient degradation products and residual components from excipient manufacturing processes which react with the API are termed '**reactive components**' in excipients. Understanding the nature and extent of the excipient degradation, and the excipient manufacturing process helps pharmaceutical scientists to design a drug product formulation with suitable and predictable stability and quality.

Common Reactive Components

Common excipient-related reactive components include peroxides, aldehydes, organic acids, and trace metals. Peroxides, aldehydes and organic acids may not only be carried over from the original excipient manufacturing process, but also potentially form when an excipient ages on storage. There are other kinds of reactive and nonreactive residual components which may exist in excipients, such as monomers and process aids that are used in manufacturing of many polymeric excipients.

Peroxides

Peroxides are very reactive and usually transient species in excipients or formulation solid matrices. They are an excipient-related reactive component that can play a major role in drug degradation.[1] Oxidative degradation of the drug substance may be caused by the formation and reaction of peroxy and alkoxy radicals, or by direct reaction of peroxides with nucleophilic groups on the API.[2] For example, the direct reaction of peroxide components in povidone and crospovidone with raloxifene hydrochloride in tablets has been reported.[2] Formation of the N-oxide derivative of raloxifene was an order of magnitude higher in the presence of povidone or crospovidone in comparison to other excipients investigated, and a strong correlation was observed between the total peroxide level and the quantity of the N-oxide formed upon accelerated storage. In addition, reactive peroxides are commonly associated with polymeric ether based excipients such as polyethylene glycol, polyethylene oxide, and polysorbate, while other cellulose based polymeric excipients such hydroxypropyl cellulose and microcrystalline cellulose may also have trace levels of peroxides.[3]

The most important source of peroxide generation in excipients and drug formulations is through oxidation of the excipients, for example the oxidation of polyethylene oxide derivatives, povidones, other polyols or cellulose-based excipients. This can occur during the manufacture and/or storage of excipients, or after they have been formulated into a drug product. Peroxides can be formed via *autoxidation*, which is known to occur with polyethylene glycol, a commonly used excipient in film coatings and other solid formulations. Autoxidation is an oxidation process that occurs in the presence of oxygen and forms 'organic' hydroperoxides (ROOH, sometimes also called alkyl hydroperoxides) and hydrogen peroxide (H_2O_2, sometimes also called hydroperoxide). Autoxidation is a free radical chain process involving three stages (*see* Figure 1): initiation (step a), propagation (steps b to d), and termination (steps e and f).[4]

Initiation involves generation of radicals in a so-called 'induction' period. Chain-initiating radicals may be generated through exposure of the system to light, heat, or catalytic levels of redox-active transition metals. Therefore, the induction period can vary significantly depending on the exposure condition, oxygen concentration, metal impurities in the excipient, and trace amount of existing peroxides. Once a radical is formed (step a), a chain reaction occurs (steps b to d) to form an alkyl hydroperoxide or a hydroperoxide. The chain reaction is terminated (steps e and f) when two radicals combine their extra electrons to form a new bond.

Peroxides can also be introduced into a drug product formulation from the raw materials and/or manufacturing process of an excipient. Examples include lower molecular weight polyethylene oxide which is often made by oxidizing a high molecular weight material using an oxidizing agent, and a synthetic polymeric excipient such as povidone which is often made with peroxide to initiate polymerization. In both cases, it is very difficult to completely eliminate the residual oxidizing agents. Thus, residual trace amounts of peroxides may be carried over to the final excipients.[1]

Analysis of trace level of peroxides in excipients and pharmaceutical formulations

Analysis of peroxides in excipients and formulations is challenging. Compendial methods for determining relatively concentrated levels of hydrogen peroxide in solutions include colorimetric determination and iodide titration.[5,6] Several more sensitive analytical techniques have been developed for analyzing trace levels of peroxides in various sample matrices, including the so-called Fox2 method[7] which analyzes total peroxides and can differentiate 'organic' hydroperoxides and hydrogen peroxide by use of catalase, as catalase reacts with hydrogen peroxide but not 'organic' hydroperoxides. Another method uses a different derivatization mechanism involving triphenylphosphine (TPP) and thus can serve as a complementary method to validate the results from the Fox2 method.[3]

Hydrogen peroxide levels have also been measured by high performance liquid chromatography (HPLC) with coulometric electrochemical detection,[8] and HPLC coupled with amperometric electrochemical detection.[9] A further method for hydrogen peroxide quantitation after derivatization uses a highly sensitive microplate-based fluorescence assay, although the relationship between the fluorescence signal and the hydrogen peroxide concentration is not linear and several interferences have been observed, which can complicate the assay design and data interpretation.[10]

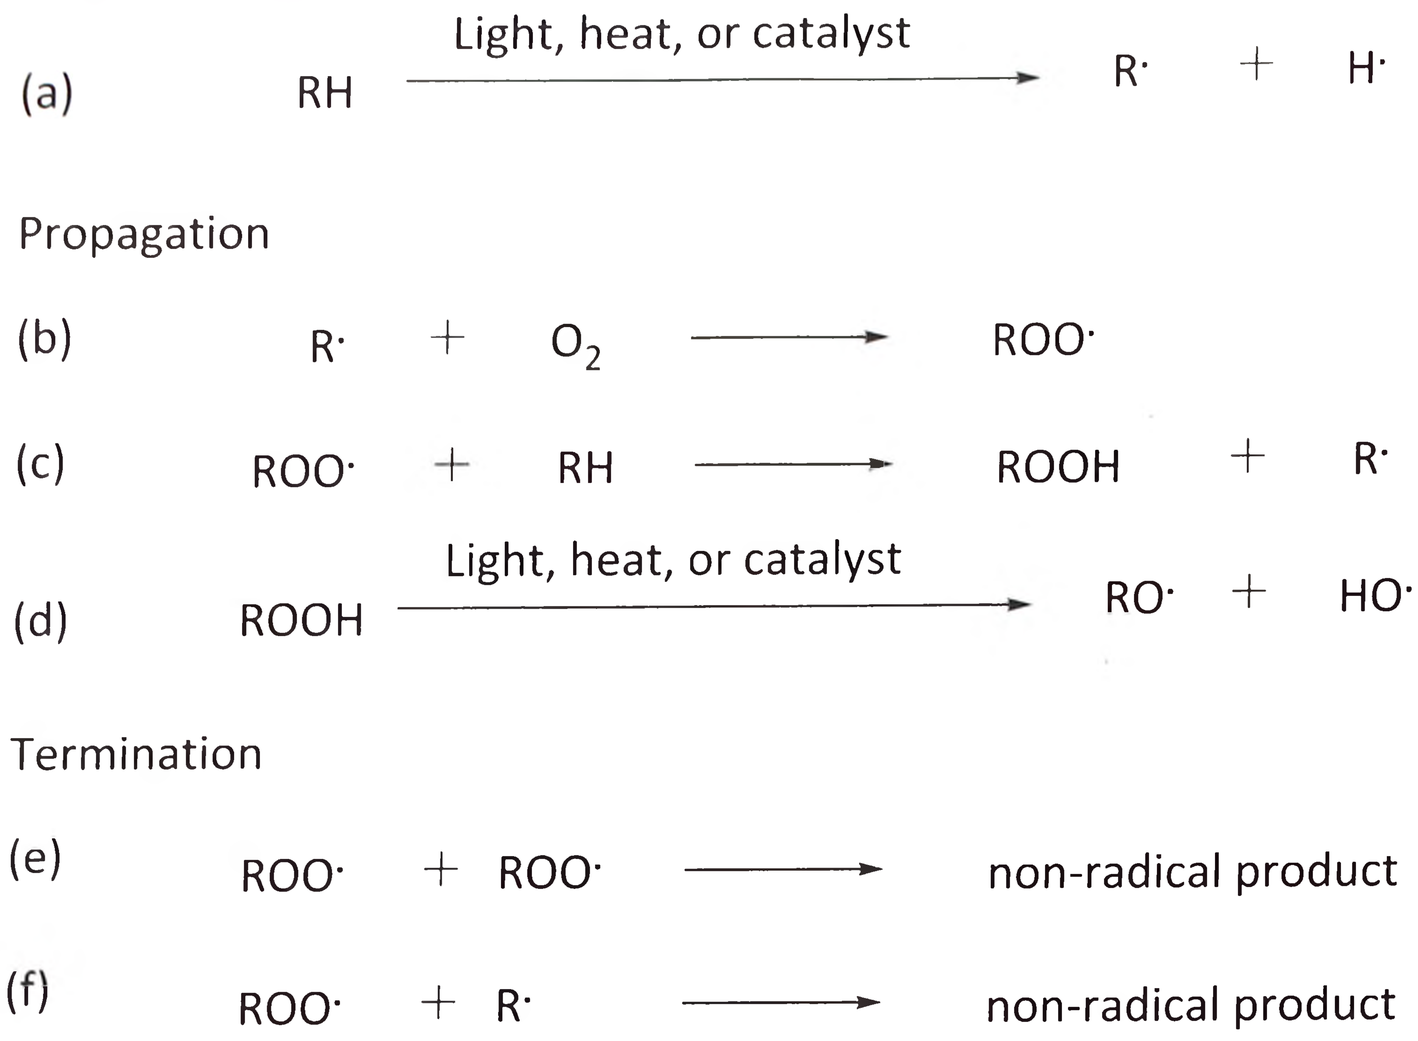

Figure 1: Illustration of free radical autoxidation chain reaction process

Aldehydes

Further reactions of peroxides, in excipients and/or formulations on storage, can lead to increased levels of aldehydes and organic acids, both of which are also known common excipient-related reactive components. Aldehydes such as formaldehyde, acetaldehyde, furfuraldehyde and glyoxal in pharmaceutical formulations can be the cause of instability in drug formulations.[11] Oxidative degradation of excipients contributes one source of aldehydes; for example, the oxidative degradation of polysorbate 80 and polyethylene glycol 300 (PEG 300) to produce formaldehyde results in the degradation of BMS-204352 (clinical parenteral formulation) to the hydroxymethyl derivative of the drug substance (formaldehyde adduct, BMS-215842).[12]

The formation of aldehyde components is also known to occur during the manufacturing process of excipients sourced from plant material. Hemicellulose, if present in the plant material, may undergo hydrolysis in the presence of sulfuric acid to produce 5-carbon sugars that can undergo dehydration to form furfuraldehyde.[1] Excipients which are known to contain aldehyde components include celluloses, starches, povidone, crospovidone, polyethylene glycol, and polysorbates.

Reducing sugar components may undergo the Maillard reaction with amine containing drugs. For example, drug-excipient compatibility studies have identified interactions with reducing sugar components introduced from microcrystalline cellulose.[1,13] Starch, mannitol, maltitol, and sucrose may also contain trace levels of reducing sugars.[1]

Analysis of trace level of aldehydes in excipients and pharmaceutical formulation

Short chain alkyl aldehydes are polar, often volatile molecules without strong chromophores, and are difficult to directly analyze. Sensitive and selective gas chromatography (GC) and HPLC methods have been developed for analyzing aldehydes after derivatization. The methods are mainly based on two types of reactions of carbonyl compounds, namely acid catalyzed condensation reactions such as those with 2,4-dinitrophenylhydrazine (DNPH)[14] and reactions with *O*-2,3,4,5,6-(pentafluorobenzyl) hydroxylamine hydrochloride (PFBHA).[15] The reaction with PFBHA has been adapted for a simple, selective and sensitive method to screen aldehydes in over thirty typical excipients.[16]

Organic Acids

Organic acids such as formic and acetic acids can contribute to unwanted reactions with the API in a formulation and destabilisation of the formulation. Formic acid can be formed via further oxidation of formaldehyde. It can also form by oxidation of the end groups of polyethers such as polyethylene glycol and surfactants containing PEG side chains. For example, the degradation of polyethylene glycol results in formaldehyde and formic acid formation, both of which have been identified to contribute to the degradation of the amine-based drug varenicline tartrate.[17] Appreciable levels ($\geq$10 ppm) of formic acid have been detected in the following excipients: povidone, polyethylene glycol 400, hypromellose, croscarmellose sodium, microcrystalline cellulose and crospovidone (*Polyplasdone XL*).[18] Acetic acid is known to be present in polyvinyl alcohol (PVA) as PVA is commonly made from hydrolysis of polyvinyl acetate.[1] A further example of an unwanted organic acid reaction is between hypromellose acetate succinate or hypromellose phthalate degradants and duloxetine hydrochloride in enteric coated formulations. It is proposed that degradation of the enteric polymer coating produces free organic acids or anhydrides which react with the drug, either via migration of the degradant products through the coating or the drug through the formulation.[19]

Analysis of trace level of organic acids in excipients and pharmaceutical formulations

Monitoring the amount of organic acids is necessary if their presence causes stability or performance issues in drug formulations. Formic acid and acetic acid can be directly analyzed by ion chromatography (IC) as formate and acetate, respectively.[20] This method has sub-ppm sensitivity. A gas chromatography/mass spectrometry (GC/MS) method for the rapid screening of trace amounts of residual formic acid, its esters and formaldehyde in pharmaceutical excipients has been developed and other short chain alkyl acids and aldehydes can be analyzed in a similar manner.[18]

Elemental impurities

Metals are present in almost all excipients. However, the types and levels can vary considerably depending on excipient type, source and manufacturing process. Some transition metals such as iron and copper at trace levels do not pose any safety concern. However, it is important to understand that their existence in drug formulations may catalyse oxidative reactions of excipients and/or the API in the formulation. A well-known transition metal mediated oxidation is the Fenton reaction where oxidation of iron(II) and reduction of iron(III) by hydrogen peroxide generate two different oxygen-radical species: a hydroxyl radical and a hydroperoxyl radical. Both are very reactive species that can further react with the API to form unwanted degradation products.[4] Metals are also associated with catalysis of hydrolysis.[21]

The International Conference on Harmonization (ICH) has issued the *Q3D Guideline for Elemental Impurities*, in which specific limits for individual elements are introduced. Accordingly, the United States Pharmacopeial Convention has published the USP–NF General Chapter <232>: *Elemental Impurities - Limits* (implementation date 1st January 2018), which lists the specific elements to be evaluated and allowable limits of these elemental impurities that may be found in drug products and replaces USP–NF General Chapter <231>: *Heavy Metals*. Similarly, the European Directorate for the Quality of Medicines & HealthCare is replacing the PhEur general chapter 5.20 with a verbatim copy of the ICH Q3D guideline (implementation date 1st January 2018). The heavy metals test is also being removed from individual monographs (implementation date 1st January 2017), and the related general chapter 2.4.8 is no longer being revised.[22,23]

Analysis of elemental impurities in excipients and pharmaceutical formulations

Although USP–NF General Chapter <231>: *Heavy Metals* has been used since early 1900s it is not adequate for testing requirements according to ICH Q3D. The USP–NF has published a general chapter <233>: *Elemental Impurities – Procedures* (official 1st December 2012), for testing elemental impurities in drug products. The methods introduce the use of closed vessel sample digestion and modern instrumental techniques to ensure the accurate recovery and determination of individual elemental impurity concentrations.

Conclusion

Excipients often are major components in a drug product to help deliver an API effectively and safely to the patient. However, reactive components in excipients can have detrimental effects on stability of a drug product. When designing a drug product, consideration should be given to the choice of excipients not only for their functionality but also for their potential impact on drug stability. A statistical designed excipient compatibility screen can help identify any incompatibility issue with a specific excipient and/or its reactive components. Risk assessment should be performed early in the design to avoid surprises during late-stage development or commercialization.

Mitigation strategies for stability issues linked to excipient-related reactive components include the following:

(a) An alternative excipient containing no, or a reduced level of the, reactive components should be considered first. If an alternative excipient is not possible, one should evaluate excipient sources and control incoming supplies with an appropriate raw material specification including control limits on reactive components and any attributes which impact the generation of the reactive components.

(b) The API properties such as solid form, salt form and particle size may be modified so that it is less susceptible to reactions with excipient related reactive components. In addition, an increase of the API to excipients ratio often can minimize impact of reaction with excipient related reactive components.

(c) Antioxidants and other stabilizers can be considered for inclusion in a formulation to help improve the stability of the formulation.

(d) Packaging of the drug product should be evaluated as a part of drug product design. An effective packaging design can mitigate stability issues. For example, adding silica gel desiccant into a high density polyethylene bottle for tablets can reduce and control water moisture level inside the bottle over shelf life. A reduced level of water moisture can slow down many chemical reactions including those oxidative reactions that generate peroxides, aldehydes and acids. A recent study demonstrated that adding an activated carbon canister into a high density polyethylene bottle can attenuate formaldehyde-induced and formic acid-induced degradation in solid dosage forms and reduce gelatin cross-linking in capsules.[24] Other packaging options include use of containers with a high moisture barrier such as bottles with increased wall thickness or laminated bottles with specific barrier layers; an oxygen absorber added to the bottle; and aluminium foil blisters.

Analysis of reactive components such as peroxides, aldehydes and organic acids often requires analytical methods capable of detecting trace levels of these components. When developing a trace level method, care should be taken to ensure that the detection limit in the presence of sample matrix, blank interference, sample matrix interference, recovery of volatile analytes and sample solution stability are carefully assessed to ensure method accuracy and precision, along with consideration of validation requirements.

Monographs

Acacia

1 Nonproprietary Names

BP: Acacia
JP: Acacia
PhEur: Acacia
USP–NF: Acacia

2 Synonyms

Acaciae gummi; acacia gum; arabic gum; E414; gum acacia; gum arabic; gummi africanum; gummi arabicum; gummi mimosae; talha gum.

3 Chemical Name and CAS Registry Number

Acacia [9000-01-5]

4 Empirical Formula and Molecular Weight

Acacia is a complex, loose aggregate of sugars and hemicelluloses with a molecular weight of approximately 240 000–580 000. The aggregate consists essentially of an arabic acid nucleus to which are connected calcium, magnesium, and potassium along with the sugars arabinose, galactose, and rhamnose.

5 Structural Formula

See Section 4.

6 Functional Category

Emulsifying agent; modified-release agent; suspending agent; tablet and capsule binder; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Acacia is mainly used in oral and topical pharmaceutical formulations as a suspending and emulsifying agent, often in combination with tragacanth. It is also used in the preparation of pastilles and lozenges, and as a tablet binder, although if used incautiously it can produce tablets with a prolonged disintegration time. Acacia has also been evaluated as a bioadhesive;[1] and has been used in novel tablet formulations,[2] and modified release tablets.[3]

See Table I.

Table I: Uses of acacia.

Use	Concentration (%)
Emulsifying agent	10–20
Pastille base	10–30
Suspending agent	5–10
Tablet binder	1–5

Acacia is also used in cosmetics, confectionery, food products, and spray-dried flavors.[4]

See also Section 18.

8 Description

Acacia is available as white or yellowish-white thin flakes, spheroidal tears, granules, powder, or spray-dried powder. It is odorless and has a bland taste.

9 Pharmacopeial Specifications

The PhEur 9.2 provides monographs on acacia and spray-dried acacia, while the USP 40–NF 35 S1 describes acacia in a single monograph that encompasses tears, flakes, granules, powder, and spray-dried powder. The USP 40–NF 35 S1 also has a monograph on acacia syrup. The JP XVII has monographs on acacia and powdered acacia; *see* Table II.

Table II: Pharmacopeial specifications for acacia.

(a) Powdered acacia.
(b) Spray-dried acacia.

10 Typical Properties

Acidity/alkalinity pH = 4.5–5.0 (5% w/v aqueous solution)

Acid value 2.5

Hygroscopicity At relative humidities of 25–65%, the equilibrium moisture content of powdered acacia at 25°C is 8–13% w/w, but at relative humidities above about 70% it absorbs substantial amounts of water.

Solubility Soluble 1 in 20 of glycerin, 1 in 20 of propylene glycol, 1 in 2.7 of water; practically insoluble in ethanol (95%). In water, acacia dissolves very slowly, although almost completely after two hours, in twice the mass of water leaving only a very small residue of powder. The solution is colorless or yellowish, viscous, adhesive, and translucent. Spray-dried acacia dissolves more rapidly, in about 20 minutes.

Specific gravity 1.35–1.49

Spectroscopy

IR spectrum *see* Figure 1.

NIR spectrum *see* Figure 2.

Raman spectrum *see* Figure 3.

Viscosity (dynamic) 100 mPa s for a 30% w/v aqueous solution at 20°C. The viscosity of aqueous acacia solutions varies depending upon the source of the material, processing, storage conditions, pH, and the presence of salts. Viscosity increases slowly up to about 25% w/v concentration and exhibits Newtonian behavior. Above this concentration, viscosity increases rapidly (non-Newtonian rheology). Increasing temperature or prolonged heating of solutions results in a decrease of viscosity owing to depolymerization or particle agglomeration.

See also Section 12.

A

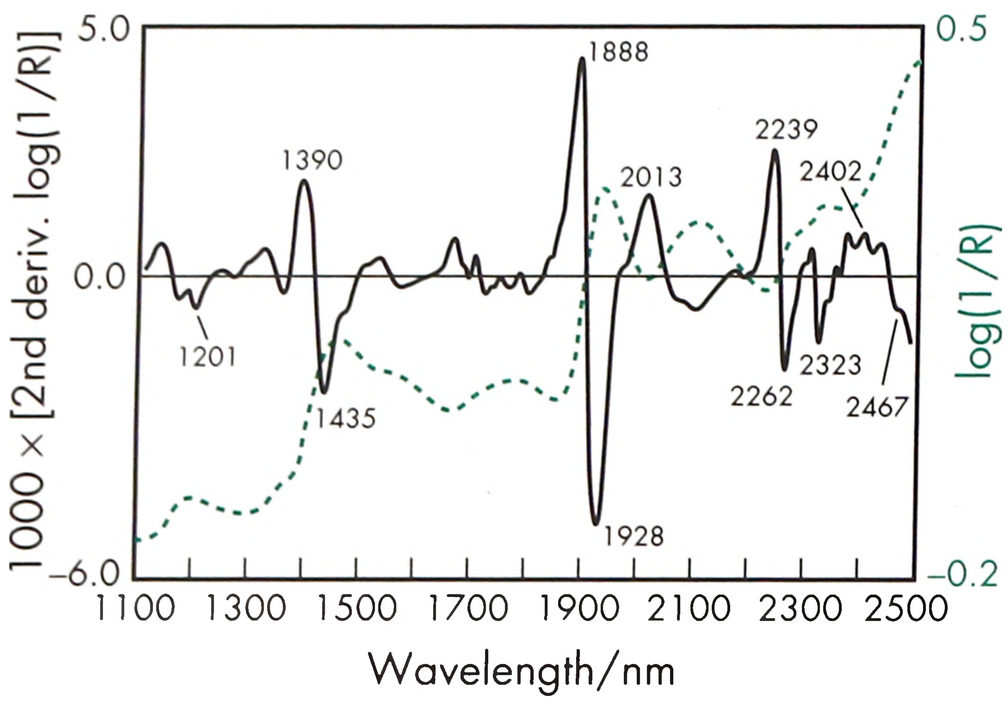

Figure 2: Near-infrared spectrum of acacia measured by reflectance.

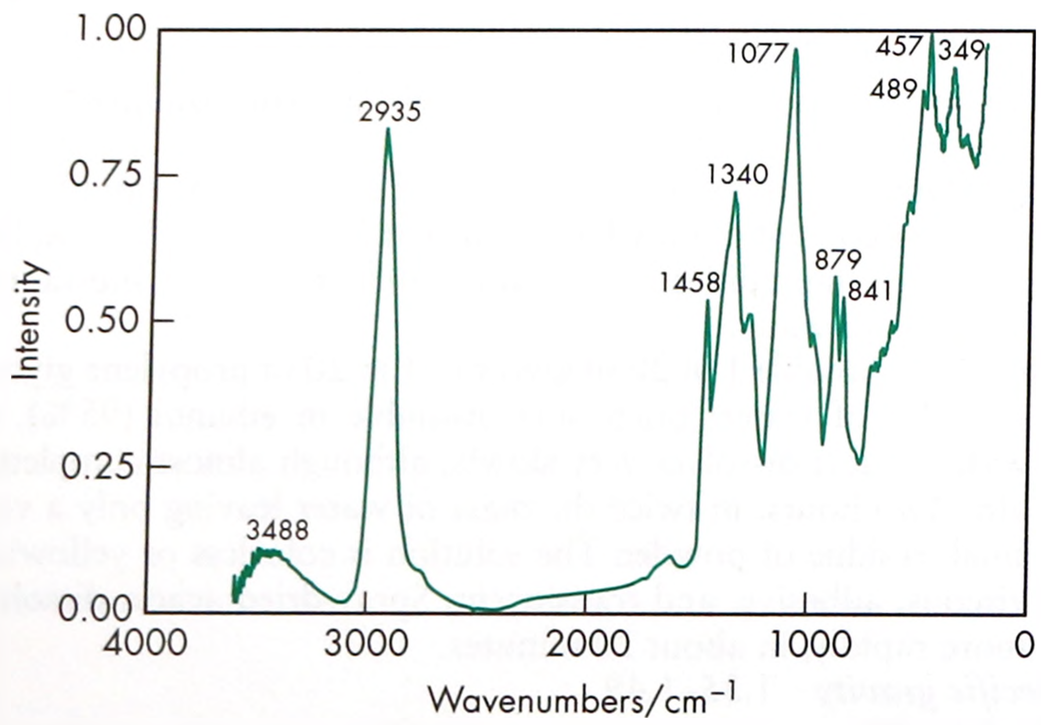

Figure 3: Raman spectrum of acacia measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

11 Stability and Storage Conditions

Aqueous solutions are subject to bacterial or enzymatic degradation but may be preserved by initially boiling the solution for a short time to inactivate any enzymes present; microwave irradiation can also be used.[5] Aqueous solutions may also be preserved by the addition of an antimicrobial preservative such as 0.1% w/v benzoic acid, 0.1% w/v sodium benzoate, or a mixture of 0.17% w/v methylparaben and 0.03% propylparaben. Powdered acacia should be stored in an airtight container in a cool, dry place.

12 Incompatibilities

Acacia is incompatible with a number of substances including amidopyrine, apomorphine, cresol, ethanol (95%), ferric salts, morphine, phenol, physostigmine, tannins, thymol, and vanillin.

An oxidizing enzyme present in acacia may affect preparations containing easily oxidizable substances. However, the enzyme may be inactivated by heating at 100°C for a short time; *see* Section 11.

Many salts reduce the viscosity of aqueous acacia solutions, while trivalent salts may initiate coagulation. In aqueous solutions acacia carries a negative charge and will form coacervates with gelatin and other substances. In the preparation of emulsions, solutions of acacia are incompatible with soaps.

13 Method of Manufacture

Acacia is the dried gummy exudate obtained from the stems and branches of *Acacia senegal* (Linné) Willdenow or other related species of *Acacia* (Fam. Leguminosae) that grow mainly in the Sudan and Senegal regions of Africa.

The bark of the tree is incised and the exudate allowed to dry on the bark. The dried exudate is then collected, processed to remove bark, sand, and other particulate matter, and graded. Various acacia grades differing in particle size and other physical properties are thus obtained. A spray-dried powder is also commercially available.

14 Safety

Acacia is used in cosmetics, foods, and oral and topical pharmaceutical formulations. Although it is generally regarded as an essentially nontoxic material, there have been a limited number of reports of hypersensitivity to acacia after inhalation or ingestion.[6,7] Severe anaphylactic reactions have occurred following the parenteral administration of acacia and it is now no longer used for this purpose.[6]

The WHO has not set an acceptable daily intake for acacia as a food additive because the levels necessary to achieve a desired effect were not considered to represent a hazard to health.[8]

LD_{50} (hamster, oral): >18 g/kg[9]
LD_{50} (mouse, oral): >16 g/kg
LD_{50} (rabbit, oral): 8.0 g/kg
LD_{50} (rat, oral): >16 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Acacia can be irritant to the eyes and skin and upon inhalation. Gloves, eye protection, and a dust respirator are recommended.

16 Regulatory Status

GRAS listed. Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (oral preparations and buccal or sublingual tablets). Included in the Canadian Natural Health Products Ingredients Database. Included in nonparenteral medicines licensed in the UK.

17 Related Substances

Ceratonia; guar gum; octenyl succinic anhydride modified gum acacia; tragacanth

Octenyl succinic anhydride modified gum acacia

CAS number [445885-22-0]

Synonyms *n*-Octenyl succinic anhydride modified gum acacia; OSA modified gum acacia.

Comments Produced from gum acacia by the introduction of lipophilic groups to the polysaccharide in gum acacia by a controlled esterification process. It has been investigated for use as an emulsifier and has been found to be as safe as acacia.[10]

LD_{50} (oral, rat): >2 g/kg

18 Comments

Concentrated aqueous solutions are used to prepare pastilles since on drying they form solid rubbery or glass-like masses depending upon the concentration used. Foreign policy changes and politically unstable conditions in Sudan, which is the principal supplier of acacia, has created a need to find a suitable replacement.[11] Poloxamer 188 (12–15% w/w) can be used to make an oil/water emulsion with similar rheological characteristics to a standard 4-2-1 acacia emulsion. Other natural by-products of foods can also be used.[12] Acacia is also used in the food industry as an emulsifier, stabilizer, and thickener. A specification for acacia is contained in the *Food Chemicals Codex* (FCC).[13]

Acacia has been investigated for its effects in patients with chronic renal failure.[14] It has also been used within Ayurvedic medicine in the management of dental conditions.[15]

The EINECS number for acacia is 232-519-5.

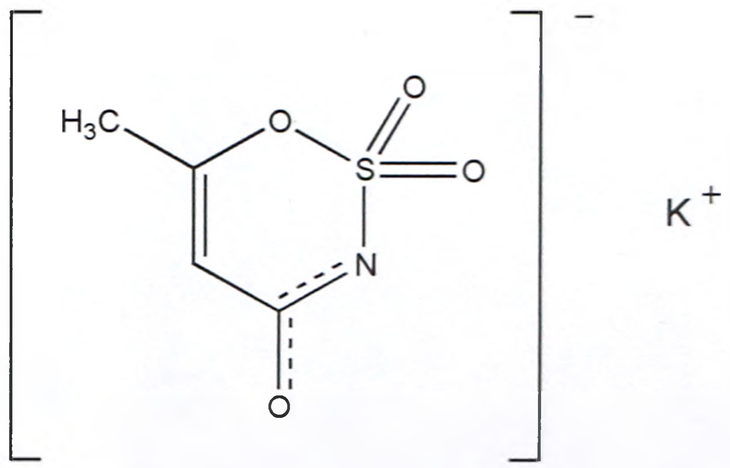
Acesulfame Potassium

1 Nonproprietary Names

BP: Acesulfame Potassium
PhEur: Acesulfame Potassium
USP–NF: Acesulfame Potassium

2 Synonyms

Acesulfame K; ace K; acesulfamum kalicum; E950; 6-methyl-3,4-dihydro-1,2,3-oxathiazin-4(3*H*)-one-2,2-dioxide potassium salt; potassium 6-methyl-2,2-dioxo-oxathiazin-4-olate; *Sunett*; *Sweet One*.



3 Chemical Name and CAS Registry Number

6-Methyl-1,2,3-oxathiazin-4(3*H*)-one-2,2-dioxide potassium salt [55589-62-3]

4 Empirical Formula and Molecular Weight

$C_4H_4KNO_4S$ 201.24

5 Structural Formula

6 Functional Category

Sweetening agent.

A

7 Applications in Pharmaceutical Formulation or Technology

Acesulfame potassium is used as an intense sweetening agent in cosmetics, foods, beverage products, table-top sweeteners, vitamin and pharmaceutical preparations, including powder mixes, tablets, and liquid products. It is widely used as a sugar substitute in compounded formulations,[1] and as a toothpaste sweetener.[2]

The approximate sweetening power is 180–200 times that of sucrose, similar to aspartame, about one-third as sweet as sucralose, one-half as sweet as sodium saccharin, and about 4–5 times sweeter than sodium cyclamate.[3] It enhances flavor systems and can be used to mask some unpleasant taste characteristics.

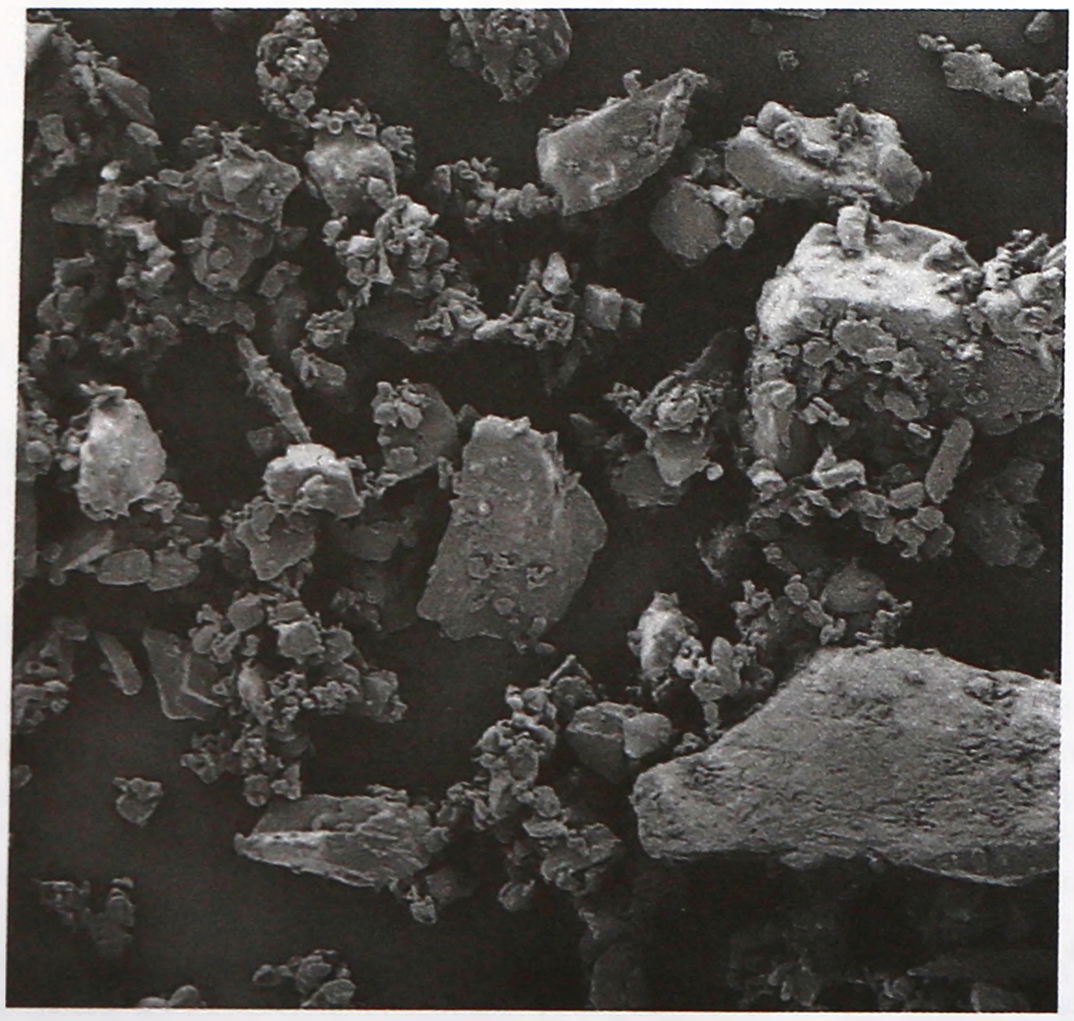
8 Description

Acesulfame potassium occurs as a colorless to white-colored, odorless, crystalline powder with an intensely sweet taste.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for acesulfame potassium.



Test	PhEur 9.2	USP 40–NF 35 S1
Characters	+	–
Identification	+	+
Appearance of solution	+	–

Tensile strength 0.5 MPa[4]
Viscoelastic index 2.6[4]

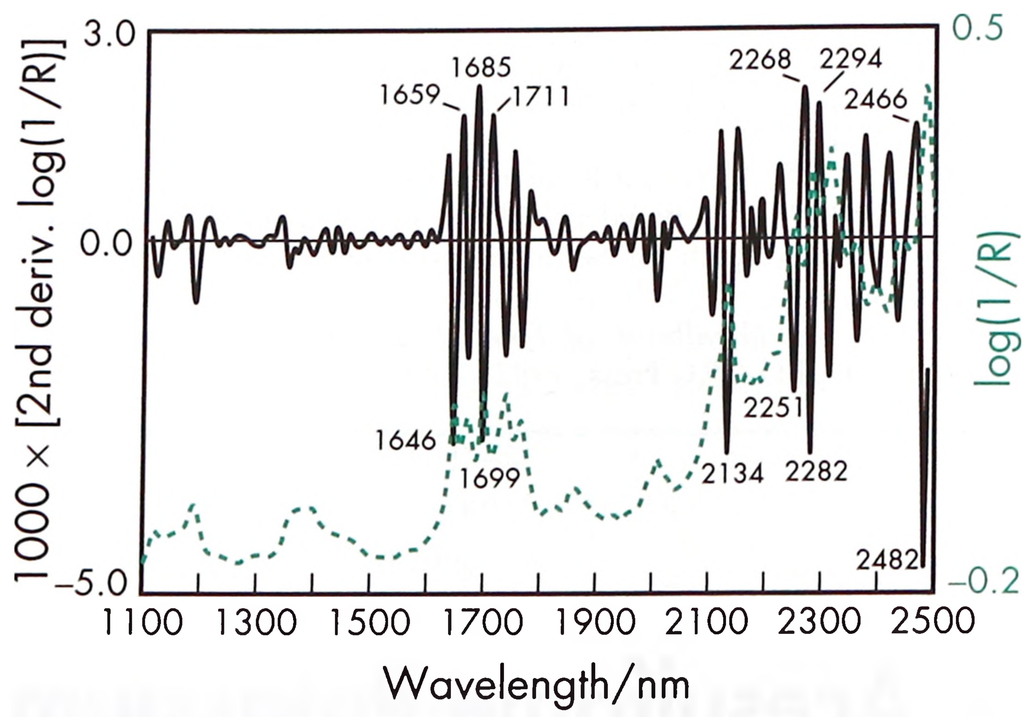

Figure 1: Near-infrared spectrum of acesulfame potassium measured by reflectance.

11 Stability and Storage Conditions

Acesulfame potassium possesses good stability. In the bulk form it shows no sign of decomposition at ambient temperature over many years. In aqueous solutions (pH 3.0–3.5 at 20°C) no reduction in sweetness was observed over a period of approximately 2 years. Stability at elevated temperatures is good, although some decomposition was noted following storage at 40°C for several months. Sterilization and pasteurization do not affect the taste of acesulfame potassium.[7]

The bulk material should be stored in a well-closed container in a cool, dry place and protected from light.

12 Incompatibilities

Acesulfame potassium is incompatible with oxidizing agents, strong acids, and metals.

13 Method of Manufacture

Acesulfame potassium is synthesized from acetoacetic acid *tert*-butyl ester and fluorosulfonyl isocyanate. The resulting compound

is transformed to fluorosulfonyl acetoacetic acid amide, which is then cyclized in the presence of potassium hydroxide to form the oxathiazinone dioxide ring system. Because of the strong acidity of this compound, the potassium salt is produced directly.[8]

An alternative synthesis route for acesulfame potassium starts with the reaction between diketene and amidosulfonic acid. In the presence of dehydrating agents, and after neutralization with potassium hydroxide, acesulfame potassium is formed.

14 Safety

Acesulfame potassium is widely used in beverages, cosmetics, foods, and pharmaceutical formulations, and is generally regarded as a relatively nontoxic and nonirritant material. It may cause allergic reactions.[9,10]

Pharmacokinetic studies have shown that acesulfame potassium is not metabolized and is rapidly excreted unchanged in the urine. Long-term feeding studies in rats and dogs showed no evidence to suggest acesulfame potassium is mutagenic or carcinogenic.[11]

The WHO has set an acceptable daily intake for acesulfame potassium of up to 15 mg/kg body-weight.[11] The Scientific Committee for Foods of the European Union has set a daily intake value of up to 9 mg/kg of body-weight.[3]

LD_{50} (rat, IP): 2.2 g/kg[7]

LD_{50} (rat, oral): 6.9–8.0 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Eye protection, gloves, and a dust mask are recommended.

16 Regulatory Status

Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (oral tablets, suspensions, solutions, powder for oral solutions and films, sublingual, dental and buccal preparations). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database. It is also accepted for use in certain food products in the USA and several countries in Central and South America, the Middle East, Africa, Asia, and Australia.

17 Related Substances

Alitame.

18 Comments

The perceived intensity of sweeteners relative to sucrose depends upon their concentration, temperature of tasting, and pH, and on the flavor and texture of the product concerned.

Intense sweetening agents will not replace the bulk, textural, or preservative characteristics of sugar, if sugar is removed from a formulation.

Synergistic effects for combinations of sweeteners have been reported, e.g. acesulfame potassium with aspartame or sodium cyclamate; *see also* Aspartame. A ternary combination of sweeteners that includes acesulfame potassium and sodium saccharin has a greater decrease in sweetness upon repeated tasting than other combinations.[12]

Note that free acesulfame acid is not suitable for use as a sweetener.

A specification for acesulfame potassium is contained in the *Food Chemicals Codex* (FCC).[13]

The EINECS number for acesulfame potassium is 259-715-3. The PubChem Compound ID (CID) for acesulfame potassium is 11074431.

A Acetic Acid, Glacial

1 Nonproprietary Names

BP: Glacial Acetic Acid

JP: Glacial Acetic Acid

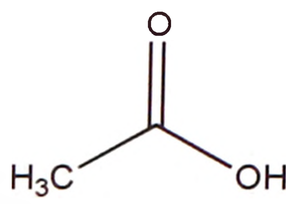
PhEur: Acetic Acid, Glacial

USP–NF: Glacial Acetic Acid

2 Synonyms

Acidum aceticum glaciale; E260; ethanoic acid; ethylic acid; methane carboxylic acid; vinegar acid.

See also Section 17 and Section 18.



3 Chemical Name and CAS Registry Number

Ethanolic acid [64-19-7]

4 Empirical Formula and Molecular Weight

$C_2H_4O_2$ 60.05

5 Structural Formula

6 Functional Category

Acidulant; buffering agent.

7 Applications in Pharmaceutical Formulations or Technology

Glacial and diluted acetic acid solutions are widely used as acidulants in a variety of pharmaceutical formulations and food preparations. Acetic acid is used in pharmaceutical products as a buffer system when combined with an acetate salt such as sodium acetate.

8 Description

Glacial acetic acid occurs as a crystalline mass or a clear, colorless volatile solution with a pungent odor.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for glacial acetic acid.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters	+	+	–
Freezing point	≥14.5°C	≥14.8°C	≥15.6°C
Nonvolatile matter	≤1.0 mg	≤0.01%	≤1.0 mg
Sulfate	+	+	+
Chloride	+	+	+
Heavy metals	≤10 ppm	–	≤5 ppm
Iron	–	≤5 ppm	–
Readily oxidizable impurities	+	+	+
Assay	≥99.0%	99.5–100.5%	99.5–100.5%

10 Typical Properties

Acidity/alkalinity

pH = 2.4 (1 M aqueous solution);

pH = 2.9 (0.1 M aqueous solution);

pH = 3.4 (0.01 M aqueous solution).

Boiling point 118°C

Dissociation constant $pK_a = 4.76$

Flash point 39°C (closed cup); 57°C (open cup).

Melting point 17°C

Refractive index $n_D^{20} = 1.3718$

Solubility Miscible with ethanol, ether, glycerin, water, and other fixed and volatile oils.

Specific gravity 1.045

Spectroscopy

IR spectrum *see* Figure 1.

Raman spectrum *see* Figure 2.

11 Stability and Storage Conditions

Acetic acid should be stored in an airtight container in a cool, dry place.

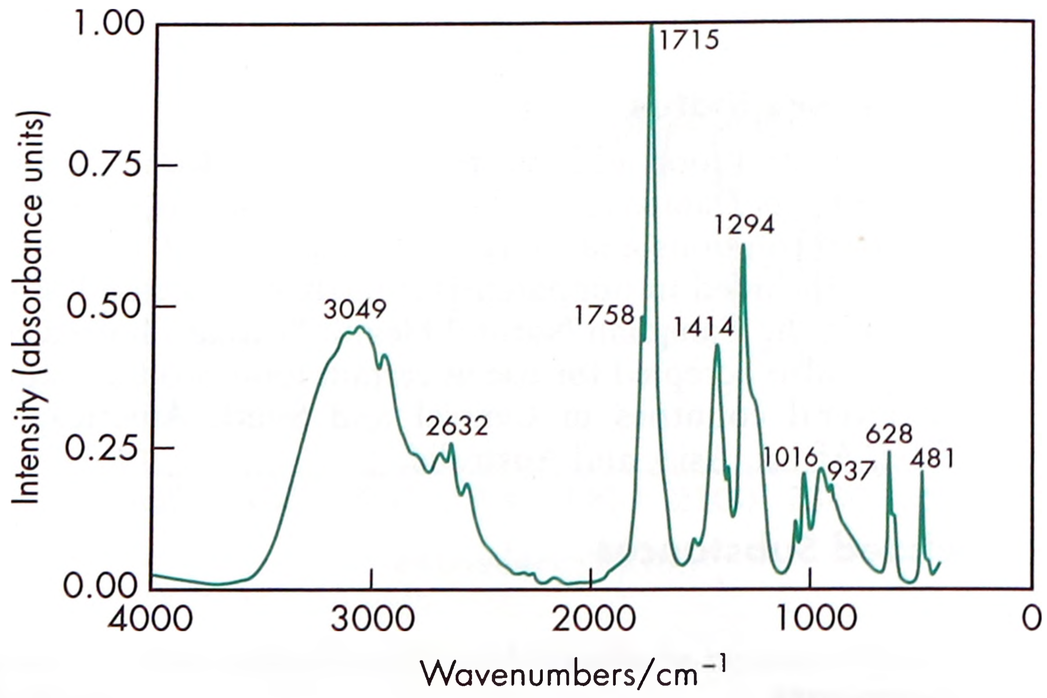


Figure 1: Infrared spectrum of acetic acid measured by transmission. Adapted with permission of Informa Healthcare.

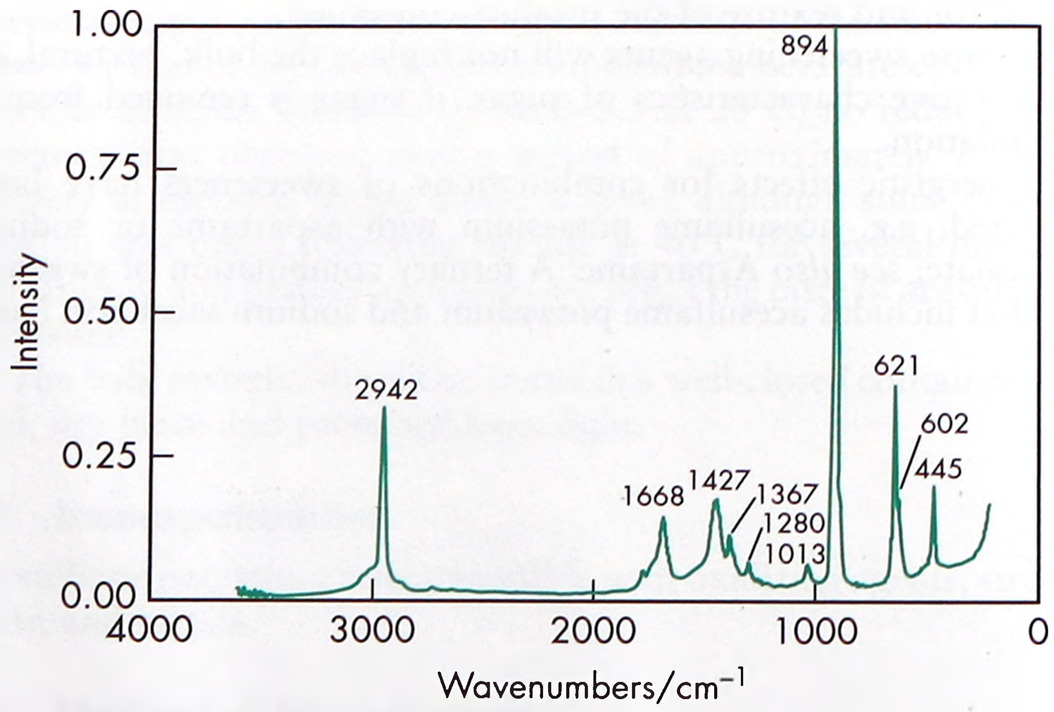

Figure 2: Raman spectrum of acetic acid measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

12 Incompatibilities

Acetic acid reacts with alkaline substances.

13 Method of Manufacture

Acetic acid is usually made by one of three routes: acetaldehyde oxidation, involving direct air or oxygen oxidation of liquid acetaldehyde in the presence of manganese acetate, cobalt acetate, or copper acetate; liquid-phase oxidation of butane or naphtha; methanol carbonylation using a variety of techniques.

14 Safety

Acetic acid is widely used in pharmaceutical applications primarily to adjust the pH of formulations and is thus generally regarded as relatively nontoxic and nonirritant. However, glacial acetic acid or solutions containing over 50% w/w acetic acid in water or organic solvents are considered corrosive and can cause damage to skin, eyes, nose, and mouth. If swallowed, glacial acetic acid causes severe gastric irritation similar to that caused by hydrochloric acid.[1]

Dilute acetic acid solutions containing up to 10% w/w of acetic acid have been used topically following jellyfish stings.[2] Dilute acetic acid solutions containing up to 5% w/w of acetic acid have also been applied topically to treat wounds and burns infected with *Pseudomonas aeruginosa*.[3]

The lowest lethal oral dose of glacial acetic acid in humans is reported to be 1470 µg/kg.[4] The lowest lethal concentration on inhalation in humans is reported to be 816 ppm.[4] Humans, are, however, estimated to consume approximately 1 g/day of acetic acid from the diet.

LD_{50} (mouse, IV): 0.525 g/kg[4]
LD_{50} (rabbit, skin): 1.06 g/kg
LD_{50} (rat, oral): 3.31 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Acetic acid, particularly glacial acetic acid, can cause burns on contact with the skin, eyes, and mucous membranes. Splashes should be washed with copious quantities of water. Protective clothing, gloves, and eye protection are recommended.

16 Regulatory Status

GRAS listed. Accepted as a food additive in Europe. Included in the FDA Inactive Ingredients Database (injections, nasal, ophthalmic, and oral preparations). Included in parenteral and nonparenteral preparations licensed in the UK.

17 Related Substances

Acetic acid; artificial vinegar; dilute acetic acid.

Acetic acid

Comments A diluted solution of glacial acetic acid containing 30–37% w/w of acetic acid. *See* Section 18.

Artificial vinegar

Comments A solution containing 4% w/w of acetic acid.

Dilute acetic acid

Comments A weak solution of acetic acid which may contain between 5.7–6.3% w/w of acetic acid. *See* Section 18.

18 Comments

In addition to glacial acetic acid, many pharmacopeias contain monographs for diluted acetic acid solutions of various strengths. For example, the USP 40–NF 35 S1 has monographs for acetic acid, which is defined as a solution containing 36.0–37.0% w/w of acetic acid, and for diluted acetic acid, which is defined as a solution containing 5.7–6.3% w/w of acetic acid. Similarly, the BP 2017 contains separate monographs for glacial acetic acid, acetic acid (33%), and acetic acid (6%). Acetic acid (33%) BP 2017 contains 32.5–33.5% w/w of acetic acid. Acetic acid (6%) BP 2017 contains 5.7–6.3% w/w of acetic acid. The JP XVII also contains a monograph for acetic acid that specifies that it contains 30.0–32.0% w/w of acetic acid.

Acetic acid is also claimed to have some antibacterial and antifungal properties.

A specification for glacial acetic acid is contained in the *Food Chemicals Codex* (FCC).[5]

The EINECS number for acetic acid is 200-580-7. The PubChem Compound ID (CID) for glacial acetic acid is 176.

A Acetone

1 Nonproprietary Names

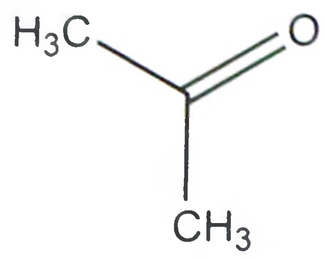
BP: Acetone

PhEur: Acetone

USP–NF: Acetone

2 Synonyms

Acetonum; dimethylformaldehyde; dimethyl ketone; β-ketopropane; pyroacetic ether.



3 Chemical Name and CAS Registry Number

2-Propanone [67-64-1]

4 Empirical Formula and Molecular Weight

C_3H_6O 58.08

5 Structural Formula

6 Functional Category

Solvent.

7 Applications in Pharmaceutical Formulation or Technology

Acetone is used as a solvent or cosolvent in topical preparations up to a concentration of 13%, and as an aid in wet granulation.[1,2] It has also been used when formulating tablets with water-sensitive active ingredients, or to solvate poorly water-soluble binders in a wet granulation process.

Acetone has also been used in the formulation of microspheres[3] and polymeric nanoparticles[4] to enhance drug release.

8 Description

Acetone is a colorless volatile, flammable, transparent liquid, with a sweetish odor and pungent sweetish taste.

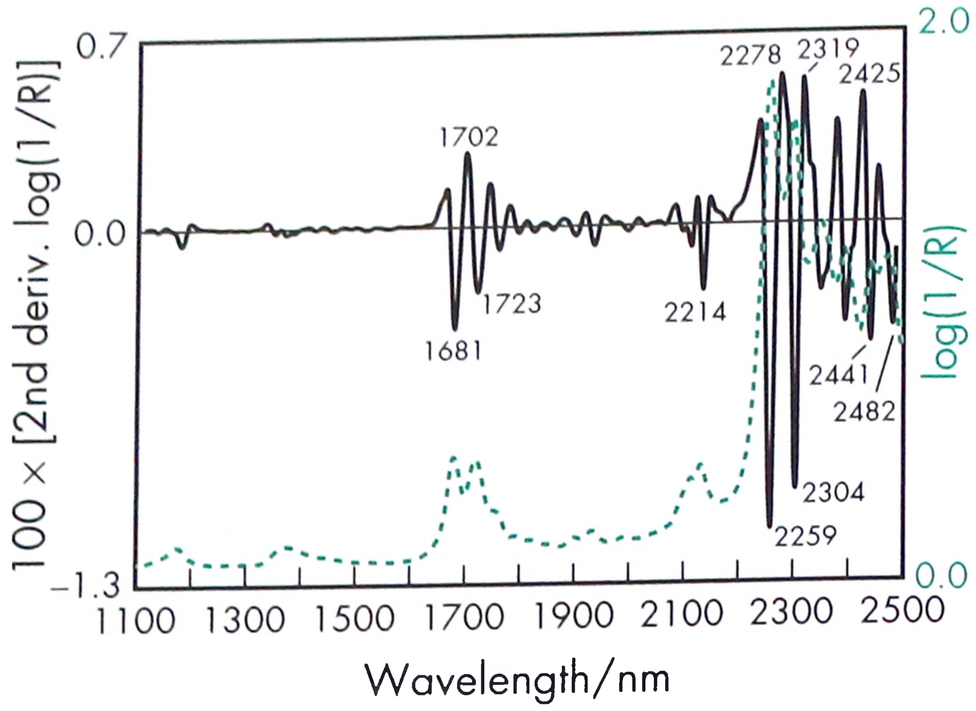


Figure 1: Near-infrared spectrum of acetone measured by transflectance (1 mm path-length).

9 Pharmacopeial Specifications

See Table I. *See also* Section 18.

10 Typical Properties

Boiling point 56.2°C
Flash point −20°C
Melting point 94.3°C
Refractive index $n_D^{20} = 1.359$
Solubility Soluble in water; freely soluble in ethanol (95%).
Spectroscopy

NIR spectrum *see* Figure 1.

Vapor pressure 185 mmHg at 20°C

11 Stability and Storage Conditions

Acetone should be stored in a cool, dry, well-ventilated place out of direct sunlight.

12 Incompatibilities

Acetone reacts violently with oxidizing agents, chlorinated solvents, and alkali mixtures. It reacts vigorously with sulfur dichloride, potassium *t*-butoxide, and hexachloromelamine. Acetone should not be used as a solvent for iodine, as it forms a volatile compound that is extremely irritating to the eyes.[5]

Table I: Pharmacopeial specifications for acetone.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	–
Appearance of solution	+	–
Acidity or alkalinity	+	–
Relative density	0.790–0.793	≤0.789
Related substances	+	–
Matter insoluble in water	+	–
Reducing substances	+	+
Residue on evaporation	≤50 ppm	≤0.004%
Water	≤3 g/L	+
Assay	–	≥99.0%

13 Method of Manufacture

Acetone is obtained by fermentation as a by-product of *n*-butyl alcohol manufacture, or by chemical synthesis from isopropyl alcohol; from cumene as a by-product in phenol manufacture; or from propane as a by-product of oxidation-cracking.

14 Safety

Acetone is considered moderately toxic, and is a skin irritant and severe eye irritant. It is important to remove it completely from the finished dosage if it was used as a solvent during manufacture. Skin irritation has been reported due to its defatting action, and prolonged inhalation may result in headaches. Inhalation of acetone can produce systemic effects such as conjunctival irritation, respiratory system effects, nausea, and vomiting.[6]

LD_{50} (mouse, oral): 3.0 g/kg[6]
LD_{50} (mouse, IP): 1.297 g/kg
LD_{50} (rabbit, oral): 5.340 g/kg
LD_{50} (rabbit, skin): 0.2 g/kg
LD_{50} (rat, IV): 5.5 g/kg
LD_{50} (rat, oral): 5.8 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Acetone is a skin and eye irritant (*see* Section 14); therefore gloves, eye protection, and a respirator are recommended. In the UK, the long-term (8-hour TWA) workplace exposure limit for acetone is 1210 mg/m^3 (500 ppm). The short-term (15-minute) exposure limit is 3620 mg/m^3 (1500 ppm).[7]

Using acetone as a coating solvent requires the use of an approved collection system, often including a catalytic converter, to ensure that the solvent is not released into the atmosphere. Failure in the system can lead to catastrophic explosions and thus its use should be carefully considered. If at all possible, a water-based system is preferred for coating of beads or finished tablets.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (implantation pellets; oral capsules and tablets; topical preparations). Included in the Canadian Natural Health Products Ingredients Database. Included in nonparenteral medicines licensed in the UK.

17 Related Substances

—

18 Comments

The rate of removal of acetone from finished dosage forms may be a function of humidity.[8] Owing to its low boiling point, acetone has been used to extract thermolabile substances from crude drugs.[5]

A specification for acetone is included in the *Japanese Pharmaceutical Excipients* (JPE).[9]

The EINECS number for acetone is 200-662-2. The PubChem Compound ID (CID) for acetone is 180.

Acetone Sodium Bisulfite

1 Nonproprietary Names

None adopted.

2 Synonyms

Acetone sulfite; sodium acetone bisulfite.

3 Chemical Name and CAS Registry Number

2-Hydroxy-2-propanesulfonic acid, sodium salt [540-92-1]

4 Empirical Formula and Molecular Weight

$C_3H_7NaO_4S$ 162.14

5 Structural Formula

6 Functional Category

Antimicrobial preservative; antioxidant.

A

7 Applications in Pharmaceutical Formulation or Technology

Acetone sodium bisulfite is used in injections and solution inhalers. It has been used in nonaqueous solutions of doxorubicin as an antioxidant at concentrations of 0.1–20.0 mg/mL,[1] and may also be used in antifungal parenteral products.[2]

8 Description

Acetone sodium bisulfite occurs as a crystalline white powder with a slight odor of sulfur dioxide. It can feel waxy to the touch.

9 Pharmacopeial Specifications

—

10 Typical Properties

Solubility Freely soluble in water; sparingly soluble in ethanol (95%).

11 Stability and Storage Conditions

Acetone sodium bisulfite should be kept refrigerated at 2–8°C.

12 Incompatibilities

Acetone sodium bisulfite decomposes in the presence of acids.

13 Method of Manufacture

Acetone sodium bisulfite is prepared by the reaction of acetone with sodium bisulfite.

14 Safety

Acetone sodium bisulfite, being a sulfite, may cause allergic-type reactions in certain susceptible people.[3–5] Sulfite sensitivity is seen more frequently in asthmatics.[6]

See also Potassium Metabisulfite for more safety information regarding the sulfites in general.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. Acetone sodium bisulfite is combustible.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (injections and inhalation solutions).

17 Related Substances

Sodium sulfite.

18 Comments

Like all sulfites, acetone sodium bisulfite is not recommended for use in foods that are a source of thiamin, owing to the instability of the vitamin in their presence. Such foods include meat, raw fruits and vegetables, fresh potatoes, and foods that are a source of vitamin B_{12}. The EINECS number for acetone sodium bisulfite is 208-761-2. The PubChem Compound ID (CID) for acetone sodium bisulfite is 23673833.

Acetyltributyl Citrate

1 Nonproprietary Names

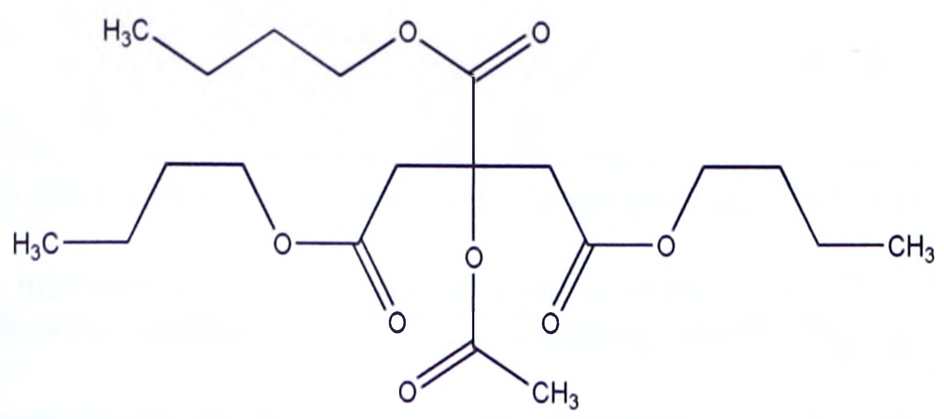
BP: Tributyl Acetylcitrate

PhEur: Tributyl Acetylcitrate

USP–NF: Acetyltributyl Citrate

2 Synonyms

Acetylbutyl citrate; acetylcitric acid, tributyl ester; ATBC; *Citrofol BII*; *Citroflex A-4*; tributylis acetylcitras; tributyl *O*-acetylcitrate; tributyl citrate acetate.



3 Chemical Name and CAS Registry Number

1,2,3-Propanetricarboxylic acid, 2-acetyloxy, tributyl ester [77-90-7]

4 Empirical Formula and Molecular Weight

$C_{20}H_{34}O_8$ 402.5

5 Structural Formula

6 Functional Category

Plasticizing agent.

7 Applications in Pharmaceutical Formulation or Technology

Acetyltributyl citrate is used to plasticize polymers in formulated pharmaceutical coatings,[1–7] including capsules, tablets, beads, and granules for taste masking, immediate release, sustained-release and enteric formulations.

8 Description

Acetyltributyl citrate is a clear, odorless, practically colorless, oily liquid.

Table I: Pharmacopeial specifications for acetyltributyl citrate.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Appearance	+	–
Characters	+	–

9 Pharmacopeial Specifications

See Table I.

10 Typical Properties

Acid value 0.02

Boiling point 326°C (decomposes)

Flash point 204°C

Pour point −59°C

Solubility Miscible with acetone, ethanol, and vegetable oil; practically insoluble in water.

Spectroscopy

IR spectrum *see* Figure 1.

Raman spectrum *see* Figure 2.

Vapor density 14.1 (air = 1) for *Citroflex A-4*

Viscosity (dynamic) 33 mPa s (33 cP) at 25°C

11 Stability and Storage Conditions

Acetyltributyl citrate should be stored in a well-closed container in a cool, dry location at temperatures not exceeding 38°C. When stored in accordance with these conditions, acetyltributyl citrate is a stable product.

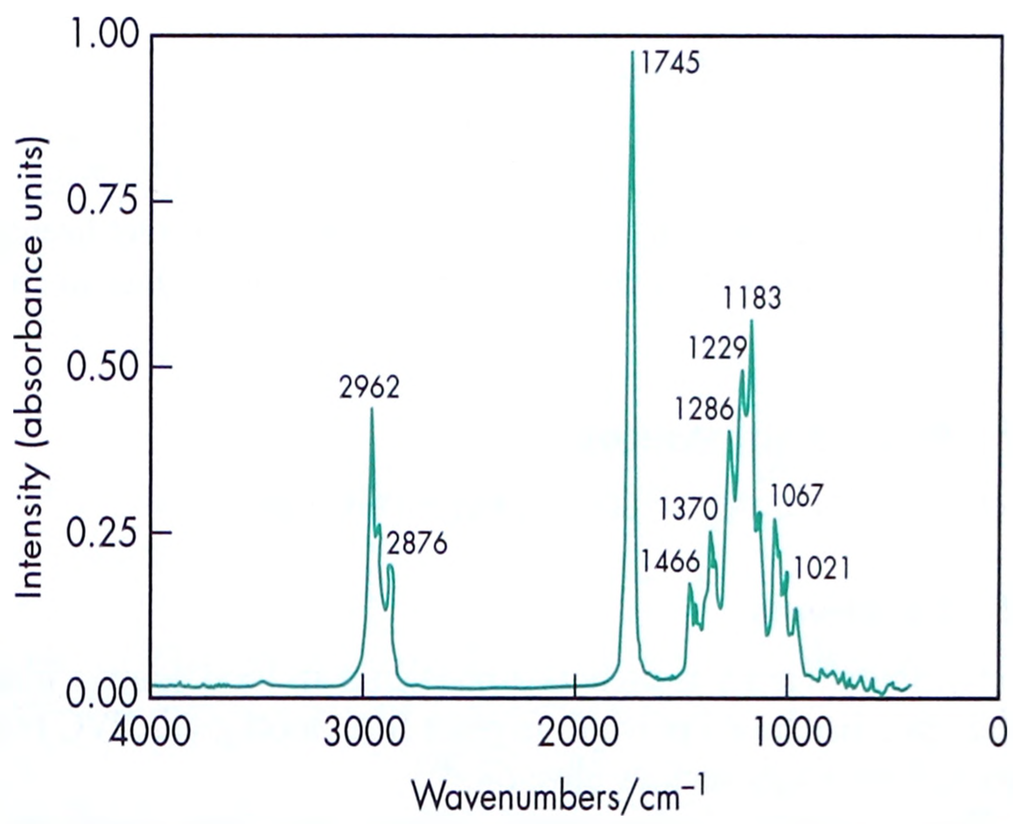

Figure 1: Infrared spectrum of acetyltributyl citrate measured by transmission. Adapted with permission of Informa Healthcare.

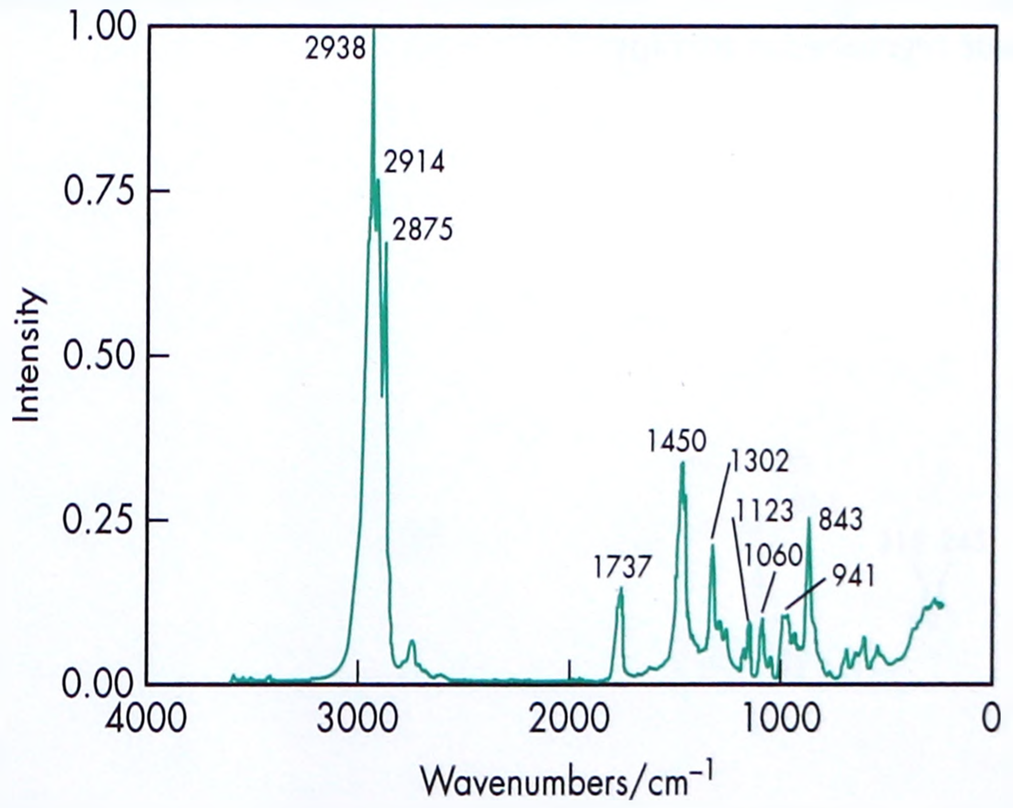

Figure 2: Raman spectrum of acetyltributyl citrate measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

A

12 Incompatibilities

Acetyltributyl citrate is incompatible with strong alkalis and oxidizing materials.

13 Method of Manufacture

Acetyltributyl citrate is prepared by the esterification of citric acid with butanol followed by acylation with acetic anhydride.

14 Safety

Acetyltributyl citrate is used in oral pharmaceutical formulations and films intended for direct food contact. It is also used in self-adhesive thin films used for topical delivery systems.[8] It is generally regarded as a relatively nontoxic and nonirritating material. However, ingestion of large quantities may be harmful.

The Cosmetic Ingredient Review Expert Panel has assessed acetyltributyl citrate and concluded that the material is safe as used in cosmetics and personal care products.[9]

LD_{50} (mouse, IP): >4 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

Acetyltributyl citrate is slightly irritating to the eyes and may be irritating to the respiratory system as a mist or at elevated temperatures. Gloves and eye protection are recommended for normal handling, and a respirator is recommended when using acetyltributyl citrate at elevated temperatures.

16 Regulatory Status

Included in FDA Inactive Ingredients Database (oral capsules and tablets). Included in the Canadian Natural Health Products Ingredients Database. Included in nonparenteral medicines licensed in the UK. Approved in the USA for direct food contact in food films.

17 Related Substances

Acetyltriethyl citrate; tributyl citrate; triethyl citrate.

18 Comments

Acetyltributyl citrate is used as a plasticizer in food contact films, although it has been known to migrate from food-grade PVC films into high-fat foods such as olive oil.[10]

Therapeutically, acetyltributyl citrate has been used as a plasticizer in *in-situ* forming implants for periodontitis treatment.[11] Polylactide plasticized with acetyltributyl citrate has been investigated as a biodegradable barrier for use in guided-tissue regeneration therapy.[12–13]

The EINECS number for acetyltributyl citrate is 201-067-0. The PubChem Compound ID (CID) for acetyltributyl citrate is 6505.

Viscosity (dynamic) 54 mPa s (54 cP) at 25°C.

11 Stability and Storage Conditions

Acetyltriethyl citrate should be stored in dry, closed containers at temperatures not exceeding 38°C. When stored in accordance with these conditions, acetyltriethyl citrate is a stable product.

12 Incompatibilities

Acetyltriethyl citrate is incompatible with strong alkalis and oxidizing materials.

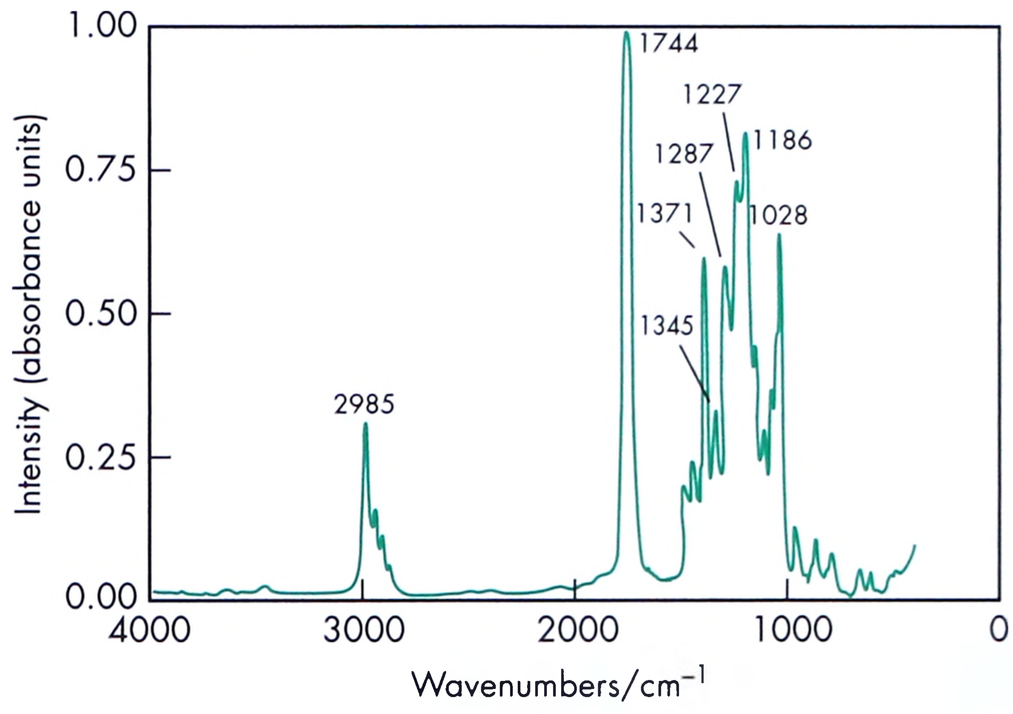

Figure 1: Infrared spectrum of acetyltriethyl citrate measured by transmission. Adapted with permission of Informa Healthcare.

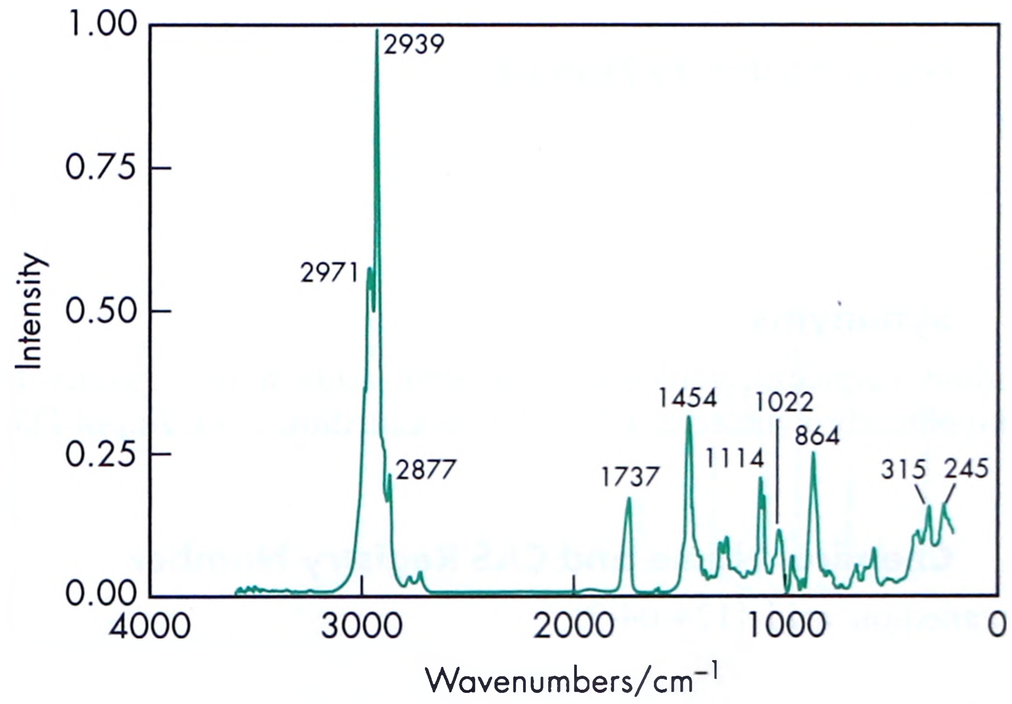

Figure 2: Raman spectrum of acetyltriethyl citrate measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

A

13 Method of Manufacture

Acetyltriethyl citrate is prepared by the esterification of citric acid with ethanol followed by acylation with acetic anhydride.

14 Safety

Acetyltriethyl citrate is used in oral pharmaceutical formulations and is generally regarded as a nontoxic and nonirritating material. However, ingestion of large quantities may be harmful.

The Cosmetic Ingredient Review Expert Panel has assessed acetyltriethyl citrate and concluded that the material is safe as used in cosmetics and personal care products.[8]

LD_{50} (mouse, IP): 1.15 g/kg[7]
LD_{50} (rat, oral): 7 g/kg[7]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

Acetyltriethyl citrate may be irritating to the eyes or the respiratory system as a mist or at elevated temperatures. Gloves and eye protection are recommended for normal handling and a respirator is recommended if used at elevated temperatures.

16 Regulatory Status

Approved in the USA for direct food contact in food films.

17 Related Substances

Acetyltributyl citrate; tributyl citrate; triethyl citrate.

18 Comments

The EINECS number for acetyltriethyl citrate is 201-066-5. The PubChem Compound ID (CID) for acetyltriethyl citrate is 6504.

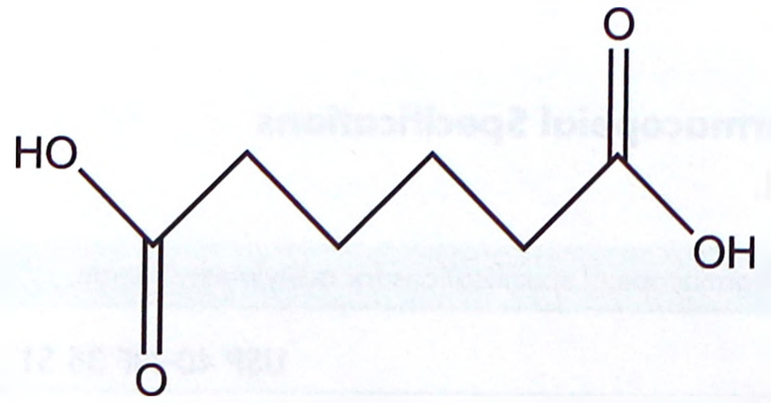
Adipic Acid

1 Nonproprietary Names

PhEur: Adipic Acid
USP–NF: Adipic Acid

2 Synonyms

Acidum adipicum; acifloctin; acinetten; adilactetten; asapic; 1,4-butanedicarboxylic acid; E355; 1,6-hexanedioic acid; *Inipol DS*.



3 Chemical Name and CAS Registry Number

Hexanedioic acid [124-04-9]

4 Empirical Formula and Molecular Weight

$C_6H_{10}O_4$ 146.14

5 Structural Formula

6 Functional Category

Acidulant; buffering agent; flavoring agent; modified-release agent.

7 Applications in Pharmaceutical Formulation or Technology

Adipic acid is used as an acidifying and buffering agent in intramuscular, intravenous, and vaginal formulations. It is also used in food products as a leavening, pH-controlling, or flavoring agent.

Adipic acid has been incorporated into controlled-release formulation matrix tablets to obtain pH-independent release for both weakly basic[1,2] and weakly acidic drugs.[3,4] It has also been incorporated into the polymeric coating of hydrophilic monolithic systems to modulate the intragel pH, resulting in zero-order release of a hydrophilic drug.[5] The disintegration at intestinal pH of the enteric polymer shellac has been reported to improve when adipic acid was used as a pore-forming agent without affecting release in the acidic media.[6] Other controlled-release formulations have included adipic acid with the intention of obtaining a late-burst release profile.[7]

8 Description

Adipic acid occurs as a white or almost white, odorless nonhygroscopic crystalline powder. The crystal structure of adipic acid is monoclinic holohedral.

9 Pharmacopeial Specifications

See Table I.

Raman spectrum *see* Figure 2.

Vapor pressure 133.3 Pa (1 mmHg) at 159.5°C

Viscosity (dynamic) 4.54 mPa s (4.54 cP) at 160°C for molten adipic acid.

Table II: Solubility of adipic acid.

Solvent	Solubility at 20°C unless otherwise stated
Acetone	Soluble
Benzene	Practically insoluble
Cyclohexane	Slightly soluble
Ethanol (95%)	Freely soluble
Ether	1 in 157.8 at 19°C
Ethyl acetate	Soluble
Methanol	Freely soluble
Petroleum ether	Practically insoluble
Water	1 in 71.4 1 in 0.6 at 100°C

11 Stability and Storage Conditions

Adipic acid is normally stable but decomposes above boiling point. It should be stored in a tightly closed container in a cool, dry place, and should be kept away from heat, sparks, and open flame.

12 Incompatibilities

Adipic acid is incompatible with strong oxidizing agents as well as strong bases and reducing agents. Contact with alcohols, glycols, aldehydes, epoxides, or other polymerizing compounds can result in violent reactions.

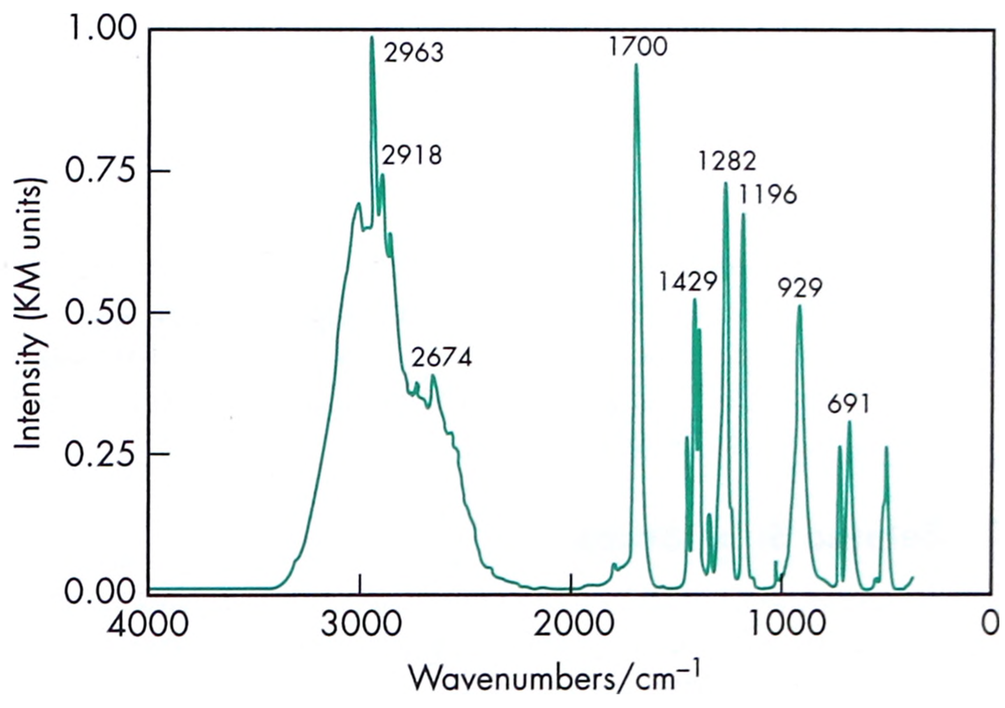

Figure 1: Infrared spectrum of adipic acid measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

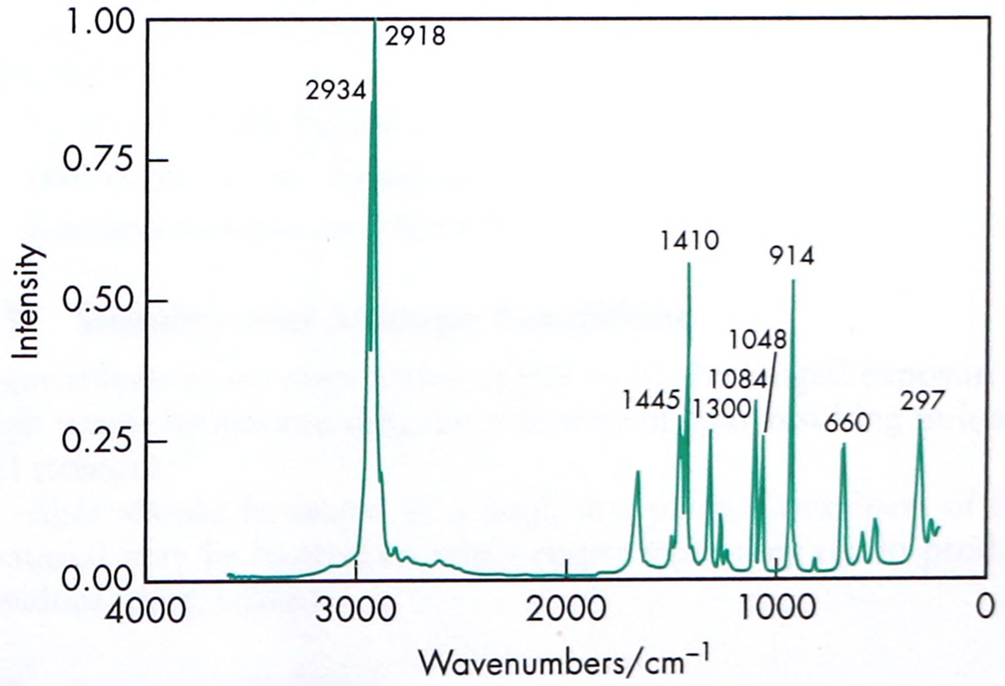

Figure 2: Raman spectrum of adipic acid measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

A

13 Method of Manufacture

Adipic acid is prepared by nitric acid oxidation of cyclohexanol or cyclohexanone or a mixture of the two compounds. Recently, oxidation of cyclohexene with 30% aqueous hydrogen peroxide under organic solvent- and halide-free conditions has been proposed as an environmentally friendly alternative for obtaining colorless crystalline adipic acid.[8]

14 Safety

Adipic acid is used in pharmaceutical formulations and food products. The pure form of adipic acid is toxic by the IP route, and moderately toxic by other routes. It is a severe eye irritant, and may cause occupational asthma.

LD_{50} (mouse, IP): 0.28 g/kg[9]
LD_{50} (mouse, IV): 0.68 g/kg
LD_{50} (mouse, oral): 1.9 g/kg
LD_{50} (rat, IP): 0.28 g/kg
LD_{50} (rat, oral): >11 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled.

Adipic acid is combustible and can react with oxidizing materials when exposed to heat and flame. It emits acrid smoke and fumes when heated to decomposition. Dust explosion is possible if in powder or granular form, mixed with air.

Adipic acid irritates the eyes and respiratory tract. Protective equipment such as respirators, safety goggles, and heavy rubber gloves should be worn when handling adipic acid.

16 Regulatory Status

GRAS listed. Included in the FDA Inactive Ingredients Database (IM, IV, and vaginal preparations). Accepted for use as a food additive in Europe. Included in an oral pastille formulation available in the UK. Included in the Canadian Natural Health Products Ingredients Database.

Agar

1 Nonproprietary Names

JP: Agar

PhEur: Agar

USP–NF: Agar

2 Synonyms

Agar-agar; agar-agar flake; agar-agar gum; Bengal gelatin; Bengal gum; Bengal isinglass; Ceylon isinglass; Chinese isinglass; E406; gelosa; gelose; Japan agar; Japan isinglass; layor carang; vegetable gelatin.

3 Chemical Name and CAS Registry Number

Agar [9002-18-0]

4 Empirical Formula and Molecular Weight

See Section 5.

5 Structural Formula

Agar is a dried, hydrophilic, colloidal polysaccharide complex extracted from the agarocytes of algae of the Rhodophyceae. The structure is believed to be a complex range of polysaccharide chains having alternating α-(1→3) and β-(1→4) linkages. There are three extremes of structure noted: namely neutral agarose; pyruvated agarose having little sulfation; and a sulfated galactan. Agar can be separated into a natural gelling fraction, agarose, and a sulfated nongelling fraction, agaropectin.

6 Functional Category

Emulsifying agent; gelling agent; modified-release agent; suppository base; suspending agent; tablet and capsule binder; tablet and capsule disintegrant (treated agar); viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Agar is widely used in food applications as a stabilizing agent. In pharmaceutical applications, agar is used in a handful of oral tablet and topical formulations. It has also been investigated in a number of experimental pharmaceutical applications including as a sustained-release agent in gels, beads, microspheres, and tablets.[1–5] It has been reported to work as a disintegrant in tablets.[6–8] Agar has been used in a floating controlled-release tablet; the buoyancy in part being attributed to air entrapped in the agar gel network.[9] It has been used as a polymeric carrier for buccal delivery in the form of thin films containing a drug[10–12] and as a co-processing excipient to improve compressibility of a poorly compressible drug.[13] It can be used as a viscosity-increasing agent in aqueous systems. Agar can also be used as a base for nonmelting, and nondisintegrating suppositories.[14] Agar has an application as a suspending agent in pharmaceutical suspensions.[15] Agar co-processed with mannitol has been used as a fast disintegrating excipient for orodispersible tablets of a drug.[16] It has also been used to modify the properties of other natural polymers by chemically grafting agar with these natural polymers or by simple hydrogen bonding to result in better hydrogel systems.[17,18]

8 Description

Agar occurs as transparent, odorless, tasteless strips or as a coarse or fine powder. It may be weak yellowish-orange, yellowish-gray to pale-yellow colored, or colorless. Agar is tough when damp, brittle when dry.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for agar.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters	+	+	–

Acid-insoluble ash	≤0.5%	–	≤0.5%
Foreign organic matter	–	–	≤1.0%
Limit of foreign starch	–	–	+

(a) Total viable aerobic count, determined by plate-count.

10 Typical Properties

Gelling Agar gels are thermo-reversible, rigid, brittle, and have sharp melting and gelling points. They further demonstrate the phenomenon of syneresis and hysteresis. Gelling occurs at temperatures far below the gel melting temperature. A 1.5% solution of agar forms a gel on cooling to about 32°C to 45°C. The gel strength of agar is influenced by concentration, time, pH and sugar content. The pH demonstrates the most noticeable effect on gel strength where gel strength decreases with a decrease in pH.

Solubility Soluble in boiling water to form a viscous solution; practically insoluble in ethanol (95%), and cold water. A 1% w/v aqueous solution forms a stiff jelly on cooling.

Spectroscopy

IR spectrum *see* Figure 1.

NIR spectrum *see* Figure 2.

Raman spectrum *see* Figure 3.

11 Stability and Storage Conditions

Agar solutions are most stable at pH 4–10. Prolonged exposure to high temperatures can degrade solutions of agar resulting in lower gel strength.

Agar should be stored in a cool, dry, place. Containers of this material may be hazardous when empty since they retain product residues (dust, solids).

12 Incompatibilities

Agar is incompatible with strong oxidizing agents. Agar is dehydrated and precipitated from solution by ethanol (95%). Tannic

A

acid causes precipitation; electrolytes cause partial dehydration and decrease in viscosity of sols.[19]

13 Method of Manufacture

Agar is obtained by freeze-drying a mucilage derived from *Gelidium amansii* Lamouroux, other species of the same family (Gelidiaceae), or other red algae (Rhodophyta).

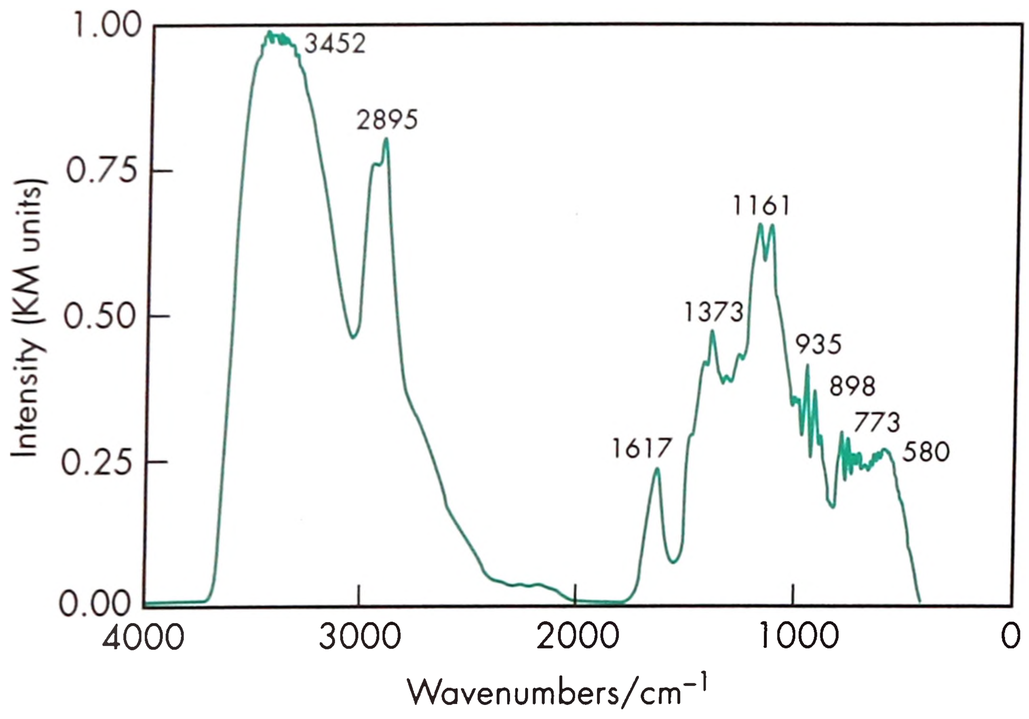

Figure 1: Infrared spectrum of agar measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

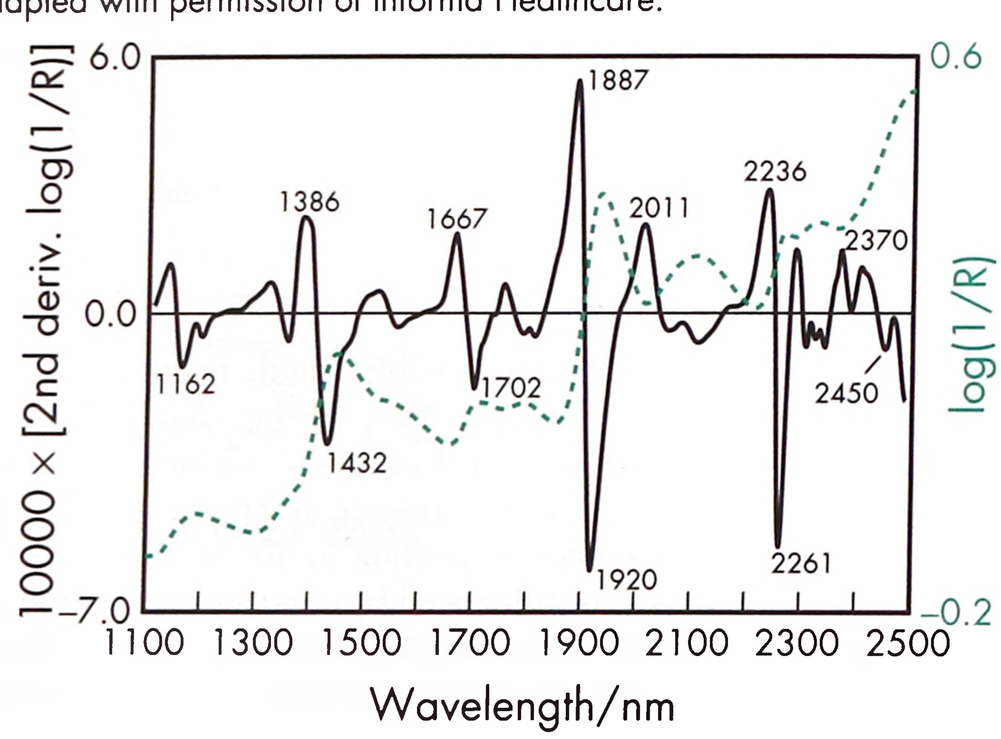

Figure 2: Near-infrared spectrum of agar measured by reflectance.

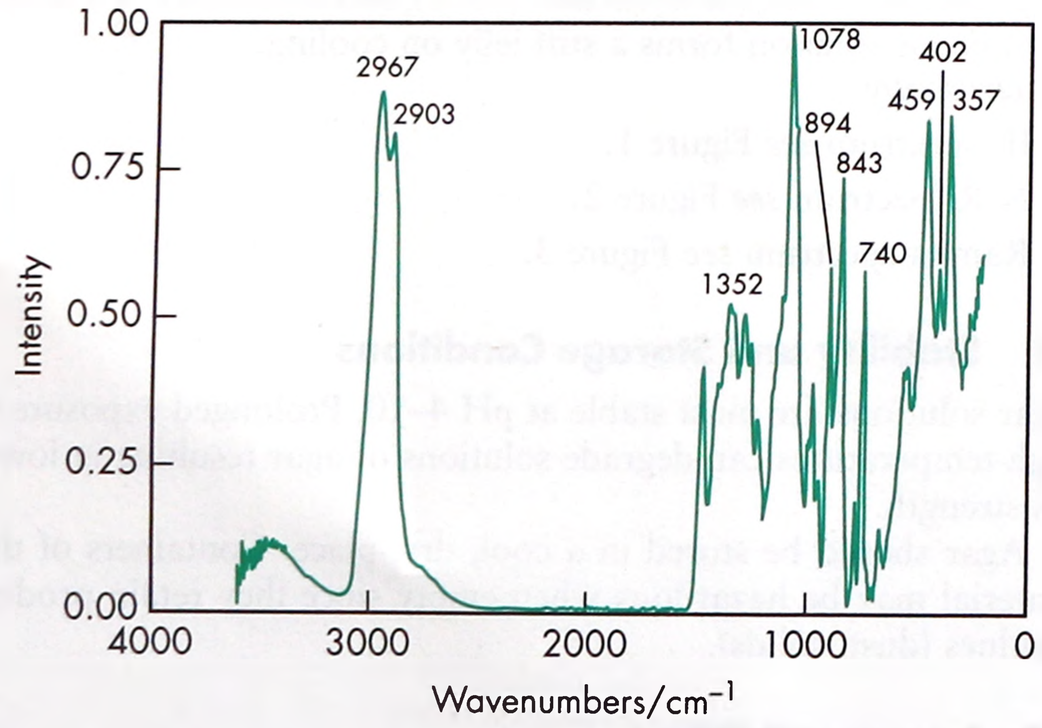

Figure 3: Raman spectrum of agar measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

14 Safety

Agar is widely used in food applications and has been used in oral and topical pharmaceutical applications. It is generally regarded as relatively nontoxic and nonirritant when used as an excipient.

LD_{50} (hamster, oral): 6.1 g/kg[20]
LD_{50} (mouse, oral): 16.0 g/kg
LD_{50} (rabbit, oral): 5.8 g/kg
LD_{50} (rat, oral): 11.0 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. When heated to decomposition, agar emits acrid smoke and fumes.

16 Regulatory Status

GRAS listed. Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (oral tablets). Included in the Canadian Natural Health Products Ingredients Database. Included in nonparenteral medicines licensed in the UK.

17 Related Substances

Albumin

1 Nonproprietary Names

BP: Albumin Solution

PhEur: Human Albumin Solution

USP–NF: Albumin Human

2 Synonyms

Alba; *Albuconn*; *Albuminar*; albumin human solution; albumini humani solutio; *Albumisol*; *Albuspan*; *Albutein*; *Buminate*; human serum albumin; normal human serum albumin; *Octalbin*; *Plasbumin*; plasma albumin; *Pro-Bumin*; *Proserum*; *Zenalb*.

3 Chemical Name and CAS Registry Number

Serum albumin [70024-90-7]

4 Empirical Formula and Molecular Weight

Human serum albumin has a molecular weight of about 66 500 and is a single polypeptide chain consisting of 585 amino acids. Characteristic features are a single tryptophan residue, a relatively low content of methionine (6 residues), and a large number of cysteine (17) and of charged amino acid residues of aspartic acid (36), glutamic acid (61), lysine (59), and arginine (23).

5 Structural Formula

Primary structure Human albumin is a single polypeptide chain of 585 amino acids and contains seven disulfide bridges.

Secondary structure Human albumin is known to have a secondary structure that is about 55% α-helix. The remaining 45% is believed to be divided among turns, disordered, and β structures.[1]

Albumin is the only major plasma protein that does not contain carbohydrate constituents. Assays of crystalline albumin show less than one sugar residue per molecule.

6 Functional Category

Adsorbent; cryoprotectant; dispersing agent.

7 Applications in Pharmaceutical Formulation or Technology

Albumin is primarily used as an excipient in parenteral pharmaceutical formulations, where it is used as a stabilizing agent for formulations containing proteins and enzymes.[2,3] Albumin has also been used to prepare microspheres, microcapsules and nanoparticles for experimental drug-delivery systems.[4–13]

As a stabilizing agent, albumin has been employed in protein formulations at concentrations as low as 0.003%, although concentrations of 1–5% are commonly used. Albumin has also been used as a cosolvent[14] for parenteral drugs, as a cryoprotectant during lyophilization,[15,16] and to prevent adsorption of other proteins to surfaces.

8 Description

The USP 40–NF 35 S1 describes albumin human as a sterile nonpyrogenic preparation of serum albumin obtained from healthy human donors; *see* Section 13. It is available as a solution containing 4, 5, 20, or 25 g of serum albumin in 100 mL of solution, with not less than 96% of the total protein content as albumin. The solution contains no added antimicrobial preservative but may contain sodium acetyltryptophanate with or without sodium caprylate as a stablizing agent.

The PhEur 9.2 similarly describes albumin solution as an aqueous solution of protein obtained from human plasma; *see* Section 13. It is available as a concentrated solution containing 150–250 g/L of total protein or as an isotonic solution containing 35–50 g/L of total protein. Not less than 95% of the total protein content is albumin. A suitable stabilizer against the effects of heat, such as sodium caprylate (sodium octanoate) or *N*-acetyltryptophan or a combination of these two at a suitable concentration, may be added, but no antimicrobial preservative is added.

Aqueous albumin solutions are slightly viscous and range in color from almost colorless to amber depending upon the protein concentration. In the solid state, albumin appears as brownish amorphous lumps, scales, or powder.

9 Pharmacopeial Specifications

See Table I.

10 Typical Properties

Acidity/alkalinity pH = 6.7–7.3 for a 1% w/v solution, in 0.9% w/v sodium chloride solution, at 20°C.

Osmolarity A 4–5% w/v aqueous solution is isoosmotic with serum.

A

Table I: Pharmacopeial specifications for albumin.

Aluminum	≤200 µg/L	–
Sterility	+	+
Hepatitis B surface antigen	–	+
Pyrogens	+	+
Total protein	95–105%	≥96%
for 4 g in 100 mL	–	93.75–106.25%
for 5 to 25 g in 100 mL	–	94.0–106.0%
Prekallikrein activator	≤35 IU/mL	–

Solubility Freely soluble in dilute salt solutions and water. Aqueous solutions containing 40% w/v albumin can be readily prepared at pH 7.4. The high net charge of the peptide contributes to its solubility in aqueous media. The seven disulfide bridges contribute to its chemical and spatial conformation. At physiological pH, albumin has a net electrostatic charge of about –17. Aqueous albumin solutions are slightly viscous and range in color from almost colorless to amber depending on the protein concentration.

Spectroscopy

NIR spectrum *see* Figure 1.

11 Stability and Storage Conditions

Albumin is a protein and is therefore susceptible to chemical degradation and denaturation by exposure to extremes of pH, high salt concentrations, heat, enzymes, organic solvents, and other chemical agents.

Albumin solutions should be protected from light and stored at a temperature of 2–25°C or as indicated on the label.

12 Incompatibilities

See Section 11.

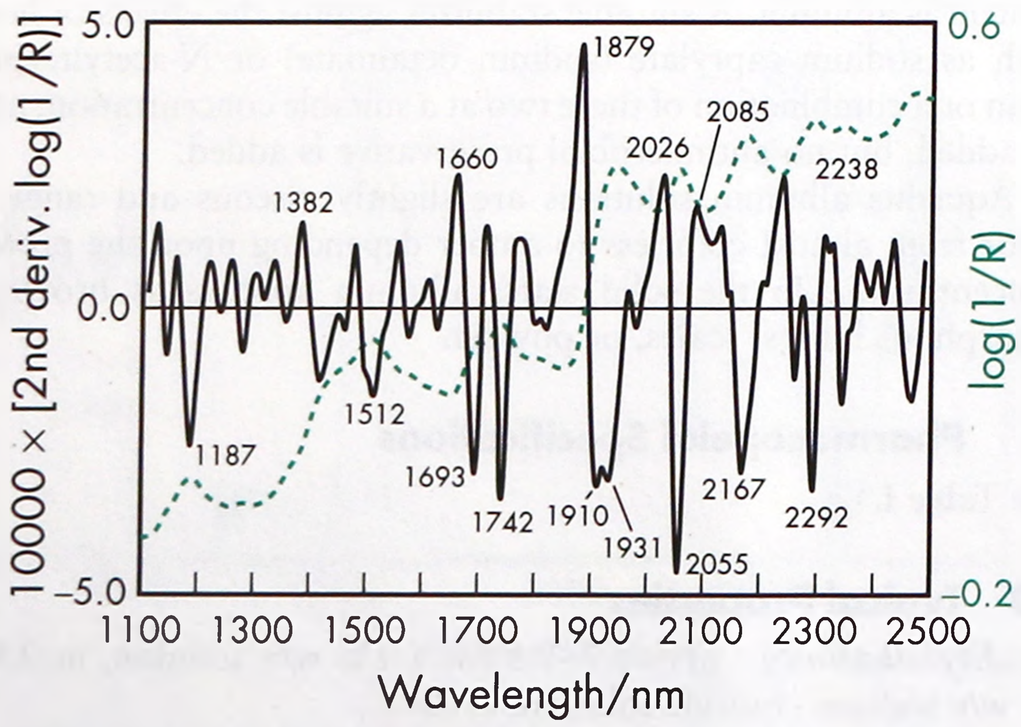

Figure 1: Near-infrared spectrum of albumin measured by reflectance.

13 Method of Manufacture

Albumin human (USP 40–NF 35 S1) Albumin human is a sterile nonpyrogenic preparation of serum albumin that is obtained by fractionating material (source blood, plasma, serum, or placentas) from healthy human donors. The source material is tested for the absence of hepatitis B surface antigen. It is made by a process that yields a product safe for intravenous use.

Human albumin solution (PhEur 9.2) Human albumin solution is an aqueous solution of protein obtained from plasma. Separation of the albumin is carried out under controlled conditions so that the final product contains not less than 95% albumin. Human albumin solution is prepared as a concentrated solution containing 150–250 g/L of total protein or as an isotonic solution containing 35–50 g/L of total protein. A suitable stabilizer against the effects of heat such as sodium caprylate (sodium octanoate) or *N*-acetyltryptophan or a combination of these two at a suitable concentration, may be added, but no antimicrobial preservative is added at any stage during preparation. The solution is passed through a bacteria-retentive filter and distributed aseptically into sterile containers, which are then closed so as to prevent contamination. The solution in its final container is heated to 60 ± 1.0°C and maintained at this temperature for not less than 10 hours. The containers are then incubated at 30–32°C for not less than 14 days or at 20–25°C for not less than 4 weeks and examined visually for evidence of microbial contamination.

14 Safety

Albumin occurs naturally in the body, comprising about 60% of all the plasma proteins. As an excipient, albumin is used primarily in parenteral formulations and is generally regarded as an essentially nontoxic and nonirritant material. Adverse reactions to albumin infusion rarely occur but include nausea, vomiting, increased salivation, chills, and febrile reactions. Urticaria and skin rash have been reported. Allergic reactions, including anaphylactic shock, can occur. Albumin infusions are contraindicated in patients with severe anemia or cardiac failure. Albumin solutions with aluminum content of less than 200 µg/L should be used in dialysis patients and premature infants.[17]

LD_{50} (monkey, IV): >12.5 g/kg[18]

LD_{50} (rat, IV): >12.5 g/kg

15 Handling Precautions

Observe handling precautions appropriate for a biologically derived blood product.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (IV injections, IV infusions and subcutaneous injectables). Included in parenteral products licensed in the UK.

17 Related Substances

Albumins derived from animal sources are also commercially available, e.g. bovine serum albumin.

Recombinant albumin, human.

Recombinant albumin, human

Synonyms rAlbumin human; rHA

Description It is presented as a sterile and nonpyrogenic aqueous liquid consisting of a 10% or 20% solution in water for injection. It contains no added antimicrobial agents, but it may contain appropriate stabilizing agents. Clear, slightly viscous, and colorless to yellow-amber in color.

Stability and storage conditions Store in airtight glass containers at a temperature of 2–8°C. Do not allow to freeze.

Comments Listed in USP 40–NF 35 S1. Produced by recombinant DNA expression in *Saccharomyces cerevisiae*. Structural equivalence (primary, secondary and tertiary) between rHA and human serum albumin (HSA) has been demonstrated.

18 Comments

A 100 mL aqueous solution of albumin containing 25 g of serum albumin is osmotically equivalent to 500 mL of normal human plasma.

Therapeutically, albumin solutions have been used parenterally for plasma volume replacement and to treat severe acute albumin loss. However, the benefits of using albumin in such applications in critically ill patients has been questioned.[19]

The EINECS number for albumin is 274-272-6.

Alginic Acid

1 Nonproprietary Names

BP: Alginic Acid

PhEur: Alginic Acid

USP–NF: Alginic Acid

2 Synonyms

Acidum alginicum; E400; *Kelacid*; L-gulo-D-mannoglycuronan; polymannuronic acid; *Protacid*; *Satialgine H8*.

3 Chemical Name and CAS Registry Number

Alginic acid [9005-32-7]

4 Empirical Formula and Molecular Weight

Alginic acid is a linear glycuronan polymer consisting of a mixture of β-(1→4)-D-mannosyluronic acid and α-(1→4)-L-gulosyluronic acid residues, of general formula $(C_6H_8O)_n$. The molecular weight is typically 20 000–240 000.

5 Structural Formula

The PhEur 9.2 describes alginic acid as a mixture of polyuronic acids $[(C_6H_8O_6)_n]$ composed of residues of D-mannuronic and L-glucuronic acid, and obtained mainly from algae belonging to the Phaeophyceae. A small proportion of the carboxyl groups may be neutralized.

See also Section 4.

A

6 Functional Category

Modified-release agent; suspending agent; tablet and capsule binder; tablet and capsule disintegrant; taste-masking agent; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

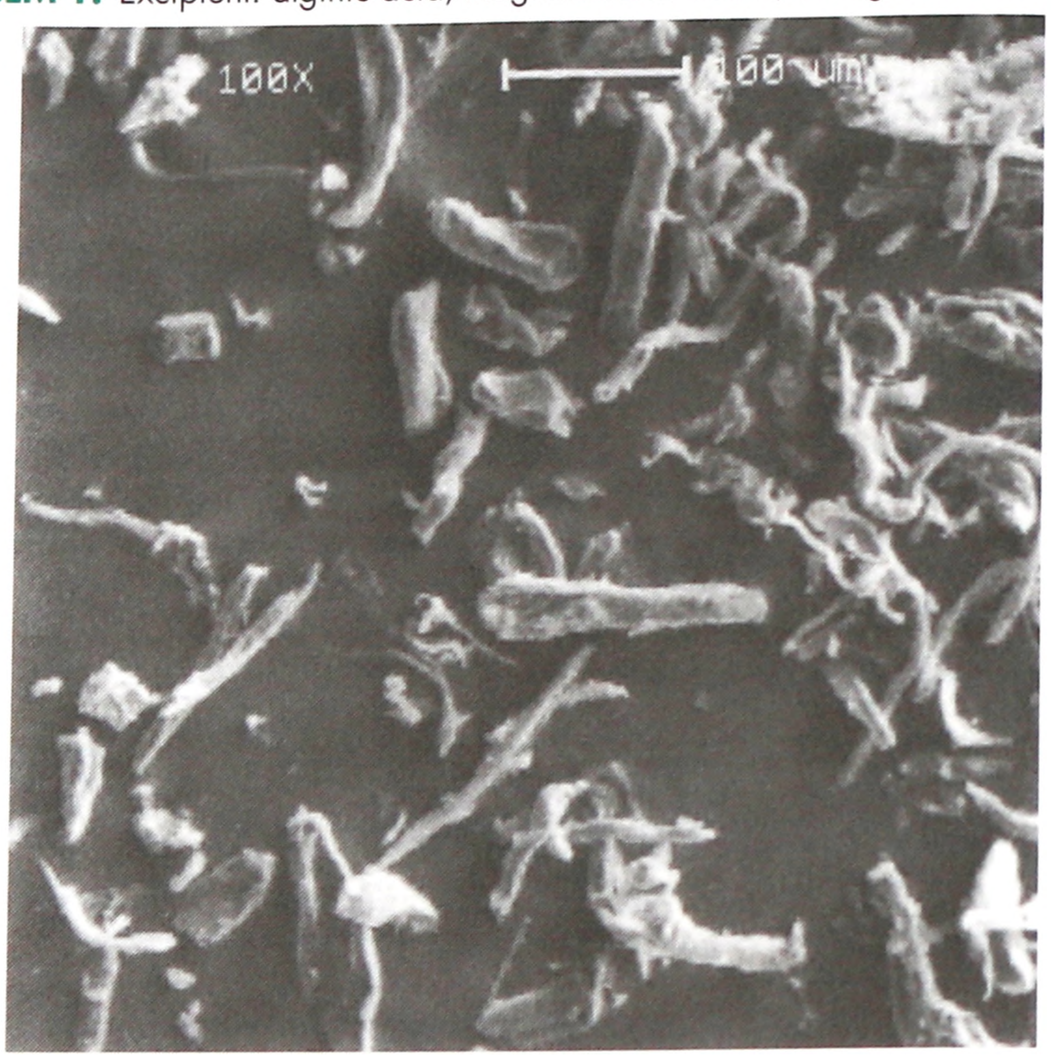
Alginic acid is a natural biodegradable, biocompatible, non-toxic and low-cost polymer[1] used in a variety of oral and topical pharmaceutical formulations. In tablet and capsule formulations, alginic acid is used as both a binder and disintegrating agent at concentrations of 1–5% w/w.[2,3] Alginic acid is widely used as a thickening and suspending agent in a variety of pastes, creams, and gels, and as a stabilizing agent for oil-in-water emulsions.

Alginic acid has been used to improve the stability of levosimendan[4] and has been investigated for use in an ocular formulation of carteolol.[5]

In the area of controlled release, the preparation of indomethacin sustained-release microparticles from alginic acid (alginate)–gelatin hydrocolloid coacervate systems has been investigated.[6] In addition, as controlled-release systems for liposome-associated macromolecules, microspheres have been produced encapsulating liposomes coated with alginic acid and poly-L-lysine membranes.[7] Alginate gel beads capable of floating in the gastric cavity have been prepared, the release properties of which were reported to be applicable for sustained release of drugs, and for targeting the gastric mucosa.[8]

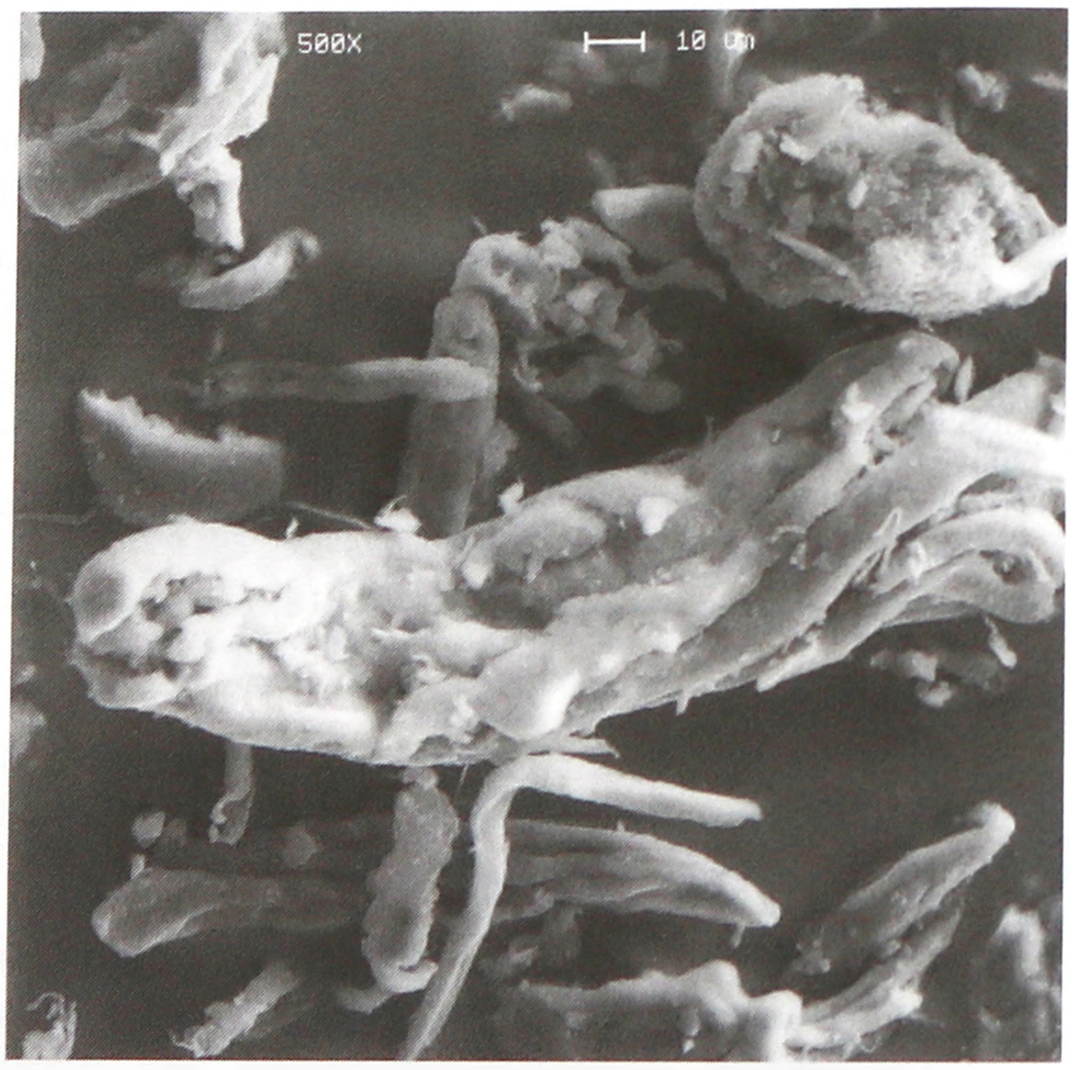
Mechanical properties, water uptake, and permeability properties of a sodium salt of alginic acid have been characterized for controlled-release applications.[9] In addition, sodium alginate has been incorporated into an ophthalmic drug delivery system for pilocarpine nitrate.[10] Sodium alginate has been used to improve pelletization due to polyelectrolyte complex formation between cationic polymers such as chitosan.[11] Alginic acid has also been shown to be beneficial in the development of alginate gel-encapsulated, chitosan-coated nanocores, where the alginates act as a protective agent for sensitive macromolecules such as proteins and peptides for prolonged release.[12] In addition, the crosslinking of dehydrated paracetamol sodium alginate pellets has been shown to successfully mask the drug's unpleasant taste by an extrusion/spheronization technique.[13]

It has also been reported that associated chains of alginic acid complexed with cations can bind to cell surfaces and exert pharmacological effects, which depend on the cell type and the complexed cation. These complexes can be used to treat rheumatic disorders, diseases associated with atopic diathesis and liver diseases.[14]



An alginic oligosaccharide, obtained from a natural edible polysaccharide, has been shown to suppress Th2 responses and IgE production by inducing IL-12 production, and was found to be a useful approach for preventing allergic disorders.[15] Chemically modified alginic acid derivatives have also been researched for their anti-inflammatory, antiviral, and antitumor activities.[16] Alginate/antacid antireflux preparations have been reported to provide symptomatic relief by forming a physical barrier on top of the stomach contents in the form of a raft.[17]

Alginic acid gels for use in drug delivery systems may be prepared by adding D-glucono-D-lactone, which hydrolyzes in the presence of water to produce gluconic acid with a continuous lowering of pH.[18] Alginic acid forms a gel in the presence of di- or trivalent cations, and may be used as a carrier for treating joint disorders.[19,20]



8 Description

Alginic acid is a tasteless, practically odorless, white to yellowish-white, fibrous powder.

SEM 1: Excipient: alginic acid; magnification: 100×; voltage: 25 kV.

SEM 2: Excipient: alginic acid; magnification: 500×; voltage: 25 kV.

9 Pharmacopeial Specifications

See Table I.

10 Typical Properties

Acidity/alkalinity pH = 1.5–3.5 for a 3% w/v aqueous dispersion.

Crosslinking Addition of a calcium salt, such as calcium citrate or calcium chloride, causes crosslinking of the alginic acid polymer resulting in an apparent increase in molecular weight. Films crosslinked with triphosphate (tripolyphosphate) and calcium chloride were found to be insoluble but permeable to water vapor. Drug permeability varies with pH and the extent of crosslinking.[9]

Density (true) 1.601 g/cm^3

Table I: Pharmacopeial specifications for alginic acid.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	—
Microbial limits	$\leq 10^2$ cfu/g	≤200 cfu/g
pH (3% dispersion)	—	1.5–3.5
Loss on drying	≤15.0%	≤15.0%
Ash	—	≤4.0%
Sulfated ash	≤8.0%	—
Arsenic	—	≤3 ppm
Chloride	≤1.0%	—
Lead	—	≤10 ppm
Heavy metals	—	≤4 ppm
Acid value (dried basis)	—	≥230
Assay (of COOH groups)	19.0–25.0%	—

Moisture content 7.01%

Solubility Soluble in alkali hydroxides, producing viscous solutions; very slightly soluble or practically insoluble in ethanol (95%) and other organic solvents. Alginic acid swells in water but does not dissolve; it is capable of absorbing 200–300 times its own weight of water.

Spectroscopy

NIR spectrum *see* Figure 2.

Raman spectrum *see* Figure 3.

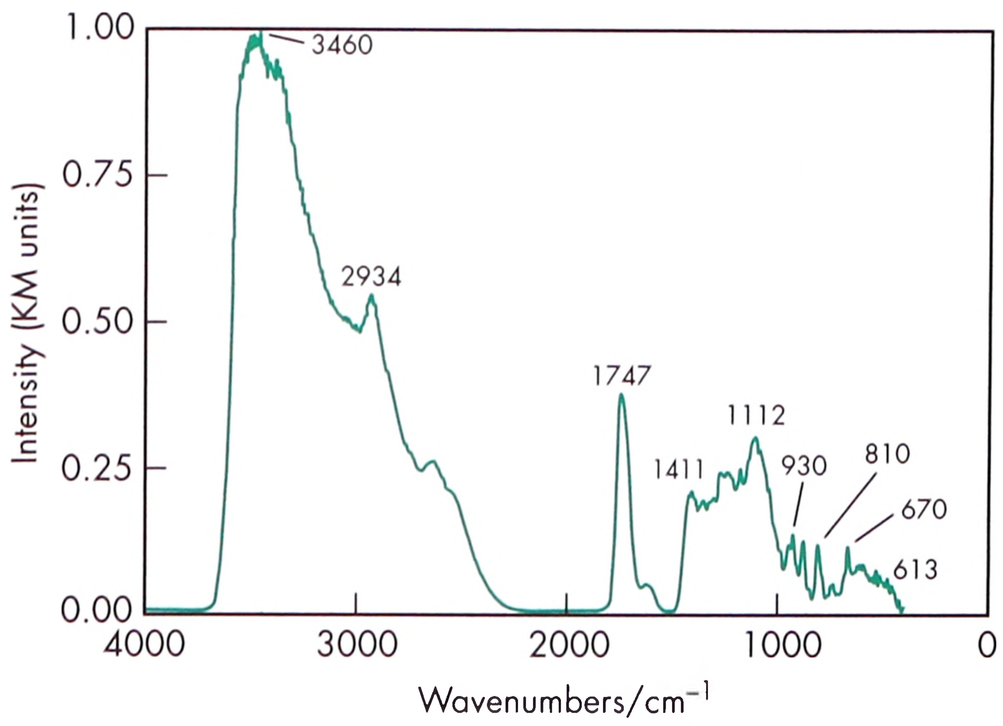

Figure 1: Infrared spectrum of alginic acid measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

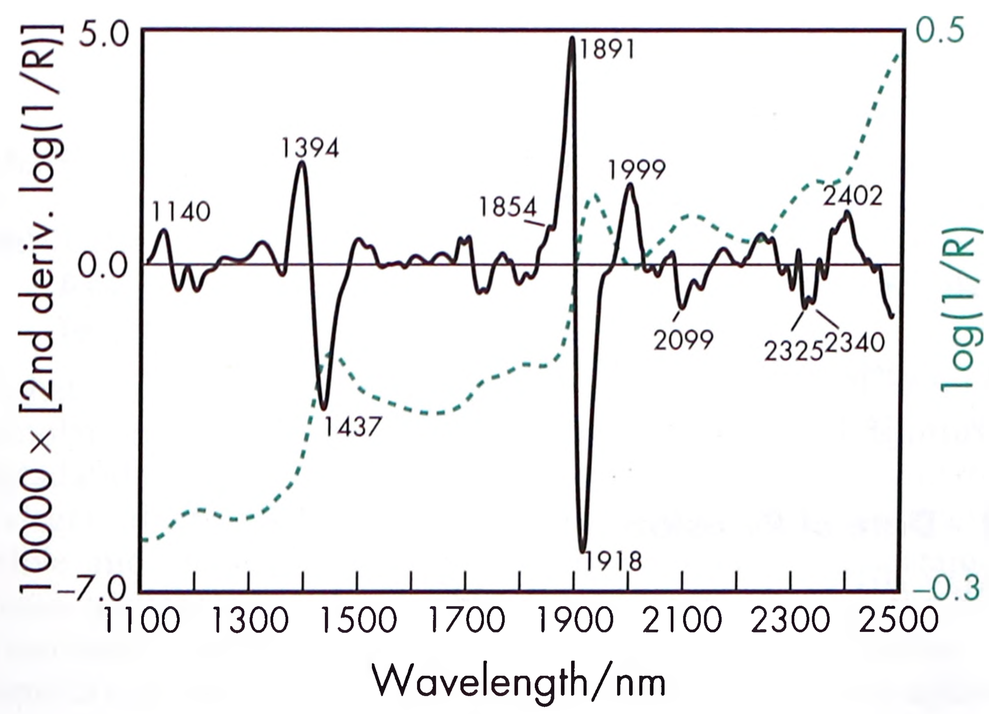

Figure 2: Near-infrared spectrum of alginic acid measured by reflectance.

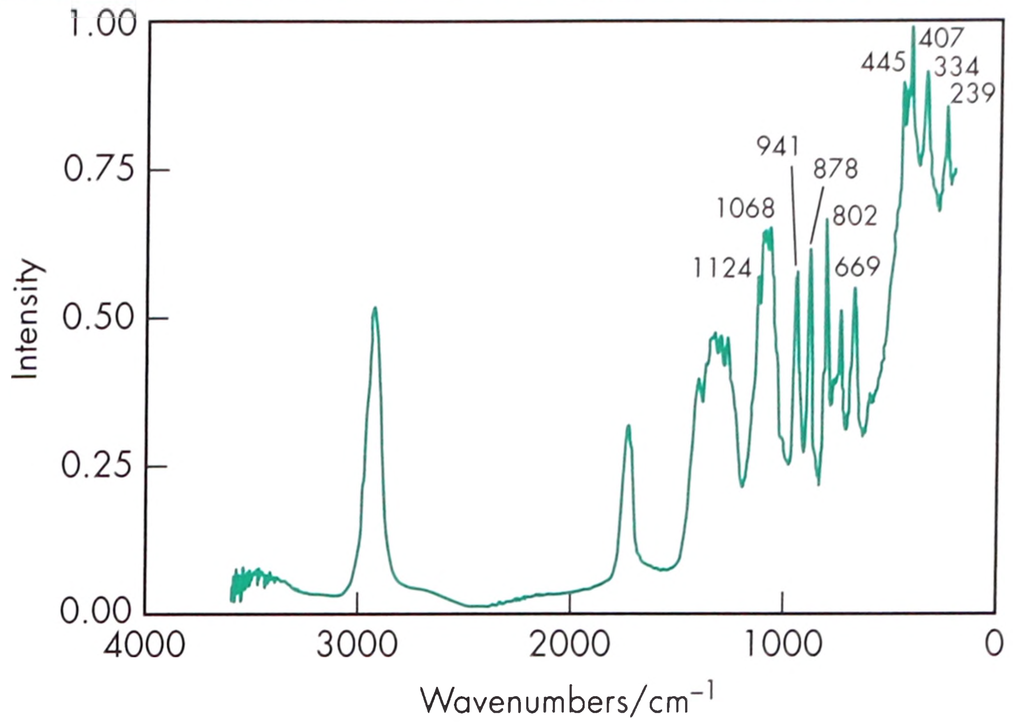

Figure 3: Raman spectrum of alginic acid measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

Viscosity (dynamic) Various grades of alginic acid are commercially available that vary in their molecular weight and hence viscosity. Viscosity increases considerably with increasing concentration; typically a 0.5% w/w aqueous dispersion will have a viscosity of approximately 20 mPa s, while a 2.0% w/w aqueous dispersion will have a viscosity of approximately 2000 mPa s. The viscosity of dispersions decreases with increasing temperature. As a general rule, a 1°C increase in temperature results in a 2.5% reduction in viscosity. At low concentrations, the viscosity of an alginic acid dispersion may be increased by the addition of a calcium salt, such as calcium citrate. *See also* Section 11 and Section 18.

11 Stability and Storage Conditions

Alginic acid hydrolyzes slowly at warm temperatures producing a material with a lower molecular weight and lower dispersion viscosity. When heated, alginic acid initially undergoes dehydration at approximately 80°C followed by decomposition at approximately 200°C.

Alginic acid dispersions are susceptible to microbial spoilage on storage, which may result in some depolymerization and hence a decrease in viscosity. Dispersions should therefore be preserved with an antimicrobial preservative such as benzoic acid; potassium sorbate; sodium benzoate; sorbic acid; or paraben. Concentrations of 0.1–0.2% are usually used.

Alginic acid dispersions may be sterilized by autoclaving or filtration through a 0.22 µm filter. Autoclaving may result in a decrease in viscosity which can vary depending upon the nature of any other substances present.[21]

Alginic acid should be stored in a well-closed container in a cool, dry place.

12 Incompatibilities

Alginic acid is incompatible with strong oxidizing agents; alginic acid forms insoluble salts in the presence of alkaline earth metals and group III metals with the exception of magnesium.

13 Method of Manufacture

Alginic acid is a hydrophilic colloid carbohydrate that occurs naturally in the cell walls and intercellular spaces of various species of brown seaweed (Phaeophyceae). The seaweed occurs widely throughout the world and is harvested, crushed, and treated with dilute alkali to extract the alginic acid.

A

14 Safety

Alginic acid is widely used in food products and topical and oral pharmaceutical formulations. It is generally regarded as a nontoxic and nonirritant material, although excessive oral consumption may be harmful. Inhalation of alginate dust may be an irritant and has been associated with industrially related asthma in workers involved in alginate production. However, it appears that the cases of asthma were linked to exposure to unprocessed seaweed dust rather than pure alginate dust.[22]

An acceptable daily intake of alginic acid and its ammonium, calcium, potassium, and sodium salts was not set by the WHO because the quantities used, and the background levels in food, did not represent a hazard to health.[23]

LD_{50} (rat, IP): 1.6 g/kg[24]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Alginic acid may be irritant to the eyes or respiratory system if inhaled as dust; *see* Section 14. Eye protection, gloves, and a dust respirator are recommended. Alginic acid should be handled in a well-ventilated environment.

16 Regulatory Status

GRAS listed. Included in the FDA Inactive Ingredients Database (ophthalmic preparations, oral capsules, and tablets). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database. Accepted in Europe for use as a food additive.

17 Related Substances

Ammonium alginate; calcium alginate; potassium alginate; propylene glycol alginate; sodium alginate.

18 Comments

Alginic acid dispersions are best prepared by pouring the alginic acid slowly and steadily into vigorously stirred water. Dispersions should be stirred for approximately 30 minutes. Premixing the alginic acid with another powder, such as sugar, or a water-miscible liquid such as ethanol (95%) or glycerin, aids dispersion.

When using alginic acid in tablet formulations, the alginic acid is best incorporated or blended using a dry granulation process.

Therapeutically, alginic acid has been used as an antacid.[25] In combination with an H_2-receptor antagonist, it has also been utilized for the management of gastroesophageal reflux.[26]

A specification for alginic acid is contained in the *Food Chemicals Codex* (FCC).[27]

The EINECS number for alginic acid is 232-680-1.

Aliphatic Polyesters

1 Nonproprietary Names

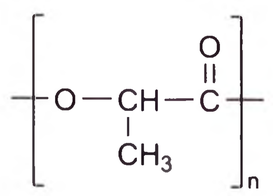
None adopted.

2 Synonyms

DL-PLA; DL-PLGA; *Lactel*; poly(lactic acid); poly(DL-lactic-*co*-glycolic acid); poly(DL-lactide); poly(DL-lactide-*co*-glycolide); *Purasorb*; *Resomer*; *Resomer Select*.

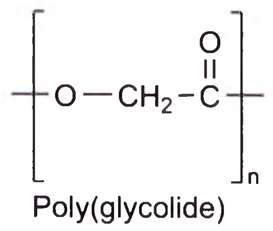
See also Table I.

3 Chemical Name and CAS Registry Number



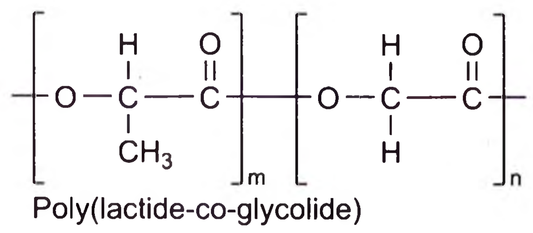
See Table I.

4 Empirical Formula and Molecular Weight



Aliphatic polyesters that have been approved for drug delivery are synthetic homopolymers or copolymers of lactic acid, glycolic acid, lactide and glycolide. Typically, the molecular weights of homopolymers and copolymers range from 2 000 to >100 000 Da.

Co-monomer ratios of lactic acid and glycolic acid (or lactide and glycolide) for poly(DL-lactide-*co*-glycolide) range from 85 : 15 to 50 : 50. Table I shows the generic and trade names of different commercially available aliphatic polyesters.



5 Structural Formula

Poly(lactide)

Poly(glycolide)

Poly(lactide-co-glycolide)

6 Functional Category

Biocompatible material; biodegradable material; gelling agent; microencapsulating agent; modified-release agent.

7 Applications in Pharmaceutical Formulation or Technology

Aliphatic polyesters are of special interest in pharmaceutical formulations because they are generally sensitive to hydrolytic degradation.[1] Owing to their reputation as safe materials and their biodegradability, aliphatic polyesters are primarily used as biocompatible and biodegradable carriers in many types of sustained-release implantable or injectable drug-delivery systems for both human and veterinary use, such as *in situ* gels and microspheres.[2–4] Properties of the polymer, such as degradation and water uptake, can be controlled by modifying the end-group chemistry (either acid or ester):[5] *see also* Table I.

See also Section 18.

8 Description

Aliphatic polyesters occur as white to off-white or light gold solid powders, pellets or granules, and are almost odorless.

9 Pharmacopeial Specifications

—

10 Typical Properties

For typical resorption duration, physicochemical and mechanical properties of selected aliphatic polyesters, *see* Tables II, III.

Polymer composition and crystallinity play important roles in the solubility of these aliphatic polyesters. The crystalline homopolymers of glycolide or glycolic acid are soluble only in strong solvents, such as hexafluoroisopropanol. The crystalline homopolymers of lactide or lactic acid also do not have good solubility in most organic solvents. However, amorphous polymers of DL-lactide or DL-lactic acid and copolymers of lactide or lactic acid with a low glycolide or glycolic acid content are soluble in many organic solvents (Table II). Aliphatic polyesters are slightly soluble or insoluble in water, methanol, ethylene glycol, heptane, and hexane.

11 Stability and Storage Conditions

The aliphatic polyesters are easily susceptible to hydrolysis in the presence of moisture. Hence, they should be packaged under high-purity dry nitrogen and stored at 5°C in airtight containers with desiccant, preferably refrigerated at –10°C or below. It is necessary to allow the polymers to reach room temperature in a dry environment before opening the container. After the original package has been opened, it is recommended to re-purge the package with high-purity dry nitrogen prior to resealing. Protect from sunlight and keep away from sources of heat.

12 Incompatibilities

—

13 Method of Manufacture

Aliphatic polyesters are mainly synthesized via polycondensation of hydroxycarboxylic acids and catalytic ring-opening polymerization of lactones. Ring-opening polymerization is preferred because polyesters with high molecular weights and specific end groups can be produced.[6]

Enzymatic polymerization is an alternative method carried out under mild conditions avoiding the use of toxic reagents, with the possibility to recycle the catalyst. Regional and stereo selectivity of enzymes provides attractive possibilities for the direct synthesis of functional polyesters, avoiding the use of protected monomers. Block copolymers may also be synthesized using enzymatic polymerization. However, the major drawback of this method is the relatively low molecular weight of the polymers obtained.[2]

14 Safety

Poly(lactic acid) or poly(lactide) and poly (lactic-*co*-glycolic acid) or poly(lactide-*co*-glycolide), are used in parenteral pharmaceutical formulations and are biodegradable, biocompatible, and bioabsorbable materials. Their biodegradation products are nontoxic, noncarcinogenic, and nonteratogenic. In general, these polyesters exhibit very little hazard.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Contact with eyes, skin, and clothing, and breathing the dust of the polymers should be avoided. Aliphatic polyesters produce acid materials such as hydroxyacetic and/or lactic acid in the presence of moisture; thus, contact with materials that will react with acids, especially in moist conditions, should be avoided.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (IM powder for injections, lyophilized suspensions; periodontal drug delivery system). Poly(lactide) and poly(lactide-*co*-glycolide) have been used in drug products approved by the FDA. Included in parenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Glycolic acid; lactic acid.

Glycolic acid

Empirical formula $C_2H_4O_3$
Molecular weight 76.05
CAS number [79-14-1]
Synonyms 2-Hydroxyacetic acid; hydroxyethanoic acid.
Appearance Odorless, somewhat hygroscopic crystals.
Acidity/alkalinity pH of aqueous solution

2.5 (0.5%);
2.33 (1.0%);
2.16 (2.0%);
1.91 (5.0%);
1.73 (10.0%).

Dissociation constant 3.83 at 25°C
Melting point 80°C
Solubility Soluble in water, methanol, alcohol, acetone, acetic acid, and ether.
Safety LD_{50} (rat, oral): 1.95 g/kg
Comments A constituent of sugar cane juice. Manufactured by the action of sodium hydroxide on monochloroacetic acid; also by the electrolytic reduction of oxalic acid.

18 Comments

Aliphatic polyesters are a group of synthesized, nontoxic, biodegradable polymers. In an aqueous environment, the polymer backbone undergoes hydrolytic degradation, through cleavage of the ester linkages, into nontoxic hydroxycarboxylic acids. Aliphatic polyesters are eventually metabolized to carbon dioxide and water, via the citric acid cycle.

The rate of biodegradation and drug-release characteristics from injectable drug-delivery systems formulated with the aliphatic polyesters can be controlled by changing the physicochemical properties of the polymers, such as crystalline versus amorphous character, monomer ratio, end group, molecular weight, porosity and geometry of the formulation.

Although other biodegradable aliphatic polyesters such as poly-ε-caprolactone, poly(DL-lactide-co-ε-caprolactone) and poly(dioxanone) are commercially available, they have not been utilized in drug products approved by the FDA.

Alitame

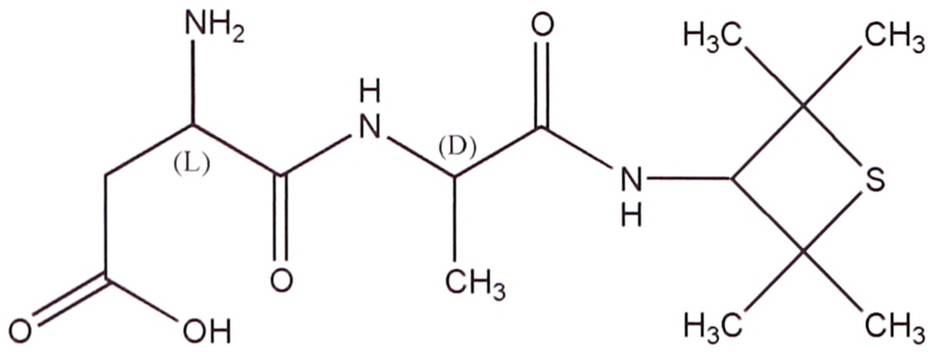
1 Nonproprietary Names

None adopted.

2 Synonyms

Aclame; (3S)-3-amino-4-oxo-4-[[(2R)-1-oxo-1-[(2,2,4,4-tetramethylthietan-3-yl)amino]propan-2-yl]amino]butanoic acid; L-aspartyl-D-alanine-*N*-(2,2,4,4-tetramethylthietan-3-yl)amide; 3-(L-aspartyl-D-alaninamido)-2,2,4,4-tetramethylthietane.

3 Chemical Name and CAS Registry Number



Lα-Aspartyl-*N*-(2,2,4,4-tetramethyl-3-thietanyl)-D-alaninamide anhydrous [80863-62-3]

L-α-Aspartyl-*N*-(2,2,4,4-tetramethyl-3-thietanyl)-D-alaninamide hydrate [99016-42-9]

4 Empirical Formula and Molecular Weight

$C_{14}H_{25}N_3O_4S$ 331.44 (for anhydrous)
$C_{14}H_{25}N_3O_4S{\cdot}2\frac{1}{2}H_2O$ 376.50 (for hydrate)

5 Structural Formula

6 Functional Category

Sweetening agent.

7 Applications in Pharmaceutical Formulation or Technology

Alitame is an intense sweetening agent developed in the early 1980s and is approximately 2000 times sweeter than sucrose. It has an insignificant energy contribution of 6 kJ (1.4 kcal) per gram of alitame.

Alitame is currently primarily used in a wide range of foods and beverages at a maximum level of 40–300 mg/kg.[1,2]

8 Description

Alitame occurs as a white nonhygroscopic crystalline powder, and is odorless or has a slight characteristic odor.

9 Pharmacopeial Specifications

—

10 Typical Properties

Acidity/alkalinity pH = 5–6 (5% w/v aqueous solution)
Isoelectric point pH 5.6
Melting point 136–147°C
Solubility Freely soluble in water, ethanol, methanol, and propylene glycol; very slightly soluble in chloroform; practically insoluble in n-heptane.[3]
Specific rotation $[\alpha]_D^{25}$ = +40° to +50° (1% w/v aqueous solution)

11 Stability and Storage Conditions

Alitame is stable in dry, room temperature conditions but undergoes degradation at elevated temperatures or when in solution at low pH. Alitame can degrade in a one-stage process to aspartic acid and alanine amide (under harsh conditions) or in a slow two-stage process by first degrading to its β-aspartic isomer and then to aspartic acid and alanine amide. At pH 5–8, alitame solutions at 23°C have a half-life of approximately 4 years. At pH 2 and 23°C the half-life is 1 year.[4]

Alitame should be stored in a well-closed container in a cool, dry place.

12 Incompatibilities

Alitame may be incompatible with oxidizing and reducing substances or strong acids and bases.

13 Method of Manufacture

Alitame may be synthesized by a number of routes.[5,6] For example, 3-(D-alaninamido)-2,2,4,4-tetramethylthietane is dissolved in water and L-aspartic acid *N*-thiocarboxyanhydride is then added in portions with vigorous stirring, maintaining the pH of 8.5–9.5. The pH is then adjusted to 5.5 and *p*-toluenesulfonic acid monohydrate is added over a period of one hour. The precipitated crystalline *p*-toluenesulfonate salt is collected by filtration. To obtain alitame from its salt, a mixture of *Amberlite LA-1* (liquid anion exchange resin), dichloromethane, deionized water, and the salt is stirred for one hour, resulting in two clear layers. The aqueous layer is treated with carbon, clarified by filtration, and cooled to crystallize alitame.

Alternatively, tetramethylthietane amine is condensed with an *N*-protected form of D-alanine to give alanyl amide. This is then coupled to a protected analogue of L-aspartic acid to give a crude form of alitame. The crude product is then purified.

The major impurities are L-β-aspartyl-*N*-(2,2,4,4-tetramethyl-3-thietanyl)-D-alaninamide hydrate (2 : 5) (referred to a β-isomer), formed after rearrangement of the aspartyl unit; and *N*-(2,2,4,4-tetramethyl-3-thietanyl)-D-alaninamide (referred to as alanine amide), formed after hydrolysis of the L-aspartic/D-alanine bond.

14 Safety

Alitame is an intense sweetening agent used primarily in foods and confectionary. It is generally regarded as a relatively nontoxic and nonirritant material.

Chronic animal studies in mice, rats, and dogs carried out for a minimum of 18 months at concentrations >100 mg/kg per day exhibited no toxic or carcinogenic effects. In people, no evidence of untoward effects were observed following ingestion of 15 mg/kg per day for two weeks.

Following oral administration, 7–22% of alitame is unabsorbed and excreted in the feces. The remaining amount is hydrolyzed to aspartic acid and alanine amide. The aspartic acid is metabolized normally and the alanine amide excreted in the urine as a sulfoxide isomer, as the sulfone, or conjugated with glucuronic acid.

The WHO has set an acceptable daily intake of alitame at up to 1 mg/kg body-weight.[1,2]

LD_{50} (mouse, oral): >5 g/kg
LD_{50} (rabbit, skin): >2 g/kg
LD_{50} (rat, oral): >5 g/kg

A

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Eye protection and gloves are recommended. Alitame should be stored in tightly closed containers, and protected from exposure to direct sunlight and higher than normal room temperatures.

16 Regulatory Status

Alitame is approved for use in food applications in a number of countries worldwide including Australia, Chile, China, Colombia, Indonesia, Mexico, and New Zealand.

Although a petition proposing the safe use of alitame as a sweetening agent or flavoring in food was filed with the FDA in 1986, it was withdrawn in 2008.[7]

17 Related Substances

Acesulfame potassium; aspartame; saccharin; saccharin sodium; sodium cyclamate; sucrose.

18 Comments

A specification for alitame is contained in the *Food Chemicals Codex* (FCC).[8]

The PubChem Compound ID (CID) for alitame is 64763.

Almond Oil

1 Nonproprietary Names

BP: Virgin Almond Oil

PhEur: Almond Oil, Virgin

USP–NF: Almond Oil

2 Synonyms

Almond oil, bitter; amygdalae oleum virginale; artificial almond oil; bitter almond oil; expressed almond oil; huile d'amande; oleo de amêndoas; olio di mandorla; sweet almond oil; virgin almond oil.

3 Chemical Name and CAS Registry Number

Almond oil [8007-69-0]

4 Empirical Formula and Molecular Weight

Almond oil consists chiefly of glycerides of oleic acid, with smaller amounts of linoleic and palmitic acids.

5 Structural Formula

See Section 4.

6 Functional Category

Emollient; oleaginous vehicle; solvent.

7 Applications in Pharmaceutical Formulation or Technology

Almond oil is used as a vehicle in parenteral preparations,[1] such as oily phenol injections. It is also used in nasal sprays,[2] topical preparations,[3–7] and eye drops.[8] It has also been used to prepare solid lipid nanoparticles[9,10] as well as various emulsions.[11,12]

8 Description

Almond oil occurs as a clear, colorless, or pale-yellow colored oil with a bland, nutty taste.

The PhEur 9.2 describes almond oil as the fatty oil obtained by cold expression from the ripe seeds of *Prunus dulcis* (Miller) DA Webb var. *dulcis* or *Prunus dulcis* (Miller) DA Webb var. *amara* (DC) Buchheim or a mixture of both varieties. A suitable antioxidant may be added.

The USP 40–NF 35 S1 describes almond oil as the refined fixed oil obtained by expression from the kernels of varieties of *Prunus dulcis* (Miller) DA Webb (formerly known as *Prunus amygdalus* Batsch) (Fam. Rosaceae) except for *Prunus dolcis* (Miller) DA Webb var. *amara* (De Candolle) Focke).

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for almond oil.

(a) The USP 40–NF 35 S1 monograph refers to refined almond oil.

10 Typical Properties

Flash point 320°C
Melting point −18°C
Refractive index n_D^{40} = 1.4630–1.4650
Smoke point 220°C
Solubility Miscible with chloroform, and ether; slightly soluble in ethanol (95%).

11 Stability and Storage Conditions

Almond oil should be stored in a well-closed container in a cool, dry place away from direct sunlight and odors. It may be sterilized by heating at 150°C for 1 hour. Almond oil is relatively resistant to oxidation.

12 Incompatibilities

—

13 Method of Manufacture

Almond oil is expressed from the seeds of the bitter or sweet almond, *Prunus dulcis (Prunus amygdalus; Amygdalus communis)* var. *amara* or var. *dulcis* (Rosaceae).[13] *See also* Section 4.

14 Safety

Almond oil is widely consumed as a food and is used both therapeutically and as an excipient in topical and parenteral pharmaceutical formulations, where it is generally regarded as a nontoxic and nonirritant material. However, there has been a single case reported of a 5-month-old child developing allergic dermatitis attributed to the application of almond oil for 2 months to the cheeks and buttocks.[14]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

16 Regulatory Status

Included in the FDA Inactive Ingredient Database (topical emulsions and creams). Included in nonparenteral and parenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Canola oil; corn oil; cottonseed oil; peanut oil; refined almond oil; sesame oil; soybean oil.

Refined almond oil

Synonyms Amygdalae oleum raffinatum.
Comments Refined almond oil is defined in some pharmacopeias such as the PhEur 9.2. Refined almond oil is a clear, pale yellow colored oil with virtually no taste or odor. It is obtained by expression of almond seeds followed by subsequent refining. It may contain a suitable antioxidant.

18 Comments

A 100 g quantity of almond oil has a nutritional energy value of 3700 kJ (900 kcal) and contains 100 g of fat of which 28% is polyunsaturated, 64% is monounsaturated and 8% is saturated fat.

Almond oil is used therapeutically as an emollient and to soften ear wax.[15,16] Studies have suggested that almond consumption is associated with health benefits, including a decreased risk of colon cancer.[17]

A specification for bitter almond oil is contained in the *Food Chemicals Codex* (FCC)[18] and in the *Japanese Pharmaceutical Excipients* (JPE).[19]

Alpha Tocopherol

1 Nonproprietary Names

BP: all-*rac*-α-Tocopherol
JP: Tocopherol
PhEur: all-*rac*-α-Tocopherol
USP–NF: Vitamin E
See also Sections 3, 9, and 17.

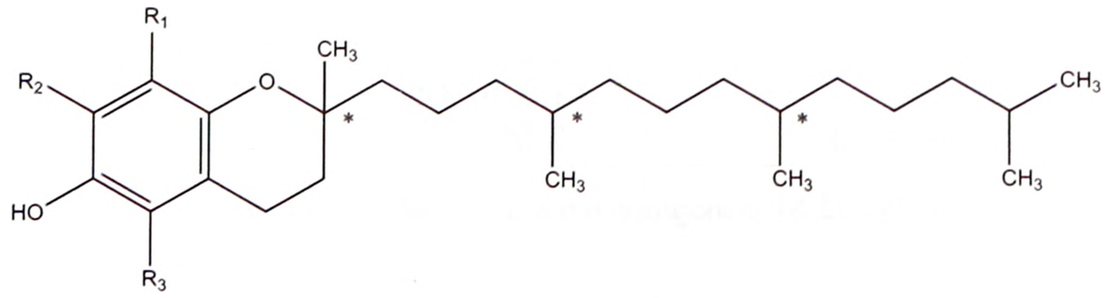
2 Synonyms

Copherol F1300; (±)-3,4-dihydro-2,5,7,8-tetramethyl-2-(4,8,12-trimethyltridecyl)-2*H*-1-benzopyran-6-ol; E307; synthetic alpha tocopherol; *dl*-α-tocopherol; int-*rac*-α-tocopherol; 5,7,8-trimethyltocol.

3 Chemical Name and CAS Registry Number

(±)-(2*RS*,4'*RS*,8'*RS*)-2,5,7,8-Tetramethyl-2-(4',8',12'-trimethyltridecyl)-6-chromanol [10191-41-0]

Note that alpha tocopherol has three chiral centers, giving rise to eight isomeric forms. The naturally occurring form is known as *d*-alpha tocopherol or (2*R*,4'*R*,8'*R*)-alpha-tocopherol (*see* Section 17). The synthetic form, *dl*-alpha tocopherol or simply alpha tocopherol, occurs as a racemic mixture containing equimolar quantities of all the isomers.



Similar considerations apply to beta, delta, and gamma tocopherol and tocopherol esters.

See Section 17 for further information.

4 Empirical Formula and Molecular Weight

$C_{29}H_{50}O_2$ 430.72

5 Structural Formula

Alpha tocopherol: $R^1 = R^2 = R^3 = CH_3$
Beta tocopherol: $R^1 = R^3 = CH_3$; $R^2 = H$
Delta tocopherol: $R^1 = CH_3$; $R^2 = R^3 = H$
Gamma tocopherol: $R^1 = R^2 = CH_3$; $R^3 = H$
* Indicates chiral centers.

6 Functional Category

Antioxidant; nonionic surfactant; plasticizing agent.

7 Applications in Pharmaceutical Formulation or Technology

Alpha tocopherol is primarily recognized as a source of vitamin E, and the commercially available materials and specifications reflect this purpose. While alpha tocopherol also exhibits antioxidant properties,[1,2] the beta, delta, and gamma tocopherols are considered to be more effective as antioxidants.

Alpha tocopherol is a highly lipophilic compound, is an excellent solvent for many poorly soluble drugs,[3–6] and can increase the stability of formulations.[7] Of widespread regulatory acceptability, tocopherols are of value in oil- or fat-based pharmaceutical products and are normally used in the concentration range 0.001–0.05% v/v. There is frequently an optimum concentration; thus the autoxidation of linoleic acid and methyl linolenate is reduced at low concentrations of alpha tocopherol, and is acceler-

ated by higher concentrations. Antioxidant effectiveness can be increased by the addition of oil-soluble synergists such as lecithin and ascorbyl palmitate.[5]

Alpha tocopherol may be used as an efficient plasticizer.[8] and has been used in the development of deformable liposomes as topical formulations.[9] It has also been used in the formulation of alpha tocopherol-based nanoparticles and polymeric micelles for anticancer drug delivery.[10–12]

Molecularly imprinted polymers for use in the controlled release of alpha tocopherol in gastrointestinal simulating fluids have been investigated.[13]

8 Description

Alpha tocopherol is a natural product. The PhEur 9.2 describes alpha tocopherol as a clear, colorless or yellowish-brown, viscous, oily liquid. *See also* Section 17.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for alpha tocopherol.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters	–	+	–
Acidity	–	–	+
Optical rotation	–	–0.01° to +0.01°	+
Heavy metals	≤20 ppm	–	–
Related substances	–	+	–
Absorbance at 292 nm	+ 71.0–76.0	– –	– –
Refractive index	1.503–1.507	–	–
Specific gravity	0.947–0.955	–	–
Clarity and color of solution	+	–	–
Assay	96.0–102.0%	96.0–102.0%	96.0–102.0%

Note that the USP 40–NF 35 S1 describes vitamin E as comprising *d*- or *dl*-alpha tocopherol, *d*- or *dl*-alpha tocopheryl acetate, or *d*- or *dl*-alpha tocopheryl acid succinate. However, the PhEur 9.2 describes *dl*-alpha tocopherol, *d*-alpha tocopherol, and alpha tocopheryl acetate in separate monographs.
The diversity of the tocopherols described in the various pharmacopeial monographs makes the comparison of specifications more complicated; *see* Section 17.

10 Typical Properties

Boiling point 200–220°C (0.1 mm)
Density 0.947–0.958 g/cm^3
Flash point 240°C
Ignition point 340°C
Refractive index n_D^{20} = 1.503–1.507
Solubility Practically insoluble in water; freely soluble in acetone, ethanol, ether, and vegetable oils.

11 Stability and Storage Conditions

Tocopherols are oxidized slowly by atmospheric oxygen and rapidly by ferric and silver salts. Oxidation products include tocopheroxide, tocopherylquinone, and tocopherylhydroquinone, as well as dimers and trimers. Tocopherol esters are more stable to oxidation than the free tocopherols but are in consequence less effective antioxidants. *See also* Section 17.

Tocopherols should be stored under an inert gas, in an airtight container in a cool, dry place and protected from light.

12 Incompatibilities

Tocopherols are incompatible with peroxides and metal ions, especially iron, copper, and silver. Tocopherols may be absorbed into plastic.[14]

13 Method of Manufacture

Naturally occurring tocopherols are obtained by the extraction or molecular distillation of steam distillates of vegetable oils; for example, alpha tocopherol occurs in concentrations of 0.1–0.3% in corn, rapeseed, soybean, sunflower, and wheat germ oils.[15] Beta and gamma tocopherol are usually found in natural sources along with alpha tocopherol. Racemic synthetic tocopherols may be prepared by the condensation of the appropriate methylated hydroquinone with racemic isophytol.[16]

14 Safety

Tocopherols (vitamin E) occur in many food substances that are consumed as part of the normal diet. The daily nutritional requirement has not been clearly defined but is estimated to be 3.0–20.0 mg. Absorption from the gastrointestinal tract is dependent upon normal pancreatic function and the presence of bile. Tocopherols are widely distributed throughout the body, with some ingested tocopherol metabolized in the liver; excretion of metabolites is via the urine or bile. Individuals with vitamin E deficiency are usually treated by oral administration of tocopherols, although intramuscular and intravenous administration may sometimes be used.

Tocopherols are well tolerated, although excessive oral intake may cause headache, fatigue, weakness, digestive disturbance, and nausea. Prolonged and intensive skin contact may lead to erythema and contact dermatitis.

The use of tocopherols as antioxidants in pharmaceuticals and food products is unlikely to pose any hazard to human health since the daily intake from such uses is small compared with the intake of naturally occurring tocopherols in the diet.

The WHO has set an acceptable daily intake of tocopherol used as an antioxidant at 0.15–2.0 mg/kg body-weight.[17]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Gloves and eye protection are recommended.

16 Regulatory Status

Tocopherols (CAS 1406-66-2) are GRAS listed. Included in the FDA Inactive Ingredients Database (IV injections, powder, lyophilized powder for liposomal suspension; buccal films; oral capsules, solutions, tablets, and topical preparations). Included in nonparenteral medicines licensed in the UK. Accepted for use as a food additive in Europe. Included in the Canadian Health Products Ingredients Database.

17 Related Substances

d-Alpha tocopherol; *d*-alpha tocopherol acetate; *dl*-alpha tocopherol acetate; *d*-alpha tocopherol acid succinate; *dl*-alpha tocopherol acid succinate; beta tocopherol; delta tocopherol; gamma tocopherol; tocopherols excipient; vitamin E polyethylene glycol succinate.

d-Alpha tocopherol

Empirical formula $C_{29}H_{50}O_2$
Molecular weight 430.72
CAS number [59-02-9]
Synonyms Natural alpha tocopherol; (+)-(2*R*,4'*R*,8'*R*)-2,5,7,8-tetramethyl-2-(4',8',12'-trimethyltridecyl)-6-chromanol; *d*-α-

tocopherol; *RRR*-alpha-tocopherol; *RRR*-α-tocopherol; vitamin E.

Appearance A practically odorless, clear, yellow, or greenish-yellow viscous oil.

Melting point 2.5–3.5°C

Solubility Practically insoluble in water; soluble in ethanol (95%). Miscible with acetone, chloroform, ether, and vegetable oils.

Specific gravity 0.95

Comments *d*-Alpha tocopherol is the naturally occurring form of alpha tocopherol. *d*-Alpha tocopherol has also been used as a nonionic surfactant in oral and injectable formulations.[3]

d-Alpha tocopherol acetate

Empirical formula $C_{31}H_{52}O_3$

Molecular weight 472.73

CAS number [58-95-7]

Synonyms (+)-(2*R*,4'R,8'*R*)-2,5,7,8-Tetramethyl-2-(4',8',12'-trimethyltridecyl)-6-chromanyl acetate; *d*-α-tocopheryl acetate; vitamin E.

Appearance A practically odorless, clear, yellow, or greenish-yellow colored viscous oil that may solidify in the cold.

Melting point 28°C

Solubility Practically insoluble in water; soluble in ethanol (95%). Miscible with acetone, chloroform, ether, and vegetable oils.

Specific rotation $[\alpha]_D^{25} = +0.25°$ (10% w/v solution in chloroform)

Comments GRAS listed. Unstable to alkalis.

dl-Alpha tocopherol acetate

Empirical formula $C_{31}H_{52}O_3$

Molecular weight 472.73

CAS number [7695-91-2] and [133-80-2]

Synonyms (±)-3,4-Dihydro-2,5,7,8-tetramethyl-2-(4,8,12-trimethyltridecyl)-2*H*-1-benzopyran-6-ol acetate; (±)-(2*RS*,4'*RS*,8'*RS*)-2,5,7,8-tetramethyl-2-(4',8',12'-trimethyltridecyl)-6-chromanyl acetate; (±)-α-tocopherol acetate; α-tocopheroli acetas; all-rac-α-tocopheryl acetate; *dl*-α-tocopheryl acetate; vitamin E.

Appearance A practically odorless, clear, yellow, or greenish-yellow viscous oil.

Density 0.953 g/cm^3

Melting point −27.5°C

Refractive index $n_D^{20} = 1.4950–1.4972$

Solubility Practically insoluble in water; freely soluble in acetone, chloroform, ethanol, ether, and vegetable oils; soluble in ethanol (95%).

Comments Unstable to alkali. However, unlike alpha tocopherol, the acetate is much less susceptible to the effects of air, light, or ultraviolet light. Alpha tocopherol acetate concentrate, a powdered form of alpha tocopherol acetate, is described in the PhEur. The concentrate may be prepared by either dispersing alpha tocopherol acetate in a suitable carrier such as acacia or gelatin, or by adsorbing alpha tocopherol acetate on silicic acid.

d-Alpha tocopherol acid succinate

Empirical formula $C_{33}H_{54}O_5$

Molecular weight 530.8

CAS number [4345-03-3]

Synonyms (+)-α-Tocopherol hydrogen succinate; *d*-α-tocopheryl acid succinate; vitamin E.

Appearance A practically odorless white powder.

Melting point 76–77°C

Solubility Practically insoluble in water; slightly soluble in alkaline solutions; soluble in acetone, ethanol (95%), ether, and vegetable oils; very soluble in chloroform.

Comments Unstable to alkalis.

dl-Alpha tocopherol acid succinate

Empirical formula $C_{33}H_{54}O_5$

Molecular weight 530.8

CAS number [17407-37-3]

Synonyms (±)-α-Tocopherol hydrogen succinate; *dl*-α-tocopheryl acid succinate; *dl*-α-tocopherol succinate; vitamin E.

Appearance A practically odorless, white crystalline powder.

Solubility Practically insoluble in water; slightly soluble in alkaline solutions; soluble in acetone, ethanol (95%), ether, and vegetable oils; very soluble in chloroform.

Comments Unstable to alkalis.

Beta tocopherol

Empirical formula $C_{28}H_{48}O_2$

Molecular weight 416.66

CAS number [148-03-8]

Synonyms Cumotocopherol; (±)-3,4-dihydro-2,5,8-trimethyl-2-(4,8,12-trimethyltridecyl)-2*H*-1-β-benzopyran-6-ol; 5,8-dimethyltocol; neotocopherol; *dl*-β-tocopherol; vitamin E; *p*-xylotocopherol.

Appearance A pale yellow-colored viscous oil.

Solubility Practically insoluble in water; freely soluble in acetone, chloroform, ethanol (95%), ether, and vegetable oils.

Specific rotation $[\alpha]_D^{20} = +6.37°$

Comments Less active biologically than alpha tocopherol. Obtained along with alpha tocopherol and gamma tocopherol from natural sources. Beta tocopherol is very stable to heat and alkalis, and is slowly oxidized by atmospheric oxygen.

Delta tocopherol

Empirical formula $C_{27}H_{46}O_2$

Molecular weight 402.64

CAS number [119-13-1]

Synonyms (±)-3,4-Dihydro-2,8-dimethyl-2-(4,8,12-trimethyltridecyl)-2*H*-1-benzopyran-6-ol; E309; 8-methyltocol; *dl*-δ-tocopherol; vitamin E.

Appearance A pale yellow-colored viscous oil.

Solubility Practically insoluble in water; freely soluble in acetone, chloroform, ethanol (95%), ether, and vegetable oils.

Comments Occurs naturally as 30% of the tocopherol content of soybean oil. Delta tocopherol is said to be the most potent antioxidant of the tocopherols.

Gamma tocopherol

Empirical formula $C_{28}H_{48}O_2$

Molecular weight 416.66

CAS number [7616-22-0]

Synonyms (±)-3,4-Dihydro-2,7,8-trimethyl-2-(4,8,12-trimethyltridecyl)-2*H*-1-benzopyran-6-ol; 7,8-dimethyltocol; E308; *dl*-γ-tocopherol; vitamin E; *o*-xylotocopherol.

Appearance A pale yellow-colored viscous oil.

Melting point −30°C

Solubility Practically insoluble in water; freely soluble in acetone, chloroform, ethanol (95%), ether, and vegetable oils.

Specific rotation $[\alpha]_D^{20} = -2.4°$ (in ethanol (95%))

Comments Occurs in natural sources along with alpha and beta tocopherol. Gamma tocopherol is biologically less active than alpha tocopherol. Very stable to heat and alkalis; slowly oxidized by atmospheric oxygen and gradually darkens on exposure to light.

Tocopherols excipient

Synonyms *Embanox tocopherol.*

Appearance A pale yellow-colored viscous oil.

Comments Tocopherols excipient is described in the USP 40–NF 35 S1 as a vegetable oil solution containing not less than 50.0% of total tocopherols, of which not less than 80.0% consists of varying amounts of beta, delta, and gamma tocopherols.

18 Comments

Note that most commercially available tocopherols are used as sources of vitamin E, rather than as antioxidants in pharmaceutical formulations.

Various mixtures of tocopherols, and mixtures of tocopherols with other excipients, are commercially available, and individual manufacturers should be consulted for specific information on their products.

Therapeutically, alpha tocopherol or their derivatives have been studied as antiviral agents against influenza in combination with oseltamivir[18] and for their anticancer activity.[19]

A specification for alpha tocopherol is contained in the Food Chemicals Codex (FCC).[20]

The EINECS numbers for alpha tocopherol, *d*-alpha tocopherol, and *dl*-alpha tocopherol are 215-798-8, 200-412-2, and 233-466-0, respectively. The PubChem Compound ID (CID) for alpha tocopherol includes 14 985 and 1 548 900.

Aluminum Hydroxide Adjuvant

1 Nonproprietary Names

PhEur: Aluminium Hydroxide, Hydrated, for Adsorption

2 Synonyms

Alhydrogel; aluminii hydroxidum hydricum ad adsorptionem; aluminium hydroxide adjuvant; aluminium oxyhydroxide; poorly crystalline boehmite; pseudoboehmite; *Rehydragel*.

3 Chemical Name and CAS Registry Number

Aluminum oxyhydroxide [21645-51-2]

4 Empirical Formula and Molecular Weight

AlO(OH) 59.99

5 Structural Formula

Structural hydroxyl groups form bonds between AlO(OH) octahedral sheets, where hydroxyl groups are exposed at the surface. The surface hydroxyl groups produce a pH-dependent surface charge by accepting a proton to produce a positive site, or donating a proton to produce a negative site. The pH-dependent surface charge is characterized by the point of zero charge, which is equivalent to the isoelectric point in protein chemistry. The surface hydroxyl groups may also undergo ligand exchange with fluoride, phosphate, carbonate, sulfate, or borate anions.

6 Functional Category

Adsorbent; vaccine adjuvant.

A

7 Applications in Pharmaceutical Formulation or Technology

Aluminum hydroxide adjuvant is used in parenteral human and veterinary vaccines[1] based on its ability to enhance antibody production; *see* Section 18.

8 Description

Aluminum hydroxide adjuvant is a white hydrogel that sediments slowly and forms a clear supernatant.

9 Pharmacopeial Specifications

See Table I. Note that the USP 40–NF 35 S1 includes a monograph for aluminum hydroxide gel, which is a form of aluminum hydroxide that is used as an antacid, in which there is a partial substitution of carbonate for hydroxide.

Table I: Pharmacopeial specifications for aluminum hydroxide adjuvant.

Test	PhEur 9.2
Identification	+
Characters	+
Solution	+
pH	5.5–8.5
Adsorption power	+
Sedimentation	+
Chlorides	≤0.33%
Nitrates	≤100 ppm
Sulfates	≤0.5%
Ammonium	≤50 ppm
Arsenic	≤1 ppm
Iron	≤15 ppm
Bacterial endotoxins	+
Assay	90.0–110.0%

See Section 17.

10 Typical Properties

Acidity/alkalinity pH = 5.5–8.5

Particle size distribution Primary particles are fibrous with average dimensions of 4.5 × 2.2 × 10 nm. The primary particles form aggregates of 0.1–10 μm.

Point of zero charge pH = 11.4

Protein binding capacity >0.5 mg BSA/mg equivalent Al_2O_3

Solubility Soluble in alkali hydroxides and mineral acids. Heat may be required to dissolve the aluminum hydroxide adjuvant.

Specific surface area 500 m^2/g.[2]

X-ray diffractogram Exhibits characteristic x-ray diffraction pattern having diffraction bands at 6.46, 3.18, 2.35, 1.86, 1.44 and 1.31 Å.

11 Stability and Storage Conditions

Aluminum hydroxide adjuvant is stable for at least 2 years when stored at 4–30°C in well-sealed inert containers. It must not be allowed to freeze as the hydrated colloid structure will be irreversibly damaged.

12 Incompatibilities

When exposed to phosphate, carbonate, sulfate, or borate anions, the point of zero charge for aluminum hydroxide adjuvant decreases.

13 Method of Manufacture

Aluminum hydroxide adjuvant is prepared by the precipitation of a soluble aluminum salt by an alkali hydroxide, or the precipitation of an alkali aluminate by acid.

14 Safety

Aluminum hydroxide adjuvant is intended for use in parenteral vaccines and is generally regarded as nontoxic. It may cause mild irritation, dryness, and dermatitis on skin contact. On eye contact, aluminum hydroxide adjuvant may also cause redness, conjunctivitis, and short-term mild irritation. Ingestion of large amounts may cause gastrointestinal irritation with nausea, vomiting, and constipation. Inhalation of the dried product may cause respiratory irritation and cough. Type I hypersensitivity reactions following parenteral administration have been reported.[3]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Eye protection and gloves are recommended.

16 Regulatory Status

GRAS listed. Accepted for use in human and veterinary parenteral vaccines in Europe and the USA. The limits for use in human vaccines are 0.85 mg aluminum/dose if determined by assay, 1.14 mg aluminum/dose if determined by calculation and 1.25 mg aluminum/dose if safety and efficacy data justify it (FDA), and 1.25 mg aluminum/dose (WHO). There are no established limits for use in veterinary vaccines. Reported in the EPA TSCA Inventory.

17 Related Substances

Aluminum phosphate adjuvant.

18 Comments

Different grades of aluminum hydroxide adjuvant with various concentrations, protein binding capacities, and points of zero charge are available.

The impurity limits at 2% equivalent Al_2O_3 are: Cl <0.5%; SO_4 <0.5%; PO_4 <0.1%; NO_3 <0.1%; NH_4 <0.1%; Fe <20 ppm; As <0.6 ppm; and heavy metals <20 ppm.

Aluminum hydroxide adjuvant activates Th2 immune responses, including IgG and IgE antibody responses.[4,5]

The aluminum hydroxide gel referred to in USP 37–NF 32 S1 is used in cosmetics as an emollient, filler, humectant, a mild astringent, and viscosity controlling agent. In pharmaceutical preparations it is used as an adsorbent, and as a protein binder.[6] It is also used therapeutically as an antacid, and as an abrasive in dentrifrices. In addition, the protein adsorption capability of aluminum hydroxide gel is used for the isolation of certain serum components such as blood clotting factors.[7] It is not, however, used as a vaccine adjuvant.

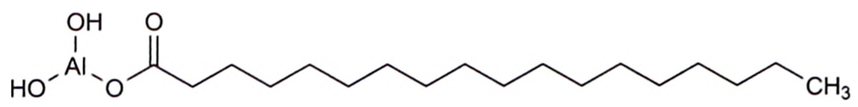
Aluminum Monostearate

1 Nonproprietary Names

BP: Aluminium Stearate
JP: Aluminum Monostearate
PhEur: Aluminium Stearate
USP–NF: Aluminum Monostearate

2 Synonyms

Aluminii stearas; aluminum stearate; aluminum, dihydroxy (octadecanoate-*O*-); dihydroxyaluminum monostearate; octadecanoic acid aluminum salt; stearic acid aluminum salt; stearic acid aluminum dihydroxide salt; *Synpro*.



3 Chemical Name and CAS Registry Number

Aluminum monostearate [7047-84-9]

4 Empirical Formula and Molecular Weight

$C_{18}H_{37}AlO_4$ 344.50

5 Structural Formula

6 Functional Category

Emollient; emulsion stabilizing agent; gelling agent; opacifier; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Aluminum monostearate is mainly used in microencapsulation[1-5] and in the manufacture of ointments. Aluminum monostearate produces a high gel strength and is used as a thixotropic agent and viscosity-increasing agent in nonaqueous cosmetic and pharmaceutical formulations.

8 Description

Aluminum monostearate is an aluminum compound of stearic acid and palmitic acid. The USP–NF states that aluminum monostearate contains the equivalent of not less than 14.5% and not more than 16.5% of Al_2O_3, calculated on the dried basis. The JP states that it contains not less than 7.2% and not more than 8.9% of aluminum. The value given by the PhEur is not less than 3.0% and not more than 9.0% of Aluminum (dried substance).

Aluminum monostearate occurs as a white, fine, bulky powder with a slight odor of fatty acid. It is a solid material.

9 Pharmacopeial Specifications

See Table I. *See also* Section 18.

10 Typical Properties

See Table II.
Melting point 220–225°C
Solubility Practically insoluble in water. Soluble in ethanol (95%) and benzene.
Specific gravity 1.14

11 Stability and Storage Conditions

Aluminum monostearate should be stored in a well-closed container in a cool, dry, place. It is stable under ordinary conditions of use and storage.

12 Incompatibilities

Aluminum monostearate is incompatible with oxidizing agents.

13 Method of Manufacture

Aluminum monostearate is prepared by reacting aluminum with stearic acid.

A

Table I: Pharmacopeial specifications for aluminum monostearate.

Synpro Aluminum Monostearate NF	15.5	0.8	7.0
Synpro Aluminum Monostearate NF Gellant	15.3	1.6	—

14 Safety

Aluminum monostearate is generally regarded as relatively nontoxic and nonirritant when used as an excipient.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. When heated to decomposition, aluminum monostearate emits acrid smoke and irritating vapors.

16 Regulatory Status

Aluminum monostearate and aluminum stearate are included in the FDA Inactive Ingredients Database (oral capsules and tablets; topical creams, emulsions, and ointments). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Aluminum distearate; aluminum tristearate.

Aluminum distearate

Empirical formula $C_{36}H_{37}AlO_5$
Molecular weight 877.39
CAS number [300-92-5]
Synonyms Hydroxyaluminum distearate; aluminum stearate; aluminum monobasic stearate.
Description Aluminum distearate occurs as a fine white to off-white colored powder with a slight odor of fatty acid.
Melting point 150–165°C
Specific gravity 1.01
Solubility Soluble in benzene, and in ethanol (95%); practically insoluble in water.
Comments The EINECS number for aluminum distearate is 206-101-8.

Aluminum tristearate

Empirical formula $C_{54}H_{105}AlO_6$
Molecular weight 610.9
CAS number [637-12-7]
Synonyms Hydroxyaluminum tristearate; aluminum stearate.
Description Aluminum tristearate occurs as a fine white to off-white colored powder with a slight odor of fatty acid.
Melting point 117–120°C
Specific gravity 1.01
Solubility Practically insoluble in water. Soluble in ethanol (95%), benzene, turpentine oil, and mineral oils when freshly prepared.
Comments The EINECS number for aluminum tristearate is 211-279-5.

18 Comments

Aluminum monostearate can be used as an emulsion stabilizer in cosmetic emulsions and is used in cosmetics such as mascara, moisturizers, and sunscreens. It is also used to improve the flow properties and adherence of cosmetic powders.

Aluminum monostearate has also been used to modify chitosan sponges in a sustained drug delivery system for porous wound dressings.[6]

A specification for aluminum stearate, described as consisting mainly of the distearate, is included in the *Japanese Pharmaceutical Excipients* (JPE).[7]

It should be noted that unless otherwise specified, aluminum stearate could refer to the monostearate (CAS number 7047-84-9), distearate (CAS number 300-92-5) or tristearate (CAS number 637-12-7). The distearate exhibits the same excipient properties as the tristearate and is used in similar pharmaceutical applications. However, the monostearate is more widely used in both cosmetic and pharmaceutical preparations.

The EINECS number for aluminum monostearate is 230-325-5.

Aluminum Oxide

1 Nonproprietary Names

USP–NF: Aluminum Oxide

2 Synonyms

Activated alumina; activated aluminum oxide; alpha aluminum oxide; alumina; alumina, calcined; alumina, tabular; aluminum oxide alumite; aluminum trioxide; gamma aluminum oxide.

3 Chemical Name and CAS Registry Number

Aluminum oxide [1344-28-1]

4 Empirical Formula and Molecular Weight

Al_2O_3 101.96

5 Structural Formula

Aluminum oxide occurs naturally as the minerals bauxite, bayerite, boehmite, corundum, diaspore, and gibbsite.

6 Functional Category

Adsorbent; dispersing agent.

7 Applications in Pharmaceutical Formulation or Technology

Aluminum oxide is used mainly in tablet formulations.[1] It is used for decoloring powders and is particularly widely used in antibiotic formulations. It is also used in suppositories, pessaries, and urethral inserts.

Table I: Pharmacopeial specifications for aluminum oxide.

Test	USP 40–NF 35 S1
Identification	+
Arsenic	≤4 ppm
Heavy metals	≤60 ppm
Chloride	≤10 000 ppm
Sulfate	≤10 000 ppm
Microbial limits	
Bacteria	≤1000 cfu/g
Molds and yeasts	≤100 cfu/g
Clarity of solution	+
Alkaline impurities	+
Neutralizing capacity	+
Assay	47.0–60.0%

Aluminum oxide in the form of nanoparticles has been investigated for glidant properties in tablet formulation. It was shown to be effective but produced a large reduction in tablet tensile strength.[2]

Hydrated aluminum oxide (*see* Section 18) is used in cosmetic formulations.

8 Description

Aluminum oxide occurs as a white crystalline powder in two crystalline forms: α-aluminum oxide is composed of colorless hexagonal crystals, and γ-aluminum oxide is composed of minute colorless cubic crystals that are transformed to the α-form at high temperatures.

9 Pharmacopeial Specifications

See Table I. *See also* Section 18.

10 Typical Properties

Boiling point 2977°C
Density (bulk) 0.9–1.1 g/cm^3
Flammability Nonflammable.
Hardness (Mohs) 8.8
Hygroscopicity Very hygroscopic.
Melting point 2050°C
Solubility Slowly soluble in aqueous alkaline solutions with the formation of hydroxides; practically insoluble in nonpolar organic solvents, diethyl ether, ethanol (95%), and water.
Specific gravity 2.8 (becomes 4.0 at 800°C)
Vapor pressure 133.3 Pa at 2158°C

11 Stability and Storage Conditions

Aluminum oxide should be stored in a well-closed container in a cool, dry place. It is very hygroscopic.

12 Incompatibilities

Aluminum oxide should be kept well away from water. It is incompatible with strong oxidizers and chlorinated rubber. Aluminum oxide also reacts with chlorine trifluoride, ethylene oxide, sodium nitrate, and vinyl acetate. Exothermic reactions above 200°C with halocarbon vapors produce toxic hydrogen chloride and phosgene fumes.

A

13 Method of Manufacture

Most of the aluminum oxide produced commercially is obtained by the calcination of aluminum hydroxide.

14 Safety

Aluminum oxide is generally regarded as relatively nontoxic and nonirritant when used as an excipient. The Cosmetic Ingredient Review (CIR) Expert Panel have assessed aluminum oxide and concluded that the material is safe as used in the present practices of use and concentration.[3]

Overexposure by direct contact may cause irritation of the eyes, skin, and respiratory system. Inhalation of finely divided particles may cause lung damage (Shaver's disease).[4]

LD_{50} (mouse, IP): >3600 mg/kg[5]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. An exothermic reaction occurs above 200°C with halocarbon vapors and produces toxic hydrochloric acid and phosgene.[5] Gloves, eye protection, and a dust mask or respirator are recommended.

In the UK, the workplace exposure limits for aluminum oxide are 10 mg/m^3 long-term (8-hour TWA) for total inhalable dust and 4 mg/m^3 for respirable dust.[6] In the USA, the OSHA limit is 15 mg/m^3 total dust, 5 mg/m^3 respirable fraction for aluminum oxide.[7]

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral tablets and topical sponge). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

—

18 Comments

The PhEur 9.2 includes a specification for hydrated aluminum oxide that contains the equivalent of 47.0–60.0% of Al_2O_3. Hydrated aluminum oxide is used in mordant dyeing to make lake pigments. It has been shown that use of hydrated aluminum oxide as an adsorbent for dyes can improve the stability of tablet formulations, probably through separation of interacting ingredients.[8]

Aluminum oxide is used therapeutically as an antacid, and is reported to have therapeutic application as an abrasive in topical preparations.[9] Anodic aluminum oxide nanotubes have been investigated for use as controlled-release drug carrier systems for therapeutic surface coatings on medical implants.[10,11]

Selexsorb (BASF) contains 96.6% aluminum oxide and is used as an adsorbent in the purification of pharmaceutical formulations.

A specification for aluminum oxide is included in the *Japanese Pharmaceutical Excipients* (JPE).[12] A specification for light aluminum oxide is also included.

The EINECS number for aluminum oxide is 215-691-6.

Aluminum Phosphate Adjuvant

1 Nonproprietary Names

None adopted.

2 Synonyms

Adju-Phos; aluminium hydroxyphosphate; aluminum hydroxyphosphate; *Rehydraphos*.

3 Chemical Name and CAS Registry Number

Aluminum phosphate [7784-30-7]

4 Empirical Formula and Molecular Weight

$Al(OH)_x (PO_4)_y$

The molecular weight is dependent on the degree of substitution of phosphate groups for hydroxyl groups.

5 Structural Formula

Aluminum phosphate adjuvant occurs as a precipitate of amorphous aluminum hydroxide in which some sites contain phosphate groups instead of hydroxyl groups. Both hydroxyl and phosphate groups are exposed at the surface. The hydroxyl groups produce a pH-dependent surface charge by accepting a proton to produce a positive site, or donating a proton to produce a negative site. The pH-dependent surface charge is characterized by the point of zero charge, which is equivalent to the isoelectric point in protein chemistry. The surface hydroxyl groups may also undergo ligand exchange with fluoride, phosphate, carbonate, sulfate, or borate anions.

Aluminum phosphate adjuvant is not a stoichiometric compound. Rather, the degree of phosphate group substitution for hydroxyl groups depends on the precipitation recipe and conditions.

6 Functional Category

Adsorbent; vaccine adjuvant.

7 Applications in Pharmaceutical Formulation or Technology

Aluminum phosphate adjuvant is used in parenteral human and veterinary vaccines.[1] based on its ability to enhance antibody production; see Section 18.

8 Description

Aluminum phosphate adjuvant is a white hydrogel that sediments slowly and forms a clear supernatant.

9 Pharmacopeial Specifications

—

10 Typical Properties

Acidity/alkalinity pH = 6.0–8.0
Al : P atomic ratio 1.0–1.4 : 1.0
Aluminum (%) 0.5–0.75
Particle size distribution Primary particles are platy with an average diameter of 50 nm. The primary particles form aggregates of 1–10 μm.
Point of zero charge pH = 4.6–5.6, depending on the Al : P atomic ratio.
Protein binding capacity >0.6 mg lysozyme/mg equivalent Al_2O_3
Solubility Soluble in mineral acids and alkali hydroxides.
X-ray diffractogram Amorphous to x-rays.

11 Stability and Storage Conditions

Aluminum phosphate adjuvant is stable for at least 2 years when stored at 4–30°C in well-sealed inert containers. It must not be allowed to freeze as the hydrated colloid structure will be irreversibly damaged.

12 Incompatibilities

The point of zero charge is related directly to the Al : P atomic ratio. Therefore, the substitution of additional phosphate groups for hydroxyl groups will lower the point of zero charge. Substitution of carbonate, sulfate, or borate ions for hydroxyl groups will also lower the point of zero charge.

13 Method of Manufacture

Aluminum phosphate adjuvant can be formed by the reaction of a solution of aluminum chloride and phosphoric acid with alkali hydroxide.

14 Safety

Aluminum phosphate adjuvant is intended for use in parenteral vaccines and is generally regarded as safe. It may cause mild irritation, dryness, and dermatitis on skin contact. It may also cause redness, conjunctivitis, and short-term mild irritation on eye contact. Ingestion of large amounts of aluminum phosphate adjuvant may cause respiratory irritation with nausea, vomiting, and constipation. Inhalation is unlikely, although the dried product may cause respiratory irritation and cough. Type I hypersensitivity reactions following parenteral administration have also been reported.[2]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Eye protection and gloves are recommended.

16 Regulatory Status

GRAS listed. Accepted for use in human and veterinary vaccines in Europe and the USA. The limits for use in human vaccines are 0.85 mg aluminum/dose if determined by assay, 1.14 mg aluminum/dose if determined by calculation and 1.25 mg aluminum/dose if safety and efficacy data justify it (FDA), and 1.25 mg aluminum/dose (WHO). There are no established limits for use in veterinary vaccines. Reported in the EPA TSCA Inventory.

17 Related Substances

Aluminum hydroxide adjuvant.

18 Comments

Aluminum phosphate adjuvant activates Th2 immune responses, including IgG and IgE antibody responses.[3]

Ammonia Solution

1 Nonproprietary Names

BP: Strong Ammonia Solution

PhEur: Ammonia Solution, Concentrated

USP–NF: Strong Ammonia Solution

2 Synonyms

Ammoniaca; ammoniacum; ammoniae solution concentrata; aqua ammonia; concentrated ammonia solution; spirit of hartshorn; stronger ammonia water.

3 Chemical Name and CAS Registry Number

Ammonia [7664-41-7]

4 Empirical Formula and Molecular Weight

NH_3 17.03

5 Structural Formula

See Section 4.

6 Functional Category

Alkalizing agent.

7 Applications in Pharmaceutical Formulation or Technology

Ammonia solution is typically not used undiluted in pharmaceutical applications and is generally present in a formulation in a highly diluted form. Generally, it is used as a buffering agent or to adjust the pH of solutions. Most commonly, ammonia solution (the concentrated form) is used to produce more dilute ammonia solutions.

8 Description

Strong ammonia solution occurs as a clear, colorless liquid having an exceedingly pungent, characteristic odor. The PhEur 9.2 states that concentrated ammonia solution contains not less than 25.0% and not more than 30.0% w/w of ammonia (NH_3). The USP 40–NF 35 S1 states that strong ammonia solution contains not less than 27.0% and not more than 31.0% w/w of ammonia (NH_3).

See also Section 17.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for ammonia solution.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	–
Appearance of solution	+	–
Oxidizable substances	+	+
Pyridine and related substances	≤2 ppm	–
Carbonates	≤60 ppm	–
Chlorides	≤1 ppm	–
Sulfates	≤5 ppm	–
Iron	≤0.25 ppm	–
Heavy metals	–	≤13 ppm
Residue on evaporation	≤20 mg/L	–
Limit of nonvolatile residue	–	≤0.05%
Assay (of NH_3)	25.0–30.0%	27.0–31.0%

10 Typical Properties

Solubility Miscible with ethanol (95%) and water.

Specific gravity 0.892–0.910

11 Stability and Storage Conditions

On exposure to the air, ammonia solution rapidly loses ammonia. Ammonia solution should be stored in a well-closed container, protected from the air, in a cool, dry place. The storage temperature should not exceed 20°C.

12 Incompatibilities

Ammonia solution reacts vigorously with sulfuric acid or other strong mineral acids and the reaction generates considerable heat; the mixture boils.

13 Method of Manufacture

Ammonia is obtained commercially chiefly by synthesis from its constituent elements, nitrogen and hydrogen, which are combined under high pressure and temperature in the presence of a catalyst. Ammonia solution is produced by dissolving ammonia gas in water.

14 Safety

Ingestion of strong solutions of ammonia is very harmful and causes severe pain in the mouth, throat, and gastrointestinal tract as well as severe local edema with cough, vomiting, and shock. Burns to the esophagus and stomach may result in perforation. Inhalation of the vapor causes sneezing, coughing, and, in high concentration, pulmonary edema.[1] Asphyxia has been reported. The vapor is irritant to the eyes. Strong solutions are harmful when applied to the conjunctiva and mucous membranes.[2] Topical application of even dilute ammonia solutions, used to treat insect bites, has caused burns, particularly when used with a subsequent dressing.[3,4]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

Care should be used in handling strong or concentrated ammonia solutions because of the caustic nature of the solution and the irritating properties of its vapor. Before containers are opened, they should be well cooled. The closure should be covered with a cloth or similar material while opening. Ammonia solution should not be tasted and inhalation of the vapor should be avoided.

Ammonia solution should be handled in a fume cupboard. Eye protection, gloves, and a respirator are recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral suspensions, topical preparations). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Dilute ammonia solution.

Dilute ammonia solution

Synonyms Ammonia water

Specific gravity 0.95–0.96

Comments Several pharmacopeias include monographs for dilute ammonia solution. The JP XVII, for example, states that ammonia water contains not less than 9.5% and not more than 10.5% w/v of ammonia (NH_3).

18 Comments

Therapeutically, dilute ammonia solution is used as a reflex stimulant in 'smelling salts', as a rubefacient, and as a counter-irritant to neutralize insect bites or stings.[5]

Where 'ammonia solution' is prescribed therapeutically, dilute ammonia solution should be dispensed or supplied.

Ammonia solution has been used in studies on the anitifungal activity of silver nanoparticles colloidal suspensions for biofilms on dentures.[6]

The EINECS number for ammonia solution is 231-635-3. The PubChem Compound ID (CID) for ammonia solution is 222.

A Ex Ammonium Alginate

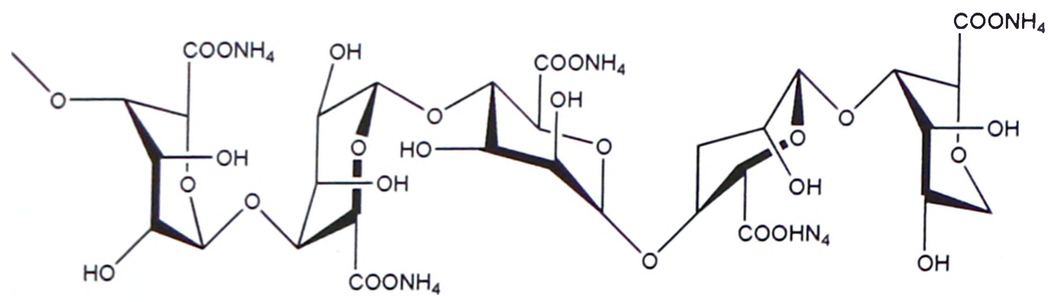
1 Nonproprietary Names

None adopted.

2 Synonyms

Alginic acid, ammonium salt; ammonium polymannuronate; E404.

3 Chemical Name and CAS Registry Number



Ammonium alginate [9005-34-9]

4 Empirical Formula and Molecular Weight

$(C_6H_{11}NO_6)_n$ 193.16 (calculated)
217 (actual, average)

Ammonium alginate is the ammonium salt of alginic acid.

5 Structural Formula

The number and sequence of the mannuronate and glucuronate residues shown above vary in the naturally occurring alginate. The associated water molecules are not shown.

6 Functional Category

Emulsifying agent; film-forming agent;gelling agent; humectant; tablet and capsule binder; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Ammonium alginate is used in pharmaceutical preparations as an emulsifier, film-former, and humectant.

Hydrophilic matrix tablets based on an alginate system have been investigated for modified drug release.[1] Alginates have also been investigated for use in microparticle and hydrogel systems.[2–8] Alginate microspheres have been produced by internal gelation using emulsificiation methods.[9,10]

8 Description

Ammonium alginate occurs as white to yellowish brown filamentous, grainy, granular, or powdered forms.

9 Pharmacopeial Specifications

See Section 18.

10 Typical Properties

Moisture content Not more than 15% at 105°C for 4 hours.
Solubility Dissolves slowly in water to form a viscous solution; insoluble in chloroform, ethanol, ether and in acids having a pH lower than 3.0

11 Stability and Storage Conditions

Ammonium alginate is a hygroscopic material, although it is stable if stored at low relative humidities and cool temperatures.

12 Incompatibilities

Ammonium alginate is incompatible with oxidizing agents and strong acids and alkalis.

13 Method of Manufacture

Ammonium alginate is prepared from alginic acid, which is a polysaccharide extracted from the giant brown seaweed species of Phaeophyceae (*see* Alginic Acid), by an ion-exchange reaction whereby the alginic acid is neutralized with ammonium hydroxide and sufficient water. Final preparation includes a drying stage and milling to the desired particle size.

14 Safety

Ammonium alginate is widely used in cosmetics and food products, and also in pharmaceutical formulations such as tablets. It is generally regarded as a nontoxic and nonirritant material, although excessive oral consumption may be harmful.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. Eye protection, gloves, and a dust respirator are recommended.

16 Regulatory Status

GRAS listed. Accepted in Europe for use as a food additive. Included in the FDA Inactive Ingredients Database (oral, tablets). Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Alginic Acid; calcium alginate; potassium alginate; propylene glycol alginate; sodium alginate.

18 Comments

Ammonium alginate and other alginate salts bind water very strongly due to the large number of carboxylate anions they contain.

Protanal (formerly *Keltose*; FMC Biopolymer) is a blend of ammonium alginate and calcium alginate.

Therapeutically, alginates provide an ideal moist healing environment, which makes them ideal for use in wound dressings.[11,12] Chitosan and alginates have been used together to produce sponges for use as wound dressings, or matrices for tissue engineering.[13]

Ammonium alginate is also widely used in foods as a thickener and emulsifier.

Table I: FCC specification for ammonium alginate.[14]

Test	FCC 10 S2
Identification	+
Arsenic	≤3 mg/kg
Residue on ignition	≤7.0%
Lead	≤5 mg/kg
Loss on drying	≤15.0%
Assay	18–21% of CO_2, corresponding to 88.7–103.6% ammonium alginate

Although not included in any pharmacopeias, a specification for ammonium alginate is included in the *Food Chemicals Codex* (FCC),[14] *see* Table I.

Ammonium Chloride

1 Nonproprietary Names

BP: Ammonium Chloride
PhEur: Ammonium Chloride
USP–NF: Ammonium Chloride

2 Synonyms

Ammonii chloridum; ammonium muriate; E510; sal ammoniac; salmiac.

3 Chemical Name and CAS Registry Number

Ammonium chloride [12125-02-9]

4 Empirical Formula and Molecular Weight

NH_4Cl 53.49

5 Structural Formula

See Section 4.

6 Functional Category

Acidulant.

7 Applications in Pharmaceutical Formulation or Technology

Ammonium chloride is used as an acidifying agent in oral formulations and as a food additive.

8 Description

Ammonium chloride occurs as colorless, odorless crystals or crystal masses. It is a white, granular powder with a cooling, saline taste. It is hygroscopic and has a tendency to cake.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for ammonium chloride.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	–
Appearance of solution	+	–
Acidity or alkalinity	+	+
Loss on drying	≤1.0%	≤0.5%
Residue on ignition	–	≤0.1%
Thiocyanate	–	+
Bromides and iodides	+	–
Sulfates	≤150 ppm	–
Sulfated ash	≤0.1%	–
Calcium	≤200 ppm	–
Iron	≤20 ppm	–
Heavy metals	–	≤0.001%
Assay (dried basis)	99.0–100.5%	99.5–100.5%

A

10 Typical Properties

Acidity/alkalinity pH = 4.5–5.5 (5.5% w/w aqueous solutions at 25°C)
Density (bulk) 0.6–0.9 g/cm^3
Hygroscopicity Hygroscopic with potential to cake.
Melting point Decomposes at 338°C; sublimes without melting.[1]
Solubility Soluble in water; hydrochloric acid and sodium chloride decrease its solubility in water. Also soluble in glycerin; sparingly soluble in methanol and ethanol. Almost insoluble in acetone, ether, and ethyl acetate.
Specific gravity 1.527
Vapor pressure 133.3 Pa (1 mmHg) at 160°C

11 Stability and Storage Conditions

Ammonium chloride is chemically stable. It decomposes completely at 338°C to form ammonia and hydrochloric acid. Store in airtight containers in a cool, dry place.

12 Incompatibilities

Ammonium chloride is incompatible with strong acids and strong bases. It reacts violently with ammonium nitrate and potassium chlorate, causing fire and explosion hazards. It also attacks copper and its compounds.

13 Method of Manufacture

Ammonium chloride is prepared commercially by reacting ammonia with hydrochloric acid.

14 Safety

Ammonium chloride is used in oral pharmaceutical formulations. The pure form of ammonium chloride is toxic by SC, IV, and IM routes, and moderately toxic by other routes. Potential symptoms of overexposure to fumes are irritation of eyes, skin, respiratory system (cough, dyspnea, and pulmonary sensitization).[2] Ammonium salts are an irritant to the gastric mucosa and may induce nausea and vomiting.

LD_{50} (mouse, IP): 1.44 g/kg[3]
LD_{50} (mouse, oral): 1.3 g/kg
LD_{50} (rat, IM): 0.03 g/kg[4]
LD_{50} (rat, oral): 1.65 g/kg[5]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled.

All grades of ammonium chloride must be kept well away from nitrites and nitrates during transport and storage. They must be stored in a dry place, and effluent must not be discharged into the drains without prior treatment.

Ammonium chloride decomposes on heating, producing toxic and irritating fumes (nitrogen oxides, ammonia, and hydrogen chloride).

16 Regulatory Status

GRAS listed. Included in the FDA Inactive Ingredients Database (oral syrup and tablets). Accepted for use as a food additive in Europe. Included in medicines licensed in the UK (eye drops and oral syrup). Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Ammonia solution.

18 Comments

Ammonium chloride has the ability to cross the red blood cell membrane, and a solution that is isotonic to blood will still cause hemolytic rupture because it acts as a hypotonic solution.[6]

Therapeutically, ammonium chloride is used in the treatment of severe metabolic alkalosis to maintain the urine at an acid pH in the treatment of some urinary tract disorders or in forced acid diuresis.[7–9] It is also used as an antiseptic agent[10] and as an expectorant in cough medicines.[11] Ammonium chloride has been investigated as an effective agent for enhancing drug cytotoxicity in cancer treatment.[12]

A specification for ammonium chloride is contained in the *Food Chemicals Codex* (FCC).[13]

The EINECS number for ammonium chloride is 235-186-4. The PubChem Compound ID (CID) for ammonium chloride is 25517.

Ammonium Glycyrrhizate

1 Nonproprietary Names

BP: Ammonium Glycyrrhizinate

PhEur: Ammonium Glycyrrhizate

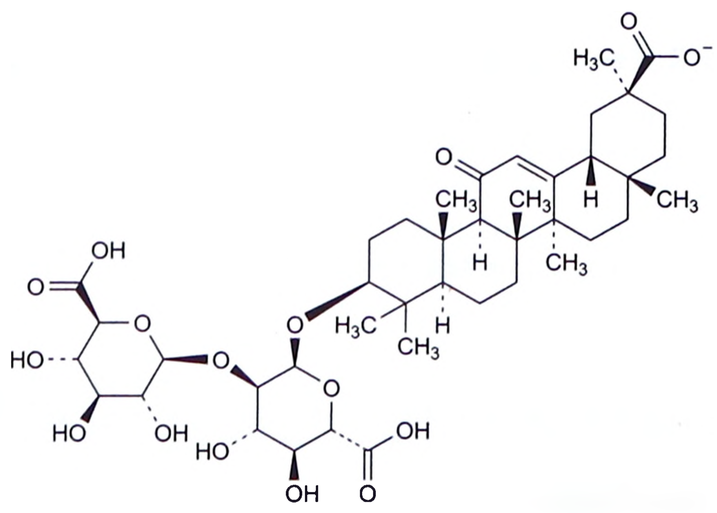
USP–NF: Ammonium Glycyrrhizate

2 Synonyms

Ammoniated glycyrrhizin; ammonium glycyrrhizinate; α-D-glucopyranosiduric acid, (3β,20β)-20-carboxy-11-oxo-30-norlean-12-en-3-yl-2-*O*-β-D-glucopyranuronosyl-, ammoniate; glycamil; glycyram; glycyrram; glycyrrhizic acid ammonium salt; glycyrrhizic acid, monoammonium salt; mag; *Magnasweet*; monoammonium glycyrrhizate; monoammonium glycyrrhizinate.

3 Chemical Name and CAS Registry Number

α-D-Glucopyranosiduric acid, (3β,20β)-20-carboxy-11-oxo-30-norlean-12-en-3-yl-2-*O*-β-D-glucopyranuronosyl-, monoammonium salt; anhydrous [53956-04-0]



α-D-Glucopyranosiduric acid, (3β,20β)-20-carboxy-11-oxo-30-norlean-12-en-3-yl-2-*O*-β-D-glucopyranuronosyl-, monoammonium salt; pentahydrate [1407-03-0]

The USP 40–NF 35 S1 and PhEur 9.2 describe ammonium glycyrrhizate as a mixture of ammonium 18α- and 18β-glycyrrhizate (ammonium salt of (20β)-3β-[[2-*O*-(β-D-glucopyranosyluronic acid)-α-D-glucopyranosyluronic acid]oxy]-11-oxoolean-12-en-29-oic acid), the 18β-isomer being the main component.

4 Empirical Formula and Molecular Weight

$C_{42}H_{65}NO_{16}$ (anhydrous)	840.08
$C_{42}H_{65}NO_{16}\cdot 5H_2O$ (pentahydrate)	930.04

5 Structural Formula

6 Functional Category

Emulsifying agent; flavoring agent; sweetening agent; taste-masking agent

7 Applications in Pharmaceutical Formulation or Technology

Ammonium glycyrrhizate is an intense sweetening agent, approximately 50 times sweeter than sucrose. It is used as a flavoring and taste-masking agent[1,2] in oral pharmaceutical formulations, and it is also used to stabilize emulsions.[3]

It has also been investigated as a penetration enhancer in a topical gel preparation of idoxuridine.[4]

8 Description

Ammonium glycyrrhizate occurs as a white to yellowish-white or brown, hygroscopic powder, with an intensely sweet taste.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for ammonium glycyrrhizate.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	—
Appearance of solution	+	—
Specific optical rotation (anhydrous)	+49.0 to +54.0	+49.0 to +55.0
Related substances	+	—
Water	≤6.0%	≤6.0%
Sulfated ash	≤0.2%	—
Residue on ignition	—	≤0.5%
Organic impurities		
24-Hydroxy-glycyrrhizinic acid	—	≤5.7%
Other impurities	—	≤2.0%
Sum of other impurities	—	≤8.0%
Assay (anhydrous)		
18α- and 18β-glycyrrhizate	98.0–102.0%	78.0–102.0%
18α-glycyrrhizate	—	≤13.0%

10 Typical Properties

Absorption maximum UV max: 248 nm (ε 11400) (pentahydrate)

Acidity/alkalinity pH = 4.5 (6×10^{-5} M aqueous solution)[5]

Melting point 209°C with decomposition (anhydrous); 212–217°C with decomposition (pentahydrate)

Solubility Soluble in ammonia solution and glacial acetic acid; slightly soluble in water; very slightly soluble in anhydrous ethanol; practically insoluble in acetone.

11 Stability and Storage Conditions

Ammonium glycyrrhizate should be stored in tight containers in a cool, dry place.

Stability studies have indicated ammonium glycyrrhizate is thermostable and photostable between pH 7–9.[5,6]

12 Incompatibilities

Ammonium glycyrrhizate is incompatible with strong oxidizing agents.

13 Method of Manufacture

Ammonium glycyrrhizate is the ammonium salt of glycyrrhizic acid. It is prepared by the acid precipitation of aqueous licorice extract from the roots of Glycyrrhiza glabra, followed by neutralization with ammonia to produce ammoniated glycyrrhizin. Further solvent extraction and separation produces ammonium glycyrrhizate.[7]

14 Safety

Ammonium glycyrrhizate is widely used in foods, cosmetics and oral pharmaceutical preparations, and is generally regarded as safe

A

for use as an excipient. Acute exposure may cause eye, skin and respiratory tract irritation.

In vitro studies have shown no overt morphological damage to ovine nasal mucosa after short-term exposure to ammonium glycyrrhizate.[8] However, a study in rats has shown possible embryotoxicity effects.[9] An upper limit of 100 mg/day has been recommended in humans.[7]

The Cosmetic Ingredient Review Expert Panel has assessed ammonium glycyrrhizate and concluded that the material is safe as used in cosmetics and personal care products.[10]

LD_{50} (rat, IP): >0.30 g/kg
LD_{50} (mouse, IV): 0.54 g/kg
LD_{50} (rat, oral): >10 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. When heated to decomposition, ammonium glycyrrhizate emits acrid smoke and irritating fumes.

Avoid inhalation and contact with eyes and skin. Suitable protective clothing, gloves, eye protection, and a respirator are recommended.

16 Regulatory Status

GRAS listed. Included in the FDA inactive ingredient database (oral solutions, suspensions, syrups, tablets, granules, and powders for solutions). Included in nonparental medicines licensed in the UK. Listed in the EAFUS list compiled by the FDA. Included in the Canadian Natural Ingredients Database.

17 Related Substances

Glycyrrhizin.

18 Comments

Ammonium glycyrrhizate is also used as a flavoring agent, flavor enhancer and emulsifying agent in a wide variety of applications in foods, beverages, cosmetics, personal care, and nutraceuticals. It may also be used as a cytoprotective agent.[11]

Therapeutically, ammonium glycyrrhizate has been widely used as an anti-inflammatory agent[12–14] and has been investigated for its potential cardioprotective effects *in vivo*.[15]

Specifications for ammoniated glycyrrhizin and monoammonium glycyrrhizinate are included in the *Food Chemical Codex* (FCC).[16]

The EINECS number for ammonium glycyrrhizate is 258-887-7. The PubChem Compound ID (CID) for ammonium glycyrrhizate includes 62074, 16213697, and 45357226.

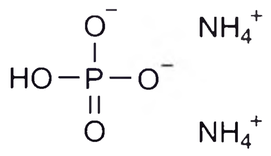
Ammonium Phosphate

1 Nonproprietary Names

USP-NF: Ammonium Phosphate

2 Synonyms

DAP; diammonium hydrogen orthophosphate; diammonium hydrogen phosphate; diammonium phosphate; dibasic ammonium phosphate; E342; phosphoric acid; Phosphoric acid ammonium salt (1:2); secondary ammonium phosphate.



3 Chemical Name and CAS Registry Number

Diammonium hydrogen orthophosphate [7783-28-0]

4 Empirical Formula and Molecular Weight

$(NH_4)_2HPO_4$ 132.06

5 Structural Formula

6 Functional Category

Buffering agent.

7 Applications in Pharmaceutical Formulation or Technology

Dibasic ammonium phosphate is used as a buffering agent in oral pharmaceutical formulations. It has also been used to investigate the mineralization of hyaluronic acid nanoparticles as stable drug carriers.[1,2]

8 Description

Dibasic ammonium phosphate occurs as colorless or white granules or powder, with a saline, cooling taste.

9 Pharmacopeial Specifications

See Table I

Table I: Pharmacopeial specifications for dibasic ammonium phosphate.

Test	USP 40–NF 35 S1
Identification	+
Chlorides	0.03%
Sulfates	0.15%
Arsenic	≤3 ppm
Heavy metals	≤10 ppm
pH (1 in 100 solution)	7.6–8.2
Assay	96.0–102.0%

10 Typical Properties

Density 1.619 g/cm^3

Melting point 155°C with decomposition;[3–5] also reported as 185°C with decomposition,[6] and 235°C with decomposition at 280°C and above.[7]

Solubility Freely soluble in water. Practically insoluble in acetone and ethanol.

11 Stability and Storage Conditions

Dibasic ammonium phosphate is stable under normal temperatures and pressures although it gradually loses about 8% NH_3 on exposure to air.[7] It is hygroscopic and tends to cake on storage.[6] Store in airtight containers in a cool, dry, well-ventilated area.

12 Incompatibilities

Dibasic ammonium phosphate is incompatible with strong oxidizing agents, strong acids, strong bases, sodium hypochlorite, and magnesium.[4,5]

13 Method of Manufacture

Dibasic ammonium phosphate is produced commercially by reacting ammonia with phosphoric acid.[8] The grade used medicinally is 98-99% pure.

14 Safety

Dibasic ammonium phosphate in pure form can cause skin and eye irritation, and may cause respiratory irritation. Ingestion of large quantities may cause nausea, vomiting, diarrhoea, and abdominal cramps.[5]

When heated to decomposition, dibasic ammonium phosphate emits very toxic fumes of phosphorous oxides (PO_x), nitrogen oxides (NO_x) and NH_3.

LD_{50} (rabbit, skin): 7.95 g/kg[9]

LD_{50} (rat, oral): 3 g/kg;[10] 6.5 g/kg[4,9]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled.

Avoid direct or prolonged contact with skin and eyes, and avoid breathing dusts or vapors. Gloves, eye protection, a respirator, and other protective clothing should be worn.

16 Regulatory Status

GRAS listed. Dibasic ammonium phosphate is included in FDA Inactive Ingredients Database (oral tablets; sublingual and sustained action). Also included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Ammonia solution; ammonium chloride; ammonium sulfate; monobasic ammonium phosphate.

Monobasic ammonium phosphate

Empirical formula $(NH_4)H_2PO_4$

Molecular weight 115.03

CAS number [7722-76-1]

Synonyms Ammonium dihydrogen phosphate; ammonium dihydrogen orthophosphate; phosphoric acid ammonium salt (1:1); ammonium biphosphate; monoammonium phosphate; primary ammonium phosphate.

Appearance Occurs as odorless white crystals, a crystalline powder, or granules.

Acidity/alkalinity pH 4.2 (0.2M aqueous solution)

Density 1.803 g/cm^3 at 19°C[6]

A

Boiling point 376.1°C with decomposition
Melting point 193.3°C; 190°C[6]
pH 3.8–4.4 (5% w/v) at 25°C
Solubility Soluble in water; slightly soluble in alcohol; practically insoluble in acetone.
Comments Used in buffer solutions. In food production, it is used in baking powder with sodium bicarbonate, and in yeast fermentations. Also used in the fireproofing of paper, wood, and fibreboard. Therapeutically, it has been used to acidify urine and as a phosphate supplement.[11]

GRAS listed. Although not included in any pharmacopeias, a specification for monobasic ammonium phosphate is included in the *Food Chemicals Codex* (FCC), *see* Table II.[12] Included in the Canadian Natural Health Products Ingredients Database.

The EINECS number for monobasic ammonium phosphate is 231-764-5. The PubChem Compound ID (CID) number for monobasic ammonium phosphate is 24402.

Table II: FCC specification for monobasic ammonium phosphate

Test	FCC 10 S2
Identification	+
Characters	+
Arsenic	≤3 mg/kg
Fluoride	≤10 mg/kg
Lead	≤4 mg/kg
pH (1 in 100 solution)	4.3–5.0
Assay	96.0–102.0%

18 Comments

Dibasic ammonium phosphate is widely used in fertilizers and as a flame retardant for textiles, paper, wood, and vegetable fibers. It is also used in purifying sugar, in dentifrices, and as a buffering agent, dough conditioner, leavening agent, and yeast nutrient source in food and wine production.[13]

Therapeutically, ammonium phosphate has formerly been used as a diuretic.[11]

A specification for dibasic ammonium phosphate is included in the *Food Chemicals Codex* (FCC).[12]

The EINECS number for dibasic ammonium phosphate is 231-987-8. The PubChem Compound ID (CID) number for dibasic ammonium phosphate is 24540.

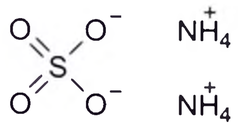
Ammonium Sulfate

1 Nonproprietary Names

USP-NF: Ammonium Sulfate

2 Synonyms

E517; diammonium sulfate; mascagnite; sulfuric acid, ammonium salt (1:2); sulfuric acid, diammonium salt.



3 Chemical Name and CAS Registry Number

Ammonium sulfate [7783-20-2]

4 Empirical Formula and Molecular Weight

$(NH_4)_2SO_4$ 132.14

5 Structural Formula

6 Functional Category

Buffering agent, viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Ammonium sulfate is used as a buffer and viscosity-control agent in pharmaceutical and cosmetic formulations.[1] It is used in the pharmaceutical industry as a biochemical aid for protein purification by selective precipitation or as a nutrient for microorganisms in the production of enzymes.[2] It is also used as a water purification agent,[3,4] and is in intravenous pharmaceutical preparations. It is listed as an ingredient in many vaccines in the US.[5]

Ammonium sulfate gradients are used for drug loading into liposomes for stable drug delivery vehicles.[6–10]

8 Description

Ammonium sulfate occurs as odorless, white orthorhombic crystals or granules.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for ammonium sulfate.

Test	USP 40–NF 35 S1
Identification	+
Residue on ignition	≤0.005%
Insoluble matter	≤0.005%
Phosphates	≤5 ppm
Chlorides	≤5 ppm
Nitrates	≤10 ppm
Iron	≤5 ppm
Microbial contamination	
Aerobic microbial count	$\leq 10^3$ cfu/g
Yeast and molds	≤10 cfu/g
pH	5.0–6.0
Assay	99.0–100.5%

10 Typical Properties

Density 1.77 g/cm^3
Flash point >93.3°C (closed cup)
Melting point >280°C with decomposition
Solubility Soluble in water: 77g/100 mL (25°C); insoluble in acetone and ethanol.

11 Stability and Storage Conditions

Ammonium sulfate is stable under normal temperatures and pressures. It is slightly hygroscopic and may cake on storage. Store in well-closed containers in a cool, dry place.

12 Incompatibilities

Ammonium sulfate is incompatible with chlorates, nitrites, oxidizing agents, bases, and alkali metals.[11]

13 Method of Manufacture

Ammonium sulfate is prepared commercially by reacting ammonia with sulfuric acid.[12,13] It is also produced by adding gypsum to an ammonium carbonate solution.

Ammonium sulfate occurs naturally as the rare mineral mascagnite found in volcanic fumaroles.[14]

14 Safety

Ammonium sulfate in the pure form is moderately toxic by several routes[15] and may cause skin, eye, and respiratory irritation.[16] Ingestion of large quantities may cause hypermotility, diarrhea, nausea, vomiting,[11,15] and can cause death.[17]

When heated to decomposition, ammonium sulfate emits very toxic fumes of sulfur oxides (SOx), nitrogen oxides (NOx) and ammonia (NH_3).[11,15] An incandescent reaction occurs on heating with potassium chlorate. A reaction with sodium hypochlorite gives the unstable explosive nitrogen trichloride.[15]

LD_{50} (mouse, IP): 0.61 g/kg[15]
LD_{50} (mouse, oral): 0.64 g/kg[18]
LD_{50} (rat, oral): 3 g/kg[15]
LD_{50} (rat, skin): 2 g/kg[19]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled.

Avoid generating or breathing dusts or vapors. Avoid direct or prolonged contact with skin and eyes. Gloves, eye protection, a respirator, and other protective clothing should be worn.

16 Regulatory Status

GRAS listed. Accepted for use as a food additive in Europe and US. Included in FDA Inactive Ingredients Database (IV injections, liposomal suspension). Also included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Ammonium solution; ammonium bisulfate; ammonium chloride; dibasic ammonium phosphate; monobasic ammonium phosphate.

Ammonium bisulfate
Empirical Formula $(NH_4)HSO_4$
Molecular weight 115.11

A

CAS number [7803-63-6]
Synonyms Acid ammonium sulfate; ammonium hydrogen sulfate; sulfuric acid, ammonium salt (1:1)
Appearance White solid
Melting point 147°C
Specific Gravity 1.78
Solubility Very soluble in cold water; soluble in methanol; insoluble in acetone.
Comments Accepted for use as a food additive in Europe and US. Included in the Canadian Natural Health Products Ingredients Database.

18 Comments

Ammonium sulfate is used as a buffering agent and food additive in the food industry. It is commonly added to bread products as a dough conditioner, and is used as a yeast nutrient source in wine production.[20]

It is used in a wide variety of other industrial applications including, water treatment, fertilizers, galvanizing, leather tanning, textile dyeing, viscose silk manufacture, cellulose and fiberglass insulation, and fire extinguisher chemicals. It is used to produce aluminum ammonium sulfate, and is used in the manufacture of hydrogen sulfide to free it from nitrogen oxides.

Therapeutically, ammonium sulfate is a non-narcotic anesthetic agent. Few side effects have been reported in adult studies, with pain relief lasting from days to weeks.[21] It is included in medicated shampoos licensed in the UK.[22]

A specification for ammonium sulfate is included in the Food Chemicals Codex (FCC).[23]

The EINECS number for ammonium sulfate is 231-984-1. The PubChem Compound ID (CID) for ammonium sulfate is 6097028.

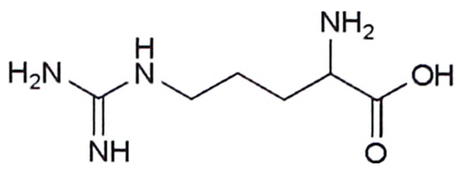
Arginine

1 Nonproprietary Names

BP: Arginine
JP: L-Arginine
PhEur: Arginine
USP–NF: Arginine

2 Synonyms

AjiPure; (*S*)-2-Amino-5-[(aminoiminomethyl)amino]pentanoic acid; 2-amino-5-guanidinovaleric acid; Arg; argininum; R.



3 Chemical Name and CAS Registry Number

L-Arginine [74-79-3]

4 Empirical Formula and Molecular Weight

$C_6H_{14}N_4O_2$ 174.2

5 Structural Formula

6 Functional Category

Buffering agent; dispersing agent.

7 Applications in Pharmaceutical Formulation or Technology

Arginine is used in injectable formulations as a stabilizer to suppress formation of aggregates.[1] Arginine also reduces the viscosity of high concentration antibody formulations, allowing for a shorter administration time. Arginine is most effective at concentrations exceeding 0.1 M.[2]

8 Description

Arginine occurs as white or almost white crystals or crystalline powder.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for arginine.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters	—	+	—

pH	10.5–12.0	—	—
Assay	98.5%–101.0%	98.5%–101.0%	98.5%–101.5%

(a) 0.2% for each impurity.

10 Typical Properties

Bulk density 640 kg/m^3[3]
Dissociation constant

$pK_{a1} = 2.17$;
$pK_{a2} = 9.04$;
$pK_{a3} = 12.5$.[4]

Melting point Melts at 238°C[3] with decomposition at 244°C.[4]
Solubility Soluble in water, slightly soluble in alcohol, insoluble in ether.[4]

11 Stability and Storage Conditions

Store in well-closed containers protected from light in a cool area. Do not store above 24°C.

12 Incompatibilities

Arginine is incompatible with oxidizing agents.

13 Method of Manufacture

Arginine is a naturally occurring amino acid.

14 Safety

Arginine is generally regarded as a nontoxic and nonirritant excipient. Some studies in animals have reported mutagenic effects.[5]

LD_{50} (rat, oral): >5 g/kg[3]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. Arginine can cause irritation of skin, eyes, respiratory tract and gastrointestinal tract. When heated to decomposition, arginine emits toxic carbon and nitrogen oxides. Wear suitable protective clothing to avoid inhalation of dust and contact with eyes. Keep away from heat and sources of ignition. Evaporate residue from empty containers under a fume hood as they may otherwise pose a fire risk.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (injections and oral tablets) and the Canadian Natural Health Products Ingredients Database. Arginine is also included in oral and parenteral products licensed in the UK.

17 Related Substances

Arginine hydrochloride.

A

Arginine Hydrochloride

Synonyms Arginine HCl; arginini hydrochloridum; arginine monohydrochloride; L-2-amino-5-guanidinovaleric acid monohydrochloride; L-arginine hydrochloride; L-arginine monohydrochloride.

Empirical formula $C_6H_{14}N_4O_2.HCl$

Molecular weight 210.7

CAS number [1119-34-2]

Description Arginine hydrochloride occurs as a white, odourless crystalline powder.

Typical Properties

Bulk density 1250 kg/m^3[3]

Melting point Sinters at 218°C , solidifies again at 225°C, decomposes at 235°C.[4]

Solubility Soluble in water, and formic acid, slightly soluble in hot ethanol (95%), insoluble in ether.[4]

Storage Keep in well-closed containers.

Comments Arginine hydrochloride is listed in the USP 40–NF 35 S1, JP XVI and PhEur 9.2. The EINECS number for arginine hydrochloride is 214-275-1.

18 Comments

Arginine is a basic amino acid essential for growth. It is used as a dietary supplement, to treat or prevent deficiency, or to aid recovery during convalescence.[6] It is also used as an ammonia detoxicant in hepatic failure.[4]

A specification for arginine is included in the Food Chemicals Codex (FCC).[7]

The EINECS number for arginine is 200-811-1. The PubChem Compound ID (CID) for arginine include 232, 6322 and 71070.

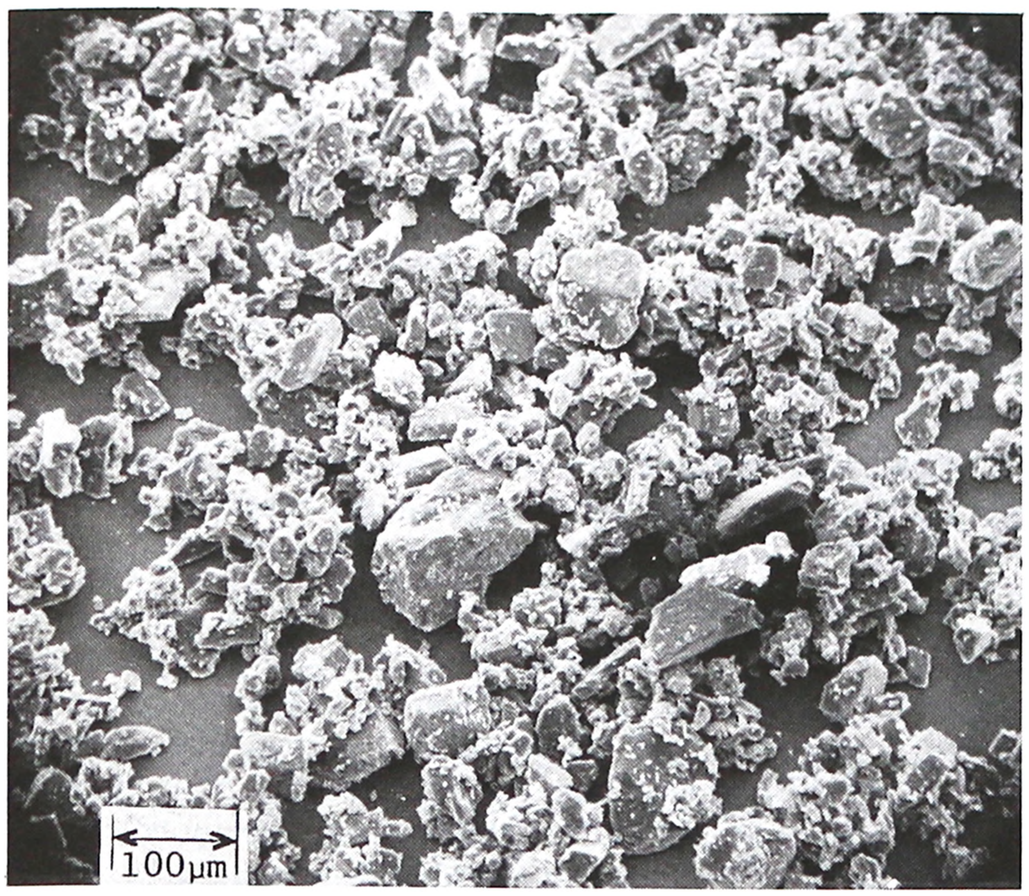
L-(+)-Ascorbic acid [50-81-7]

4 Empirical Formula and Molecular Weight

$C_6H_8O_6$ 176.13

5 Structural Formula



6 Functional Category

Acidulant; antioxidant.

7 Applications in Pharmaceutical Formulation or Technology

Ascorbic acid is used as an antioxidant in aqueous pharmaceutical formulations at a concentration of 0.01–0.1% w/v. Ascorbic acid has been used to adjust the pH of solutions for injection, and as an adjunct for oral liquids. It is also widely used in foods as an antioxidant. Ascorbic acid has also proven useful as a stabilizing agent in mixed micelles containing tetrazepam.[1]

pK_{a1} = 4.17;
pK_{a2} = 11.57.
Melting point 190°C (with decomposition)
Moisture content 0.1% w/w
Solubility *see* Table II.
Spectroscopy
IR spectrum *see* Figure 1.
NIR spectrum *see* Figure 2.
Raman spectrum *see* Figure 3.

A

11 Stability and Storage Conditions

In powder form, ascorbic acid is relatively stable in air. In the absence of oxygen and other oxidizing agents it is also heat stable. Ascorbic acid is unstable in solution, especially alkaline solution, readily undergoing oxidation on exposure to the air.[2,3] The oxidation process is accelerated by light and heat and is catalyzed by traces of copper and iron. Ascorbic acid solutions exhibit maximum stability at about pH 5.4. Solutions may be sterilized by filtration.

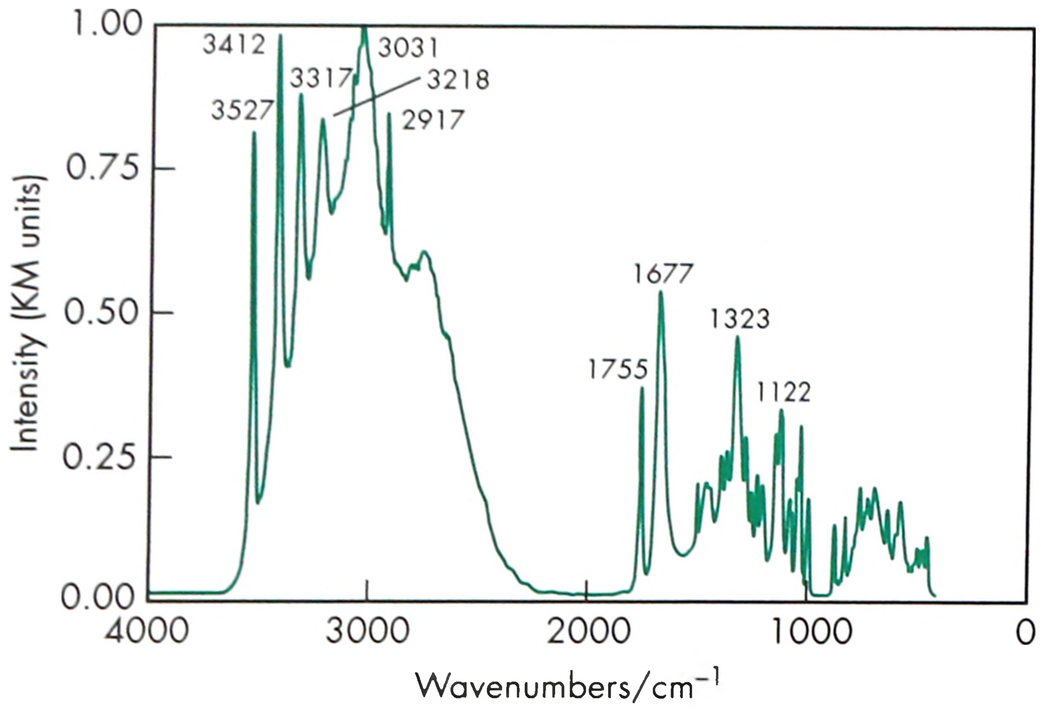

Figure 1: Infrared spectrum of ascorbic acid measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

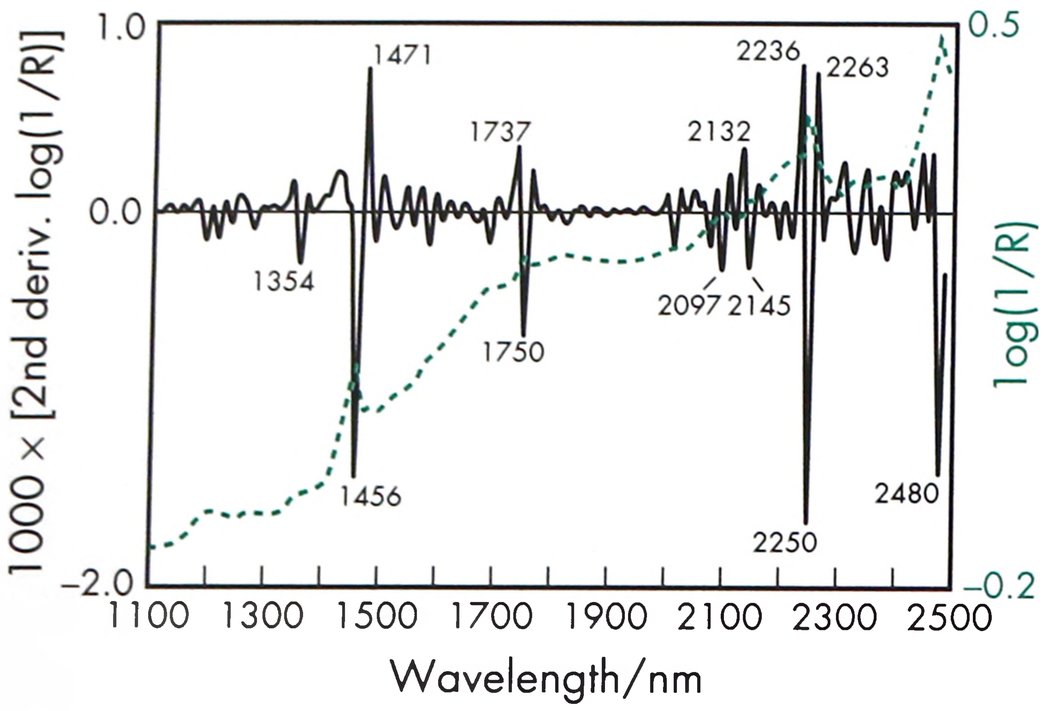

Figure 2: Near-infrared spectrum of ascorbic acid measured by reflectance.

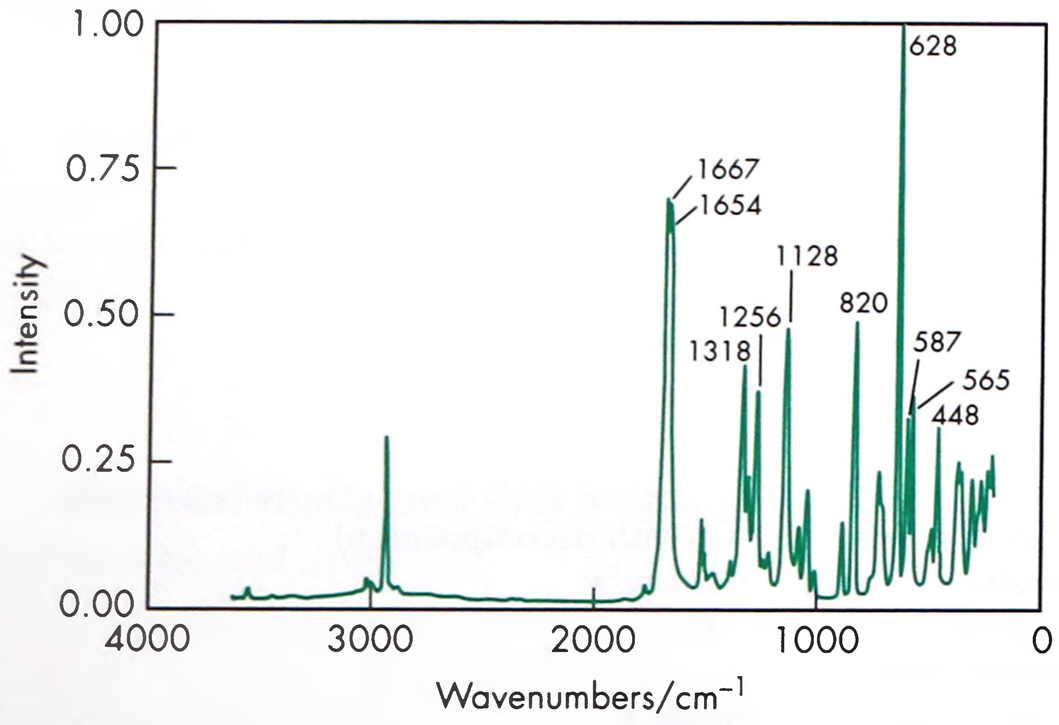

Figure 3: Raman spectrum of ascorbic acid measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

Table II: Solubility of ascorbic acid.

Solvent	Solubility at 20°C
Chloroform	Practically insoluble
Ethanol	1 in 50
Ethanol (95%)	1 in 25
Ether	Practically insoluble
Fixed oils	Practically insoluble
Glycerin	1 in 1000
Propylene glycol	1 in 20
Water	1 in 3.5

The bulk material should be stored in a well-closed nonmetallic container, protected from light, in a cool, dry place.

12 Incompatibilities

Incompatible with alkalis, heavy metal ions, especially copper and iron, oxidizing materials, methenamine, phenylephrine hydrochloride, pyrilamine maleate, salicylamide, sodium nitrite, sodium salicylate, theobromine salicylate, and picotamide.[4,5] Additionally, ascorbic acid has been found to interfere with certain colorimetric assays by reducing the intensity of the color produced.[6]

13 Method of Manufacture

Ascorbic acid is prepared synthetically or extracted from various vegetable sources in which it occurs naturally, such as rose hips, blackcurrants, the juice of citrus fruits, and the ripe fruit of *Capsicum annuum* L. A common synthetic procedure involves the hydrogenation of D-glucose to D-sorbitol, followed by oxidation using *Acetobacter suboxydans* to form L-sorbose. A carboxyl group is then added at C1 by air oxidation of the diacetone derivative of L-sorbose and the resulting diacetone-2-keto-L-gulonic acid is converted to L-ascorbic acid by heating with hydrochloric acid.

14 Safety

Ascorbic acid is an essential part of the human diet, with 40 mg being the recommended daily dose in the UK[7] and 60 mg in the USA.[8] However, these figures are controversial, with some advocating doses of 150 or 250 mg daily. Megadoses of 10 g daily have also been suggested to prevent illness although such large doses are now generally considered to be potentially harmful.[9–11]

Ascorbic acid may be harmful if ingested in large quantities and may be irritating to the eyes. The body can absorb about 500 mg of ascorbic acid daily with any excess immediately excreted by the kidneys. Large doses may cause diarrhea or other gastrointestinal disturbances. Damage to the teeth has also been reported,[12] which is most probably due to acid impact on the enamel and is no different to any other acid that might be ingested. However, no adverse effects have been reported at the levels employed as an antioxidant in foods, beverages,[13] and pharmaceuticals.

The WHO has set an acceptable daily intake of ascorbic acid, potassium ascorbate, and sodium ascorbate, as antioxidants in food, at up to 15 mg/kg body-weight in addition to that naturally present in food.[14]

LD_{50} (mouse, IV): 0.52 g/kg[15]
LD_{50} (mouse, oral): 3.37 g/kg
LD_{50} (rat, oral): 11.9 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Eye protection and rubber or plastic gloves are recommended.

16 Regulatory Status

GRAS listed. Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (inhalations; injections; oral capsules, suspensions, and tablets; topical preparations; suppositories). Included in medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Ascorbyl palmitate; erythorbic acid; sodium ascorbate.

18 Comments

Many dosage forms for ascorbic acid have been developed for its administration to patients, including microencapsulation.[16] Supplements have been tested with treatment in surgical procedures and fractures to improve recovery but no definitive beneficial results have been reported.[17,18]

A specification for ascorbic acid is contained in the *Food Chemicals Codex* (FCC).[19]

The EINECS number for ascorbic acid is 200-066-2. The PubChem Compound ID (CID) for ascorbic acid is 5785.

A Ascorbyl Palmitate

1 Nonproprietary Names

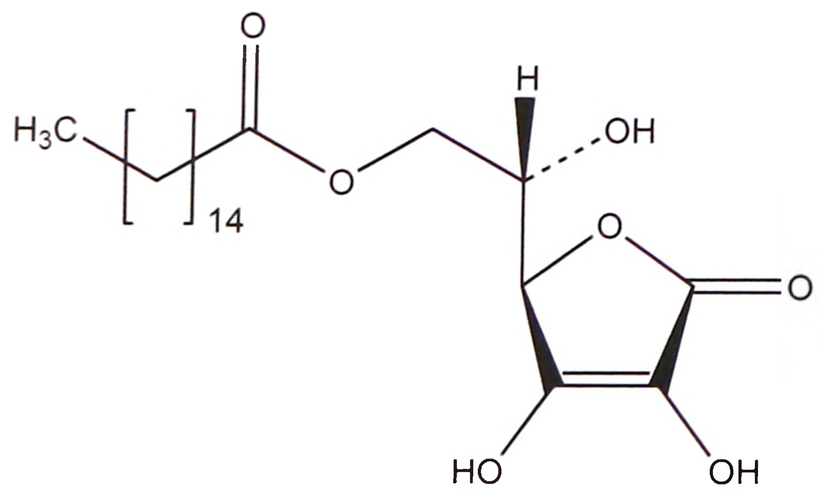
BP: Ascorbyl Palmitate

PhEur: Ascorbyl Palmitate

USP–NF: Ascorbyl Palmitate

2 Synonyms

L-Ascorbic acid 6-palmitate; ascorbylis palmitas; E304; 3-oxo-L-gulofuranolactone 6-palmitate; Vitamin C ester; Vitamin C palmitate.



3 Chemical Name and CAS Registry Number

L-Ascorbic acid 6-hexadecanoate [137-66-6]

4 Empirical Formula and Molecular Weight

$C_{22}H_{38}O_7$ 414.54

5 Structural Formula

6 Functional Category

Antioxidant.

7 Applications in Pharmaceutical Formulation or Technology

Ascorbyl palmitate is primarily used alone or in combination with alpha tocopherol as a stabilizer for oils in oral pharmaceutical formulations and food products; generally, a concentration of 0.05% w/v is used. It may also be used in oral and topical preparations as an antioxidant for drugs unstable to oxygen. The combination of ascorbyl palmitate with alpha tocopherol shows marked synergism, which increases the effect of the components and allows the amount used to be reduced. The solubility of ascorbyl palmitate in alcohol (freely soluble) permits it to be used in both nonaqueous and aqueous systems and emulsions.

8 Description

Ascorbyl palmitate is a practically odorless, white to yellowish powder.

9 Pharmacopeial Specifications

See Table I.

10 Typical Properties

Solubility *see* Table II.[1]

Spectroscopy

IR spectrum *see* Figure 1.

NIR spectrum *see* Figure 2.

Raman spectrum *see* Figure 3.

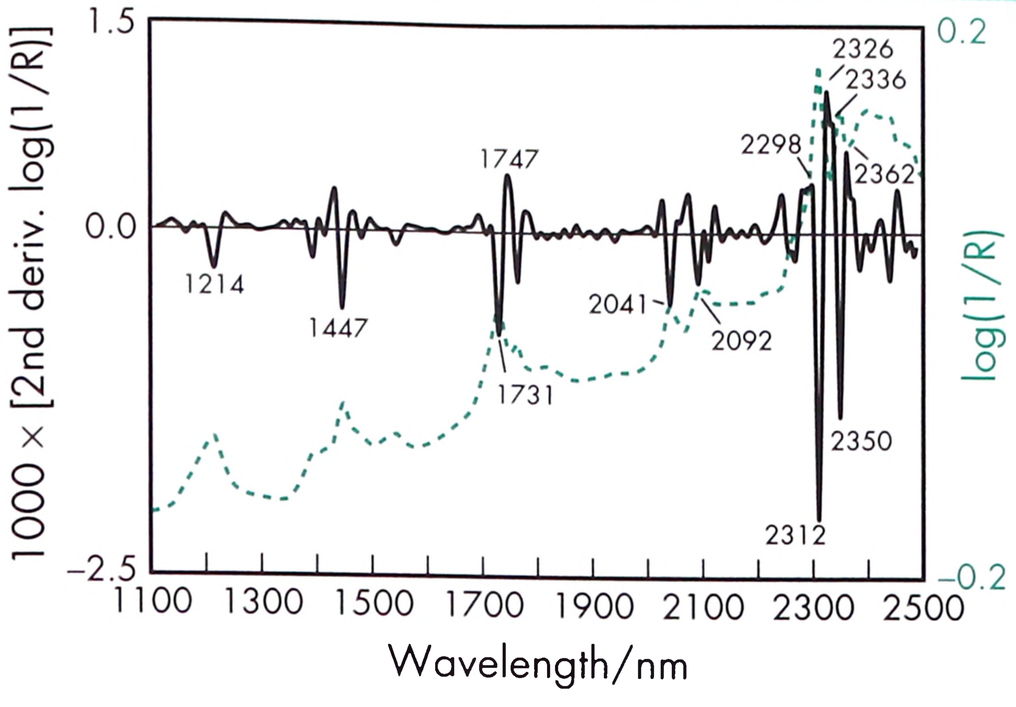

Figure 2: Near-infrared spectrum of ascorbyl palmitate measured by reflectance.

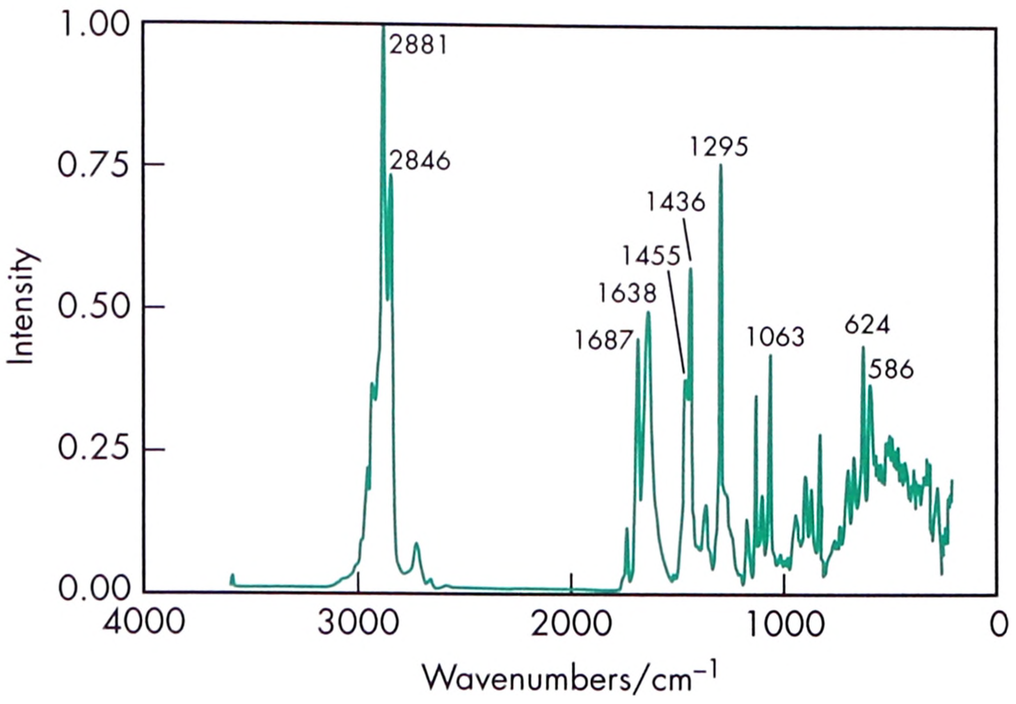

Figure 3: Raman spectrum of ascorbyl palmitate measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

11 Stability and Storage Conditions

Ascorbyl palmitate is stable in the dry state, but is gradually oxidized and becomes discolored when exposed to light and high humidity. It has a shelf life of at least 12 months when stored in a sealed container in a cool place (8–15°C) and protected from light. During processing, temperatures greater than 65°C should be avoided.

12 Incompatibilities

Incompatibilities are known with oxidizing agents; e.g. in solution oxidation is catalyzed by trace metal ions such as Cu^{2+} and Fe^{3+}.

13 Method of Manufacture

Ascorbyl palmitate is prepared synthetically by the reaction of ascorbic acid with sulfuric acid followed by reesterification with palmitic acid. Enzymatic catalysis is used to increase the production yield at lower cost.[2]

14 Safety

Ascorbyl palmitate is used in oral pharmaceutical formulations and food products, and is generally regarded as an essentially nontoxic and nonirritant material. The WHO has set an estimated acceptable daily intake for ascorbyl palmitate at up to 1.25 mg/kg bodyweight.[3]

LD_{50} (mouse, oral): 25 g/kg[4]

LD_{50} (rat, oral): 10 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Ascorbyl palmitate dust may cause irritation to the eyes and respiratory tract. Eye protection is recommended.

16 Regulatory Status

GRAS listed. Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (oral, rectal, topical preparations). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Ascorbic acid; sodium ascorbate.

18 Comments

In order to maximize the stability and efficacy of ascorbyl palmitate the following precautions are recommended: stainless steel, enamel, or glass should be used; deaeration (vacuum) procedures and inert gas treatment are recommended where feasible; protect from light and radiant energy.

The potential of ascorbyl palmitate-cholesterol vesicles (Aspasomes) as a novel drug delivery platform has been investigated.[5,6]

A specification for ascorbyl palmitate is contained in the *Food Chemicals Codex* (FCC)[7] and the *Japanese Pharmaceutical Excipients* (JPE).[8]

The EINECS number for ascorbyl palmitate is 205-305-4. The PubChem Compound ID (CID) for ascorbyl palmitate is 5282566.

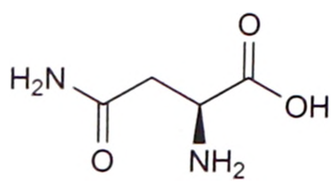
A Asparagine

1 Nonproprietary Names

BP: Asparagine Monohydrate
PhEur: Asparagine Monohydrate
USP-NF: Asparagine

2 Synonyms

Agedoite; altheine; (*S*)-2-aminosuccinic acid 4-amide; Asn; L-asparagine; (*S*)-asparagine; asparamide; aspartamic acid; L-aspartic acid 4-amide; L-aspartic acid β-amide; (2*S*)-2,4-diamino-4-oxobutanoic acid monohydrate.



3 Chemical Name and CAS Registry Number

L-α-Aminosuccinamic acid [70-47-3]
L-α-Aminosuccinamic acid monohydrate [5794-13-8]

4 Empirical Formula and Molecular Weight

$C_4H_8N_2O_3$ (anhydrous)	132.12
$C_4H_8N_2O_3 \cdot H_2O$ (monohydrate)	150.13

5 Structural Formula

6 Functional Category

Buffering agent; dry powder inhaler carrier; lyophilization aid; tablet and capsule disintegrant.

7 Applications in Pharmaceutical Formulation or Technology

Asparagine is used in nutritional supplements, vaccines, and intravesical injections; *see* Section 16. It is an ingredient in the strain growth medium for preparation of freeze-dried attenuated Bacillus Calmette-Guérin formulations.[1] It has been used experimentally as a lyophilization aid or buffering agent for stabilizing peptides,[2] proteins,[3] and antineoplastic agents in pharmaceutical preparations.[4] Asparagine has been investigated as a matrix supporting and disintegration enhancing agent in lyophilized rapid disintegrating tablets at concentrations of 10–70%,[5] and has also been studied in spray-dried disodium cromoglycate inhalation powder formulations at a concentration of 5.1%.[6]

Asparagine is used in the cosmetics industry in hair and skin conditioning products.[7]

8 Description

L-Asparagine occurs as a tasteless[8] white or almost white, crystalline powder or colorless crystals.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for asparagine.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	–
Appearance of solution	+	–
Residue on ignition	–	≤0.1%
Sulfated ash	≤0.1%	–
Lead	–	≤5 ppm
Chlorides	≤200 ppm	–

Ammonium	≤0.1%	–
Iron	≤10 ppm	–
Chromatographic purity	–	+
Ninhydrin-positive substances	+	–
Specific rotation	+ 33.7° to + 36.0°	+33.0° to +36.5°
pH	4.0 to 6.0	–
Microbial Contamination		
Aerobic microbes	–	10^3 cfu/g
Yeasts and molds	–	10^2 cfu/g
Loss on drying		
Anhydrous	–	≤1.0%
Monohydrate	10.5–12.5%	11.5–12.5%
Assay	99.0–101.0%	98.0–101.5%

10 Typical Properties

Dissociation Content
pK_{a1} 2.02;
pK_{a2} 8.80[9]
Melting Point 234–235°C[9]
Partition Coefficient log K_{ow} (octanol : water) = -3.82[10]
Specific Gravity 1.543[9]
Solubility Soluble in acids, alkalis, and in water at 2.94×10^4 mg/L (25°C);[9] practically insoluble in methanol and benzene; insoluble in ethanol and ether.[11]
Vapor pressure 0.64×10^{-8} kPa (4.8×10^{-8} mmHg) at 25°C[9]

11 Stability and Storage Conditions

Exposure to temperatures above 30°C can cause decomposition. Preserve in well-closed, light-resistant containers at room temperature. Avoid moisture, direct sunlight, and contact with acids, bases, and oxidizers.[12]

12 Incompatibilities

Asparagine is incompatible with strong oxidizing agents.

13 Method of Manufacture

Asparagine is a naturally occurring amino acid, widely distributed in both plants and animals.[13] Industrially, it may be isolated from the by-products of potato starch production[14] or chemically synthesized from aspartic acid.[15,16] Direct microbial fermentation from carbohydrates is an alternative method for asparagine production.[17]

14 Safety

Asparagine is used as a food additive and is permitted for direct addition to food for human consumption.[18]

No observed adverse effect level (NOAEL) (rat, oral):

1.65 g/kg/day (males);
1.73 g/kg/day(females).[19]

15 Handling Precautions

Observe normal precautions to the circumstances and quantity of the material handled.

When heated to decomposition asparagine emits toxic fumes of nitrogen oxides.[11]

16 Regulatory Status

Included in parenteral products (suspensions for intravesical installation) licensed in the UK. Included in EAFUS database and parenteral products licensed in the US. Included in parenteral products licensed in Finland. Both asparagine and asparagine monohydrate are included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

D-Asparagine; DL-aspartic acid

D-Asparagine

Empirical Formula $C_4H_8N_2O_3$
Molecular Weight 132.12
CAS number 2058-58-4
Synonyms (*R*)-2-Aminosuccinamic acid; (*R*)-2-aminosuccinic acid 4-amide; D-aspartic acid 4-amide
Melting Point 280°C
Comments The D-form of asparagine has a sweet taste.[8] The EINECS number for D-asparagine is 218-163-3.

DL-Aspartic Acid

Empirical Formula $C_4H_7NO_4$
Molecular Weight 133.10
CAS number 617-45-8
Synonyms DL-Aminosuccinic acid; DL-asparagic acid.
Comments The EINECS number for DL-aspartic acid is 210-513-3. Asparagine is easily converted to aspartic acid by deamination.[9]

18 Comments

Asparagine is a non-essential amino acid, which is used as a nutritional food supplement[20] and in cell culture media.[21] It has also been investigated as a food additive for the prevention of ethanol toxicity.[22,23]

The EINECS number for asparagine is 200-735-9. The PubChem Compound ID (CID) for anhydrous asparagine is 6267, and the CID for asparagine monohydrate is 170358.

3 Chemical Name and CAS Registry Number

N-L-α-Aspartyl-L-phenylalanine 1-methyl ester [22839-47-0]

4 Empirical Formula and Molecular Weight

$C_{14}H_{18}N_2O_5$ 294.30

5 Structural Formula

6 Functional Category

Sweetening agent.

7 Applications in Pharmaceutical Formulation or Technology

Aspartame is used as an intense sweetening agent in beverage products, food products, and table-top sweeteners, and in pharmaceutical preparations including tablets,[1] powder mixes, and vitamin preparations. It enhances flavor systems and can be used to mask some unpleasant taste characteristics; the approximate sweetening power is 180–200 times that of sucrose.

8 Description

Aspartame occurs as an off-white, almost odorless crystalline powder with an intensely sweet taste.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for aspartame.

11 Stability and Storage Conditions

Aspartame is stable in dry conditions. In the presence of moisture, hydrolysis occurs to form the degradation products L -aspartyl-L-phenylalanine and 3-benzyl-6-carboxymethyl-2,5-diketopiperazine with a resulting loss of sweetness. A third-degradation product is also known, β-L-aspartyl-L-phenylalanine methyl ester. For the stability profile at 25°C in aqueous buffers, *see* Figure 4.

Stability in aqueous solutions has been enhanced by the addition of cyclodextrins,[3,4] and by the addition of polyethylene glycol 400

at pH 2.[5] However, at pH 3.5–4.5 stability is not enhanced by the replacement of water with organic solvents.[6]

Aspartame degradation also occurs during prolonged heat treatment; losses of aspartame may be minimized by using processes that employ high temperatures for a short time followed by rapid cooling.

The bulk material should be stored in a well-closed container, in a cool, dry place.

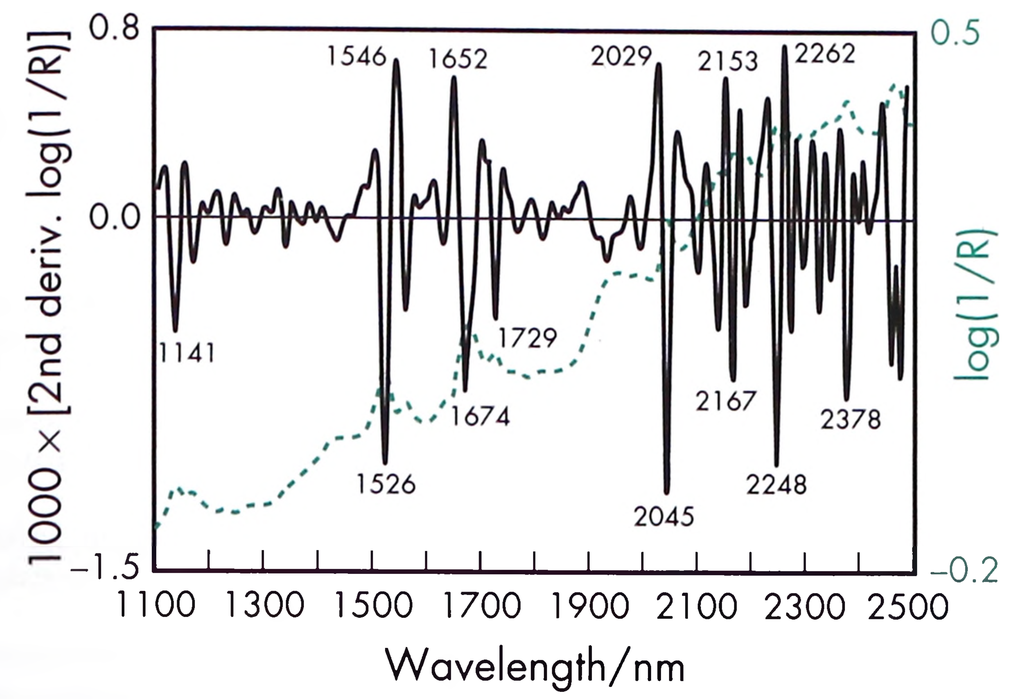

Figure 2: Near-infrared spectrum of aspartame measured by reflectance.

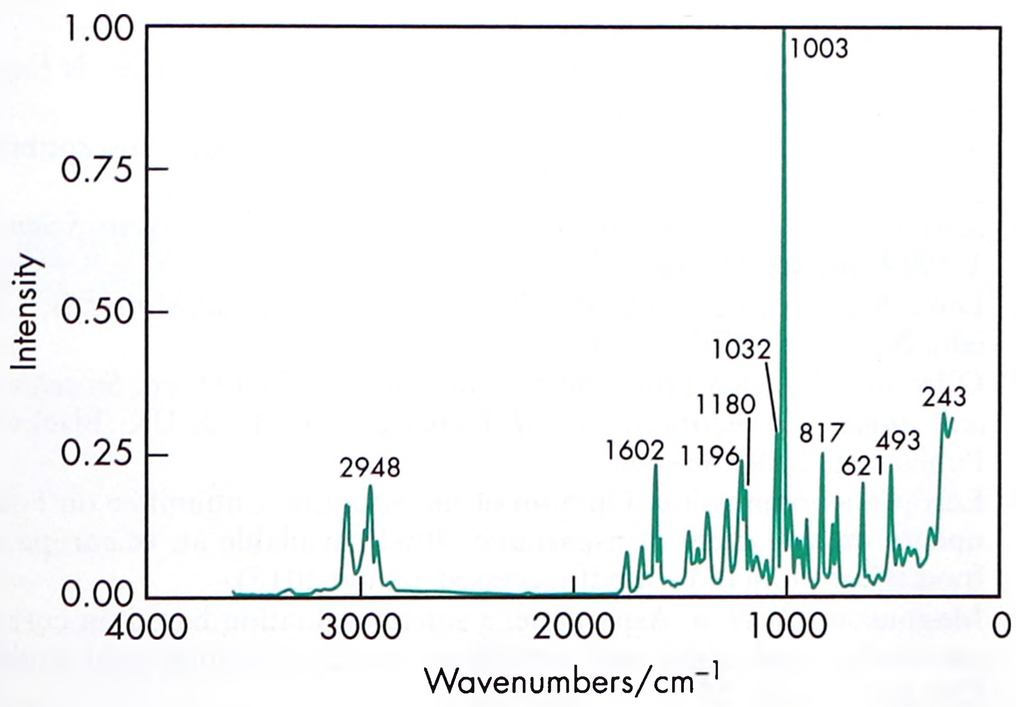

Figure 3: Raman spectrum of aspartame measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

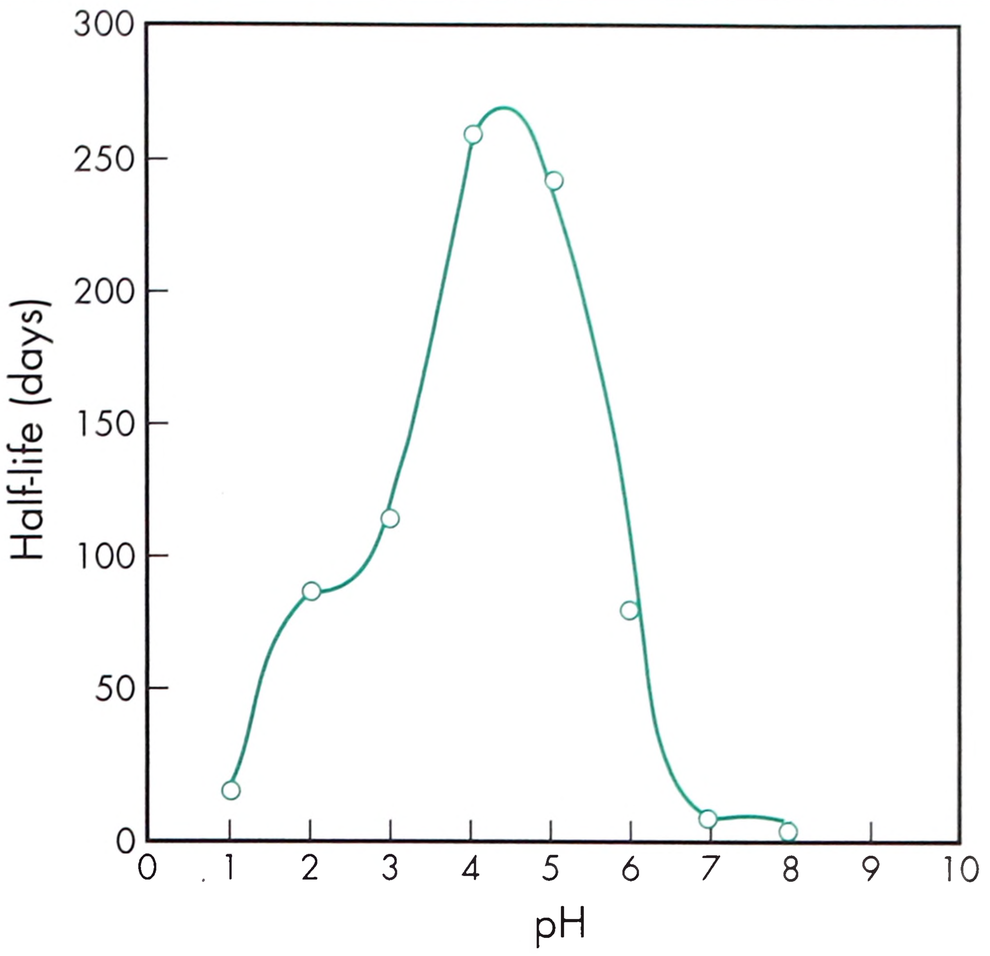

Figure 4: Stability profile of aspartame in aqueous buffers at 25°C.[7]

SEM 1: Excipient: aspartame; magnification: 70×; voltage: 3 kV.

12 Incompatibilities

Differential scanning calorimetry experiments with some directly compressible tablet excipients suggests that aspartame is incompatible with dibasic calcium phosphate and also with the lubricant magnesium stearate.[8] Reactions between aspartame and sugar alcohols are also known.

13 Method of Manufacture

Aspartame is produced by coupling together L-phenylalanine (or L-phenylalanine methyl ester) and L-aspartic acid, either chemically or enzymatically. The former procedure yields both the sweet α-aspartame and nonsweet β-aspartame from which the α-aspartame has to be separated and purified. The enzymatic process yields only α-aspartame.

A

14 Safety

Aspartame is widely used in oral pharmaceutical formulations, beverages, and food products as an intense sweetener, and is generally regarded as a nontoxic material. However, the use of aspartame has been of some concern owing to the formation of the potentially toxic metabolites methanol, aspartic acid, and phenylalanine. Of these materials, only phenylalanine is produced in sufficient quantities, at normal aspartame intake levels, to cause concern. In the normal healthy individual any phenylalanine produced is harmless; however, it is recommended that aspartame be avoided or its intake restricted by those persons with phenylketonuria.[9,10]

The WHO has set an acceptable daily intake for aspartame at up to 40 mg/kg body-weight.[11] Additionally, the acceptable daily intake of diketopiperazine (an impurity found in aspartame) has been set by the WHO at up to 7.5 mg/kg body-weight.[12]

A number of adverse effects have been reported following the consumption of aspartame,[9,12] particularly in individuals who drink large quantities (up to 8 L/day in one case) of aspartame-sweetened beverages. Reported adverse effects include headaches,[13] grand mal seizure,[14] memory loss,[15] gastrointestinal symptoms, and dermatological symptoms.[16] However, scientifically controlled peer-reviewed studies have consistently failed to produce evidence of a causal effect between aspartame consumption and adverse health events.[17,18] Controlled and thorough studies have confirmed aspartame's safety and found no credible link between consumption of aspartame at levels found in the human diet and conditions related to the nervous system and behavior, nor any other symptom or illness. Aspartame is well documented to be nongenotoxic and there is no credible evidence that aspartame is carcinogenic.[19]

Although aspartame has been reported to cause hyperactivity and behavioral problems in children, a double-blind controlled trial of 48 preschool-age children fed diets containing a daily intake of 38 ± 13 mg/kg body-weight of aspartame for 3 weeks showed no adverse effects attributable to aspartame, or dietary sucrose, on children's behavior or cognitive function.[20]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Measures should be taken to minimize the potential for dust explosion. When heated to decomposition it emits toxic fumes of NO_x.[16] Eye protection is recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral powder for reconstitution, granules, syrups, troches, and tablets; buccal and transdermal patches). Included in nonparenteral medicines licensed in the UK. Accepted for use as a food additive in Europe and in the USA. Aspartame is listed as a food additive in the EAFUS list compiled by the FDA. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Alitame; aspartame acesulfame; neotame.

Aspartame acesulfame

Empirical formula $C_{18}H_{23}O_9N_3S$
Molecular weight 457.46
CAS number [106372-55-8]
Comments A compound of aspartame and acesulfame approx. 350 times sweeter than sucrose. Aspartame acesulfame is listed in the USP 40–NF 35 S1.

18 Comments

The intensity of sweeteners relative to sucrose depends upon their concentration, temperature of tasting, and pH, and on the flavor and texture of the product concerned. Unlike some other intense sweeteners, aspartame is metabolized in the body and consequently has some nutritive value: 1 g provides approximately 17 kJ (4 kcal). However, in practice, the small quantity of aspartame consumed provides a minimal nutritive effect.

Intense sweetening agents will not replace the bulk, textural, or preservative characteristics of sugar, if sugar is removed from a formulation.

Synergistic effects for combinations of sweeteners have been reported, e.g. aspartame with acesulfame potassium.

Aspartame can cause browning when used at high temperatures.

A specification for aspartame is contained in the *Food Chemicals Codex* (FCC).[21]

The EINECS number for aspartame is 245-261-3. The PubChem Compound ID (CID) for aspartame includes 2242 and 21462246.

Attapulgite

1 Nonproprietary Names

BP: Attapulgite

2 Synonyms

Actapulgite; *Attaclay*; *Attacote*; *Attagel*; attapulgus; palygorscite; palygorskite; *Pharmasorb Colloidal*; *Pharmasorb Regular*.

3 Chemical Name and CAS Registry Number

Attapulgite [12174-11-7]

4 Empirical Formula and Molecular Weight

$Mg(Al_{0.5-1}Fe_{0-0.5})Si_4O_{10}(OH)\cdot 4H_2O$

5 Structural Formula

See Section 4.

6 Functional Category

Adsorbent; tablet and capsule binder; suspending agent; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Attapulgite is widely used as an adsorbent in solid dosage forms. Colloidal clays, such as attapulgite, absorb considerable amounts of water to form gels and in concentrations of 2–5% w/v usually form oil-in-water emulsions.

Table I: Pharmacopeial specifications for attapulgite.

Test	BP 2017
Identification	+
Characters	+
Acidity or alkalinity (5% w/v aqueous suspension)	7.0–9.5
Adsorptive capacity	5–14%
Arsenic	≤8 ppm
Heavy metals	≤20 ppm
Acid-soluble matter	+
Water-soluble matter	+
Loss on drying	≤17.0%
Loss on ignition	15.0–27.0%

8 Description

Attapulgite occurs as a light cream-colored, very fine powder containing crystalline fibers.[1] Particle size ranges depend on the grade and manufacturer.

9 Pharmacopeial Specifications

See Table I. *See also* Section 17.

10 Typical Properties

Acidity/alkalinity pH = 9.5 (5% w/v aqueous suspension)
Angle of repose 37.2–45.2°[2]
Density 2.2 g/cm^3
Density (tapped) 0.33 g/cm^3 [2]
Flowability 20.9–29.6% (Carr compressibility index)[2]
Particle size distribution

<2 μm in size for powder;
2–5 μm in size for aggregate.[2]

11 Stability and Storage Conditions

Attapulgite can adsorb water. It should be stored in an airtight container in a cool, dry, location.

12 Incompatibilities

Attapulgite may decrease the bioavailability of some drugs such as loperamide[3] and riboflavin.[4] Oxidation of hydrocortisone is increased in the presence of attapulgite.[5]

13 Method of Manufacture

Attapulgite is a purified native hydrated magnesium aluminum silicate that occurs naturally as the mineral palygorskite.

14 Safety

Attapulgite is widely used in pharmaceutical formulations and is generally regarded as an essentially nontoxic and nonirritant material when used as an excipient. It is not absorbed following oral administration. In oral preparations, activated attapulgite up to 9 g is used in daily divided doses as an adjunct in the management of diarrhea.[6] The Cosmetic Ingredient Review (CIR) Expert Panel have assessed attapulgite and concluded that the material is safe as used in cosmetics and personal care products.[1]

The bulk material may be harmful if absorbed into the body by inhalation. The lungs may be affected by repeated or prolonged exposure to fibers, resulting in fibrosis.[7] Attapulgite is suspected to be carcinogenic to humans.[7,8]

A

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

Attapulgite should be handled in a well-ventilated environment and dust generation should be minimized. When heated to decomposition, attapulgite emits acrid smoke and irritating fumes. Eye protection, gloves, and a dust mask are recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral powders). Included in nonparenteral medicines licensed in a number of countries worldwide including the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Activated attapulgite; magnesium aluminum silicate.

Activated attapulgite

Comments Activated attapulgite is a processed native magnesium aluminum silicate that has been carefully heated to increase its adsorptive capacity. Monographs for activated attapulgite are included in the BP 2017, USP 40–NF 35 S1, and other pharmacopeias. The USP 40–NF 35 S1 also includes a monograph for colloidal activated attapulgite. Activated attapulgite is used therapeutically in the management of diarrhea.[6]

18 Comments

Attapulgite is also widely used in industry in paints, building products, oil well drilling mud, agricultural suspensions, catalyst and molecular sieves, fertilizers and pesticides, and is produced in gel and absorbent grades.[9]

The EINECS number for attapulgite is 302-243-0. The PubChem Compound ID (CID) for attapulgite is 56842194.

Bentonite

1 Nonproprietary Names

BP: Bentonite

JP: Bentonite

PhEur: Bentonite

USP–NF: Bentonite

2 Synonyms

Albagel; bentonitum; E558; *Expanda*; mineral soap; *Polargel*; soap clay; taylorite; *Vanatural*; wilkinite.

3 Chemical Name and CAS Registry Number

Bentonite [1302-78-9]

4 Empirical Formula and Molecular Weight

$Al_2O_3 \cdot 4SiO_2 \cdot H_2O$ 359.16

Bentonite is a native colloidal hydrated aluminum silicate consisting mainly of montmorillonite, $Al_2O_3 \cdot 4SiO_2 \cdot H_2O$; it may also contain calcium, magnesium, and iron. The average chemical analysis is expressed as oxides, *see* Table I, in comparison with magnesium aluminum silicate.

Table I: Average chemical analysis of bentonite expressed as oxides in comparison with magnesium aluminum silicate.

	Bentonite	Magnesium aluminum silicate
Silicon dioxide	59.92%	61.1%
Aluminum oxide	19.78%	9.3%
Magnesium oxide	1.53%	13.7%
Ferric oxide	2.96%	0.9%
Calcium oxide	0.64%	2.7%
Sodium oxide	2.06%	2.9%
Potassium oxide	0.57%	0.3%

5 Structural Formula

The PhEur 9.2 describes bentonite as a natural clay containing a high proportion of montmorillonite, a native hydrated aluminum silicate in which some aluminum and silicon atoms may be replaced by other atoms such as magnesium and iron.

The USP 40–NF 35 S1 describes bentonite, purified benonite, and bentonite magma in three separate monographs. Bentonite is described as a native, colloidal, hydrated aluminum silicate; purified bentonite is described as a colloidal montmorillonite that has been processed to remove grit and nonswellable ore compounds; and bentonite magma is a mixture of bentonite and purified water, stirred or blended to form a uniform magma.

See also Section 4.

6 Functional Category

Adsorbent; suspending agent; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Bentonite occurs as a naturally occurring hydrated aluminum silicate used primarily in the formulation of suspensions, gels, and sols, for topical pharmaceutical applications. It is also used to suspend powders in aqueous preparations and to prepare cream bases containing oil-in-water emulsifying agents.

Bentonite may also be used in oral pharmaceutical preparations, cosmetics, and food products, *see* Section 18. In oral preparations, bentonite, and other similar silicate clays, can be used to adsorb cationic drugs and so retard their release.[1–3] Adsorbents are also used to mask the taste of certain drugs. *See* Table II.

Table II: Uses of bentonite.

Use	Concentration (%)
Adsorbent (clarifying agent)	1.0–2.0
Emulsion stabilizer	1.0
Suspending agent	0.5–5.0

8 Description

Bentonite occurs as a crystalline, claylike mineral, and is available as an odorless, pale buff, or cream to grayish-colored fine powder, which is free from grit. It consists of particles about 50–150 μm in size along with numerous particles about 1–2 μm. Microscopic examination of samples stained with alcoholic methylene blue solution reveals strongly stained blue particles. Bentonite may have a slight earthy taste.

9 Pharmacopeial Specifications

See Table III.

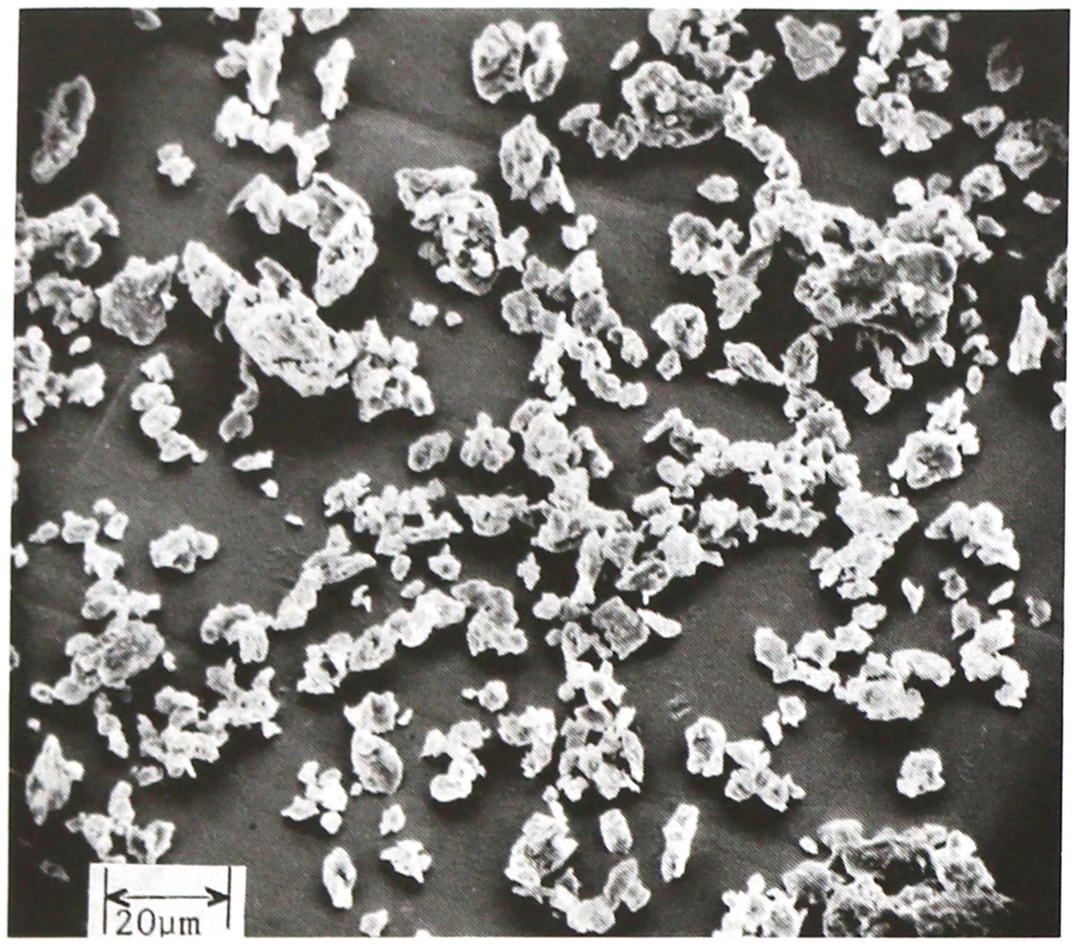
Table III: Pharmacopeial specifications for bentonite.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters	+	+	—
Alkalinity	—	+	—
Microbial limit	—	≤10^3 cfu/g	+
Coarse particles	—	≤0.5%	—
pH (2% w/v suspension)	9.0–10.5	—	9.5–10.5
Loss on drying	5.0–10.0%	≤15%	5.0–8.0%
Arsenic	≤2 ppm	—	≤5 ppm
Lead	—	—	≤40 ppm
Heavy metals	≤50 ppm	—	—
Gel formation	+	—	+
Sedimentation volume	—	≤2 mL	—
Swelling power	≥20 mL	≥22 mL	≥24 mL
Fineness of powder	+	—	+

The USP 40–NF 35 S1 also contains specifications for bentonite magma and purified bentonite. *See* Section 17.

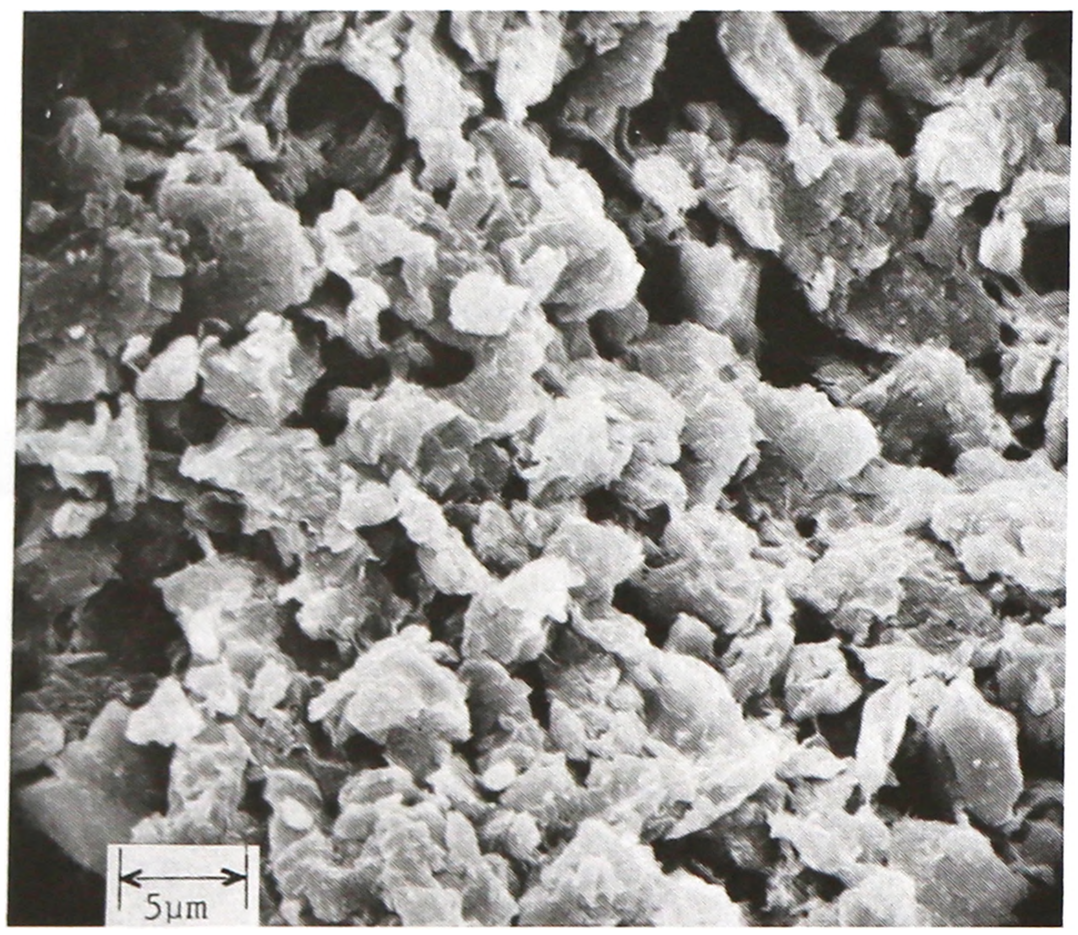
10 Typical Properties

Acidity/alkalinity pH = 9.5–10.5 for a 2% w/v aqueous suspension.



Flowability No flow.

Hygroscopicity Bentonite is hygroscopic.[4] *See also* Figure 1.



Moisture content 5–12%.

Solubility Practically insoluble in ethanol, fixed oils, glycerin, propan-2-ol, and water. Bentonite swells to about 12 times its

SEM 1: Excipient: bentonite; manufacturer: American Colloid Co.; lot no.: NMD 11780; magnification: 600×; voltage: 10 kV.

SEM 2: Excipient: bentonite; manufacturer: American Colloid Co.; lot no.: NMD 11780; magnification: 2400×; voltage: 20 kV.

original volume in water, to form viscous homogeneous suspensions, sols, or gels depending upon the concentration. Bentonite does not swell in organic solvents. Sols and gels may be conveniently prepared by sprinkling the bentonite on the surface of hot water and allowing to stand for 24 hours, stirring occasionally when the bentonite has become thoroughly wetted. Water should not be added to bentonite alone, but bentonite may be satisfactorily dispersed in water if it is first triturated with glycerin or mixed with a powder such as zinc oxide. A 7% w/v aqueous suspension of bentonite is just pourable. *See also* Section 12.

Spectroscopy

NIR spectrum *see* Figure 2.

Viscosity (dynamic) 75–225 mPa s (75–225 cP) for a 5.5% w/v aqueous suspension at 25°C. Viscosity increases with increasing concentration.

11 Stability and Storage Conditions

Bentonite is hygroscopic, and sorption of atmospheric water should be avoided.

Aqueous bentonite suspensions may be sterilized by autoclaving. The solid material may be sterilized by maintaining it at 170°C for 1 hour after drying at 100°C.

Bentonite should be stored in an airtight container in a cool, dry place.

12 Incompatibilities

Aqueous bentonite suspensions retain their viscosity above pH 6, but are precipitated by acids. Acid-washed bentonite does not have suspending properties. The addition of alkaline materials, such as magnesium oxide, increases gel formation.

Addition of significant amounts of alcohol to aqueous preparations will precipitate bentonite, primarily by dehydration of the lattice structure; *see also* Section 18.

Bentonite particles are negatively charged and flocculation occurs when electrolytes or positively charged suspensions are added. Bentonite is thus said to be incompatible with strong electrolytes, although this effect is sometimes used beneficially to clarify turbid liquids.

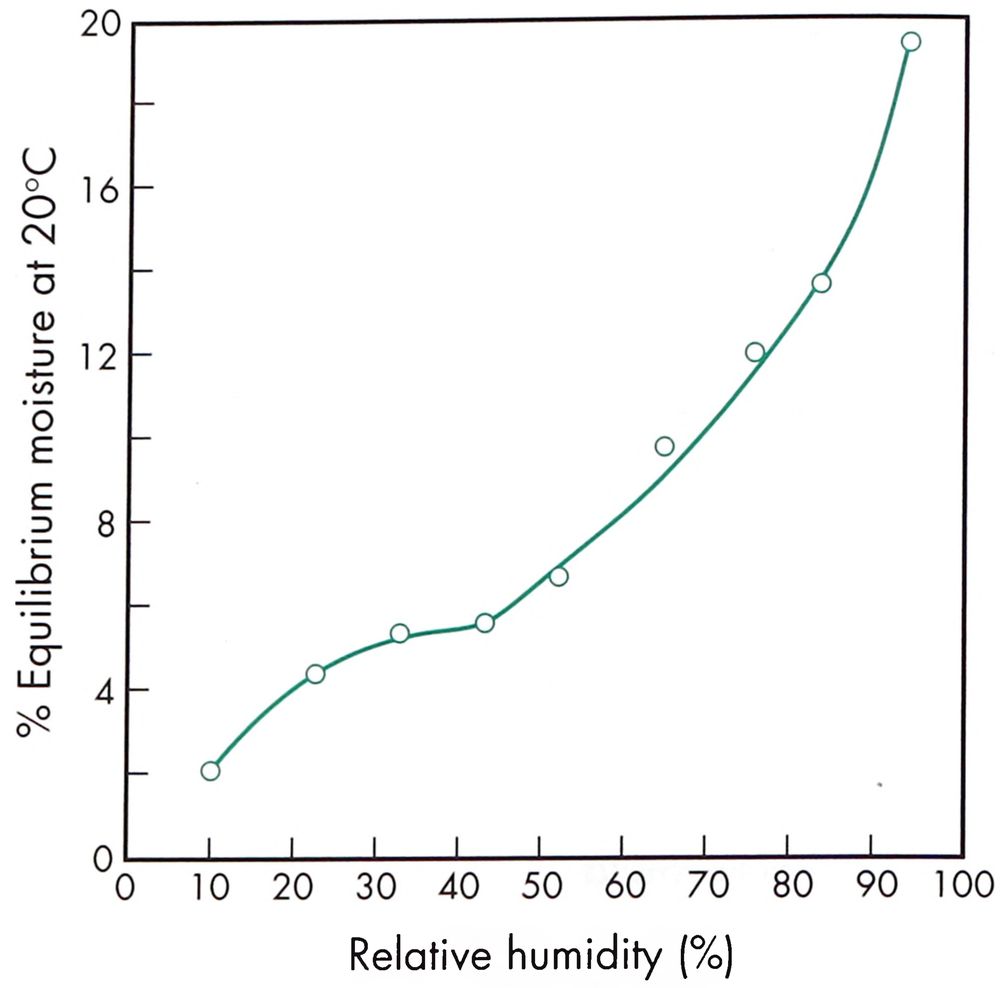


Figure 1: Equilibrium moisture content of bentonite USP–NF.

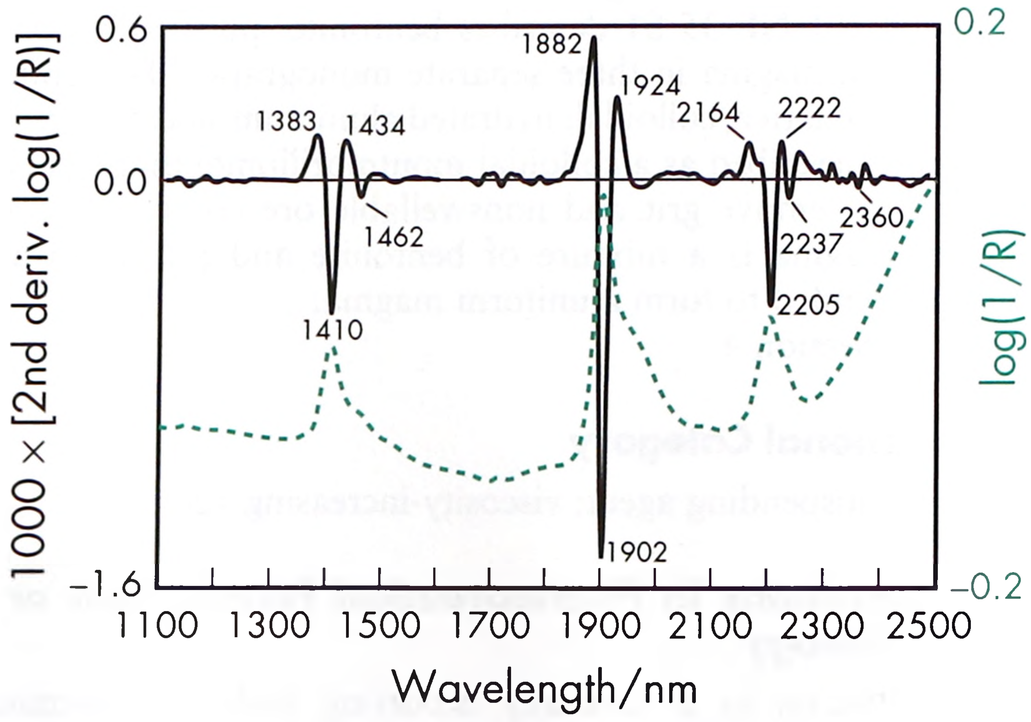

Figure 2: Near-infrared spectrum of bentonite measured by reflectance.

The antimicrobial efficacy of cationic preservatives may be reduced in aqueous bentonite suspensions, but nonionic and anionic preservatives are unaffected.[5]

Bentonite is incompatible with acriflavine hydrochloride.

13 Method of Manufacture

Bentonite is a native, colloidal, hydrated aluminum silicate, found in regions of Canada and the USA. The mined ore is processed to remove grit and nonswelling materials so that it is suitable for pharmaceutical applications.

14 Safety

Bentonite is mainly used in topical pharmaceutical formulations but has also been used in oral pharmaceutical preparations, food products, and cosmetics.

Following oral administration, bentonite is not absorbed from the gastrointestinal tract. Bentonite is generally regarded as a nontoxic and nonirritant material.

LD_{50} (rat, IV): 0.035 g/kg[6]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

Bentonite should be handled in a well-ventilated environment and dust generation minimized. Eye protection, gloves, and a dust mask are recommended.

16 Regulatory Status

Accepted in Europe as a food additive in certain applications. Included in the FDA Inactive Ingredients Database (oral capsules, tablets and suspensions, topical powders, lotions and suspensions; controlled release transdermal films and patches; vaginal suppositories). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Bentonite magma; kaolin; magnesium aluminum silicate; magnesium trisilicate; purified bentonite; talc.

Bentonite magma

Comments A 5% w/w suspension of bentonite in purified water appears in some pharmacopeias, such as the USP 40–NF 35 S1.

Purified bentonite

Acidity/alkalinity pH = 9.0–10.0 for a 5% w/w aqueous suspension.

Viscosity (dynamic) 40–200 mPa s (40–200 cP) for a 5% w/w aqueous suspension.

Comments Specifications for purified bentonite occur in some pharmacopeias such as the USP 40–NF 35 S1. Purified bentonite is bentonite that has been processed to remove grit and nonswellable ore components.

18 Comments

Bentonite may be used with concentrations of up to 30% ethanol or propan-2-ol; 50% glycerin; 30% propylene glycol; or high molecular weight polyethylene glycols.

Bentonite is used in the food industry as a processing aid as a clarifying or filter agent. A specification for bentonite is contained in the *Food Chemicals Codex* (FCC).[7]

Bentonite has been investigated as a diagnostic agent for magnetic resonance imaging.[8]

Therapeutically, bentonite has been investigated as an adsorbent for lithium poisoning.[9]

The EINECS number for bentonite is 215-108-5.

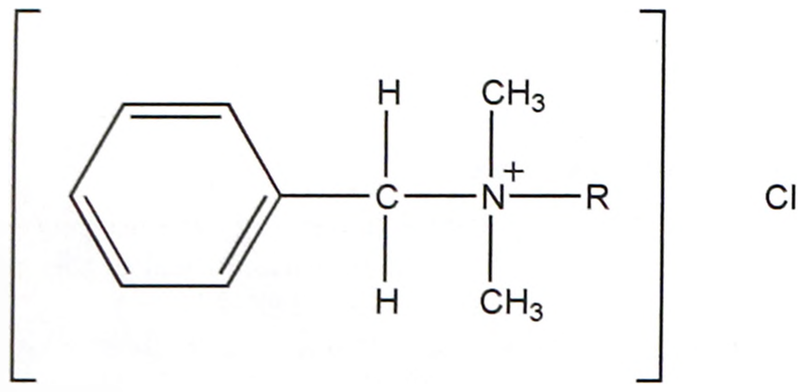
PhEur: Benzalkonium Chloride
USP–NF: Benzalkonium Chloride

2 Synonyms

Alkylbenzyldimethylammonium chloride; alkyl dimethyl benzyl ammonium chloride; benzalkonii chloridum; BKC; *Hyamine 3500*; *Pentonium*; *Zephiran*.

3 Chemical Name and CAS Registry Number



Alkyldimethyl(phenylmethyl)ammonium chloride [8001-54-5]

4 Empirical Formula and Molecular Weight

The USP 40–NF 35 S1 describes benzalkonium chloride as a mixture of alkylbenzyldimethylammonium chlorides of the general formula $[C_6H_5CH_2N(CH_3)_2R]Cl$, where R represents a mixture of alkyls, including all or some of the group beginning with *n*-C_8H_{17} and extending through higher homologs, with *n*-$C_{12}H_{25}$, *n*-$C_{14}H_{29}$, and *n*-$C_{16}H_{33}$ comprising the major portion.

The average molecular weight of benzalkonium chloride is 360.

5 Structural Formula

R = mixture of alkyls: *n*-C_8H_{17} to *n*-$C_{18}H_{37}$; mainly *n*-$C_{12}H_{25}$ (dodecyl), *n*-$C_{14}H_{29}$ (tetradecyl), and *n*-$C_{16}H_{33}$ (hexadecyl).

6 Functional Category

Antimicrobial preservative; cationic surfactant; penetration enhancer; solubilizing agent.

7 Applications in Pharmaceutical Formulation or Technology

Benzalkonium chloride is a quaternary ammonium compound used in pharmaceutical formulations as an antimicrobial preservative in applications similar to other cationic surfactants, such as cetrimide.

In ophthalmic preparations, benzalkonium chloride is one of the most widely used preservatives,[1] at a concentration of 0.01–0.02% w/v. Often it is used in combination with other preservatives or excipients, particularly 0.1% w/v edetate disodium, to enhance its antimicrobial activity against strains of *Pseudomonas*.

In nasal[2] and otic formulations a concentration of 0.002–0.02% w/v is used, sometimes in combination with 0.002–0.005% w/v thimerosal. Benzalkonium chloride 0.01% w/v is also employed as a preservative in small-volume parenteral products.

Benzalkonium chloride is also used in topical preparations, and has been shown to enhance the topical penetration of lorazepam[3] and olanzapine.[4]

Benzalkonium chloride is additionally used as a preservative in cosmetics.

8 Description

Benzalkonium chloride occurs as a white or yellowish-white amorphous powder, a thick gel, or gelatinous flakes. It is hygroscopic, soapy to the touch, and has a mild aromatic odor and very bitter taste.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for benzalkonium chloride.

10 Typical Properties

Acidity/alkalinity pH = 5–8 for a 10% w/v aqueous solution.

Antimicrobial activity Benzalkonium chloride solutions are active against a wide range of bacteria, yeasts, and fungi. Activity is more marked against Gram-positive than Gram-negative bacteria and minimal against bacterial endospores and acid-fast bacteria, *see* Table II. The antimicrobial activity of benzalkonium chloride is significantly dependent upon the alkyl composition of the homolog mixture.[5] Benzalkonium chloride is ineffective against some *Pseudomonas aeruginosa* strains, *Mycobacterium tuberculosis*, *Trichophyton interdigitale*, and *T. rubrum*. However, combined with edetate disodium (0.01–0.1% w/v), benzyl alcohol, phenylethanol, or phenylpropanol, the activity against *Pseudomonas aeruginosa* is

increased.[6] Antimicrobial activity may also be enhanced by the addition of phenylmercuric acetate, phenylmercuric borate, chlorhexidine, cetrimide, or *m*-cresol.[7,8] In the presence of citrate and phosphate buffers (but not borate), activity against *Pseudomonas* can be reduced. *See also* Sections 11 and 12. Benzalkonium chloride is relatively inactive against spores and molds, but is active against some viruses, including HIV.[9] Inhibitory activity increases with pH, although antimicrobial activity occurs at pH 4–10.

Table II: Minimum inhibitory concentrations (MICs) of benzalkonium chloride.

Microorganism	MIC (μg/mL)
Aerobacter aerogenes	64
Clostridium histolyticum	5
Clostridium oedematiens	5
Clostridium tetani	5
Clostridium welchii	5
Escherichia coli	16
Pneumococcus II	5
Proteus vulgaris	64
Pseudomonas aeruginosa	30
Salmonella enteritidis	30
Salmonella paratyphi	16
Salmonella typhosa	4
Shigella dysenteriae	2
Staphylococcus aureus	1.25
Streptococcus pyrogenes	1.25
Vibrio cholerae	2

Density ≈0.98 g/cm^3 at 20°C

Melting point 34–37°C

Partition coefficients The octanol : water partition coefficient varies with the alkyl chain length of the homolog: 9.98 for C_{12}, 32.9 for C_{14}, and 82.5 for C_{16}.

Solubility Practically insoluble in ether; very soluble in acetone, ethanol (95%), methanol, propanol, and water. Aqueous solutions of benzalkonium chloride foam when shaken, have a low surface tension, and possess detergent and emulsifying properties.

Spectroscopy

IR spectrum *see* Figure 1.

NIR spectrum *see* Figure 2.

Raman spectrum *see* Figure 3.

11 Stability and Storage Conditions

Benzalkonium chloride is hygroscopic and may be affected by light, air, and metals.

Solutions are stable over a wide pH and temperature range and may be sterilized by autoclaving without loss of effectiveness. Solutions may be stored for prolonged periods at room temperature. Dilute solutions stored in polyvinyl chloride or polyurethane foam containers may lose antimicrobial activity.

The bulk material should be stored in an airtight container, protected from light and contact with metals, in a cool, dry place.

12 Incompatibilities

Incompatible with aluminum, anionic surfactants, citrates, cotton, fluorescein, hydrogen peroxide, hypromellose,[10] iodides, kaolin, lanolin, nitrates, nonionic surfactants in high concentration, permanganates, protein, salicylates, silver salts, soaps, sulfonamides, tartrates, zinc oxide, zinc sulfate, some rubber mixes, and some plastic mixes.

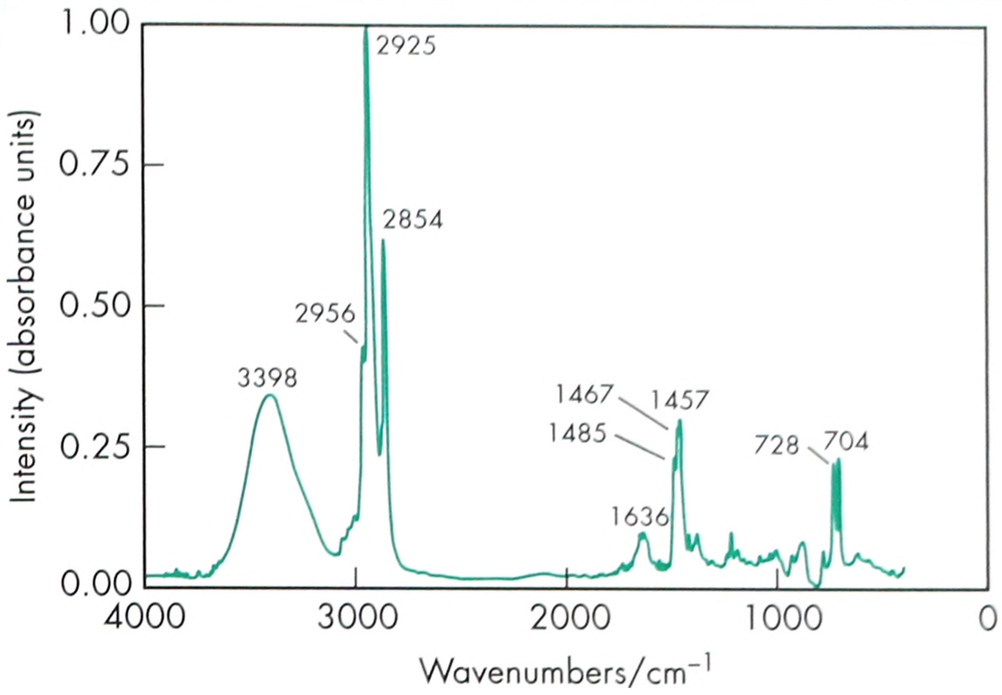

Figure 1: Infrared spectrum of benzalkonium chloride measured by transmission. Adapted with permission of Informa Healthcare.

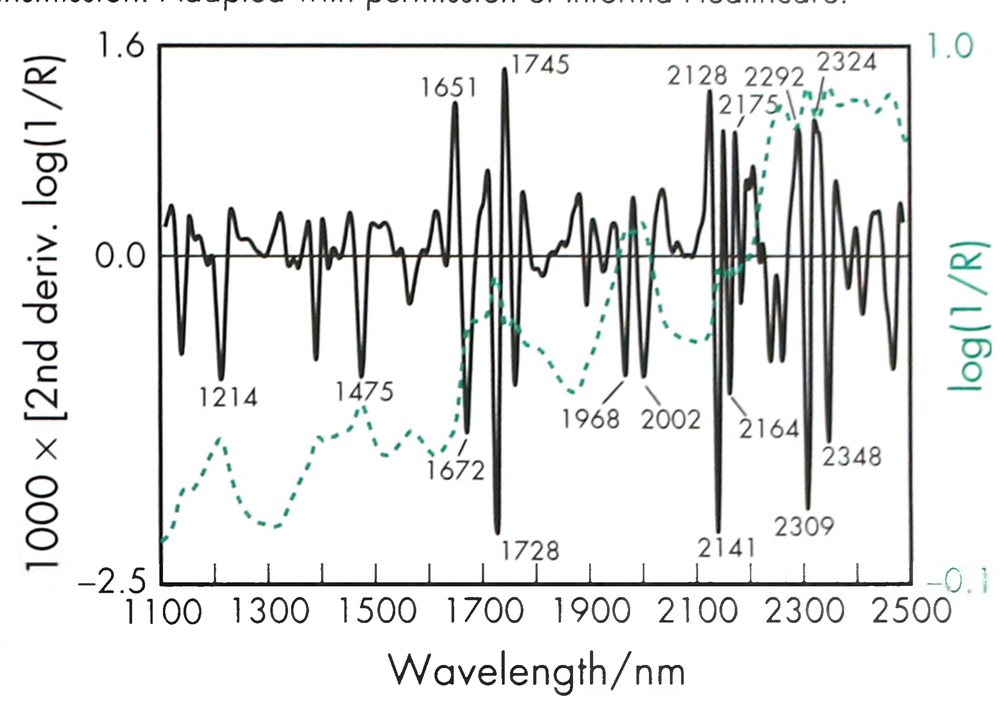

Figure 2: Near-infrared spectrum of benzalkonium chloride measured by reflectance.

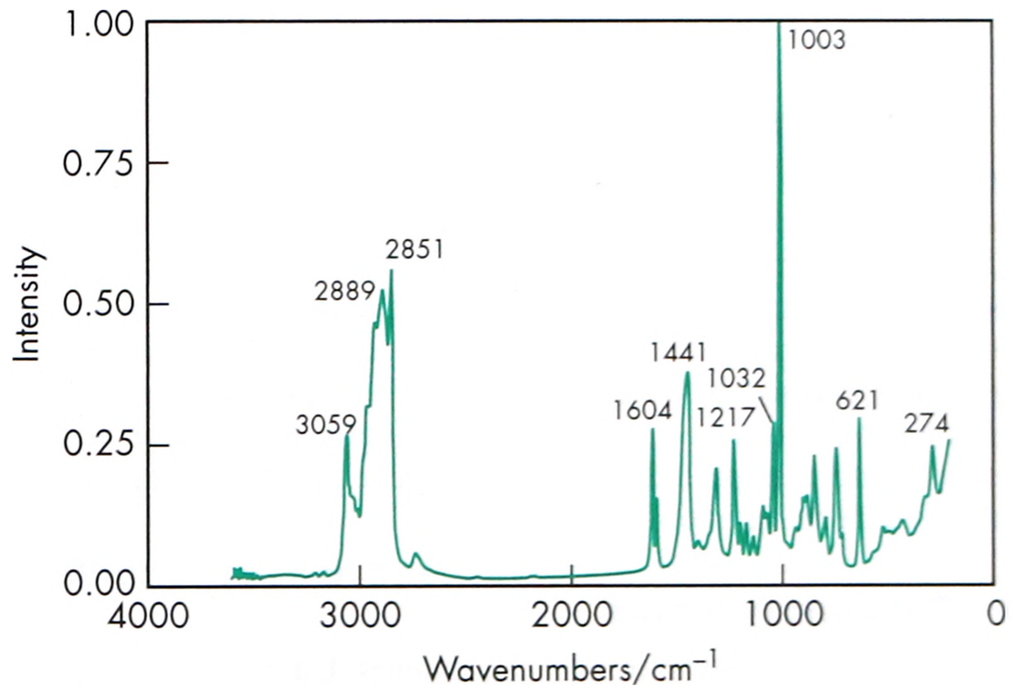

Figure 3: Raman spectrum of benzalkonium chloride measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

Benzalkonium chloride has been shown to be adsorbed by various filtering membranes, especially those that are hydrophobic or anionic.[11]

13 Method of Manufacture

Benzalkonium chloride is formed by the reaction of a solution of *N*-alkyl-*N*-methylbenzamine with methyl chloride in an organic solvent suitable for precipitating the quaternary compound as it is formed.

B

14 Safety

Benzalkonium chloride is usually nonirritating, nonsensitizing, and is well tolerated in the dilutions normally employed on the skin and mucous membranes. However, benzalkonium chloride has been associated with adverse effects when used in some pharmaceutical formulations.[12]

Ototoxicity can occur when benzalkonium chloride is applied to the ear[13] and prolonged contact with the skin can occasionally cause irritation and hypersensitivity.[14,15] Benzalkonium chloride is also known to cause bronchoconstriction in some asthmatics when used in nebulizer solutions.[16–18]

Toxicity experiments with rabbits have shown benzalkonium chloride to be harmful to the eye in concentrations higher than that normally used as a preservative. However, the human eye appears to be less affected than the rabbit eye and many ophthalmic products have been formulated with benzalkonium chloride 0.01% w/v as the preservative. Eye formulations containing lower concentrations of benzalkonium chloride (0.001% w/v) have been developed to minimise adverse effects without the loss of preservative efficacy.[19]

Benzalkonium chloride is not suitable for use as a preservative in solutions used for storing and washing hydrophilic soft contact lenses, as the benzalkonium chloride can bind to the lenses and may later produce ocular toxicity when the lenses are worn.[20] Solutions stronger than 0.03% w/v concentration entering the eye require prompt medical attention.

The use of benzalkonium chloride as a preservative in intranasal solutions at concentrations of between 0.00045% and 0.1% in treatments for up to one year has been found to demonstrate no toxic effects.[21]

Local irritation of the throat, esophagus, stomach, and intestine can occur following contact with strong solutions (>0.1% w/v). The fatal oral dose of benzalkonium chloride in humans is estimated to be 1–3 g. Adverse effects following oral ingestion include vomiting, collapse, and coma. Toxic doses lead to paralysis of the respiratory muscles, dyspnea, and cyanosis.

LD_{50} (mouse, oral): 0.15 g/kg[22]

LD_{50} (rat, oral): 0.3 g/kg[22]

LD_{50} (rat, skin): 1.42 g/kg[22]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

Benzalkonium chloride is irritant to the skin and eyes and repeated exposure to the skin may cause hypersensitivity. Concentrated benzalkonium chloride solutions accidentally spilled on the skin may produce corrosive skin lesions with deep necrosis and scarring, and should be washed immediately with water, followed by soap solutions applied freely. Gloves, eye protection, and suitable protective clothing should be worn.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (inhalations, injections, nasal, ophthalmic, otic, and topical preparations). Included in nonparenteral medicines licensed in the UK. It is also included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Benzethonium chloride; cetrimide; cetrimonium bromide.

18 Comments

Preservative-free eye preparations have been developed to reduce exposure to benzalkonium chloride due to its potential adverse effects,[23–25] and alternatives such as polyquaternium-1 have been used.[26]

Benzalkonium chloride has been used in antiseptic wipes and has been shown to produce significantly less stinging or burning than isopropyl alcohol and hydrogen peroxide.[27]

The EINECS numbers for benzalkonium chloride are 264-151-6; 260-080-8; 269-919-4; 270-325-2; 287-089-1. The PubChem Compound ID (CID) for benzalkonium chloride is 3014024.

$C_{27}H_{42}ClNO_2.H_2O$	466.17

5 Structural Formula

6 Functional Category

Antimicrobial preservative; cationic surfactant.

7 Applications in Pharmaceutical Formulation or Technology

Benzethonium chloride is a quaternary ammonium compound used in pharmaceutical formulations as an antimicrobial preservative. Typically, it is used for this purpose in injections, ophthalmic, nasal, and otic preparations at concentrations between 0.01–0.02% w/v. Benzethonium chloride may also be used as a wetting and solubilizing agent, and has been used as a surfactant in hydrogels for modified drug release.[1]

In cosmetics such as deodorants, benzethonium chloride may be used as an antimicrobial preservative in concentrations up to 0.5% w/v.

The physical properties and applications of benzethonium chloride are similar to those of other cationic surfactants such as cetrimide.

8 Description

Benzethonium chloride occurs as a white crystalline material with a mild odor and very bitter taste.

9 Pharmacopeial Specifications

See Table I.

Flash point 43°C (closed cup) for *Hyamine 1622*

Solubility Soluble 1 in less than 1 of acetone, chloroform, ethanol (95%), and water; soluble 1 in 6000 of ether. Dissolves in water to produce a foamy, soapy solution.

Spectroscopy

IR spectrum *see* Figure 1.

NIR spectrum *see* Figure 2.

Raman spectrum *see* Figure 3.

Vapor pressure 0.8 kPa (0.116 psia)

11 Stability and Storage Conditions

Benzethonium chloride is stable. Aqueous solutions may be sterilized by autoclaving.

The bulk material should be stored in an airtight container protected from light, in a cool, dry place.

12 Incompatibilities

Benzethonium chloride is incompatible with soaps and other anionic surfactants and may be precipitated from solutions greater than 2% w/v concentration by the addition of mineral acids and some salt solutions.

13 Method of Manufacture

p-Diisobutylphenol is condensed in the presence of a basic catalyst with β, β'-dichlorodiethyl ether to yield 2-[2-[4-(1,1,3,3-tetramethylbutyl)phenoxy]ethoxy]ethyl chloride. Alkaline dimethylamination then produces the corresponding tertiary amine which, after purification by distillation, is dissolved in a suitable organic solvent and treated with benzyl chloride to precipitate benzethonium chloride.[3]

14 Safety

Benzethonium chloride is readily absorbed and is generally regarded as a toxic substance when administered orally. Ingestion may cause vomiting, collapse, convulsions, and coma. The probable lethal human oral dose is estimated to be 50–500 mg/kg bodyweight.

Benzethonium chloride rarely causes skin sensitization when used as an excipient in topical preparations,[4] although the use of solutions containing greater than 5% w/v may cause irritation.

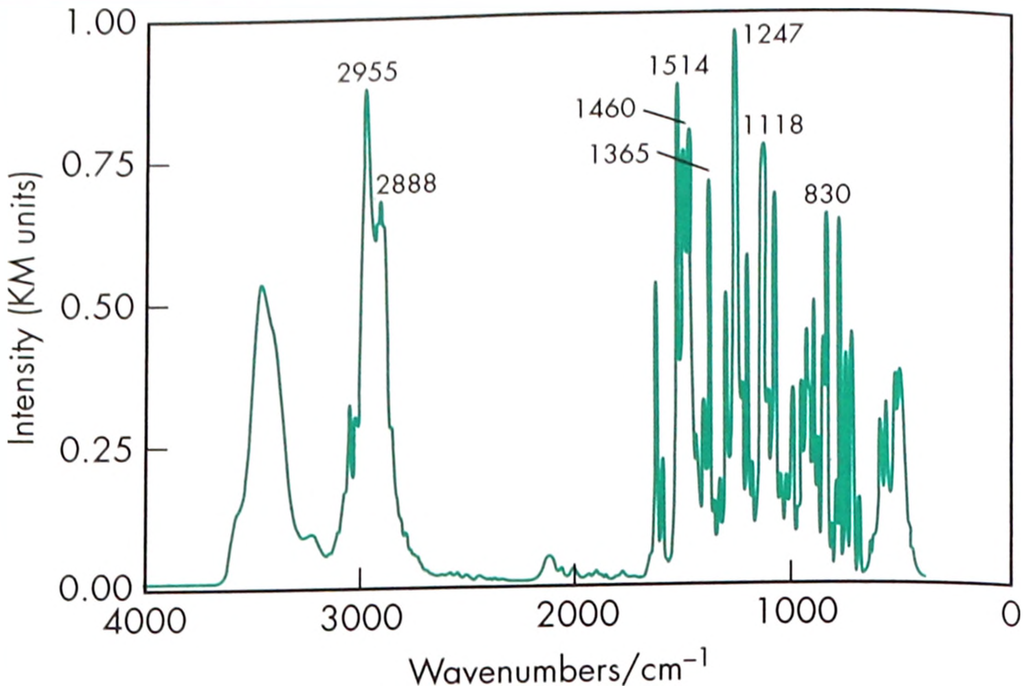

Figure 1: Infrared spectrum of benzethonium chloride measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

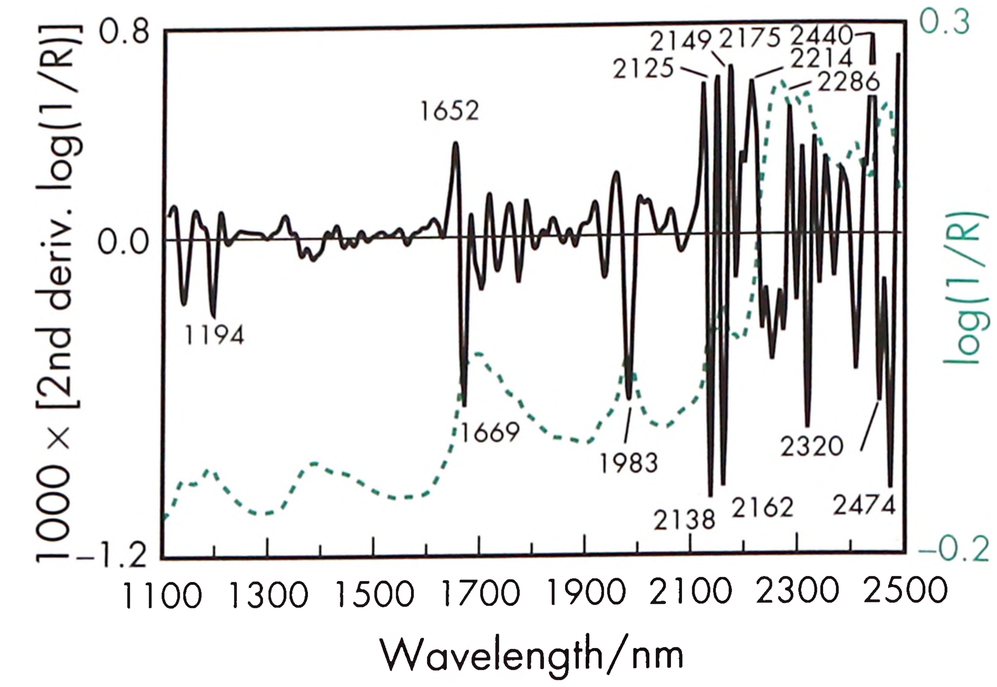

Figure 2: Near-infrared spectrum of benzethonium chloride measured by reflectance.

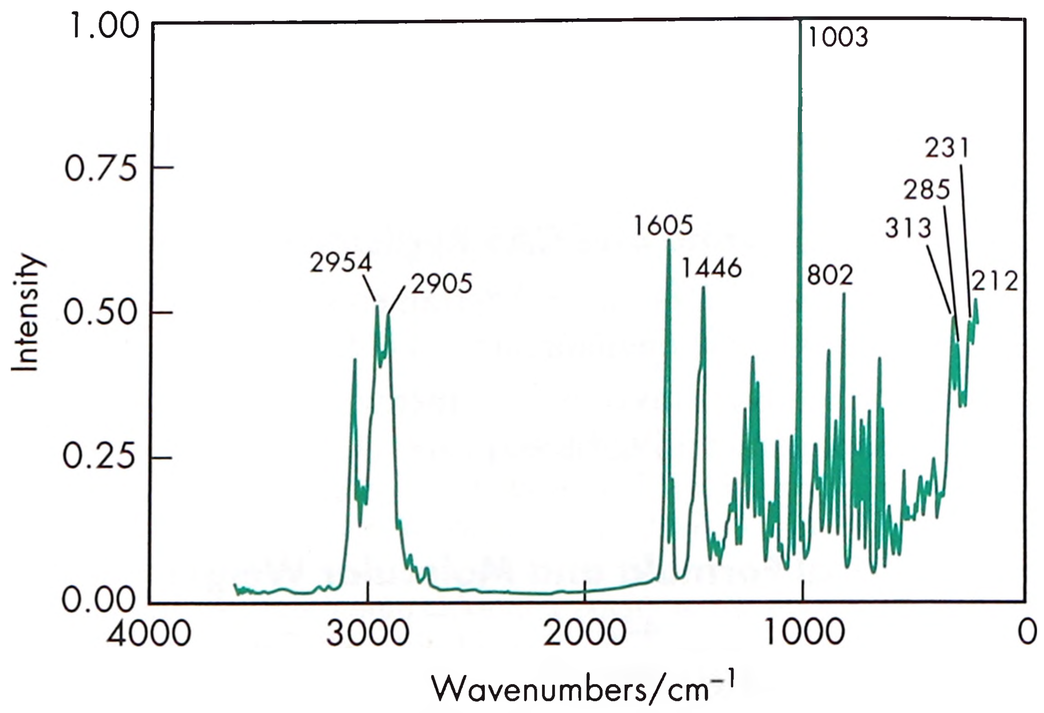

Figure 3: Raman spectrum of benzethonium chloride measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

The use of 0.5% w/v benzethonium chloride in cosmetics is associated with few adverse effects. A maximum concentration of 0.02% w/v benzethonium chloride is recommended for use in cosmetics used in the eye area and this is also the maximum concentration generally used in pharmaceutical formulations such as injections and ophthalmic preparations.[5]

See also Benzalkonium Chloride.

LD_{50} (mouse, IP): 0.015 g/kg[6]

LD_{50} (mouse, IV): 0.03 g/kg

LD_{50} (mouse, oral): 0.338 g/kg
LD_{50} (rat, IP): 0.0165 g/kg
LD_{50} (rat, IV): 0.019 g/kg
LD_{50} (rat, oral): 0.368 g/kg
LD_{50} (rat, SC): 0.119 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Eye protection and gloves are recommended.

Benzethonium chloride is highly flammable and should be kept away from sources of ignition. When heated to decomposition it emits very toxic fumes of hydrogen chloride, ammonia (NH_3), and nitrogen oxides (NO_x). Suitable eye, skin, and respiratory protection are recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (IM and IV injections; nasal, ophthalmic, and otic preparations). Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Benzalkonium chloride; cetrimide; cetrimonium bromide.

18 Comments

Benzethonium chloride has been used therapeutically as a disinfectant and topical anti-infective agent.[7–10] However, its use in these applications has largely been superseded by other more effective antimicrobials and it is now largely used solely as a preservative in a limited number of pharmaceutical and cosmetic formulations.

The EINECS number for benzethonium chloride is 204-479-9. The PubChem Compound ID (CID) for benethonium chloride includes 8478 and 547429.

Benzoic acid [65-85-0]

4 Empirical Formula and Molecular Weight

$C_7H_6O_2$ 122.12

5 Structural Formula

6 Functional Category

Antimicrobial preservative.

7 Applications in Pharmaceutical Formulation or Technology

Benzoic acid is widely used in pharmaceuticals (*see* Table I), as an antimicrobial preservative.[1–3] The greatest antimicrobial activity is seen at pH values between 2.5–4.5; *see* Section 10.

Benzoic acid has been investigated for use in co-crystal formulations for improved physicochemical properties, such as solubility and dissolution rate.[4–6] Benzoic acid spherical agglomerates have been studied for use in direct tabletting.[7]

Table I: Uses of benzoic acid.

Use	Concentration (%)
IM and IV injections	0.17
Oral solutions	0.01–0.1
Oral suspensions	0.1
Oral syrups	0.15
Topical preparations	0.1–0.2
Vaginal preparations	0.1–0.2

8 Description

Benzoic acid occurs as feathery, light, white or colorless crystals or powder. It is essentially tasteless and odorless or with a slight characteristic odor suggestive of benzoin.

9 Pharmacopeial Specifications

See Table II.

10 Typical Properties

Acidity/alkalinity pH = 2.8 (saturated aqueous solution at 25°C)

Antimicrobial activity Only the undissociated acid shows antimicrobial properties; the activity therefore depends on the pH of the medium. Optimum activity occurs at pH values below 4.5; at values above pH 5, benzoic acid is almost inactive.[8] It has been reported that antimicrobial activity is enhanced by the addition of protamine, a basic protein.[9]

Bacteria Moderate bacteriostatic activity against most species of Gram-positive bacteria. Typical MIC is 100 µg/mL. Activity is less, in general, against Gram-negative bacteria. MIC for Gram-negative bacteria may be up to 1600 µg/mL.

Molds Moderate activity. Typical MICs are 400–1000 µg/mL at pH 3; 1000–2000 µg/mL at pH 5.

Spores Inactive against spores.

Yeasts Moderate activity. Typical MIC is 1200 µg/mL. The addition of propylene glycol may enhance the fungistatic activity of benzoic acid.

Autoignition temperature 570°C

Boiling point 249.2°C

Density

1.311 g/cm^3 for solid at 24°C;

1.075 g/cm^3 for liquid at 130°C.

Dissociation constant The dissociation of benzoic acid in mixed solvents is dictated by specific solute–solvent interactions as well as by relative solvent basicity. Increasing the organic solvent fraction favors the free acid form.[10]

pK_a = 4.19 at 25°C;

pK_a = 5.54 in methanol 60%.

Flash point 121–131°C

Melting point 122°C (begins to sublime at 100°C)

Moisture content 0.17–0.42% w/w

Partition coefficients

Benzene : water = 0.0044;[11]

Cyclohexane : water = 0.30;[12]

Octanol : water = 1.87.[13]

Refractive index

n_D^{15} = 1.5397 for solid;

n_D^{132} = 1.504 for liquid.

Solubility Apparent aqueous solubility of benzoic acid may be enhanced by the addition of citric acid or sodium acetate to the solution; *see* Table III.

Table III: Solubility of benzoic acid.

11 Stability and Storage Conditions

Aqueous solutions of benzoic acid may be sterilized by autoclaving or by filtration.

A 0.1% w/v aqueous solution of benzoic acid has been reported to be stable for at least 8 weeks when stored in polyvinyl chloride bottles, at room temperature.[15]

When added to a suspension, benzoic acid dissociates, with the benzoate anion adsorbing onto the suspended drug particles. This

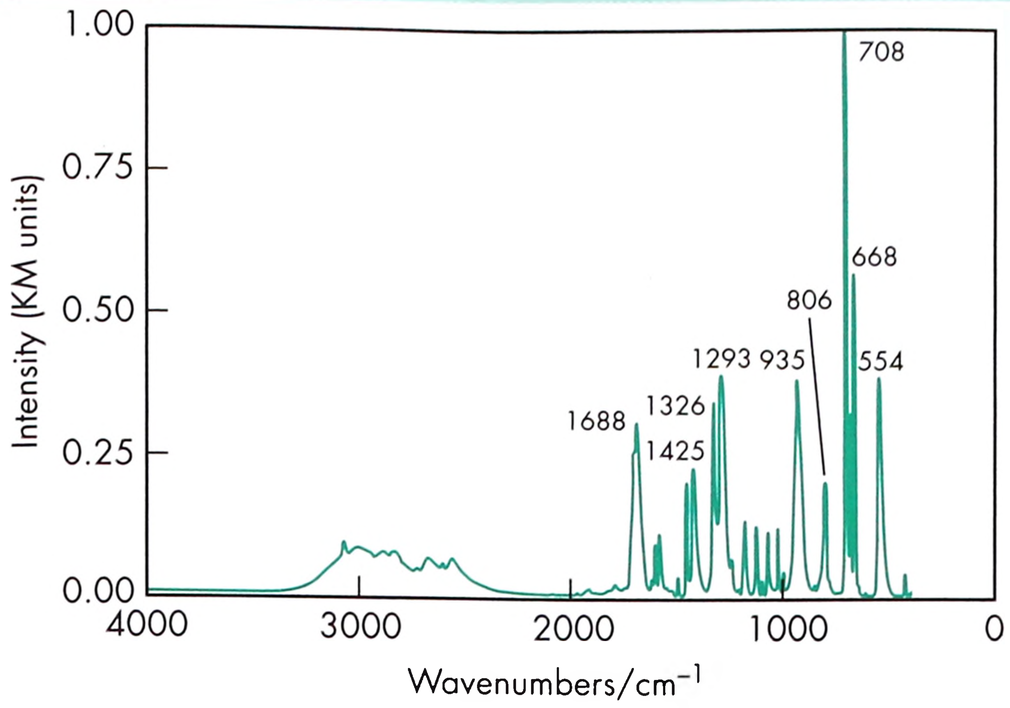

Figure 1: Infrared spectrum of benzoic acid measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

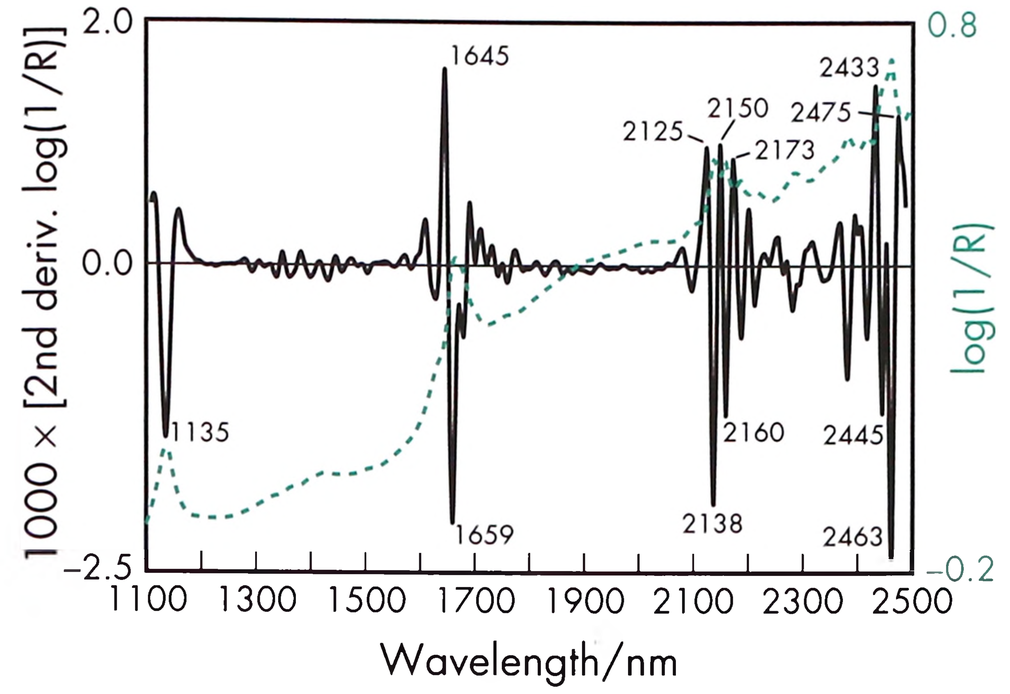

Figure 2: Near-infrared spectrum of benzoic acid measured by reflectance.

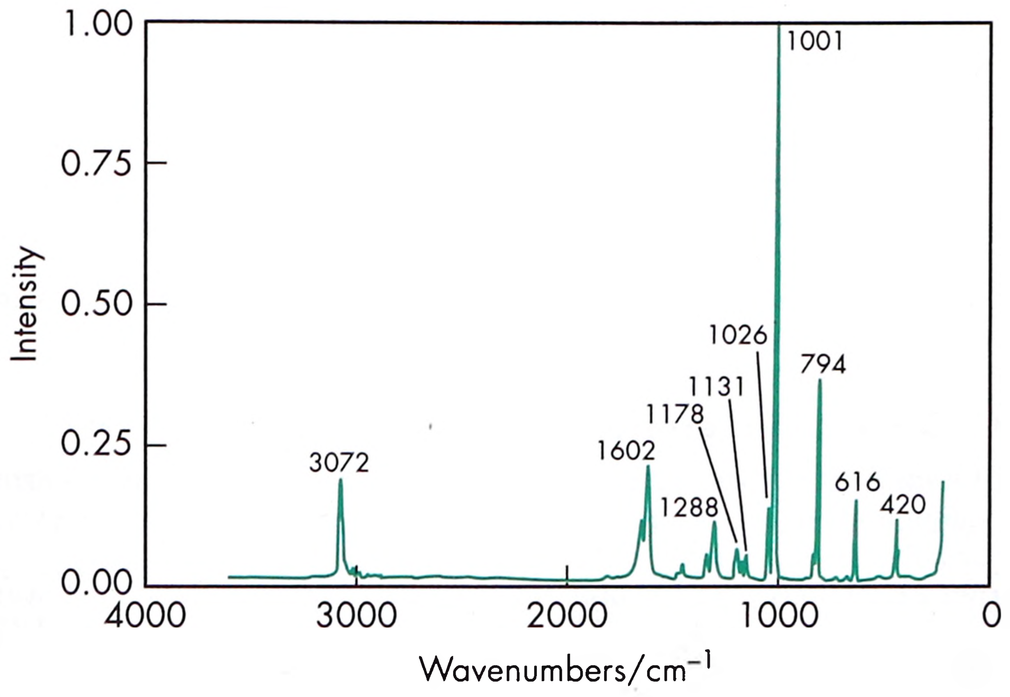

Figure 3: Raman spectrum of benzoic acid measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

adsorption alters the charge at the surface of the particles, which may in turn affect the physical stability of the suspension.[16–18] The addition of sodium azide has been shown to increase the stability of benzoic acid in skin permeation experiments.[19]

The bulk material should be stored in a well-closed container in a cool, dry place.

12 Incompatibilities

Benzoic acid undergoes typical reactions of an organic acid, e.g. with alkalis or heavy metals. Preservative activity may be reduced by interaction with kaolin.[20]

13 Method of Manufacture

Although benzoic acid occurs naturally, it is produced commercially by several synthetic methods. One process involves the continuous liquid-phase oxidation of toluene in the presence of a cobalt catalyst at 150–200°C and 0.5–5.0 MPa (5.0–50.0 atm) pressure to give a yield of approximately 90% benzoic acid.

Benzoic acid can also be produced commercially from benzotrichloride or phthalic anhydride. Benzotrichloride, produced by chlorination of toluene, is reacted with 1 mole of benzoic acid to yield 2 moles of benzoyl chloride. The benzoyl chloride is then converted to 2 moles of benzoic acid by hydrolysis. The yield of benzoic acid is 75–80%.

In another commercial process, phthalic anhydride is converted to benzoic acid, in about an 85% yield, by hydrolysis in the presence of heat and chromium and disodium phthalates.

Crude benzoic acid is purified by sublimation or recrystallization.

14 Safety

Ingested benzoic acid is conjugated with glycine in the liver to yield hippuric acid, which is then excreted in the urine;[21] care should be taken when administering benzoic acid to patients with chronic liver disease.[22] Benzoic acid is a gastric irritant, and a mild irritant to the skin.[23–26] It is also a mild irritant to the eyes and mucous membranes.[27] Allergic reactions to benzoic acid have been reported, although a controlled study indicated that the incidence of urticaria in patients given benzoic acid is no greater than in those given a lactose placebo.[28] It has been reported that asthmatics may become adversely affected by benzoic acid contained in some antiasthma drugs.[29] Benzoic acid may also cause genotoxic effects.[30]

The WHO acceptable daily intake of benzoic acid and other benzoates, calculated as benzoic acid, has been set at up to 5 mg/kg body-weight.[31,32] The minimum lethal human oral dose of benzoic acid is 500 mg/kg body-weight.[33,34]

LD_{50} (cat, oral): 2 g/kg[33]
LD_{50} (dog, oral): 2 g/kg[33]
LD_{50} (mouse, IP): 1.46 g/kg[33]
LD_{50} (mouse, oral): 1.94 g/kg[33]
LD_{50} (rat, oral): 1.7 g/kg[33]

See also Sodium benzoate.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Benzoic acid may be harmful by inhalation, ingestion, or skin absorption and may be irritant to the eyes, skin, and mucous membranes. Benzoic acid should be handled in a well-ventilated environment; eye protection, gloves, and a dust mask or respirator are recommended. Benzoic acid is flammable.

16 Regulatory Status

GRAS listed. Accepted as a food additive in Europe. Included in the FDA Inactive Ingredients Database (IM and IV injections; irrigation solutions; oral solutions, sprays, suspensions, syrups and tablets; rectal, topical, and vaginal preparations). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Health Products Ingredients Database.

B

17 Related Substances

Potassium benzoate; sodium benzoate.

18 Comments

Benzoic acid is also used as an antimicrobial preservative in cosmetics and foods.

Benzoic acid is known to dimerize in many nonpolar solvents. This property, coupled with pH-dependent dissociation in aqueous media, comprises a classic textbook example of the effects of dissociation and molecular association on apparent partitioning behavior. The principles involved may be practically applied in determination of the total concentration of benzoate necessary to provide a bacteriostatic level of benzoic acid in the aqueous phase of an oil-in-water emulsion.

Benzoic acid also has a long history of use as an antifungal agent[35] in topical therapeutic preparations such as Whitfield's ointment (benzoic acid 6% and salicylic acid 3%).

A specification for benzoic acid is contained in the *Food Chemicals Codex* (FCC).[36]

The EINECS number for benzoic acid is 200-618-2. The PubChem Compound ID (CID) for benzoic acid is 243.

Benzyl Alcohol

1 Nonproprietary Names

BP: Benzyl Alcohol

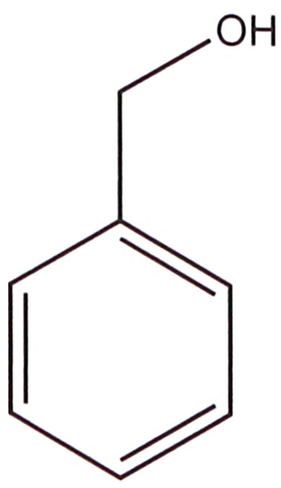
JP: Benzyl Alcohol

PhEur: Benzyl Alcohol

USP–NF: Benzyl Alcohol

2 Synonyms

Alcohol benzylicus; bentanol; benzal alcohol; benzenecarbinol; benzenemethanol; benzoyl alcohol; α-hydroxytoluene; phenolcarbinol; phenylcarbinol; phenylmethanol; phenylmethyl alcohol; α-toluenol.



3 Chemical Name and CAS Registry Number

Benzenemethanol [100-51-6]

4 Empirical Formula and Molecular Weight

C_7H_8O 108.14

5 Structural Formula

6 Functional Category

Antimicrobial preservative; solvent.

7 Applications in Pharmaceutical Formulation or Technology

Benzyl alcohol is an antimicrobial preservative used in a wide range of pharmaceutical formulations,[1–4] including oral and parenteral preparations, at concentrations up to 2.0% v/v. The typical concentration used is 1% v/v, and it has been reported to be used in protein, peptide and small molecule products, although its frequency of use has decreased.[5] Concentrations of 5% v/v or more are employed as a solubilizer, while a 10% v/v solution is used as a disinfectant.

Although widely used as an antimicrobial preservative, benzyl alcohol has been associated with some fatal adverse reactions when administered to neonates. It is now recommended that parenteral products preserved with benzyl alcohol, or other antimicrobial preservatives, should not be used in newborn infants if at all possible; *see* Section 14.

8 Description

A clear, colorless, oily liquid with a faint aromatic odor and a sharp, burning taste.

9 Pharmacopeial Specifications

The pharmacopeial specifications for benzyl alcohol have undergone harmonization of many attributes for JP, PhEur, and USP–NF.

See Table I. *See also* Section 18.

Table I: Pharmacopeial specifications for benzyl alcohol.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification[a]	+	+	+
Characters	+	+	—
Solubility	+	+	—
Acidity	+	+	+
Clarity and color of solution[a]	+	+	+

Benzaldehyde	+	+	0.05–0.15
Peroxide value	≤5	≤5	≤5
Assay	98.0–100.5%	98.0–100.5%	98.0–100.5%

(a) These tests have not been fully harmonized at the time of publication.

10 Typical Properties

Acidity/alkalinity Aqueous solutions are neutral to litmus.

Antimicrobial activity Benzyl alcohol is bacteriostatic and is used as an antimicrobial preservative against Gram-positive bacteria, molds, fungi, and yeasts, although it possesses only modest bactericidal properties. Optimum activity occurs at pH below 5; little activity is shown above pH 8. Antimicrobial activity is reduced in the presence of nonionic surfactants, such as polysorbate 80. However, the reduction in activity is less than is the case with either hydroxybenzoate esters or quaternary ammonium compounds. The activity of benzyl alcohol may also be reduced by incompatibilities with some packaging materials, particularly polyethylene; *see* Section 12.

See Table II for reported minimum inhibitory concentrations (MICs).

Table II: Minimum inhibitory concentrations (MICs) of benzyl alcohol.[4]

Microorganism	MIC (μg/mL)
Aspergillus niger	5000
Candida albicans	2500
Escherichia coli	2000
Pseudomonas aeruginosa	2000
Staphylococcus aureus	25

Bacteria Benzyl alcohol is moderately active against most Gram-positive organisms (typical MICs are 3–5 mg/mL), although some Gram-positive bacteria are very sensitive (MICs 0.025–0.05 mg/mL). In general, benzyl alcohol is less active against Gram-negative organisms.

Fungi Benzyl alcohol is effective against molds and yeasts; typical MICs are 3–5 mg/mL.

Spores Benzyl alcohol is inactive against spores, but activity may be enhanced by heating. Benzyl alcohol 1% v/v, at pH 5–6, has been claimed to be as effective as phenylmercuric

nitrate 0.002% w/v against *Bacillus stearothermophilus* at 100°C for 30 min.

Autoignition temperature 436.5°C

Boiling point 204.7°C

Flammability Flammable. Limits in air 1.7–15.0% v/v.

Flash point

100.6°C (closed cup);

104.5°C (open cup).

Freezing point −15°C

Partition coefficients

Liquid paraffin : water = 0.2;

Octanol : water = 1.10;

Peanut oil : water = 1.3.

Refractive index 1.540

Solubility *see* Table III.

Table III: Solubility of benzyl alcohol.

Solvent	Solubility at 20°C unless otherwise stated
Chloroform	Miscible in all proportions
Ethanol	Miscible in all proportions
Ethanol (50%)	1 in 1.5
Ether	Miscible in all proportions
Fixed and volatile oils	Miscible in all proportions
Water	1 in 25 at 25°C 1 in 14 at 90°C

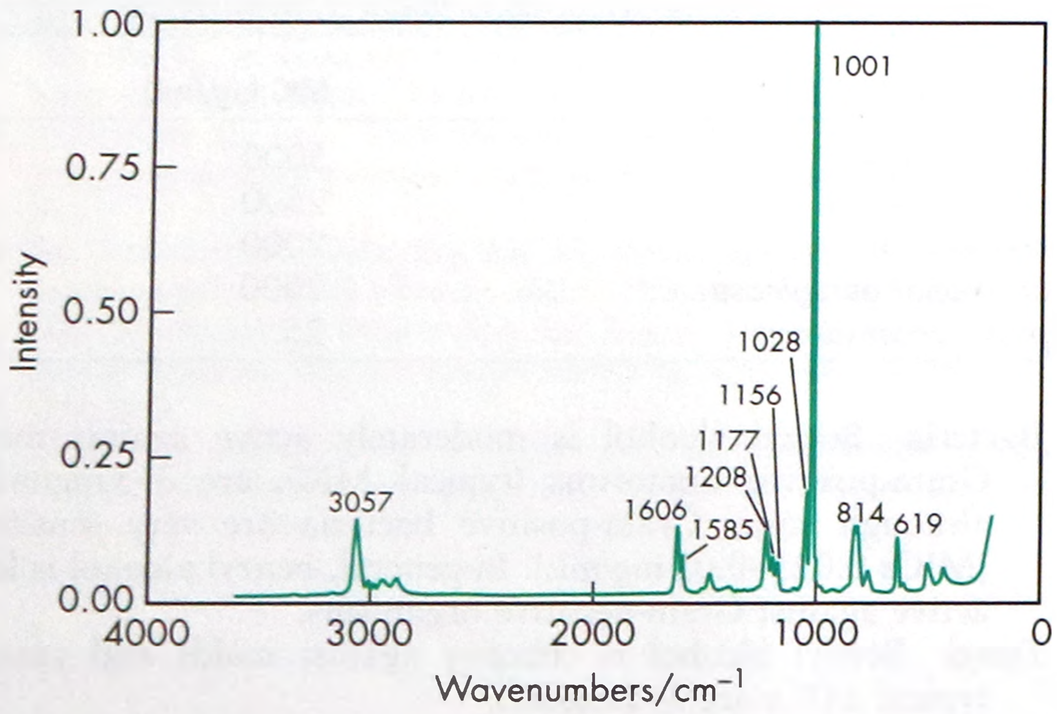

Figure 2: Raman spectrum of benzyl alcohol measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

Spectroscopy

IR spectrum *see* Figure 1.

Raman spectrum *see* Figure 2.

Surface tension 38.8 mN/m (38.8 dynes/cm)

Vapor density (relative) 3.72 (air = 1)

Vapor pressure

13.3 Pa (0.1 mmHg) at 30°C;

1.769 kPa (13.3 mmHg) at 100°C.

Viscosity (dynamic) 6 mPa s (6 cP) at 20°C

11 Stability and Storage Conditions

Benzyl alcohol oxidizes slowly in air to benzaldehyde and benzoic acid; it does not react with water. Aqueous solutions may be sterilized by filtration or autoclaving; some solutions may generate benzaldehyde during autoclaving.

Benzyl alcohol may be stored in metal or glass containers. Plastic containers should not be used; exceptions to this include polypropylene containers or vessels coated with inert fluorinated polymers such as Teflon; *see* Section 12.

Benzyl alcohol should be stored in an airtight container, protected from light, in a cool, dry place.

12 Incompatibilities

Benzyl alcohol is incompatible with oxidizing agents, methylcellulose and strong acids. It can also accelerate the autoxidation of fats.

Although antimicrobial activity is reduced in the presence of nonionic surfactants, such as polysorbate 80, the reduction is less than is the case with hydroxybenzoate esters or quaternary ammonium compounds.

Benzyl alcohol is only slowly sorbed by closures composed of natural rubber, neoprene, and butyl rubber closures, the resistance of which can be enhanced by coating with fluorinated polymers.[6] However, a 2% v/v aqueous solution in a polyethylene container, stored at 20°C, may lose up to 15% of its benzyl alcohol content in 13 weeks.[7] Losses to polyvinyl chloride and polypropylene containers under similar conditions are usually negligible. Benzyl alcohol can damage polystyrene syringes by extracting some soluble components.[8]

13 Method of Manufacture

Benzyl alcohol is prepared commercially by the distillation of benzyl chloride with potassium or sodium carbonate. It may also be prepared by the Cannizzaro reaction of benzaldehyde and potassium hydroxide.

14 Safety

Benzyl alcohol is used in a wide variety of pharmaceutical formulations. It is metabolized to benzoic acid, which is further metabolized in the liver by conjugation with glycine to form hippuric acid, which is excreted in the urine.

Ingestion or inhalation of benzyl alcohol may cause headache, vertigo, nausea, vomiting, and diarrhea. Overexposure may result in CNS depression and respiratory failure. However, the concentrations of benzyl alcohol normally employed as a preservative are not associated with such adverse effects.

Reports of adverse reactions to benzyl alcohol[9,10] used as an excipient include toxicity following intravenous administration;[11–13] neurotoxicity in patients administered benzyl alcohol in intrathecal preparations;[14,15] hypersensitivity,[16–18] although relatively rare; and a fatal toxic syndrome in premature infants.[19–22]

The fatal toxic syndrome in low-birth-weight neonates, which includes symptoms of metabolic acidosis and respiratory depression, was attributed to the use of benzyl alcohol as a preservative in solutions used to flush umbilical catheters. As a result of this, the FDA has recommended that benzyl alcohol should not be used in

such flushing solutions and has advised against the use of medicines containing preservatives in the newborn.[23–25]

Benzyl alcohol has been reported to cause protein aggregation when used as an antimicrobial preservative in multi-dose formulations,[26–28] which can lead to serious immunogenic and toxic side-effects.[28]

The WHO has set the estimated acceptable daily intake of the benzyl/benzoic moiety at up to 5 mg/kg body-weight daily.[29]

LD_{50} (mouse, IV): 0.32 g/kg[30]

LD_{50} (mouse, oral): 1.36 g/kg[30]

LD_{50} (rat, IP): 0.4 g/kg[30]

LD_{50} (rat, IV): 0.05 g/kg[30]

LD_{50} (rat, oral): 1.23 g/kg[30]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Benzyl alcohol (liquid and vapor) is irritant to the skin, eyes, and mucous membranes. Eye protection, gloves, and protective clothing are recommended. Benzyl alcohol should be handled in a well-ventilated environment; a self-contained breathing apparatus is recommended in areas of poor ventilation. Benzyl alcohol is flammable.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (injections; oral capsules, solutions and tablets; dental pastes; otic, ophthalmic, topical, rectal, ureteral and vaginal preparations). Included in parenteral and nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

18 Comments

Benzyl alcohol has undergone harmonization of many attributes for JP, PhEur, and USP–NF by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

Benzyl alcohol is also used as an antimicrobial preservative in cosmetics and foods. In cosmetics, concentrations up to 3.0% v/v may be used as a preservative.

The EINECS number for benzyl alcohol is 202-859-9. The PubChem Compound ID (CID) for benzyl alcohol is 244.

Benzyl alcohol 10% v/v solutions also have some local anesthetic properties, which are exploited in some parenterals, cough products, ophthalmic solutions, ointments, and dermatological aerosol sprays.

A specification for benzyl alcohol is contained in the *Food Chemicals Codex* (FCC).[31]

The EINECS number for benzyl alcohol is 202-859-9. The PubChem Compound ID (CID) for benzyl alcohol is 244.

Benzyl Benzoate

1 Nonproprietary Names

BP: Benzyl Benzoate

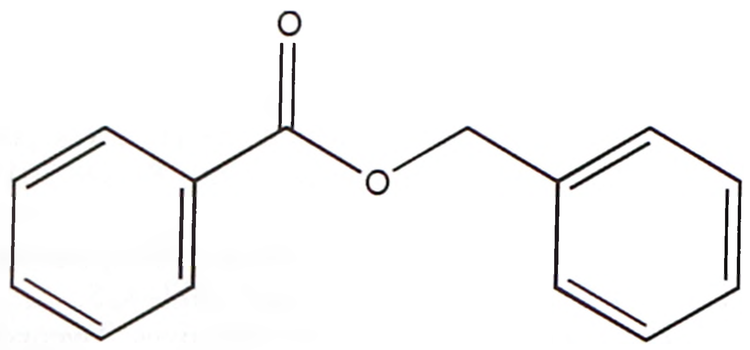
JP: Benzyl Benzoate

PhEur: Benzyl Benzoate

USP–NF: Benzyl Benzoate

2 Synonyms

Benylate; benzoic acid, benzyl ester; benzyl benzene carboxylate; benzylis benzoas; benzyl phenylformate; phenylmethyl benzoate.



3 Chemical Name and CAS Registry Number

Benzoic acid phenylmethyl ester [120-51-4]

4 Empirical Formula and Molecular Weight

$C_{14}H_{12}O_2$ 212.24

5 Structural Formula

6 Functional Category

Antimicrobial preservative; flavoring agent; plasticizing agent; solubilizing agent; solvent.

7 Applications in Pharmaceutical Formulation or Technology

Benzyl benzoate is used as a solubilizing agent and nonaqueous solvent in intramuscular injections at concentrations of 0.01–46.0% v/v,[1] and as a solvent and plasticizer for cellulose acetate and nitrocellulose. It is also used in the preparation of spray-dried powders using nanocapsules.[2,3] Benzyl benzoate is also used in pharmaceutical preparations as a preservative and flavoring agent. It has been investigated for injectable controlled-release formulations functioning as a cosolvent for *in situ* forming implants and gels.[4–6]

8 Description

Benzyl benzoate is a clear, colorless, oily liquid with a slightly aromatic odor. It produces a sharp, burning sensation on the tongue. At temperatures below 17°C it exists as clear, colorless crystals.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for benzyl benzoate.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters	+	+	–
Specific gravity	≈1.123	1.118–1.122	1.116–1.120
Congealing temperature	≈17°C	≥17.0°C	≥18.0°C
Boiling point	≈323°C	≈320°C	–
Refractive index	1.568–1.570	1.568–1.570	1.568–1.570
Aldehyde	–	–	≤0.05%
Acidity	+	+	+
Sulfated ash	≤0.05%	≤0.1%	–
Assay	≥99.0%	99.0–100.5%	99.0–100.5%

10 Typical Properties

Autoignition temperature 481°C

Boiling point 323–324°C

Flash point 148°C

Partition coefficient Octanol : water log k_{ow} = 3.97

Solubility Soluble in acetone and benzene; practically insoluble in glycerin and water; miscible with chloroform, ethanol (96%), methylene chloride, ether, and with fatty acids and essential oils.

Spectroscopy

IR spectrum *see* Figure 1.

Raman spectrum *see* Figure 2.

Vapor density (relative) 7.3 (air = 1)

11 Stability and Storage Conditions

Benzyl benzoate is stable when stored in tight, well-filled, light-resistant containers. Exposure to excessive heat (above 40°C) should be avoided.

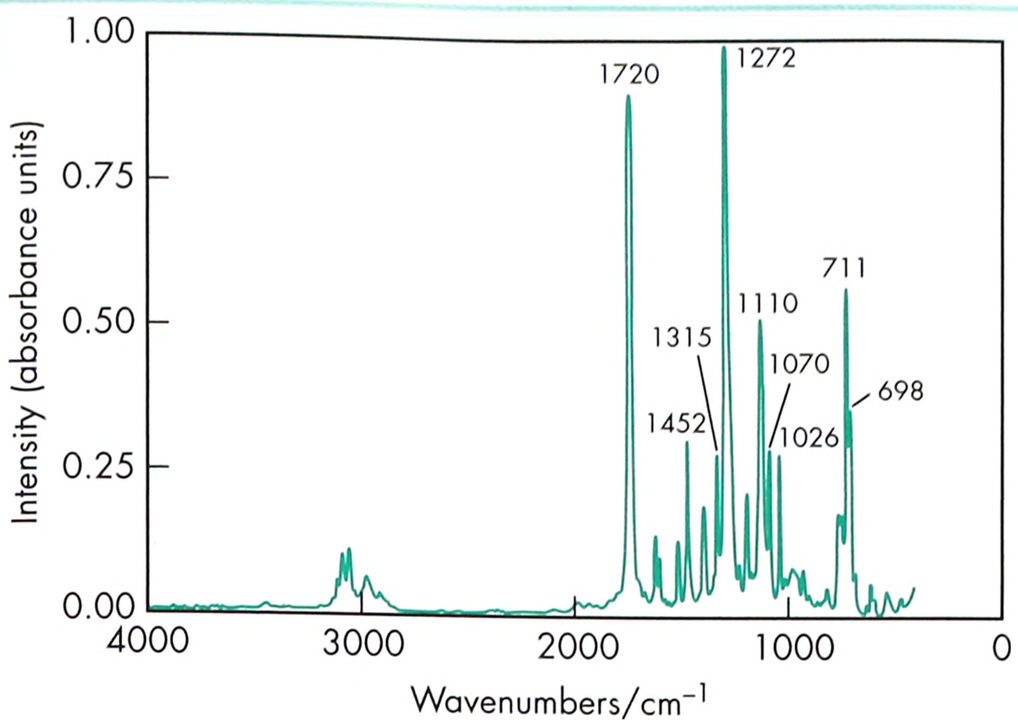


Figure 1: Infrared spectrum of benzyl benzoate measured by transmission. Adapted with permission of Informa Healthcare.

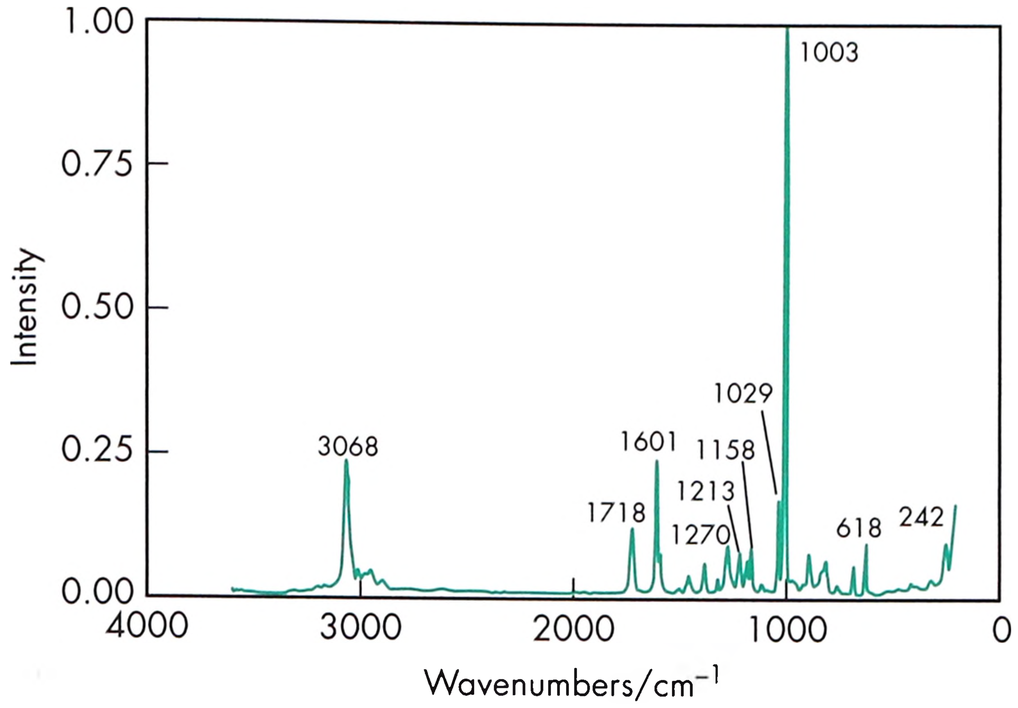

Figure 2: Raman spectrum of benzyl benzoate measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

12 Incompatibilities

Benzyl benzoate is incompatible with alkalis and oxidizing agents.

13 Method of Manufacture

Benzyl benzoate is a constituent of Peru balsam and occurs naturally in certain plant species. Commercially, benzyl benzoate is produced synthetically by the dry esterification of sodium benzoate and benzoyl chloride in the presence of triethylamine or by the reaction of sodium benzylate with benzaldehyde.

14 Safety

Adverse reactions to benzyl benzoate include irritation of the skin, eyes and mucous membranes, and hypersensitivity reactions.[7,8] Benzyl benzoate should be avoided by people with perfume allergy.[9] Oral ingestion may cause harmful stimulation of the CNS and convulsions.[10] It is metabolized by rapid hydrolysis to benzoic acid and benzyl alcohol. Benzyl alcohol is then further metabolized to hippuric acid, which is excreted in the urine.

Benzyl benzoate has been reported as moderately toxic to humans with a probable lethal dose of 0.5–5.0 g/kg.[11]

LD_{50} (cat, oral): 2.24 g/kg[12]
LD_{50} (guinea pig, oral): 1.0 g/kg
LD_{50} (mouse, oral): 1.4 g/kg
LD_{50} (rabbit, oral): 1.68 g/kg
LD_{50} (rabbit, skin): 4.0 g/kg
LD_{50} (rat, oral): 1.7 g/kg
LD_{50} (rat, skin): 4.0 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. When heated to decomposition, benzyl benzoate emits acrid smoke and irritating fumes of carbon oxides. Eye protection, gloves, and a respirator should be worn. It is recommended that benzyl benzoate is handled in a fume cupboard.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (IM injections and oral capsules). Included, as an active ingredient, in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

—

18 Comments

Benzyl benzoate is used as a solvent and fixative for flavors and perfumes in cosmetics and food products.

The most widespread pharmaceutical use of benzyl benzoate is as a topical therapeutic agent in the treatment of scabies (25% v/v), although other treatments are recommended in preference.[13–17] It has also been used as a pediculicide.

Benzyl benzoate has been shown to have an inhibitory effect on angiotensin II-induced hypertension.[18]

Benzyl benzoate is also used as a parasiticide in veterinary medicine.[19] It has been reported that cats are particularly sensitive to benzyl benzoate if applied over too wide an area or too frequently.[20]

A specification for benzyl benzoate is included in the Food Chemicals Codex.[21]

The EINECS number for benzyl benzoate is 204-402-9. The PubChem Compound ID (CID) for benzyl benzoate is 2345.

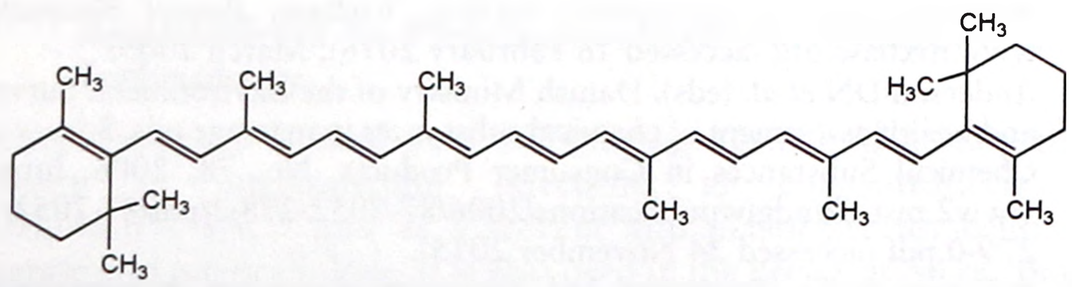
Beta Carotene

1 Nonproprietary Names

BP: Betacarotene
PhEur: Betacarotene
USP–NF: Beta Carotene

2 Synonyms

all-*trans*-β-Carotene; beta-carotene; betacarotenum; β-carotene; β,β-carotene; *Carotaben*; E160a; *Lumitene*; *Provatene*; provitamin A; *Solatene*.



3 Chemical Name and CAS Registry Number

(*all-E*)-1,1′-(3,7,12,16-Tetramethyl-1,3,5,7,9,11,13,15,17-octadecanonaene-1,18-diyl)bis[2,6,6-trimethylcyclohexene] [7235-40-7]

4 Empirical Formula and Molecular Weight

$C_{40}H_{56}$ 536.87

5 Structural Formula

6 Functional Category

Colorant.

7 Applications in Pharmaceutical Formulation or Technology

Beta carotene is used as a colorant in pharmaceutical tablets, capsules, and oral granules and powders for solution. It is capable of producing colors varying from pale yellow to dark orange, and can be used as a color for sugar-coated tablets prepared by the ladle process.

Because of its poor water solubility, beta carotene cannot be used to color clear aqueous systems, and cosolvents such as ethanol must be used.

Suppositories have been successfully colored with beta carotene in approximately 0.1% concentration.

8 Description

Beta carotene is a member of the carotenoids, which are colored fat-soluble compounds naturally present in many fruits, grains, oil, and vegetables. It occurs as red or reddish-brown to violet-brown crystals or crystalline powder, producing red crystals when recrystallized from petroleum ether and deep-purple crystals from benzene and methanol. Beta carotene is also available as micronized crystals suspended in edible oil, such as peanut oil.

9 Pharmacopeial Specifications

See Table I.

10 Typical Properties

Absorption maximum (chloroform) 497, 466 nm
Density 1 g/cm^3 at 20°C[(1)]
Melting point 183°C (evacuated tube)
Solubility Soluble in carbon disulfide, benzene, and 1 in 30 parts of chloroform; moderately soluble in ether, petroleum ether, and oils; very sparingly soluble in methanol and ethanol; practically

Table I: Pharmacopeial specifications for beta carotene.

Test	PhEur 9.2	USP 40–NF 35 S1

Related compounds (including alpha carotene)	–	≤5.0%
Assay (total carotenoids as beta carotene $C_{40}H_{56}$)	96.0–101.0%	96.0–101.0%[a]

(a) Content of all-*trans*-beta carotene in total carotenoids is ≥95.0%.

insoluble in glycerin, acids, and water; 100 mL hexane dissolves 109 mg at 0°C. Beta carotene is less soluble than alpha carotene.

11 Stability and Storage Conditions

Beta carotene is very susceptible to oxidation, and antioxidants such as ascorbic acid, sodium ascorbate, or tocopherols should be added to improve chemical stability. It is also very unstable to light, and therefore, products containing this material should be securely packaged to minimize degradation.

Beta carotene is particularly unstable when used in spray-coating processes, probably owing to atmospheric oxygen attacking the finely dispersed spray droplets.

Store protected from light at a low temperature (–20°C) in containers sealed under nitrogen.

12 Incompatibilities

Beta carotene is generally incompatible with oxidizing agents, which can result in decolorization.

13 Method of Manufacture

All industrial processes for preparing carotenoids are based on β-ionone. Beta carotene can be obtained by total synthesis from acetone and acetylene via dehydrolinalol. The commercially available material is usually 'extended' on a matrix such as acacia or maltodextrin. These extended forms of beta carotene are dispersible in aqueous systems.

Beta carotene can be obtained by fermentation of the fungus *Blakeslea trispora*.[2–4] A process for recovering carotene by solvent extraction of carrots has also been described.[5]

14 Safety

Beta carotene is used in oral pharmaceutical preparations and as a dietary supplement, and is therefore generally recognized as a safe material when used as an excipient.[6,7]

No acute oral toxicity of synthetic beta carotene has been observed at relatively high doses of 5000 mg/kg body weight in rats, and it is not of concern with respect to genotoxicity.[7,8]

High serum beta carotene levels have been associated with a decrease in the incidence of cancer, including lung cancer, in humans.[9] However, increased incidences of lung cancer have occurred in heavy smokers who were receiving long-term beta carotene supplementation,[9] which may have been due to possible growth-promoting effects of beta carotene on lung cancer cells.[10]

According to a rough estimate by the Scientific Committee on Food, intake of beta carotene as an additive is about 1–2 mg/person/day, in addition to an average of 2–5 mg/person/day consumed through natural food sources, with the total intake considered to be 3–7 mg/person/day.[7] Based on these data, it has been concluded that an acceptable daily intake of 0–5 mg/kg body weight, as set by the Joint FAO/WHO Expert Committee on Food Additives (JECFA),[11] is unlikely to be exceeded.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

16 Regulatory Status

GRAS listed. Beta carotene is included in the FDA inactive ingredient database (oral emulsion). Included in nonparenteral medicines licensed in the UK. Beta carotene is listed as a food additive in the EAFUS list compiled by the FDA. Accepted for use as a food additive in Europe. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Coloring agents.

18 Comments

Beta carotene is a carotenoid precursor of vitamin A and is used as a dietary supplement for multivitamin mineral tablets made by direct compression. It is also used as a colorant in foods and cosmetics. Beta carotene is more vitamin A active than the alpha- or gamma-isomeric forms of carotene.

Therapeutically, beta carotene is used to reduce the severity of photosensitivity reactions in patients with erythropoietic protoporphyria.[12] It has also been investigated in a polysorbate-80 nanoparticle drug delivery system for use as an anticonvulsant.[13]

The EINECS number for beta carotene is 230-636-6. The Color Index number for beta carotene is CI 75130 for natural color and CI 40800 for the synthetic color.

Betadex Sulfobutyl Ether Sodium

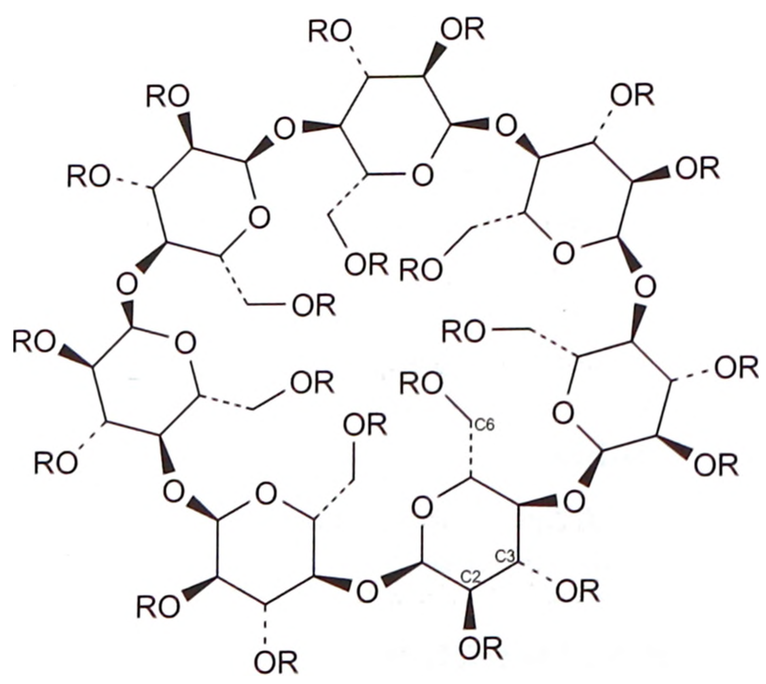
1 Nonproprietary Names

USP–NF: Betadex Sulfobutyl Ether Sodium

2 Synonyms

ADVASEP-7; beta-cyclodextrin sulfobutylethers, sodium salts; *Captisol*; β-cyclodextrin sulfobutylethers, sodium salts; $(SBE)_{7m}$-beta-CD; SBE7-β-CD; SBE-β-CD; SBECD; sodium sulfobutylether β-cyclodextrin; sodium sulfobutylether-beta-cyclodextrin; sulfobutylether β-cyclodextrin; sulfobutylether-β-cyclodextrin, sodium salt; sulfobutylether cycloheptaamylose heptasodium salt.

3 Chemical Name and CAS Registry Number



β-Cyclodextrin sulfobutylether, sodium salt [182410-00-0]

4 Empirical Formula and Molecular Weight

$C_{42}H_{70-n}O_{35}\cdot(C_4H_8SO_3Na)_n$ 2 163 (where n = approximately 6.5)

β-Cyclodextrin is a cyclic oligosaccharide containing seven D-(+)-glucopyranose units attached by α(1→4) glucoside bonds (*see* Cyclodextrins). Betadex sulfobutyl ether sodium is an anionic β-cyclodextrin derivative with a sodium sulfonate salt separated from the hydrophobic cavity by a butyl spacer group. Through a solvent-free, all aqueous process, the substituent is reproducibly introduced at positions 2, 3, and 6 in at least one of the glucopyranose units in the cyclodextrin structure. The process by which the sulfobutylether is introduced into β-cyclodextrin produces materials with different degrees of substitution, theoretically from 1 to 21. Betadex sulfobutyl ether sodium can be isolated with a range in degree of substitution between 6 and 7 and averages 6.5, which provides for the lowest levels for residual β-cyclodextrin and other process impurities while providing for improved complexation and beneficial drug carrier properties.

5 Structural Formula

R = H_{21-n} or $(CH_2CH_2CH_2CH_2SO_2ONa)_n$ where n = 6.2–6.9

Note: the substitution pattern is more or less random, and reproducible by the specific process, yielding a heterogeneous mixture both in terms of the site of substitution as well as degree of substitution. The n value is derived from the average degree of substitution.

6 Functional Category

Antimicrobial preservative; complexing agent; direct compression excipient; modified-release agent; solubilizing agent; tablet and capsule diluent; taste-masking agent; tonicity agent; transdermal delivery component; viscosity-increasing agent.

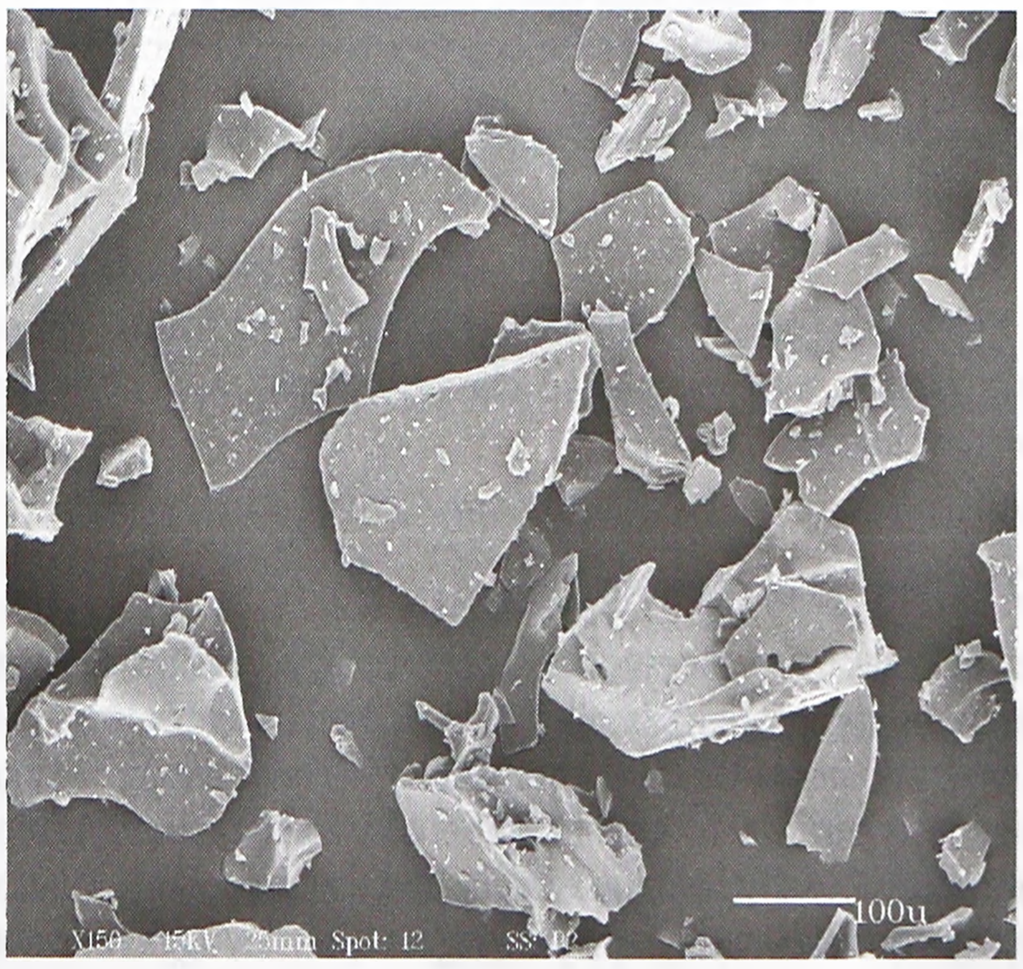
7 Applications in Pharmaceutical Formulation or Technology

Betadex sulfobutyl ether sodium has primarily been used in parenteral drug products as it is one of only a few of the cyclodextrins that are sufficiently safe to be used parenterally, and is therefore used in more parenteral products than any other cyclodextrin.[1] It can form noncovalent host–guest complexes with many types of compounds including small organic molecules,[2] peptides,[3] and proteins.[4] It can also enhance their solubility[5,6] and stability[6–8] in water.

Betadex sulfobutyl ether sodium is also used in a number of other formulations for improved bioavailability and efficient drug

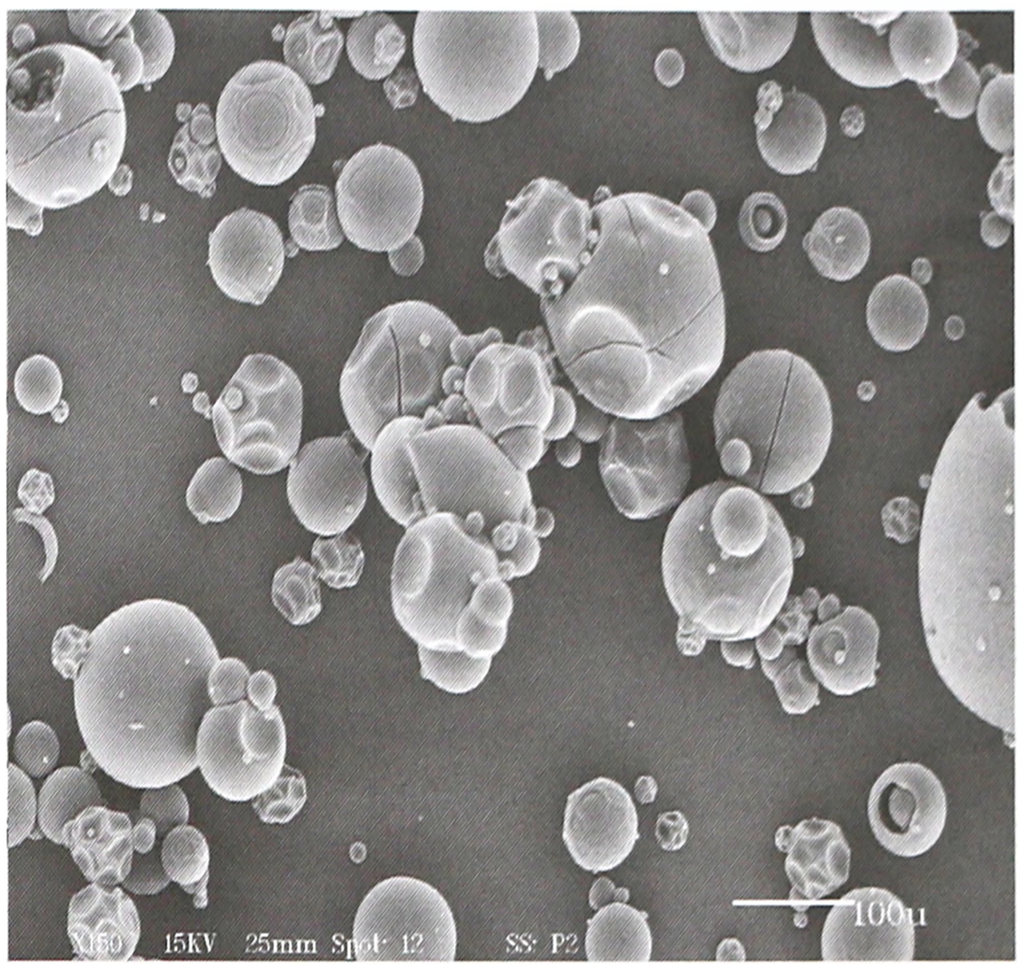
delivery. Formulations include oral solid;[9–11] hot-melt;[12,13] liquid-filled capsules;[14] taste-masked pediatric;[15] orodispersible films[16] or mouth wafers;[17] liquid dosage forms;[18] ophthalmic;[19,20] dermal;[21,22] inhalation;[23,24] and intranasal.[25] Betadex sulfobutyl ether sodium can also function as an osmotic agent and/or a solubilizer for controlled-release delivery,[10] and has antimicrobial preservative properties when present at sufficient concentrations.[26]

Betadex sulfobutyl ether sodium has also been considered for preventing precipitation or sustaining supersaturation as a solubilized drug moves from acidic conditions of the stomach into the neutral pH conditions of the upper gastrointestinal tract, and so mitigate absorption and exposure variability issues.[27,28]



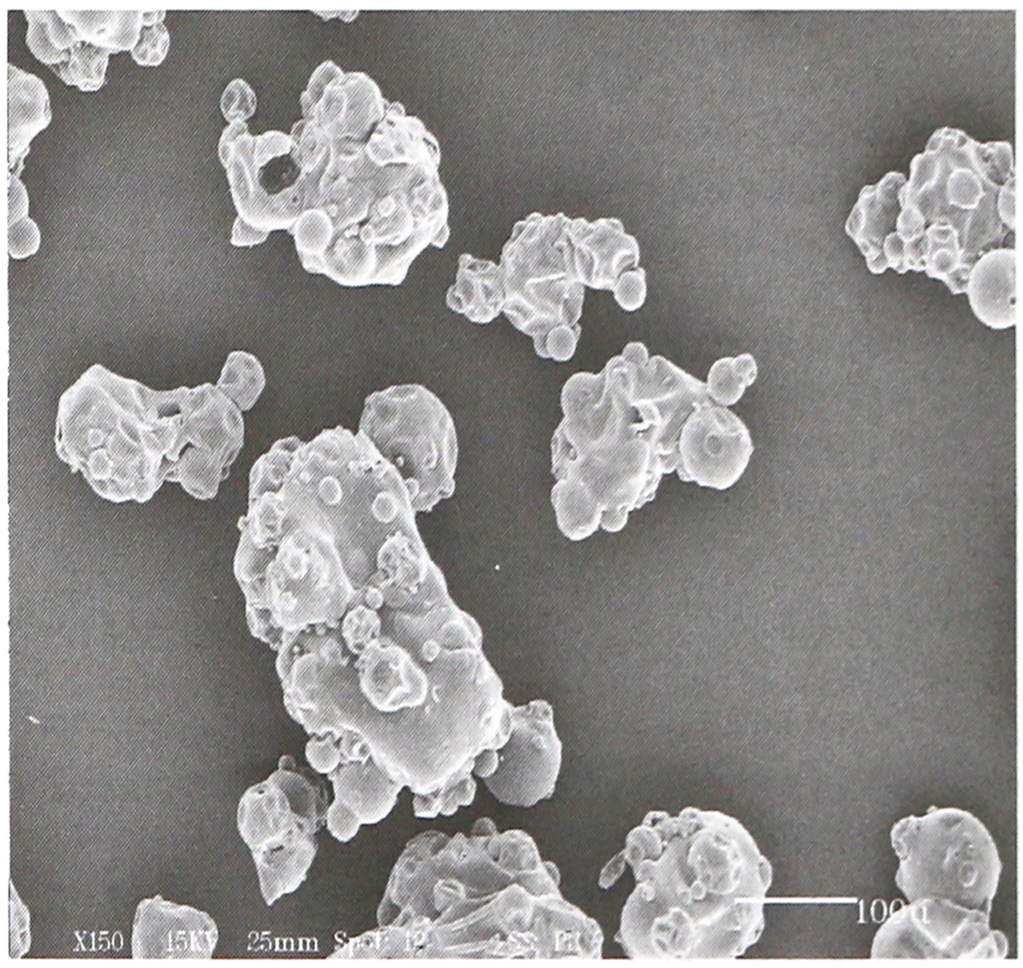
The amount of betadex sulfobutyl ether sodium that may be used is dependent on the purpose for incorporation in the formulation, the route of administration, and the ability of the cyclodextrin to complex with the drug being delivered. The amount required for solubilization is, in general, a cyclodextrin/drug molar ratio of approximately 1–5 (the exact ratio in this range being experimentally determined from complexation data). The maximum amount in a formulation may be limited by physicochemical constraints such as viscosity (e.g. syringeable concentrations may be considered up to 50% w/v), tonicity, or the total weight and size of solid dosage forms (e.g. less than a gram in an individual tablet). It may also be limited by pharmacokinetic/pharmacodynamic (PK/PD) considerations. As dilution of a cyclodextrin formulation leads to an increase in the amount of uncomplexed drug, formulations that are not diluted upon administration, such as ophthalmic formulations, are sensitive to cyclodextrin concentration. In formulations such as these, cyclodextrin concentrations greater than the minimum required for solubilization can reduce the availability of uncomplexed drug and thereby affect PK/PD expectations by producing effects such as slower onset, lower C_{max}, and altering bioavailability.[29]

8 Description



Native cyclodextrins are crystalline, nonhygroscopic, cyclic oligosaccharides derived from starch (*see* Cyclodextrins). Betadex sulfobutyl ether sodium is an amorphous, anionic substituted β-cyclodextrin derivative (*see* Section 8); other substituted cyclodextrin derivatives are also available (*see* Section 17).

Betadex sulfobutyl ether sodium occurs as a white amorphous powder. SEM 3 shows a spray-agglomerated form of the material, which provides better powder flow, ease of incorporation and dissolution, and improved compressibility without further granulation.[30]



SEM 1: Excipient: freeze-dried betadex sulfobutyl ether sodium (*Captisol*); manufacturer: Ligand Pharmaceuticals; magnification: 150×; voltage 15 kV.

SEM 2: Excipient: spray-dried betadex sulfobutyl ether sodium (*Captisol*); manufacturer: Ligand Pharmaceuticals; magnification: 150×; voltage 15 kV.

SEM 3: Excipient: spray-agglomerated betadex sulfobutyl ether sodium (*Captisol*); manufacturer: Ligand Pharmaceuticals; magnification: 150×; voltage 15 kV.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for betadex sulfobutyl ether sodium

Test	USP 40–NF 35 S1
Identification	+
Heavy metals	≤5 ppm
Beta Cyclodextrin	≤0.1%
1,4-Butane Sultone	≤0.5 ppm
Sodium Chloride	≤0.2%
4-Hydroxybutane-1-Sulfonic Acid	≤0.09%
Disodium Bis(4-sulfobutyl) Ether	≤0.05%
Bacterial endotoxins	+
Microbial contamination	+
Aerobic	≤100 cfu/g
Fungi and yeast	≤50 cfu/g
Clarity of solution	+
Average degree of substitution (CE)	6.2–6.9
pH	4.0–6.8
Water	≤10.0%
Assay (anhydrous basis)	95.0%–105.0%

10 Typical Properties

Acidity/alkalinity pH = 4.0–6.8 (30% w/v aqueous solution)[1]

Angle of repose

20.5° for freeze-dried *Captisol*;

31.6° for spray-dried *Captisol*.

Appearance/clarity of solution A 30% w/v solution in water is clear and essentially free from particles of foreign matter.

Average degree of substitution 6.2–6.9[1]

Compressibility *see* Figure 1.

Density (bulk)

0.446–0.482 g/cm^3 for freeze-dried *Captisol*;

0.524 g/cm^3 for spray-dried *Captisol*;

0.482 g/cm^3 for spray-agglomerated *Captisol*.

Density (tapped)

0.565–0.597 g/cm^3 for freeze-dried *Captisol*;

0.624 g/cm^3 for spray-dried *Captisol*;

0.595 g/cm^3 for spray-agglomerated *Captisol*.

Flowability 50 g/s for freeze-dried *Captisol*.

Glass transition temperature –25°C[31]

Hygroscopicity Reversibly picks up water at relative humidities (RH) up to 60%. Equilibration at RH equal to or above 60% will result in deliquescence and a water content of approximately 16% w/w.

See Figure 2.

Melting point 234.5–236°C.

Moisture content 3–6% typically; maximum 10%.

Osmolarity Solutions of *Captisol* in the range 9.5–11.4% w/v are isoosmotic with serum.[1]

Particle size distribution Typical mean particle size for spray-dried betadex sulfobutyl ether sodium is 70–120 µm. Various processing and handling methods may result in different nominal mean particle sizes.

Specific rotation $[\alpha]_D^{20} = +94° \pm 3°$

Solubility Soluble 1 in less than 1 of water; 1 in 30–40 of methanol; practically insoluble in ethanol, *n*-hexane, 1-butanol, acetonitrile, 2-propanol, and ethyl acetate.

Viscosity (dynamic)

1.75 mPa s (1.75 cP) for a 8.5% w/w aqueous solution at 25°C, 1.09 mPa s (1.09 cP) at 60°C;

528 mPa s (528 cP) for a 60% w/w aqueous solution at 25°C, 87 mPa s (87 cP) at 60°C.[31]

11 Stability and Storage Conditions

Betadex sulfobutyl ether sodium is stable in the solid state and should be protected from high humidity. It should be stored in a tightly sealed container.

It will reversibly take up moisture without any effect on the appearance of the material at humidities up to 60% RH. Equilibration at RH values above 60% will result in deliquescence. Once in this state, the material can be dried, but will give a glasslike product. This water absorption behavior is typical of amorphous hygroscopic materials.

Betadex sulfobutyl ether sodium is stable in aqueous solutions at values above about pH 1. It can degrade in highly acidic (pH <1) solutions, only apparent at elevated temperatures, producing the ring-opened form, followed by hydrolysis of the α(1→4) glucoside bonds.

Betadex sulfobutyl ether sodium solutions may be autoclaved.[1]

12 Incompatibilities

Betadex sulfobutyl ether sodium can interact with and extract some plastic tubing components.[32] Compatibility with rubber stoppers in terms of extractables/leachables has been investigated.[33]

The preservative activity of benzalkonium chloride is reduced in the presence of betadex sulfobutyl ether sodium.

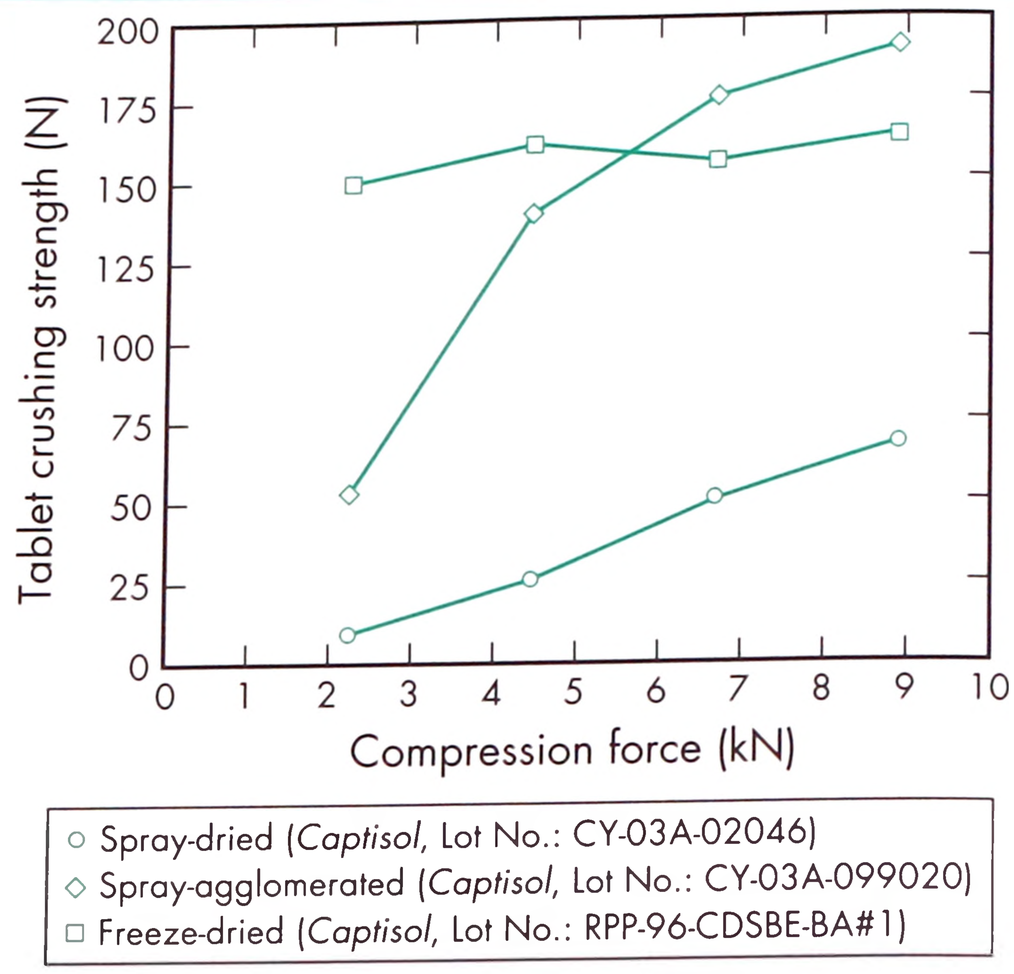


Figure 1: Compression characteristics of betadex sulfobutyl ether sodium (*Captisol*, Ligand Pharmaceuticals).
Mean tablet weight: 220 mg
Tablet dimensions: 5/16 inch std concave
Lubricated with 0.5% magnesium stearate
Tablet machine: Instrumented Stokes Model F, Single Punch Press

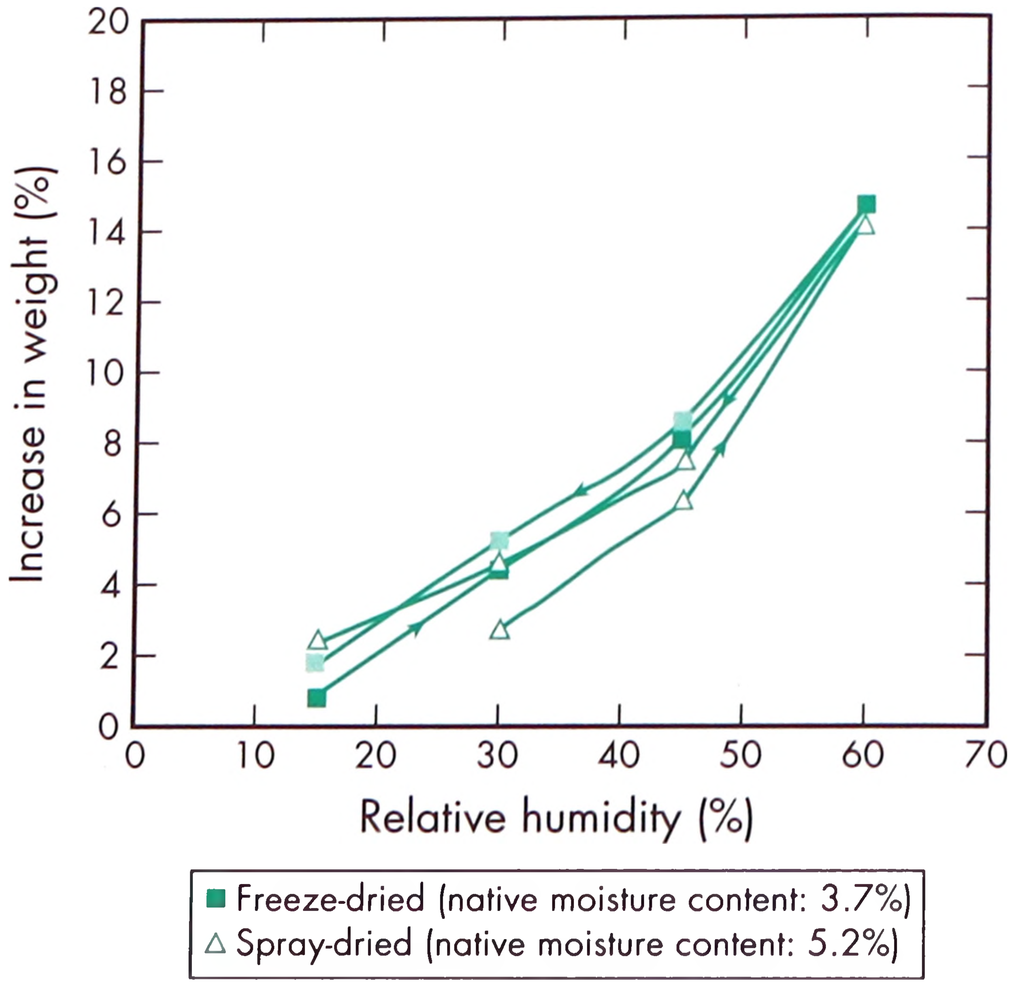

Figure 2: Moisture sorption–desorption isotherm of betadex sulfobutyl ether sodium at 30°C.

Substituting betadex sulfobutyl ether sodium for hydroxypropyl betadex may alter established chromatography and necessitate method changes.[34]

13 Method of Manufacture

Betadex sulfobutyl ether sodium is prepared by a solvent-free (water only) process consisting of alkylation of β-cyclodextrin using 1,4-butane sultone under basic conditions.[35] The resulting reaction mixture is purified by ultrafiltration and phosphate-free carbon treatment. The distilled concentrate is isolated as a dry solid by drying, e.g. freeze-drying, spray drying, or spray dry agglomeration.

The degree of substitution of β-cyclodextrin is controlled by the stoichiometric ratio of β-cyclodextrin to sultone used in the process. The purification steps remove residual starting reactants, salts and levels of known impurities, and reduce bioburden as well as remove bacterial endotoxins to dramatically improve functionality.[36]

14 Safety

Betadex sulfobutyl ether sodium is derived from β-cyclodextrin, which is nephrotoxic when administered parenterally (*see* Cyclodextrins). However, studies have shown that solvent-free processed (water only) betadex sulfobutyl ether sodium is well tolerated when administered via intravenous, intramuscular, and subcutaneous injections, orally, and ophthalmically.[37–39]

Solvent-free processed betadex sulfobutyl ether sodium has been subjected to an extensive battery of *in vitro* and *in vivo* genotoxicity and pharmacological evaluations.[35] No genotoxic or mutagenic changes were observed with betadex sulfobutyl ether sodium administration. Betadex sulfobutyl ether sodium is biocompatible and is rapidly eliminated unmetabolized when administered intravenously.

In humans, solvent-free processed betadex sulfobutyl ether sodium has been administered intravenously up to 35 g/day for up to a week per infusions every 6 h over durations from 30 to 5 min.[40,41] Orally, it has been reportedly administered clinically at least as high as 12 g.[38] An early concern for the use of drug products containing betadex sulfobutyl ether sodium was that it may accumulate in renally compromised patients and worsen renal function.[37] However, it has been reported that administration of voriconazole containing betadex sulfobutyl ether sodium in renally compromised patients does not result in further deterioration of renal function nor renal damage that is attributable to its inclusion in the formulation.[1,42,43]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

16 Regulatory Status

Solvent-free processed betadex sulfobutyl ether sodium is included in six approved IV and IM injectable products currently marketed in more than 60 countries, including the US, Europe, and Japan. It is included in the FDA Inactive Ingredients Database for IM and IV use. It is included in parenteral medicines licensed in the UK. Its use by other routes, including subcutaneous, oral, inhalation, nasal, dermal and ophthalmic, has been evaluated in clinical studies.

Betadex sulfobutyl ether sodium is also contained in a subcutaneous injection for veterinary use.

17 Related Substances

Cyclodextrins (α, β and γ-cyclodextrin); dimethyl-β-cyclodextrin; hydroxyethyl-β-cyclodextrin; hydroxypropyl betadex; 3-hydroxypropyl-β-cyclodextrin; trimethyl-β-cyclodextrin.

18 Comments

Cyclodextrins have been particularly useful as suitable vehicles for drug discovery and early toxicology formulations of poorly soluble drug candidates.[44–48]

An amiodarone hydrochloride premixed injection (*Nexterone*; Baxter International Inc., Deerfield, IL, USA) is supplied as a betadex sulfobutyl ether sodium-based, ready-to-use room temperature-stable solution in a specially designed multilayered plastic container where the solution is in contact with a polyethylene layer, and has been shown to be compatible over short-use periods in polyolefin and polyvinylchloride containers.[49]

Therapeutically, betadex sulfobutyl ether sodium has demonstrated a protective effect on the kidney when co-administered with certain renal toxic drugs and diagnostics.[50] It has also been shown to mediate rapid changes in sterol balance in mice lacking the Niemann Pick type C protein,[51] and has been used to attenuate cocaine–induced cardiovascular depression, and act as a potential rescue agent from cardiac toxicity due to cocaine overdose.[52] In addition, betadex sulfobutyl ether sodium in a reformulated imatinib markedly increased drug delivery to the brain,[53] and a betadex sulfobutyl ether sodium-containing vehicle has been shown to preserve axonal transport integrity in an animal model of Alzheimer's disease,[54] provide direct delivery of Vitamin A to the retina,[55] and when coupled with prodrug designs it enhanced colonic absorption.[56]

In addition to its use in pharmaceutical formulations, betadex sulfobutyl ether sodium is also used in chromatographic separations, particularly in chiral separations by HPLC[57] and capillary electrophoresis,[58–61] and in tissue imaging.[62]

Sugammadex (Org 25969, *Bridion*; Merck & Co. Inc., Kenilworth, NJ, USA) is a modified γ-cyclodextrin, which has been modified from its natural state by placing eight carboxyl thio-ether groups at the sixth carbon positions. Other related cyclodextrins include hydroxypropyl-sulfobutyl-β-cyclodextrin (HP-SBE-β-CD), α- and γ-cyclodextrin sulfobutyl ethers, and β-cyclodextrin sulfobutyl ethers-ethyl ethers.[63]

Boric Acid

1 Nonproprietary Names

BP: Boric Acid
JP: Boric Acid
PhEur: Boric Acid
USP–NF: Boric Acid

2 Synonyms

Acidum boricum; boracic acid; boraic acid; *Borofax*; boron trihydroxide; E284; orthoboric acid; trihydroxyborene.

3 Chemical Name and CAS Registry Number

Orthoboric acid [10043-35-3]
Metaboric acid [13460-50-9]

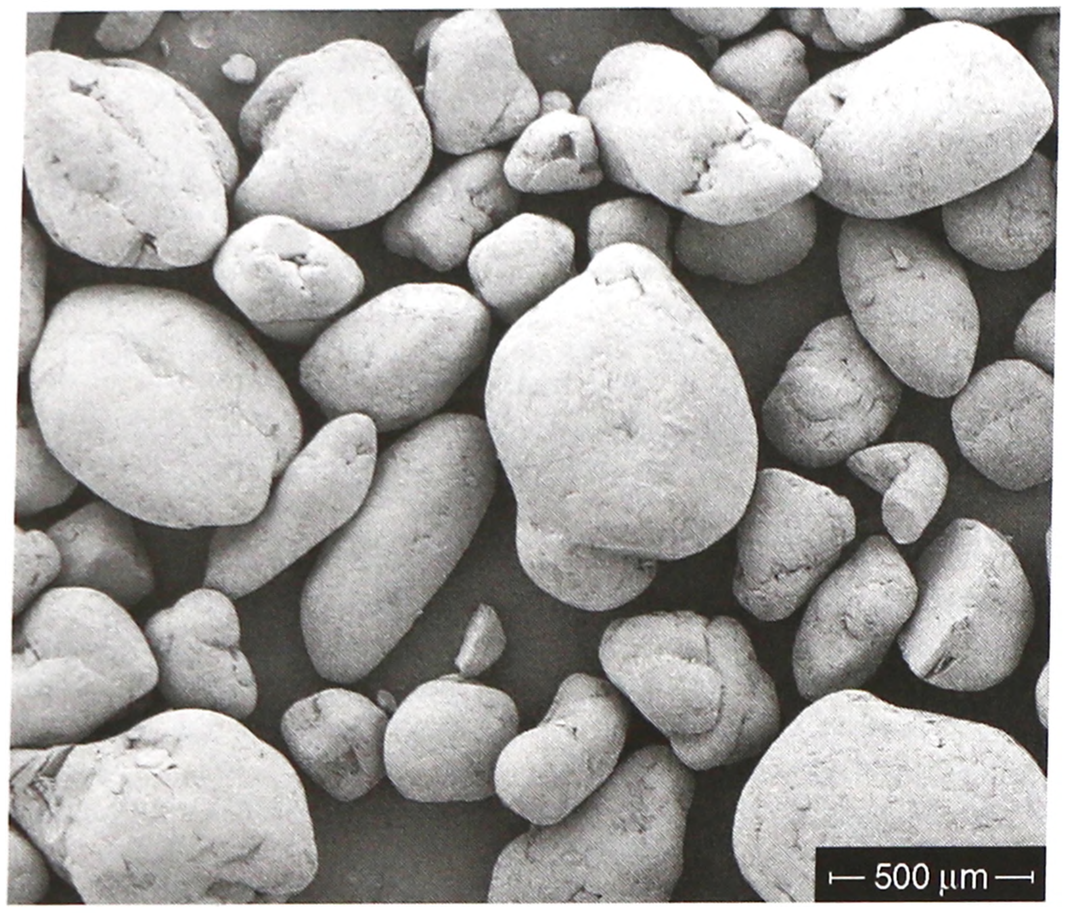
4 Empirical Formula and Molecular Weight

HBO_2 43.82 (for monohydrate)
H_3BO_3 61.83 (for trihydrate)

5 Structural Formula

See Section 4.

6 Functional Category



Antimicrobial preservative; buffering agent.

7 Applications in Pharmaceutical Formulation or Technology

Boric acid is used as an antimicrobial preservative[1] in eye drops, cosmetic products, ointments, and topical creams. It is also used as an antimicrobial preservative in foods.

B

SEM 1: Excipient: boric acid; manufacturer: Alfa Aesar; lot no.: 23672; magnification: 100×; voltage: 5 kV.

SEM 2: Excipient: boric acid; manufacturer: Aldrich Chemical Company Inc.; lot no.: 01559BU; magnification: 100×; voltage: 5 kV.

Boric acid and borate have good buffering capacity and are used to control pH; they have been used for this purpose in external preparations such as eye drops.[2]

In dilute concentrations it is used as a mild antiseptic, with weak bacteriostatic and fungistatic properties, although it has generally been superseded by more effective and less toxic disinfectants.[3] *See* Section 14.

8 Description

Boric acid occurs as a hygroscopic, white crystalline powder, colorless shiny plates, or white crystals.

9 Pharmacopeial Specifications

See Table I.

10 Typical Properties

Acidity/alkalinity pH = 3.5–4.1 (5% w/v aqueous solution)
Density 1.435 g/cm^3

Table I: Pharmacopeial specifications for boric acid.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters	–	+	–
Appearance of solution	+	+	–
Loss on drying	≤0.50%	–	≤0.50%
Sulfate	–	≤450 ppm	–
Heavy metals	≤10 ppm	–	≤0.002%
Organic matter	–	+	–
Arsenic	≤5 ppm	–	–
pH	3.5–4.1	3.8–4.8	–
Solubility in ethanol (96%)	–	+	+
Completeness of solution	–	–	+
Assay	≥99.5%	99.0–100.5%	99.5–100.5%

Melting point 170.9°C. When heated slowly to 181.0°C, boric acid loses water to form metaboric acid (HBO_2); tetraboric acid ($H_2B_4O_7$) and boron trioxide (B_2O_3) are formed at higher temperatures.[4]

Solubility Soluble in ethanol, ether, glycerin, water, and other fixed and volatile oils. Solubility in water is increased by addition of hydrochloric, citric, or tartaric acids.

Specific gravity 1.517

Spectroscopy

IR spectrum *see* Figure 1.

Raman spectrum *see* Figure 2.

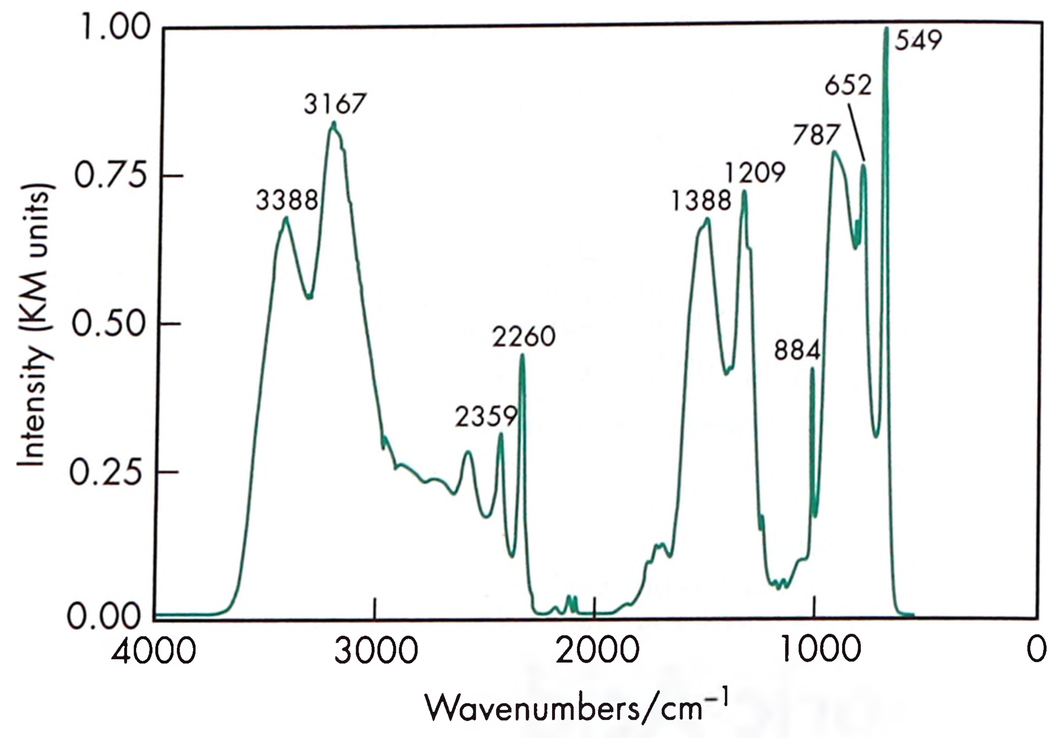


Figure 1: Infrared spectrum of boric acid measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

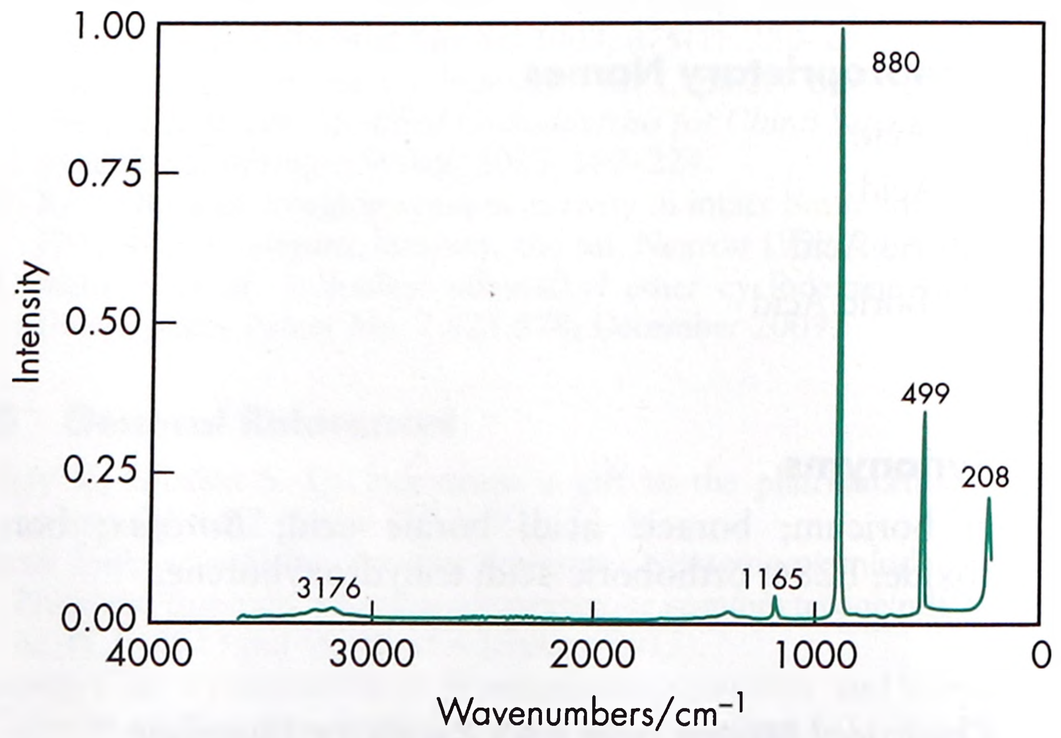

Figure 2: Raman spectrum of boric acid measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

11 Stability and Storage Conditions

Boric acid is hygroscopic and should therefore be stored in an airtight, sealed container. The container must be labeled 'Not for Internal Use'.

12 Incompatibilities

Boric acid is incompatible with water, strong bases, and alkali metals. It reacts violently with potassium and acid anhydrides. It also forms a complex with glycerin, which is a stronger acid than boric acid.

13 Method of Manufacture

Boric acid occurs naturally as the mineral sassolite. However, the majority of boric acid is produced by reacting inorganic borates with sulfuric acid in an aqueous medium. Sodium borate and partially refined calcium borate (colemanite) are the principal raw materials. When boric acid is made from colemanite, the fine-ground ore is vigorously stirred with mother liquor and sulfuric acid at about 90°C. The by-product calcium sulfate is removed by filtration, and the boric acid is crystallized by cooling the filtrate.

14 Safety

Boric acid is a weak bacteriostatic and antimicrobial agent, and has been used in topical preparations such as eye lotions, mouthwashes and gargles. It has also been used in US- and Japanese-approved intravenous products. Solutions of boric acid were formerly used to wash out body cavities, and as applications to wounds and ulcers, although the use of boric acid for these purposes is now regarded as inadvisable owing to the possibility of absorption.[3] Boric acid is not used internally owing to its toxicity. It is poisonous by ingestion and moderately toxic by skin contact. Experimentally it has proved to be toxic by inhalation and subcutaneous routes, and moderately toxic by intraperitoneal and intravenous routes.

Boric acid is absorbed from the gastrointestinal tract and from damaged skin, wounds, and mucous membranes, although it does not readily permeate intact skin. The main symptoms of boric acid poisoning are abdominal pain, diarrhea, erythematous rash involving both skin and mucous membrane, and vomiting. These symptoms may be followed by desquamation, and stimulation or depression of the central nervous system. Convulsions, hyperpyrexia, and renal tubular damage have been known to occur.[5]

Death has occurred from ingestion of less than 5 g in young children, and of 5–20 g in adults. Fatalities have occurred most frequently in young children after the accidental ingestion of solutions of boric acid, or after the application of boric acid powder to abraded skin.

The permissible exposure limit (PEL) of boric acid is 15 mg/m^3 total dust, and 5 mg/m^3 respirable fraction for nuisance dusts.[6]

LD_{Lo} (man, oral): 429 mg/kg[7]
LD_{Lo} (woman, oral): 200 mg/kg
LD_{Lo} (infant, oral): 934 mg/kg
LD_{Lo} (man, skin): 2.43 g/kg
LD_{Lo} (infant, skin): 1.20 g/kg
LD_{50} (mouse, oral): 3.45 g/kg
LD_{50} (mouse, IV): 1.24 g/kg
LD_{50} (mouse, SC): 1.74 g/kg
LD_{50} (rat, oral): 2.660 g/kg
LD_{50} (rat, IV): 1.33 g/kg
LD_{50} (rat, SC): 1.4 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Boric acid is irritating to the skin and is potentially toxic by inhalation. Gloves, eye protection, protective clothing, and a respirator are recommended.

16 Regulatory Status

Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (IV injections; ophthalmic preparations; (auricular) otic solutions; topical preparations). Reported in the EPA TSCA Inventory. In the UK, the use of boric acid in cosmetics and toiletries is restricted. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Sodium borate.

18 Comments

Boric acid has been used experimentally as a model oxo-acid to retard mannitol crystallization in the solid state.[8]

Boric acid has also been used therapeutically in the form of suppositories to treat yeast infections.[9,10]

The EINECS number for boric acid is 233-139-2. The PubChem Compound ID (CID) for boric acid includes 7628 and 24492.

Bronopol

B

1 Nonproprietary Names

BP: Bronopol

2 Synonyms

2-Bromo-2-nitro-1,3-propanediol; β-bromo-β-nitrotrimethyleneglycol; *Myacide*.

3 Chemical Name and CAS Registry Number

2-Bromo-2-nitropropane-1,3-diol [52-51-7]

4 Empirical Formula and Molecular Weight

$C_3H_6BrNO_4$ 200.00

5 Structural Formula

6 Functional Category

Antimicrobial preservative.

7 Applications in Pharmaceutical Formulation or Technology

Bronopol 0.01–0.1% w/v is used as an antimicrobial preservative either alone or in combination with other preservatives in topical pharmaceutical formulations, cosmetics, and toiletries; the usual concentration is 0.02% w/v.

8 Description

Bronopol is a white or almost white crystalline powder; odorless or with a faint characteristic odor.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for bronopol.

Test	BP 2017
Identification	+
Characters	+
Acidity or alkalinity (1% w/v solution)	5.0–7.0
Related substances	+
Sulfated ash	≤0.1%
Water	≤0.5%
Assay (anhydrous basis)	99.0–101.0%

10 Typical Properties

Antimicrobial activity Bronopol is active against both Gram-positive and Gram-negative bacteria including *Pseudomonas aeruginosa*, with typical minimum inhibitory concentrations (MICs) between 10–50 µg/mL;[1–8] *see also* Table II. At room temperature, a 0.08% w/v aqueous solution may reduce the viability of culture collection strains of *Escherichia coli* and *Pseudomonas aeruginosa* by 100-fold or more in 15 minutes. Antimicrobial activity is not markedly influenced by pH in the range 5.0–8.0, nor by common anionic and nonionic surfactants, lecithin, or proteins.[2,5,6] Bronopol is less active against yeasts and molds, with typical MICs of 50–400 µg/mL or more, and has little or no useful activity against bacterial spores. *See also* Section 12.

Table II: Minimum inhibitory concentrations (MICs) of bronopol.[2,9]

Microorganism	MIC (µg/mL)
Aspergillus niger	3200
Bacillus subtilis	12.5
Burkholderia (Pseudomonas) cepacia	25
Candida albicans	1600
Escherichia coli	12.5–50
Klebsiella aerogenes	25
Legionella pneumophilia	50
Penicillium roqueforti	400
Penicillium funiculosum	1600
Pityrosporum ovale	125
Proteus mirabilis	25–50
Proteus vulgaris	12.5–50
Pseudomonas aeruginosa	12.5–50
Saccharomyces cerevisiae	3200
Salmonella gallinarum	25
Staphylococcus aureus	12.5–50
Staphylococcus epidermidis	50
Streptococcus faecalis	50
Trichophyton mentagrophytes	200
Trichoderma viride	6400

Melting point 128–132°C

Partition coefficients

Mineral oil : water = 0.043 at 22–24°C;

Peanut oil : water = 0.11 at 22–24°C.

Solubility *see* Table III.

Table III: Solubility of bronopol.

Solvent	Solubility at 20°C
Cottonseed oil	Slightly soluble
Ethanol (95%)	1 in 2
Glycerol	1 in 100
Isopropyl myristate	1 in 200
Mineral oil	Slightly soluble
Propan-2-ol	1 in 4
Propylene glycol	1 in 2
Water	1 in 4

Spectroscopy

NIR spectrum *see* Figure 1.

11 Stability and Storage Conditions

Bronopol is stable and its antimicrobial activity is practically unaffected when stored as a solid at room temperature and ambient relative humidity for up to 2 years.[3]

The pH of a 1.0% w/v aqueous solution is 5.0–6.0 and falls slowly during storage; solutions are more stable in acid conditions. Half-lives of bronopol in buffered aqueous solutions at 0.03% w/v are shown in Table IV.[9]

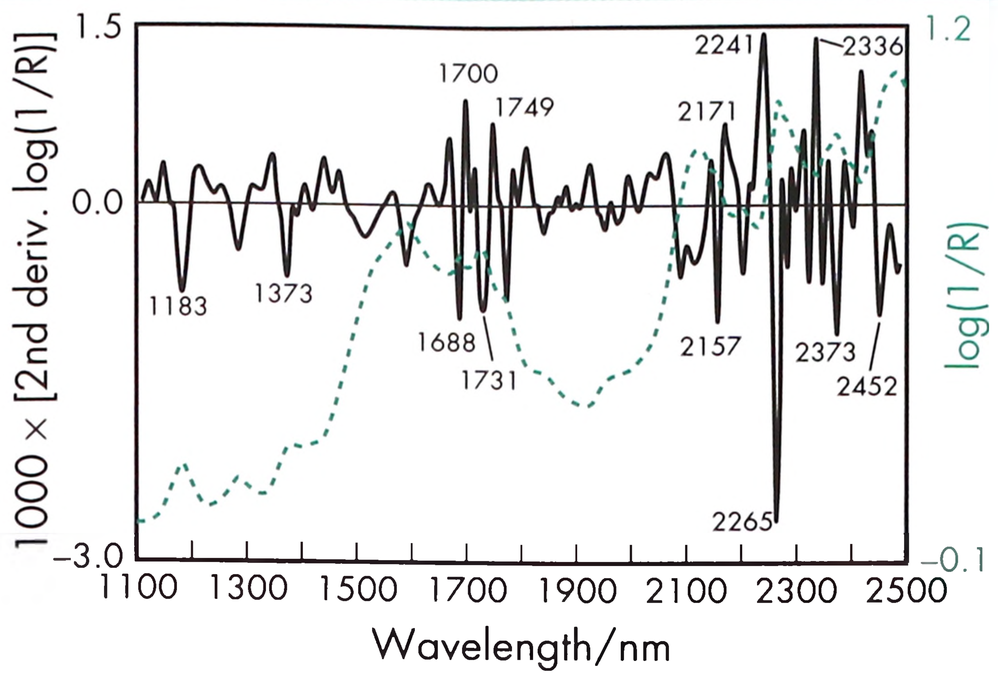

Figure 1: Near-infrared spectrum of bronopol measured by reflectance.

Microbiological assay results indicate longer half-lives than those obtained by HPLC and thus suggest that degradation products may contribute to antimicrobial activity. Formaldehyde and nitrites are among the decomposition products, but formaldehyde arises in such low concentrations that its antimicrobial effect is not likely to be significant. On exposure to light, especially under alkaline conditions, solutions become yellow or brown-colored but the degree of discoloration does not directly correlate with loss of antimicrobial activity.

The bulk material should be stored in a well-closed, non-aluminum container protected from light, in a cool, dry place.

Table IV: Half-lives of bronopol under different storage conditions.

Temperature (°C)	pH 4	pH 6	pH 8
5	>5 years	>5 years	6 months
25	>5 years	>5 years	4 months
40	2 years	4 months	8 days
60	2 weeks	<2 days	<1 day

12 Incompatibilities

Sulfhydryl compounds cause significant reductions in the activity of bronopol, and cysteine hydrochloride may be used as the deactivating agent in preservative efficacy tests; lecithin/polysorbate combinations are unsuitable for this purpose.[5] Bronopol is incompatible with sodium thiosulfate, with sodium metabisulfite, and with amine oxide or protein hydrolysate surfactants. Owing to an incompatibility with aluminum, the use of aluminum in the packaging of products that contain bronopol should be avoided.

13 Method of Manufacture

Bronopol is synthesized by the reaction of nitromethane with paraformaldehyde in an alkaline environment, followed by bromination. After crystallization, bronopol powder may be milled to produce a powder of the required fineness.

14 Safety

Bronopol is used widely in topical pharmaceutical formulations and cosmetics as an antimicrobial preservative.

Although bronopol has been reported to cause both irritant and hypersensitivity adverse reactions following topical use,[10–14] it is generally regarded as a nonirritant and nonsensitizing material at concentrations up to 0.1% w/v. At a concentration of 0.02% w/v, bronopol is frequently used as a preservative in 'hypoallergenic' formulations.

Animal toxicity studies have shown no evidence of phototoxicity or tumor occurrence when bronopol is applied to rodents topically or administered orally; and there is no *in vitro* or *in vivo* evidence of mutagenicity;[1] this is despite the demonstrated potential of bronopol to liberate nitrite on decomposition, which in the presence of certain amines may generate nitrosamines. Formation of nitrosamines in formulations containing amines may be reduced by limiting the concentration of bronopol to 0.01% w/v and including an antioxidant such as 0.2% w/v alpha tocopherol or 0.05% w/v butylated hydroxytoluene;[15] other inhibitor systems may also be appropriate.[16]

LD_{50} (dog, oral): 250 mg/kg [17]
LD_{50} (mouse, IP): 15.5 mg/kg
LD_{50} (mouse, IV): 48 mg/kg
LD_{50} (mouse, oral): 270 mg/kg
LD_{50} (mouse, SC): 116 mg/kg
LD_{50} (mouse, skin): 4.75 g/kg
LD_{50} (rat, IP): 26 mg/kg
LD_{50} (rat, IV): 37.4 mg/kg
LD_{50} (rat, oral): 180 mg/kg
LD_{50} (rat, SC): 170 mg/kg
LD_{50} (rat, skin): 1.6 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Bronopol may be harmful upon inhalation and the solid or concentrated solutions can be irritant to the skin and eyes. Eye protection, gloves, and dust respirator are recommended. Bronopol burns to produce toxic fumes.

16 Regulatory Status

Included in topical pharmaceutical formulations licensed in Europe. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

—

18 Comments

Bronopol owes its usefulness as a preservative largely to its activity against *Pseudomonas aeruginosa*, and its affinity for polar solvents, which prevents the loss of preservative into the oil phase of emulsions that is seen with some other preservatives. Other advantages include a low incidence of microbial resistance; low concentration exponent;[18] and good compatibility with most surfactants, other excipients, and preservatives, with which it can therefore be used in combination. Bronopol is used therapeutically as an antiseptic.

The major disadvantages of bronopol are relatively poor activity against yeasts and molds, instability at alkaline pH, and the production of formaldehyde and nitrite on decomposition, although there is no evidence of serious toxicity problems associated with bronopol that are attributable to these compounds.

The EINECS number for bronopol is 200-143-0. The PubChem Compound ID (CID) for bronopol is 2450.

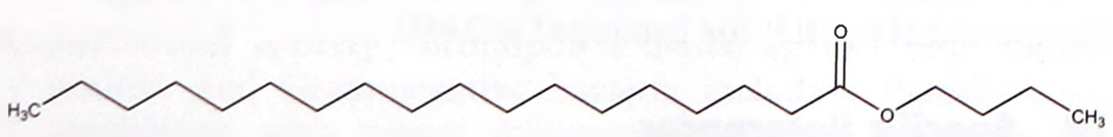
Butyl Stearate

1 Nonproprietary Names

USP–NF: Butyl Stearate

2 Synonyms

Butyl octadecanoate; *Butyl Stearate*; *Crodamol BS*; *n*-butyl octadecanoate; *n*-butyl stearate; *Histar BS*; octadecanoic acid, butyl ester.



3 Chemical Name and CAS Registry Number

Butyl octadecanoate [123-95-5]

4 Empirical Formula and Molecular Weight

$C_{22}H_{44}O_2$ 340.58

5 Structural Formula

6 Functional Category

Emollient; plasticizing agent.

7 Applications in Pharmaceutical Formulation or Technology

Butyl stearate is used as an emollient in pharmaceutical preparations such as topical emulsions, lotions and creams, normally up to a concentration of 3.7%.[1] It can be used as a plasticizer in film-coating formulations of ethylcellulose.[2]

8 Description

The USP 40–NF 35 S1 states that butyl stearate consists of the esters of butyl alcohol and fatty acids composed chiefly of stearic acid ($C_{18}H_{36}O_2$) and a minor amount of palmitic acid ($C_{16}H_{32}O_2$).

At room temperature it is a practically odorless, colorless or yellowish liquid, and at lower temperatures it is an oily solid.

9 Pharmacopeial Specifications

See Table I.

10 Typical Properties

Boiling point 343–360°C
Density 0.86–0.88 g/cm^3 at 20°C
Flash point Approx 160°C (closed cup); 196°C (open cup)
Refractive index $n_D^{20} = 1.442$
Solubility Soluble in acetone, ethanol, ether, mineral and vegetable oils; practically insoluble in water and propylene glycol.
Specific gravity 0.853–0.860 at 20°C
Surface tension 30 mN/m at 20°C
Vapor density (relative) 11.4 (air = 1)

Table I: Pharmacopeial specifications for butyl stearate.

Test	USP 40–NF 35 S1
Identification	+
Melting range	19–24°C
Acid value	≤0.5
Iodine value	≤1.0
Saponification value	165–180
Water determination	≤0.5%
Assay	
Butyl stearate	≥90.0%
Sum of butyl stearate and butyl palmitate	≥96.0%

Vapor pressure 1.467 kPa at 150°C
Viscosity (dynamic) 8 mPa s (8 cP) at 20°C

11 Stability and Storage Conditions

Butyl stearate solidifies at about 19°C. Store in tightly closed containers. Keep away from heat and sources of ignition.

12 Incompatibilities

Butyl stearate is incompatible with oxidizing agents and alkalis.

13 Method of Manufacture

Butyl stearate is prepared by reacting silver stearate and *n*-butyl iodide or stearic acid and *n*-butanol.[3]

14 Safety

Butyl stearate is only mildly toxic by ingestion. May cause adverse reproductive effects based on animal test data, but no human data are available. May cause irritation of the digestive tract if swallowed in large amounts. Prolonged or repeated skin contact may cause skin irritation.

The Cosmetic Ingredient Review Expert Panel has assessed butyl stearate and concluded that the material is safe as used in cosmetics and personal care products.[4] However, comedogenicity is a potential health effect that should be considered when stearates are used in cosmetic formulations.[5,6]

LD_{50} (rat, oral): 32 g/kg[4,7]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. When heated, butyl stearate emits acrid smoke and irritating fumes. Wear suitable protective clothing. Avoid contact with skin and eyes.

16 Regulatory Status

Approved by the FDA as a food additive and included on the EAFUS list. Included in the FDA Inactive Ingredients Database (topical emulsions, creams, lotions). Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Ethyl oleate.

18 Comments

Butyl stearate is also used in cosmetics and as a flavoring agent in foods.[4,8] Therapeutically, studies have shown that butyl stearate isolated from *Ocimum basilicum* may have an antisickling effect in sickle cell anemia.[9]

A specification for butyl stearate is included in the *Food Chemicals Codex* (FCC).[8]

The EINECS number for butyl stearate is 204-665-5. The PubChem Compound ID (CID) is 31278.

Butylated Hydroxyanisole

B

1 Nonproprietary Names

BP: Butylated Hydroxyanisole

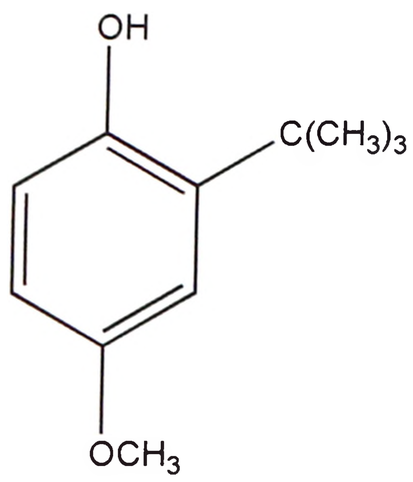
PhEur: Butylhydroxyanisole

USP–NF: Butylated Hydroxyanisole

2 Synonyms

BHA; butylhydroxyanisolum; tert-butyl-4-methoxyphenol; 1,1-dimethylethyl-4-methoxyphenol; E320; *Nipanox BHA*; *Nipantiox 1-F*; *Tenox BHA*.

3 Chemical Name and CAS Registry Number



2-tert-Butyl-4-methoxyphenol [25013-16-5]

4 Empirical Formula and Molecular Weight

$C_{11}H_{16}O_2$ 180.25

The PhEur 9.2 describes butylated hydroxyanisole as 2-(1,1-dimethylethyl)-4-methoxyphenol containing not more than 10% of 3-(1,1-dimethylethyl)-4-methoxyphenol.

5 Structural Formula

6 Functional Category

Antioxidant; antimicrobial preservative.

7 Applications in Pharmaceutical Formulation or Technology

Butylated hydroxyanisole is an antioxidant (*see* Table I) with some antimicrobial properties.[1–5] It is used in a wide range of cosmetics, foods, and pharmaceuticals. When used in foods, it is used to delay or prevent oxidative rancidity of fats and oils and to prevent loss of activity of oil-soluble vitamins.

Table I: Antioxidant uses of butylated hydroxyanisole.

Antioxidant use	Concentration (%)
β-Carotene	0.01
Essential oils and flavoring agents	0.02–0.5
IM injections	0.03
IV injections	0.0002–0.0005
Oils and fats	0.02
Topical formulations	0.005–0.02
Vitamin A	10 mg per million units

Butylated hydroxyanisole is frequently used in combination with other antioxidants, particularly butylated hydroxytoluene and alkyl gallates, and with sequestrants or synergists such as citric acid.

FDA regulations direct that the total content of antioxidant in vegetable oils and direct food additives shall not exceed 0.02% w/w (200 ppm) of fat or oil content or essential (volatile) oil content of food.

USDA regulations require that the total content of antioxidant shall not exceed 0.01% w/w (100 ppm) of any one antioxidant or 0.02% w/w combined total of any antioxidant combination in animal fats.

Japanese regulations allow up to 1 g/kg in animal fats.

8 Description

Butylated hydroxyanisole occurs as a white or almost white crystalline powder or a yellowish-white waxy solid with a faint, characteristic aromatic odor.

9 Pharmacopeial Specifications

See Table II.

Table II: Pharmacopeial specifications for butylated hydroxyanisole.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	–
Appearance of solution	+	–
Residue on ignition	–	≤0.01%
Sulfated ash	≤0.1%	–
Related substances	+	–
Heavy metals	–	≤10 ppm
Assay	–	≥98.5%

10 Typical Properties

Antimicrobial activity Activity is similar to that of the *p*-hydroxybenzoate esters (parabens). The greatest activity is against molds and Gram-positive bacteria, with less activity against Gram-negative bacteria.

Boiling point 264°C at 745 mmHg

Density (true) 1.117 g/cm^3

Flash point 130°C

Melting point 47°C (for pure 2-*tert*-butyl-4-methoxyphenol); *see also* Section 18.

Solubility Practically insoluble in water; soluble in methanol; freely soluble in ≥50% aqueous ethanol, propylene glycol, chloroform, ether, hexane, cottonseed oil, peanut oil, soybean oil, glyceryl monooleate, and lard, and in solutions of alkali hydroxides.

Spectroscopy

IR spectrum *see* Figure 1.

NIR spectrum *see* Figure 2.

Raman spectrum *see* Figure 3.

Viscosity (kinematic) 3.3 mm^2/s (3.3 cSt) at 99°C.

11 Stability and Storage Conditions

Exposure to light causes discoloration and loss of activity. Butylated hydroxyanisole should be stored in a well-closed container, protected from light, in a cool, dry place.

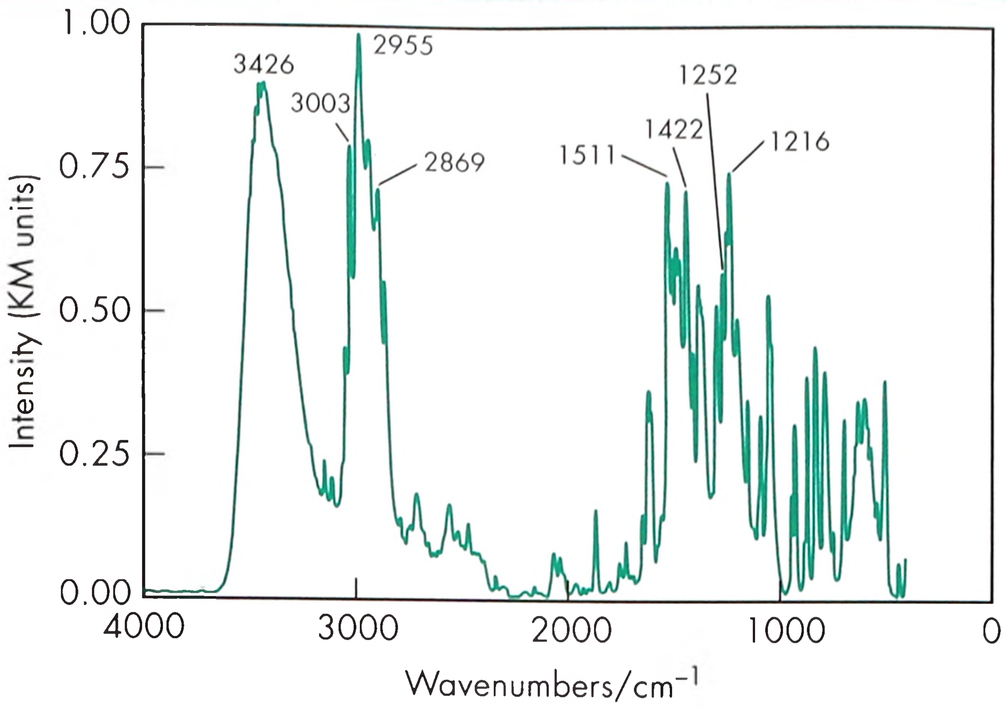


Figure 1: Infrared spectrum of butylated hydroxyanisole measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

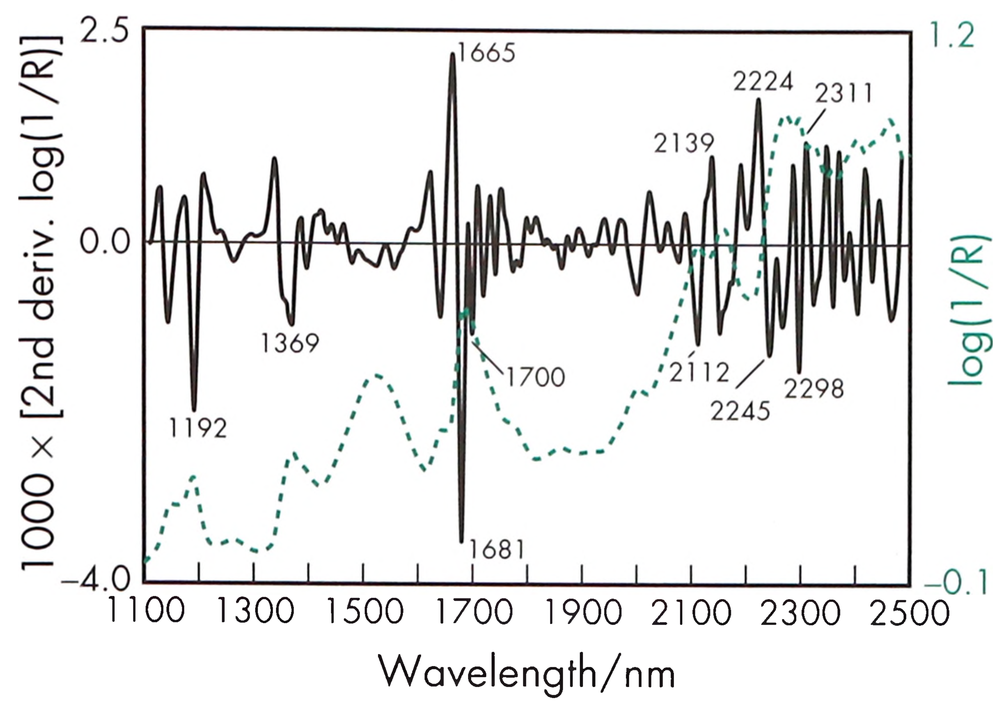

Figure 2: Near-infrared spectrum of butylated hydroxyanisole measured by reflectance.

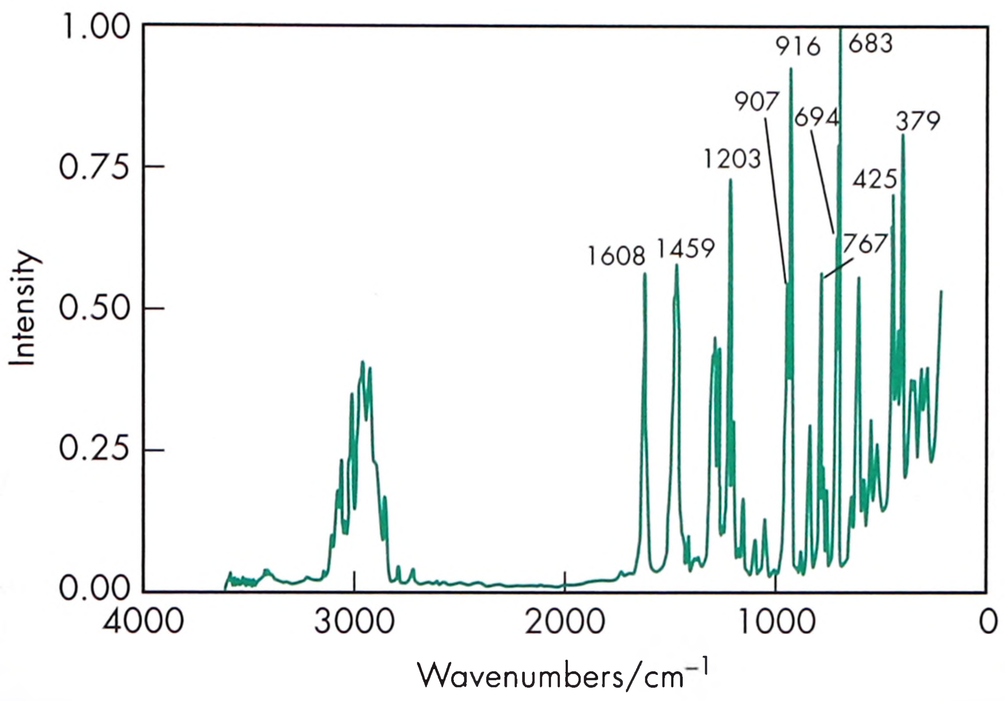

Figure 3: Raman spectrum of butylated hydroxyanisole measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

12 Incompatibilities

Butylated hydroxyanisole is phenolic and undergoes reactions characteristic of phenols. It is incompatible with oxidizing agents and ferric salts. Trace quantities of metals and exposure to light cause discoloration and loss of activity.

13 Method of Manufacture

Butylated hydroxyanisole is prepared by the reaction of *p*-methoxyphenol with isobutene.

14 Safety

Butylated hydroxyanisole is absorbed from the gastrointestinal tract and is metabolized and excreted in the urine with less than 1% unchanged within 24 hours of ingestion.[6] Although there have been some isolated reports of adverse skin reactions to butylated hydroxyanisole,[7,8] it is generally regarded as nonirritant and nonsensitizing at the levels employed as an antioxidant.

Concern over the use of butylated hydroxyanisole has occurred following long-term animal feeding studies. Although previous studies in rats and mice fed butylated hydroxyanisole at several hundred times the US-permitted level in the human diet showed no adverse effects, a study in which rats, hamsters, and mice were fed butylated hydroxyanisole at 1–2% of the diet produced benign and malignant tumors of the forestomach, but in no other sites. However, humans do not have any region of the stomach comparable to the rodent forestomach and studies in animals that also do not have a comparable organ (dogs, monkeys, and guinea pigs) showed no adverse effects. Thus, the weight of evidence does not support any relevance to the human diet where butylated hydroxyanisole is ingested at much lower levels.[9] The WHO acceptable daily intake of butylated hydroxyanisole has been set at 500 µg/kg body-weight.[9]

LD_{50} (mouse, oral): 1.1–2.0 g/kg[10]
LD_{50} (rabbit, oral): 2.1 g/kg
LD_{50} (rat, IP): 0.88 g/kg
LD_{50} (rat, oral): 2.0 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Butylated hydroxyanisole may be irritant to the eyes and skin, and on inhalation. It should be handled in a well-ventilated environment; gloves and eye protection are recommended. On combustion, toxic fumes may be given off.

16 Regulatory Status

GRAS listed. Accepted as a food additive in Europe. Included in the FDA Inactive Ingredients Database (IM and IV injections, nasal sprays, oral capsules and tablets, and sublingual, rectal, topical, and vaginal preparations). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Butylated hydroxytoluene.

18 Comments

The commercially available material can have a wide melting point range (47–57°C) owing to the presence of varying amounts of 3-*tert*-butyl-4-methoxyphenol.

Tenox brands contain 0.1% w/w citric acid as a stabilizer.

A specification for butylated hydroxyanisole is contained in the *Food Chemicals Codex* (FCC).[11]

The EINECS number for butylated hydroxyanisole is 246-563-8. The PubChem Compound ID (CID) for butylated hydroxyanisole includes 8456 and 11954184.

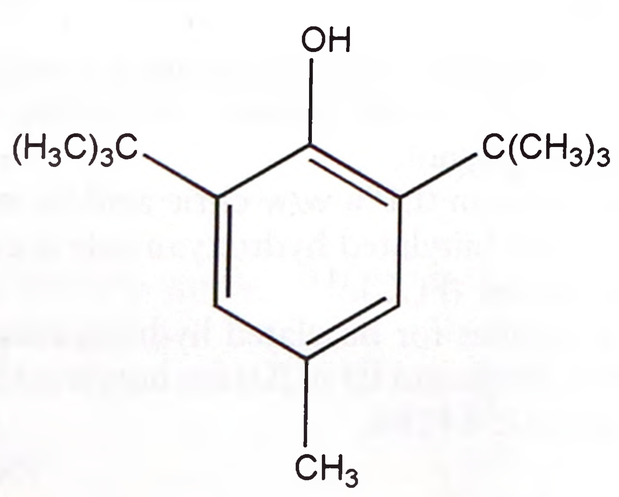
USP–NF: Butylated Hydroxytoluene

2 Synonyms

Agidol; BHT; 2,6-bis(1,1-dimethylethyl)-4-methylphenol; butylhydroxytoluene; butylhydroxytoluenum; *Dalpac*; dibutylated hydroxytoluene; 2,6-di-tert-butyl-p-cresol; 3,5-di-tert-butyl-4-hydroxytoluene; E321; *Embanox BHT*; *Impruvol*; *Ionol CP*; *Nipanox BHT*; *OHS28890*; *Sustane*; *Tenox BHT*; *Topanol*; *Vianol*.



3 Chemical Name and CAS Registry Number

2,6-Di-tert-butyl-4-methylphenol [128-37-0]

4 Empirical Formula and Molecular Weight

$C_{15}H_{24}O$ 220.35

5 Structural Formula

6 Functional Category

Antioxidant.

7 Applications in Pharmaceutical Formulation or Technology

Butylated hydroxytoluene is used as an antioxidant (*see* Table I) in cosmetics, foods, and pharmaceuticals.[1–5] It is mainly used to delay or prevent the oxidative rancidity of fats and oils and to prevent loss of activity of oil-soluble vitamins.[6]

Table I: Antioxidant uses of butylated hydroxytoluene.

Antioxidant use	Concentration (%)
β-Carotene	0.01
Edible vegetable oils	0.01
Essential oils and flavoring agents	0.02–0.5
Fats and oils	0.02
Fish oils	0.01–0.1
Inhalations	0.01
IM injections	0.03
IV injections	0.0009–0.002
Topical formulations	0.0075–0.1
Vitamin A	10 mg per million units

8 Description

Butylated hydroxytoluene occurs as a white or pale yellow crystalline solid or powder with a faint characteristic phenolic odor.

9 Pharmacopeial Specifications

See Table II.

10 Typical Properties

Boiling point 265°C
Density (bulk) 0.48–0.60 g/cm^3
Density (true) 1.031 g/cm^3
Flash point 127°C (open cup)
Melting point 70°C
Moisture content ≤0.05%

Table II: Pharmacopeial specifications for butylated hydroxytoluene.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	–
Appearance of solution	+	–
Congealing temperature	–	≥69.2°C
Freezing point	69–70°C	–
Residue on ignition	–	≤0.002%
Sulfated ash	≤0.1%	–
Heavy metals	–	≤10 ppm
Related substances	+	+
Assay	–	99.0–101.5%

Partition coefficient Octanol : water = 4.17–5.80
Refractive index $n_D^{75} = 1.4859$
Solubility Practically insoluble in water, glycerin, propylene glycol, solutions of alkali hydroxides, and dilute aqueous mineral acids. Freely soluble in acetone, benzene, ethanol (95%), ether, methanol, toluene, fixed oils, and mineral oil. More soluble than butylated hydroxyanisole in food oils and fats.
Specific gravity

1.006 at 20°C;
0.890 at 80°C;
0.883 at 90°C;
0.800 at 100°C.

Specific heat

1.63 J/g/°C (0.39 cal/g/°C) for solid;
2.05 J/g/°C (0.49 cal/g/°C) for liquid.

Spectroscopy

IR spectrum *see* Figure 1.
NIR spectrum *see* Figure 2.
Raman spectrum *see* Figure 3.

Vapor density (relative) 7.6 (air = 1)
Vapor pressure

1.33 Pa (0.01 mmHg) at 20°C;
266.6 Pa (2 mmHg) at 100°C.

Viscosity (kinematic) 3.47 mm^2/s (3.47 cSt) at 80°C.

11 Stability and Storage Conditions

Exposure to light, moisture, and heat causes discoloration and a loss of activity. Butylated hydroxytoluene should be stored in a well-closed container, protected from light, in a cool, dry place.

12 Incompatibilities

Butylated hydroxytoluene is phenolic and undergoes reactions characteristic of phenols. It is incompatible with strong oxidizing agents such as peroxides and permanganates. Contact with oxidizing agents may cause spontaneous combustion. Iron salts cause discoloration with loss of activity. Heating with catalytic amounts of acids causes rapid decomposition with the release of the flammable gas isobutene.

13 Method of Manufacture

Butylated hydroxytoluene is prepared by the reaction of *p*-cresol with isobutene.

14 Safety

Butylated hydroxytoluene is readily absorbed from the gastrointestinal tract and is metabolized and excreted in the urine mainly as glucuronide conjugates of oxidation products. Although there have been some isolated reports of adverse skin reactions, butylated hydroxytoluene is generally regarded as nonirritant and nonsensitizing at the levels employed as an antioxidant.[7,8]

The WHO has set a temporary estimated acceptable daily intake for butylated hydroxytoluene at up to 125 µg/kg body-weight.[9]

Ingestion of 4 g of butylated hydroxytoluene, although causing severe nausea and vomiting, has been reported to be nonfatal.[10]

LD_{50} (guinea pig, oral): 10.7 g/kg[11]
LD_{50} (mouse, IP): 0.14 g/kg

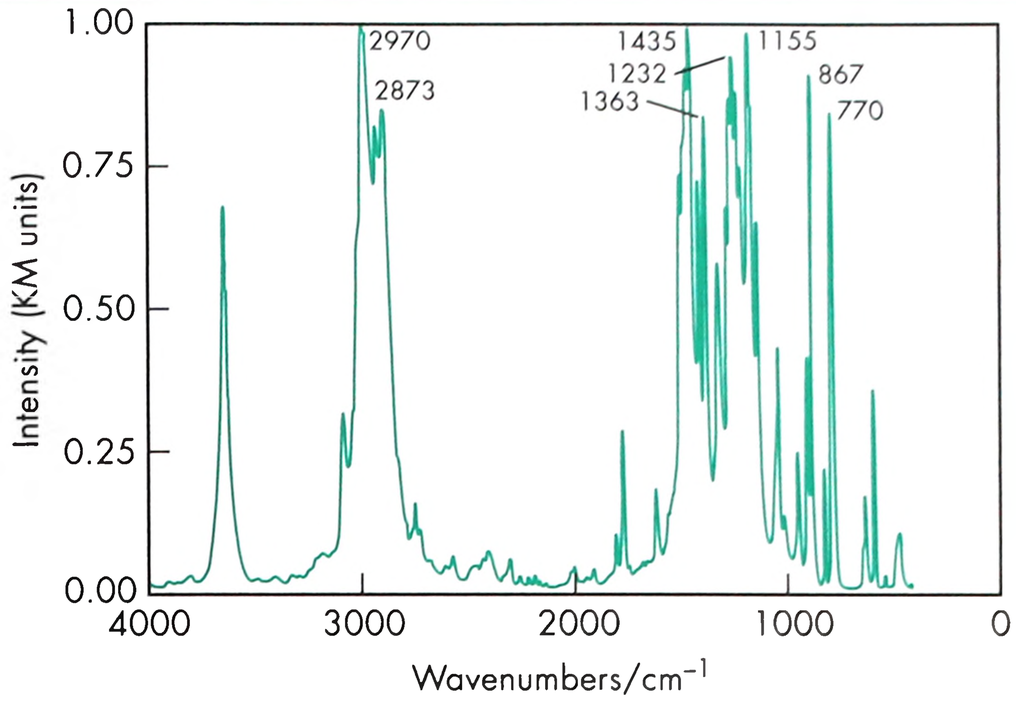


Figure 1: Infrared spectrum of butylated hydroxytoluene measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

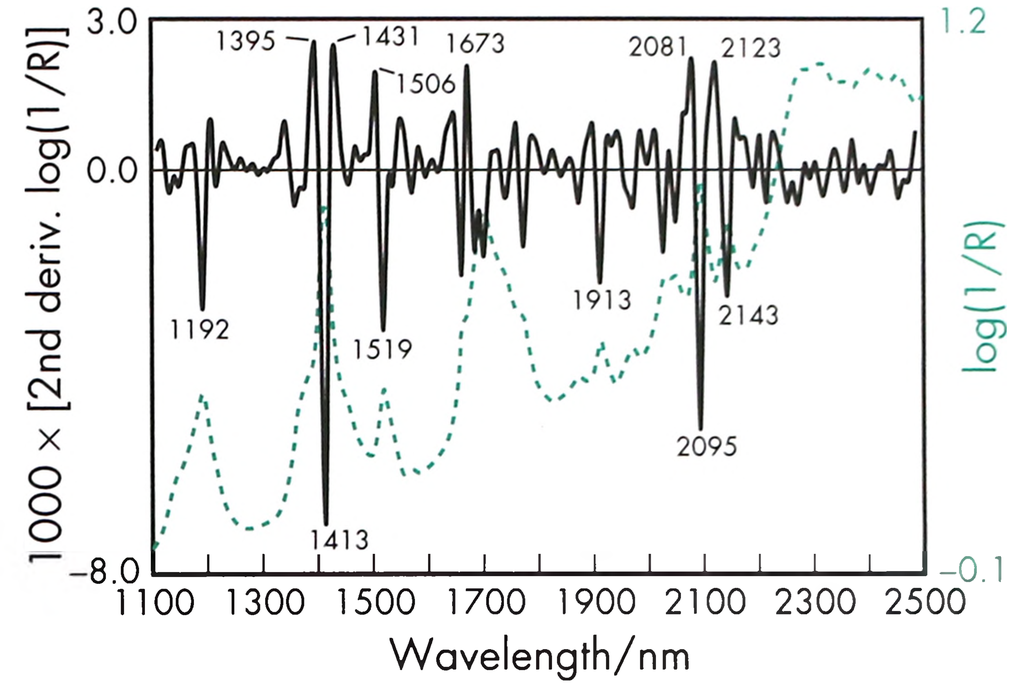

Figure 2: Near-infrared spectrum of butylated hydroxytoluene measured by reflectance.

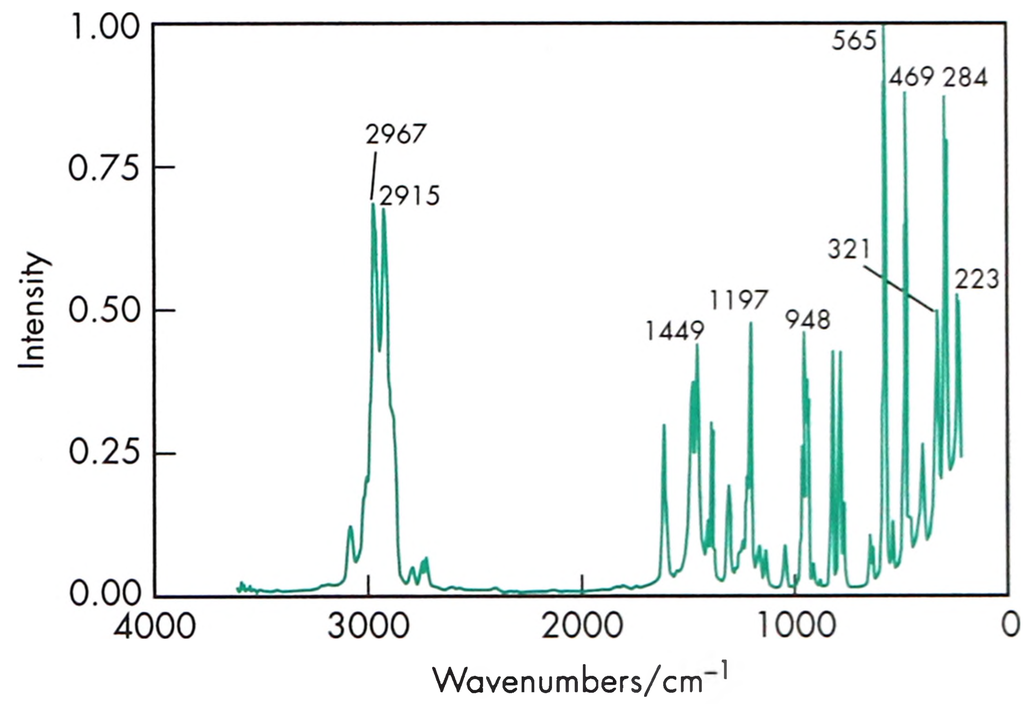

Figure 3: Raman spectrum of butylated hydroxytoluene measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

LD_{50} (mouse, IV): 0.18 g/kg
LD_{50} (mouse, oral): 0.65 g/kg
LD_{50} (rat, oral): 0.89 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Butylated hydroxytoluene may be irritant to the eyes and skin, and on inhalation. It should be handled in a well-ventilated environment; gloves and eye protection are recommended. Closed containers may explode owing to pressure build-up when exposed to extreme heat.

16 Regulatory Status

GRAS listed. Accepted as a food additive in Europe. Included in the FDA Inactive Ingredients Database (IM and IV injections, nasal sprays, oral capsules and tablets, rectal, topical, and vaginal preparations). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Butylated hydroxyanisole.

18 Comments

Butylated hydroxytoluene is also used at 0.5–1.0% w/w concentration in natural or synthetic rubber to provide enhanced color stability.

Butylated hydroxytoluene has some antiviral activity[12] and has been used therapeutically to treat herpes simplex labialis.[13]

A specification for butylated hydroxytoluene is contained in the *Food Chemicals Codex* (FCC).[14]

The EINECS number for butylated hydroxytoluene is 204-881-4. The PubChem Compound ID (CID) for butylated hydroxytoluene is 31404.

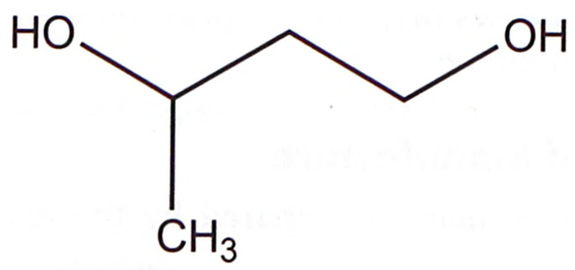
Butylene Glycol

1 Nonproprietary Names

USP–NF: Butylene Glycol

2 Synonyms

1,3-Butanediol; butane-1,3-diol; 1,3-butylene glycol; β-butylene glycol; 1,3-dihydroxybutane; methyltrimethylene glycol.



3 Chemical Name and CAS Registry Number

Butane-1,3-diol [107-88-0]

4 Empirical Formula and Molecular Weight

$C_4H_{10}O_2$ 90.12

5 Structural Formula

6 Functional Category

Antimicrobial preservative; humectant; solvent; transdermal delivery component.

7 Applications in Pharmaceutical Formulation or Technology

Butylene glycol is used as a solvent and cosolvent for injectables.[1] It is used in topical ointments, creams, and lotions,[2–4] and it is also used as a vehicle in transdermal patches. Butylene glycol is a good solvent for many pharmaceuticals, especially estrogenic substances.[5]

In an oil-in-water emulsion, butylene glycol exerts its best antimicrobial effects at approximately 8% concentration.[6] Higher concentrations above 16.7% are required to inhibit fungal growth.[7]

8 Description

Butylene glycol occurs as a clear, colorless, viscous liquid with a sweet flavor and bitter aftertaste.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for butylene glycol.

Test	USP 40–NF 35 S1
Identification	+
Acidity and alkalinity	5.5–7.0
Water	≤0.5%
Residue on ignition	≤0.05%
Lead	≤2 µg/g
Organic impurities	+
Assay	98.0–102.0%

10 Typical Properties

Antimicrobial activity Butylene glycol is effective against Gram-positive and Gram-negative bacteria, molds, and yeast, though it is not sporicidal.[6]
Density 1.004–1.006 (at 20°C)
Distillation range 200–215°C[8]
Flash point 115–121°C (open cup)
Hygroscopicity Absorbs 38.5% w/w of water in 144 hours at 81% RH.
Melting point −77°C
Refractive index $n_D^{20} = 1.440$
Solubility Miscible with acetone, ethanol (95%), castor oil, dibutyl phthalate, ether, water; practically insoluble in mineral oil, linseed oil, ethanolamine, aliphatic hydrocarbons; dissolves most essential oils and synthetic flavoring substances.
Specific heat 2.34 J/g (0.56 cal/g) at 20°C
Surface tension 37.8 mN/m (37.8 dyne/cm) at 25°C
Vapor density (relative) 3.1 (air = 1)
Vapor pressure 8 Pa (0.06 mmHg) at 20°C
Viscosity (dynamic) 104 mPa s (104 cP) at 25°C

11 Stability and Storage Conditions

Butylene glycol is hygroscopic and should be stored in tightly closed containers in a cool, dry, well-ventilated place. Do not store above 50°C.

12 Incompatibilities

Butylene glycol is incompatible with oxidizing reagents.

13 Method of Manufacture

Butylene glycol is prepared by catalytic hydrogenation of aldol using Raney nickel.

14 Safety

Butylene glycol is used in a wide variety of cosmetic formulations and is generally regarded as a relatively nontoxic material. It is mildly toxic by oral and subcutaneous routes.

In topical preparations, butylene glycol is regarded as minimally irritant. Butylene glycol can cause allergic contact dermatitis, with local sensitivity reported in patch tests.[3,9–12] Some local irritation is produced on eye contact.

LD_{50} (guinea pig, oral): 11.0 g/kg[13]
LD_{50} (mouse, oral): 12.98 g/kg
LD_{50} (rat, oral): 18.61 g/kg
LD_{50} (rat, SC): 20.0 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled.

Butylene glycol should be handled in a well-ventilated environment; eye protection is recommended. Butylene glycol is combustible when exposed to heat or flame. When heated to decomposition, it emits acrid smoke and irritating fumes.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (transdermal patches). Included in licensed medicines in the UK (topical gel patches/medicated plasters). Included in the Canadian Natural Health Products Ingredients Database.

Although not GRAS listed, butylene glycol is listed as a food additive in the EAFUS list compiled by the FDA.

17 Related Substances

Propylene glycol.

18 Comments

Butylene glycol is used in shaving lather preparations and cosmetics, where it can be used to replace glycerin.[2] Because of its high viscosity at low temperatures, heating may be required for pumping.

A specification for butylene glycol is included in the *Food Chemicals Codex* (FCC).[8]

The EINECS number for butylene glycol is 203-529-7. The PubChem Compound ID (CID) for butylene glycol is 7896.

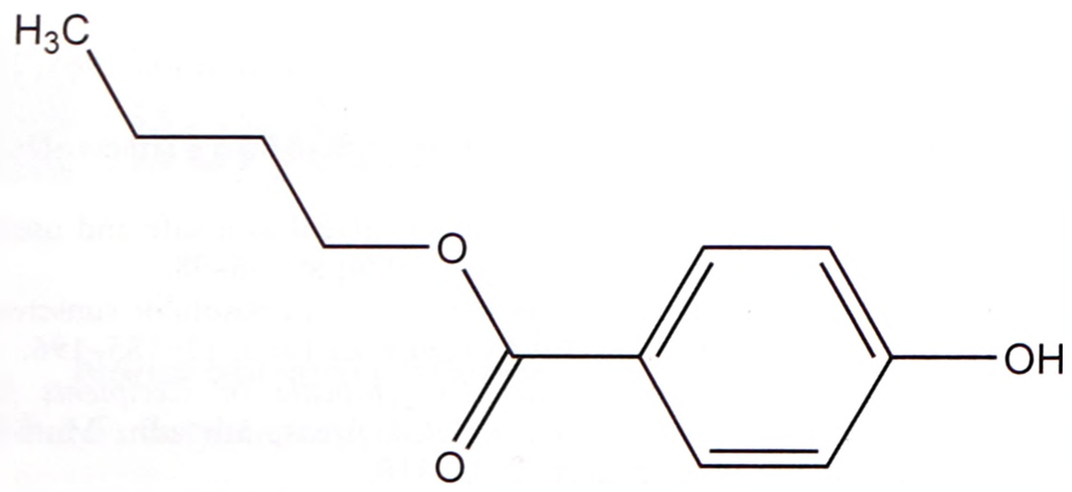
Butylparaben

1 Nonproprietary Names

BP: Butyl Hydroxybenzoate
JP: Butyl Parahydroxybenzoate
PhEur: Butyl Parahydroxybenzoate
USP–NF: Butylparaben

2 Synonyms

Benzoic acid, 4-hydroxy-, butyl ester; *Butoben*; *Butyl Chemosept*; butyl *p*-hydroxybenzoate; butyl parahydroxybenzoate; *Butyl Parasept*; butylis parahydroxybenzoas; *CoSept B*; 4-hydroxybenzoic acid butyl ester; *Nipagin*; *Lexgard B*; *Nipabutyl*; *Tegosept B*; *Trisept B*; *Uniphen P-23*; *Unisept B*.



3 Chemical Name and CAS Registry Number

Butyl-4-hydroxybenzoate [94-26-8]

4 Empirical Formula and Molecular Weight

$C_{11}H_{14}O_3$ 194.23

5 Structural Formula

6 Functional Category

Antimicrobial preservative.

7 Applications in Pharmaceutical Formulation or Technology

Butylparaben is widely used as an antimicrobial preservative in cosmetics and pharmaceutical formulations; *see* Table I. It may be used either alone or in combination with other paraben esters or with other antimicrobial agents. In cosmetics, it is the fourth most frequently used preservative.[1]

As a group, the parabens are effective over a wide pH range and have a broad spectrum of antimicrobial activity, although they are most effective against yeasts and molds; *see* Section 10.

Owing to the poor solubility of the parabens, paraben salts, particularly the sodium salt, are frequently used in formulations. However, this may raise the pH of poorly buffered formulations.

See Methylparaben for further information.

Table I: Uses of butylparaben.

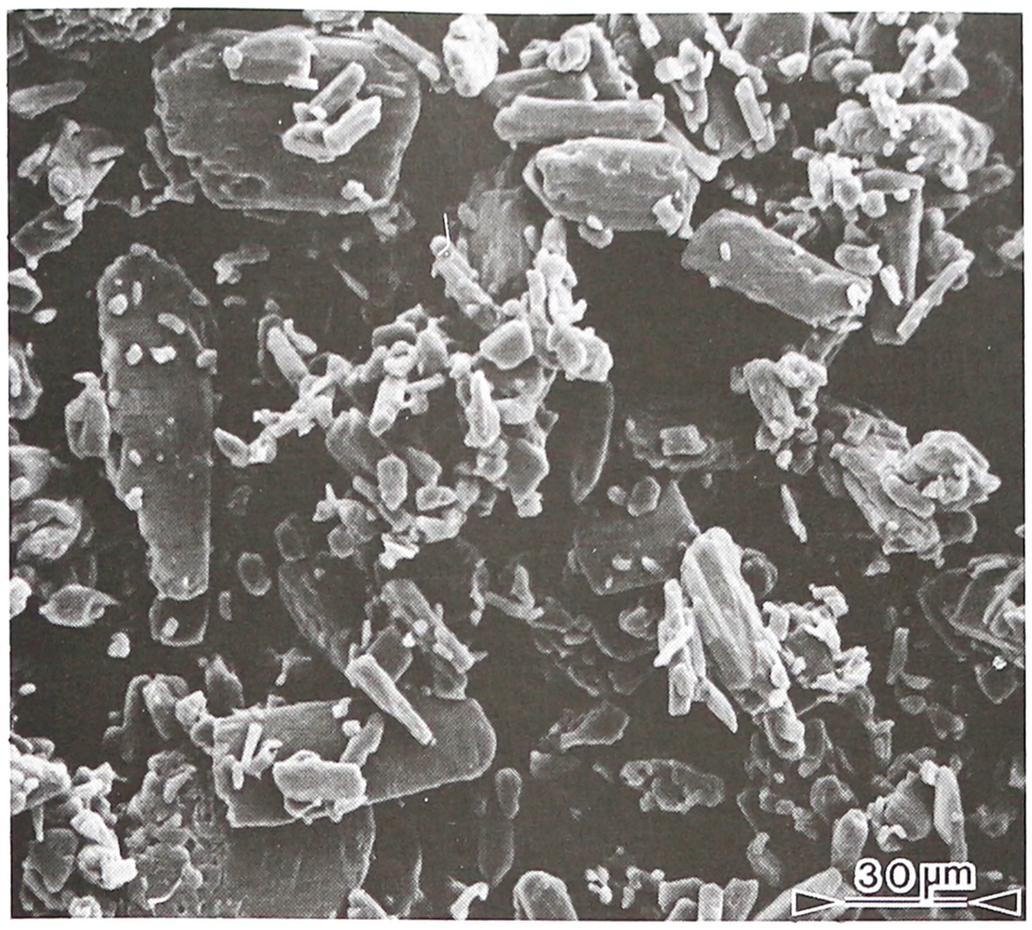
Use	Concentration (%)
Oral suspensions	0.006–0.05
Topical preparations	0.02–0.4

8 Description

Butylparaben occurs as colorless crystals or a white, crystalline, odorless or almost odorless, tasteless powder.

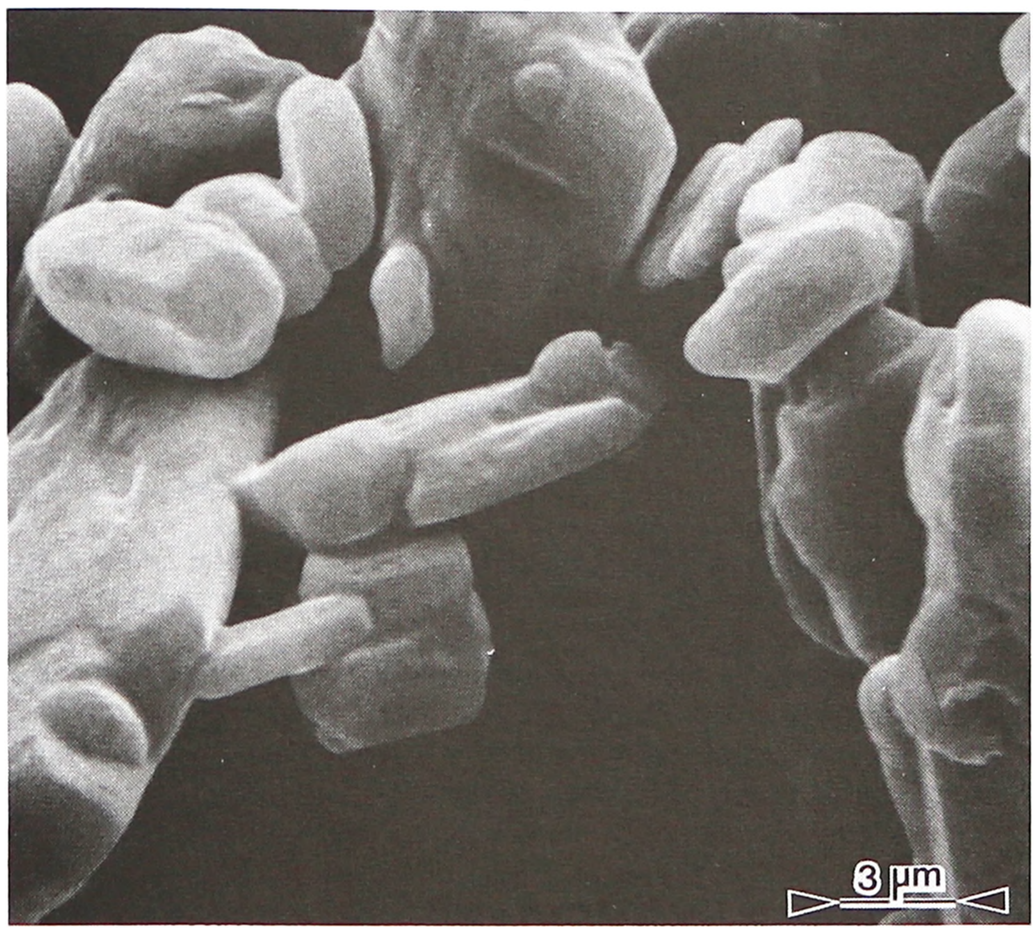
9 Pharmacopeial Specifications

The pharmacopeial specifications for butylparaben have undergone harmonization of many attributes for JP, PhEur, and USP–NF.



See Table II. *See also* Section 18.

Table II: Pharmacopeial specifications for butylparaben.



Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters	+	+	–
Appearance of solution	+	+	+
Melting range	68–71°C	68–71°C	68–71°C
Acidity	+	+	+
Residue on ignition	≤0.1%	–	≤0.1%
Sulfated ash	–	≤0.1%	–
Related substances	+	+	+
Heavy metals[a]	≤20 ppm	–	–
Assay (dried basis)	98.0–102.0%	98.0–102.0%	98.0–102.0%

(a) These tests have not been fully harmonized at the time of publication.

SEM 1: Excipient: butylparaben; magnification: 240×.

SEM 2: Excipient: butylparaben; magnification: 2400×.

10 Typical Properties

Antimicrobial activity Butylparaben exhibits antimicrobial activity between pH 4–8. Preservative efficacy decreases with increasing pH owing to the formation of the phenolate anion. Parabens are more active against yeasts and molds than against bacteria. They are also more active against Gram-positive than against Gram-negative bacteria; *see* Table III.[2]

The activity of the parabens increases with increasing chain length of the alkyl moiety, but solubility decreases. Butylparaben is thus more active than methylparaben. Activity may be improved by using combinations of parabens since synergistic effects occur. Activity has also been reported to be improved by the addition of other excipients; *see* Methylparaben for further information.

Density (bulk) 0.731 g/cm^3

Density (tapped) 0.819 g/cm^3

Melting point 68–71°C

Partition coefficients Values for different vegetable oils vary considerably and are affected by the purity of the oil; *see* Table IV.[3]

Table III: Minimum inhibitory concentrations (MICs) for butylparaben in aqueous solution.[2]

Microorganism	MIC (µg/mL)
Aerobacter aerogenes ATCC 8308	400
Aspergillus niger ATCC 9642	125
Aspergillus niger ATCC 10254	200

Ether	Freely soluble
Glycerin	1 in 330
Methanol	1 in 0.5
Mineral oil	1 in 1000
Peanut oil	1 in 20
Propylene glycol	1 in 1
Water	1 in >5000 1 in 670 at 80 °C

Solubility *see* Table V.

Spectroscopy

NIR spectrum *see* Figure 1.

11 Stability and Storage Conditions

Aqueous butylparaben solutions at pH 3–6 can be sterilized by autoclaving, without decomposition.[4] At pH 3–6, aqueous solutions are stable (less than 10% decomposition) for up to about 4 years at room temperature, while solutions at pH 8 or above are subject to rapid hydrolysis (10% or more after about 60 days at room temperature).[5]

Butylparaben should be stored in a well-closed container, in a cool, dry place.

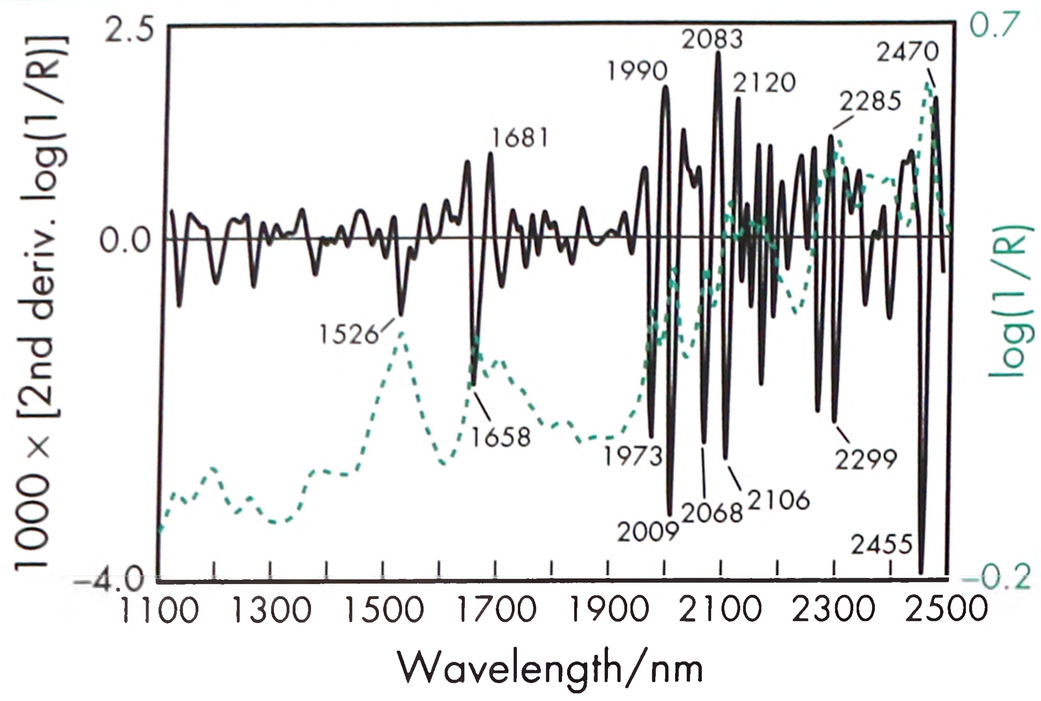

Figure 1: Near-infrared spectrum of butylparaben measured by reflectance.

12 Incompatibilities

The antimicrobial activity of butylparaben is considerably reduced in the presence of nonionic surfactants as a result of micellization.[6] Absorption of butylparaben by plastics has not been reported but appears probable given the behavior of other parabens. Some pigments, e.g. ultramarine blue and yellow iron oxide, absorb butylparaben and thus reduce its preservative properties.[7]

Butylparaben is discolored in the presence of iron and is subject to hydrolysis by weak alkalis and strong acids.

See also Methylparaben.

13 Method of Manufacture

Butylparaben is prepared by esterification of *p*-hydroxybenzoic acid with *n*-butanol.

14 Safety

Butylparaben and other parabens are widely used as antimicrobial preservatives in cosmetics and oral and topical pharmaceutical formulations.

Systemically, no adverse reactions to parabens have been reported, although they have been associated with hypersensitivity reactions generally appearing as contact dematitis. Immediate reactions with urticaria and bronchospasm have occurred rarely.

Some possible estrogenic effects have been reported.[8–10]

A report has been published on the safety assessment of parabens including butylparaben in cosmetic products.[11]

See Methylparaben for further information.

LD_{50} (mouse, IP): 0.23 g/kg[12]

LD_{50} (mouse, oral): 13.2 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Butylparaben may be irritant to the skin, eyes, and mucous membranes, and should be handled in a well-ventilated environment. Eye protection, gloves, and a dust mask or respirator are recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (injections; oral capsules, drops, solutions, suspensions, syrups and tablets; rectal, and topical preparations). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Butylparaben sodium; ethylparaben; methylparaben; propylparaben.

Butylparaben sodium

Empirical formula $C_{11}H_{13}NaO_3$
Molecular weight 216.23
CAS number [36457-20-2]
Synonyms Butyl-4-hydroxybenzoate sodium salt; sodium butyl hydroxybenzoate.
Appearance White, odorless or almost odorless, hygroscopic powder.
Acidity/alkalinity pH = 9.5–10.5 (0.1% w/v aqueous solution)
Solubility 1 in 10 of ethanol (95%); 1 in 1 of water.
Comments Butylparaben sodium may be used instead of butylparaben because of its greater aqueous solubility. In unbuffered formulations, pH adjustment may be required.

18 Comments

Butylparaben has undergone harmonization for many attributes for JP, PhEur, and USP–NF by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

See Methylparaben for further information and references.

The EINECS number for butylparaben is 202-318-7. The PubChem Compound ID (CID) for butylparaben is 7184.

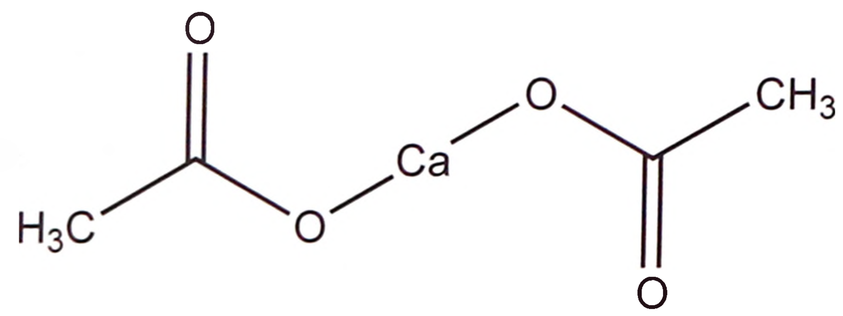
Calcium Acetate

1 Nonproprietary Names

BP: Calcium Acetate
PhEur: Calcium Acetate
USP–NF: Calcium Acetate

2 Synonyms

Acetate of lime; acetic acid, calcium salt; brown acetate; calcii acetas; calcium diacetate; E263; gray acetate; lime acetate; lime pyrolignite; vinegar salts.



3 Chemical Name and CAS Registry Number

Calcium acetate [62-54-4]
Calcium acetate monohydrate [5743-26-0]

4 Empirical Formula and Molecular Weight

$C_4H_6CaO_4$ 158.18
$C_4H_6CaO_4 \cdot H_2O$ 176.17 (for monohydrate)

5 Structural Formula

6 Functional Category

Antimicrobial preservative; complexing agent.

7 Applications in Pharmaceutical Formulation or Technology

Calcium acetate is used as a preservative in oral and topical formulations.

Calcium acetate is also used in the food industry as a stabilizer, buffer, and sequestrant.

8 Description

Calcium acetate occurs as a white or almost white, odorless or almost odorless, hygroscopic powder. Calcium acetate monohydrate occurs as needles, granules, or powder.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for calcium acetate.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Readily oxidizable substances	+	+
pH	7.2–8.2	6.3–9.6
Nitrates	+	+
Chlorides	≤330 ppm	≤0.05%
Sulfates	≤600 ppm	≤0.06%
Heavy metals	—	≤25 ppm
Magnesium	≤500 ppm	≤0.05%
Arsenic	≤3 ppm	≤3 ppm
Aluminum	≤1 ppm	≤2 ppm
Barium	≤50 ppm	+
Potassium	≤500 ppm	≤0.05%
Sodium	≤500 ppm	≤0.5%
Strontium	≤500 ppm	≤0.05%
Water	≤7.0%	≤7.0%
Fluoride	≤50 ppm	≤50 ppm
Lead	—	≤10 ppm
Assay (anhydrous substance)	98.0–102.0%	99.0–100.5%

10 Typical Properties

Acidity/alkalinity pH = 6.3–9.6 (5% solution); pH = 7.6 (0.2 M aqueous solution) for monohydrate
Density: 1.50 g/cm^3
Solubility Soluble in water; slightly soluble in methanol; practically insoluble in acetone, ethanol (dehydrated alcohol), and benzene. The monohydrate is soluble in water, slightly soluble in alcohol.

11 Stability and Storage Conditions

Calcium acetate is stable although very hygroscopic, and so the monohydrate is the common form. It decomposes on heating (above 160°C) to form calcium carbonate and acetone.

Store in well-closed airtight containers.

12 Incompatibilities

Calcium acetate is incompatible with strong oxidizing agents and moisture.[1]

13 Method of Manufacture

Calcium acetate is manufactured by the reaction of calcium carbonate or calcium hydroxide with acetic acid or pyroligneous acid.[2]

14 Safety

Calcium acetate is used in oral and topical formulations. The pure form of calcium acetate is toxic by IP and IV routes.

LD_{50} (mouse, IP): 0.075 g/kg[3]
LD_{50} (mouse, IV): 0.052 g/kg[3]
LD_{50} (rat, oral): 4.28 g/kg[1]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. Although regarded as safe during normal industrial handling, calcium acetate may cause eye and respiratory tract irritation.[1] It is combustible and when heated to decomposition, it emits acrid smoke and fumes. Avoid contact with eyes, skin, and clothing. Avoid breathing dust. Gloves, eye protection, respirator, and other protective clothing should be worn.

16 Regulatory Status

GRAS listed. Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (oral suspensions and tablets; topical emulsions, lotions, and creams). Included in nonparenteral medicines (oral tablets) licensed in the UK.

17 Related Substances

Sodium acetate.

18 Comments

Calcium acetate is used in the chemical industry for the manufacture of acetic acid, acetates, and acetone, and for the precipitation of oxalates.

Therapeutically, parenteral calcium acetate acts as a source of calcium ions for hypocalcemia or electrolyte balance.[4] Oral calcium acetate is used as a complexing agent for hyperphosphatemia in dialysis patients.[5,6]

A specification for calcium acetate is contained in the *Food Chemicals Codex* (FCC).[7]

The EINECS number for calcium acetate is 200-540-9. The PubChem Compound ID (CID) for calcium acetate is 6116.

Calcium Alginate

1 Nonproprietary Names

None adopted.

2 Synonyms

Alginato calcico; algin; alginic acid, calcium salt; *CA33*; calc algin; calcium polymannuronate; *Calginate*; E404; *Kaltostat*.

3 Chemical Name and CAS Registry Number

Calcium alginate [9005-35-0]

4 Empirical Formula and Molecular Weight

$[(C_6H_7O_6)_2Ca]_n$ 195.16 (calculated); 219.00 (actual, average)

Each calcium ion binds with two alginate molecules. The molecular weight of 195.16 relates to one alginate molecule, and the equivalent of half a calcium ion, therefore $n = \frac{1}{2}$.

Calcium alginate is a polyuronide made up of a sequence of two hexuronic acid residues, namely D-mannuronic acid and L-guluronic acid. The two sugars form blocks of up to 20 units along the chain, with the proportion of the blocks dependent on the species of seaweed and also the part of the seaweed used. The number and length of the blocks are important in determining the physical properties of the alginate produced; the number and sequence of the mannuronate and guluronate residues varies in the naturally occurring alginate.

It has a typical macromolecular weight between 10 000 and 600 000.

5 Structural Formula

See Section 4.

6 Functional Category

Emulsifying agent; modified-release agent; tablet and capsule disintegrant; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

In pharmaceutical formulations, calcium alginate and calcium-sodium alginate have been used as tablet disintegrants.[1] The use of a high concentration (10%) of calcium-sodium alginate has been reported to cause slight speckling of tablets.[1]

A range of different types of delivery systems intended for oral administration have been investigated. These exploit the gelling properties of calcium alginate.[2] Calcium alginate beads have been used to prepare floating dosage systems[3–7] containing amoxicillin,[8] furosemide,[9] meloxicam,[10] and barium sulfate,[11] and as a means of providing a sustained or controlled-release action for sulindac,[12] diclofenac,[13] glibenclamide,[14] tiaramide,[15] insulin,[16] and ampicillin.[17] The effect of citric acid in prolonging the gastric retention of calcium alginate floating dosage forms has been reported.[18,19] Impregnating meloxicam in calcium alginate beads may reduce the risk of ulceration and mucosal inflammation following oral administration.[20] The use of calcium alginate beads, reinforced with chitosan, has been shown to slow the release of verapamil,[21] and may be useful for the controlled release of protein drugs to the gastrointestinal tract.[22] The release rate of bovine serum albumin of two molecular weights loaded into calcium

alginate beads, which were embedded in silk fibroin to form a three-dimensional dual release scaffold, was found to be dependent on the molecular weight of the protein.[23] The bioadhesive properties,[24] swelling and drug release[25] of calcium alginate beads have also been investigated. The mechanical properties of calcium alginate hydrogels have been investigated,[26] and a novel injectable and *in situ*-forming gel composite composed of calcium alginate gel and nanohydroxyapatite/collagen has been described.[27]

A series of studies investigating the production,[28] formulation,[29] and drug release[30] from calcium alginate matrices for oral administration have been published. The release of diltiazem hydrochloride from a polyvinyl alcohol matrix was shown to be controlled by coating with a calcium alginate membrane; the drug release profile could be modified by increasing the coating thickness of the calcium alginate layer.[31] The microencapsulation of live attenuated Bacillus Calmette–Guérin (BCG) cells within a calcium alginate matrix has also been reported.[32]

It has been shown that a modified drug release can be obtained from calcium alginate microcapsules,[33] pellets,[34,35] and microspheres.[36] When biodegradable bone implants composed of calcium alginate spheres and containing gentamicin were introduced into the femur of rats, effective drug levels in bone and soft tissue were obtained for 30 days and 7 days, respectively.[37] The incorporation of radioactive particles into calcium alginate gels may be useful for the localized delivery of radiation therapy to a wide range of organs and tissues.[38]

8 Description

Calcium alginate is an odorless or almost odorless, tasteless, white to pale yellowish-brown powder or fibers.

9 Pharmacopeial Specifications

See Section 18.

10 Typical Properties

Moisture content Loses not more than 22% of its weight on drying.

Solubility Practically insoluble in chloroform, ethanol, ether, water, and other organic solvents. Soluble in dilute solutions of sodium citrate and of sodium bicarbonate and in sodium chloride solution. Soluble in alkaline solutions or in solutions of substances that combine with calcium.

11 Stability and Storage Conditions

Calcium alginate can be sterilized by autoclaving at 115°C for 30 minutes or by dry heat at 150°C for 1 hour. Calcium alginate should be stored in airtight containers.

12 Incompatibilities

Calcium alginate is incompatible with alkalis and alkali salts. Propranolol hydrochloride has been shown to bind to alginate molecules, suggesting that propranolol and calcium ions share common binding sites in the alginate chains; the formation of the calcium alginate gel structure was impeded in the presence of propranolol molecules.[39] It has been reported that commonly used topical antimicrobials could potentially be incompatible with calcium alginate dressings.[40]

13 Method of Manufacture

Calcium alginate can be obtained from seaweed, mainly species of *Laminaria*.

Solutions of sodium alginate interact with an ionized calcium salt, resulting in the instantaneous precipitation of insoluble calcium alginate, which can then be further processed. Introducing varying proportions of sodium ions during manufacture can produce products having different absorption rates.

14 Safety

Calcium alginate is widely used in oral and topical formulations, and in foods.

In 1974, the WHO set an estimated acceptable daily intake of calcium alginate of up to 25 mg, as alginic acid, per kilogram body-weight.[41]

When heated to decomposition, it emits acrid smoke and irritating fumes.

LD_{50} (rat, IP): 1.41 g/kg[42]

LD_{50} (rat, IV): 0.06 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled.

16 Regulatory Status

GRAS listed. Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (oral tablets). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Alginic acid; potassium alginate; propylene glycol alginate; sodium alginate.

18 Comments

Protanal (formerly *Keltose*; FMC Biopolymer) has been used as a brand name for blends of ammonium alginate and calcium alginate.

Therapeutically, the gelling properties of calcium alginate are utilized in wound dressings in the treatment of leg ulcers, pressure sores, and other exuding wounds. These dressings are highly absorbent and are suitable for moderately or heavily exuding wounds. Calcium alginate dressings also have hemostatic properties, with calcium ions being exchanged for sodium ions in the blood; this stimulates both platelet activation and whole blood coagulation. A mixed calcium–sodium salt of alginic acid is used as fibers in dressings or wound packing material.

Sterile powder consisting of a mixture of calcium and sodium alginates has been used in place of talc in glove powders.

In foods, calcium alginate is used as an emulsifier, thickener, and stabilizer.

Although not included in any pharmacopeias, a specification for calcium alginate is contained in the *Food Chemicals Codex* (FCC),[43] and has been included in the *British Pharmaceutical Codex* (BPC);[44] *see* Table I.

Table I: FCC[43] and BPC[44] specifications for calcium alginate.

Test	FCC 10 S2	BPC 1973
Arsenic	≤3 mg/kg	≤3 ppm
Iron	–	≤530 ppm
Lead	≤5 mg/kg	≤10 ppm
Loss on drying	≤15%	22.00%
Sulfated ash	–	31.0–34.0%
Assay	89.6–104.5%	–

Calcium Carbonate

C

1 Nonproprietary Names

BP: Calcium Carbonate
JP: Precipitated Calcium Carbonate
PhEur: Calcium Carbonate
USP–NF: Calcium Carbonate

2 Synonyms

Balcarb; *Cal-Carb*; calcii carbonas; calcii carbonas praecipitatus; calcium carbonate (1 : 1); *Calcipress*; *Calopake*; carbonic acid calcium salt (1 : 1); creta preparada; *Destab*; E170; *MagGran CC*; *Pharma-Carb*; precipitated calcium carbonate; precipitated carbonate of lime; precipitated chalk; *Sturcal*; *Vicality*; *Vivapress*; *Witcarb*; *Vivapress Ca*.

3 Chemical Name and CAS Registry Number

Carbonic acid, calcium salt (1 : 1) [471-34-1]

4 Empirical Formula and Molecular Weight

$CaCO_3$ 100.09

5 Structural Formula

See Section 4.

6 Functional Category

Buffering agent; opacifier; tablet and capsule binder; tablet and capsule diluent.

7 Applications in Pharmaceutical Formulation or Technology

Calcium carbonate, employed as a pharmaceutical excipient, is mainly used in solid-dosage forms as a diluent.[1–5] It is also used as a base for medicated dental preparations,[6] as a buffering agent, and as a dissolution aid in dispersible tablets. Calcium carbonate is used as a bulking agent in tablet sugar-coating processes and as an opacifier in tablet film-coating.

Calcium carbonate is also used as a food additive.

8 Description

Calcium carbonate occurs as an odorless and tasteless white powder or crystals.

9 Pharmacopeial Specifications

See Table I. *See also* Section 18.

10 Typical Properties

Acidity/alkalinity pH = 9.0 (10% w/v aqueous dispersion)
Density (bulk) 0.8 g/cm^3
Density (tapped) 1.2 g/cm^3
Flowability Cohesive.
Melting point Decomposes at 825°C.
Moisture content *see* Figure 1.
Particle size *see* Figure 2.
Refractive index 1.59
Solubility Practically insoluble in ethanol (95%) and water. Solubility in water is increased by the presence of ammonium salts or carbon dioxide. The presence of alkali hydroxides reduces solubility.

Table I: Pharmacopeial specifications for calcium carbonate.

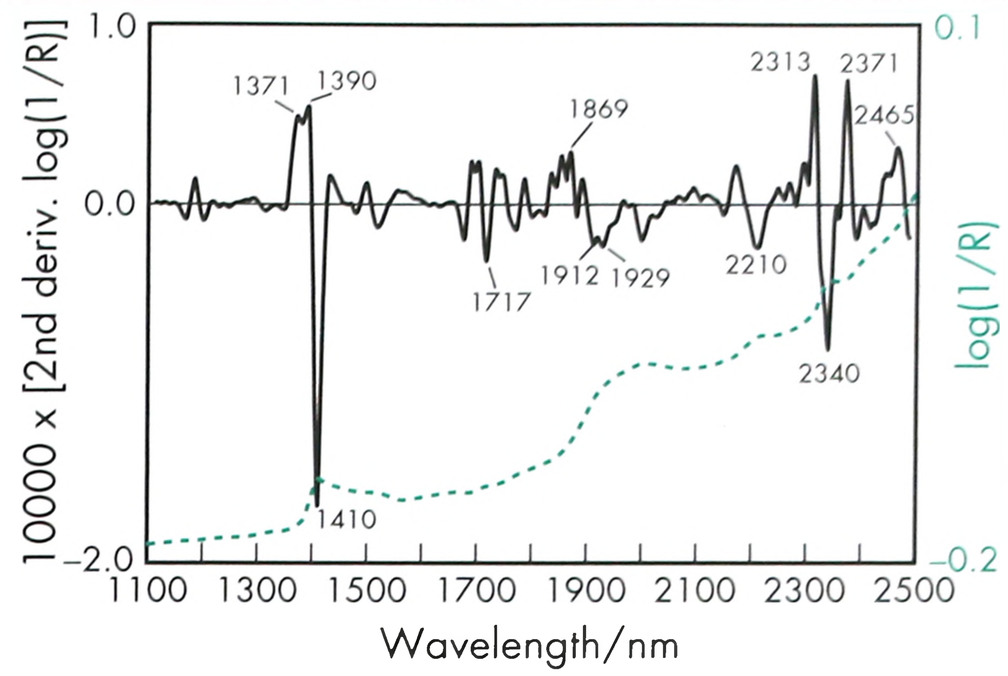

Figure 4: Near-infrared spectrum of calcium carbonate measured by reflectance.

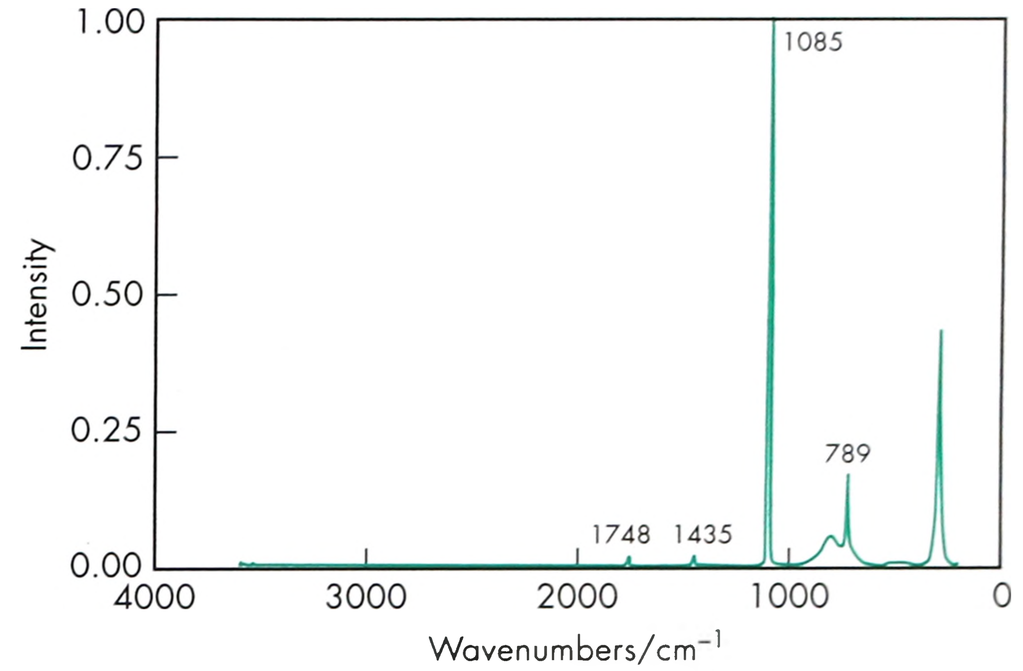

Figure 5: Raman spectrum of calcium carbonate measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

carbonate may interfere with the absorption of other drugs from the gastrointestinal tract if administered concomitantly.

LD_{50} (rat, oral): 6.45 g/kg

12 Incompatibilities

Incompatible with acids and ammonium salts (*see also* Sections 10 and 18).

13 Method of Manufacture

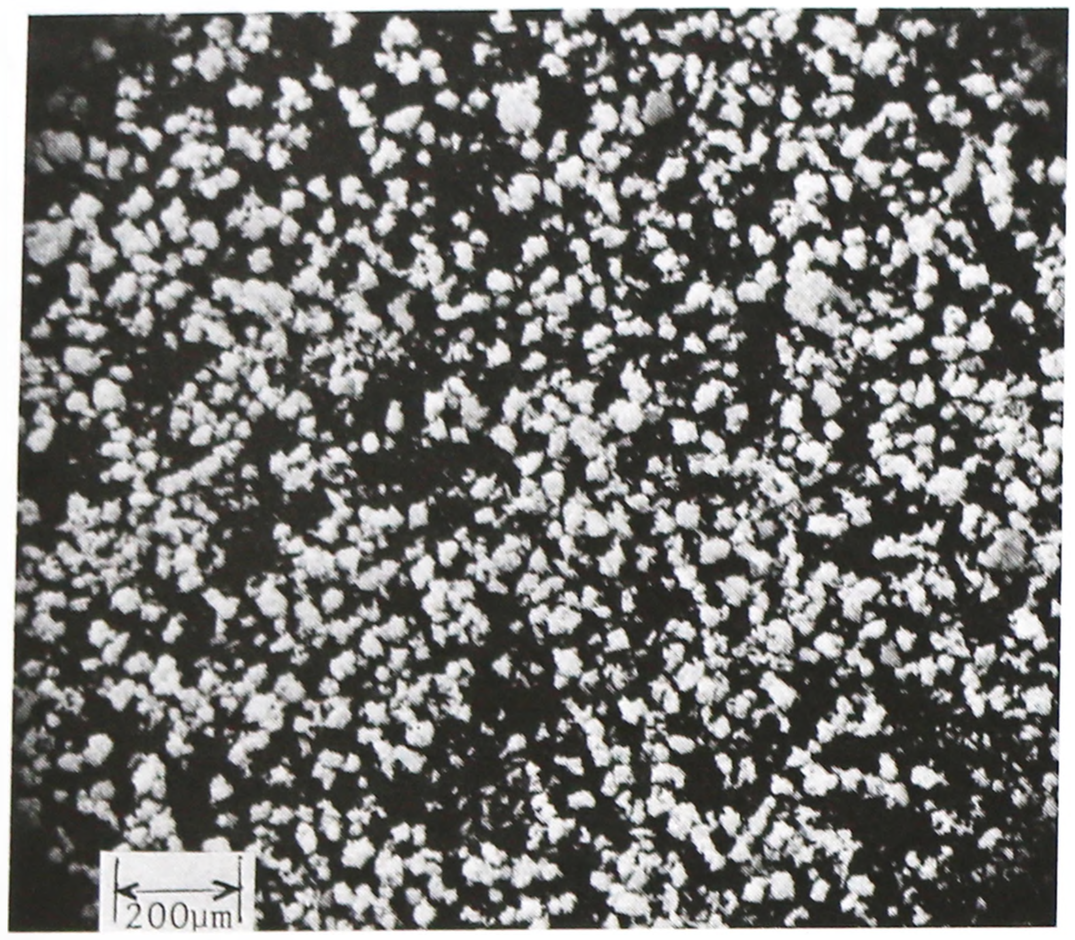
Calcium carbonate is prepared by double decomposition of calcium chloride and sodium bicarbonate in aqueous solution. Density and fineness are governed by the concentrations of the solutions. Calcium carbonate is also obtained from the naturally occurring minerals aragonite, calcite, and vaterite.

14 Safety

Calcium carbonate is mainly used in oral pharmaceutical formulations and is generally regarded as a nontoxic material. However, calcium carbonate administered orally may cause constipation and flatulence. Consumption of large quantities (4–60 g daily) may also result in hypercalcemia or renal impairment.[7] Therapeutically, oral doses of up to about 1.5 g are employed as an antacid. In the treatment of hyperphosphatemia in patients with chronic renal failure, oral daily doses of 2.5–17 g have been used. Calcium

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Calcium carbonate may be irritant to the eyes and on inhalation. Eye protection, gloves, and a dust mask are recommended. Calcium carbonate should be handled in a well-ventilated environment. In the UK, the long-term (8-hour TWA) workplace exposure limit for calcium carbonate is 10 mg/m^3 for total inhalable dust and 4 mg/m^3 for respirable dust.[8]



16 Regulatory Status

GRAS listed. Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (buccal chewing gum, oral capsules and tablets; otic solutions; respiratory inhalation solutions). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

SEM 4: Excipient: calcium carbonate; manufacturer: Whittaker, Clark & Daniels; lot no.: 15A-4; magnification: 2400×; voltage: 20 kV.

18 Comments

Calcium carbonate is one of the materials that have been selected for harmonization by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

When calcium carbonate is used in tablets containing aspirin and related substances, traces of iron may cause discoloration. This may be overcome by inclusion of a suitable chelating agent. Grades with reduced lead levels are commercially available for use in antacids and calcium supplements.

Directly compressible grades containing only calcium carbonate are commercially available, such as *MagGran CC* (Magnesia GmbH). *Barcroft CS90* (SPI Pharma) is a directly compressible grade containing 10% starch and *Calci-Press MD* (Particle Dynamics Inc.) is a directly compressible blend of calcium carbonate and maltodextrin.

A specification for calcium carbonate is contained in the *Food Chemicals Codex* (FCC).[9]

The EINECS number for calcium carbonate is 207-439-9. The PubChem Compound ID (CID) for calcium carbonate includes 10112 and 516889.

Calcium carbonate is used therapeutically as an antacid and calcium supplement.

Calcium Chloride

1 Nonproprietary Names

BP: Calcium Chloride Dihydrate
Calcium Chloride Hexahydrate
JP: Calcium Chloride Hydrate
PhEur: Calcium Chloride Dihydrate
Calcium Chloride Hexahydrate
USP–NF: Calcium Chloride

Note that the JP XVII and USP 40–NF 35 S1 monographs list the dihydrate form.

2 Synonyms

Calcii chloridum dihydricum; calcii chloridum hexahydricum.

3 Chemical Name and CAS Registry Number

Calcium chloride anhydrous [10043-52-4]
Calcium chloride dihydrate [10035-04-8]
Calcium chloride hexahydrate [7774-34-7]

4 Empirical Formula and Molecular Weight

$CaCl_2$	110.98 (for anhydrous)
$CaCl_2 \cdot 2H_2O$	147.0 (for dihydrate)
$CaCl_2 \cdot 6H_2O$	219.1 (for hexahydrate)

5 Structural Formula

See Section 4.

6 Functional Category

Antimicrobial preservative; desiccant.

7 Applications in Pharmaceutical Formulation or Technology

The main applications of calcium chloride as an excipient relate to its dehydrating properties and, therefore, it has been used as an antimicrobial preservative, and as a desiccant.

8 Description

Calcium chloride occurs as a white or colorless crystalline powder, granules, or crystalline mass, and is hygroscopic (deliquescent).

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for calcium chloride.

10 Typical Properties

Acidity/alkalinity pH = 4.5–9.2 (5% w/v aqueous solution)
Boiling point >1600°C (anhydrous)
Density (bulk) 0.835 g/cm^3 (dihydrate)
Melting point

772°C (anhydrous);

176°C (dihydrate);

30°C (hexahydrate).

Solidification temperature 28.5–30°C (hexahydrate)
Solubility Freely soluble in water and ethanol (95%); insoluble in diethyl ether.

11 Stability and Storage Conditions

Calcium chloride is chemically stable; however, it should be protected from moisture. Store in airtight containers in a cool, dry place.

12 Incompatibilities

Calcium chloride is incompatible with soluble carbonates, phosphates, sulfates, and tartrates.[1] It reacts violently with bromine trifluoride, and a reaction with zinc releases explosive hydrogen gas. It has an exothermic reaction with water, and when heated to decomposition it emits toxic fumes of chlorine.

13 Method of Manufacture

Calcium chloride is a principal byproduct of the Solvay process.

14 Safety

Calcium chloride is used in topical, ophthalmic, and injection preparations. The pure form of calcium chloride is toxic by intravenous, intramuscular, intraperitoneal, and subcutaneous routes, and moderately toxic by ingestion, causing stomach and heart disturbances. It is a severe eye irritant and can cause dermatitis.

LD_{50} (mouse, IP): 0.21 g/kg[2]
LD_{50} (mouse, IV): 0.042 g/kg
LD_{50} (mouse, oral): 1.94 g/kg
LD_{50} (mouse, SC): 0.82 g/kg
LD_{50} (rat, IM): 0.025 g/kg
LD_{50} (rat, IP): 0.26 g/kg
LD_{50} (rat, oral): 1.0 g/kg
LD_{50} (rat, SC): 2.63 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. Calcium chloride is irritating to eyes, the respiratory system, and skin. Gloves, eye protection, respirator, and other protective clothing should be worn.

16 Regulatory Status

GRAS listed. Included in the FDA Inactive Ingredients Database (injections, ophthalmic preparations, suspensions, creams). Included in medicines licensed in the UK (eye drops; intraocular irrigation; vaccines; injection powders for reconstitution; nebulizer solution; oral suspension).

17 Related Substances

—

18 Comments

The dissolution of calcium chloride in water is an exothermic reaction and, along with other excipients such as sodium sulfate, sodium acetate, and water, it has a potential application in hot packs.[3] Calcium chloride has been used to control the release of active ingredients from solid oral dosage forms by crosslinking pectin,[4] or by its interaction with chitosan.[5]

Therapeutically, calcium chloride injection 10% (as the dihydrate form) is used to treat hypocalcemia.[6] It has also been used as an astringent in eye lotions.

A specification for calcium chloride is contained in the *Food Chemicals Codex* (FCC).[7]

The EINECS number for calcium chloride is 233-140-8. The PubChem Compound ID (CID) for calcium chloride is 5284359.

Calcium Hydroxide

1 Nonproprietary Names

BP: Calcium Hydroxide
JP: Calcium Hydroxide
PhEur: Calcium Hydroxide
USP–NF: Calcium Hydroxide

2 Synonyms

Calcii hydroxidum; calcium hydrate; E526; hydrated lime; slaked lime.

3 Chemical Name and CAS Registry Number

Calcium hydroxide [1305-62-0]

4 Empirical Formula and Molecular Weight

$Ca(OH)_2$ 74.1

5 Structural Formula

See Section 4.

6 Functional Category

Alkalizing agent.

7 Applications in Pharmaceutical Formulation or Technology

Calcium hydroxide is a strong alkali and is used as a pharmaceutical pH adjuster/buffer and antacid in topical medicinal ointments, creams, lotions, and suspensions, often as an aqueous solution (lime water).[1,2] It forms calcium soaps of fatty acids, which produce water-in-oil emulsions (calamine liniment).[3,4]

Calcium hydroxide is a common cosmetic ingredient in hair-straightening and hair-removal products, and in shaving preparations.[1]

8 Description

Calcium hydroxide occurs as a white or almost white, crystalline or granular powder. It has a bitter, alkaline taste. Calcium hydroxide readily absorbs carbon dioxide to form calcium carbonate.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for calcium hydroxide.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Acid-insoluble substances	≤25 mg	≤0.5%	≤0.5%
Carbonates	—	≤5.0%	+
Chlorides	—	≤330 ppm	—
Sulfates	—	≤0.4%	—
Heavy metals	≤40 ppm	—	≤20 µg/g
Arsenic	≤4 ppm	≤4 ppm	—
Magnesium and alkali (metals) salts	≤24 mg	≤4.0%	≤4.8%
Assay	≥90.0%	95.0–100.5%	95.0–100.5%

10 Typical Properties

Acidity/alkalinity pH = 12.4 (saturated solution at 25°C)
Density 2.08–2.34 g/cm^3
Melting point When heated above 580°C, it dehydrates forming the oxide.
Solubility Soluble in glycerol and ammonium chloride solutions; dissolves in sucrose solutions to form calcium saccharosates;[2] soluble in acids with the evolution of heat; soluble 1 in 600 water (less soluble in hot water); insoluble in ethanol (95%).

11 Stability and Storage Conditions

Calcium hydroxide should be stored in an airtight container, in a cool, dry, well-ventilated place. Calcium hydroxide powder may be sterilized by heating for 1 hour at a temperature of at least 160°C.[2]

12 Incompatibilities

Incompatible with strong acids, maleic anhydride, phosphorus, nitroethane, nitromethane, nitroparaffins, and nitropropane. Calcium hydroxide can be corrosive to some metals.

13 Method of Manufacture

Calcium hydroxide is manufactured by adding water to calcium oxide, a process called slaking.

14 Safety

Calcium hydroxide is used in oral and topical pharmaceutical formulations. It is mildly toxic by ingestion. In the pure state, calcium hydroxide is a severe skin, eye, and respiratory irritant, and it is corrosive, causing burns. Typical exposure limits are TLV 5 mg/m^3 in air.[5]

LD_{50} (mouse, oral): 7.3 g/kg
LD_{50} (rat, oral): 7.34 g/kg[6]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. Avoid contact with eyes, skin, and clothing. Avoid breathing the dust. Gloves, eye protection, respirator, and other protective clothing should be worn. In the USA, the OSHA permissible exposure limit is 15 mg/m^3 for total dust and 5 mg/m^3 respirable fraction for calcium hydroxide.[7]

16 Regulatory Status

GRAS listed. Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (intravenous and subcutaneous injections; oral suspensions and tablets; topical emulsions and creams). Included in parenteral preparations licensed in the UK.

17 Related Substances

Potassium hydroxide; sodium hydroxide.

18 Comments

Therapeutically, calcium hydroxide has been used as a topical astringent.[3,4]

In dentistry, it is used as a filling agent and in dental pastes to encourage deposition of secondary dentine.[8] Calcium hydroxide was traditionally used as an escharotic in Vienna Paste.[9]

A specification for calcium hydroxide is contained in the *Food Chemicals Codex* (FCC).[10]

The EINECS number for calcium hydroxide is 215-137-3. The PubChem Compound ID (CID) for calcium hydroxide is 14777.

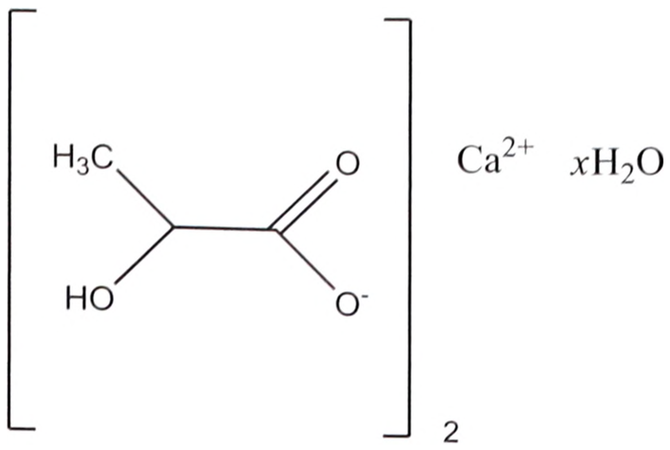
Calcium Lactate

1 Nonproprietary Names

BP: Calcium Lactate Pentahydrate
JP: Calcium Lactate Hydrate
PhEur: Calcium Lactate
USP–NF: Calcium Lactate

2 Synonyms

Calcii lactas pentahydricus; calcium bis(2-hydroxypropanoate) pentahydrate; calcium dilactate; calcium lactate (1 : 2) hydrate; calcium lactate (1 : 2) pentahydrate; E327; 2-hydroxypropanoic acid, calcium salt; lactic acid, calcium salt; mixture of calcium (2*R*)-, (2*S*)- and (2*RS*)-2-hydroxypropanoates pentahydrates; propanoic acid, 2-hydroxy-, calcium salt (2 : 1), hydrate; *Puracal*.



3 Chemical Name and CAS Registry Number

Calcium lactate anhydrous [814-80-2]
Calcium lactate monohydrate and trihydrate [41372-22-9]
Calcium lactate pentahydrate [5743-47-5] and [63690-56-2]

4 Empirical Formula and Molecular Weight

$C_6H_{10}CaO_6$	218.2 (anhydrous)
$C_6H_{10}CaO_6 \cdot H_2O$	236.0 (monohydrate)
$C_6H_{10}CaO_6 \cdot 3H_2O$	272.3 (trihydrate)
$C_6H_{10}CaO_6 \cdot 5H_2O$	308.3 (pentahydrate)

5 Structural Formula

6 Functional Category

Antimicrobial preservative; buffering agent; tablet and capsule binder; tablet and capsule diluent; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Calcium lactate is used as a bioavailability enhancer and nutrient supplement in pharmaceutical formulations.

A spray-dried grade of calcium lactate pentahydrate has been used as a tablet diluent in direct compression systems,[1] and has been shown to have good compactability. The properties of the pentahydrate form have been considered superior to those of calcium lactate trihydrate when used in direct compression tablet formulations.[2] Tablet properties may be affected by the hydration state of the calcium lactate and particle size of the material: reducing particle size increased crushing strength, whereas storage of tablets at elevated temperature resulted in dehydration accompanied by a reduction in crushing strength.[3]

Calcium lactate has also been used as the source of calcium ions in the preparation of calcium alginate microspheres for controlled-release delivery of active agents. It has been shown to result in lower calcium concentrations in the finished microspheres when compared with calcium acetate.[4]

8 Description

Calcium lactate occurs as white or almost white, crystalline or granular powder. It is slightly efflorescent.

9 Pharmacopeial Specifications

See Table I. *See also* Section 18.

10 Typical Properties

Acidity/alkalinity pH = 6.0–8.5 for a 10% aqueous solution for *Puracal PP*[5]

Density (bulk) 0.56 g/cm^3;[2] 0.3–0.5 g/cm^3 for *Puracal PP*[5]

Density (tapped) 0.67 g/cm^3[2]

Density (true) 1.494 g/cm^3[2]

Hygroscopicity The pentahydrate form is nonhygroscopic (*see* Section 11).

Melting point >200°C for *Puracal PP*[5]

Solubility Soluble in water, freely soluble in boiling water; very slightly soluble in ethanol (95%).

11 Stability and Storage Conditions

Calcium lactate can exist in a number of hydration states, which are characterized as anhydrous, monohydrate, trihydrate, and pentahydrate. Dehydration of the pentahydrate form is rapid at temperatures of 55°C and above. Dehydration is reported to be accompanied by some loss of crystallinity.[6] Tablet crushing strength has been reported to be reduced following dehydration of calcium lactate pentahydrate.[3]

Table I: Pharmacopeial specifications for calcium lactate.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+

Trihydrate	—	15.0–20.0%	15.0–20.0%
Pentahydrate	25–30%	22.0–27.0%	22.0–27.0%
Arsenic	≤4 ppm	—	—
Volatile fatty acid	+	—	+
Assay (dried basis)	≥97.0%	98–102%	98.0–101.0%

12 Incompatibilities

Calcium salts, including the lactate, can display physical incompatibility with phosphate in the diet or therapeutic preparations, for example in enteral feed mixtures.[7]

13 Method of Manufacture

Calcium lactate is prepared commercially by neutralization, with calcium carbonate or calcium hydroxide, of lactic acid obtained from fermentation of dextrose, molasses, starch, sugar, or whey.[8]

14 Safety

Calcium lactate was found to have no toxic or carcinogenic effects when dosed at levels of 0%, 2.5%, and 5% in drinking water to male and female rats for 2 years.[9]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled.

16 Regulatory Status

GRAS listed except for infant foods/formulas.[10] Accepted as a food additive in Europe. Calcium lactate (anhydrous) is included in the FDA Inactive Ingredients Database (vaginal, tablet). It is used in oral dosage forms. Included in vaginal pessary formulations licensed in the UK.

17 Related Substances

Lactic acid; sodium lactate.

18 Comments

Calcium lactate is available in a number of grades with respect to hydration state, purity, and particle size. Care should be taken to understand the hydration state of the material in use. The USP 40–NF 35 S1 states that on product labeling, 'calcium lactate' should be understood to be an amount of calcium equivalent to that contained in the stated amount of calcium lactate pentahydrate. Each 1.0 g of calcium lactate pentahydrate contains 130 mg (3.2 mmol) of calcium.

The use of calcium lactate in film coatings as an alternative white pigment to titanium dioxide has been reported.[11] The white coloration may be due to interactions between the hypromellose polymer and calcium ions in the film. The use of films containing calcium lactate as edible coatings for food products has also been reported. Milk proteins have been used as the film former, crosslinked by the calcium salt.[12]

Lactate salts, including calcium lactate, have been reported as having antimicrobial properties and have been applied as preservatives in foods.[13]

Therapeutically, calcium lactate has been used in preparations for the treatment of calcium deficiency.

The USP 40–NF 35 S1 monograph for calcium lactate covers the anhydrous and hydrous forms. The PhEur 9.2 lists separate monographs for calcium lactate, anhydrous, calcium lactate monohydrate, calcium lactate pentahydrate, and calcium lactate trihydrate. The calcium in calcium lactate is bioavailable when administered orally; there are monographs for calcium lactate tablets in both BP 2017 and USP 40–NF 35 S1. A specification for calcium lactate is contained in the *Food Chemicals Codex* (FCC).[14]

The optically active L-form of calcium lactate has a higher solubility in water than the racemic DL-form.[15]

The EINECS number for anhydrous calcium lactate is 212-406-7. The PubChem Compound ID (CID) for anhydrous calcium lactate is 521805 and for calcium lactate pentahydrate it is 165341.

Calcium Phosphate, Dibasic Anhydrous

1 Nonproprietary Names

BP: Calcium Hydrogen Phosphate
JP: Anhydrous Dibasic Calcium Phosphate
PhEur: Calcium Hydrogen Phosphate
USP–NF: Anhydrous Dibasic Calcium Phosphate

2 Synonyms

A-TAB; calcii hydrogenophosphas anhydricus; calcium monohydrogen phosphate; calcium orthophosphate; *DI-CAFOS A*; dicalcium orthophosphate; E341; *Emcompress Anhydrous*; *Fujicalin*; phosphoric acid calcium salt (1 : 1); secondary calcium phosphate.

3 Chemical Name and CAS Registry Number

Dibasic calcium phosphate [7757-93-9]

4 Empirical Formula and Molecular Weight

$CaHPO_4$ 136.06

5 Structural Formula

See Section 4.

6 Functional Category

Tablet and capsule diluent.

7 Applications in Pharmaceutical Formulation or Technology

Anhydrous dibasic calcium phosphate is used both as an excipient and as a source of calcium in nutritional supplements. It is used particularly in the nutritional/health food sectors. It is also used in pharmaceutical products because of its compaction properties, and the good flow properties of the coarse-grade material.[1–5] The predominant deformation mechanism of anhydrous dibasic calcium phosphate coarse-grade is brittle fracture and this reduces the strain-rate sensitivity of the material, thus allowing easier transition from the laboratory to production scale. However, unlike the dihydrate, anhydrous dibasic calcium phosphate when compacted at higher pressures can exhibit lamination and capping. This phenomenon can be observed when the material represents a

substantial proportion of the formulation, and is exacerbated by the use of deep concave tooling. This phenomenon also appears to be independent of rate of compaction.

Anhydrous dibasic calcium phosphate is abrasive and a lubricant is required for tableting, for example 1% w/w magnesium stearate or 1% w/w sodium stearyl fumarate.

Two particle-size grades of anhydrous dibasic calcium phosphate are used in the pharmaceutical industry. Milled material is typically used in wet-granulated or roller-compacted formulations. The 'unmilled' or coarse-grade material is typically used in direct-compression formulations.

Anhydrous dibasic calcium phosphate is nonhygroscopic and stable at room temperature. It does not hydrate to form the dihydrate.

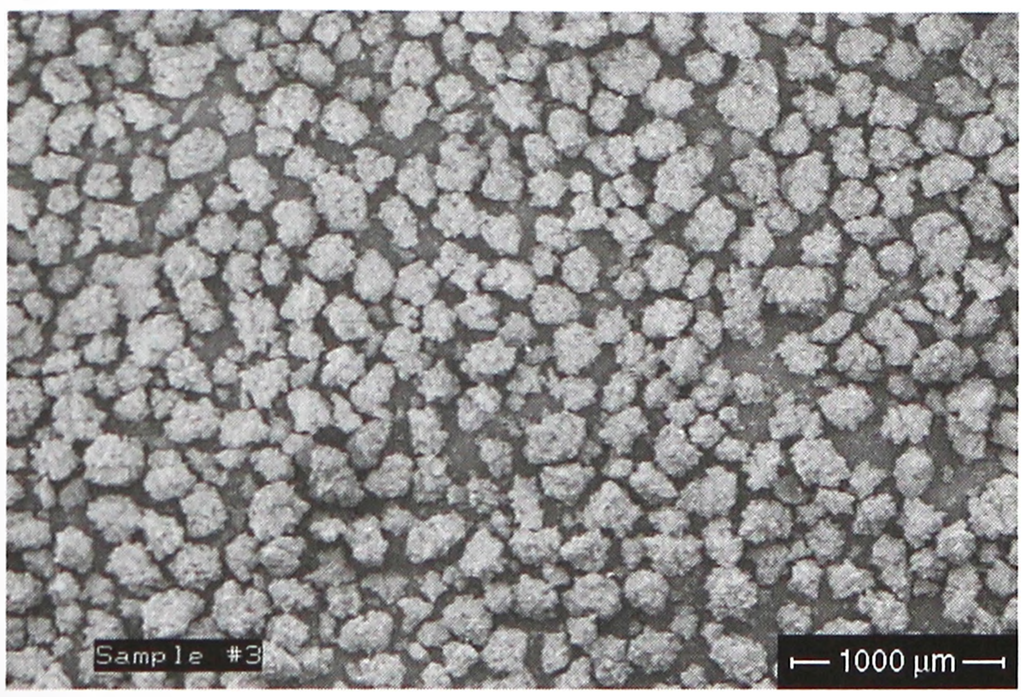
Anhydrous dibasic calcium phosphate is used in toothpaste and dentifrice formulations for its abrasive properties.

8 Description

Anhydrous dibasic calcium phosphate is a white, odorless, tasteless powder or crystalline solid. It occurs as triclinic crystals.

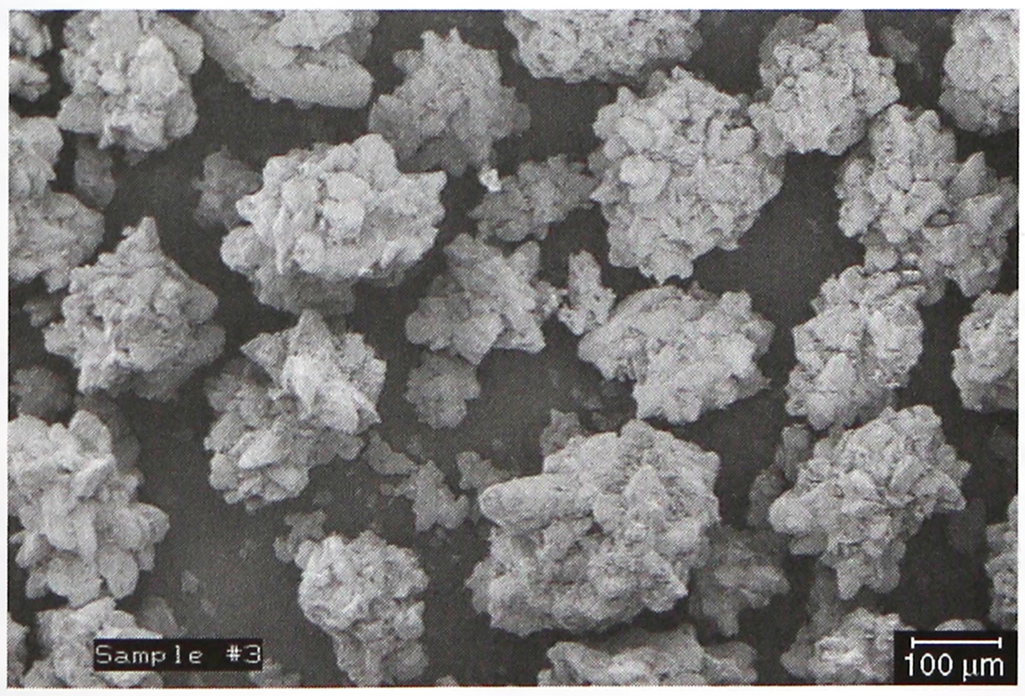
9 Pharmacopeial Specifications

The pharmacopeial specifications for anhydrous dibasic calcium phosphate have undergone harmonization of many attributes for JP, PhEur, and USP–NF.



See Table I. *See also* Section 18.

Table I: Pharmacopeial specifications for calcium phosphate, dibasic anhydrous.



Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters	+	+	—
Loss on ignition	6.6–8.5%	6.6–8.5%	6.6–8.5%
Acid-insoluble substances	≤0.2%	≤0.2%	≤0.2%
Heavy metals[a]	≤31 ppm	—	≤30 ppm

(a) These tests have not been fully harmonized at the time of publication.

SEM 1: Excipient: *Emcompress Anhydrous*; manufacturer: JRS Pharma LP; magnification: 50×; voltage: 5 kV.

SEM 2: Excipient: *Emcompress Anhydrous*; manufacturer: JRS Pharma LP; magnification: 200×; voltage: 5 kV.

10 Typical Properties

Acidity/alkalinity

pH = 7.3 (20% slurry);

pH = 5.1 (20% slurry of *A-TAB*);

pH = 6.1–7.2 (5% slurry of *Fujicalin*).

Angle of repose 32° (for *Fujicalin*)

Density 2.89 g/cm^3

Density (bulk)

0.78 g/cm^3 for *A-TAB*;

0.45 g/cm^3 for *Fujicalin*.

Density (tapped)

0.82 g/cm^3 for *A-TAB*;

0.46 g/cm^3 for *Fujicalin*.

Melting point Does not melt; decomposes at ≈425°C to form calcium pyrophosphate.

Moisture content Typically 0.1–0.2%. The anhydrous material contains only surface-adsorbed moisture and cannot be rehydrated to form the dihydrate.

Particle size distribution

A-TAB: average particle diameter 180 µm;

Emcompress Anhydrous: average particle diameter 136 µm;

Fujicalin: average particle diameter 94 µm;

Powder: average particle diameter: 15 µm.

Solubility Practically insoluble in ether, ethanol, and water; soluble in dilute acids.

Specific surface area

20–30 m^2/g for *A-TAB*;

35 m^2/g for *Fujicalin*.

Spectroscopy

NIR spectrum *see* Figure 1.

11 Stability and Storage Conditions

Dibasic calcium phosphate anhydrous is a nonhygroscopic, relatively stable material. Under conditions of high humidity it does not hydrate to form the dihydrate.

The bulk material should be stored in a well-closed container in a dry place.

12 Incompatibilities

Dibasic calcium phosphate should not be used to formulate tetracyline antibiotics.[6]

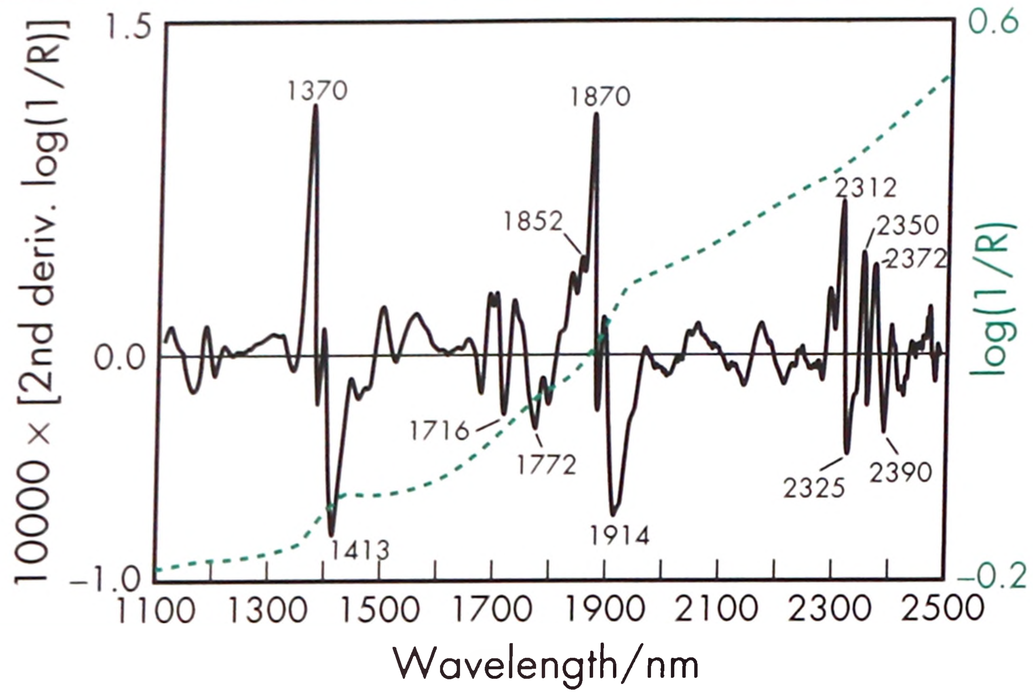

Figure 1: Near-infrared spectrum of anhydrous dibasic calcium phosphate measured by reflectance.

The surface of milled anhydrous dibasic calcium phosphate is alkaline[2] and consequently it should not be used with drugs that are sensitive to alkaline pH. However, reports[7,8] suggest there are differences in the surface alkalinity/acidity between the milled and unmilled grades of anhydrous dibasic calcium phosphate; the unmilled form has an acidic surface environment. This difference has important implications for drug stability, particularly when reformulating from, e.g. roller compaction to direct compression, when the particle size of the anhydrous dibasic calcium phosphate might be expected to change.

Dibasic calcium phosphate dihydrate has been reported to be incompatible with a number of drugs and excipients, and many of these incompatibilities are expected to occur with dibasic calcium phosphate, anhydrous; *see* Calcium phosphate, dibasic dihydrate.

13 Method of Manufacture

Calcium phosphates are usually prepared by reacting very pure phosphoric acid with calcium hydroxide, $Ca(OH)_2$ obtained from limestone, in stoichiometric ratio in aqueous suspension[2] followed by drying at a temperature that will allow the correct hydration state to be achieved. After drying, the coarse-grade material is obtained by means of a classification unit; the fine particle-size material is obtained by milling. Dibasic calcium phosphate, anhydrous, may also be prepared by spray-drying.[5,9]

14 Safety

Dibasic calcium phosphate anhydrous is widely used in oral pharmaceutical products, food products, and toothpastes, and is generally regarded as a relatively nontoxic and nonirritant material.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. The fine-milled grades can generate nuisance dusts and the use of a respirator or dust mask may be necessary.

16 Regulatory Status

GRAS listed. Accepted as a food additive in Europe. Included in the FDA Inactive Ingredients Database (oral capsules and tablets). Included in nonparenteral medicines licensed in Europe. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Calcium phosphate, dibasic dihydrate; calcium phosphate, tribasic; calcium sulfate.

18 Comments

Anhydrous dibasic calcium phosphate has undergone harmonization of many attributes for JP, PhEur, and USP–NF by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

Grades of anhydrous dibasic calcium phosphate available for direct compression include *A-TAB* (Innophos), *Di-Cafos AN* (Chemische Fabrik Budenheim), *Emcompress Anhydrous* (JRS Pharma LP), and *Fujicalin* (Fuji Chemical Industry Co. Ltd.). A study has examined the use of calcium phosphate in reducing microbial contamination during direct compression in tableting.[10]

The EINECS number for calcium phosphate is 231-837-1. The PubChem Compound ID (CID) for anhydrous dibasic calcium phosphate is 24441.

Calcium Phosphate, Dibasic Dihydrate

1 Nonproprietary Names

BP: Calcium Hydrogen Phosphate Dihydrate
JP: Dibasic Calcium Phosphate Hydrate
PhEur: Calcium Hydrogen Phosphate Dihydrate
USP–NF: Dibasic Calcium Phosphate Dihydrate

2 Synonyms

Calcii hydrogenophosphas dihydricus; calcium hydrogen orthophosphate dihydrate; calcium monohydrogen phosphate dihydrate; *DI-CAFOS D*; dicalcium orthophosphate; *DI-TAB*; E341; *Emcompress*; phosphoric acid calcium salt (1:1) dihydrate; secondary calcium phosphate.

3 Chemical Name and CAS Registry Number

Dibasic calcium phosphate dihydrate [7789-77-7]

4 Empirical Formula and Molecular Weight

$CaHPO_4 \cdot 2H_2O$ 172.09

5 Structural Formula

See Section 4.

6 Functional Category

Tablet and capsule diluent.

7 Applications in Pharmaceutical Formulation or Technology

Dibasic calcium phosphate dihydrate is widely used in tablet formulations both as an excipient and as a source of calcium and phosphorus in nutritional supplements.[1–8] It is one of the more widely used materials, particularly in the nutritional/health food sectors. It is also used in pharmaceutical products because of its compaction properties, and the good flow properties of the coarse-grade material. The predominant deformation mechanism of dibasic calcium phosphate coarse-grade is brittle fracture and this reduces the strain-rate sensitivity of the material, thus allowing easier transition from the laboratory to production scale. However, dibasic calcium phosphate dihydrate is abrasive and a lubricant is required for tableting, for example about 1% w/w of magnesium stearate or about 1% w/w of sodium stearyl fumarate is commonly used.

Two main particle-size grades of dibasic calcium phosphate dihydrate are used in the pharmaceutical industry. The milled material is typically used in wet-granulated, roller-compacted or slugged formulations. The 'unmilled' or coarse-grade material is typically used in direct-compression formulations.

Dibasic calcium phosphate dihydrate is nonhygroscopic and stable at room temperature. However, under certain conditions of temperature and humidity, it can lose water of crystallization below 100°C. This has implications for certain types of packaging and aqueous film coating since the loss of water of crystallization appears to be initiated by high humidity and by implication high moisture vapor concentrations in the vicinity of the dibasic calcium phosphate dihydrate particles.[8]

Dibasic calcium phosphate dihydrate is also used in toothpaste and dentifrice formulations for its abrasive properties.

Table I: Pharmacopeial specifications for calcium phosphate, dibasic dihydrate.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+

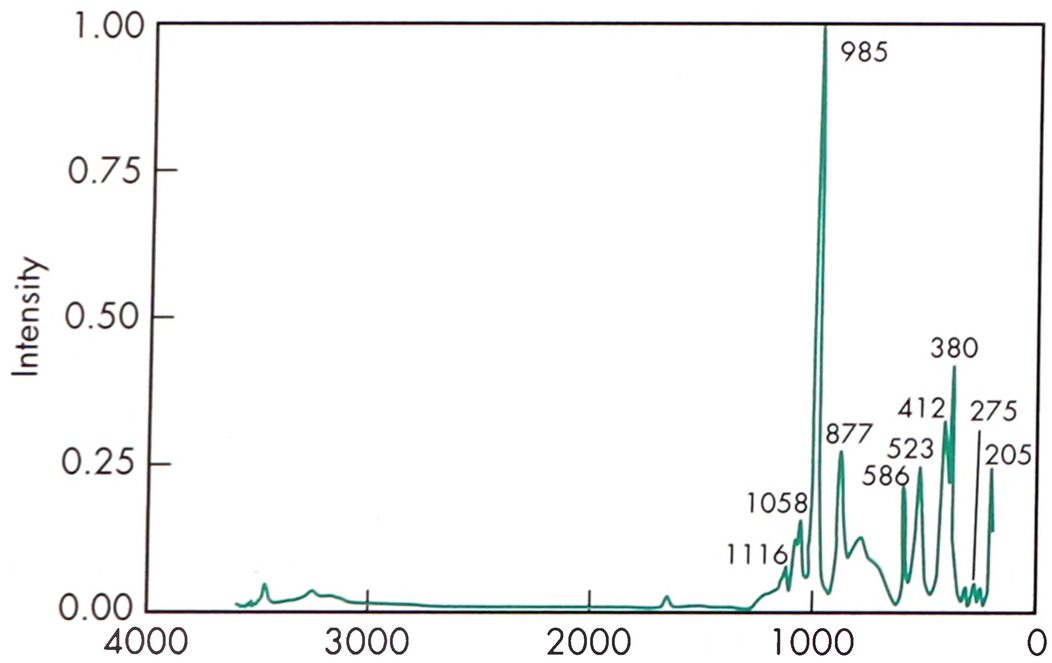

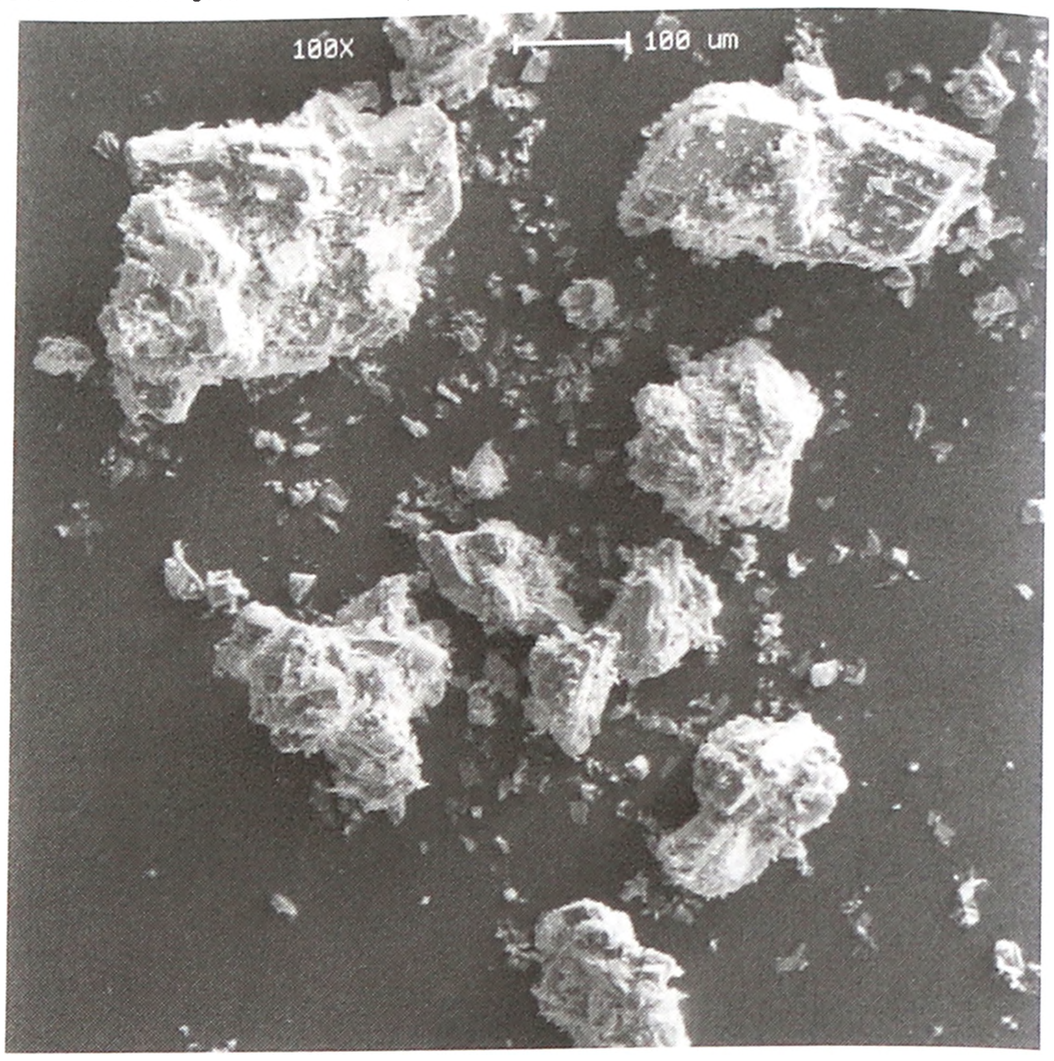

Figure 3: Raman spectrum of dibasic calcium phosphate dihydrate measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

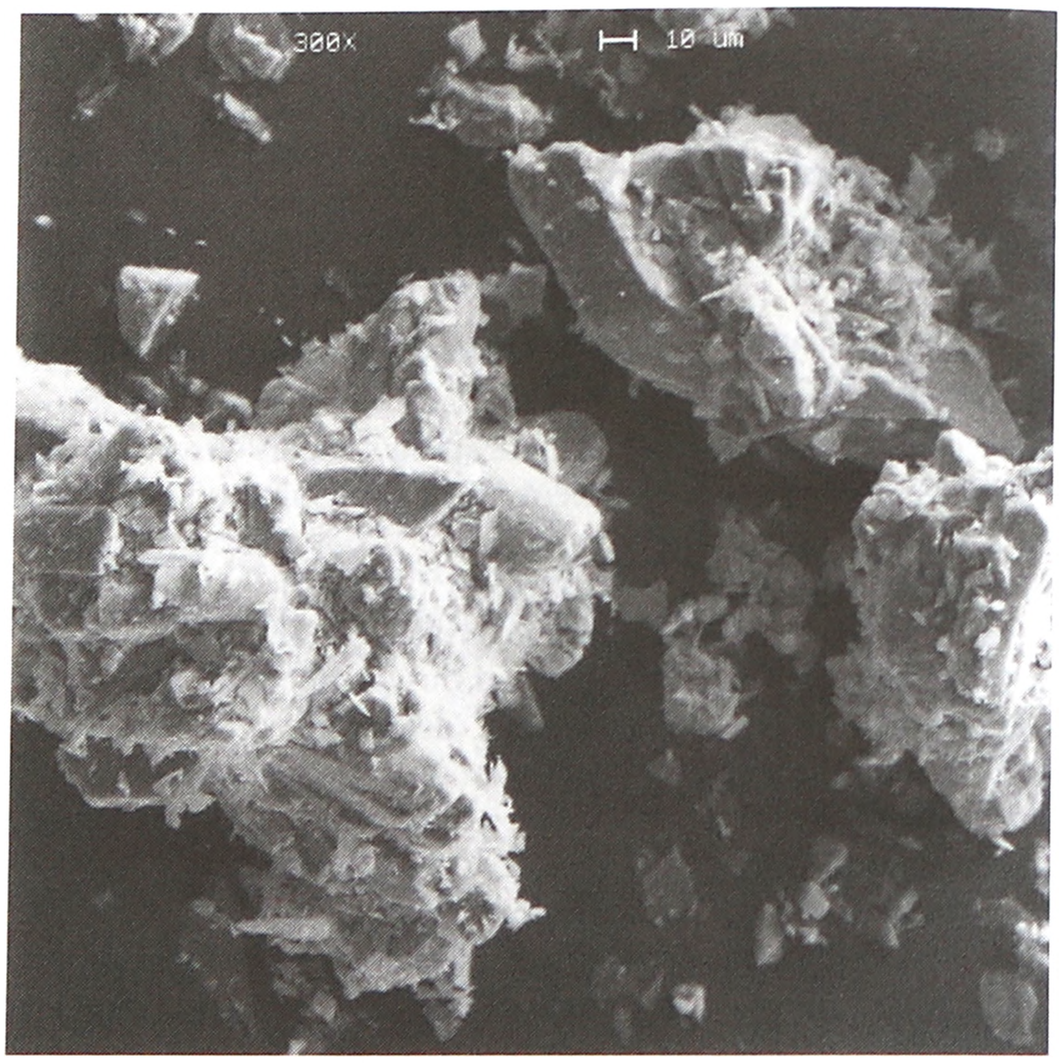
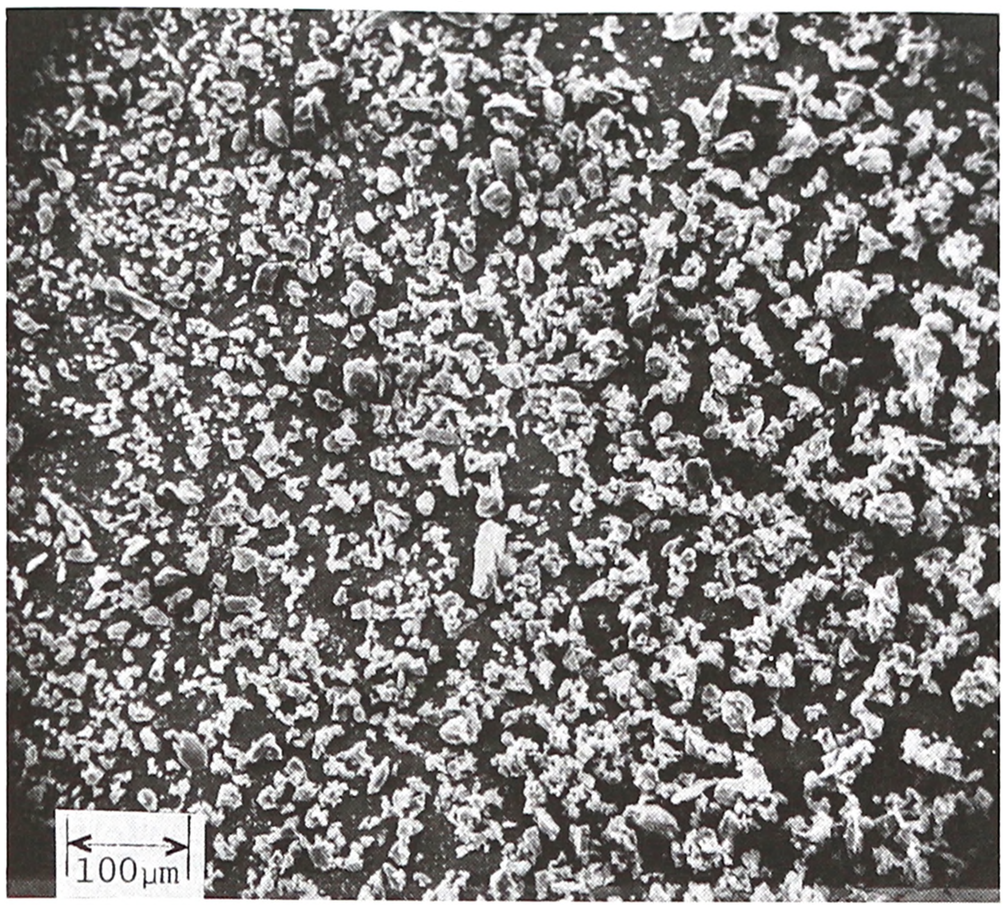


12 Incompatibilities

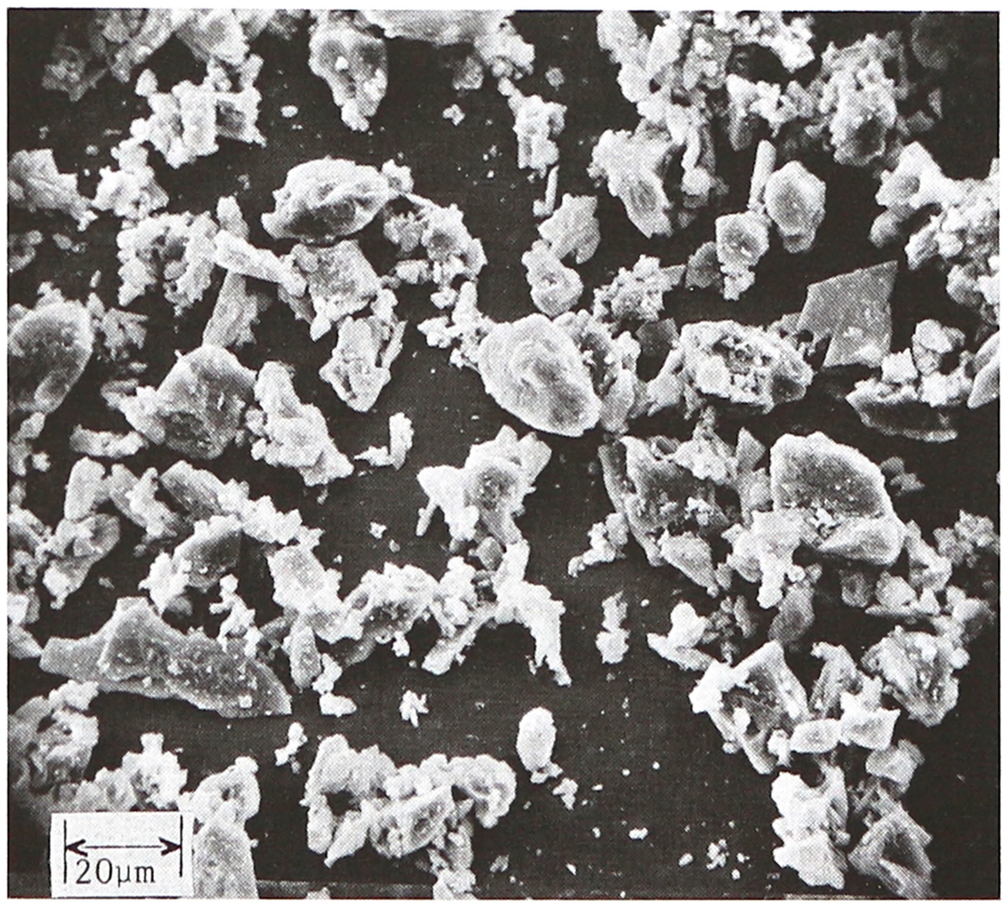
Dibasic calcium phosphate dihydrate should not be used to formulate tetracycline antibiotics.[10] Dibasic calcium phosphate dihydrate has been reported to be incompatible with indomethacin,[11] aspirin,[12] aspartame,[13] ampicillin,[14] cephalexin,[15] and erythromycin.[16] The surface of dibasic calcium phosphate

SEM 1: Excipient: dibasic calcium phosphate dihydrate, coarse grade; manufacturer: JRS Pharma LP; lot no.: W28C; magnification: 100×.

SEM 2: Excipient: dibasic calcium phosphate dihydrate, coarse grade; manufacturer: JRS Pharma LP; lot no.: W28C; magnification: 300×.



dihydrate is alkaline[16] and consequently it should not be used with drugs that are sensitive to alkaline pH.



13 Method of Manufacture

Calcium phosphates are usually manufactured by reacting very pure phosphoric acid with calcium hydroxide, $Ca(OH)_2$ obtained from limestone, in stoichiometric ratio in aqueous suspension followed by drying at a temperature that will allow the correct hydration state to be achieved. After drying, the coarse-grade material is obtained by means of a classification unit; the fine particle-size material is obtained by milling.

SEM 3: Excipient: dibasic calcium phosphate dihydrate; manufacturer: Innophos; lot no.: 16A-1 (89); magnification: 120×.

SEM 4: Excipient: dibasic calcium phosphate dihydrate, coarse grade; manufacturer: Innophos; lot no.: 16A-1 (89); magnification: 600×.

14 Safety

Dibasic calcium phosphate dihydrate is widely used in oral pharmaceutical products, food products, and toothpastes, and is generally regarded as a nontoxic and nonirritant material. However, oral ingestion of large quantities may cause abdominal discomfort.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. The fine-milled grades can generate nuisance dusts and the use of a respirator or dust mask may be necessary.

16 Regulatory Status

GRAS listed. Accepted as a food additive in Europe. Included in the FDA Inactive Ingredients Database (oral capsules and tablets). Included in nonparenteral medicines licensed in Europe. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Calcium phosphate, dibasic anhydrous; calcium phosphate, tribasic.

18 Comments

Dibasic calcium phosphate dihydrate has undergone harmonization of many attributes for JP, PhEur, and USP–NF by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

Grades of dibasic calcium phosphate dihydrate available for direct compression include *Di-Cafos* (Chemische Fabrik Budenheim), *DI-TAB* (Innophos), and *Emcompress* (JRS Pharma LP).

Accelerated stability studies carried out at elevated temperatures on formulations containing significant proportions of dibasic calcium phosphate dihydrate can give erroneous results owing to irreversible dehydration of the dihydrate to the anhydrous form. Depending on the type of packaging and whether or not the tablet is coated, the phenomenon can be observed at temperatures as low as 40°C after 6 weeks of storage. As the amount of dibasic calcium phosphate dihydrate in the tablet is reduced, the effect is less easy to observe.

The EINECS number for calcium phosphate is 231-837-1. The PubChem Compound ID (CID) for dibasic calcium phosphate dibydrate is 104805.

Calcium Phosphate, Tribasic

1 Nonproprietary Names

BP: Calcium Phosphate

PhEur: Calcium Phosphate

USP–NF: Tribasic Calcium Phosphate

2 Synonyms

Calcium orthophosphate; E341(iii); hydroxylapatite; phosphoric acid calcium salt (2:3); precipitated calcium phosphate; tertiary calcium phosphate; *TRI-CAFOS*; tricalcii phosphas; tricalcium diorthophosphate; tricalcium orthophosphate; tricalcium phosphate; *TRI-CAL WG*; *TRI-TAB*.

3 Chemical Name and CAS Registry Number

Tribasic calcium phosphate is not a clearly defined chemical entity but is a mixture of calcium phosphates. Several chemical names, CAS Registry Numbers, and molecular formulas have therefore been used to describe this material. Those most frequently cited are shown below.

Calcium hydroxide phosphate [12167-74-7]

Tricalcium orthophosphate [7758-87-4]

See also Sections 4 and 8.

4 Empirical Formula and Molecular Weight

$Ca_3(PO_4)_2$	310.20
$Ca_5(OH)(PO_4)_3$	502.32

5 Structural Formula

See Sections 3 and 4.

6 Functional Category

Anticaking agent; buffering agent; tablet and capsule diluent.

7 Applications in Pharmaceutical Formulation or Technology

Tribasic calcium phosphate is widely used as a capsule diluent and tablet filler/binder in either direct-compression or wet-granulation processes. The primary bonding mechanism in compaction is plastic deformation. As with dibasic calcium phosphate, a lubricant and a disintegrant should usually be incorporated in capsule or tablet formulations that include tribasic calcium phosphate. In some cases tribasic calcium phosphate has been used as a disintegrant.[1] It is most widely used in vitamin and mineral preparations[2] as a filler and as a binder.

In food applications, tribasic calcium phosphate powder is widely used as an anticaking agent. *See* Section 18.

See also Calcium phosphate, dibasic dihydrate.

8 Description

The PhEur 9.2 states that tribasic calcium phosphate consists of a mixture of calcium phosphates. It contains not less than 35.0% and not more than the equivalent of 40.0% of calcium. The USP 40–NF 35 S1 specifies that tribasic calcium phosphate consists of variable mixtures of calcium phosphates having the approximate composition $10CaO{\cdot}3P_2O_5{\cdot}H_2O$. This corresponds to a molecular formula of $Ca_5(OH)(PO_4)_3$ or $Ca_{10}(OH)_2(PO_4)_6$.

Tribasic calcium phosphate is a white, odorless and tasteless powder.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for tribasic calcium phosphate.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	–
Loss on ignition	≤8.0%	≤8.0%
Water-soluble substances	–	≤0.5%
Acid-insoluble substances	≤0.2%	≤0.2%
Carbonate	–	+
Chloride	≤0.15%	≤0.14%
Fluoride	≤75 ppm	≤75 ppm
Nitrate	–	+
Sulfate	≤0.5%	≤0.8%
Arsenic	≤4 ppm	≤3 ppm
Barium	–	+
Iron	≤400 ppm	–
Dibasic salt and calcium oxide	–	+
Heavy metals	–	≤30 ppm
Assay (as Ca)	35.0–40.0%	34.0–40.0%

10 Typical Properties

Acidity/alkalinity pH = 6.8 (20% slurry in water)

Density 3.14 g/cm^3

Density (bulk)

0.3–0.4 g/cm^3 for powder form;

0.80 g/cm^3 for granular *TRI-TAB*.[3]

Density (tapped) 0.95 g/cm^3 for granular *TRI-TAB*.[3]
Flowability 25.0 g/s for granular *TRI-TAB*.[3]
Melting point 1670°C
Moisture content Slightly hygroscopic. A well-defined crystalline hydrate is not formed, although surface moisture may be picked up or contained within small pores in the crystal structure. At relative humidities between about 15% and 65%, the equilibrium moisture content at 25°C is about 2.0%. At relative humidities above about 75%, tribasic calcium phosphate may absorb small amounts of moisture.
Particle size distribution

Tribasic calcium phosphate powder: typical particle diameter 5–10 µm; 98% of particles <44 µm.

TRI-CAL WG: average particle diameter 180 µm; 99% of particles <420 µm, 46% <149 µm, and 15% <44 µm.

TRI-TAB: average particle diameter 350 µm; 97% of particles <420 µm, and 2% <149 µm.

Solubility Soluble in dilute mineral acids; very slightly soluble in water; practically insoluble in acetic acid and alcohols.
Specific surface area 70–80 m^2/g[3]
Spectroscopy

IR spectrum *see* Figure 1.

NIR spectrum *see* Figure 2.

Raman spectrum *see* Figure 3.

11 Stability and Storage Conditions

Tribasic calcium phosphate is a chemically stable material, and is also not liable to cake during storage.

The bulk material should be stored in a well-closed container in a cool, dry place.

12 Incompatibilities

All calcium salts are incompatible with tetracycline antibiotics. Tribasic calcium phosphate is incompatible with tocopheryl acetate (but not tocopheryl succinate). Tribasic calcium phosphate may form sparingly soluble phosphates with hormones.

13 Method of Manufacture

Tribasic calcium phosphate occurs naturally as the minerals hydroxylapatite, voelicherite, and whitlockite. Commercially, it is prepared by treating phosphate-containing rock with sulfuric acid. Tribasic calcium phosphate powder is then precipitated by the addition of calcium hydroxide. Tribasic calcium phosphate is alternatively prepared by treating calcium hydroxide from limestone with purified phosphoric acid. It may also be obtained from calcined animal bones.[4] Some tribasic calcium phosphate products may be prepared in coarser, directly compressible forms by granulating the powder using roller compaction or spray drying.

14 Safety

Tribasic calcium phosphate is widely used in oral pharmaceutical formulations and food products, and is generally regarded as nontoxic and nonirritant at the levels employed as a pharmaceutical excipient.

Ingestion or inhalation of excessive quantities may result in the deposition of tribasic calcium phosphate crystals in tissues. These crystals may lead to inflammation and cause tissue lesions in the areas of deposition.

Oral ingestion of very large quantities of tribasic calcium phosphate may cause abdominal discomfort such as nausea and vomiting.

No teratogenic effects were found in chicken embryos exposed to a dose of 2.5 mg of tribasic calcium phosphate.[5]

LD_{50} (rat, oral): >1 g/kg[3]

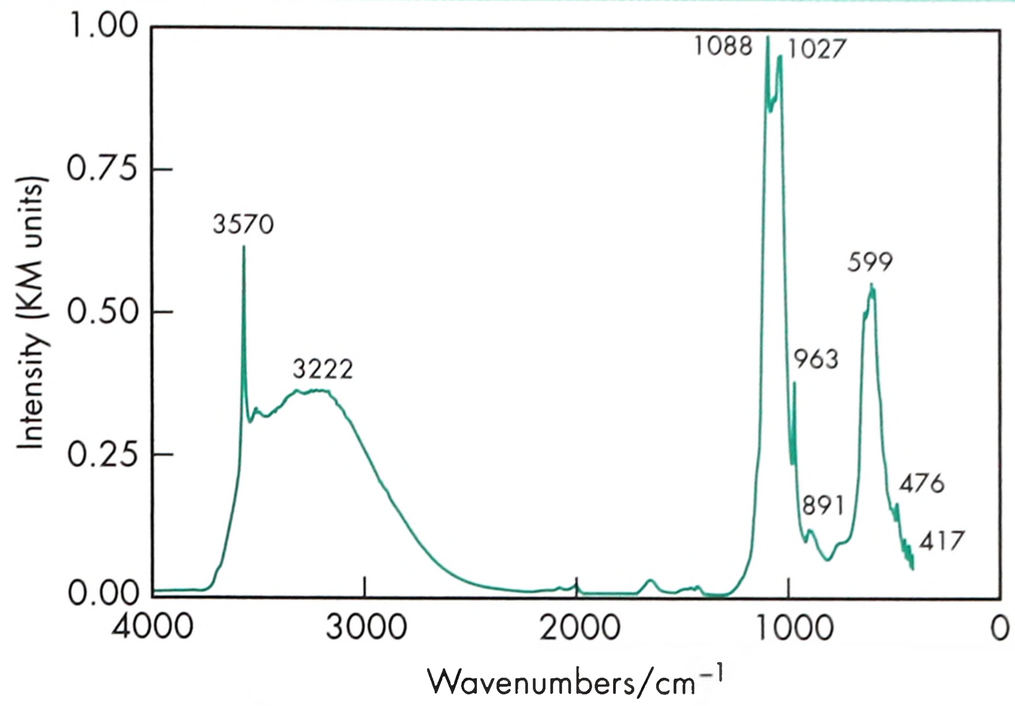

Figure 1: Infrared spectrum of tribasic calcium phosphate measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

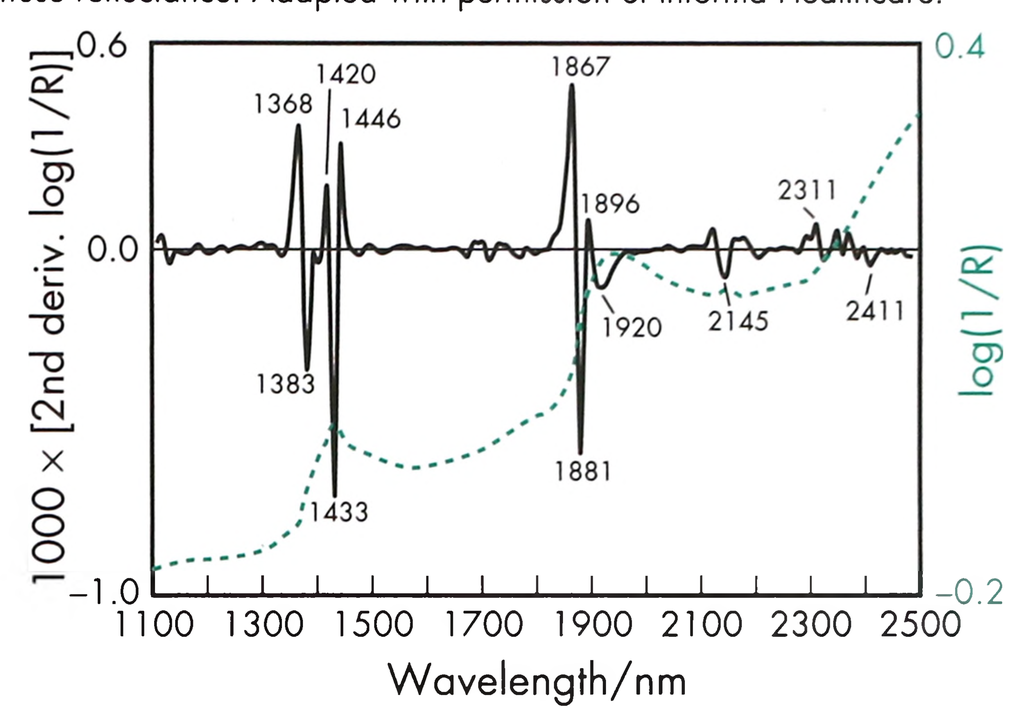

Figure 2: Near-infrared spectrum of tribasic calcium phosphate ($Ca_5(OH)(PO_4)_3$) measured by reflectance.

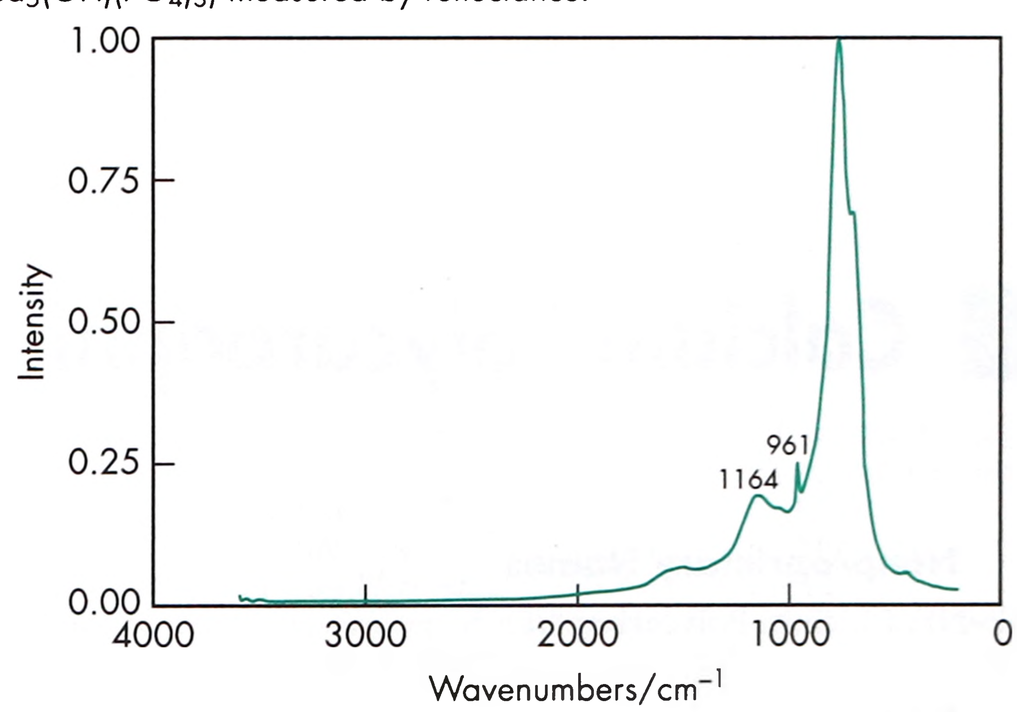

Figure 3: Raman spectrum of tribasic calcium phosphate measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Eye protection and gloves are recommended. Handle in a well-ventilated environment since dust inhalation may be an irritant. For processes generating large amounts of dust, the use of a respirator is recommended.

16 Regulatory Acceptance

GRAS listed. Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (oral capsules and tablets). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Calcium phosphate, dibasic anhydrous; calcium phosphate, dibasic dihydrate.

18 Comments

One gram of tribasic calcium phosphate represents approximately 10.9 mmol of calcium and 6.4 mmol of phosphate; 38% calcium and 17.3% phosphorus by weight.[3] Tribasic calcium phosphate provides a higher calcium load than dibasic calcium phosphate and a higher Ca/P ratio. Granular and fine powder forms of tribasic calcium phosphate are available from various manufacturers.

A specification for calcium phosphate tribasic is contained in the *Food Chemicals Codex* (FCC).[6]

The EINECS number for calcium phosphate is 231-837-1. The PubChem Compound ID (CID) for tribasic calcium phosphate includes 24456 and 516943.

Tribasic calcium phosphate is a source of both calcium and phosphorus, the two main osteogenic minerals for bone health. The bioavailability of the calcium is well known to be improved by the presence of cholecalciferol. Recent research reports that combinations of tribasic calcium phosphate and vitamin D3 are a cost-effective advance in bone fracture prevention.[7]

Calcium Polycarbophil

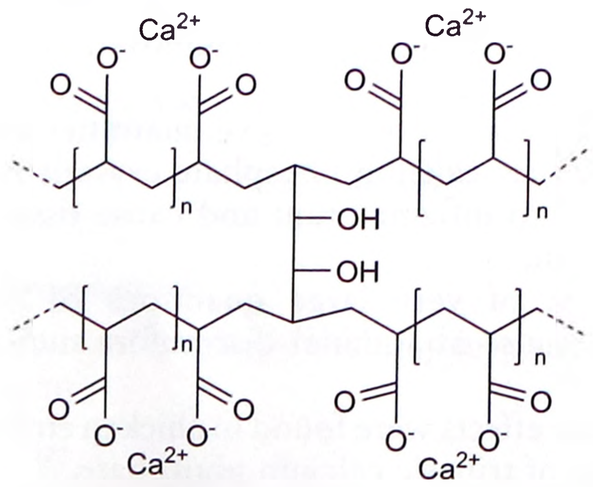
1 Nonproprietary Names

USP–NF: Calcium Polycarbophil

2 Synonyms

Noveon CA; polycarbophil calcium.

3 Chemical Name and CAS Registry Number



Calcium polycarbophil [9003-97-8] and [126040-58-2]

4 Empirical Formula and Molecular Weight

$(C_6H_{10}O_2)_n.(C_3H_3O_2)_n.Ca$

Calcium polycarbophil is the calcium salt of polyacrylic acid polymers crosslinked with divinyl glycol.[1] The molecular weight of these polymers is theoretically estimated to range from 700 000 to 3–4 billion. There are, however, no methods currently available to measure the actual molecular weight of a crosslinked (i.e. three-dimensional) polymer of this type.

5 Structural Formula

See Section 4.

6 Functional Category

Adsorbent; modified-release agent; tablet and capsule binder.

7 Applications in Pharmaceutical Formulation or Technology

Calcium polycarbophil is a water-absorbing polymer[1,2] used in the formulation of oral lozenges, troches and tablets. Water absorption is dependent upon the length of the polymer chain, degree of cross-polymerization and environmental pH.[1] It is used in the formulation of nicotine lozenges as a binder for diluent and buffering agent granule formation, as well as to modify the release of the buffering agent.[3] Calcium polycarbophil is also used as an excipient in veterinary oral sprays.[4]

8 Description

Calcium polycarbophil occurs as a white to creamy white powder with a slightly acetic odor.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for calcium polycarbophil.

Test	USP 40–NF 35 S1
Identification	+
Loss on drying	≤10.0%
Absorbing power	≥35.0 g/g
Calcium content (on dried basis)	18.0–22.0%

10 Typical Properties

Acidity/alkalinity pH = 6.0–8.0 (1% w/v aqueous dispersion)
Dissociation Constant pKa = 4.75 (approximate value)[2]
Solubility Insoluble in water, dilute acids, dilute alkalis, and in common organic solvents.

11 Stability and Storage Conditions

Calcium polycarbophil should be stored in sealed, tightly closed containers, and protected from moisture and excessive temperatures.

12 Incompatibilities

—

13 Method of Manufacture

Calcium polycarbophil is produced synthetically by crosslinking the calcium salt of polyacrylic acid with divinyl glycol.[1]

14 Safety

The WHO has not specified an acceptable daily intake for calcium polycarbophil.[5] *See* Polycarbophil.

LD_{50}: (rat, oral): 20 g/kg[1]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Eye protection and gloves are recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral, troche). Included in nonparenteral products licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Polycarbophil.

18 Comments

In general, calcium polycarbophil does not share the bioadhesive property of polycarbophil although bioadhesive forms of calcium polycarbophil can be prepared.[6] Under acidic conditions, for example in the stomach, calcium polycarbophil is decalcified to polycarbophil and behaves as such; *see* Polycarbophil.[2,6] At pH 4 and below decalcification of calcium polycarbophil is complete.[2]

Therapeutically, calcium polycarbophil is used as a bulk laxative and antidiarrheal due to the natural water absorbancy of polycarbophil. It swells in the gastrointestinal tract to form a gel, which then moves through the intestinal tract. Calcium polycarbophil is therefore useful in improving colonic transit, bowel movements, stool form and abdominal pain in patients with irritable bowel syndrome.[7–9]

Ciprofloxacin absorption impairment by calcium polycarbophil has been reported. Similar effects have also been reported for mycophenolate coadministered with calcium polycarbophil. This is thought to be due to calcium chelate complexes forming.[10,11]

Calcium Silicate

1 Nonproprietary Names

USP–NF: Calcium Silicate

2 Synonyms

Calcium hydrosilicate; calcium metasilicate; calcium monosilicate; calcium polysilicate; *Micro-Cel*; okenite; silicic acid, calcium salt; tobermorite.

3 Chemical Name and CAS Registry Number

Calcium silicate [1344-95-2]

4 Empirical Formula and Molecular Weight

$CaSiO_3$ 116.2

5 Structural Formula

See Section 4.

6 Functional Category

Adsorbent; anticaking agent; opacifier; tablet and capsule diluent.

7 Applications in Pharmaceutical Formulation or Technology

Calcium silicate is used as a filler aid for oral pharmaceuticals. It has also been used in pharmaceutical preparations as an antacid.

The main applications of calcium silicate relate to its anticaking properties, and it has therefore been used in dusting powders and a range of different cosmetic products (e.g. face powders, eye shadow).[1]

8 Description

Calcium silicate occurs as a crystalline or amorphous white or off-white material, and often exists in different hydrate forms.

9 Pharmacopeial Specifications

The USP 40–NF 35 S1 describes the material as containing not less than 4% of calcium oxide and not less than 35% of silicon dioxide.

See Table I.

Table I: Pharmacopeial specifications for calcium silicate.

Test	USP 40–NF 35 S1
Identification	+
pH	8.4–11.2
Loss on ignition	≤20%
Heavy metals	≤20 ppm
Fluoride	≤50 ppm
Lead	≤10 ppm
Assay for silicon dioxide	90–110%
Assay for calcium oxide	90–110%
Ratio of silicon dioxide to calcium oxide	0.5 : 20
Sum of calcium oxide, silicon dioxide and loss on ignition	≥90%

10 Typical Properties

Acidity/alkalinity pH = 8.4–10.2 (5% w/v aqueous solution)
Density 2.10 g/cm^3
Melting point 1540°C
Solubility Practically insoluble in water; forms a gel with mineral acids. It can absorb up to 2.5 times its weight of liquids and still remain a free-flowing powder.

11 Stability and Storage Conditions

Calcium silicate is chemically stable and nonflammable, but it should be protected from moisture. Store in airtight containers in a cool, dry place.

12 Incompatibilities

—

13 Method of Manufacture

Calcium silicate is a naturally occurring mineral, but for commercial applications it is usually prepared from lime and diatomaceous earth under carefully controlled conditions.

14 Safety

When used in oral formulations, calcium silicate is practically nontoxic. Inhalation of the dust particles may cause respiratory tract irritation.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. In large quantities, calcium silicate is irritating to eyes, the respiratory system, and skin. Gloves, eye protection, a respirator, and other protective clothing should be worn. In the UK, the long-term (8-hour TWA) workplace exposure standards for calcium silicate are 10 mg/m^3 for total inhalable dust and 4 mg/m^3 for respirable dust.[2]

16 Regulatory Status

GRAS listed. Included in the FDA Inactive Ingredients Database (oral dosage forms). Included in nonparenteral (oral, orodispersible, effervescent and enteric-coated tablets) formulations licensed in the UK.

17 Related Substances

Calcium diorthosilicate; calcium trisilicate.

Calcium diorthosilicate

Empirical formula Ca_2SiO_4
Molecular weight 172.2
CAS number [10034-77-2]
Synonyms Belite; dicalcium silicate
Comments The EINECS number for calcium diorthosilicate is 233-107-8.

Calcium trisilicate

Empirical formula Ca_3SiO_5
Molecular weight 228.3
CAS number [12168-85-3]
Synonyms Tricalcium silicon pentaoxide
Comments The EINECS number for calcium trisilicate is 235-336-9.

18 Comments

Studies utilizing the porous properties of calcium silicate granules have shown their ability to form floating structures, giving rise to potentially gastroretentive formulations.[3,4]

A specification for calcium silicate is contained in the *Food Chemicals Codex* (FCC).[5]

The EINECS number for calcium silicate is 215-710-8. The PubChem Compound ID (CID) for calcium silicate is 518851.

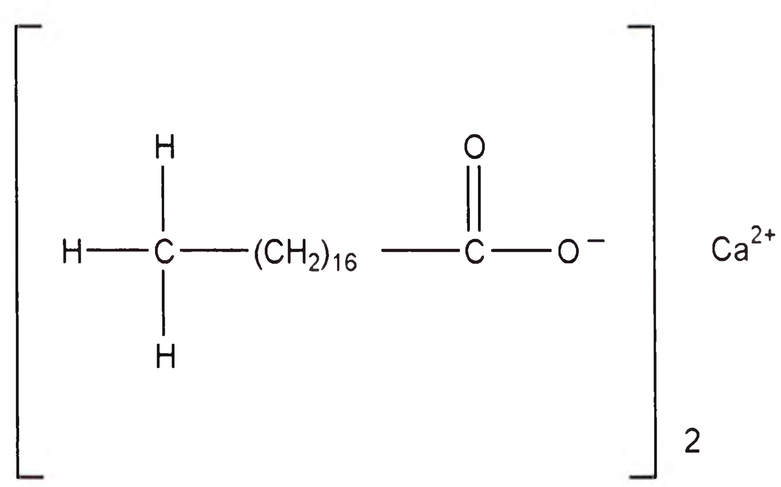
USP–NF: Calcium Stearate

2 Synonyms

Calcii stearas; calcium distearate; calcium octadecanoate; *Ceasit PC*; *Kemistab EC-F*; octadecanoic acid, calcium salt; stearic acid, calcium salt; *Synpro*.

3 Chemical Name and CAS Registry Number

Octadecanoic acid calcium salt [1592-23-0]



4 Empirical Formula and Molecular Weight

$C_{36}H_{70}CaO_4$ 607.03 (for pure material)

The USP 40–NF 35 S1 describes calcium stearate as a compound of calcium with a mixture of solid organic acids obtained from sources of vegetable or animal origin, and consists mainly of variable proportions of calcium stearate and calcium palmitate. It contains the equivalent of 6.4–7.4% of calcium calculated on the dried basis. The content of stearic acid in the fatty acid fraction is a minimum of 40.0% of the total content. The sum of stearic acid and palmitic acid in the fatty acid fraction is a minimum of 90.0% of the total content.

The PhEur 9.2 describes calcium stearate as a mixture of calcium salts of different fatty acids consisting mainly of stearic acid [$(C_{17}H_{35}COO)_2Ca$] and palmitic acid [$(C_{15}H_{31}COO)_2Ca$] with minor proportions of other fatty acids. It contains a minimum of 40.0% stearic acid in the fatty acid fraction. The sum of stearic acid and palmitic acid in the fatty acid fraction is a minimum of 90.0%. It contains the equivalent of 9.0–10.5% of calcium oxide.

5 Structural Formula

6 Functional Category

Tablet and capsule lubricant.

7 Applications in Pharmaceutical Formulation or Technology

Calcium stearate is primarily used in pharmaceutical formulations as a lubricant in tablet and capsule manufacture at concentrations up to 1.0% w/w. Although it has good antiadherent and lubricant properties, calcium stearate has poor glidant properties.

Calcium stearate is employed as an emulsifier, stabilizing agent, and suspending agent, used in cosmetics and food products.

8 Description

Calcium stearate occurs as a fine, white to yellowish-white, bulky powder having a slight, characteristic odor. It is unctuous and free from grittiness.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for calcium stearate.

Particle size distribution 1.7–60 µm; 100% through a 73.7 µm (#200 mesh); 99.5% through a 44.5 µm (#325 mesh).

Shear strength 14.71 MPa

Solubility Practically insoluble or insoluble in ethanol (95%), ether, chloroform, acetone, and water. Slightly soluble in hot alcohol, and hot vegetable and mineral oils. Soluble in hot pyridine.

Specific surface area 4.73–8.03 m^2/g

Spectroscopy

NIR spectrum *see* Figure 1.

Sulfate <0.25%

11 Stability and Storage Conditions

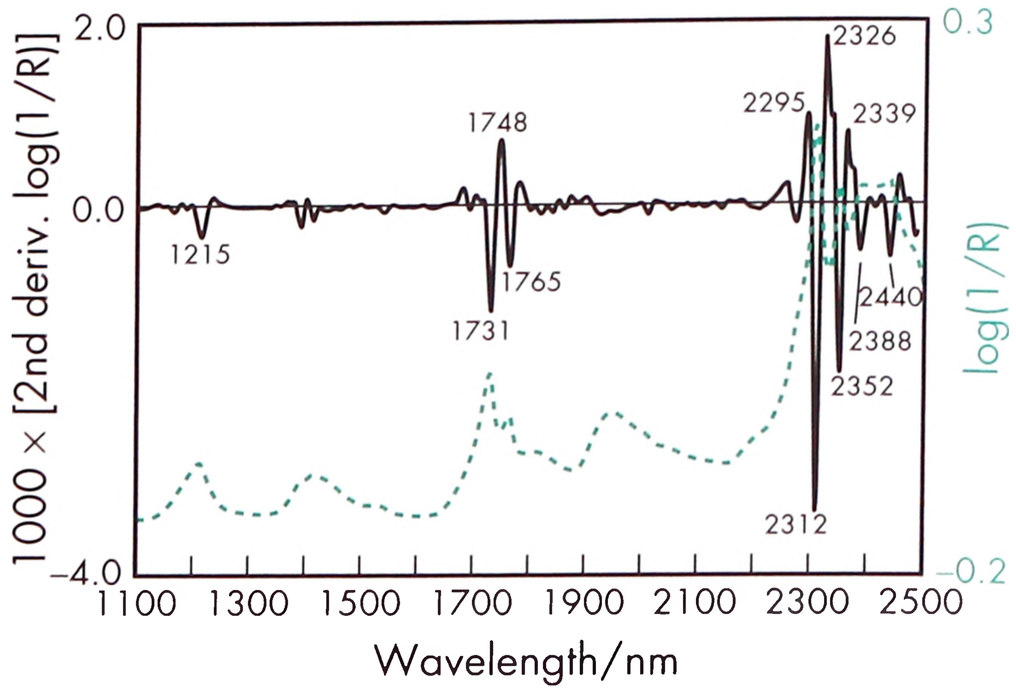
Calcium stearate is stable and should be stored in a well-closed container in a cool, dry place.

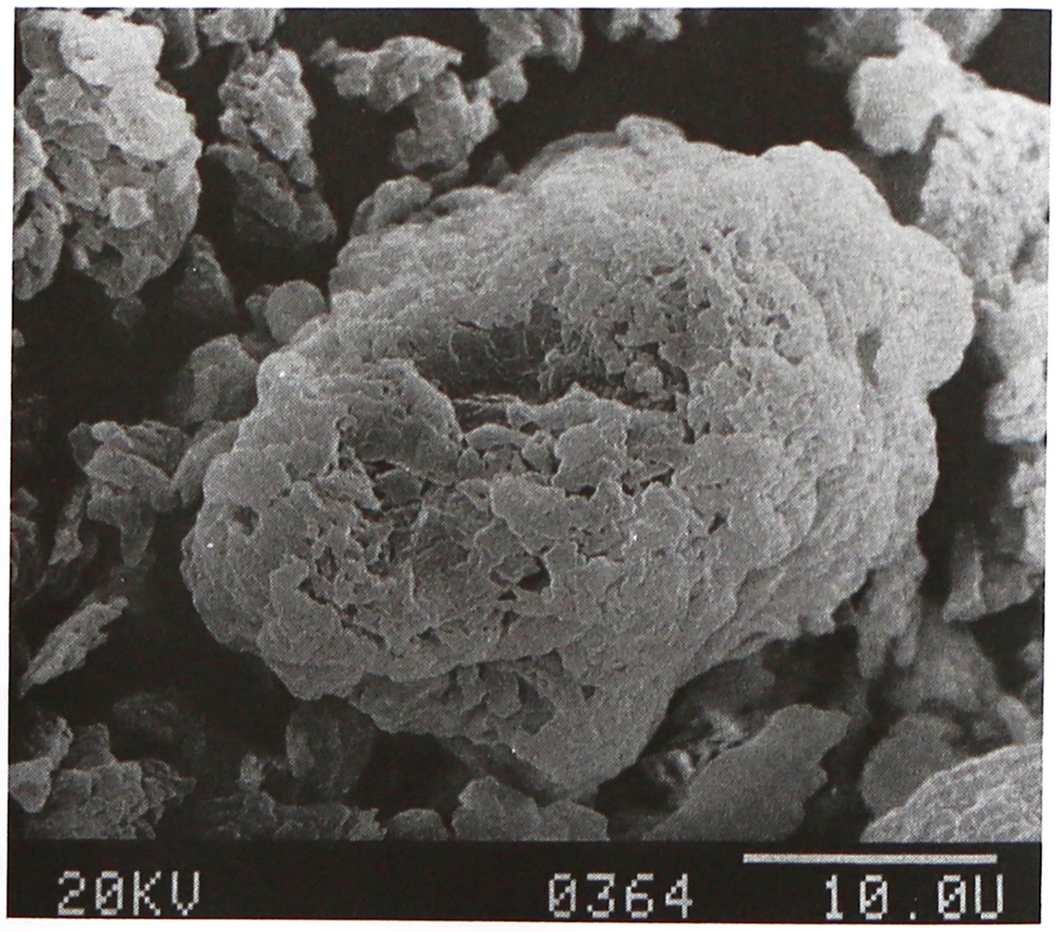
12 Incompatibilities

Calcium stearate is incompatible with strong oxidizing agents, mineral acids, alkalis, organic acids, and amines of low molecular weight.

13 Method of Manufacture

Calcium stearate is prepared by the reaction of calcium chloride with a mixture of the sodium salts of stearic and palmitic acids. The





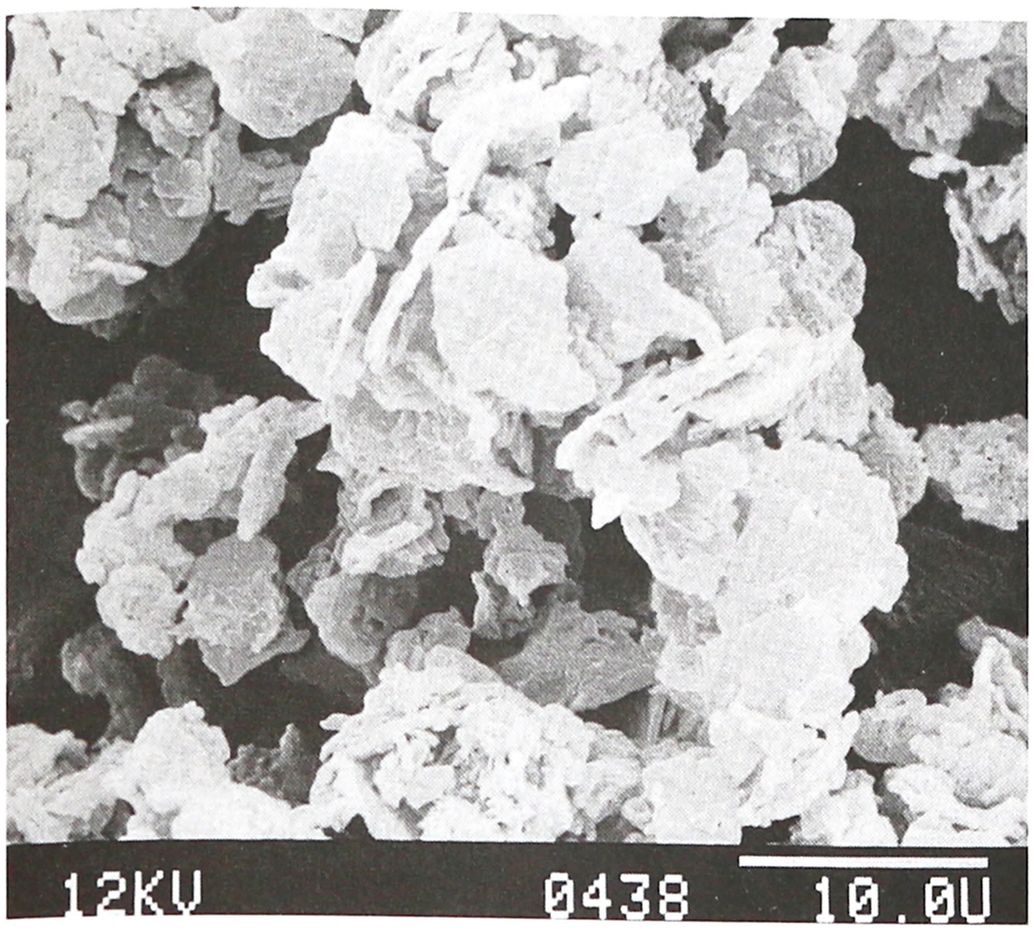


Figure 1: Near-infrared spectrum of calcium stearate measured by reflectance.

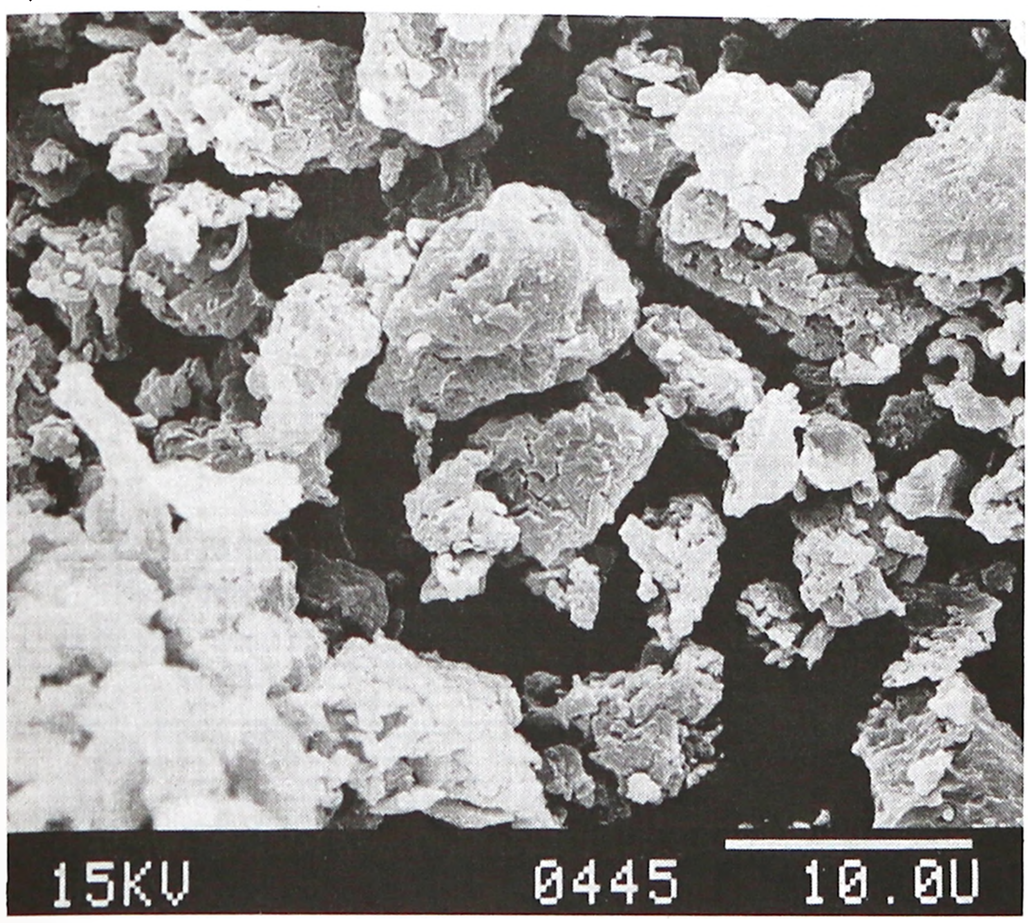

SEM 1: Excipient: calcium stearate (standard); manufacturer: Durham Chemicals; lot no.: 0364; voltage: 20 kV.

SEM 2: Excipient: calcium stearate (precipitated); manufacturer: Witco Corporation; lot no.: 0438; voltage: 12 kV.

SEM 3: Excipient: calcium stearate (fused); manufacturer: Witco Corporation; voltage: 15 kV.

calcium stearate formed is collected and washed with water to remove any sodium chloride.

14 Safety

Calcium stearate is used in oral pharmaceutical formulations and is generally regarded as a relatively nontoxic and nonirritant material.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Calcium stearate should be used in a well-ventilated environment; eye protection, gloves, and a respirator are recommended.

16 Regulatory Status

GRAS listed. Included in the FDA Inactive Ingredients Database (oral capsules and tablets). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Magnesium stearate; stearic acid; zinc stearate.

18 Comments

Calcium stearate exhibits interesting properties when heated: softening between 120–130°C, and exhibiting a viscous consistency at approximately 160°C. At approximately 100°C, it loses about 3% of its weight, corresponding to 1 mole of water of crystallization. The crystalline structure changes at this point, leading to the collapse of the crystal lattice at a temperature of about 125°C.[1]

Calcium stearate was studied as a component of a 'cushioning pellet' during compression of enteric-coated pellets to protect the enteric coating. The cushioning pellets were composed of stearic acid/microcrystalline cellulose (4 : 1 w/w) and were successful in avoiding rupture of the enteric coating during the compression process.[2]

Calcium stearate was hot-melt extruded with testosterone in a study to characterize testosterone solid lipid microparticles to be applied as a transdermal delivery system. The results showed good release of the drug from the matrix.[3]

Calcium stearate has been investigated in the preparation and evaluation of novel directly compressed fast-disintegrating furosemide tablets.[4] It has also been studied as a component of nanostructured lipid carriers containing minoxidil for topical formulations.[5]

See Magnesium Stearate for further information and references.

A specification for calcium stearate is contained in the *Food Chemicals Codex* (FCC).[6]

The EINECS number for calcium stearate is 216-472-8. The PubChem Compound ID (CID) for calcium stearate is 15324.

Calcium sulfate dihydrate [10101-41-4]

4 Empirical Formula and Molecular Weight

$CaSO_4$ 136.14
$CaSO_4 \cdot 2H_2O$ 172.17

5 Structural Formula

6 Functional Category

Desiccant; tablet and capsule diluent.

7 Applications in Pharmaceutical Formulation or Technology

Calcium sulfate dihydrate is used in the formulation of tablets and capsules. In granular form it has good compaction properties and moderate disintegration properties.[1,2]

Anhydrous calcium sulfate is hygroscopic and is used as a desiccant. The uptake of water can cause the tablets to become very hard and to fail to disintegrate on storage. Therefore, anhydrous calcium sulfate is not recommended for the formulation of tablets, capsules, or powders for oral administration.

8 Description

Both calcium sulfate and calcium sulfate dihydrate are white or off-white, fine, odorless, and tasteless powder or granules.

9 Pharmacopeial Specifications

See Table I. *See also* Section 18.

NIR spectrum *see* Figure 4.

Raman spectra *see* Figures 5 and 6.

11 Stability and Storage Conditions

Calcium sulfate is chemically stable. Anhydrous calcium sulfate is hygroscopic and may cake on storage. Store in a well-closed container in a dry place, avoiding heat.

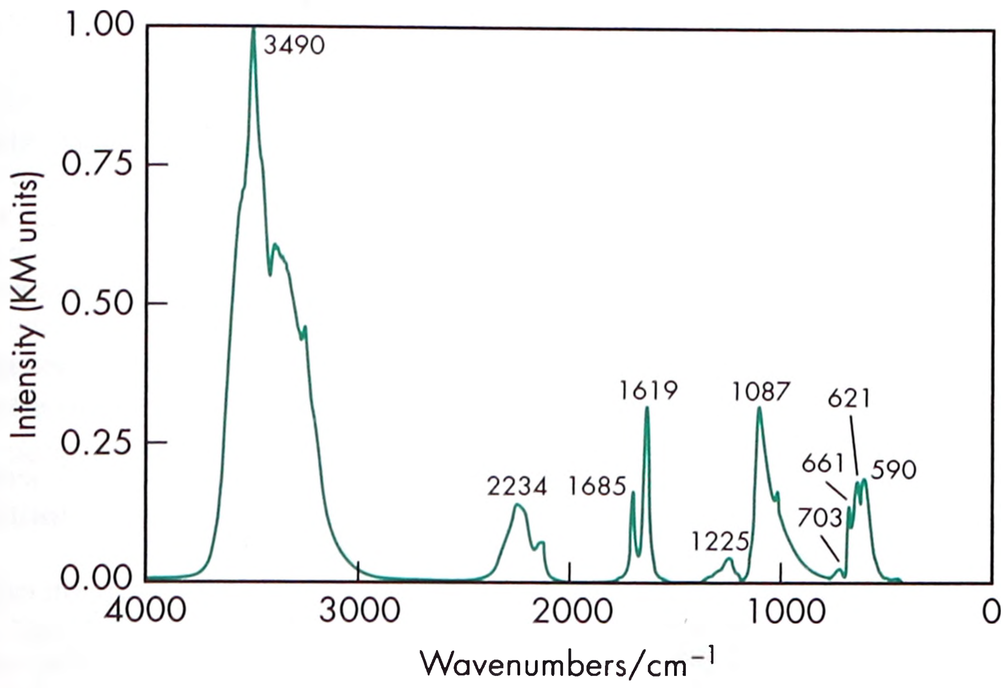

Figure 2: Infrared spectrum of anhydrous calcium sulfate measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

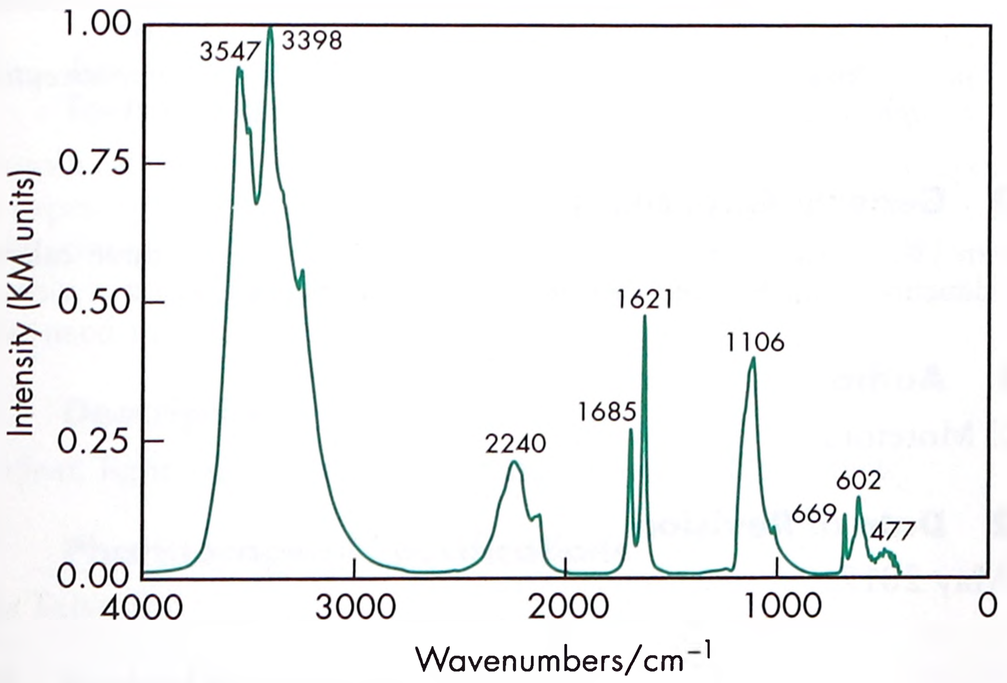

Figure 3: Infrared spectrum of calcium sulfate dihydrate measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

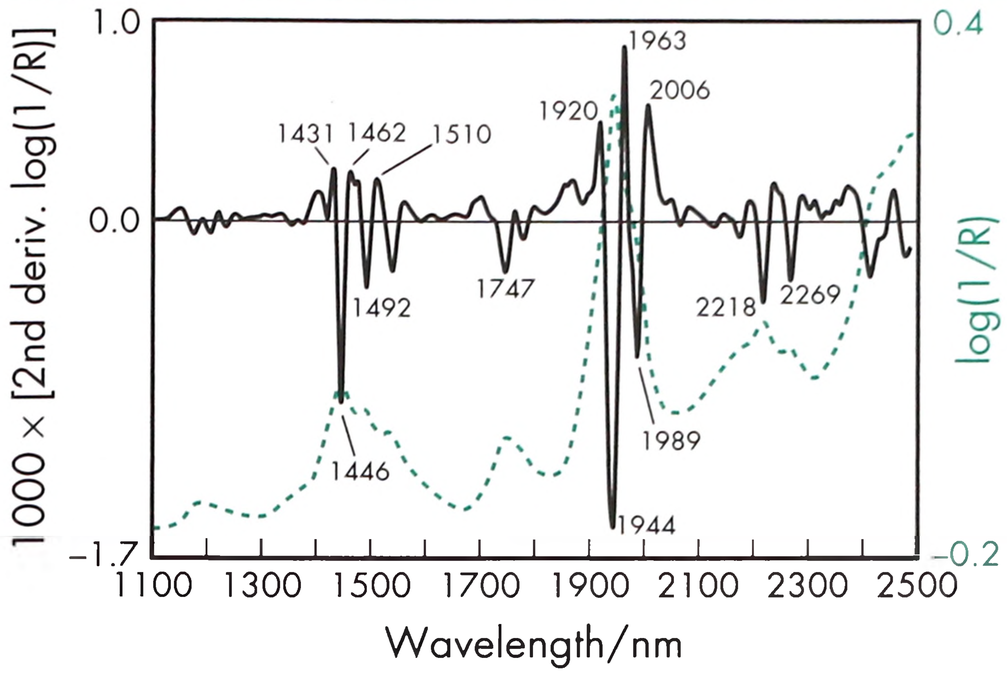

Figure 4: Near-infrared spectrum of calcium sulfate dihydrate measured by reflectance.

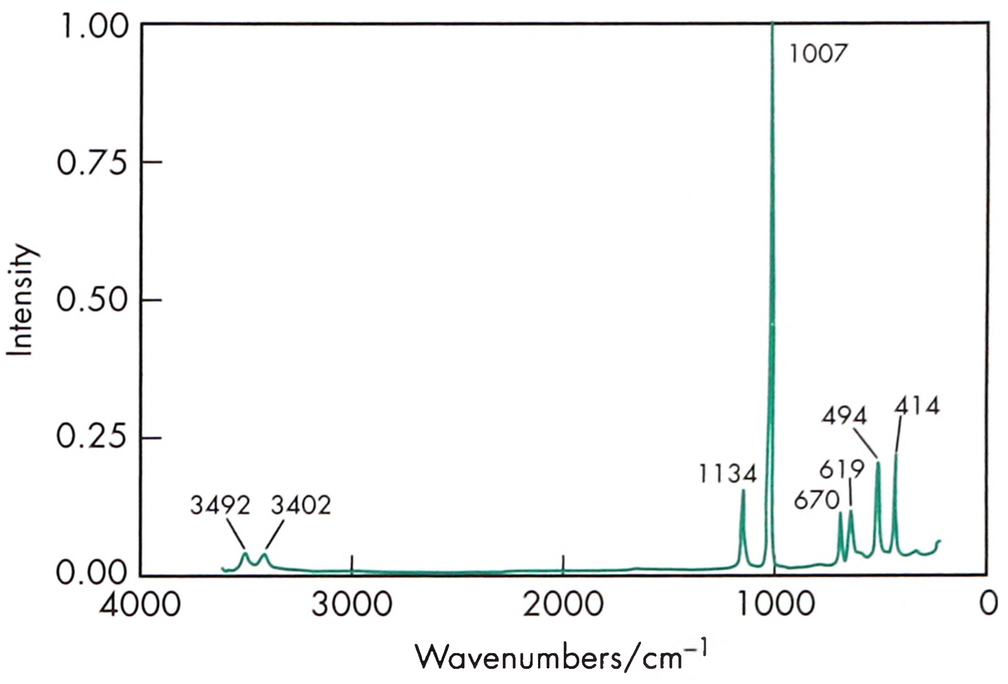

Figure 5: Raman spectrum of calcium sulfate measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

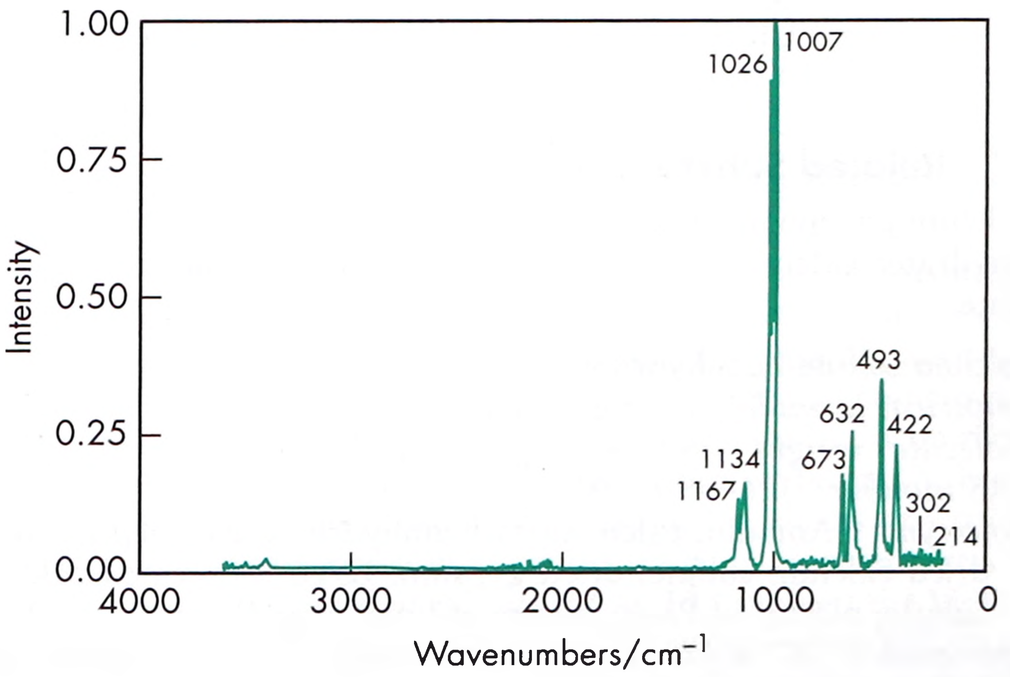

Figure 6: Raman spectrum of calcium sulfate dihydrate measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

12 Incompatibilities

In the presence of moisture, calcium salts may be incompatible with amines, amino acids, peptides, and proteins, which may form complexes. Calcium salts will interfere with the bioavailability of tetracycline antibiotics.[3] It is also anticipated that calcium sulfate would be incompatible with indomethacin,[4] aspirin,[5] aspartame,[6] ampicillin,[7] cephalexin,[8] and erythromycin[9] since these materials are incompatible with other calcium salts.

Calcium sulfate may react violently, at high temperatures, with phosphorus and aluminum powder; it can react violently with diazomethane.

13 Method of Manufacture

Anhydrous calcium sulfate occurs naturally as the mineral anhydrite. The naturally occurring rock gypsum may be crushed and ground for use as the dihydrate or calcined at 150°C to produce the hemihydrate. A purer variety of calcium sulfate may also be obtained chemically by reacting calcium carbonate with sulfuric acid or by precipitation from calcium chloride and a soluble sulfate.

14 Safety

Calcium sulfate dihydrate is used as an excipient in oral capsule and tablet formulations. At the levels at which it is used as an excipient, it is generally regarded as nontoxic. However, ingestion of a sufficiently large quantity can result in obstruction of the upper intestinal tract after absorption of moisture.

Owing to the limited intestinal absorption of calcium from its salts, hypercalcemia cannot be induced even after the ingestion of massive oral doses.

Calcium salts are soluble in bronchial fluid. Pure salts do not induce pneumoconiosis.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. The fine-milled grades can generate nuisance dusts that may be irritant to the eyes or on inhalation. The use of a respirator or dust mask is recommended to prevent excessive powder inhalation since excessive inhalation may saturate the bronchial fluid, leading to precipitation and thus blockage of the air passages.

16 Regulatory Status

GRAS listed. Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (oral capsules, sustained release, tablets). Included in nonparenteral medicines licensed in the UK and Europe. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Calcium phosphate, dibasic anhydrous; calcium phosphate, dibasic dihydrate; calcium phosphate, tribasic; calcium sulfate hemihydrate.

Calcium sulfate hemihydrate

Empirical formula $CaSO_4 \cdot \frac{1}{2}H_2O$

Molecular weight 145.14

CAS number [26499-65-0]

Synonyms Annalin; calcii sulfas hemihydricus; calcined gypsum; dried calcium sulfate; dried gypsum; E516; exsiccated calcium sulfate; plaster of Paris; sulfate of lime; yeso blanco.

Appearance A white or almost white, odorless, crystalline, hygroscopic powder.

Solubility Practically insoluble in ethanol (95%); slightly soluble in water; more soluble in dilute mineral acids.

Comments The BP 2017 defines dried calcium sulfate as predominantly the hemihydrate, produced by drying powdered gypsum ($CaSO_4 \cdot 2H_2O$) at about 150°C, in a controlled manner, such that minimum quantities of the anhydrous material are produced. Dried calcium sulfate may also contain suitable setting accelerators or decelerators.

Calcium sulfate hemihydrate is used in the preparation of plaster of Paris bandage, which is used for the immobilization of limbs and fractures; it should not be used in the formulation of tablets or capsules.

18 Comments

Calcium sulfate will absorb moisture and therefore should be used with caution in the formulation of products containing drugs that easily decompose in the presence of moisture.

Therapeutically, calcium sulfate is used in dental and craniofacial surgical procedures.[10,11]

A specification for calcium sulfate is contained in the *Food Chemicals Codex* (FCC)[12] and the *Japanese Pharmaceutical Excipients* (JPE).[13]

The EINECS number for calcium sulfate is 231-900-3. The PubChem Compound ID (CID) for calcium sulfate is 24497.

Canola Oil

1 Nonproprietary Names

BP: Refined Rapeseed Oil

PhEur: Rapeseed Oil, Refined

USP–NF: Canola Oil

2 Synonyms

Canbra oil; *Colzao CT*; huile de colza; *Lipex 108*; *Lipex 204*; *Lipovol CAN*; low erucic acid colza oil; low erucic acid rapeseed oil; rapae oleum raffinatum; tower rapeseed oil.

3 Chemical Name and CAS Registry Number

Canola oil [120962-03-0]

4 Empirical Formula and Molecular Weight

Canola oil contains approximately 6% saturated acids, 62% monounsaturated acids, and 32% polyunsaturated acids. Additionally, sulfur-containing fatty acids may also be present as minor constituents.

Unrefined canola oil is said to contain low levels of sulfur-containing fatty acids, resulting in the presence of sulfur in the oil in the stable form of triglycerides. These triglycerides resist refining procedures.[2] *See* Table I for the sulfur content of crude, refined, and deodorized canola oils.[3]

Table I: Total sulfur content in crude, refined, and bleached and deodorized canola oil.[a]

Oil sample	Range (mg/kg)	Mean	Standard deviation
Crude	23.6–24.1	23.8	1.0
Refined	19.1–20.2	19.7	2.85
Bleached and deodorized	15.6–16.5	16.2	2.7

(a) Determined using five replicates of each sample analyzed by ion chromatography.

5 Structural Formula

See Section 4.

6 Functional Category

Emollient; lubricant; oleaginous vehicle.

7 Applications in Pharmaceutical Formulation or Technology

Canola oil is a refined rapeseed oil obtained from particular species of rapeseed that have been genetically selected for their low erucic acid content.[4] In pharmaceutical formulations, canola oil is used mainly in topical preparations such as soft soaps and liniments. It is also used in cosmetics.

8 Description

A clear, light yellow-colored oily liquid with a bland taste.

9 Pharmacopeial Specifications

See Table II.

Table II: Pharmacopeial specifications for canola oil.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	—
Specific gravity	—	0.906–0.920
Acid value	≤0.5	≤6.0

Linolenic acid	6.0–14.0%	<14%
Oleic acid	50.0–67.0%	>50%
Palmitic acid	2.5–6.0%	<6.0%
Stearic acid	≤3.0%	<2.5%

10 Typical Properties

Boiling point 313°C

Density 0.913–0.917 g/cm^3

Flash point 290–330°C

Free fatty acid ≤0.05% as oleic acid

Freezing point −10 to −2°C

Solubility Soluble in chloroform and ether; practically insoluble in ethanol (95%); miscible with fixed oils.

Viscosity (dynamic) 77.3–78.3 mPa s (77.3–78.3 cP) at 20°C

11 Stability and Storage Conditions

Canola oil is stable and should be stored in an airtight, light-resistant container in a cool, dry place. The USP 40–NF 35 S1 specifies that contact between canola oil and metals should be avoided. Containers should be filled to the top, while partially filled containers should be flushed with nitrogen. During storage, grassy, paintlike, or rancid off-flavors can develop.

Flavor deterioration has been attributed mainly to secondary oxidation products of linolenic acid, which normally makes up 6–14% of the fatty acids in canola oil. Storage tests of canola oil showed sensory changes after 2–4 days at 60–65°C in comparison to 16 weeks at room temperature. Canola oil seems to be more stable to storage in light than cottonseed oil and soybean oils, but is less stable than sunflower oil.[5] In addition, the effects of various factors on sediment formation in canola oil have been reported.[6]

It has been reported that oils stored at 2°C showed the highest rate of sediment formation, followed by those stored at 6°C.[5] All samples showed little sediment formation, as measured by turbidity, during storage at 12°C. Removal of sediment from canola oil prior to storage by cold precipitation and filtration did not eliminate this phenomenon, which still developed rapidly at 2°C.

A study on the effect of heating on the oxidation of low linolenic acid canola oil at frying temperatures under nitrogen and air clearly showed that a significantly lower development of oxidation was evident for the low linolenic acid canola oil. Reduction in the linolenic acid content of canola oil reduced the development of room odor at frying temperatures.

The thermal oxidation of canola oil studied during oven heating revealed an increase in peroxide values of pure and antioxidant-treated oils. Peroxide values were shown to differ between pure and antioxidant-treated canola oil during the initial stages of microwave

heating (6 minutes). Formation of secondary products of oxidation, which contribute to off-flavors, were also observed.[7]

12 Incompatibilities

Canola oil is incompatible with strong oxidizing agents.

13 Method of Manufacture

Canola oil is obtained by mechanical expression or *n*-hexane extraction from the seeds of *Brassica napus (Brassica campestris)* var. *oleifera* and certain other species of *Brassica* (Cruciferae). The crude oil thus obtained is refined, bleached, and deodorized to substantially remove free fatty acids, phospholipids, color, odor and flavor components, and miscellaneous nonoil materials.

14 Safety

Canola oil is generally regarded as an essentially nontoxic and nonirritant material, and has been accepted by the FDA for use in cosmetics, foods, and pharmaceuticals.

Rapeseed oil has been used for a number of years in food applications as a cheap alternative to olive oil. However, there are large amounts of erucic acid and glucosinolates in conventional rapeseed oil, both substances being toxic to humans and animals.[8] Canola oil derived from genetically selected rapeseed plants that are low in erucic acid content has been developed to overcome this problem. The FDA specifies 165.55 mg as the maximum amount for each route or dosage form containing the ingredient.

Feeding studies in rats have suggested that canola oil is nontoxic to the heart, although it has also been suggested that the toxicological data may be unclear.[9]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Spillages of this material are very slippery and should be covered with an inert absorbent material prior to disposal. Canola oil poses a slight fire hazard.

16 Regulatory Status

Accepted for use by the FDA in cosmetics and foods. Included in the FDA Inactive Ingredients Database (oral capsules). Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Almond oil; corn oil; cottonseed oil; peanut oil; rapeseed oil; sesame oil; soybean oil.

Rapeseed oil

CAS number [8002-13-9]
Synonyms *Calchem H-102*; colza oil; rape oil.
Appearance A clear, yellow to dark yellow-colored oily liquid.
Iodine number 94–120
Peroxide value <5
Saponification value 168–181
Comments Rapeseed oil contains 40–55% erucic acid. It is an edible oil and has been primarily used as an alternative, in foods and some pharmaceutical applications, to the more expensive olive oil. However, the safety of rapeseed oil as part of the diet has been questioned; *see* Section 14.

18 Comments

Canola oil has the lowest level of saturated fat compared to all other oils on the market at present and canola is now second only to soybean as the most important source of vegetable oil in the world. Canola has both a high protein (28%) and a high oil content (40%). When the oil is extracted, a high-quality and highly palatable feed concentrate of 37% protein remains. Canola oil is also high in the monounsaturated fatty acid oleic acid; *see* Table III.

The content of tocopherol, a natural antioxidant in canola oil, is comparable to those of peanut and palm oil. This is an important factor for oils with high linolenic acid content, which can reduce the shelf-life of the product, while the natural antioxidant, if present, can prevent oxidation during storage and processing.

The sulfur-containing compounds have been held responsible for the unpleasant odors from heated rapeseed oil. It has been suggested that the sulfur compounds in rapeseed oil are of three types: volatile, thermolabile, and nonvolatile.[1]

A specification for canola oil is contained in the *Food Chemicals Codex* (FCC).[10]

The EINECS number for canola oil is 232-313-5.

Table III: Comparison of the composition of crude soybean, canola, palm, and peanut oils.

Components	Canola	Palm	Peanut	Soybean
Fatty acid (%)	0.4–1.0	4.6	0.5–1.0	0.3–0.7
Phosphatides (gum) (%)	3.6	0.05–0.1	0.3–0.4	1.2–1.5
Sterols/ triterpene alcohol (%)	0.53	0.1–0.5	0.2	0.33
Tocopherols (%)	0.06	0.003–0.1	0.02–0.06	0.15–0.21
Carotenoids (mg/kg)	25–50	500–1600	>1	40–50
Chlorophyll/ pheophytins (ppm)	5–25	—	—	1–2
Sulfur (ppm)	—	—	—	12–17
Iodine value	112–131	44–60	84–100	123–139

Carbomer

1 Nonproprietary Names

BP: Carbomers

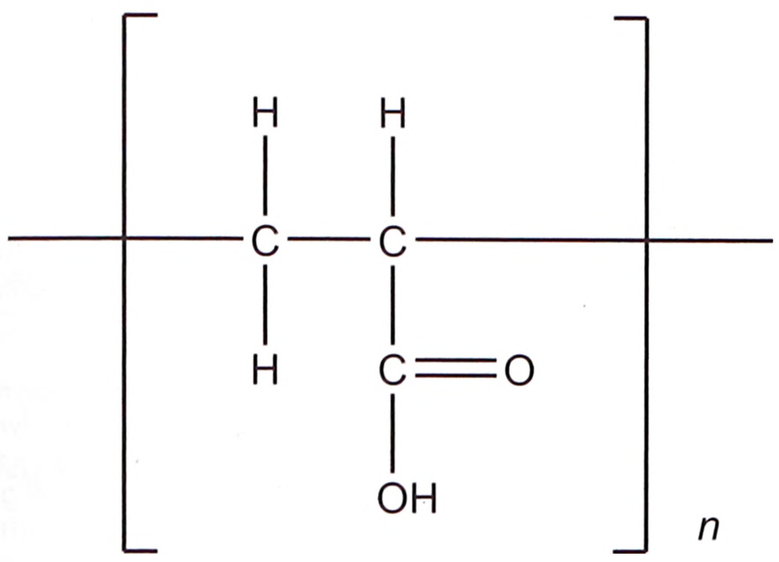
PhEur: Carbomers

USP–NF: Carbomer

2 Synonyms

Acrypol; *Acritamer*; acrylic acid polymer; carbomera; *Carbopol*; carboxy polymethylene; carboxyvinyl polymer; *Pemulen*; polyacrylic acid; *Tego Carbomer*.

3 Chemical Name and CAS Registry Number



Carbomer [9003-01-4]

Note that alternative CAS registry numbers have been used: carbomer 934 [9007-16-3]; carbomer 940 and carbomer homopolymer Type C [9007-17-4]; and 941 [9062-04-08]. The CAS registry number [9007-20-9] has also been used for carbomer (carboxypolymethylene).

4 Empirical Formula and Molecular Weight

Carbomers are synthetic high-molecular-weight polymers of acrylic acid that are crosslinked with either allyl sucrose or allyl ethers of pentaerythritol. They contain between 52% and 68% of carboxylic acid (COOH) groups calculated on the dry basis. The BP 2017 and PhEur 9.2 have a single monograph describing carbomer; the USP 40–NF 35 S1 contains several monographs describing individual carbomer grades that vary in aqueous viscosity, polymer type, and polymerization solvent. The molecular weight of carbomer is theoretically estimated at 7×10^5 to 4×10^9.

5 Structural Formula

Acrylic acid monomer unit in carbomer polymers.

Carbomer polymers are formed from repeating units of acrylic acid. The monomer unit is shown above. The polymer chains are crosslinked with allyl sucrose or allyl pentaerythritol. *See also* Section 4.

6 Functional Category

Bioadhesive material; emulsifying agent; emulsion stabilizing agent; modified-release agent; suspending agent; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Carbomers are used in liquid or semisolid pharmaceutical and cosmetic formulations as rheology modifiers and emulsifying agents in the preparation of oil-in-water emulsions for external administration. Formulations include creams, gels, lotions and ointments for use in ophthalmic,[1–3] rectal,[4–6] topical[7–12] and vaginal[13–16] preparations; *see* Table I.

In tablet formulations, carbomers are used as controlled-release agents either alone[17–26] or in combination with other polymers such as hypromellose and polyvinyl acetate phthalate.[27–29] In contrast to linear polymers, higher viscosity does not result in slower drug release with carbomers. Lightly crosslinked carbomers (lower viscosity) are generally more efficient in controlling drug release than highly crosslinked carbomers (higher viscosity).

Carbomers are also used as binders in wet granulation using water, organic solvents, or their mixtures as the granulating fluid.

Carbomer polymers have also been studied in the preparation of multiparticulate systems for oral delivery[30–34] and in oral mucoadhesive controlled drug delivery systems.[35–39]

Table I: Uses of carbomers.

Use	Typical concentration (%)
Emulsifying agent	0.1–0.5
Gelling agent	0.5–2.0
Suspending agent	0.5–1.0
Tablet binder	0.75–3.0
Controlled-release agent	5.0–30.0

8 Description

Carbomers are white-colored, 'fluffy', acidic, hygroscopic powders with a characteristic slight odor. A granular carbomer is also available (*Carbopol 71G*).

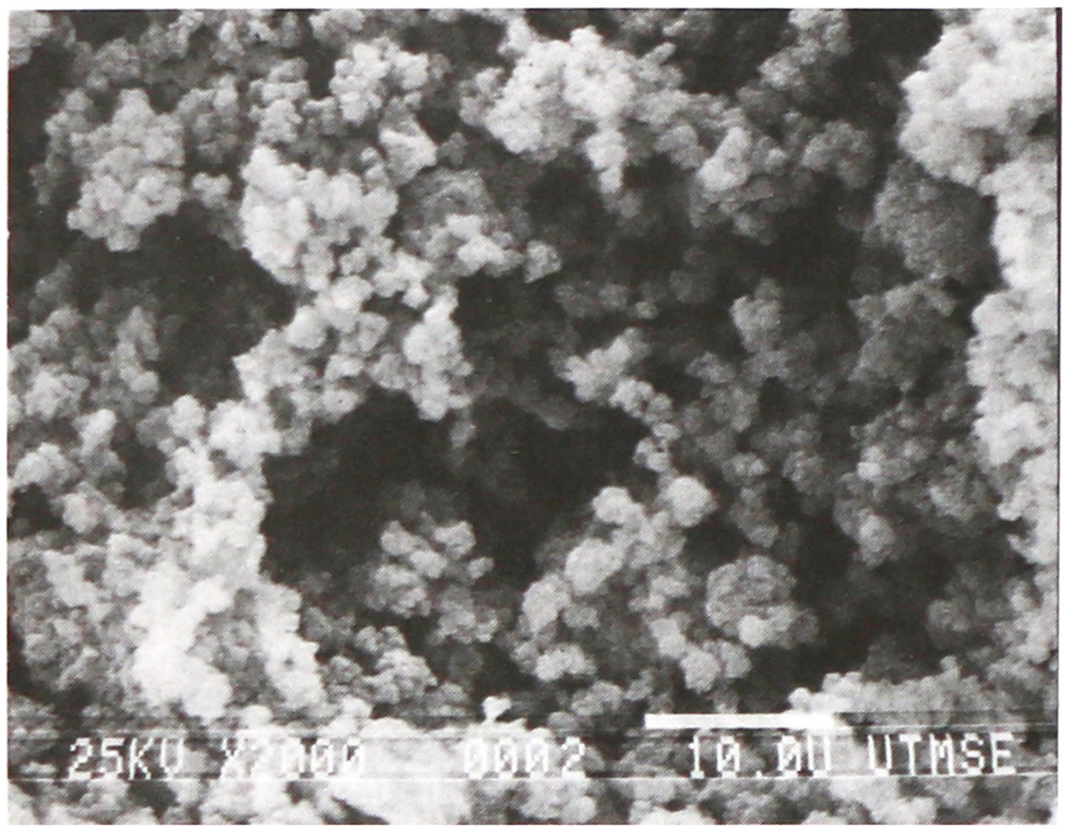
9 Pharmacopeial Specifications

The USP–NF has several monographs for different carbomer grades, while the BP and PhEur have only a single monograph.

The USP–NF lists three umbrella monographs, carbomer copolymer, carbomer homopolymer and carbomer interpolymer, which separate carbomer products based on polymer structure and apply to products not polymerized in benzene. The differentiation within each umbrella monograph is based on viscosity characteristics (Type A, Type B and Type C).

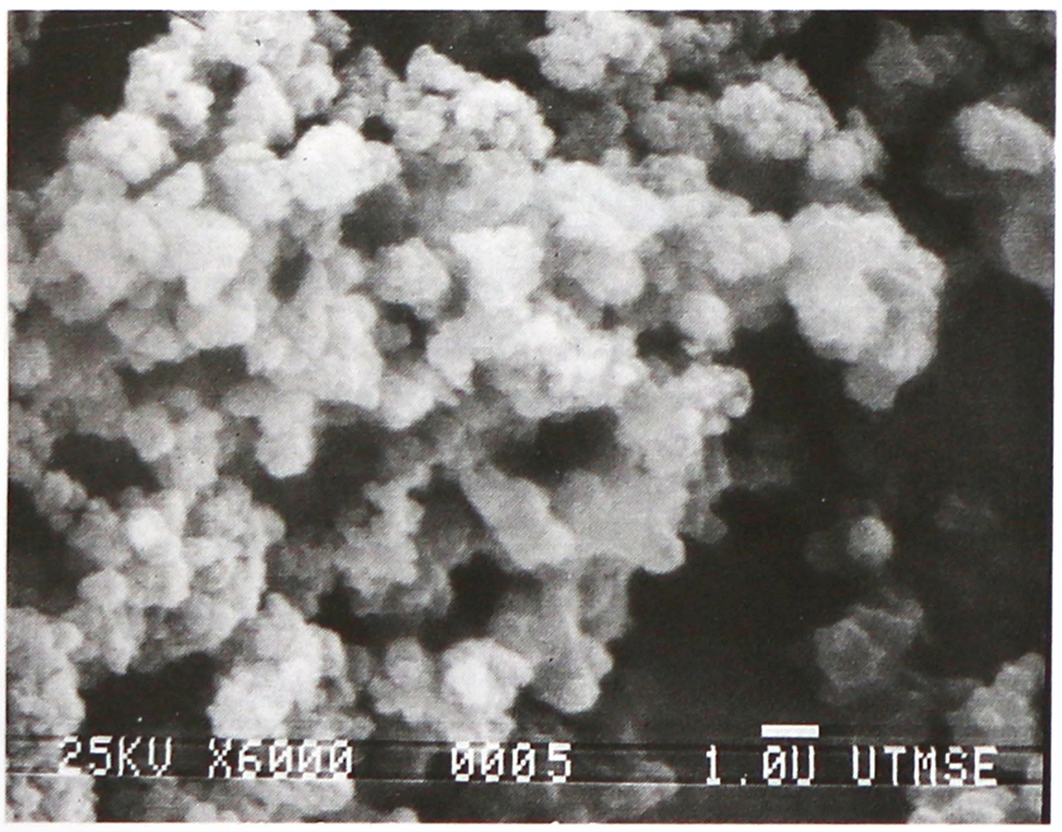
The USP–NF also lists monographs for carbomer 934, 934P, 940 and 941, which are manufactured using benzene. Effective since January 1 2011, products manufactured without the use of benzene are officially titled Carbomer Homopolymer provided they comply with the carbomer homopolymer monograph. The USP–NF also includes carbomer 1342, which applies to carbomer copolymers manufactured using benzene.

Carbomer polymers are also covered either individually or together in other pharmacopeias.



See Table II. *See also* Section 18.

10 Typical Properties



Acidity/alkalinity

pH = 2.5–4.0 for a 0.2% w/v aqueous dispersion

SEM 1: Excipient: *Carbopol 971P*; manufacturer: Lubrizol Advanced Materials, Inc.; magnification: 2000×; voltage: 25 kV.

SEM 2: Excipient: *Carbopol 971P*; manufacturer: Lubrizol Advanced Materials, Inc.; magnification: 6000×; voltage: 25 kV.

Density (bulk)
0.2 g/cm^3 (powder);
0.4 g/cm^3 (granular).

Density (tapped)
0.3 g/cm^3 (powder);
0.4 g/cm^3 (granular).

Density (true) 1.41 g/cm^3

Dissociation constant $pK_a = 6.0 \pm 0.5$

Glass transition temperature 100–105°C

Melting point Decomposition occurs within 30 minutes at 260°C. *See* Section 11.

Moisture content Typical water content is up to 2% w/w. However, carbomers are hygroscopic and a typical equilibrium moisture content at 25°C and 50% relative humidity is 8–10% w/w. The moisture content of a carbomer does not affect its thickening efficiency, but an increase in the moisture content makes the carbomer more difficult to handle because it is less readily dispersed.

Particle size distribution Primary particles average about 0.2 μm in diameter. The flocculated powder particles average 2–7 μm in diameter and cannot be broken down into the primary particles.

Table II: Pharmacopeial specifications for carbomers.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	–
Aqueous viscosity (mPa s)	300–115 000	+
Carbomer 934 (0.5% w/v)	–	30 500–39 400
Carbomer 934P (0.5% w/v)	–	29 400–39 400
Carbomer 940 (0.5% w/v)	–	40 000–60 000
Carbomer 941 (0.5% w/v)	–	4 000–11 000
Carbomer 1342 (1.0% w/v)	–	9 500–26 500
Carbomer copolymer (1% w/v)		
Type A	–	4 500–13 500
Type B	–	10 000–29 000
Type C	–	25 000–45 000
Carbomer homopolymer (0.5% w/v)		
Type A	–	4 000–11 000
Type B	–	25 000–45 000
Type C	–	40 000–60 000
Carbomer interpolymer		
Type A (0.5% w/v)	–	45 000–65 000
Type B (1% w/v)	–	47 000–77 000
Type C (0.5% w/v)	–	8 500–16 500
Loss on drying	≤3.0%	≤2.0%
Residue on ignition	≤4.0%	≤4.0%[a]
Heavy metals	–	≤0.002%
Benzene	≤2 ppm	+
Carbomer 934	–	≤0.5%
Carbomer 934P	–	≤0.01%
Carbomer 940	–	≤0.5%
Carbomer 941	–	≤0.5%
Carbomer 1342	–	≤0.2%
Carbomer copolymer	–	≤0.0002%
Carbomer homopolymer	–	≤0.0002%
Carbomer interpolymer	–	≤0.0002%
Free acrylic acid	≤0.25%	≤0.25%[b]
Ethylacetate	–	+
Carbomer copolymer	–	≤0.5%
Carbomer homopolymer	–	≤0.5%
Carbomer interpolymer	–	≤0.35%
Cyclohexane	–	+
Carbomer copolymer	–	≤0.3%
Carbomer homopolymer	–	≤0.3%
Carbomer interpolymer	–	≤0.15%
Assay (COOH content)	56.0–68.0%	56.0–68.0%[c]

(a) For carbomer homopolymer only.
(b) For carbomer copolymer, carbomer homopolymer and carbomer interpolymer only.
(c) Except for carbomer 1342, carbomer copolymer, and carbomer interpolymer, where the limits are 52.0–62.0%.
Note that unless otherwise indicated, the test limits shown above apply to all grades of carbomer.

A granular carbomer has a particle size in the range 150–425 μm.

Solubility Swellable in water and glycerin and, after neutralization, in ethanol (95%). Carbomers do not dissolve but merely swell to a remarkable extent, since they are three-dimensionally crosslinked microgels.

Spectroscopy

IR spectrum *see* Figure 1.

NIR spectrum *see* Figure 2.

Raman spectrum *see* Figure 3.

Viscosity (dynamic) Carbomers disperse in water to form acidic colloidal dispersions that, when neutralized, produce highly viscous gels. Neutralized aqueous gels are more viscous at pH 6–11. The viscosity is considerably reduced at pH values less

than 3 or greater than 12, or in the presence of strong electrolytes.[40,41]

11 Stability and Storage Conditions

Carbomers are stable, hygroscopic materials that may be heated at temperatures below 104°C for up to 2 hours without affecting their thickening efficiency. However, exposure to excessive temperatures can result in discoloration and reduced stability. Complete decomposition occurs with heating for 30 minutes at 260°C. Dry powder forms of carbomer do not support the growth of molds and fungi. In contrast, microorganisms grow well in unpreserved aqueous dispersions, and therefore an antimicrobial preservative such as 0.1% w/v chlorocresol, 0.18% w/v methylparaben–0.02% w/v propylparaben, or 0.1% w/v thimerosal should be added. The addition of certain antimicrobials, such as benzalkonium chloride or sodium benzoate, in high concentrations (0.1% w/v) can cause cloudiness and a reduction in viscosity of carbomer dispersions. Aqueous gels may be sterilized by autoclaving[3] with minimal changes in viscosity or pH, provided care is taken to exclude oxygen from the system, or by gamma irradiation, although this technique may increase the viscosity of the formulation.[42,43] At room temperature, carbomer dispersions maintain their viscosity during storage for prolonged periods. Similarly, dispersion viscosity is maintained, or only slightly reduced, at elevated storage temperatures if an antioxidant is included in the formulation or if the dispersion is stored protected from light. Exposure to light causes oxidation that is reflected in a decrease in dispersion viscosity. Stability to light may be improved by the addition of 0.05–0.1% w/v of a water-soluble UV absorber such as benzophenone-2 or benzophenone-4 in combination with 0.05–0.1% w/v edetic acid.

Carbomer powder should be stored in an airtight, corrosion-resistant container and protected from moisture. The use of glass, plastic, or resin-lined containers is recommended for the storage of formulations containing carbomer.

12 Incompatibilities

Carbomers are discolored by resorcinol and are incompatible with phenol, cationic polymers, strong acids, and high levels of electrolytes. Certain antimicrobial adjuvants should also be avoided or used at low levels, *see* Section 11. Trace levels of iron and other transition metals can catalytically degrade carbomer dispersions.

Certain amino-functional actives form complexes with carbomer; often this can be prevented by adjusting the pH of the dispersion and/or the solubility parameter by using appropriate alcohols and polyols.

Carbomers also form pH-dependent complexes with certain polymeric excipients. Adjustment of pH and/or solubility parameter can also work in this situation.

13 Method of Manufacture

Carbomers are synthetic, high-molecular-weight, crosslinked polymers of acrylic acid. These acrylic acid polymers are crosslinked with allyl sucrose or allyl pentaerythritol. The polymerization solvent used previously was benzene; however, some of the newer commercially available grades of carbomer are manufactured using either ethyl acetate or a cyclohexane–ethyl acetate cosolvent mixture. The *Carbopol ETD* and *Carbopol Ultrez* polymers are produced in the cosolvent mixture with a proprietary polymerization aid.

14 Safety

Carbomers are used extensively in nonparenteral products, particularly topical liquid and semisolid preparations. Grades polymerized in ethyl acetate may also be used in oral formulations; *see* Section 18. There is no evidence of systemic absorption of carbomer polymers following oral administration.[44] Acute oral toxicity studies in animals indicate that carbomer 934P has a low oral toxicity, with doses up to 8 g/kg being administered to dogs without fatalities occurring. Carbomers are generally regarded as essentially nontoxic and nonirritant materials;[45] there is no evidence in humans of hypersensitivity reactions to carbomers used topically.

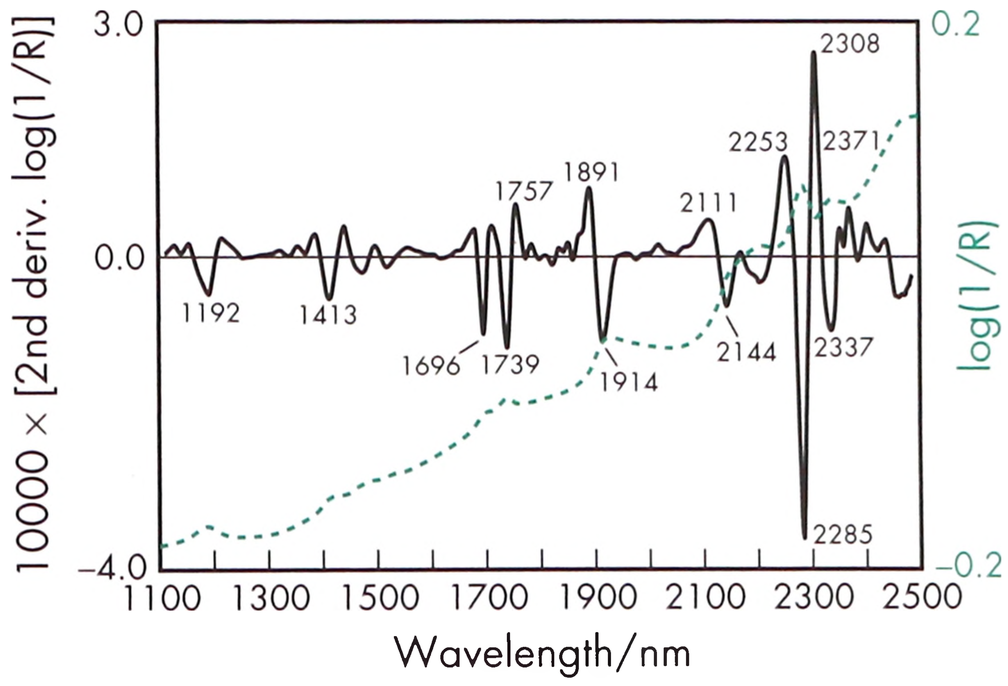

Figure 2: Near-infrared spectrum of carbomer measured by reflectance.

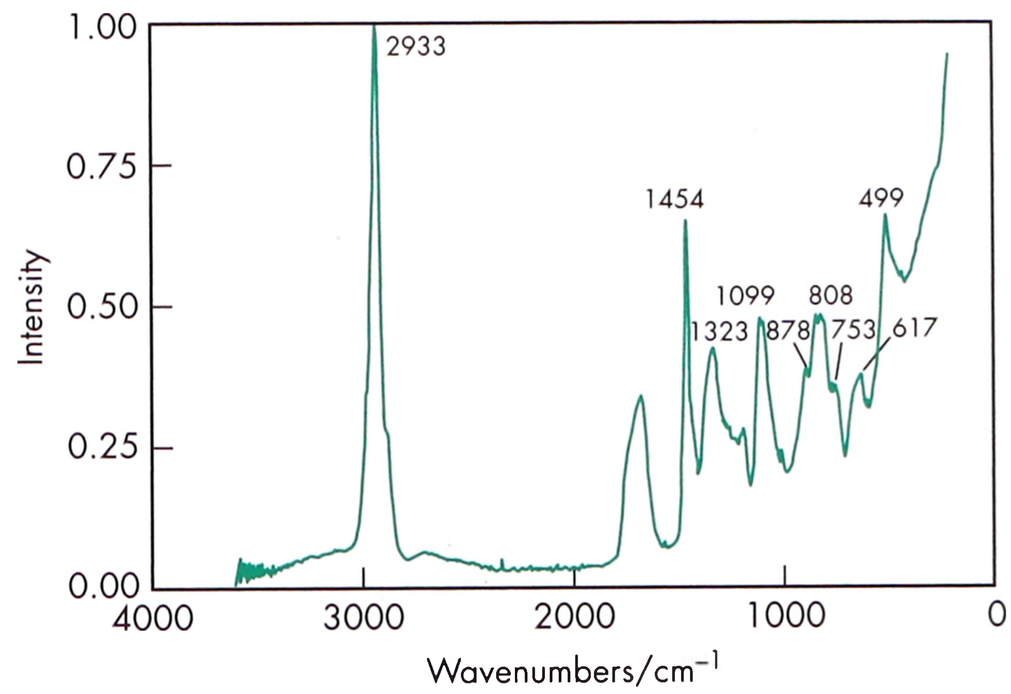

Figure 3: Raman spectrum of carbomer measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

LD_{50} (guinea pig, oral): 2.5 g/kg for carbomer 934[46]
LD_{50} (guinea pig, oral): 2.5 g/kg for carbomer 934P
LD_{50} (guinea pig, oral): 2.5 g/kg for carbomer 940
LD_{50} (mouse, IP): 0.04 g/kg for carbomer 934P
LD_{50} (mouse, IP): 0.04 g/kg for carbomer 940

LD_{50} (mouse, IV): 0.07 g/kg for carbomer 934P
LD_{50} (mouse, IV): 0.07 g/kg for carbomer 940
LD_{50} (mouse, oral): 4.6 g/kg for carbomer 934P
LD_{50} (mouse, oral): 4.6 g/kg for carbomer 934
LD_{50} (mouse, oral): 4.6 g/kg for carbomer 940
LD_{50} (rat, oral): 10.25 g/kg for carbomer 910
LD_{50} (rat, oral): 2.5 g/kg for carbomer 934P
LD_{50} (rat, oral): 4.1 g/kg for carbomer 934
LD_{50} (rat, oral): 2.5 g/kg for carbomer 940
LD_{50} (rat, oral): >1 g/kg for carbomer 941

No observed adverse effect level (NOAEL) (rat, dog, oral): 1.5 g/kg for carbomer homopolymer type B.[47]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Excessive dust generation should be minimized to avoid the risk of explosion (lowest explosive concentration is 130 g/m^3). Carbomer dust is irritating to the eyes, mucous membranes, and respiratory tract. In the event of eye contact with carbomer dust, saline should be used for irrigation purposes. Gloves, eye protection, and a dust respirator are recommended during handling.

A solution of electrolytes (sodium chloride) or alkaline detergent is recommended for cleaning equipment after processing carbomers.

16 Regulatory Acceptance

Included in the FDA Inactive Ingredients Database (oral suspensions and tablets; ophthalmic, rectal, topical, and transdermal preparations; vaginal suppositories). Included in nonparenteral medicines licensed in Europe. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Polycarbophil.

18 Comments

Carbomers have been investigated for formulations for nasal and pulmonary delivery routes.[48–51] The polymeric gels may be used as a vehicle for liposomes, niosomes, microemulsions, and nanoparticles.[52–57] Carbomers have also been investigated as inhibitors of intestinal proteases in peptide-containing dosage forms.[58–60] The polymers have been studied in dosage forms for colonic drug delivery,[61,62] in magnetic granules for site-specific drug delivery to the esophagus,[63] as a bioadhesive for a cervical patch[64] or in oral care formulations.[65,66]

A number of different carbomer grades are commercially available that vary in their chemical structure, degree of crosslinking, and residual components. These differences account for the specific rheological, handling, and use characteristics of each grade. Carbomer grades that have the polymer backbone modified with long-chain alkyl acrylates are used as polymeric emulsifiers or in formulations requiring increased resistance to ions.

Polycarbophils, poly(acrylic acid) polymers crosslinked with divinyl glycol, are available for bioadhesive or medicinal applications. In general, carbomers designated with the letter 'P', e.g. *Carbopol 971P*, are the pharmaceutical grade polymers for oral or mucosal contact products.

In an effort to measure the molecular weight between crosslinks, M_C, researchers have extended the network theory of elasticity to swollen gels and have utilized the inverse relationship between the elastic modulus and M_C.[67–69] Estimated M_C values of 237 600 g/mol for *Carbopol 941* and of 104 400 g/mol for *Carbopol 940* have been reported.[70] In general, carbomer polymers with lower viscosity and lower rigidity will have higher M_C values. Conversely, higher-viscosity, more rigid carbomer polymers will have lower M_C values.

Carbomer copolymer (or homopolymer or interpolymer) obtained from different manufacturers or produced in different solvents with different manufacturing processes may not have identical properties with respect to their use for specific pharmaceutical purposes, e.g. as tablet controlled-release agents, bioadhesives, topical gellants, etc. Therefore, types of carbomer copolymer (or homopolymer or interpolymer) should not be interchanged unless performance equivalency has been ascertained.

In the preparation of gels, carbomer powders should first be dispersed into vigorously stirred water, taking care to avoid the formation of indispersible agglomerates, then neutralized by the addition of a base. The *Carbopol ETD* and *Ultrez* series of carbomers have been introduced to overcome some of the problems of dispersing the powder into aqueous solvents. These carbomers wet quickly yet hydrate slowly, while possessing a lower unneutralized dispersion viscosity. Agents that may be used to neutralize carbomer polymers include amino acids, potassium hydroxide, sodium bicarbonate, sodium hydroxide, and organic amines such as triethanolamine. One gram of carbomer is neutralized by approximately 0.4 g of sodium hydroxide. During preparation of the gel, the solution should be agitated slowly with a broad, paddlelike stirrer to avoid introducing air bubbles.

Therapeutically, carbomer formulations have proved efficacious in improving symptoms of moderate-to-severe dry eye syndrome.[71,72]

A specification for carbomer (carboxyvinyl polymer) is contained in the *Japanese Pharmaceutical Excipients* (JPE).[73]

Carbon Dioxide

1 Nonproprietary Names

BP: Carbon Dioxide
JP: Carbon Dioxide
PhEur: Carbon Dioxide
USP–NF: Carbon Dioxide

2 Synonyms

Carbonei dioxidum; carbonic acid gas; carbonic anhydride; E290.

3 Chemical Name and CAS Registry Number

Carbon dioxide [124-38-9]

4 Empirical Formula and Molecular Weight

CO_2 44.01

5 Structural Formula

See Section 4.

6 Functional Category

Aerosol propellant; air displacement; solvent.

7 Applications in Pharmaceutical Formulation or Technology

Carbon dioxide and other compressed gases such as nitrogen and nitrous oxide are used as propellants for topical pharmaceutical aerosols. They are also used in other aerosol products that work satisfactorily with the coarse aerosol spray that is produced with compressed gases, e.g. cosmetics, furniture polish, and window cleaners.[1–3]

The advantages of compressed gases as aerosol propellants are that they are less expensive; are of low toxicity; and are practically odorless and tasteless. Also, in comparison to liquefied gases, their pressures change relatively little with temperature. However, the disadvantages of compressed gases are that there is no reservoir of propellant in the aerosol and pressure consequently decreases as the product is used. This results in a change in spray characteristics. Additionally, if a product that contains a compressed gas as a propellant is actuated in an inverted position, the vapor phase, rather than the liquid phase, is discharged. Most of the propellant is contained in the vapor phase and therefore some of the propellant will be lost and the spray characteristics will be altered. Also, sprays produced using compressed gases are very wet. Valves, such as the vapor tap or double dip tube, are currently available and will overcome these problems.

Carbon dioxide is also used to displace air from pharmaceutical products by sparging and hence to inhibit oxidation. As a food additive it is used to carbonate beverages and to preserve foods such as bread from spoilage by mold formation, the gas being injected into the space between the product and its packaging.[4,5]

Solid carbon dioxide is also widely used to refrigerate products temporarily, while liquid carbon dioxide, which can be handled at temperatures up to 31°C under high pressure, is used as a solvent for flavors and fragrances, primarily in the perfumery and food manufacturing industries.

8 Description

Carbon dioxide occurs naturally as approximately 0.03% v/v of the atmosphere. It is a colorless, odorless, noncombustible gas with a faint acid taste. Solid carbon dioxide, also known as dry ice, is usually encountered as white-colored pellets or blocks.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for carbon dioxide.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Characters	+	+	–
Production	–	+	–
Total sulfur	–	≤1 ppm	–
Water	–	≤67 ppm	≤150 mg/m^3
Identification	+	+	+
Carbon monoxide	+	≤5 ppm	≤0.001%
Sulfur dioxide	–	≤2 ppm	≤5 ppm
Nitrogen monoxide and nitrogen dioxide	–	≤2 ppm	≤2.5 ppm
Impurities	–	+	–
Limit of ammonia	–	–	≤0.0025%
Limit of nitric oxide	–	–	≤2.5 ppm
Acid	+	–	–
Hydrogen phosphide, hydrogen sulfide or reducing organic substances	+	≤1 ppm	≤1 ppm
Oxygen and nitrogen	+	–	–
Assay	≥99.5%	≥99.5%	≥99.0%

10 Typical Properties

Density

0.714 g/cm^3 for liquid at 25°C;

0.742 g/cm^3 for vapor at 25°C.

Flammability Nonflammable.

Solubility 1 in about 1 of water by volume at normal temperature and pressure.

Vapor density (absolute) 1.964 g/m^3

Vapor density (relative) 1.53 (air = 1)

Viscosity (kinematic) 0.14 mm^2/s (0.14 cSt) at −17.8°C.

11 Stability and Storage Conditions

Extremely stable and chemically nonreactive. Store in a tightly sealed cylinder. Avoid exposure to excessive heat.

12 Incompatibilities

Carbon dioxide is generally compatible with most materials although it may react violently with various metal oxides or reducing metals such as aluminum, magnesium, titanium, and zirconium. Mixtures with sodium and potassium will explode if shocked.

13 Method of Manufacture

Carbon dioxide is obtained industrially in large quantities as a by-product in the manufacture of lime; by the incineration of coke or other carbonaceous material; and by the fermentation of glucose by yeast. In the laboratory it may be prepared by dropping acid on a carbonate.

14 Safety

In formulations, carbon dioxide is generally regarded as an essentially nontoxic material.

15 Handling Precautions

Handle in accordance with standard procedures for handling metal cylinders containing liquefied or compressed gases. Carbon dioxide is an asphyxiant, and inhalation in large quantities is hazardous. It should therefore be handled in a well-ventilated environment equipped with suitable safety devices for monitoring vapor concentration.

It should be noted that carbon dioxide is classified as a greenhouse gas responsible for global warming. At the present time there are no restrictions on its use for aerosols and other pharmaceutical applications.

In the UK, the workplace exposure limits for carbon dioxide are 9150 mg/m^3 (5000 ppm) long-term (8-hour TWA) and 27 400 mg/m^3 (15 000 ppm) short-term (15-minute).[6] In the USA, the permissible exposure limits are 9000 mg/m^3 (5000 ppm) long-term and the recommended exposure limits are 18 000 mg/m^3 (10 000 ppm) short-term and 54 000 mg/m^3 (30 000 ppm) maximum, short-term.[7]

Solid carbon dioxide can produce severe burns in contact with the skin and appropriate precautions, depending on the circumstances and quantity of material handled, should be taken. A face shield and protective clothing, including thick gloves, are recommended.

16 Regulatory Status

GRAS listed. Accepted for use in Europe as a food additive. Included in the FDA Inactive Ingredients Database (aerosol formulation for nasal preparations; IM and IV injections). Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Nitrogen; nitrous oxide.

18 Comments

Supercritical carbon dioxide has been used in the formation of fine powders of stable protein formulations.[8,9]

Carbon dioxide has also been investigated for its suitability in Aerosol Solvent Extraction Systems (ASES), to generate microparticles of proteins suitable for aerosol delivery from aqueous based solutions.[10]

A specification for carbon dioxide is contained in the *Food Chemicals Codex* (FCC).[11]

The EINECS number for carbon dioxide is 204-696-9. The PubChem Compound ID (CID) for carbon dioxide is 280.

Carboxymethylcellulose Calcium

1 Nonproprietary Names

BP: Carmellose Calcium

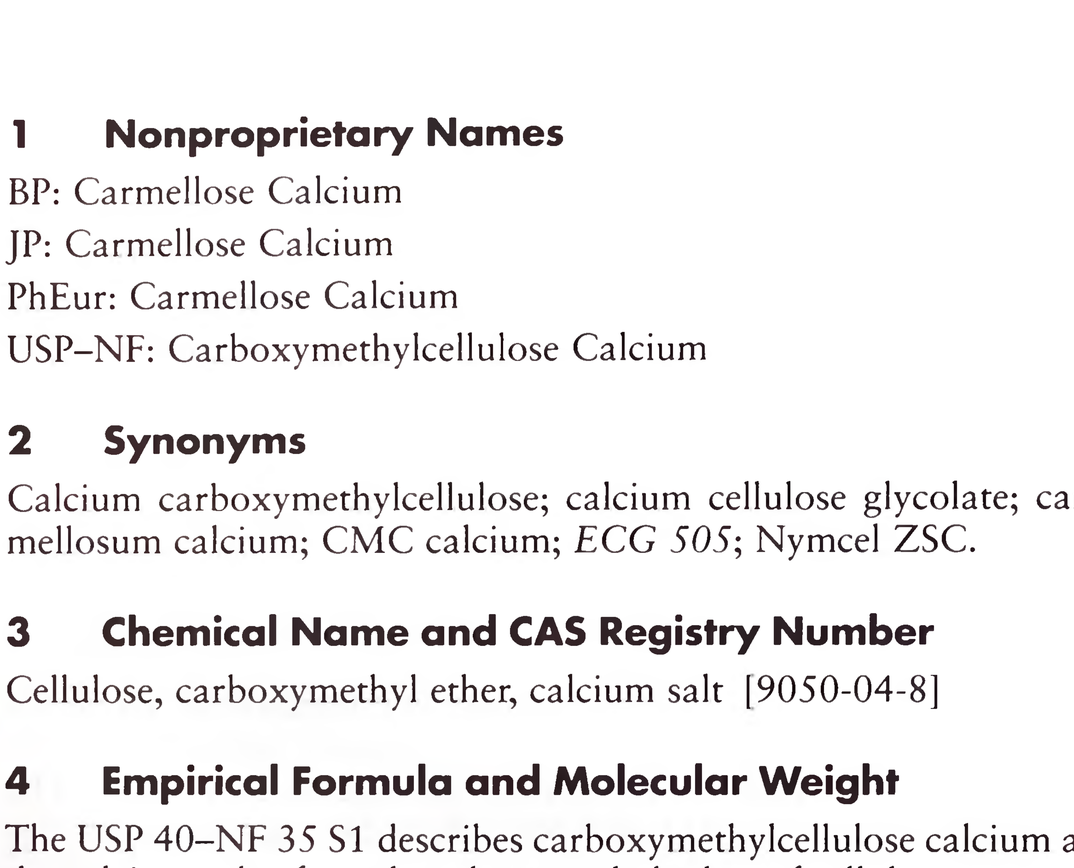
JP: Carmellose Calcium

PhEur: Carmellose Calcium

USP–NF: Carboxymethylcellulose Calcium

2 Synonyms

Calcium carboxymethylcellulose; calcium cellulose glycolate; carmellosum calcium; CMC calcium; *ECG 505*; Nymcel ZSC.



3 Chemical Name and CAS Registry Number

Cellulose, carboxymethyl ether, calcium salt [9050-04-8]

4 Empirical Formula and Molecular Weight

The USP 40–NF 35 S1 describes carboxymethylcellulose calcium as the calcium salt of a polycarboxymethyl ether of cellulose.

5 Structural Formula

Structure shown with a degree of substitution (DS) of 1.0.

6 Functional Category

Adsorbent; coating agent; suspending agent; tablet and capsule binder; tablet and capsule disintegrant; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

The main use of carboxymethylcellulose calcium is in tablet formulations (*see* Table I), where it is used as a binder, diluent, and disintegrant.[1–4] Although carboxymethylcellulose calcium is insoluble in water, it is an effective tablet disintegrant as it swells to several times its original bulk on contact with water. Concentrations up to 15% w/w may be used in tablet formulations; above this concentration, tablet hardness is reduced.

Carboxymethylcellulose calcium is also used in other applications similarly to carboxymethylcellulose sodium; for example, as a suspending or viscosity-increasing agent in oral and topical pharmaceutical formulations. Carboxymethylcellulose calcium is also used in modern wound dressings for its water absorption, retention and hemostatic properties.

Table I: Uses of carboxymethylcellulose calcium.

Use	Concentration (%)
Tablet binder	5–15
Tablet disintegrant	1–15

8 Description

Carboxymethylcellulose calcium occurs as a white to yellowish-white, hygroscopic powder.

9 Pharmacopeial Specifications

The pharmacopeial specifications for carboxymethylcellulose calcium have undergone harmonization of many attributes for JP, PhEur, and USP–NF.

See Table II. *See also* Section 18.

Table II: Pharmacopeial specifications for carboxymethylcellulose calcium.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters	—	+	—
Alkalinity	+	+	+
pH	4.5–6.0	—	—
Loss on drying	≤10.0%	≤10.0%	≤10.0%
Residue on ignition	10.0–20.0%	—	10.0–20.0%
Chloride	≤0.36%	≤0.36%	≤0.36%
Sulfate	≤1.0%	≤1.0%	≤1.0%
Heavy metals[a]	≤20 ppm	—	≤20 ppm

(a) These tests have not been fully harmonized at the time of publication.

10 Typical Properties

Acidity/alkalinity pH = 4.5–6.0 for a 1% w/v aqueous dispersion.

Solubility Practically insoluble in acetone, chloroform, ethanol (95%), toluene, and ether. Insoluble in water, but swells to form a suspension.

11 Stability and Storage Conditions

Carboxymethylcellulose calcium is a stable, though hygroscopic material. It should be stored in a well-closed container in a cool, dry place.

See also Carboxymethylcellulose Sodium.

12 Incompatibilities

See Carboxymethylcellulose Sodium.

13 Method of Manufacture

Cellulose, obtained from wood pulp or cotton fibers, is carboxymethylated, followed by conversion to the calcium salt. It is then graded on the basis of its degree of carboxymethylation and pulverized.

14 Safety

Carboxymethylcellulose calcium is used in oral and topical pharmaceutical formulations, similarly to carboxymethylcellulose sodium, and is generally regarded as a nontoxic and nonirritant material. However, as with other cellulose derivatives, oral consumption of large amounts of carboxymethylcellulose calcium may have a laxative effect.

See also Carboxymethylcellulose Sodium.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Carboxymethylcellulose calcium may be irritant to the eyes; eye protection is recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral capsules and tablets). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Carboxymethylcellulose sodium; croscarmellose sodium.

18 Comments

Carboxymethylcellulose calcium has undergone harmonization of many attributes for JP, PhEur, and USP–NF by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

Carboxymethylcellulose Sodium

C

1 Nonproprietary Names

BP: Carmellose Sodium

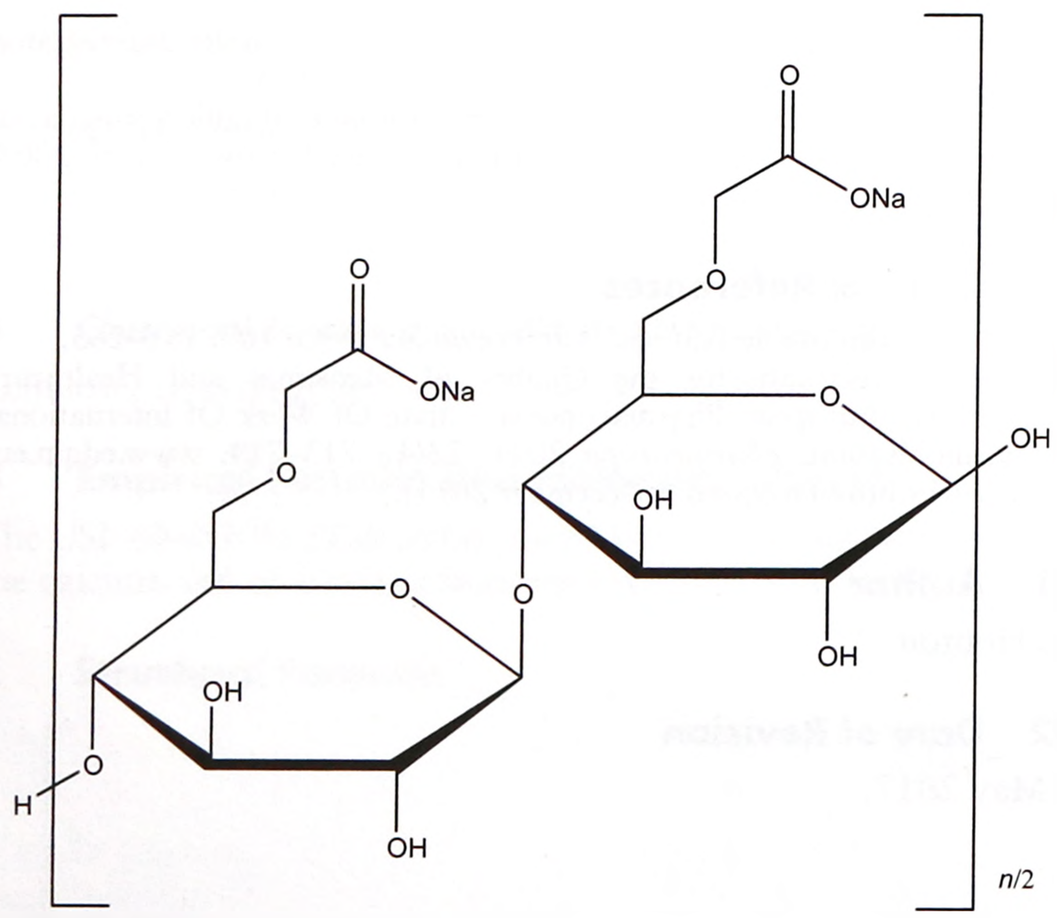
JP: Carmellose Sodium

PhEur: Carmellose Sodium

USP–NF: Carboxymethylcellulose Sodium

2 Synonyms

Akucell; *Aqualon CMC*; *Blanose*; *Carbose D*; carmellosum natricum; cellulose gum; CMC sodium; *Dynacel*; E466; *Finnfix*; *KiccolateNymcel ZSB*; SCMC; sodium carboxymethylcellulose; sodium cellulose glycolate; *Sunrose*; *Tylose CB*; *Tylose MGA*; *Walocel C*; *Walocel CRT*; *Xylo-Mucine*.



3 Chemical Name and CAS Registry Number

Cellulose, carboxymethyl ether, sodium salt [9004-32-4]

4 Empirical Formula and Molecular Weight

The USP 40–NF 35 S1 describes carboxymethylcellulose sodium as the sodium salt of a polycarboxymethyl ether of cellulose.

5 Structural Formula

Structure shown with a degree of substitution (DS) of 1.0.

6 Functional Category

Adsorbent; emulsifying agent; suspending agent; tablet and capsule binder; tablet and capsule disintegrant; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Carboxymethylcellulose sodium is widely used in oral and topical pharmaceutical formulations, primarily for its viscosity-increasing properties. Viscous aqueous solutions are used to suspend powders intended for either topical application or oral and parenteral administration.[1,2] Carboxymethylcellulose sodium may also be used as a tablet binder and disintegrant,[3–6] and to stabilize emulsions.[7,8]

Encapsulation with carboxymethylcellulose sodium can affect drug protection and delivery.[6,9]

Higher concentrations, usually 3–6%, of the medium-viscosity grade are used to produce gels that can be used as the base for applications and pastes; glycols are often included in such gels to prevent them drying out.

Carboxymethylcellulose sodium is also used in cosmetics, toiletries,[10] personal hygiene, and food products.

See Table I.

Table I: Uses of carboxymethylcellulose sodium.

Use	Concentration (%)
Emulsifying agent	0.25–1.0
Gel-forming agent	3.0–6.0
Injections	0.05–0.75
Oral solutions	0.1–1.0
Tablet binder	1.0–6.0

8 Description

Carboxymethylcellulose sodium occurs as a white to almost white, odorless, tasteless, granular powder. It is hygroscopic after drying.

See also Section 18.

9 Pharmacopeial Specifications

See Table II. *See also* Section 18.

Table II: Pharmacopeial specifications for carboxymethylcellulose sodium.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters	+	+	—
pH (1% w/v solution)	6.0–8.0	6.0–8.0	6.5–8.5
Appearance of solution	+	+	—
Viscosity	—	+	+
Loss on drying	≤10.0%	≤10.0%	≤10.0%

NIR spectrum *see* Figure 3.

Raman spectrum *see* Figure 4.

Viscosity Various grades of carboxymethylcellulose sodium are commercially available that have differing aqueous viscosities; *see* Table III. Aqueous 1% w/v solutions with viscosities of 5–2000 mPa s (5–2000 cP) may be obtained. An increase in concentration results in an increase in aqueous solution viscosity.[10] Prolonged heating at high temperatures will depolymerize the gum and permanently decrease the viscosity. The viscosity of sodium carboxymethylcellulose solutions is fairly stable over a pH range of 4–10. The optimum pH range is neutral.

See Section 11.

11 Stability and Storage Conditions

Carboxymethylcellulose sodium is a stable, though hygroscopic material. Under high-humidity conditions, carboxymethylcellulose

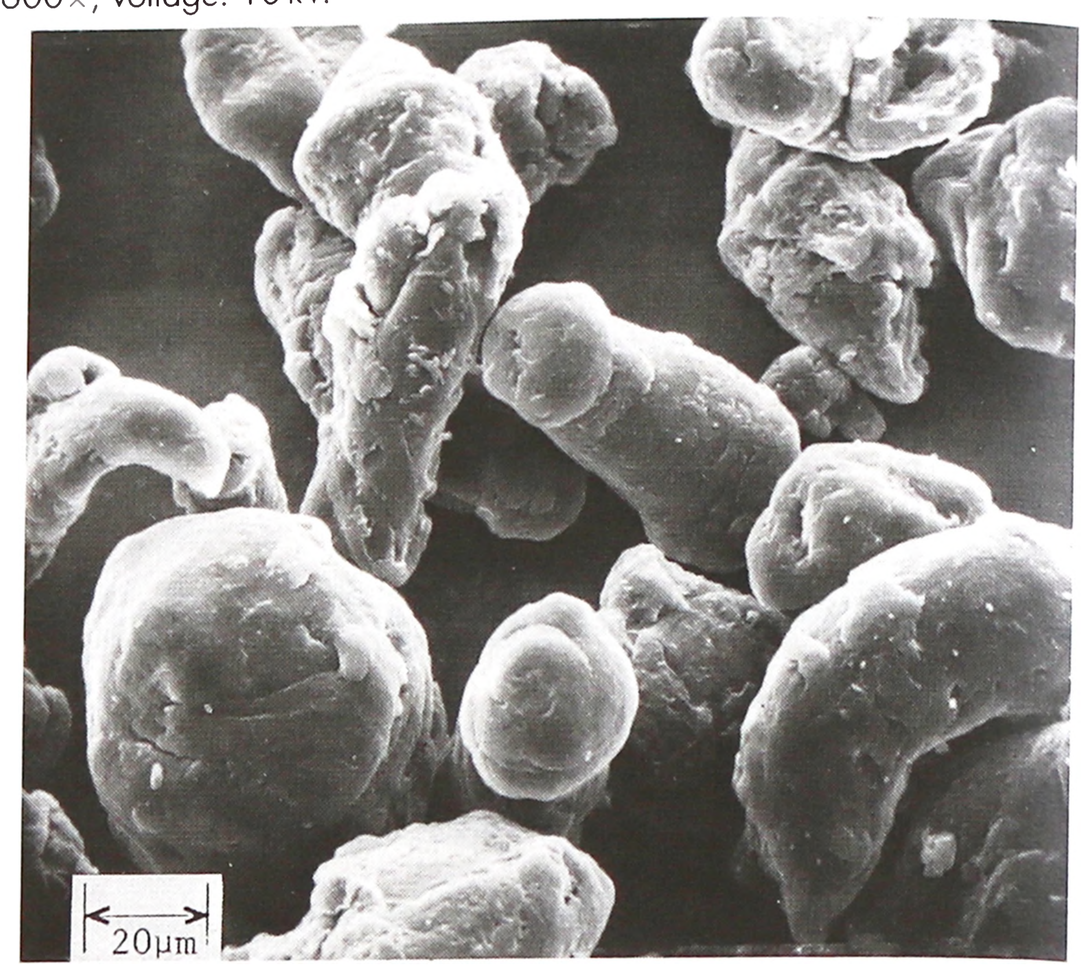
Table III: Viscosity of aqueous carboxymethylcellulose sodium 1% w/v solutions. (Measurements made with a Brookfield LVT viscometer at 25°C.)

	Grade	Viscosity (mPa s)	Spindle	Speed
Low viscosity	*Akucell AF 0305*	10–15	#1	60 rpm
Medium viscosity	*Akucell AF 2785*	1500–2500	#3	30 rpm
High viscosity	*Akucell AF 3085*	8000–12000	#4	30 rpm

sodium can absorb a large quantity (>50%) of water. In tablets, this has been associated with a decrease in tablet hardness and an increase in disintegration time.[11]

Aqueous solutions are stable at pH 2–10; precipitation can occur below pH 2, and solution viscosity decreases rapidly above pH 10. Generally, solutions exhibit maximum viscosity and stability at pH 7–9.



Carboxymethylcellulose sodium may be sterilized in the dry state by maintaining it at a temperature of 160°C for 1 hour. However, this process results in a significant decrease in viscosity and some deterioration in the properties of solutions prepared from the sterilized material.

Aqueous solutions may similarly be sterilized by heating, although this also results in some reduction in viscosity. After autoclaving, viscosity is reduced by about 25%, but this reduction is less marked than for solutions prepared from material sterilized in the dry state. The extent of the reduction is dependent on the molecular weight and degree of substitution; higher molecular weight grades generally undergo a greater percentage reduction in

SEM 1: Excipient: carboxymethylcellulose sodium; manufacturer: Buckeye Cellulose Corp.; lot no.: 9247 AP; magnification: 120×; voltage: 10 kV.

SEM 2: Excipient: carboxymethylcellulose sodium; manufacturer: Ashland Aqualon Functional Ingredients; lot no.: 21 A-1 (44390); magnification: 600×; voltage: 10 kV.

viscosity.[12] Sterilization of solutions by gamma irradiation also results in a reduction in viscosity.

Aqueous solutions stored for prolonged periods should contain an antimicrobial preservative.[13]

The bulk material should be stored in a well-closed container in a cool, dry place.

12 Incompatibilities

Carboxymethylcellulose sodium is incompatible with strongly acidic solutions and with the soluble salts of iron and some other metals, such as aluminum, mercury, and zinc. It is also incompatible with xanthan gum. Precipitation may occur at pH <2, and also when it is mixed with ethanol (95%).

Carboxymethylcellulose sodium forms complex coacervates with gelatin and pectin. It also forms a complex with collagen and is capable of precipitating certain positively charged proteins.

13 Method of Manufacture

Alkali cellulose is prepared by steeping cellulose obtained from wood pulp or cotton fibers in sodium hydroxide solution. The alkaline cellulose is then reacted with sodium monochloroacetate to produce carboxymethylcellulose sodium. Sodium chloride and sodium glycolate are obtained as by-products of this etherification.

14 Safety

Carboxymethylcellulose sodium is used in oral, topical, and some parenteral formulations. It is also widely used in cosmetics, toiletries, and food products, and is generally regarded as a nontoxic and nonirritant material. However, oral consumption of large amounts of carboxymethylcellulose sodium can have a laxative effect; therapeutically, 4–10 g in daily divided doses of the medium- and high-viscosity grades of carboxymethylcellulose sodium have been used as bulk laxatives.[14]

The WHO has not specified an acceptable daily intake for carboxymethylcellulose sodium as a food additive since the levels necessary to achieve a desired effect were not considered to be a hazard to health.[15–18] However, in animal studies, subcutaneous administration of carboxymethylcellulose sodium has been found to cause inflammation, and in some cases of repeated injection fibrosarcomas have been found at the site of injection.[19]

Hypersensitivity and anaphylactic reactions have occurred in cattle and horses, which have been attributed to carboxymethylcellulose sodium in parenteral formulations such as vaccines and penicillins.[20–23]

LD_{50} (guinea pig, oral): 16 g/kg[24]

LD_{50} (rat, oral): 27 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Carboxymethylcellulose sodium may be irritant to the eyes. Eye protection is recommended.

16 Regulatory Status

GRAS listed. Accepted as a food additive in Europe. Included in the FDA Inactive Ingredients Database (dental preparations; intra-articular, intrabursal, intradermal, intralesional, and intrasynovial injections; oral drops, solutions, suspensions, syrups and tablets; topical preparations). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Carboxymethylcellulose calcium.

18 Comments

Carboxymethylcellulose sodium is one of the materials that have been selected for harmonization by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

A number of grades of carboxymethylcellulose sodium are commercially available, such as *Accelerate*. These have a degree of substitution (DS) in the range 0.7–1.2. The DS is defined as the average number of hydroxyl groups substituted per anhydroglucose unit and it is this that determines the aqueous solubility of the polymer. Thermal crosslinking reduces solubility while retaining water absorption, therefore producing materials suitable for water absorption.

Grades are typically classified as being of low, medium, or high viscosity. The degree of substitution and the maximum viscosity of

an aqueous solution of stated concentration should be indicated on any carboxymethylcellulose sodium labeling.

Carboxymethylcellulose sodium has been reported to give false positive results in the LAL test for endotoxins.[25]

Carboxymethylcellulose sodium is used in self-adhesive ostomy, wound care,[26] and dermatological patches as a mucoadhesive and to absorb wound exudate or transepidermal water and sweat. The mucoadhesive property is used in products designed to prevent post-surgical tissue adhesions;[27–29] to localize and modify the release kinetics of active ingredients applied to mucous membranes; and for bone repair. There have also been reports of its use as a cytoprotective agent.[30,31] Carboxymethylcellulose sodium is also used in concentrations of up to 1% as artificial saliva preparations for the management of dry mouth, and in eye drops for the management of dry eye. It has also been used in surgical prosthetics,[32] and in the treatment of constipation and incontinence.

The PubChem Compound ID (CID) for carboxymethylcellulose sodium is 23706213.

Carrageenan

1 Nonproprietary Names

BP: Carrageenan

PhEur: Carrageenan

USP–NF: Carrageenan

2 Synonyms

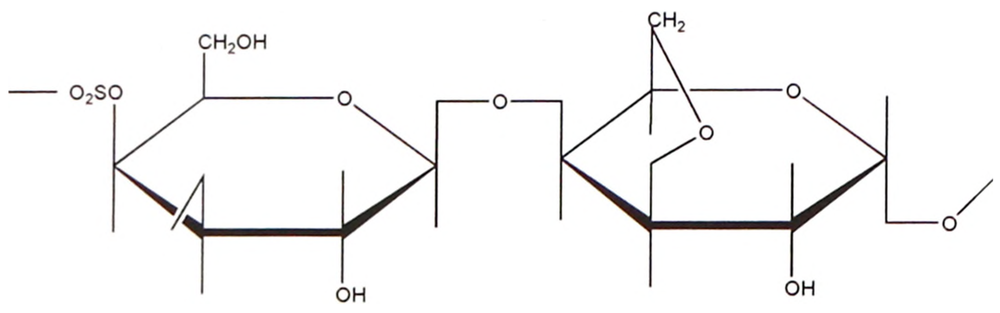
Carrageenanum; chondrus extract; E407; *Gelcarin*; *Genu*; *Grindsted*; *Hygum TP-1*; Irish moss extract; *Marine Colloids*; *Satiagel U*; *SeaSpen PF*; *Viscarin*.

3 Chemical Name and CAS Registry Number

Carrageenan [9000-07-1]

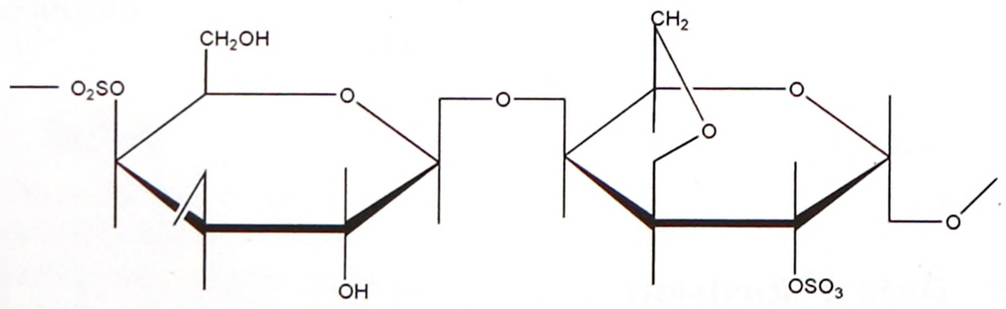
ι-Carrageenan [9062-07-1]

κ-Carrageenan [11114-20-8]



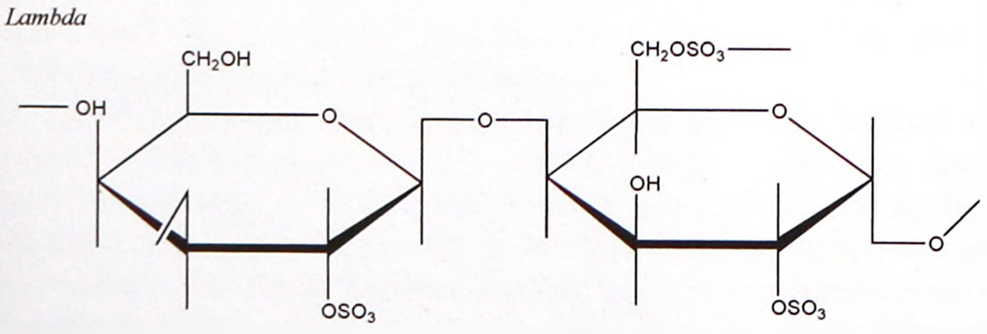
λ-Carrageenan [9064-57-7]

4 Empirical Formula and Molecular Weight



The USP 40–NF 35 S1 describes carrageenan as the hydrocolloid obtained by extraction with water or aqueous alkali from some members of the class Rhodophyceae (red seaweeds). It consists chiefly of potassium, sodium, calcium, magnesium, and ammonium sulfate esters of galactose and 3,6-anhydrogalactose copolymers. These hexoses are alternately linked at the α-1,3 and β-1,4 sites in the polymer.

5 Structural Formula



Kappa

Iota

Lambda

Three commercially important carrageenans exist currently and are divided according to the number and position of ester sulfate groups and the percentage of 3,6-anhydrogalactose.

κ-Carrageenan (kappa-carrageenan) is mainly the alternating polymer of D-galactose-4-sulfate and 3,6-anhydro-D-galactose. It contains approximately 25% ester sulfate and 34% 3,6-anhydrogalactose.

ι-Carrageenan (iota-carrageenan) is similar except that 3,6-anhydrogalactose is sulfated at carbon 2. It contains approximately 32% ester sulfate and 30% 3,6-anhydrogalactose.

λ-Carrageenan (lambda-carrageenan) has alternating monomeric units, which are mostly D-galactose-2-sulfate (1,3-linked) and D-galactose-2,6-disulfate (1,4-linked). It contains approximately 35% ester sulfate by weight and little or no 3,6-anhydrogalactose.

6 Functional Category

Capsule shell material; emulsion stabilizing agent; gelling agent; microencapsulating agent; modified-release agent; suspending agent; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Carrageenan is used in a wide variety of nonparenteral dosage forms, including suspensions (wet and reconstitutable), emulsions, gels, creams, lotions, eye drops, suppositories, tablets, and capsules; *see* Table I.

In suspension formulations, usually only the ι-carrageenan and λ-carrageenan fractions are used. λ-Carrageenan is generally used at levels of 0.7% w/v or less, and provides viscosity to the liquid. With pure ι-carrageenan, about 0.4% w/v is required for most suspensions, plus the addition of calcium ions to establish a gel network. However, if *SeaSpen PF* is used, it should be used at about 0.75% w/v level, although no additional calcium is required as it is already present in the product to control the rate of gelation. Carrageenan has been shown to mask the chalkiness of antacid suspensions when used as a suspending agent in these preparations.[1] When used in concentrations of 0.1–0.5%, carrageenan gives stable emulsions.

Transdermal patches of cubic gels using carrageenan as the matrix have been formulated.[2,3] Carrageenan has also been used in the preparation of hard capsule shells.[4]

ι-Carrageenan and κ-Carrageenan are claimed to provide a creamy mouthfeel in chewable tablet formulations. κ-Carrageenan, along with other excipients, is also used for oral instant-release formulations.[5] Carrageenan-based chewing gums are reported to be useful in the treatment of xerostomia.[6]

κ-Carrageenan is known as a novel pelletization aid in the manufacture of pellets by extrusion/spheronization.[7–10]

Due to its mucoadhesive properties, carrageenan has been evaluated for oral,[11] nasal,[12] and vaginal drug delivery.[13,14] It was found to prolong the local residence time of a poloxamer 407-based *in situ* vaginal gel, and also showed a synergistic bioadhesive effect with acrylic acid polymers.[15] Carrageenan in combination with poloxamers have been also investigated as a mucoadhesive polymer for buccal drug delivery.[16–19]

Different carrageenans along with various drugs and other excipients in tablet matrices have been shown to retard drug release in oral controlled-release[20–24] and ophthalmic formulations.[25,26] Furthermore, the inclusion of calcium or potassium salts in the tablet creates a microenvironment for gelation to occur, which further controls drug release.

Carrageenan is used in toothpastes and cosmetic preparations such as hair conditioners, shampoos, moisturizers and other skin lotions. It is also widely used in food applications such as dairy products and dessert gels and glazes.

Table I: Typical uses of commercially available grades of carrageenan (FMC BioPolymer).

Carrageenan type	Trade name	Use concentration (%)	Use examples
Iota	*Gelcarin GP-379*	0.3–1.0	Creams, suspensions
Iota	*SeaSpen PF*	0.5–1.0	Suspensions, topical lotions/creams, reconstitutable suspensions
Kappa	*Gelcarin GP-812*	0.3–1.0	Gels
Kappa	*Gelcarin GP-911*	0.25–2.0	Encapsulation/delivery systems
Lambda	*Viscarin GP-109*	0.1–1.0	Creams, lotions
Lambda	*Viscarin GP-209*	0.1–1.0	Creams, lotions

8 Description

Carrageenan occurs as a yellowish or tan to white colored, coarse to fine powder that is odorless with a mucilaginous taste.

9 Pharmacopeial Specifications

See Table II.

Table II: Pharmacopeial specifications for carrageenan.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	—
Acid insoluble matter	≤2.0%	≤2.0%
Arsenic	≤3.0 ppm	≤3 ppm
Cadmium	≤2.0 ppm	—
Mercury	≤1.0 ppm	—
Heavy metals	—	≤40 ppm
Lead	≤5.0 ppm	≤10 ppm
Loss on drying	≤12%	≤12.5%
Total ash	≤40.0%	≤35.0%
Viscosity (at 75°C)	≥5 mPa s	≥5 mPa s
Microbial limits	—	≤200 cfu/g[(a)]

(a) Tests for *Salmonella* and *Escherichia coli* are negative.

10 Typical Properties

Because of the vast differences in the material that can be referred to as carrageenan, it is difficult to give descriptions of typical properties. *See* Table III.

Gelation ι-Carrageenan forms elastic gels and thixotropic fluids in the presence of calcium ions. κ-Carrageenan forms firm gels in the presence of potassium ions. λ-Carrageenan forms viscous, nongelling solutions. *See* Table IV

pH 7.0–10.5 (in solution)

Rheology Kappa gels cannot be sheared to form a flowable liquid; however, iota gels display thixotropic behavior when sheared. λ-Carrageenan displays pseudoplastic behavior under all conditions. *See* Table IV.

Solubility Soluble in water at 80°C. *See also* Tables III and IV.

Spectroscopy

IR spectrum *see* Figure 1.

NIR spectra *see* Figures 2, 3, 4 and 5.

Raman spectrum *see* Figure 6.

Table III: Typical Properties of commercially available grades of carrageenan (FMC BioPolymer).

Carrageenan type	Trade name	Solubility in water	Viscosity
Iota	*Gelcarin GP-379*	Hot	High, thixotropic
Iota	*SeaSpen PF*	Cold, delayed gel formation	Medium, thixotropic
Kappa	*Gelcarin GP-812*	Hot	Low
Kappa	*Gelcarin GP-911*	Hot, partial in cold	Low
Lambda	*Viscarin GP-109*	Partial cold, full in hot	Medium
Lambda	*Viscarin GP-209*	Partial cold, full in hot	High

Table IV: Solubility and gelation properties of ι-, κ-, and λ-carrageenans.

	Iota	Kappa	Lambda
Solubility in water			
20°C	Na^+ salt only; Ca^{2+} salt swells to form thixotropic dispersion	Na^+ salt only; K^+, Ca^+, and NH_4^+ salts swell	Yes
80°C	Yes	Yes	Yes
Solubility in 5% salt solution			
Hot	Swell	Swell	Soluble
Cold	No	No	Soluble
Gelation			
Ions necessary	Ca^{2+}	K^+	No gel
Gel texture	Elastic	Brittle	No gel
Re-gelation after shear	Yes	No	No
Acid stability	>pH 3.8	>pH 3.8	—
Syneresis	No	Yes	No
Freeze/thaw stability	Yes	No	Yes
Synergism with other gums	No	Yes	No

Viscosity (dynamic) 5 mPa s (5 cP) at 75°C. *See also* Table III.

11 Stability and Storage Conditions

Carrageenan is a stable, though hygroscopic, polysaccharide and should be stored in an airtight container, in a dry place at room temperature (approx. 25°C).

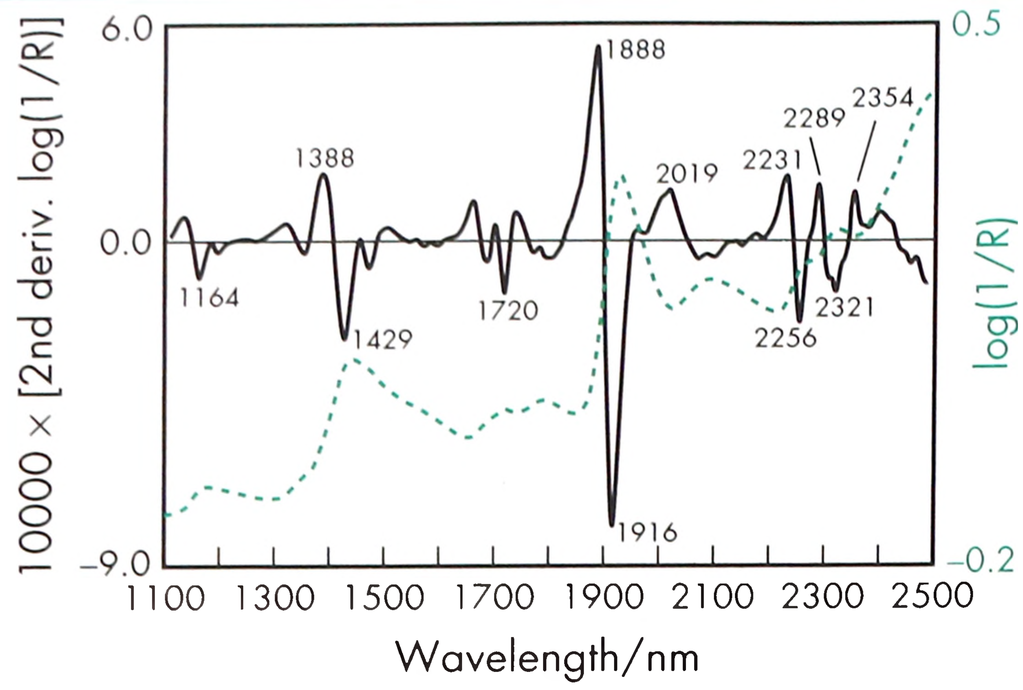

Figure 2: Near-infrared spectrum of carrageenan measured by reflectance.

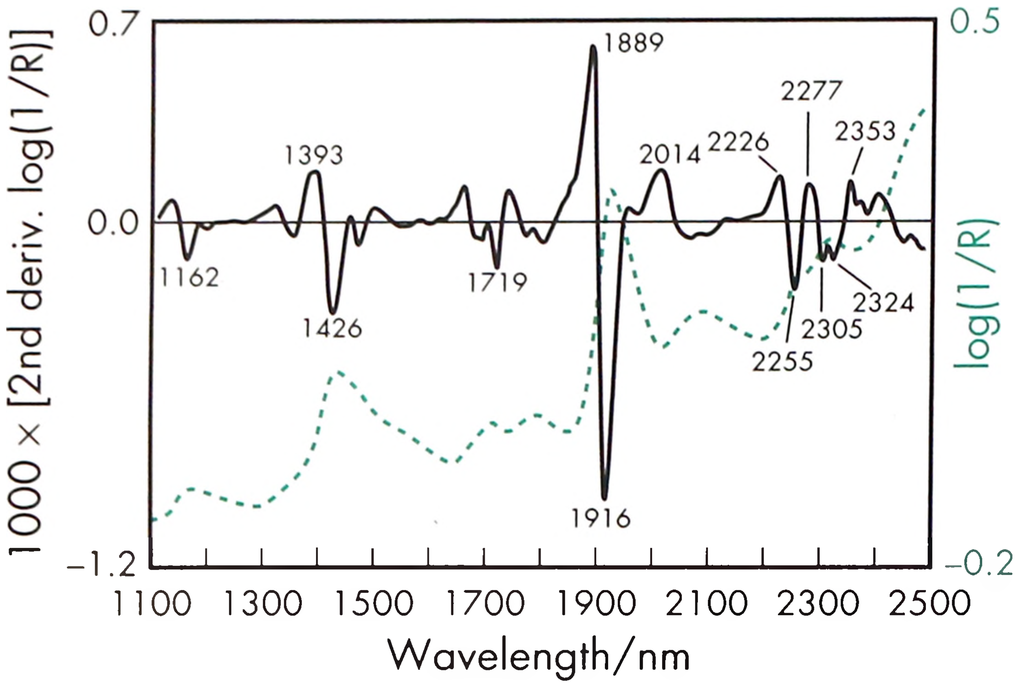

Figure 3: Near-infrared spectrum of carrageenan (iota) measured by reflectance.

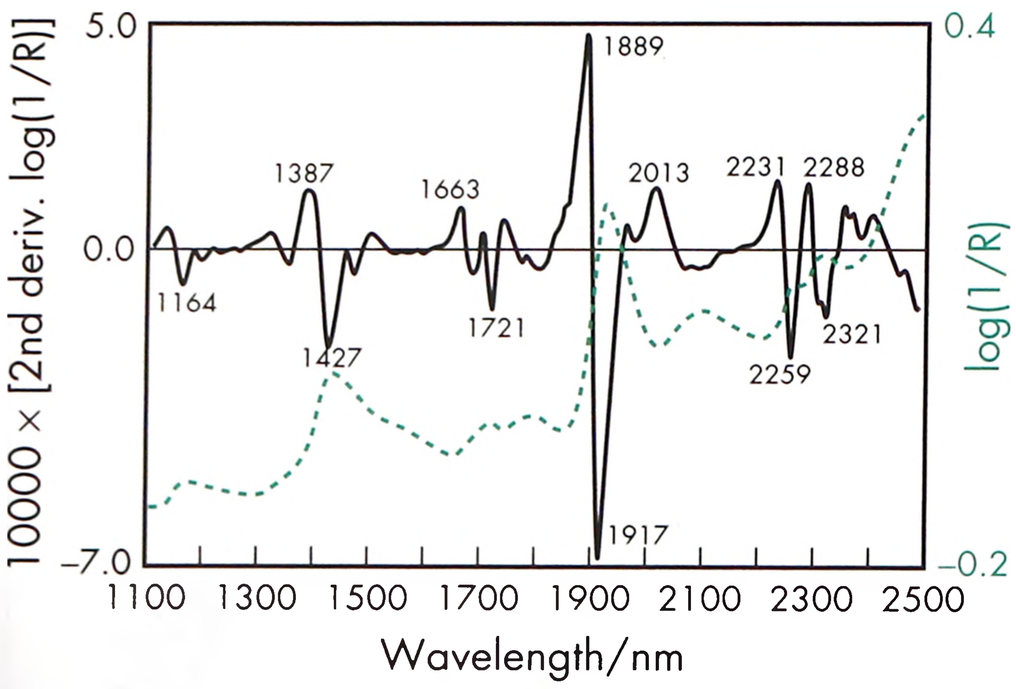

Figure 4: Near-infrared spectrum of carrageenan (kappa) measured by reflectance.

All carrageenans are generally most stable at neutral and alkaline pH. Carrageenan solutions will lose viscosity and gel strength in systems below pH values of about 4.3 due to autohydrolysis. The rate of autohydrolysis increases at elevated temperatures and at low cation levels. Kappa and iota carrageenans in the gelled state are stable at low pH ($pH \geq 3$). Lambda solutions are relatively more acid stable than kappa or iota solutions; *see* Table V.

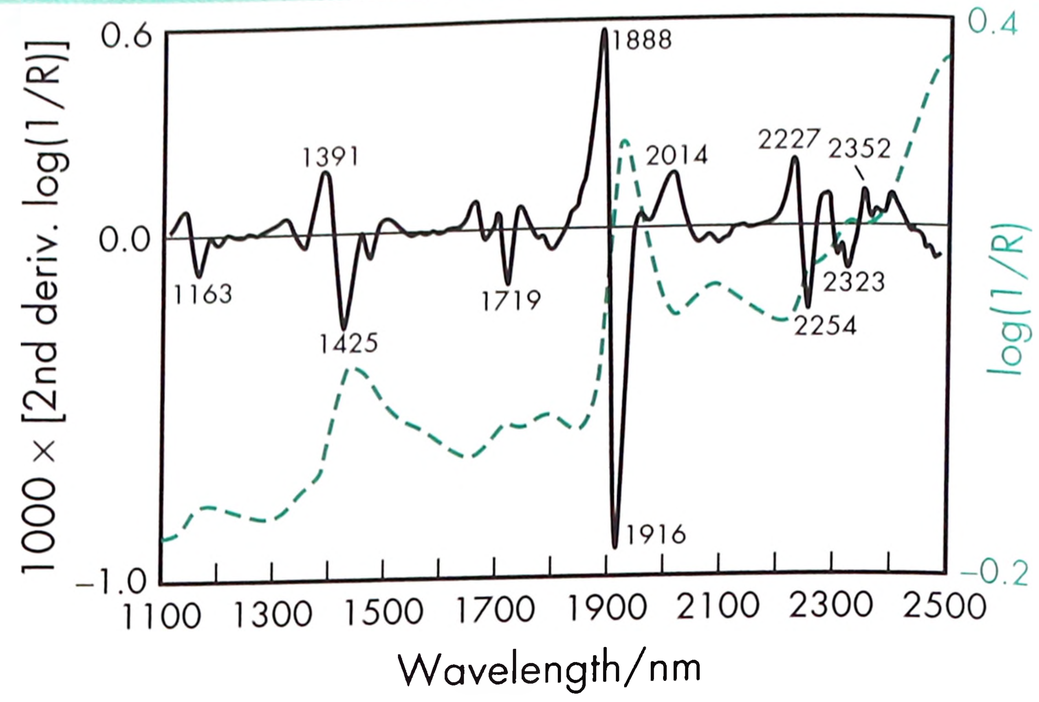

Figure 5: Near-infrared spectrum of carrageenan (lambda) measured by reflectance.

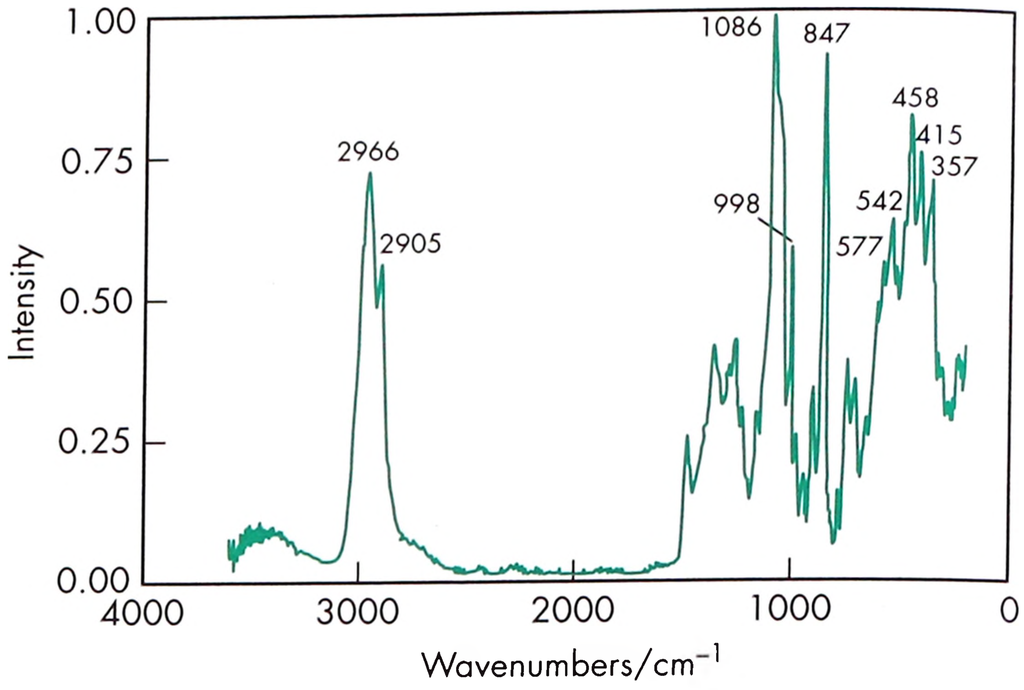

Figure 6: Raman spectrum of carrageenan measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

Table V: Stability of different grades of carrageenan.

Grade	Stability at neutral and alkaline pH	Stability at acid pH
Iota	Stable	Hydrolyzed in solution. Stable in gelled form.
Kappa	Stable	Hydrolyzed in solution when heated. Stable in gelled form.
Lambda	Stable	Hydrolyzed

12 Incompatibilities

Carrageenan can form complexes with cationic materials.

Carrageenan may interact with other charged macromolecules, e.g. proteins, to give various effects such as viscosity increase, gel formation, stabilization, or precipitation.

13 Method of Manufacture

The main species of seaweed from which carrageenan is manufactured are *Eucheuma*, *Chondrus*, and *Gigartina*. The weed is dried quickly to prevent degradation. The seaweed is washed and then undergoes a hot alkali extraction process, releasing the carrageenan from the cell. It is then clarified and concentrated.

Three processes may be used to prepare dried carrageenan. The 'freeze–thaw' technique gels the solution with various salts before

freezing. After thawing, the water is removed and the resultant mass of carrageenan and salt is ground to the desired particle size.

The alcohol precipitation method adds the concentrated solution of carrageenan to alcohol, causing precipitation. The precipitated carrageenan is recovered by drum drying.

The 'KCl precipitation' process uses evaporation to reduce the filtrate volume. The filtrate is then extruded through spinnerets into a cold 1.0–1.5% solution of potassium chloride. The resulting gel threads are washed with potassium chloride solution before drying and milling.

14 Safety

Carrageenan is widely used in numerous food applications and is increasingly being used in pharmaceutical formulations. Carrageenan is generally regarded as a relatively nontoxic and nonirritating material when used in nonparenteral pharmaceutical formulations.

However, carrageenan is known to induce inflammatory responses in laboratory animals, and for this reason it is frequently used in experiments for the investigation of anti-inflammatory drugs.[27,28] Animal studies suggest that degraded carrageenan (which is not approved for use in food products) may be associated with cancer in the intestinal tract, although comparable evidence does not exist in humans.[29,30]

The WHO has set an acceptable daily intake of carrageenan of 'not specified' as the total daily intake was not considered to represent a hazard to health.[31] In the UK, the Food Advisory Committee has recommended that carrageenan should not be used as an additive for infant formulas.[32]

LD_{50} (rat, oral): >5 g/kg

LD_{50} (rabbit, skin): >2 g/kg

LC_{50} (rat, inhalation): >0.93 mg/L (4 h)[33]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. On heating, carrageenan decomposes to produce oxides of sulfur.

16 Regulatory Status

GRAS listed. Accepted as a food additive in Europe, USA, and Canada. Included in the FDA Inactive Ingredients Database (dental pastes; oral capsules, granules, powders for suspension, and syrups; topical lotions; transdermal preparations; and controlled-release film preparations). Included in the Canadian Natural Health Products Ingredients Database. Included in nonparenteral medicines (oral granules for suspensions, capsules (shells), prolonged release and orodispersible tablets; powder for rectal suspension) licensed in the UK.

17 Related Substances

—

18 Comments

ι-Carrageenan and κ-carrageenan form thermoreversible gels. The gels become fluid when heated above their melting temperature and reset upon cooling with minimal to no loss of their original gel strength. κ-Carrageenan is synergistic with locust bean gum and konjac flour. The interaction significantly increases gel strength, improves moisture binding capabilities, and modifies gel texture to be more elastic. ι-Carrageenan increases the viscosity of starch systems as compared with the viscosity of starch alone. Carrageenans have been studied alone or in combination for use as gelling agents as alternative drug carrier systems for topical formulations.[34,35] κ-Carrageenan has been investigated as a component of complex gels for oral delivery of probiotic bacteria.[36]

Carrageenan has been shown to minimize polymorphic or pseudopolymorphic transitions from amorphous to crystalline forms in a tablet matrix[37] and in spray-dried co-precipitates.[38]

Carrageenan has been investigated in the preparation of nanospheres,[39,40] polyspheres,[41] microcapsules,[42] encapsulating proteins,[43] and probiotic bacteria.[44] Enzyme loaded in κ-carrageenan beads was found to improve the stability of the formulation.[45] Hydrogel beads based on κ-carrageenan and sodium alginate/chitosan have been used as new carriers for floating and controlled delivery systems.[46,47] Carrageenan in combination with other polymers has been used for development of floating matrix tablet formulations.[48,49]

Carrageenan is also used as a cryoprotectant in freeze drying[50] and as a vaccine adjuvant.[51]

Studies have shown that carrageenan compounds block infections by the herpes simplex[52] and human papilloma viruses.[53] Other investigations have revealed that carrageenan fails to prevent the sexual transmission of HIV.[54] However, the combination of carrageenan with a nonnucleoside reverse transcriptase inhibitor is more efficacious against HIV-1 and HIV-2.[55] Recent studies have indicated that a combination of zinc acetate and carrageenan gel is effective in limiting the transmission of HIV and Herpes simplex virus 2.[56,57]

Poly(*N*-vinyl-2–pyrrolidone)-κ-carrageenan hydrogels (PVP-KC) have been evaluated for their usability in wound dressing applications.[58]

A specification for carrageenan is included in the *Food Chemicals Codex* (FCC)[59] and in the *Japanese Pharmaceutical Excipients* (JPE).[60]

The EINECS number for carrageenan is 232-524-2.

Castor Oil

1 Nonproprietary Names

BP: Virgin Castor Oil
JP: Castor Oil
PhEur: Castor Oil, Virgin
USP–NF: Castor Oil

2 Synonyms

Crystal; *EmCon CO*; *Lipovol CO*; oleum ricini; ricini oleum virginale; ricinoleum; ricinus communis; ricinus oil; tangantangan.

3 Chemical Name and CAS Registry Number

Castor oil [8001-79-4]

4 Empirical Formula and Molecular Weight

Castor oil is a triglyceride of fatty acids. The fatty acid composition is approximately ricinoleic acid (87%); oleic acid (7%); linoleic acid (3%); palmitic acid (2%); stearic acid (1%) and trace amounts of dihydroxystearic acid.

5 Structural Formula

See Section 4.

6 Functional Category

Emollient; oleaginous vehicle; solvent.

7 Applications in Pharmaceutical Formulation or Technology

Castor oil is widely used in cosmetics, food products, and pharmaceutical formulations. In pharmaceutical formulations, castor oil is most commonly used in topical creams and ointments at concentrations of 5–12.5%. However, it is also used in oral tablet and capsule formulations, ophthalmic emulsions, and as a solvent in intramuscular injections.[1–3]

See also Section 18.

8 Description

Castor oil is a clear, almost colorless or pale yellow-colored viscous oil. It has a slight odor and a taste that is initially bland but afterwards slightly acrid.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for castor oil.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	–
Characters	+	+	–
Specific gravity	0.953–0.965	≈0.958	0.957–0.961
Heavy metals	–	–	≤10 ppm
Iodine value	80–90	–	83–88
Saponification value	176–187	–	176–182
Hydroxyl value	155–177	≥160	160–168
Acid value	≤1.5	≤1.5	–
Peroxide value	–	≤10.0	–
Refractive index	–	≈1.479	–
Optical rotation	–	+3.5° to +6.0°	–
Water	–	≤0.3%	–
Absorbance	+	≤0.7	–
Composition of fatty acids	–	+	–
Purity	+	–	–
Distinction from most other fixed oils	–	–	+
Free fatty acids	–	–	+
Unsaponifiable matter	–	≤0.8%	–

10 Typical Properties

Autoignition temperature 449°C
Boiling point 313°C
Density 0.955–0.968 g/cm^3 at 25°C
Flash point 229°C
Melting point −12°C
Moisture content ≤0.25%
Refractive index

n_D^{25} = 1.473–1.477;
n_D^{40} = 1.466–1.473.

Solubility Miscible with chloroform, diethyl ether, ethanol, glacial acetic acid, and methanol; freely soluble in ethanol (95%) and petroleum ether; practically insoluble in water; practically insoluble in mineral oil unless mixed with another vegetable oil.

See also Section 11.

Spectroscopy

IR spectrum *see* Figure 1.

Raman spectrum *see* Figure 2.

Surface tension

39.0 mN/m at 20°C;
35.2 mN/m at 80°C.

Viscosity (dynamic)

1000 mPa s (1000 cP) at 20°C;
200 mPa s (200 cP) at 40°C.

11 Stability and Storage Conditions

Castor oil is stable and does not turn rancid unless subjected to excessive heat. On heating at 300°C for several hours, castor oil polymerizes and becomes soluble in mineral oil. When cooled to 0°C, it becomes more viscous.

Castor oil should be stored at a temperature not exceeding 25°C in well-filled airtight containers protected from light.

12 Incompatibilities

Castor oil is incompatible with strong oxidizing agents.

13 Method of Manufacture

Castor oil is the fixed oil obtained by cold-expression of the seeds of *Ricinus communis* Linné (Fam. Euphorbiaceae). No other substances are added to the oil.

14 Safety

Castor oil is used in cosmetics and foods and orally, parenterally, and topically in pharmaceutical formulations. It is generally regarded as a relatively nontoxic and nonirritant material when used as an excipient.[4]

Castor oil has been used therapeutically as a laxative and oral administration of large quantities may cause nausea, vomiting,

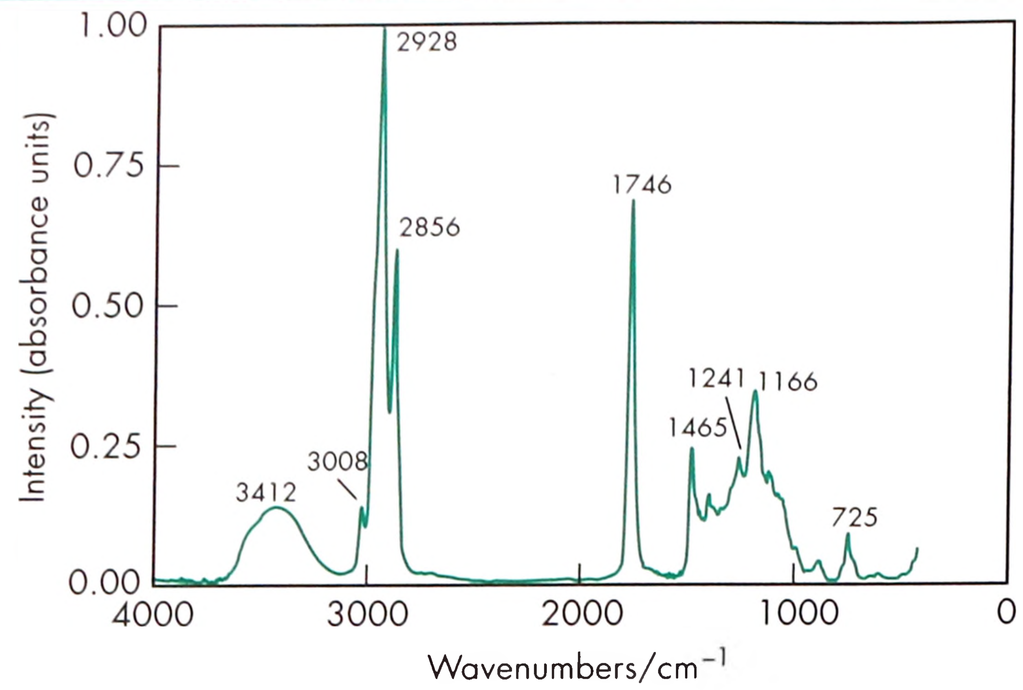

Figure 1: Infrared spectrum of castor oil measured by transmission. Adapted with permission of Informa Healthcare.

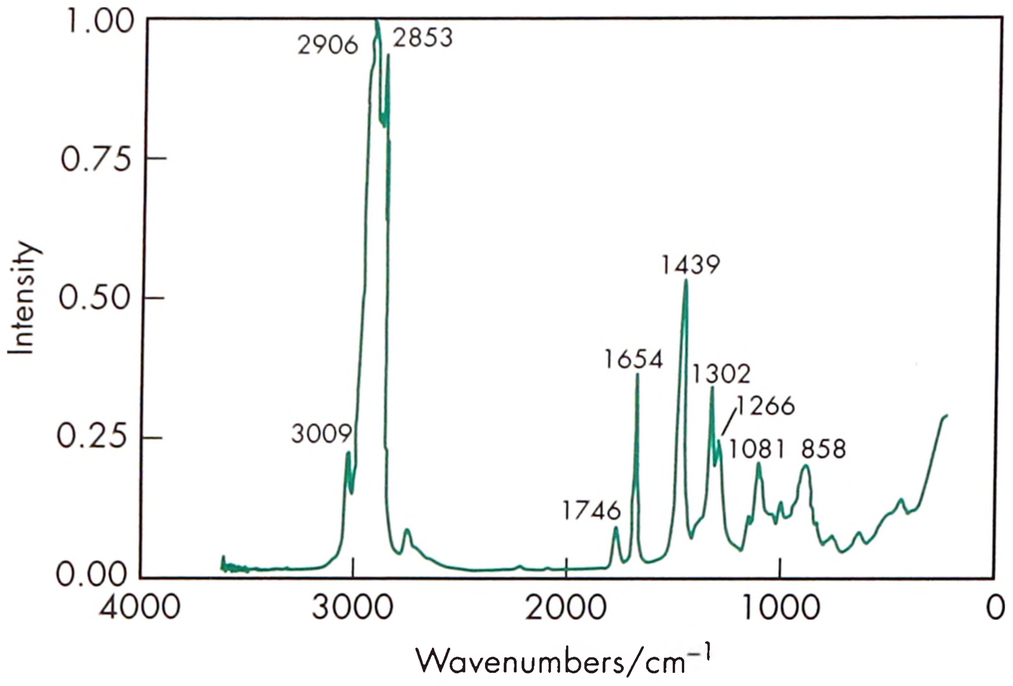

Figure 2: Raman spectrum of castor oil measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

colic, and severe purgation. It should not be given when intestinal obstruction is present.

Although widely used in topical preparations, including ophthalmic formulations, castor oil has been associated with some reports of allergic contact dermatitis, mainly to cosmetics such as lipsticks.[5–8]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Castor oil may cause mild irritation to the skin and eyes. Castor oil is flammable when exposed to heat. Spillages are slippery and should be covered with an inert absorbant before collection and disposal.

16 Regulatory Status

GRAS listed. Included in the FDA Inactive Ingredients Database (IM injections; ophthalmic emulsions; oral capsules and tablets; topical creams, emulsions, ointments, and solutions). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Castor oil, hydrogenated.

18 Comments

Castor oil has been described as a component in the formulation of microemulsions used for the solubilization of poorly soluble drug substances.[9] Studies into the development of nanolipidic formulations as drug delivery systems using castor oil have been reported.[10,11]

Therapeutically, castor oil has been administered orally for its laxative action, but such use is now obsolete.

A specification for castor oil is contained in the *Food Chemicals Codex* (FCC).[12]

The EINECS number for castor oil is 232-293-8. The PubChem Compound ID (CID) for castor oil is 6850719.

Castor Oil, Hydrogenated

1 Nonproprietary Names

BP: Hydrogenated Castor Oil

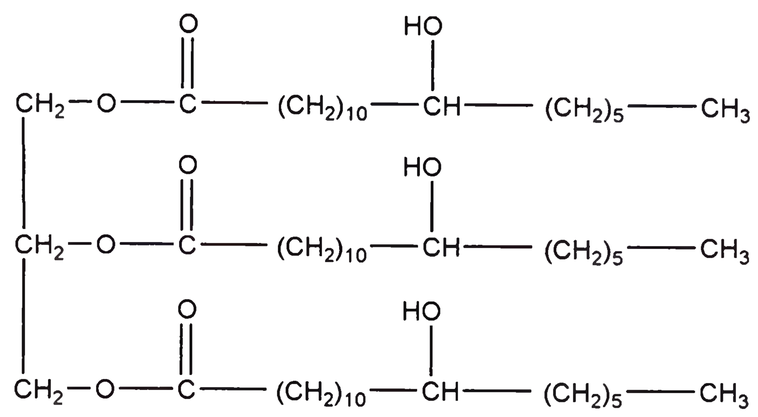
PhEur: Castor Oil, Hydrogenated

USP–NF: Hydrogenated Castor Oil

2 Synonyms

Castorwax; *Croduret*; *Cutina HR*; *Fancol*; 12-hydroxyoctadecanoic acid, 1,2,3-propanetriyl ester; *Kolliwax HCO*; octadecanoic acid, 12-hydroxy-, 1,2,3-propanetriyl ester; 1,2,3-propanetriol tri(12-hydroxystearate); ricini oleum hydrogenatum; trihydroxystearin.

3 Chemical Name and CAS Registry Number



Glyceryl-tri-(12-hydroxystearate) [8001-78-3]

4 Empirical Formula and Molecular Weight

$C_{57}O_9H_{110}$ 939.50

The USP 40–NF 35 S1 describes hydrogenated castor oil as refined, bleached, hydrogenated, and deodorized castor oil, consisting mainly of the triglyceride of hydroxystearic acid.

5 Structural Formula

6 Functional Category

Coating agent; modified-release agent; stiffening agent; tablet and capsule lubricant.

7 Applications in Pharmaceutical Formulation or Technology

Hydrogenated castor oil is a hard wax with a high melting point used in oral and topical pharmaceutical formulations; *see* Table I.

Table I: Uses of hydrogenated castor oil.

Use	Concentration (%)
Coating agent (delayed release)	5.0–20.0
Delayed release drug matrix	5.0–10.0
Tablet die lubricant	0.1–2.0

In topical formulations, hydrogenated castor oil is used to provide stiffness to creams and emulsions.[1] In oral formulations, it is used to prepare sustained-release tablet and capsule preparations,[2–4] and may be used as a coat or to form a solid matrix. Hydrogenated castor oil is additionally used to lubricate the die walls of tablet presses.[5,6]

Studies have shown that hydrogenated castor oil may be used to enhance the stability of moisture-sensitive drug products[7] and it has been used in experimental systems to evaluate nanoemulsions,[8] microemulsions,[9] nanoparticles,[10] and solid dispersion systems[11] as a means to enhance delivery and bioavailability of drugs.

8 Description

Hydrogenated castor oil occurs as a fine, almost white or pale yellow powder or flakes. The PhEur 9.2 describes hydrogenated castor oil as the oil obtained by hydrogenation of virgin castor oil. It consists mainly of the triglyceride of 12-hydroxystearic acid.

9 Pharmacopeial Specifications

See Table II.

Table II: Pharmacopeial specifications for hydrogenated castor oil.

Test	PhEur 9.2	USP 40–NF 35 S1
Characters	+	–
Identification	+	–
Acid value	≤4.0	≤11
Hydroxyl value	145–165	154–162
Iodine value	≤5.0	≤5.0
Saponification value	–	176–182
Alkaline impurities	+	–
Composition of fatty acids	+	–
Palmitic acid	≤2.0%	–
Stearic acid	7.0–14.0%	–
Arachidic acid	≤1.0%	–
12-Oxostearic acid	≤5.0%	–
12-Hydroxystearic acid	78.0–91.0%	–
Any other fatty acid	≤3.0%	–
Nickel	≤1 ppm	–
Heavy metals	–	≤0.001%
Melting range	83–88°C	85–88°C

10 Typical Properties

Acid value ≤5

Density 0.98–1.10 g/cm^3

Flash point 316°C (open cup)

Melting point 87°C for *Castorwax*

Moisture content ≤0.1%

Particle size distribution 97.7% ≥1000 µm in size for flakes.

Solubility Practically insoluble in water; soluble in acetone, chloroform, and methylene chloride.

Specific gravity 1.023 at 25°C for *Castorwax*

11 Stability and Storage Conditions

Hydrogenated castor oil is stable at temperatures up to 150°C.

Clear, stable, chloroform solutions containing up to 15% w/v of hydrogenated castor oil may be produced. Hydrogenated castor oil may also be dissolved at temperatures greater than 90°C in polar solvents and mixtures of aromatic and polar solvents, although the hydrogenated castor oil precipitates out on cooling below 90°C.

Hydrogenated castor oil should be stored in a well-closed container in a cool, dry place.

12 Incompatibilities

Hydrogenated castor oil is compatible with most natural vegetable and animal waxes.

13 Method of Manufacture

Hydrogenated castor oil is prepared by the hydrogenation of castor oil using a catalyst.

14 Safety

Hydrogenated castor oil is used in oral and topical pharmaceutical formulations and is generally regarded as an essentially nontoxic and nonirritant material.

Acute oral toxicity studies in animals have shown that hydrogenated castor oil is a relatively nontoxic material. Irritation tests with rabbits show that hydrogenated castor oil causes mild, transient irritation to the eye.

LD_{50} (rat, oral): >10 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

16 Regulatory Status

Accepted in the USA as an indirect food additive. Included in the FDA Inactive Ingredients Database (oral capsules, tablets, sublingual tablets, topical suspensions, and emulsion creams).

Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Castor oil; vegetable oil, hydrogenated.

18 Comments

Various different grades of hydrogenated castor oil are commercially available, the composition of which may vary considerably. *Sterotex K* (Karlshamns Lipid Specialities), for example, is a mixture of hydrogenated castor oil and hydrogenated cottonseed oil. *See* Vegetable Oil, Hydrogenated for further information.

Hydrogenated castor oil is used as a lubricant in food processing and is also used in cosmetics.

The EINECS number for hydrogenated castor oil is 232-292-2.

Cellaburate

1 Nonproprietary Names

BP: Cellulose Acetate Butyrate

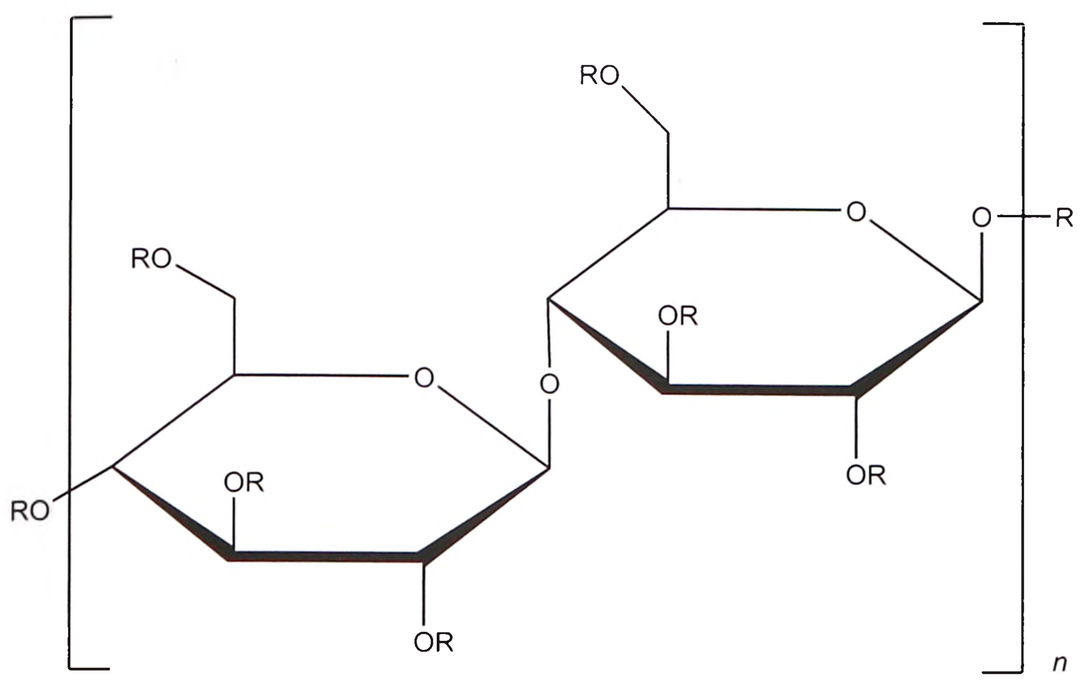
PhEur: Cellulose Acetate Butyrate

USP–NF: Cellaburate

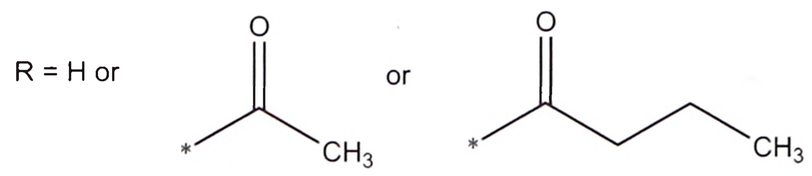
2 Synonyms

Acetylbutyrylcellulose; cellaburatum; cellulose acetate butanoate; cellulose butyrate acetate; cellulosi acetas butyras.

3 Chemical Name and CAS Registry Number



Cellulose acetate butanoate [9004-36-8]



4 Empirical Formula and Molecular Weight

Cellaburate is a cellulose derivative in which between 1% and 41% of the hydroxyl groups are acetylated, and between 5% and 56% of hydroxyl groups are butyrylated.

The PhEur 9.2 describes cellaburate as a partly or completely *O*-acetylated and *O*-butyrylated cellulose containing not less than 2.0% and not more than 30.0% acetyl groups, and not less than 16.0% and not more than 53.0% of butyryl groups, calculated with reference to the dried substance.

5 Structural Formula

6 Functional Category

Coating agent; film-forming agent; membrane-forming agent; modified-release agent; tablet and capsule diluent.

7 Applications in Pharmaceutical Formulation or Technology

Cellaburate has been used in the formulation of oral modified-release drug delivery systems.[1] It is an alternative to cellulose acetate as the semipermeable barrier layer in osmotic pump devices.[2] Cellaburate has also been used in controlled release solid dosage forms resistant to alcohol-induced dose dumping.[3]

8 Description

Cellaburate occurs as a white to off-white, slightly hygroscopic powder or granules.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for cellaburate.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Residue on ignition	≤0.1%	≤0.1%
Heavy metals	–	≤0.002%
Free acid	–	≤0.1%
Acidity	+	–
Water determination	–	≤5.0%
Loss on drying	≤2.0%	–
Assay		
C_2H_3O groups	2.0–30.0%	1.0–41.0%
C_4H_7O groups	16.0–53.0%	5.0–56.0%

10 Typical Properties

Density 1.26 g/cm^3

Density (bulk) 0.224 g/cm^3

Density (tapped) 0.256 g/cm^3

Dielectric strength 784–984 kV/cm

Glass transition temperature (T_g) 151°C

Hardness 27 Knoops

Melting point 230–240°C

Refractive index 1.475

Solubility Practically insoluble in water and in ethanol (95%); soluble in acetone, formic acid, and in a mixture of equal volumes of methanol and dichloromethane.

Specific gravity 1.26

11 Stability and Storage Conditions

Slow hydrolysis of cellaburate will occur under prolonged adverse conditions such as high temperatures and high humidity, with a resultant increase in free acid content and water content. Store in airtight containers in a cool, dry place.

12 Incompatibilities

Cellaburate is incompatible with oxidizing materials. Mixing cellulose esters in a nonpolar hydrocarbon, such as toluene or xylene, may result in the buildup of static electricity, which can cause a flash fire or an explosion. When adding cellulose ester to any flammable liquid, an inert gas atmosphere should be maintained within the vessel.

13 Method of Manufacture

Cellaburate is produced by reacting cellulose with acetic anhydride and *n*-butyric anhydride in the presence of a tertiary organic base or a strong acid.

14 Safety

Cellaburate has been used in oral pharmaceutical formulations, and is generally regarded as a safe material. It may cause slight skin irritation but no skin sensitization has been observed in guinea pigs.

LD_{50} (guinea pig, skin): >1.0 g/kg (highest dose tested)[4]
LD_{50} (rat, oral): >6.4 g/kg (highest dose tested)[4]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. Precautions to prevent combustible dust concentrations in the air should be taken.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral extended-release tablets). Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Cellulose acetate; cellulose acetate phthalate.

18 Comments

Cellaburate has been used in the manufacture of hydrophobic contact lens materials.

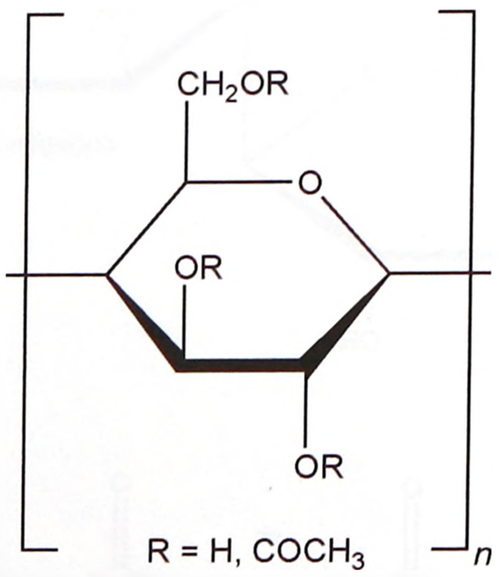
Cellulose Acetate

1 Nonproprietary Names

BP: Cellulose Acetate
PhEur: Cellulose Acetate
USP–NF: Cellulose Acetate

2 Synonyms

Acetic acid, cellulose ester;acetose;acetyl cellulose; cellulose diacetate; cellulose triacetate; cellulosi acetas;monoacetylcellulose



3 Chemical Name and CAS Registry Number

Cellulose acetate [9004-35-7]
Cellulose diacetate [9035-69-2]
Cellulose triacetate [9012-09-3]

4 Empirical Formula and Molecular Weight

Cellulose acetate is cellulose in which a portion or all of the hydroxyl groups are acetylated. Cellulose acetate is available in a wide range of acetyl levels and chain lengths and thus molecular weights and viscosities. It contains not less than 29.0% and not more than 44.8% by weight of acetyl groups, calculated on the dried basis; *see* Table I.

5 Structural Formula

6 Functional Category

Coating agent; modified-release agent; tablet and capsule diluent; transdermal delivery component.

7 Applications in Pharmaceutical Formulation or Technology

Cellulose acetate is widely used in pharmaceutical formulations both in sustained-release applications and for taste masking.

Cellulose acetate is used as a semipermeable coating on tablets, especially on osmotic pump-type tablets and implants. This allows for controlled, extended release of actives.[1–5] Cellulose acetate films, in conjunction with other materials, also offer sustained

Table I: Comparison of different types of cellulose acetate.[2]

Type	Acetyl (%)	Viscosity (mPa s)[a]	Hydroxyl (%)	Melting range (°C)	T_g[b] (°C)	Density (g/cm^3)	MW_n[c]
CA-320S NF/EP	32.0	2.1	8.7	230–250	180	1.31	38 000
CA-398-3	39.8	11.4	3.5	230–250	180	1.31	30 000

CA-398-30	39.7	114.0	3.5	230–250	189	1.31	50 000
CA-394-60S	39.5	228.0	4.0	240–260	186	1.32	60 000

(a) ASTM D 817 (formula A) and D 1343.
(b) Glass transition temperature.
(c) Number average molecular weight in polystyrene equivalents determined using size-exclusion chromatography.

release without the necessity of drilling a hole in the coating as is typical with osmotic pump systems. Cellulose acetate and other cellulose esters have also been used to form drug-loaded microparticles with controlled-release characteristics.[6–8]

Cellulose acetate films are used in transdermal drug delivery systems[9,10] and also as film coatings on tablets[11,12] or granules for taste masking. For example, acetaminophen granules have been coated with a cellulose acetate-based coating before being processed to provide chewable tablets. Extended-release tablets can also be formulated with cellulose acetate as a directly compressible matrix former.[2] The release profile can be modified by changing the ratio of active to cellulose acetate and by incorporation of plasticizer, but was shown to be insensitive to cellulose acetate molecular weight and particle size distribution.

8 Description

Cellulose acetate occurs as a hygroscopic white to off-white, free-flowing powder, pellet, or flake. It is tasteless and odorless, or may have a slight odor of acetic acid.

9 Pharmacopeial Specifications

The pharmacopeial specifications for cellulose acetate have undergone harmonization of many attributes for PhEur, and USP–NF.

See Table II. *See also* Section 18.

Table II: Pharmacopeial specifications for cellulose acetate.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	—
Loss on drying	≤5.0%	≤5.0%
Residue on ignition	—	≤0.1%
Sulfated ash	≤0.1%	—
Free acid	≤0.1%	≤0.1%
Heavy metals[a]	—	≤10 µg/g
Microbial contamination		
Aerobic microbial count	≤10^3 cfu/g	≤10^3cfu/g
Yeasts and molds	≤10^2 cfu/g	≤10^2cfu/g
Assay (acetyl groups)	29.0–44.8%	29.0–44.8%

(a) These tests have not been fully harmonized at the time of publication.

10 Typical Properties

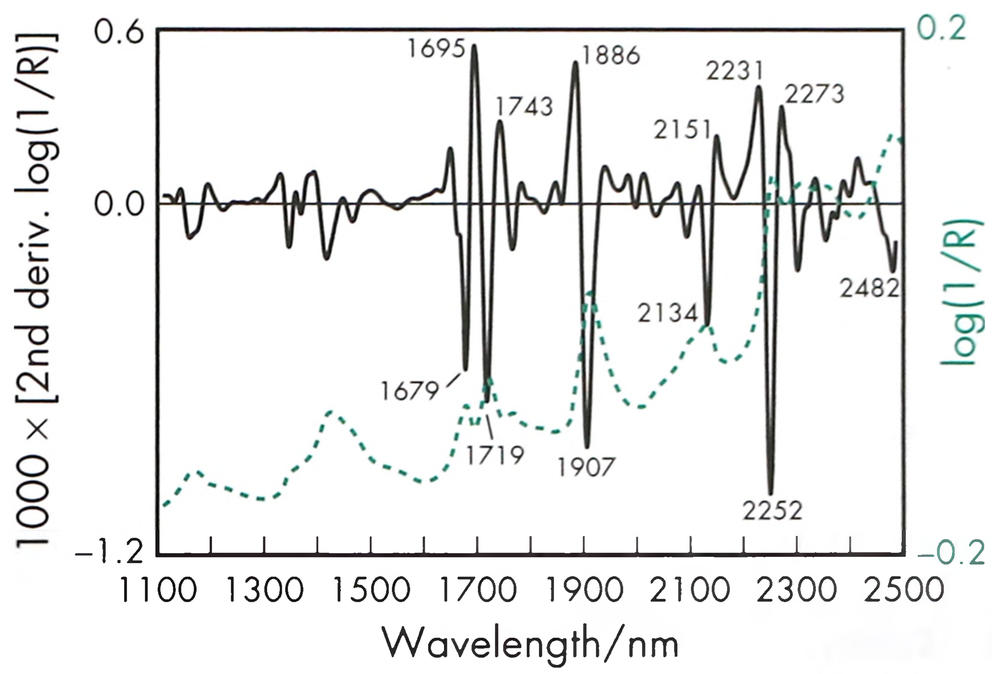
Density (bulk) Typically 0.4 g/cm^3 for powders.
Glass transition temperature 170–190°C
Melting point Melting range 230–300°C
Solubility The solubility of cellulose acetate is greatly influenced by the level of acetyl groups present. The cellulose acetates of higher acetyl level are generally more limited in solvent choice than are the lower-acetyl materials. Practically insoluble in water and ethanol (96%); soluble in acetone, dioxane, dimethylformamide, formic acid, and in a mixture of equal volumes of methyl alcohol and dichloromethane.

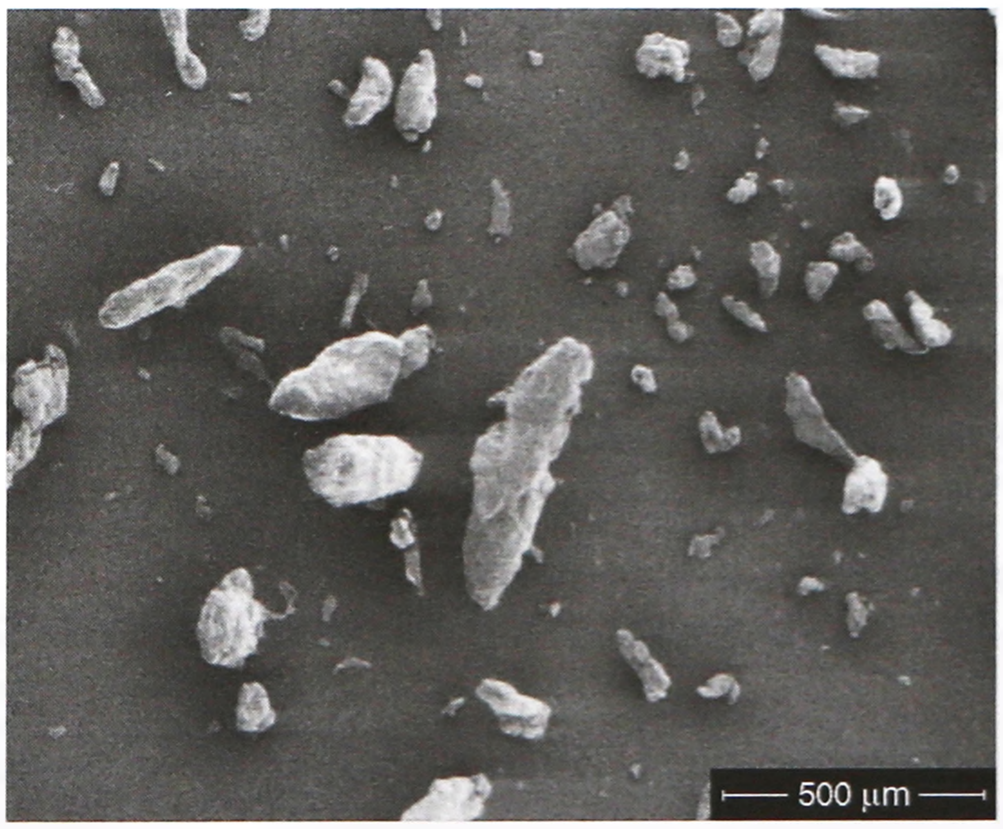
Spectroscopy

NIR spectrum *see* Figure 1.

Viscosity (dynamic) Various grades of cellulose acetate are commercially available that differ in their acetyl content and degree of polymerization. They can be used to produce 10% w/v solutions in organic solvents with viscosities of 10–230 mPa s (10–230 cP). Blends of cellulose acetates may also be prepared with intermediate viscosity values.

See also Table I.





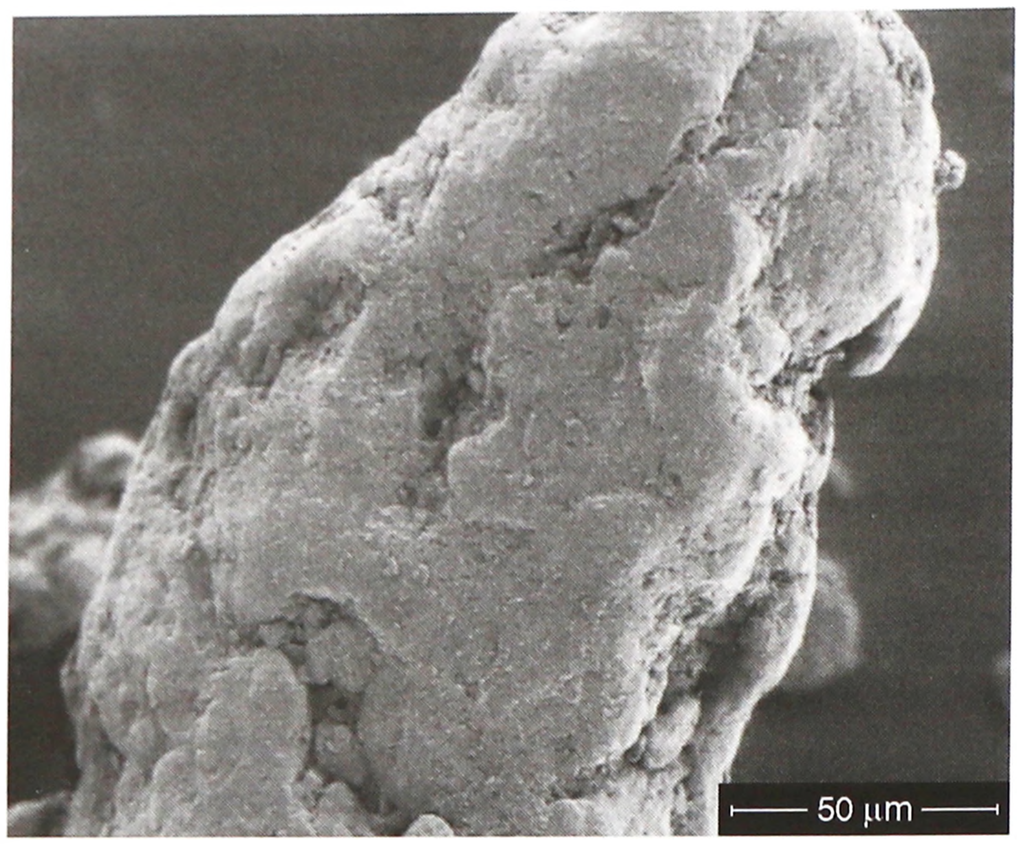


Figure 1: Near-infrared spectrum of cellulose acetate measured by reflectance.

SEM 1: Excipient: cellulose acetate, CA-398-10; manufacturer: Eastman Chemical Co.; lot no.: AC65280; magnification: 60×; voltage: 3 kV.

SEM 2: Excipient: cellulose acetate, CA-398-10; manufacturer: Eastman Chemical Co.; lot no.: AC65280NF; magnification: 600×; voltage: 2 kV.

11 Stability and Storage Conditions

Cellulose acetate is stable if stored in a well-closed container in a cool, dry place. Cellulose acetate hydrolyzes slowly under prolonged adverse conditions such as high temperature and humidity, with a resultant increase in free acid content and odor of acetic acid.

12 Incompatibilities

Cellulose acetate is incompatible with strongly acidic or alkaline substances. Cellulose acetate is compatible with the following plasticizers: diethyl phthalate, polyethylene glycol, triacetin, and triethyl citrate.

13 Method of Manufacture

Cellulose acetate is prepared from highly purified cellulose by treatment with acid catalysis and acetic anhydride.

14 Safety

Cellulose acetate is widely used in oral pharmaceutical products and is generally regarded as a nontoxic and nonirritant material.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Dust may be irritant to the eyes and eye protection should be worn. Like most organic materials in powder form, these materials are capable of creating dust explosions. Cellulose acetate is combustible.

16 Regulatory Status

GRAS listed. Included in the FDA Inactive Ingredients Database (oral tablets). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Cellulose acetate phthalate.

18 Comments

Cellulose acetate has undergone harmonization of many attributes for PhEur, and USP–NF by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

Therapeutically, cellulose acetate has been used to treat cerebral aneurysms, and also for spinal perimedullary arteriovenous fistulas.[13]

When solutions are being prepared, cellulose acetate should always be added to the solvent, not the reverse. Various grades of cellulose acetate are available with varying physical properties; *see* Table I.

Cellulose Acetate Phthalate

1 Nonproprietary Names

BP: Cellacefate

JP: Cellacefate

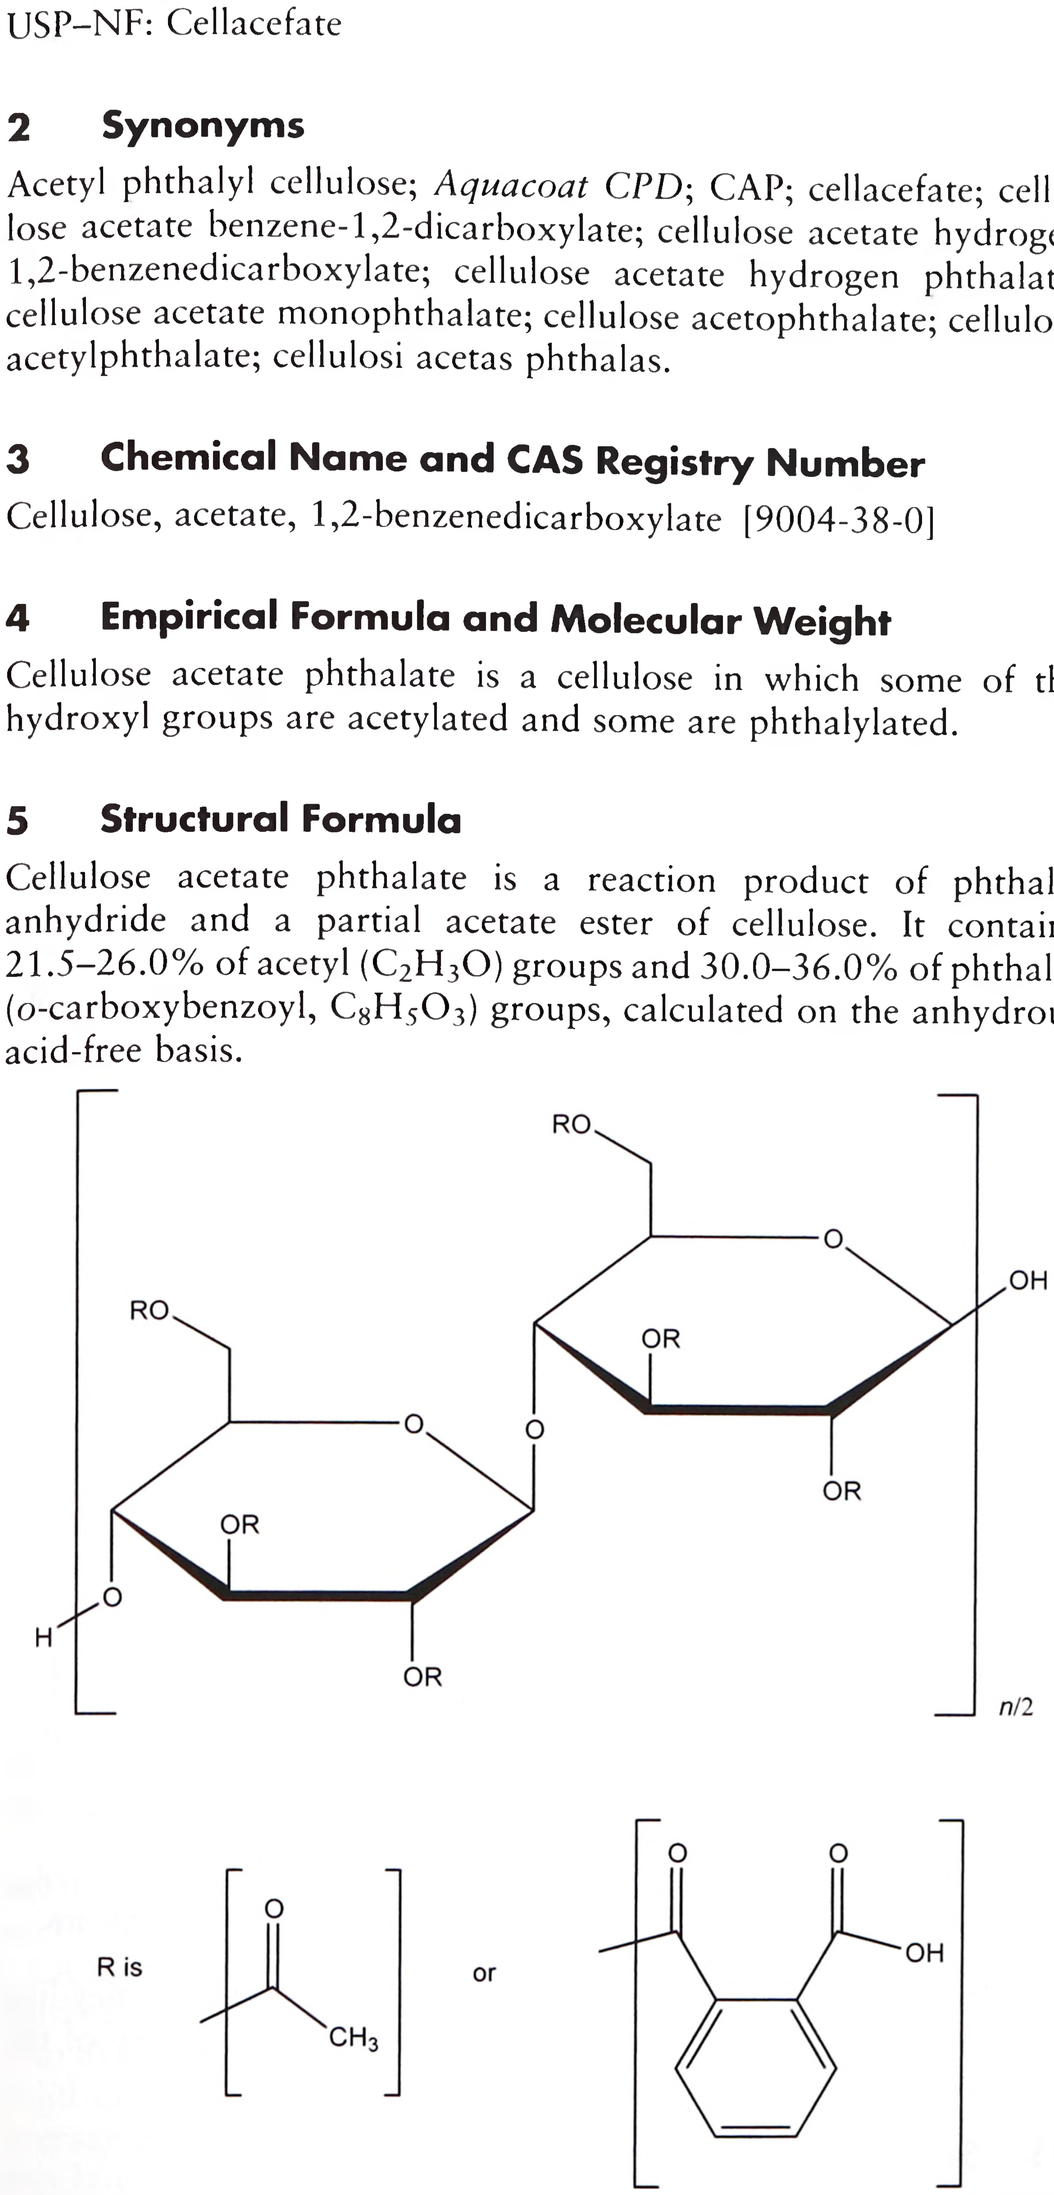
PhEur: Cellulose Acetate Phthalate

USP–NF: Cellacefate

2 Synonyms

Acetyl phthalyl cellulose; *Aquacoat CPD*; CAP; cellacefate; cellulose acetate benzene-1,2-dicarboxylate; cellulose acetate hydrogen 1,2-benzenedicarboxylate; cellulose acetate hydrogen phthalate; cellulose acetate monophthalate; cellulose acetophthalate; cellulose acetylphthalate; cellulosi acetas phthalas.

3 Chemical Name and CAS Registry Number



Cellulose, acetate, 1,2-benzenedicarboxylate [9004-38-0]

4 Empirical Formula and Molecular Weight

Cellulose acetate phthalate is a cellulose in which some of the hydroxyl groups are acetylated and some are phthalylated.

5 Structural Formula

Cellulose acetate phthalate is a reaction product of phthalic anhydride and a partial acetate ester of cellulose. It contains 21.5–26.0% of acetyl (C_2H_3O) groups and 30.0–36.0% of phthalyl (*o*-carboxybenzoyl, $C_8H_5O_3$) groups, calculated on the anhydrous acid-free basis.

6 Functional Category

Coating agent; microencapsulating agent; tablet and capsule binder.

7 Applications in Pharmaceutical Formulation or Technology

Cellulose acetate phthalate is used as an enteric film-coating material, as a microencapsulation agent, or as a matrix binder for tablets and capsules.[1–8] Such coatings resist prolonged contact with the strongly acidic gastric fluid, but dissolve in the mildly acidic or neutral intestinal environment.

Cellulose acetate phthalate is commonly applied to solid-dosage forms either by coating from organic or aqueous solvent systems, or by direct compression. Concentrations generally used are 0.5–9.0% of the core weight. The addition of plasticizers improves the water resistance of this coating material, and formulations using such plasticizers are more effective than when cellulose acetate phthalate is used alone.

Cellulose acetate phthalate is compatible with many plasticizers, including acetylated monoglyceride; butyl phthalybutyl glycolate; dibutyl tartrate; diethyl phthalate; dimethyl phthalate; ethyl phthalylethyl glycolate; glycerin; propylene glycol; triacetin; triacetin citrate; and tripropionin. It is also used in combination with other coating agents such as ethyl cellulose in controlled-release preparations.

8 Description

Cellulose acetate phthalate occurs as a hygroscopic, white to off-white, free-flowing powder, granule, or flake. It is tasteless and odorless, or might have a slight odor of acetic acid.

9 Pharmacopeial Specifications

The pharmacopeial specifications for cellulose acetate phthalate have undergone harmonization of many attributes for JP, PhEur, and USP–NF.

See Table I. *See also* Section 18.

Table I: Pharmacopeial specifications for cellulose acetate phthalate.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters[a]	+	+	—
Free acid	≤3.0%	≤3.0%	≤3.0%
Heavy metals[a]	≤10 ppm	—	≤0.001%
Residue on ignition	≤0.1%	—	≤0.1%
Sulfated ash	—	≤0.1%	—
Viscosity (15% w/v solution)	45–90 mPa s	45.0–90.0 mPa s	45.0–90.0 mPa s
Water	≤5.0%	≤5.0%	≤5.0%
Assay	+	+	+
Acetyl groups	21.5–26.0%	21.5–26.0%	21.5–26.0%
Phthalyl (*O*-carboxybenzoyl) groups	30.0–36.0%	30.0–36.0%	30.0–36.0%

(a) These tests have not been fully harmonized at the time of publication.

10 Typical Properties

Density (bulk) 0.260 g/cm^3

Density (tapped) 0.266 g/cm^3

Melting point 192°C. Glass transition temperature is 160–170°C.[9]

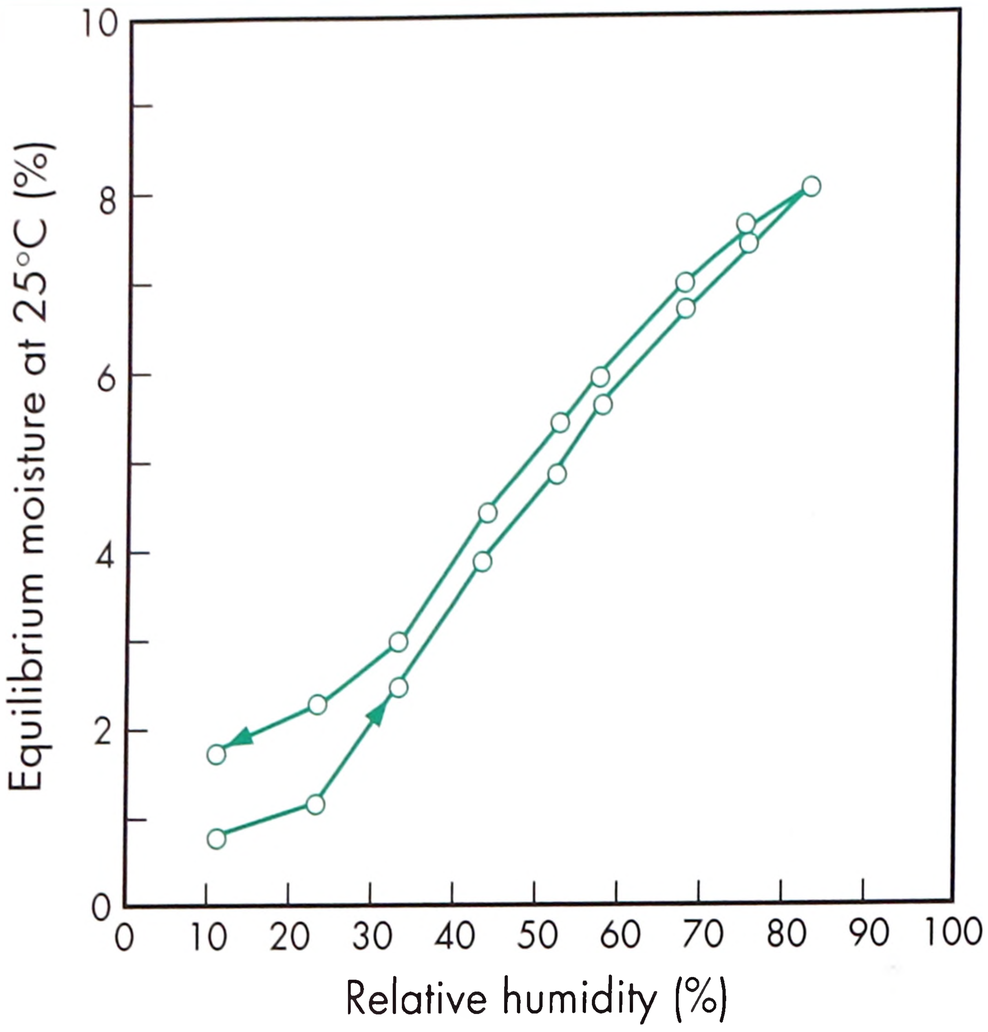


Figure 1: Sorption–desorption isotherm of cellulose acetate phthalate.

Moisture content Cellulose acetate phthalate is hygroscopic and precautions are necessary to avoid excessive absorption of moisture. Equilibrium moisture content has been reported as 2.2%, but moisture content is a function of relative humidity.[10] *See also* Figure 1.

Solubility Practically insoluble in water, alcohols, and chlorinated and nonchlorinated hydrocarbons. Soluble in a number of ketones, esters, ether alcohols, cyclic ethers, and in certain solvent mixtures. It can be soluble in certain buffered aqueous solutions as low as pH 6.0. Cellulose acetate phthalate has a solubility of ≤10% w/w in a wide range of solvents and solvent mixtures; *see* Table II and Table III.

Table II: Examples of solvents with which cellulose acetate phthalate has ≤10% w/w solubility.

Acetone
Diacetone alcohol
Dioxane
Ethoxyethyl acetate
Ethyl glycol monoacetate
Ethyl lactate
Methoxyethyl acetate
β-Methoxyethylene alcohol
Methyl acetate
Methyl ethyl ketone

Table III: Examples of solvent mixtures with which cellulose acetate phthalate has ≤10% w/w solubility.

Acetone : ethanol (1 : 1)
Acetone : water (97 : 3)
Benzene : methanol (1 : 1)
Ethyl acetate : ethanol (1 : 1)
Methylene chloride : ethanol (3 : 1)

Spectroscopy

IR spectrum *see* Figure 2.

NIR spectrum *see* Figure 3.

Raman spectrum *see* Figure 4.

Viscosity (dynamic) A 15% w/w solution in acetone with a moisture content of 0.4% has a viscosity of 50–90 mPa s (50–90 cP). This is a good coating solution with a honey-like consistency, but the viscosity is influenced by the purity of the solvent.

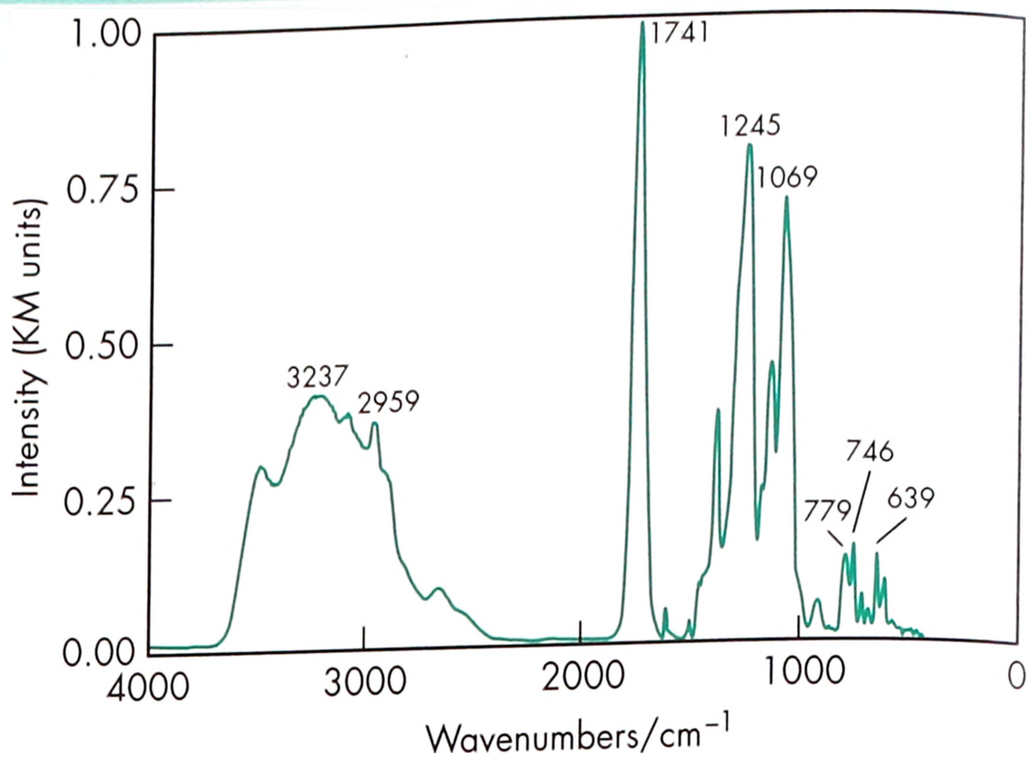

Figure 2: Infrared spectrum of cellulose acetate phthalate measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

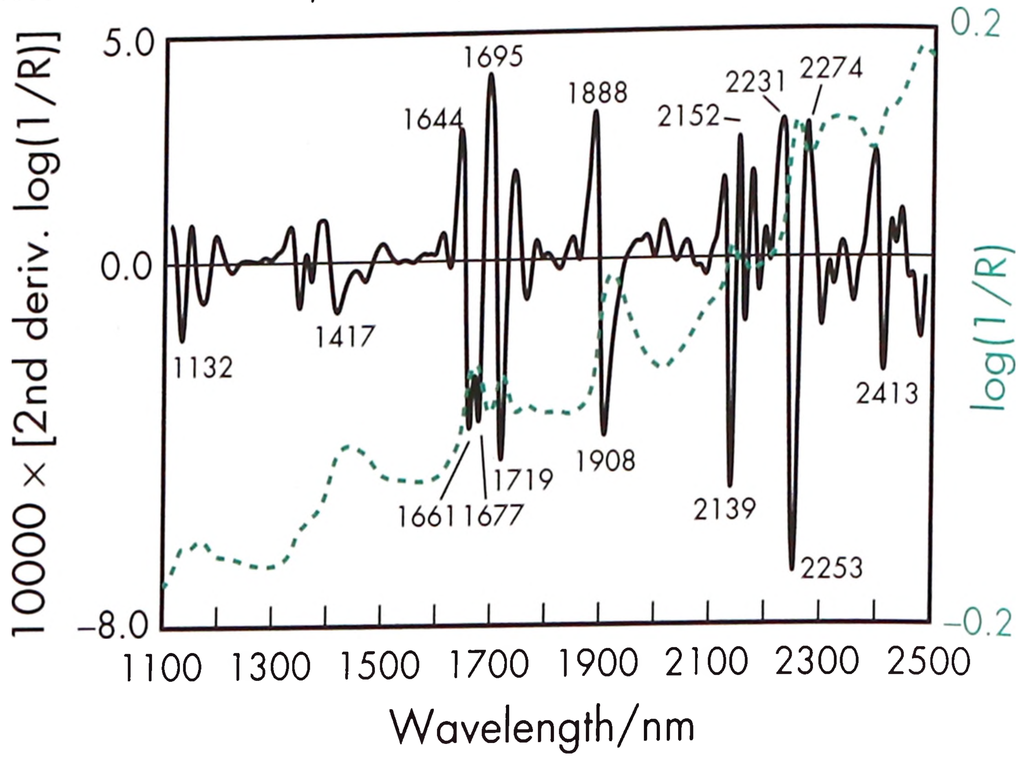

Figure 3: Near-infrared spectrum of cellulose acetate phthalate measured by reflectance.

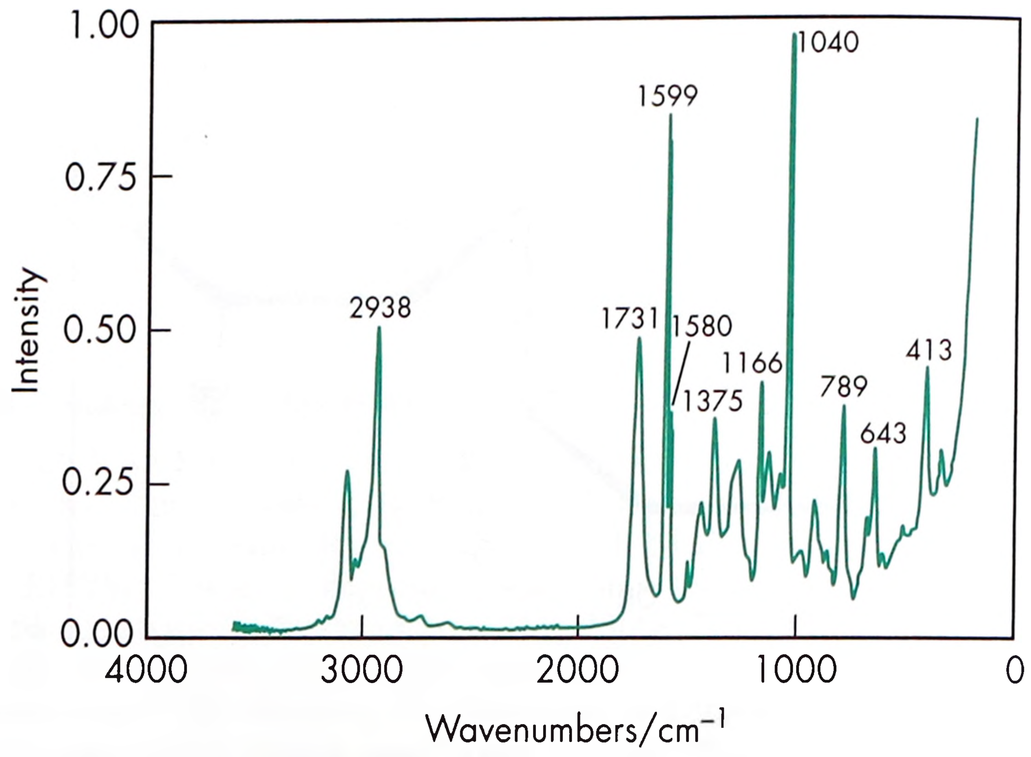

Figure 4: Raman spectrum of cellulose acetate phthalate measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

11 Stability and Storage Conditions

Slow hydrolysis of cellulose acetate phthalate will occur under prolonged adverse conditions such as high temperatures and high humidity, with a resultant increase in free acid content, viscosity, and odor of acetic acid. However, cellulose acetate phthalate is stable if stored in a well-closed container in a cool, dry place.

12 Incompatibilities

Cellulose acetate phthalate is incompatible with ferrous sulfate, ferric chloride, silver nitrate, sodium citrate, aluminum sulfate, calcium chloride, mercuric chloride, barium nitrate, basic lead acetate, and strong oxidizing agents such as strong alkalis and acids.

13 Method of Manufacture

Cellulose acetate phthalate is produced by a reaction between the partial acetate ester of cellulose and phthalic anhydride in the presence of a tertiary organic base such as pyridine, or a strong acid such as sulfuric acid.

14 Safety

Cellulose acetate phthalate is widely used in oral pharmaceutical products and is generally regarded as a nontoxic material, free of adverse effects. However, it may be irritant to the eyes, mucous membranes, and upper respiratory tract.

Results of long-term feeding in rats and dogs have indicated a low oral toxicity. Rats survived daily feedings of up to 30% in the diet for up to 1 year without showing a depression in growth. Dogs fed 16 g daily in the diet for 1 year remained normal.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Cellulose acetate phthalate should be handled in a well-ventilated environment; use of a respirator is recommended when handling large quantities. Eye protection and gloves are recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral tablets). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Cellulose acetate; hypromellose phthalate; polyvinyl acetate phthalate.

18 Comments

Cellulose acetate phthalate has undergone harmonization of many attributes for JP, PhEur, and USP–NF by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

Any plasticizers that are used with cellulose acetate phthalate to improve performance should be chosen on the basis of experimental evidence. The same plasticizer used in a different tablet base coating may not yield a satisfactory product.

In using mixed solvents, it is important to dissolve the cellulose acetate phthalate in the solvent with the greater dissolving power, and then to add the second solvent. Cellulose acetate phthalate should always be added to the solvent, not the reverse.

Cellulose acetate phthalate films are permeable to certain ionic substances, such as potassium iodide and ammonium chloride. In such cases, an appropriate sealer subcoat should be used.

A reconstituted colloidal dispersion of latex particles rather than solvent solution coating material of cellulose acetate phthalate is also available. This white, water-insoluble powder is composed of solid or semisolid submicrometer-sized polymer spheres with an average particle size of 0.2 μm. A typical coating system made from this latex powder is a 10–30% solid-content aqueous dispersion with a viscosity in the 50–100 mPa s (50–100 cP) range.

Therapeutically, cellulose acetate phthalate has been reported to exhibit experimental microbicidal activity against sexually transmitted disease pathogens, such as the HIV-1 retrovirus.[11,12]

Cellulose, Microcrystalline

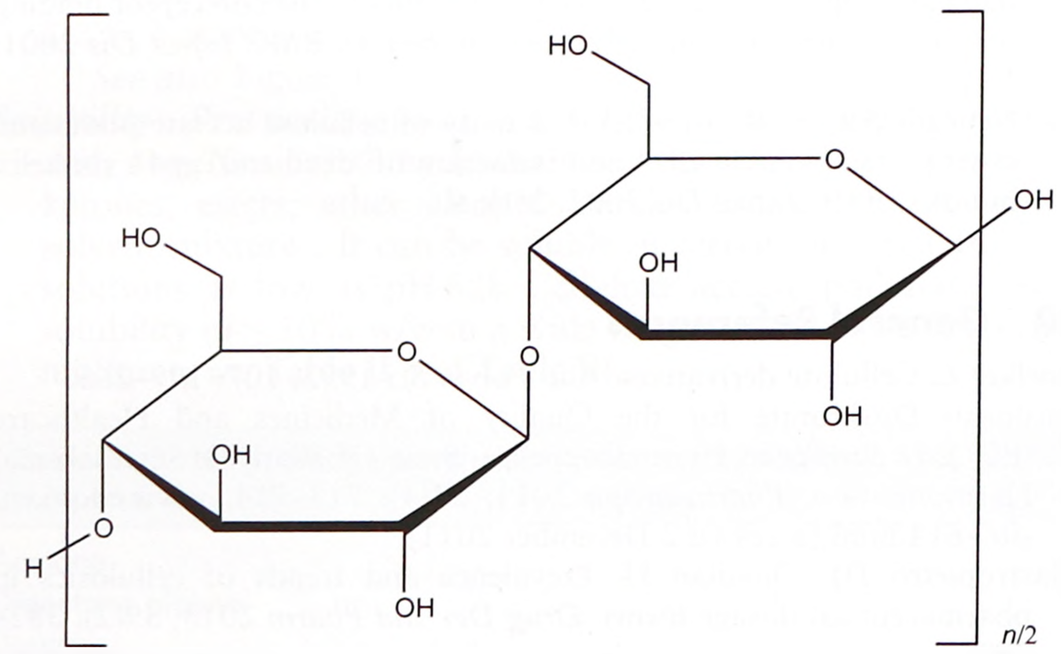
C

1 Nonproprietary Names

BP: Microcrystalline Cellulose
JP: Microcrystalline Cellulose
PhEur: Cellulose, Microcrystalline
USP–NF: Microcrystalline Cellulose

2 Synonyms

Avicel PH; *Cellets*; *Celex*; cellulose gel; cellulosum microcristallinum; *Celphere*; *Ceolus KG*; crystalline cellulose; *Cyclocel*; E460; *Emcocel*; *Fibrocel*; *Grinsted MCC*; *MCC Sanaq*; *Microcel*; *Pharmacel*; *Tabulose*; *Vivapur*.



3 Chemical Name and CAS Registry Number

Cellulose [9004-34-6]

4 Empirical Formula and Molecular Weight

$(C_6H_{10}O_5)_n$ ≈36 000 where $n \approx 220$.

5 Structural Formula

6 Functional Category

Adsorbent; direct compression excipient; suspending agent; tablet and capsule diluent.

7 Applications in Pharmaceutical Formulation or Technology

Microcrystalline cellulose is widely used in pharmaceuticals, primarily as a binder/diluent in oral tablet and capsule formulations where it is used in dry-granulation, wet-granulation, and direct-compression processes.[1–6] In addition to its use as a binder/diluent, microcrystalline cellulose may also reduce friction during tablet ejection[7] and facilitate tablet disintegration.[8] Microcrystalline cellulose has been used with nanoparticles and nanogels for modified drug release.[9,10] Certain spherical-shaped grades may be used for drug layering.[11] *See* Table I for some of the uses and concentrations of microcrystalline cellulose.

8 Description

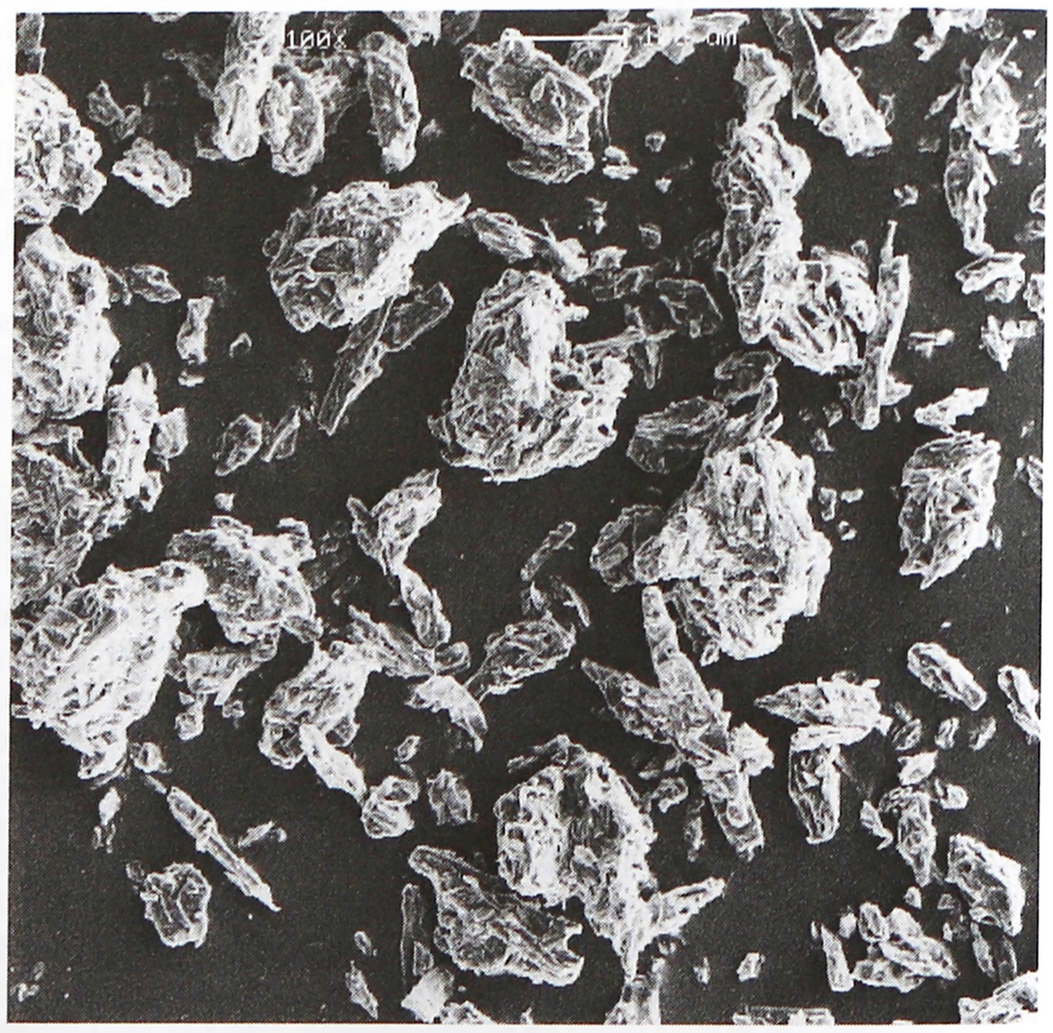
Microcrystalline cellulose is a purified, partially depolymerized cellulose that occurs as a white, odorless, tasteless powder composed of porous particles.

Table I: Uses of microcrystalline cellulose.

Use	Concentration (%)
Adsorbent	20–90
Antiadherent	5–20
Capsule binder/diluent	20–90
Tablet disintegrant	5–15
Tablet binder/diluent	20–90

9 Pharmacopeial Specifications

The pharmacopeial specifications for microcrystalline cellulose have undergone harmonization of many attributes for JP, PhEur, and USP–NF.



See Table II. *See also* Section 18.

Table II: Pharmacopeial specifications for microcrystalline cellulose.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters[a]	+	+	–

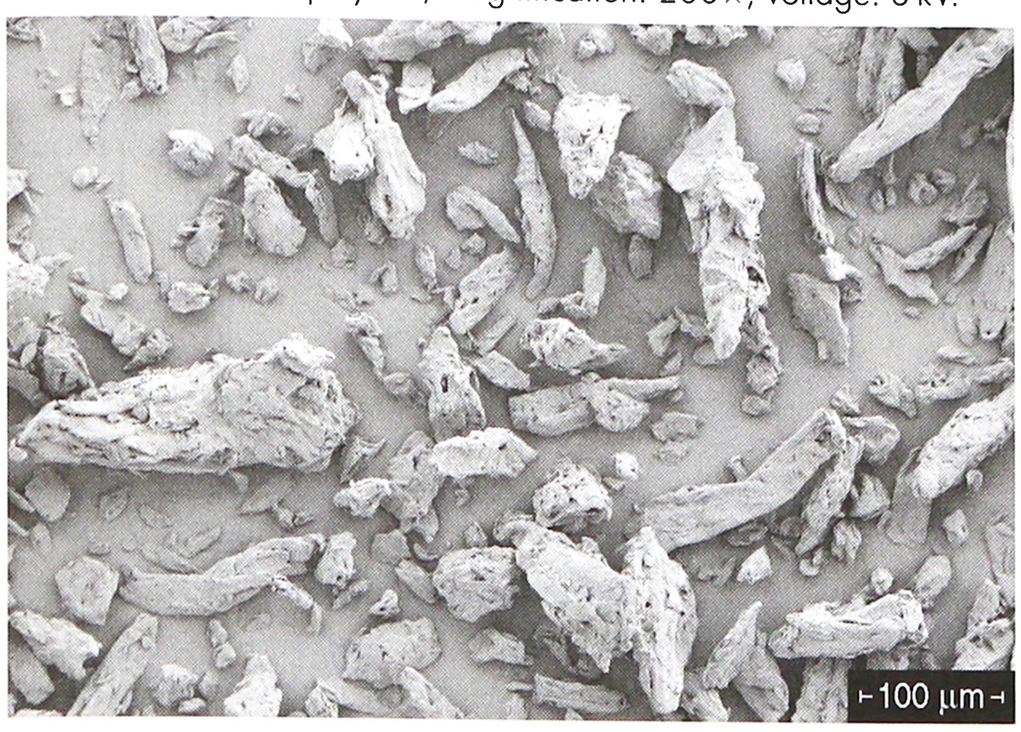
(a) This test has not been fully harmonized at the time of publication.



SEM 1: Excipient: microcrystalline cellulose; manufacturer: JRS Pharma LP; lot no.: 98662; magnification: 100×.

SEM 2: Excipient: microcrystalline cellulose (*Avicel PH-101*); manufacturer: FMC Biopolymer; magnification: 200×; voltage: 3 kV.

SEM 3: Excipient: microcrystalline cellulose (*Avicel PH-102*); manufacturer: FMC Biopolymer; magnification: 200×; voltage: 3 kV.

10 Typical Properties

Angle of repose

49° for *Ceolus KG*;

34.4° for *Emcocel 90M*.[12]

Density (bulk)

0.337 g/cm^3;

0.32 g/cm^3 for *Avicel PH-101*;[13]

0.80 ± 0.05 g/cm^3 for *Cellets 100*, *200*, *350*, *500*, *700*, *1000*;

0.29 g/cm^3 for *Emcocel 90M*;[12]

0.26–0.31 g/cm^3 for *MCC Sanaq 101*;

0.28–0.33 g/cm^3 for *MCC Sanaq 102*;

0.29–0.36 g/cm^3 for *MCC Sanaq 200*;

0.34–0.45 g/cm^3 for *MCC Sanaq 301*;

0.35–0.46 g/cm^3 for *MCC Sanaq 302*;

0.13–0.23 g/cm^3 for *MCC Sanaq UL-002*;

0.29 g/cm^3 for *Vivapur 101*.

Density (tapped)

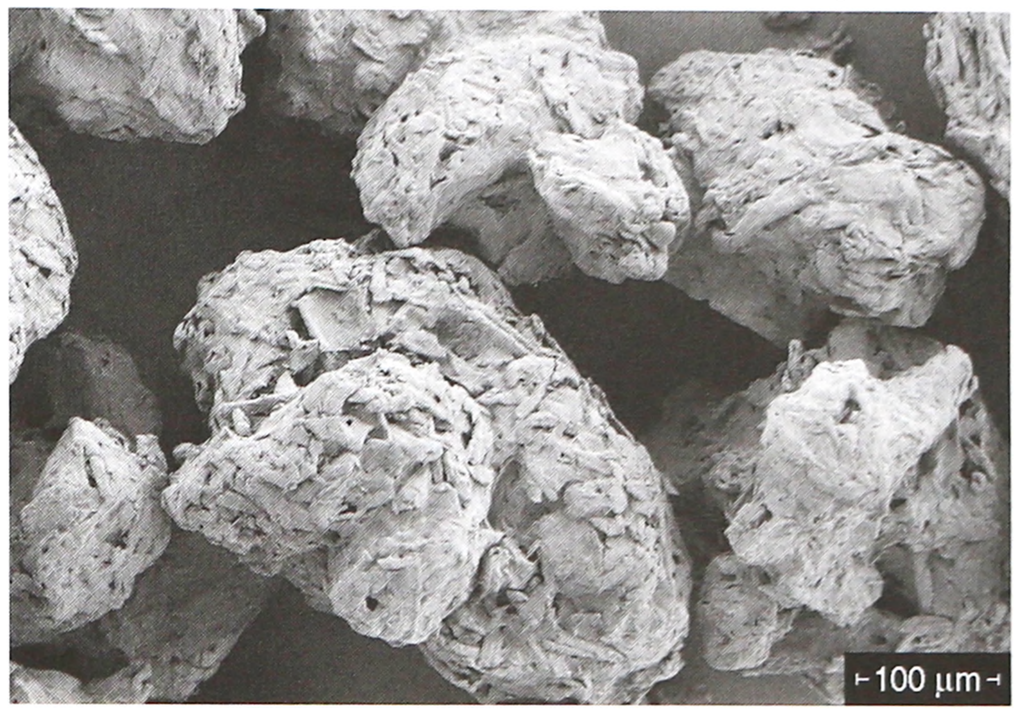
0.478 g/cm^3;

0.45 g/cm^3 for *Avicel PH-101*;

0.35 g/cm^3 for *Emcocel 90M*.[12]

Density (true)

1.512–1.668 g/cm^3;



1.420–1.460 g/cm^3 for *Avicel PH-102*.[14]

Flowability 1.41 g/s for *Emcocel 90M*.[12] *Avicel PH–102* exhibits flow properties adequate for high-speed tableting.[15]

SEM 4: Excipient: microcrystalline cellulose (*Avicel PH-105*); manufacturer: FMC Biopolymer; magnification: 500×; voltage: 3 kV.

SEM 5: Excipient: microcrystalline cellulose (*Avicel PH-200*); manufacturer: FMC Biopolymer; magnification: 200×; voltage: 3 kV.

SEM 6: Excipient: microcrystalline cellulose (*Avicel PH-302*); manufacturer: FMC Biopolymer; magnification: 200×; voltage: 3 kV.

Moisture content Typically less than 5% w/w. However, different grades may contain varying amounts of water. Microcrystalline cellulose is hygroscopic.[16]

See Table III.

Particle size distribution Different grades may have a different nominal mean particle size; *see* Table III.

Solubility Slightly soluble in 5% w/v sodium hydroxide solution; practically insoluble in water, dilute acids, and most organic solvents.

Specific surface area

1.06–1.12 m^2/g for *Avicel PH-101*;
1.21–1.30 m^2/g for *Avicel PH-102*;
0.78–1.18 m^2/g for *Avicel PH-200*.

Spectroscopy

IR spectrum *see* Figure 1.
NIR spectrum *see* Figure 2.
Raman spectrum *see* Figure 3.

11 Stability and Storage Conditions

Microcrystalline cellulose is stable, physically and chemically, in ambient conditions, charring at 260–270°C. The bulk material is hygroscopic and should be stored in well-closed containers in a cool, dry place.

12 Incompatibilities

Microcrystalline cellulose is incompatible with strong oxidizing agents.

13 Method of Manufacture

Microcrystalline cellulose is typically manufactured by controlled hydrolysis with dilute mineral acid solutions of α-cellulose, obtained as a pulp from fibrous plant materials. Following hydrolysis, the hydrocellulose is washed with water and filtered. The aqueous slurry is then spray-dried to form a dry powder.

14 Safety

Microcrystalline cellulose is widely used in oral pharmaceutical formulations and food products, and is generally regarded as a relatively nontoxic and nonirritant material.

Microcrystalline cellulose is not absorbed systemically following oral administration and thus has little toxic potential. Consumption of large quantities of cellulose may have a laxative effect, although this is unlikely to be a problem when cellulose is used as an excipient in pharmaceutical formulations.

Deliberate abuse of formulations containing cellulose, either by inhalation or by injection, has resulted in the formation of cellulose granulomas.[17]

LD_{50} (rat, oral): 3.16 g/kg[18]
LD_{50} (rat, IP): 3.16 g/kg[18]
LD_{50} (rat, skin): 2.0 g/kg[18]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Microcrystalline cellulose may be irritating to the eyes. Gloves, eye protection, and a dust mask are recommended. In the UK, the workplace exposure limits for cellulose have been set at 10 mg/m^3 long-term (8-hour TWA) for total inhalable dust and 4 mg/m^3 for respirable dust; the short-term limit for total inhalable dust has been set at 20 mg/m^3.[19]

16 Regulatory Status

Although not GRAS listed, the Select Committee on GRAS Substances (SCOGS) regard the current and future use of Microcrystalline Cellulose as non-hazardous.[20] Included in the FDA Inactive Ingredients Database (inhalations; injections; oral capsules, powders, granules, suspensions, syrups, and tablets; topical and vaginal preparations; transdermal patches.) Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database. Accepted for use as a food additive in Europe.

Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

Microcrystalline cellulose exhibits birefringence when observed under polarized light microscopy but is X-ray amorphous probably due to the small size (nanometers) of crystalline domains. Several different grades of microcrystalline cellulose are commercially available that differ in their method of manufacture,[21,22] particle size, moisture, flow, and other physical properties.[32] The larger-particle-size grades generally provide better flow properties in pharmaceutical machinery. Low-moisture grades are used with moisture-sensitive materials. Higher-density grades have improved flowability.

Microcrystalline cellulose is generally regarded as a plastic material, with its plasticity affected by moisture content. The tabletability of raw powders and granulated powders depends on particle size, porosity, and moisture content.[33–36] Although microcrystalline cellulose is widely recognized to be one of the most important excipients for the large-scale manufacture of tablets by direct compression, there is an inevitable variability in its tableting properties.[37] Novel tableting excipients have been developed, which may be more advantageous with regard to their specific surface area and other tableting properties.[38]

Several coprocessed mixtures of microcrystalline cellulose with other excipients such as dibasic calcium phosphate, mannitol, and guar gum are commercially available; and used, for example, in roller compaction, chewable tablet formation and direct compression. For coprocessed mixtures with carboxymethylcellulose sodium*see* Section 17.

Celphere (Asahi Kasei Corporation) is a pure spheronized microcrystalline cellulose available in several different particle size ranges. *Balocel Sanaq* (Pharmatrans Sanaq AG) is an excipient used mainly in the production of pellets and granulates in direct tableting, which contains lactose, microcrystalline cellulose, and sodium carboxymethylcellulose.

According to PhEur 9.2, microcrystalline cellulose has certain functionality related characteristics that are recognized as being relevant control parameters for one or more functions of the substance when used as an excipient. Non-mandatory testing procedures have been described for particle size distribution (2.9.31 or 2.9.38) and powder flow (2.9.36).

Microcrystalline cellulose is also used in cosmetics and food products.

A specification for microcrystalline cellulose is contained in the *Food Chemicals Codex* (FCC).[39]

The PubChem Compound ID (CID) for microcrystalline cellulose is 14055602.

Cellulose, Microcrystalline and Carboxymethylcellulose Sodium, Coprocessed

1 Nonproprietary Names

BP: Dispersible Cellulose

PhEur: Microcrystalline Cellulose and Carmellose Sodium

USP–NF: Microcrystalline Cellulose and Carboxymethylcellulose Sodium

2 Synonyms

Avicel CL-611; *Avicel RC-591*; *Avicel RC/CL*; cellulosum microcristallinum et carmellosum natricum; colloidal cellulose; *Vivapur MCG 591 PCG*; *Vivapur MCG 611 PCG*.

3 Chemical Name and CAS Registry Number

See Section 8.

4 Empirical Formula and Molecular Weight

See Section 8.

5 Structural Formula

See Section 8.

6 Functional Category

Dispersing agent; emulsion stabilizing agent; suspending agent; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Coprocessed microcrystalline cellulose and carboxymethylcellulose sodium is used to produce thixotropic gels suitable as suspending vehicles in pharmaceutical and cosmetic formulations. The sodium carboxymethylcellulose aids dispersion and serves as a protective colloid.

Concentrations of less than 1% solids produce fluid dispersions, while concentrations of more than 1.2% solids produce thixotropic gels. However, *Avicel Cl 611* needs a concentration slightly higher than 1.2% for thixotropy. Colloidal *Avicel* is compatible with many other hydrocolloids such as alginate, carrageenans, carbomer, guar gum, pectin and the cellulose ether polymers. When properly dispersed, it imparts emulsion stability, opacity, and suspension to a variety of products, and is used in nasal sprays, topical sprays and lotions, oral suspensions,[1] emulsions, creams[2] and gels.

8 Description

Coprocessed microcrystalline cellulose and carboxymethylcellulose sodium occurs as a white or off-white odorless and tasteless hygroscopic powder. It has a composition, on a dry basis, of 82–89% microcrystalline cellulose and 11–18% sodium carboxymethylcellulose, medium viscosity. It is a water-dispersible anionic hydrocolloid.

9 Pharmacopeial Specifications

See Table I. *See also* Section 18.

Table I: Pharmacopeial specifications for coprocessed microcrystalline cellulose and carboxymethylcellulose sodium.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
pH	6.0–8.0	6.0–8.0
Solubility	+	–
Loss on drying	≤8.0%	≤8.0%
Sulfated ash	≤7.4%	–
Residue on ignition	–	≤5.0%
Apparent viscosity of nominal value	60–140%	60–140%
Heavy metals	–	≤10 µg/g
Assay (dried basis)	75–125%	75–125%

10 Typical Properties

Acidity/alkalinity pH 6–8 for a 1.2% w/v aqueous dispersion.

Density (bulk) 0.6 g/cm^3

Microbial content Total aerobic microbial count ≤100 cfu/g for *Avicel RC/CL* (*Escherichia coli*, *Staphylococcus aureus*, *Pseudomonas aeruginosa* and *Salmonella* species absent); total yeast and mold count ≤20 cfu/g for *Avicel RC/CL*.

Moisture content Not more than 6.0% w/w

Particle size distribution

Avicel CL-611: ≤0.1% retained on a #60 mesh and ≤50% retained on a #325 mesh;

Avicel RC-591: ≤0.1% retained on a #60 mesh and ≤45% retained on a #325 mesh;

Vivapur MCG 591 PCG: ≤5% retained on a #30 mesh and ≤50% retained on a #60 mesh;

Vivapur MCG 611 PCG: ≤5% retained on a #30 mesh and ≤50% retained on a #60 mesh.

Sodium content 940 mg/100 mg of *Avicel RC-591* and 1000 mg/100 mg of *Avicel CL-611*; or 0.94% w/w for *Avicel RC 591* and 1.0% w/w for *Avicel CL 611*.

Solubility Practically insoluble in dilute acids and organic solvents. Partially soluble in dilute alkali and water (carboxymethylcellulose sodium fraction).

Viscosity (dynamic)

39–91 mPa s (39–91 cP) for *Avicel RC-591/ Vivapur MCG 591 PCG* (1.2% w/v aqueous dispersion);

50–118 mPa s (50–118 cP) for *Avicel CL-611/Vivapur MCG 611 PCG* (2.4% w/v aqueous dispersion).

11 Stability and Storage Conditions

Coprocessed microcrystalline cellulose and carboxymethylcellulose sodium is hygroscopic and should not be exposed to moisture. It is stable over a pH range of 4–11. Store in a cool, dry place. Avoid exposure to excessive heat.

Changes in temperature have little effect on the viscosity of *Avicel RC-591* and *Avicel CL-611* dispersions. This is beneficial in maintaining long-term stability. *Avicel* dispersions can be sterilized. However, there is a minimal change in the viscoelastic properties of the gel. Suspensions prepared with Colloidal *Avicel* show little to no viscosity changes after exposure to accelerated temperatures, prolonged (over 5 years) storage at room temperature at 5°C (refrigeration), or after freeze-thaw shock and stress testing.

12 Incompatibilities

Coprocessed microcrystalline cellulose and carboxymethylcellulose sodium is incompatible with strong oxidizing agents. Colloidal *Avicel* being anionic by nature flocculates when small amounts of electrolyte, cationic polymers or surfactants are added. *See* Cellulose, Microcrystalline, and Carboxymethylcellulose Sodium.

13 Method of Manufacture

Coprocessed microcrystalline cellulose and carboxymethylcellulose sodium is a spray- or bulk-dried blend of microcrystalline cellulose and sodium carboxymethylcellulose. It is prepared by the chemical depolymerization of highly purified wood pulp. The original crystalline areas of the pulp fibers are combined with sodium carboxymethylcellulose, which serves as a protective colloid and also facilitates dispersion of the product; it is then either spray- or bulk-dried.

14 Safety

Coprocessed microcrystalline cellulose and carboxymethylcellulose sodium is used in a wide range of pharmaceutical formulations and has low oral, dermal, and inhalation toxicity. It is nonirritating to the eyes and skin, and nonsensitizing to the skin. No significant acute toxicological effects are expected.

LD_{50} (rabbit, skin): >2.0 g/kg

LD_{50} (rat, oral): >5.0 g/kg

For further safety information, *see* Cellulose, Microcrystalline, and Carboxymethylcellulose Sodium.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Eye protection is recommended. *See also* Cellulose, Microcrystalline, and Carboxymethylcellulose Sodium.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (nasal sprays; oral, powders, suspensions, and tablets). Included in nonparenteral medicines licensed in the UK.

Coprocessed microcrystalline cellulose and carboxymethylcellulose sodium is a mixture of two materials both of which are generally regarded as nontoxic.

17 Related Substances

Carboxymethylcellulose sodium; cellulose, microcrystalline.

18 Comments

Microcrystalline cellulose is one of the materials that have been selected for harmonization by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

The properties of preparations containing coprocessed microcrystalline cellulose and carboxymethylcellulose sodium depend on the development of maximum colloidal dispersions in water.[3–5] *Avicel RC/CL* dispersions yield a highly thixotropic vehicle, which is primarily the result of the large number of colloidal microcrystal particles that result from full dispersion in aqueous media. The network establishes a weak gel structure with a measurable yield point that prevents drug particles from settling in a formulation. This gel structure is easily broken by mild shaking to yield a readily pourable liquid. Upon removal of shear, the gel structure re-establishes, providing a suspension medium with long-term stability against phase separation. *Avicel RC-591* has been found to have optimal formulation properties compared with other suspending agents in metronidazole benzoate suspensions.[6] *Avicel RC/CL* was included within the *in-situ* hot melt dispersion mini-pellet formulation to enhance the physiochemical properties such as matrix hardness and total disintegration time.[7] *Avicel RC* has been evaluated as one of the pore-forming agents in a controlled release coating agent.[8]

A specification for microcrystalline cellulose and carmellose sodium is contained in the *Japanese Pharmaceutical Excipients* (JPE).[9]

Cellulose, Powdered

1 Nonproprietary Names

BP: Powdered Cellulose

JP: Powdered Cellulose

PhEur: Cellulose, Powdered

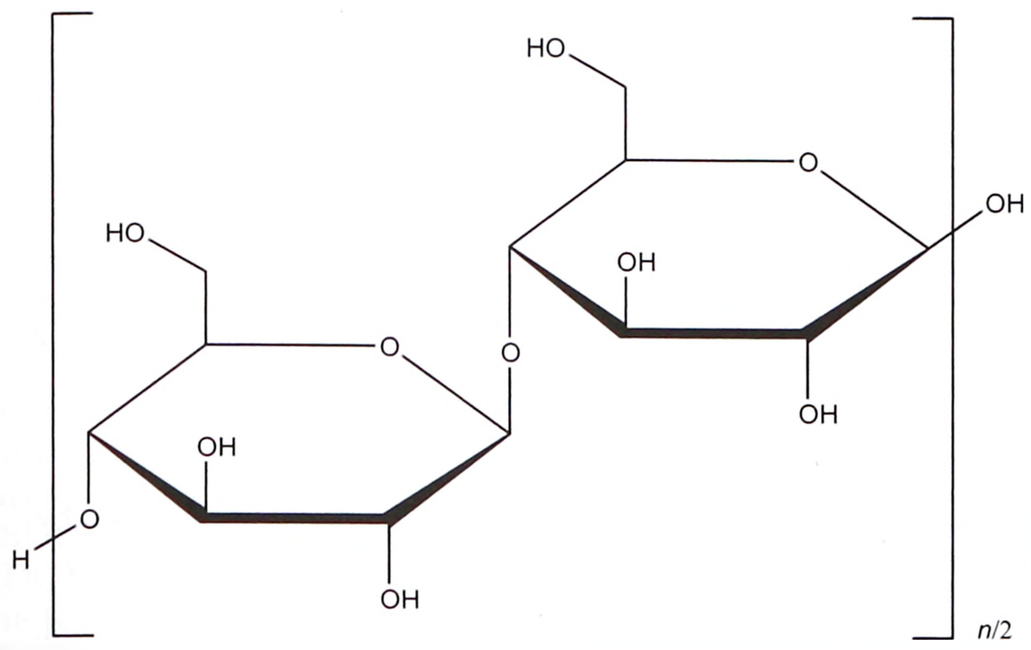
USP–NF: Powdered Cellulose

2 Synonyms

Alpha-cellulose; *Arbocel*; cellulosi pulvis; E460; Elcema; *JustFiber*; *KC Flock*; *Sanacel*; *Sanacel Pharma*; *Sancel-W*; *Sanacel Wheat*; *Solka-Floc*.

3 Chemical Name and CAS Registry Number

Cellulose [9004-34-6]



4 Empirical Formula and Molecular Weight

$(C_6H_{10}O_5)_n$ ≈243 000 where $n \approx 500$.

Since cellulose is derived from a natural polymer, it has variable chain length and thus variable molecular weight.

See also Sections 8 and 13.

5 Structural Formula

6 Functional Category

Adsorbent; glidant; suspending agent; tablet and capsule diluent; tablet and capsule disintegrant; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Powdered cellulose is used as a tablet diluent and filler in two-piece hard capsules; *see* Table I. In both contexts it acts as a bulking agent to increase the physical size of the dosage form for formulations containing a small amount of active substance.

Powdered cellulose has acceptable compression properties, although the flow properties of most brands are poor. However, low-crystallinity powdered cellulose has exhibited properties that are different from standard powdered cellulose materials, and has shown potential as a direct-compression excipient.[1]

In soft gelatin capsules, powdered cellulose may be used to reduce the sedimentation rate of oily suspension fills. It is also used as the powder base material of powder dosage forms, and as a suspending agent in aqueous suspensions for peroral delivery. It may also be used to reduce sedimentation during the manufacture of suppositories.

Powdered cellulose has been investigated as an alternative to microcrystalline cellulose as an agent to assist the manufacture of pellets by extrusion/spheronization.[2,3] However, powdered cellulose alone requires too much water and due to water movement during extrusion cannot be used as an extrusion/spheronization aid on its own.[4]

Powdered cellulose is also used widely in cosmetics and food products as an adsorbent and thickening agent.

Table I: Uses of powdered cellulose.

Use	Concentration (%)
Capsule filler	5–30
Tablet and capsule binder	5–40 (wet granulation) 10–30 (dry granulation)
Tablet disintegrant	5–20
Tablet glidant	1–2

8 Description

Powdered cellulose occurs as a white or almost white, odorless and tasteless powder of various particle sizes, ranging from a free-flowing fine or granular dense powder, to a coarse, fluffy, nonflowing material.

9 Pharmacopeial Specifications

The pharmacopeial specifications for powdered cellulose have undergone harmonization of many attributes for JP, PhEur, and USP–NF. *See* Table II.

See also Section 18.

Table II: Pharmacopeial specifications for powdered cellulose.

Test	JP XVII	PhEur 9.2[a]	USP 40–NF 35 S1

Solka-Floc 300 FCC	22

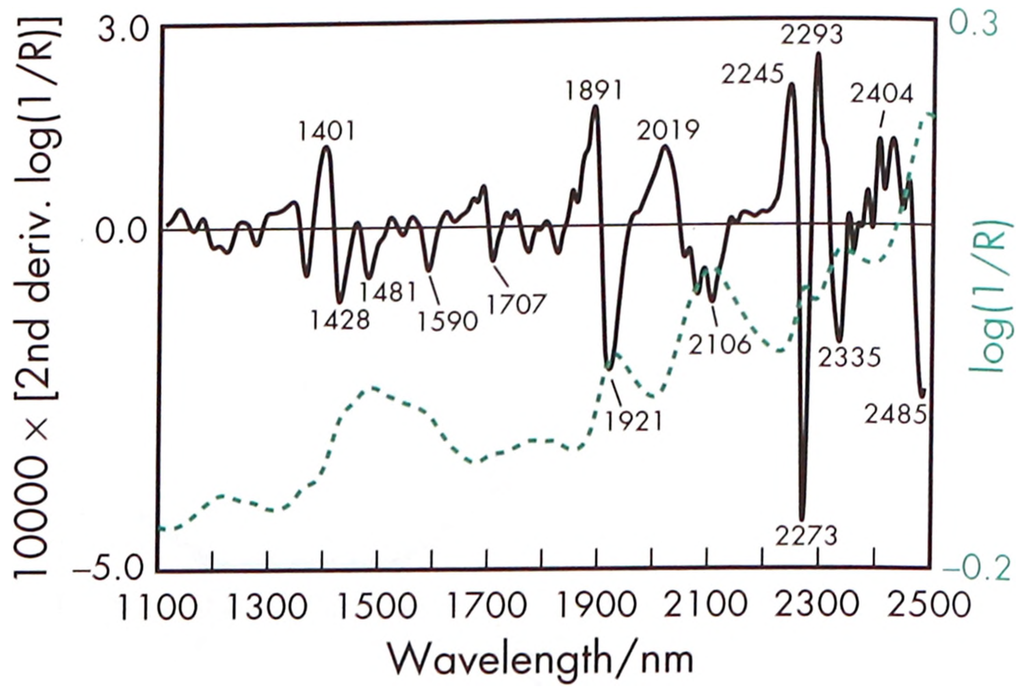

Figure 3: Near-infrared spectrum of powdered cellulose measured by reflectance.

Spectroscopy

NIR spectrum *see* Figure 3.

11 Stability and Storage Conditions

Powdered cellulose is a stable, slightly hygroscopic material.[7] The bulk material should be stored in a well-closed container in a cool, dry place.

12 Incompatibilities

Incompatible with strong oxidizing agents, bromine pentafluoride, sodium nitrite and fluorine.[6]

13 Method of Manufacture

Powdered cellulose is manufactured by the purification and mechanical size reduction of α-cellulose obtained as a pulp from fibrous plant materials.

14 Safety

Powdered cellulose is widely used in oral pharmaceutical formulations and food products and is regarded as a nontoxic and

nonirritant material. However, allergic reactions when inhaled, ingested or in contact with the skin are possible.[6]

Powdered cellulose is not absorbed systemically following peroral administration and thus has little toxic potential. Consumption of large quantities of cellulose may, however, have a laxative effect, although this is unlikely to be a problem when cellulose is used as an excipient in pharmaceutical formulations.

Deliberate abuse of formulations containing cellulose, either by inhalation or by injection, has resulted in the formation of cellulose granulomas.[8]

LD_{50} (rat, oral): >5 g/kg [6]

LD_{50} (rat, inhalation): 5.8 g/m^3/4 h [6]

LD_{50} (rabbit, skin): >2 g/kg [6]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Powdered cellulose may be an irritant to the eyes. The material emits toxic fumes under fire conditions and when heated to decomposition.[6] Gloves, eye protection, and a dust mask (NIOSH approved), and engineering controls such as exhaust ventilation are recommended. In the UK, the workplace exposure limits for cellulose have been set at 10 mg/m^3 long-term (8-hour TWA) for total inhalable dust and 4 mg/m^3 for respirable dust; the short-term limit for total inhalable dust has been set at 20 mg/m^3.[9] In the US, the TWA exposure values are defined by NIOSH as 5 mg/m^3 (respirable fraction) and 10 mg/m^3 (total dust).[6]

16 Regulatory Status

GRAS listed. Accepted for use as a food additive in Europe (except for infant food in the UK). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Cellulose, microcrystalline.

18 Comments

Powdered cellulose has undergone harmonization of many attributes for JP, PhEur, and USP–NF by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

When powdered cellulose was used as a tablet disintegrant, tablets could be stored up to 78% RH without losing their rapid disintegration properties.[10] Tablets disintegrating rapidly in the oral cavity were also successfully prepared with powdered cellulose.[11] Coprocessing of powdered cellulose with magnesium carbonate by roller compaction has resulted in a promising excipient for direct tableting.[12] Highly porous matrices from powdered cellulose may be suitable for stabilization and handling of liquid drug substances.[13] Powdered cellulose can be converted into a direct-compressible free-flowing powder using an anionic sodium polystyrene sulfonate/polyvinyl pyrrolidone bilayer nano-coating technology.[14]

A specification for powdered cellulose is contained in the *Food Chemicals Codex* (FCC).[15]

The EINECS number for powdered cellulose is 232-674-9.

Cellulose, Silicified Microcrystalline

1 Nonproprietary Names

USP–NF: Silicified Microcrystalline Cellulose

2 Synonyms

ProSolv.

3 Chemical Name and CAS Registry Number

See Section 8.

4 Empirical Formula and Molecular Weight

See Section 8.

5 Structural Formula

See Section 8.

6 Functional Category

Tablet and capsule diluent.

7 Applications in Pharmaceutical Formulation or Technology

Silicified microcrystalline cellulose is used as a diluent in the formulation of capsules and tablets. It has improved compaction properties in both wet granulation and direct compression compared to conventional microcrystalline cellulose.[1–5] Silicified microcrystalline cellulose was specifically developed to address the loss of compactability that occurs with microcrystalline cellulose after wet granulation. Silicified microcrystalline cellulose also appears to have beneficial properties for use in the formulation of powder-filled capsules.[6,7]

8 Description

Silicified microcrystalline cellulose is a synergistic, co-processed mixture of two components: microcrystalline cellulose and colloidal silicon dioxide (for further information *see* Cellulose, Microcrystalline and Colloidal Silicon Dioxide). Silicified microcrystalline cellulose contains 2% w/w colloidal silicon dioxide.

9 Pharmacopeial Specifications

See Table I. *See also* Section 18.

10 Typical Properties

Acidity/alkalinity pH = 5.0–7.5 (12.5% w/v suspension)
Density 1.58 g/cm[5]
Density (bulk) 0.31 g/cm^3
Density (tapped) 0.39 g/cm[5]
Melting point The microcrystalline cellulose component chars at 260–270°C.
Moisture content Typically less than 6% w/w.
Particle size distribution Typical particle size is 20–200 µm. Different grades may have a different median particle size.
Solubility Practically insoluble in water, dilute acids, and most organic solvents. The microcrystalline cellulose component is slightly soluble in 5% w/w sodium hydroxide solution.
Spectroscopy

NIR spectrum *see* Figure 1.

11 Stability and Storage Conditions

Silicified microcrystalline cellulose is stable when stored in a well-closed container in a cool, dry place.

12 Incompatibilities

See Cellulose, Microcrystalline and Colloidal Silicon Dioxide.

13 Method of Manufacture

Silicified microcrystalline cellulose is manufactured by co-spray drying a suspension of microcrystalline cellulose particles and colloidal silicon dioxide such that the dried finished product contains 2% w/w colloidal silicon dioxide.

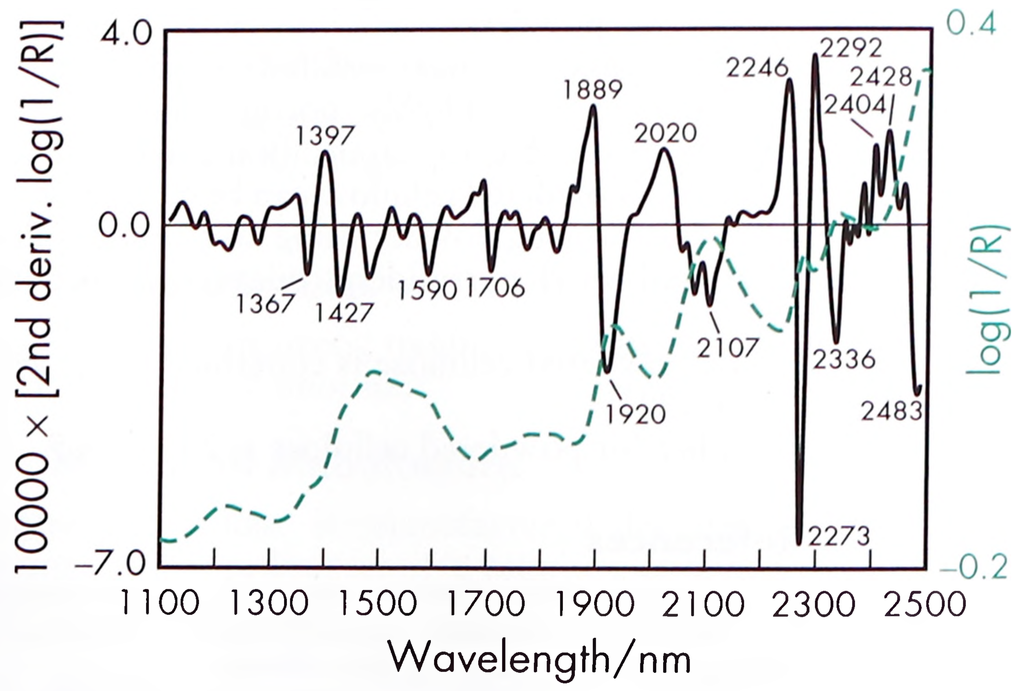
The colloidal silicon dioxide appears physically bound onto the surface and inside the silicified microcrystalline cellulose particles. Extensive studies using different spectroscopic methods have failed to show any form of covalent chemical interaction.[4,8,9]

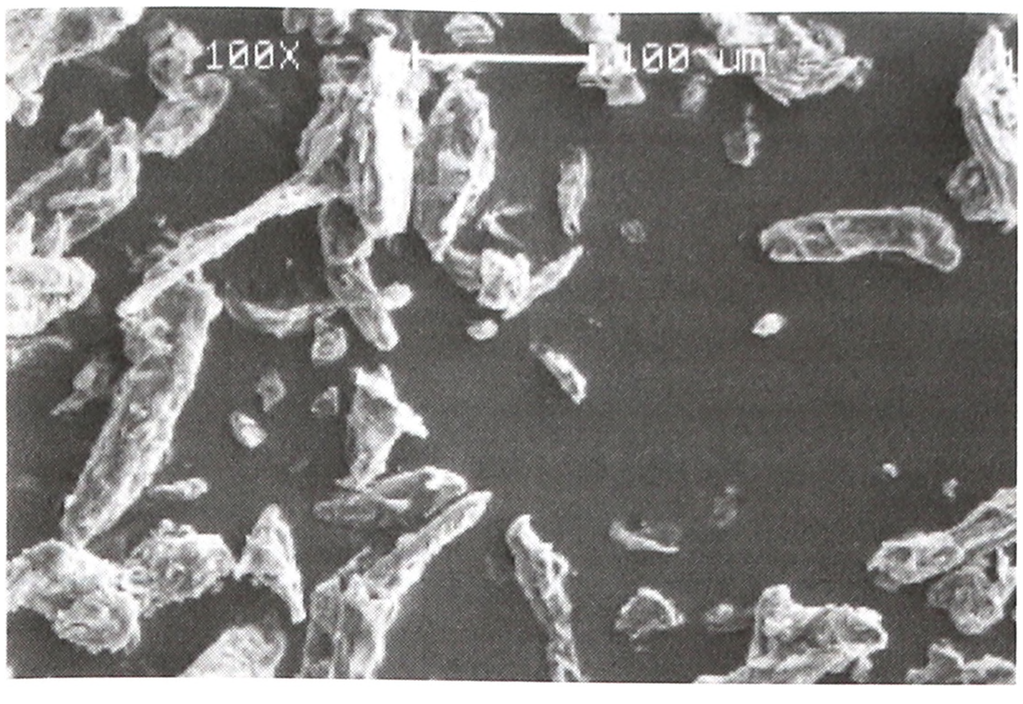
14 Safety

See Cellulose, Microcrystalline and Colloidal Silicon Dioxide.

Table I: Pharmacopeial specifications for silicified microcrystalline cellulose.

Test	USP 40–NF 35 S1
Identification	+
Microbial contamination	
Aerobic bacteria	≤1000 cfu per g
Fungi	≤100 cfu per g
Conductivity	+
pH	5.0–7.5
Loss on drying	7.0%
Residue on ignition	1.8–2.2%
Bulk density	+
Degree of polymerization	≤350
Particle size and distribution	+
Water-soluble substances	≤12.5 mg
Ether-soluble substances	≤5.0 mg
Heavy metals	≤0.001%





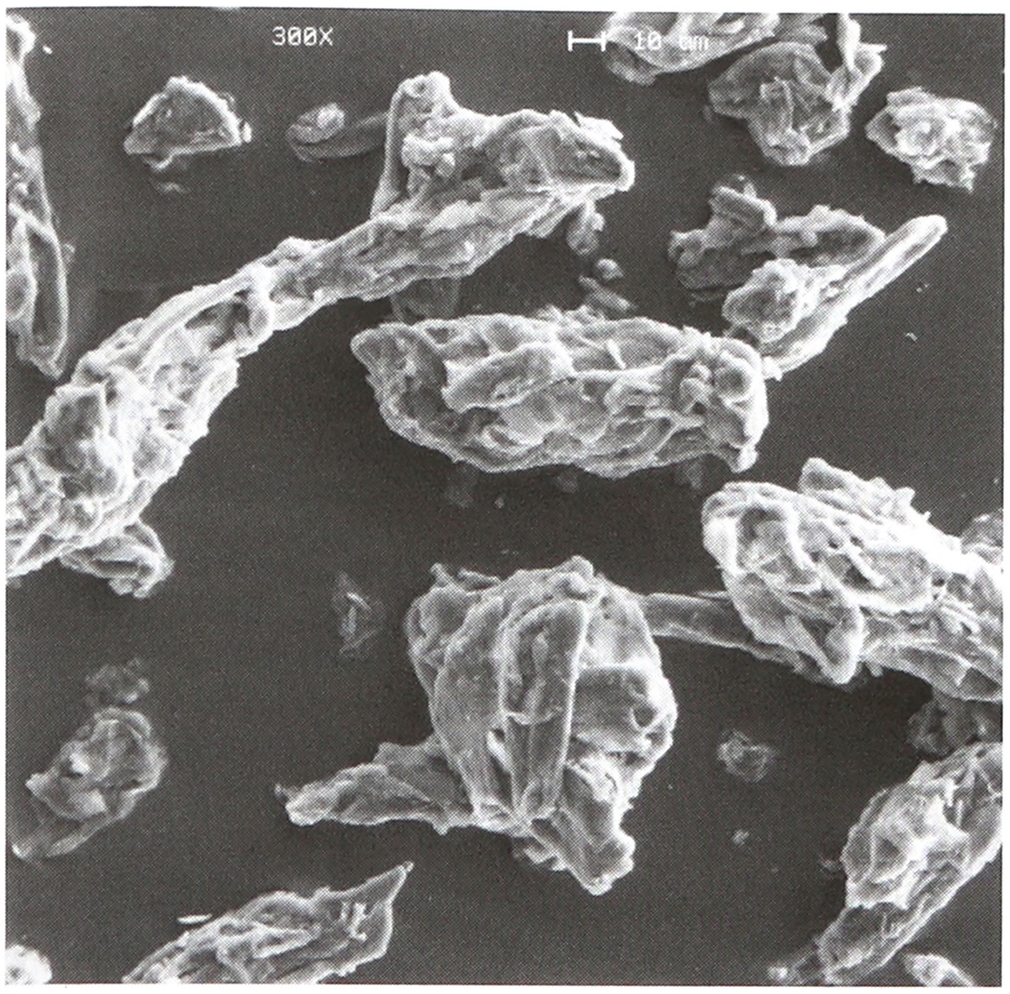


Figure 1: Near-infrared spectrum of silicified microcrystalline cellulose measured by reflectance.

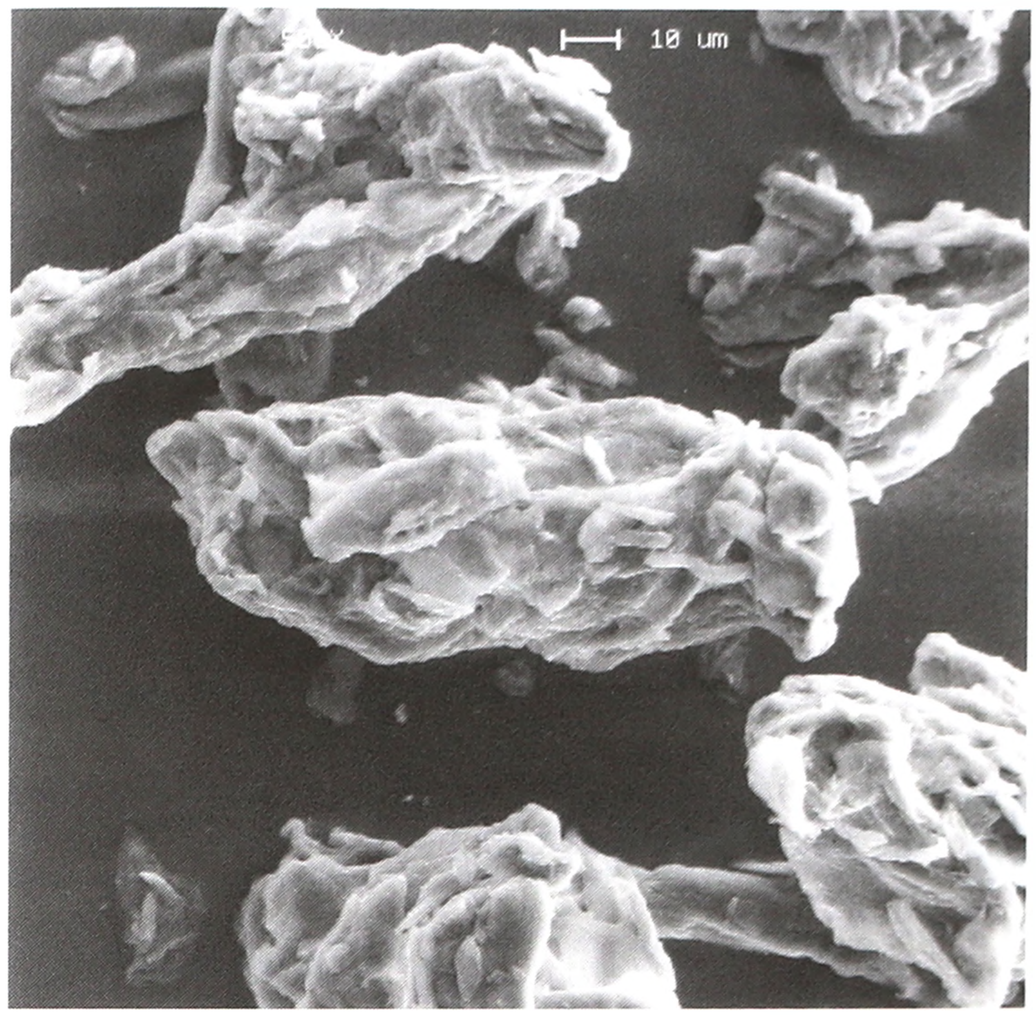

SEM 1: Excipient: silicified microcrystalline cellulose; manufacturer: JRS Pharma LP; lot no.: CSD5866; magnification: 100×.

SEM 2: Excipient: silicified microcrystalline cellulose; manufacturer: JRS Pharma LP; lot no.: CSD5866; magnification: 300×.

SEM 3: Excipient: silicified microcrystalline cellulose; manufacturer: JRS Pharma LP; lot no.: CSD5866; magnification: 500×.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Handling of silicified microcrystalline cellulose can generate nuisance dusts and the use of a respirator or dust mask may be necessary.

Microcrystalline cellulose may be irritant to the eyes. Gloves, eye protection, and a dust mask are recommended. In the UK the long-term workplace exposure limits (8-hour TWA) have been set at 10 mg/m^3 for total inhalable dust and 4 mg/m^3 for respirable dust; short-term limit for total inhalable dust has been set at 20 mg/m^3.[10]

Since the colloidal silicon dioxide is physically bound to the microcrystalline cellulose the general recommendations of gloves, eye protection, and a dust mask should be followed when handling silicified microcrystalline cellulose.

16 Regulatory Status

Silicified microcrystalline cellulose is a physical mixture of two materials both of which are generally regarded as nontoxic. For details of the Regulatory Status of the component materials, see individual monographs for Microcrystalline cellulose and Colloidal silicone dioxide.

17 Related Substances

Cellulose, microcrystalline; colloidal silicon dioxide.

18 Comments

Colloidal silicon dioxide and microcrystalline cellulose are two of the materials that have been selected for harmonization by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

Tablets prepared using silicified microcrystalline cellulose have greater tensile strength and require lower compression pressures than tablets prepared using regular grades of microcrystalline cellulose. Furthermore, silicified microcrystalline cellulose maintains its compactability after wet granulation; the compacts exhibit greater stiffness and they require considerably more energy for tensile failure to occur.[4,11,12]

Ceratonia

1 Nonproprietary Names

None adopted.

2 Synonyms

Algaroba; carob bean gum; carob flour; carob gum; carob seed gum; caruba; carubin; ceratonia gum; *Ceratonia siliqua*; *Ceratonia siliqua* gum; cheshire gum; E410; gomme de caroube; locust bean gum; *Meyprofleur*; St. John's bread.

3 Chemical Name and CAS Registry Number

Carob gum [9000-40-2]

4 Empirical Formula and Molecular Weight

Ceratonia is a naturally occurring plant material that is obtained from milling of the seed endosperm of the leguminous plant *Ceratonia siliqua* Linn. (carob tree). It consists chiefly of a high molecular weight hydrocolloidal polysaccharide, composed of D-galactose and D-mannose units combined through glycosidic linkages, which may be described chemically as galactomannan. These glycosidic linkages have a linear chain of (1→ 4) –linked β-D-mannopyranosyl units with (1→6)-linked α-D-galactopyranosyl side chain residues. The side chains are not uniformly distributed across the mannose backbone and vary according to the region where the plant has grown. Ceratonia has the lowest galactose content (20-25%) amongst the commercially available galactomannans (e.g. guar gum and tara gum).[1,2] The molecular weight is approximately 310 000. However, this varies significantly depending on the seed source and preparation procedure.

5 Structural Formula

See Section 4.

6 Functional Category

Coating agent; emulsifying agent; gelling agent; modified-release agent; suspending agent; tablet and capsule binder; tablet and capsule disintegrant; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Ceratonia is a naturally occurring material generally used as a substitute for tragacanth or other similar gums of the galactomannan group (e.g. guar and tara gums). A ceratonia mucilage that is slightly more viscous than tragacanth mucilage may be prepared by boiling 1.0–1.5% of powdered ceratonia with water. The viscosity and water-solubility of the gum is determined by its galactose content.[2] As a viscosity-increasing agent, ceratonia is said to be five times as effective as starch and twice as effective as tragacanth. Ceratonia has also been used as a tablet binder[3] and is used in oral controlled-release drug delivery systems approved in Europe and the US. An example is the TIMERx® system that is based on a hydrophilic matrix formed by xanthan gum and ceratonia with dextrose.[4]

Ceratonia has a wide range of applications in the pharmaceutical industry. It is known to be used in the manufacture of films, beads, micro and nano-particles, solid monolithic matrices and viscous formulations of liquids and gels. Here, it may function as a stabilizing agent, binder, coating ingredient, modifier of drug release pattern, emulsifying agent, thickener, disintegrants, suspending agent, solubilizer or gelling agent. It has also been used as a biologically active substance to reduce elevated plasma cholesterol.[5]

8 Description

Ceratonia occurs as a yellow-green or white colored powder depending on the method of isolation from the plant. Although odorless and tasteless in the dry powder form, ceratonia acquires a leguminous taste when boiled in water.

9 Pharmacopeial Specifications

See Section 18.

10 Typical Properties

Acidity/alkalinity pH = 5.3 (1% w/v aqueous solution)
Solubility The gum has shown very low solubility in most organic solvents and requires heating at temperatures greater than 85°C in order to be completely soluble in water. Ceratonia is dispersible in hot water (>70°C), forming a sol having a

pH 5.4–7.0 that may be converted to a gel by the addition of small amounts of sodium borate. In cold water, ceratonia hydrates very slowly and incompletely due to its generally lower galactose content in comparison to other gums and it is dependent on the purity of the compound.[6] Ceratonia is practically insoluble in ethanol.

Spectroscopy

NIR spectrum *see* Figure 1.

Viscosity (dynamic) 1200–2500 mPa s (1200–2500 cP) for a 1% w/v aqueous dispersion at 25°C. Viscosity is unaffected by pH within the range pH 3–11. Viscosity is increased by heating: if heated to 95°C then cooled, practically clear solutions may be obtained that are more viscous than prior to heating.

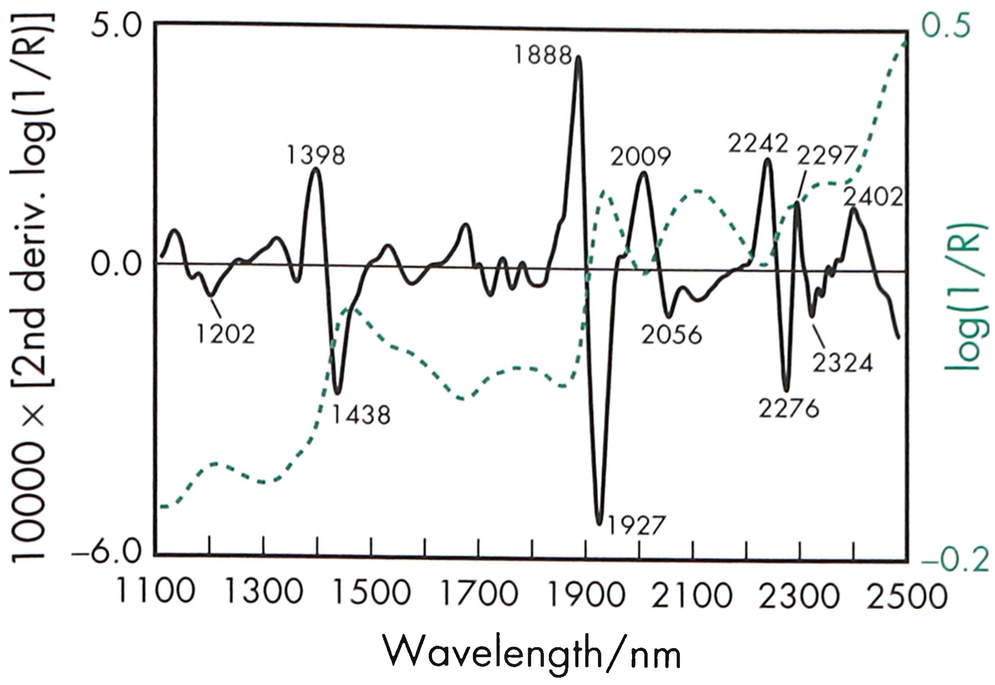

Figure 1: Near-infrared spectrum of ceratonia measured by reflectance.

11 Stability and Storage Conditions

The bulk material should be stored in a well-closed container in a cool, dry place. Ceratonia loses not more than 15% of its weight on drying. Heating above 80°C may result in oxidative-reductive depolymerisation of the galactomannan chain and thereby reduce viscosity.

12 Incompatibilities

The viscosity of xanthan gum solutions is increased in the presence of ceratonia.[7] This interaction is used synergistically in controlled-release drug delivery systems such as the TIMERx® system.[4]

13 Method of Manufacture

Ceratonia is a naturally occurring material obtained from the ground endosperms separated from the seeds of the locust bean tree, *Ceratonia siliqua* (Leguminosae). The tree is indigenous to southern Europe and the Mediterranean region. Properties of the material will be influenced from the seed source and method of processing.

14 Safety

Ceratonia is generally regarded as an essentially noncarcinogenic,[8] nontoxic and nonirritant material. It has been reported that at levels ≥ 0.1%, no component of ceratonia has been established to be a probable, possible or confirmed carcinogen in humans. Therapeutically, it has historically been used in oral formulations for the control of vomiting and diarrhea in adults and children; 20–40 g daily in adults has been used dispersed in liquid.[9] As an excipient, ceratonia is used in oral controlled-release formulations approved in Europe and the US. Its biodegradability, low toxicity and low cost account for the rise in its use in various fields. In combination with glycerol, it is also used in topical cosmetic products.[10]

Ceratonia is also widely used in food products. The WHO has not specified an acceptable total daily intake for ceratonia as the total daily intake arising from its use at the levels necessary to achieve the desired effect, and from its acceptable background in food, was not considered to represent a hazard to health.[11] Ceratonia hypersensitivity has been reported, in a single case report, in an infant.[12] However, ceratonia is said to be nonallergenic in children with known allergy to peanuts.[13]

LD_{50} (hamster, oral): 10.0 g/kg[14]

LD_{50} (mouse, oral): 13.0 g/kg

LD_{50} (rabbit, oral): 9.1 g/kg

LD_{50} (rat, oral): 13.0 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. When heated to decomposition ceratonia emits acrid smoke and irritating fumes.

16 Regulatory Status

GRAS listed. Accepted for use in Europe as a food additive. In Europe and the US, ceratonia has been used in oral tablet formulations. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Acacia; ceratonia extract; guar gum; tragacanth; xanthan gum.

Ceratonia extract

Synonyms Ceratonia siliqua extract; extract of carob; locust tree extract.

CAS number [84961-45-5]

Comments Ceratonia extract is used as an emollient. The EINECS number for ceratonia extract is 284-634-5.

18 Comments

Therapeutically, ceratonia mucilage is used orally in adults and children to regulate intestinal function; *see* Section 14.

Ceratonia is widely used as a binder, thickening agent, and stabilizing agent in the cosmetics and food industry. In foods, 0.15–0.75% is used.

The EINECS number for ceratonia is 232-541-5.

Although not included in any pharmacopeias, a new USP monograph for Locust Bean Gum is in development,[15] and a specification for ceratonia is contained in the *Food Chemicals Codex* (FCC); *see* Table I.[16]

Table I: Food Chemicals Codex specifications for ceratonia (locust (Carob) bean gum).[16]

Ceresin

1 Nonproprietary Names

None adopted.

2 Synonyms

Cera microcrystallina; cera mineralis alba; ceresin refined; ceresine; ceresine wax; ceresine wax white; ceresin wax; cerin; cerosin; *Cirashine CS*; earth wax; *GS-Ceresin*; *Koster Keunen Ceresine*; microcrystalline wax; mineral wax; purified ozokerite; *Ross Ceresine Wax*; white ceresin wax; white ozokerite wax. *See also* Section 13.

3 Chemical Name and CAS Registry Number

Ceresin wax [8001-75-0]

4 Empirical Formula and Molecular Weight

Ceresin is a mineral wax composed of a wide and complex range of long-chain, high-molecular-weight, saturated and unsaturated hydrocarbons related to methane, ranging from C_{20} to C_{32}.

5 Structural Formula

See Section 4.

6 Functional Category

Coating agent; emulsion stabilizing agent; gelling agent; opacifier; stiffening agent; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Ceresin is used as a stiffening agent in creams[1,2] and ointments,[3,4] and as an emulsion stabilizer, opacifier, viscosity-increasing agent, gelling agent, and thickener in pharmaceutical protective, topical, and vaginal creams.[7] It is also used in cosmetics[5–7] and in a wide variety of personal care products[8,9] (*see* Section 18).

Ceresin is often used as a substitute for ozokerite wax, beeswax, and paraffin wax. It acts as a rheological modifier at low concentrations (2–3%) and has the ability to create very small crystallites, which crosslink and establish a network structure that does not allow flow in practical conditions.[10] Ceresin produces

stable mixtures with oils and prevents bleeding or sweating of oil, and it produces a lighter cream that is less greasy.

Ceresin is also used for pharmaceutical coating applications of medicaments, for example, protective coatings,[11] enteric coatings,[12] and sustained-release coatings.[13] It has been used in the formulation of multivesicular emulsion topical delivery systems.[14]

8 Description

Ceresin is a natural, white-to-yellow waxy mixture of hydrocarbons of high molecular weight obtained by purification of ozokerite. It occurs as odorless, tasteless, solid, amorphous (noncrystalline) brittle, waxy cakes or pastilles.

Ceresin waxes are blends of complex hydrocarbons, sold in various grades, differing from one another chiefly in melting point and in the distribution of the hydrocarbons (*see* Table I).

9 Pharmacopeial Specifications

See Section 18.

10 Typical Properties

Acid value *See* Table I
Boiling point 343°C[15]
Congealing point 60–69°C; *see* Table I
Density 0.91–0.92 g/cm^3
Flash point ≥204.4°C[15]
Iodine value 7–9[16]
Melting point 54–78°C; *see* Table I
Saponification value *See* Table I
Solubility Soluble in benzene, chloroform, naphtha, hot oils, petroleum ether, 30 parts absolute ethanol, turpentine, carbon disulfide, and most organic solvents. Insoluble in water.
Specific gravity ~0.880–0.935[17]
Viscosity (kinematic) 4.0 mm^2/s (4.0 cSt) at 100°C[18]

Table I: Typical Properties of various commercial grades of ceresin (Koster Keunen).

Grade	Acid value	Congealing point °C	Melting point °C	Saponification value
Ceresin 130–135	<1	53.8–57.2	54.4–57.2	<1
Ceresin 140–145	<1	59.4–65.0	60.0–65.6	<1
Ceresin 155	<1	66.7–69.4	67.2–70.0	<1
Ceresin 1556	<1	72.8–78.3	74.0–79.4	<1
Ceresin 145	<1	59.4–62.2	60.0–62.8	<1
Ceresin 150–160	<1	65.0–70.6	65.6–71.1	<1

11 Stability and Storage Conditions

Ceresin is a stable material and should be stored in well-closed containers in a cool, dry, well-ventilated place, away from extreme heat, ignition sources and strong oxidizing agents.

12 Incompatibilities

Ceresin is incompatible with strong oxidizing agents. It is compatible with most animal, vegetable, and mineral waxes, as well as mineral oil and petrolatum.

13 Method of Manufacture

Ceresin is a complex combination of hydrocarbons prepared by extraction and purification of the native mineral fossil wax ozokerite, which is derived from coal and shale, with sulfuric acid and filtration through bone black to form waxy cakes. Ozokerite is mined from deposits in various localities around the world. It is found as irregular mineral veins or as a black mass in clay strata. Mined ozokerite is heated to melt it, and any earth or rock is removed. If necessary, it is heated to 115–120°C to remove any moisture and then treated with sulfuric acid or fuming sulfuric acid. After neutralization, it is decolorized using activated charcoal, bone black or silica gel, and filtered. If decolorizing is not sufficient, it is repeatedly treated with sulfuric acid and subjected to adsorption filtration to produce more refined ceresin.

Another method of producing ceresin involves dissolving ozokerite in ligroin, treating it with activated clay, and then removing the high-boiling-point fraction.

14 Safety

Ceresin is nontoxic, nonhazardous, and safe for use in personal care and cosmetic ingredients in the present practices of concentration and use. The Cosmetic Ingredient Review Expert Panel has concluded that ceresin does not result in dermal sensitization. When formulations containing these ingredients were tested, they produced no skin irritation and the formulations were not phototoxic.[19]

Ceresin may be slightly hazardous on ingestion and inhalation and may cause allergic reactions.[20] No definitive information is available on carcinogenicity, mutagenicity, target organs, or developmental toxicity. The FDA has established a cumulative estimated daily intake of ceresin of 0.00035 mg/kg body weight, and a cumulative dietary concentration in food of not more than 7 ppb.[21]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. Ceresin should be handled in areas with adequate ventilation. Inhalation of vapors and contact with eyes, skin, and clothes should be avoided. Eye protection and gloves are recommended. Wash hands thoroughly after handling.

Ceresin should be kept away from heat and sources of ignition as it may be combustible at high temperature. It forms oxides of carbon as a hazardous decomposition product. The recommended operation temperatures are in the range of 75–95°C.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (topical ointments; vaginal emulsions and creams). Included in the Canadian Natural Health Products Ingredients Database. Included in nonparenteral medicines (topical creams) licensed in the UK. Accepted for use in cosmetics and personal care products marketed in Europe.

17 Related Substances

Wax, microcrystalline; wax, white; wax, yellow.

18 Comments

A specification for ceresin is included in *Japanese Pharmaceutical Excipients* (JPE); *see* Table II.[22]

Ceresin is used in many types of cosmetics and personal care products[23–25] including lipsticks,[26] lip salve, baby products, eye and facial makeup, as well as nail care, skin care, suntan, and sunscreen preparations,[27] deodorant sticks, fragrance, perfumes, pomades, and noncoloring hair preparations.[28] Ceresin is used in formulas that do not use animal products. It lessens the brittleness of cosmetic stick products, adding strength and stability, and it has been used in hair products as a waxy carrier.[29]

Ceresin is used in dentistry as one of the primary components of dental wax compounds[30] along with beeswax and microcrystalline and paraffin wax, and it is used in dental impressions.[31] It has also been used as a biodegradable wax in a sprayable, controlled-release insect control formulation.[32]

The EINECS number for ceresin is 232-290-1. The PubChem Substance ID (SID) for ceresin is 204276.

Cetostearyl Alcohol

1 Nonproprietary Names

BP: Cetostearyl Alcohol

PhEur: Cetostearyl Alcohol

USP–NF: Cetostearyl Alcohol

2 Synonyms

Alcohol cetylicus et stearylicus; cetearyl alcohol; cetyl stearyl alcohol; *Crodacol CS90*; *DUB SC 20D*; *Kolliwax CSA*; *Lanette O*; *Speziol C16-18 Pharma*; *Tego Alkanol 1618*; *Tego Alkanol 6855*.

3 Chemical Name and CAS Registry Number

Cetostearyl alcohol [67762-27-0] and [8005-44-5]

4 Empirical Formula and Molecular Weight

Cetostearyl alcohol is a mixture of solid aliphatic alcohols consisting mainly of stearyl ($C_{18}H_{38}O$) and cetyl ($C_{16}H_{34}O$) alcohols. The proportion of stearyl to cetyl alcohol varies considerably, but the material usually consists of about 50–70% stearyl alcohol and 20–35% cetyl alcohol, with limits specified in pharmacopeias. The combined stearyl alcohol and cetyl alcohol comprise at least 90% of the material. Small quantities of other alcohols, chiefly myristyl alcohol, make up the remainder of the material.

5 Structural Formula

See Section 4.

6 Functional Category

Emollient; emulsifying agent; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Cetostearyl alcohol is used in topical pharmaceutical formulations to increase viscosity and act as an emulsifier in both water-in-oil and oil-in-water emulsions. Cetostearyl alcohol will stabilize an emulsion and also act as a co-emulsifier, thus decreasing the total amount of surfactant required to form a stable emulsion.

Cetostearyl alcohol has been used for ocular delivery of methazolamide[1] and as a co-surfactant in conjunction with propylene glycol to increase skin penetration of piroxicam.[2] Controlled-release tablet formulations of etodolac have also been studied using a variety of lipid matrices.[3] *See also* Section 18.

8 Description

Cetostearyl alcohol occurs as white or cream-colored unctuous masses, flakes, pellets or granules. It has a faint, characteristic sweet odor. On heating, cetostearyl alcohol melts to a clear, colorless or pale yellow-colored liquid free of suspended matter.

9 Pharmacopeial Specifications

See Table I. *See also* Section 18.

10 Typical Properties

Boiling point ≈ 300-360°C (degradation temperature)
Density (bulk) ≈ 0.8 g/cm^3 at 20°C.
Solubility Soluble in ethanol (95%), ether, and oil; practically insoluble in water.

Table I: Pharmacopeial specifications for cetostearyl alcohol.

11 Stability and Storage Conditions

Cetostearyl alcohol is stable under normal storage conditions. It should be stored in a well-closed container in a cool, dry place.

12 Incompatibilities

Cetostearyl alcohol is incompatible with strong oxidizing agents and metal salts.

13 Method of Manufacture

Cetostearyl alcohol is prepared by the reduction of the appropriate fatty acids from vegetable and animal sources. Cetostearyl alcohol can also be prepared directly from hydrocarbon sources.

14 Safety

Cetostearyl alcohol is mainly used in topical pharmaceutical formulations and topical cosmetic formulations.

Cetostearyl alcohol is generally regarded as a nontoxic material.[4] Although it is essentially nonirritating, sensitization reactions to cetostearyl, cetyl, and stearyl alcohols[5–10] have been reported.

Gamma radiation has been shown to be feasible for sterilization of petrolatum containing cetostearyl alcohol resulting in low levels of radiolysis products, which are of low toxicity.[11]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

Cetostearyl alcohol is flammable and on combustion may produce fumes containing carbon monoxide. Eye protection and gloves are recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral tablets; topical emulsions, lotions, ointments and suspensions; vaginal creams and suppositories). Included in nonparenteral medicines licensed in the UK. Accepted as an indirect food additive, as an adhesive, and a component of packaging coatings in the US. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Anionic emulsifying wax; cetyl alcohol; sodium lauryl sulfate; stearyl alcohol.

18 Comments

The composition of cetostearyl alcohol from different sources may vary considerably. The composition of the minor components, typically straight-chain and branched-chain alcohols, varies greatly depending upon the source, which may be animal, vegetable, or synthetic. This has been reported in the literature to impart differences in emulsification behavior, particularly with respect to emulsion consistency or stability.[12–15]

Cetostearyl alcohol has also been reported to control or slow the dissolution rate of tablets or microspheres containing water-soluble drugs,[16–20] or poorly water-soluble drugs,[21–25] as well as to stabilize amorphous systems.[26] In combination with other surfactants, cetostearyl alcohol forms emulsions with very complex microstructures, which can include liquid crystals, lamellar structures, and gel phases.[12–15,27–35]

The PhEur 9.2 contains specifications for cetostearyl alcohol, emulsifying Type A, and Type B, respectively. Each contains at least 7% surfactant, with Type A containing sodium cetostearyl sulfate and Type B containing sodium lauryl sulfate. *See also* Wax, Anionic Emulsifying.

Cetostearyl alcohol is also used in cosmetics applications, the preparation of nonaqueous creams and sticks, and in nonlathering shaving creams.[36]

The EINECS number for cetostearyl alcohol is 267-008-6.

Cetrimide

1 Nonproprietary Names

BP: Cetrimide
PhEur: Cetrimide

2 Synonyms

Cetavlon; *Cetraol*; cetrimidum; *Lissolamine V*; *Micol*; *Morpan CHSA*; *Morphans*; *Quammonium*; *Sucticide*.

3 Chemical Name and CAS Registry Number

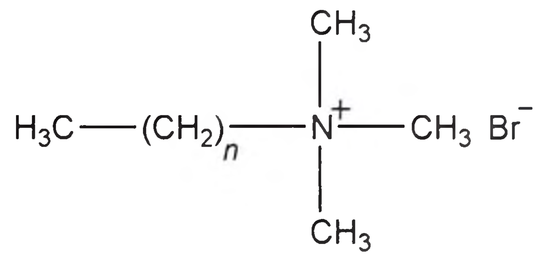
Cetrimide [8044-71-1]

Note that the above name, CAS Registry Number, and synonyms refer to the PhEur 9.2 material which, although it consists predominantly of trimethyltetradecylammonium bromide, may also contain smaller amounts of other bromides; *see* Section 4.

There is some confusion in the literature regarding the synonyms, CAS Registry Number, and molecular weight applied to cetrimide. Chemical Abstracts has assigned [8044-71-1] to cetrimide and describes that material as a mixture of alkyltrimethylammonium bromides of different alkyl chain lengths. Different CAS Registry Numbers have been assigned to the individual pure components. While these numbers should not be interchanged, it is common to find the molecular weight and CAS Registry Number of trimethyltetradecylammonium bromide [1119-97-7] used for cetrimide, as this is the principal component, defined in both the BP 2017 and PhEur 9.2. It should be noted however, that the original BP 1953 described the principal component of cetrimide as hexadecyltrimethylammonium bromide.

The CAS Registry Number for hexadecyltrimethylammonium hydroxide [505-86-2] has also been widely applied to cetrimide. Therefore, careful inspection of experimental details and suppliers' specifications in the literature is encouraged to determine the specific nature of the 'cetrimide' material used in individual studies.

See Section 17 for further information.



4 Empirical Formula and Molecular Weight

Cetrimide consists mainly of trimethyltetradecylammonium bromide ($C_{17}H_{38}BrN$), and may contain smaller amounts of dodecyltrimethylammonium bromide ($C_{15}H_{34}BrN$) and hexadecyltrimethylammonium (cetrimonium) bromide ($C_{19}H_{42}BrN$).

$C_{17}H_{38}BrN$ 336.40

See also Section 17.

5 Structural Formula

where
n = 11 for dodecyltrimethylammonium bromide
n = 13 for trimethyltetradecylammonium bromide
n = 15 for hexadecyltrimethylammonium (cetrimonium) bromide

6 Functional Category

Antimicrobial preservative; cationic surfactant.

7 Applications in Pharmaceutical Formulation or Technology

Cetrimide occurs as a quaternary ammonium compound that is used in cosmetics and pharmaceutical formulations as an antimicrobial preservative; *see* Section 10. It may also be used as a cationic surfactant. In eye-drops, it is used as a preservative at a concentration of 0.005% w/v.

Cetrimide is also used as a cleanser and disinfectant for hard contact lenses, although it should not be used on soft lenses. It is an ingredient of cetrimide emulsifying wax, and is used in o/w creams (e.g. cetrimide cream) and emulsions.[1]

8 Description

Cetrimide is a white to creamy white, free-flowing powder, with a faint but characteristic odor and a bitter, soapy taste.

9 Pharmacopeial Specifications

See Table I.

10 Typical Properties

Acidity/alkalinity pH = 5.0–7.5 (1% w/v aqueous solution)
Antimicrobial activity Cetrimide has good bactericidal activity against Gram-positive species but is less active against Gram-negative species. *Pseudomonas* species, particularly *Pseudomo-*

Table I: Pharmacopeial specifications for cetrimide.

Test	PhEur 9.2
Identification	+
Characters	+
Acidity or alkalinity	+
Appearance of solution	+
Amines and amine salts	+
Loss on drying	≤2.0%
Sulfated ash	≤0.5%
Assay (as $C_{17}H_{38}BrN$, dried basis)	96.0–101.0%

nas aeruginosa, may exhibit resistance. Cetrimide is most effective at neutral or slightly alkaline pH values, with activity appreciably reduced in acidic media and in the presence of organic matter. The activity of cetrimide is enhanced in the presence of alcohols.

The antibacterial effectiveness of cetrimide against *Enterococcus faecalis* biofilms is comparable to that of chlorhexidine. However, the effectiveness of cetrimide may depend on its concentration and the duration of application, and its association with antiseptic agents.[2,3]

The activity of cetrimide against resistant strains of *Pseudomonas aeruginosa*, *Aspergillus niger*, and *Candida albicans* is significantly increased by the addition of edetic acid.[4] The combination of maleic acid with cetrimide has been shown to be significantly more effective in increasing activity against *E. faecalis* biofilm than combinations of cetrimide with edectic acid or citric acid.[5]

Cetrimide has variable antifungal activity,[6,7] is effective against some viruses, and is inactive against bacterial spores.

Typical minimum inhibitory concentrations (MICs) are shown in Table II.

Table II: Minimum inhibitory concentrations (MIC) of cetrimide.

Microorganism	MIC (μg/mL)
Escherichia coli	30
Pseudomonas aeruginosa	300
Staphylococcus aureus	10
Camphylobacter jejuni	8[8]
Staphylococcus aureus (NCTC-8325-4)	0.25[9]
Staphylococcus aureus (SH1000)	0.63[10]
Pseudomonas aeruginosa (PAO1 (ATCC 15692))	36[11]
Streptococcus pneumoniae R919	1.0[12]

Critical micelle concentration 3.08 mmol/kg[13] (in water)

Melting point 232–247°C

Moisture content At 40–50% relative humidity and 20°C, cetrimide absorbs sufficient moisture to cause caking and retard flow properties.

Partition coefficients

Liquid paraffin : water = <1;

Vegetable oil : water = <1.

Solubility Freely soluble in chloroform, ethanol (95%), and water; practically insoluble in ether. A 2% w/v aqueous solution foams strongly on shaking.

Spectroscopy

IR spectrum *see* Figure 1.

NIR spectrum *see* Figure 2.

Raman spectrum *see* Figure 3.

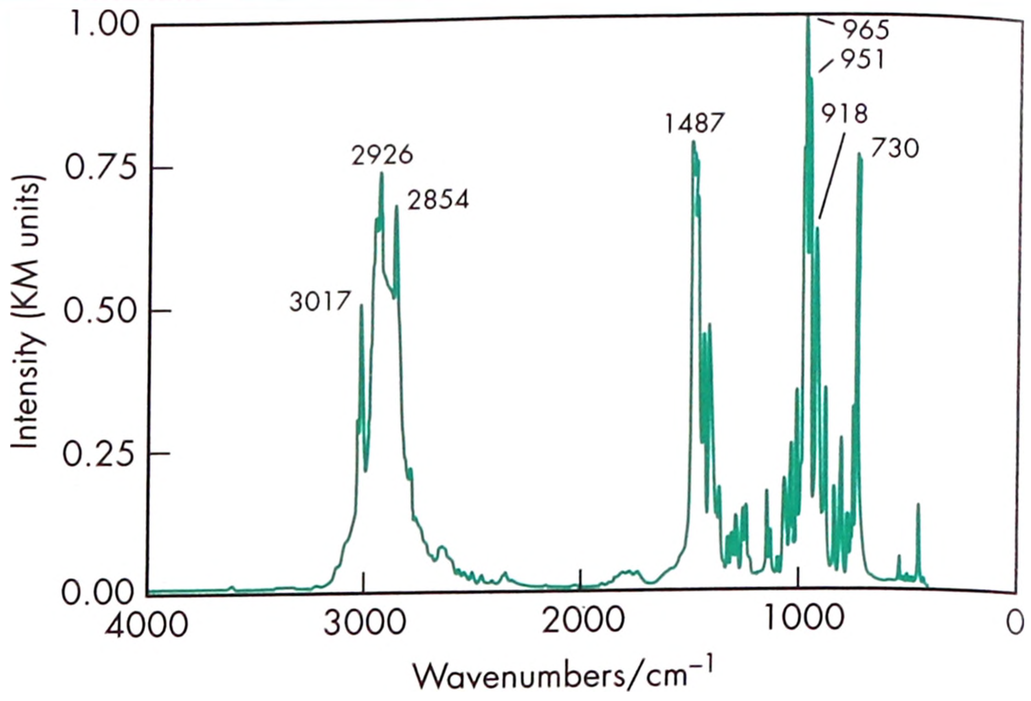


Figure 1: Infrared spectrum of cetrimide measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

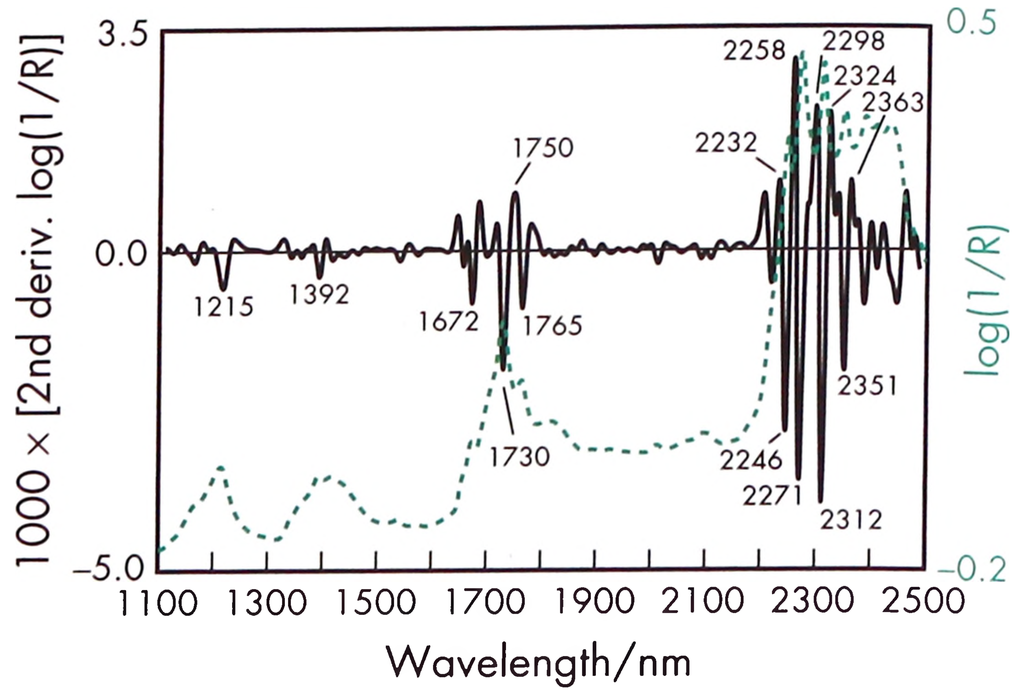

Figure 2: Near-infrared spectrum of cetrimide measured by reflectance.

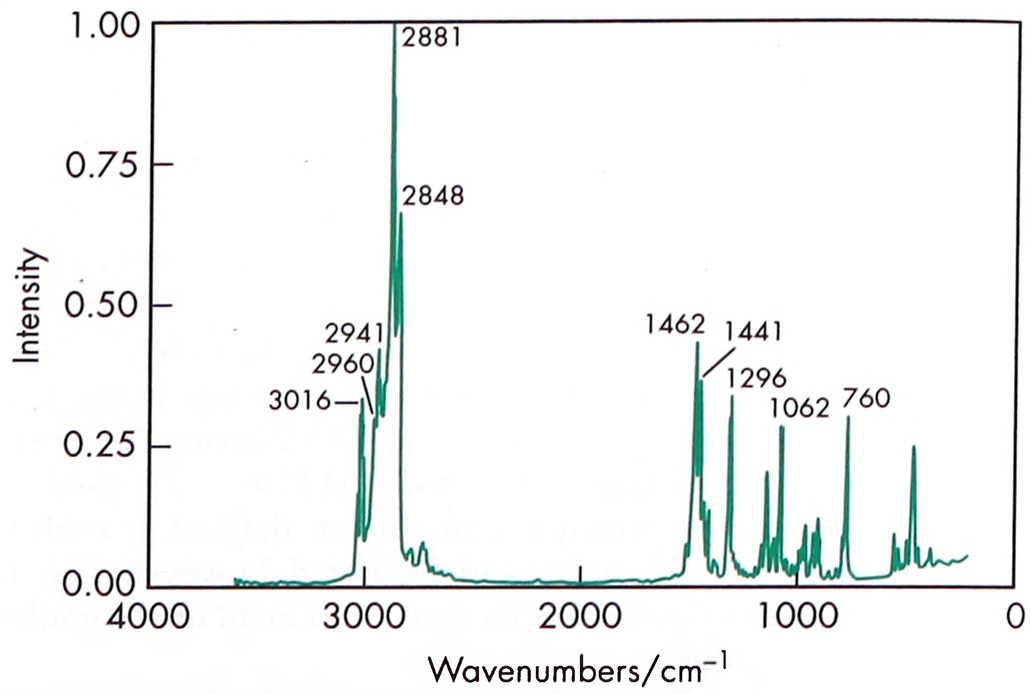

Figure 3: Raman spectrum of cetrimide measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

11 Stability and Storage Conditions

Cetrimide is chemically stable in the dry state, and also in aqueous solution at ambient temperatures. Aqueous solutions may be sterilized by autoclaving. Water containing metal ions and organic matter may reduce the antimicrobial activity of cetrimide.

The bulk material should be stored in a well-closed container in a cool, dry place.

12 Incompatibilities

Incompatible with soaps, anionic surfactants, high concentrations of nonionic surfactants, bentonite, iodine, phenylmercuric nitrate,

alkali hydroxides, and acid dyes. Aqueous solutions react with metals.

13 Method of Manufacture

Cetrimide is prepared by the condensation of suitable alkyl bromides and trimethylamine.

14 Safety

Most adverse effects reported relate to the therapeutic use of cetrimide. If ingested orally, cetrimide and other quaternary ammonium compounds can cause nausea, vomiting, muscle paralysis, CNS depression, and hypotension; concentrated solutions may cause esophageal damage and necrosis. The fatal oral human dose is estimated to be 1.0–3.0 g.[14]

At the concentrations used topically, solutions do not generally cause irritation, although concentrated solutions have occasionally been reported to cause burns. Cases of hypersensitivity have been reported following repeated application.[15,16]

Adverse effects that have been reported following irrigation of hydatid cysts with cetrimide solution include chemical peritonitis,[17] and methemoglobinemia with cyanosis.[18]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Cetrimide powder and concentrated cetrimide solutions are irritant; avoid inhalation, ingestion, and skin and eye contact. Eye protection, gloves, and a respirator are recommended.[19]

16 Regulatory Status

Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

Cetrimide is on the list of 'Existing Active Substances' on the market in the Europe, and is registered according to REACH regulation.[20] Cetrimide is not present in any approved product in the US.

17 Related Substances

Benzalkonium chloride; benzethonium chloride; dodecyltrimethylammonium bromide; cetrimonium bromide; trimethyltetradecylammonium bromide.

Dodecyltrimethylammonium bromide

Empirical formula $C_{15}H_{34}BrN$
Molecular weight 308.35
CAS number [1119-94-4]
Synonyms DTAB; *N*-lauryl-*N*,*N*,*N*-trimethylammonium bromide; *N*,*N*,*N*-trimethyldodecylammonium bromide.
Safety

LD_{50} (mouse, IV): 5.2 mg/kg[21]

LD_{50} (rat, IV): 6.8 mg/kg

Trimethyltetradecylammonium bromide

Empirical formula $C_{17}H_{38}BrN$
Molecular weight 336.40
CAS number [1119-97-7]
Synonyms Myristyltrimethylammonium bromide; tetradecyltrimethylammonium bromide; *N*,*N*,*N*-trimethyl-1-tetradecanaminium bromide.
Safety

LD_{50} (mouse, IV): 12 mg/kg[22]

LD_{50} (rat, IV): 15 mg/kg

18 Comments

The BP 2017 also includes cetrimide solution and strong cetrimide solution.

Therapeutically, cetrimide is used in relatively high concentrations, generally as 0.1–1.0% w/v aqueous solutions, cream or spray as a topical antiseptic for skin, burns, and wounds.[23] Solutions containing up to 10% w/v cetrimide are used as shampoos to remove the scales in seborrheic dermatitis.

As a precaution against contamination with *Pseudomonas* species resistant to cetrimide, stock solutions may be further protected by adding at least 7% v/v ethanol or 4% v/v propan-2-ol.

The EINECS number for cetrimide is 214-291-9. The PubChem Compound ID (CID) for cetrimide includes 68166 (trimethylhexadecylammonium hydroxide) and 14250 (trimethyltetradecylammonium bromide).

Antimicrobial preservative; cationic surfactant.

7 Applications in Pharmaceutical Formulation or Technology

Cetrimonium bromide is a cationic quaternary ammonium compound used as an antimicrobial preservative and cationic surfactant in topical pharmaceutical preparations.[1–4] It has also been used in suppository formulations,[5] and in microemulsions or nanoparticles for controlled drug delivery.[6–12]

Cetrimonium bromide has been investigated in the synthesis of gold nanoparticles for the detection and treatment of cancers by controlled drug release.[13]

8 Description

Cetrimonium bromide occurs as a white powder or crystals, with a characteristic faint odor.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for cetrimonium bromide.

Test	USP 40–NF 35 S1
Identification	+
Acidity or alkalinity	+
Appearance of solution	+
Amines and amine salts	+
Loss on drying	≤2.0%
Residue on ignition	≤0.5%
Microbial limits	
Aerobic microbial count	$\leq 10^3$ cfu/g
Yeasts and molds	≤10 cfu/g
Assay (as $C_{17}H_{38}BrN$, dried basis)	96.0–101.0%

10 Typical Properties

Acidity/alkalinity pH = 5.0–7.0 for a 3.64% w/v aqueous solution at 25°C

Antimicrobial activity Cetrimonium bromide is active at alkaline pH against both Gram-positive and Gram-negative organisms.[14] Its activity is neutralized by soaps and anionic detergents, such as sodium dodecyl sulfate (SDS). Typical minimum inhibitory concentrations (MICs) are shown in Table II.[1]

Critical micelle concentration (CMC) 0.92 to 1.0 mM (water)[15]

Decomposition temperature 237°C; >230°C for *RonaCare*
Flash point 244°C (closed cup)
Melting point 237–243°C; also reported as 248–251°C[16]
Partition coefficient Log *P* (octanol : water) = 3.18
Vapor density (relative) 13 (air = 1)
Solubility Freely soluble in ethanol (95%); soluble 1 in 10 parts of water; sparingly soluble in acetone; practically insoluble in ether and benzene.

Table II: Minimum inhibitory concentrations (MIC) of cetrimonium bromide.[1]

Microorganism	MIC (μg/mL)
Staphylococcus aureus (CIP 53154)	1
Escherichia coli (CIP 54127)	8

11 Stability and Storage Conditions

Cetrimonium bromide is a hygroscopic material but is stable under recommended storage conditions. It is stable in acid solution.

Keep in tightly closed containers in a cool, dry, and well-ventilated place. Keep away from sources of heat, ignition, or flame.

12 Incompatibilities

Cetrimonium bromide is incompatible with strong oxidizing agents.

13 Method of Manufacture

Cetrimonium bromide is prepared from cetyl bromide and trimethylamine.[17]

14 Safety

Cetrimonium bromide is used in topical pharmaceutical preparations, and is generally considered safe for its intended use as an excipient. The Cosmetic Ingredient Review (CIR) Expert Panel have assessed cetrimonium bromide and concluded that the material is safe as used in cosmetics and personal care products.[18,19]

Acute exposure to cetrimonium bromide can cause serious eye damage, and is harmful if swallowed. Large systemic doses may cause nausea, vomiting, muscle paralysis, CNS depression, hypotension, and local tissue damage.[20] Cetrimonium bromide may also cause skin[21,22] and respiratory tract irritation.

Metabolic acidosis following irrigation with cetrimonium bromide solutions in the treatment of hydatid cysts has also been reported.[23,24]

LD_{50} (guinea pig, SC): 0.1 g/kg[25]
LD_{50} (mouse, IP): 0.106 g/kg[25]
LD_{50} (mouse, IV): 0.032 g/kg[25]
LD_{50} (rabbit, IP): 0.125 g/kg[25]
LD_{50} (rabbit, SC): 0.125 g/kg[25]
LD_{50} (rat, IV): 0.044 g/kg[25]
LD_{50} (rat, oral): 0.410 g/kg[25]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled.

When heated to decomposition, cetrimonium bromide emits very toxic fumes of ammonia, nitrous vapors, hydrogen bromide, carbon monoxide, and carbon dioxide.

Avoid contact with skin and eyes. Avoid inhalation and ensure adequate ventilation. Wear suitable protective equipment and clothing.

16 Regulatory Status

Included in the Canadian Natural Health Products Ingredients Database. Included in the 'List of Preservatives allowed in Cosmetic Products' in Europe at a maximum concentration of 0.1% in ready-to-use preparations. Cetrimonium bromide is not present in any approved product in the US.

Included in the list of possible trace compounds used in the manufacturing process for influenza vaccines in the UK.

17 Related Substances

Cetrimide; cetrimonium chloride; cetrimonium tosylate; benzalkonium chloride; benzethonium chloride.

Cetrimonium chloride

Empirical formula $C_{19}H_{42}ClN$
Molecular weight 320.01
CAS number [112-02-7]
Synonyms *Arquad*; cetyl trimethyl ammonium chloride; *Daistat CM*; hexadecyltrimethyl ammonium chloride; *Nissan Cation*; palmityltrimethylammonium chloride; *N,N,N*-trimethyl-1-hexadecanaminium chloride.
Comments A cationic quaternary ammonium compound used as an antimicrobial preservative and surfactant in pharmaceutical and cosmetic preparations. Included in the FDA Inactive Ingredients Database (topical lotions). Included in the Canadian Natural Health Products Ingredients Database. The EINECS number for cetrimonium chloride is 203-928-6.

Cetrimonium tosylate

Empirical formula $C_{26}H_{49}NO_3S$
Molecular weight 455.74
CAS number [138-32-9]
Synonyms Cetats; cetyltrimethylammonium *p*-toluenesulfonate; hexadecyltrimethylammonium *p*-toluenesulfonate; *N,N,N*-trimethyl-1-hexadecanaminium salt with 4-methylbenzenesulfonic acid.
Comments A cationic quaternary ammonium compound used as an antimicrobial preservative and surfactant in pharmaceutical and cosmetic preparations. The EINECS number for cetrimonium tosylate is 205-324-8.

18 Comments

The name cetrimonium bromide was formerly applied to cetrimide. The original cetrimide BP 1953 consisted largely of hexadecyltrimethylammonium bromide, with smaller amounts of analogous alkyltrimethylammonium bromides. It contained a considerable proportion of inorganic salts, chiefly sodium bromide, and was less soluble than the present product.

Therapeutically, cetrimonium bromide is used as a topical antiseptic in higher concentrations. It has also been used to lethally target cancer cells,[26] and to combat bacterial infection in biodegradable polymers for medical implantation devices.[27]

Cetrimonium bromide has been used as a cationic detergent in buffer solutions for the extraction of DNA,[28,29] and for the precipitation and quantification of capsular polysaccharides during the process development of multivalent vaccines.[30] It has also been used for the determination of protein molecular weights in electrophoretic systems and for the critical micelle concentration determination of detergents.[31–33]

Cetrimonium bromide is widely used in hair and skincare products in the cosmetics industry.

The EINECS number for cetrimonium bromide is 200-311-3. The PubChem Compound ID (CID) for cetrimonium bromide is 5974.

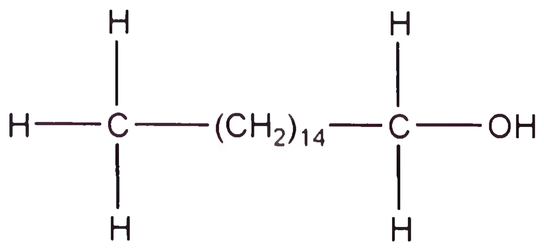
3 Chemical Name and CAS Registry Number

Hexadecan-1-ol [36653-82-4]



4 Empirical Formula and Molecular Weight

$C_{16}H_{34}O$ 242.44 (for pure material)

Cetyl alcohol, used in pharmaceutical preparations, is a mixture of solid aliphatic alcohols comprising mainly 1-hexadecanol ($C_{16}H_{34}O$). The USP 40–NF 35 S1 specifies not less than 90.0% of cetyl alcohol, the remainder consisting chiefly of related alcohols.

Commercially, many grades of cetyl alcohol are available as mixtures of cetyl alcohol (60–70%) and stearyl alcohol (20–30%), the remainder being related alcohols.

5 Structural Formula

6 Functional Category

Coating agent; emollient; emulsifying agent; stiffening agent.

7 Applications in Pharmaceutical Formulation or Technology

Cetyl alcohol is widely used in cosmetics and pharmaceutical formulations such as suppositories, modified-release solid dosage forms, emulsions, lotions, creams, and ointments.

In suppositories cetyl alcohol is used to raise the melting point of the base, and in modified-release dosage forms it may be used to form a permeable barrier coating. In lotions, creams, and ointments cetyl alcohol is used because of its emollient, water-absorptive, and emulsifying properties. It enhances stability, improves texture, and increases consistency. The emollient properties are due to absorption and retention of cetyl alcohol in the epidermis, where it lubricates and softens the skin while imparting a characteristic 'velvety' texture.

Cetyl alcohol is also used for its water absorption properties in water-in-oil emulsions. For example, a mixture of petrolatum and cetyl alcohol (19:1) will absorb 40–50% of its weight of water. Cetyl alcohol acts as a weak emulsifier of the water-in-oil type, thus allowing a reduction of the quantity of other emulsifying agents used in a formulation. Cetyl alcohol has also been reported to increase the consistency of water-in-oil emulsions.

In oil-in-water emulsions, cetyl alcohol is reported to improve stability by combining with the water-soluble emulsifying agent. The combined mixed emulsifier produces a close packed, monomolecular barrier at the oil–water interface which forms a mechanical barrier against droplet coalescence.

In semisolid emulsions, excess cetyl alcohol combines with the aqueous emulsifier solution to form a viscoelastic continuous phase that imparts semisolid properties to the emulsion and also prevents droplet coalescence. Therefore, cetyl alcohol is sometimes referred to as a 'consistency improver' or a 'bodying agent', although it may be necessary to mix cetyl alcohol with a hydrophilic emulsifier to impart this property.

It should be noted that pure or pharmacopeial grades of cetyl alcohol may not form stable semisolid emulsions and may not show the same physical properties as grades of cetyl alcohol that contain significant amounts of other similar alcohols. *See* Section 4.

See Table I.

Table I: Uses of cetyl alcohol.

Use	Concentration (%)
Emollient	2–5
Emulsifying agent	2–5
Stiffening agent	2–10
Water absorption	5

8 Description

Cetyl alcohol occurs as waxy, white flakes, granules, cubes, or castings. It has a faint characteristic odor and bland taste.

9 Pharmacopeial Specifications

See Table II.

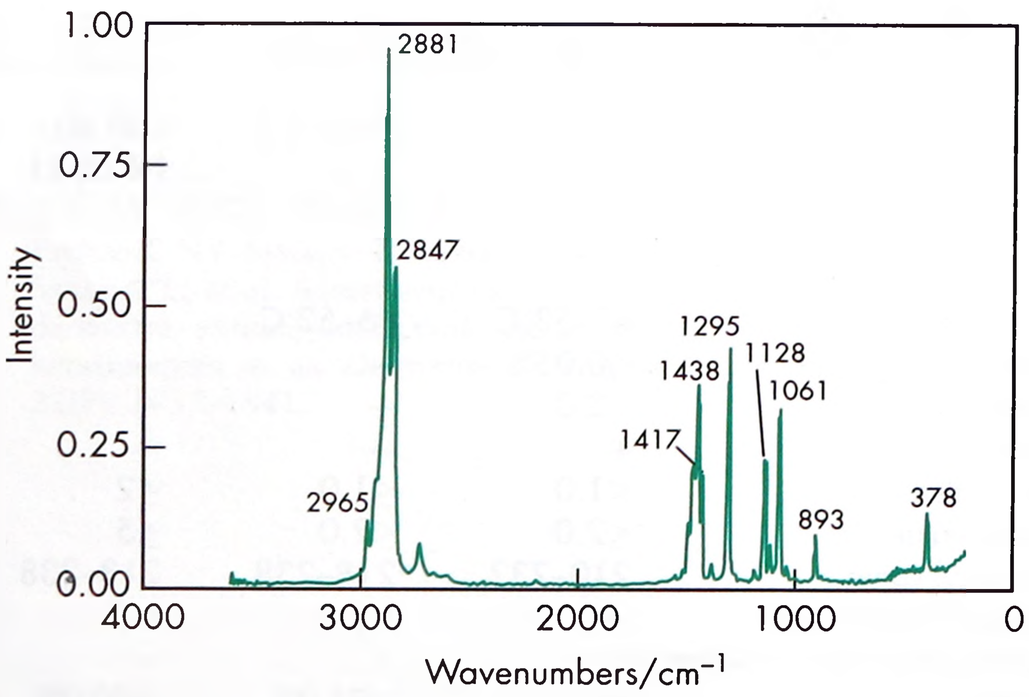

Figure 2: Raman spectrum of cetyl alcohol measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

11 Stability and Storage Conditions

Cetyl alcohol is stable in the presence of acids, alkalis, light, and air; it does not become rancid. It should be stored in a well-closed container in a cool, dry place.

12 Incompatibilities

Incompatible with strong oxidizing agents. Cetyl alcohol is responsible for lowering the melting point of ibuprofen, which results in sticking tendencies during the process of film coating ibuprofen crystals.[1]

13 Method of Manufacture

Cetyl alcohol may be manufactured by a number of methods such as esterification and hydrogenolysis of fatty acids or by catalytic hydrogenation of the triglycerides obtained from coconut oil or tallow. Cetyl alcohol may be purified by crystallization and distillation.

14 Safety

Cetyl alcohol is mainly used in topical formulations, although it has also been used in oral and rectal preparations.

Cetyl alcohol has been associated with allergic delayed-type hypersensitivity reactions in patients with stasis dermatitis.[2] Cross-sensitization with cetostearyl alcohol, lanolin, and stearyl alcohol has also been reported.[3,4] It has been suggested that hypersensitivity may be caused by impurities in commercial grades of cetyl alcohol since highly refined cetyl alcohol (99.5%) has not been associated with hypersensitivity reactions.[5]

LD_{50} (mouse, IP): 1.6 g/kg[6]

LD_{50} (mouse, oral): 3.2 g/kg

LD_{50} (rat, IP): 1.6 g/kg

LD_{50} (rat, oral): 5 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Eye protection and gloves are recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (ophthalmic preparations, oral capsules and tablets, otic and rectal preparations, topical aerosols, creams, emulsions, ointments and solutions, and vaginal preparations). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Cetostearyl alcohol; stearyl alcohol.

18 Comments

The EINECS number for cetyl alcohol is 253-149-0. The PubChem Compound ID (CID) for cetyl alcohol is 2682.

Cetyl Palmitate

1 Nonproprietary Names

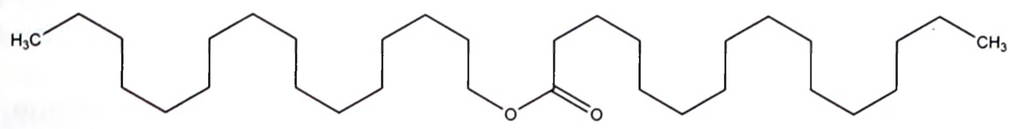
BP: Cetyl Palmitate

PhEur: Cetyl Palmitate

USP–NF: Cetyl Palmitate

2 Synonyms

Cetaceum; cetyl esters wax; cetylis palmitas; *Crodamol CP*; *DUBCARE PC*; *Dynacerin CP*; *Estol 3694*; *Hallstar 653*; hexadecanoic acid hexadecyl ester; hexadecyl palmitate; N-hexadecyl palmitate; *Kessco CP*; *Palmil C*; palmitic acid N-hexadecyl ester; palmityl palmitate; *Pelemol CP*; *Sabowax CP*; spermaceti (synthetic); *Stepan 653*.



3 Chemical Name and CAS Registry Number

Hexadecyl hexadecanoate [540-10-3]

4 Empirical Formula and Molecular Weight

$C_{32}H_{64}O_2$ 480.87

5 Structural Formula

6 Functional Category

Emollient; emulsifying agent; emulsion stabilizing agent; stiffening agent; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Cetyl palmitate is used as an emollient for topical products. It is also used as an emulsion stabilizing agent in shampoos, and as an emulsifying agent and viscosity-increasing agent in various lotions and creams. It also helps add texture and body to various personal care and cosmetic products, including sunscreens and anti-aging treatments.

8 Description

The USP 40–NF 35 S1 describes cetyl palmitate as consisting of esters of cetyl alcohol and saturated high-molecular-weight fatty acids, principally palmitic acid. The PhEur 9.2 describes cetyl palmitate as a mixture of esters of C_{14}–C_{18} alcohols with lauric (dodecanoic), myristic (tetradecanoic), palmitic (hexadecanoic), and stearic (octadecanoic) acids ('cetyl esters wax').

Cetyl palmitate occurs as white or almost white waxy plates, flakes, or powder.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for cetyl palmitate.

Test	PhEur 9.2	USP 40–NF 35 S1
Characters	+	–
Identification	+	+

Water	≤0.3%	–
Assay	+	+

10 Typical Properties

Boiling point 360–534°C[1–3]
Density 0.989 g/cm^3 [2,3]
Flash point >238°C for *Hallstar 653* (closed cup);[4] 269.8°C[1]
Iodine value 0.5 for *Hallstar 653*[4]
Melting point 43–56°C;
approx. 50°C for *Pelemol CP*;[5]
53°C for *Hallstar 653*.[4]
Refractive index 1.4425 (at 49.8°C)[2]
Solubility Soluble in boiling anhydrous ethanol and in methylene chloride; slightly soluble in light petroleum; practically insoluble in anhydrous ethanol and in water.
Vapor pressure <0.1 at 20°C for *Pelemol C*[5]

11 Stability and Storage Conditions

Cetyl palmitate should be stored in tightly closed containers in a cool, dry place away from direct sunlight and odors. Avoid exposure to excessive heat.

12 Incompatibilities

Cetyl palmitate is incompatible with strong oxidizing agents.

13 Method of Manufacture

Cetyl palmitate is an ester produced from the reaction of cetyl alcohol and palmitic acid, a naturally occurring fatty acid found in both plants and animals. If manufactured from plants, cetyl esters may be used in cosmetics and personal care products marketed in Europe according to the general provisions of the Cosmetics Directive of the European Union.[6] If components of cetyl esters are manufactured from animal sources, they must comply with the EU's animal by-products regulations.

Cetyl palmitate also occurs naturally as a chief constituent of spermaceti (wax derived from sperm whale oil). In the past, spermaceti was extracted from sperm whale oil under pressure using a solution of caustic alkali, followed by crystallization at 6°C. However, the Endangered Species Act of 1973 in the US outlawed the killing of whales and the use of materials derived from those animals.

14 Safety

Cetyl palmitate is a wax ester of palmitic acid widely used in cosmetic and personal care products. The Cosmetic Ingredient Review (CIR) Expert Panel reviewed the safety of this ingredient and assessed it as nontoxic and nonsensitizing, deeming it safe for use in cosmetic formulations in the present practices of use and concentration.[7]

It is slightly irritating to eyes and skin. While some palmitates have been reported to cause contact dermatitis, human skin tests of moisturizers containing between 2.5% and 2.7% of cetyl palmitate were found to be minimally irritating to the skin and showed no systemic toxicity or photosensitization. May cause irritation of the respiratory tract and digestive tract.

LD_{50} (oral, rat): >14.4 g/kg[7]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. Cetyl palmitate may be combustible at high temperatures. Protective clothing, gloves, and safety goggles are recommended. Wear suitable respiratory equipment.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (topical creams, ointments, emulsions, and solutions; vaginal emulsions and creams). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Cetostearyl alcohol.

18 Comments

Cetyl palmitate has recently been used in the development of several new drug delivery systems such as nanostructured lipid carriers (NLC) and solid lipid nanoparticles (SLN). A NLC containing the endogenous cellular antioxidant coenzyme Q_{10} has been evaluated[8] and SLN formulations containing both nitrendipine[9] and insulin[10] have been shown to have superior properties in terms of stability[9] and bioavailability[10] compared with conventional formulations. An SLN dispersion prepared using 10% cetyl palmitate, 1.5% sucrose stearate, and 88.5% water incorporated into a cream has been shown to exhibit increased skin hydration.[11]

Cetyl palmitate is a cetylated fatty acid and it has been used in combination with other members of this class of chemical compounds (i.e. cetyl myristoleate) in the formulation of topical creams for the treatment of rheumatoid arthritis, osteoarthritis, fibromyalgia, and a variety of other syndromes.[12,13] Cetylated fatty acids may also be an alternative to the use of nonsteroidal anti-inflammatory drugs for the treatment of osteoarthritis.[14]

A botanical alternative to spermaceti wax is a derivative of jojoba oil, namely jojoba esters.

A specification for cetyl palmitate is included in the *Japanese Pharmaceutical Excipients* (JPE).[15]

The EINECS number for cetyl palmitate is 208-736-6. The PubChem Compound ID (CID) for cetyl palmitate is 10889.

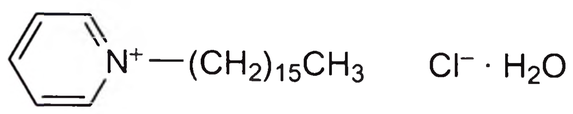
Cetylpyridinium Chloride

1 Nonproprietary Names

BP: Cetylpyridinium Chloride
PhEur: Cetylpyridinium Chloride
USP–NF: Cetylpyridinium Chloride

2 Synonyms

C16-alkylpyridinium chloride; *Cepacol*; *Cepacol Chloride*; *Cetamiun*; cetylpridinii chloridum; cetyl pyridium chloride; *Dobendan*; hexadecylpyridinium chloride; 1-hexadecylpyridinium chloride; *Medilave*; *Pristacin*; *Pyrisept*.



3 Chemical Name and CAS Registry Number

1-Hexadecylpyridinium chloride [123-03-5]
1-Hexadecylpyridinium chloride monohydrate [6004-24-6]

4 Empirical Formula and Molecular Weight

$C_{21}H_{38}ClN$ 339.9 (for anhydrous)
$C_{21}H_{38}ClN{\cdot}H_2O$ 358.1 (for monohydrate)

5 Structural Formula

6 Functional Category

Antimicrobial preservative; cationic surfactant; penetration enhancer; solubilizing agent.

7 Applications in Pharmaceutical Formulation or Technology

Cetylpyridinium chloride is a quaternary ammonium cationic surfactant, used in pharmaceutical and cosmetic formulations as an antimicrobial preservative; *see* Section 10.

Cetylpyridinium chloride is used in nonparenteral formulations licensed in the UK, and in oral and inhalation preparations at concentrations of 0.04–1.5 mg (*see* Section 16).

Cetylpyridinium chloride is also used in transdermal drug delivery preparations, and has been shown to enhance the topical penetration of meloxicam[1] and doxorubicin.[2]

8 Description

Cetylypyridinium chloride is a white powder with a characteristic odor, and is slightly soapy to the touch.

9 Pharmacopeial Specifications

See Table I.

10 Typical Properties

Antibacterial activity Bactericidal to Gram-positive bacteria; relatively ineffective against some Gram-negative bacteria.[3] Cetylpyridinium chloride is also antibacterial against a number of oral bacteria;[4] *see* Table II.[5]

Critical micelle concentration 0.034% w/v aqueous solution (25°C).[6,7]

Melting point 77–83°C

Table I: Pharmacopeial specifications for cetylpyridinium chloride.

Raman spectrum *see* Figure 2.

11 Stability and Storage Conditions

Cetylpyridinium chloride is stable under normal conditions. It should be stored in well-closed containers.

12 Incompatibilities

Cetylpyridinium chloride is incompatible with strong oxidizing agents and bases. It is also incompatible with methylcellulose.

Magnesium stearate suspensions in cetylpyridinium chloride have been shown to significantly reduce its antimicrobial activity. This is due to the absorption of cetylpyridinium chloride on magnesium stearate.[8] The cetylpyridinium chloride ion also interacts with gelatin, resulting in reduced bioavailability.[9]

13 Method of Manufacture

Cetylpyridinium chloride is prepared from cetyl chloride by treatment with pyridine.

14 Safety

Cetylpyridinium chloride is used widely in mouthwashes as a bactericidal antiseptic. It is generally regarded as a relatively nontoxic material when used at a concentration of 0.05% w/v, although minor adverse effects such as mild burning sensations on the tongue have been reported.[10]

At higher concentrations, cetylpyridinium chloride may damage the mucous membranes in the mouth. It is harmful when ingested or

inhaled. It can cause eye irritation, and is irritant to the respiratory system and the skin.

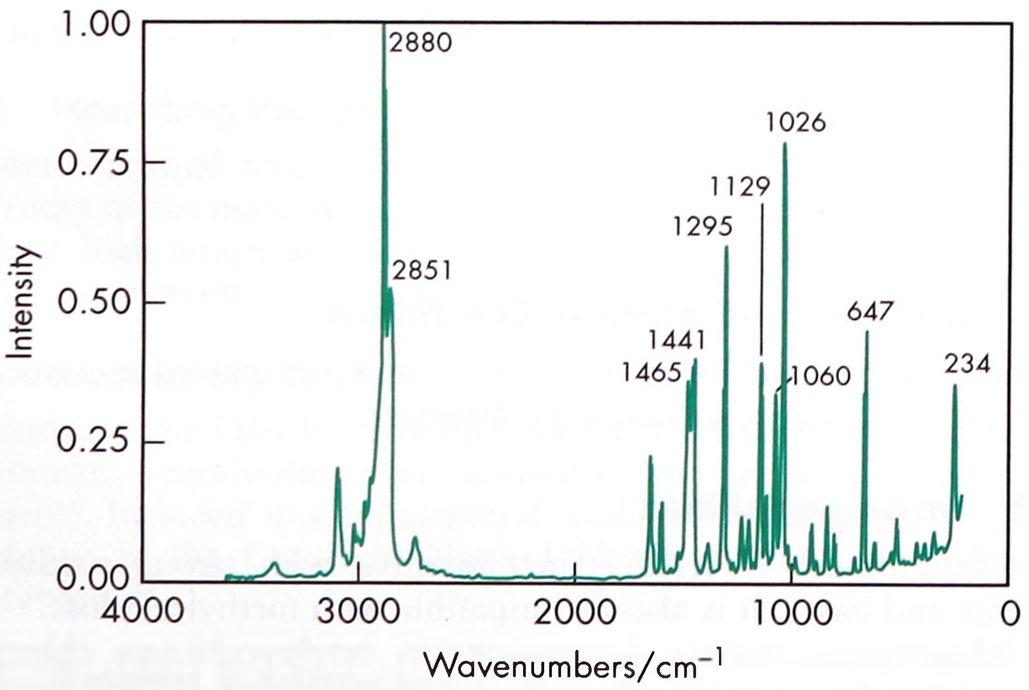

Figure 2: Raman spectrum of cetylpyridinium chloride (anhydrous) measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. When significant quantities are being handled, the use of a respirator with an appropriate gas filter is advised. When heated to decomposition, cetylpyridinium chloride emits very toxic fumes of nitrogen oxides (NO_x) and chlorides (Cl^-). Eye protection, gloves and adequate ventilation are recommended.

16 Regulatory Status

Included in nonparenteral formulations licensed in the UK. Included in the FDA Inactive Ingredients Database (inhalation, oral, and transdermal preparations). Reported in the EPA TSCA Inventory. It is not approved for use in Japan. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Cetylpyridinium bromide.

Cetylpyridinium bromide

Empirical formula $C_{21}H_{38}BrN$
Molecular weight 384.51
CAS number [140-72-7]
Synonyms *Aceloquat CPB*; *Bromocet*; *Cetapharm*; *Cetasol*; *N*-cetylpyridinium bromide; hexadexylpyridinium bromide; *Nitrogenol*; *Seprison*; *Sterogenol*.
Melting point 63°C
Comments When heated to decomposition it emits toxic vapors of nitrogen oxides (NO_x) and bromides (Br^-).

18 Comments

Cetylpyridinium chloride has been investigated for use as a surfactant in suppository preparations at a concentration of 0.5% w/v.[12]

Cetylpyridinium chloride is used therapeutically as an antiseptic agent. It has been studied for use as an antimicrobial preservative for meat[13] and vegetables.[14] However, the residual levels after treatment are considered excessive for human consumption; *see* Section 14.

Cetylpyridinium chloride is used alone or in combination with other drugs for oral and throat care. Mouthwashes containing cetylpyridinium chloride have been shown to inhibit plaque formation,[15,16] although efficacy is variable owing to limited published data.[17,18]

The EINECS number for cetylpyridinium chloride is 204-593-9. The PubChem Compound ID (CID) for cetylpyridinium chloride monohydrate is 22324.

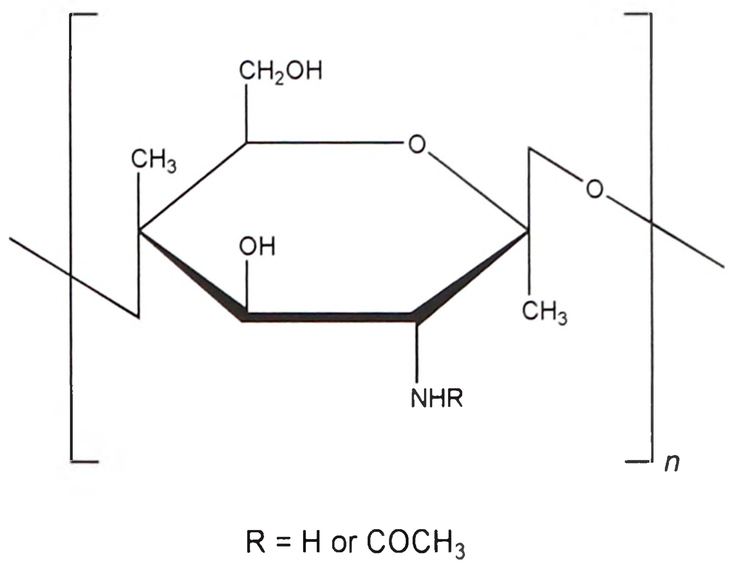
Chitosan

1 Nonproprietary Names

BP: Chitosan Hydrochloride
PhEur: Chitosan Hydrochloride
USP–NF: Chitosan

2 Synonyms

2-Amino-2-deoxy-(1,4)-β-D-glucopyranan; *Chitopharm*; chitosani hydrochloridum; deacetylated chitin; deacetylchitin; β-1,4-poly-D-glucosamine; poly-D-glucosamine; poly-(1,4-β-D-glucopyranosamine); *Protasan*; *Protasan UP CL 113*.



3 Chemical Name and CAS Registry Number

Poly-β-(1,4)-2-amino-2-deoxy-D-glucose [9012-76-4]

4 Empirical Formula and Molecular Weight

Partial deacetylation of chitin results in the production of chitosan, which is a polysaccharide comprising copolymers of glucosamine and *N*-acetylglucosamine. Chitosan is the term applied to deacetylated chitins in various stages of deacetylation and depolymerization and it is therefore not easily defined in terms of its exact chemical composition. A clear nomenclature with respect to the different degrees of *N*-deacetylation between chitin and chitosan has not been defined,[1–3] and as such chitosan is not one chemical entity but varies in composition depending on the manufacturer. In essence, chitosan is chitin sufficiently deacetylated to form soluble amine salts. The degree of deacetylation necessary to obtain a soluble product must be greater than 80–85%. Chitosan is commercially available in several types and grades that vary in molecular weight by 10 000–1 000 000, and vary in degree of deacetylation and viscosity.[4]

5 Structural Formula

R = H or $COCH_3$

6 Functional Category

Coating agent; tablet and capsule disintegrant; bioadhesive material; film-forming agent; tablet and capsule binder; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Chitosan is used in cosmetics and is under investigation for use in a number of pharmaceutical formulations. The suitability and performance of chitosan as a component of pharmaceutical formulations for drug delivery applications has been investigated in numerous studies.[3,5–8] These include controlled drug delivery applications,[9–14] use as a component of mucoadhesive dosage forms,[14–16] rapid release dosage forms,[17,18] improved peptide delivery,[19,20] colonic drug delivery systems,[21,22] and use for gene delivery.[23] Chitosan has been processed into several pharmaceutical forms including gels,[24,25] films,[11,12,26,27] beads,[28,29] microspheres,[30,31] tablets,[32,33] and coatings for liposomes.[34] Furthermore, chitosan may be processed into drug delivery systems using several techniques including spray-drying,[15,16] coacervation,[35] direct compression,[32] and conventional granulation processes.[36]

8 Description

Chitosan occurs as odorless, white or creamy-white powder or flakes. Fiber formation is quite common during precipitation and the chitosan may look 'cottonlike'.

10 Typical Properties

Chitosan is a cationic polyamine with a high charge density at pH <6.5, and so adheres to negatively charged surfaces and chelates metal ions. It is a linear polyelectrolyte with reactive hydroxyl and amino groups (available for chemical reaction and salt formation).[7] The properties of chitosan relate to its polyelectrolyte and polymeric carbohydrate character. The presence of a number of amino groups allows chitosan to react chemically with anionic systems, which results in alteration of physicochemical characteristics of such combinations. The nitrogen in chitosan is mostly in the form of primary aliphatic amino groups. Chitosan therefore undergoes reactions typical of amines: for example, *N*-acylation and Schiff reactions.[3] Almost all functional properties of chitosan depend on the chain length, charge density, and charge distribution.[8] Numerous studies have demonstrated that the salt form, molecular weight, and degree of deacetylation as well as pH at which the chitosan is used all influence how this polymer is utilized in pharmaceutical applications.[7]

Acidity/alkalinity pH = 4.0–6.0 (1% w/v aqueous solution)

Density 1.35–1.40 g/cm^3

Glass transition temperature 203°C[37]

Moisture content Chitosan adsorbs moisture from the atmosphere, the amount of water adsorbed depending upon the initial moisture content and the temperature and relative humidity of the surrounding air.[38]

Particle size distribution <30 µm

Solubility Sparingly soluble in water; practically insoluble in ethanol (95%), other organic solvents, and neutral or alkali solutions at pH above approximately 6.5. Chitosan dissolves readily in dilute and concentrated solutions of most organic acids and to some extent in mineral inorganic acids (except phosphoric and sulfuric acids). Upon dissolution, amine groups of the polymer become protonated, resulting in a positively charged polysaccharide (RNH_3^+) and chitosan salts (chloride, glutamate, etc.) that are soluble in water; the solubility is affected by the degree of deacetylation.[7] Solubility is also greatly influenced by the addition of salt to the solution. The higher the ionic strength, the lower the solubility as a result of a salting-out effect, which leads to the precipitation of chitosan in solution.[39] When chitosan is in solution, the repulsions between the deacetylated units and their neighboring glucosamine units cause it to exist in an extended conformation. Addition of an electrolyte reduces this effect and the molecule possesses a more random, coil-like conformation.[40]

Viscosity (dynamic) A wide range of viscosity types is commercially available. Owing to its high molecular weight and linear, unbranched structure, chitosan is an excellent viscosity-enhancing agent in an acidic environment. It acts as a pseudo-plastic material, exhibiting a decrease in viscosity with increasing rates of shear.[7] The viscosity of chitosan solutions increases with increasing chitosan concentration, decreasing temperature, and increasing degree of deacetylation; *see* Table II.[40]

Table II: Typical viscosity (dynamic) values for chitosan 1% w/v solutions in different acids.[40]

Acid	1% acid concentration		5% acid concentration		10% acid concentration	
	Viscosity (mPa s)	pH	Viscosity (mPa s)	pH	Viscosity (mPa s)	pH
Acetic	260	4.1	260	3.3	260	2.9

Malic	180	3.3	205	2.3	220	2.1
Malonic	195	2.5	—	—	—	—
Oxalic	12	1.8	100	1.1	100	0.8
Tartaric	52	2.8	135	2.0	160	1.7

11 Stability and Storage Conditions

Chitosan powder is a stable material at room temperature, although it is hygroscopic after drying. Chitosan should be stored in a tightly closed container in a cool, dry place. The PhEur 9.2 specifies that chitosan should be stored at a temperature of 2–8°C, and be protected from moisture and light.

12 Incompatibilities

Chitosan is incompatible with strong oxidizing agents.

13 Method of Manufacture

Chitosan is manufactured commercially by chemically treating the shells of crustaceans such as shrimps and crabs. The basic manufacturing process involves the removal of proteins by treatment with alkali and of minerals, such as calcium carbonate and calcium phosphate, by treatment with acid.[3,40] Before these treatments, the shells are ground to make them more accessible.

The shells are initially deproteinized by treatment with an aqueous sodium hydroxide 3–5% solution. The resulting product is neutralized and calcium is removed by treatment with an aqueous hydrochloric acid 3–5% solution at room temperature to precipitate chitin. The chitin is dried so that it can be stored as a stable intermediate for deacetylation to chitosan at a later stage. *N*-Deacetylation of chitin is achieved by treatment with an aqueous sodium hydroxide 40–45% solution at elevated temperature (110°C), and the precipitate is washed with water. The crude sample is dissolved in acetic acid 2% and the insoluble material is removed. The resulting clear supernatant solution is neutralized with aqueous sodium hydroxide solution to give a purified white precipitate of chitosan. The product can then be further purified and ground to a fine uniform powder or granules.[1]

The animals from which chitosan is derived must fulfil the requirements for the health of animals suitable for human consumption to the satisfaction of the competent authority. The method of production must consider inactivation or removal of any contamination by viruses or other infectious agents.

14 Safety

Chitosan is being investigated widely for use as an excipient in oral and other pharmaceutical formulations. It is also used in cosmetics. Chitosan is generally regarded as a nontoxic and nonirritant material. It is biocompatible[41] with both healthy and infected skin.[42] Chitosan has been shown to be biodegradable.[3,41]

LD_{50} (mouse, oral): >16 g/kg[43]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Chitosan is combustible; open flames should be avoided. Chitosan is temperature-sensitive and should not be heated above 200°C. Airborne chitosan dust may explode in the presence of a source of ignition, depending on its moisture content and particle size. Water, dry chemicals, carbon dioxide, sand, or foam fire-fighting media should be used.

Chitosan may cause skin or eye irritation. It may be harmful if absorbed through the skin or if inhaled, and may be irritating to mucous membranes and the upper respiratory tract. Eye and skin protection and protective clothing are recommended; wash thoroughly after handling. Prolonged or repeated exposure (inhalation) should be avoided by handling in a well-ventilated area and wearing a respirator.

16 Regulatory Status

Chitosan is registered as a food supplement in some countries. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

See Section 18.

18 Comments

Chitosan derivatives are easily obtained under mild conditions and can be considered as substituted glucens.[3]

The PubChem Compound ID (CID) for chitosan includes 439300 and 3086191.

Chlorhexidine

1 Nonproprietary Names

BP: Chlorhexidine Acetate
Chlorhexidine Gluconate Solution
Chlorhexidine Hydrochloride

JP: Chlorhexidine Gluconate Solution
Chlorhexidine Hydrochloride

PhEur: Chlorhexidine Diacetate
Chlorhexidine Digluconate Solution
Chlorhexidine Dihydrochloride

USP–NF: Chlorhexidine Acetate
Chlorhexidine Gluconate Solution
Chlorhexidine Hydrochloride

Chlorhexidine is usually encountered as the acetate, gluconate, or hydrochloride salt, and a number of pharmacopeias contain monographs for such materials. *See* Sections 9 and 17.

2 Synonyms

See Table I.

Table I: Synonyms of chlorhexidine and its salts.

Name	Synonym
Chlorhexidine	1,6-bis[*N*′-(*p*-Chlorophenyl)-*N* ^{5}-biguanido]hexane; *N*,*N*″-bis(4-chlorophenyl)-3,12-diimino-2,4,11,13-tetraazatetradecanediimidamide; 1,6-di(4′-chlorophenyldiguanido)hexane; 1,1′-hexamethylene-bis[5-(*p*-chlorophenyl)biguanide]; Hibitane.
Chlorhexidine acetate	Chlorhexidini acetas; chlorhexidini diacetas; chlorhexidine diacetate; 1,1′-hexamethylenebis[5-(4-chlorophenyl)biguanide] diacetate; Hibitane diacetate.
Chlorhexidine gluconate	Chlorhexidine digluconate; chlorhexidini digluconatis;chlorhexidini digluconatis solutio; 1,1′-hexamethylenebis[5-(4-chlorophenyl)biguanide] digluconate.
Chlorhexidine hydrochloride	Chlorhexidini dihydrochloridum; chlorhexidine dihydrochloride; chlorhexidini hydrochloridum; 1,1′-hexamethylenebis[5-(4-chlorophenyl)biguanide]dihydrochloride.

3 Chemical Name and CAS Registry Number

Chlorhexidine 1*E*-2-[6-[[Amino-[[amino-[(4-chlorophenyl)amino]methylidene]amino]methylidene]amino]hexyl]-1-[amino-[(4-chlorophenyl)amino]methylidene]guanidine [55-56-1]
See Table II for CAS registry numbers of chlorhexidine salts.

4 Empirical Formula and Molecular Weight

See Table III.

5 Structural Formula

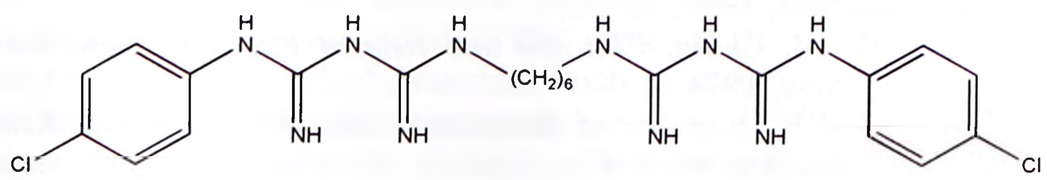

Table II: CAS registry number for chlorhexidine salts.

Name	CAS number
Chlorhexidine acetate	[56-95-1]
Chlorhexidine gluconate	[18472-51-0]
Chlorhexidine hydrochloride	[3697-42-5]

Table III: Empirical formula and molecular weight of chlorhexidine and its salts.

Name	Formula	Molecular weight
Chlorhexidine	$C_{22}H_{30}Cl_2N_{10}$	505.48
Chlorhexidine acetate	$C_{22}H_{30}Cl_2N_{10}\cdot 2C_2H_4O_2$	625.64
Chlorhexidine gluconate	$C_{22}H_{30}Cl_2N_{10}\cdot 2C_6H_{12}O_7$	897.88
Chlorhexidine hydrochloride	$C_{22}H_{30}Cl_2N_{10}\cdot 2HCl$	578.44

6 Functional Category

Antimicrobial preservative.

7 Applications in Pharmaceutical Formulation or Technology

Chlorhexidine salts are widely used in pharmaceutical formulations in Europe and Japan for their antimicrobial properties.[1,2] Although mainly used as disinfectants, chlorhexidine salts are also used as antimicrobial preservatives.

As excipients, chlorhexidine salts are mainly used for the preservation of eye-drops at a concentration of 0.01% w/v; generally the acetate or gluconate salt is used for this purpose. Solutions containing 0.002–0.006% w/v chlorhexidine gluconate have also been used for the disinfection of hydrophilic contact lenses.

8 Description

Chlorhexidine occurs as an odorless, bitter tasting, white crystalline powder. Chlorhexidine acetate and chorhexidine hydrochloride both occur as white or almost white, microcrystalline powder. Chlorhexidine gluconate solution is almost colorless or pale yellow-colored aqueous solution with pH value of 5.5–7.0 (5% w/v aqueous dilution).

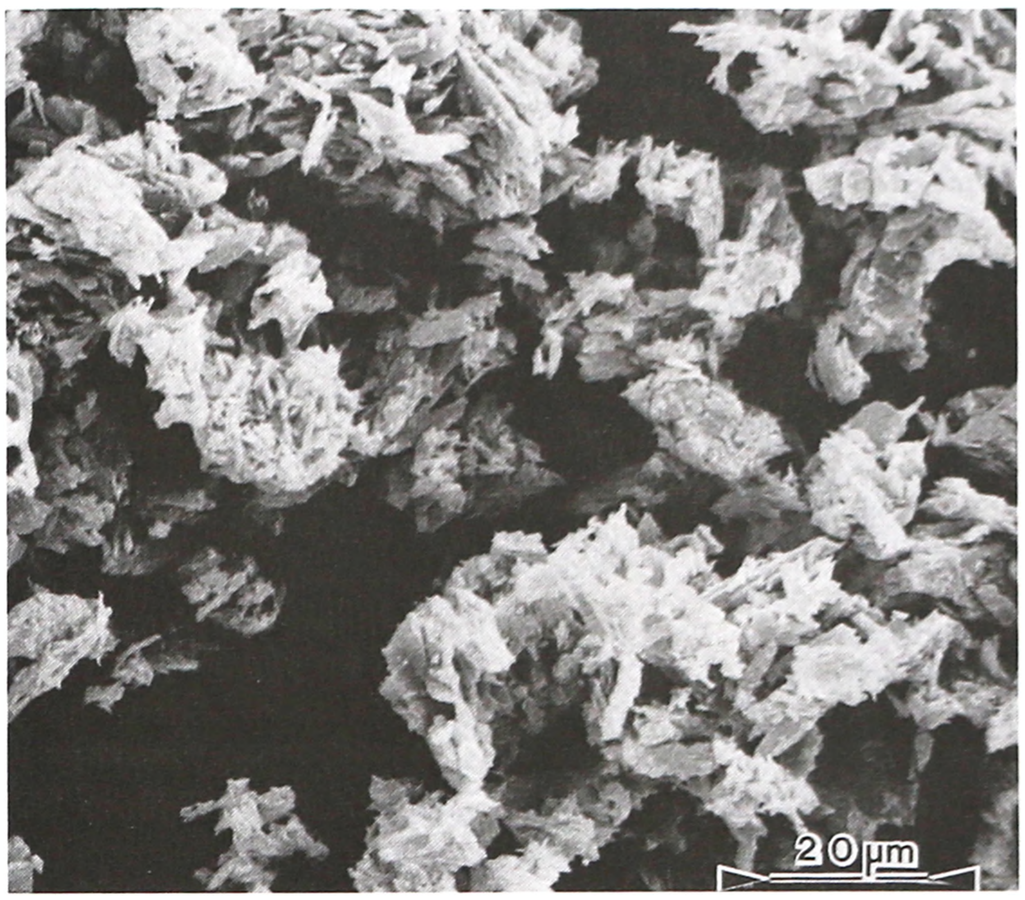
9 Pharmacopeial Specifications

See Table IV.

See also Section 17.

10 Typical Properties

Antimicrobial activity Chlorhexidine and its salts exhibit antimicrobial activity against Gram-positive and Gram-negative microorganisms.[3] At the low concentrations normally used for preservation and antisepsis, chlorhexidine salts are rapidly bactericidal. However, species of *Proteus* and *Pseudomonas* are less susceptible to chlorhexidine, which is also inactive against acid-fast bacilli, bacterial spores, and some fungi. Chlorhexidine salts are effective against some lipophilic viruses such as adenovirus, herpes virus, and influenza virus. Optimum antimicrobial activity occurs at pH 5–7. Above pH 8, the chlorhexidine base may precipitate from aqueous solutions.



Bacteria (Gram-positive) Chlorhexidine salts are active against most species; the minimum inhibitory concentration (MIC) is normally in the range 1–10 μg/mL, although much higher concentrations are necessary for *Streptococcus faecalis*. Typical MIC values are shown in Table V.

Bacteria (Gram-negative) Chlorhexidine salts are less active against Gram-negative species than against Gram-positive species. Typical MICs are 1–15 μg/mL, but pseudomonads, particularly *Pseudomonas aeruginosa*, may be more resistant. *Serratia marcescens* may also be resistant. Combinations of chlorhexidine acetate with the following substances have shown enhanced or more than additive activity towards *Pseudomonas aeruginosa*: benzalkonium chloride; benzyl alcohol; bronopol; edetic acid; phenylethanol, and phenylpropanol.[4,5] Typical MIC values are shown in Table VI.

Fungi Chlorhexidine salts are slowly active against molds and yeasts, although they are generally less potent in their inhibitory activity against fungi than against bacteria. Typical MIC values are shown in Table VII.

Spores Chlorhexidine salts are inactive against spores at normal room temperature.[6] At 98–100°C there is some activity against mesophilic spores.

Chlorhexidine acetate	154 °C
Chlorhexidine gluconate	132–136 °C
Chlorhexidine hydrochloride	261 °C

(a) With decomposition.

Table IX: Solubility of chlorhexidine salts.

Name	Solubility
Chlorhexidine acetate	Chlorhexidine acetate is soluble 1 in 15 of ethanol (95%), 1 in 55 of water; slightly soluble in glycerin, propylene glycol and polyethylene glycols. Its partition coefficients for mineral oil : water is 0.075 and for peanut oil : water 0.04.
Chlorhexidine gluconate	Chlorhexidine gluconate is miscible with water and soluble in acetone and ethanol (95%).
Chlorhexidine hydrochloride	Chlorhexidine hydrochloride is sparingly soluble in water, very slightly soluble in ethanol (95%) and soluble 1 in 50 of propylene glycol.

11 Stability and Storage Conditions

Chlorhexidine and its salts are stable at normal storage temperatures when in the powdered form. However, chlorhexidine hydrochloride and chlorhexidine acetate are hygroscopic, absorbing significant amounts of moisture at temperatures up to 37 °C and relative humidities up to 80%.

Heating to 150 °C causes decomposition of chlorhexidine and its salts, yielding trace amounts of 4-chloroaniline. However, chlorhexidine hydrochloride is more thermostable than the acetate and can be heated at 150 °C for 1 hour without appreciable formation of 4-chloroaniline.

In aqueous solution, chlorhexidine salts may undergo hydrolysis to form 4-chloroaniline, catalyzed by heating and an alkaline pH. Following autoclaving of a 0.02% w/v chlorhexidine gluconate solution at pH 9 for 30 minutes at 120 °C, it was found that 1.56% w/w of the original chlorhexidine content had been converted into 4-chloroaniline; for solutions at pH 6.3 and 4.7 the 4-chloroaniline content was 0.27% w/w and 0.13% w/w, respectively, of the

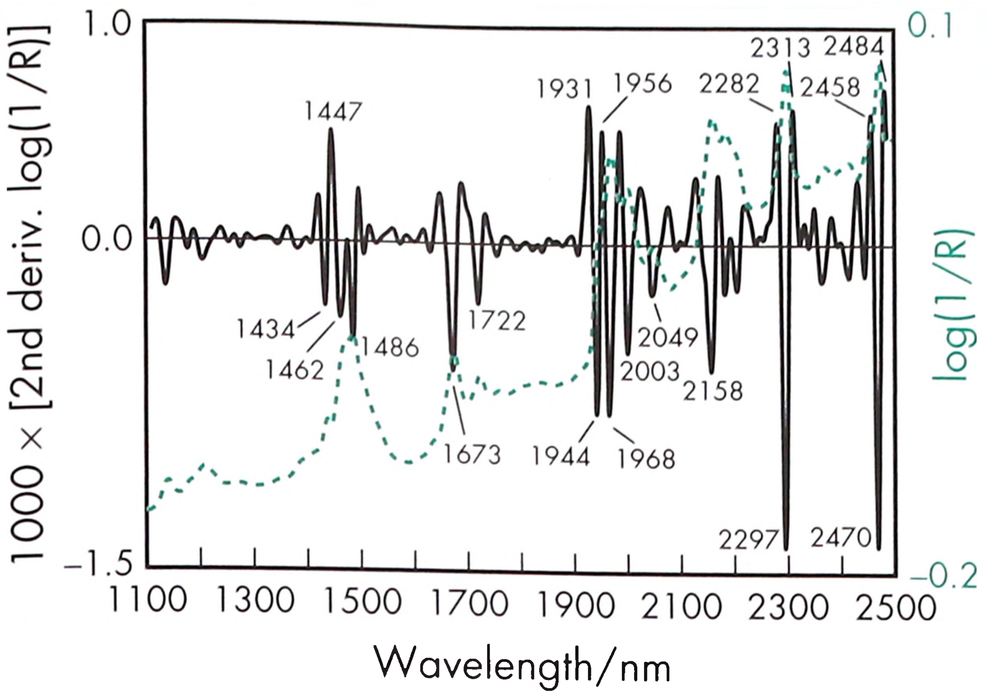

Figure 1: Near-infrared spectrum of chlorhexidine measured by reflectance.

original gluconate content.[8] In buffered 0.05% w/v chlorhexidine acetate solutions, maximum stability occurs at pH 5.6.

When chlorhexidine solutions were autoclaved at various time and temperature combinations, the rate of hydrolysis increased markedly above 100°C, and as pH increased or decreased from pH 5.6. At a given pH, chlorhexidine gluconate produced more 4-chloroaniline than the acetate.

It was predicted that in an autoclaved solution containing 0.01% w/v chlorhexidine, the amount of 4-chloroaniline formed would be about 0.00003%. At these low concentrations there would be little likelihood of any toxic hazard as a result of the increase in 4-chloroaniline content in the autoclaved solution.

Aqueous solutions of chlorhexidine acetate may be sterilized by autoclaving; the solutions should not be alkaline or contain other ingredients that affect the stability of chlorhexidine. Aqueous dilutions of commercially available chlorhexidine gluconate solutions may also be sterilized by autoclaving. Chlorhexidine hydrochloride may be sterilized by dry heat.

Chlorhexidine solutions and aqueous-based products may be packaged in glass and high-density polyethylene or polypropylene bottles provided that they are protected from light. If not protected from light, chlorhexidine solutions containing 4-chloroaniline discolor owing to polymerization of the 4-chloroaniline.[9–11]

Cork-based closures or liners should not be used in packaging in contact with chlorhexidine solutions as chlorhexidine salts are inactivated by cork.

As a precaution against contamination with *Pseudomonas* species resistant to chlorhexidine, stock solutions may be protected by the inclusion of 7% w/v ethanol or 4% w/v propan-2-ol.

Chlorhexidine salts, and their solutions, should be stored in well-closed containers, protected from light, in a cool, dry place.

12 Incompatibilities

Chlorhexidine salts are cationic in solution and are therefore incompatible with soaps and other anionic materials. Chlorhexidine salts are compatible with most cationic and nonionic surfactants, but in high concentrations of surfactant chlorhexidine activity can be substantially reduced owing to micellar binding.

Chlorhexidine salts of low aqueous solubility are formed and may precipitate from chlorhexidine solutions of concentration greater than 0.05% w/v, when in the presence of inorganic acids, certain organic acids, and salts (e.g. benzoates, bicarbonates, borates, carbonates, chlorides, citrates, iodides, nitrates, phosphates, and sulfates).[12] At chlorhexidine concentrations below 0.01% w/v precipitation is less likely to occur.

In hard water, insoluble salts may form owing to interaction with calcium and magnesium cations. Solubility may be enhanced by the inclusion of surfactants such as cetrimide.

Other substances incompatible with chlorhexidine salts include viscous materials such as acacia, sodium alginate, sodium carboxymethylcellulose, starch, and tragacanth.[13,14] Also incompatible are brilliant green, chloramphenicol, copper sulfate, fluorescein sodium, formaldehyde, silver nitrate, and zinc sulfate.

Interaction has been reported between chlorhexidine gluconate and the hydrogel poly(2-hydroxyethyl methacrylate), which is a component of some hydrophilic contact lenses.[15,16]

13 Method of Manufacture

Chlorhexidine may be prepared either by condensation of polymethylene bisdicyandiamide with 4-chloroaniline hydrochloride or by condensation of 4-chlorophenyl dicyandiamine with hexamethylenediamine dihydrochloride. Chlorhexidine may also be synthesized from a series of biguanides.[17]

14 Safety

Chlorhexidine and its salts are widely used, primarily as topical disinfectants. Adverse skin reactions and chemical burns, including fatalities, have been reported with topical disinfectant use in premature infants.[18,19] As excipients, chlorhexidine salts are mainly used as antimicrobial preservatives in ophthalmic formulations.

Animal studies suggest that the acute oral toxicity of chlorhexidine is low, with little or no absorption from the gastrointestinal tract. However, although humans have consumed up to 2 g of chlorhexidine daily for 1 week, without untoward symptoms, chlorhexidine is not generally used as an excipient in orally ingested formulations.

Reports have suggested that there may be some systemic effects in humans following oral consumption of chlorhexidine.[20–22] Similarly, the topical application of chlorhexidine or its salts produced evidence of very slight percutaneous absorption of chlorhexidine, although the concentrations absorbed were insufficient to produce systemic adverse effects.[23]

Severe hypersensitivity reactions, including anaphylactic shock, have been reported following the topical administration of chlorhexidine,[24–28] although such instances are rare given the extensive use of chlorhexidine and it salts.

In ophthalmic preparations, irritation of the conjunctiva occurs with chlorhexidine solutions of concentration stronger than 0.1% w/v. Accidental eye contact with 4% w/v chlorhexidine gluconate solution may result in corneal damage.[29]

The aqueous concentration of chlorhexidine normally recommended for contact with mucous surfaces is 0.05% w/v. At this concentration, there is no irritant effect on soft tissues, nor is healing delayed. The gluconate salt (1% w/v) is frequently used in creams, lotions, and disinfectant solutions.

Direct instillation of chlorhexidine into the middle ear can result in ototoxicity[30] when used in dental preparations, staining of teeth and oral lesions may occur.[31,32]

Use of chlorhexidine on the brain or meninges is extremely dangerous.

The commercially available 5% w/v chlorhexidine gluconate solution contains a nonionic surfactant to prevent precipitation and is not suitable for use in body cavities or for the disinfection of surgical instruments containing cemented glass components.

See Table X for LD_{50} values.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. The dust of chlorhexidine and its salts may be irritant to the skin, eyes, and respiratory tract. Gloves, eye protection, and a respirator are recommended.

Table X: LD_{50} values for chlorhexidine and its salts.

	Chlorhexidine	Chlorhexidine acetate	Chlorhexidine gluconate	Chlorhexidine hydrochloride
LD_{50} (mouse, IP)	0.04 g/kg[33]	0.04 g/kg[33]	—	—
LD_{50} (mouse, IV)	—	0.03 g/kg	0.02 g/kg[33]	—

LD_{50} (rat, oral)	9.2 g/kg	—	2 g/kg	—
LD_{50} (rat, SC)	—	—	3.32 g/kg	—

16 Regulatory Status

Chlorhexidine salts are included in nonparenteral and parenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

—

18 Comments

For skin disinfection, chlorhexidine has been formulated as a 0.5% w/v solution in 70% v/v ethanol and, in conjunction with detergents, as a 4% w/v surgical scrub. Chlorhexidine salts may also be used in topical antiseptic creams, mouthwashes, dental gels, and in urology for catheter sterilization and bladder irrigation.[1,2,34,35]

Chlorhexidine salts have additionally been used as constituents of medicated dressings, dusting powders, sprays, and creams.

The EINECS number for chlorhexidine is 200-238-7, for chlorhexidine acetate 200-302-4, for chlorhexidine gluconate 242-354-0, and for chlorhexidine hydrochloride 223-026-6. The PubChem Compound ID (CID) for chlorhexidine is 9552079.

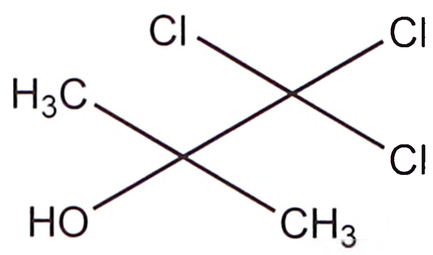
Chlorobutanol

1 Nonproprietary Names

BP: Chlorobutanol
JP: Chlorobutanol
PhEur: Chlorobutanol, Anhydrous
USP–NF: Chlorobutanol

2 Synonyms

Acetone chloroform; anhydrous chlorbutol; chlorbutanol; chlorobutanolum anhydricum; chlorbutol; chloretone; *Coliquifilm*; methaform; sedaform; trichloro-*tert*-butanol; β,β,β-trichloro-*tert*-butyl alcohol; trichloro-*t*-butyl alcohol.



3 Chemical Name and CAS Registry Number

1,1,1-Trichloro-2-methyl-2-propanol [57-15-8]
1,1,1-Trichloro-2-methyl-2-propanol hemihydrate [6001-64-5]

4 Empirical Formula and Molecular Weight

$C_4H_7Cl_3O$ 177.46 (for anhydrous)
$C_4H_7Cl_3O \cdot \frac{1}{2}H_2O$ 186.46 (for hemihydrate)

5 Structural Formula

6 Functional Category

Antimicrobial preservative; plasticizing agent.

7 Applications in Pharmaceutical Formulation or Technology

Chlorobutanol is primarily used in ophthalmic or parenteral dosage forms as an antimicrobial preservative at concentrations up to 0.5% w/v; *see* Section 10. It is commonly used as an antibacterial agent for epinephrine solutions, posterior pituitary extract solutions, and ophthalmic preparations intended for the treatment of miosis. It is especially useful as an antibacterial agent in nonaqueous formulations. Chlorobutanol is also used as a preservative in cosmetics (*see* Section 16); as a plasticizer for cellulose esters and ethers.

8 Description

Volatile, colorless or white crystals with a musty, camphoraceous odor.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for chlorobutanol.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters	+	+	–
Appearance of solution	–	+	–
Melting point	≥76°C	+	–
Anhydrous	–	≈95°C	–
Hemihydrate	–	≈78°C	–
Acidity	+	+	+
Water (anhydrous form)	≤6.0%	≤1.0%	≤1.0%
Hemihydrate	–	4.5–5.5%	≤6.0%
Chloride	≤0.071%	+	≤0.07%
Anhydrous	–	≤300 ppm	–
Hemihydrate	–	≤100 ppm	–
Residue on ignition	≤0.10%	–	–
Sulfated ash	–	≤0.1%	–
Assay (anhydrous basis)	≥98.0%	98.0–101.0%	98.0–100.5%

Note: the JP XVII and USP 40–NF 35 S1 allow either the anhydrous form or the hemihydrate; the PhEur includes them as separate monographs.

10 Typical Properties

Antimicrobial activity Chlorobutanol has both antibacterial and antifungal properties. It is effective against Gram-positive and Gram-negative bacteria and some fungi, e.g. *Candida albicans*, *Pseudomonas aeruginosa*, and *Staphylococcus albus*. Antimicrobial activity is bacteriostatic, rather than bactericidal, and is considerably reduced above pH 5.5. In addition, activity may also be reduced by increasing heat and by incompatibilities between chlorobutanol and other excipients or packaging materials; *see* Sections 11 and 12. However, activity may be increased by combination with other antimicrobial preservatives; *see* Section 18. Typical minimum inhibitory concentrations (MICs) are: Gram-positive bacteria 650 µg/mL; Gram-negative bacteria 1000 µg/mL; yeasts 2500 µg/mL; fungi 5000 µg/mL.
Boiling point 167°C
Melting point
76–78°C for the hemihydrate;
95–97°C for the anhydrous form.
Partition coefficient Octanol : water log k_{ow} = 2.03
Refractive index n_D^{25} = 1.4339
Solubility *see* Table II.

Table II: Solubility of chlorobutanol.

Solvent	Solubility at 20°C unless otherwise stated
Acetic acid, glacial	Freely soluble
Acetone	Freely soluble
Chloroform	Freely soluble
Ethanol (95%)	Freely soluble (1 in 1)
Ether	Freely soluble
Glycerin	Freely soluble (1 in 10)
Methanol	Freely soluble
Volatile oils	Freely soluble
Water	Slightly soluble (1 in 125) Freely soluble in hot water

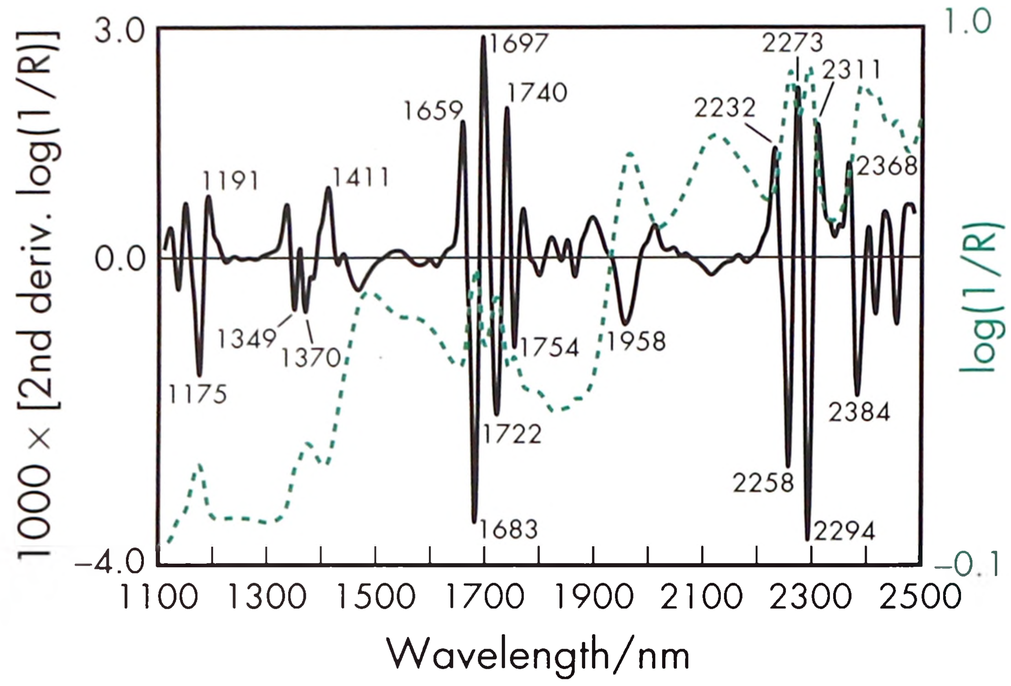


Figure 1: Near-infrared spectrum of chlorobutanol measured by reflectance.

Spectroscopy

NIR spectrum *see* Figure 1.

11 Stability and Storage Conditions

Chlorobutanol is volatile and readily sublimes. In aqueous solution, degradation to carbon monoxide, acetone and chloride ion is catalyzed by hydroxide ions. Stability is good at pH 3 but becomes progressively worse with increasing pH.[1] The half-life at pH 7.5 for a chlorobutanol solution stored at 25°C was determined to be approximately 3 months.[2] In a 0.5% w/v aqueous chlorobutanol solution at room temperature, chlorobutanol is almost saturated and may crystallize out of solution if the temperature is reduced.

Losses of chlorobutanol also occur owing to its volatility, with appreciable amounts being lost during autoclaving; at pH 5 about 30% of chlorobutanol is lost.[3] Porous containers result in losses from solutions, and polyethylene containers result in rapid loss. Losses of chlorobutanol during autoclaving in polyethylene containers may be reduced by pre-autoclaving the containers in a solution of chlorobutanol; the containers should then be used immediately.[4] There is also appreciable loss of chlorobutanol through stoppers in parenteral vials.

The bulk material should be stored in an airtight container at a temperature of 8–15°C.

12 Incompatibilities

Owing to problems associated with sorption, chlorobutanol is incompatible with plastic vials,[4–8] rubber stoppers, bentonite,[9] magnesium trisilicate,[9] polyethylene, and polyhydroxyethylmethacrylate, which has been used in soft contact lenses.[10] To a lesser extent, carboxymethylcellulose and polysorbate 80 reduce antimicrobial activity by sorption or complex formation.

13 Method of Manufacture

Chlorobutanol is prepared by condensing acetone and chloroform in the presence of solid potassium hydroxide.

14 Safety

Chlorobutanol is widely used as a preservative in a number of pharmaceutical formulations, particularly ophthalmic preparations. Although animal studies have suggested that chlorobutanol may be harmful to the eye, in practice the widespread use of chlorobutanol as a preservative in ophthalmic preparations has been associated with few reports of adverse reactions. A study of the irritation potential of a local anesthetic on the murine cornea indicated significant corneal surface damage in the presence of 0.5% w/v chlorobutanol, which may be related to the preservative's effective concentration.[11] Reported adverse reactions to chlorobutanol include: cardiovascular effects following intravenous administration of heparin sodium injection preserved with chlorobutanol;[12] neurological effects following administration of a large dose of morphine infusion preserved with chlorobutanol;[13] and hypersensitivity reactions, although these are regarded as rare.[14–16]

The lethal human dose of chlorobutanol is estimated to be 50–500 mg/kg.[17]

LD_{Lo} (dog, oral): 0.24 g/kg[18,19]
LD_{50} (mouse, oral): 0.15 g/kg[18]
LD_{Lo} (rabbit, oral): 0.21 g/kg[18,19]
LD_{50} (rat, oral): 0.51 g/kg[18]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Chlorobutanol may be irritant to the skin, eyes, and mucous membranes. Eye protection and gloves are recommended along with a respirator in poorly ventilated environments. There is a slight fire hazard on exposure to heat or flame.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (IM, IV, and SC injection; inhalations; nasal, otic, ophthalmic, and topical preparations). Labeling must state 'contains chlorobutanol up to 0.5%.' Included in nonparenteral and parenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

In the UK, the maximum concentration of chlorobutanol permitted for use in cosmetics, other than foams, is 0.5%. It is not suitable for use in aerosols.

17 Related Substances

Phenoxyethanol; phenylethyl alcohol.

18 Comments

It has been reported that a combination of chlorobutanol and phenylethanol, both at 0.5% w/v concentration, has shown greater antibacterial activity than either compound alone. An advantage of the use of this combination is that chlorobutanol dissolves in the alcohol; the resulting liquid can then be dissolved in an aqueous pharmaceutical preparation without the application of heat.

Chlorobutanol has been used therapeutically as a mild sedative and local analgesic in dentistry.

The EINECS number for chlorobutanol is 200-317-6. The PubChem ID Compound (CID) for chlorobutanol is 5977.

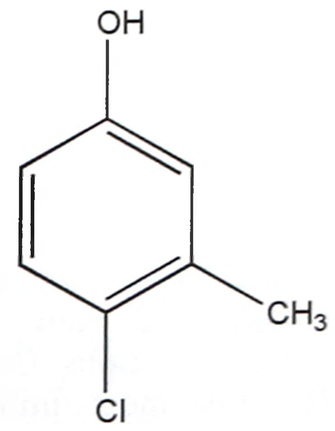
USP–NF: Chlorocresol

2 Synonyms

Aptal; *Baktol*; 4-chloro-*m*-cresol; *p*-chloro-*m*-cresol; chlorocresolum; 1-chloro-4-hydroxy-2-methylbenzene; 2-chloro-5-hydroxytoluene; 6-chloro-3-hydroxytoluene; 4-chloro-3-methylphenol; 3-methyl-4-chlorophenol; *Nipacide PC*; parachlorometacresol; PCMC.



3 Chemical Name and CAS Registry Number

4-Chloro-3-methylphenol [59-50-7]

4 Empirical Formula and Molecular Weight

C_7H_7ClO 142.58

5 Structural Formula

6 Functional Category

Antimicrobial preservative.

7 Applications in Pharmaceutical Formulation or Technology

Chlorocresol is used as an antimicrobial preservative in cosmetics and pharmaceutical formulations. It is generally used in concentrations up to 0.2% in a variety of preparations except those intended for oral administration or that contact mucous membrane. Chlorocresol is effective against bacteria, spores, molds, and yeasts; it is most active in acidic media. Preservative efficacy may be reduced in the presence of some other excipients, particularly nonionic surfactants; *see* Sections 10 and 12.

In higher concentrations, chlorocresol is an effective disinfectant. *See* Table I.

Table I: Uses of chlorocresol.

Use	Concentration (%)
Eye drops	0.05
Injections	0.1
Shampoos and other cosmetics	0.1–0.2
Topical creams and emulsions	0.075–0.2

8 Description

Colorless or almost colorless, dimorphous crystals or crystalline powder with a characteristic phenolic odor.

9 Pharmacopeial Specifications

See Table II. *See also* Section 18.

Table II: Pharmacopeial specifications for chlorocresol.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	—
Appearance of solution	+	—
Completeness of solution	—	+
Melting range	64–67°C	63–66°C
Nonvolatile residue	≤0.1%	≤0.1%
Acidity	+	—
Related substances	≤1.0%	—
Assay	98.0–101.0%	99.0–101.0%

10 Typical Properties

Acidity/alkalinity pH = 5.6 for a saturated aqueous solution

Antimicrobial activity Chlorocresol has bactericidal activity against both Gram-positive and Gram-negative organisms (including *Pseudomonas aeruginosa*), spores, molds, and yeasts. It is most active in acidic solutions, with antimicrobial effectiveness decreasing with increasing pH; it is inactive above pH 9. Antimicrobial activity may also be reduced by loss of chlorocresol from a formulation due to incompatibilities with packaging materials or other excipients, such as nonionic surfactants; *see* Section 12. Synergistic antimicrobial effects between chlorocresol and other antimicrobial preservatives, such as 2-phenylethanol, have been reported.[1,2] Reported minimum inhibitory concentrations (MICs) for chlorocresol are shown in Table III.[3] Like most antimicrobials, chlorocresol has a non-linear dose response.[4,5]

Table III: Minimum inhibitory concentrations (MICs) for chlorocresol.[3]

Microorganism	MIC (μg/mL)
Aspergillus niger	2500
Candida albicans	2500
Escherichia coli	1250
Klebsiella pneumoniae	625
Pseudomonas aeruginosa	1250
Pseudomonas fluorescens	1250
Staphylococcus aureus	625

Bacteria Concentrations of approximately 0.08%, with a contact time of 10 minutes, are bactericidal. A typical MIC is 0.02%.

Fungi Chlorocresol is active against molds and yeasts. Fungicidal concentrations (after 24 hours of contact) are in the range 0.01–0.04%.

Spores At temperatures of 80°C or above and in concentrations greater than 0.012%, chlorocresol is active against spores. It is much less active at room temperature. Heating at 98–100°C for 30 minutes in the presence of 0.2% chlorocresol has previously been used as a compendial method for the sterilization of solutions of substances that would not withstand autoclaving.

Boiling point 235°C

Dissociation constant $pK_a = 9.55$

Flash point 117.8°C

Melting point Dimorphous crystals with a melting point of 55.5°C and 65°C.

Partition coefficients

Cyclohexane/water = 0.15;

Hexane : water = 0.34;

Liquid paraffin : water = 1.53;

Octanol : water = 3.10;

Peanut oil : water = 117.

Refractive index 1.5403

Solubility *see* Table IV.

Table IV: Solubility of chlorocresol.

Solvent	Solubility at 20°C unless otherwise stated
Acetone	Soluble
Alkali hydroxide solutions	Soluble
Chloroform	Soluble
Ethanol	1 in 0.4
Ether	Soluble
Fixed oils	Soluble

Terpenes	Soluble
Water	1 in 260[a]
	1 in 50 at 100°C[a]

(a) Aqueous solubility is decreased in the presence of electrolytes, particularly sodium chloride, potassium chloride, and potassium sulfonate.[6]

Specific gravity 1.37 at 20°C

Spectroscopy

NIR spectrum *see* Figure 1.

Vapor pressure

0.008 kPa at 20°C;

0.67 kPa at 100°C.

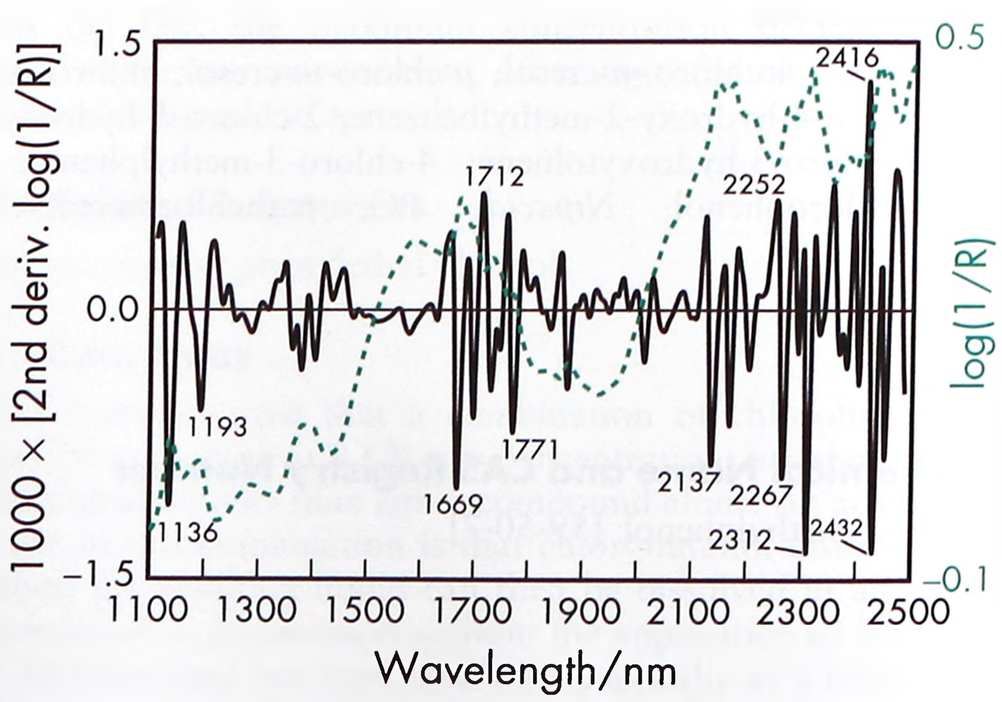

Figure 1: Near-infrared spectrum of chlorocresol measured by reflectance.

11 Stability and Storage Conditions

Chlorocresol is stable at room temperature but is volatile in steam. Aqueous solutions may be sterilized by autoclaving. On exposure to air and light, aqueous solutions may become yellow colored. Solutions in oil or glycerin may be sterilized by heating at 160°C for 1 hour. The bulk material should be stored in a well-closed container, protected from light, in a cool, dry place.

12 Incompatibilities

Chlorocresol can decompose on contact with strong alkalis, evolving heat and fumes that ignite explosively. It is also incompatible with oxidizing agents, copper, and with solutions of calcium chloride, codeine phosphate, diamorphine hydrochloride, papaveretum, and quinine hydrochloride.[7] Chlorocresol is corrosive to metals and forms complex compounds with transition metal ions; discoloration occurs with iron salts. Chlorocresol also exhibits strong sorption or binding tendencies to organic materials such as rubber, certain plastics, and nonionic surfactants.[8–11]

Chlorocresol may be lost from solutions to rubber closures, and in contact with polyethylene may initially be rapidly removed by sorption and then by permeation, the uptake being temperature dependent. Presoaking of components may reduce losses due to sorption, but not those by permeation.[12,13] Chlorocresol may also be taken up by polymethylmethacrylate and by cellulose acetate. Losses to polypropylene or rigid polyvinyl chloride are usually small.[14]

At a concentration of 0.1%, chlorocresol may be completely inactivated in the presence of nonionic surfactants, such as polysorbate 80.[9] However, other studies have suggested an enhancement of antimicrobial properties in the presence of surfactants.[15,16] Bactericidal activity is also reduced, due to binding, by cetomacrogol, methylcellulose, pectin, or cellulose derivatives.[9,11] In emulsified or solubilized systems, chlorocresol readily partitions into the oil phase, particularly into vegetable oils, and higher concentrations will be required for efficient preservation.[10,17]

13 Method of Manufacture

Chlorocresol is prepared by the chlorination of *m*-cresol.

14 Safety

Chlorocresol is used primarily as a preservative in topical pharmaceutical formulations but has also been used in nebulized solutions[18] and ophthalmic and parenteral preparations. It should not, however, be used in formulations for intrathecal, intracisternal, or peridural injection.

Chlorocresol is metabolized by conjugation with glucuronic acid and sulfate and is excreted in the urine, mainly as the conjugate, with little chlorocresol being excreted unchanged.

Although less toxic than phenol, chlorocresol may be irritant to the skin, eyes, and mucous membranes, and has been reported to cause some adverse reactions when used as an excipient.[19,20]

Sensitization reactions may follow the prolonged application of strong solutions to the skin, although patch tests have shown that chlorocresol is not a primary irritant at concentrations up to 0.2%. Chlorocresol is recognized as a rare cause of allergic contact dermatitis.[21] Cross sensitization with the related preservative chloroxylenol has also been reported.[22,23] At concentrations of 0.005% w/v, chlorocresol has been shown to produce a reversible reduction in the ciliary movement of human nasal epithelial cells *in vitro*, and at concentrations of 0.1% chlorocresol produces irreversible ciliostasis; therefore it should be used with caution in nasal preparations.[24] However, a clinical study in asthma patients challenged with chlorocresol or saline concluded that preservative might be used safely in nebulizer solution.[18]

Chlorocresol is approved as safe for use in cosmetics in Europe at a maximum concentration of 0.2%, although not in products intended to come in contact with mucous membranes.[25]

Chlorocresol at a concentration as low as 0.05% produces ocular irritation in rabbits.[20] Despite such reports, chlorocresol has been tested in ophthalmic preparations.[26,27]

When used systemically, notably in a heparin injection preserved with chlorocresol 0.15%, delayed irritant and hypersensitivity reactions attributed to chlorocresol have been reported.[28,29] *See also* Section 18.

LD_{50} (mouse, IV): 0.07 g/kg[30]
LD_{50} (mouse, oral): 0.6 g/kg
LD_{50} (mouse, SC): 0.36 g/kg
LD_{50} (rabbit, dermal): >5 g/kg
LD_{50} (rat, dermal): >2 g/kg
LD_{50} (rat, oral): 1.83 g/kg
LD_{50} (rat, SC): 0.4 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Chlorocresol can be irritant to the skin, eyes, and mucous membranes. Eye protection, gloves, and protective clothing are recommended. Chlorocresol presents a slight fire hazard when exposed to heat or flame. It burns to produce highly toxic fumes containing phosgene and hydrogen chloride.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (topical creams and emulsions). Included in nonparenteral and parenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

In Europe, chlorocresol is approved for use in cosmetics at a maximum concentration of 0.2%; however, it is prohibited for use in products intended to come into contact with mucous membranes. In Japan, use of chlorocresol in cosmetics is restricted to a level of 0.5 g/100 g.

17 Related Substances

Cresol; chloroxylenol.

18 Comments

A specification for chlorocresol is contained in the *Japanese Pharmaceutical Excipients* (JPE).[31] The *Japanese Pharmaceutical Excipient Directory* (JPED) states a maximum concentration of 1 mg/g of chlorocresol in external pharmaceutical preparations.[32]

Chlorocresol has a characteristic odor which is difficult to mask in formulations, even at concentrations of 0.05–0.1%.

Although used in Europe, chlorocresol is not used in the US in parenteral formulations. Chlorocresol has also been used as an experimental *in vitro* diagnostic agent for the diagnosis of hyperthermia.[33,34]

The EINECS number for chlorocresol is 200-431-6.

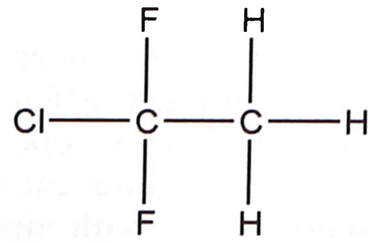
Chlorodifluoroethane (HCFC)

1 Nonproprietary Names

None adopted.

2 Synonyms

1,1-Difluoro-1-chloroethane; *Dymel 142b*; *Genetron 142b*; HCFC 142b; propellant 142b; R-142b; refrigerant 142b; *Solkane 142b*.



3 Chemical Name and CAS Registry Number

1-Chloro-1,1-difluoroethane [75-68-3]

4 Empirical Formula and Molecular Weight

$C_2H_3ClF_2$ 100.50

5 Structural Formula

6 Functional Category

Aerosol propellant.

7 Applications in Pharmaceutical Formulation or Technology

Chlorodifluoroethane is a hydrochlorofluorocarbon (HCFC) aerosol propellant previously used in topical pharmaceutical formulations. However, it is no longer permitted for use in pharmaceutical formulations because of its harmful effects on the environment. It was also generally used in conjunction with difluoroethane to form a propellant blend with a specific gravity of 1. Chlorodifluoroethane was also used in combination with chlorodifluoromethane and hydrocarbon propellants.

8 Description

Chlorodifluoroethane is a liquefied gas and exists as a liquid at room temperature when contained under its own vapor pressure, or as a gas when exposed to room temperature and atmospheric pressure. The liquid is colorless and has faint ether-like odor.[1–3] Chlorodifluoroethane is noncorrosive and nonirritating.

9 Pharmacopeial Specifications

—

10 Typical Properties

Autoignition temperature 632°C
Boiling point −10 to −9.2°C[2,3]
Critical temperature 137.1°C
Density

1.11 g/cm^3 for liquid at 25°C;

1.03 g/cm^3 for liquid at 54.5°C.

Flammability Flammable. Limits of flammability 6.2–17.9% v/v in air.
Melting point −131°C
Solubility Soluble 1 in 715 parts of water at 20°C.
Vapor density (absolute) 4.487 g/m^3 at standard temperature and pressure.
Vapor density (relative) 3.48 (air = 1)
Vapor pressure

290 kPa (42.1 psia) at 20°C;

339 kPa (49.2 psia) at 25°C;

772 kPa (112.0 psia) at 54.5°C.

Viscosity (dynamic) 0.33 mPa s (0.33 cP) for liquid at 21°C.

11 Stability and Storage Conditions

Chlorodifluoroethane is a nonreactive and stable material. The liquefied gas is stable and should be stored in a metal cylinder in a cool, dry, well-ventilated place.

12 Incompatibilities

Chlorodifluoroethane is incompatible with alkali metals, alkaline earth metals, powdered metals, chlorine, and can react vigorously with oxidizing materials.[1] However, it is compatible with the usual ingredients used in the formulation of pharmaceutical aerosols.

13 Method of Manufacture

Chlorodifluoroethane is prepared by the chlorination of difluoroethane in the presence of a suitable catalyst; hydrochloric acid is also formed. The chlorodifluoroethane is purified to remove all traces of water and hydrochloric acid, as well as traces of the starting and intermediate materials.

14 Safety

Chlorodifluoroethane is no longer permitted for use as an aerosol propellant in topical pharmaceutical formulations. It is generally regarded as an essentially nontoxic and nonirritant material.

Deliberate inhalation of excessive quantities of chlorofluorocarbon propellant may result in death, and the following 'warning' statements must appear on the label of all aerosols:

> **WARNING:** Avoid inhalation. Keep away from eyes or other mucous membranes.

In the USA, the Environmental Protection Agency (EPA) additionally requires the following information on all aerosols containing chlorofluorocarbons as the propellant:

> **WARNING:** Contains a chlorofluorocarbon that may harm the public health and environment by reducing ozone in the upper atmosphere.

LC_{50} (rat, inhalation): 2050 g/m^3[3(3)]
LC_{50} (mouse, inhalation): 1750 g/m^3[3(3)]

15 Handling Precautions

Chlorodifluoroethane is usually encountered as a liquefied gas and appropriate precautions for handling such materials should be taken. Eye protection, gloves, and protective clothing are recommended. Chlorodifluoroethane should be handled in a well-ventilated environment. Chlorofluorocarbon vapors are heavier than air and do not support life; therefore, when cleaning large tanks that have contained chlorofluorocarbons, adequate provisions for oxygen supply in the tanks must be made in order to protect workers cleaning the tanks. The maximum acceptable concentration of chlorodifluoroethane at the workplace is 1000 ppm, as reported by the German Research Foundation.[4]

Chlorodifluoroethane is extremely flammable; *see* Section 10. When heated to decomposition, chlorodifluoroethane emits toxic fumes of hydrogen fluoride, hydrogen chloride, flurophosgene, phosgene, carbonyl fluoride and carbon monoxide.[1,2]

16 Regulatory Status

Chlorodifluoroethane is listed as a controlled substance in the Montreal Protocol; see Chloroflurocarbons (CFC).[5]

17 Related Substances

—

18 Comments

Chlorodifluoroethane is considered an ozone-depleting substance with an ozone depletion potential value of 0.065.[5,6]

Although chlorodifluoroethane is no longer available for use in pharmaceutical formulation, the monograph remains in the *Handbook* to assist formulators in their understanding of old products, whose properties they may need to reproduce. It may also still be present in some commercial products.

For a discussion of the numerical nomenclature applied to this aerosol propellant, *see* Chlorofluorocarbons (CFC).

The EINECS number for chlorodifluoroethane is 200-891-8.

Aerosol propellant.

7 Applications in Pharmaceutical Formulation or Technology

Dichlorodifluoromethane, dichlorotetrafluoroethane, and trichloromonofluoromethane are chlorofluorocarbon (CFC) aerosol propellants used in pharmaceutical formulations. They are no longer used in metered-dose inhaler (MDI) formulations, with few exceptions for existing MDIs; *see also* Section 18.

Dichlorodifluoromethane is used as an aerosol propellant in MDIs, either as the sole propellant or in combination with dichlorotetrafluoroethane, trichloromonofluoromethane, or mix-

tures of these chlorofluorocarbons. Dichlorodifluoromethane may also be used as a propellant in an aerosolized sterile talc used for intrapleural administration and is also used alone in some MDIs containing a steroid.

Dichlorotetrafluoroethane is used in combination with dichlorodifluoromethane, and in several cases with dichlorodifluoromethane and trichloromonofluoromethane, as the propellant in metered-dose oral and nasal aerosols.

Trichloromonofluoromethane was used in combination with dichlorodifluoromethane as the propellant in metered-dose inhaler aerosols. It is also used in combination with dichlorotetrafluoroethane and dichlorodifluoromethane.

These three propellants have been blended to obtain suitable solubility characteristics for MDIs when formulated as solutions. They will produce suitable vapor pressures so that optimum particle-size distribution as well as suitable respiratory fractions may be achieved.

Blends of trichloromonofluoromethane and dichlorodifluoromethane (propellant 11/12) or propellant 11/114/12 produce vapor pressures of 103–484 kPa (15–70 psig) at 25°C, which adequately cover the range of pressures required to produce the proper particle-size distribution for satisfactory aerosol products. Trichloromonofluoromethane is unique among the chlorofluorocarbon propellants in that it is a liquid at room temperature and atmospheric pressure, and can be used to prepare a slurry with insoluble medicinal agents. These CFC propellants have been replaced by more environmentally accepted hydrofluoroalkane (HFA) propellants (HFA 134a and HFA 227) for use with the metered-dose inhalers.

8 Description

Dichlorodifluoromethane is a liquefied gas and exists as a liquid at room temperature when contained under its own vapor pressure, or as a gas when exposed to room temperature and atmospheric pressure. The liquid is practically odorless and colorless. The gas in high concentrations has a faint etherlike odor. Dichlorodifluoromethane is noncorrosive, nonirritating, and nonflammable.

Dichlorotetrafluoroethane is a colorless, nonflammable liquefied gas with a faint, ethereal odor.

Trichloromonofluoromethane is a clear, volatile liquid at room temperature and atmospheric pressure. It has a characteristic carbon tetrachloride-like odor and is nonirritating and nonflammable.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications from USP 40–NF 35 S1.

Test	Propellant 12	Propellant 114	Propellant 11
Identification	+	+	+
Boiling temperature	–30°C	4°C	24°C
Water	≤0.001%	≤0.001%	≤0.001%
High-boiling residues	≤0.01%	≤0.01%	≤0.01%
Inorganic chlorides	+	+	+
Chromatographic purity	+	+	+
Assay	99.6–100.0%	99.6–100.0%	99.6–100.0%

10 Typical Properties

See Table II for selected typical properties.

11 Stability and Storage Conditions

Chlorofluorocarbon propellants are nonreactive and stable at temperatures up to 550°C. The liquefied gas is stable when used as a propellant and should be stored in a metal cylinder in a cool, dry place.

12 Incompatibilities

The presence of greater than 5% water in solutions that contain trichloromonofluoromethane may lead to hydrolysis of the propellant and the formation of traces of hydrochloric acid, which may be irritant to the skin or cause corrosion of metallic canisters. Trichloromonofluoromethane may also react with aluminum, in the presence of ethanol, to cause corrosion within a cylinder with the formation of hydrogen gas. Similarly, alcohols in the presence of trace amounts of oxygen, peroxides, or other free-radical catalysts may react with trichloromonofluoromethane to form trace quantities of hydrochloric acid.

Both dichlorodifluoromethane and dichlorotetrafluoroethane are compatible with most ingredients used in pharmaceutical aerosols. Because of their poor miscibility with water, most MDIs are formulated as suspensions. However, solution MDIs can be prepared through the use of ethanol as a cosolvent for water and propellant, resulting in a clear solution (provided the water content is less than 5%).

13 Method of Manufacture

Dichlorodifluoromethane is prepared by the reaction of hydrogen fluoride with carbon tetrachloride in the presence of a suitable catalyst, such as polyvalent antimony. The dichlorodifluoromethane formed is further purified to remove all traces of water and hydrochloric acid as well as traces of the starting and intermediate materials. Trichloromonofluoromethane is also obtained by this process.

Dichlorotetrafluoroethane is prepared by the reaction of hydrogen fluoride with chlorine and perchloroethylene in the presence of a suitable catalyst such as polyvalent antimony.

14 Safety

Dichlorodifluoromethane, dichlorotetrafluoroethane, and trichloromonofluoromethane have been used for over 50 years as propellants in topical, oral, and nasal aerosol formulations, and are generally regarded as nontoxic and nonirritant materials when used as directed.

The propellants used for metered-dose inhalant aerosol products generally vaporize quickly and most of the vapors escape and are not inhaled. However, a small amount of the propellant may be inhaled with the active ingredient and be carried to the respiratory system. These amounts of propellant do not present a toxicological problem and are quickly cleared from the lungs. Deliberate inhalation of excessive quantities of fluorocarbon propellant may result in death, and the following 'warning' statements must appear on the label of all aerosols:

> **WARNING:** Avoid inhalation. Keep away from eyes or other mucous membranes.

(Aerosols designed specifically for oral inhalation need not contain this statement.)

> **WARNING:** Do not inhale directly; deliberate inhalation of contents can cause death.

or

> **WARNING:** Use only as directed; intentional misuse by deliberately concentrating and inhaling the contents can be harmful or fatal.

Additionally, the label should contain the following information:

> **WARNING:** Contents under pressure. Do not puncture or incinerate container. Do not expose to heat or store at room temperature above 120°F (49°C). Keep out of the reach of children.

Table II: Selected typical properties for chlorofluorocarbon propellants.

Test	Propellant 12	Propellant 114	Propellant 11
Boiling point	−29.8°C	4.1°C	23.7°C
Critical pressure	4.01 MPa (39.6 atm)	3268 kPa (474 psia)	4.38 MPa (43.2 atm)
Critical temperature	111.5°C	145.7°C	198°C
Density

Viscosity (dynamic)			
Liquid at 21°C	0.262 mPa s (0.262 cP)	0.386 mPa s (0.386 cP)	0.439 mPa s (0.439 cP)
Liquid at 54.5°C	0.227 mPa s (0.227 cP)	0.296 mPa s (0.296 cP)	0.336 mPa s (0.336 cP)

In the USA, the Environmental Protection Agency (EPA) additionally requires the following information on all aerosols containing chlorofluorocarbons as the propellant:

> **WARNING:** Contains a chlorofluorocarbon that may harm the public health and environment by reducing ozone in the upper atmosphere.

(Metered-dose inhalers are exempt from this regulation.)

15 Handling Precautions

Dichlorodifluoromethane and dichlorotetrafluoroethane are usually encountered as a liquefied gas and appropriate precautions for handling such materials should be taken. Eye protection, gloves, and protective clothing are recommended. These propellants should be handled in a well-ventilated environment. Chlorofluorocarbon vapors are heavier than air and do not support life; therefore, when cleaning large tanks that have contained chlorofluorocarbons, adequate provisions for supply of oxygen in the tanks must be made in order to protect workers cleaning the tanks.

Although nonflammable, when heated to decomposition chlorofluorocarbons emit toxic fumes containing phosgene and fluorides. Although not as volatile as dichlorodifluoroethane or dichlorotetrafluoroethane, trichloromonofluoromethane should be handled as indicated above. Since it is a liquid at room temperature, caution should be exercised in handling this material to prevent spillage onto the skin. It is an irritant to the eyes.

The long-term workplace exposure limit (8-hour TWA) for dichlorodifluoromethane and dichlorotetrafluoroathane is 7110 mg/m^3 (1000 ppm). The short-term workplace exposure limit (15-minute) for both compounds is 8890 mg/m^3 (1250 ppm).[1]

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (aerosol formulations for inhalation, nasal, oral, and topical applications). With few exceptions for existing MDIs, the FDA and EPA banned the use of CFCs in the US after 31st December 2008, with all CFCs phased out by 2010–2013.

The FDA has published its timeline for removing MDIs containing CFCs from the shelves of US pharmacies and hospitals. Most of the inhalers containing CFCs will no longer be sold after the year 2010, and any other CFC-containing MDIs will not be sold after mid-2011. The final two MDIs containing CFCs will no longer be available after 2013. Following this date, CFC-containing MDIs will no longer be available in the US and only those MDIs that contain an HFA as the propellant will be available.

17 Related Substances

—

18 Comments

Although chlorofluorocarbons are no longer available for use in pharmaceutical formulation, the monograph remains in the *Handbook* to assist formulators in their understanding of old products, whose properties they may need to reproduce. They may still be present in some commercial products.

Fluorocarbon (FC) aerosol propellants may be identified by a standardized numbering nomenclature; for example, dichlorodifluoromethane is known as propellant 12, while dichlorotetrafluoroethane is known as propellant 114.

Usually, three digits are used to describe the propellant, except when the first digit would be zero, in which case only two digits are used. The first digit is one less than the number of carbon atoms in the molecule. Thus, if the molecule is a methane derivative the first digit would be zero (1 – 1) and is ignored, so that only two digits are used in the propellant description; e.g. propellant 12. For an ethane derivative, the first digit would be a one (2 – 1); e.g. propellant 114.

The second digit is one more than the number of hydrogen atoms in the molecule, while the third digit represents the number of fluorine atoms in the molecule. The difference between the sum of the fluorine and hydrogen atoms and the number of atoms required to saturate the carbon chain is the number of chlorine atoms in the molecule. Isomers of a compound have the same identifying number and an additional letter; a, b, c, and so on. Cyclic derivatives are indicated by the letter C before the identifying number. With

unsaturated propellants, the number 1 is used as the fourth digit from the right to indicate an unsaturated double bond.

Thus for dichlorodifluoromethane (propellant 12):

(a) First digit = 0 signifies number of C atoms = 1

(b) Second digit = 1 signifies number of H atoms = 0

(c) Third digit = 2 signifies number of F atoms = 2

(d) Number of Cl atoms = 4 – (2 – 0) = 2

Under the terms of the Montreal Protocol, aimed at reducing damage to the ozone layer, the use of chlorofluorocarbons, including dichlorodifluoromethane, dichlorotetrafluoroethane, and trichloromonofluoromethane, has been prohibited from January 1996.[2–6] However, this prohibition does not apply to essential uses such as existing pharmaceutical formulations for which no alternative chlorofluorocarbon-free product is available. The EPA and FDA approved essential-use status for dichlorodifluoromethane for a sterile aerosol talc used in the treatment of malignant pleural effusion in patients with lung cancer.

Chloroxylenol

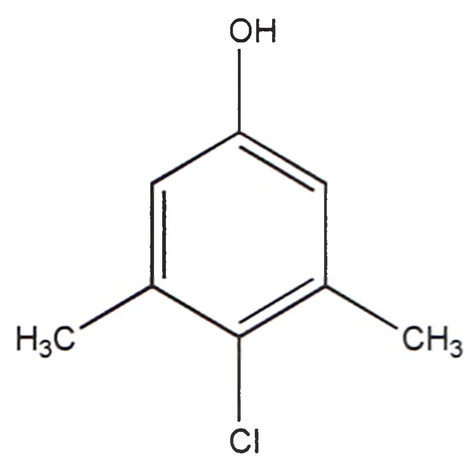
1 Nonproprietary Names

BP: Chloroxylenol

USP–NF: Chloroxylenol

2 Synonyms

4-Chloro-3,5-dimethylphenol; 2-chloro-5-hydroxy-1,3-dimethylbenzene; 4-chloro-1-hydroxy-3,5-dimethylbenzene; 2-chloro-5-hydroxy-*m*-xylene; 2-chloro-*m*-xylenol; 3,5-dimethyl-4-chlorophenol; *Nipacide PX*; parachlorometaxylenol; *p*-chloro-*m*-xylenol; PCMX.



3 Chemical Name and CAS Registry Number

4-Chloro-3,5-xylenol [88-04-0]

4 Empirical Formula and Molecular Weight

C_8H_9ClO 156.61

5 Structural Formula

6 Functional Category

Antimicrobial preservative.

7 Applications in Pharmaceutical Formulation or Technology

As a pharmaceutical excipient, chloroxylenol is commonly used in low concentrations, typically at concentrations of 0.1–0.8%, as an

antimicrobial preservative in topical formulations such as creams and ointments. Chloroxylenol is also used in a number of cosmetic formulations.

8 Description

White or cream-colored crystals or crystalline powder with a characteristic phenolic odor. Volatile in steam.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for chloroxylenol.

Test	BP 2017	USP 40–NF 35 S1
Identification	+	+
Characters	+	–
Residue on ignition	–	≤0.1%
Water	–	≤0.5%
Iron	–	≤0.01%
Organic impurities	–	+
Melting range	114–116°C	–
Related substances	+	+
Assay	98.0–103.0%	≥98.5%

10 Typical Properties

Antimicrobial activity Chloroxylenol is effective against Gram-positive bacteria but less active against Gram-negative bacteria. The activity of chloroxylenol against Gram-negative bacilli can be increased by the addition of a chelating agent such as edetic acid.[1] Chloroxylenol is inactive against bacterial spores. Antimicrobial activity may be reduced by loss of chloroxylenol from a formulation due to incompatibilities with packaging materials or other excipients, such as nonionic surfactants.[2] Solution pH does not have a marked effect on the activity of chloroxylenol.[3] Minimum inhibitory concentration (MIC) determinations may be affected by growth conditions and the exact strain of organism tested. Reported ranges for chloroxylenol MIC against common microorganisms are: *Pseudomonas aeruginosa* 200–1000 ppm; *Escherichia coli* 125–500 ppm; *Staphylococcus aureus* 100–500 ppm; *Aspergillus niger* 50–100 ppm.[4]

Acidity $pK_a = 9.7$[5]

Boiling point 246°C

Density 0.89 g/cm^3 at 20°C[5]

Melting point 115.5°C

Partition coefficient Octanol : water log $k_{ow} = 3.27$[5]

Solubility Freely soluble in ethanol (95%); soluble in ether, terpenes, and fixed oils; very slightly soluble in water. Dissolves in solutions of alkali hydroxides.

See also Table II.

Table II: Solubility of chloroxylenol.[6]

Solvent	Solubility at 15°C unless otherwise stated (g/100 mL)
Petroleum ether	0.5
Benzene	6.0
Acetone	58.0
Toluene	7.0
Chloroform	6.2
Isopropanol	38.0
Water (15°C)	0.03
Water (100°C)	0.5

11 Stability and Storage Conditions

Chloroxylenol is stable at normal room temperature, but is volatile in steam. Contact with natural rubber should be avoided. Aqueous solutions of chloroxylenol are susceptible to microbial contamination and appropriate measures should be taken to prevent contamination during storage or dilution. Chloroxylenol should be stored in polyethylene, mild steel or stainless steel containers, which should be well-closed and kept in a cool, dry place. Chloroxylenol does not absorb at wavelengths >290 nm and has been reported to be stable to sunlight for up to 24 hours.[5]

12 Incompatibilities

Chloroxylenol has been reported to be incompatible with nonionic surfactants and methylcellulose.

13 Method of Manufacture

Chloroxylenol is prepared by treating 3,5-dimethylphenol with chlorine or sulfuryl chloride (SO_2Cl_2).

14 Safety

Chloroxylenol is generally regarded as a relatively nontoxic and nonirritant material when used as an excipient in topical products. However, chloroxylenol has been placed in Toxicity Category I for eye irritation effects.[6] In addition, allergic skin reactions have been reported.[7–11] Taken orally, chloroxylenol is mildly toxic. However, ingestion of a chloroxylenol-containing disinfectant product has been associated with reports of fatal[12] or severe instances of self-poisoning.[13,14]

LD_{50} (mouse, IP): 0.115 g/kg[15]

LD_{50} (rat, dermal): >2.0 g/kg[5]

LD_{50} (rat, oral): 3.83 g/kg[15]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Chloroxylenol is an eye irritant, and eye protection is recommended. When heated to decomposition, chloroxylenol emits toxic fumes.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (otic preparations; topical creams and emulsions). Included in nonparenteral medicines licensed in the UK. Approved in Europe as a preservative in cosmetics with a maximum authorized concentration of 0.5%.[16]

17 Related Substances

Chlorocresol.

18 Comments

Therapeutically, chloroxylenol has been investigated as a treatment for acne vulgaris,[17,18] for treating infected root canals,[19] and as an antifungal agent when impregnated into medical devices.[20] Chloroxylenol is included in drug products approved for topical acne, treatment of superficial fungal infections, and dandruff/seborrheic dermatitis/psoriasis. However the data supporting safety and effectiveness of chloroxylenol in the treatment of topical acne is stated to be inadequate.[21] Chloroxylenol is a common constituent of many proprietary disinfectants used for skin and wound disinfection, typically at concentrations of 2–5%.

The EINECS number for chloroxylenol is 201-793-8. The PubChem Compound ID (CID) for chloroxylenol described in this monograph is 2723.

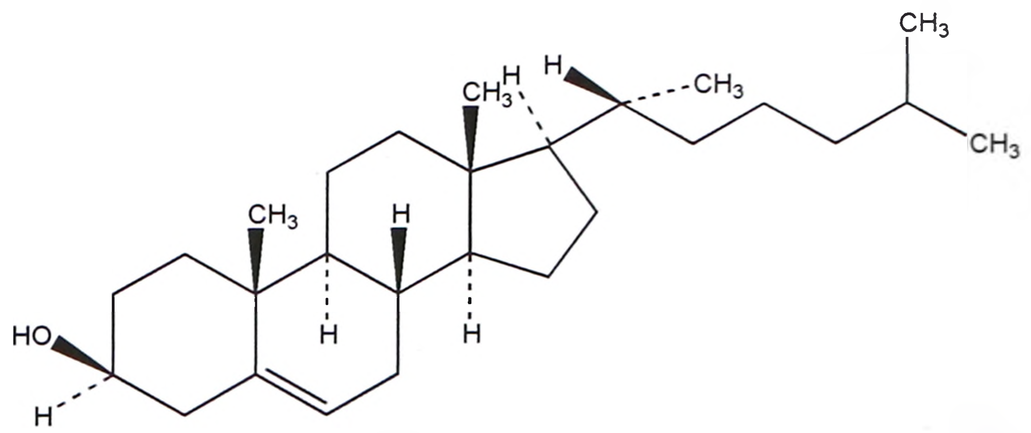
Cholesterol

1 Nonproprietary Names

BP: Cholesterol
JP: Cholesterol
PhEur: Cholesterol
USP–NF: Cholesterol

2 Synonyms

Cholest-5-ene-3β-ol; Cholesterin; cholesterolum; 3β-hydroxy-5-cholestene.



3 Chemical Name and CAS Registry Number

Cholest-5-en-3β-ol [57-88-5]

4 Empirical Formula and Molecular Weight

$C_{27}H_{46}O$ 386.65

5 Structural Formula

6 Functional Category

Emollient; emulsifying agent.

7 Applications in Pharmaceutical Formulation or Technology

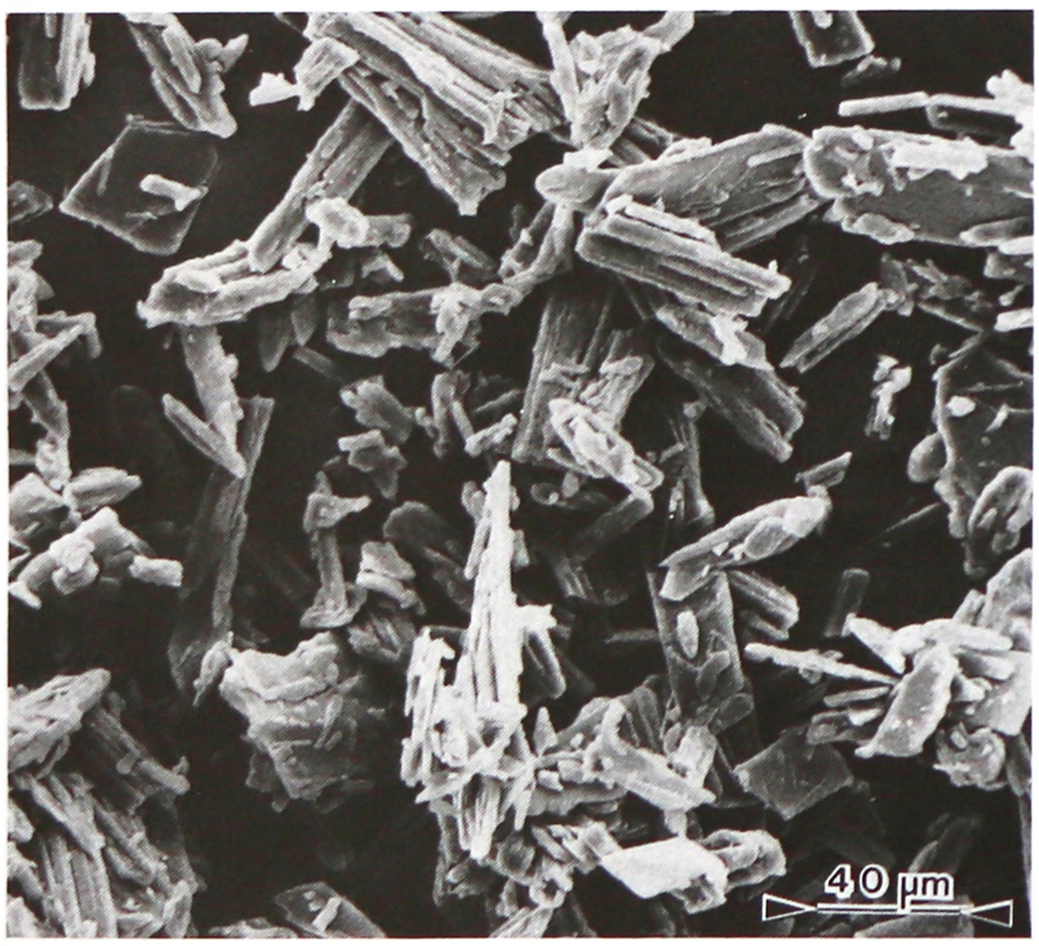
Cholesterol is used in cosmetics and topical pharmaceutical formulations at concentrations of 0.3–5.0% w/w as an emulsifying

agent. It imparts water-absorbing power to an ointment and has emollient activity. It has been used as an emulsion stabilizing agent for parenteral lipid emulsions,[1] liposomes[2,3] and niosomes.[4,5]

8 Description

Cholesterol occurs as white or faintly yellow, almost odorless, pearly leaflets, needles, powder, or granules. On prolonged exposure to light and air, cholesterol acquires a yellow to tan color.

9 Pharmacopeial Specifications



See Table I. The PhEur also contains a specification for cholesterol for parenteral use.

10 Typical Properties

Boiling point 360°C (some decomposition)
Density 1.067 g/cm^3 at 25°C.[6]
Dielectric constant D^{20} = 5.41
Flash Point >93°C (closed cup)[6]
Melting point 147–150°C
Solubility *see* Table II.[7–9]
Specific rotation

$[\alpha]_D^{20}$ = −39.5° (2% w/v solution in chloroform);
$[\alpha]_D^{20}$ = −31.5° (2% w/v solution in ether).

Vegetable oils	Soluble
Water	Practically insoluble

11 Stability and Storage Conditions

Cholesterol is stable and should be stored in a well-closed container, protected from light.

12 Incompatibilities

Cholesterol is precipitated by digitonin.

13 Method of Manufacture

The commercial material is normally obtained from the spinal cord of cattle by extraction with petroleum ethers, but it may also be obtained from wool fat. Purification is normally accomplished by repeated bromination. Cholesterol may also be produced by entirely synthetic means.[10]

Cholesterol produced from animal organs will always contain cholestanol and other saturated sterols.

See also Section 14.

14 Safety

Cholesterol is generally regarded as an essentially nontoxic and nonirritant material at the levels employed as an excipient.[9] It has, however, exhibited experimental teratogenic and reproductive effects, and mutation data have been reported.[11]

Cholesterol is often derived from animal sources and this must be done in accordance with the regulations for human consumption. The risk of bovine spongiform encephalopathy (BSE) contamination has caused some concern over the use of animal-derived cholesterol in pharmaceutical products.[12] However, synthetic methods of cholesterol manufacture have been developed.[10]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Rubber or plastic gloves, eye protection, and a respirator are recommended.

May be harmful following inhalation or ingestion of large quantities, or over prolonged periods of time, owing to the possible involvement of cholesterol in atherosclerosis and gallstones. May be irritant to the eyes. When heated to decomposition, cholesterol emits acrid smoke and irritating fumes.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (injections; ophthalmic, topical, and vaginal preparations).

Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Lanolin; lanolin alcohols; lanolin, hydrous.

18 Comments

A novel cholesterol-based cationic lipid has been developed that promotes DNA transfer in cells.[13,14] Cholesterol monohydrate becomes anhydrous at 70–80°C.

Cholesterol also has a physiological role. It is the major sterol of the higher animals, and it is found in all body tissues, especially in the brain and spinal cord. It is also the main constituent of gallstones. Cholesterol has been reported to improve utilization of parenteral lipid emulsion when used as a nutritional substrate in parenteral nutrition.[15]

The EINECS number for cholesterol is 200-353-2. The PubChem Compound ID (CID) for cholesterol includes 304 and 5997.

Cholestyramine Resin

1 Nonproprietary Names

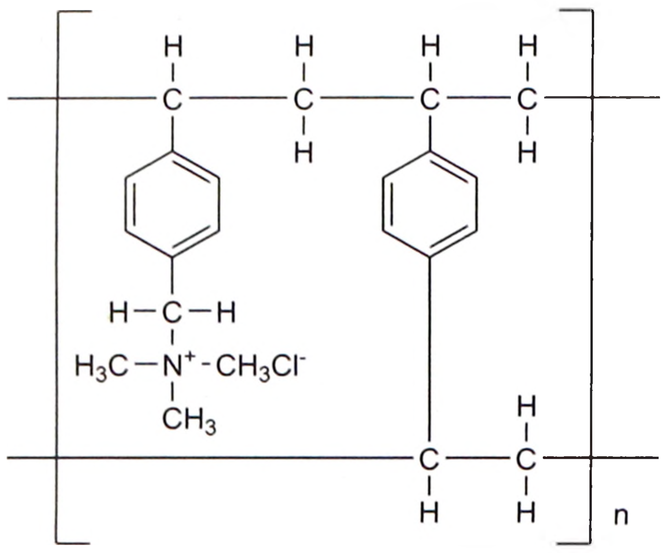
PhEur: Colestyramine

USP–NF: Cholestyramine Resin

2 Synonyms

Cholestyramine; colestyraminum; *DUOLITE AP143*; *Purolite A430MR*.

3 Chemical Name and CAS Registry Number



Cholestyramine [11041-12-6]

4 Empirical Formula and Molecular Weight

Cholestyramine resin is a strongly basic anion exchange-resin in the chloride form, consisting of styrene-divinylbenzene copolymer with quaternary ammonium functional groups.

Cholestyramine resin is a polymer of infinite molecular weight. The infinite molecular weight is due to the cross-linked structure of the styrene-divinylbenzene copolymer. The cross-linking nature of styrene and divinylbenzene leads to one large polymer molecule (tri-dimensional matrix). Due to this chemistry, an average molecular weight determination is not possible.

5 Structural Formula

6 Functional Category

Complexing agent; modified-release agent; solubilizing agent; taste-masking agent.

7 Applications in Pharmaceutical Formulation or Technology

Cholestyramine resin is used as an excipient to form a complex ('resinate') with molecules to modify the release profile, and to improve solubility and taste-masking. The chloride ion is exchanged with the anionic drug, which is released by further exchange with anions in the gastrointestinal tract.[1] It has also been identified for uses as an abuse deterrent, to increase drug stability, and to eliminate polymorphism.[2]

Typical drug loadings of cholestyramine resin range between 5–50% of the total exchange capacity. The amount of drug loaded is dependent on factors such as selectivity of exchange resin for the drug, concentration of the drug for exchange, or competition from anions in the exchange solution. The rate of loading will be influenced by the drug size and the extent of resin swelling.[1] The drug can be loaded onto the resin by a batch or continuous column process, however batch equilibration is preferred when the resin is a finely divided powder. It may be necessary to repeat the loading stage two or more times to achieve maximum drug loading.[1] High drug charge density, low drug molecular weight, and high concentration of the drug with few competing anions are properties that favor high loading capacity. Drug release *in vivo* is controlled by the diffusion rate of the drug from the resin, the selectivity of the drug for the resin, and concentration of electrolytes in the exchange environment.[1]

Diclofenac potassium–cholestyramine resin complexes have been shown to improve the onset and length of action of the drug, and drug tolerability.[3]

See also The Selection of Excipients for Oral Solid Dosage Forms.

8 Description

Cholestyramine resin occurs as a white or almost white, hygroscopic, fine powder. It is odorless or has not more than a slight amine-like odor.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for cholestyramine resin.

Test	USP 40–NF 35 S1	PhEur 9.2
Identification	+	+
pH	4.0–6.0	4.0–6.0
Loss on drying	≤12.0%	≤12%
Residue on ignition	≤0.1%	—
Sulfated ash	—	≤0.1%
Heavy metals	0.002%	—
Dialyzable quaternary amines	≤0.05%	≤500 ppm
Chloride content (dried basis)	13.0–17.0%	13.0–17.0%
Exchange capacity (dried basis)	1.8–2.2 g/g	1.8–2.2 g/g
Styrene	—	≤1 ppm

10 Typical Properties

Autoignition temperature >500°C[4]
Bulk density 500 g/L[5]
Flash point >93.3°C (closed cup)[4]
Moisture content 12%
Relative density 1.15–1.20[6]
Solubility Insoluble in water, alcohol, benzene, chloroform, and ether.[6,7]
Specific gravity 1.08[4]
Spectroscopy IR spectrum *see* Figure 1.

11 Stability and Storage Conditions

Cholestyramine resin is stable for at least 2 years. It is recommended to store the product in its original air-tight packaging, and under normal storage conditions, away from heat, light or moisture.

12 Incompatibilities

Cholestyramine resin is incompatible with oxidising agents, which may lead to degradation of the ion exchange resin. Strong oxidising agents and nitric acid may cause explosive reactions.

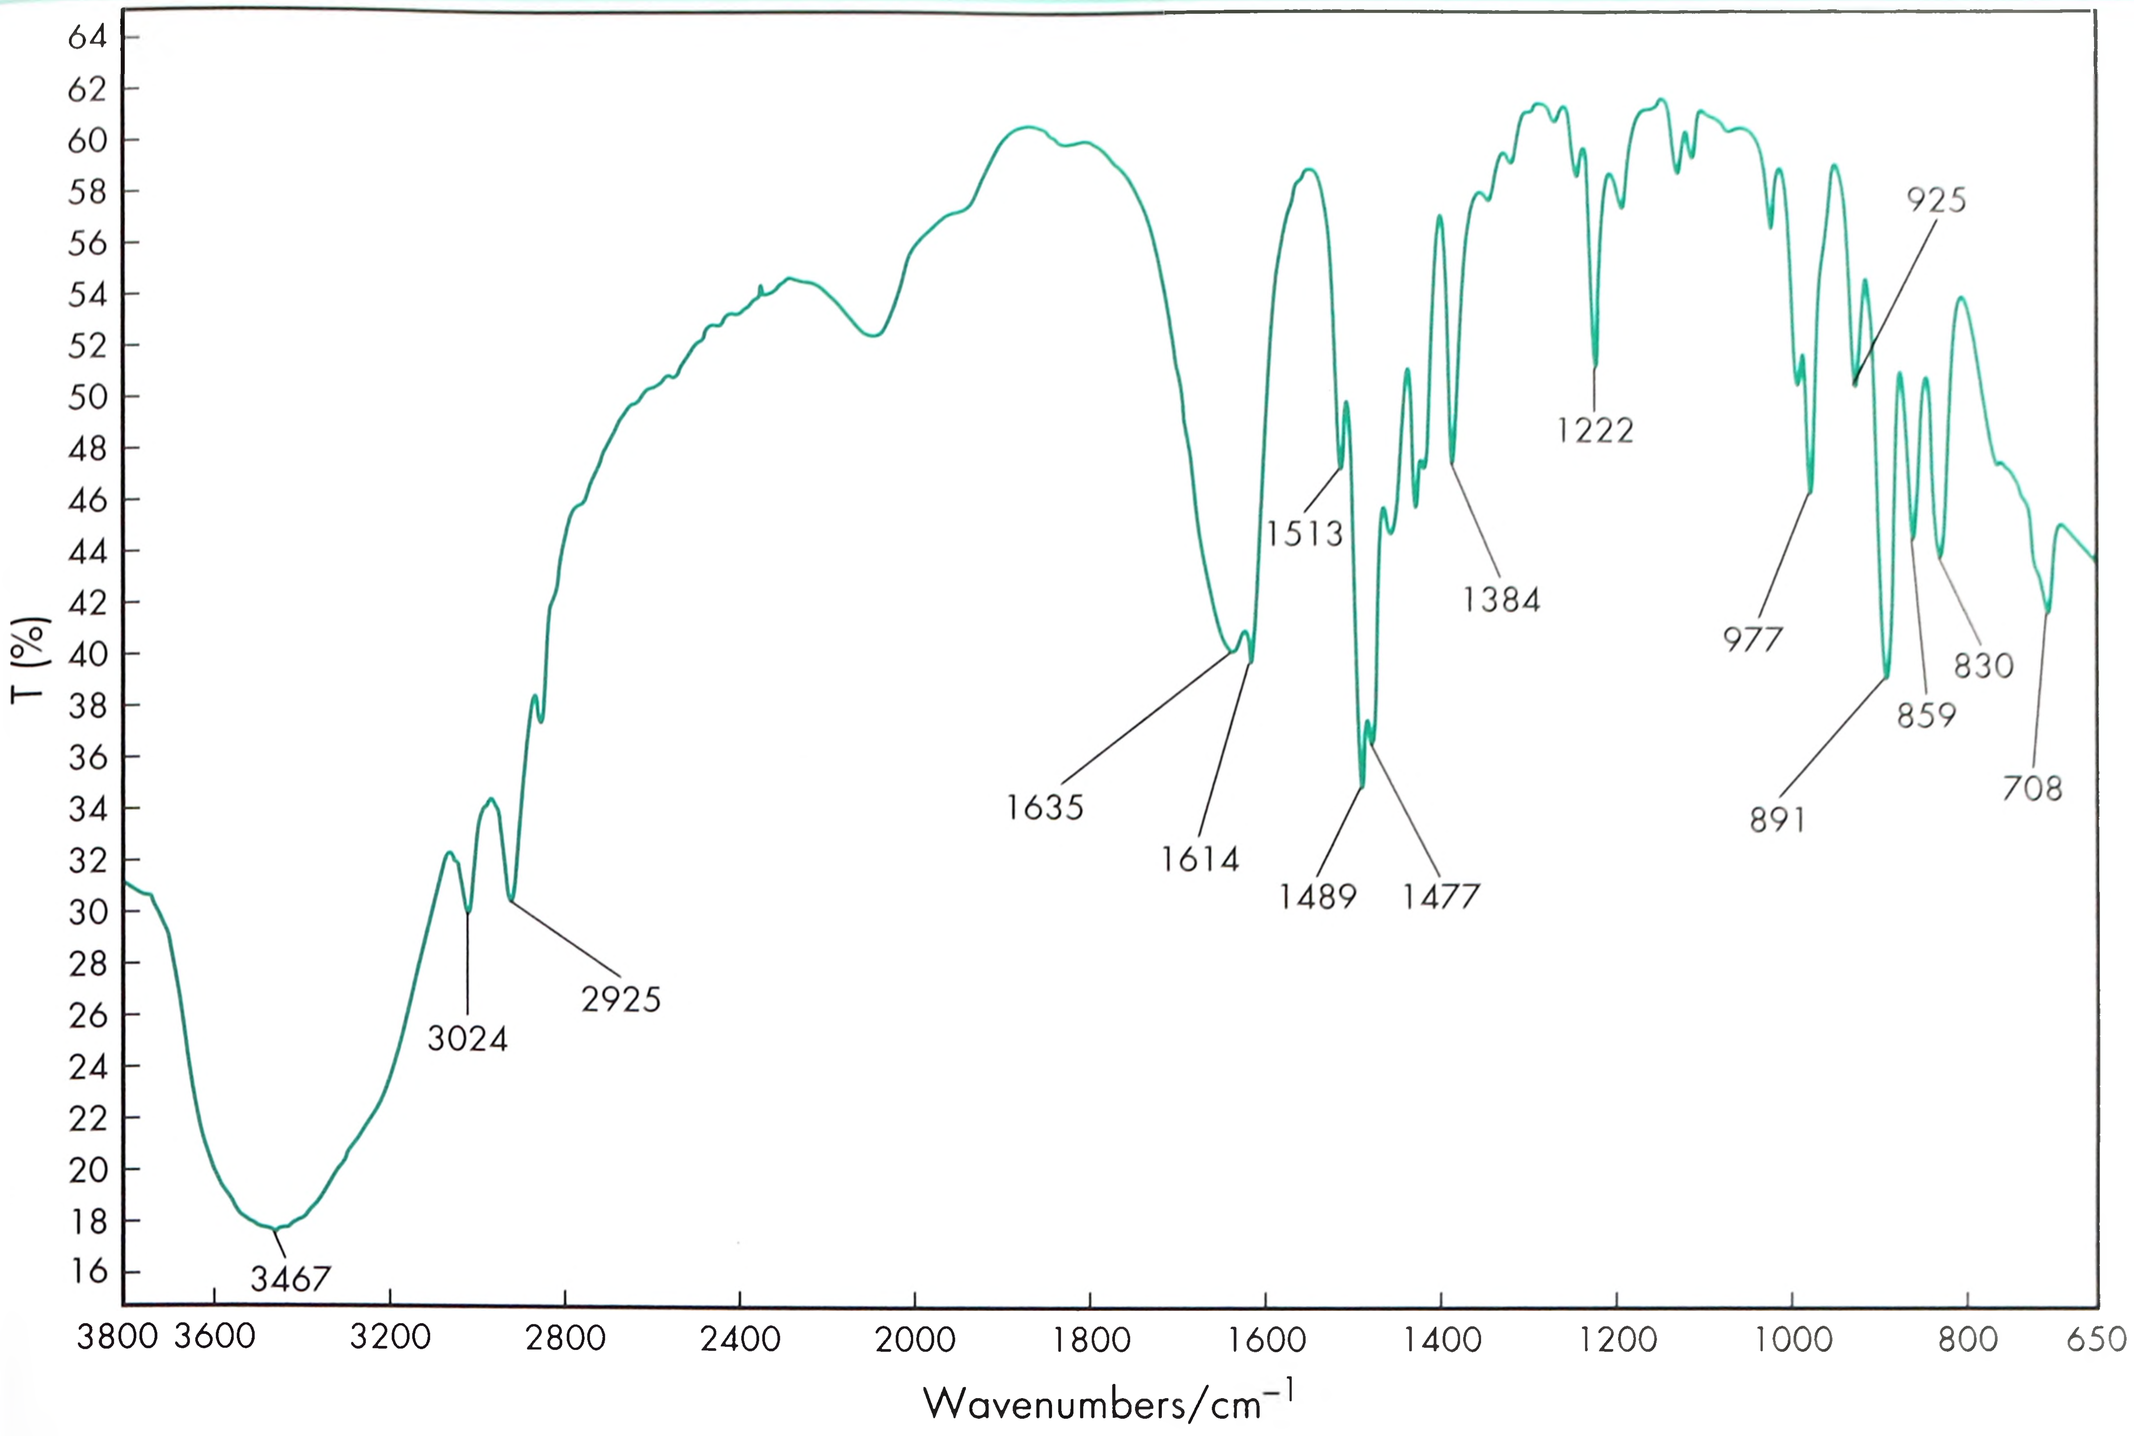


Figure 1: Infrared spectrum of cholestyramine measured by transmission.

13 Method of Manufacture

Cholestyramine resin is produced from a styrene-divinylbenzene copolymer which is chloromethylated (Friedel-Crafts reaction) and further aminated using a quaternary amine such as trimethylamine. This leads to an anion–exchange resin in the form of spherical beads, which is further ground to obtain a powder.[8]

14 Safety

Cholestyramine resin is not mutagenic in the Ames test.[9] Ingestion, inhalation or contact with eyes or skin may cause irritation.[4,6]

LD_{50} (rat, oral): >2 g/kg[9]
LD_{50} (rabbit, oral): >3 g/kg[4]
LD_{50} (mouse, oral): >7.5 g/kg[4]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. Dust formation should be avoided. Avoid contact with eyes. Eye protection and gloves are recommended.

Temperatures over 220°C should be avoided. When heated to decomposition, cholestyramine resin may emit carbon oxides, nitrogen oxides, styrene and ammonia.

16 Regulatory Status

Used as an inactive ingredient in *Flotac* ('resinate' with diclofenac) in Brazil, Chile, Mexico, and Venezuela. Included in the Canadian Natural Health Products database.

17 Related Substances

—

18 Comments

Cholestyramine resin is described in the USP 40–NF 35 S1 and PhEur 9.2 as a powder; however no specific particle size distribution is prescribed. Manufacturers have developed cholestyramine powders meeting a wide range of particle size distributions, in order to meet specific customer's requirements. For example:

DUOLITE AP143/1092 (Dow Chemical Co.): Fine (only 10–30% of the powder is retained on a 50 µm sieve);

DUOLITE AP143/1083 and *DUOLITE AP143/1073* (Dow Chemical Co.): Middle (about 30% of the powder is retained on a 75 µm sieve);

DUOLITE AP143/1096 (Dow Chemical Co.): Coarse (50% of the powder is retained on a 110 µm sieve);

DUOLITE AP143/1016 (Dow Chemical Co.): Coarse (about 40% of the powder is retained on a 125 µm sieve).

Cholestyramine resin is a bile acid sequestrant. It is used as to treat hypercholesterolemia,[8] and it may be used to treat certain kinds of diarrheas.[10] It is included as an active ingredient in a number of approved drug products worldwide including USA, UK, Canada and France. Cholestyramine is also recommended in some washout procedures to mitigate hepatoxicity induced by certain drugs (e.g. *Leflunomide*).[11]

The EINECS number for cholestyramine resin is 234-270-8. The PubChem Compound ID (CID) for cholestyramine resin is 70695640. The UNII code for cholestyramine resin is 4B33BGI082.

Citric Acid Monohydrate

1 Nonproprietary Names

BP: Citric Acid Monohydrate

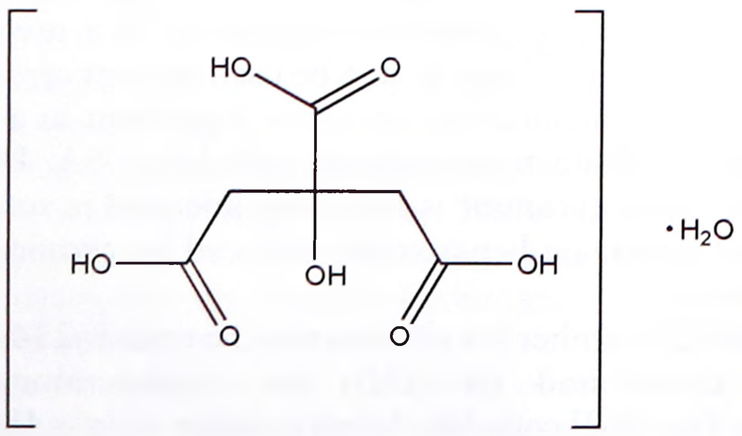
JP: Citric Acid Hydrate

PhEur: Citric Acid Monohydrate

USP–NF: Citric Acid Monohydrate

2 Synonyms

Acidum citricum monohydricum; E330; 2-hydroxypropane-1,2,3-tricarboxylic acid monohydrate.



3 Chemical Name and CAS Registry Number

2-Hydroxy-1,2,3-propanetricarboxylic acid monohydrate [5949-29-1]

4 Empirical Formula and Molecular Weight

$C_6H_8O_7 \cdot H_2O$ 210.14

5 Structural Formula

6 Functional Category

Acidulant; antioxidant; buffering agent; complexing agent; flavor enhancer.

7 Applications in Pharmaceutical Formulation or Technology

Citric acid (as either the monohydrate or anhydrous material) is widely used in pharmaceutical formulations and food products, primarily to adjust the pH of solutions. Citric acid monohydrate is used in the preparation of effervescent granules, while anhydrous citric acid is widely used in the preparation of effervescent tablets.[1–3] Citric acid has also been shown to improve the stability of spray-dried insulin powder in inhalation formulations.[4]

In food products, citric acid is used as a flavor enhancer for its tart, acidic taste. Citric acid monohydrate is used as a sequestering agent and antioxidant synergist; *see* Table I. It is also a component of anticoagulant citrate solutions.

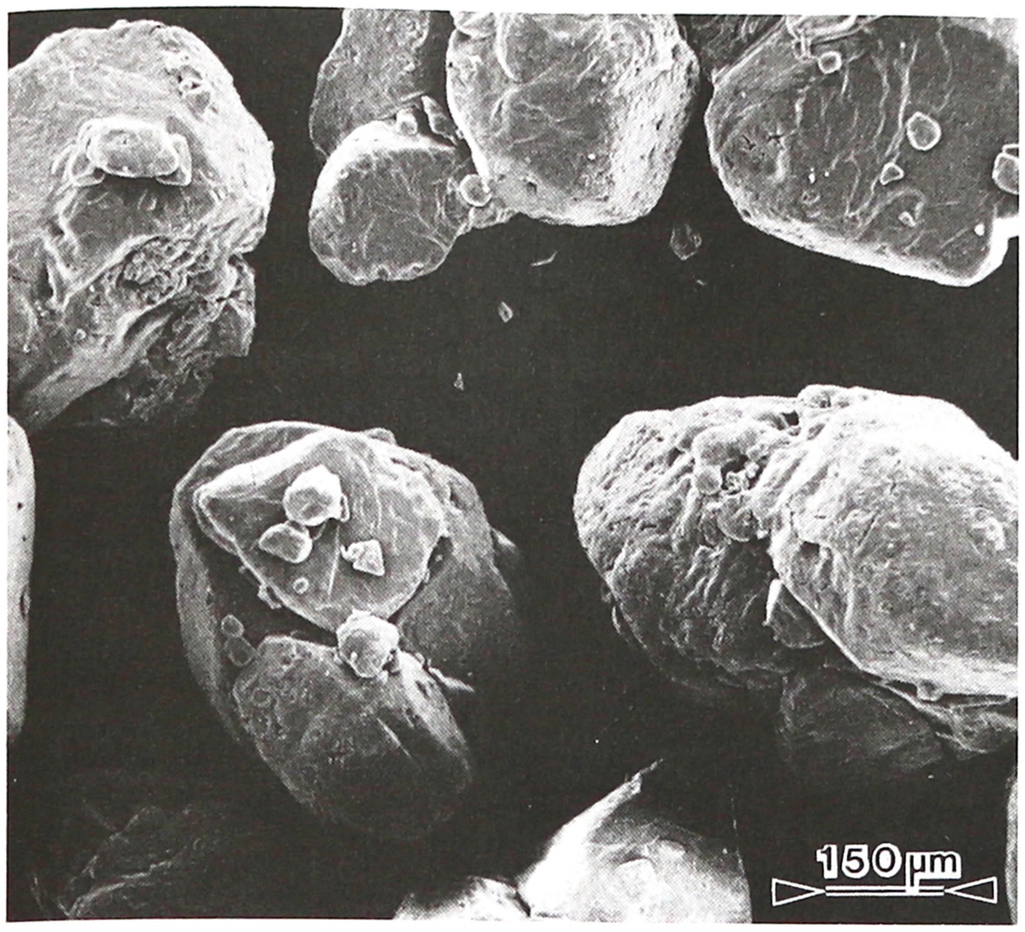


Table I: Uses of citric acid monohydrate.

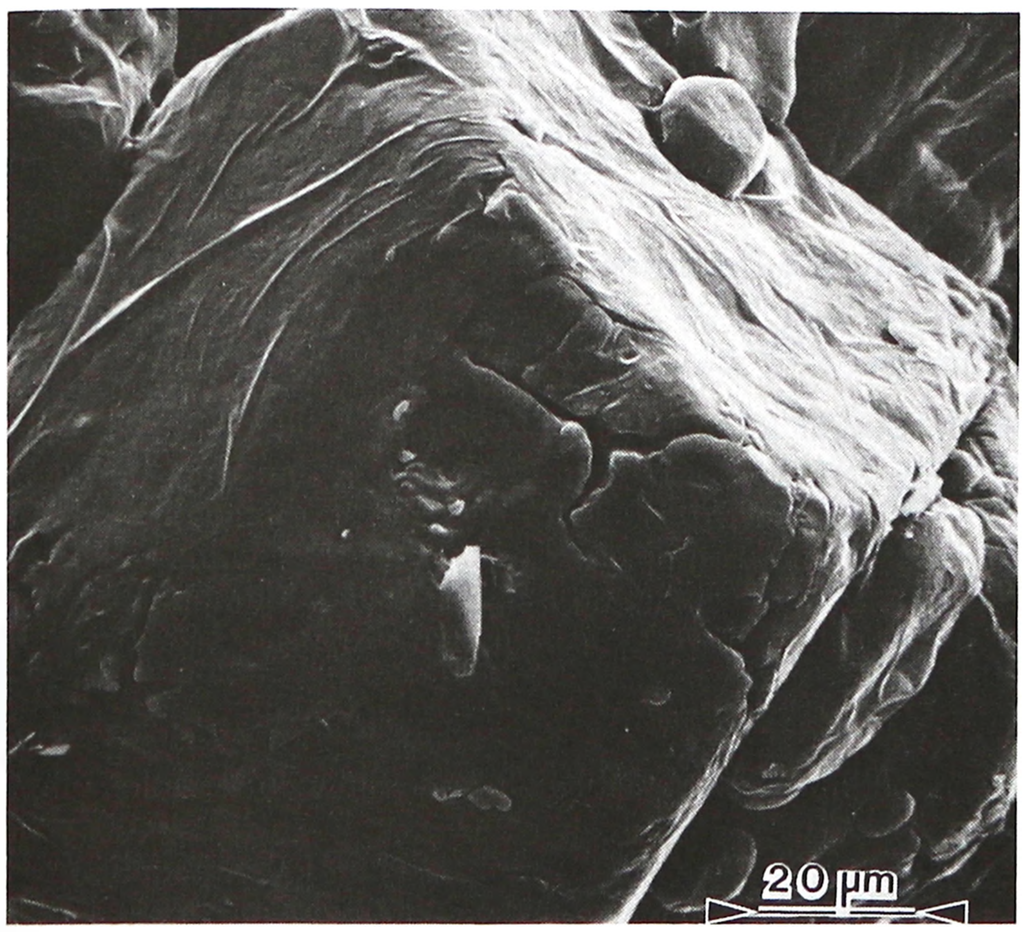
Use	Concentration (%)
Buffer solutions	0.1–2.0
Complexing agent	0.3–2.0
Flavor enhancer for liquid formulations	0.3–2.0



8 Description

Citric acid monohydrate occurs as colorless or translucent crystals, or as a white crystalline, efflorescent powder. It is odorless and has a strong acidic taste. The crystal structure is orthorhombic.

SEM 1: Excipient: citric acid monohydrate; manufacturer: Pfizer Ltd; magnification: 60×.

SEM 2: Excipient: citric acid monohydrate; manufacturer: Pfizer Ltd; magnification: 600×.

9 Pharmacopeial Specifications

The pharmacopeial specifications for citric acid monohydrate have undergone harmonization of many attributes for JP, PhEur, and USP–NF.

See Table II. *See also* Sections 17 and 18.

Note that the JP XVII, PhEur 9.2 and USP 40–NF 35 S1 have separate monographs for the monohydrate and anhydrous material.

10 Typical Properties

Acidity/alkalinity pH = 2.2 (1% w/v aqueous solution)

Dissociation constant

pK_{a1}: 3.128 at 25°C;

pK_{a2}: 4.761 at 25°C;

pK_{a3}: 6.396 at 25°C.

Density 1.542 g/cm^3

Heat of combustion −1972 kJ/mol (−471.4 kcal/mol)

Table II: Pharmacopeial specifications for citric acid monohydrate (and anhydrous).

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters[a]	—	+	—
Appearance of solution	+	+	+
Water			
(hydrous form)	7.5–9.0%	7.5–9.0%	7.5–9.0%
(anhydrous form)	≤1.0%	≤1.0%	≤1.0%
Sterility[a]	—	—	+

(a) These tests have not been fully harmonized at the time of publication.
(b) If intended for use in parenteral preparations.
(c) Where it is labeled as intended for use in dialysis.

Heat of solution −16.3 kJ/mol (−3.9 kcal/mol) at 25°C

Hygroscopicity At relative humidities less than about 65%, citric acid monohydrate effloresces at 25°C, the anhydrous acid being formed at relative humidities less than about 40%. At relative humidities between about 65% and 75%, citric acid monohydrate absorbs insignificant amounts of moisture, but under more humid conditions substantial amounts of water are absorbed.

Melting point ≈100°C (softens at 75°C)

Particle size distribution Various grades of citric acid monohydrate with different particle sizes are commercially available.

Solubility Soluble 1 in 1.5 parts of ethanol (95%) and 1 in less than 1 part of water; sparingly soluble in ether.

Spectroscopy

IR spectrum *see* Figure 1.

NIR spectrum *see* Figure 2.

Raman spectrum *see* Figure 3.

Viscosity (dynamic) 6.5 mPa s (6.5 cP) for a 50% w/v aqueous solution at 25°C.

See also Section 17.

11 Stability and Storage Conditions

Citric acid monohydrate loses water of crystallization in dry air or when heated to about 40°C. It is slightly deliquescent in moist air. Dilute aqueous solutions of citric acid may ferment on standing.

The bulk monohydrate or anhydrous material should be stored in airtight containers in a cool, dry place.

12 Incompatibilities

Citric acid is incompatible with potassium tartrate, alkali and alkaline earth carbonates and bicarbonates, acetates, and sulfides. Incompatibilities also include oxidizing agents, bases, reducing agents, and nitrates. It is potentially explosive in combination with metal nitrates. On storage, sucrose may crystallize from syrups in the presence of citric acid.

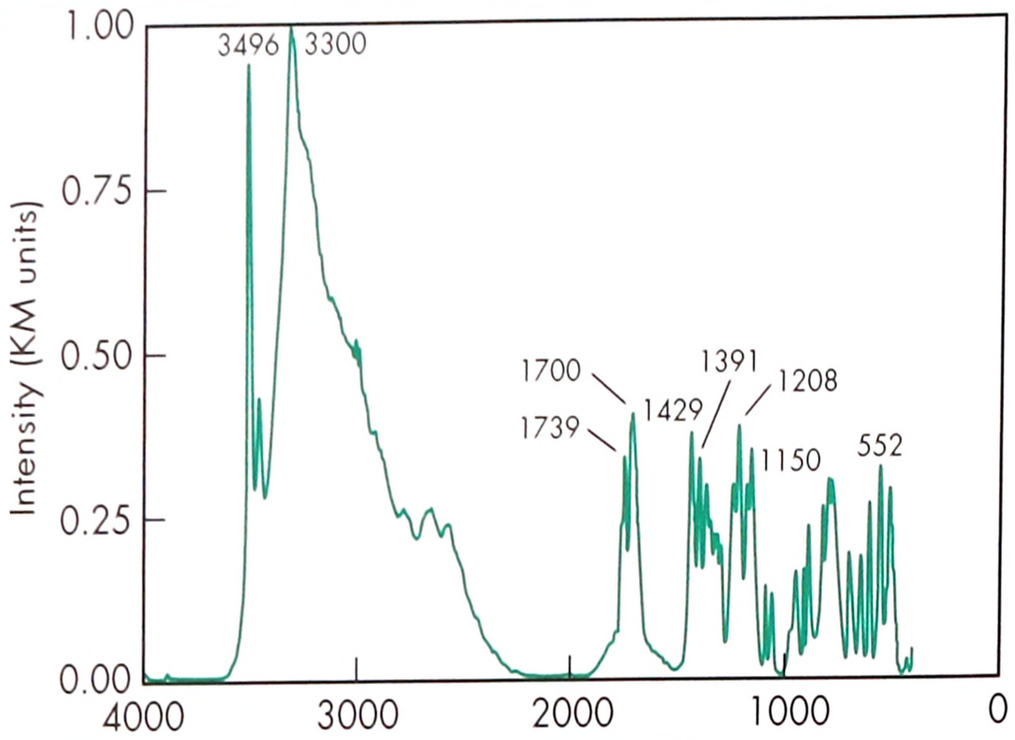

Figure 1: Infrared spectrum of citric acid monohydrate measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

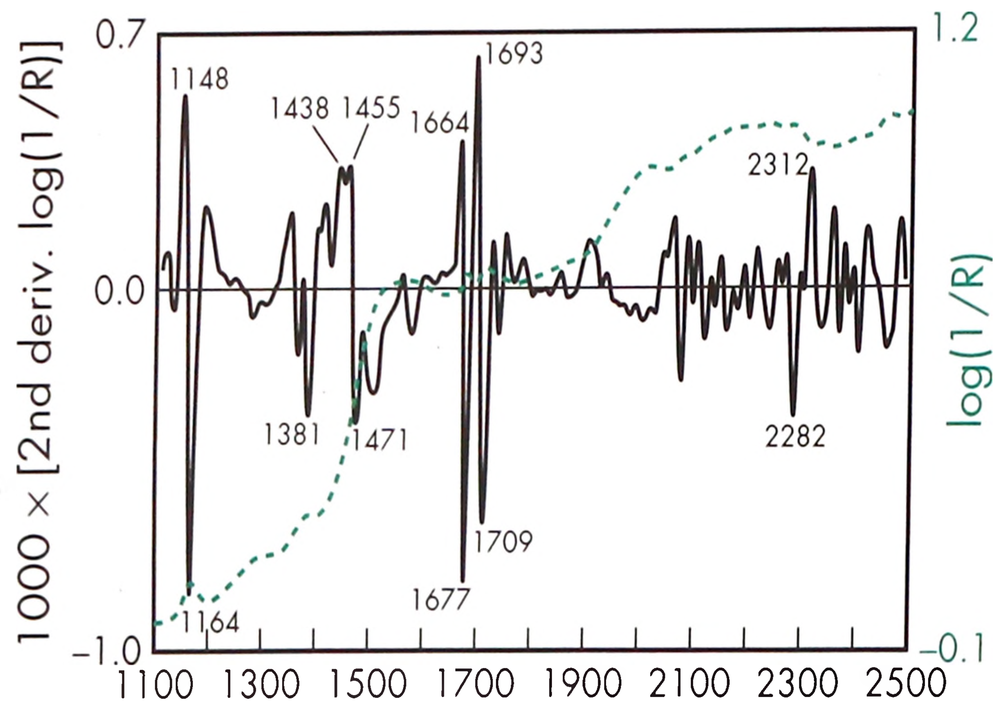

Figure 2: Near-infrared spectrum of citric acid monohydrate measured by reflectance.

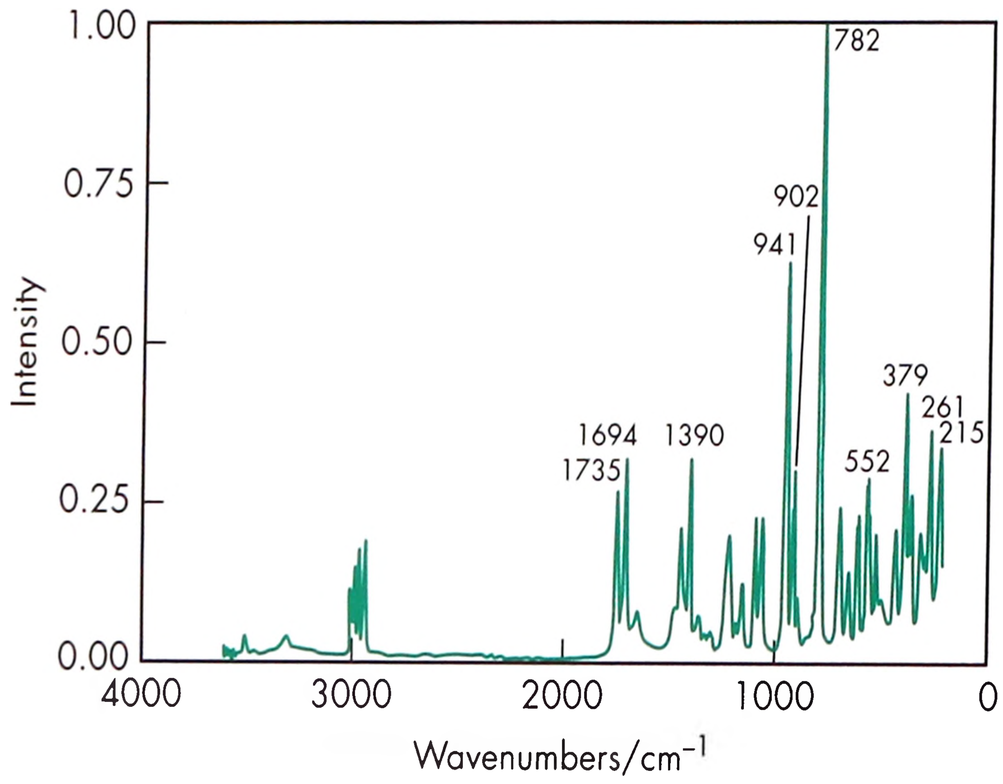

Figure 3: Raman spectrum of citric acid monohydrate measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

13 Method of Manufacture

Citric acid occurs naturally in a number of plant species and may be extracted from lemon juice, which contains 5–8% citric acid, or pineapple waste. Anhydrous citric acid may also be produced industrially by mycological fermentation of crude sugar solutions such as molasses, using strains of *Aspergillus niger*. Citric acid is purified by recrystallization; the anhydrous form is obtained from a hot concentrated aqueous solution and the monohydrate from a cold concentrated aqueous solution.

14 Safety

Citric acid is found naturally in the body, mainly in the bones, and is commonly consumed as part of a normal diet. Orally ingested citric acid is absorbed and is generally regarded as a nontoxic material when used as an excipient. However, excessive or frequent consumption of citric acid has been associated with erosion of the teeth.[5]

Citric acid and citrates also enhance intestinal aluminum absorption in renal patients, which may lead to increased, harmful serum aluminum levels. It has therefore been suggested that patients with renal failure taking aluminum compounds to control phosphate absorption should not be prescribed citric acid or citrate-containing products.[6]

See Section 17 for anhydrous citric acid animal toxicity data.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Eye protection and gloves are recommended. Direct contact with eyes can cause serious damage. Citric acid should be handled in a well-ventilated environment or a dust mask should be worn. It is combustible.

16 Regulatory Status

GRAS listed. The anhydrous form is accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (inhalations; IM, IV, and other injections; ophthalmic preparations; oral capsules, solutions, suspensions and tablets; topical and vaginal preparations). Included in nonparenteral and parenteral medicines licensed in Japan and the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Anhydrous citric acid; fumaric acid; malic acid; sodium citrate dihydrate; tartaric acid.

Anhydrous citric acid

Empirical formula $C_6H_8O_7$

Molecular weight 192.12

CAS number [77-92-9]

Synonyms Acidum citricum anhydricum; citric acid; E330; 2-hydroxy-β-1,2,3-propanetricarboxylic acid; 2-hydroxypropane 1,2,3-tricarboxylic acid.

Appearance Odorless or almost odorless, colorless crystals or a white crystalline powder. Crystal structure is monoclinic holohedral.

Dissociation constants

pK_{a1}: 3.128 at 25°C;

pK_{a2}: 4.761 at 25°C;

pK_{a3}: 6.396 at 25°C.

Density 1.665 g/cm^3

Heat of combustion −1985 kJ/mol (−474.5 kcal/mol)

Hygroscopicity At relative humidities between about 25–50%, anhydrous citric acid absorbs insignificant amounts of water at 25°C. However, at relative humidities between 50% and 75%, it absorbs significant amounts, with the monohydrate being formed at relative humidities approaching 75%. At relative humidities greater than 75% substantial amounts of water are absorbed by the monohydrate.

Melting point 153°C

Solubility Soluble 1 in 1 part of ethanol (95%) and 1 in 1 of water; sparingly soluble in ether.

Safety

LD_{50} (mouse, IP): 0.9 g/kg[7]

LD_{50} (mouse, IV): 0.04 g/kg

LD_{50} (mouse, oral): 5.04 g/kg

LD_{50} (mouse, SC): 2.7 g/kg

LD_{50} (rabbit, IV): 0.33 g/kg
LD_{50} (rat, IP): 0.88 g/kg
LD_{50} (rat, oral): 3.0 g/kg
LD_{50} (rat, SC): 5.5 g/kg

Comments Anhydrous citric acid is listed in the PhEur 9.2 and USP 40–NF 35 S1. Anhydrous citric acid is one of the materials that have been selected for harmonization by the Pharmacopeial Discussion Group. For further information see the General Information Chapter <1196> in the USP–NF, the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

18 Comments

Citric acid monohydrate has undergone harmonization of many attributes for JP, PhEur, and USP–NF by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

Citric acid monohydrate has been used experimentally to adjust the pH of tablet matrices in enteric-coated formulations for colon-specific drug delivery.[8]

Therapeutically, preparations containing citric acid have been used to dissolve renal calculi.

A specification for citric acid monohydrate is contained in the *Food Chemicals Codex* (FCC).[9]

The EINECS number for citric acid is 201-069-1. The PubChem Compound ID (CID) for citric acid monohydrate is 22230.

Coconut Oil

1 Nonproprietary Names

BP: Coconut Oil
JP: Coconut Oil
PhEur: Coconut Oil, Refined
USP–NF: Coconut Oil

2 Synonyms

Aceite de coco; cocois oleum raffinatum; coconut butter; coconut palm oil; copra oil; oleum cocois; *Pureco 76*; refined coconut oil.

3 Chemical Name and CAS Registry Number

Coconut oil [8001-31-8]

4 Empirical Formula and Molecular Weight

Coconut oil contains triglycerides, the fatty acid constituents of which are mainly lauric and myristic acids with smaller proportions of capric, caproic, caprylic, oleic, palmitic and stearic acids.

The PhEur 9.2 and USP 40–NF 35 S1 state that the fatty acid composition for coconut oil is caproic acid (≤1.5%), caprylic acid (5.0–11.0%), capric acid (4.0–9.0%), lauric acid (40.0–50.0%), myristic acid (15.0–20.0%), palmitic acid (7.0–12.0%), stearic acid (1.5–5.0%), arachidic acid (≤0.2%), palmitoleic acid (≤1.0%), oleic acid (4.0–10.0%), linoleic acid (1.0–3.0%), linolenic acid (≤0.2%), and eicosenoic acid (≤0.2%).

5 Structural Formula

See Section 4.

6 Functional Category

Emollient; ointment base.

7 Applications in Pharmaceutical Formulation or Technology

Coconut oil has traditionally been used in ointments where it forms a readily absorbable base. It has been used particularly in preparations intended for application to the scalp, where it could

be applied as a solid but would liquefy when applied to the skin. Coconut oil is readily saponified by strong alkalis even in the cold and, as the soap produced is not readily precipitated by sodium chloride, it has been used in the making of 'marine' soap.

Coconut oil may be used in the formulation of a range of other preparations including emulsions,[1,2] nanoemulsions,[3,4] microemulsions,[5] polymeric nanocapsules,[6] intranasal solutions,[7] rectal capsules[8] and suppositories.[9]

See Table I.

Table I: Uses of coconut oil.

Use	Concentration (%)
Liquid soaps	4–20
Shampoos	1–20
Soaps	60–75
Topical ointments	50–70

8 Description

Coconut oil generally occurs as a white to light-yellow mass or colorless or light-yellow clear oil, with a slight odor characteristic of coconut and a mild taste. Refined coconut oil is a white or almost white unctuous mass.

The form that coconut oil takes depends on temperature; it occurs as a pale yellow to colorless liquid between 28°C and 30°C, as a semisolid at 20°C , and as a hard brittle crystalline solid below 15°C.

9 Pharmacopeial Specifications

See Table II.

Table II: Pharmacopeial specifications for coconut oil.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	—	+	+
Characters	+	+	—
Melting point	20–28°C	23–26°C	23–26°C
Acid value	≤0.2	≤0.5	≤0.5
Peroxide value	—	≤5.0	≤5.0
Saponification value	246–264	—	—
Unsaponifiable matter	≤1.0%	≤1.0%	≤1.0%
Iodine value	7–11	—	—
Alkaline impurities in fatty oils	—	+	+
Composition of fatty acids	—	+	+
Water	—	≤0.1%	≤0.1%
Arsenic	—	—	≤0.5 µg/g
Refractive index at 40°C		≈1.449	—

Note: both the USP 40–NF 35 S1 and PhEur 9.2 specify the fatty acid composition for coconut oil. In addition, the USP 40–NF 35 S1 includes a specification for palmitoleic acid (≤0.1%).

10 Typical Properties

Boiling point >450°C
Flash point 216°C (closed cup)
Saponification number 255–258
Specific gravity 0.918–0.923
Solubility Practically insoluble in water; freely soluble in dichloromethane and in light petroleum (bp: 65–70°C); soluble in ether, carbon disulfide, and chloroform; soluble at 60°C in 2 parts of ethanol (95%) but less soluble at lower temperatures.
Surface tension

33.4 mN/m (33.4 dyne/cm) at 20°C;

28.4 mN/m (28.4 dyne/cm) at 80°C.

11 Stability and Storage Conditions

Coconut oil remains edible, and mild in taste and odor, for several years under ordinary storage conditions. However, on exposure to air, the oil readily oxidizes and becomes rancid, acquiring an unpleasant odor and strong acid taste.

Store in a tight, well-filled container, protected from light at a temperature not exceeding 25°C. Coconut oil may be combustible at high temperature, and may spontaneously heat and ignite if stored under hot and wet conditions.

12 Incompatibilities

Coconut oil reacts with oxidizing agents, acids and alkalis. Polyethylene is readily permeable to coconut oil.

It has been shown that the increased force required to expel coconut oil from plastic syringes was due to uptake of the oil into the rubber plunger; this resulted in swelling of the rubber plunger and an increased resistance to movement down the syringe barrel.[10]

13 Method of Manufacture

Coconut oil is the fixed oil obtained from the seeds of *Cocos nucifera* Linn. (Palmae). This oil is then refined to produce refined coconut oil, which is referred to in the coconut industry as RBD (refined, bleached, and deodorized) coconut oil.

14 Safety

When administered orally, coconut oil is essentially nontoxic, although ingestion of large amounts may cause digestive or gastrointestinal irritation or upset. Coconut oil can act as an irritant when applied to the skin and when in contact with the eyes; it may be absorbed through the skin. Inhalation of mist or vapor may cause respiratory tract irritation.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. Coconut oil should be kept away from heat and sources of ignition, and contact with oxidizing agents, acids, and alkalis should be avoided.

If in the solid form, large spillages of coconut oil should be dealt with by shoveling the material into a waste disposal container. For liquid spillages, the oil should be absorbed with an inert material before removal for disposal.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database as a single ingredient (oral capsules and tablets; topical creams, solutions, and ointments) and as a multiple ingredient with hydrogenated palm kernel oil glycerides (rectal and vaginal suppositories). Included in scalp ointments and therapeutic shampoos licensed in the UK.

17 Related Substances

Almond oil; canola oil; castor oil; castor oil, hydrogenated; corn oil; cottonseed oil; medium-chain triglycerides; olive oil; peanut oil; sesame oil; soybean oil; sunflower oil.

Hydrogenated Coconut Oil

CAS number [84836-98-6]
Synonyms Coconut oil, hydrogenated; .
Acid value ≤2
Melting range 30–38°C
Peroxide value ≤5
Unsaponifiable matter ≤0.8%
Loss on drying ≤0.1%
Heavy metals ≤10 µg/g
Nickel ≤1 µg/g
Residue on ignition ≤0.1%

Comments Obtained by refining and hydrogenating the oil obtained from the seeds of *Cocos nucifera*. Included in the FDA Inactive Ingredients Database (rectal suppositories). The USP 40–NF 35 S1 includes a monograph for Hydrogenated Coconut Oil. Included in the Canadian Natural Health Products Ingredients Database. Store in tight, light-resistant containers at a temperature not exceeding 55°C. The EINECS number for hydrogenated coconut oil is 284-283-8.

18 Comments

Coconut oil has been reported to have antifungal activity against a range of *Candida* species.[11]

Coconut oil has been used therapeutically in a lotion for the eradication of head lice,[12] and was included in a regime used to treat a patient who had ingested 16.8 g aluminum phosphide.[13] Virgin coconut oil may have anti-inflammatory, analgesic and antipyretic properties.[14]

Concern has been expressed at the potential use of coconut oil as a suntan lotion as it does not afford any protection against ultraviolet light.[15]

The FDA Inactive Ingredients Database also lists fractionated coconut oil (oral capsules; topical emulsions, creams and ointments). Unhydrogenated coconut oil is listed in the Canadian Natural Health Products Ingredients Database. A specification for coconut oil (unhydrogenated) is contained in the *Food Chemicals Codex* (FCC).[16]

The EINECS number for coconut oil is 232-282-8.

Colloidal Silicon Dioxide

1 Nonproprietary Names

BP: Colloidal Anhydrous Silica

JP: Light Anhydrous Silicic Acid

PhEur: Silica, Colloidal Anhydrous

USP–NF: Colloidal Silicon Dioxide

2 Synonyms

Aerosil; *Aeroperl*; *Cab-O-Sil*; colloidal silica; fumed silica; fumed silicon dioxide; hochdisperses silicum dioxid; SAS; silica colloidalis anhydrica; silica sol; silicic anhydride; silicon dioxide colloidal; silicon dioxide fumed; synthetic amorphous silica; *HDK*.

3 Chemical Name and CAS Registry Number

Colloidal silicon dioxide [112945–52–5]

4 Empirical Formula and Molecular Weight

SiO_2 60.08

5 Structural Formula

O=Si=O

6 Functional Category

Adsorbent; anticaking agent; emulsion stabilizing agent; glidant; suspending agent; tablet and capsule disintegrant; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Colloidal silicon dioxide is widely used in pharmaceuticals, cosmetics, and food products; *see* Table I. Its small particle size and large specific surface area give it desirable flow characteristics that are exploited to improve the flow properties of dry powders[1] in a number of processes such as tableting[2–4] and capsule filling.[5]

Colloidal silicon dioxide is also used to stabilize emulsions and as a thixotropic thickening and suspending agent in gels,[6] microemulsions,[7] and semisolid preparations.[6] With other ingredients of similar refractive index, transparent gels may be formed. The degree of viscosity increase depends on the polarity of the liquid (polar liquids generally require a greater concentration of colloidal silicon dioxide than nonpolar liquids).[8] Viscosity is largely independent of temperature but may be affected by pH;[8] *see* Section 11.

In aerosols, other than those for inhalation, colloidal silicon dioxide is used to promote particulate suspension, eliminate hard settling, and minimize the clogging of spray nozzles. Colloidal silicon dioxide is also used as a tablet disintegrant and as an adsorbent dispersing agent for liquids in powders.[9] Colloidal silicon dioxide is frequently added to suppository formulations containing lipophilic excipients to increase viscosity, prevent sedimentation during molding, and decrease the release rate.[10,11]

Colloidal silicon dioxide is also used as an adsorbent during the preparation of wax microspheres;[12] as a thickening agent for topical preparations;[13] as a freeze-drying aid for nanocapsules and nanosphere suspensions.[14] as an inert core in solid dispersions;[15] and as a gel-former for transdermal systems.[8]

Table I: Uses of colloidal silicon dioxide.

Use	Concentration (wt %)
Aerosols	0.5–3.0
Emulsion stabilizing agent	1.0–5.0
Glidant	0.1–1.0
Suppositories	0.5–2.0
Suspending and thickening agent	2.0–10.0

8 Description

Colloidal silicon dioxide is a submicroscopic fumed silica with a particle size of about 15 nm. It is a light, loose, bluish-white-colored, odorless, tasteless, amorphous powder.

9 Pharmacopeial Specifications

See Table II. *See also* Section 18.

Table II: Pharmacopeial specifications for colloidal silicon dioxide.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters	—	+	—

Grade	Specific surface area[a] (m^2/g)	Density (tapped) (g/cm^3)
M-5P	200 ± 25	0.04
M-5DP	200 ± 25	0.04

(a) BET method.

Table V: Physical properties of *HDK*.

Grade	Specific surface area[a] (m^2/g)	Density (tapped) (g/cm^3)
V15	150 ± 20	0.05
V15P	150 ± 20	0.05
N20	200 ± 30	0.04
N20P	200 ± 30	0.04

(a) BET method.

Melting point 1600°C

Moisture content *see* Figure 1.[16,17]

Particle size distribution Primary particle size is 7–16 nm. *Aerosil* forms loose agglomerates of 10–200 µm. *See also* Figure 2.

Refractive index 1.48[8]

Solubility Practically insoluble in organic solvents, water, and acids, except hydrofluoric acid; soluble in hot solutions of alkali hydroxide. Forms a colloidal dispersion with water. For *Aerosil*, solubility in water is 150 mg/L at 25°C (pH 7).

Specific gravity 2.2

Specific surface area

100–400 m^2/g depending on grade. *See also* Tables III, IV,and V.

Several grades of colloidal silicon dioxide are commercially available, which are produced by modifying the manufacturing process. The modifications do not affect the silica content, specific gravity, refractive index, color, or amorphous form. However, particle size, surface areas, and densities are affected. The physical properties of three commercially available colloidal silicon dioxides, *Aerosil* (Evonik Degussa Corporation), *Cab-O-Sil* (Cabot Corporation), and *HDK* (Wacker-Chemie GmbH) are shown in Tables III, IV and V, respectively.

11 Stability and Storage Conditions

Colloidal silicon dioxide is hygroscopic but adsorbs large quantities of water without liquefying. When used in aqueous systems at a pH 0–7.5, colloidal silicon dioxide is effective in increasing the viscosity of a system. However, at a pH greater than 7.5 the viscosity-increasing properties of colloidal silicon dioxide are reduced; and at a pH greater than 10.7 this ability is lost entirely since the silicon dioxide dissolves to form silicates.[18] Colloidal silicon dioxide powder should be stored in a well-closed container.

12 Incompatibilities

Incompatible with diethylstilbestrol preparations.[19]

13 Method of Manufacture

Colloidal silicon dioxide is prepared by the flame hydrolysis of chlorosilanes, such as silicon tetrachloride, at 1800°C using a hydrogen–oxygen flame. Rapid cooling from the molten state during manufacture causes the product to remain amorphous.[20]

14 Safety

Colloidal silicon dioxide is widely used in oral and topical pharmaceutical products and is generally regarded as an essentially nontoxic and nonirritant excipient. However, intraperitoneal and subcutaneous injection may produce local tissue reactions and/or granulomas. Colloidal silicon dioxide should therefore not be administered parenterally.

LD_{50} (rat, IV): 0.015 g/kg[21]

LD_{50} (rat, oral): 3.16 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Eye protection and gloves are recommended. Considered a nuisance dust, precautions should be taken to avoid inhalation of colloidal silicon dioxide. In the absence of suitable containment facilities, a dust mask should be worn when handling small quantities of material. For larger quantities, a dust respirator is recommended.[22] Colloidal silica may build up static charge due to friction during pneumatic conveying and some engineering risk controls may be required.[23]

Inhalation of amorphous colloidal silicon dioxide dusts may cause irritation to the respiratory tract but it is not associated with fibrosis of the lungs (silicosis), which can occur upon exposure to crystalline silica.[8,20,21]

16 Regulatory Acceptance

GRAS listed. Included in the FDA Inactive Ingredients Database (oral capsules, suspensions, and tablets; transdermal, rectal, and vaginal preparations). Also approved by the FDA as a food additive and for food contact. Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Hydrophobic colloidal silica.

18 Comments

Colloidal silicon dioxide is one of the materials that have been selected for harmonization by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

The PhEur 9.2 also contains a specification for hydrated colloidal silicon dioxide (SiO_2,xH_2O). The incidence of microbial contamination of colloidal silicon dioxide is low[24] due to the high production temperatures and inorganic precursor materials.

Note that porous silica gel particles may also be used as a glidant, thickener, dispersant and to adsorb moisture, which may be an advantage for some formulations. *Syloid 244FP* meets the USP–NF requirements for silicon dioxide, and *Syloid 244 FP-BU* meets the PhEur and JP requirements for silicon dioxide.[25]

The former CAS number for colloidal silicon dioxide was 7631–86–9.[8]

Listed on the Japanese Ministry of International Trade and Industry (MITI) list of Existing and New Chemical Substances (ENCS) as 1-548.

The EINECS number for colloidal silicon dioxide is 231-545-4. The PubChem Compound ID (CID) for colloidal silicon dioxide is 24261.

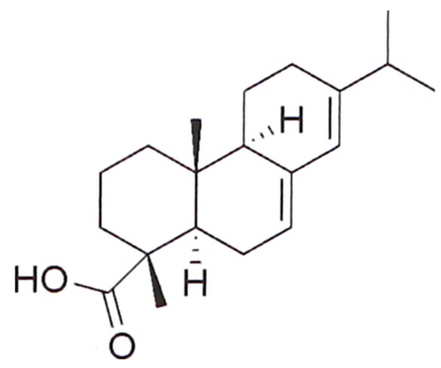
Colophony

1 Nonproprietary Names

BP: Colophony
JP: Rosin
PhEur: Colophony

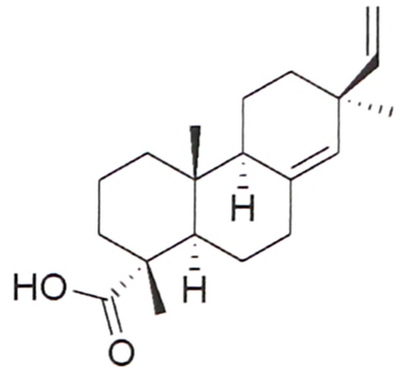
2 Synonyms

Abietic anhydride; colofonia; coloph; colophane; colophonium; colophony; disproportionated rosin; gum rosin; pine rosin; resin terebinthinae; rosin; wood rosin; yellow resin.



3 Chemical Name and CAS Registry Number

(2*R*,3*S*,4*S*,5*R*,6*R*)-2-(Hydroxymethyl)-6-[(*E*)-3-phenylprop-2-enoxy]oxane-3,4,5-triol [8050-09-7] and [8050-10-0]



4 Empirical Formula and Molecular Weight

Colophony is a mixture composed of approximately 90% acids. Rosin acids are monocarboxylic and have a typical molecular formula of $C_{20}H_{30}O_2$. The acids are diterpenes of two main types: abietic with conjugated double bonds and pimaric with nonconjugated double bonds. The molecular weight of abietic and primaric acids is 302.45. The 10% other components include a mixture of dihydroabietic acid ($C_{20}H_{32}O_2$) with a molecular weight of 302.45 and dehydroabietic acid ($C_{20}H_{28}O_2$) with a molecular weight of 300.44.

5 Structural Formula

Abietic acid

Pimaric acid

6 Functional Category

Coating agent; emulsifying agent; film-forming agent; microencapsulating agent; modified-release agent; tablet and capsule binder.

7 Applications in Pharmaceutical Formulation or Technology

Colophony is used as a binder and coating agent in both capsules and tablets for oral delivery. It has also been used to prepare microcapsules for the controlled release of both aspirin[1] and diltiazem.[2]

8 Description

Colophony occurs as translucent, pale yellow to dark amber, angular and irregularly shaped, brittle, glassy fragments of different sizes, with surfaces that bear conchoidal markings. Colophony has a slight turpentine odor and taste.

Colophony has been classified into various color grades starting with D (very dark red) through E, F, G, H, I, K, M, N (golden amber), WG, WW, and finally X (pale yellow), according to the United States Department of Agriculture's standard method.

See also Sections 10 and 17.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for colophony.

Test	JP XVII	PhEur 9.2
Characters	+	+
Identification	–	+
Acid value	150–177	145–180
Total ash	≤0.1%	≤0.2%

10 Typical Properties

Acid value

160 for grades N, WG, WW, X;

155 for grades D, H, K, M.

Ash content

0.05% for grades N, WG, WW, X, D;

0.2% for grades H, K, M.

Boiling point 318°C (100 mmHg)

Flash point 187°C

Insoluble matter

0.1% for grades N, WG, WW, X, D;

0.4% for grades H, K, M.

Melting point 100–150°C

Softening point 70–78°C

Solubility Insoluble in water; soluble in ethanol (96%), benzene, ether, methanol, glacial acetic acid, chloroform, oils, and carbon disulfide. Also soluble in dilute solutions and fixed alkali hydroxides.

Specific gravity 1.07–1.09

Unsaponifiable matter 6.0%

Volatile matter ≤2.0%

11 Stability and Storage Conditions

Stable under normal temperature and pressure. Colophony is combustible and is not stable in the presence of strong oxidizing agents and excess heat. It is biodegradable and biocompatible.[3]

Store in airtight containers in a dry, cool, well-ventilated area, away from heat or sources of ignition and oxidation. The PhEur 9.2 specifies that colophony should not be reduced to powder.

12 Incompatibilities

Colophony is incompatible with strong oxidizing agents.

13 Method of Manufacture

Colophony is the resinous constituent of the oleoresin exuded by various species of pine, known in commerce as crude turpentine. Natural sources include *Pinus soxburghi*, *Pinus lognifolium*, *Pinus palustris*, *Pinus pinaceae*, *Pinus caribaea*, and *Pinus toeda*.[4]

Colophony is obtained by tapping of the living pine tree to collect oleoresin, which is distilled to yield a vitreous resin. Wood rosin is derived by solvent extraction of aged and ground pine stump wood. The trunk of the pine tree is used as raw material in the production of tall oil rosin. Owing to their common source, gum, wood, and tall oil rosins are similar in composition. The crude colophony is treated by chemical and physical means to produce refined colophony with desired characteristics and applications.[5,6]

14 Safety

Colophony is generally considered to be a nontoxic material. However, it may be harmful if ingested in large quantities. Colophony may be irritating to the skin upon topical exposure and may cause allergic contact dermatitis.[7,8] It may also be an irritant to the respiratory system if inhaled as a dust.

LD_{50} (guinea pig, oral): 4.1 g/kg[9]

LD_{50} (mouse, oral): 0.002 g/kg[10]

LD_{50} (rat, oral): 0.003 g/kg[10]

LD_{50} (rat, inhalation): 0.11 g/kg[10]

Acute oral LD_{50} values for colophony in mice, rat and guinea pig were reported to be 4600, 7600 and 4100 mg/kg bw, respectively.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

Eye protection and gloves are recommended. Avoid the generation and accumulation of colophony dust. Regularly vacuum dust to minimise the potential of air-borne exposure. Provide adequate general and local exhaust ventilation. A respirator is not normally required in well-ventilated areas but is indicated for prolonged contact with heavy dust concentrations. Use impervious gloves made of polyvinyl chloride (PVC). Ground container and transfer equipment to eliminate static electric sparks. Do not breathe dust from this material. If product is in dust form, it is classified as a dust explosion hazard class II.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral capsules and oral coated, sustained-action, extended release and repeat-action tablets). Included in the Canadian Natural Health Products Ingredients Database. Included in Health Canada's List of Permitted Food Additives with Other Generally Accepted Uses (Lists of Permitted Food Additives). Included in nonparenteral medicines licensed in the UK.

17 Related Substances

Glycerol ester of gum rosin; hydrogenated rosin; pentaerythritol ester of gum rosin; polymerized rosin.

Glycerol ester of gum rosin

Molecular weight ≈700–750 g/mol

CAS number [8050-31-5]

Synonyms *FloraRez G85, G85-L*; *Dertoline*; ester gum; glycerol-modified gum rosin; glycerol abietate; glycerol triabietate; rosin glycerol ester.

Solubility Soluble in acetone and toluene; insoluble in methanol, ethanol and water.

Storage Store in well-closed containers.

Comments A hard, pale amber-colored resin obtained by glycerol esterification of refined gum rosin.[11] The Joint FAO/WHO Expert Committee on Food Additives (JECFA) and Health Canada established the group average daily intake 0–25 mg/kg body weight for glycerol ester of gum rosin and glycerol ester of wood rosin.[9]

A specification for glycerol ester of gum rosin is included in the *Food Chemicals Codex* (FCC);[11] *see* Table II.

Table II: FCC specification for glycerol ester of gum rosin.

Test	FCC 10 S2
Description	+
Identification	+
Lead	≤1 mg/kg
Acid number	3–9
Softening point	82°C

The EINECS number for glycerol ester of gum rosin is 232-482-5.

Hydrogenated rosin

Molecular weight ≈400 g/mol
CAS number [65997-06-0]
Synonyms *FloraRez HR*; *Hydrogral.*
Acid number 165
Softening point 74–84°C
Solubility Soluble in alcohols, esters, ketones, hydrocarbons, chlorinated solvents, and mineral oils; insoluble in water.
Comments A thermoplastic acidic resin obtained by hydrogenation of rosin.

The EINECS number for hydrogenated rosin is 266-041-3.

Pentaerythritol ester of gum rosin

Molecular weight ≈1 200 g/mol
CAS number [8050-26-8]
Synonyms *FloraRez PE100*; *Granolite*; pentaerythritol ester of rosin; pentaerythritol rosinate; pentaerythritol resin; #145 resin ester.
Acid number 20
Softening point 95–105°C
Solubility Soluble in aromatic, aliphatic and chlorinated solvents; insoluble in water and alcohols.
Comments Obtained by pentaerythritol esterification of gum rosin.

The EINECS number for pentaerythritol ester of gum rosin is 232-479-9.

Polymerized rosin

Molecular weight ≈680 g/mol
CAS number [65997-05-9]
Synonyms *FloraRez DR105, 115,140, 95*; *Dertopol*; dimerized rosin; *Dymerex*; *Polyrosin*; rosin oligomer
Acid number 145
Softening point 90–145°C
Solubility Slightly soluble in alcohols and aliphatic hydrocarbons. Soluble in aromatic hydrocarbons. Insoluble in methanol, ethanol, isopropanol and water.
Comments Obtained by polymerization of abietic acid, which is initially changed to a dimer by linking two of its molecules.[12,13] Polymerized rosin is pale in color and has a lower acid number and higher melting point than rosin.[14]

The EINECS number for polymerized rosin is 500-163-2.

18 Comments

Therapeutically, colophony has been used as an ingredient of ointments and dressings for wounds and minor skin disorders.[15]

The reactive centers of the rosin acid molecule are often used for chemical modifications to synthesize rosin polymers with customized properties. Rosin derivatives show film-forming and coating properties,[16] and may be used for tablet film- and enteric-coating purposes. Polymerized rosins show superior film-forming and sustained-release properties.[17] Plasticized film formulations of rosins may be used to sustain the drug release from drug-layered nonpareil seeds.[18] Rosin and polymerized rosin have also been evaluated for the development of transdermal delivery systems.[19,20] Rosin ester resin comprises rosin glycerin ester, a hydrogenated rosin glycerin ester, a rosin pentaerythritol ester used in transepidermal drug delivery of Rivastigmine.

Rosin-glycerol ester, pentaester, propylene glycol ester, and polymerized colophony derivatives also exhibit wall-forming and encapsulating properties.[21–23] They have been used to formulate microcapsules[24] and nanoparticles.[25] PEGylated rosin derivatives have recently been investigated as controlled-release film formers and microencapsulating agents.[26–28]

Abietic acid, a principle component of rosin, and its glycerol derivative have been investigated as microencapsulating materials. Modified abietic acids, such as maleoabietic acid and diabietic acid, are used as hydrophobic matrix materials for controlled release of drugs from tablets.[29–31] Glycerol, sorbitol, and mannitol esters of rosin are used as chewing gum bases for medicinal applications.[32,33] Custom synthesized rosin derivatives can also be used as emulsifying and surface-active agents in formulating creams and lotions.[34]

The degradation and biocompatibility of colophony and rosin acid-based biomaterials (glycerol ester of maleic rosin and pentaerythritol ester of maleic rosin) have been examined *in vitro* and *in vivo*, and they are reported to have good biocompatibility.[3,35] These polymers have been used as implant materials for controlled antibiotic release.[36] Rosin esters are used in fragrances (perfumes) to retard rapid evaporation.

Glycerol ester of gum rosin, purified by steam stripping to have an acid number of 3 to 9, a drop-softening point of 79 to 88°C, and a color grade of N or paler, is approved for use as an indirect food additive. Gum rosin ester and wood rosin ester are approved for use as a direct food additive as a plasticizing agent in chewing gum (21 CFR 172.615).

Colophony is widely used in cosmetics such as lipstick, mascara, depilatories, hair tonics, and shampoo formulations.[37–39] Food-related applications of colophony esters include use as coating agents on fruits and can linings, as polishing agents for roasted coffee beans, and for density adjustment of citrus oils in beverages.[39]

The glycerol ester of hydrogenated rosin [8050-29-1] is included in the FDA Inactive Ingredients Database (nasal ointment).

Monographs of other colophony derivatives such as glycerol ester of partially dimerized rosin, glycerol ester of partially hydrogenated gum rosin, glycerol ester of polymerized rosin, glycerol ester of tall oil rosin, pentaerythritol ester of partially hydrogenated wood rosin, glycerol ester of wood rosin, glycerol ester of partially hydrogenated wood rosin, and pentaerythritol ester of wood rosin are included in the *Food Chemicals Codex*.[14]

The EINECS number for colophony is 232-475-7. The PubChem Compound ID (CID) for colophony is 5280656.

Coloring Agents

1 Nonproprietary Names

See Section 17 and Tables I, II, III, and IV.

2 Synonyms

See Section 17 for specific, selected coloring agents.

3 Chemical Name and CAS Registry Number

See Tables I, II, III, and IV.

4 Empirical Formula and Molecular Weight

See Section 17 for specific selected coloring agents.

5 Structural Formula

See Section 17 for specific selected coloring agents.

6 Functional Category

Colorant; opacifier.

7 Applications in Pharmaceutical Formulation or Technology

Coloring agents are used mainly to impart a distinctive appearance to a pharmaceutical dosage form. The main categories of dosage form that are colored are:

- Tablets: either the core itself or the coating.
- Hard or soft gelatin capsules: the capsule shell or coated beads.
- Oral liquids.
- Topical creams and ointments.

Color is a useful tool to help identify a product in its manufacturing and distribution stages. Patients, especially those using multiple products, often rely on color to be able to recognize the prescribed

Table I: European Union list of coloring materials authorized for coloring medicinal products up to January 2008. *See also* Section 16.

E number	Common name	CAS number	Alternate name

medication.[1] The use of different colors for different strengths of the same drug can also help eliminate errors.

Many drug products look similar; hence color in combination with shape and/or an embossed or printed logo can help with identification. Also, this combination can assist in the prevention of counterfeiting.

Unattractive medication can be made more acceptable to the patient by the use of color, and color can also be used to make a preparation more uniform when an ingredient in the formulation has itself a variable appearance from batch to batch.[2]

Some of the insoluble colors or pigments have the additional benefit when used in tablet coatings or gelatin shells of providing useful opacity, which can contribute to the stability of light-sensitive active materials in the tablet or capsule formulation. Pigments such as the iron oxides, titanium dioxide, and some of the aluminum lakes are especially useful for this purpose.[3]

Of the many classifications possible for pharmaceutical coloring agents, one of the most useful is to simply divide the colors into those that are soluble in water (dyes) and those that are insoluble in water (pigments).

Colors for clear liquid preparations are limited to the dyes;[4] e.g. *see* Section 17.

For surface coloration, which includes coated tablets, the choice of color is usually restricted to insoluble pigments. The reasons for this include their lack of color migration, greater opacity, and enhanced color stability over water-soluble colors.[5]

Lakes are largely water-insoluble forms of the common synthetic water-soluble dyes. They are prepared by adsorbing a sodium or potassium salt of a dye onto a very fine substrate of hydrated alumina, followed by treatment with a further soluble aluminum salt. The lake is then purified and dried.[6]

Table II: Permanently listed color additives subject to US certification in 2008, excluding those approved exclusively for use in medical devices.

Color	Common name	CAS number	21 CFR references to drug use

D&C yellow #10	Quinoline yellow WS	[8004-92-0]	74.1710
D&C yellow #11	Quinoline yellow SS	[8003-22-3]	74.1711

(a) Dye is permanently listed. The lake is not permitted in medicinal products (*see* Table III).

Lakes are frequently used in coloring tablet coatings since, for this purpose, they have the general advantages of pigments over water-soluble colors. *See* Table V.

8 Description

The physical appearances of coloring agents vary widely. *See* Section 17 for specific selected coloring agents.

9 Pharmacopeial Specifications

Some materials used as pharmaceutical coloring agents are included in various pharmacopeias; for example, titanium dioxide is included in the PhEur 9.2. However, if titanium dioxide is being used exclusively as a colorant, then the specific purity criteria from Regulation (EU) 231/2012 apply.[7]

10 Typical Properties

Typical properties of specific selected coloring agents are shown in Section 17. Selected properties are shown in Tables V, VI, and VII.

11 Stability and Storage Conditions

Pharmaceutical coloring agents form a chemically diverse group of materials that have widely varying stability properties. Specific information for selected colors is shown in Table VII and can be found in Woznicki and Schoneker.[4] *See also* Section 17.

While some colors, notably the inorganic pigments, show excellent stability, other coloring agents, such as some organic colors, have poor stability properties but are used in formulations because of their low toxicity.[8]

Some natural and synthetic organic colors are particularly unstable in light. However, with appropriate manufacturing procedures, combined with effective product packaging, these colors may be used successfully in formulations, thus making a wide choice of colors practically available.

Lakes, inorganic dyes, and synthetic dyes should be stored in well-closed, light-resistant containers at a temperature below 30°C.

For most natural and nature-identical colors, the storage conditions are more stringent and a manufacturer's recommendations for a particular coloring agent should be followed.

To extend their shelf-life, some natural colors are supplied as gelatin-encapsulated or similarly encapsulated powders and may be sealed in containers under nitrogen.

12 Incompatibilities

See Section 17 for incompatibilities of specific selected coloring agents; see also Woznicki and Schoneker,[4] and Walford.[9,10]

Table III: Provisionally listed color additives subject to US certification in 2008.

13 Method of Manufacture

See Section 17 and Walford[9,10] for information on specific selected coloring agents.

14 Safety

Coloring agents are used in a variety of oral and topical pharmaceutical formulations, in addition to their extensive use in foodstuffs and cosmetic products.

Toxicology studies are routinely conducted on an ongoing basis by organizations such as the World Health Organization (WHO), the US Food and Drug Administration (FDA), and the European Union (EU). The outcome of this continuous review is that the various regulatory bodies around the world have developed lists of permitted colors that are generally regarded as being free from serious adverse toxicological effects. However, owing to the widespread and relatively large use of colors in food, a number of coloring agents in current use have been associated with adverse effects, although in a relatively small number of people.[11,12] Restrictions or bans on the use of some coloring agents have been imposed in some countries, while the same colors may be permitted for use in a different country. As a result the same color may have a different regulatory status in different territories of the world.

In 2007, a study was published linking the use of six colors, tartrazine (E102), quinoline yellow (E104), sunset yellow (E110), carmoisine (E122), ponceau 4R (E124) and allura red (E129)[13] with behavior issues in childen. However, after reviewing the results of the study, the European Food Standards Agency concluded that no change in legislation was needed.

The lake of erythrosine (FD&C red #3), for example, has been delisted (*see* Section 16) in the USA since 1990, following studies in rats that suggested it was carcinogenic. This delisting was as a result of the Delaney Clause, which restricts the use of any color shown to induce cancer in humans or animals in any amount. However, erythrosine was not regarded as being an immediate hazard to health and products containing it were permitted to be used until supplies were exhausted.[14]

Tartrazine (FD&C yellow #5) has also been the subject of controversy over its safety, and restrictions are imposed on its use in some countries; *see* Section 17.

In general, concerns over the safety of coloring agents in pharmaceuticals and foods are associated with reports of hypersensitivity[15–17] and hyperkinetic activity, especially among children.[18]

In the USA, specific labeling requirements are in place for prescription drugs that contain tartrazine (*see* Section 18) as this color was found to be the potential cause of hives in fewer than one in 10 000 people. In the EU, medicinal products containing tartrazine, sunset yellow, carmoisine, amaranth, ponceau 4R or brilliant black BN must carry a warning on the label concerning possible allergic reactions.

15 Handling Precautions

Pharmaceutical coloring agents form a diverse group of materials and manufacturers' data sheets should be consulted for safety and handling data for specific colors.

In general, inorganic pigments and lakes are of low hazard and standard chemical handling precautions should be observed

Table IV: List of color additives exempt from certification permitted for drug use in the USA in 2008.

Color	CAS number	21 CFR references to drug use

Tartrazine	15	18	8	Trace	4
Sunset yellow	18	15	2	Trace	2

(a) The solubility of individual batches of commercial product will differ widely depending on the amounts of salt, pure dye, moisture and subsidiary dyes present.

depending upon the circumstances and quantity of material handled. Special care should be taken to prevent excessive dust generation and inhalation of dust.

The organic dyes, natural colors, and nature-identical colors present a greater hazard and appropriate precautions should accordingly be taken.

16 Regulatory Status

Coloring agents have an almost unique status as pharmaceutical excipients in that most regulatory agencies of the world hold positive lists of colors that may be used in medicinal products. Only colors on these lists may be used and some colors may be restricted quantitatively. The legislation also defines purity criteria for the individual coloring agents. In many regions around the world there is a distinction between colors that may be used in drugs and those for food use.

European Union legislation The primary legislation that governs coloring matters that may be added to medicinal products is Council Directive 2009/35/EC of 23 April 2009.[19] This Directive links the pharmaceutical requirements with those for foods in the EU by direct reference to those substances listed in Annex I to Council Directive 94/36/EC.[20] This Directive has now been repealed by Regulation (EC) 1333/2008.[21] In addition, the Scientific Committee on Medicinal Products and Medical Devices has delivered opinions on the suitability and safety of amaranth,[22] erythrosine,[23] canthaxanthin,[24] aluminum,[25] and silver[26] as colors for medicines. Silver was considered unsuitable. Table I gives the current position taking the above information into account. Regulation (EU) 231/2012[7] lays down specific purity criteria for food colors. EU legislation relating to colors in medicines is clarified by the Committee for Medicinal Products for Human Use note for guidance on excipients in the dossier for application for marketing authorization of a medicinal product, EMEA/CHMP/QWP/396951/2006.[27]

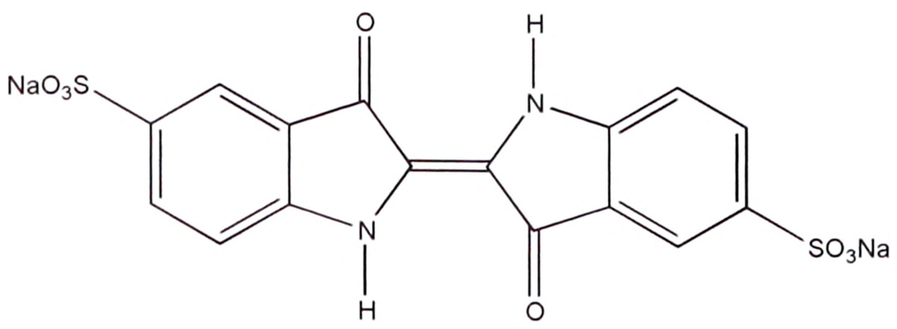
United States legislation The 1960 Color Additive Amendment to the Food Drug and Cosmetic Act defines the responsibility of the Food and Drug Administration in the area of pharmaceutical colorants. Tables II, III, and IV provide lists of permitted colors.[28] The list is superficially long, but many of the coloring agents have restricted use. For the so-called certified colors, the FDA operates a scheme whereby each batch of color produced is certified as analytically correct by the FDA prior to the issuing of a certification number and document that will permit sale of the batch in question. Colors requiring certification are described as FD&C (Food Drug and Cosmetic); D&C (Drug and Cosmetic) or External D&C. The remaining colors are described as uncertified colors and are mainly of natural origin. The USA also operates a system of division of certified colors into permanently and provisionally listed colors. Provisionally listed colors require the regular intervention of the FDA Commissioner to provide continued listing of these colors. Should the need arise, the legislative process for removal of these colors from use is comparatively easy.

Licensing authority approval In addition to national approvals and lists, a pharmaceutical licensing authority can impose additional restrictions at the time of application review. Within the EU this generally takes the form of restricting colors, such as tartrazine and other azo colors, in medicinal products for chronic administration, and especially in medicines for allergic conditions.

17 Related Substances

Beta-carotene; indigo carmine; iron oxides; sunset yellow FCF; tartrazine; titanium dioxide.

Indigo carmine



Empirical formula $C_{16}H_8N_2Na_2O_8S_2$
Molecular weight 466.37
CAS number [860-22-0]

Table VII: Stability properties of selected colors.

Color	Heat	Light	Acid	Base	Oxidizing agents	Reducing agents
Brilliant blue FCF	Good	Moderate	Very good	Moderate	Moderate	Poor
Indigo carmine	Good	Very poor	Moderate	Poor	Poor	Good
FD&C green #3	Good	Fair	Good	Poor	Poor	Very poor
Erythrosine	Good	Poor	Insoluble	Good	Fair	Very poor
Allura red AC	Good	Moderate	Good	Moderate	Fair	Fair
Tartrazine	Good	Good	Good	Moderate	Fair	Fair
Sunset yellow	Good	Moderate	Good	Moderate	Fair	Fair
D&C yellow #10	Good	Fair	Good	Moderate	Poor	Good

Synonyms 2-(1,3-Dihydro-3-oxo-5-sulfo-2*H*-indol-2-ylidene)-2,3-dihydro-3-oxo-1*H*-indole-5-sulfonic acid disodium salt; disodium 5,5′-indigotin disulfonate; E132; FD&C blue #2; indigotine; sodium indigotin disulfonate; soluble indigo blue.

Structure

Appearance Dark blue powder. Aqueous solutions are blue or bluish-purple.

Absorption maximum 604 nm

Color Index No. CI 73015

Purity (EU)

Arsenic: ≤3 ppm

Lead: ≤2 ppm

Mercury: ≤1 ppm

Cadmium: ≤1 ppm

Ether-extractable matter: ≤0.2% under neutral conditions

Accessory colorings: ≤1.0%

Water-insoluble matter: ≤0.2%

Assay: ≥85% total coloring matters, calculated as the sodium salt

Disodium 3,3′-dioxo-2,2′-biindoylidene-5,7′-disulfonate: ≤18%.

Subsidiary coloring matters: excluding provision above, ≤1.0%

Organic compounds other than coloring matters: ≤0.5%

Unsulfonated primary aromatic amines: ≤0.01%, as aniline

Purity (US)

Arsenic: ≤3 ppm

2-(1,3-Dihydro-3-oxo-2*H*-indol-2-ylidene)-2,3-dihydro-3-oxo-1*H*-indole-5-sulfonic acid sodium salt: ≤2%

2-(1,3-Dihydro-3-oxo-7-sulfo-2*H*-indol-2-ylidene)-2,3-dihydro-3-oxo-1*H*-indole-5-sulfonic acid disodium salt: ≤18%

Isatin-5-sulfonic acid: ≤0.4%

Lead: ≤10 ppm

Mercury: ≤1 ppm

5-Sulfoanthranilic acid: ≤0.2%

Total color: ≥85%

Volatile matter, chlorides and sulfates (calculated as the sodium salts): ≤15.0% at 135°C

Water-insoluble matter: ≤0.4%

Solubility *see* Table VIII.

Incompatibilities Poorly compatible with citric acid and saccharose solutions. Incompatible with ascorbic acid, gelatin, glucose, lactose, oxidizing agents, and saturated sodium bicarbonate solution.

Table VIII: Solubility of indigo carmine.

Solvent	Solubility at 20°C unless otherwise stated
Acetone	Practically insoluble
Ethanol (75%)	1 in 1430
Glycerin	1 in 100
Propylene glycol	1 in 1000
Propylene glycol (50%)	1 in 167
Water	1 in 125 at 2°C
	1 in 63 at 25°C
	1 in 45 at 60°C

Stability Sensitive to light.

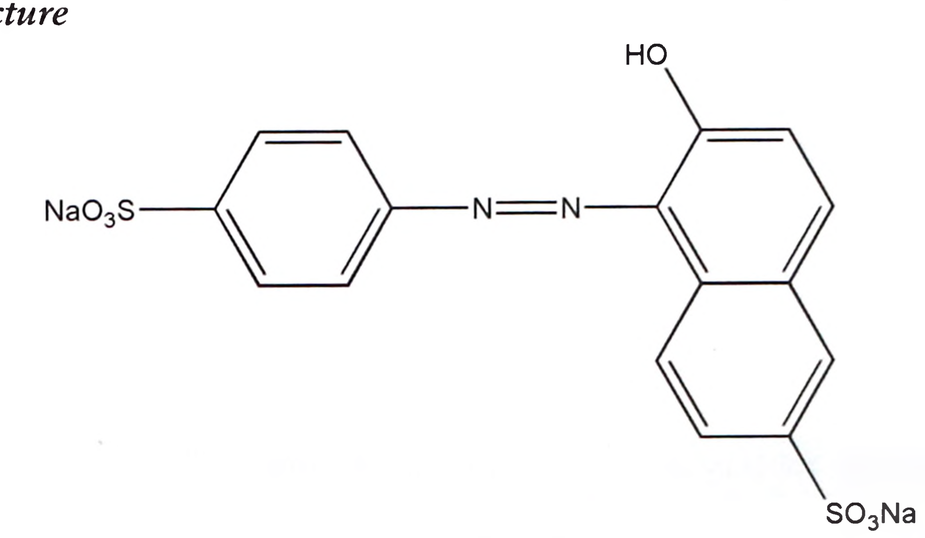
Method of manufacture Indigo is sulfonated with concentrated or fuming sulfuric acid.

Safety

LD_{50} (rat, IV): 93 mg/kg

Comments Indigo carmine is an indigoid dye used to color oral and topical pharmaceutical preparations. It is used with yellow colors to produce green colors. Indigo carmine is also used to color nylon surgical sutures and is used diagnostically as a 0.8% w/v injection.

Sunset yellow FCF



Empirical formula $C_{16}H_{10}N_2Na_2O_7S_2$

Molecular weight 452.37

CAS number [2783-94-0]

Synonyms E110; FD&C yellow #6; 6-hydroxy-5-[(4-sulfophenyl)azo]-2-naphthalenesulfonic acid disodium salt; 1-*p*-sulfophenylazo-2-naphthol-6-sulfonic acid disodium salt; yellow orange S.

Structure

Appearance Reddish yellow powder. Aqueous solutions are bright orange colored.

Absorption maximum 482 nm

Color Index No. CI 15985

Purity (EU)

Arsenic: ≤3 ppm

Lead: ≤2 ppm

Mercury: ≤1 ppm

Cadmium: ≤1 ppm
Ether-extractable matter: ≤0.2% under neutral conditions
Assay: ≥85% total coloring matters as the sodium salt
Subsidiary colors: ≤5%
1-(Phenylazo)-2-napththalenol (Sudan 1): ≤0.5 mg/kg
Water-insoluble matter: ≤0.2%
Organic compounds other than coloring matters: ≤0.5%
Unsulfonated primary aromatic amines: ≤0.01% as aniline

Purity (US)

Arsenic: ≤3 ppm
Lead: ≤10 ppm
Mercury: ≤1 ppm
4-Aminobenzenesulfonic acid: ≤0.2% as the sodium salt
6-Hydroxy-2-naphthalenesulfonic acid: ≤0.3% as the sodium salt
6,6′-Oxybis[2-naphthalenesulfonic acid]: ≤1% as the disodium salt
4,4′-(1-Triazene-1,3-diyl)bis[benzenesulfonic acid]: ≤0.1% as the disodium salt
Sum of the sodium salt of 6-hydroxy-5-(phenylazo)-2-naphthalenesulfonic acid and the sodium salt of 4-[(2-hydroxy-1-naphthalenyl)azo]benzenesulfonic acid: ≤1%
Sum of the trisodium salt of 3-hydroxy-4-[(4-sulfophenyl)azo]-2,7-naphthalenedisulfonic acid and other higher sulfonated subsidiaries: ≤5%
4-Aminobenzene: ≤50 ppb
4-Aminobiphenyl: ≤15 ppb
Aniline: ≤250 ppb
Azobenzene: ≤200 ppb
Benzidine: ≤1 ppb
1,3-Diphenyltriazene: ≤40 ppb
1-(Phenylazo)-2-naphthalenol: ≤10 ppm
Total color: ≥87%
Sum of volatile matter at 135°C, chlorides and sulfates: ≤13.0%
Water-insoluble matter: ≤0.2%

Solubility *see* Table IX.

Incompatibilities Poorly compatible with citric acid, saccharose solutions, and saturated sodium bicarbonate solutions. Incompatible with ascorbic acid, gelatin, and glucose.

Method of manufacture Diazotized sulfanilic acid is coupled with Schaeffer's salt (sodium salt of β-naphthol-6-sulfonic acid).

Safety

LD_{50} (mouse, IP): 4.6 g/kg
LD_{50} (mouse, oral): >6 g/kg
LD_{50} (rat, IP): 3.8 g/kg
LD_{50} (rat, oral): >10 g/kg

Comments

Sunset yellow FCF is a monoazo dye.

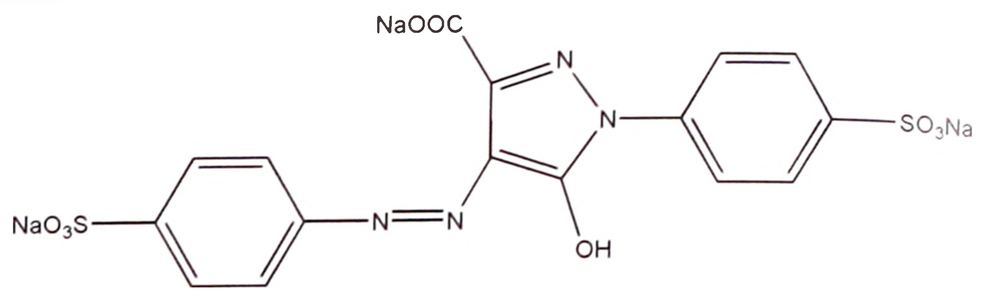


Table IX: Solubility of Sunset yellow FCF.

Solvent	Solubility at 20°C unless otherwise stated
Acetone	1 in 38.5
Ethanol (75%)	1 in 333
Glycerin	1 in 5
Propylene glycol	1 in 45.5
Propylene glycol (50%)	1 in 5
Water	1 in 5.3 at 2°C 1 in 5.3 at 25°C 1 in 5 at 60°C

The EINECS number for sunset yellow FCF is 220-491-7.

Tartrazine

Empirical formula $C_{16}H_9N_4Na_3O_9S_2$
Molecular weight 534.39
CAS number [1934-21-0]
Synonyms 4,5-Dihydro-5-oxo-1-(4-sulfophenyl)-4-[(4-sulfophenyl)azo]-1*H*-pyrazole-3-carboxylic acid trisodium salt; E102; FD&C yellow #5; hydrazine yellow.
Structure

Appearance Yellow or orange-yellow powder. Aqueous solutions are yellow-colored; the color is retained upon addition of hydrochloric acid solution, but with sodium hydroxide solution a reddish color is formed.
Absorption maximum 425 nm
Color Index No. CI 19140

Purity (EU)

Arsenic: ≤3 ppm
Lead: ≤2 ppm
Mercury: ≤1 ppm
Cadmium: ≤1 ppm
Assay: ≥85% total coloring matters as the sodium salt
Organic compounds other than coloring matters: ≤0.5%
Unsulfonated primary aromatic amines: ≤0.01% as aniline
Ether-extractable matter: ≤0.2% under neutral conditions
Accessory colorings: ≤1.0%
Water-insoluble matter: ≤0.2%

Purity (US)

Arsenic: ≤3 ppm
Lead: ≤10 ppm
Mercury: ≤1 ppm
Total color: ≥87.0%
Volatile matter, chlorides and sulfates (calculated as the sodium salts): ≤13.0% at 135°C
Water-insoluble matter: ≤0.2%
4,4′-[4,5-Dihydro-5-oxo-4-[(4-sulfophenyl)hydrazono]-1*H*-pyrazol-1,3-diyl]bis[benzenesulfonic acid]: ≤1% as the trisodium salt
4-[(4',5-Disulfo[1,1'-biphenyl]-2-yl)hydrazono]-4,5-dihydro-5-oxo-1-(4-sulfophenyl)-1*H*-pyrazole-3-carboxylic acid, tetrasodium salt: ≤1%
Ethyl or methyl 4,5-dihydro-5-oxo-1-(4-sulfophenyl)-4-[(4-sulfophenyl)hydrazono]-1*H*-pyrazole-3-carboxylate, disodium salt: ≤1%
Sum of 4,5-dihydro-5-oxo-1-phenyl-4-[(4-sulfophenyl)azo]-1*H*-pyrazole-3-carboxylic acid, disodium salt, and 4,5-dihydro-5-oxo-4-(phenylazo)-1-(4-sulfophenyl)-1H-pyrazole-3-carboxylic acid, disodium salt: ≤0.5%
4-Aminobenzenesulfonic acid: ≤0.2% as the sodium salt
4,5-Dihydro-5-oxo-1-(4-sulfophenyl)-1*H*-pyrazole-3-carboxylic acid: ≤0.2% as the disodium salt
Ethyl or methyl 4,5-dihydro-5-oxo-1-(4-sulfophenyl)-1*H*-pyrazole-3-carboxylate: ≤0.1% as the sodium salt
4,4′-(1-Triazene-1,3-diyl)bis[benzenesulfonic acid]: ≤0.05% as the disodium salt
4-Aminobenzene: ≤75 ppb

4-Aminobiphenyl: ≤5 ppb
Aniline: ≤100 ppb
Azobenzene: ≤40 ppb
Benzidine: ≤1 ppb
1,3-Diphenyltriazene: ≤40 ppb

Solubility *see* Table X.

Table X: Solubility of tartrazine.

Solvent	Solubility at 20°C unless otherwise stated
Acetone	Practically insoluble
Ethanol (75%)	1 in 91
Glycerin	1 in 5.6
Propylene glycol	1 in 14.3
Propylene glycol (50%)	1 in 5
Water	1 in 26 at 2°C 1 in 5 at 25°C 1 in 5 at 60°C

Incompatibilities Poorly compatible with citric acid solutions. Incompatible with ascorbic acid, lactose, 10% glucose solution, and saturated aqueous sodium bicarbonate solution. Gelatin accelerates the fading of the color.

Method of manufacture Phenylhydrazine *p*-sulfonic acid is condensed with sodium ethyl oxalacetate; the product obtained from this reaction is then coupled with diazotized sulfanilic acid.

Safety

LD_{50} (mouse, oral): >6 g/kg
LD_{50} (mouse, IP): 4.6 g/kg
LD_{50} (rat, oral): 10 g/kg
LD_{50} (rat, IP): 3.8 g/kg

Comments Tartrazine is a monoazo, or pyrazolone, dye. It is used to improve the appearance of a product and to impart a distinctive coloring for identification purposes.

US regulations require that prescription drugs for human use containing tartrazine bear the warning statement:

This product contains FD&C yellow #5 (tartrazine) which may cause allergic-type reactions (including bronchial asthma) in certain susceptible persons.

Although the overall incidence of sensitivity to FD&C yellow #5 (tartrazine) in the general population is low, it is frequently seen in patients who are also hypersensitive to aspirin.

18 Comments

Titanium dioxide is used extensively to impart a white color to film-coated tablets, sugar-coated tablets, and gelatin capsules. It is also used in lakes as an opacifier, to 'extend' the color. *See* Titanium dioxide for further information.

In the EU, colors used in pharmaceutical formulations and colors used in cosmetics are controlled by separate regulations. Cosmetic colors are also classified according to their use, e.g. those that may be used in external products that are washed off after use.

Copovidone

1 Nonproprietary Names

BP: Copovidone

PhEur: Copovidone

USP–NF: Copovidone

2 Synonyms

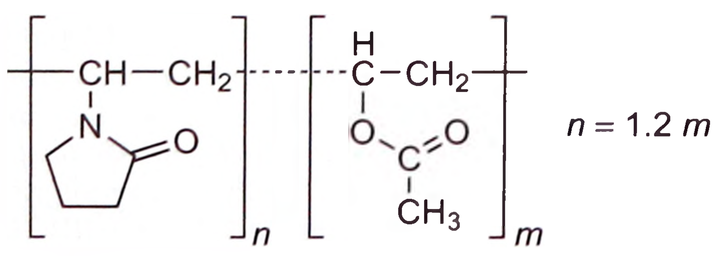
Acetic acid vinyl ester, polymer with 1-vinyl-2-pyrrolidinone; copolymer of 1-vinyl-2-pyrrolidone and vinyl acetate in a ratio of 3:2 by mass; copolyvidone; copovidonum; *Kollidon VA 64*; *Luviskol VA*; *Plasdone S-630*; poly(1-vinylpyrrolidone-co-vinyl acetate); polyvinylpyrrolidone-vinyl acetate copolymer; PVP/VA; PVP/VA copolymer.

3 Chemical Name and CAS Registry Number

Acetic acid ethenyl ester, polymer with 1-ethenyl-2-pyrrolidinone [25086-89-9]

4 Empirical Formula and Molecular Weight

$(C_6H_9NO)_n \cdot (C_4H_6O_2)_m$ $(111.1)_n + (86.1)_m$



The ratio of n to m is approximately $n = 1.2m$. Molecular weights of 45 000–70 000 have been determined for *Kollidon VA 64*. The average molecular weight of copovidone is usually expressed as a *K*-value.

The *K*-value of *Kollidon VA 64* is nominally 28, with a range of 25.2–30.8. The *K*-value of *Plasdone S 630* is specified between 25.4 and 34.2. *K*-values are calculated from the kinematic viscosity of a 1% aqueous solution. Molecular weight can be calculated with the formula:

$$M = 22.22\ (K + 0.075K^{2})^{1.65}$$

The USP 40–NF 35 S1 describes copovidone as a copolymer of 1-vinyl-2–pyrrolidinone and vinyl acetate in the mass proportion of 3:2. The PhEur 9.2 describes copovidone as a copolymer of 1-ethenylpyrrolidin-2-one and ethenyl acetate in the mass proportion of 3:2.

5 Structural Formula

6 Functional Category

Film-forming agent; modified-release agent; tablet and capsule binder.

7 Applications in Pharmaceutical Formulation or Technology

Copovidone is used as a tablet binder, a film-former, and as part of the matrix material used in controlled-release formulations. In tableting, copovidone can be used as a binder for direct compression[1–4] and as a binder in wet granulation.[5,6] Copovidone is often added to coating solutions as a film-forming agent.[7] It provides good adhesion, elasticity, and hardness, and can be used as a moisture barrier.

See Table I.

Table I: Uses of copovidone.

Use	Concentration (%)
Film-forming agent	0.5–5.0[a]
Tablet binder, direct compression	2.0–5.0
Tablet binder, wet granulation	2.0–5.0

(a) This corresponds to the % w/w copovidone in the film-forming solution formulation, before spraying.

8 Description

Copovidone is a white to yellowish-white amorphous powder. It is typically spray-dried with a relatively fine particle size. It has a slight odor and a faint taste.

9 Pharmacopeial Specifications

See Table II. *See also* Section 18.

Table II: Pharmacopeial specifications for copovidone.

Test	PhEur 9.2	USP 40–NF 35 S1
Aldehydes	≤500 ppm	≤0.05%
Appearance of solution	+	+
Characters	+	—
Ethenyl acetate	35.3–42.0%	35.3–41.4%
Heavy metals	—	≤20 ppm
Hydrazine	≤1 ppm	≤1 ppm
Identification	+	+
K-value	90.0–110.0%	90.0–110.0%
Loss on drying	≤5.0%	≤5.0%
Monomers	≤0.1%	+
1-vinyl-2-pyrrolidone	—	≤0.001%
Vinyl acetate	—	≤0.001%
2-pyrrolidone	—	≤0.5%
Nitrogen content	7.0–8.0%	7.0–8.0%
Peroxides	≤400 ppm	≤0.04%
2-Pyrrolidone	≤0.5%	—
Sulfated ash	≤0.1%	—
Residue on ignition	—	≤0.1%
Viscosity, expressed as *K*-value	+	—

10 Typical Properties

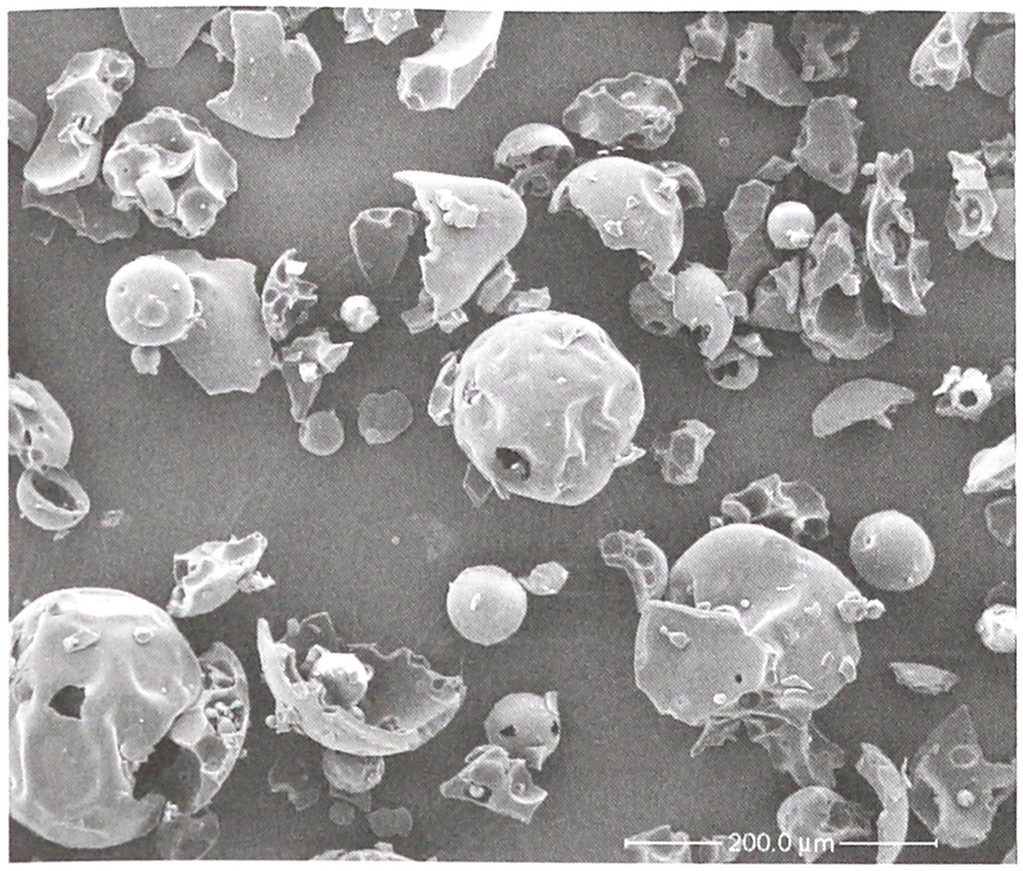
Density (bulk) 0.24–0.28 g/cm^3

Density (tapped) 0.35–0.45 g/cm^3

Flash point 215°C

Flowability Relatively free-flowing powder.

Glass transition temperature 106°C for *Plasdone S-630*.[8]



Hygroscopicity At 50% relative humidity, copovidone gains less than 10% weight.

K-*value* 25.4–34.2 for *Plasdone S-630*.[8]

Melting point 140°C

Solubility Greater than 10% solubility in 1,4-butanediol, glycerol, butanol, chloroform, dichloromethane, ethanol (95%), glycerol, methanol, polyethylene glycol 400, propan-2-ol, propanol, propylene glycol, and water. Less than 1% solubility in cyclohexane, diethyl ether, liquid paraffin, and pentane.

SEM 1: Excipient: copovidone (*Kollidon VA 64*); manufacturer: BASF; magnification: 400×; voltage: 10 kV.

Viscosity (dynamic) The viscosity of aqueous solutions depends on the molecular weight and the concentration. At concentrations less than 10%, the viscosity is less than 10 mPa s (25°C).

11 Stability and Storage Conditions

Copovidone is stable and should be stored in a well-closed container in a cool, dry place.

12 Incompatibilities

Copovidone is compatible with most organic and inorganic pharmaceutical ingredients. When exposed to high water levels, copovidone may form molecular adducts with some materials; *see* Crospovidone and Povidone.

13 Method of Manufacture

Copovidone is manufactured by free-radical polymerization of vinylpyrrolidone and vinyl acetate in a ratio of 6 : 4. The synthesis is conducted in an organic solvent owing to the insolubility of vinyl acetate in water.

14 Safety

Copovidone is used widely in pharmaceutical formulations and is generally regarded as nontoxic. However, it is moderately toxic by ingestion, producing gastric disturbances. It has no irritating or sensitizing effects on the skin. A study was conducted to look at the carcinogenicity and chronic toxicity of copovidone (*Kollidon VA 64*) in Wistar rats and Beagle dogs. The results of these studies demonstrated the absence of any significant toxicological findings of high dietary levels of copodivone in rats and dogs, resulting in no-observed-adverse-effect levels of 2800 mg/kg body-weight/day in rats and 2500 mg/kg body-weight/day in dogs, the highest doses tested.[9]

LD_{50} (rat, oral): >0.63 g/kg[10]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. When heated to decomposition, copovidone emits toxic vapors of NO_x. Eye protection, gloves, and a dust mask are recommended.

16 Regulatory Status

Copovidone is included in the FDA Inactive Ingredients Database (oral tablets, oral film-coated tablets, sustained action).

17 Related Substances

Crospovidone; povidone.

18 Comments

Copovidone is one of the materials that have been selected for harmonization by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

Kollidon VA 64 has a spherical structure, with a high proportion of damaged spheres. The shell-like structure reduces flowability, but the damaged spheres cover a greater surface area of the filler particles, increasing the efficacy of its use as a dry binder.[11] Furthermore, when used in transdermal drug delivery systems, copovidone has been shown to significantly alter the melting behavior, by reducing the heat of fusion and the melting point of estradiol and various other sex steroids.[12]

Plasdone S-630 has been used in direct compression experiments with active substances that are difficult to compress, such as acetaminophen (paracetamol); and has been shown to produce harder tablets than those containing the same actives but made with microcrystalline cellulose.[13]

In general, copovidone has better plasticity than povidone as a tablet binder, and is less hygroscopic, more elastic, and less tacky in film-forming applications than povidone.

Up to about 1975, copovidone was marketed by BASF under the name *Luviskol VA 64*. *Luviskol* is currently used only for the technical/cosmetic grade of copovidone.

A specification for copovidone is contained in the *Food Chemicals Codex* (FCC).[14]

Corn Oil

1 Nonproprietary Names

BP: Refined Maize Oil
JP: Corn Oil
PhEur: Maize Oil, Refined
USP–NF: Corn Oil

2 Synonyms

Maize oil; *Majsao CT*; maydis oleum raffinatum; maydol.

3 Chemical Name and CAS Registry Number

Corn oil [8001-30-7]

4 Empirical Formula and Molecular Weight

Corn oil is composed of fatty acid esters with glycerol, known commonly as triglycerides. Typical corn oil produced in the USA, which is rich in polyunsaturated fatty acids, contains five major fatty acids: linoleic 58.9%; oleic 25.8%; palmitic 11.0%; stearic 1.7%; and linolenic 1.1%. Corn grown outside the USA yields corn oil with lower linoleic, higher oleic, and higher saturated fatty acid levels. Corn oil also contains small quantities of plant sterols.

The USP 40–NF 35 S1 describes corn oil as the refined fixed oil obtained from the embryo of *Zea mays* Linné (Fam. Gramineae).

5 Structural Formula

See Section 4.

6 Functional Category

Oleaginous vehicle; solvent.

7 Applications in Pharmaceutical Formulation or Technology

Corn oil is used primarily in pharmaceutical formulations as a solvent for intramuscular injections or as a vehicle for topical preparations. Emulsions containing up to 67% corn oil are also used as oral nutritional supplements; *see also* Section 18. When combined with surfactants and gel-forming polymers, it is used to formulate veterinary vaccines.

Corn oil has a long history of use as an edible oil and may be used in tablets or capsules for oral administration.

8 Description

Corn oil occurs as a clear, light yellow-colored, oily liquid with a faint characteristic odor and slightly nutty, sweet taste resembling cooked sweet corn.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for corn oil.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	–	+	+
Characters	+	+	–
Acid value	≤0.2	≤0.5[a]	≤0.2
Alkaline impurities	–	+	+
Cottonseed oil	–	–	–
Fatty acid composition	–	+	+
Fatty acids $<C_{16}$	–	≤0.6%	–

Unsaponifiable matter	≤1.5%	≤2.8%	≤1.5%

(a) If intended for parenteral use.

10 Typical Properties

Acid value 2–6
Autoignition temperature 393°C
Density 0.915–0.918 g/cm^3

Flash point 254°C (closed cup);[1] 321°C
Hydroxyl value 8–12
Iodine value 109–133
Melting point −18 to −10°C
Refractive index

n_D^{25} = 1.470–1.474;

n_D^{40} = 1.464–1.468.

Saponification value 187–196
Solubility Miscible with benzene, chloroform, dichloromethane, ether, hexane, and petroleum ether; practically insoluble in ethanol (95%) and water.
Viscosity (dynamic) 37–39 mPa s (37–39 cP)

11 Stability and Storage Conditions

Corn oil is stable when protected with nitrogen in tightly sealed bottles. Prolonged exposure to air leads to thickening and rancidity. Corn oil may be sterilized by dry heat, maintaining it at 150°C for 1 hour.[2]

Corn oil should be stored in an airtight, light-resistant container in a cool, dry place. Exposure to excessive heat should be avoided. Keep away from oxidizing materials.[1]

12 Incompatibilities

The photooxidation of corn oil is sensitized by cosmetic and drug-grade samples of coated titanium oxide and zinc oxide.[3]

13 Method of Manufacture

Refined corn oil is obtained from the germ or embryo of *Zea mays* Linné (Fam. Gramineae), which contains nearly 50% of the fixed oil compared with 3.0–6.5% in the whole kernel. The oil is obtained from the embryo by expression and/or solvent extraction. Refining involves the removal of free fatty acids, phospholipids, and impurities; decolorizing with solid adsorbents; dewaxing by chilling; and deodorization at high temperature and under vacuum.

14 Safety

Corn oil is generally regarded as a relatively nontoxic and nonirritant material with an extensive history of usage in food preparation. Slightly irritant on contact with skin and eyes, and on inhalation.[1]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Spillages of this material are very slippery and should be covered with an inert absorbent material prior to disposal. Gloves, eye protection, respirator, and other protective clothing are recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (IM injections; oral capsules, suspensions, and tablets). Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Almond oil; canola oil; cottonseed oil; peanut oil; sesame oil; soybean oil; sunflower oil.

18 Comments

Corn oil demonstrates good oxidative flavor stability owing to its nonrandom fatty acids distribution on the triglycerides and the presence of antioxidants (tocopherol and ferulic acid) in its composition.

Owing to its high content of unsaturated acids, corn oil has been used as a replacement for fats and oils containing a high content of saturated acids in the diets of patients with hypercholesterolemia.

A specification for corn oil is contained in the *Food Chemicals Codex* (FCC).[4]

The EINECS number for corn oil is 232-281-2.

Corn Starch and Pregelatinized Starch, Coprocessed

C

1 Nonproprietary Names

None adopted.

2 Synonyms

StarCap 1500, *Starch 1500*, *SuperStarch 200*, *Lycatab C*, *Lycatab C-LM*.

3 Chemical Name and CAS Registry Number

See Starch, and Starch, Pregelatinized.

4 Empirical Formula and Molecular Weight

See Starch, and Starch, Pregelatinized.

5 Structural Formula

See Starch, and Starch, Pregelatinized.

6 Functional Category

Direct compression excipient; tablet and capsule diluent; tablet and capsule disintegrant.

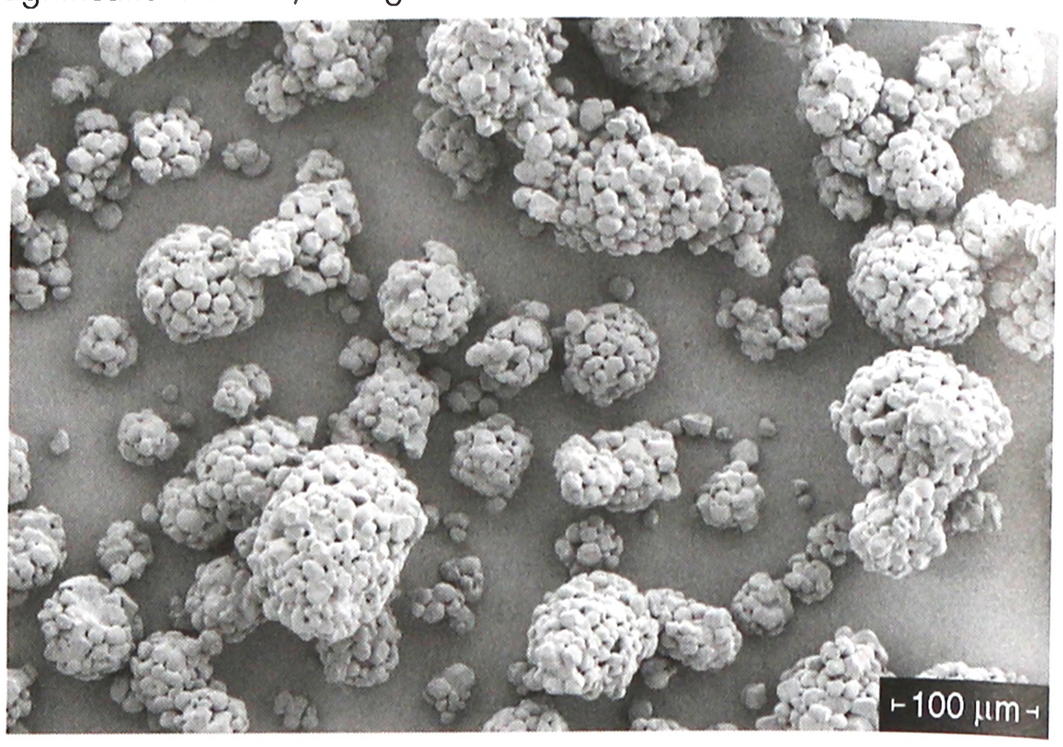
7 Applications in Pharmaceutical Formulation or Technology

Coprocessed corn starch and pregelatinized starch can be used in both capsules and tablets to improve flowability, enhance disintegration, and improve hardness. Good compactibility and disintegration of tablets is best achieved in combination with common excipients (soluble or insoluble), such as lactose, microcrystalline cellulose or dibasic calcium phosphate.[1]

8 Description

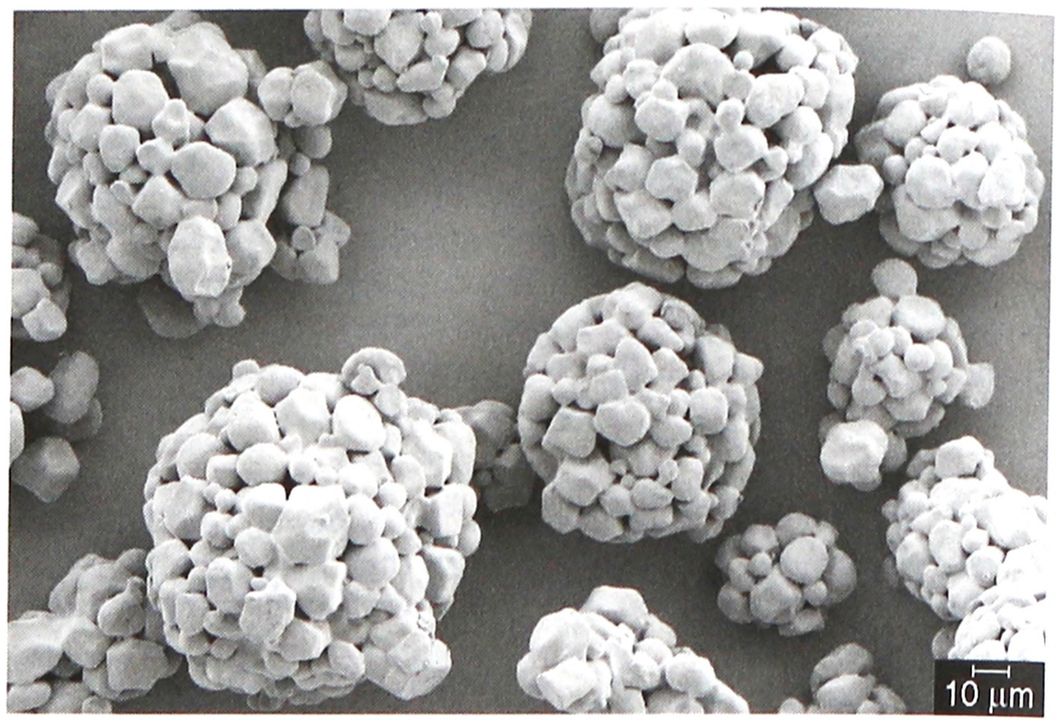
Coprocessed corn starch and pregelatinized starch occurs as a white free-flowing powder. It is a coprocessed mixture of predominantly corn starch together with pregelatinized starch. *See also* Starch, and Starch, Pregelatinized.

9 Pharmacopeial Specifications



Both corn starch and pregelatinized starch are listed as separate monographs in the JP, PhEur, and USP–NF, but the combination is not listed. The pharmacopeial specifications for corn starch have undergone harmonization for many attributes for JP, PhEur, and USP–NF.

See Starch, and Starch, Pregelatinized. *See also* Section 18.



10 Typical Properties

Acidity/alkalinity 4.5–7.0 for *StarCap 1500*
Iron ≤0.001% for *StarCap 1500*
Loss on drying 7–13% for *StarCap 1500*
Microbial content Total aerobes count ≤100 cfu/g; molds and yeasts ≤100 cfu/g (*Escherichia coli*, *Pseudomonas aeruginosa*, and *Salmonella* species absent) for *StarCap 1500*.
Particle size distribution 9–42% retained on #120 mesh (125 µm), 25–50% retained on #200 mesh (74 µm), 20–55% passing #200 mesh (74 µm) for *StarCap 1500*.
Solubility Insoluble in water for *StarCap 1500*
Sulfur dioxide ≤0.005% for *StarCap 1500*

SEM 1: Excipient: *StarCap 1500*; manufacturer: Colorcon; magnification: 200×; voltage: 3 kV.

SEM 2: Excipient: *StarCap 1500*; manufacturer: Colorcon; magnification: 500×; voltage: 3 kV.

11 Stability and Storage Conditions

Store in sealed containers at below 30°C, avoiding high humidity.

12 Incompatibilities

See Starch, and Starch, Pregelatinized.

13 Method of Manufacture

Coprocessed corn starch and pregelatinized starch is produced by a proprietary spray-drying technique.

14 Safety

See Starch, and Starch, Pregelatinized.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

16 Regulatory Status

Corn starch and pregelatinized starch is a coprocessed mixture of two materials both of which are regarded as nontoxic:

Starch GRAS listed. Included in the FDA Inactive Ingredients Database (buccal tablets, oral capsules, powders, suspensions and tablets; topical preparations; and vaginal tablets). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

Pregelatinized starch Included in the FDA Inactive Ingredients Database (oral capsules, suspensions, and tablets; vaginal preparations). Included in nonparenteral medicines licensed in the UK.

Coprocessed corn starch and pregelatinized starch is included in nonparenteral medicines licensed in the UK, and has been included in approved drug products in the EU, Latin America and Asia.[2]

17 Related Substances

Starch; Starch, Pregelatinized.

18 Comments

Corn starch has undergone harmonization for many attributes for JP, PhEur, and USP-NF by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

StarCap 1500 is a free-flowing, low-dust excipient with disintegration and dissolution properties independent of medium pH, which help promote deaggregation of the powder mass into primary drug particles and speeds up the dissolution rate of the drug substance, providing rapid disintegration across the pH range present in the human digestive tract.[3–5] *StarCap 1500* has been used in studies to determine the influence of disintegrants on the release rate of theophylline.[6] The coprocessed product has been designed specifically for use in capsules and directly compressed tablets, and has enhanced physical properties that cannot be achieved by single blend. It has been reported as having excellent properties for high-dose, high-solubility capsule formulations, with low weight and good content uniformity.[3] The product acts as a compression aid, diluent, and disintegrant, which allows for robust but simple capsule and directly compressible tablet formulations.

Corn Syrup Solids

1 Nonproprietary Names

PhEur: Glucose Liquid Spray-Dried

USP–NF: Corn Syrup Solids

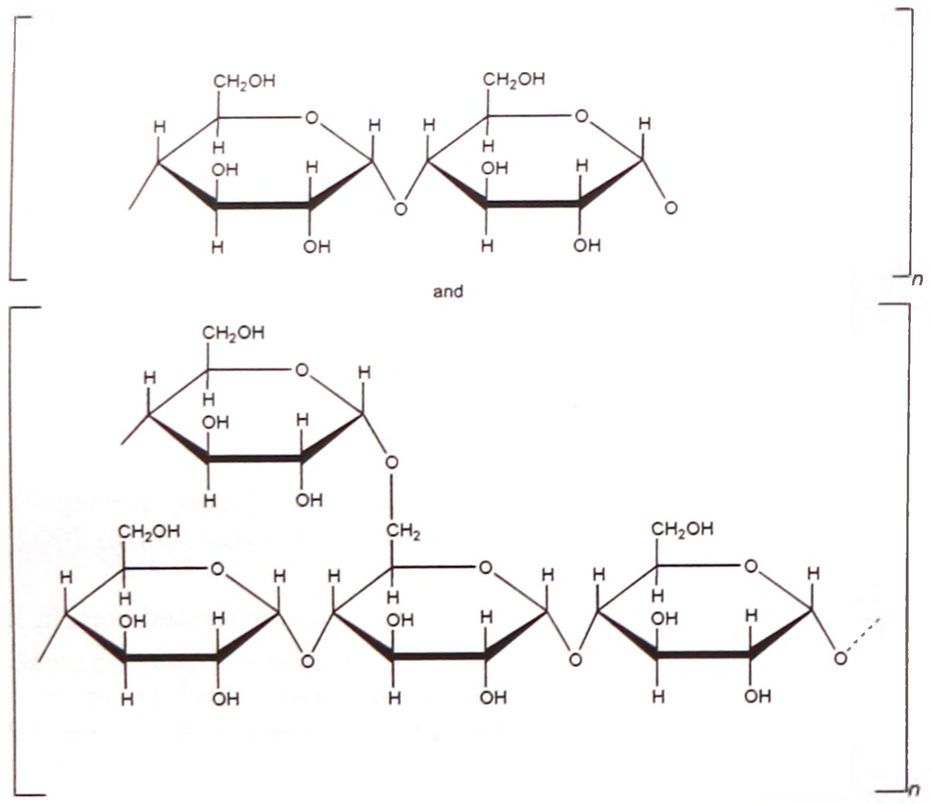
2 Synonyms

Dehydrated hydrolyzed starch syrup; dried glucose syrup; glucosum liquidum dispersione desiccatum; *Maltrin*; soluble corn fiber; resistant maltodextrin.

3 Chemical Name and CAS Registry Number

Corn syrup solids [68131-37-3]

4 Empirical Formula and Molecular Weight



$(C_6H_{10}O_5)_nH_2O$ $\leq 4\,000$

Corn syrup solids are mixtures of amylose (D-glucose units connected by 1→4 glycosidic bonds) and to a lesser extent, amylopectin (D-glucose units connected by 1→4 glycosidic bonds and branched chains connected by 1→6 glycosidic bonds).

The relative amounts of monosaccharides, disaccharides, trisaccharides, and polysaccharides depend on the process used for starch hydrolysis. Dextrose Equivalence (DE) is a quantitative measure of the degree of starch polymer hydrolysis. It is a measure of reducing power compared to a dextrose standard of 100. Products with higher DE have a greater extent of starch hydrolysis. As the product is further hydrolyzed (higher DE), the average molecular weight decreases and the carbohydrate profile changes accordingly.

USP 40–NF 35 S1 describes corn syrup solids as a dried mixture of saccharides resulting from the partial hydrolysis of edible corn starch by food-grade acids or enzymes. The DE (reducing sugar as D-glucose) is not less than 20.0% on a dried basis.

5 Structural Formula

6 Functional Category

Coating agent; humectant; suspending agent; sweetening agent; tablet and capsule binder; tablet and capsule diluent; tonicity agent; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Corn syrup solids are used in pharmaceutical preparations as sweeteners, viscosity-increasing agents, tablet binders and lubricants.[1–3] They may also be used as carriers for high-potency active ingredients to improve content uniformity for direct compression formulations.[3]

Corn syrup solids are also used in a variety of products including foods, confectionery, and personal care products. They can enhance flavors such as fruit flavors. In some applications, corn syrup solids can be used to control moisture levels.[4]

8 Description

Corn syrup solids occur as bland to slightly sweet, odorless powders or granules. Sweetness increases as DE increases.

9 Pharmacopeial Specifications

See Table I.

10 Typical Properties

Compressibility Compressibility increases as DE increases.

Density (tapped)

0.54–0.70 g/cm^3 for Maltrin QD M200;

0.32–0.45 g/cm^3 for Maltrin QD M600.

Moisture content Hygroscopicity increases as the DE value increases. Generally, the moisture content does not increase substantially at relative humidities less than 50%.

Solubility Freely soluble in water; slightly soluble in ethanol 95%. Solubility increases as the DE value increases.

Viscosity Viscosity decreases as the DE value increases. *See* Table II.

Table I: Pharmacopeial specifications for corn syrup solids.

Test	PhEur 9.2	USP 40–NF 35 S1[a]
Identification	+	+
Characters	+	–
pH	4.0–7.0	–
Loss on drying	≤6.0%	–
Microbial limit	+	+
Aerobic[b]	≤1000 cfu/g	≤1000 cfu/g
Mold and yeast	≤100 cfu/g	≤100 cfu/g
Residue on ignition	≤0.5%	≤0.5%
Heavy metals	–	≤5 µg/g
Starch	–	+
Total solids	–	≥90.0%[c] ≥93.0%[d]
Sulfur dioxide	≤20 ppm	≤40 µg/g
Lead	–	≤0.5 µg/g
Assay (reducing sugar content, dried basis)	≥20.0	≥20.0%

(a) The USP 40–NF 35 S1 states that corn syrup solids should be labeled with the nominal DE value and if the amount of sulfur dioxide is greater than 10 µg/g.
(b) *Escherichia coli* and *Salmonella* species absent
(c) When the reducing sugar content is 88.0% or greater
(d) When the reducing sugar content is between 20.0% and 88.0%

Table II: Relationship between DE value and viscosity of selected corn syrup solids at 30% and 60% w/w.[5]

DE Value	Viscosity of 30% w/w solution mPa s (cP)	Viscosity of 60 % w/w solution mPa s (cP)
20	~20	~300
25	<20	~200
36	<20	~100

11 Stability and Storage Conditions

Corn syrup solids are stable for at least 2 years when stored at 30°C or below and at a relative humidity less than 50%. Deviations from these conditions will not affect the stability of corn syrups solids except for moisture content which will change depending on the temperature and humidity and should be checked at regular intervals.[6] Store in a well-closed container in a cool, dry place.

12 Incompatibilities

At very low and high pH, corn syrup solids can form degradation products that are colored brown or yellow. In some cases, these degradation products will affect the flavor of the preparation. Corn syrup solids may react with amine compounds (e.g. amino acids) in a Maillard reaction.

13 Method of Manufacture

Corn syrup solids are prepared by heating and treating starch with acid and/or enzymes in the presence of water. This process partially hydrolyzes the starch, to produce a solution of glucose polymers of varying chain length. The solution is filtered, concentrated, and dried to obtain corn syrup solids. The manufacturing process is similar to that of maltodextrin. *See* Maltodextrin.

14 Safety

Corn syrup solids are considered nontoxic and nonirritating materials when used as excipients or as a food ingredient. May cause eye or respiratory tract irritation.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Corn syrup solids should be handled in a well-ventilated area and excessive dust generation should be

avoided. Protective eye goggles and respiratory apparatus are recommended.

16 Regulatory Status

Included in nonparenteral medicines licensed in the UK. Listed in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Dextrates; dextrin; maltodextrin; starch.

18 Comments

Maltodextrins may be used as the term for maltodextrins and corn syrup solids. Corn syrup is used to describe hydrolyzed starches with a DE ranging from 20 to ≈99.

Corn syrup solids are used to control sugar crystallization, with the lower DE values being the most effective. They are used frequently as a secondary sweetener to sucrose because corn syrup solids aid in resisting discoloration caused by heat.

Corn syrup solids are digestible carbohydrates with a nutritional value of ≈17 kJ/g or 4 kcal/g. In oral nutritional supplements, they are used as a carbohydrate source with a lower osmolarity than an isocaloric amount of dextrose. For diabetics, they should be considered as a source of carbohydrate similar to dextrose. Partially hydrolyzed corn syrup solids have been investigated as a replacement for lactose in manufactured liquid diets for neonatal pigs.[7] Corn syrup solids used in the food industry include *Clintose CR 24* (Archer Daniels Midland Company, USA), *Dry GL* (Cargill, USA), *Dri-Sweet 36* (Ramsen, USA), *Globe* (Corn Products, USA), and *Star-Dri* (Tate & Lyle, USA).

A specification for corn syrup solids (dried glucose syrup) is listed in the *Food Chemicals Codex* (FCC).[8]

Cottonseed Oil

1 Nonproprietary Names

USP–NF: Cottonseed Oil

2 Synonyms

Cotton oil; refined cottonseed oil.

3 Chemical Name and CAS Registry Number

Cottonseed oil [8001-29-4]

4 Empirical Formula and Molecular Weight

A typical analysis of refined cottonseed oil indicates the composition of the acids present as glycerides to be as follows: linoleic acid 39.3%; oleic acid 33.1%; palmitic acid 19.1%; stearic acid 1.9%; arachidic acid 0.6%, and myristic acid 0.3%. Also present are small quantities of phospholipid, phytosterols, and pigments. The toxic polyphenolic pigment gossypol is present in raw cottonseed and in the oil cake remaining after expression of oil; it is not found in the refined oil.

5 Structural Formula

See Section 4.

6 Functional Category

Oleaginous vehicle; solvent.

7 Applications in Pharmaceutical Formulation or Technology

Cottonseed oil is used in pharmaceutical formulations primarily as a solvent for intramuscular injections. It has been used in intravenous emulsions as a fat source in parenteral nutrition regimens, although its use for this purpose has been superseded by soybean oil emulsions; *see* Section 14. It is also used as an emollient vehicle for other medications.

Cottonseed oil has been used as a tablet binder for acetaminophen; for characterization of the hot-melt fluid bed coating process;[1] in the manufacturing of stable oral pharmaceutical

powders; in encapsulation of enzymes; and as an aqueous dispersion in pharmaceutical coating.

8 Description

Cottonseed oil occurs as a pale yellow or bright golden yellow-colored, clear oily liquid. It is odorless, or nearly so, with a bland, nutty taste. At temperatures below 10°C particles of solid fat may separate from the oil, and at about −5 to 0°C the oil becomes solid or nearly so. If it solidifies, the oil should be remelted and thoroughly mixed before use.

9 Pharmacopeial Specifications

See Table I. *See also* Section 18.

Table I: Pharmacopeial specifications for cottonseed oil.

Test	USP 40–NF 35 S1
Identification	+
Fatty acid composition	+
Arachidic acid	≤1.0%
Behenic acid	≤0.6%
Erucatic acid	≤0.5%
Lignoceric acid	≤0.5%
Linoleic acid	46.7–58.3%
Linolenic acid	≤1.0%
Myristic acid	0.3–1.0%
Oleic acid	14.0–21.7%
Palmitic acid	18.0–26.4%
Stearic acid	2.1–3.3%
Free fatty acids	+
Heavy metals	≤10 ppm

10 Typical Properties

Autoignition temperature 344°C
Density 0.916 g/cm^3
Flash point 252°C (closed cup);[2] 321°C
Freezing point −5 to 0°C
Heat of combustion 37.1 kJ/g
Refractive index n_D^{40} = 1.4645–1.4655
Solubility Slightly soluble in ethanol (95%); miscible with carbon disulfide, chloroform, ether, hexane, and petroleum ether.
Spectroscopy

IR spectrum *see* Figure 1.

Raman spectrum *see* Figure 2.

Surface tension

35.4 mN/m (35.4 dynes/cm) at 20°C;

31.3 mN/m (31.3 dynes/cm) at 80°C.

Viscosity (dynamic) Up to 70.4 mPa s (70.4 cP) at 20°C.

11 Stability and Storage Conditions

Cottonseed oil is stable if stored in a well-filled, airtight, light-resistant container in a cool, dry place. Avoid exposure to excessive heat. Keep away from oxidizing materials.[2]

12 Incompatibilities

—

13 Method of Manufacture

Cottonseed oil is the refined fixed oil obtained from the seed of cultivated varieties of *Gossypium hirsutum* Linné or of other species of *Gossypium* (Fam. Malvaceae). The seeds contain about 15% oil. The testae of the seeds are first separated and the kernels are then exposed to high pressure in a hydraulic press. The crude oil thus

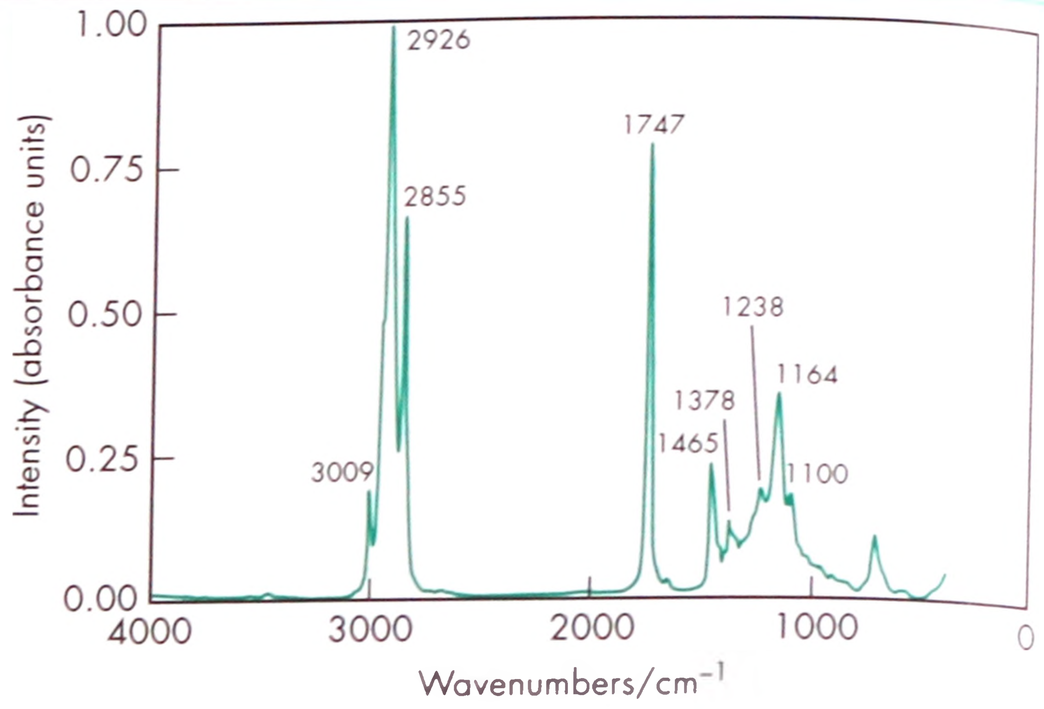

Figure 1: Infrared spectrum of cottonseed oil measured by transmission. Adapted with permission of Informa Healthcare.

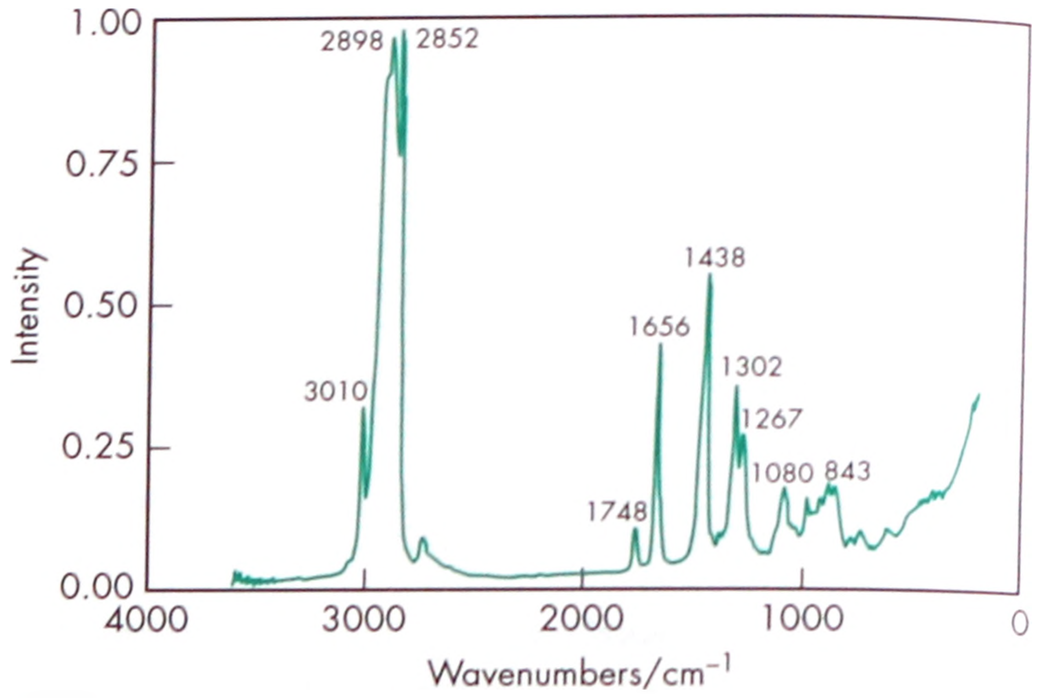

Figure 2: Raman spectrum of cottonseed oil measured in the 180 reflectance mode. Adapted with permission of Informa Healthcare.

obtained has a bright red or blackish-red color and requires purification before it is suitable for food or pharmaceutical purposes.

Cottonseed oil is refined by treatment with diluted alkali to neutralize acids, decolorized with fuller's earth or activated carbon, deodorized with steam under reduced pressure, and then chilled to separate glycerides and resinous substances of higher melting point to prevent it turning cloudy at 4–10°C or solidifying at about 0 C.

14 Safety

Cottonseed oil emulsions have in the past been used in long-term intravenous nutrition regimens.[3,4] A complex of adverse reactions called the 'overloading syndrome'[5] has been seen with chronic administration of cottonseed oil emulsion. This consisted of anorexia, nausea, abdominal pain, headache, fever, and sore throat. Signs of impaired liver function, anemia, hepatosplenomegaly, thrombocytopenia, and spontaneous hemorrhage due to delayed blood clotting have been reported. For parenteral nutrition purposes, cottonseed oil has been replaced by soybean oil,[3,6,7] especially in pregnant women, where the use of cottonseed lipid emulsion has been associated with adverse effects.[8]

A notable difference between the cottonseed oil emulsion and the soybean oil emulsion is the particle size. The cottonseed oil emulsion has much larger particles than the soybean oil emulsion. These larger particles may have been handled differently by the body, thus perhaps accounting for some of the toxic reactions.

Slightly irritant on contact with skin and eyes, and on inhalation.[2]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Spillages of this material are very slippery and should be covered with an inert absorbent material prior to disposal.

Cottonseed oil is a combustible liquid when exposed to heat or flame. If it is allowed to impregnate rags or oily waste, there is a risk due to spontaneous heating. Dry chemicals such as carbon dioxide should be used to fight any fires.

Gloves, eye protection, respirator, and other protective clothing are recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (IM injections; oral, capsule, tablet and sublingual preparations). Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Almond oil; canola oil; corn oil; hydrogenated vegetable oil; peanut oil; sesame oil; soybean oil; sunflower oil.

18 Comments

The USP 40–NF 35 S1, PhEur 9.2, and BP 2017 also list hydrogenated cottonseed oil.

Cottonseed oil has been used as an adjuvant in cholecystography and as a pediculicide and acaricide. It has the nutritive and emollient properties of fixed vegetable oils. By virtue of its high content of unsaturated acid glycerides (especially linoleic acid), it is used for dietary control of blood cholesterol levels in the prophylaxis and treatment of atherosclerosis. It can also retard gastric secretion and motility, and increase caloric intake.

Cottonseed oil has also been used in the manufacture of soaps, oleomargarine, lard substitutes, glycerin, lubricants, and cosmetics.

Gossypol, a natural toxin in cottonseed, interferes with spermatogenesis and is also a causative factor for paralysis among men. It can increase high-density lipoproteins in the body leading to cardiovascular diseases such as artherosclerosis, heart attack and angina. It may also lead to deficiency of omega-3 essential fatty acid. In a dose of 30 mL or more it is used as a mild cathartic.

A specification for unhydrogenated cottonseed oil is contained in the *Food Chemicals Codex* (FCC)[9] and the *Japanese Pharmaceutical Excipients* (JPE).[10]

The EINECS number for cottonseed oil is 232-280-7.

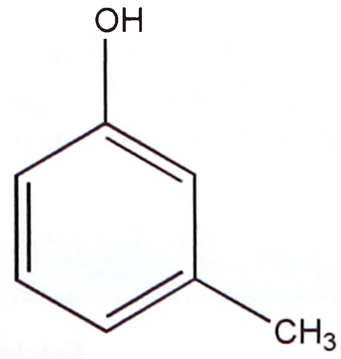
Cresol

1 Nonproprietary Names

BP: Cresol
JP: Cresol
USP–NF: Cresol

2 Synonyms

Cresylic acid; cresylol; hydroxytoluene; tricresol.



3 Chemical Name and CAS Registry Number

Methylphenol [1319-77-3]

4 Empirical Formula and Molecular Weight

C_7H_8O 108.14

5 Structural Formula

m-Cresol

6 Functional Category

Antimicrobial preservative.

7 Applications in Pharmaceutical Formulation or Technology

Cresol is used at 0.15–0.3% concentration as an antimicrobial preservative in intramuscular, intradermal, and subcutaneous injectable pharmaceutical formulations. Cresol is not suitable as a preservative for preparations that are to be freeze-dried.[1]

8 Description

Cresol consists of a mixture of cresol isomers, predominantly *m*-cresol, and other phenols obtained from coal tar or petroleum. It is a colorless, yellowish to pale brownish-yellow, or pink-colored liquid, with a characteristic odor similar to phenol but more tarlike. An aqueous solution has a pungent taste.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for cresol.

Test	BP 2017	JP XVII	USP 40–NF 35 S1
Identification	+	+	+
Characters	+	–	–
Specific gravity	1.029–1.044	1.032–1.041	1.030–1.038
Distilling range	+	196–206°C	195–205°C
Acidity	+	–	–
Hydrocarbons	≤0.15%	+	+
Volatile bases	≤0.15%	–	–
Hydrocarbons and volatile bases combined	≤0.25%	–	–
Phenol	–	–	≤5.0%
Sulfur compounds	+	+	–
Nonvolatile matter	≤0.1%	–	–

10 Typical Properties

Acidity/alkalinity A saturated aqueous solution is neutral or slightly acidic to litmus.

Antimicrobial activity Cresol is similar to phenol but has slightly more antimicrobial activity. It is moderately active against Gram-positive bacteria, less active against Gram-negative bacteria, yeasts, and molds. Cresol is active below pH 9; optimum activity is obtained in acidic conditions. Synergistic effects between cresol and other preservatives have been reported.[2,3] When used as a disinfectant most common pathogens are killed within 10 minutes by 0.3–0.6% solutions. Cresol has no significant activity against bacterial spores.

Solubility *see* Table II.

Table II: Solubility of cresol.

Solvent	Solubility at 20°C
Benzene	Miscible
Chloroform	Freely soluble
Ethanol (95%)	Freely soluble
Ether	Freely soluble
Fixed alkali hydroxides	Freely soluble
Fixed and volatile oils	Freely soluble
Glycerin	Miscible
Water	1 in 50

11 Stability and Storage Conditions

Cresol and aqueous cresol solutions darken in color with age and on exposure to air and light.

Cresol should be stored in a well-closed container, protected from light, in a cool, dry place.

12 Incompatibilities

Cresol has been reported to be incompatible with chlorpromazine.[4] A recent *in vitro* study in pooled human liver microsomes demonstrated inhibitory effects of *p*-cresol on losartan metabolism.[5] Antimicrobial activity is reduced in the presence of nonionic surfactants.

13 Method of Manufacture

Cresol may be obtained from coal tar or prepared synthetically by either sulfonation or oxidation of toluene.

14 Safety

Reports of adverse reactions to cresol are generally associated with the use of either the bulk material or cresol-based disinfectants, which may contain up to 50% cresol, rather than for its use as a preservative. However, a recent case of cutaneous hypersensitivity reaction to the *m*-cresol component of an insulin formulation detected via intradermal and patch testing has been reported.[6]

Cresol is similar to phenol although it is less caustic and toxic. However, cresol is sufficiently caustic to be unsuitable for skin and wound disinfection. In studies in rabbits, cresol was found to be metabolized and excreted primarily as the glucuronide.[7]

A patient has survived ingestion of 12 g of cresol though with severe adverse effects.[8] Two further cases of nonfatal cresol poisoning have also been reported, although no information on levels of intake were given.[9,10]

LD_{50} (mouse, oral): 0.76 g/kg[11]

LD_{50} (rabbit, skin): 2 g/kg

LD_{50} (rat, oral): 1.45 g/kg

See also Sections 17 and 18.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Cresol may be irritant to the skin, eyes, and mucous membranes. Eye protection, gloves, and a respirator are recommended. In the US, the permissible and recommended exposure limits are 22 mg/m^3 long-term and 10 mg/m^3 long-term respectively.[12]

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (IM, IV, intradermal, and SC injections). Included in parenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Chlorocresol; *m*-cresol; *o*-cresol; *p*-cresol; phenol.

m-Cresol

Empirical formula C_7H_8O

Molecular weight 108.14

CAS number [108-39-4]

Synonyms *m*-Cresylic acid; 3-hydroxytoluene; *meta*-cresol; 3-methylphenol.

Appearance Colorless or yellowish liquid with a characteristic phenolic odor.

Boiling point 202°C

Density 1.034 g/cm^3 at 20°C

Flash point 86°C (closed cup)

Melting point 11–12°C
Refractive index n_D^{20} = 1.5398
Solubility Soluble in organic solvents; soluble 1 in 40 parts of water.
Safety
LD_{50} (cat, SC): 0.15 g/kg[11,13]
LD_{50} (mouse, IP): 0.17 g/kg

Empirical formula C_7H_8O
Molecular weight 108.14
CAS number [106-44-5]
Synonyms *p*-Cresylic acid; 4-hydroxytoluene; 4-methylphenol; *para*-cresol.
Appearance Crystalline solid.
Boiling point 201.8°C
Density 1.0341 g/cm^3 at 20°C
Flash point 86°C (closed cup)
Melting point 35.5°C
Refractive index n_D^{20} = 1.5395
Solubility Soluble in ethanol (95%) and ether; very slightly soluble in water.
Safety
LD_{50} (cat, SC): 0.08 g/kg[11,13]
LD_{50} (mouse, IP): 0.03 g/kg
LD_{50} (mouse, oral): 0.34 g/kg
LD_{50} (mouse, SC): 0.15 g/kg
LD_{50} (rabbit, IV): 0.16 g/kg
LD_{50} (rabbit, oral): 1.1 g/kg
LD_{50} (rabbit, SC): 0.3 g/kg
LD_{50} (rabbit, skin): 0.3 g/kg
LD_{50} (rat, oral): 0.21 g/kg
LD_{50} (rat, skin): 0.75 g/kg

18 Comments

m-Cresol is generally considered the least toxic of the three cresol isomers.[13] Inhalation of aerosolized *m*-cresol in pulmonary insulin delivery formulations has been shown to be safe in animal models.[14]

Cresol is also used as a preservative in some topical formulations and as a disinfectant.

The PhEur 9.2 contains a specification for cresol, crude.

The EINECS number for cresol is 203-577-9. The PubChem Compound ID (CID) for *m*-cresol is 342.

Croscarmellose Sodium

C

1 Nonproprietary Names

BP: Croscarmellose Sodium

JP: Croscarmellose Sodium

PhEur: Croscarmellose Sodium

USP–NF: Croscarmellose Sodium

2 Synonyms

Ac-Di-Sol; carmellosum natricum conexum; crosslinked carboxymethylcellulose sodium; *Explocel*; *Kiccolate*; modified cellulose gum; *Nymcel ZSX*; *Pharmacel XL*; *Primellose*; *Solutab*; *Vivasol*.

3 Chemical Name and CAS Registry Number

Cellulose, carboxymethyl ether, sodium salt, crosslinked [74811-65-7]

4 Empirical Formula and Molecular Weight

Croscarmellose sodium is a crosslinked polymer of carboxymethylcellulose sodium.

See Carboxymethylcellulose sodium.

5 Structural Formula

See Carboxymethylcellulose sodium.

6 Functional Category

Tablet and capsule disintegrant.

7 Applications in Pharmaceutical Formulation or Technology

Croscarmellose sodium is used in oral pharmaceutical formulations as a disintegrant for capsules,[1,2] tablets,[3–14] and granules.

In tablet formulations, croscarmellose sodium may be used in both direct-compression and wet-granulation processes. When used in wet granulations, the croscarmellose sodium should be added in both the wet and dry stages of the process (intra- and extragranularly) so that the wicking and swelling ability of the disintegrant is best utilized.[11,12] Croscarmellose sodium at concentrations up to 5% w/w may be used as a tablet disintegrant, although normally 2% w/w is used in tablets prepared by direct compression and 3% w/w in tablets prepared by a wet-granulation process.

Croscarmellose sodium and other superdisintegrants have been evaluated for fast dissolving and melt-in-mouth tablet formulations.[15–19]

See Table I.

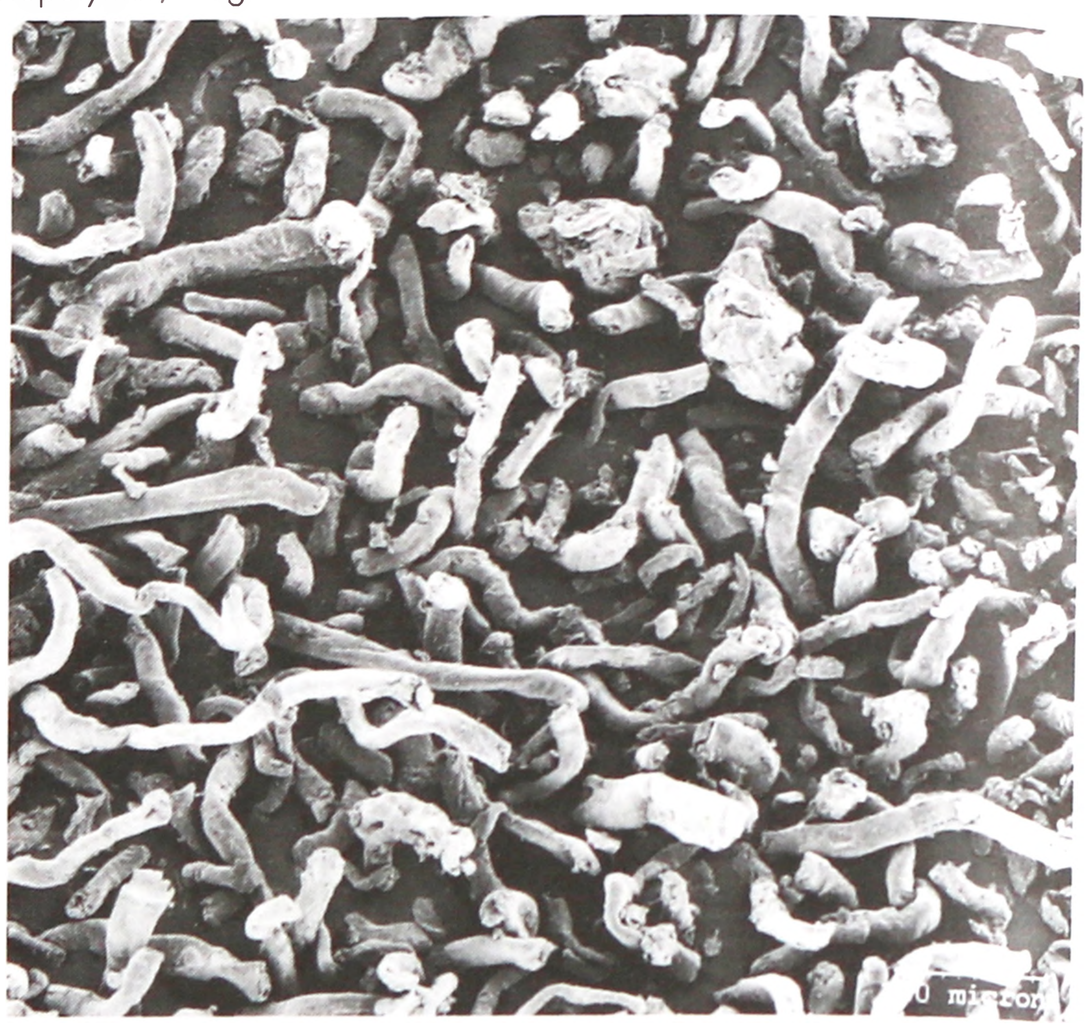

Table I: Uses of croscarmellose sodium.

Use	Concentration (%)
Disintegrant in capsules	10.0–25.0
Disintegrant in tablets	0.5–5.0

8 Description

Croscarmellose sodium occurs as an odorless, white or grayish-white powder.

SEM 1: Excipient: croscarmellose sodium (*Ac-Di-Sol*); manufacturer: FMC Biopolymer; magnification: 100×.

SEM 2: Excipient: croscarmellose sodium (*Ac-Di-Sol*); manufacturer: FMC Biopolymer; magnification: 1000×.

9 Pharmacopeial Specifications

The pharmacopeial specifications for croscarmellose sodium have undergone harmonization of many attributes for JP, PhEur, and USP–NF.

See Table II. *See also* Section 18.

10 Typical Properties

Acidity/alkalinity pH = 5.0–7.0 in aqueous dispersions.

Table II: Pharmacopeial specifications for croscarmellose sodium.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1

Solubility Insoluble in water, although croscarmellose sodium rapidly swells to 4–8 times its original volume on contact with water. Practically insoluble in acetone, ethanol and toluene.
Specific surface area 0.81–0.83 m^2/g
Spectroscopy

IR spectrum *see* Figure 1.

NIR spectrum *see* Figure 2.

Raman spectrum *see* Figure 3.

11 Stability and Storage Conditions

Croscarmellose sodium is a stable though hygroscopic material.

A model tablet formulation prepared by direct compression, with croscarmellose sodium as a disintegrant, showed no significant difference in drug dissolution after storage at 30°C for 14 months.[9]

Croscarmellose sodium should be stored in a well-closed container in a cool, dry place.

12 Incompatibilities

The efficacy of disintegrants, such as croscarmellose sodium, may be slightly reduced in tablet formulations prepared by either the wet-granulation or direct-compression process that contain hygroscopic excipients such as sorbitol.[10] Incompatibility of croscarmellose sodium with alkaline excipients in a tablet formulation has been observed.[20]

Croscarmellose sodium is not compatible with strong acids or with soluble salts of iron and some other metals such as aluminum, mercury, and zinc.

13 Method of Manufacture

Alkali cellulose is prepared by steeping cellulose, obtained from wood pulp or cotton fibers, in sodium hydroxide solution. The

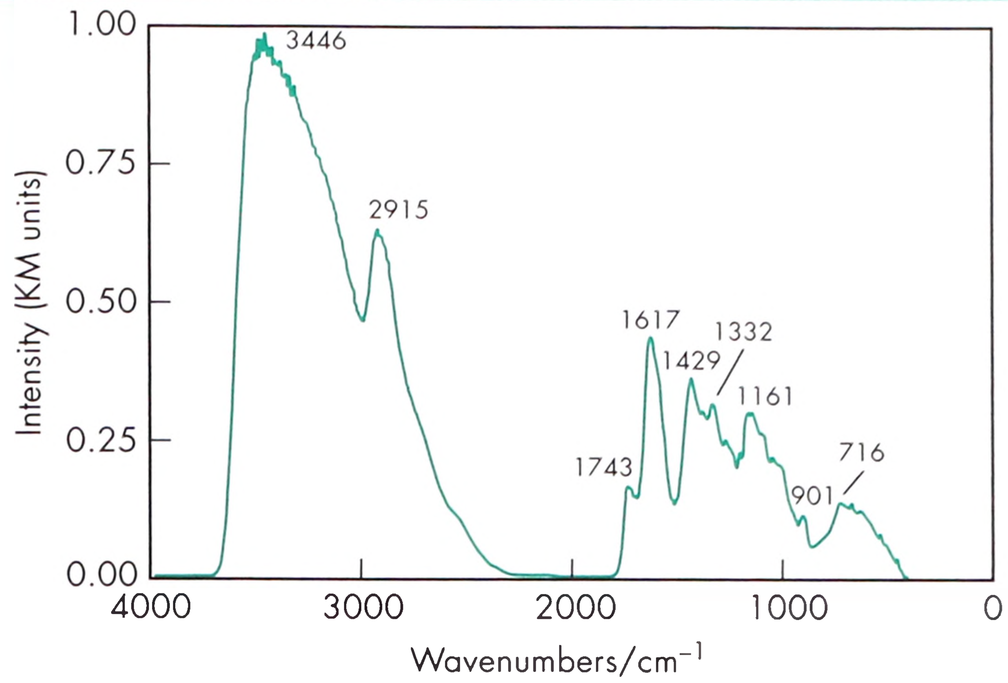

Figure 1: Infrared spectrum of croscarmellose sodium measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

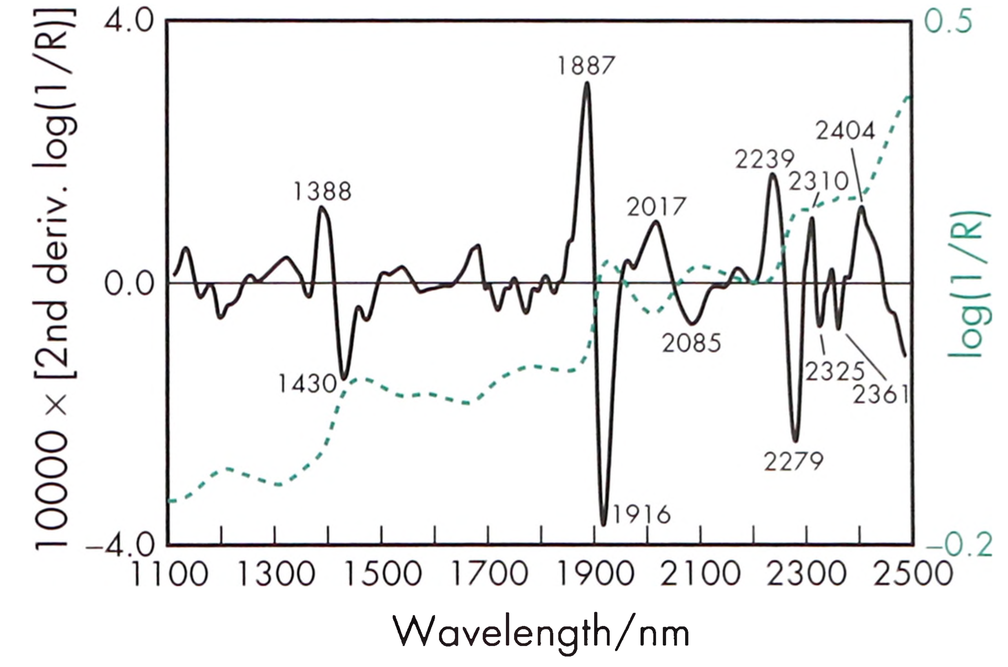

Figure 2: Near-infrared spectrum of croscarmellose sodium measured by reflectance.

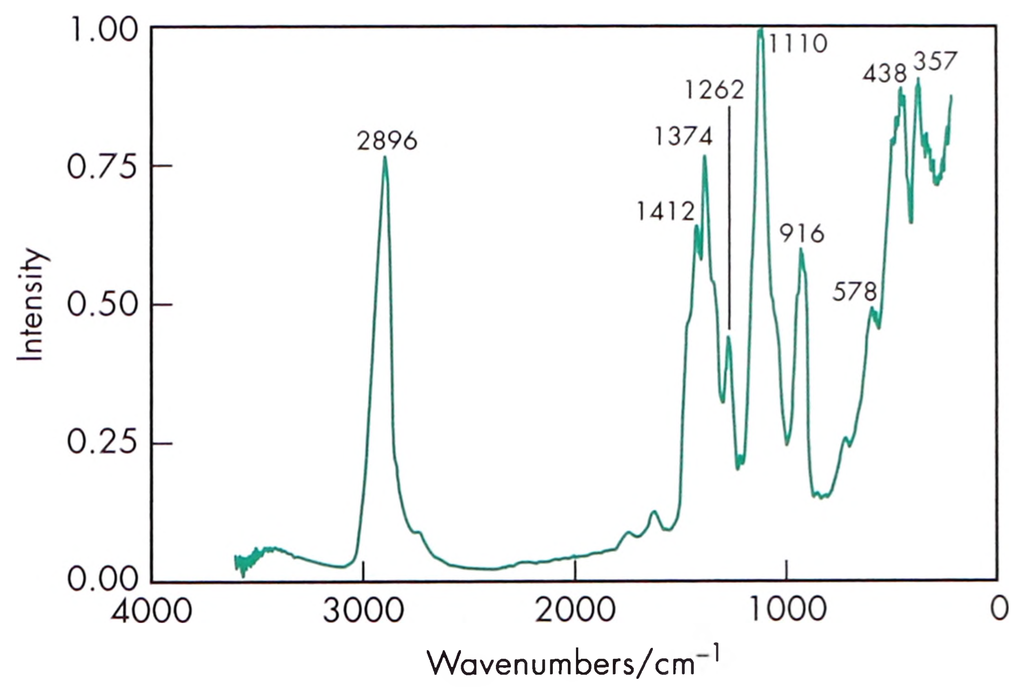

Figure 3: Raman spectrum of croscarmellose sodium measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

alkali cellulose is then reacted with sodium monochloroacetate to obtain carboxymethylcellulose sodium. After the substitution reaction is completed and all of the sodium hydroxide has been used, the excess sodium monochloroacetate slowly hydrolyzes to glycolic acid. The glycolic acid changes a few of the sodium carboxymethyl groups to the free acid and catalyzes the formation of crosslinks to produce croscarmellose sodium. The croscarmellose sodium is then extracted with aqueous alcohol and any remaining sodium chloride or sodium glycolate is removed. After purification, croscarmellose

sodium of purity greater than 99.5% is obtained.[4] The croscarmellose sodium may be milled to break the polymer fibers into shorter lengths and hence improve its flow properties.

14 Safety

Croscarmellose sodium is mainly used as a disintegrant in oral pharmaceutical formulations and is generally regarded as an essentially nontoxic and nonirritant material. However, oral consumption of large amounts of croscarmellose sodium may have a laxative effect, although the quantities used in solid dosage formulations are unlikely to cause such problems.

In the UK, croscarmellose sodium is accepted for use in dietary supplements.

The WHO has not specified an acceptable daily intake for the related substance carboxymethylcellulose sodium, used as a food additive, since the levels necessary to achieve a desired effect were not considered sufficient to be a hazard to health.[21]

See also Carboxymethylcellulose Sodium.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Croscarmellose sodium may be irritant to the eyes; eye protection is recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (IM injections; oral capsules, granules, suspensions, and tablets; sublingual tablets and lozenges). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Carboxymethylcellulose calcium; carboxymethylcellulose sodium.

18 Comments

Croscarmellose sodium has undergone harmonization of many attributes for JP, PhEur, and USP–NF by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

Typically, the degree of substitution for croscarmellose sodium is 0.7.

The EINECS number for croscarmellose sodium is 232-674-9.

Crospovidone

1 Nonproprietary Names

BP: Crospovidone

JP: Crospovidone

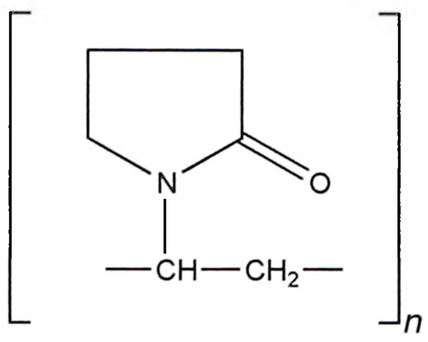
PhEur: Crospovidone

USP–NF: Crospovidone

2 Synonyms

Crospopharm; crospovidonum; crosslinked povidone; E1202; *Kollidon CL*; *Kollidon CL-M*; *Polyplasdone XL*; *Polyplasdone XL-10*; polyvinylpolypyrrolidone; PVPP; 1-vinyl-2-pyrrolidinone homopolymer.

3 Chemical Name and CAS Registry Number



1-Ethenyl-2-pyrrolidinone homopolymer [9003-39-8]

4 Empirical Formula and Molecular Weight

$(C_6H_9NO)_n$ >1 000 000

The USP 40–NF 35 S1 describes crospovidone as a water-insoluble synthetic crosslinked homopolymer of *N*-vinyl-2-pyrrolidinone. An exact determination of the molecular weight has not been established because of the insolubility of the material. The structural formula in Section 5 is for the monomer used in the synthesis of crospovidone and does not show the crosslinking that occurs which makes it distinct from povidone.

5 Structural Formula

See also Section 4.

6 Functional Category

Tablet and capsule disintegrant.

7 Applications in Pharmaceutical Formulation or Technology

Crospovidone is a water-insoluble tablet disintegrant and dissolution agent used at 2–5% concentration in tablets prepared by direct-compression or wet- and dry-granulation methods.[1–6] It rapidly exhibits high capillary activity and pronounced hydration capacity, with little tendency to form gels. Studies suggest that the particle size of crospovidone strongly influences disintegration of analgesic tablets.[7] Larger particles provide a faster disintegration than smaller particles. Crospovidone has been suggested as an alternative to microcrystalline cellulose as an aid in pelletization.[8]

Crospovidone can also be used as a solubility enhancer. With the technique of co-evaporation, crospovidone can be used to enhance the solubility of poorly soluble drugs. The drug is adsorbed on to crospovidone in the presence of a suitable solvent and the solvent is then evaporated. This technique results in a faster dissolution rate.

Crospovidone has been studied as a superdisintegrant. The ability of the compound to swell has been examined directly using scanning electron microscopy.[9] The impact of crospovidone on percolation[10] and on dissolution of poorly soluble drugs in tablets[11] has also been investigated. It has also been evaluated for use in fast disintegrating tablets,[12] and has been shown to be effective with highly hygroscopic drugs.[13] It continues to be examined for its uses in a number of tablet formulations; specifically in the development of floating tablets,[14] rapidly dissolving tablets[15] and controlled-release formulations,[16] where crospovidone acted as a swelling agent, and a buoyancy, disintegrant and compression aid.

8 Description

Crospovidone is a white to creamy-white, finely divided, free-flowing, practically tasteless, odorless or nearly odorless, hygroscopic powder.

9 Pharmacopeial Specifications

The pharmacopeial specifications for crospovidone have undergone harmonization of many attributes for PhEur, and USP–NF.

See Table I. *See also* Section 18.

Table I: Pharmacopeial specifications for crospovidone.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification[a]	+	+	+
Characters[a]	–	+	–
Residue on ignition	≤0.1%	≤0.1%	≤0.1%
Water-soluble substances	+	≤1.5%	≤1.5%
Peroxides			
Type A	≤400 ppm	≤400 ppm	≤400 ppm
Type B	≤1000 ppm	≤1000 ppm	≤1000 ppm
Heavy metals[a]	≤10 ppm	–	≤10 ppm
Vinylpyrrolidinone	≤10 ppm	≤10 ppm	≤10 ppm
Loss on drying	≤5.0%	≤5.0%	≤5.0%
Nitrogen content (anhydrous basis)	11.0–12.8%	11.0–12.8%	11.0–12.8%

(a) These tests have not been fully harmonized at the time of publication.

10 Typical Properties

Acidity/alkalinity pH = 5.0–8.0 (1% w/v aqueous slurry)

Density 1.22 g/cm^3

Density (bulk) *see* Table II.

Density (tapped) *see* Table II.

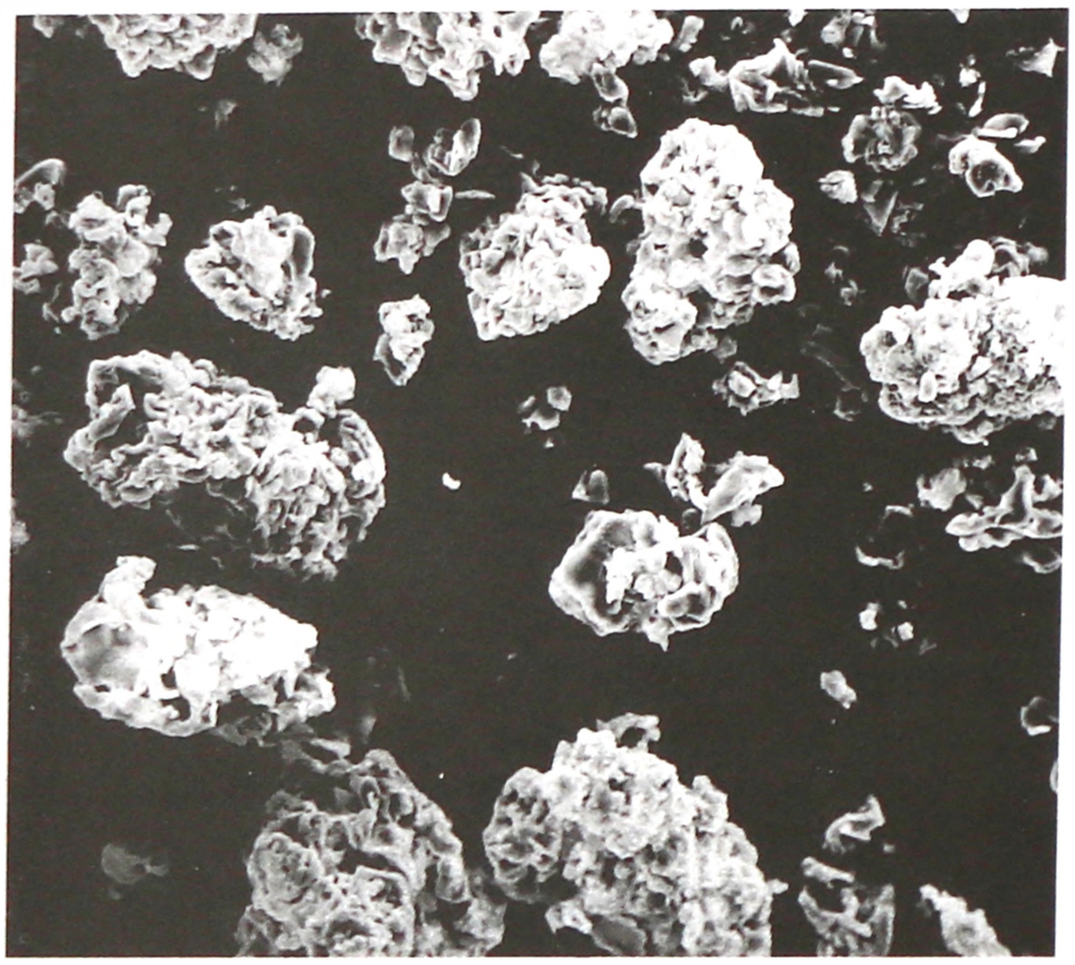


Table II: Density values of commercial grades of crospovidone.

Commercial grade	Density (bulk) (g/cm^3)	Density (tapped) (g/cm^3)
Kollidon CL	0.3–0.4	0.4–0.5
Kollidon CL-M	0.15–0.25	0.3–0.5
Polyplasdone XL	0.213	0.273
Polyplasdone XL-10	0.323	0.461

Moisture content Maximum moisture sorption is approximately 60%.

Particle size distribution Less than 400 μm for *Polyplasdone XL*; less than 74 μm for *Polyplasdone XL-10*. Approximately 50% greater than 50 μm and maximum of 3% greater than 250 μm in

SEM 1: Excipient: crospovidone (*Polyplasdone XL-10*); manufacturer: ISP Corp.; lot no.: S81031; magnification: 400×; voltage: 10 kV.

size for *Kollidon CL*. Minimum of 90% of particles are below 15 µm for *Kollidon CL-M*. The average particle size for *Crospopharm* type A is 100 µm and for *Crospopharm* type B it is 30 µm.

Solubility Practically insoluble in water and most common organic solvents.

Specific surface area *see* Table III.

Spectroscopy

IR spectrum *see* Figure 1.

NIR spectrum *see* Figure 2.

Raman spectrum *see* Figure 3.

Table III: Specific surface areas for commercial grades of crospovidone.

Commercial grade	Surface area (m^2/g)
Kollidon CL	1.0
Kollidon CL-M	3.0–6.0
Polyplasdone XL	0.6–0.8
Polyplasdone XL-10	1.2–1.4

11 Stability and Storage Conditions

Since crospovidone is hygroscopic, it should be stored in an airtight container in a cool, dry place.

12 Incompatibilities

Crospovidone is compatible with most organic and inorganic pharmaceutical ingredients. When exposed to a high water level, crospovidone may form molecular adducts with some materials; *see* Povidone.

13 Method of Manufacture

Acetylene and formaldehyde are reacted in the presence of a highly active catalyst to form butynediol, which is hydrogenated to butanediol and then cyclodehydrogenated to form butyrolactone. Pyrrolidone is produced by reacting butyrolactone with ammonia. This is followed by a vinylation reaction in which pyrrolidone and acetylene are reacted under pressure. The monomer vinylpyrrolidone is then polymerized in solution, using a catalyst. Crospovidone is prepared by a 'popcorn polymerization' process which is distinctly different to the process for the manufacture of povidone.

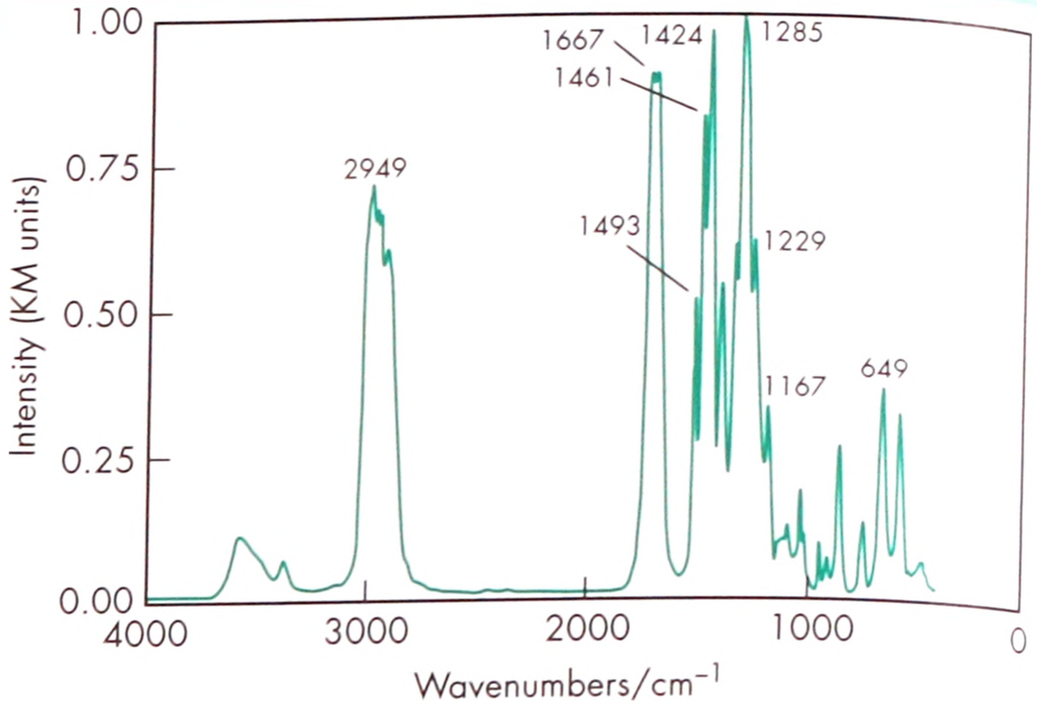

Figure 1: Infrared spectrum of crospovidone measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

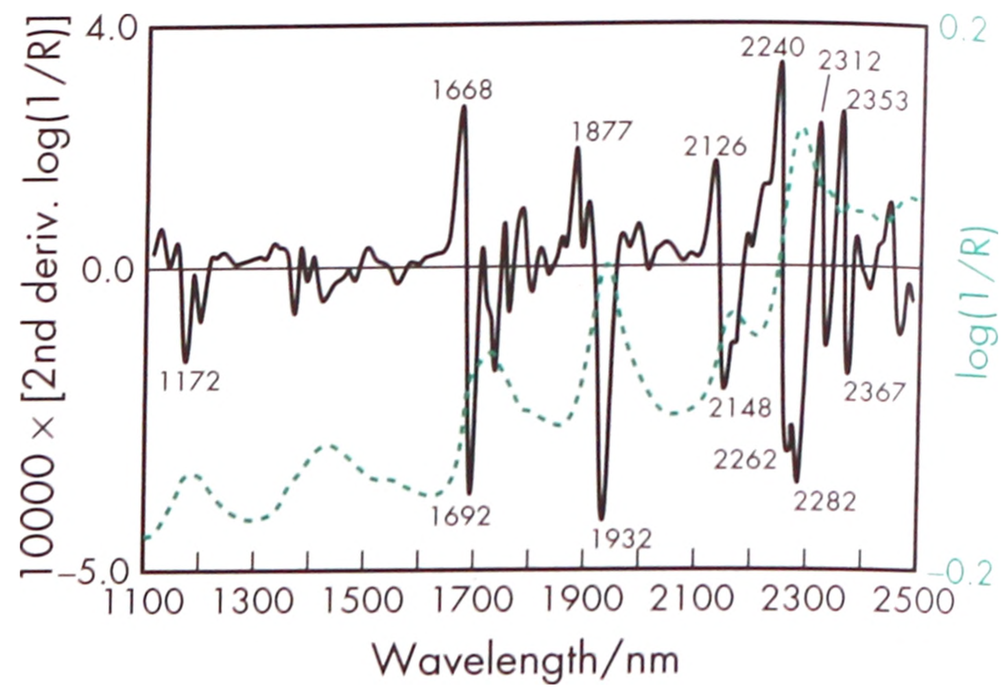

Figure 2: Near-infrared spectrum of crospovidone measured by reflectance.

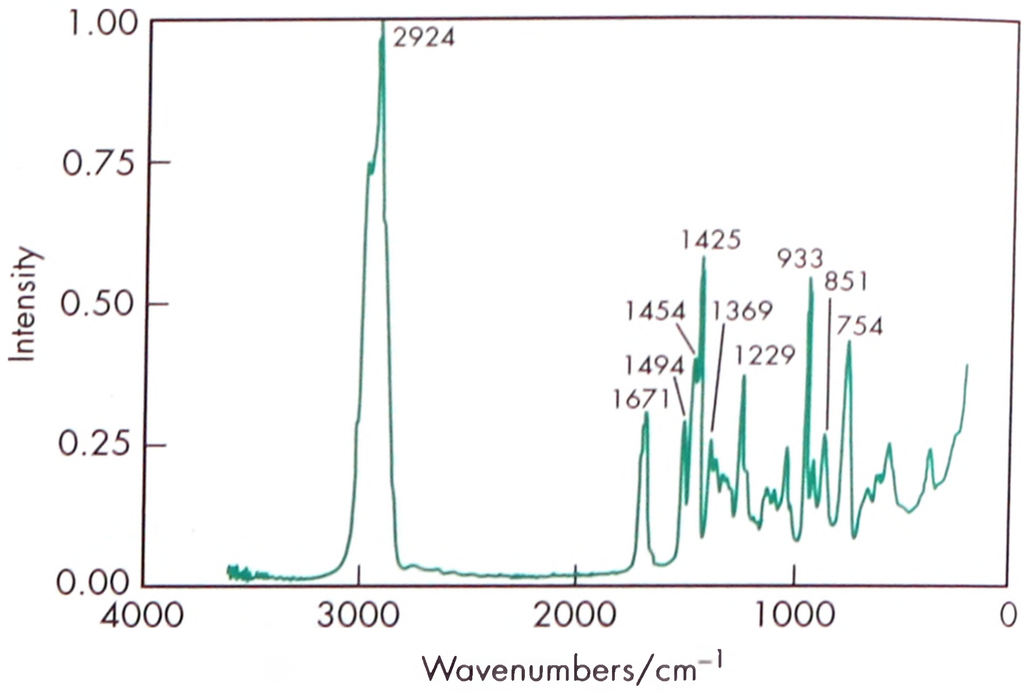

Figure 3: Raman spectrum of crospovidone measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

14 Safety

Crospovidone is used in oral pharmaceutical formulations and is generally regarded as a nontoxic and nonirritant material. Short-term animal toxicity studies have shown no adverse effects associated with crospovidone.[17] However, owing to the lack of available data, an acceptable daily intake in humans has not been specified by the WHO.[17]

LD_{50} (mouse, IP): 12 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Eye protection, gloves, and a dust mask are recommended.

16 Regulatory Status

Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (IA, IM and intrauterine injections; implantation pellets; oral capsules, granules, pellets, suspensions and tablets; topical, transdermal, and vaginal preparations). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Copovidone; povidone.

18 Comments

Crospovidone is one of the materials that have been selected for harmonization by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

A specification for crospovidone is contained in the *Food Chemicals Codex* (FCC).[18]

The PubChem Compound ID (CID) for crospovidone is 6917.

Cyclodextrins

1 Nonproprietary Names

BP: Alfadex
Betadex

PhEur: Alfadex
Betadex

USP–NF: Alfadex
Betadex
Gamma Cyclodextrin

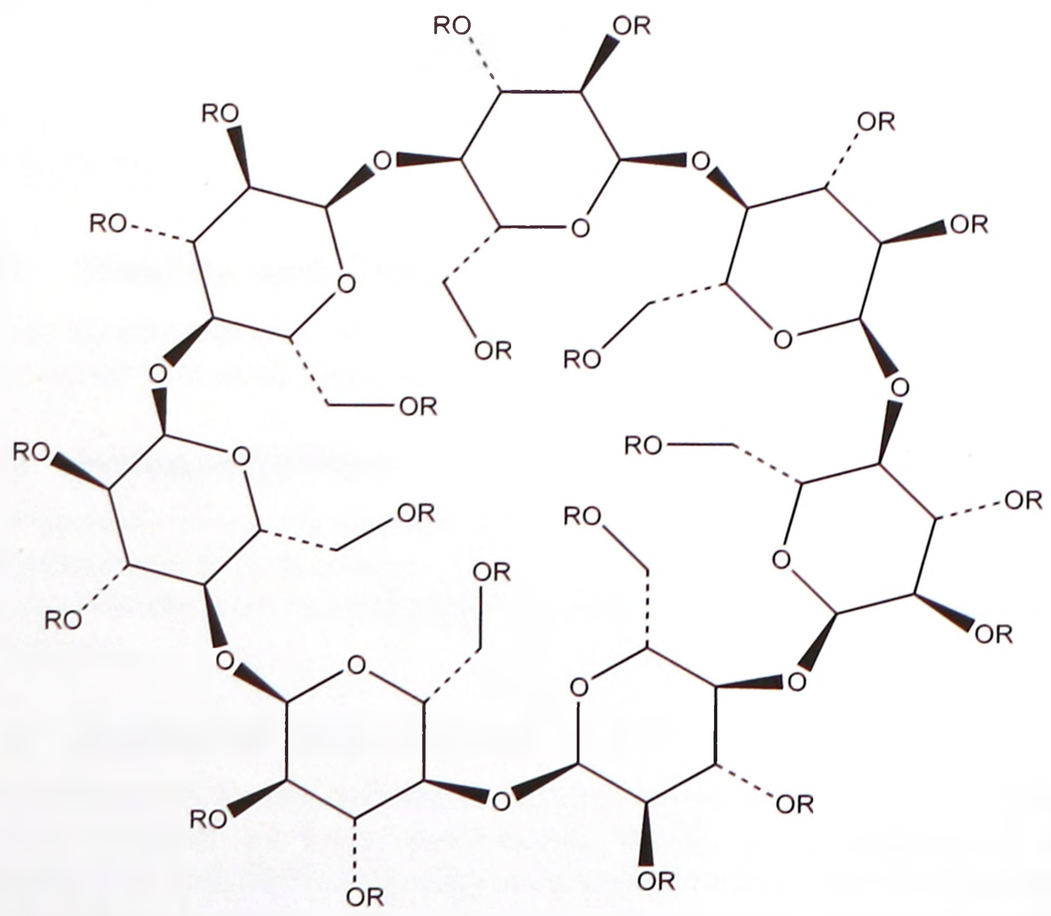
2 Synonyms

Cyclodextrin *Cavitron*; cyclic oligosaccharide; cycloamylose; cycloglucan; *Encapsin*; Schardinger dextrin.

α-*Cyclodextrin* alfadexum; alpha-cycloamylose; alpha-cyclodextrin; alpha-dextrin; *Cavamax W6 Pharma*; cyclohexaamylose; cyclomaltohexose.

β-*Cyclodextrin* beta-cycloamylose; beta-dextrin; betadexum; *Cavamax W7 Pharma*; cycloheptaamylose; cycloheptaglucan; cyclomaltoheptose; E459; *Kleptose*.

γ-*Cyclodextrin* *Cavamax W8 Pharma*; cyclooctaamylose; cyclomaltooctaose.



3 Chemical Name and CAS Registry Number

α-Cyclodextrin [10016-20-3]
β-Cyclodextrin [7585-39-9]
γ-Cyclodextrin [17465-86-0]

4 Empirical Formula and Molecular Weight

α-Cyclodextrin	$C_{36}H_{60}O_{30}$	972
β-Cyclodextrin	$C_{42}H_{70}O_{35}$	1 135
γ-Cyclodextrin	$C_{48}H_{80}O_{40}$	1 297

5 Structural Formula

Note: the structure of betadex (β-cyclodextrin) with 7 glucose units is shown.

R = H for 'natural' α, β, and γ-cyclodextrins with 6, 7, and 8 glucose units, respectively

R = H or CH_3 for methyl cyclodextrins

R = H or $CHOHCH_3$ for 2-hydroxyethyl cyclodextrins

R = H or $CH_2CHOHCH_3$ for 2-hydroxypropyl cyclodextrins

6 Functional Category

Complexing agent; solubilizing agent.

7 Applications in Pharmaceutical Formulation or Technology

Cyclodextrins are 'bucketlike' or 'conelike' toroid molecules, with a rigid structure and a central cavity, the size of which varies according to the cyclodextrin type; *see* Section 8. The internal surface of the cavity is hydrophobic and the outside of the torus is hydrophilic; this is due to the arrangement of hydroxyl groups within the molecule. This arrangement permits the cyclodextrin to accommodate a guest molecule within the cavity, forming an inclusion complex.

Cyclodextrins may be used to form inclusion complexes with a variety of drug molecules, resulting primarily in improvements to dissolution and bioavailability owing to enhanced solubility,[1] photostability,[2,3] and improved chemical and physical stability; *see* Section 18. Cyclodextrin inclusion complexes have also been used to mask the unpleasant taste of active materials[4] and to convert a liquid substance into a solid material.

β-Cyclodextrin is the most commonly used cyclodextrin, although it is the least soluble; *see* Section 10. It is the least expensive cyclodextrin; is commercially available from a number of sources; and is able to form inclusion complexes with a number of molecules of pharmaceutical interest.[5–8] However, β-cyclodextrin is nephrotoxic and should not be used in parenteral formulations; *see* Section 14. β-Cyclodextrin is primarily used in tablet and capsule formulations.

α-Cyclodextrin is used mainly in parenteral formulations, and has also been used in supramolecular polymer gels in a controlled drug release system.[9] However, as it has the smallest cavity of the cyclodextrins it can form inclusion complexes with only relatively few, small-sized molecules. In contrast, γ-cyclodextrin has the largest cavity and can be used to form inclusion complexes with large molecules; it has low toxicity and enhanced water solubility, and has been used in topical,[10] ophthalmic,[11] and parenteral[12] formulations.

In oral tablet formulations, β-cyclodextrin may be used in both wet-granulation and direct-compression processes. The physical properties of β-cyclodextrin vary depending on the manufacturer. However, β-cyclodextrin tends to possess poor flow properties and requires a lubricant, such as 0.1% w/w magnesium stearate, when it is directly compressed.[13,14]

In parenteral formulations, cyclodextrins have been used to produce stable and soluble preparations of drugs that would otherwise have been formulated using a nonaqueous solvent.[15]

In eye drop formulations, cyclodextrins form water-soluble complexes with lipophilic drugs such as corticosteroids. They have been shown to: increase the water solubility of the drug; enhance drug absorption into the eye; improve aqueous stability; and reduce local irritation.[16] Developments in ophthalmic formulations have included the use of cyclodextrins in gel and colloidal systems for controlled drug delivery and improved drug solubility, stability and/or ocular bioavailability.[17,18]

Cyclodextrins have also been used in the formulation of solutions,[19,20] suppositories,[21,22] and in nanoparticles,[23–25]

nanosponges,[26] hydrogel[27] and silicon-based drug delivery systems.[28]

8 Description

Cyclodextrins are crystalline, nonhygroscopic, cyclic oligosaccharides derived from starch, containing at least six D-(+)-glucopyranose units attached by α(1→4) glucoside bonds. Among the most commonly used forms are the three natural cyclodextrins α-, β-, and γ-cyclodextrin, which differ in their ring size and solubility, and have 6, 7, and 8 glucose units respectively; *see* Section 5. Substituted cyclodextrin derivatives are also available; *see* Section 17.

Cyclodextrins occur as white, practically odorless, fine crystalline powders, having a slightly sweet taste. Some cyclodextrin derivatives occur as amorphous powders.

See also Table I.

9 Pharmacopeial Specifications

10 Typical Properties

Compressibility 21.0–44.0% for β-cyclodextrin.

Density (bulk)

α-cyclodextrin: 0.526 g/cm^3;

β-cyclodextrin: 0.523 g/cm^3;

γ-cyclodextrin: 0.568 g/cm^3.

Density (tapped)

α-cyclodextrin: 0.685 g/cm^3;

β-cyclodextrin: 0.754 g/cm^3;

γ-cyclodextrin: 0.684 g/cm^3.

Density (true)

α-cyclodextrin: 1.521 g/cm^3;

γ-cyclodextrin: 1.471 g/cm^3.

Melting point

α-cyclodextrin: 250–260°C; also reported as 278°C;[29]

β-cyclodextrin: 255–265°C; also reported as 290–300°C with decomposition;[29]

γ-cyclodextrin: 240–245°C.

Moisture content

α-cyclodextrin: 10.2% w/w;

β-cyclodextrin: 13.0–15.0% w/w;

γ-cyclodextrin: 8–18% w/w.

Particle size distribution β-cyclodextrin: 7.0–45.0 µm

Physical characteristics *see* Table IV.

Table III: Pharmacopeial specifications for γ-cyclodextrin (Gamma Cyclodextrin).

Test	USP 40–NF 35 S1
Identification	+
Color and clarity of solution	+
Specific rotation	+174° to +180°
Microbial limits	≤1000 cfu/g[a]
Residue on ignition	≤0.1%
Heavy metals	≤5 ppm
Loss on drying	≤11.0%
Related substances	+
Reducing sugars	≤0.5%
Assay (anhydrous basis)	98.0–102.0%

(a) Tests for *Salmonella* and *Escherichia coli* are negative.

Table IV: Physical characteristics of cyclodextrins.

Characteristic	Cyclodextrin		
	α	β	γ
Cavity diameter (A)	4.7–5.3	6.0–6.5	7.5–8.3
Height of torus (A)	7.9	7.9	7.9
Diameter of periphery (A)	14.6	15.4	17.5
Approximate volume of cavity (A^3)	174	262	472
Approximate cavity volume			
Per mol cyclodextrin (mL)	104	157	256
Per g cyclodextrin (mL)	0.1	0.14	0.20

Note: 1 A = 0.1 nm.

Solubility

α-cyclodextrin: soluble 1 in 7 parts of water at 20°C, 1 in 3 at 50°C;

β-cyclodextrin: soluble 1 in 200 parts of propylene glycol, 1 in 50 of water at 20°C, 1 in 20 at 50°C; practically insoluble in acetone, ethanol (95%), and methylene chloride;

γ-cyclodextrin: soluble 1 in 4.4 parts of water at 20°C, 1 in 2 at 45°C.

Specific rotation

α-cyclodextrin: $[\alpha]_D^{25} = +150.5°$;

β-cyclodextrin: $[\alpha]_D^{25} = +162.0°$;

γ-cyclodextrin: $[\alpha]_D^{25} = +177.4°$.

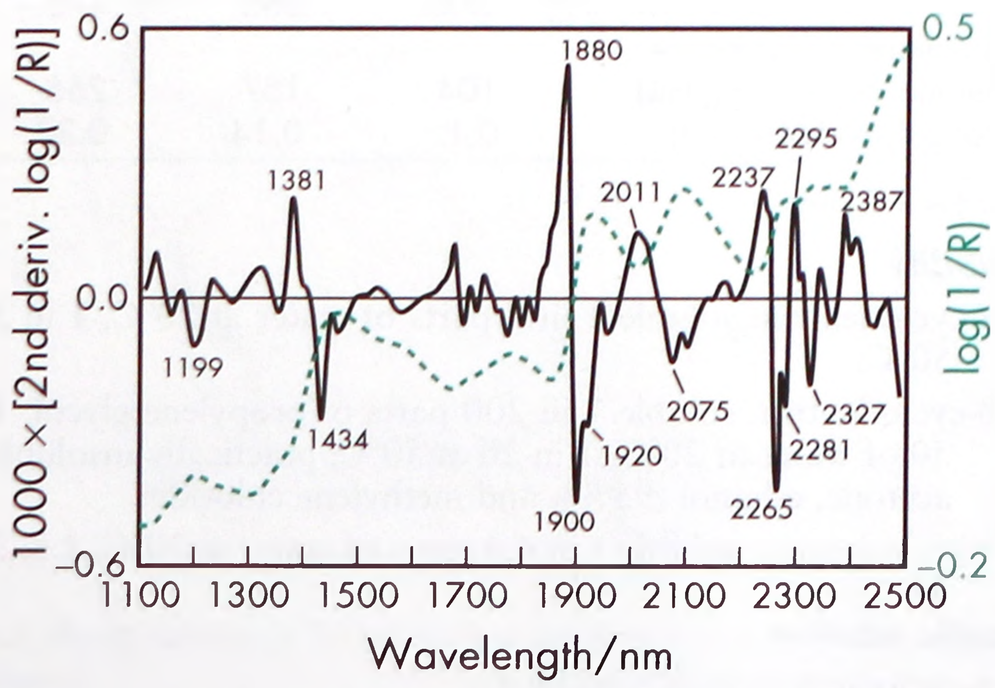

Figure 3: Near-infrared spectrum of β-cyclodextrin measured by reflectance.

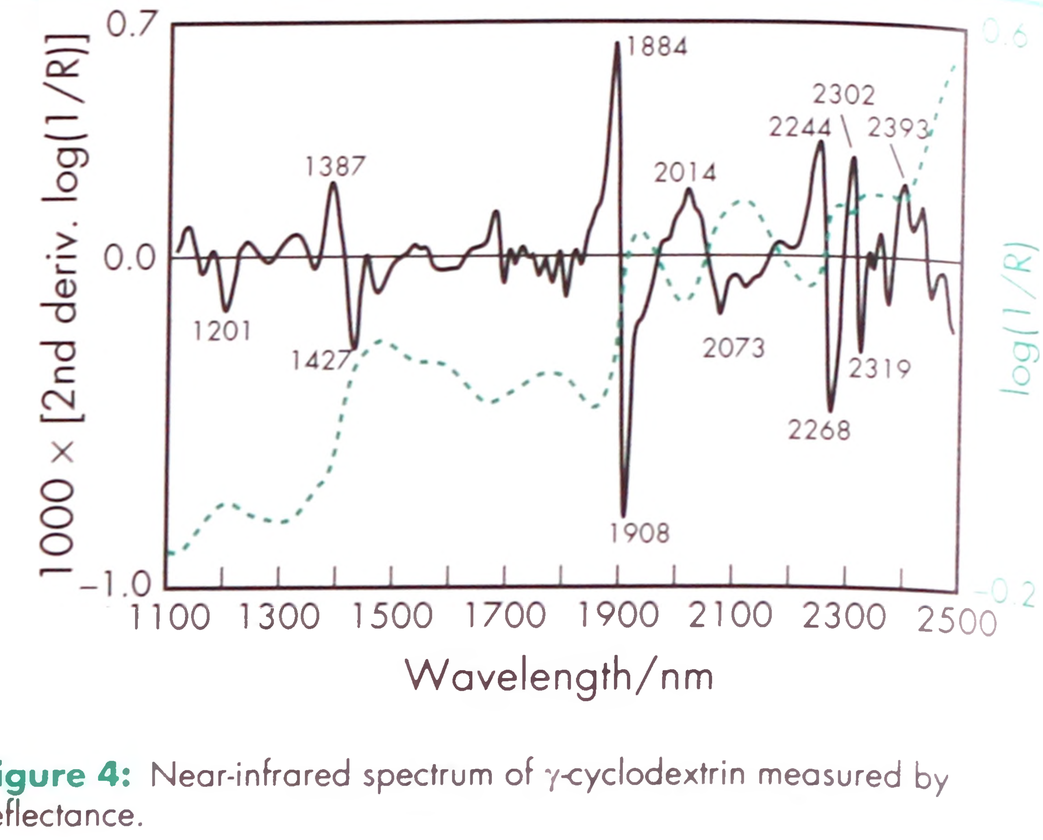

Figure 4: Near-infrared spectrum of γ-cyclodextrin measured by reflectance.

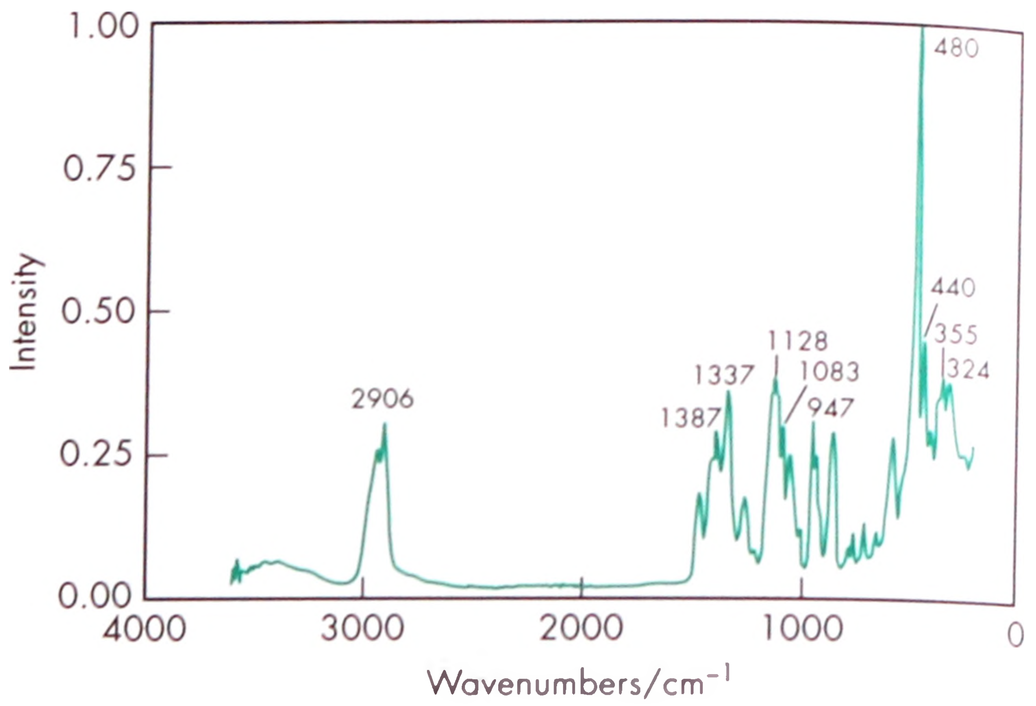

Figure 5: Raman spectrum of β-cyclodextrin measured in the 180 reflectance mode. Adapted with permission of Informa Healthcare.

11 Stability and Storage Conditions

β-Cyclodextrin and other cyclodextrins are stable in the solid state if protected from high humidity.

Cyclodextrins should be stored in a tightly sealed container, in a cool, dry place.

12 Incompatibilities

Cyclodextrins are incompatible with strong oxidizing agents.

13 Method of Manufacture

Cyclodextrins are manufactured by the enzymatic degradation of starch using specialized bacteria. For example, β-cyclodextrin is produced by the action of the enzyme cyclodextrin glucosyltransferase upon starch or a starch hydrolysate. An organic solvent is used to direct the reaction that produces β-cyclodextrin, and to prevent the growth of microorganisms during the enzymatic reaction. The insoluble complex of β-cyclodextrin and organic solvent is separated from the noncyclic starch, and the organic solvent is removed *in vacuo* so that less than 1 ppm of solvent remains in the β-cyclodextrin. The β-cyclodextrin is then carbon treated and crystallized from water, dried, and collected.

14 Safety

Cyclodextrins are starch derivatives and are mainly used in oral and parenteral pharmaceutical formulations. They are also used in topical and ophthalmic formulations.[3]

Cyclodextrins are also used in cosmetics and food products, and are generally regarded as essentially nontoxic and nonirritant materials. However, when administered parenterally, β-cyclodextrin is not metabolized but accumulates in the kidneys as insoluble cholesterol complexes, resulting in severe nephrotoxicity.[30]

Cyclodextrin administered orally is metabolized by microflora in the colon, forming the metabolites maltodextrin, maltose, and glucose; these are themselves further metabolized before being finally excreted as carbon dioxide and water. Although a study published in 1957 suggested that orally administered cyclodextrins were highly toxic,[31] more recent animal toxicity studies in rats and dogs have shown this not to be the case, and cyclodextrins are now approved for use in food products and orally administered pharmaceuticals in a number of countries.

Cyclodextrins are not irritant to the skin and eyes, or upon inhalation. There is also no evidence to suggest that cyclodextrins are mutagenic or teratogenic.

The Joint FAO/WHO Expert Committee on Food Additives (JECFA) has reviewed the safety of β-cyclodextrin and recommended an acceptable daily intake of up to 5 mg/kg body weight.[32]

α-Cyclodextrin

LD_{50} (rat, IP): 1.0 g/kg[33]

LD_{50} (rat, IV): 0.79 g/kg

LD_{50} (rat, oral): >10.0 g/kg[34]

β-Cyclodextrin

LD_{50} (mouse, IP): 0.33 g/kg[34]

LD_{50} (mouse, SC): 0.41 g/kg

LD_{50} (rat, IP): 0.36 g/kg

LD_{50} (rat, IV): 1.0 g/kg

LD_{50} (rat, oral): 18.8 g/kg

LD_{50} (rat, SC): 3.7 g/kg

γ-Cyclodextrin

LD_{50} (rat, IP): 4.6 g/kg[33]

LD_{50} (rat, IV): 4.0 g/kg

LD_{50} (rat, oral): 8.0 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Cyclodextrins are fine organic powders and should be handled in a well-ventilated environment. Efforts should be made to limit the generation of dust, which can be explosive.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database: α-cyclodextrin (injection preparations); β-cyclodextrin (oral tablets, topical gels); γ-cyclodextrin (IV injections).

Included in the Canadian Natural Health Products Ingredients Database, and in oral and rectal pharmaceutical formulations licensed in Europe, Japan, and the USA.

17 Related Substances

Dimethyl-β-cyclodextrin; hydroxyethyl-β-cyclodextrin; hydroxypropyl betadex; betadex sulfobutyl ether sodium; trimethyl-β-cyclodextrin.

18 Comments

β-Cyclodextrin derivatives are more water-soluble than β-cyclodextrin, and studies have shown that they have greater solubilizing action with some drugs such as ibuproxam, a poorly water-soluble anti-inflammatory agent.[35,36] *See also* Section 17.

In addition to their use in pharmaceutical formulations, cyclodextrins have also been investigated for use in various industrial applications. Analytically, cyclodextrin polymers are used in chromatographic separations, particularly of chiral materials. Cyclodextrins have also been used in cosmetics.[37,38]

Therapeutically, results of a study using γ-cyclodextrin complexed with α-lipoic acid in mice have shown an antidiabetic effect.[39]

Specifications for α-cyclodextrin and β-cyclodextrin are included in the *Japanese Pharmaceutical Excipients* (JPE).[40]

Specifications for α-cyclodextrin, β-cyclodextrin, and γ-cyclodextrin are listed separately in the *Food Chemicals Codex* (FCC).[41]

The EINECS numbers for cyclodextrins are 233-007-4 (α-cyclodextrin); 231-493-2 (β-cyclodextrin); and 241-482-4 (γ-cyclodextrin). The PubChem Compound ID (CID) for cyclodextrins includes 444913 (α-cyclodextrin), 24238 (β-cyclodextrin), and 86575 (γ-cyclodextrin).

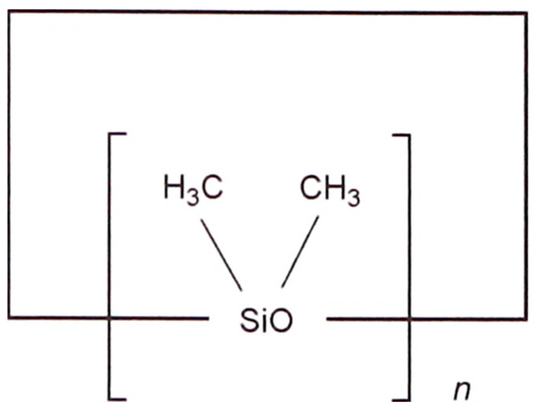
Cyclomethicone

1 Nonproprietary Names

USP–NF: Cyclomethicone

2 Synonyms

Dimethylcyclopolysiloxane; *Dow Corning 245 Fluid*; *Dow Corning 246 Fluid*; *Dow Corning 345 Fluid*; polydimethylcyclosiloxane.



3 Chemical Name and CAS Registry Number

Cyclopolydimethylsiloxane [69430-24-6]

4 Empirical Formula and Molecular Weight

The USP 40–NF 35 S1 describes cyclomethicone as a fully methylated cyclic siloxane containing repeating units of the formula $[-(CH_3)_2SiO-]_n$ in which n is 4, 5, or 6, or a mixture of them.

5 Structural Formula

6 Functional Category

Emollient; humectant; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Cyclomethicone is mainly used in topical pharmaceutical and cosmetic formulations such as water-in-oil creams.[1–3] The use of cyclomethicone pentamer has been evaluated in mucoadhesive vaginal emulsions to control the release of progesterone.[4]

Cyclomethicone has been used in cosmetic formulations, at concentrations of 0.1–50%, since the late 1970s and is now the most widely used silicone in the cosmetics industry. Its high volatility and mild solvent properties make it ideal for use in topical formulations. Its low heat of vaporization means that when applied to skin it has a 'dry' feel.

See also Dimethicone.

8 Description

Cyclomethicone occurs as a clear, colorless and tasteless volatile liquid.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for cyclomethicone.

Test	USP 40–NF 35 S1
Identification	+
Limit of nonvolatile residue	≤0.15%
Assay of $(C_2H_6OSi)_n$ calculated as the sum of cyclomethicone 4, cyclomethicone 5, and cyclomethicone 6	≥98.0%
Assay of individual cyclomethicone components	95.0–105.0%

10 Typical Properties

Solubility Soluble in ethanol (95%), isopropyl myristate, isopropyl palmitate, mineral oil, and petrolatum at 80°C; practically insoluble in glycerin, propylene glycol, and water.

See also Table II.

11 Stability and Storage Conditions

Cyclomethicone should be stored in an airtight container in a cool, dry, place.

12 Incompatibilities

—

13 Method of Manufacture

Cyclomethicone is manufactured by the distillation of crude polydimethylsiloxanes.

14 Safety

Cyclomethicone is generally regarded as a relatively nontoxic and nonirritant material. Although it has been used in oral pharmaceutical applications, cyclomethicone is mainly used in topical pharmaceutical formulations. It is also widely used in cosmetics.[5] Studies of the animal and human toxicology of cyclomethicone suggest that it is nonirritant and not absorbed through the skin. Only small amounts are absorbed orally; an acute oral dose in rats produced no deaths.[6,7]

The Cosmetic Ingredient Review (CIR) Expert Panel have assessed cyclomethicone and concluded that the material is safe as used in the present practices of use and concentration.[6,8]

See also Dimethicone.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

Table II: Typical physical properties of selected commercially available cyclomethicones.

Grade	Boiling point (°C)	Flash point (°C)	Freezing point (°C)	Refractive index at 25°C	Surface tension (mN/m)	Specific gravity at 25°C	Viscosity (kinematic) (mm^2/s)	Water content (%)
Dow Corning 245 Fluid	205	77	<−50	1.397	18.0	0.95	4.0	0.025
Dow Corning 246 Fluid	245	93	<−40	1.402	18.8	0.96	6.8	0.025
Dow Corning 345 Fluid	217	77	<−50	1.398	20.8	0.957	6.0	0.025

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (topical creams, emulsions, solutions, lotions, gels, and aerosols). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Dimethicone; simethicone.

Decyl Oleate

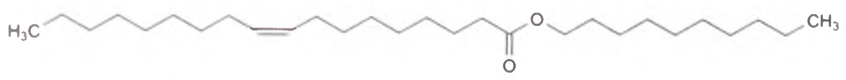
1 Nonproprietary Names

BP: Decyl Oleate

PhEur: Decyl Oleate

2 Synonyms

Ceraphyl 140; decyl 9-octadecenoate; decyl octadec-9-enote; decylis oleas; decyloleat; *DUBCARE OD*; *Kollicream DO*; oleic acid, decyl ester; *Tegosoft DO*.



3 Chemical Name and CAS Registry Number

9-Octadecenoic acid (9Z)-, decyl ester [3687-46-5]

4 Empirical Formula and Molecular Weight

$C_{28}H_{54}O_2$ 422.74

5 Structural Formula

6 Functional Category

Emollient; oleaginous vehicle.

7 Applications in Pharmaceutical Formulation or Technology

Decyl oleate is used as an emollient in pharmaceutical creams and lotions for skin and personal care products.

Decyl oleate has also been used in combination with carnauba wax as an encapsulation system for inorganic sunscreens.[1–4]

In has been evaluated as a skin penetration enhancer for flurbiprofen[5] and as a topical vehicle to be used in ready-to-use pharmaceutical bases,[6] microemulsions[7] and nanostructured lipid carriers.[8]

8 Description

The BP 2017 defines decyl oleate as a mixture of decyl esters of fatty acids, mainly oleic (*cis*-9-octadecenoic) acid.

Decyl oleate occurs as a clear, colorless, or pale yellow liquid.

9 Pharmacopeial Specifications

See Table I. *See also* Section 18.

Table I: Pharmacopeial specifications for decyl oleate.

Test	PhEur 9.2
Identification	+
Characters	+
Relative density	0.86–0.87
Acid value	≤ 1.0
Iodine value	55–70
Peroxide value	≤ 10.0
Saponification value	130–140
Oleic acid	≥ 60%
Water	≤ 1.0%
Total ash	≤ 0.1%

10 Typical Properties

Boiling point >300°C
Flash point 215°C
Pour point −6°C for *Tegosoft DO*[9]
Refractive index 1.453–1.456
Solubility Practically insoluble in water; miscible with ethanol (96%), methylene chloride, and light petroleum (40–60°C). Soluble in isopropyl myristate and oleyl alcohol.
Surface tension 31 mN/m at 25°C for *Tegosoft DO*[9]
Viscosity 16.6 mPa s (16.6 cP) at 25°C; approx 14.0 mPa s (14.0 cP) for *Tegosoft DO* at 25°C.[9]

11 Stability and Storage Conditions

Decyl oleate should be stored below 30°C and protected from moisture. Through the addition of mixed tocopherols, the product is protected from auto-oxidation.

Depending on the storage temperature, the peroxide value may increase. The product quality is not impaired as long as the peroxide value remains below 8.0.

12 Incompatibilities

Decyl oleate is incompatible with strong oxidizing agents.

13 Method of Manufacture

Decyl oleate is manufactured from decyl alcohol and oleic acid.

14 Safety

Decyl oleate is used in cosmetics and topical pharmaceutical formulations, and is generally regarded as a nontoxic and nonirritant material.

A 15% solution of decyl oleate in corn oil has been shown to be practically nonirritating in rabbit eye studies and nonsensitizing to guinea pig skin, and a 10% solution has been shown to be nonirritating to rabbit skin.[10] Repeat patch testing in humans with 5.5% decyl oleate produced a low number of reactions with a low total irritation score.[10]

LD_{50} (rat, oral): 34.68 g/kg (40 mL/kg)[10]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled.

16 Regulatory Status

Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Isodecyl oleate.

Isodecyl oleate

Empirical formula $C_{28}H_{54}O_2$
CAS number [59231-34-4]
Synonyms 9-Octadecenoic acid, isodecyl ester; *Ceraphyl 140A*; *Schercemol* IDO ester.
Appearance A white to straw-colored liquid with characteristic odor.
Acid value ≤ 5.0 for *Schercemol* IDO ester.[11]
Iodine value 50–65 for *Schercemol* IDO ester.
Refractive index 1.455 for *Schercemol* IDO ester.

Saponification value 130–140 for *Schercemol* IDO ester.
Solubility Soluble in isopropyl myristate, peanut oil, mineral oil, ethanol (95%), and oleyl alcohol; insoluble in water, glycerin, and propylene glycol.
Specific gravity 0.850–0.890 for *Schercemol* IDO ester.
Safety Nonirritating to eyes; mildly irritating to skin. LD_{50} (rat, oral): > 40 mL/kg.[10]
Comments Used as an emollient and solvent for pharmaceutical topical formulations. Also used in cosmetic products. The PubChem Compound ID (CID) for isodecyl oleate is 6436737. The EINECS number for isodecyl oleate is 261-673-6.

18 Comments

A specification for decyl oleate is included in the *Japanese Pharmaceutical Excipients* (JPE).[12]

The EINECS number for decyl oleate is 222-981-6. The PubChem Compound ID (CID) for decyl oleate is 5363234.

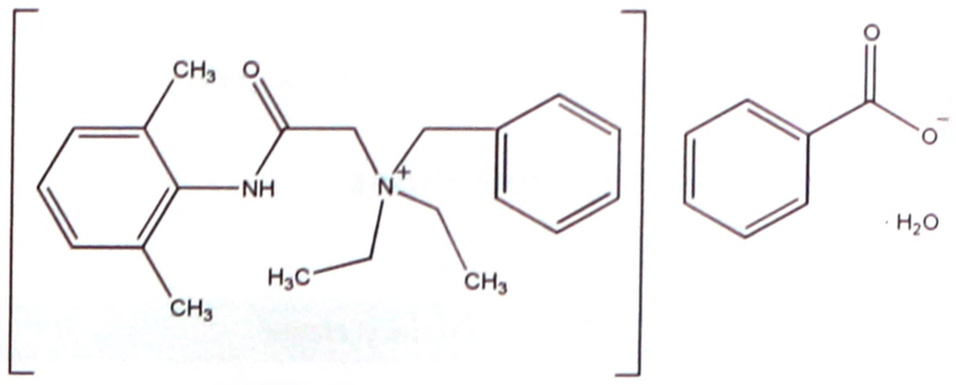
Denatonium Benzoate

1 Nonproprietary Names

USP–NF: Denatonium Benzoate

2 Synonyms

Bitrex; *Bitterguard*; denatonii benzoas; *N*-[2-(2,6-dimethylphenyl)amino]-2-oxoethyl]-*N*,*N*-diethylbenzenemethanaminium benzoate; lignocaine benzyl benzoate.



3 Chemical Name and CAS Registry Number

Benzyldiethyl[(2,6-xylylcarbamolyl)methyl]ammonium benzoate anhydrous [3734-33-6]
Benzyldiethyl[(2,6-xylylcarbamolyl)methyl]ammonium benzoate monohydrate [86398-53-0]

4 Empirical Formula and Molecular Weight

$C_{28}H_{34}N_2O_3$ 446.59 (for anhydrous)
$C_{28}H_{34}N_2O_3 \cdot H_2O$ 464.60 (for monohydrate)

5 Structural Formula

6 Functional Category

Alcohol denaturant; flavoring agent.

7 Applications in Pharmaceutical Formulation or Technology

Denatonium benzoate is among the most bitter of substances known and is detectable at concentrations of approximately 10 ppb. In pharmaceutical and other industrial applications it is added to

some products as a deterrent to accidental ingestion,[1–4] although its effectiveness in reducing the frequency or severity of pediatric antifreeze poisonings has been questioned.[5,6] It is most commonly used at levels of 5–500 ppm. Denatonium benzoate may also be used to replace brucine or quassin as a denaturant for ethanol.

In pharmaceutical formulations, denatonium benzoate has been used as a flavoring agent in placebo tablets.

8 Description

Denatonium benzoate occurs as an odorless, very bitter tasting, white crystalline powder or granules.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for denatonium benzoate.

Test	USP 40–NF 35 S1
Identification	+
Melting range	163–170°C
pH (3% aqueous solution)	6.5–7.5
Loss on drying (monohydrate)	≤3.5–4.5%
Loss on drying (anhydrous)	≤1.0%
Residue on ignition	≤0.1%
Chloride	≤0.2%
Assay (dried basis)	99.5–101.0%

10 Typical Properties

Acidity/alkalinity pH = 6.5–7.5 (3% w/v aqueous solution)
Density (bulk) 0.3–0.6 g/cm^3
Density (tapped) 0.4–0.7 g/cm^3
Partition coefficient Octanol : water = 1.8
Solubility *see* Table II.

Table II: Solubility of denatonium benzoate.

Solvent	Solubility at 20°C
Acetone	Sparingly soluble
Chloroform	1 in 2.9
Ethanol (95%)	1 in 2.4
Ether	1 in 5000
Methanol	Very soluble
Water	1 in 20

Spectroscopy

IR spectrum *see* Figure 1.

Raman spectrum *see* Figure 2.

11 Stability and Storage Conditions

Denatonium benzoate is stable up to 140°C and over a wide pH range. It should be stored in a well-closed container (such as polythene-lined steel) in a cool, dry place. Aqueous or alcoholic solutions retain their bitterness for several years even when exposed to light.

12 Incompatibilities

Denatonium benzoate is incompatible with strong oxidizing agents.

13 Method of Manufacture

Denatonium benzoate was first synthesized in the 1950s and is usually prepared by reacting denatonium chloride with benzyl benzoate.

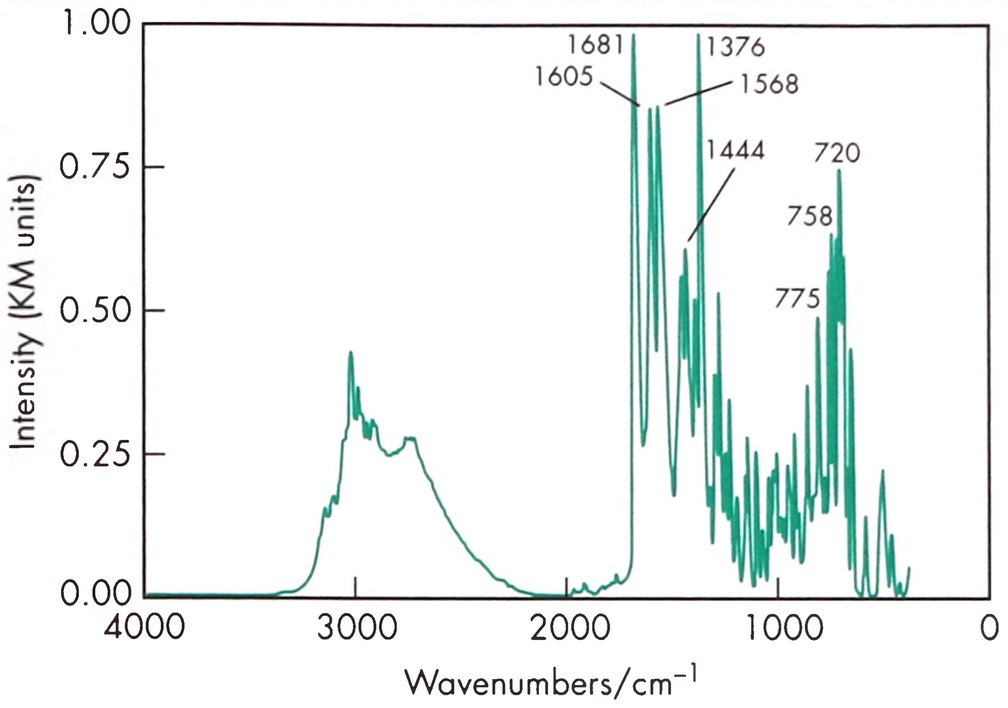


Figure 1: Infrared spectrum of denatonium benzoate measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

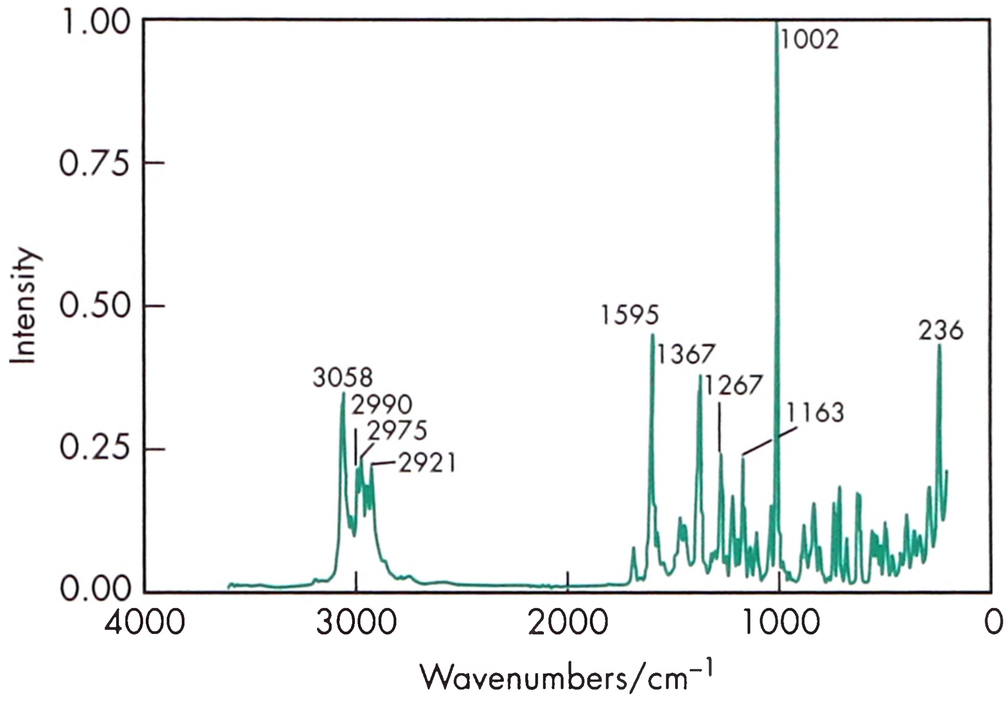

Figure 2: Raman spectrum of denatonium benzoate measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

14 Safety

Denatonium benzoate is generally regarded as a nonirritant and nonmutagenic substance. However, there has been a single report of contact urticaria attributed to denatonium benzoate occurring in a 30-year-old man who developed asthma and pruritus after using an insecticidal spray denatured with denatonium benzoate.[7] The safety of pest control products containing denatonium benzoate has been evaluated by Health Canada, and they have not been found to present unacceptable risks to human health or the environment when used as directed.[8]

The Cosmetic Ingredient Review Expert Panel have assessed denatonium benzoate and concluded that the material is safe as used in cosmetics.[9]

LD_{50} (rabbit, oral): 0.508 g/kg [10]
LD_{50} (rat, oral): 0.584 g/kg [10]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Containers should be kept tightly closed and handled in areas with good ventilation.

Denatonium benzoate is moderately toxic by ingestion and when heated to decomposition emits toxic vapors of NO_x. Denatonium benzoate may also cause hypersensitization. Eye protection, gloves, and a dust mask are recommended.

D

16 Regulatory Status

Denatonium benzoate is used worldwide as a denaturant for alcohol. It is included in the FDA Inactive Ingredients Database (topical gel, solution and swab). Included in the Canadian Natural Health Products Ingredients Database.

As there is a lack of adequate data, any over the counter drug product containing ingredients offered for use as a nail-biting or thumb-sucking deterrent (including denatonium benzoate) cannot be generally recognized as safe and effective.[11]

17 Related Substances

Sucrose octaacetate.

18 Comments

The EINECS number for denatonium benzoate is 223-095-2. The PubChem Compound ID (CID) for denatonium benzoate is 19518.

Dextran

1 Nonproprietary Names

BP: Dextran 1 for Injection
Dextran 40 for Injection
Dextran 60 for Injection
Dextran 70 for Injection

JP: Dextran 40
Dextran 70

PhEur: Dextran 1 for Injection
Dextran 40 for Injection
Dextran 60 for Injection
Dextran 70 for Injection

USP–NF: Dextran 1
Dextran 40
Dextran 70

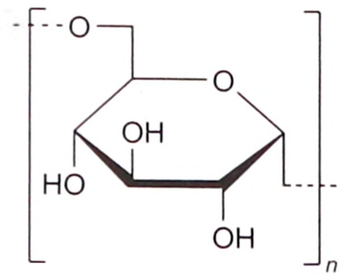
2 Synonyms

Glucose polymer; dextrans.

3 Chemical Name and CAS Registry Number

2,3,4,5-Tetrahydroxy-6-[3,4,5-trihydroxy-6-[[3,4,5-trihydroxy-6-(hydroxymethyl)oxan-2-yl]oxymethyl]oxan-2-yl]oxyhexanal [9004-54-0]

4 Empirical Formula and Molecular Weight



$[C_6H_{10}O_5]_n$

Dextran is a branched high-molecular-weight polymer of α-D-glucose (dextrose). Dextran polymers are available in various average molecular weight fractions from 1000 Da (dextran 1) to 2 000 000 Da (dextran 2000), with the most common fractions being 1000 Da (dextran 1), 40 000 Da (dextran 40), and 70 000 Da (dextran 70).[1]

The polymer main chain has α(1→6) glycosidic linkages with branching occurring primarily at C3, α(1→3) glycosidic linkages, and occasionally at C4, α(1→4) glycosidic linkages or C2 α(1→2) glycosidic linkages. Commercially available dextrans contain about 95% α(1→6) glycosidic linkages of the main chain and about 5% side branching. About 80% of the side branches are single α-D-glucose subunits with the remaining branches a mixture of side-chains of various lengths.[2]

Dextran is a fermentation product of sucrose by bacteria containing the enzyme dextransucrase capable of synthesizing polysaccharides from sucrose. The native dextran polymer has a broad polydispersity index (range of polymer length and weight). The polydispersity is decreased by purification and separation into molecular weight fractions via partial acid hydrolysis.[1] Polydispersity usually increases with increasing average molecular weight.[3]

5 Structural Formula

See Section 4.

6 Functional Category

Lyophilization aid.

7 Applications in Pharmaceutical Formulation or Technology

Dextran is used in pharmaceutical preparations as a lyophile bulking agent[4] and as a lyoprotectant in lyophilized protein products.[5] Dextran has been evaluated as a tablet binder for immediate-release tablets[6] and as a controlled-release tablet excipient.[6,7] It has also been evaluated for conjugation to proteins for parenteral targeted delivery and protein stabilization,[5,8] for formation of dextran–acid conjugate nanoparticles for parenteral targeted drug delivery to cancer cells,[9,10] and as a mucoadhesive to prolong residence time in the nasal cavity for nasal powder delivery.[11] It has shown limited application as a conjugate for targeted drug delivery by the oral route due to minimal pharmacokinetic absorption.[8] In gene therapy, cation modified dextran is one of the most widely studied non-viral polymeric gene delivery systems.[12,13]

8 Description

Dextran occurs as a white to off-white amorphous hygroscopic powder.

9 Pharmacopeial Specifications

See Table I.

10 Typical Properties

Hygroscopicity Hygroscopic. In lyophiles, dextran is amorphous and hygroscopic before and after lyophilization.[14]

Solubility Readily soluble in water (>50% w/v); soluble in methyl sulfide, formamide, ethylene glycol, and glycerol; insoluble in methanol, ethanol, isopropanol, acetone, and other ketone solvents.[15]

Viscosity Increases linearly with increasing polymer molecular weight.[16]

11 Stability and Storage Conditions

Store in well-closed containers to avoid water uptake. The USP 40–NF 35 S1 states that Dextran 1 can be stored between 4°C and 30°C, while Dextran 40 and Dextran 70 should be stored between 15°C and 30°C. Dextran powder can be stored for up to 5 years at room temperature and aqueous solutions of dextran can be autoclaved.[15] Dextran solutions are stable under mild acidic and basic conditions.[8]

12 Incompatibilities

—

13 Method of Manufacture

Dextran is commercially produced by bacterial enzymatic synthesis with a culture of *Leuconostoc mesenteroides* in presence of sucrose. Ethanol or methanol are used to precipitate the dextran polymer from the culture, and hydrolysis with dilute acid produces the desired molecular weight fraction.[1,17]

14 Safety

Dextran is considered safe for oral administration.[18] There is a risk of severe anaphylactic adverse effects including respiratory distress and death from injection of dextran 40 and dextran 70.[17,19] The anaphylactic response is related to the level of dextran-reactive antibodies present. The risk of anaphylaxis from intravenously administered higher-molecular-weight dextrans (dextran 40) is greatly reduced by pretreating with dextran 1 (15% dextran 1 in normal saline).[20]

LD_{50} (mouse, IV): 12.1 g/kg[21]
LD_{50} (mouse, SC): 13.9 g/kg
LD_{50} (rabbit, IV): 17.4 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (IV liquid concentrate injection; IV lyophile powder for injection). Included in parental medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database

In the EU, dextran is approved for use in baked products at up to 5% and limited use in clinical nutrition, and as an additive in ice cream and candy.[18]

17 Related Substances

Dextrin; pullulan; starch; maltodextrin.

18 Comments

Dextran, dextrin, pullulan, maltodextrin and starch are all polydisperse polysaccharide polymers, with the monomer unit as dextrose (α-D-glucose), but can differ in average polymer length (average molecular weight) and polydispersity, which is a function of the botanical source for plant-based starch, a function of the hydrolysis process used to process starch into dextrin, and a function of the conditions used to fraction native dextran and native pullulan after microbial fermentation.

Dextran and pullulan and are both polysaccharides derived from microbial fermentation of starch or other sugar sources.

As an active ingredient, dextran is used for dry eyes in topical ophthalmic artificial tear products and as an intravenous emergency blood plasma expander and anticoagulant.[22]

Dextran was formerly listed as GRAS for food use prior to 1977, but was removed because not enough safety data was available at higher levels, and a survey of food manufacturers indicated that it was no longer used as a food ingredient.

A specification for dextran is included in the *Japanese Pharmaceutical Excipients* (JPE).[23]

The PubChem Compound ID (CID) for dextrans is 4125253.

Dextrates

1 Nonproprietary Names

USP–NF: Dextrates

2 Synonyms

Candex; dextratos; *Emdex*.

3 Chemical Name and CAS Registry Number

Dextrates [39404-33-6]

4 Empirical Formula and Molecular Weight

The USP 40–NF 35 S1 describes dextrates as a purified mixture of saccharides resulting from the controlled enzymatic hydrolysis of starch. It is either hydrated or anhydrous. Its dextrose equivalent is not less than 93.0% and not more than 99.0%, calculated on the dried basis. In addition to dextrose, dextrates contains 3–5% w/w maltose and higher polysaccharides.

5 Structural Formula

See Section 4.

6 Functional Category

Tablet and capsule binder; tablet and capsule diluent.

7 Applications in Pharmaceutical Formulation or Technology

Dextrates is a directly compressible tablet diluent used in chewable, nonchewable, soluble, dispersible, and effervescent tablets.[1–3] Dextrates has been evaluated as diluent in effervescent[4,5] and orally disintegrating tablets.[6] It is a free-flowing material and glidants are thus unnecessary. Lubrication with magnesium stearate (0.5–1.0% w/w) is recommended.[7] Dextrates may also be used as a binding agent by the addition of water, no further binder being required.[7]

Tablets made from dextrates increase in crushing strength in the first few hours after manufacture, but no further increase occurs on storage.[8]

8 Description

Dextrates is a purified mixture of saccharides resulting from the controlled enzymatic hydrolysis of starch. It is either anhydrous or hydrated. In addition to dextrose, dextrates contains 3–5% w/w maltose and higher polysaccharides.

Dextrates comprises white spray-crystallized free-flowing porous spheres. It is odorless with a sweet taste (about half as sweet as sucrose).

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for dextrates.

Test	USP 40–NF 35 S1
pH (20% aqueous solution)	3.8–5.8
Loss on drying	
Anhydrous	≤2.0%
Hydrated	7.8–9.2%
Residue on ignition	≤0.1%
Heavy metals	≤5 ppm
Dextrose equivalent (dried basis)	93.0–99.0%

10 Typical Properties

Angle of repose 26.4° [9]
Compressibility *see* Figure 1.[9]
Density (bulk) 0.68 g/cm^3 [9]
Density (tapped) 0.72 g/cm^3 [9]
Density (true) 1.539 g/cm^9
Hausner ratio 1.05
Flowability 9.3 g/s [9]
Heat of combustion 16.8–18.8 J/g (4.0–4.5 cal/g)
Heat of solution −105 J/g (−25 cal/g)
Melting point 141°C
Moisture content 7.8–9.2% w/w (hydrated form). *See also* Figure 2.[10]
Particle size distribution Not more than 3% retained on a 840 μm sieve; not more than 25% passes through a 150 μm sieve. Mean particle size 190–220 μm.

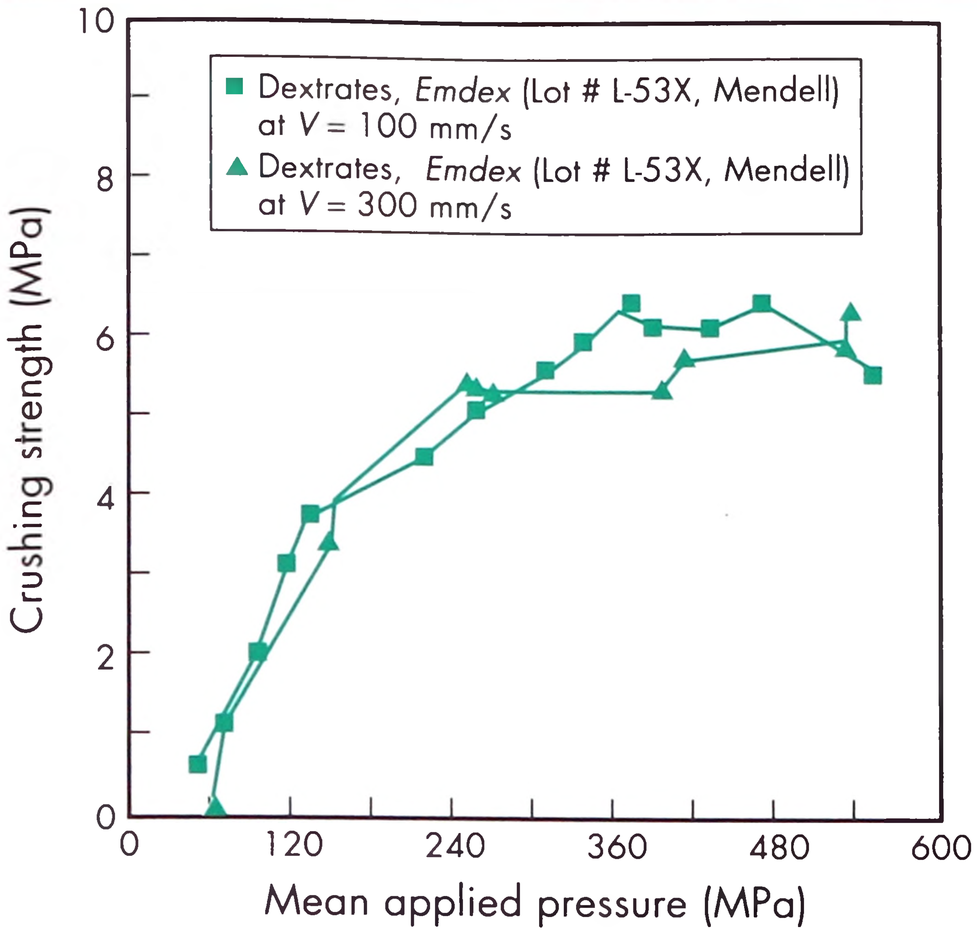

Figure 1: Crushing strength for dextrates.

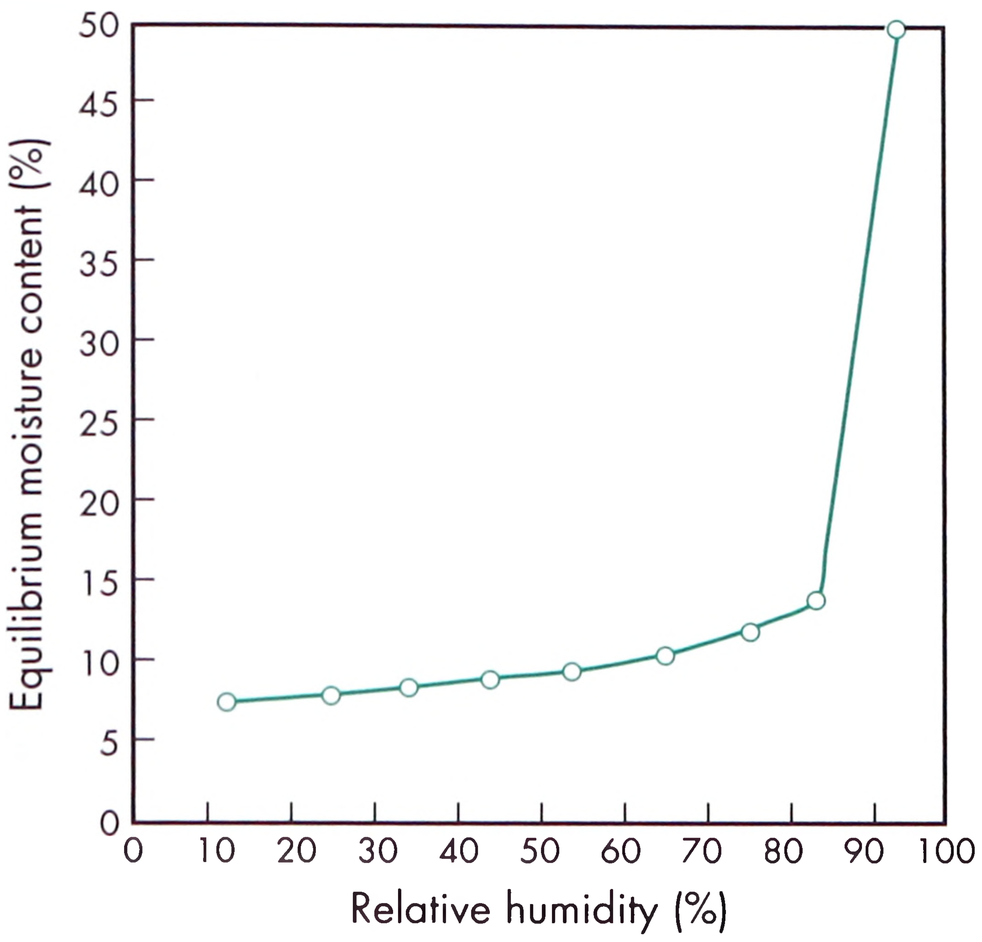

Figure 2: Equilibrium moisture content of dextrates at 25°C.[10]

Solubility Soluble 1 in 1 part of water; insoluble in ethanol (95%), propan-2-ol, and common organic solvents.
Specific surface area 0.70 m^2/g
Spectroscopy

IR spectrum *see* Figure 3.

NIR spectrum *see* Figure 4.

Raman spectrum *see* Figure 5.

11 Stability and Storage Conditions

Dextrates may be heated to 50°C without any appreciable darkening of color. Dextrates should be stored in a well-closed container in conditions that do not exceed 25°C and 60% relative humidity. When correctly stored in unopened containers, dextrates has a shelf-life of 3 years.

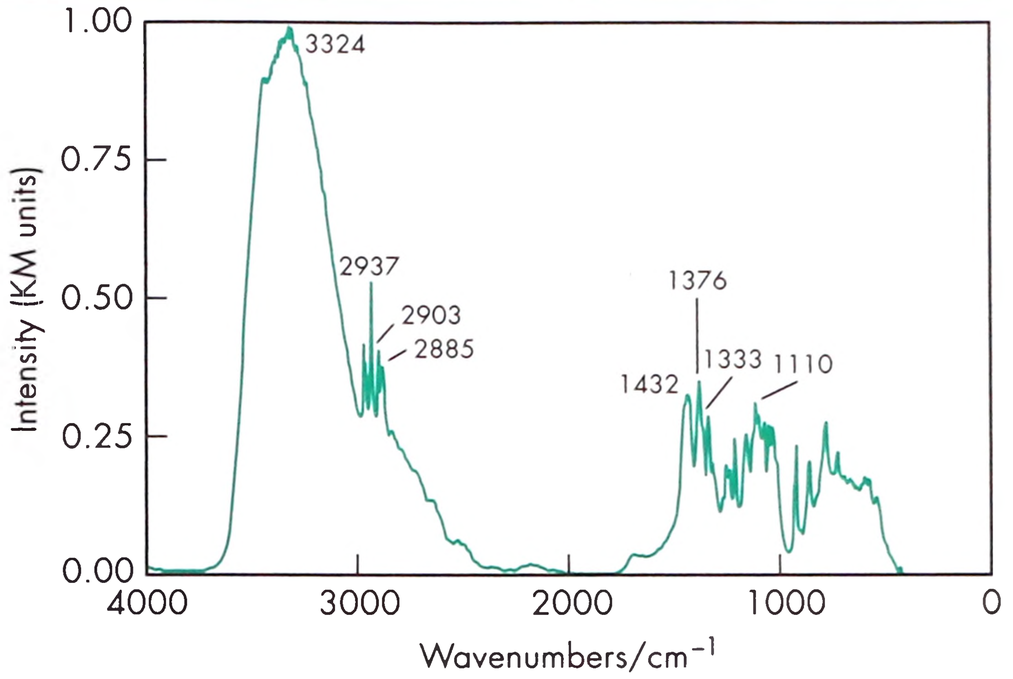

Figure 3: Infrared spectrum of dextrates measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

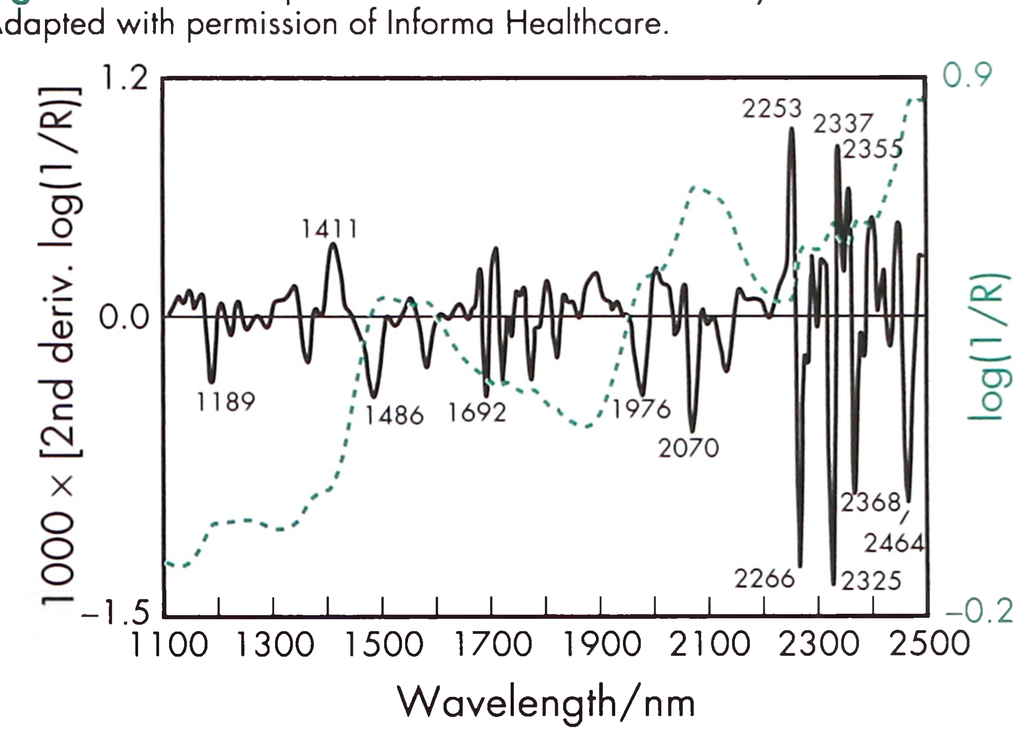

Figure 4: Near-infrared spectrum of dextrates measured by reflectance.

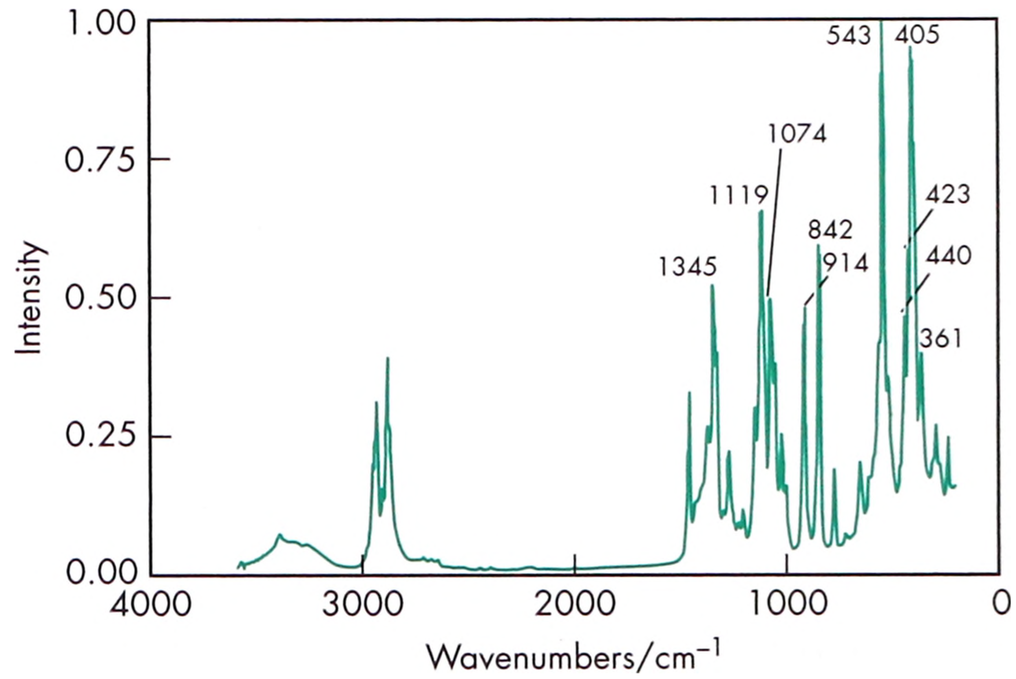

Figure 5: Raman spectrum of dextrates measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

12 Incompatibilities

At high temperatures and humidities, dextrates may react with substances containing a primary amino group (Maillard reaction).[11,12] Also incompatible with oxidizing agents.

13 Method of Manufacture

Dextrates is produced by controlled enzymatic hydrolysis of starch. The product is spray-crystallized, and may be dried to produce an anhydrous form.

14 Safety

Dextrates is used in oral pharmaceutical formulations and is generally regarded as a relatively nontoxic and nonirritant material.

15 Handling Precautions

Observe normal handling precautions appropriate to the circumstances and quantity of material handled. Eye protection, gloves, and a dust mask are recommended.

D

16 Regulatory Status

GRAS listed. Included in the FDA Inactive Ingredient Database (oral; tablets, chewable and sustained action). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Dextrose; maltodextrin.

18 Comments

Only the hydrated form of dextrates is currently commercially available and is described as a minimum of 93% dextrose and the balance as maltodextrin.[7]

Dextrin

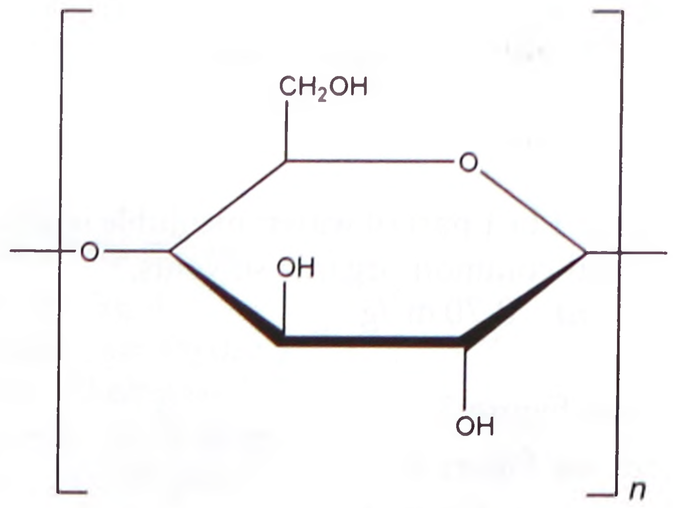
1 Nonproprietary Names

BP: Dextrin
JP: Dextrin
PhEur: Dextrin
USP–NF: Dextrin

2 Synonyms

Avedex; British gum; *Caloreen*; canary dextrin; *C*Pharm*; *Crystal Gum*; dextrinum; dextrinum album; β-limit dextrin; *Primogran W*; starch gum; yellow dextrin; white dextrin.

3 Chemical Name and CAS Registry Number



Dextrin [9004-53-9]

4 Empirical Formula and Molecular Weight

$(C_6H_{10}O_5)_n{\cdot}xH_2O$

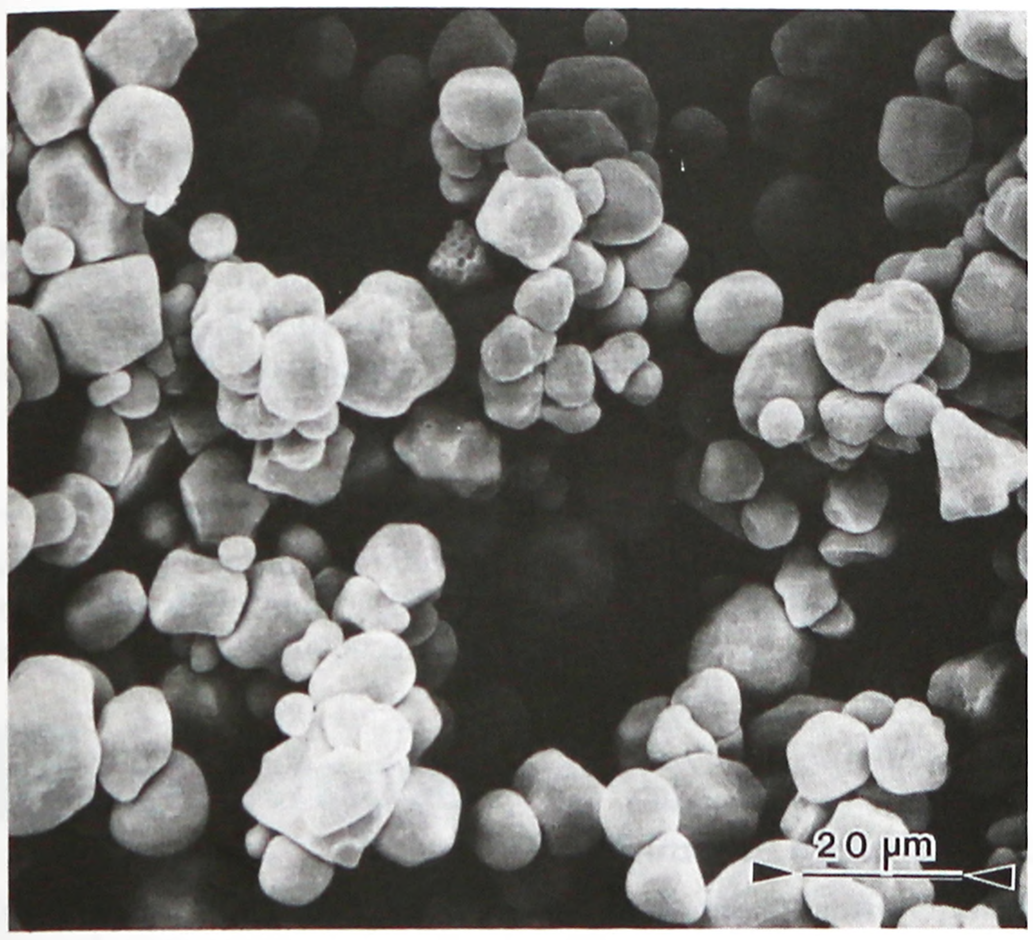
The USP 40–NF 35 S1, and the PhEur 9.2 describes dextrin as partially hydrolysed starch modified by heating with or without acids, alkalis or pH control agents. The average molecular weight of dextrin can range between 1000 Da to 3 000 000 Da.

5 Structural Formula

A structure for straight chain dextrin with α-D-(1→4) linkages is shown. Dextrins may be straight chain or contain branches with α-D-(1→6) linkages depending on the method of starch hydrolysis used to produce them.

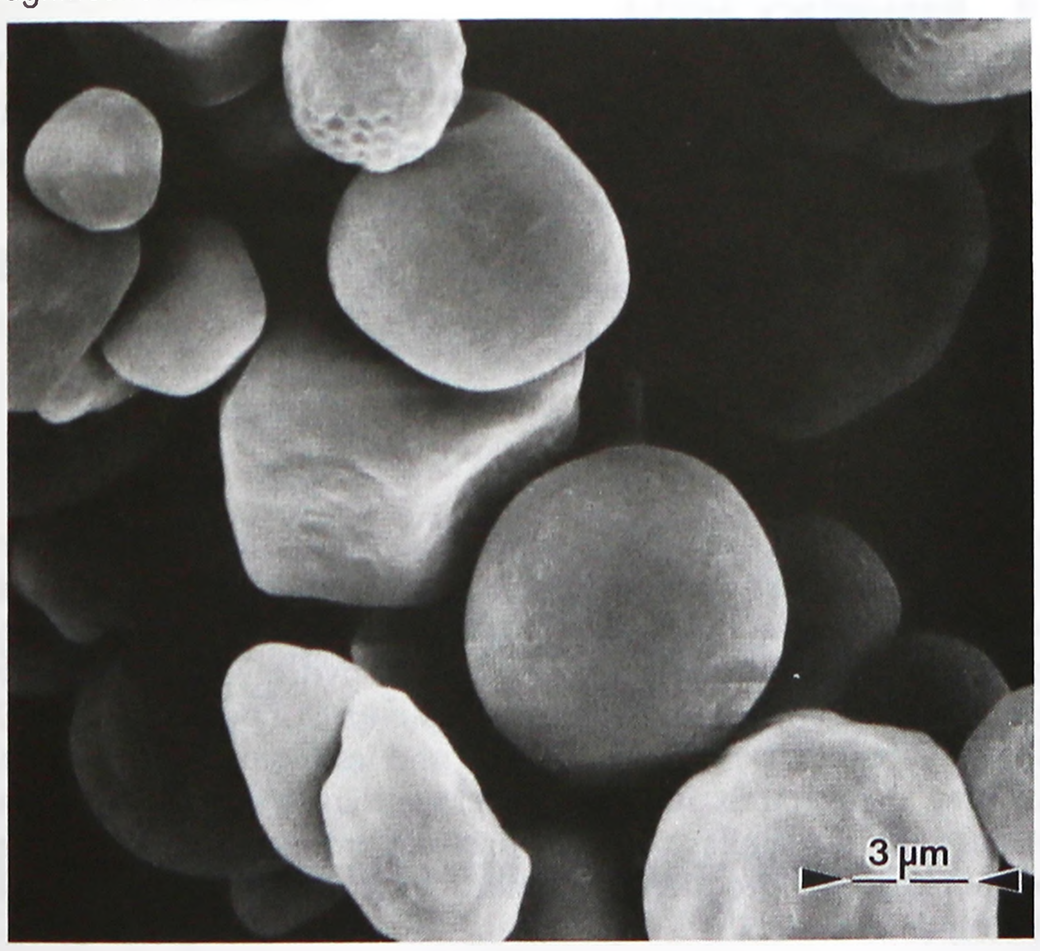
6 Functional Category

Microencapsulating agent; stiffening agent; suspending agent; tablet and capsule binder; tablet and capsule diluent; viscosity-increasing agent.



7 Applications in Pharmaceutical Formulation or Technology

Dextrin is a dextrose polymer used as an adhesive and stiffening agent for surgical dressings. It is also used as a tablet and capsule diluent; as a binder for tablet granulation; as a sugar-coating ingredient that serves as a plasticizer and adhesive; and as a thickening agent for suspensions. Dextrin has been evaluated as a substrate for fast dissolving buccal delivery (buccal melt wafer) with bioadhesive properties,[1,2] a sustained-release excipient for matrix tablets,[3] a nanogel encapsulation of proteins for protein stabilization,[4] a microencapsulating agent for orally disentigrating tablets,[5] and for conjugation to proteins for protein stabilization and subsequent controlled release.[6]



8 Description

Dextrin is partially hydrolyzed maize (corn), potato, or cassava starch. It is a white, pale yellow, or brown-colored powder with a slight characteristic odor.

SEM 1: Excipient: dextrin; manufacturer: Matheson Colleman & Bell; magnification: 600×.

SEM 2: Excipient: dextrin; manufacturer: Matheson Colleman & Bell; magnification: 2400×.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for dextrin.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Botanical characteristics	—	—	+
Characters	—	+	—

Particle size distribution *see* Figure 1.

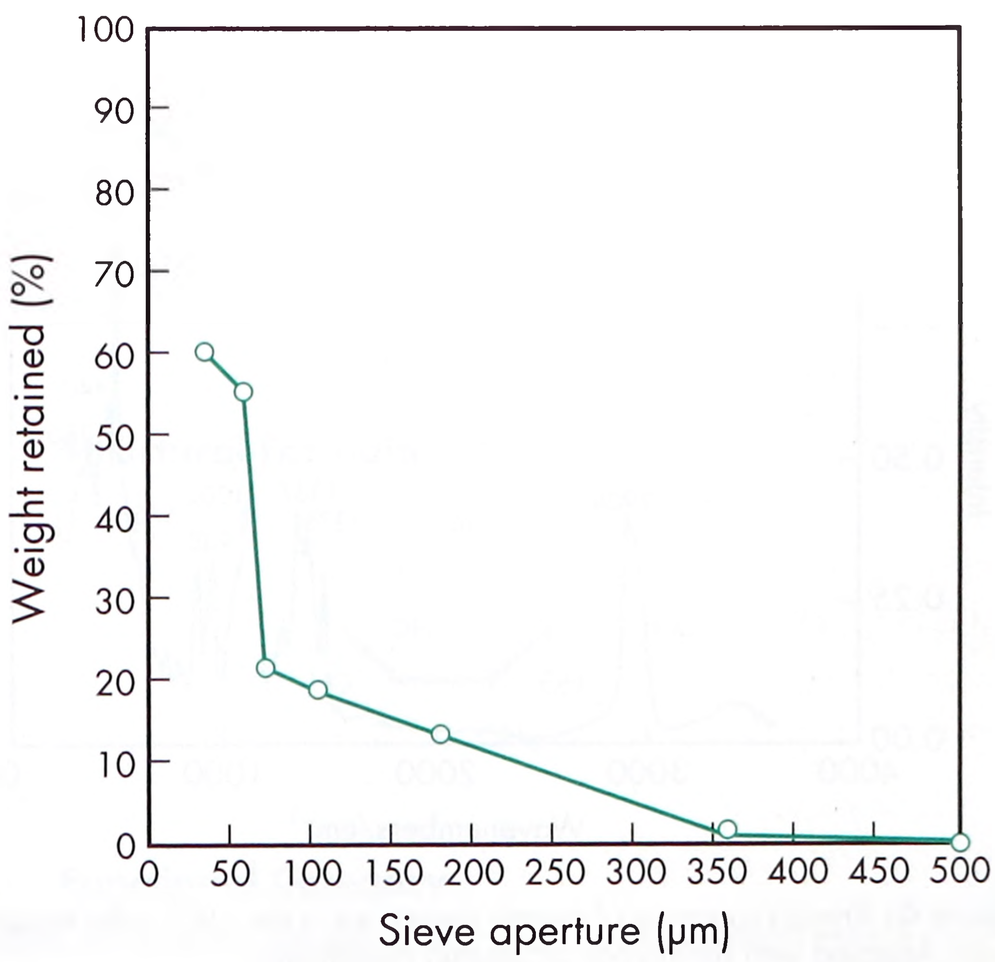

Figure 1: Particle size distribution of dextrin.

Solubility Practically insoluble in chloroform, ethanol (95%), ether, and propan-2-ol; slowly soluble in cold water; very soluble in boiling water, forming a mucilaginous solution.
Specific surface area 0.14 m^2/g
Spectroscopy

IR spectrum *see* Figure 2.

NIR spectrum *see* Figure 3.

Raman spectrum *see* Figure 4.

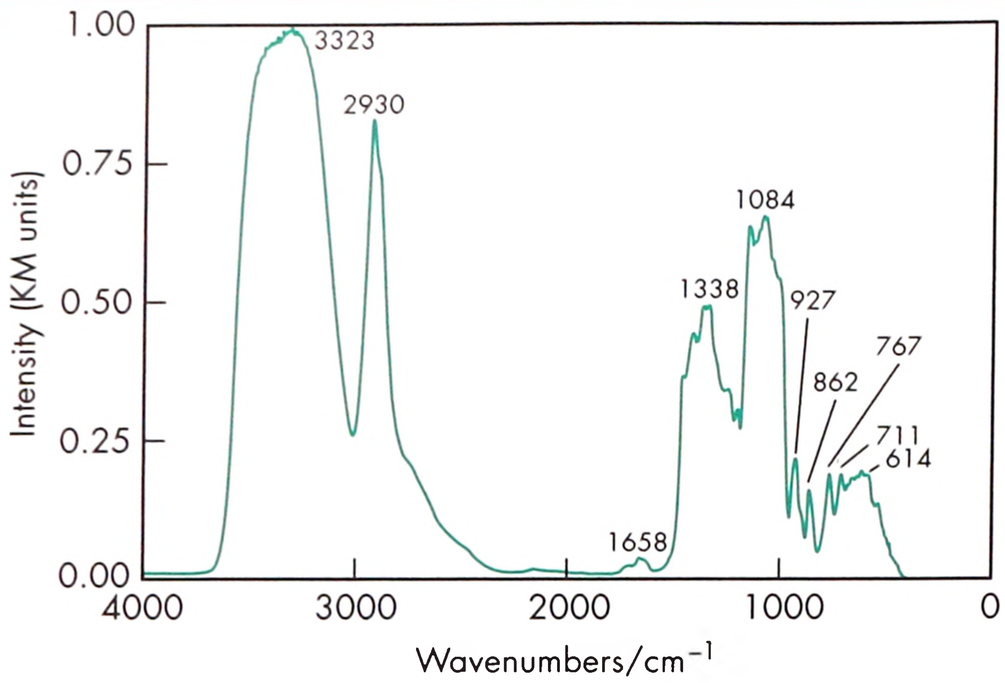

Figure 2: Infrared spectrum of dextrin measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

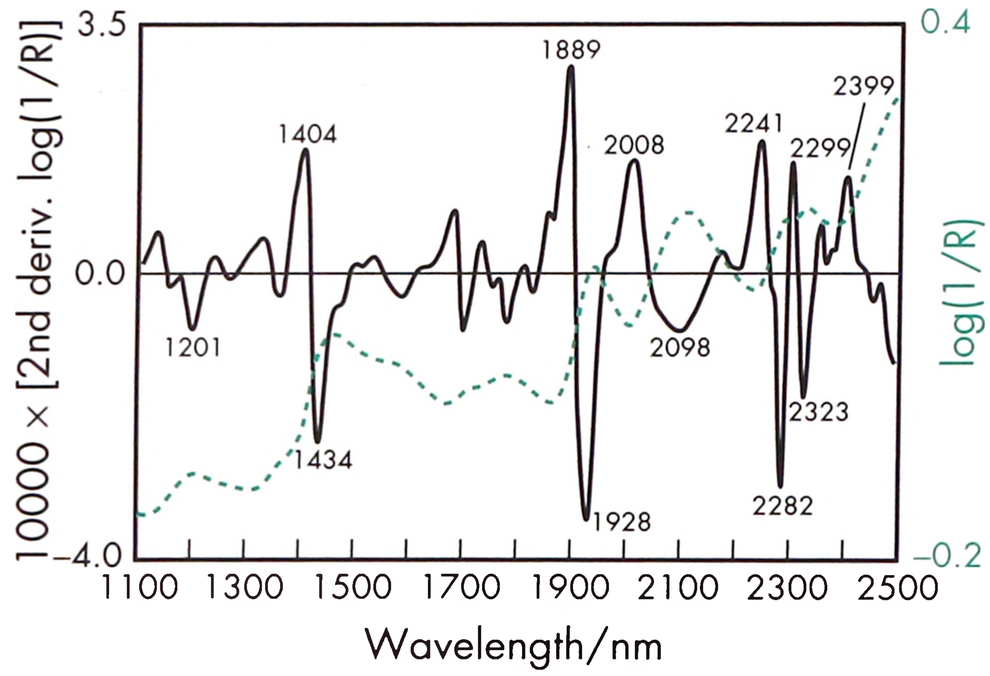

Figure 3: Near-infrared spectrum of dextrin measured by reflectance.

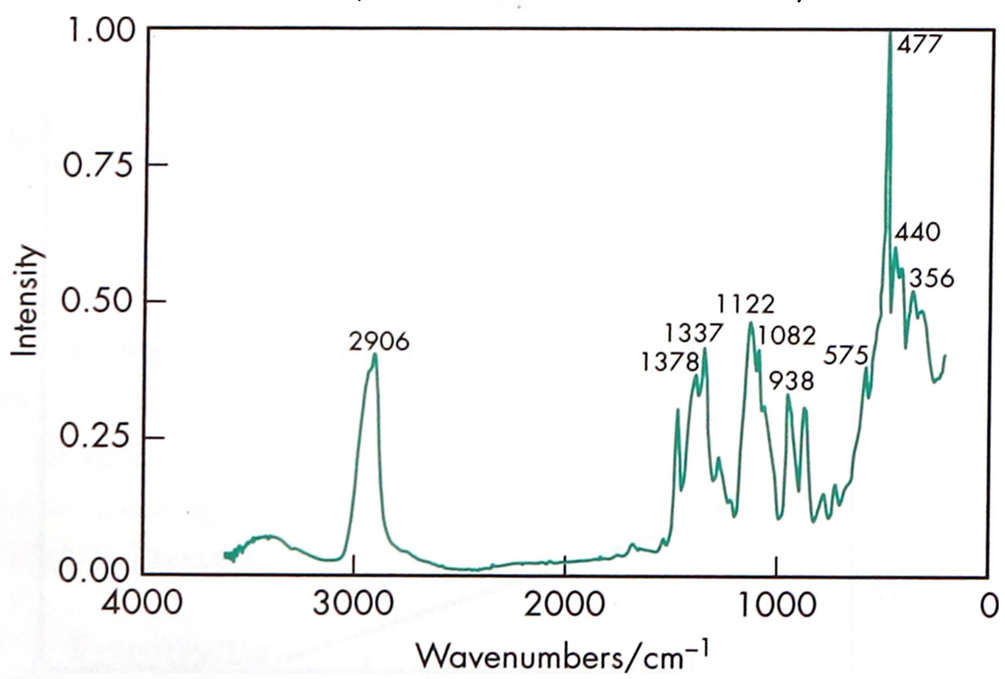

Figure 4: Raman spectrum of dextrin measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

Viscosity (dynamic)

88 mPa s (88 cP) for 10% w/v aqueous solutions with dextrose equivalent (DE) of 9.

54 mPa s (54 cP) for 10% w/v aqueous solutions with DE of 15.[7] The viscosity of Dextrin solutions decreases as the DE increases.

11 Stability and Storage Conditions

Physical characteristics of dextrin may vary slightly depending on the method of manufacture and on the source material. In aqueous solutions, dextrin molecules tend to aggregate as density, temperature, pH, or other characteristics change. Dextrin solutions are thixotropic, becoming less viscous when sheared and thickening to a soft paste or gel depending on concentration when allowed to stand. An increase in viscosity is caused by gelation or retrogradation as dextrin solutions age, and is particularly noticeable in the less-soluble maize starch dextrins. The viscosity characteristics of dextrin aqueous solutions can be impacted by impurities in the dextrin; acids that are present in dextrin as residues from manufacturing can cause further hydrolysis in solution, which results in a gradual thinning of solutions. Residual acid, often found in less-soluble dextrins such as pyrodextrin, can cause further hydrolysis of dextrin during dry storage, imparting a lower viscosity to solution made with aged dextrin. To eliminate these problems, dextrin manufacturers neutralize dextrins of low solubility with ammonia or sodium carbonate in the cooling vessel.

The bulk material should be stored in a well-closed container in a cool, dry place.

12 Incompatibilities

Incompatible with strong oxidizing agents.

13 Method of Manufacture

Dextrin is prepared by the incomplete hydrolysis of starch by heating in the dry state with or without the aid of suitable acids and buffers; moisture may be added during heating. Dextrin is also produced by enzyme hydrolysis with α-amylase or β-amylase.[1,7] The PhEur 9.2 specifies that dextrin is derived from maize (corn), potato or cassava starch. A specification for cassava (tapioca starch) is included in the USP 40–NF 35 S1.

14 Safety

Dextrin is generally regarded as a nontoxic and nonirritant material at the levels employed as an excipient. Larger quantities are used as a dietary supplement without adverse effects, although ingestion of very large quantities may be harmful.

LD_{50} (mouse, IV): 0.35 g/kg[8]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Dextrin may be an irritant to the eyes. Eye protection, gloves, and a dust mask are recommended.

16 Regulatory Status

GRAS listed. Included in the FDA Inactive Ingredients Database (IV injections, oral tablets, and topical preparations). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Dextran; maltodextrin; pullulan; starch.

See also Section 18.

18 Comments

Dextrin and starch are both botanical polysaccharides derived from plant sources such as corn, potato, and rice. Starch is purified from the plant source but not further modified, while dextrin is produced by further processing of starch via partial hydrolysis. Like starch, dextrin is a carbohydrate polydisperse mixture of polymers of α–D-glucose subunits. Dextrin is a smaller and less complexly branched polymer than starch. Dextrin generally has a larger molecular weight than the similar starch hydrolysis product maltodextrin as maltodextrin is produced by more extensive acid or enzyme hydrolysis of starch.[1,2]

Dextrin is available from suppliers in a number of modified forms and mixtures such as dextrimaltose, a mixture of maltose and dextrin obtained by the enzymatic action of barley malt on corn flour. It is a light, amorphous powder, readily soluble in milk or water.

Crystal Gum is a grade of dextrin containing carbohydrate not less than 98% of dry weight. *Caloreen* has been described as dextrin consisting predominantly of polysaccharides containing an average of 5 dextrose molecules, with a mean molecular weight (MW) of 840,[9] and also described as bimodal distribution consisting of 67% 'low' MW fraction (<12 glucose subunits) and a 33% 'high' MW fraction (>12 glucose subunits); weight average MW 7000 Da, which does not change after heating.[10]

Dextrin has been used as a source of carbohydrate by people with special dietary requirements because it has a low electrolyte content and is free of lactose and sucrose.[9] Dextrin is also used in cosmetics.

A specification for dextrin is contained in the *Food Chemicals Codex* (FCC).[12]

The EINECS number for dextrin is 232-675-4. The PubChem Compound ID (CID) for dextrin is 62698.

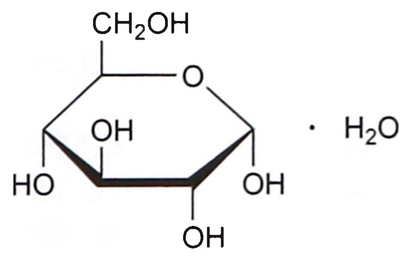
Dextrose

1 Nonproprietary Names

BP: Glucose Monohydrate
PhEur: Glucose Monohydrate
USP–NF: Dextrose

2 Synonyms

Blood sugar; *Caridex*; *Cerelose 2001*; *C*PharmDex*; *Dextrofin*; D-(+)-glucose monohydrate; glucosum monohydricum; grape sugar; *Lycadex PF*; *Meritose*; starch sugar; *Tabfine D-100*.



3 Chemical Name and CAS Registry Number

D-(+)-Glucopyranose monohydrate [5996-10-1] and [14431–43–7]

4 Empirical Formula and Molecular Weight

$C_6H_{12}O_6 \cdot H_2O$ 198.17

5 Structural Formula

6 Functional Category

Tablet and capsule binder; tablet and capsule diluent; tonicity agent; sweetening agent.

7 Applications in Pharmaceutical Formulation or Technology

Dextrose is widely used in solutions to adjust tonicity and as a sweetening agent. Dextrose is also used as a wet granulation diluent and binder, and as a direct-compression tablet diluent and binder, primarily in chewable tablets. Although dextrose is comparable as a tablet diluent to lactose, tablets produced with dextrose monohydrate require more lubrication, are less friable, and have a tendency to harden.[1–3]

Dextrose has been studied as a diluent in hydrophilic matrix controlled-release tablet formulations, where its high solubility is used to produce an increased initial release rate.[4] It has also been shown that dextrose and other soluble sugars used as diluents in hypromellose matrix tablets can increase the drug release rate in the presence of dissolved sucrose.[5] Dextrose has also been used as a solvent in self-assembled peptide nanostructure formulations.[6]

Dextrose has been evaluated as a dry powder inhaler carrier.[7] It was reported to produce formulations that were more sensitive to storage at elevated temperature and humidity than formulations containing lactose monohydrate.[8]

8 Description

Dextrose occurs as odorless, sweet-tasting, colorless crystals or as a white crystalline or granular powder.

9 Pharmacopeial Specifications

The PhEur 9.2 provides individual monographs for Glucose Monohydrate and Glucose Anhydrous, whereas the USP 40–NF 35 S1 describes both Dextrose Monohydrate and Dextrose Anhydrous in the specification for Dextrose. The pharmacopeial specifications for both dextrose monohydrate and dextrose anhydrous have undergone harmonization of many attributes for JP, PhEur, and USP–NF.

See Table I. *See also* Section 18.

Table I: Pharmacopeial specifications for dextrose.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters[a]	+	+	—

Assay (dried basis)	≥99.5%	97.5–102.0%	—

(a) This test has not been fully harmonized at the time of publication.
(b) If intended for large volume parenteral use.

10 Typical Properties

Acidity/alkalinity pH = 3.5–5.5 (20% w/v aqueous solution)
Density (bulk) 0.826 g/cm^3
Density (tapped) 1.020 g/cm^3
Density (true) 1.54 g/cm^3
Heat of solution 105.4 J/g (25.2 cal/g)
Melting point 83°C
Moisture content Dextrose monohydrate absorbs moisture at around 85% relative humidity and 25°C.
Osmolarity A 5.51% w/v aqueous solution is isoosmotic with serum. However, it is not isotonic since dextrose can pass through the membrane of red cells and cause hemolysis.
Solubility *see* Table II.

Table II: Solubility of dextrose monohydrate.

Solvent	Solubility at 20°C
Chloroform	Practically insoluble
Ethanol (95%)	1 in 60
Ether	Practically insoluble
Glycerin	Soluble
Water	1 in 1

Spectroscopy

NIR spectrum *see* Figure 1.

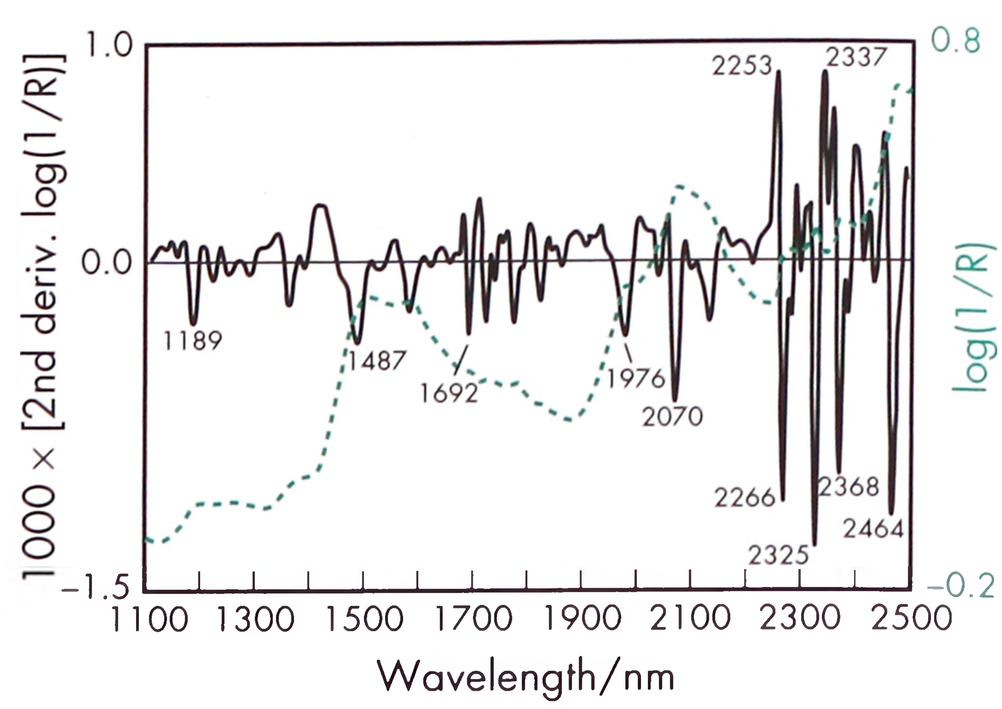

Figure 1: Near-infrared spectrum of dextrose monohydrate measured by reflectance.

11 Stability and Storage Conditions

Dextrose has good stability under dry storage conditions. Aqueous solutions may be sterilized by autoclaving. However, excessive heating can cause a reduction in pH and caramelization of solutions.[9–12]

The bulk material should be stored in a well-closed container in a cool, dry place.

12 Incompatibilities

Dextrose solutions are incompatible with a number of drugs such as cyanocobalamin, kanamycin sulfate, novobiocin sodium, and warfarin sodium.[13] Erythromycin gluceptate is unstable in dextrose solutions at a pH less than 5.05.[14] Decomposition of B-complex vitamins may occur if they are warmed with dextrose.

In the aldehyde form, dextrose can react with amines, amides, amino acids, peptides, and proteins. Brown coloration and decomposition occur with strong alkalis.

Dextrose may cause browning of tablets containing amines (Maillard reaction).

13 Method of Manufacture

Dextrose, a monosaccharide sugar, occurs widely in plants and is manufactured on a large scale by the acid or enzymatic hydrolysis of starch, usually maize (corn) starch. Below 50°C α-D-dextrose monohydrate is the stable crystalline form produced; above 50°C

the anhydrous form is obtained; and at still higher temperatures β-D-dextrose is formed, which has a melting point of 148–155°C.

14 Safety

Dextrose is rapidly absorbed from the gastrointestinal tract. It is metabolized to carbon dioxide and water with the release of energy.

Concentrated dextrose solutions given by mouth may cause nausea and vomiting. Dextrose solutions of concentration greater than 5% w/v are hyperosmotic and are liable to cause local vein irritation following intravenous administration. Thrombophlebitis has been observed following the intravenous infusion of isoosmotic dextrose solution with low pH, probably owing to the presence of degradation products formed by overheating during sterilization. The incidence of phlebitis may be reduced by adding sufficient sodium bicarbonate to raise the pH of the infusion above pH 7.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

Dust generation should be minimized to reduce the risk of explosion. Eye protection and gloves are recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (inhalations; injections; capsules; tablets, oral solutions, and syrups). Included in nonparenteral and parenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Dextrates; dextrin; dextrose anhydrous; fructose; glucose liquid; polydextrose; sucrose.

18 Comments

Dextrose monohydrate is one of the materials that have been selected for harmonization by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

The way in which the strengths of dextrose solutions are expressed varies from country to country. Approximately 1.1 g of dextrose monohydrate is equivalent to 1 g of anhydrous dextrose.

Therapeutically, dextrose is the preferred source of carbohydrate in parenteral nutrition regimens.

The PubChem Compound ID (CID) for dextrose is 66370.

Dextrose Anhydrous

D

1 Nonproprietary Names

BP: Glucose

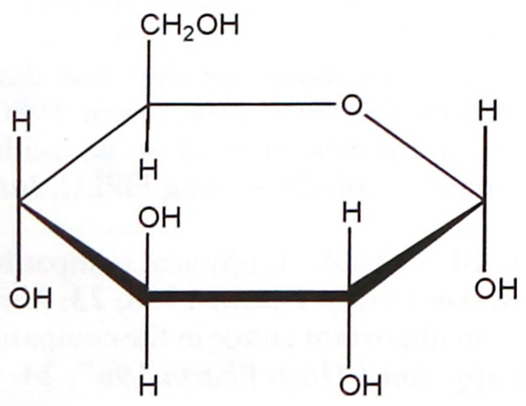
JP: Glucose

PhEur: Glucose

USP–NF: Dextrose

2 Synonyms

Anhydrous dextrose; anhydrous glucose; *Cerelose 2401*; corn sugar; dextrosol; dextrosum anhydricum; D-glucose.



3 Chemical Name and CAS Registry Number

D-(+)-Glucopyranose anhydrous [50-99-7]

4 Empirical Formula and Molecular Weight

$C_6H_{12}O_6$ 180.2

5 Structural Formula

6 Functional Category

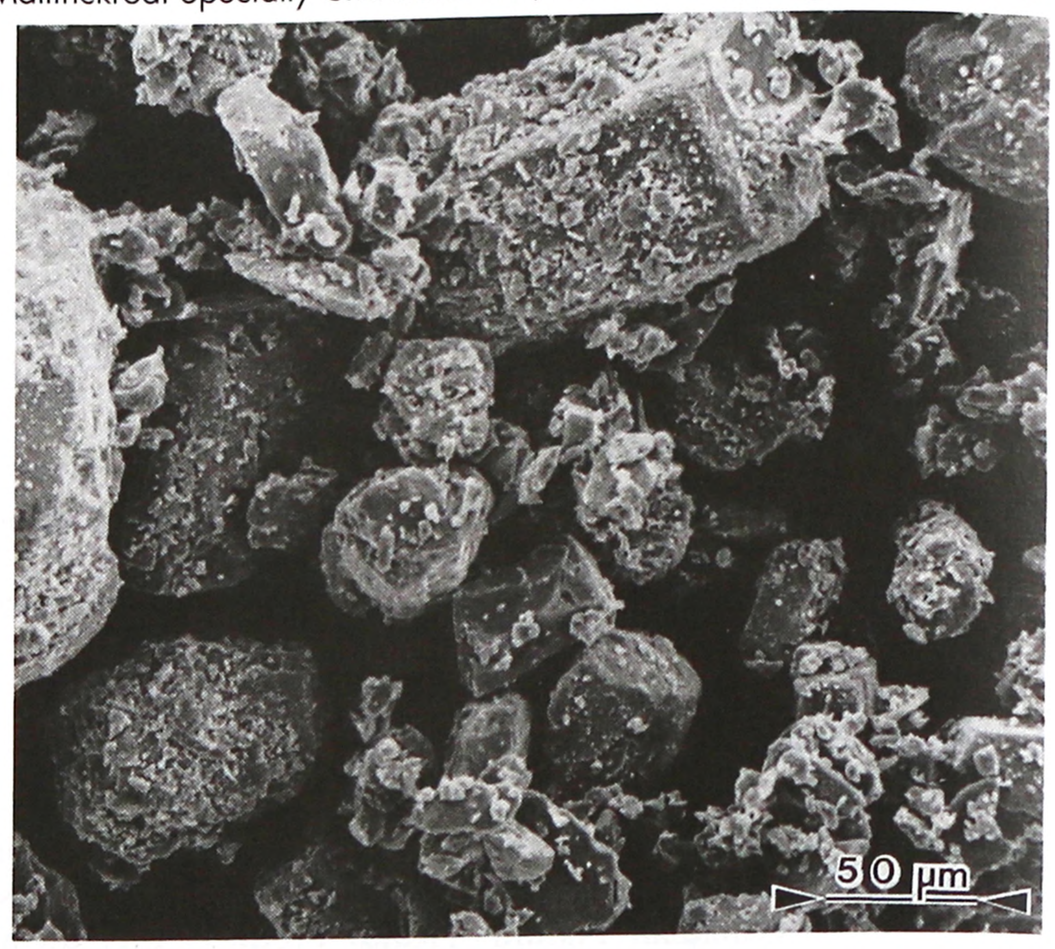
Tablet and capsule binder; tablet and capsule diluent; tonicity agent; sweetening agent.

7 Applications in Pharmaceutical Formulation or Technology

Dextrose anhydrous is used in tablet formulations as a binder and diluent in both direct-compression and wet-granulation processes.[1] It is also used in solutions to adjust tonicity and as a sweetening agent. Dextrose anhydrous has the sweetening power of about 70% that of sucrose.[2]

The water content of dextrose anhydrous has an impact on the compression properties of the material depending on the point of the sorption cycle. An initial increase in tensile strength and tablet toughness is observed with increasing water content, before a substantial decrease is seen. For the monohydrate, any increase in moisture content results in a decrease in these properties.[3] Dehydration of the monohydrate has shown an increased crushing strength as the moisture content decreases.[4]

8 Description



Dextrose anhydrous occurs as colorless crystals or as a white, crystalline or granular powder. It is odorless and has a sweet taste.

The JP XVII describes dextrose anhydrous as α-D-glucopyranose, β-D-glucopyranose, or a mixture of these, and when dried, it contains not less than 99.5% of $C_6H_{12}O_6$.

Information for the crystal structure is described in the literature.[5,6]

For the monohydrate form *see* Dextrose.

SEM 1: Excipient: dextrose anhydrous (granular); manufacturer: Mallinckrodt Specialty Chemicals Co.; lot no.: KLKZ; magnification: 180×.

9 Pharmacopeial Specifications

The PhEur 9.2 provides individual monographs for Glucose Monohydrate and Glucose Anhydrous, whereas the USP 40–NF 35 S1 describes both Dextrose Monohydrate and Dextrose Anhydrous in the specification for Dextrose. The pharmacopeial specifications for both dextrose monohydrate and dextrose anhydrous have undergone harmonization of many attributes for JP, PhEur, and USP–NF.

See Table I.

10 Typical Properties

Acidity/alkalinity pH = 5.9 (10% w/v aqueous solution)

Density (bulk) 1.3–1.4 g/cm^3

Density (tapped) 1.1–1.2 g/cm^3

Glass Transition Temperature ≈38°C[7]

Melting point 146°C; also reported as 150–152°C.[8] Further information on melting behavior is described in the literature.[9,10]

Moisture content Dextrose anhydrous absorbs significant amounts of moisture at 25°C and a relative humidity of about 85% to form the monohydrate. *See* Figure 1.

NIR spectra *see* Figure 2.

Osmolarity A 5.05% w/v aqueous solution is isoosmotic with serum.

Refractive Index n_D^{20} = 1.3479 (10% w/v aqueous solution)

Solubility *see* Table II.

Specific gravity *see* Table III.

Specific surface area 0.22–0.29 m^2/g

11 Stability and Storage Conditions

Store in tightly closed containers in a cool, dry, and well-ventilated place.

12 Incompatibilities

Dextrose anhydrous is incompatible with strong oxidizing agents.

Dextrose anhydrous is a reducing sugar. It will undergo a Maillard reaction with primary and secondary amine drugs.

13 Method of Manufacture

Dextrose anhydrous is a naturally occurring sugar and is obtained commercially from starch by acid or enzymatic hydrolysis. *See also* Dextrose.

Table I: Pharmacopeial specifications for dextrose anhydrous

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1

(b) If intended for large volume parenteral use.

Table II: Solubility of dextrose anhydrous.

Solvent	Solubility at 20°C unless otherwise stated
Ethanol (95%)	Sparingly soluble
Ether	Sparingly soluble
Methanol	1 in 120
Water	1 in 1.1 at 25°C 1 in 0.8 at 30°C 1 in 0.41 at 50°C 1 in 0.28 at 70°C 1 in 0.18 at 90°C

Table III: Specific gravity of dextrose anhydrous aqueous solutions.

Concentration of aqueous dextrose solution (%w/v)	Specific gravity at 17.5°C
5	1.019
10	1.038
20	1.076
30	1.113
40	1.149

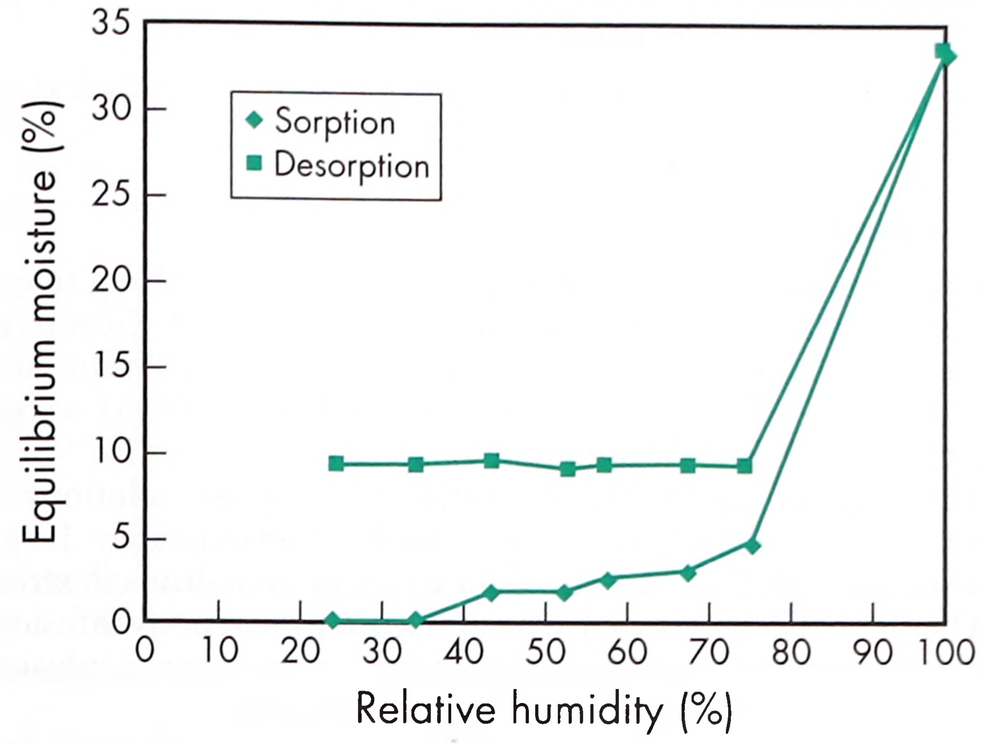

Figure 1: Sorption–desorption isotherm for anhydrous dextrose granules.

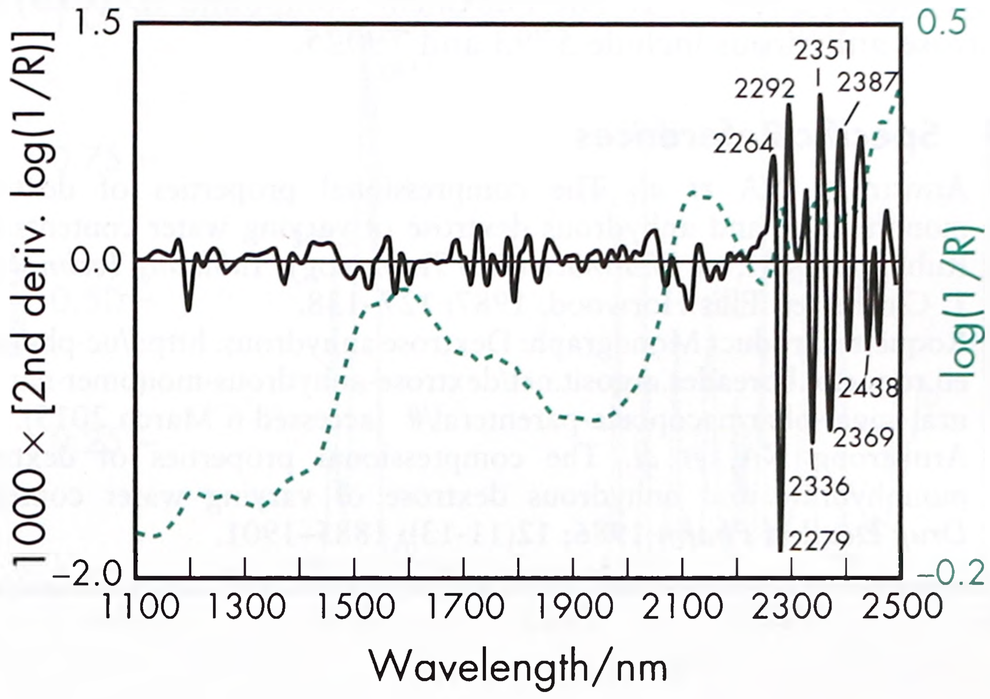

Figure 2: Near-infrared spectrum of dextrose anhydrous measured by reflectance.

14 Safety

In the US, dextrose anhydrous is generally recognized as safe (GRAS) as a direct human food ingredient at levels consistent with current good manufacturing practices. As an excipient, dextrose anhydrous is generally regarded as a nonirritant and nontoxic material.

LD_{50} (mouse, IV): 9 g/kg[11]
LD_{50} (rat, oral): 25.8 g/kg[11]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

Dust generation should be avoided. Dextrose anhydrous has a potentially explosive reaction with potassium nitrate and sodium peroxide when heated in a sealed container. Mixtures of anhydrous dextrose and alkali release carbon monoxide when heated. When heated to decomposition, it emits acrid smoke and irritating fumes. Eye protection and gloves are recommended.

16 Regulatory Status

GRAS listed. Included in the FDA Inactive Ingredients Database (inhalations; injections; capsules, tablets and oral granules). Included in nonparenteral and parenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Dextrates; dextrin; dextrose; fructose; glucose liquid; polydextrose; sucrose.

18 Comments

Dextrose anhydrous is one of the materials that have been selected for harmonization by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

The way in which the strengths of dextrose solutions are expressed varies from country to country. Approximately 1.1 g of dextrose monohydrate is equivalent to 1 g of anhydrous dextrose.

The BP 2017 directs that when Glucose Intravenous Infusion is required as a diluent for official injections or intravenous infusions, Glucose Intravenous Infusion 5% should be used.

A specification for dextrose anhydrous is contained in the Food Chemicals Codex (FCC).[12] The EINECS number for dextrose anhydrous is 200-075-1. The PubChem Compound ID (CID) for dextrose anhydrous include 5793 and 79025.

Dibutyl Phthalate

1 Nonproprietary Names

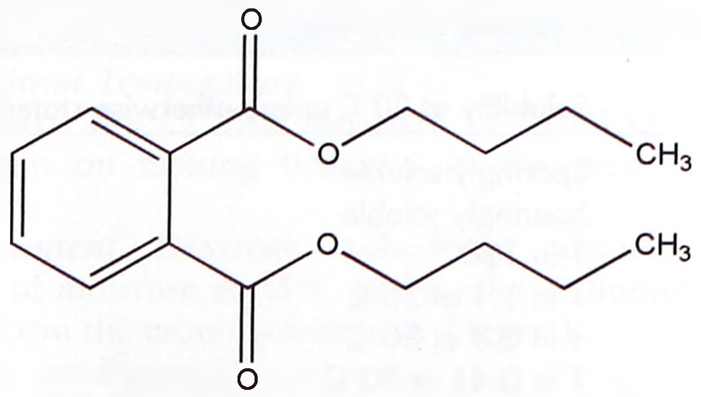
BP: Dibutyl Phthalate

PhEur: Dibutyl Phthalate

USP–NF: Dibutyl Phthalate

2 Synonyms

Araldite 502; benzenedicarboxylic acid, dibutyl ester; benzene-*o*-dicarboxylic acid di-*n*-butyl ester; butyl phthalate; *Celluflex DBP*; DBP; dibutyl 1,2-benzenedicarboxylate; dibutyl benzene 1,2-dicarboxylate; dibutyl ester of 1,2-benzenedicarboxylic acid; dibutylis phthalas; dibutyl-*o*-phthalate; di-*n*-butyl phthalate; *Eastman DBP*; *Elaol*; *Ergoplast FDB*; *Genoplast B*; *Hatcol DBP*; *Hexaplast M/B*; *Kodaflex DBP*; *Monocizer DBP*; *Palatinol C*; phthalic acid dibutyl ester; *Polycizer DBP*; *PX 104*; *RC Plasticizer DBP*; *Staflex DBP*; *Unimoll DB*; *Vestimol C*; *Witcizer 300*.



3 Chemical Name and CAS Registry Number

Dibutyl benzene-1,2-dicarboxylate [84-74-2]

4 Empirical Formula and Molecular Weight

$C_{16}H_{22}O_4$ 278.34

5 Structural Formula

6 Functional Category

Plasticizing agent; solvent.

7 Applications in Pharmaceutical Formulation or Technology

Dibutyl phthalate is used in pharmaceutical formulations as a plasticizing agent in film-coatings. It has been evaluated as a pore-forming agent in novel delivery systems,[3,4] and as a plasticizer in ocular inserts[5] and transdermal delivery systems.[6,7] It is also used

extensively as a solvent, particularly in cosmetic formulations such as antiperspirants, hair shampoos, and hair sprays.

8 Description

Dibutyl phthalate occurs as an odorless, oily, colorless, or very slightly yellow-colored, viscous liquid.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for dibutyl phthalate.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	–
Appearance	+	+
Relative density	1.043–1.048	1.043–1.048
Refractive index	1.490–1.495	1.490–1.495
Acidity	+	+
Related substances	+	+
Water	≤0.2%	≤0.2%
Sulfated ash	≤0.1%	–
Residue on ignition	–	≤0.1%
Assay	99.0–101.0%	99.0–101.0%

10 Typical Properties

Boiling point 340°C
Density *see* Table II.
Flash point 157°C (closed cup); 191°C (open cup)
Melting point −35°C
Partition coefficient Octanol : water log k_{ow} = 4.50
Refractive index n_D^{20} = 1.491–1.495
Solubility Very soluble in acetone, benzene, ethanol (95%), and ether; soluble 1 in 2500 of water at 20°C.
Spectroscopy

IR spectrum *see* Figure 1.

Raman spectrum *see* Figure 2.

Vapor density 9.58 (air = 1)
Viscosity (dynamic) *see* Table II.

Table II: Density and dynamic viscosity of dibutyl phthalate at specified temperatures.

Temperature (°C)	Density (g/cm^3)	Dynamic viscosity (mPa s)
0	1.0627	59
10	1.0546	33
20	1.0465	20
30	1.0384	13
40	1.0303	9
50	1.0222	7

11 Stability and Storage Conditions

Dibutyl phthalate should be stored in a well-closed container in a cool, dry location. Containers may be hazardous when empty since they can contain product residues such as vapors and liquids.

12 Incompatibilities

Dibutyl phthalate reacts violently with chlorine. It also reacts with oxidizing agents, acids, bases, and nitrates.

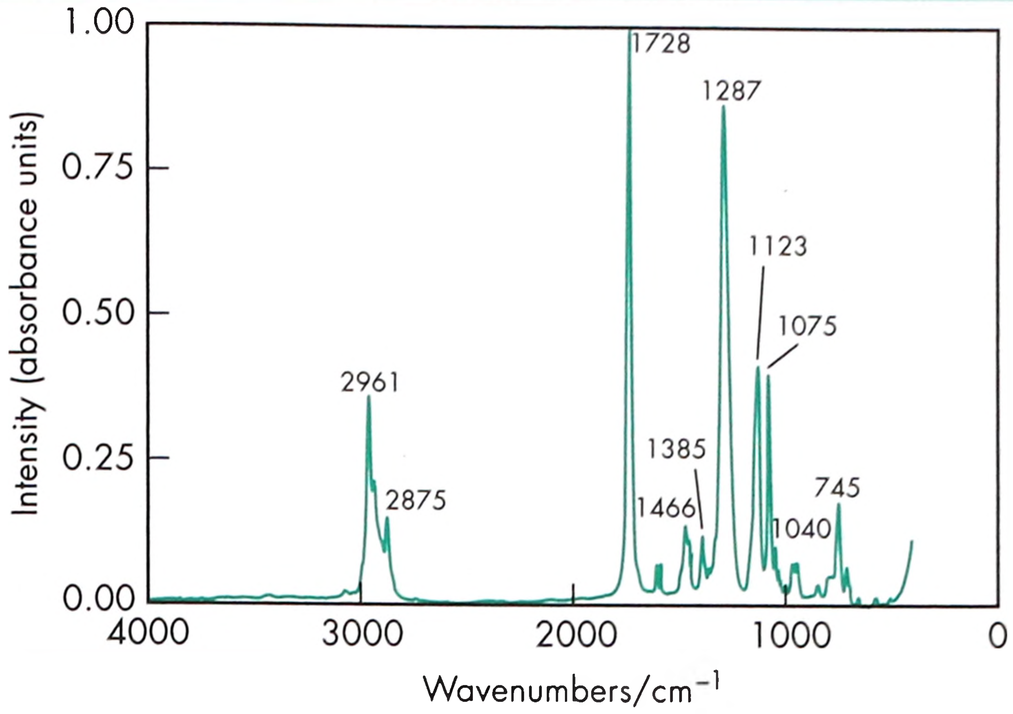


Figure 1: Infrared spectrum of dibutyl phthalate measured by transmission. Adapted with permission of Informa Healthcare.

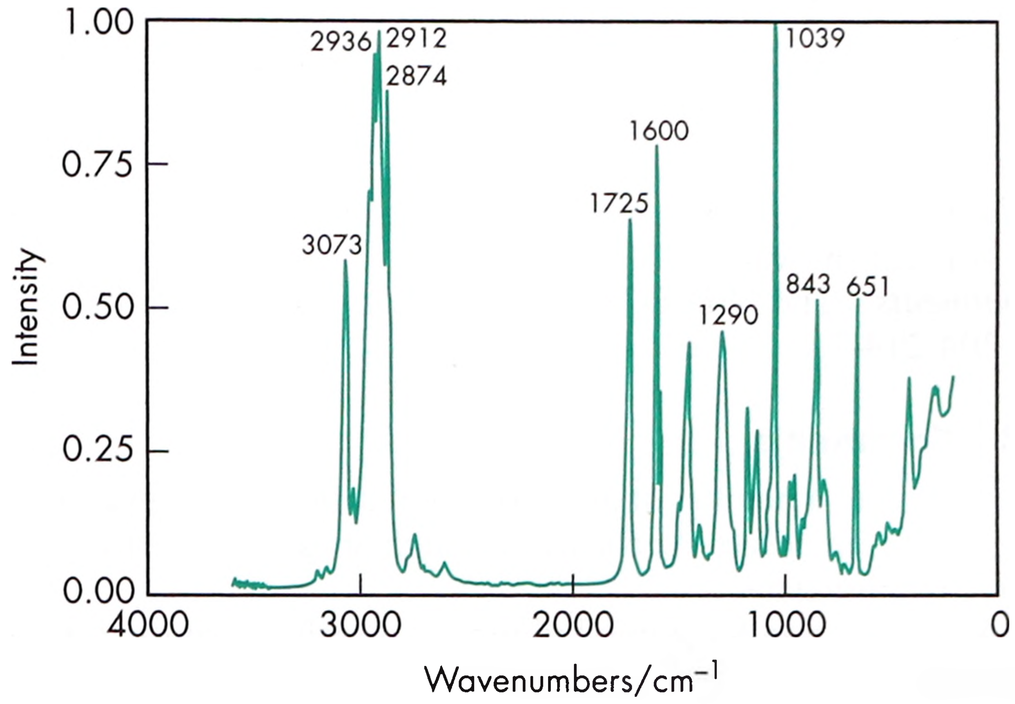

Figure 2: Raman spectrum of dibutyl phthalate measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

13 Method of Manufacture

Dibutyl phthalate is produced from *n*-butanol and phthalic anhydride in an ester formation reaction.

14 Safety

Dibutyl phthalate is generally regarded as a relatively nontoxic material, although it has occasionally been reported to cause hypersensitivity reactions. It is widely used in topical cosmetic and some oral pharmaceutical formulations.

LD_{50} (mouse, IV): 0.72 g/kg[1]
LD_{50} (mouse, oral): 5.3 g/kg
LD_{50} (rat, oral): 8.0 g/kg
LD_{50} (rat, IP): 3.05 mL/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Contact with the skin and eyes should be avoided. Decomposition produces toxic fumes, carbon monoxide and carbon dioxide.

In the US, the permitted 8-hour exposure limit for dibutyl phthalate is 5 mg/m^3. In the UK, the long-term (8-hour TWA) workplace exposure limit for dibutyl phthalate is 5 mg/m^3. The short-term (15-minute) workplace exposure limit is 10 mg/m^3.[2]

D

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral capsules and tablets). Included in nonparenteral medicines licensed in the UK (oral capsules; topical creams and solutions). Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Diethyl phthalate; dimethyl phthalate; dioctyl phthalate.

Dioctyl phthalate

Empirical formula $C_{24}H_{38}O_4$
Molecular weight 390.55
CAS number Dioctyl phthalate occurs commercially in two isomeric forms: di-*n*-octyl phthalate [117-84-0] and di(2-ethylhexyl) phthalate [117-81-7].
Synonyms 1,2-Benzenedicarboxylic acid bis(2-ethylhexyl) ester; bis(2-ethylhexyl) phthalate; di(2-ethyl-hexyl)phthalate; DEHP; DOP; *Octoil*.
Description Clear, colorless, odorless, and anhydrous liquid.
Boiling point 384°C
Flash point 206°C (closed cup)
Melting point −50°C
Refractive index $n_D^{20} = 1.50$
Solubility Soluble in conventional organic solvents; practically insoluble in water.
Comments The EINECS number for dioctyl phthalate is 204-214-7.

18 Comments

In addition to a number of industrial applications, dibutyl phthalate is used as an insect repellent, although it is not as effective as dimethyl phthalate.

A specification for dibutyl phthalate is included in the *Japanese Pharmaceutical Excipients* (JPE).[8]

The EINECS number for dibutyl phthalate is 201-557-4. The PubChem Compound ID (CID) for dibutyl phthalate is 3026.

Dibutyl Sebacate

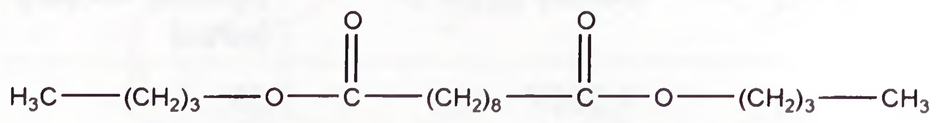
1 Nonproprietary Names

USP–NF: Dibutyl Sebacate

2 Synonyms

Bis(*n*-butyl)sebacate; butyl sebacate; DBS; decanedioic acid, dibutyl ester; dibutyl decanedioate; dibutyl 1,8-octanedicarboxylate; *Kodaflex DBS*; *Morflex DBS*; *Proviplast 1944*; sebacic acid dibutyl ester; *Stelliesters DBS*.

3 Chemical Name and CAS Registry Number



Decanedioic acid, di-*n*-butyl ester [109-43-3]

4 Empirical Formula and Molecular Weight

$C_{18}H_{34}O_4$ 314.47

The USP 40–NF 35 S1 describes dibutyl sebacate as consisting of the esters of *n*-butyl alcohol and saturated dibasic acids, principally sebacic acid.

5 Structural Formula

6 Functional Category

Plasticizing agent.

7 Applications in Pharmaceutical Formulation or Technology

Dibutyl sebacate is used in oral pharmaceutical formulations as a plasticizer for film coatings on tablets, beads, and granules, at concentrations of 10–30% by weight of polymer.[1–3] It is also used as a plasticizer in controlled-release tablets and microcapsule preparations.[4–7]

Dibutyl sebacate has been used in the preparation of controlled-release buccal and trandermal patches as a component of the adhesive.[8,9]

8 Description

Dibutyl sebacate occurs as a clear, colorless, oily liquid with a bland to slight butyl odor.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for dibutyl sebacate.

Test	USP 40–NF 35 S1
Specific gravity	0.935–0.939
Refractive index	1.429–1.441
Acid value	≤0.1
Saponification value	352–360
Assay (of $C_{18}H_{34}O_4$)	92.0–102.0%

10 Typical Properties

Acid value 0.02
Boiling point 344–349°C; 180°C at 3 mmHg for *Morflex DBS*
Flash point 193°C; 178°C for *Morflex DBS* and *Proviplast 1944*
Melting point −11°C; −10°C for *Proviplast 1944*
Refractive index n_D^{25} = 1.429–1.441 at 25°C for *Morflex DBS*; 1.441–1.442 at 20°C for *Proviplast 1944*
Solubility Soluble in ethanol (95%), ether, isopropanol, mineral oil, and toluene; practically insoluble in water.
Specific gravity 0.869 at 20°C; 0.941 at 15°C
Spectroscopy

IR spectrum *see* Figure 1.

Raman spectrum *see* Figure 2.

Vapor density (relative) 10.8 (air = 1)
Vapor pressure 0.4 kPa (3 mmHg) at 180°C
Viscosity 8-10 mPa s (8-10 cP) at 20°C for *Proviplast 1944*

11 Stability and Storage Conditions

Dibutyl sebacate should be stored in a closed container in a cool, dry location. Dibutyl sebacate is stable under the recommended storage conditions and as used in specified applications under most conditions of use. As an ester, dibutyl sebacate may hydrolyze in the presence of water at high or low pH conditions.

12 Incompatibilities

Dibutyl sebacate is incompatible with strong oxidizing materials and strong alkalis.

13 Method of Manufacture

Dibutyl sebacate is manufactured by the esterification of *n*-butanol and sebacic acid in the presence of a suitable catalyst, and by the distillation of sebacic acid with *n*-butanol in the presence of concentrated acid.

14 Safety

Dibutyl sebacate is used in cosmetics, foods, and oral pharmaceutical formulations, and is generally regarded as a nontoxic and nonirritant material. Following oral administration, dibutyl sebacate is metabolized in the same way as fats. In humans, direct eye contact and prolonged or repeated contact with the skin may cause very mild irritation. Acute animal toxicity tests and long-term animal feeding studies have shown no serious adverse effects to be associated with orally administered dibutyl sebacate.

LD_{50} (rat, oral): 16 g/kg[10]

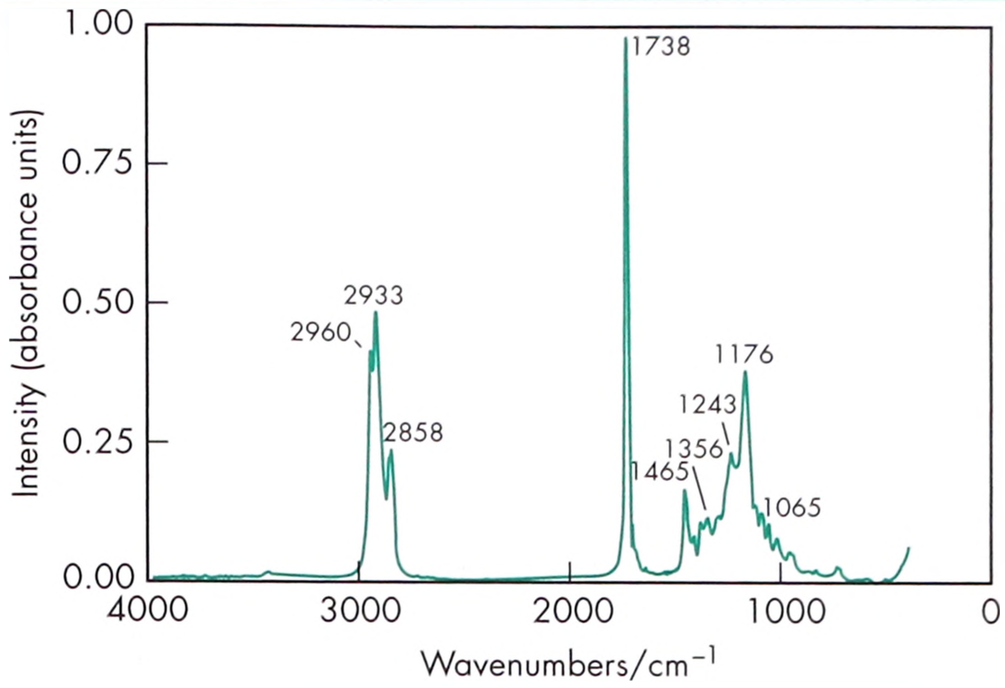


Figure 1: Infrared spectrum of dibutyl sebacate measured by transmission. Adapted with permission of Informa Healthcare.

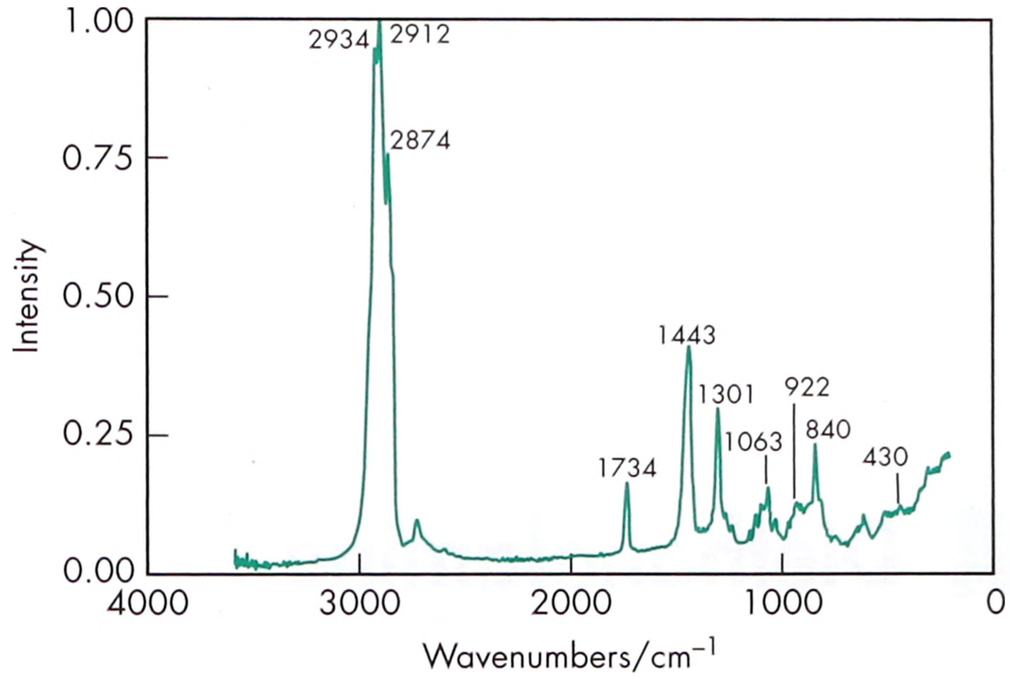

Figure 2: Raman spectrum of dibutyl sebacate measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. It is recommended that eye protection be used at all times. When heating this product, it is recommended to have a well-ventilated area, and the use of a respirator is advised.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral capsules, granules, and tablets). Dibutyl sebacate is listed as a food additive in the EAFUS list compiled by the FDA. Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Diethyl sebacate.

18 Comments

As dibutyl sebacate is an emollient ester, the personal care grade is recommended for use in cosmetics, hair products, lotions, and creams. Dibutyl sebacate is also used as a synthetic flavor and flavor adjuvant in food products;[11] for example, up to 5 ppm is used in ice cream and nonalcoholic beverages.

The EINECS number for dibutyl sebacate is 203-672-5. The PubChem Compound ID (CID) for dibutyl sebacate is 7986.

Hygroscopicity Very hygroscopic.
Melting point 28°C
Refractive index n_D^{30} = 1.4753
Solubility *see* Table II.

Table II: Solubility of diethanolamine.

Solvent	Solubility at 20°C
Acetone	Miscible
Benzene	1 in 24
Chloroform	Miscible
Ether	1 in 125
Glycerin	Miscible
Methanol	Miscible
Water	1 in 1

Surface tension 49.0 mN/m (49.0 dynes/cm) at 20°C
Vapor density (relative) 3.65 (air = 1)
Vapor pressure >1 Pa at 20°C
Viscosity (dynamic)

351.9 mPa s (351.9 cP) at 30°C;

53.85 mPa s (53.85 cP) at 60°C.

11 Stability and Storage Conditions

Diethanolamine is hygroscopic and light- and oxygen-sensitive; it should be stored in an airtight container, protected from light, in a cool, dry place.

See Monoethanolamine for further information.

12 Incompatibilities

Diethanolamine is a secondary amine that contains two hydroxy groups. It is capable of undergoing reactions typical of secondary amines and alcohols. The amine group usually exhibits the greater activity whenever it is possible for a reaction to take place at either the amine or a hydroxy group.

Diethanolamine will react with acids, acid anhydrides, acid chlorides, and esters to form amide derivatives, and with propylene carbonate or other cyclic carbonates to give the corresponding carbonates. As a secondary amine, diethanolamine reacts with aldehydes and ketones to yield aldimines and ketimines. Diethanolamine also reacts with copper to form complex salts. Discoloration and precipitation will take place in the presence of salts of heavy metals.

13 Method of Manufacture

Diethanolamine is prepared commercially by the ammonolysis of ethylene oxide. The reaction yields a mixture of monoethanolamine, diethanolamine, and triethanolamine which is separated to obtain the pure products.

14 Safety

Diethanolamine is used in topical and parenteral pharmaceutical formulations, with up to 1.5% w/v being used in intravenous infusions. Experimental studies in dogs have shown that intravenous administration of larger doses of diethanolamine results in sedation, coma, and death.

Animal toxicity studies suggest that diethanolamine is less toxic than monoethanolamine, although in rats the oral acute and subacute toxicity is greater.[1] Diethanolamine is said to be heptacarcinogenic in mice and has also been reported to induce hepatic choline deficiency in mice.[2]

Diethanolamine is an irritant to the skin, eyes, and mucous membranes when used undiluted or in high concentration. However, in rabbits, aqueous solutions containing 10% w/v diethanolamine produce minor irritation. The lethal human oral dose of diethanolamine is estimated to be 5–15 g/kg body-weight.

The US Cosmetic Ingredient Review Expert Panel evaluated diethanolamine and concluded that it is safe for use in cosmetic formulations designed for discontinuous, brief use followed by thorough rinsing from the surface of the skin. In products intended for prolonged contact with the skin, the concentration of ethanolamines should not exceed 5%. Diethanolamine should not be used in products containing *N*-nitrosating agents.[1]

See also Section 18.

LD_{50} (guinea pig, oral): 2.0 g/kg[3]
LD_{50} (mouse, IP): 2.3 g/kg
LD_{50} (mouse, oral): 3.3 g/kg
LD_{50} (rabbit, skin): 12.2 g/kg
LD_{50} (rat, IM): 1.5 g/kg
LD_{50} (rat, IP): 0.12 g/kg
LD_{50} (rat, IV): 0.78 g/kg
LD_{50} (rat, oral): 0.71 g/kg
LD_{50} (rat, SC): 2.2 g/kg

15 Handling Precautions

Diethanolamine is irritating to the skin, eyes, and mucous membranes. Protective clothing, gloves, eye protection, and a respirator are recommended. Ideally, diethanolamine should be handled in a fume cupboard. Diethanolamine poses a slight fire hazard when exposed to heat or flame.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (IV infusions, ophthalmic solutions, and topical preparations). Included in medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Monoethanolamine; triethanolamine.

18 Comments

Through a standard battery of rodent studies, diethanolamine has been identified by the US National Toxicology Program as a potential carcinogen following topical administration. Several possible confounding issues have been noted during the review of these studies, which may affect the ultimate conclusion made regarding the carcinogenicity of diethanolamine and the relevance of these findings to humans. Diethanolamine is not permitted for use in cosmetics sold within the EU.

The EINECS number for diethanolamine is 203-868-0. The PubChem Compound ID (CID) for diethanolamine is 8113.

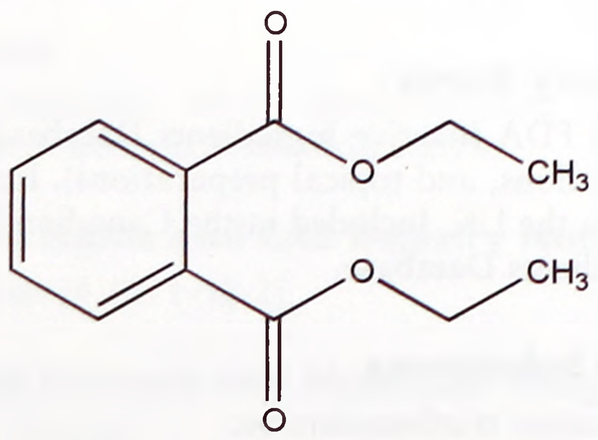
Diethyl Phthalate

1 Nonproprietary Names

BP: Diethyl Phthalate
PhEur: Diethyl Phthalate
USP–NF: Diethyl Phthalate

2 Synonyms

DEP; diethyl benzene-1,2-dicarboxylate; diethylis phthalas; *Eastman DEP*; ethyl benzene-1,2-dicarboxylate; ethyl phthalate; *Kodaflex DEP*; *Neantine*; *Palatinol A*; phthalic acid diethyl ester.



3 Chemical Name and CAS Registry Number

1,2-Benzenedicarboxylic acid, diethyl ester [84-66-2]

4 Empirical Formula and Molecular Weight

$C_{12}H_{14}O_4$ 222.24

5 Structural Formula

6 Functional Category

Plasticizing agent; solvent.

7 Applications in Pharmaceutical Formulation or Technology

Diethyl phthalate is used as a plasticizing agent for film coatings on tablets, beads, and granules at concentrations of 10–30% by weight of polymer.[1–3]

8 Description

Diethyl phthalate is a clear, colorless, oily liquid. It is practically odorless, or with a very slight aromatic odor and a bitter, disagreeable taste.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for diethyl phthalate.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	–
Specific gravity	1.117–1.121	1.118–1.122
Refractive index	1.500–1.505	1.500–1.505
Appearance	+	–
Acidity	+	+
Related substances	+	–
Water	≤0.2%	≤0.2%
Residue on ignition	–	≤0.02%
Sulfated ash	≤0.1%	–
Assay (anhydrous basis)	99.0–101.0%	98.0–102.0%

10 Typical Properties

Boiling point 295°C
Flash point 160°C (open cup)
Melting point −40°C
Refractive index $n_D^{25} = 1.501$
Solubility Miscible with ethanol (95%), ether, and many other organic solvents; practically insoluble in water.
Specific gravity 1.120 at 25°C

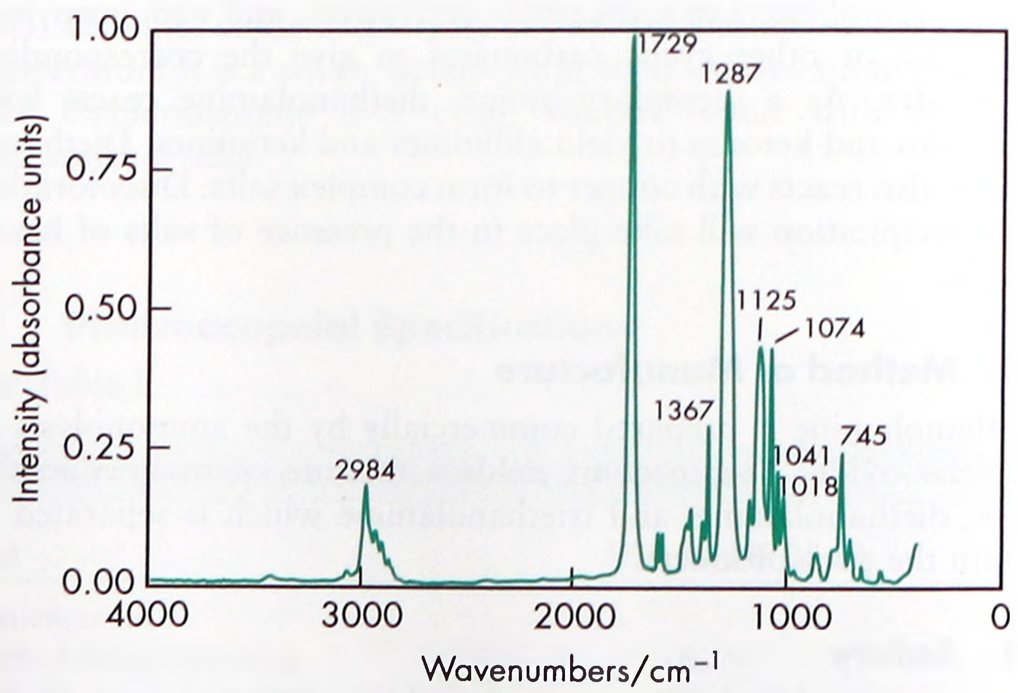


Figure 1: Infrared spectrum of diethyl phthalate measured by transmission. Adapted with permission of Informa Healthcare.

Spectroscopy
IR spectrum *see* Figure 1.
Vapor density (relative) 7.66 (air = 1)
Vapor pressure 1.87 kPa (14 mmHg) at 163°C

11 Stability and Storage Conditions

Diethyl phthalate is stable when stored in a well-closed container in a cool, dry place.

12 Incompatibilities

Diethyl Phthalate is incompatible with strong oxidizing materials, acids, and permanganates.

13 Method of Manufacture

Diethyl phthalate is produced by the reaction of phthalic anhydride with ethanol in the presence of sulfuric acid.

14 Safety

Diethyl phthalate is used in oral pharmaceutical formulations and is generally regarded as a nontoxic and nonirritant material at the levels employed as an excipient. However, if consumed in large quantities it can act as a narcotic and cause paralysis of the central nervous system.

Although some animal studies have suggested that high concentrations of diethyl phthalate may be teratogenic, other studies have shown no adverse effects.[4]

LD_{50} (guinea pig, oral): 8.6 g/kg[5]
LD_{50} (mouse, IP): 2.7 g/kg
LD_{50} (mouse, oral): 6.2 g/kg
LD_{50} (rat, IP): 5.1 g/kg
LD_{50} (rat, oral): 8.6 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Diethyl phthalate is irritant to the skin, eyes, and mucous membranes. Protective clothing, eye protection, and nitrile gloves are recommended. Diethyl phthalate should be handled in a fume cupboard or a well-ventilated environment; a respirator is recommended. In the UK, the long-term (8-hour TWA) workplace exposure limit for diethyl phthalate is 5 mg/m^3. The short-term (15-minute) workplace exposure limit is 10 mg/m^3.[6]

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral capsules and tablets). Included in nonparenteral medicines licensed in the UK (oral capsules and tablets). Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Dibutyl phthalate; dimethyl phthalate.

18 Comments

Diethyl phthalate is used as an alcohol denaturant and as a solvent for cellulose acetate in the manufacture of varnishes and dopes. In perfumery, diethyl phthalate is used as a perfume fixative at a concentration of 0.1–0.5% of the weight of the perfume used.

A specification for diethyl phthalate is included in the *Japanese Pharmaceutical Excipients* (JPE).[7]

The EINECS number for diethyl phthalate is 201-550-6. The PubChem Compound ID (CID) for diethyl phthalate is 6781.

Diethyl Sebacate

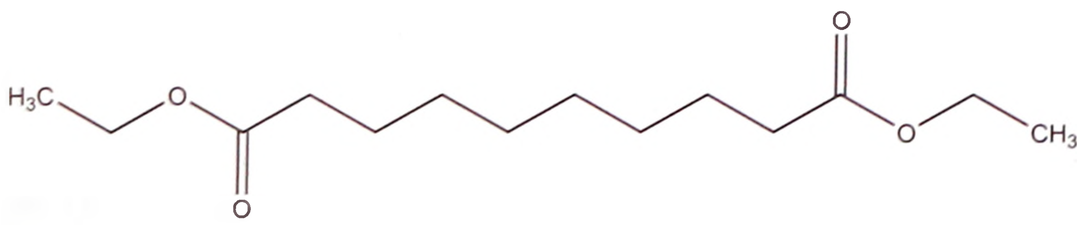
D

1 Nonproprietary Names

USP–NF: Diethyl Sebacate

2 Synonyms

Bisoflex DES; decanedioic acid, diethyl ester; DES; diethyl 1,10-decanedioate; diethyl 1,8-octanedicarboxylate; ethyl sebacate; *DES-SP*; sebacic acid, diethyl ester; *Stelliesters DES*.



3 Chemical Name and CAS Registry Number

Diethyl decanedioate [110-40-7]

4 Empirical Formula and Molecular Weight

$C_{14}H_{26}O_4$ 258.35

5 Structural Formula

6 Functional Category

Emollient; penetration enhancer.

7 Applications in Pharmaceutical Formulation or Technology

Diethyl sebacate is used as an emollient in topical creams, emulsions, and solutions. It has been shown to aid skin penetration of various anti-inflammatory,[1,2] antifungal,[3] and local anesthetic[4] drugs, at concentrations of up to 24%.

Diethyl sebacate is also used as a flavoring agent in foods.[5]

8 Description

Diethyl sebacate is a colorless or yellowish liquid with a characteristic fruity odor.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for diethyl sebacate.

Test	USP 40–NF 35 S1
Identification	+
Residue on ignition	≤0.10%
Heavy metals	≤20 ppm
Specific gravity	0.958–0.968
Refractive index	1.435–1.437
Acid value	≤0.5
Iodine value	≤0.5
Assay	98.0%–100.5%

10 Typical Properties

Boiling point 307–312°C (with some decomposition)
Flash point > 93°C (closed cup); 113°C (open cup)
Melting point 1–3°C
Partition coefficient Log *P* (octanol : water) = 3.8–4.3 (calculated)
Refractive index $n_D^{20} = 1.435$
Solubility Miscible with alcohol, ether, hydrocarbons, fixed oils and fats; soluble 1 in 700 cold water, 1 in 50 boiling water.
Specific Gravity 0.960–0.965 at 20°C
Surface tension 33.2 mN/m at 20°C
Viscosity (dynamic) 6.1 mPa s (6.1 cP) at 20°C

11 Stability and Storage Conditions

Diethyl sebacate is stable to hydrolysis at room temperature and does not tend to go rancid.

Store in tightly closed containers in a cool, well-ventilated area. Protect from light. Keep away from heat and sources of ignition.

12 Incompatibilities

Diethyl sebacate is incompatible with oxidizing agents and alkalis.

13 Method of Manufacture

Diethyl sebacate is prepared by the esterification of sebacic acid and ethanol in the presence of sulfuric acid.

14 Safety

Diethyl sebacate is mildly toxic by ingestion and a skin irritant. It may cause irritation to the eyes and mucous membranes. Contact dermatitis due to diethyl sebacate has been reported.[6,7]

LD_{50} (guinea pig, oral): 7.28 g/kg[8]
LD_{50} (rat, oral): 14.47 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. When heated, diethyl sebacate emits acrid smoke and irritating fumes. Wear suitable protective clothing. Avoid contact with skin and eyes.

16 Regulatory Status

GRAS listed. Included in the FDA Inactive Ingredients Database (topical; emulsions, creams, solutions). Diethyl sebacate is listed as a food additive in the EAFUS list compiled by the FDA.

17 Related Substances

Dibutyl sebacate.

18 Comments

Diethyl sebacate has been used in PEG-poly(amine-co-ester) block copolymer micelles as a novel anticancer drug delivery system.[9]

A specification for diethyl sebacate is included in the *Food Chemicals Codex* (FCC)[5] and in the *Japanese Pharmaceutical Excipients* (JPE);[10] *see* Table II.

The EINECS number for diethyl sebacate is 203-764-5. The PubChem Compound ID (CID) is 8049.

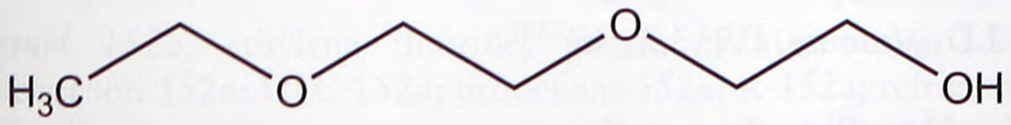
Diethylene Glycol Monoethyl Ether

1 Nonproprietary Names

BP: Diethylene Glycol Monoethyl Ether
PhEur: Diethylene Glycol Monoethyl Ether
USP–NF: Diethylene Glycol Monoethyl Ether

2 Synonyms

Carbitol; DEGEE; DGME; diethylenglycoli aether monoethilicus; 3,6-dioxa-1-octanol; ethoxydiglycol; ethyl carbitol; ethyl digol; ethyl dioxitol; 1-hydroxy-3,6-dioxaoctane; *Transcutol HP*; *Transcutol P*.



3 Chemical Name and CAS Registry Number

2-(2-Ethoxyethoxy)ethanol [111-90-0]

4 Empirical Formula and Molecular Weight

$C_6H_{14}O_3$ 134.17

5 Structural Formula

6 Functional Category

Solubilizing agent; solvent.

7 Applications in Pharmaceutical Formulation or Technology

Diethylene glycol monoethyl ether is a solubilizing agent with broad chemical compatibility and widely used in oral, dermal, and parenteral pharmaceutical preparations. It is used as a cosolvent in oral drug delivery systems to enhance drug solubility, with the level of use limited to 10%. Purified diethylene glycol monoethyl ether is also used in some injectable products.[1]

Diethylene glycol monoethyl ether has been reported to enhance skin penetration for a variety of drugs, and is used in creams, lotions, microemulsions, and aqueous gels.[2–14] Diethylene glycol monoethyl ether is also used in cosmetic formulations.

8 Description

Diethylene glycol monoethyl ether is a clear, colorless, hygroscopic liquid with a mild odor.

9 Pharmacopeial Specifications

See Table I.

10 Typical Properties

Autoignition temperature
201°C for *Carbitol*;[15]
204°C for *Transcutol*.[16]
Boiling point
201°C for *Carbitol*;
198°C for *Transcutol*.
Density 0.988 g/cm^3

Table I: Pharmacopeial specifications for diethylene glycol monoethyl ether.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	–
Relative density	≈0.991	–
Refractive index at 20°C	1.426–1.428	1.426–1.428

Diethylene glycol	≤250 ppm	≤150 µg/g
Total impurities	≤0.2%	–
Water	≤0.1%	≤0.1%
Assay	–	99–101%

Evaporation rate

0.01 for *Carbitol*;

0.02 for *Transcutol* (*n*-butyl acetate = 1.0).

Explosive limit

1.2% volume at 135°C (lower limit);

23.5% volume at 182°C (upper limit) for *Transcutol*.

Flash point

90°C for *Carbitol*;

96.1°C for *Transcutol*.

Freezing point

–43°C for *Carbitol*;

–105°C for *Transcutol*.

Hygroscopicity At a relative humidity of 8–50% the equilibrium moisture content at 25°C is approx. 8% w/w, but at a relative humidity of 70% it is approx. 24% w/w.

Partition coefficient Log *P* (octanol : water) = –0.54

Solubility Soluble in water; miscible in acetone, benzene, chloroform, ethanol (95%), ether, and pyridine; partially soluble in vegetable oils; insoluble in mineral oils.

Specific heat 2.193 J/g/°C (0.52 cal/g/°C) at 25°C for *Carbitol*

Spectroscopy

IR spectrum *see* Figure 1.

Raman spectrum *see* Figure 2.

Vapor density 4.6 (air = 1)

Vapor pressure

9.33 Pa (0.07 mmHg) at 20°C for *Carbitol*;

16.0 Pa (0.12 mmHg) at 20°C for *Transcutol*.

Viscosity 4.5 mPa s (4.5 cP) at 25°C for *Carbitol*.

11 Stability and Storage Conditions

Diethylene glycol monoethyl ether is very stable and inert in its original container. It is hygroscopic and sensitive to water uptake and oxidation. If the drug being formulated is sensitive to oxidation, the addition of a suitable antioxidant prior to processing is required.

Store in a cool, dry, well-ventilated area in a tightly closed container filled with nitrogen. Keep away from sources of ignition.

12 Incompatibilities

—

13 Method of Manufacture

Diethylene glycol monoethyl ether is obtained by *O*-alkylation of ethanol with two ethylene oxide units.

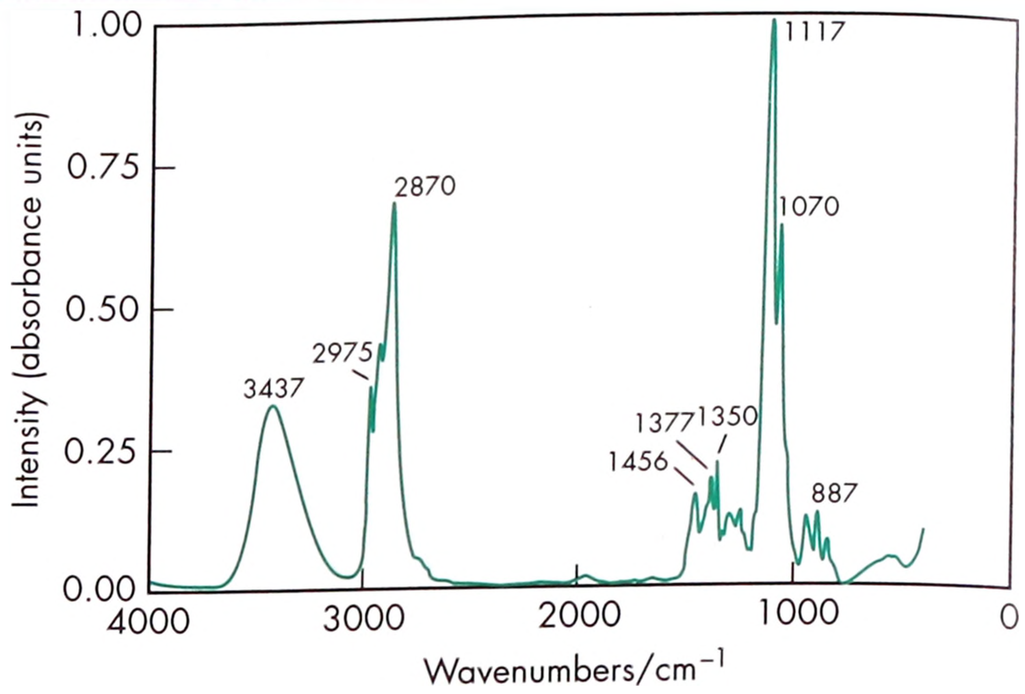

Figure 1: Infrared spectrum of diethylene glycol monoethyl ether measured by transmission. Adapted with permission of Informa Healthcare.

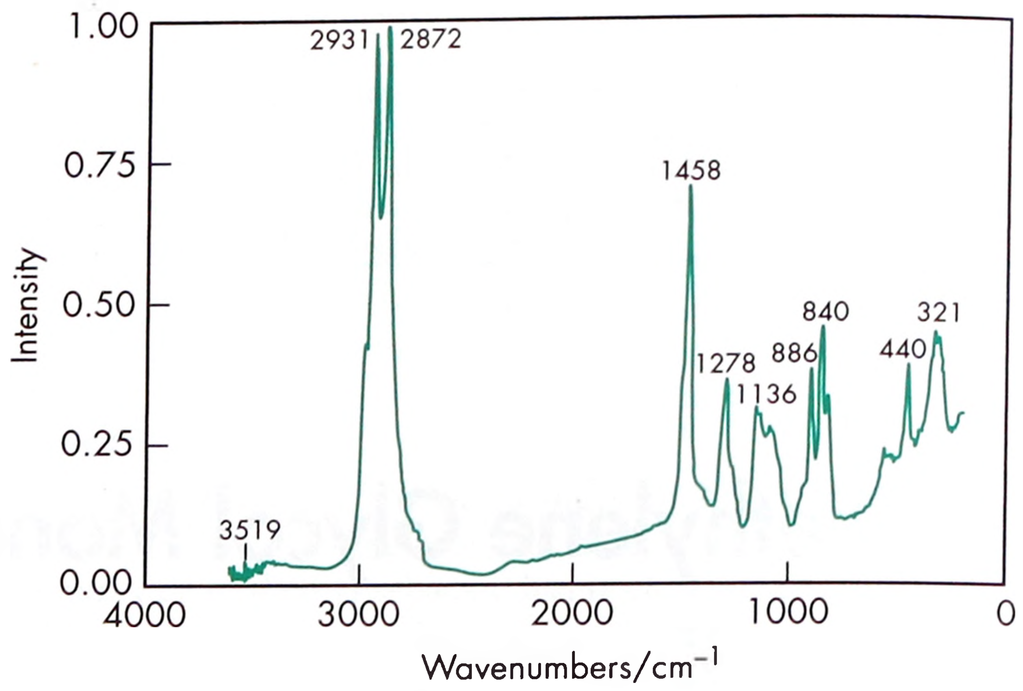

Figure 2: Raman spectrum of diethylene glycol monoethyl ether measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

14 Safety

Diethylene glycol monoethyl ether is used in a wide variety of pharmaceutical formulations for oral, dermal, and parenteral administration, and as a cosmetic ingredient. It is generally regarded as nonirritant and nontoxic.

The Cosmetic Ingredient Review (CIR) Expert Panel has evaluated diethylene glycol monoethyl ether and found it to be safe as presently used in cosmetics at a maximum concentration of 50%.[17]

The acute toxicity of diethylene glycol monoethyl ether after oral, IV, and dermal application as well as inhalation has been studied and can be regarded as very low in all species investigated. The LD_{50} values for acute oral, acute IV, and acute dermal toxicity were found to be generally much higher than 2 g/kg body weight, and the available LC_{50} value for acute inhalation was >5 mg/L (i.e. 5.24 mg/L) in rat,[18] in each case above the limit doses for classification.

LD_{50} (rat, oral): >5 g/kg[19]

LD_{50} (mouse, IV): 3.2 g/kg[20]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantities of material handled. Diethylene glycol monoethyl ether should be used with adequate ventilation. Avoid contact with eyes, skin, and clothing. Wear suitable protective clothing.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (topical and transdermal gels). Approved in the US as an indirect food additive. Included in nonparenteral formulations available in the UK and France. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

—

18 Comments

A number of studies have shown that the inclusion of diethylene glycol monoethyl ether can improve localized drug delivery by increasing drug retention in the skin. This is associated with the swelling of lipid bilayer structures which subsequently act as a depot for drug–solvent complexes, which enables the slow and localized diffusion of the drug over time.[3–5,14]

The EINECS number for diethylene glycol monoethyl ether is 203-919-7. The PubChem Compound ID (CID) for diethylene glycol monoethyl ether is 8146.

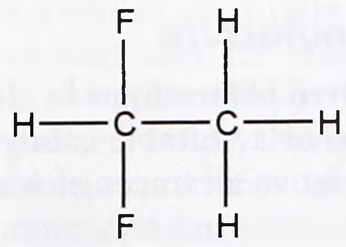
Difluoroethane (HFC)

1 Nonproprietary Names

None adopted.

2 Synonyms

Dymel 152a; ethylene fluoride; *Freon 152aGenetron 152a*; halocarbon 152a; HFC 152a; propellant 152a; R-152a; refrigerant 152a; *Solkane 152a*.



3 Chemical Name and CAS Registry Number

1,1-Difluoroethane [75-37-6]

4 Empirical Formula and Molecular Weight

$C_2H_4F_2$ 66.05

5 Structural Formula

6 Functional Category

Aerosol propellant.

7 Applications in Pharmaceutical Formulation or Technology

Difluoroethane, a hydrofluorocarbon (HFC), is an aerosol propellant and may be used in topical pharmaceutical formulations.[1]

Since difluoroethane does not contain chlorine, there are no environmental controls on the use of this material as a propellant, since it does not deplete the ozone layer and is not a greenhouse gas. However, its use in pharmaceutical aerosols is limited.

8 Description

Difluoroethane is a liquefied gas and exists as a liquid at room temperature when contained under its own vapor pressure, or as a gas when exposed to room temperature and atmospheric pressure. The liquid is colorless and has a faintly sweet odor.[2] Difluoroethane is noncorrosive and nonirritating.

9 Pharmacopeial Specifications

—

10 Typical Properties

Boiling point −25.0°C at 760 mmHg for *Dymel* 152a[3]
Critical temperature 113.5°C
Density

0.90 g/cm^3 for liquid at 25°C for *Dymel* 152a;[3]

0.81 g/cm^3 for liquid at 54.5°C.

Flammability Flammable. Limits of flammability 3.7–20.2% v/v in air.
Flash point <−50°C for *Dymel* 152a[3]
Ignition temperature 454°C for *Dymel* 152a[3]
Melting point −117°C
Partition coefficient Log *P* (octanol : water) 0.75[2]
Solubility Soluble 1 in 357 parts of water at 25°C.
Surface tension 11.25 mN/m (11.25 dynes/cm) for liquid at 20°C.
Vapor density (absolute) 2.949 g/m^3 at standard temperature and pressure.
Vapor density (relative) 2.29 (air = 1)
Vapor pressure

600 kPa (61.7 psig) at 21.1°C;

1317 kPa (191 psia) at 54.5°C.

Viscosity (dynamic) 0.243 mPa s (0.243 cP) for liquid at 20°C.

11 Stability and Storage Conditions

Difluoroethane is a nonreactive and stable material. The liquefied gas is stable when used as a propellant and should be stored in a metal cylinder in a cool, dry, well-ventilated place.

12 Incompatibilities

Difluoroethane is incompatible with alkali metals, alkaline earth metals, powdered metals, powdered metal salts, and oxidizing materials.[2–4] However, it is compatible with the usual ingredients used in the formulation of pharmaceutical aerosols.

13 Method of Manufacture

Difluoroethane is prepared from ethyne by the addition of hydrogen fluoride in the presence of a suitable catalyst. The difluoroethane formed is purified to remove all traces of water, as well as traces of the starting materials.

14 Safety

Difluoroethane is no longer used as an aerosol propellant in topical pharmaceutical formulations.

When propellants are used in topical aerosols they may cause a chilling effect on the skin, although this effect has been somewhat overcome by the use of vapor-tap valves. The propellants quickly vaporize from the skin, and are nonirritating when used as directed.

LD_{50} (rat, oral): 1.5 g/kg[5]
LC_{50} (rat, inhalation): >64 000[5]

15 Handling Precautions

Difluoroethane is usually encountered as a liquefied gas and appropriate precautions for handling such materials should be taken. Eye protection, gloves, and protective clothing are recommended. Difluoroethane should be handled in a well-ventilated environment. Fluorocarbon vapors are heavier than air and do not support life; therefore, when cleaning large tanks that have contained these propellants, adequate provision for oxygen supply in the tanks must be made in order to protect workers cleaning the tanks.

Difluoroethane is extremely flammable; *see* Section 10. When it is heated to decomposition, toxic fumes of hydrogen fluoride, and possibly carbonyl fluoride, may be formed.[3]

16 Regulatory Status

Accepted in the US, by the FDA, for use as a topical aerosol propellant. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Tetrafluoroethane.

18 Comments

Although difluoroethane is no longer available for use in pharmaceutical formulation, the monograph remains in the *Handbook* to assist formulators in their understanding of old products, whose properties they may need to reproduce. It may still be present in some commercial products.

Difluoroethane is useful as an aerosol propellant in that it shows greater miscibility with water than some other fluorocarbons. For a discussion of the numerical nomenclature applied to this aerosol propellant, *see* Chlorofluorocarbons (CFC).

Difluoroethane has also been used as a component of blowing agents used to form polystyrene foams.[6]

The PubChem Compound ID (CID) for difluoroethane is 6368. The EINECS number for difluoroethane is 200-866-1.

Dimethicone

1 Nonproprietary Names

BP: Dimeticone

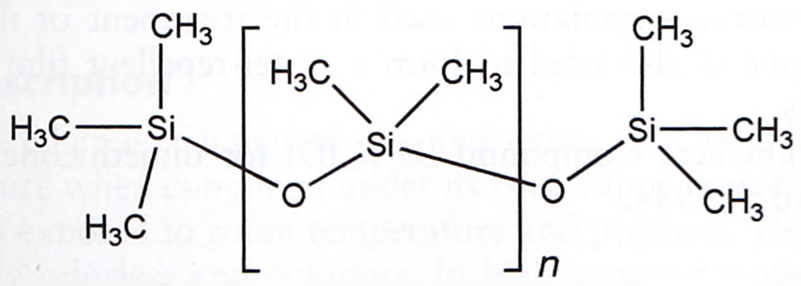
PhEur: Dimeticone

USP–NF: Dimethicone

2 Synonyms

ABIL; dimethylpolysiloxane; dimethylsilicone fluid; dimethylsiloxane; dimeticonum; *Dow Corning Q7-9120*; E900; methyl polysiloxane; PDMS; poly(dimethylsiloxane); Sentry Dimethicone; *Xiameter*.

3 Chemical Name and CAS Registry Number



α-(Trimethylsilyl)-ω-methylpoly[oxy(dimethylsilylene)]
[9006-65-9]

4 Empirical Formula and Molecular Weight

The PhEur 9.2 describes dimethicone as a polydimethylsiloxane obtained by hydrolysis and polycondensation of dichlorodimethylsilane and chlorotrimethylsilane. The degree of polymerization (n = 20–400) is such that materials with kinematic viscosities nominally 20–1300 mm^2/s (20–1300 cSt) are produced. Dimethicones with a nominal viscosity of 50 mm^2/s (50 cSt) or lower are intended for external use only.

The USP 40–NF 35 S1 describes dimethicone as a mixture of fully methylated linear siloxane polymers containing repeating units of the formula $[-(CH_3)_2SiO-]_n$ stabilized with trimethylsiloxy endblocking units of the formula $[(CH_3)_3SiO-]$, where n has an average value such that the corresponding nominal viscosity is in a discrete range 20–30 000 mm^2/s (20–30 000 cSt).

5 Structural Formula

6 Functional Category

Antifoaming agent; emollient; water-repelling agent.

7 Applications in Pharmaceutical Formulation or Technology

Dimethicones of various viscosities are widely used in cosmetic and pharmaceutical formulations. In topical oil-in-water emulsions dimethicone is added to the oil phase as an antifoaming agent. Dimethicone is hydrophobic and is also widely used in topical barrier preparations. *See* Table I.

Table I: Uses of dimethicone.

Use	Concentration (%)
Creams, lotions, and ointments	10.0–30.0
Oil–water emulsions	0.5–5.0

8 Description

Dimethicones are clear, colorless liquids available in various viscosities; *see* Section 4.

9 Pharmacopeial Specifications

See Table II.

10 Typical Properties

Acid value <0.01

Density 0.94–0.98 g/cm^3 at 25°C

Refractive index n_D^{25} = 1.401–1.405

Solubility Miscible with ethyl acetate, methyl ethyl ketone, mineral oil, ether, chloroform, and toluene; soluble in isopropyl myristate; very slightly soluble in ethanol (95%); practically insoluble in glycerin, propylene glycol, and water.

Spectroscopy

IR spectrum *see* Figure 1.

Raman spectrum *see* Figure 2.

Surface tension 20.5–21.2 mN/m at 25°C

11 Stability and Storage Conditions

Dimethicones should be stored in an airtight container in a cool, dry place; they are stable to heat and are resistant to most chemical substances although they are affected by strong acids. Thin films of dimethicone may be sterilized by dry heat for at least 2 hours at 160°C. Sterilization of large quantities of dimethicone by steam autoclaving is not recommended since excess water diffuses into the

fluid causing it to become hazy. However, thin films may be sterilized by this method. Gamma irradiation may also be used to sterilize dimethicone. Gamma irradiation can, however, cause crosslinking with a consequent increase in the viscosity of fluids.

12 Incompatibilities

—

13 Method of Manufacture

Dimethicone is a poly(dimethylsiloxane) obtained by hydrolysis and polycondensation of dichlorodimethylsilane and chlorotrimethylsilane. The hydrolysis products contain active silanol groups through which condensation polymerization proceeds. By varying the proportions of chlorotrimethylsilane, which acts as a chain terminator, silicones of varying molecular weight may be prepared. Different grades of dimethicone are produced that may be distinguished by a number placed after the name indicating the nominal viscosity. *See also* Section 4.

14 Safety

Dimethicone is generally regarded as a relatively nontoxic and nonirritant material although it can cause temporary irritation to the eyes. In pharmaceutical formulations it may be used in oral and topical preparations. Dimethicones are also used extensively in cosmetic formulations and in certain food applications.

The WHO has set a tentative estimated acceptable daily intake of dimethicone with a relative molecular mass in the range of 200–300 at up to 1.5 mg/kg body-weight.[1] Health Canada has set a temporary acceptable daily intake of up to 0.8 mg/kg body-weight for dimethicone.

Injection of silicones into tissues may cause granulomatous reactions. Accidental intravascular injection has been associated with fatalities.

The Cosmetic Ingredient Review (CIR) Expert Panel have assessed dimethicone and concluded that the material is safe as used in cosmetic formulations.[2]

LD_{50} (mouse, oral): >20 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Dimethicone is flammable and should not be exposed to naked flames or heat.

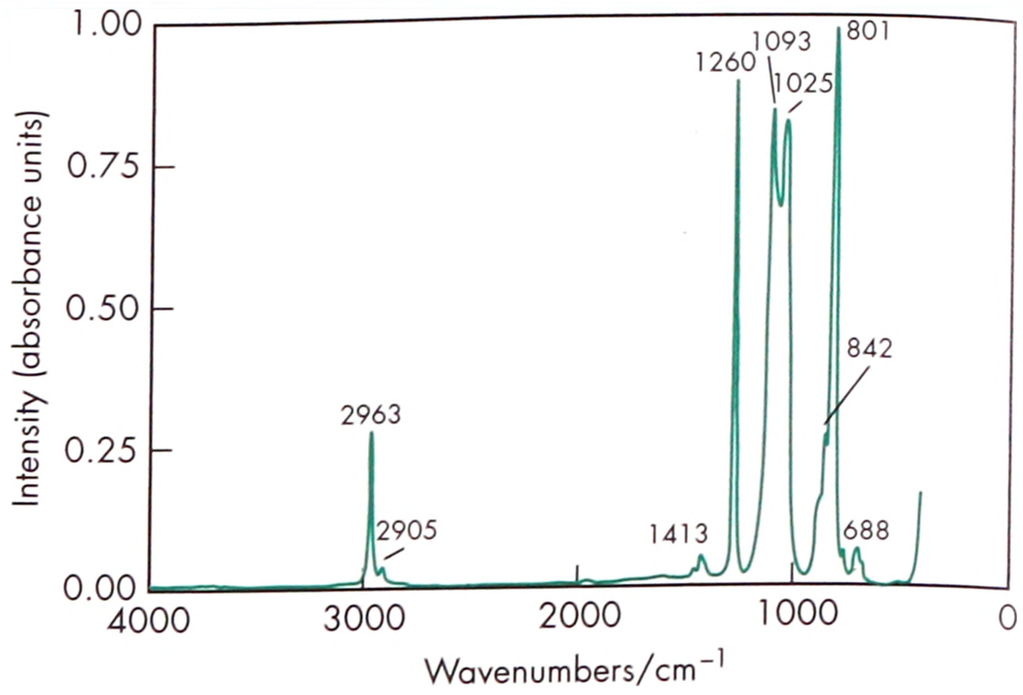

Figure 1: Infrared spectrum of dimethicone measured by transmission. Adapted with permission of Informa Healthcare.

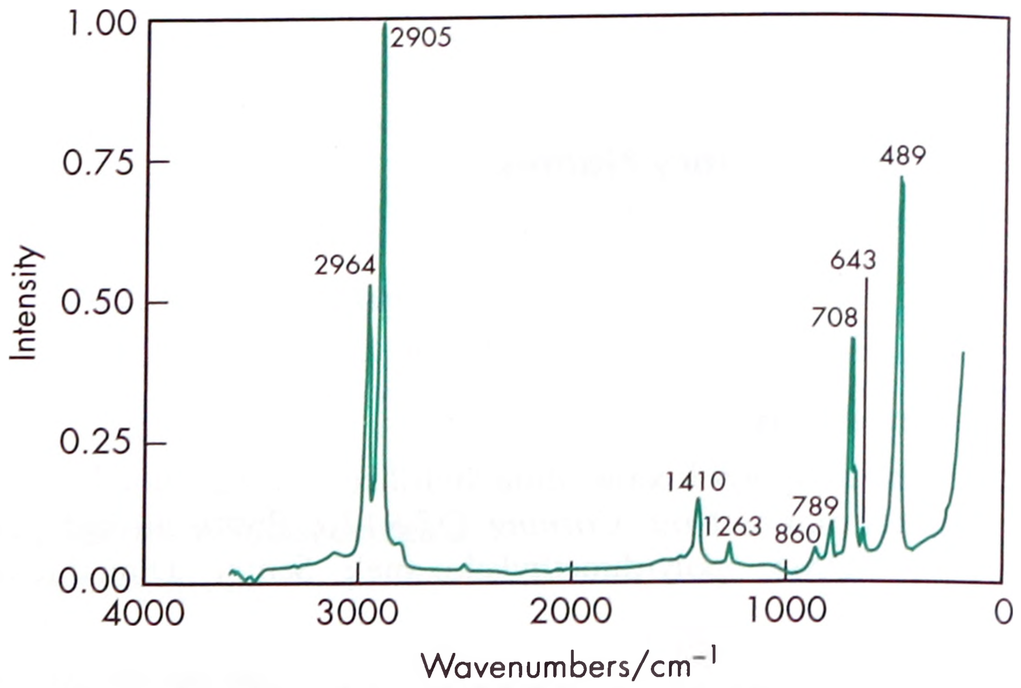

Figure 2: Raman spectrum of dimethicone measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

16 Regulatory Status

Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (IV and dental injections; oral capsules and tablets; topical creams, emulsions, gels, lotions, and solutions; and transdermal preparations). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Cyclomethicone; simethicone.

18 Comments

Therapeutically, dimethicone may be used with simethicone in oral pharmaceutical formulations used in the treatment of flatulence. Dimethicone is also used to form a water-repellent film on glass containers.

The PubChem Compound ID (CID) for dimethicone includes 24764 and 589984.

D

Dimethyl Ether

1 Nonproprietary Names

None adopted.

2 Synonyms

Demeon D; dimethyl oxide; DME; *Dymel A*; methoxymethane; methyl ether; oxybismethane; wood ether.

3 Chemical Name and CAS Registry Number

Methoxymethane [115-10-6]

4 Empirical Formula and Molecular Weight

C_2H_6O 46.07

5 Structural Formula

6 Functional Category

Aerosol propellant; solvent.

7 Applications in Pharmaceutical Formulation or Technology

Dimethyl ether may be used as an aerosol propellant for topical aerosol formulations, such as for wart removal.[1] It is used in combination with hydrocarbons and other propellants,[2–6] as it generally cannot be used alone due to its high vapor pressure.

Dimethyl ether is a good solvent, and has the unique property of high water solubility, compared to other propellants.[6]

Dimethyl ether has also been investigated for use in metered-dose inhaler aerosol formulations,[7,8] and studied for use as a propellant in chitosan foam designed to control haemorrhage during surgery for severe liver injury.[9]

8 Description

Dimethyl ether is a liquefied gas and exists as a liquid at room temperature when contained under its own vapor pressure, or as a gas when exposed to room temperature and pressure. The liquid is practically odorless and colorless. In high concentrations, the gas has a faint ether-like odor.

9 Pharmacopeial Specifications

—

10 Typical Properties

Autoignition temperature 226°C;[10] 350°C[11,12]
Boiling point −24.8°C
Critical temperature 126.9°C[11]
Density 0.66 g/cm^3 for liquid at 20°C.[11]
Flammability The pure material is flammable; limit of flammability is 3.4–18.2% v/v in air. Aqueous mixtures are nonflammable.
Freezing point −138.5°C
Flash point −41°C (closed cup)[10]
Heat of combustion −28.9 kJ/g (−6900 cal/g)
Kauri-butanol value 60 for *Dymel A*[13]
Solubility Soluble in acetone, chloroform, ethanol (95%), ether, and 1 in 3 parts of water. Dimethyl ether is generally miscible with water, nonpolar materials, and some semipolar materials. For pharmaceutical aerosols, ethanol (95%) is the most useful cosolvent. Glycols, oils, and other similar materials exhibit varying degrees of miscibility with dimethyl ether.
Surface tension 16 mN/m (16 dynes/cm) at −10°C
Vapor density (absolute) 2.058 g/m^3 at standard temperature and pressure.
Vapor density (relative) 1.59 (air = 1)[10]
Vapor pressure 533 kPa at 20°C[10] (63 psig at 21.1°C) for *Dymel A*[13]

11 Stability and Storage Conditions

The liquefied gas is stable when used as a propellant. However, exposure to the air for long periods of time may result in explosive peroxides being slowly formed.

Solutions of liquid dimethyl ether should not be concentrated either by distillation or by evaporation. Dimethyl ether should be stored in tightly closed metal cylinders in a cool, dry place, away from sunlight and potential sources of ignition.[10]

12 Incompatibilities

Dimethyl ether is incompatible with strong oxidizing agents and strong acids.[10] It is an aggressive solvent and may affect the gasket materials used in aerosol packaging. *See also* Section 10.

13 Method of Manufacture

Dimethyl ether can be produced from various sources, including biomass, natural gas, bituminous or lignite coals, which are initially converted to synthesis gas. From this, dimethyl ether is produced via either a two-step process, in which the intermediate methanol is formed in the presence of a copper-based catalyst and then

dehydrated with a silica-alumina catalyst to dimethyl ether, or directly using a dual catalyst system.[14]

14 Safety

Dimethyl ether may be used as a propellant and solvent in topical pharmaceutical aerosols, and is generally regarded as an essentially nontoxic and nonirritant material when used in such applications. The European Food Safety Authority has evaluated dimethyl ether as an extraction solvent and concluded that it is of no safety concern when used under the conditions of its intended use and within proposed residual limits.[15]

However, inhalation of high concentrations of dimethyl ether vapor is harmful. Additionally, skin contact with dimethyl ether liquid may result in freezing of the skin and severe frostbite.

When used in topical formulations, dimethyl ether may exert a chilling effect on the skin, although if it is used as directed the propellant quickly vaporizes and is nonirritating.

LC_{50} (mouse, inhalation): 386 000 ppm/30 min[12]

LC_{50} (rat, inhalation): 308 g/m^3[12]

15 Handling Precautions

Dimethyl ether is usually encountered as a liquefied gas, and appropriate precautions for handling such materials should be taken. Eye protection, gloves, and protective clothing are recommended.

Dimethyl ether should be handled in a well-ventilated environment. The vapors are heavier than air and do not support life; therefore, when cleaning large tanks that have contained this material, adequate provisions for oxygen supply in the tanks must be made in order to protect workers cleaning the tanks.

Dimethyl ether is flammable; *see* Section 10. When heated to decomposition it emits acrid smoke and irritating fumes.[12] In the UK, the long-term (8-hour TWA) exposure limit for dimethyl ether is 766 mg/m^3 (400 ppm). The short-term (15-minute) exposure limit is 958 mg/m^3 (500 ppm).[16]

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (topical aerosols). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Hydrocarbons (HC).

18 Comments

Dimethyl ether is used as a propellant in cosmetics such as hair sprays, and in other aerosol products such as air fresheners and fly sprays. Since the solubility of dimethyl ether in water is about 35%, it can be used to good effect in aqueous aerosol products.

Dimethyl ether has been used as a refrigerant and as a nonfluorocarbon alternative blowing agent for industrial insulation purposes.[17] It is also used as an extraction solvent in the food industry.[15]

The antimicrobial and preservative effects of dimethyl ether as an aerosol propellant have been investigated.[18,19]

The EINECS number for dimethyl ether is 204-065-8. The PubChem Compound ID (CID) for dimethyl ether is 8254.

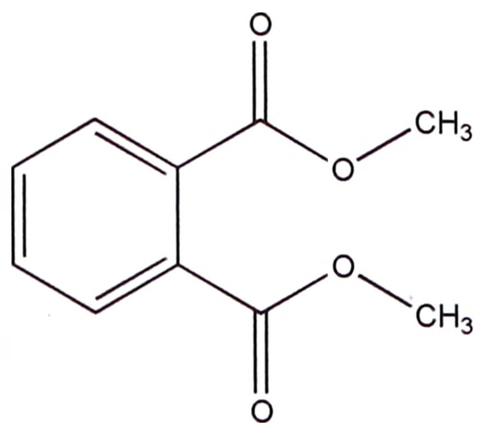
BP: Dimethyl Phthalate

2 Synonyms

Avolin; 1,2-benzenedicarboxylate, dimethyl ester; benzenedicarboxylic acid dimethyl ester; dimethyl 1,2-benzenedicarboxylate; dimethyl benzene-*o*-dicarboxylate; dimethyl benzeneorthodicarboxylate; dimethyl *o*-phthalate; *o*-dimethyl phthalate; DMP; *Eastman DMP*; *Fermine*; *Kodaflex DMP*; methyl benzene-1,2-dicarboxylate; *Mipax*; *Palatinol M*; phthalic acid dimethyl ester; phthalic acid methyl ester; *Repeftal*; *Solvanom*; *Solvarone*; *Unimoll DM*.



3 Chemical Name and CAS Registry Number

1,2-Benzenedicarboxylic acid, dimethyl ester [131-11-3]

4 Empirical Formula and Molecular Weight

$C_{10}H_{10}O_4$ 194.19

5 Structural Formula

6 Functional Category

Plasticizing agent; solvent.

7 Applications in Pharmaceutical Formulation or Technology

Dimethyl phthalate is used in pharmaceutical applications as a solvent and plasticizing agent for film-coatings such as hydroxypropyl methylcellulose, cellulose acetate and cellulose acetate–butyrate mixtures.[1,2]

8 Description

Dimethyl phthalate occurs as a colorless, or faintly colored, odorless, viscous, oily liquid.

9 Pharmacopeial Specifications

See Table I.

10 Typical Properties

Acid value ≤0.04 for *Palatinol M*
Boiling point 280°C, with decomposition
Density 1.186–1.192 g/cm^3; 1.190–1.194 g/cm^3 at 20°C for *Palatinol M*
Flash point 146°C (closed cup)
Freezing point The commercial product freezes at 0°C
Melting point 2.0–5.5°C
Partition coefficient Octanol : water = 1.56[3]
Pour point −42°C for *Palatinol M*
Solubility *see* Table II.
Surface tension 41.9 mN/m at 20°C
Vapor density (relative) 6.69 (air = 1)
Vapor pressure 120 Pa at 100°C
Viscosity 17.2 mPa s (17.2 cP) at 25°C.

Table I: Pharmacopeial specifications for dimethyl phthalate.

Test	BP 2017
Identification	+
Characters	+
Acidity	+
Refractive index	1.515–1.517
Weight per mL	1.186–1.192
Related substances	+
Sulfated ash	≤0.1%
Water	≤0.1%
Assay (dried basis)	99.0–100.5%

Table II: Solubility of dimethyl phthalate.

Solvent	Solubility at 20°C unless otherwise stated
Benzene	Miscible
Chloroform	Miscible
Ethanol (95%)	Miscible
Ether	Miscible
Mineral oil	1 in 294
Water	1 in 250 at 20°C

11 Stability and Storage Conditions

Dimethyl phthalate is sensitive to prolonged exposure to light and it should therefore be stored in a cool, dark, dry, well-ventilated area that is protected from physical damage, and isolated from incompatible substances. Containers of dimethyl phthalate may be hazardous when empty as they may retain product residues such as vapors and liquids. There is a slight fire hazard when exposed to heat, and above the flash point (*see* Section 10) explosive vapor–air mixtures may be formed. Carbon dioxide and carbon monoxide are released when dimethyl phthalate is heated to decomposition. Solutions of dimethyl phthalate in acetone, dimethyl sulfoxide, ethanol (95%), and water are stable for 24 hours under normal laboratory conditions.

12 Incompatibilities

Dimethyl phthalate is incompatible with strong acids or bases, nitrates, and strong oxidizing agents. As with other phthalates, contact with plastics should be avoided.

13 Method of Manufacture

Dimethyl phthalate is produced industrially from phthalic anhydride and methanol.

14 Safety

In pharmaceutical applications, dimethyl phthalate is used in film coating and as a topically applied insect repellent. Acute exposure to the eyes and mucous membranes can cause irritation, although dimethyl phthalate is considered less irritant than diethyl phthalate.

Inhalation of dimethyl phthalate can cause irritation of the respiratory tract; oral ingestion can cause a burning sensation in the mouth, vomiting, and diarrhea. Owing to the low water solubility and relatively high lipid solubility, dimethyl phthalate may accumulate in body tissues after chronic exposure, which may cause central nervous system depression.

Although some animal studies have suggested that high concentrations of dimethyl phthalate may be teratogenic or cause mutagenic effects with bacteria,[4,5] other studies have shown no adverse effects.[6] There are no confirmed reports of human reproductive or developmental effects, and the compound is not generally regarded as a carcinogenic material.

LD_{50} (chicken, oral): 8.5 g/kg[7]
LD_{50} (guinea pig, oral): 2.4 g/kg
LD_{50} (mouse, IP): 1.38 g/kg
LD_{50} (mouse, oral): 6.8 g/kg
LD_{50} (rabbit, oral): 4.40 g/kg
LD_{50} (rat, IP): 3.38 g/kg
LD_{50} (rat, oral): 6.80 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Skin and eye contact should be avoided; eye goggles or a full face shield should be worn where splashing may occur. Respirators should be used if the compound is heated to decomposition. In the UK, the long-term (8-hour TWA) workplace exposure limit for dimethyl phthalate is 5 mg/m^3. The short-term (15-minute) workplace exposure limit is 10 mg/m^3.[8]

16 Regulatory Status

Dimethyl phthalate is included in a number of topical pharmaceutical formulations. Included in the FDA Inactive Ingredients Database (oral tablets). As from 1992, dimethyl phthalate is no longer registered for use as a pesticide in California.

17 Related Substances

Dibutyl phthalate; diethyl phthalate.

18 Comments

In addition to a number of industrial applications, dimethyl phthalate is also widely used as an insect repellent with topical preparations typically applied as a 40% cream or lotion; it has also been applied as a tent fabric treatment.[9]

A specification for dimethyl phthalate is included in the *Japanese Pharmaceutical Excipients* (JPE).[10]

The EINECS number for dimethyl phthalate is 205-011-6. The PubChem Compound ID (CID) for dimethyl phthalate is 8554.

Dimethyl Sulfoxide

1 Nonproprietary Names

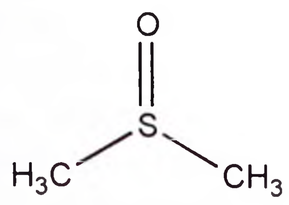
BP: Dimethyl Sulfoxide

PhEur: Dimethyl Sulfoxide

USP–NF: Dimethyl Sulfoxide

2 Synonyms

Deltan; dimexide; dimethylis sulfoxidum; dimethyl sulphoxide; DMSO; *Kemsol*; methylsulfinylmethane; methyl sulfoxide; *Procipient*; *Rimso-50*; sulphinylbismethane.



3 Chemical Name and CAS Registry Number

Sulfinylbismethane [67-68-5]

4 Empirical Formula and Molecular Weight

C_2H_6OS 78.13

5 Structural Formula

6 Functional Category

Penetration enhancer; solvent.

7 Applications in Pharmaceutical Formulation or Technology

Dimethyl sulfoxide is a highly polar substance that is aprotic, therefore lacking acidic and basic properties. It has exceptional solvent properties for both organic and inorganic components, which are derived from its capacity to associate with both ionic species and neutral molecules that are either polar or polarizable.

Dimethyl sulfoxide enhances the topical penetration of drugs owing to its ability to displace bound water from the stratum corneum; this is accompanied by the extraction of lipids and configurational changes of proteins.[1] The molecular interactions between dimethyl sulfoxide and the stratum corneum, as a function of depth and time, have been described.[2] Much of the enhancement capacity is lost if the solvent is diluted. Increases in drug penetration have been reported with dimethyl sulfoxide concentrations as low as 15%, but significant increases in permeability generally require concentrations higher than 60–80%. Furthermore, while low molecular weight substances can penetrate quickly into the deep layers of the skin, the appreciable transport of molecules with a molecular weight of more than 3000 is difficult.

Dimethyl sulfoxide is now incorporated into a number of regulated products for healthcare and drug delivery applications, including stabilizing product formulations, sustained-release applications, and for the delivery of medical polymers.[3]

The use of dimethyl sulfoxide to improve transdermal delivery has been reported for diclofenac,[4,5] ciclosporin,[6] timolol,[7], alpha-tocopherol,[8] and a wide range of other drugs.[9,10] In topical formulations of idoxuridine, dimethyl sulfoxide acts both as a solvent to increase drug solubility and a means of enabling penetration of the antiviral agent to the deeper levels of the epidermis. Dimethyl sulfoxide has been used in the formulation of buccal[11] and transdermal[12] patches, and also in suppositories and injectables containing allopurinol.[13] It has also been investigated for use in parenteral preparations for the treatment of liver tumors[14] and in polymeric *in situ* implants.[15]

Dimethyl sulfoxide has been investigated as a potential cryoprotectant,[16,17] and has been used in nanoparticles,[18] microspheres,[19] and lipid-based[20] oral drug delivery systems.

See Table I.

Table I: Uses of dimethyl sulfoxide.

Use	Concentration (%)
Solvent	≤100
Topical penetration enhancer	≥80

8 Description

Dimethyl sulfoxide occurs as a colorless, viscous liquid, or as colorless crystals that are miscible with water, alcohol, and ether. The material has a slightly bitter taste with a sweet aftertaste, and is odorless, or has a slight odor characteristic of dimethyl sulfoxide.

Dimethyl sulfoxide is extremely hygroscopic, absorbing up to 70% of its own weight in water with evolution of heat.

9 Pharmacopeial Specifications

See Table II.

Table II: Pharmacopeial specifications for dimethyl sulfoxide.

Test	PhEur 9.2	USP 40–NF 35 S1
Characters	+	–
Identification	+	+
Specific gravity	1.100–1.104	1.095–1.101
Freezing point	≥18.3°C	–
Refractive index	1.478–1.479	1.4755–1.4775
Acidity	+	+
Water	≤0.2%	≤0.1%
Ultraviolet absorbance	+	+
Limit of nonvolatile residue	–	≤0.01%
Related substances	+	+
Assay (anhydrous basis)	–	≥99.9%

10 Typical Properties

Acidity/alkalinity pH = 8.5 (for a 50 : 50 mixture with water)
Autoignition temperature 215°C
Boiling point 189°C
Density 1.1 g/cm^3; 1.0955 g/cm^3 at 25°C for *Procipient*
Dielectric constant 48.9 at 20°C
Dipole moment 4.3 Debye at 20°C[21]
Dissociation constant pK_a = 31.3[21]
Enthalpy of fusion 3.43 cal/mol[21]
Enthalpy of vaporization 12.64 cal/mol at 25°C[21]
Flash point 95°C (open cup)
Freezing point Markedly reduces the freezing point of water; a 30% aqueous solution in water has a freezing point of −14°C and a 40% aqueous solution has a freezing point of −25°C.
Partition coefficient Log *P* (octanol : water) = −2.03
Solubility Miscible with water with evolution of heat; also miscible with ethanol (95%), ether and most organic solvents;

immiscible with paraffins, hydrocarbons. Practically insoluble in acetone, chloroform, and ether.

Specific heat 0.7 cal/g (liquid)

Spectroscopy

IR spectrum *see* Figure 1.

Raman spectrum *see* Figure 2.

Vapor pressure 0.37 mm at 20°C

Viscosity (dynamic)

1.1 mPa s (1.1 cP) at 27°C;

2.0 mPa s (2.0 cP) at 25°C for *Procipient*;

2.47 mPa s (2.47 cP) at 20°C.

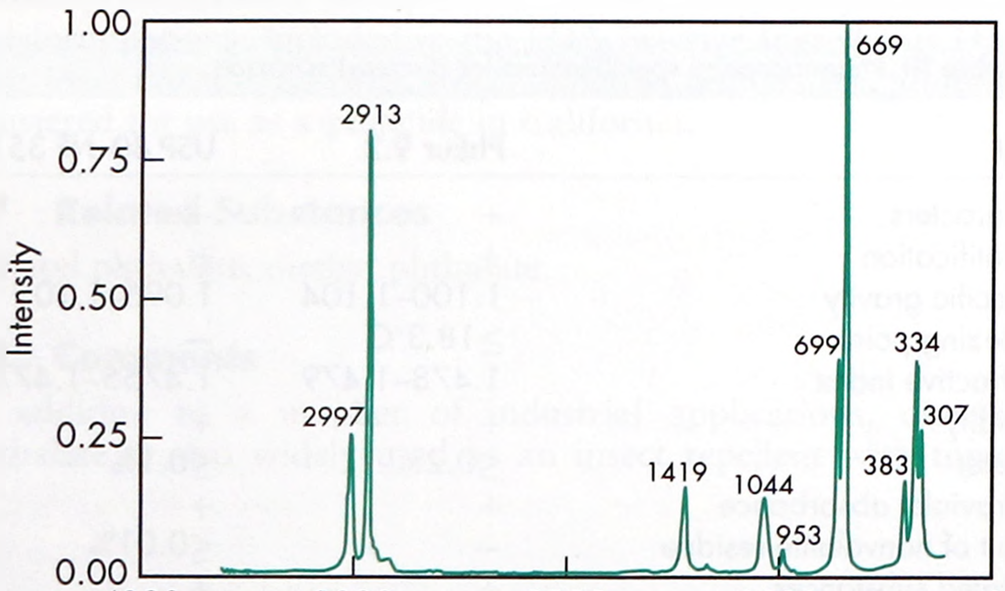

Figure 2: Raman spectrum of dimethyl sulfoxide measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

11 Stability and Storage Conditions

Dimethyl sulfoxide is reasonably stable to heat, but upon prolonged reflux it decomposes slightly to methyl mercaptan and bis-methylthiomethane. This decomposition is aided by acids, and is retarded by many bases. When heated to decomposition, toxic fumes are emitted.

At temperatures between 40°C and 60°C, it has been reported that dimethyl sulfoxide suffers a partial breakdown, which is indicated by changes in physical properties such as refractive index, density, and viscosity.[22]

Dimethyl sulfoxide should be stored in airtight, light-resistant containers. The PhEur 9.2 states that glass containers should be used. Contact with plastics should be avoided.

12 Incompatibilities

Dimethyl sulfoxide can react with oxidizing materials.

13 Method of Manufacture

Dimethyl sulfoxide is prepared by air oxidation of dimethyl sulfide in the presence of nitrogen oxides. It can also be obtained as a by-product of wood pulp manufacture for the paper and allied industries.

14 Safety

Dimethyl sulfoxide is widely used as a pharmaceutical solvent due to its apparent low systemic toxicity, and is considered to be well tolerated at concentrations <10%. However, it can cause local toxic effects,[23–25] and concentrations as low as 0.1% v/v have been found to be toxic to the retina in rats.[26]

Dimethyl sulfoxide is readily absorbed after injection or after oral or percutaneous administration and is widely distributed throughout the body. It acts as a primary irritant on skin, causing redness, burning, itching, and scaling; it also causes urticaria. Systemic symptoms include nausea, vomiting, chills, cramps, and lethargy; and it can also cause increases in intraocular pressure. Administration of dimethyl sulfoxide by any route is followed by a garlic-like odor on the breath.

Intravascular hemolysis and biochemical changes[27] and reversible neurological deterioration[28] have been reported following intravenous administration. However, it has been questioned whether these findings were directly attributable to dimethyl sulfoxide rather than to concomitant drug therapy or contaminants.[29] One report describes massive intracranial hemorrhage associated with ingestion of dimethyl sulfoxide.[30] A hypersensitivity reaction attributed to dimethyl sulfoxide has also been reported.[31] Increased psychomotor impairment has been reported in patients who drank alcohol after topical exposure to dimethyl sulfoxide, including inadvertent occupational exposure.[32]

In 1965, the FDA banned investigation in humans of dimethyl sulfoxide owing to the appearance of changes in the refractive index of the lens of the eye in experimental animals. However, in 1966, the FDA allowed the study of dimethyl sulfoxide in serious conditions such as scleroderma, persistent herpes zoster, and severe rheumatoid arthritis, and in 1968 permitted studies using short-term topical application of the solvent. By 1980, the FDA no longer specifically regulated investigations of dimethyl sulfoxide.[33]

Dimethyl sulfoxide enhances the skin penetration of several drugs, which may result in the production of the adverse effects associated with those drugs.

LD_{50} (dog, IV): 2.5 g/kg[34]

LD_{50} (rat, IP): 8.2 g/kg

LD_{50} (rat, IV): 5.36 g/kg

LD_{50} (rat, oral): 14.5 g/kg

LD_{50} (rat, SC): 12 g/kg

LD_{50} (mouse, IP): 2.5 g/kg

LD_{50} (mouse, IV): 3.8 g/kg

LD_{50} (mouse, oral): 7.92 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Dimethyl sulfoxide may cause irritation to the skin. Gloves and eye protection are recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (IV infusions, SC implants, and topical preparations). Included in the Canadian Natural Health Products Ingredients Database.

Available in the US as a 50% solution for irrigation in the treatment of interstitial cystitis. Also available in Canada as a 70% solution for use as a topical antifibrotic, and in Germany as a topical gel containing 10% dimethyl sulfoxide for the treatment of musculoskeletal and joint disorders. Included in topical formulations of idoxuridine licensed in the UK.

Also included in preparations for the treatment of alopecia and prostatitis in Russia.[32]

17 Related Substances

—

18 Comments

Dimethyl sulfoxide has been shown to have bactericidal,[35] bacteriostatic,[35,36] and fungistatic[36] activity, although the concentration required is dependent on the organism present. It has also been found to have mild to moderate neuroprotective effects.[37]

A 2.16% dimethyl sulfoxide solution in water is iso-osmotic with serum. Dimethyl sulfoxide has been used as a 50% aqueous solution for instillation into the bladder in the treatment of interstitial cystitis; it has also been tried clinically for a wide range of indications, including cutaneous and musculoskeletal disorders, but with little evidence of beneficial effects.

Dimethyl sulfoxide has also been investigated as a potential therapeutic agent in conditions such as scleroderma, interstitial cystitis,[38] rheumatoid arthritis, and acute musculoskeletal injuries, and as an analgesic.[33,39–42] It has also been recommended for the treatment of anthracycline extravasation.[43–46] However, it has been reported that it may cause the inactivation of drugs such as cisplatin, carboplatin, and oxaliplatin used for cancer treatment.[47] The EINECS number for dimethyl sulfoxide is 200-664-3. The PubChem Compound ID (CID) for dimethyl sulfoxide is 679.

C_4H_9NO 87.12

5 Structural Formula

6 Functional Category

Solvent.

7 Applications in Pharmaceutical Formulation or Technology

Dimethylacetamide is used as a solvent in oral and injectable pharmaceutical formulations.[1–3] It has been used as a cosolvent to solubilize poorly soluble drugs.[4–7] The use of dimethylacetamide has also been investigated as a vehicle for the parenteral delivery of relatively small peptides.[8]

The use of solvents such as dimethylacetamide has been shown to influence the size and rate of release of norfloxacin from nanoparticles.[9] The development of biocompatible microporous foams using dimethylacetamide as a solvent has recently been demonstrated.[10]

Dimethylacetamide has also been used in topical formulations and has been evaluated as a permeation enhancer for transdermal drug delivery.[11,12]

8 Description

Dimethylacetamide occurs as a clear, colorless, slightly hygroscopic liquid. It has a weak ammonia-like or fish-like odor.

9 Pharmacopeial Specifications

See Table I. *See also* Section 18.

Table I: Pharmacopeial specifications for dimethylacetamide.

Test	PhEur 9.2
Identification	+
Characters	+
Appearance	+
Relative density	0.941–0.944
Refractive index	1.435–1.439
Acidity	+
Alkalinity	+
Related substances	+
Heavy metals	≤10 ppm
Nonvolatile matter	≤20 ppm
Water	≤0.1%

10 Typical Properties

Autoignition temperature 490°C
Boiling point 165°C
Dielectric constant D^{20} = 37.8
Flash point 70°C
Partition coefficient Log *P* (octanol : water) = –0.77 at 25°C
Refractive index $n_D^{22.5}$ = 1.4371
Solubility Miscible with ethanol (95%), water, and most common organic solvents.
Specific gravity 0.943 at 20°C
Surface tension 35.7 mN/m (35.7 dyne/cm)
Vapor pressure 0.33 kPa at 20°C
Viscosity (dynamic) 1.02 mPa s (1.02 cP) at 25°C

11 Stability and Storage Conditions

Dimethylacetamide should be stored in an airtight container, protected from light, in a cool, dry place. Dimethylacetamide has an almost unlimited shelf-life when kept in closed containers and under nitrogen. It is combustible.

12 Incompatibilities

Dimethylacetamide is incompatible with carbon tetrachloride, oxidizing agents, halogenated compounds, and iron. It attacks plastic and rubber. Contact with strong oxidizers may cause fire.

13 Method of Manufacture

Dimethylacetamide is manufactured from acetic acid and dimethylamine in a closed system.

14 Safety

Dimethylacetamide is used in pharmaceutical preparations as a solvent in parenteral formulations and is generally regarded as a nontoxic material when used as an excipient. Animal toxicity studies indicate that dimethylacetamide is readily absorbed into the bloodstream following inhalation or topical application. Repeated exposure to dimethylacetamide may be harmful and can result in liver damage. High intravenous doses (>400 mg/kg/day for 3 days) may be hallucinogenic.[13–17]

LD_{50} (rabbit, SC): 9.6 g/kg[18]
LD_{50} (rat, IP): 2.75 g/kg
LD_{50} (rat, IV): 2.64 g/kg
LD_{50} (rat, oral): 4.93 g/kg
LD_{50} (mouse, inhalation): 7.2 g/kg
LD_{50} (mouse, IP): 2.8 g/kg
LD_{50} (mouse, IV): 3.02 g/kg
LD_{50} (mouse, SC): 9.6 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. Dimethylacetamide can be absorbed into the bloodstream by inhalation and through the skin; it is irritating to the skin and eyes.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (IM injections, IV injections and infusions). Included in parenteral medicines licensed in the UK.

17 Related Substances

—

18 Comments

Dimethylacetamide has been evaluated as a cryoprotector for use in cryopreserving erythrocytes[19] and rabbit sperm.[20]

A specification for dimethylacetamide is included in the *Japanese Pharmaceutical Excipients* (JPE).[21]

The EINECS number for dimethylacetamide is 204-826-4. The PubChem Compound ID (CID) for dimethylacetamide is 31374.

Dimethyl-β-cyclodextrin

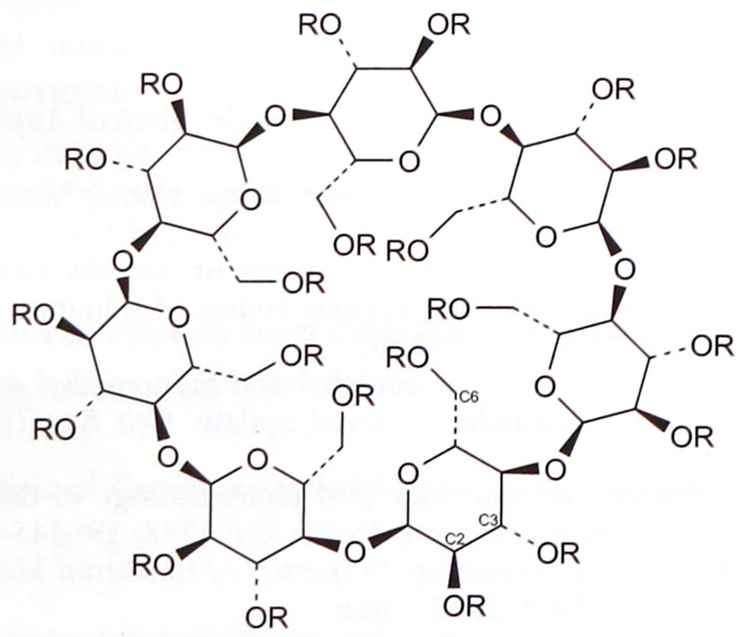
D

1 Nonproprietary Names

None adopted.

2 Synonyms

Cycloheptakis-(1→4)-(2,6-di-*O*-methyl-α-D-glucopyranosyl); dimeb; 2,6-di-*O*-methyl-β-cyclodextrin; 2,6-dimethyl-β-cyclodextrin; DM-β-CD; hepta-(2,6-di-oxy-methyl)-β-cyclodextrin; heptakis(2,6-di-*O*-methyl)-β-cyclodextrin; heptakis(2,6-di-*O*-methyl)cyclomaltoheptaose; 2A,2B,2C,2D,2E,2F,2G,6A,6B,6C,6D,6E,6F,6G-tetradeca-*O*-methyl-β-cyclodextrin; tetradeca-*O*-methyl-β-cyclodextrin; tetradecakis-2,6-*O*-methylcycloheptaamylose.



3 Chemical Name and CAS Registry Number

Di-*O*-methyl-β-cyclodextrin [51166-71-3]

4 Empirical Formula and Molecular Weight

$C_{56}H_{98}O_{35}$ 1 331.36

5 Structural Formula

R = H for C3 and CH_3 for C2 and C6.

6 Functional Category

Complexing agent; modified-release agent; microencapsulating agent; solubilizing agent; tonicity agent.

7 Applications in Pharmaceutical Formulation or Technology

Dimethyl-β-cyclodextrin is used to improve dissolution, solubility, bioavailability, and stability of poorly water-soluble drugs through the formation of inclusion complexes[1–3] in oral,[4–7] topical,[8–10] ophthalmic,[11] rectal,[12] nasal,[13] and pulmonary[14] pharmaceutical formulations. It is used in applications similar to those for β-cyclodextrin (see Cyclodextrins), and is more water-soluble than the unsubstituted β-cyclodextrin.

Dimethyl-β-cyclodextrin has been studied in nanoparticle and microsphere formulations for modified drug release,[15,16] and has also been investigated as a parenteral drug carrier.[17]

8 Description

Dimethyl-β-cyclodextrin is a nonionic methylated β-cyclodextrin derivative. It occurs as a white or almost white crystalline powder.

9 Pharmacopeial Specifications

—

10 Typical Properties

Acidity/alkalinity pH 4.6–5.7[18]
Cavity diameter 6 Å
Conductivity <200 µS/cm (25°C, 1% solution in water)[19]
Degree of substitution 12–16[19]
Melting point 295.0–300.0°C
Moisture content ≤1% w/w
Solubility

Soluble 1 in 135 parts of ethanol (95%), and 1 in 1.75 of water at 25°C.

Solubility in water and organic solvents is significantly greater when compared to the natural α-, β- and γ- cyclodextrins; however water solubility decreases with increasing temperature.[20]

Surface tension 62 mN/m (62 dynes/cm) at 25°C

11 Stability and Storage Conditions

Dimethyl-β-cyclodextrin is stable in the solid state if protected from high humidity. It is reasonably stable in alkaline medium but is hydrolyzed by strong acids producing linear oligosaccharides.[20,21]

Store in a tightly sealed container, in a cool, dry and well-ventilated place.

12 Incompatibilities

Dimethyl-β-cyclodextrin is incompatible with strong oxidizing agents.

13 Method of Manufacture

Dimethyl-β-cyclodextrin is prepared from β-cyclodextrin by the selective methylation of all C2 secondary hydroxyl groups and all C6 primary hydroxyl groups (C3 secondary hydroxyl groups remain unsubstituted).[20]

14 Safety

Dimethyl-β-cyclodextrin is used in pharmaceutical formulations, and in pure form, dimethyl-β-cyclodextrin may cause skin, eye and respiratory tract irritation, and may be harmful if swallowed.

Dimethyl-β-cyclodextrin is a cholesterol sequestering agent, which modifies lipid rafts of the cell membrane.[22] It has been shown to be associated with a high cytotoxicity through a stronger ability to deplete cholesterol from cell membranes compared with other methylated-β-cyclodextrins.[23–26]

In the USA, the OSHA permissible exposure limit is 5 mg/m^3 respirable fraction for dimethyl-β-cyclodextrin.[27]

LD50 (mouse, oral): >3.0 g/kg[7]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

Avoid contact with skin and eyes, and avoid breathing vapors, mist or gas. Gloves and eye protection should be worn. Handle in a well-ventilated environment.

16 Regulatory Status

Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Cyclodextrins (α, β and γ-cyclodextrin); hydroxethyl-β-cyclodextrin; hydroxypropyl betadex; sulfobutylether β-cyclodextrin; trimethyl-β-cyclodextrin.

18 Comments

Although dimethyl-β-cyclodextrin is not included as an official monograph in any pharmacopeias, it is listed in the General Reagents appendices in the BP and PhEur.

Methylated β-cyclodextrins have been included in nasal and eye drop preparations in Europe.[28,29]

Dimethyl-β-cyclodextrin has been used in *Bordetella pertussis* cultures for the manufacture of vaccines.[30,31]

Dimethyl-β-cyclodextrin induces the release of cholesterol from cholesterol-rich lipid rafts located on the surface of cells, and may be used for removing cholesterol from processed foods.[32]

Therapeutically, dimethyl-β-cyclodextrin has been investigated as a possible treatment for the reduction of dietary cholesterol intake.[33]

The PubChem Compound ID (CID) for dimethyl-β-cyclodextrin is 122143.

Dipropylene Glycol

D

1 Nonproprietary Names

None adopted.

2 Synonyms

Dipropylene glycol exists as three structural isomers (a, b, c) and a mixture defined by the manufacturing process (d); *see* Sections 3, 5 and 18.

(a) Bis(2-hydroxypropyl) ether; 2,2′-dihydroxydipropyl ether; 4-oxaheptane-2,6-diol; 1,1′-dimethyldiethylene glycol; 1,1′-oxydi-2-propanol; 1,1′-oxydi-2-propanol; 2-propanol, 1,1′-oxybis-

(b) 1,2-Dipropylene glycol; 2,2′-oxydipropanol; 1-propanol, 2,2′-oxybis-

(c) 1-Propanol, 2-(2-hydroxypropoxy)-

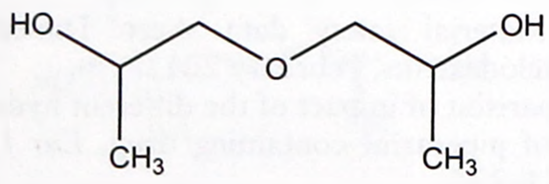
(d) 2,2,-Dihydroxyisopropyl ether; DPG; methyl-2(methyl-2)oxybispropanol; 4-oxa-2,6-heptandiol; oxydipropanol; propanol, oxybis-

3 Chemical Name and CAS Registry Number

Dipropylene glycol exists as three structural isomers (a, b, c) and a mixture defined by the manufacturing process (d). *See also* Sections 5 and 18.

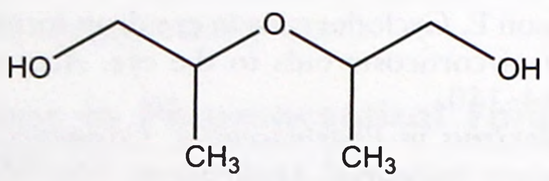
(a) 1,1′-Oxybis(2-propanol) [110-98-5]

(b) 2,2′-Oxybis(1-propanol) [108-61-2]



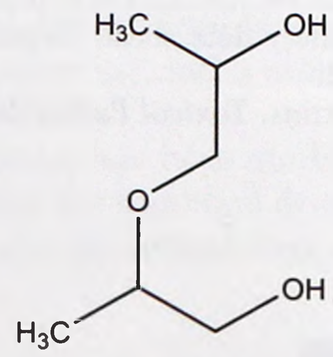
(c) 2-(2-Hydroxypropoxy)propanol [106-62-7]

(d) Oxybispropanol [25265-71-8]



4 Empirical Formula and Molecular Weight

$C_6H_{14}O_3$ 134.2



5 Structural Formula

(a) 1,1'-Oxybis(2-propanol)

(b) 2,2'-Oxybis(1-propanol)

(c) 2-(2-Hydroxypropoxy)propanol

6 Functional Category

Humectant; plasticizing agent; solvent; transdermal delivery component.

7 Applications in Pharmaceutical Formulation or Technology

Dipropylene glycol is used in the preparation of controlled-release buccal and transdermal patches as a component of the adhesive.[1,2]

Dipropylene glycol is also used in cosmetics, typically skin cleansing preparations, deodorants, lipsticks, and fragrances.

8 Description

Dipropylene glycol occurs as a practically odorless, colorless liquid.

9 Pharmacopeial Specifications

See Section 18.

10 Typical Properties

The properties listed below are for the dominant isomer (a) and mixed isomers (d).[3,4]

Boiling point 228–233°C
Density 1.023 g/cm^3 at 20°C; 0.998 g/cm^3 at 60°C
Flash point 121–124°C (closed cup)
Freezing point Approx. –39°C
Partition coefficient Log *P* (octanol: water) –1.07 to –1.486
Refractive index 1.438–1.442
Solubility Miscible with water, oils, and hydrocarbons.
Specific heat 2.18 J/g/°C (0.52 cal/g/°C) at 25°C
Surface tension 35 mN/m (35 dynes/cm)
Vapor density 4.63 (air = 1)
Vapor pressure 0.0021 kPa (0.016 mmHg) at 25°C
Viscosity
75.0 mPa s (75.0 cP) at 25°C;
10.9 mPa s (10.9 cP) at 60°C.

11 Stability and Storage Conditions

Store in closed containers away from sources of UV light below 40°C.

12 Incompatibilities

Dipropylene glycol is incompatible with strong oxidizing agents.

13 Method of Manufacture

Dipropylene glycol is produced as a byproduct of the manufacture of propylene glycol.

14 Safety

Dipropylene glycol is not acutely toxic by oral, dermal, or inhalation exposure.[5] Ingestion of high doses may cause CNS depression (fatigue, dizziness, possible loss of concentration). Ingestion of dipropylene glycol fog solution has caused acute renal failure, neuropathy, and myopathy in a 32-year old man.[6]

Dipropylene glycol is slightly irritating to skin and eyes. It has a low potential to produce allergic skin reactions.[5]

Dipropylene glycol does not appear to be genotoxic.[7] Carcinogenicity studies in rats and mice have indicated limited carcinogenic potential.[8,9]

LD_{50} (dog, IV): 11.5 g/kg[10]

LD_{50} (guinea pig, oral): 17.6 g/kg[10]
LD_{50} (mouse, IP): 4.5 g/kg[10]
LD_{50} (rabbit, eye): 0.51 g/kg[10]
LD_{50} (rabbit, skin): 0.5 g/kg[10]
LD_{50} (rat, IP): 10.0 g/kg[10]
LD_{50} (rat, IV): 5.8 g/kg[10]
LD_{50} (rat, oral): 14.85 g/kg[10]
LC_{50} (rat, inhalation): 6.0 g/m^3[7]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Do not heat higher than 28°C unless in an air-free closed system. Wear suitable protective clothing; eye protection is recommended.

16 Regulatory Status

GRAS listed. Dipropylene glycol (d) is included in the FDA Inactive Ingredients Database (buccal patches; transdermal films and patches). Dipropylene glycol (d) is included in the Canadian Natural Health Products Ingredients Database (solvent). Dipropylene glycol (unspecified isomer(s)) is included in nonparenteral medicines licensed in the UK.

17 Related Substances

Polyethylene glycol; propylene glycol.

18 Comments

A specification for dipropylene glycol (unspecified isomer(s)) is contained in the *Japanese Pharmaceutical Excipients* (JPE);[11] *see* Table I.

Table I: JPE specification for dipropylene glycol.

Test	JPE 2004
Description	+
Identification	+
Specific gravity	1.021–1.027
Acid	+
Chloride	≤0.007%
Heavy metals	≤20 ppm
Water	≤0.5%
Residue on ignition	≤0.05%
Distilling range	220–240°C (≥95.0 vol%)

Dipropylene glycol has not been cleared for use as a direct food additive. In the US it can be used as a component in food contact articles such as adhesives and paper. In the EU it has been cleared for the use of plastic materials for food contact.

Dipropylene glycol is also an ingredient of cutting oils, industrial soaps, and agriculture insecticidal formulations. It is used as an additive for carburettor fuels as a lubricant and antifreezing agent. It is used as a solvent for printing inks, lacquers and coatings.

The EINECS numbers for dipropylene glycol are:

(a) 203-821-4
(b) 203-599-9
(c) 203-416-2
(d) 246-770-3.

The PubChem Compound IDs (CID) for dipropylene glycol are:

(a) 8087
(b) 92739
(c) 32881
(d) 32857.

Docusate Sodium

D

1 Nonproprietary Names

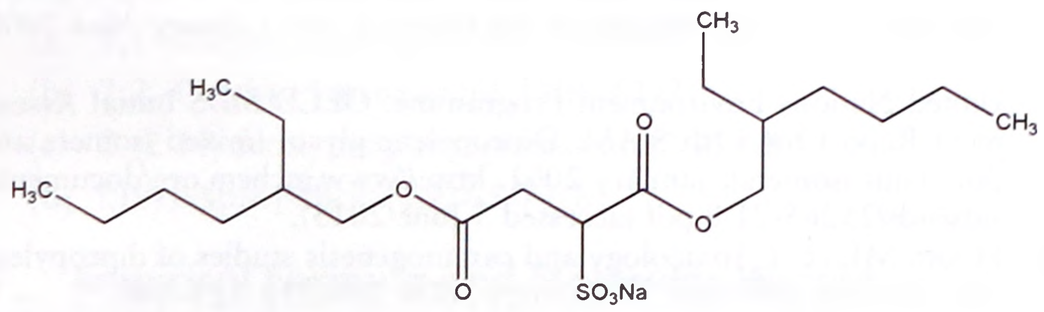
BP: Docusate Sodium

PhEur: Docusate Sodium

USP–NF: Docusate Sodium

2 Synonyms

Bis(2-ethylhexyl) sodium sulfosuccinate; dioctyl sodium sulfosuccinate; DSS; natrii docusas; sodium 1,4-bis(2-ethylhexyl) sulfosuccinate; sodium 1,4-bis[(2-ethylhexyl)oxy]-1,4-dioxobutane-2-sulfonate; sodium dioctyl sulfosuccinate; sulfo-butanedioic acid 1,4-bis(2-ethylhexyl) ester, sodium salt; sulfosuccinic acid 1,4-bis(2-ethylhexyl) ester *S*-sodium salt.



3 Chemical Name and CAS Registry Number

Sodium 1,4-bis(2-ethylhexyl) sulfosuccinate [577-11-7]

4 Empirical Formula and Molecular Weight

$C_{20}H_{37}NaO_7S$ 444.56

5 Structural Formula

6 Functional Category

Anionic surfactant.

7 Applications in Pharmaceutical Formulation or Technology

Docusate sodium and docusate salts are widely used as anionic surfactants in pharmaceutical formulations. Docusate sodium is mainly used in capsule, tablet, liquid, and syrup dosage forms, and in direct-compression tablet formulations to assist in wetting and dissolution;[1] *see* Table I.

Table I: Uses of docusate sodium.

Use	Concentration (%)
IM injections	0.015
Surfactant (wetting/dispersing/emulsifying agent)	0.01–1.0
Tablet coating agent	20[a]
Tablet disintegrant	≈0.5

(a) Formulation of a tablet coating solution: 20% docusate sodium; 2–15% sodium benzoate; 0.5% propylene glycol; solution made in ethanol (70%).

8 Description

Docusate sodium is a white or almost white, wax-like, bitter tasting, plastic solid with a characteristic octanol-like odor. It is hygroscopic and usually available in the form of pellets, flakes, or rolls of tissue-thin material.

9 Pharmacopeial Specifications

See Table II.

Table II: Pharmacopeial specifications for docusate sodium.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	–
Alkalinity	+	–
Bis(2-ethylhexyl) maleate	–	≤0.4%
Chlorides	≤350 ppm	–
Clarity of solution	–	+
Heavy metals	–	≤10 ppm
Related nonionic substances	+	–
Residue on ignition	–	15.5–16.5%
Sodium sulfate	≤2.0%	–
Water	≤3.0%	≤2.0%
Assay (dried basis)	98.0–101.0%	99.0–100.5%

10 Typical Properties

Acidity/alkalinity pH = 5.8–6.9 (1% w/v aqueous solution).
Acid value ≤2.5
Critical micelle concentration
0.11% w/v aqueous solution at 25°C.
Density 1.16 g/cm^3
Hydroxyl value 6.0–8.0
Interfacial tension
In water versus mineral oil at 25°C, *see* Table III.

Table III: Interfacial tension of docusate sodium.

Concentration (% w/v)	Interfacial tension (mN/m)
0.01	20.7
0.1	5.9
1.0	1.84

Iodine number ≤0.25
Melting point 153–157°C
Moisture content 1.51%
Saponification value 240–253
Solubility *see* Table IV.
Spectroscopy
IR spectrum *see* Figure 1.
NIR spectrum *see* Figure 2.
Raman spectrum *see* Figure 3.
Surface tension *see* Table V.

11 Stability and Storage Conditions

Docusate sodium is stable in the solid state when stored at room temperature. Dilute aqueous solutions of docusate sodium between pH 1–10 are stable at room temperature. However, at very low pH (<1) and very high pH (>10) docusate sodium solutions are subject to hydrolysis.

The solid material is hygroscopic and should be stored in an airtight container in a cool, dry place.

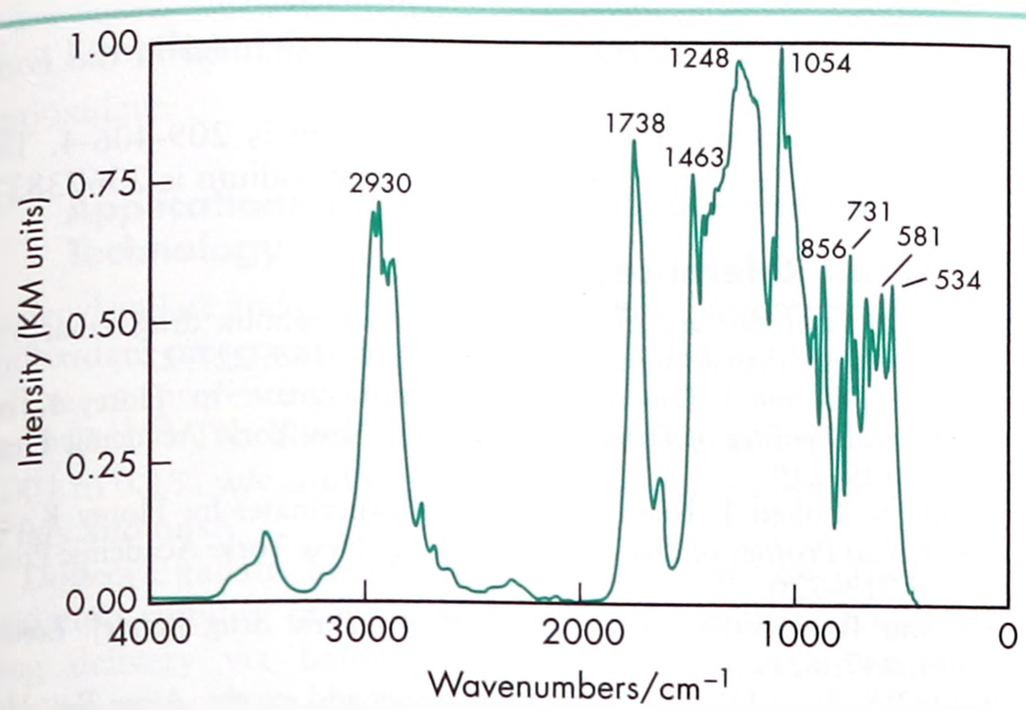


Figure 1: Infrared spectrum of docusate sodium measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

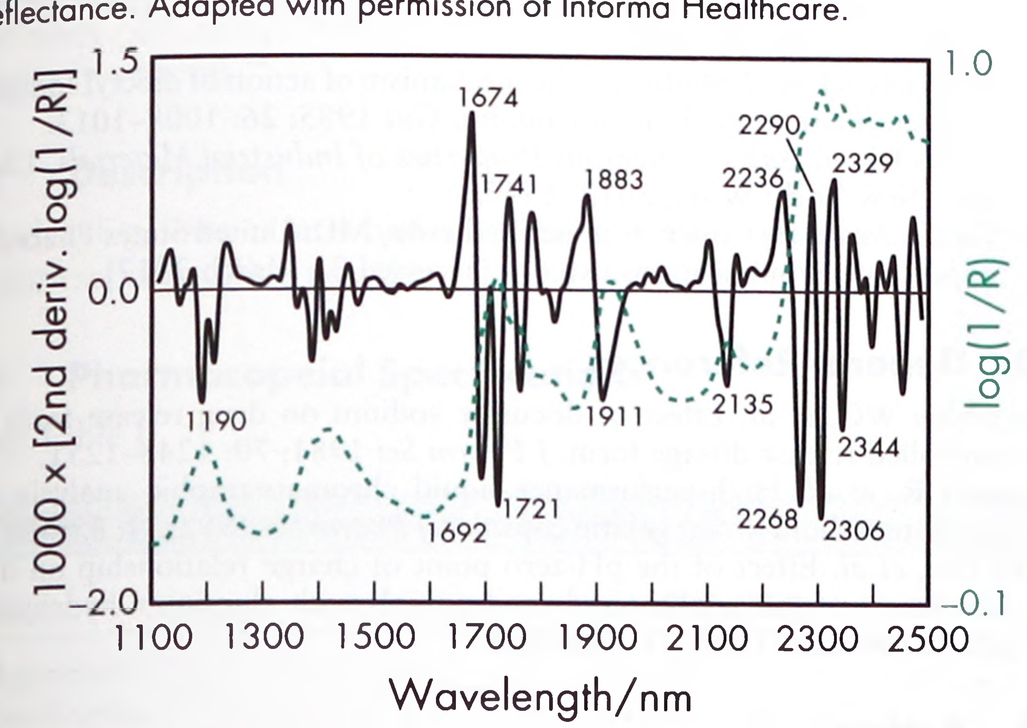

Figure 2: Near-infrared spectrum of docusate sodium measured by reflectance.

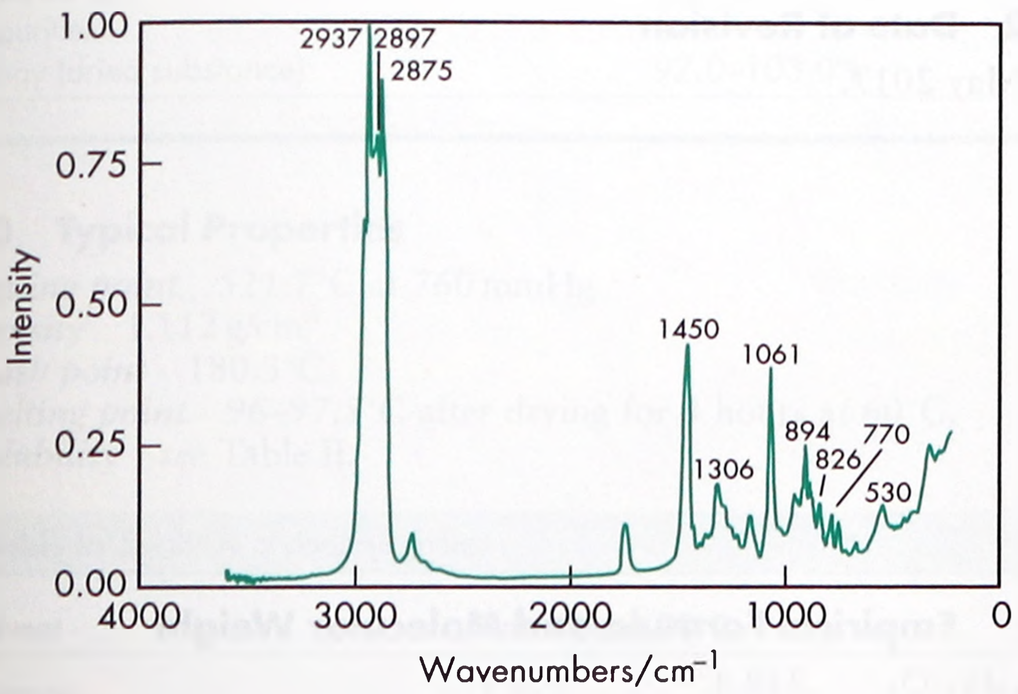

Figure 3: Raman spectrum of docusate sodium measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

12 Incompatibilities

Electrolytes, e.g. 3% sodium chloride, added to aqueous solutions of docusate sodium can cause turbidity.[2,3] However, docusate sodium possesses greater tolerance to calcium, magnesium, and other polyvalent ions than do some other surfactants. Docusate sodium is incompatible with acids at pH < 1 and with alkalis at pH > 10.

Table IV: Solubility of docusate sodium.

Solvent	Solubility at 20°C unless otherwise stated
Acetone	Soluble
Chloroform	1 in 1
Ethanol (95%)	1 in 3
Ether	1 in 1
Glycerin	Freely soluble
Vegetable oils	Soluble
Water	1 in 70 at 25°C[a]
	1 in 56 at 30°C
	1 in 44 at 40°C
	1 in 33 at 50°C
	1 in 25 at 60°C
	1 in 18 at 70°C

(a) In water, higher concentrations form a thick gel.

Table V: Surface tension of docusate sodium.

Concentration in water at 25°C (% w/v)	Surface tension (mN/m)
0.001	62.8
0.1	28.7
1.0	26.0

13 Method of Manufacture

Maleic anhydride is treated with 2-ethylhexanol to produce dioctyl maleate, which is then reacted with sodium bisulfite.

14 Safety

Docusate salts are used in oral formulations as therapeutic agents for their fecal softening and laxative properties. As a laxative in adults, up to 500 mg of docusate sodium is administered daily in divided doses; in children over 6 months old, up to 75 mg in divided doses is used. The quantity of docusate sodium used as an excipient in oral formulations should therefore be controlled to avoid unintended laxative effects.[4] Adverse effects associated with docusate sodium include diarrhea, nausea, vomiting, abdominal cramps, and skin rashes. As with the chronic use of laxatives, the excessive use of docusate sodium may produce hypomagnesemia.[5]

Docusate salts are absorbed from the gastrointestinal tract and excreted in bile; they may cause alteration of the gastrointestinal epithelium.[6,7] The gastrointestinal or hepatic absorption of other drugs may also be affected by docusate salts, enhancing activity and possibly toxicity. Docusate sodium should not be administered with mineral oil as it may increase the absorption of the oil.

LD_{50} (mouse, IV): 0.06 g/kg[8]
LD_{50} (mouse, oral): 2.64 g/kg
LD_{50} (rat, IP): 0.59 g/kg
LD_{50} (rat, oral): 1.9 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Docusate sodium may be irritant to the eyes and skin, and when inhaled. Eye protection, gloves, and a dust mask or respirator are recommended. When heated to decomposition, docusate sodium emits toxic fumes.

16 Regulatory Status

GRAS listed. Included in the FDA Inactive Ingredients Database (IM injections; oral capsules, suspensions, and tablets; topical formulations). Included in nonparenteral medicines licensed in the

UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Docusate calcium; docusate potassium.

Docusate calcium

Empirical formula $C_{40}H_{74}CaO_{14}S_2$
Molecular weight 883.23
CAS number [128-49-4]
Synonyms 1,4-Bis(2-ethylhexyl) sulfosuccinate, calcium salt; dioctyl calcium sulfosuccinate.
Appearance White amorphous solid with a characteristic octanol-like odor.
Solubility Soluble 1 in less than 1 of ethanol (95%), chloroform, and ether, and 1 in 3300 of water; very soluble in corn oil and polyethylene glycol 400.

Docusate potassium

Empirical formula $C_{20}H_{37}KO_7S$
Molecular weight 460.67
CAS number [7491-09-0]
Synonyms Dioctyl potassium sulfosuccinate; potassium 1,4-bis(2-ethylhexyl) sulfosuccinate.
Appearance White amorphous solid with a characteristic octanol-like odor.
Solubility Soluble in ethanol (95%) and glycerin; sparingly soluble in water.

18 Comments

A convenient way of making a 1% w/v aqueous solution of docusate sodium is to add 1 g of solid to about 50 mL of water and to apply gentle heat. The docusate sodium dissolves in a short time and the resulting solution can be made up to 100 mL with water. Alternatively, 1 g may be soaked overnight in 50 mL of water and the additional water may then be added with gentle heating and stirring.

Docusate sodium may alter the dissolution characteristics of certain dosage forms and the bioavailability of some drugs.

Therapeutically, docusate salts are used in oral formulations as laxatives and fecal softeners for the short-term relief of constipation.

A specification for docusate sodium is contained in the *Food Chemicals Codex* (FCC).[9]

The EINECS number for docusate sodium is 209-406-4. The PubChem Compound ID (CID) for docusate sodium is 23673837.

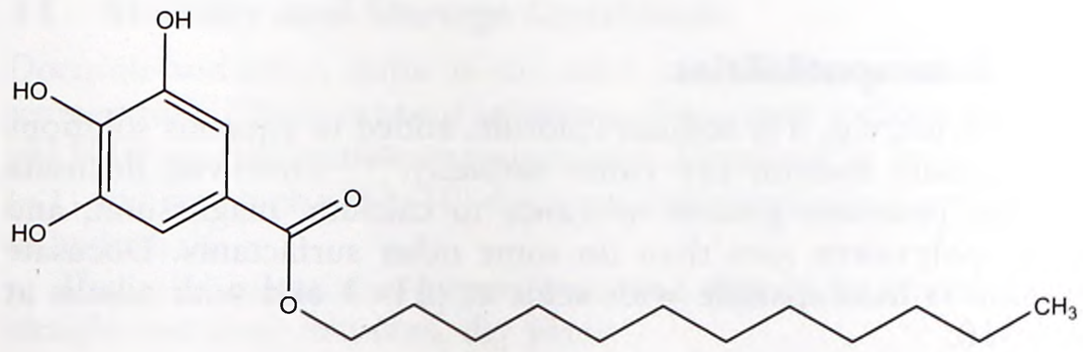
Dodecyl Gallate

1 Non-proprietary Names

BP: Dodecyl Gallate
PhEur: Dodecyl Gallate

2 Synonyms

Benzoic acid, 3,4,5-trihydroxy-, dodecyl ester; dodecylis gallas; E312; gallic acid, dodecyl ester; gallic acid, lauryl ester; lauryl gallate; *Nipagallin LA*; *Progallin LA*.



3 Chemical Name and CAS Registry Number

Dodecyl 3,4,5-trihydroxybenzoate [1166-52-5]

4 Empirical Formula and Molecular Weight

$C_{19}H_{30}O_5$ 338.4

5 Structural Formula

6 Functional Category

Antioxidant.

7 Applications in Pharmaceutical Formulation or Technology

Dodecyl gallate and other alkyl gallates have become widely used as antioxidant preservatives in pharmaceuticals since the use of propyl gallate in preventing autoxidation of oils was first described in 1943.[1–3] The alkyl gallates are effective at concentrations of 0.001 to 0.1% w/v, and used to prevent deterioration and rancidity of fats and oils.[4]

Dodecyl gallate has been investigated for its effect on the oxidation stability of ergocalciferol in ointments.[5] Experimental drug delivery via balloon catheters may also use a suitable antioxidant such as dodecyl gallate.[6] Dodecyl gallate has been identified as an antioxidant for topically administered hormone replacement therapies,[7] and to stabilize the composition of polymer or nonpolymeric matrices for modified-release drug delivery systems.[8–10]

8 Description

Dodecyl gallate is a white or almost white, odorless or almost odorless, crystalline powder.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for dodecyl gallate.

Test	PhEur 9.2
Characters	+
Identification	+
Chlorides	≤100 ppm
Loss on drying	≤0.5%
Sulfated ash	≤0.1%
Impurities	+
Assay (dried substance)	97.0–103.0%

10 Typical Properties

Boiling point 521.7°C at 760 mmHg
Density 1.112 g/cm^3
Flash point 180.3°C
Melting point 96–97.5°C after drying for 4 hours at 60°C.
Solubility *see* Table II.

Table II: Solubility of dodecyl gallate.

Solvent	Solubility at 20°C
Acetone	1 in 2
Chloroform	1 in 60
Ethanol (95%)	1 in 3.5
Ether	1 in 4
Methanol	1 in 1.5
Peanut oil	1 in 30
Propylene glycol	1 in 60
Water	Practically insoluble

11 Stability and Storage Conditions

Dodecyl gallate should be stored in a non-metallic container, protected from light, in a cool, dry place.

12 Incompatibilities

Dodecyl gallate and other alkyl gallates are incompatible with metals, e.g. sodium, potassium and iron, forming intensely colored complexes. Complex formation may be prevented, under some circumstances, by the addition of a sequestering agent, typically citric acid. Dodecyl gallate also reacts with strong oxidizing agents and strong bases.

13 Method of Manufacture

Dodecyl gallate is prepared by the esterification of gallic acid with dodecanol in the presence of an anhydrous strong acid. The product is isolated and purified by crystallization from an organic solvent, such as diethyl ether.[11,12]

14 Safety

Dodecyl gallate is widely used in food products and is generally regarded as a nontoxic and nonirritant material. However, it may cause contact sensitivity and skin reactions.[13,14] Studies of experimental sensitization in guinea pigs indicated that, of the alkyl gallates tested, dodecyl gallate was the strongest sensitizer.[15]

The WHO has not allocated an acceptable daily intake for dodecyl gallate; the previous temporary estimated acceptable daily intake for dodecyl gallate has not been extended due to the lack of additional studies.[16]

LD_{50} (rat, IP): 0.1 g/kg[17]
LD_{50} (rat, oral): 5 g/kg[18]
LD_{50} (mouse, oral): 1.6 g/kg[19]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. Dodecyl gallate is a skin irritant.[10] When heated to decomposition, dodecyl gallate may emit acrid smoke and irritating fumes. Eye protection and gloves are recommended.

16 Regulatory Status

Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database. Dodecyl gallate is listed as a food additive in the EAFUS list compiled by the FDA. Accepted for use as a food additive in Europe.

17 Related Substances

Octyl gallate; propyl gallate.

18 Comments

In essential oils and as flavorings other than essential oils, dodecyl gallate may be added up to 1 g/kg and 0.1 g/kg respectively; individually or in combination with other gallates.[20] Dodecyl gallate is an authorized ingredient for use in cosmetic products[21] and for use in the manufacture of plastic layers.[22]

Dodecyl gallate has been shown to possess antiviral activity as well as antibacterial activity against Gram-positive bacteria, including methicillin-resistant *Staphylococcus aureus* (MRSA) strains.[23–25]

Dodecyl gallate and other alkyl gallates are used as antioxidants and preservatives in foods and cosmetic formulations.[26] They are often used with other antioxidants such as butylated hydroxyanisole or butylated hydroxytoluene,[26] and with sequestrants such as citric acid,[27] to improve acceptability and efficacy.

Potential applications of dodecyl gallate include enzymatically grafting dodecyl gallate to chitosan solutions or nanofibrillated cellulose; this increases the surface hydrophobicity and improves oxygen barrier properties of films and paper substrates that may be of use in packaging foodstuffs.[28,29] The application of dodecyl

gallate also improves the oxidative stability of Ultra High Molecular Weight Polyethylene (UHMWPE) used in orthopedic implants.[30] Wool fibres may also be modified with dodecyl gallate improving their hydrophobic, antimicrobial and antioxidant properties,[31] and the use of dodecyl gallate in animal feeds has been identified due to its antimicrobial properties.[32]

The EINECS number for dodecyl gallate is 214-620-6. The PubChem Compound ID (CID) for dodecyl gallate is 14425.

Edetate Calcium Disodium

1 Nonproprietry Names

BP: Sodium Calcium Edetate
JP: Calcium Sodium Edetate Hydrate
PhEur: Sodium Calcium Edetate
USP–NF: Edetate Calcium Disodium

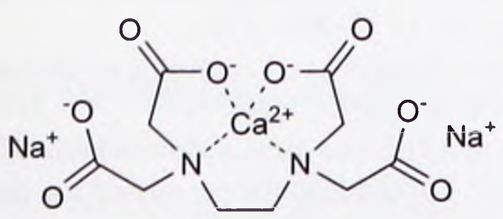
Note that edetate calcium disodium occurs as the dihydrate, trihydrate, and anhydrous material. The JP contains a single monograph for the hydrate; the PhEur contains a single monograph for the anhydrous; and the USP–NF contains a single monograph for a mixture of the anhydrous and hydrate.

2 Synonyms

Calciate (2-), [[*N*,*N*'-1,2-ethanediylbis[*N*-(carboxymethyl)glycinato]](4-)-*N*,*N*',*O*,*O*',O^N,$O^{N'}$]-, disodium, hydrate, (OC-6-21)-; calcium disodium edetate; calcium disodium ethylenediaminetetraacetate; calcium disodium (ethylenedinitrilo)tetraacetate; *Dissolvine E-CA-10*; E385; edathamil calcium disodium; edetic acid calcium disodium salt; EDTA calcium; ethylenediaminetetraacetic acid calcium disodium chelate; [(ethylenedinitrilo)tetraacetato]-calciate(2-) disodium; natrii calcii edetas; sodium calcium edetate; *Versene CA*.

3 Chemical Name and CAS Registry Number

Disodium[(ethylenedinitrilo)tetraacetato]calciate(2-) anhydrous [62-33-9]



Disodium[(ethylenedinitrilo)tetraacetato]calciate(2-) hydrate [23411-34-9]

Disodium[(ethylenedinitrilo)tetraacetato]calciate(2-) dihydrate [6766-87-6]

4 Empirical Formula and Molecular Weight

$C_{10}H_{12}CaN_2Na_2O_8$	374.27
$C_{10}H_{12}CaN_2Na_2O_8\ H_2O$	394.30
$C_{10}H_{12}CaN_2Na_2O_8\ 2H_2O$	410.30
$C_{10}H_{12}CaN_2Na_2O_8\ 3H_2O$	428.32

5 Structural Formula

6 Functional Category

Complexing agent.

7 Applications in Pharmaceutical Formulation or Technology

Edetate calcium disodium is used as a complexing agent in pharmaceutical formulations. The calcium complex is relatively weak and will preferentially exchange calcium for heavy metals, such as iron, copper, and lead, with the release of calcium ions. In parenteral biologic drug products edetate calcium disodium is used to improve the stability of the formulation by chelating trace metal ions which would otherwise result in protein degradation.[1] Typically, it is also used at concentrations between 0.01–0.1% w/v.

The synergistic antimicrobial activity of edetate calcium disodium with imipenem monohydrate has been investigated *in vivo* with results showing a statistically significant reduction in bacterial burden.[2]

See also Edetic Acid.

8 Description

Edetate calcium disodium occurs as a white or off-white, hygroscopic, crystalline powder or granules. It is odorless or has a slight odor, and is tasteless or has a faint saline taste.

9 Pharmacopeial Specifications

The pharmacopeial specifications for edetate calcium disodium have undergone harmonization of many attributes for JP, PhEur, and USP–NF. *See* Table I.

Table I: Pharmacopeial specifications for edetate calcium disodium.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Characters	—	+	—
Identification[a]	+	+	+
Appearance of solution[a]	+	+	—
pH	6.5–8.0	6.5–8.0	6.5–8.0
Nitrilotriacetic acid[a]	≤0.1%	≤0.1%	≤0.1%
Edetate disodium	≤1.0%	≤1.0%	≤1.0%
Chlorides	≤0.1%	≤0.1%	≤0.1%
Iron	—	≤80 ppm	—
Heavy metals[a]	≤20 ppm	—	≤20 ppm
Water	5.0–13.0%	5.0–13.0%	5.0–13.0%
Assay (anhydrous)	98.0–102.0%	98.0–102.0%	98.0–102.0%

(a) These tests have not been fully harmonized at the time of publication.

10 Typical Properties

Density (bulk) 0.67 g/cm^3
Melting point >300°C
Solubility Practically insoluble in chloroform, ether, and other organic solvents; very slightly soluble in ethanol (96%); freely soluble water (1 in 2).
Vapor pressure <0.1 mmHg

11 Stability and Storage Conditions

Edetate salts are more stable than edetic acid (*see* Edetic acid). Edetate calcium sodium is slightly hygroscopic and should be protected from moisture.

Edetate calcium sodium should be stored in a tight container in a cool, dry place.

12 Incompatibilities

Edetate calcium sodium is incompatible with strong oxidizing agents. It has also been reported to be incompatible with amphotericin and with hydralazine hydrochloride in infusion fluids. Contact with metals such as aluminum may produce hydrogen.

Due to the chelatation of zinc, edetate calcium disodium inactivates certain preparations of insulin.[3] *See also* Edetic acid.

13 Method of Manufacture

Edetate calcium disodium may be prepared by the addition of calcium carbonate to a solution of edetate disodium, boiling until carbon dioxide is no longer evolved, before filtrating and crystallizing the solution.[1]

14 Safety

Edetate calcium disodium is used in oral pharmaceutical formulations and as a food additive. Edetate calcium sodium may cause serious eye irritation and is a weak sensitizer.[4,5]

Therapeutically, edetate calcium disodium is used as a chelating agent for heavy metal poisoning. For the treatment of lead poisoning, a total daily dose of 80 mg/kg (as a slow infusion over two doses) for 5 days of edetate calcium disodium has been used.[6] Treatment associated adverse reactions include nephrotoxicity, abnormal liver function, fever, myalgia, fatigue, headache, nausea, and vomiting.[7] Edetate calcium disodium chelates trace metals such as zinc and can lead to zinc deficiency problems within the body.[3] Hypercalcemia may occur through displacement of calcium from edetate calcium disodium; however, as it does not chelate calcium, it is used in pharmaceutical formulations in preference to edetate disodium or sodium edetate to prevent calcium depletion occurring in the body.[8]

The WHO has set an acceptable daily intake of edetate calcium disodium of 0–2.5 mg/kg body-weight.[9]

The Cosmetic Ingredient Review Expert Panel has assessed edetate calcium disodium and concluded that the material is safe as used in cosmetic formulations.[4]

LD_{50} (mouse, IP): 4.5 g/kg[10]
LD_{50} (rabbit, IP): 6 g/kg[10]
LD_{50} (rabbit, oral): 7 g/kg[10]
LD_{50} (rat, IP): 3.85 g/kg[10]
LD_{50} (rat, IV): 3.0 g/kg[10]
LD_{50} (rat, oral): 10 g/kg[10]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. Edetate calcium disodium may cause serious eye irritation and skin irritation. Eye protection, gloves, and a dust mask are recommended.

When heated to decomposition, edetate calcium sodium emits irritating and toxic fumes of nitrogen oxides. Calcium oxalate and sodium oxalate are also formed on heating.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (injections; oral capsules, solutions, suspensions, syrups, drops and tablets; rectal, urethral and topical preparations). Included in parenteral and nonparenteral medicines licensed in the UK. Included as a food additive in the 'EAFUS' list compiled by the FDA. Accepted for use as a food additive in Europe. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Edetic acid; tetrasodium edetate.

18 Comments

Edetate calcium disodium is one of the materials that have been selected for harmonization by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

Edetate calcium disodium is used as a complexing agent in cosmetics and foods. In food products, edetate calcium disodium may be used as a preservative, and to retain color and flavor.[4,11] Unlike edetic acid and disodium edetate, edetate calcium disodium is not effective for use as a water softener, as it does not chelate calcium and magnesium ions in hard water.

Therapeutically, edetate calcium disodium is a chelator of heavy-metal polyvalent ions, and has been used in the treatment of poisoning by lead, chromium, and radioactive metals such as plutonium.[8]

A specification for calcium edetate disodium is included in the *Food Chemicals Codex*.[4]

The EINECS number for edetate calcium disodium is 200-529-9. The PubChem Compound ID (CID) for edetate calcium disodium is 6093170 and 6109 for the anhydrous material; 16210993, 73169089, and 6096880 for the monohydrate; 46245300 for the dihydrate; and 76967923 for the trihydrate.

Edetate Disodium

1 Nonproprietary Names

BP: Disodium Edetate

JP: Disodium Edetate Hydrate

PhEur: Disodium Edetate

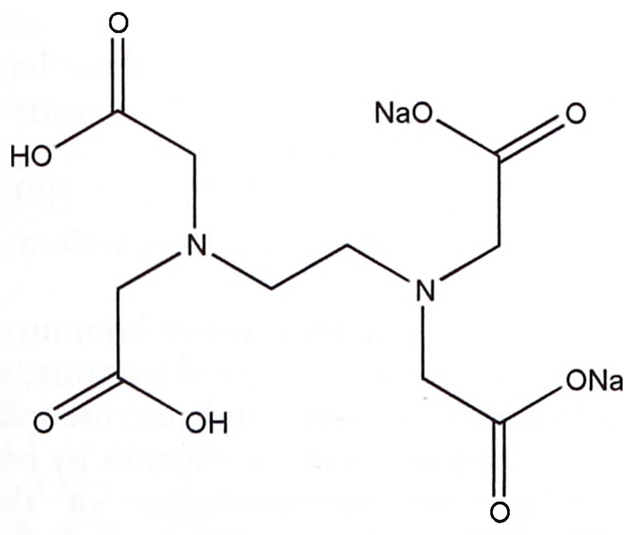
USP–NF: Edetate Disodium

2 Synonyms

Dinatrii edetas; disodium edetate; disodium EDTA; disodium ethylenediaminetetraacetate; edathamil disodium; edetic acid, disodium salt; *Versene*.

3 Chemical Name and CAS Registry Number

Ethylenediaminetetraacetic acid, disodium salt [139-33-3]



Disodium ethylenediaminetetraacetate dihydrate [6381-92-6]

4 Empirical Formula and Molecular Weight

$C_{10}H_{14}N_2Na_2O_8$ 336.2 (for anhydrous)

$C_{10}H_{18}N_2Na_2O_{10}$ 372.2 (for dihydrate)

5 Structural Formula

6 Functional Category

Complexing agent.

7 Applications in Pharmaceutical Formulation or Technology

Edetate disodium is used as a complexing agent in a wide range of pharmaceutical preparations, including mouthwashes, ophthalmic preparations, and topical preparations,[1–3] typically at concentrations between 0.005 and 0.1% w/v.

Edetate disodium forms stable water-soluble complexes (chelates) with alkaline earth and heavy-metal ions. The chelated form has few of the properties of the free ion, and for this reason chelating agents are often described as 'removing' ions from solution, a process known as sequestering. The stability of the metal–edetate complex is dependent on the metal ion involved and the pH.

Edetate disodium has been used experimentally to investigate the stability and skin penetration capacity of captopril gel, in which edetate disodium was shown to exert a potent stabilizing effect, and may be used in the development of a transdermal drug delivery system.[4] A chitosan–EDTA conjugate has been investigated as a novel polymer for use in topical gels. The conjugate was shown to be stable, colorless, and transparent, and it also demonstrated antimicrobial effects.[5] Studies have shown that edetate disodium may be effective in retarding microbial growth in propofol formulations[6] and for the prevention of biofilm formation in catheters.[7]

Research has also been done to prepare and characterize hot melt dispersion formulations of mini-pellets containing EDTA.[8] A salt complex of iron and EDTA has been used to develop chewable and orodispersible tablets in studies in humans and rats.[9]

See also Edetic Acid.

8 Description

Edetate disodium occurs as a white, crystalline, odorless powder with a slightly acidic taste.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for edetate disodium.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters	+	+	–
Appearance of solution	+	+	–
pH	4.3–4.7	4.0–5.5	4.0–6.0
Iron	–	≤80 ppm	–
Calcium	–	–	+
Heavy metals	≤10 ppm	–	≤0.005%
Cyanide	+	–	–
Arsenic	≤2 ppm	–	–
Limit of nitrilotriacetic acid	–	≤0.1%	≤0.1%

lization when heated to 120°C. Aqueous solutions of edetate disodium may be sterilized by autoclaving, and should be stored in an alkali-free container.

Edetate disodium is hygroscopic and is unstable when exposed to moisture. It should be stored in a well-closed container in a cool, dry place.

12 Incompatibilities

Edetate disodium behaves as a weak acid, displacing carbon dioxide from carbonates and reacting with metals to form hydrogen. It is incompatible with strong oxidizing agents, strong bases, metal ions, and metal alloys.

The addition of edetate disodium to phenylmercuric nitrate[10] and thimerosal[10,11] has also been reported to reduce the antimicrobial efficacy of the preservative.

See also Edetic Acid.

13 Method of Manufacture

Edetate disodium may be prepared by the reaction of edetic acid and sodium hydroxide.

14 Safety

Edetate disodium is used widely in topical, oral, and parenteral pharmaceutical formulations; it is used extensively in cosmetic and food products. Edetate disodium and edetate calcium disodium are used in a greater number and variety of pharmaceutical formulations than is edetic acid. Both edetate disodium and edetate calcium disodium are poorly absorbed from the gastrointestinal tract and are associated with few adverse effects when used as excipients in pharmaceutical formulations.

Edetate disodium, trisodium edetate, and edetic acid readily chelate calcium and can, in large doses, cause calcium depletion (hypocalcemia) if used over an extended period of time, or if administered too rapidly by intravenous infusion. If used in preparations for the mouth, they can also leach calcium from the teeth. However, edetate calcium disodium does not chelate calcium.

Edetate disodium should be used with caution in patients with renal impairment, tuberculosis, and impaired cardiac function.

Although edetate disodium is generally considered safe, there have been reports of edetate disodium toxicity in patients receiving chelation therapy,[12] and between 1971 and 2007, four deaths attributed to the therapeutic use of edetate disodium were reported to the FDA.[13]

Nasal formulations containing benzalkonium chloride and edetate disodium, both known to be local irritants, were shown to produce an inflammatory reaction, and microscopic examination showed an extended infiltration of the mucosa by eosinophils, and pronounced atrophy and disorganization of the epithelium, although these effects were subsequently shown to be reversible.[3]

The WHO has set an estimated acceptable daily intake for disodium EDTA in foodstuffs of up to 2.5 mg/kg body-weight.[14] *See also* Edetic Acid.

LD_{50} (mouse, IP): 0.26 g/kg[15]
LD_{50} (mouse, IV): 0.056 g/kg[15]
LD_{50} (mouse, OP): 2.05 g/kg[15]
LD_{50} (rabbit, IV): 0.047 g/kg[15]
LD_{50} (rabbit, OP): 2.3 g/kg[15]
LD_{50} (rat, OP): 2.0 g/kg[15]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Edetate disodium and its derivatives are mild irritants to the mucous membranes. Eye protection, gloves, and dust masks are recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (inhalations; injections; ophthalmic, otic, oral, rectal, topical, intrauterine, nasal, transdermal, urethral, iontophoresis and vaginal preparations). Included in nonparenteral and parenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Edetic acid.

18 Comments

Many solutions used for the cleaning, storage, and wetting of contact lenses contain edetate disodium.[16,17] Therapeutically, edetate disodium is used as an anticoagulant as it will chelate calcium and prevent the coagulation of blood *in vitro*.[18] Concentrations of 0.1% w/v are used in small volumes for hematological testing and 0.3% w/v in transfusions. Studies have shown how edetate disodium is facilitated by methylsulfonylmethane to cross biological membranes for regional chelation therapy.[19] It is also used therapeutically in the treatment of hypercalcemia.[13]

Edetate disodium is used as a water softener as it will chelate calcium and magnesium ions present in hard water.

A specification for edetate disodium is contained in the *Food Chemicals Codex* (FCC).[20]

The EINECS number for edetate disodium is 205-358-3. The PubChem Compound ID (CID) for edetate disodium includes 8759 and 636371.

Edetic Acid

1 Nonproprietary Names

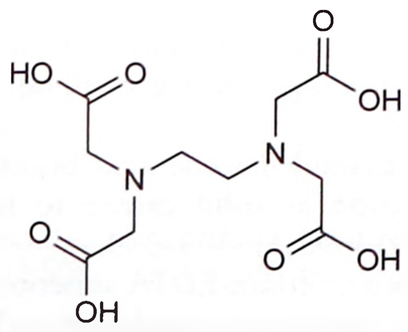
BP: Edetic Acid

PhEur: Edetic Acid

USP–NF: Edetic Acid

2 Synonyms

Acidum edeticum;3,6-bis(carboxymethyl)-3,5-diazooctanedioic acid; ethylenebis(iminodiacetic acid); *Dissolvine*; edathamil; EDTA; ethylenediaminetetraacetic acid; (ethylenedinitrilo)tetraacetic acid; *Sequestrene AA*; tetracemic acid; *Versene Acid*.



3 Chemical Name and CAS Registry Number

N,*N*-1,2-Ethanediylbis[*N*-(carboxymethyl)glycine] [60-00-4]

4 Empirical Formula and Molecular Weight

$C_{10}H_{16}N_2O_8$ 292.24

5 Structural Formula

6 Functional Category

Antimicrobial preservative; complexing agent.

7 Applications in Pharmaceutical Formulation or Technology

Edetic acid and edetate salts are used in pharmaceutical formulations as complexing agents. They form stable water-soluble complexes (chelates) with alkaline earth and heavy metal ions. The complexed form has few of the properties of the free ion, and for this reason complexing agents are often described as 'removing' ions from solution; this process is also called sequestering. The stability of the metal–edetate complex depends on the metal ion involved and also on the pH. The calcium complex is relatively weak and will preferentially exchange calcium for heavy metals, such as iron, copper, and lead, with the release of calcium ions.

Edetic acid and edetates are primarily used as antioxidant synergists, sequestering trace amounts of metal ions (particularly copper, iron, and manganese) that might otherwise catalyze autoxidation reactions. Edetic acid and edetates may be used alone or in combination with true antioxidants, the usual concentration employed being in the range 0.005–0.1% w/v. Edetates have been used to stabilize ascorbic acid, corticosteroids, epinephrine, folic acid, formaldehyde, gums and resins, hyaluronidase, hydrogen peroxide, oxytetracycline, penicillin, salicylic acid, and unsaturated fatty acids. Essential oils may be washed with a 2% w/v solution of edetate to remove trace metal impurities.

Edetic acid and edetates possess some antimicrobial activity but are most frequently used in combination with other antimicrobial preservatives owing to their synergistic effects. Typically, edetic acid and edetates are used in concentrations of 0.01–0.1% w/v as antimicrobial preservative synergists; *see* Section 10.

Edetates, particularly edetate disodium and edetate calcium disodium, are used in a greater number and variety of pharmaceutical formulations than the free acid.

See Edetate Disodium and Edetate Calcium Disodium.

8 Description

Edetic acid occurs as an odorless white or almost white crystalline powder or colorless crystals.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for edetic acid.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	—
Appearance of solution	+	—
Residue on ignition	—	≤0.2%
Sulfated ash	≤0.2%	—
Heavy metals	—	≤30 µg/g
Nitrilotriacetic acid	≤0.1%	≤0.3%
Iron	≤80 ppm	≤0.005%
Chloride	≤200 ppm	—
Assay	98.0–101.0%	98.0–100.5%

10 Typical Properties

Acidity/alkalinity pH = 2.2 for a 0.2% w/v aqueous solution.

Antimicrobial activity Edetic acid has some antimicrobial activity against Gram-negative microorganisms, *Pseudomonas aeruginosa*, some yeasts, and fungi although this activity is insufficient for edetic acid to be used effectively as an antimicrobial preservative on its own.[1,2] However, when used with other antimicrobial preservatives, edetic acid demonstrates a marked synergistic effect in its antimicrobial activity. Edetic acid and edetates are therefore frequently used in combination with such preservatives as benzalkonium chloride; bronopol; cetrimide; imidurea; parabens; and phenols, especially chloroxylenol. Typically, edetic acid is used at a concentration of 0.1–0.15% w/v. In the presence of some divalent metal ions, such as Ca^{2+} or Mg^{2+}, the synergistic effect may be reduced or lost altogether. Edetic acid and iodine form a colorless addition compound that is bactericidal.

See also Edetate Disodium.

Dissociation constant

$pK_{a1} = 2.00$;

$pK_{a2} = 2.67$;

$pK_{a3} = 6.16$;

$pK_{a4} = 10.26$.

Melting point 240–241°C, with decomposition.

Solubility Soluble in solutions of alkali hydroxides; practically insoluble in water (1 in 500) and ethanol (96%); insoluble in common organic solvents.

Specific gravity 0.721

Spectroscopy

NIR spectrum *see* Figure 1.

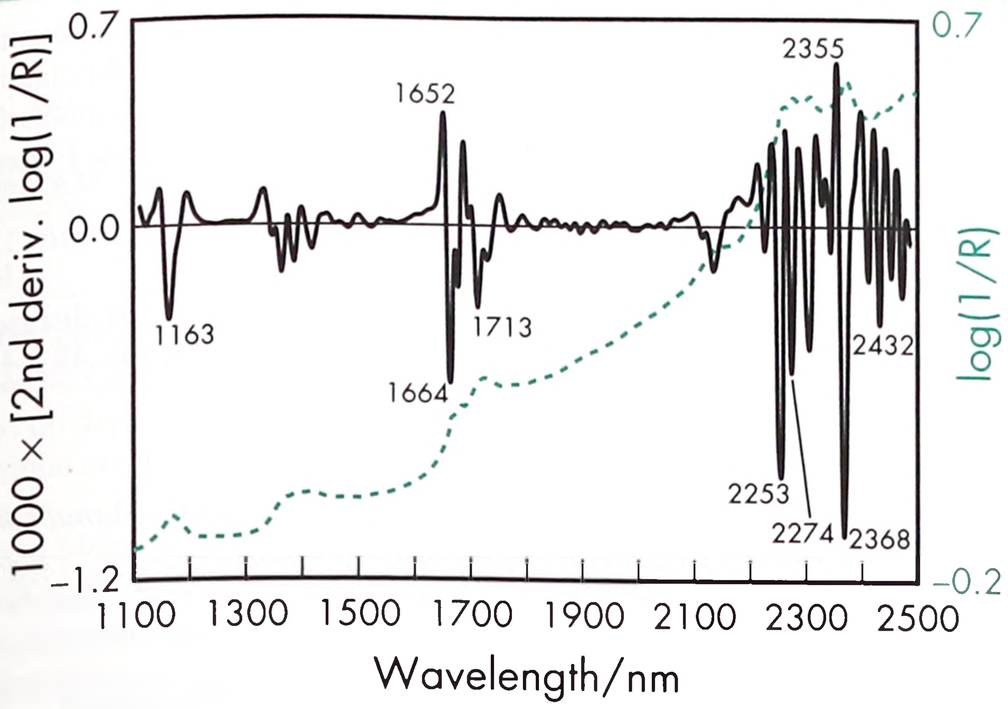


Figure 1: Near-infrared spectrum of edetic acid measured by reflectance.

11 Stability and Storage Conditions

Although edetic acid is fairly stable in the solid state, edetate salts are more stable than the free acid, which decarboxylates if heated above 150°C.

Aqueous solutions of edetic acid or edetate salts may be sterilized by autoclaving, and should be stored in an alkali-free container.

Edetic acid and edetates should be stored in well-closed containers in a cool, dry place.

12 Incompatibilities

Edetic acid and edetates are incompatible with strong oxidizing agents, strong bases, and polyvalent metal ions such as copper, nickel, and copper alloy.

Edetic acid behaves as a weak acid, displacing carbon dioxide from carbonates and reacting with metals to form hydrogen.

Other incompatibilities include the inactivation of certain types of insulin due to the chelation of zinc, and the chelation of trace metals in total parenteral nutrition (TPN) solutions following the addition of TPN additives stabilized with edetate disodium.

13 Method of Manufacture

Edetic acid may be prepared by the condensation of ethylenediamine with sodium monochloroacetate in the presence of sodium carbonate. An aqueous solution of the reactants is heated to about 90°C for 10 hours, then cooled, and hydrochloric acid is added to precipitate the edetic acid.

Edetic acid may also be prepared by the reaction of ethylenediamine with hydrogen cyanide and formaldehyde with subsequent hydrolysis of the tetranitrile, or under alkaline conditions with continuous extraction of ammonia.

14 Safety

Edetic acid and edetates are widely used in topical, oral, and parenteral pharmaceutical formulations.

Edetic acid is generally regarded as an essentially nontoxic and nonirritant material for use as an excipient. However, it has exhibited experimental teratogenic and reproductive effects, and mutation data have been reported.[3] Edetic acid been associated with dose-related bronchoconstriction when used as a preservative in nebulizer solutions. It has therefore been recommended that nebulizer solutions for bronchodilation should not contain edetic acid.[4]

Edetic acid and trisodium edetate readily chelate calcium and can, in large doses, cause calcium depletion (hypocalcemia) if used over an extended period or if administered too rapidly by intravenous infusion. If used in preparations for the mouth, they can also leach calcium from the teeth. In contrast, edetate calcium disodium does not chelate calcium. *See* Edetate Disodium and Edetate Calcium Disodium.

The Cosmetic Ingredient Review Expert Panel has assessed edetic acid and concluded that the material is safe as used in cosmetic formulations.[5]

LD_{50} (mouse, IP): 0.25 g/kg[3]

LD_{50} (rat, IP): 0.397 g/kg[3]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Edetic acid and edetates are mildly irritant to the skin, eyes, and mucous membranes. Ingestion, inhalation, and contact with the skin and eyes should therefore be avoided. When heated to decomposition, edetic acid emits very toxic fumes of nitrogen oxides. Eye protection, gloves, and a dust mask are recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral, otic, rectal, and topical preparations; IM, IV, SC, submucosal injection preparations). Included in parenteral and nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Dipotassium edetate; edetate calcium disodium; edetate disodium;-tetrasodium edetate; trisodium edetate.

Dipotassium edetate

Empirical formula $C_{10}H_{14}K_2N_2O_8$
Molecular weight 368.46
CAS number [2001-94-7]
Synonyms Dipotassium edathamil; dipotassium ethylenediaminetetraacetate; edathamil dipotassium; edetate dipotassium; edetic acid dipotassium salt; EDTA dipotassium; *N*,*N*′-1,2-ethanediylbis[*N*-(carboxymethyl)glycine] dipotassium salt; ethylenebis(iminodiacetic acid) dipotassium salt; ethylenediaminetetraacetic acid dipotassium salt; (ethylenedinitrilo)tetraacetic acid dipotassium salt; tetracemate dipotassium.
Appearance White crystalline powder.
Regulatory status Included in the Canadian Natural Health Products Ingredients Database.
Comments The EINECS number for dipotassium edetate is 217-895-0.

Trisodium edetate

Empirical formula $C_{10}H_{13}N_2Na_3O_8$
Molecular weight 358.20
CAS number [150-38-9]
Synonyms Edetate trisodium; edetic acid trisodium salt; EDTA trisodium; *N*,*N*′-1,2-ethanediylbis[*N*-(carboxymethyl)glycine] trisodium salt; ethylenediaminetetraacetic acid trisodium salt; (ethylenedinitrilo)tetraacetic acid trisodium salt; *Sequestrene NA3*; trisodium ethylenediaminetetraacetate; *Versene-9*.
Appearance White crystalline powder.
Acidity/alkalinity pH = 9.3 for a 1% w/v aqueous solution.
Melting point >300°C
Method of manufacture Trisodium edetate may be prepared by adding a solution of sodium hydroxide to edetate disodium.
Safety *see also* Section 14.

LD_{50} (mouse, IP): 0.3 g/kg[6]

LD_{50} (mouse, oral): 2.15 g/kg[6]

LD_{50} (rat, oral): 2.15 g/kg[6]

Regulatory status Included in the Canadian Natural Health Products Ingredients Database.

Comments More soluble in water than either the disodium salt or the free acid. Trisodium edetate also occurs as the monohydrate and is used in pharmaceutical formulations as a chelating agent. The EINECS number for trisodium edetate is 205-758-8.

18 Comments

Other salts of edetic acid that are commercially available include diammonium, dimagnesium, ferric sodium, and magnesium disodium edetates.

Edetic acid is used as a water softener in many cosmetic and toiletry products, e.g. soaps, as it chelates calcium and magnesium ions present in hard water.

Chelation therapy using edetic acid has been widely used for the treatment of ischemic heart disease. However, it has been suggested that the therapeutic benefits of this treatment may be due to the changes in lifestyle of the patient rather than the administration of edetic acid (40 mg/kg by infusion over a 3-hour period).[7]

The EINECS number for edetic acid is 200-449-4.

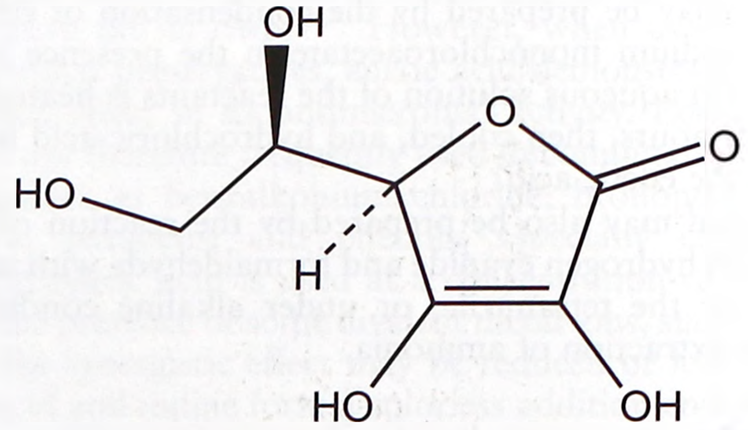
Erythorbic Acid

1 Nonproprietary Names

USP–NF: Erythorbic Acid

2 Synonyms

Araboascorbic acid; D-araboascorbic acid; 2,3-D-didehydro-D-*erythro*-hexono-1,4-lactone; E315; erycorbin; D-erythorbic acid; D-*erythro*-ascorbic acid; D-*erythro*-hex-2-enoic acid; D-*erythro*-3-ketohexonic acid lactone; D-*erythro*-3-oxohexonic acid lactone; glucosaccharonic acid; D-isoascorbic acid; isovitamin C; γ-lactone; mercate '5'; neo-cebicure; saccharosonic acid.



3 Chemical Name and CAS Registry Number

D-Isoascorbic acid [89-65-6]

4 Empirical Formula and Molecular Weight

$C_6H_8O_6$ 176.12

5 Structural Formula

6 Functional Category

Antioxidant.

7 Applications in Pharmaceutical Formulation or Technology

Erythorbic acid is used as an antioxidant in pharmaceutical formulations.

8 Description

Erythorbic acid occurs as shiny, granular, white or slightly yellow-colored crystals or powder. It gradually darkens in color upon exposure to light.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for erythorbic acid.

Test	USP 40–NF 35 S1
Identification	+
Specific rotation	−16.5° to −18.0°
Loss on drying	≤0.4%
Residue on ignition	≤0.3%
Lead	≤10 ppm
Assay (dried basis)	99.0–100.5%

10 Typical Properties

Acidity/alkalinity
pH = 2.1 (10% w/v aqueous solution at 25°C)
pH = 5–6 (16% w/v aqueous solution at 25°C)
Density (bulk) 0.704 g/cm^3
Melting point 164–172°C with decomposition at 184°C
Partition coefficient Log P (octanol : water) = −1.880
Solubility *see* Table II.

Table II: Solubility of erythorbic acid.

Solvent	Solubility at 25°C unless otherwise stated
Acetone	1 in 70
Ethanol (95%)	1 in 20
Ether	Practically insoluble
Glycerol	Slightly soluble
Methanol	1 in 5.5
Propylene glycol	1 in 6.7
Pyridine	Soluble
Water	1 in 2.3
	1 in 1.8 at 38°C
	1 in 1.6 at 50°C

11 Stability and Storage Conditions

Erythorbic acid should be stored in an airtight container, protected from light, in a cool, dry place.

12 Incompatibilities

Erythorbic acid is incompatible with chemically active metals such as aluminum, copper, magnesium, and zinc. It is also incompatible with strong bases and strong oxidizing agents.

13 Method of Manufacture

Erythorbic acid is synthesized by the reaction between methyl 2-keto-D-gluconate and sodium methoxide. It can also be synthesized from sucrose, and produced from *Penicillium* spp.

14 Safety

Erythorbic acid is widely used in oral pharmaceutical formulations and food applications as an antioxidant. Erythorbic acid is generally regarded as nontoxic and nonirritant when used as an excipient. The pure susbstance may cause skin and respiratory tract irritation, and serious eye irritation. It may also be harmful if swallowed or absorbed through the skin.

Erythorbic acid is readily metabolized and does not affect the urinary excretion of ascorbic acid. The WHO has set an acceptable daily intake of erythorbic acid and its sodium salt in foods at up to 5 mg/kg body-weight.[1]

LD_{50} (mouse, oral): 8.3 g/kg[3]
LD_{50} (rat, oral): 18.0 g/kg[3]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. When heated to decomposition, erythorbic acid emits acrid smoke and irritating fumes (carbon oxides). Avoid breathing dust or fumes. Wash skin thoroughly after handling. Use outdoors or in a well-ventilated area. Wear suitable protective clothing,

16 Regulatory Status

GRAS listed. Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (oral concentrate and tablets).

17 Related Substances

Ascorbic acid; sodium erythorbate.

Sodium erythorbate

Empirical formula $C_6H_7NaO_6$
Molecular weight 198.11
CAS number [7378-23-6]
Synonyms E316; D-*erythro*-hex-2-enoic acid sodium salt; erythorbic acid sodium salt.
Acidity/alkalinity pH = 7.2–7.9 for 10% w/v aqueous solution.
Melting point 172°C
Solubility Soluble 1 in 6.5 of water. The sodium salt is less soluble in water than the free acid.
Comments The EINECS number for sodium erythorbate is 228-973-6.

18 Comments

Erythorbic acid is a stereoisomer of L-ascorbic acid, and is used as an antioxidant in oral pharmaceutical formulations. It has approximately 5% of the vitamin C activity of L-ascorbic acid.

Erythorbic acid is also used as an antioxidant in foods. It is used in cured meats to prevent nitrosamine formation from nitrites, and to accelerate color fixing.

A specification for erythorbic acid is included in the *Food Chemicals Codex* (FCC).[2]

The EINECS number for erythorbic acid is 201-928-0. The PubChem Compound ID (CID) for erythorbic acid is 6981.

Erythritol

E

1 Nonproprietary Names

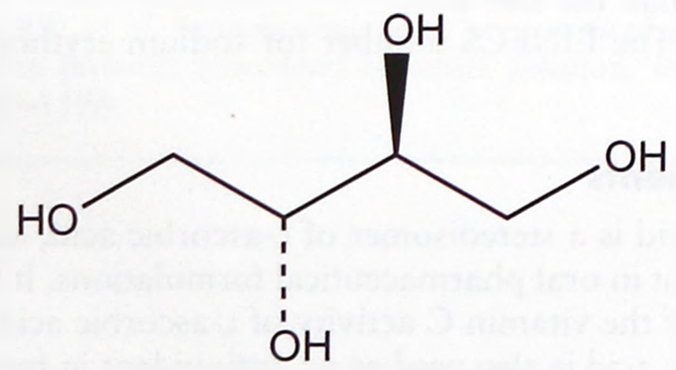
BP: Erythritol

PhEur: Erythritol

USP–NF: Erythritol

2 Synonyms

Butane 1,2,3,4-tetrol; 1,2,3,4-butanetetrol; C*Eridex; E968; erythrit; erythrite; erythritolum; erythroglucin; erythrol; *meso*-erythritol; L-(-)-threitol; paycite; phycite; phycitol; tetrahydroxybutane; *Zerose*.



3 Chemical Name and CAS Registry Number

(2*R*,3*S*)-Butane 1,2,3,4-tetrol [149-32-6]

4 Empirical Formula and Molecular Weight

$C_4H_{10}O_4$ 122.12

5 Structural Formula

6 Functional Category

Sweetening agent; tablet and capsule diluent; taste-masking agent.

7 Applications in Pharmaceutical Formulation or Technology

Erythritol is a naturally occurring noncariogenic excipient used in a variety of pharmaceutical preparations, including in solid dosage forms as a tablet filler,[1] and in coatings.[2,3] It has also been investigated for use in dry powder inhalers.[4,5] It is also used in sugar-free lozenges,[6,7] syrups, and medicated chewing gum.[6]

Erythritol can also be used as a diluent in wet granulation in combination with moisture-sensitive drugs.[8] Erythritol demonstrates superior powder flow behavior and good stability because of its low hygroscopicity, making it a suitable carrier for actives in sachets and capsules, and as a diluent in direct compression tableting.[8] In buccal applications, such as medicated chewing gums, it is used because of its high negative heat of solution which provides a strong cooling effect.[6]

Erythritol is also used as a noncaloric sweetener in syrups;[9] it is used to provide sensorial profile-modifying properties with intense sweeteners; and it is also used to mask unwanted aftertastes.[10]

Erythritol is also used as a noncariogenic sweetener in toothpastes and mouthwash solutions.

See Table I.

8 Description

Erythritol is a sugar alcohol (polyol) that occurs as a white or almost white powder or granular or crystalline substance. It is pleasant tasting with a mild sweetness approximately 60–70% that of sucrose. It also has a high negative heat of solution that provides a strong cooling effect.

Table I: Uses of erythritol.

Use	Concentration (%)
Tablet filler and binder	30.0–90.0
Taste masking in solutions	0.5–3.0
Oral care products	5.0–10.0

9 Pharmacopeial Specifications

See Table II. *See also* Section 18.

Table II: Pharmacopeial specifications for erythritol.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Melting point	119–122°C	119–123°C
Appearance of solution	+	–
Conductivity	≤ 20 µS/cm	≤ 20 µS/cm
Related substances	≤2.0%	≤2.0%
Lead	≤0.5 ppm	≤0.5 ppm
Water	≤0.5%	≤0.5%
Loss on drying	–	≤0.2%
Residue on ignition	–	≤0.1%
Microbial contamination	+	+
Bacterial endotoxins	+	–
Assay (anhydrous basis)	96.0–102.0%	96.0–102.0%

10 Typical Properties

Acidity/alkalinity pH = 5–7 at 25°C for a 5% w/v aqueous solution.

Boiling point 329–331°C

Caloric value 0.8 kJ/g

Density 1.45 g/cm^3

Dissociation constant pK_a = 13.90 at 18°C[11]

Glass transition temperature -42 to -46°C[12]

Heat of solution 23.3 kJ/mol[11]

Hygroscopicity Erythritol is nonhygroscopic; it absorbs approximately 1% w/w of water at 95% relative humidity (RH).[8]

Melting point 121.5°C, with decomposition at 160°C.

Solubility Freely soluble in water; slightly soluble in ethanol (95%); practically insoluble in ether and fats.

Spectroscopy

NIR spectrum *see* Figure 1.

Viscosity (dynamic) 3 mPa s (3 cP) at 60°C for a 30% w/w solution.

11 Stability and Storage Conditions

Erythritol has very good thermal and chemical stability. It is nonhygroscopic, and at 25°C does not significantly absorb additional water (<0.5%) up to a relative humidity (RH) of more than 90%.[8] Erythritol resists decomposition both in acidic and alkaline media and remains stable for prolonged periods at pH 2–10.[13]

Store in a cool, dry place, away from sources of ignition. When stored for up to 4 years in ambient conditions (20°C, 50% RH) erythritol has been shown to be stable.[8]

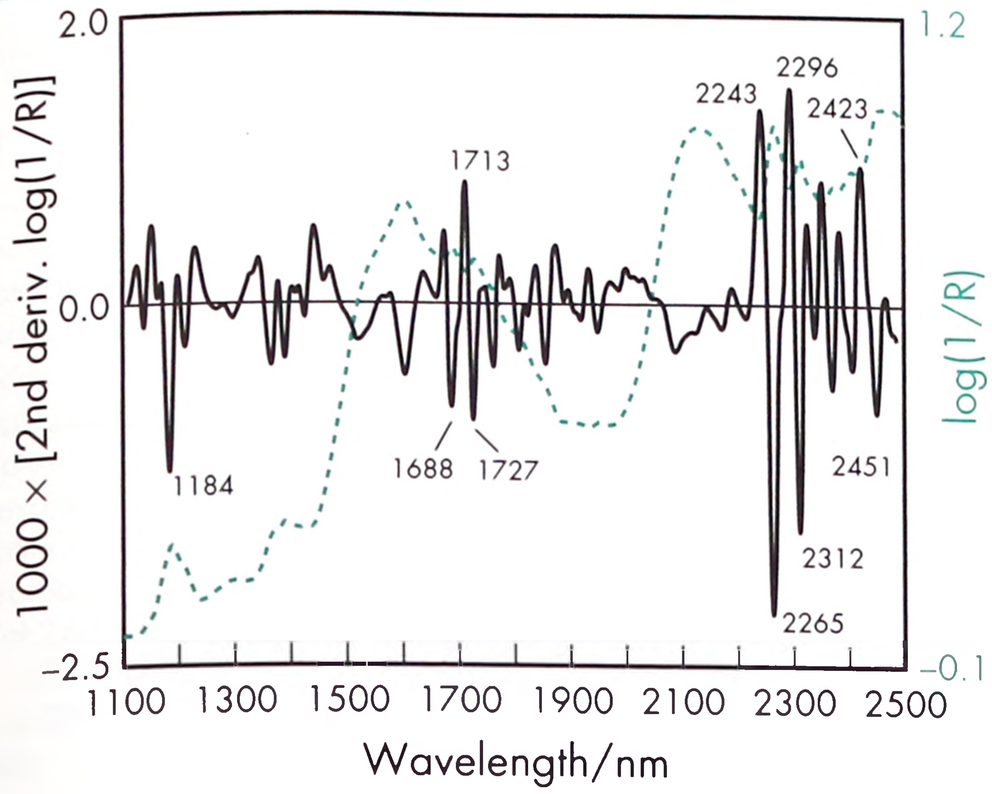


Figure 1: Near-infrared spectrum of erythritol measured by reflectance.

12 Incompatibilities

Erythritol is incompatible with strong oxidizing agents and strong bases.

13 Method of Manufacture

Erythritol is a starch-derived product. The starch is enzymatically hydrolyzed into glucose which is turned into erythritol via a fermentation process, using osmophilic yeasts or fungi (e.g. *Moniliella pollinis*, or *Trichosporonoides megachiliensis*).[14]

14 Safety

Erythritol is used in oral pharmaceutical formulations, confectionery, and food products. It is generally regarded as a nontoxic, nonallergenic, noncarcinogenic, and nonirritant material.[15] However, there has been a case report of urticaria caused by erythritol.[16]

The low molecular weight of erythritol allows more than 90% of the ingested molecules to be rapidly absorbed from the small intestine;[17] it is not metabolized and is excreted unchanged in the urine. Erythritol has a low caloric value (0.8 kJ/g). The WHO has set an acceptable daily intake of 'not specified' for erythritol.[15]

Erythritol is noncariogenic; preliminary studies suggest that it may inhibit the formation of dental plaque.[18]

In general, erythritol is well-tolerated;[19–21] furthermore, excessive consumption does not cause laxative effects. There is no significant increase in the blood glucose level after oral intake, and glycemic response is very low, making erythritol suitable for diabetics.[8]

LD_{50} (dog, IV): 5 g/kg[22]
LD_{50} (mouse, IP): 8–9 g/kg[15,22]
LD_{50} (rat, IV): 6.6 g/kg (male)[19]
LD_{50} (rat, IV): 9.6 g/kg (female)[19]
LD_{50} (rat, oral): >13 g/kg[19]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled. Eye protection and a dust mask or respirator are recommended.

16 Regulatory Status

GRAS listed. Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (ophthalmic suspensions; oral tablets and sustained-action tablets; topical preparations).

17 Related Substances

Mannitol; sorbitol; xylitol.

18 Comments

Active ingredients can be granulated with erythritol and binders such as maltodextrin or carboxymethylcellulose, resulting in coarser granules with improved flowability.[6] Coprocessing erythritol with a small amount of maltodextrin results in a proprietary compound that may be used in direct compression.[23]

A specification for erythritol is included in the *Japanese Pharmaceutical Excipients* (JPE).[24]

The EINECS number for erythritol is 205-737-3. The PubChem Compound ID (CID) for erythritol is 8998.

Ethanol

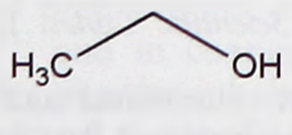
1 Nonproprietary Names

BP: Ethanol (96 per cent)
JP: Ethanol
PhEur: Ethanol (96 per cent)
USP–NF: Alcohol

Note that in the *Handbook of Pharmaceutical Excipients*, the term 'ethanol' is used for either ethanol 95% v/v or ethanol 96% v/v.

2 Synonyms

Alcohol; ethanolum (96 per centum); ethyl alcohol; ethyl alcohol, undenatured; ethyl hydrate; ethyl hydroxide; grain alcohol; methylcarbinol.



3 Chemical Name and CAS Registry Number

Ethanol [64-17-5]

4 Empirical Formula and Molecular Weight

C_2H_6O 46.07

5 Structural Formula

6 Functional Category

Antimicrobial preservative; penetration enhancer; solvent.

7 Applications in Pharmaceutical Formulation or Technology

Ethanol and aqueous ethanol solutions of various concentrations (*see* Sections 9 and 17) are widely used in pharmaceutical formulations and cosmetics; *see* Table I. Although ethanol is primarily used as a solvent, for example in solid dosage formulation,[1] it is also employed as a disinfectant, and in solutions as an antimicrobial preservative.[2,3] Topical ethanol solutions are used in the development of transdermal drug delivery systems as penetration enhancers.[4–9] Ethanol has also been used in the development of transdermal preparations as a co-surfactant.[10–12]

8 Description

Ethanol is a clear, colorless, mobile, and volatile liquid with a slight, characteristic odor and burning taste.

Table I: Uses of alcohol.

Use	Concentration (% v/v)
Antimicrobial preservative	≥10
Disinfectant	60–90
Extracting solvent in galenical manufacture	Up to 85
Solvent in film coating	Variable
Solvent in injectable solutions	Variable
Solvent in oral liquids	Variable
Solvent in topical products	60–90

9 Pharmacopeial Specifications

In the BP 2017, the term 'ethanol' used without other qualification refers to ethanol containing ≥99.5% v/v of C_2H_6O. The term 'alcohol', without other qualification, refers to ethanol 95.1–96.9% v/v. Where other strengths are intended, the term 'alcohol' or 'ethanol' is used, followed by the statement of the strength.

In the PhEur 9.2, the term ethanol (96%) is used to describe the material containing water and 95.1–96.9% v/v of C_2H_6O at 20°C. The PhEur 9.2 also includes a monograph for anhydrous ethanol, in which it states that anhydrous ethanol contains not less than 99.5% v/v of C_2H_6O at 20°C.

In the USP 40–NF 35 S1, the term 'dehydrated alcohol' refers to ethanol ≥99.5% v/v. The term 'alcohol' without other qualification refers to ethanol 94.9–96.0% v/v.

In the JP XVII, ethanol (alcohol) contains 95.1–96.9% v/v (by specific gravity) of C_2H_6O at 15°C.

The pharmacopeial specifications for ethanol have undergone harmonization of many attributes for JP, PhEur, and USP–NF.

See Table II. *See also* Sections 17 and 18.

10 Typical Properties

Antimicrobial activity Ethanol is bactericidal in aqueous mixtures at concentrations between 60% and 95% v/v; the optimum concentration is generally considered to be 70% v/v. Antimicrobial activity is enhanced in the presence of edetic acid or edetate salts.[2] Ethanol is inactivated in the presence of nonionic surfactants and is ineffective against bacterial spores.
Autoignition temperature 362°C
Boiling point 78.5°C
Flammability Readily flammable, burning with a blue, smokeless flame.
Flash point 13°C (closed cup)
Freezing point −117.3°C

Table II: Pharmacopeial specifications for ethanol.

NIR spectrum *see* Figure 2.

Raman spectrum *see* Figure 3.

Surface tension 21.99 mN/m

Vapor pressure 44.6 mmHg at 20°C

Note The above typical properties are for ethanol 95% or 96% v/v. *See* Section 17 for typical properties of dehydrated alcohol.

11 Stability and Storage Conditions

Aqueous ethanol solutions may be sterilized by autoclaving or by filtration and should be stored in airtight containers in a cool place.

12 Incompatibilities

In acidic conditions, ethanol solutions may react vigorously with oxidizing materials. Mixtures with alkali may darken in color owing to a reaction with residual amounts of aldehyde. Organic salts or acacia may be precipitated from aqueous solutions or dispersions. Ethanol solutions are also incompatible with aluminum containers and may interact with some drugs.

13 Method of Manufacture

Ethanol is manufactured by the controlled enzymatic fermentation of starch, sugar, or other carbohydrates. A fermented liquid is produced containing about 15% ethanol; ethanol 95% v/v is then obtained by fractional distillation. Ethanol may also be prepared by a number of synthetic methods.

14 Safety

Ethanol and aqueous ethanol solutions are widely used in a variety of pharmaceutical formulations and cosmetics. It is also consumed in alcoholic beverages.

Ethanol is rapidly absorbed from the gastrointestinal tract and the vapor may be absorbed through the lungs; it is metabolized, mainly in the liver, to acetaldehyde, which is further oxidized to acetate.

Ethanol is a central nervous system depressant and ingestion of low to moderate quantities can lead to symptoms of intoxication

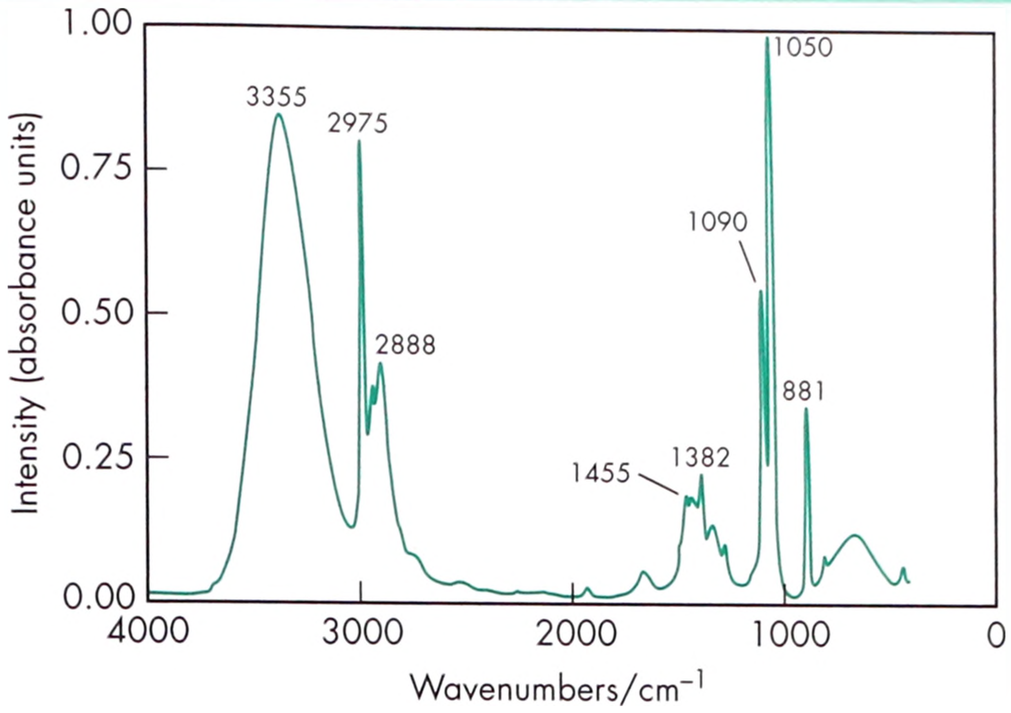

Figure 1: Infrared spectrum of ethanol measured by transmission. Adapted with permission of Informa Healthcare.

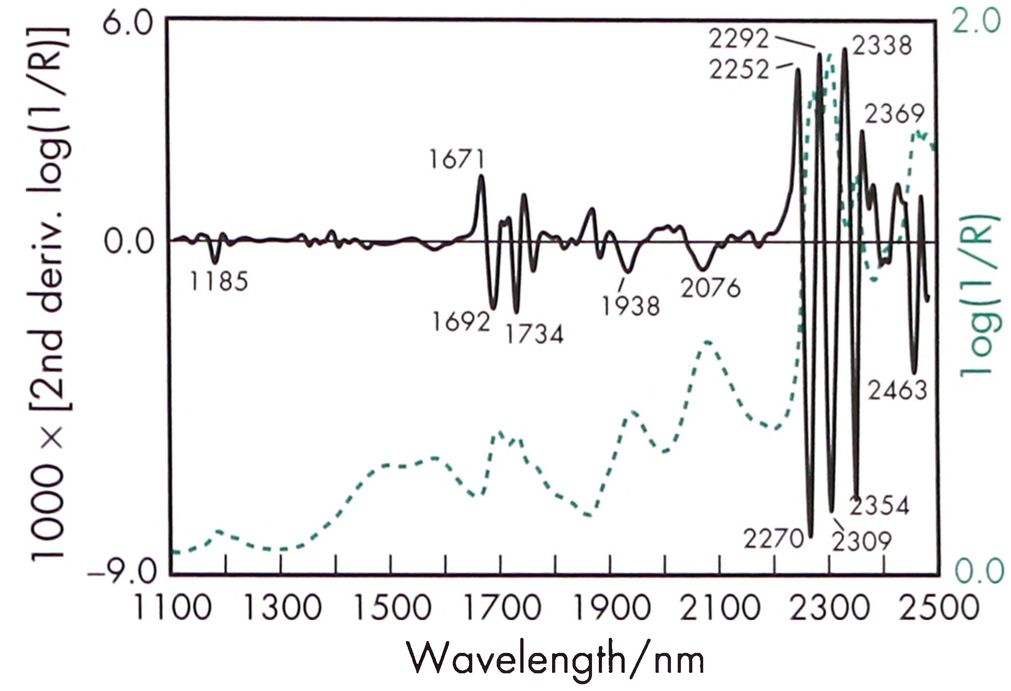

Figure 2: Near-infrared spectrum of ethanol measured by transflectance (1 mm path-length).

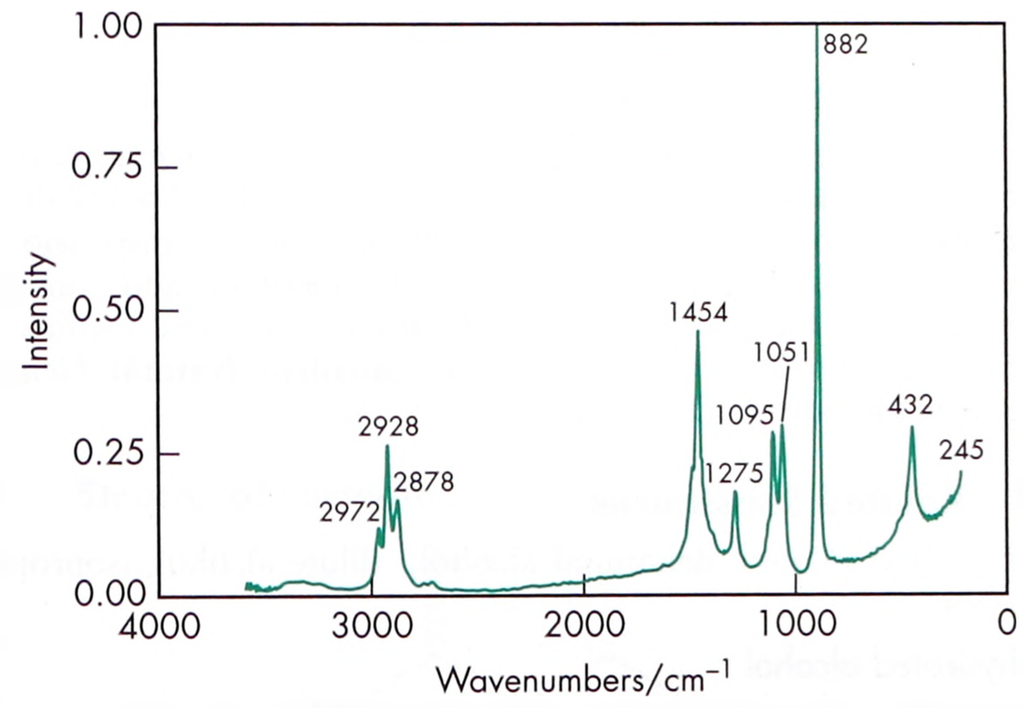

Figure 3: Raman spectrum of ethanol measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

including muscle incoordination, visual impairment, slurred speech, etc. Ingestion of higher concentrations may cause depression of medullary action, lethargy, amnesia, hypothermia, hypoglycemia, stupor, coma, respiratory depression, and cardiovascular collapse. The lethal human blood-alcohol concentration is generally estimated to be 400–500 mg/100 mL.

Although symptoms of ethanol intoxication are usually encountered following deliberate consumption of ethanol-containing beverages, many pharmaceutical products contain ethanol as a

solvent, which, if ingested in sufficiently large quantities, may cause adverse symptoms of intoxication. In the USA, the maximum quantity of alcohol included in OTC medicines is 10% v/v for products labeled for use by people of 12 years of age and older, 5% v/v for products intended for use by children aged 6–12 years of age, and 0.5% v/v for products for use by children under 6 years of age.[13]

Parenteral products containing up to 50% of ethanol have been formulated. However, such concentrations can produce pain on intramuscular injection and lower concentrations such as 5–10% v/v are preferred. Subcutaneous injection of ethanol similarly causes considerable pain followed by anesthesia. If injections are made close to nerves, neuritis and nerve degeneration may occur. This effect is used therapeutically to cause anesthesia in cases of severe pain, although the practice of using ethanol in nerve blocks is controversial. Doses of 1 mL of dehydrated alcohol have been used for this purpose.[14]

Preparations containing more than 50% v/v ethanol may cause skin irritation when applied topically.

LD_{50} (mouse, IP): 0.93 g/kg[15]
LD_{50} (mouse, IV): 1.97 g/kg[15]
LD_{50} (mouse, oral): 3.45 g/kg[15]
LD_{50} (mouse, SC): 8.29 g/kg[15]
LD_{50} (rat, IP): 3.75 g/kg[15]
LD_{50} (rat, IV): 1.44 g/kg[15]
LD_{50} (rat, oral): 7.06 g/kg[15]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Ethanol and aqueous ethanol solutions should be handled in a well-ventilated environment. In the UK, the long-term 8-hour TWA workplace exposure limit for ethanol is 1920 mg/m^3 (1000 ppm).[16] Ethanol may be irritant to the eyes and mucous membranes, and eye protection and gloves are recommended. Ethanol is flammable and should be heated with care. Fixed storage tanks should be electrically grounded to avoid ignition from electrostatic discharges when ethanol is transferred.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (dental preparations; inhalations; IM, IV, and SC injections; nasal and ophthalmic preparations; oral capsules, liquids, pellets, solutions, suspensions, syrups, and tablets; rectal, topical, transdermal, and vaginal preparations). Included in nonparenteral and parenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Dehydrated alcohol; denatured alcohol; dilute alcohol; isopropyl alcohol.

Dehydrated alcohol

Synonyms Absolute alcohol; anhydrous ethanol; ethanol.
Autoignition temperature 365°C
Boiling point 78.5°C
Explosive limits 3.5–19.0% v/v in air
Flash point 12°C (closed cup)
Melting point −112°C
Moisture content Absorbs water rapidly from the air.
Refractive index $n_D^{20} = 1.361$
Specific gravity 0.7904–0.7935 at 20°C
Spectroscopy

NIR spectrum *see* Figure 4.

Surface tension 22.75 mN/m at 20°C (ethanol/vapor)
Vapor density (relative) 1.59 (air = 1)
Vapor pressure 5.8 Pa at 20°C

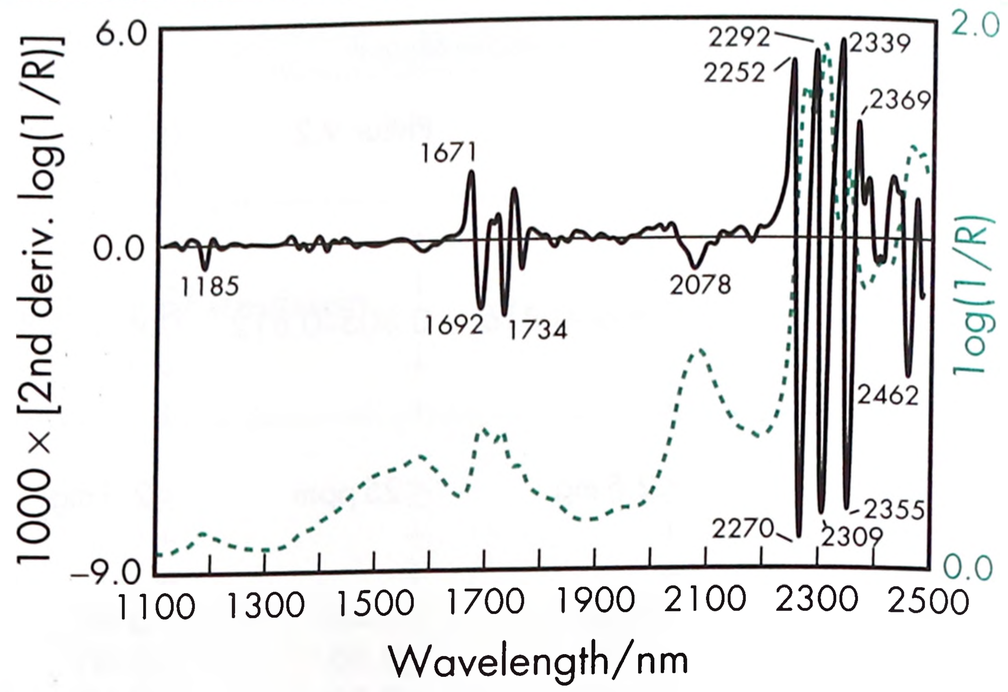

Figure 4: Near-infrared spectrum of dehydrated alcohol measured by transflectance (1 mm path-length).

Viscosity (dynamic) 1.22 mPa s (1.22 cP) at 20°C
Comments Dehydrated alcohol is ethanol ≥99.5% v/v. *See* Section 9. Dehydrated alcohol is one of the materials that have been selected for harmonization by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

Denatured alcohol

Synonyms Industrial methylated spirit; surgical spirit.
Comments Denatured alcohol is alcohol intended for external use only. It has been rendered unfit for human consumption by the addition of a denaturing agent such as methanol or methyl isobutyl ketone.

Dilute alcohol

Synonyms Dilute ethanol.
Specific gravity *See* Table III.

Table III: Specific gravity of alcohol dilutions.

Strength of alcohol (% v/v)	Specific gravity at 20°C
90	0.8289–0.8319
80	0.8599–0.8621
70	0.8860–0.8883
60	0.9103–0.9114
50	0.9314–0.9326
45	0.9407–0.9417
25	0.9694–0.9703
20	0.9748–0.9759

Comments The term 'dilute alcohol' refers to a mixture of ethanol and water of stated concentration. The USP 40–NF 35 S1 lists diluted alcohol. The BP 2017 lists eight strengths of dilute alcohol (dilute ethanol) containing 90%, 80%, 70%, 60%, 50%, 45%, 25%, and 20% v/v, respectively, of ethanol.

18 Comments

Ethanol is one of the materials that have been selected for harmonization by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

Possession and use of nondenatured alcohols are usually subject to close control by excise authorities.

A specification for alcohol is contained in the *Food Chemicals Codex* (FCC).[17]

The EINECS number for ethanol is 200-578-6. The PubChem Compound ID (CID) for alcohol is 702.

Ethyl Acetate

1 Nonproprietary Names

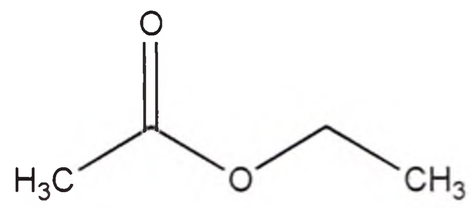
BP: Ethyl Acetate

PhEur: Ethyl Acetate

USP–NF: Ethyl Acetate

2 Synonyms

Acetic acid ethyl ester; acetic ester; acetic ether; acetoxyethane; aethylis acetas; aethylium aceticum; ethyl ethanoate; ethylis acetas; vinegar naphtha.



3 Chemical Name and CAS Registry Number

Ethyl acetate [141-78-6]

4 Empirical Formula and Molecular Weight

$C_4H_8O_2$ 88.1

5 Structural Formula

6 Functional Category

Flavoring agent; solvent.

7 Applications in Pharmaceutical Formulation or Technology

In pharmaceutical preparations, ethyl acetate is primarily used as a solvent, although it has also been used as a flavoring agent. As a solvent, it is included in topical solutions and gels, and in edible printing inks used for tablets.

Ethyl acetate has also been shown to increase the solubility of chlortalidone[1] and to modify the polymorphic crystal forms obtained for piroxicam pivalate,[2] mefenamic acid,[3] and fluconazole,[4] and has been used in the formulation of microspheres.[5–8] Ethyl acetate has been used as a solvent in the preparation of a liposomal amphotericin B dry powder inhaler formulation[9] and in the preparation of microparticles.[10] Its use as a chemical enhancer for the transdermal iontophoresis of insulin has been investigated.[11]

8 Description

Ethyl acetate occurs as a clear, colorless, volatile liquid with a characteristic fruity, fragrant, and slightly acetous odor, and has a pleasant taste when diluted.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for ethyl acetate.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	—
Boiling point	76–78°C	—
Appearance of solution	+	—
Acidity	+	+
Specific gravity	0.898–0.902	0.894–0.898
Refractive index	1.370–1.373	—
Readily carbonizable substances	—	+
Reaction with sulfuric acid	+	—
Chromatographic purity	—[a]	+
Residue on evaporation	≤30 ppm	≤0.02%
Water	≤0.1%	—
Limit of methyl compounds	—	+
Related substances	+	—
Assay	—	99.0–100.5%

(a) The PhEur 9.2 lists impurities in ethyl acetate as methyl acetate, ethanol, and methanol.

10 Typical Properties

Autoignition temperature 486.1°C
Boiling point 77°C
Dielectric constant 6.11
Density 0.902 g/cm^3 at 20°C
Explosive limit 2.2–11.5% (volume in air)
Flash point

+7.2°C (open cup);

−5.0°C (closed cup).

Freezing point −83.6°C
Partition coefficient log *P* (octanol/water) = 0.7
Refractive index n_D^{20} = 1.3719
Solubility Soluble 1 in 10 of water at 25°C; ethyl acetate is more soluble in water at lower temperatures than at higher temperatures. Soluble in fixed and volatile oils. Miscible with acetone, chloroform, dichloromethane, ethanol (95%), ether, glycerin, and with most other organic liquids.
Spectroscopy

IR spectrum *see* Figure 1.

NIR spectrum *see* Figure 2.

Raman spectrum *see* Figure 3.

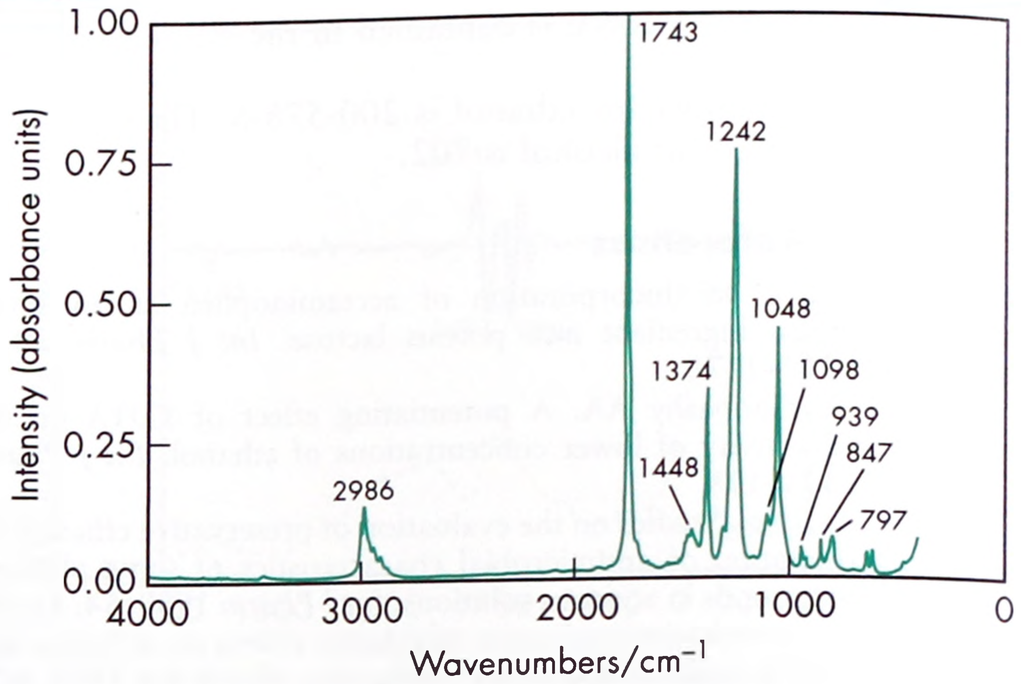


Figure 1: Infrared spectrum of ethyl acetate measured by transmission. Adapted with permission of Informa Healthcare.

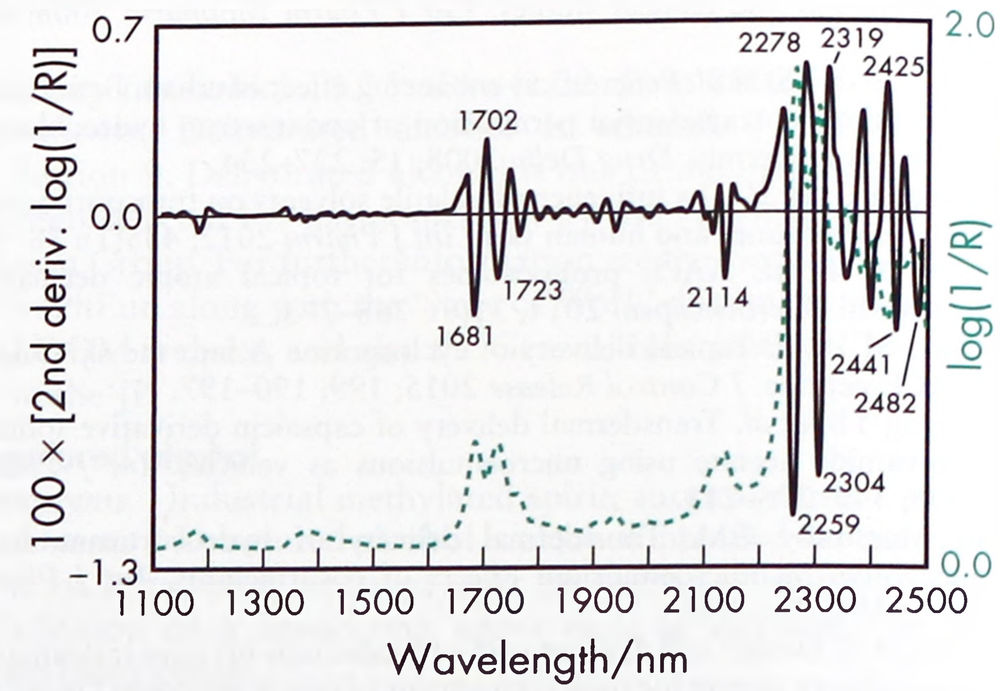

Figure 2: Near-infrared spectrum of ethyl acetate measured by transflectance (1 mm path-length).

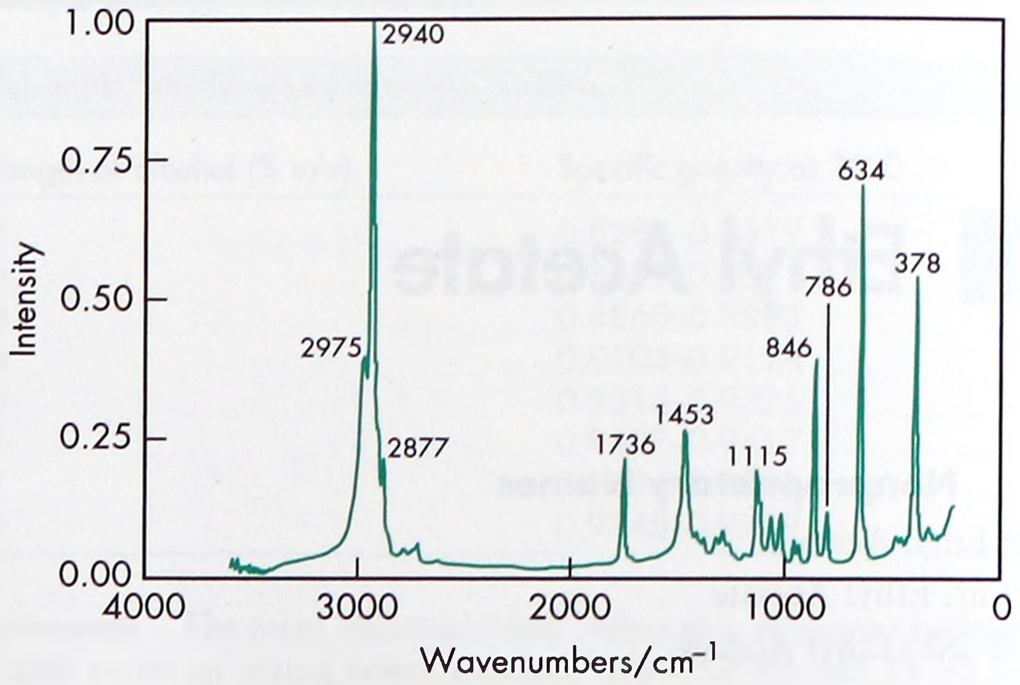

Figure 3: Raman spectrum of ethyl acetate measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

Surface tension 24 mN/m (24 dyne/cm) at 20°C
Vapor density 3.04 (air = 1)

11 Stability and Storage Conditions

Ethyl acetate is slowly decomposed by moisture and becomes acidic; the material can absorb up to 3.3% w/w water.

Ethyl acetate decomposes on heating to produce ethanol and acetic acid, and will emit acrid smoke and irritating fumes. It is

flammable and its vapor may travel a considerable distance to an ignition source and cause a 'flashback'.

The alkaline hydrolysis of ethyl acetate has been shown to be inhibited by polyethylene glycol and by mixed micelle systems.[12]

Ethyl acetate should be stored in an airtight container, protected from light and at a temperature not exceeding 30°C. Keep away from sources of ignition.

12 Incompatibilities

Ethyl acetate can react vigorously with strong oxidizers, strong alkalis, strong acids, and nitrates to cause fires or explosions. It also reacts vigorously with chlorosulfonic acid, lithium aluminum hydride, 2-chloromethylfuran, and potassium *tert*-butoxide.

13 Method of Manufacture

Ethyl acetate can be manufactured by the slow distillation of a mixture of ethanol and acetic acid in the presence of concentrated sulfuric acid. It has also been prepared from ethylene using an aluminum alkoxide catalyst.

14 Safety

Ethyl acetate is used in foods, and oral and topical pharmaceutical formulations. It is generally regarded as a relatively nontoxic and nonirritant material when used as an excipient.

However, in pure form, ethyl acetate it toxic by inhalation, moderately toxic by IP and SC routes, and mildly toxic by ingestion. It may be irritant to mucous membranes, and high concentrations may cause central nervous system depression. Potential symptoms of overexposure include irritation of the eyes, nose, and throat, narcosis, and dermatitis. Ethyl acetate has not been shown to be a human carcinogen or a reproductive or developmental toxin. The WHO has set an estimated acceptable daily intake of ethyl acetate at up to 25 mg/kg body-weight.[13]

In the UK, it has been recommended that ethyl acetate be temporarily permitted for use as a solvent in food and that the maximum concentration consumed in food should be set at 1000 ppm.[14]

LD_{50} (cat, SC): 3.00 g/kg[15]
LD_{50} (guinea-pig, oral): 5.50 g/kg
LD_{50} (guinea-pig, SC): 3.00 g/kg
LD_{50} (mouse, IP): 0.709 g/kg
LD_{50} (mouse, oral): 4.10 g/kg
LD_{50} (rabbit, oral): 4.935 g/kg
LD_{50} (rat, oral): 5.62 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

Ethyl acetate is flammable. When heated to decomposition, ethyl acetate emits acrid smoke and irritating fumes. Avoid contact with skin and eyes. Avoid inhalation of vapor or mist. Gloves, eye protection, suitable protective clothing, and respiratory equipment are recommended.

In the UK, the workplace exposure limit for ethyl acetate is 400 ppm (short-term) and 200 ppm (long-term).[16]

16 Regulatory Status

Although not GRAS listed, ethyl acetate is listed as a food additive in the EAFUS list compiled by the FDA. Included in the FDA Inactive Ingredients Database (oral tablets, capsules, and suspensions; topical and transdermal preparations; IM injections). Included in nonparenteral medicines licensed in the UK (tablets, topical solutions, and gels). Ethyl acetate is also accepted for use in food applications in a number of countries including the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

—

18 Comments

Ethyl acetate is mainly used as a flavoring agent in food applications. It is also used in artificial fruit essence and as an extraction solvent in food processing.

The following azeotropic mixtures have been reported:

Ethyl acetate (93.9% w/w)–water (6.1% w/w), boiling point 70.4°C

Ethyl acetate (83.2% w/w)–water (7.8% w/w)–ethanol (9.0% w/w), boiling point 70.3°C

Ethyl acetate (69.4%)–ethanol (30.6%), boiling point 71.8°C

Ethyl acetate (77%)–propan-2-ol (23%), boiling point 74.8°C

A specification for ethyl acetate is contained in the *Food Chemicals Codex* (FCC).[17]

The EINECS number for ethyl acetate is 205-500-4. The PubChem Compound ID (CID) for ethyl acetate is 8857.

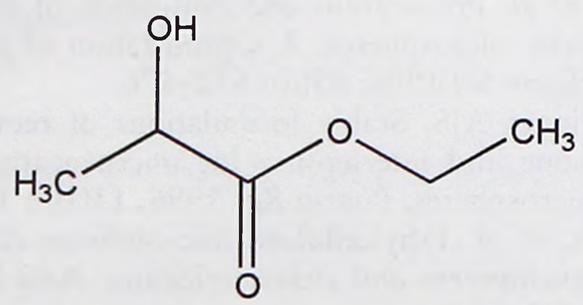
Ethyl Lactate

1 Nonproprietary Names

None adopted.

2 Synonyms

Actylol; *Acytol*; *Dermol EL*; ethyl α-hydroxypropionate; ethyl-2-hydroxypropanoate; ethyl-2-hydroxypropionate; ethyl-*S*-(–)-2-hydroxypropionate; 2-hydroxypropanoic acid ethyl ester; lactic acid ethyl ester; propanoic acid 2-hydroxy-ethyl ester; *Purasolv EL*; *Solactol*.



3 Chemical Name and CAS Registry Number

2-Hydroxy-propanoic acid ethyl ester [97-64-3]

4 Empirical Formula and Molecular Weight

$C_5H_{10}O_3$ 118.13

5 Structural Formula

6 Functional Category

Flavoring agent; solvent.

7 Applications in Pharmaceutical Formulation or Technology

Ethyl lactate is used as a solvent or co-solvent in liquid formulations[1–3] and as a co-solvent in emulsions, microemulsion, and liquid dispersion formulations.[4] It has been investigated as a solvent to prepare biodegradable and biocompatible dosage forms as a safer and greener option.[5] It has also been used as a solvent for nitrocellulose, cellulose acetate, cellulose ethers, polyvinyl and other resins.[6]

Ethyl lactate is also used as a flavoring agent in pharmaceutical preparations, and is found in food products.

8 Description

Ethyl lactate occurs as a clear colorless liquid with a sharp characteristic odor.

9 Pharmacopeial Specifications

—

10 Typical Properties

Acidity/alkalinity pH = 7 (10% w/v aqueous solution)
Boiling point 154–155°C
Density 1.0328 g/cm^3 at 20°C
Explosion limits 1.5–11.4%
Flash point 46°C
Heat of combustion 6.5 kcal/g
Melting point –26.0°C
Refractive index n_D^{20} = 1.412–1.414
Solubility Miscible with water (with partial decomposition), ethanol (95%), ether, chloroform, ketones, esters, and hydrocarbons.
Viscosity (dynamic) 0.0261 mPa s (0.0261 cP) at 20°C
Vapor density 4.07 (air = 1)
Vapor pressure 0.732 kPa at 30°C

11 Stability and Storage Conditions

Stable at normal temperature and pressure. Ethyl lactate is a flammable liquid and vapor. Store in a cool, dry, and well-ventilated location away from any fire hazard area, in a tightly closed container.

12 Incompatibilities

Incompatible with bases or strong alkalis and may cause fire or explosion with strong oxidizing agents.

13 Method of Manufacture

Ethyl lactate is produced by the esterification of lactic acid with ethanol in the presence of a little mineral oil, or by combination of acetaldehyde with hydrocyanic acid to form acetaldehyde cyanhydrin. This is followed by treatment with ethanol (95%) and hydrochloric or sulfuric acid. Purification is achieved using fractional distillation. The commercial product is a racemic mixture.

14 Safety

Ethyl lactate is used as a flavoring agent in pharmaceutical preparations, and is found in food products. The estimated acceptable daily intake for lactic acid is 12.5 mg/kg body-weight.

In general, lactate esters have an oral LD_{50} > 2000 mg/kg; and the inhalation LC_{50} is generally above 5000 mg/m^3. They have the potential of causing eye and skin irritation (on prolonged contact), but not sensitization.[7] Ethyl lactate is moderately toxic by intraperitoneal, subcutaneous, and intravenous routes. There is low oral and skin contact toxicity; although ingestion may cause

nausea, stomach and throat pain, and narcosis. Inhalation of concentrated vapor of ethyl lactate may cause irritation of the mucous membranes, drowsiness, and narcosis.

LD_{50} (rat, oral): >5.0 g/kg [8]
LD_{50} (mouse, oral): 2.5 g/kg
LD_{50} (mouse, SC): 2.5 g/kg
LD_{50} (mouse, IV): 0.6 g/kg
LD_{50} (rabbit, skin): >5.0 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Avoid skin and eye contact; eye goggles should be worn, or a full face shield where splashing may occur.

There is a slight explosion hazard in the form of vapor when it is exposed to flame. Avoid ignition sources and use adequate ventilation to keep vapor and mist as low as possible.

When heated to decomposition, it emits acrid smoke and irritating fumes. Facial respirators are recommended when dealing with excessive amounts or with prolonged exposure to the compound.

16 Regulatory Status

Although not GRAS listed, ethyl lactate is listed as a food additive in the EAFUS list compiled by the FDA. Reported in the EPA TSCA Inventory. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

n-Butyl lactate; methyl lactate.

n-Butyl lactate

Empirical formula $C_7H_{14}O_3$
Molecular weight 146.2
CAS number [138-22-7]
Synonyms Butyl α-hydroxypropionate; propanoic acid 2-hydroxy butyl ester; lactic acid butyl ester; *Purasolv BL*.
Boiling point 188°C
Melting point –43°C
Solubility Partially miscible with water and most organic solvents.
Comments *n*-Butyl lactate is used as a flavoring agent in pharmaceutical preparations.

The EINECS number for *n*-butyl lactate is 205-316-4.

Methyl lactate

Empirical formula $C_4H_8O_3$
Molecular weight 104
CAS number [547-64-8]
Synonyms Methyl hydroxy propionate; *Purasolv ML*.
Appearance Methyl lactate occurs as a clear, colorless liquid.
Boiling point 143.9°C
Comments Methyl lactate is used as a cellulose acetate solvent.

18 Comments

Owing to its biodegradability, ethyl lactate is replacing many solvents in many household products, including packaging, plastics, paints, paint strippers, grease removers, cleansers, aerosols, adhesives, and varnishes.

Therapeutically, ethyl lactate has been applied topically in the treatment of acne vulgaris,[9,10] where it accumulates in the sebaceous glands and is hydrolyzed to ethanol and lactic acid, lowering the skin pH and exerting a bactericidal effect.

Ethyl lactate is specified as a flavor chemical in the *Food Chemicals Codex* (FCC).[11]

The EINECS number for ethyl lactate is 202-598-0. The PubChem Compound ID (CID) for ethyl lactate includes 7344 and 92831.

Ethyl Maltol

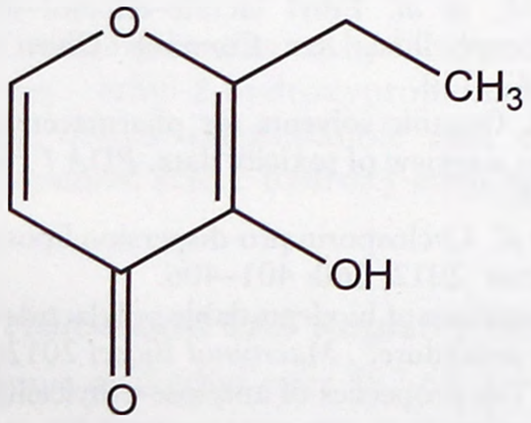
E

1 Nonproprietary Names

USP–NF: Ethyl Maltol

2 Synonyms

2-Ethyl pyromeconic acid; 3-hydroxy-2-ethyl-gamma-pyrone; 3-hydroxy-2-ethyl-4-pyrone; *Piromatol E*; *Veltol Plus*.



3 Chemical Name and CAS Registry Number

2-Ethyl-3-hydroxy-4*H*-pyran-4-one [4940-11-8]

4 Empirical Formula and Molecular Weight

$C_7H_8O_3$ 140.14

5 Structural Formula

6 Functional Category

Flavor enhancer; flavoring agent.

7 Applications in Pharmaceutical Formulation or Technology

Ethyl maltol is used in pharmaceutical formulations and food products as a flavoring agent or flavor enhancer in applications similar to maltol. It has a flavor and odor 4–6 times as intense as maltol. Ethyl maltol is used in oral syrups at concentrations of about 0.004–0.61 % and also at low levels in perfumery.

8 Description

Ethyl maltol occurs as a white crystalline solid with a characteristic, very sweet, caramel-like odor and taste. In dilute solution it possesses a sweet, fruitlike flavor and odor.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for ethyl maltol.

Test	USP 40–NF 35 S1
Identification	+
Residue on ignition	≤0.2%
Water	≤0.5%
Assay (anhydrous basis)	≥99.0%

10 Typical Properties

Melting point 85–95°C
Solubility *see* Table II.

Table II: Solubility of ethyl maltol.

Solvent	Solubility at 20°C
Chloroform	1 in 5
Ethanol (95%)	1 in 10
Glycerin	1 in 500
Propylene glycol	1 in 17
Water	1 in 55

Spectroscopy

IR spectrum *see* Figure 1.
NIR spectrum *see* Figure 2.
Raman spectrum *see* Figure 3.

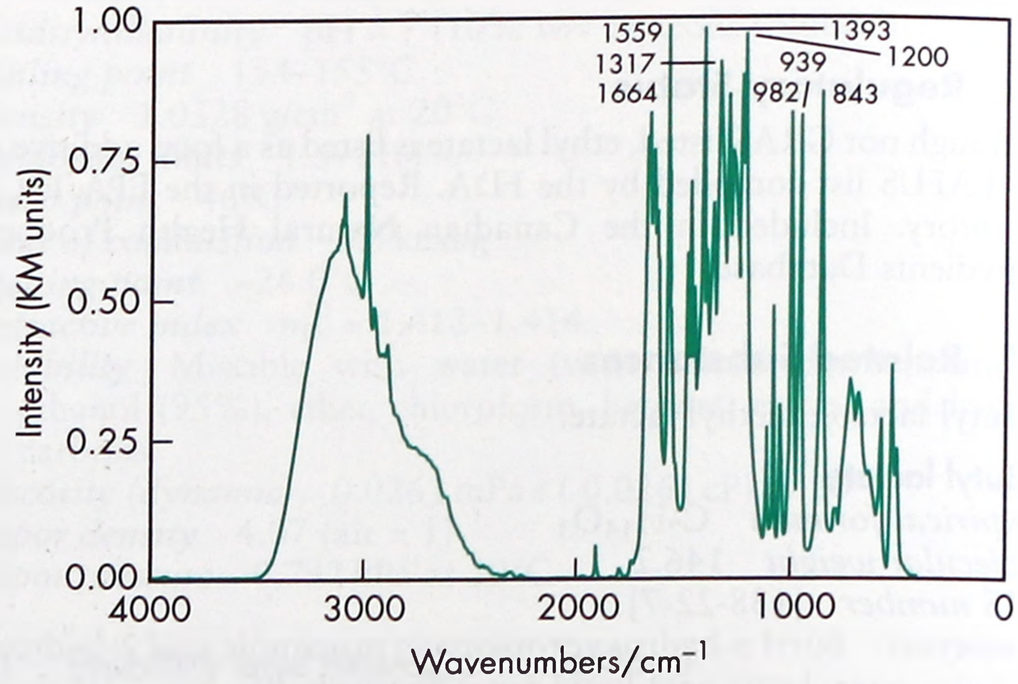


Figure 1: Infrared spectrum of ethyl maltol measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

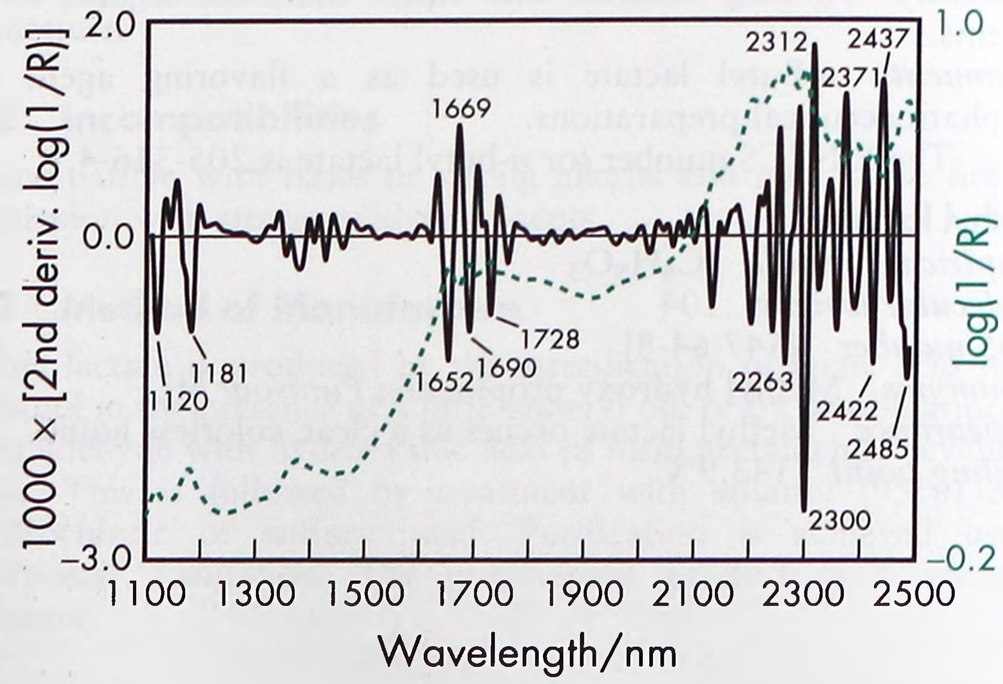

Figure 2: Near-infrared spectrum of ethyl maltol measured by reflectance.

11 Stability and Storage Conditions

Ethyl maltol forms complexes with iron and therefore should not be stored in iron containers. Solutions may be stored in glass or plastic containers. The bulk material should be stored in a well-closed container, protected from light, in a cool, dry, well-ventilated place, and away from sources of heat or ignition. Store at temperatures

7–35°C and humidity ranges 35-55%. Desiccant bags may be used to reduce moisture build-up.

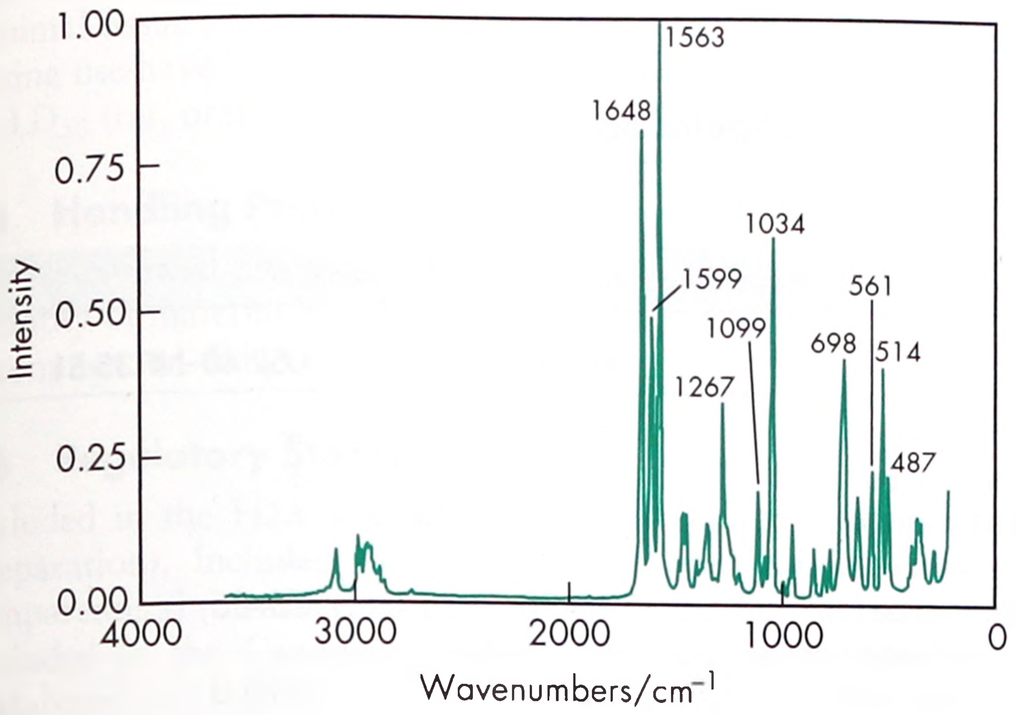

Figure 3: Raman spectrum of ethyl maltol measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

12 Incompatibilities

Ethyl maltol is incompatible with oxidizing agents. It is slightly acidic and forms salts with bases. Ethyl maltol chelates and forms complexes with metals, including iron; *see* Section 11.

13 Method of Manufacture

Unlike maltol, ethyl maltol does not occur naturally. It may be prepared by treating α-ethylfurfuryl alcohol with a halogen to produce 4-halo-6-hydroxy-2-ethyl-2*H*-pyran-3(6*H*)-one, which is converted to ethyl maltol by hydrolysis.

14 Safety

In animal feeding studies, ethyl maltol has been shown to be well tolerated with no adverse toxic, reproductive, or embryogenic effects. It has been reported that while the acute toxicity of ethyl maltol, in animal studies, is slightly greater than maltol, with repeated dosing the opposite is true.[1]

The WHO has set an acceptable daily intake for ethyl maltol at up to 2 mg/kg body-weight.[2,3]

LD_{50} (chicken, oral): 1.27 g/kg[4]
LD_{50} (mouse, oral): 0.78 g/kg (male)
LD_{50} (mouse, SC): 0.91 g/kg
LD_{50} (rabbit, skin): >5 g/kg
LD_{50} (rat, oral): 1.15 g/kg (male)
LD_{50} (rat, oral): 1.20 g/kg (female)

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

Ethyl maltol should be used in a well-ventilated environment. Dust may be irritant. When heated to decomposition, ethyl maltol produces acrid smoke and irritating fumes. Eye protection and gloves are recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral syrup, solutions, elixir). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

Although not GRAS listed, ethyl maltol is listed as a food additive in the EAFUS list compiled by the FDA.

17 Related Substances

Maltol.

18 Comments

See Maltol for further information.

A specification for ethyl maltol is contained in the *Food Chemicals Codex* (FCC).[5]

Ethyl Oleate

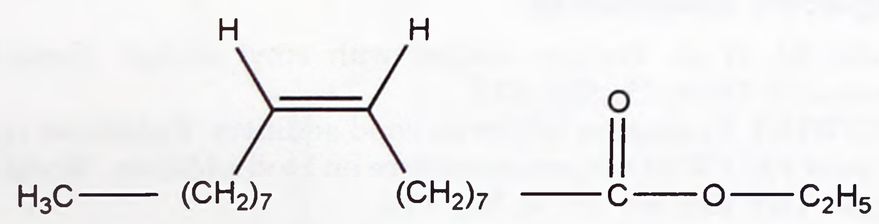
E

1 Nonproprietary Names

BP: Ethyl Oleate
PhEur: Ethyl Oleate
USP–NF: Ethyl Oleate

2 Synonyms

Crodamol EO; *DUBCARE OE*; ethylis oleas; ethyl *cis*-9-octadecenoate; ethyl 9-octadecenoate; *Kessco EO*; 9-octadecenoic acid, (*Z*)-, ethyl ester; oleic acid, ethyl ester.



3 Chemical Name and CAS Registry Number

(*Z*)-9-Octadecenoic acid, ethyl ester [111-62-6]

4 Empirical Formula and Molecular Weight

$C_{20}H_{38}O_2$ 310.51

5 Structural Formula

6 Functional Category

Oleaginous vehicle; solvent.

7 Applications in Pharmaceutical Formulation or Technology

Ethyl oleate is primarily used as a vehicle in certain parenteral preparations intended for intramuscular administration. It has also been used as a solvent for drugs formulated as biodegradable capsules for subdermal implantation[1] and in the preparation of microemulsions containing cyclosporin[2] and norcantharidin.[3] Microemulsion formulations containing ethyl oleate have been investigated,[4] and have been proposed for topical[5–8] and ocular[9] delivery, and for liver targeting following parenteral administration.[10] Ethyl oleate has been used in topical gel formulations,[11] and in self-microemulsifying drug delivery systems for oral administration,[12–15] and intravenous administration.[16]

Ethyl oleate is a suitable solvent for steroids and other lipophilic drugs. Its properties are similar to those of almond oil and peanut oil. However, it has the advantage that it is less viscous than fixed oils and is more rapidly absorbed by body tissues.[17]

Ethyl oleate has also been evaluated for extended-release injectable formulations,[18] and as a vehicle for subcutaneous injection.[19]

8 Description

Ethyl oleate occurs as a pale yellow to almost colorless, mobile, oily liquid with a taste resembling that of olive oil and a slight, but not rancid odor.

Ethyl oleate is described in the USP 40–NF 35 S1 as consisting of esters of ethyl alcohol and high molecular weight fatty acids, principally oleic acid. It contains not less than 65.0% of ethyl (*Z*)-9-octadecenoate ($C_{20}H_{38}O_2$) and may contain suitable stabilizers.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for ethyl oleate.

Test	PhEur 9.2	USP 40–NF 35 S1
Characters	+	–
Identification	+	+
Specific gravity	0.866–0.874	–
Acid value	≤0.5	–
Iodine value	75–90	75–85
Saponification value	177–188	–
Peroxide value	≤10.0	≤10.0
Oleic acid	≥60.0%	–
Water content	≤1.0%	≤1.0%
Total ash	≤0.1%	≤0.1%
Assay	–	+

10 Typical Properties

Boiling point ~205–208°C (some decomposition); also reported as 216–218°C (15 mm)[20]
Flash point 175.3°C
Freezing point ~−32°C
Moisture content At 20°C and 52% relative humidity, the equilibrium moisture content of ethyl oleate is 0.08%.
Refractive index 1.451
Solubility Miscible with chloroform, ethanol (96%), ether, fixed oils, liquid paraffin, and most other organic solvents; practically insoluble in water.
Surface tension 32.3 mN/m (32.3 dynes/cm) at 25°C[17]
Viscosity (dynamic) 3.9 mPa s (3.9 cP) at 25°C[17]
Viscosity (kinematic) 0.046 mm^2/s (4.6 cSt) at 25°C[17]

11 Stability and Storage Conditions

Ethyl oleate should be stored in a cool, dry place in a small, well-filled, well-closed container, protected from light. When a partially filled container is used, the air should be replaced by nitrogen or another inert gas. Ethyl oleate oxidizes on exposure to air, resulting in an increase in the peroxide value. It remains clear at 5°C, but darkens in color on standing. Antioxidants are frequently used to extend the shelf life of ethyl oleate. Protection from oxidation for over 2 years has been achieved by storage in amber glass bottles with the addition of combinations of propyl gallate, butylated hydroxyanisole, butylated hydroxytoluene, and citric or ascorbic acid.[21,22] A concentration of 0.03% w/v of a mixture of propyl gallate (37.5%), butylated hydroxytoluene (37.5%), and butylated hydroxyanisole (25%) was found to be the best antioxidant for ethyl oleate.[22]

Ethyl oleate may be sterilized by heating at 150°C for 1 hour.

12 Incompatibilities

Ethyl oleate dissolves certain types of rubber and causes others to swell.[23,24] It may also react with oxidizing agents.

13 Method of Manufacture

Ethyl oleate is prepared by the reaction of ethanol with oleoyl chloride in the presence of a suitable hydrogen chloride acceptor.

14 Safety

Ethyl oleate is generally considered to be of low toxicity but ingestion should be avoided. Ethyl oleate has been found to cause minimal tissue irritation.[25] No reports of intramuscular irritation during use have been recorded.

LD_{50} (rat, oral): >5.0 g/kg[20]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Eye protection and nitrile gloves are recommended. Ethyl oleate is flammable.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (transdermal preparation). Included in parenteral (IM depot injections) and nonparenteral (transdermal patches) medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Methyl oleate; oleic acid.

Methyl oleate

Empirical formula $C_{19}H_{36}O_2$
Molecular weight 296.49
CAS number [112-69-9]
Synonyms Methyl 9-octadecenoate; (*Z*)-9-octadecenoic acid, methyl ester.
Boiling point 168–170°C
Density 0.879 g/cm^3
Iodine number 85.6
Refractive index n_D^{26} = 1.4510
Solubility Miscible with ethanol (95%) and ether.
Comments Prepared by refluxing oleic acid with *p*-toluenesulfonic acid in methanol.

18 Comments

Ethyl oleate is used therapeutically as a diagnostic aid.[20]

A specification for ethyl oleate is contained in the *Food Chemicals Codex* (FCC).[26]

The EINECS number for ethyl oleate is 203-889-5. The PubChem Compound ID (CID) for ethyl oleate includes 8123 and 5364430.

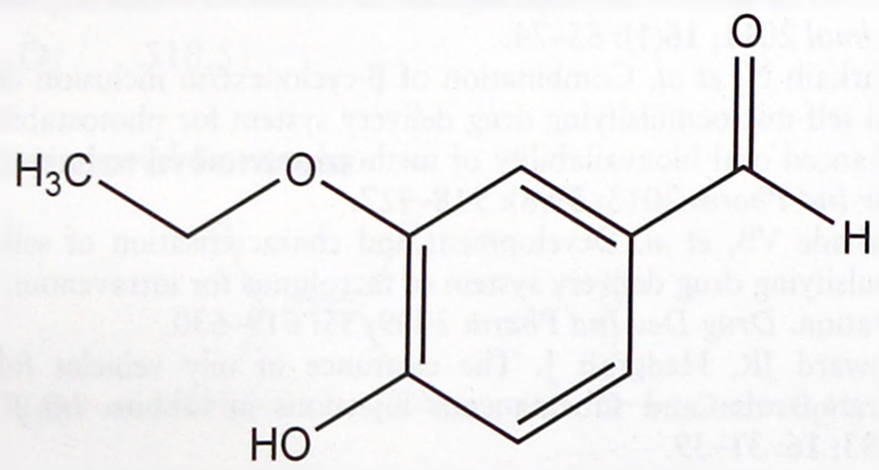
Ethyl Vanillin

1 Nonproprietary Names

USP–NF: Ethyl Vanillin

2 Synonyms

Bourbonal; ethavan; ethovan; ethylprotal; ethylprotocatechuic aldehyde; 4-hydroxy-3-ethoxybenzaldehyde; *Rhodiarome*; vanillal.



3 Chemical Name and CAS Registry Number

3-Ethoxy-4-hydroxybenzaldehyde [121-32-4]

4 Empirical Formula and Molecular Weight

$C_9H_{10}O_3$ 166.17

5 Structural Formula

6 Functional Category

Flavoring agent.

7 Applications in Pharmaceutical Formulation or Technology

Ethyl vanillin is used in pharmaceutical preparations as an alternative flavoring agent to vanillin.

Ethyl vanillin possesses a flavor and odor approximately three times as intense as vanillin; hence the quantity of material necessary to produce an equivalent vanilla flavor may be reduced, causing less discoloration to a formulation and potential savings in material costs. However, exceeding certain concentration limits may impart an unpleasant, slightly bitter taste to a product due to the intensity of the ethyl vanillin flavor. *See* Table I.

Table I: Uses of ethyl vanillin.

Use	Concentration (%)
Foods and confectionery	0.002–0.025
Oral syrups	0.01

8 Description

Ethyl vanillin occurs as white or slightly yellowish crystals with a characteristic intense vanilla odor and flavor.

9 Pharmacopeial Specifications

See Table II.

10 Typical Properties

Boiling point 285°C
Density (bulk) 1.05 g/cm^3
Flash point 127°C
Solubility *see* Table III.
Spectroscopy

NIR spectrum *see* Figure 1.

Table II: Pharmacopeial specifications for ethyl vanillin.

Test	USP 40–NF 35 S1
Identification	+
Melting range	76–78°C
Loss on drying	≤1.0%
Residue on ignition	≤0.1%
Assay (dried basis)	98.0–101.0%

Table III: Solubility of ethyl vanillin.

Solvent	Solubility at 20°C unless otherwise stated
Alkaline hydroxide solutions	Freely soluble
Chloroform	Freely soluble
Ethanol (95%)	1 in 2
Ether	Freely soluble
Glycerin	Soluble
Propylene glycol	Soluble
Water	1 in 250
	1 in 100 at 50°C

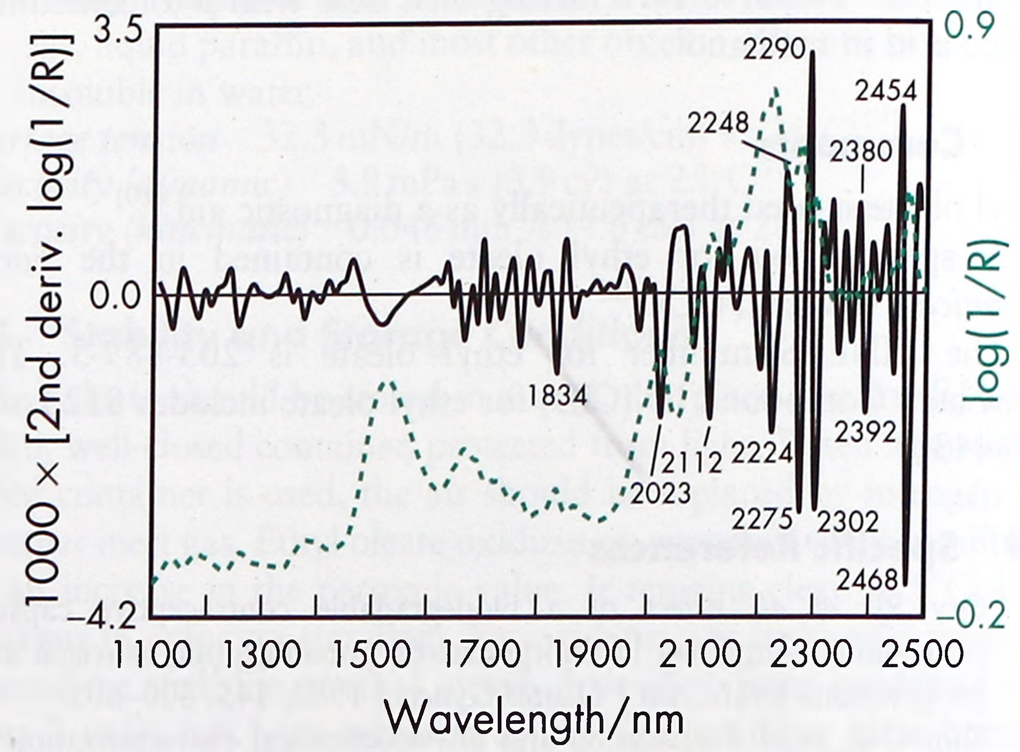


Figure 1: Near-infrared spectrum of ethyl vanillin measured by reflectance.

11 Stability and Storage Conditions

Store in a well-closed container, protected from light, in a cool, dry place. *See* Vanillin for further information.

12 Incompatibilities

Ethyl vanillin is unstable in contact with iron or steel, forming a red-colored, flavorless compound. In aqueous media with neomycin sulfate or succinylsulfathiazole, tablets of ethyl vanillin produced a yellow color.[1] *See* Vanillin for other potential incompatibilities.

13 Method of Manufacture

Unlike vanillin, ethyl vanillin does not occur naturally. It may be prepared synthetically by the same methods as vanillin, using guethol instead of guaiacol as a starting material; *see* Vanillin.

14 Safety

Ethyl vanillin is regarded as an essentially nontoxic and nonirritant material. However, cross-sensitization with other structurally similar molecules may occur; (*see* Vanillin), and in its pure form, ethyl vanillin is a skin irritant and is moderately toxic by ingestion, IP, IV, and SC routes.

The WHO has allocated an acceptable daily intake for ethyl vanillin of up to 3 mg/kg body-weight.[2]

LD_{50} (guinea pig, IP): 1.14 g/kg[3,4]

LD_{50} (mouse, IP): 0.75 g/kg[4]

LD_{50} (rat, oral): 1.59 g/kg[4]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

When heated to decomposition it emits acrid smoke and irritating fumes.[4] Heavy airborne concentrations of dust may present an explosion hazard. Eye protection is recommended.

16 Regulatory Status

Although not GRAS listed, ethyl vanillin is listed as a food additive in the EAFUS list compiled by the FDA. Included in the FDA Inactive Ingredients Database (oral capsules, tablets, suspensions, and syrups). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Vanillin.

18 Comments

Ethyl vanillin is widely used as a flavoring agent in foods, beverages, and confectionery. It is also used in perfumery.

Ethyl vanillin can be distinguished analytically from vanillin by the yellow color developed in the presence of concentrated sulfuric acid.

A study into the effect of ethyl vanillin on cytochrome P450 enzymes, indicated no significant effect in human *in vitro* samples. However an *in vivo* animal study reported some induction or inhibition of cytochrome P450 enzymes; *see also* Vanillin.[5]

A specification for ethyl vanillin is contained in the *Food Chemicals Codex* (FCC).[6]

The EINECS number for ethyl vanillin is 204-464-7. The PubChem Compound ID (CID) for ethyl vanillin is 8467.

4 Empirical Formula and Molecular Weight

Ethylcellulose is partially ethoxylated. Ethylcellulose with complete ethoxyl substitution (DS = 3) is $C_{12}H_{23}O_6(C_{12}H_{22}O_5)_nC_{12}H_{23}O_5$ where *n* can vary to provide a wide variety of molecular weights. Ethylcellulose, an ethyl ether of cellulose, is a long-chain polymer of β-anhydroglucose units joined together by acetal linkages.

5 Structural Formula

6 Functional Category

Coating agent; microencapsulating agent; tablet and capsule binder; tablet and capsule diluent; taste-masking agent; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Ethylcellulose is widely used in oral and topical pharmaceutical formulations; *see* Table I.

The main use of ethylcellulose in oral formulations is as a hydrophobic coating agent for tablets and granules.[1–8] Ethylcellulose coatings are used to modify the release of a drug,[7–10] to mask an unpleasant taste,[11,12] or to improve the stability of a formulation; for example, where granules are coated with ethylcellulose to inhibit oxidation. Modified-release tablet formulations may also be produced using ethylcellulose as a matrix former.[13–16]

Ethylcellulose, dissolved in an organic solvent or solvent mixture, can be used on its own to produce water-insoluble films. Higher-viscosity ethylcellulose grades tend to produce stronger and more durable films. Ethylcellulose films may be modified to alter their solubility[17] by the addition of hypromellose[18] or a plasticizer;[19–21] *see* Section 18. An aqueous polymer dispersion (or latex) of ethylcellulose such as *Aquacoat ECD* (FMC Biopolymer) or *Surelease* (Colorcon) may also be used to produce ethylcellulose films without the need for organic solvents.

Drug release through ethylcellulose-coated dosage forms can be controlled by diffusion through the film coating. This can be a slow process unless a large surface area (e.g. pellets or granules compared with tablets) is utilized. In those instances, aqueous ethylcellulose dispersions are generally used to coat granules or pellets. Ethylcellulose-coated beads and granules have also demonstrated the ability to absorb pressure and hence protect the coating from fracture during compression.[21]

High-viscosity grades of ethylcellulose are used in drug microencapsulation.[10,22–24]

Release of a drug from an ethylcellulose microcapsule is a function of the microcapsule wall thickness and surface area.

In tablet formulations, ethylcellulose may additionally be employed as a binder, the ethylcellulose being blended dry or wet-granulated with a solvent such as ethanol (95%). Ethylcellulose produces hard tablets with low friability, although they may demonstrate poor dissolution.

Ethylcellulose has also been used as an agent for delivering therapeutic agents from oral (e.g. dental) appliances.[25]

In topical formulations, ethylcellulose is used as a thickening agent in creams, lotions, or gels, provided an appropriate solvent is used.[26] Ethylcellulose has been studied as a stabilizer for emulsions.[27]

Ethylcellulose is additionally used in cosmetics and food products.

Table I: Uses of ethylcellulose.

Use	Concentration (%)
Microencapsulation	10.0–20.0
Sustained-release tablet coating	3.0–20.0
Tablet coating	1.0–3.0
Tablet granulation	1.0–3.0
Taste-masking	5.0-50.0

8 Description

Ethylcellulose is a tasteless, free-flowing, white to light tan-colored powder.

9 Pharmacopeial Specifications

The pharmacopeial specifications for ethylcellulose have undergone harmonization of many attributes for PhEur, and USP–NF.

See Table II. *See also* Section 18.

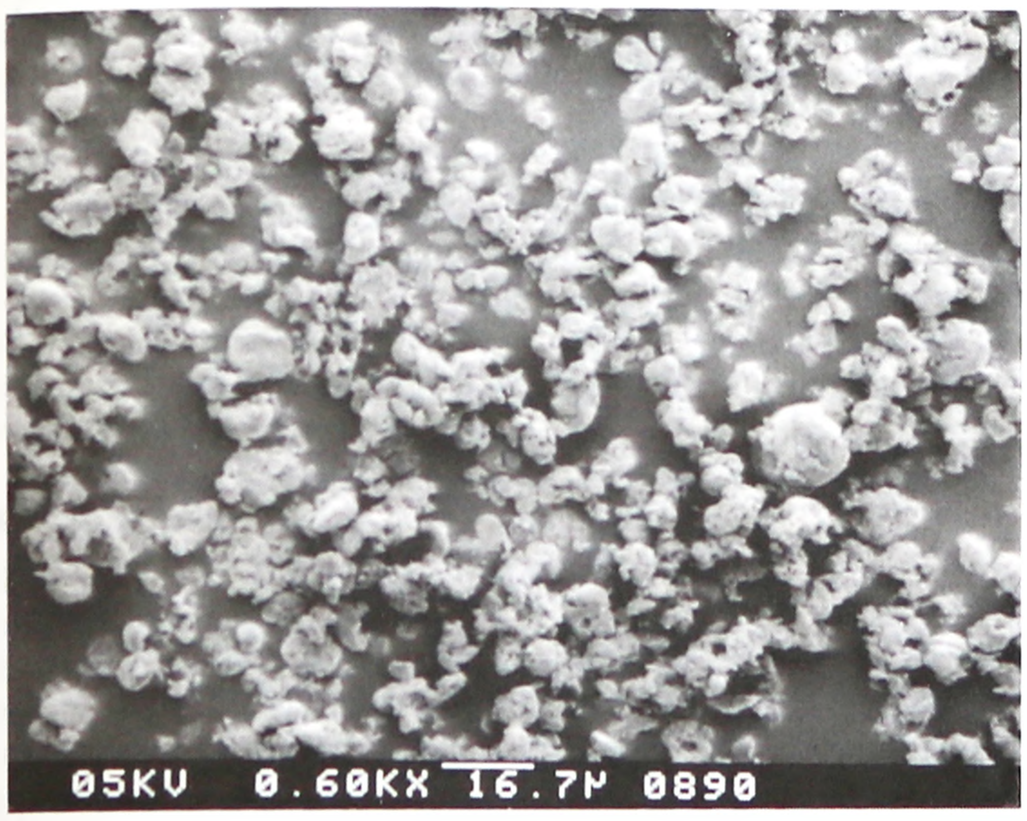
10 Typical Properties

Density (bulk) 0.4 g/cm^3

Glass transition temperature 129–133°C[28]

Moisture content Ethylcellulose absorbs very little water from humid air or during immersion, and that small amount evaporates readily.[29,30]

See also Figure 1.



Particle size distribution *see* Table III; *see also* Figures 2 and 3.

Solubility Ethylcellulose is practically insoluble in glycerin, propylene glycol, and water. Ethylcellulose that contains less than 46.5% of ethoxyl groups is freely soluble in chloroform, methyl acetate, and tetrahydrofuran, and in mixtures of aromatic hydrocarbons with ethanol (95%). Ethylcellulose

(b) Of that stated for its nominal viscosity.

that contains not less than 46.5% of ethoxyl groups is freely soluble in chloroform, ethanol (95%), ethyl acetate, methanol, and toluene.

Specific gravity 1.12–1.15 g/cm^3

Spectroscopy

IR spectrum *see* Figure 4.

Raman spectrum *see* Figure 5.

Viscosity The viscosity of ethylcellulose is measured typically at 25°C using 5% w/v ethylcellulose dissolved in a solvent blend of 80% toluene : 20% ethanol (w/w). Grades of ethylcellulose with various viscosities are commercially available; *see* Table III. They may be used to produce 5% w/v solutions in organic solvent blends with viscosities nominally ranging from 7 to 100 mPa s (7–100 cP). Specific ethylcellulose grades, or blends of different grades, may be used to obtain solutions of a desired viscosity. Solutions of higher viscosity tend to be composed of longer polymer chains and produce strong and durable films.

The viscosity of an ethylcellulose solution increases with an increase in ethylcellulose concentration; e.g. the viscosity of a 5% w/v solution of *Ethocel Standard 4 Premium* is 4 mPa s (4 cP) and of a 25% w/v solution of the same ethylcellulose grade is

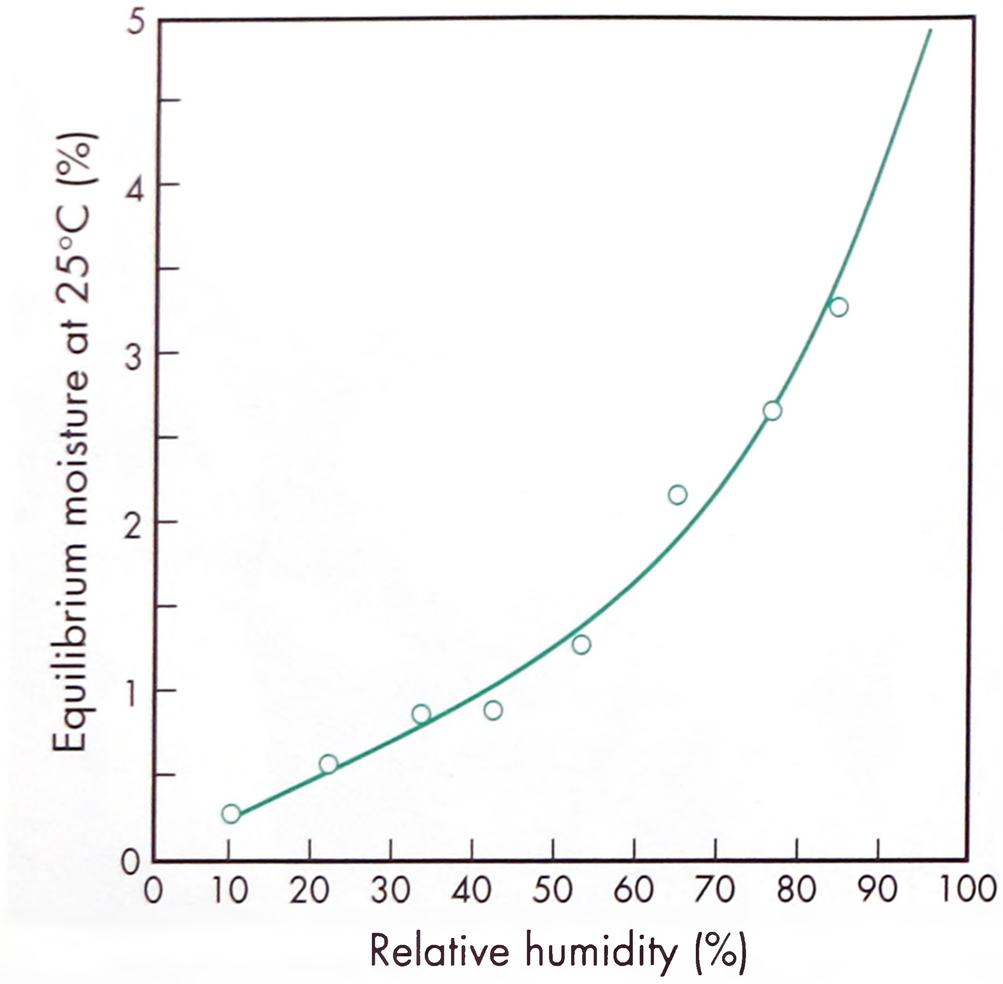

Figure 1: Equilibrium moisture content of ethylcellulose.

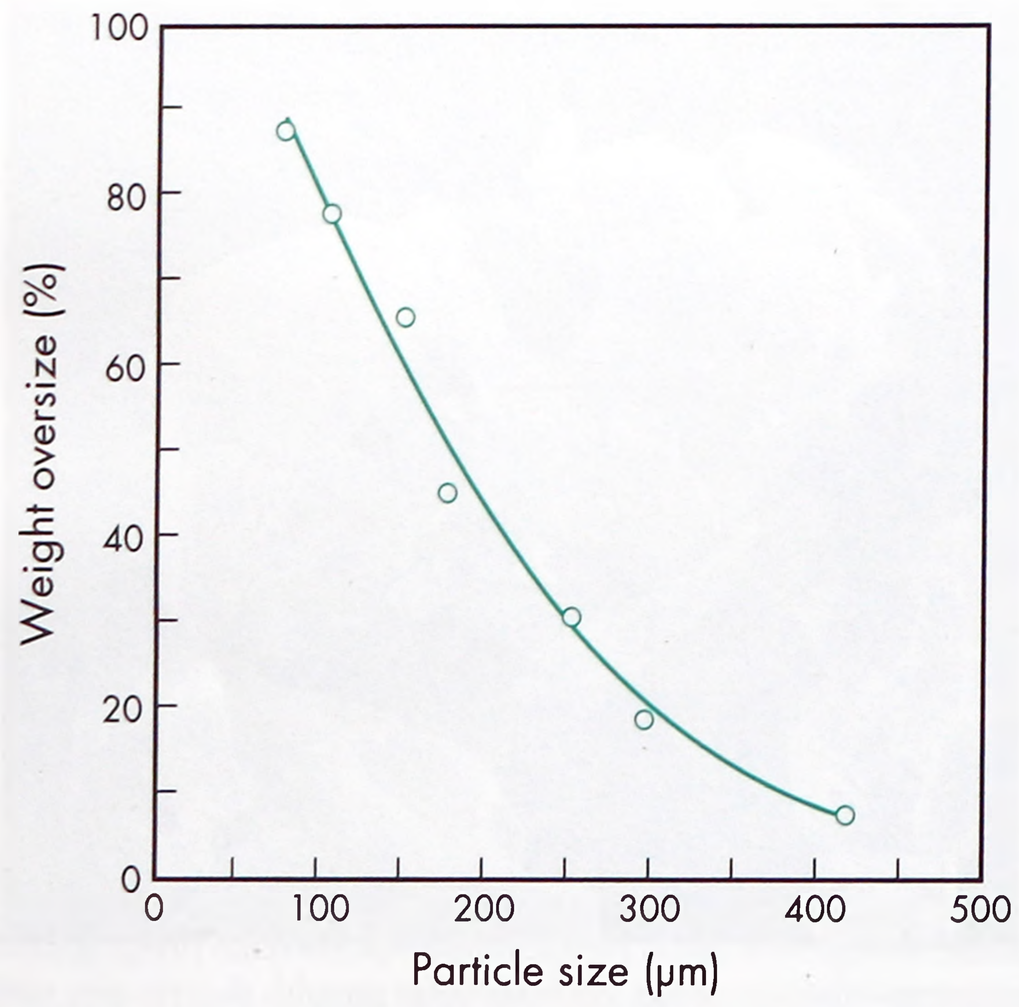

Figure 2: Particle size distribution of ethylcellulose.

850 mPa s (850 cP). Solutions with a lower viscosity may be obtained by incorporating a higher percentage (30–40%) of a low-molecular-weight aliphatic alcohol such as ethanol, butanol, propan-2-ol, or *n*-butanol with toluene. The viscosity of such solutions depends almost entirely on the alcohol content and is independent of toluene.

11 Stability and Storage Conditions

Ethylcellulose is a stable, slightly hygroscopic material. It is chemically resistant to alkalis, both dilute and concentrated, and to salt solutions, although it is more sensitive to acidic materials than are cellulose esters.

Ethylcellulose is subject to oxidative degradation in the presence of sunlight or UV light at elevated temperatures. This may be prevented by the use of antioxidant and chemical additives that absorb light in the 230–340 nm range.

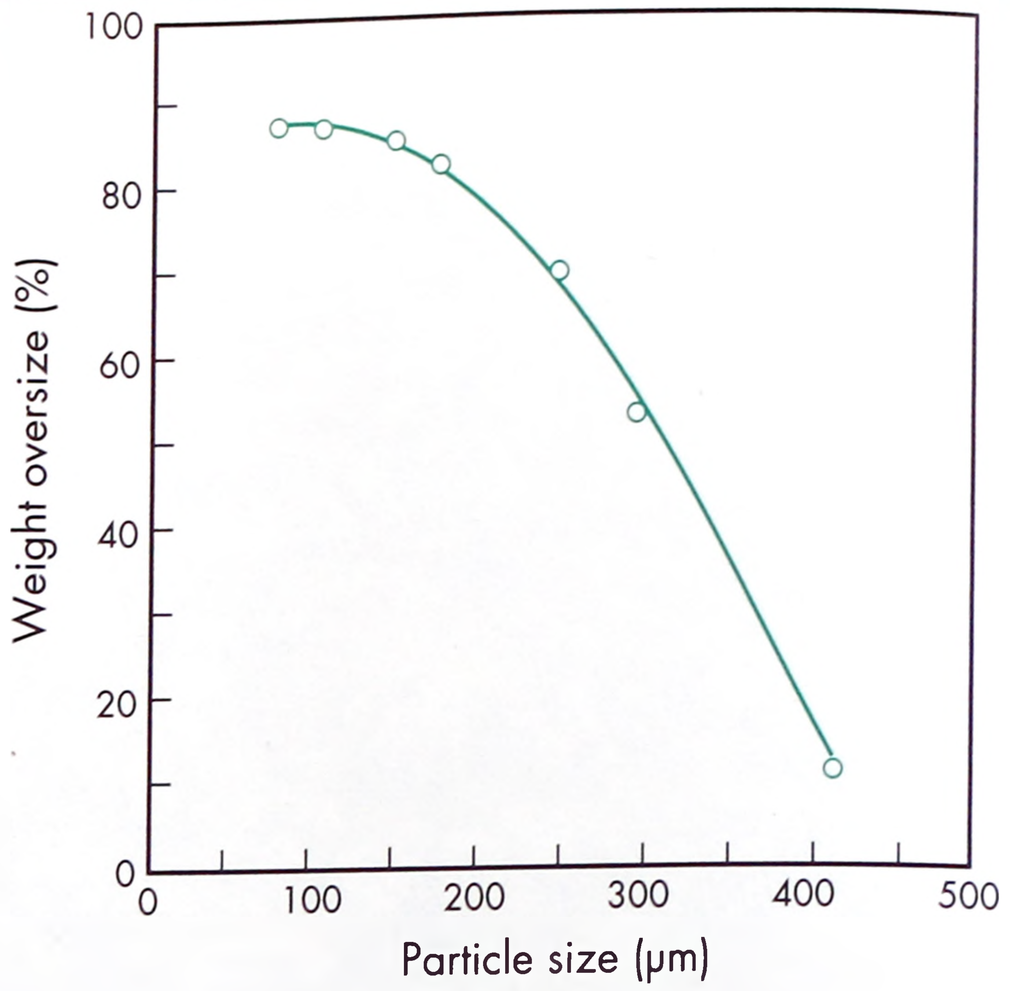

Figure 3: Particle size distribution of ethylcellulose (*Ethocel*, Dow Chemical Co.).

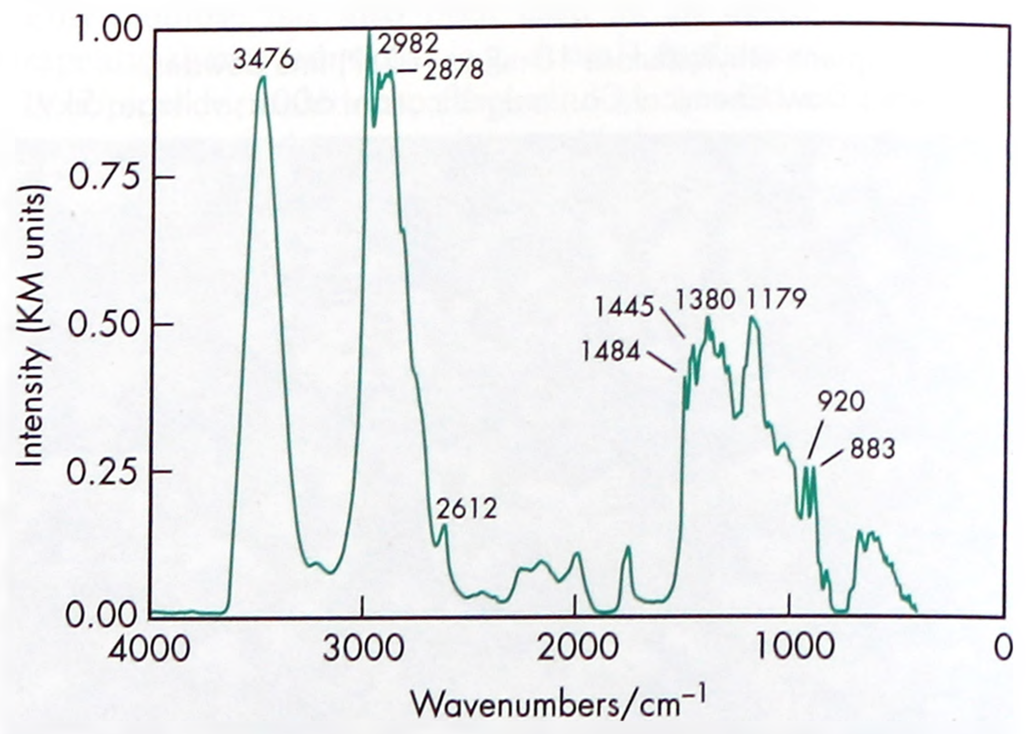

Figure 4: Infrared spectrum of ethylcellulose measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

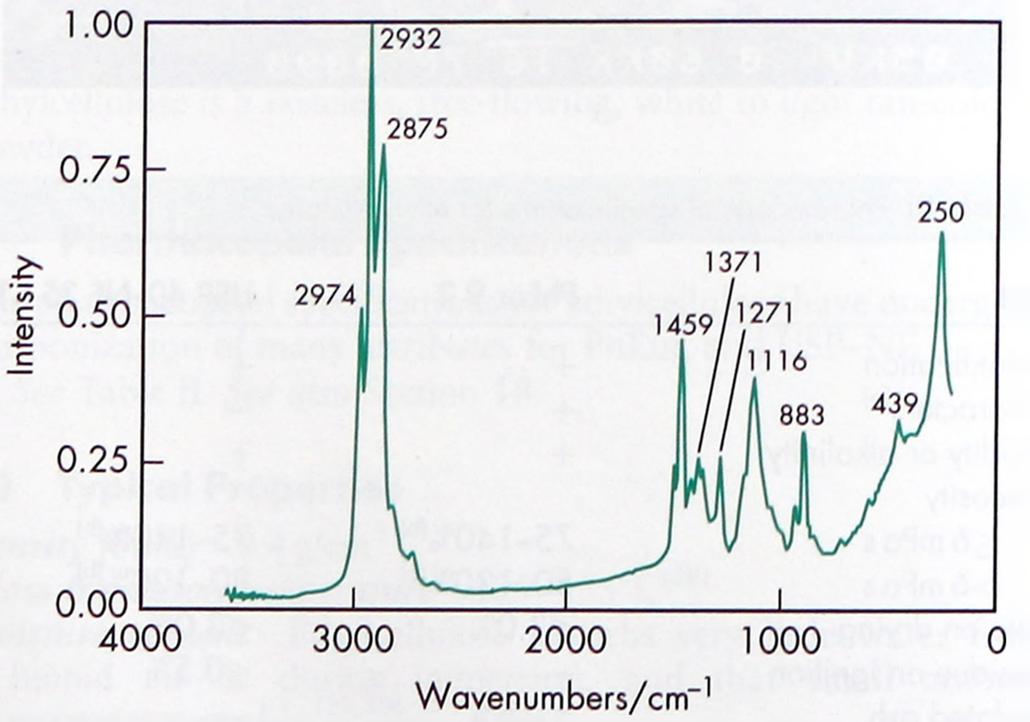

Figure 5: Raman spectrum of ethylcellulose measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

Ethylcellulose should be stored at a temperature not exceeding 32°C (90°F) in a dry area away from all sources of heat. It should not be stored next to peroxides or other oxidizing agents.

Table III: Summary of ethylcellulose grades, suppliers, viscosity, and particle size.

Ethocel Std 100 Premium	Dow Chemical	90.0–110.0	465.0

12 Incompatibilities

Incompatible with paraffin wax and microcrystalline wax.

13 Method of Manufacture

Ethylcellulose is prepared by treating purified cellulose (sourced from chemical-grade cotton linters and wood pulp) with an alkaline solution, followed by ethylation of the alkali cellulose with chloroethane as shown below, where R represents the cellulose radical:

$$RONa + C_2H_5Cl \rightarrow ROC_2H_5 + NaCl$$

The manner in which the ethyl group is added to cellulose can be described by the degree of substitution (DS). The DS designates the average number of hydroxyl positions on the anhydroglucose unit that have been reacted with ethyl chloride. Since each anhydroglucose unit of the cellulose molecule has three hydroxyl groups, the maximum value for DS is three.

14 Safety

Ethylcellulose is widely used in oral and topical pharmaceutical formulations. It is also used in food products. Ethylcellulose is not metabolized following oral consumption and is therefore a noncalorific substance. Because ethylcellulose is not metabolized it is not recommended for parenteral products; parenteral use may be harmful to the kidneys.

Ethylcellulose is generally regarded as a nontoxic, nonallergenic, and nonirritating material.

As ethylcellulose is not considered to be a health hazard, the WHO has not specified an acceptable daily intake.[31] The highest reported level used in an oral product is 308.8 mg in an oral sustained release tablet.[32]

LD_{50} (rabbit, skin): >5 g/kg[33]

LD_{50} (rat, oral): >5 g/kg

15 Handling Precautions

It is important to prevent fine dust clouds of ethylcellulose from reaching potentially explosive levels in the air. Ethylcellulose is combustible. Ethylcellulose powder may be an irritant to the eyes and eye protection should be worn.

16 Regulatory Status

GRAS listed. Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (oral capsules, suspensions and tablets; topical emulsions and vaginal preparations). Included in nonparenteral medicines licensed in Europe. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Hydroxyethyl cellulose; hydroxyethylmethyl cellulose; methylcellulose.

18 Comments

Ethylcellulose has undergone harmonization for many attributes for PhEur, and USP–NF by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur 9.2, along with the 'State of Work' document on the PhEur EDQM website.

Ethylcellulose is compatible with the following plasticizers: dibutyl phthalate; diethyl phthalate; dibutyl sebacate; triethyl citrate; tributyl citrate; acetylated monoglyceride; acetyl tributyl citrate; triacetin; dimethyl phthalate; benzyl benzoate; butyl and glycol esters of fatty acids; refined mineral oils; oleic acid; stearic acid; ethyl alcohol; stearyl alcohol; castor oil; corn oil; and camphor.

Ethylcellulose has also been used as a backing membrane on mucoadhesive patches intended for buccal administration. The membrane had high tensile strength, and provided excellent unidirectional drug flow.[34] Studies have also suggested ethylcellulose for use in floating microparticles based on low-density foam powder, for gastroretentive drug delivery systems.[35]

A specification for ethylcellulose is contained in the *Food Chemicals Codex* (FCC).[36]

The PubChem Compound ID (CID) for ethylcellulose is 24832091.

Ethylene Glycol and Vinyl Alcohol Grafted Copolymer

1 Nonproprietary Names

PhEur: Macrogol Poly(Vinyl Alcohol) Grafted Copolymer

USP–NF: Ethylene Glycol and Vinyl Alcohol Grafted Copolymer

2 Synonyms

Copolymerum macrogolo et alcoholi poly(vinylico) constatum; ethenol graft polymer with oxirane; *Kollicoat IR*; polyvinyl alcohol-polyethylene glycol graft copolymer; polyvinylalcohol-co-polyethylene glycol; PVA-co-PEG; PVA-PEG graft copolymer.

3 Chemical Name and CAS Registry Number

Polyvinyl alcohol polyethylene glycol copolymer, poly(ethan-1,2-diol-grafted-ethenol) [96734-39-3]

4 Empirical Formula and Molecular Weight

Ethylene glycol and vinyl alcohol grafted copolymer is a synthetic branched copolymer. On average, 2-4 polyvinyl alcohol side chains are grafted onto a polyethylene glycol backbone. The polymer comprises approx. 25% w/w polyethylene glycol and 75% polyvinyl alcohol units. The mean molecular weight of the polymer is 40 000 to 50 000.

Ethylene glycol and vinyl alcohol grafted copolymer may contain a glidant such as colloidal silicon dioxide to improve flowability.

5 Structural Formula

See Section 4.

6 Functional Category

Coating agent; film-forming agent; tablet and capsule binder.

7 Applications in Pharmaceutical Formulation or Technology

Ethylene glycol and vinyl alcohol grafted copolymer is a synthetic polymer that was introduced to the market as an excipient for oral pharmaceutical applications in 2002. It is mainly used as a film-forming agent in instant-release tablet coatings.

The hydrophilic polymer is readily soluble in water, independent of the pH value. The polyvinyl alcohol part of the copolymer provides good film-forming properties, whereas the polyethylene glycol part acts as an internal plasticizer. The grafted copolymer offers functional advantages over the individual components, such as high flexibility of the polymer and low viscosity in aqueous solutions. The low viscosity of aqueous ethylene glycol and vinyl alcohol grafted copolymer solutions allows the processing of highly concentrated coating suspensions.[1,2] Owing to the high flexibility of the polymer, it may be suitable as a carrier in drug-loaded film strips or wafers.[3] It also presents advantages as a hydrophilic pore former in combination with different sustained-release coating agents (e.g. ethylcellulose and polyvinyl acetate), where drug release rates can be adjusted by adding varying amounts of the polymer.[4–8]

Ethylene glycol and vinyl alcohol grafted copolymer has been investigated as a wet binder[2] and as a carrier in solid dispersions.[9–11] It acts as a protective colloid and effectively stabilizes dispersions (e.g. ethylcellulose dispersions) and emulsions (e.g. medium-chain triglycerides/water).

8 Description

Ethylene glycol and vinyl alcohol grafted copolymer occurs as a free-flowing white to slightly yellowish powder. It is an amorphous polymer with partially crystalline domains.[11]

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for ethylene glycol and vinyl alcohol grafted copolymer.

Test	PhEur 9.2	USP 40–NF 35 S1
Characters	+	–
Identification	+	+
pH	5.0–8.0	5.0– 8.0
Ester value	10–75	10–75
Ethylene oxide	≤ 1 ppm	≤ 1 ppm
Dioxan	≤ 10 ppm	≤ 10 ppm
Impurity A (vinyl acetate)	≤ 100 ppm	≤ 100 ppm
Impurity B (acetic acid)	≤ 1.5%	≤ 1.5%
Sulfated ash	≤ 3%	–
Residue on ignition	–	≤ 3%
Loss on drying	≤ 5%	≤ 5%
Viscosity	≤ 250 mPa s[a]	25–250 mPa s

(a) Functionality-related characteristic in PhEur 9.2.

10 Typical Properties

Solubility Dissolves quickly in water and aqueous systems, e.g. weak acids or alkalis up to 40% w/w; solutions of up to 25% w/w can be prepared in a 1 : 1 ethanol–water mixture. Solubility in nonpolar solvents is low. If silicon dioxide is present, solutions are slightly turbid.

11 Stability and Storage Conditions

Ethylene glycol and vinyl alcohol grafted copolymer is slightly hygroscopic. Store in a tightly closed container.

12 Incompatibilities

—

13 Method of Manufacture

Ethylene glycol and vinyl alcohol grafted copolymer is produced using polyethylene glycol and vinyl acetate as starting materials. Polyethylene glycol forms the polymer backbone onto which polyvinyl acetate is grafted. Saponification of the polyvinyl acetate moieties leads to formation of polyvinyl alcohol grafted chains.

14 Safety

Ethylene glycol and vinyl alcohol grafted copolymer is used in oral pharmaceutical preparations, and is generally regarded as a safe material. It has been found to be nonirritating to rabbit eyes and skin, and also nonmutagenic.

LD_{50} (rat, oral): > 2.0 g/kg[12]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled.

16 Regulatory Status

Approved for use in medicinal products in Europe, Japan and the US.

17 Related Substances

Polyethylene glycol; polyvinyl alcohol.

18 Comments

Ethylene glycol and vinyl alcohol grafted copolymer is available as a spray-dried powder (*Kollicoat IR*), in combination with polyvinyl alcohol as a basis for moisture protective coatings (*Kollicoat IR* Protect), or as a ready-to-use colored system (*Kollicoat IR* Coating Systems, *Sepifilm IR*).

Emollient; emulsion stabilizing agent.

7 Applications in Pharmaceutical Formulation or Technology

Ethylene glycol stearates are used as stabilizers for water-in-oil emulsions, although they have poor emulsifying properties. They have emollient properties and are also used as opacifying, thickening, and dispersing agents.

In cosmetics, ethylene glycol stearates are used as a 'fatty body' for lipsticks, as pearling agents in opalescent and cream shampoos, and as additives for tanning lubricants.

8 Description

The USP 40–NF 35 S1 and PhEur 9.2 describe ethylene glycol stearates as a mixture of ethylene glycol monoesters and diesters of stearic and palmitic acids, containing not less than 50% of monoesters produced from the condensation of ethylene glycol and stearic acid, of vegetable or animal origin.

Ethylene glycol stearates occur as a white or almost white waxy solid.

9 Pharmacopeial Specifications

See Table I.

Table 1: Pharmacopeial specifications for ethylene glycol stearates.

Test	PhEur 9.2	USP 40–NF 35 S1
Characters	+	–
Identification	+	+
Melting point	54–60°C	54–60°C
Acid value	≤3.0	≤3.0
Iodine value	≤3.0	≤3.0
Saponification value	170–195	170–195
Composition of fatty acids		
Stearic acid	40.0–60.0%	40.0–60.0%
Total of palmitic acid and stearic acid	≥90.0%	≥90.0%
Free ethylene glycol	≤5.0%	≤5.0%
Total ash	≤0.1%	≤0.1%

10 Typical Properties

Melting point 54–60°C
Solubility Soluble in acetone and hot ethanol (95%); practically insoluble in water.

11 Stability and Storage Conditions

Ethylene glycol stearates should be stored in a cool, dark place, protected from light.

12 Incompatibilities

—

13 Method of Manufacture

Ethylene glycol stearates are produced from the condensation of ethylene glycol with stearic acid 50 of vegetable or animal origin.

14 Safety

Ethylene glycol stearates are mainly used in cosmetics and topical pharmaceutical formulations, where they are generally regarded as relatively nontoxic and nonirritant materials.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

16 Regulatory Status

Included in nonparenteral medicines licensed in Europe.

17 Related Substances

Diethylene glycol monopalmitostearate; ethylene glycol monopalmitate; ethylene glycol monostearate; glyceryl monostearate; glyceryl palmitostearate.

Diethylene glycol monopalmitostearate

Synonyms Diethyleneglycoli monopalmitostearas; diethylene glycol palmitostearate.
Description The PhEur 9.2 describes diethylene glycol monopalmitostearate as a mixture of diethylene glycol monoesters and diesters of stearic and palmitic acids. It contains not less than 45.0% of monoesters produced from the condensation of diethylene glycol and stearic acid 50 of vegetable or animal origin. Diethylene glycol monopalmitostearate occurs as a white or almost white waxy solid.
Acid value ≤4.0
Iodine value ≤3.0
Melting point 43–50°C
Saponification value 150–170
Solubility Soluble in acetone and hot ethanol (95%); practically insoluble in water.

Ethylene glycol monopalmitate

CAS number [4219-49-2]

Ethylene glycol monostearate

Synonyms Ethylene glycol stearate; ethylene glycoli monostearas; ethyleni glycoli stearas; 2-hydroxyethyl ester stearic acid; *Monestriol EN-A*; *Monthyle*.
CAS number [111-60-4]
Empirical formula $C_{20}H_{40}O_3$
Molecular weight 328.60
Description Occurs as pale yellow flakes.
Melting point 57–63°C
Safety

LD_{50} (mouse, IP): 0.20 g/kg[1]

Ethylene Vinyl Acetate

1 Nonproprietary Names

None adopted.

2 Synonyms

Acetic acid, ethylene ester polymer with ethane; *CoTran*; ethylene/vinyl acetate copolymer; EVA; EVA copolymer; EVM; poly(ethylene-*co*-vinyl acetate); VA/ethylene copolymer; vinyl acetate/ethylene copolymer.

3 Chemical Name and CAS Registry Number

Ethylene vinyl acetate copolymer [24937-78-8]

4 Empirical Formula and Molecular Weight

$(CH_2CH_2)_x[CH_2CH(CO_2CH_3)]_y$

See Section 5.

5 Structural Formula

Ethylene vinyl acetate copolymer is a random copolymer of ethylene and vinyl acetate.

6 Functional Category

Transdermal delivery component.

7 Applications in Pharmaceutical Formulation or Technology

Ethylene vinyl acetate copolymers are used as membranes and backings in laminated transdermal drug delivery systems. They can also be incorporated as components in backings in transdermal systems. Ethylene vinyl acetate copolymers have been shown to be an effective matrix and membrane for the controlled delivery.[1–11] The system for controlled release of atenolol can be further developed using ethylene vinyl acetate copolymers and plasticizers.[1]

8 Description

Ethylene vinyl acetate copolymers occur as odorless white waxy solids in pellet or powder form. Films are translucent.

9 Pharmacopeial Specifications

—

10 Typical Properties

Density 0.92–0.94 g/cm^3
Flash point 260°C
Melting point 75–102°C depending on polymer ratios.
Moisture vapor transmission rate *see* Table I.
Solubility Insoluble in water
Thickness *see* Table I.
Vinyl acetate content *see* Table I.

11 Stability and Storage Conditions

Ethylene vinyl acetate copolymers are stable under normal conditions and should be stored in a cool, dry, well-ventilated area. Films of ethylene vinyl acetate copolymers should be stored at 0–30°C and less than 75% relative humidity.

Table I: Characteristics of different *CoTran* (3M Drug Delivery Systems) film grades.

Grade	Thickness (μm)	Vinyl acetate (%)	Moisture vapor transmission rate (g/m^2/24 h)
CoTran 9702	50.8	9	52.8
CoTran 9705	76.2	9	35.2
CoTran 9706	101.6	9	26.4
CoTran 9707	50.8	4.5	15.7
CoTran 9712	50.8	18.5	97.2
CoTran 9715	76.2	18.5	64.8
CoTran 9716	101.6	18.5	48.6
CoTran 9728	50.8	18.5	97.2

12 Incompatibilities

Ethylene vinyl acetate is incompatible with strong oxidizing agents and bases.

13 Method of Manufacture

Various molecular weights of random ethylene vinyl acetate copolymers can be obtained by catalytic copolymerization of ethylene and vinyl acetate, high-pressure radical polymerization, bulk continuous polymerization, or solution polymerization. Film membranes of ethylene vinyl acetate copolymers are manufactured using a melt-cast process.

14 Safety

Ethylene vinyl acetate is mainly used in topical pharmaceutical applications as a membrane or film backing. Generally it is regarded as a relatively nontoxic and nonirritant excipient.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Ethylene vinyl acetate powder may form an explosive mixture with air.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (subcutaneous rod; intrauterine suppository; ophthalmic preparations; periodontal film; transdermal film). Included in nonparenteral medicines licensed in the UK.

17 Related Substances

—

18 Comments

Ethylene vinyl acetate copolymers have a wide variety of industrial uses. Properties of ethylene vinyl acetate copolymer films in terms of oxygen and moisture transfer rate are related to the vinyl acetate content and thickness. Higher levels of vinyl acetate result in increased lipophilicity, increased oxygen and moisture vapor permeability, and increased clarity, flexibility, toughness, and solvent solubility.

The PubChem Compound ID (CID) for ethylene vinyl acetate is 32742.

Ethylparaben

1 Nonproprietary Names

BP: Ethyl Hydroxybenzoate

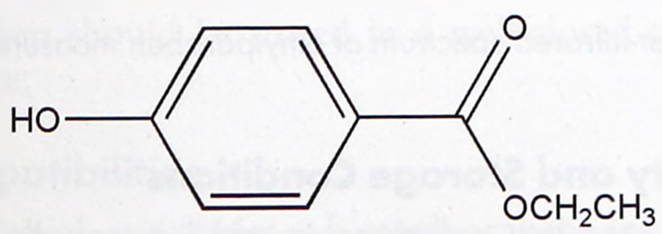
JP: Ethyl Parahydroxybenzoate

PhEur: Ethyl Parahydroxybenzoate

USP–NF: Ethylparaben

2 Synonyms

Aethylum hydrobenzoicum; *CoSept E*; E214; ethylis parahydroxybenzoas; ethyl *p*-hydroxybenzoate; *Ethyl parasept*; 4-hydroxybenzoic acid ethyl ester; *Nipagin A*; *Solbrol A*; *Tegosept E*; *Uniphen P-23*.



3 Chemical Name and CAS Registry Number

Ethyl-4-hydroxybenzoate [120-47-8]

4 Empirical Formula and Molecular Weight

$C_9H_{10}O_3$ 166.18

5 Structural Formula

6 Functional Category

Antimicrobial preservative.

7 Applications in Pharmaceutical Formulation or Technology

Ethylparaben is widely used as an antimicrobial preservative in cosmetics,[1] food products, and pharmaceutical formulations.

It may be used either alone or in combination with other paraben esters or with other antimicrobial agents. In cosmetics it is one of the most frequently used preservatives.

The parabens are effective over a wide pH range and have a broad spectrum of antimicrobial activity, although they are most effective against yeasts and molds; *see* Section 10.

Owing to the poor solubility of the parabens, paraben salts, particularly the sodium salt, are frequently used. However, this may cause the pH of poorly buffered formulations to become more alkaline.

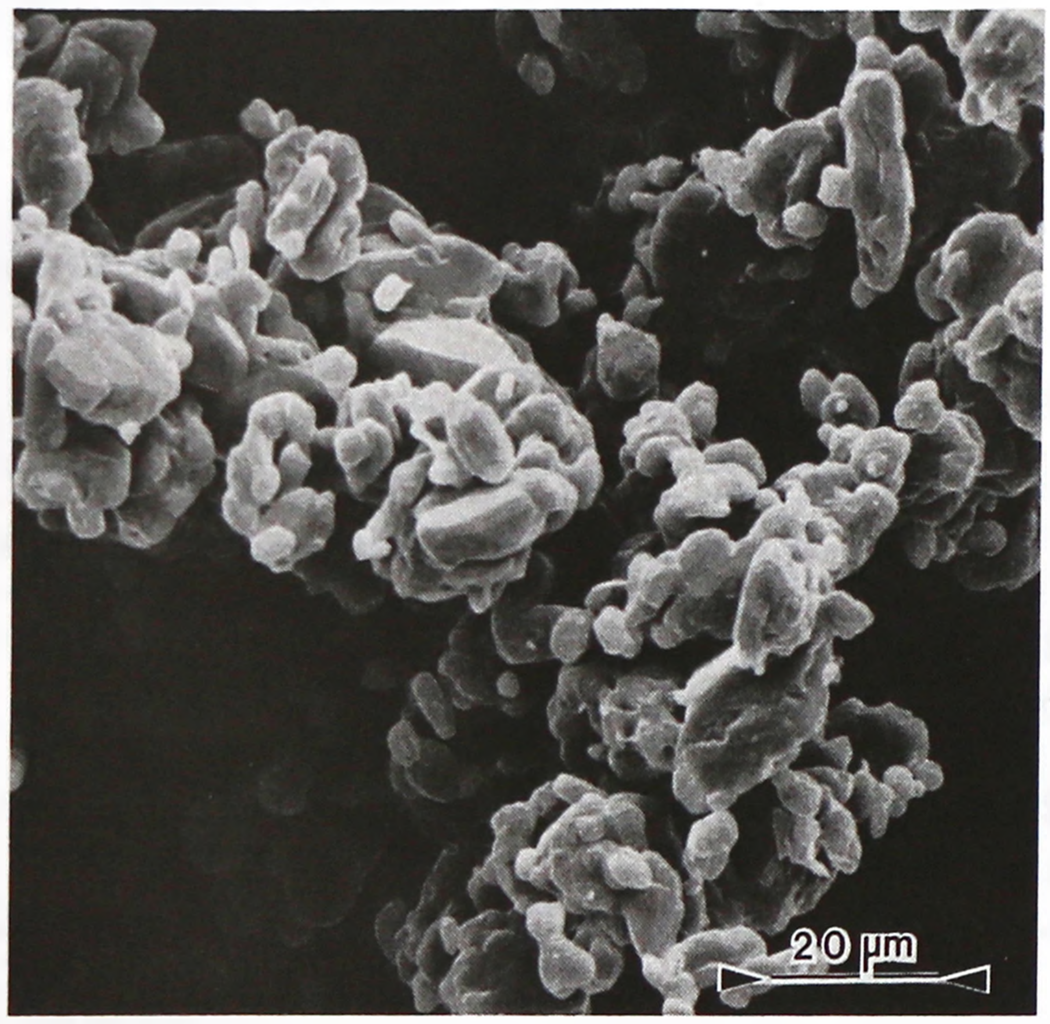
See Methylparaben for further information.

8 Description

Ethylparaben occurs as a white, odorless or almost odorless, crystalline powder.

9 Pharmacopeial Specifications

The pharmacopeial specifications for ethylparaben have undergone harmonization of many attributes for JP, PhEur, and USP–NF.



See Table I. *See also* Section 18.

10 Typical Properties

Antimicrobial activity Ethylparaben exhibits antimicrobial activity from pH 4–8. Preservative efficacy decreases with increasing pH owing to the formation of the phenolate anion. Parabens are more active against yeasts and molds than against bacteria. They are also more active against Gram-positive than against Gram-negative bacteria.

The activity of the parabens increases with increasing chain length of the alkyl moiety, but solubility decreases.

SEM 1: Excipient: ethylparaben; magnification: 600×.

SEM 2: Excipient: ethylparaben; magnification: 3000×.

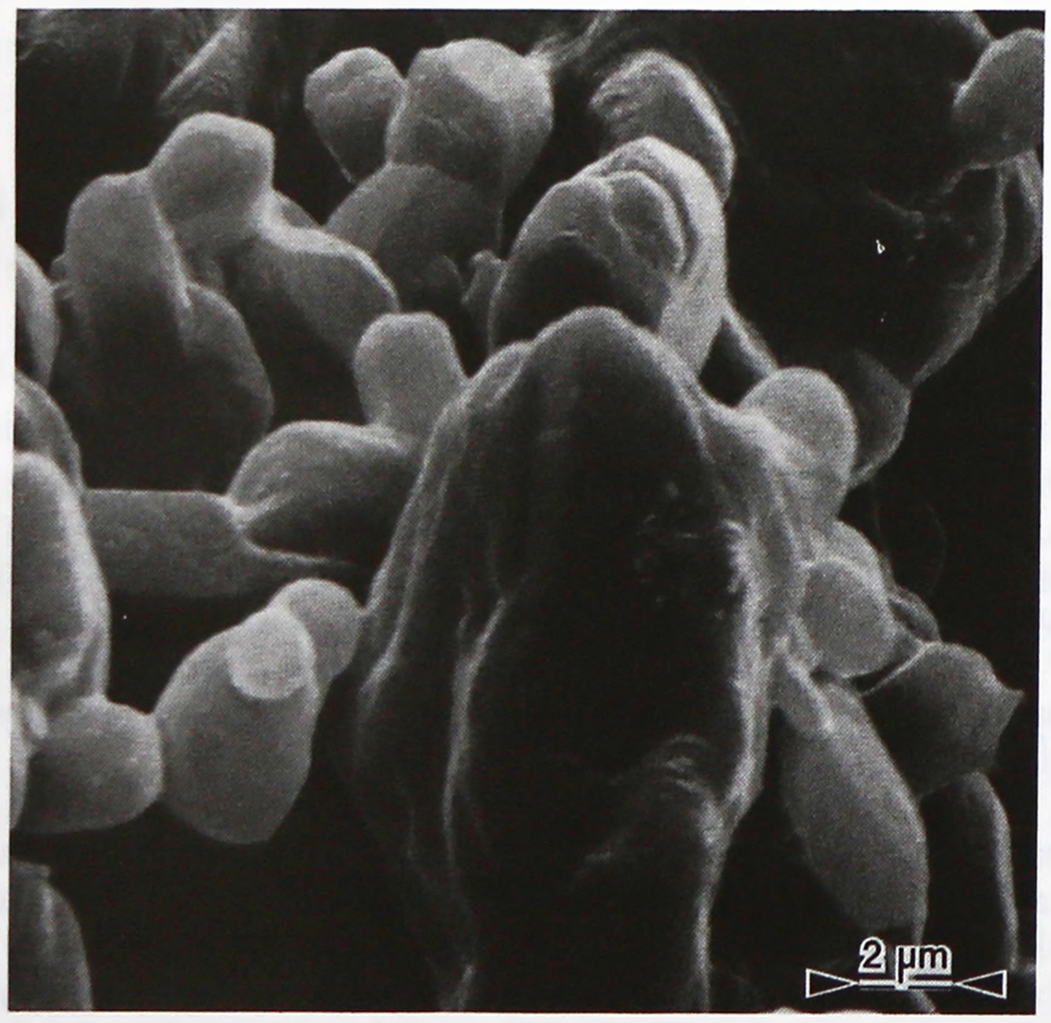


Table I: Pharmacopeial specifications for ethylparaben.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Appearance of solution	+	+	+
Characters	–	+	–
Heavy metals[a]	≤20 ppm	–	–
Acidity	+	+	+
Melting range	115–118°C	115–118°C	115–118°C
Related substances	+	+	+
Residue on ignition	≤0.1%	≤0.1%	≤0.1%
Assay (dried basis)	98.0–102.0%	98.0–102.0%	98.0–102.0%

(a) These tests have not been fully harmonized at the time of publication.

Activity may be improved by using combinations of parabens since synergistic effects occur. Ethylparaben is commonly used with methylparaben and propylparaben in oral and topical formulations (such mixtures are commercially available; for example, *Nipasept* (Nipa Laboratories Inc.). Activity has also been reported to be improved by the addition of other excipients; *see* Methylparaben for further information.

See Table II for minimum inhibitory concentrations of ethylparaben.[2]

Boiling point 297–298°C with decomposition.

Melting point 115–118°C

Partition coefficient The values for different vegetable oils vary considerably and are affected by the purity of the oil; *see* Table III.[3]

Solubility *see* Table IV.

Spectroscopy

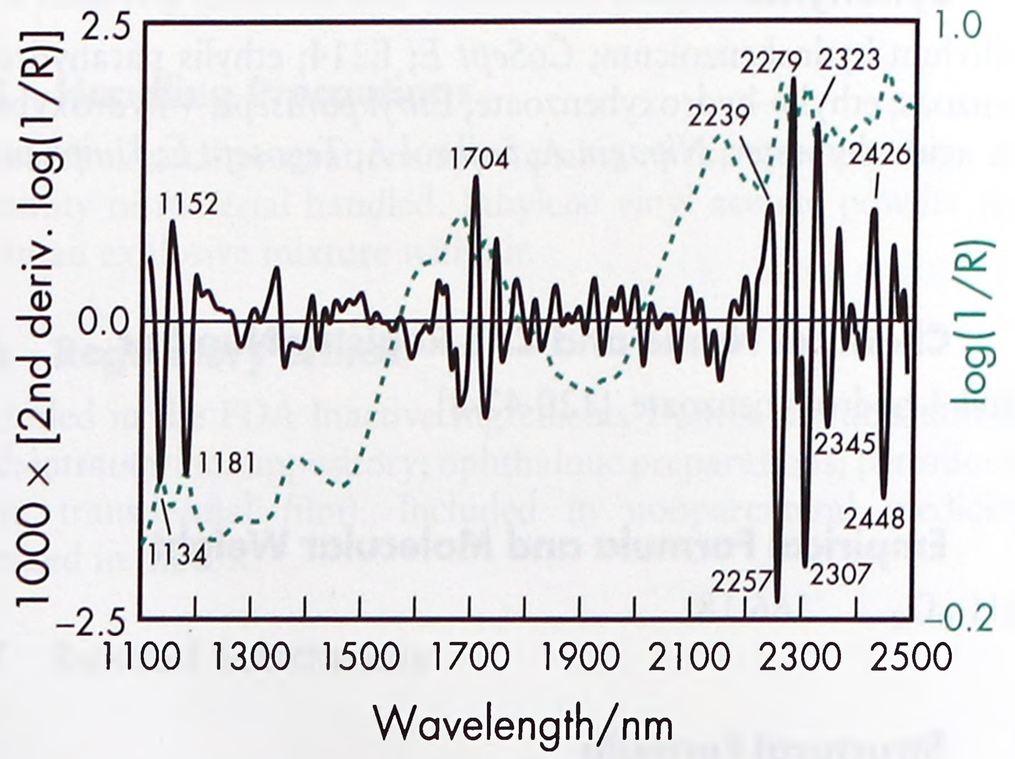

Figure 2: Near-infrared spectrum of ethylparaben measured by reflectance.

11 Stability and Storage Conditions

Aqueous ethylparaben solutions at pH 3–6 can be sterilized by autoclaving, without decomposition.[4] At pH 3–6, aqueous solutions are stable (less than 10% decomposition) for up to about 4 years at room temperature, while solutions at pH 8 or above are subject to rapid hydrolysis (10% or more after about 60 days at room temperature).[5]

Table III: Partition coefficients for ethylparaben in vegetable oil and water.[3]

Solvent	Partition coefficient oil : water
Corn oil	14.0
Mineral oil	0.13
Peanut oil	16.1
Soybean oil	18.8

Ethylparaben should be stored in a well-closed container in a cool, dry place.

12 Incompatibilities

The antimicrobial properties of ethylparaben are considerably reduced in the presence of nonionic surfactants as a result of micellization.[6] Absorption of ethylparaben by plastics has not been reported, although it appears probable given the behavior of other parabens. Ethylparaben is coabsorbed on silica in the presence of ethoxylated phenols.[7] Yellow iron oxide, ultramarine blue, and aluminum silicate extensively absorb ethylparaben in simple aqueous systems, thus reducing preservative efficacy.[8,9]

Table IV: Solubility of ethylparaben in various solvents.

Solvent	Solubility at 20°C unless otherwise stated
Acetone	Freely soluble
Ethanol	1 in 1.4
Ethanol (95%)	1 in 2
Ether	1 in 3.5
Glycerin	1 in 200
Methanol	1 in 0.9
Mineral oil	1 in 4000
Peanut oil	1 in 100
Propylene glycol	1 in 4
Water	1 in 1250 at 15°C
	1 in 910
	1 in 120 at 80°C

Ethylparaben is discolored in the presence of iron and is subject to hydrolysis by weak alkalis and strong acids.

See also Methylparaben.

13 Method of Manufacture

Ethylparaben is prepared by the esterification of *p*-hydroxybenzoic acid with ethanol (95%).

14 Safety

Ethylparaben and other parabens are widely used as antimicrobial preservatives in cosmetics, food products, and oral and topical pharmaceutical formulations.

Systemically, no adverse reactions to parabens have been reported, although they have been associated with hypersensitivity reactions. Parabens, *in vivo*, have also been reported to exhibit estrogenic responses in fish.[10] The WHO has set an estimated total acceptable daily intake for methyl- and ethylparabens at up to 10 mg/kg body-weight.[11,12] A report has been published on the safety assessment of parabens including ethylparaben in cosmetic products.[13]

LD_{50} (mouse, IP): 0.52 g/kg[14]

LD_{50} (mouse, oral): 3.0 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Ethylparaben may be irritant to the skin, eyes, and mucous membranes, and should be handled in a well ventilated environment. Eye protection, gloves, and a dust mask or respirator are recommended.

16 Regulatory Status

Accepted as a food additive in Europe. Included in the FDA Inactive Ingredients Database (oral and topical preparations). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Butylparaben; ethylparaben potassium; ethylparaben sodium; methylparaben; propylparaben.

Ethylparaben potassium

Empirical formula $C_9H_9KO_3$
Molecular weight 204.28
CAS number [36547-19-9]
Synonyms Ethyl 4-hydroxybenzoate potassium salt; potassium ethyl hydroxybenzoate.

Ethylparaben sodium
Empirical formula $C_9H_9NaO_3$
Molecular weight 188.17
CAS number [35285-68-8]
Synonyms E215; ethyl 4-hydroxybenzoate sodium salt; sodium ethyl hydroxybenzoate.

18 Comments

Ethylparaben has undergone harmonization of many attributes for JP, PhEur, and USP–NF by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

See Methylparaben for further information.

The EINECS number for ethylparaben is 204-399-4. The PubChem Compound ID (CID) for ethylparaben is 8434.

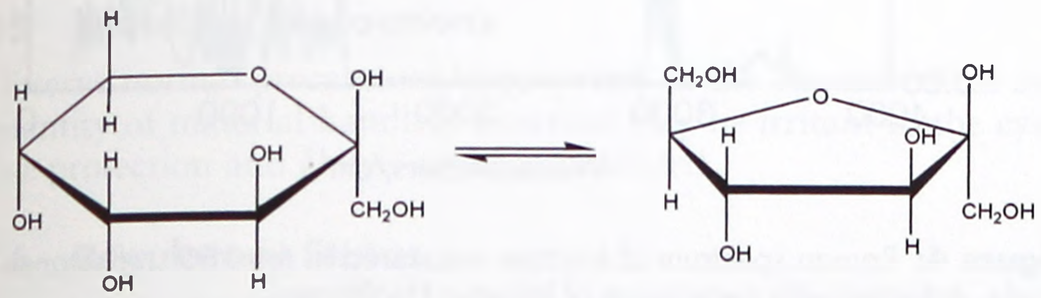
Fructose

1 Nonproprietary Names

BP: Fructose
JP: Fructose
PhEur: Fructose
USP–NF: Fructose

2 Synonyms

Advantose FS 95; D-arabino-2-hexulose; D-arabino-hex-2-ulopyranose; *Fructamyl*; *Fructofin*; D-(−)-fructopyranose; β-D-fructose; fructosum; fruit sugar; *Fruitose*; *Krystar*; laevulose; levulose; nevulose.



3 Chemical Name and CAS Registry Number

D-Fructose [57-48-7]

4 Empirical Formula and Molecular Weight

$C_6H_{12}O_6$ 180.16

5 Structural Formula

Pyranose form

Furanose form

See Section 18.

6 Functional Category

Flavoring agent; sweetening agent; taste-masking agent.

7 Applications in Pharmaceutical Formulation or Technology

Fructose is used in tablets, syrups, and solutions as a flavoring and sweetening agent.

When used as a sweetening agent, fructose is perceived as sweeter than mannitol and sorbitol at equivalent concentration. The sweet taste is perceived more rapidly than that of sucrose and dextrose; *see* Table I. Fructose has greater solubility in ethanol than dextrose and sucrose and may therefore be a more suitable sweetener for alcohol-based formulations.

Fructose is more water soluble than sucrose and dextrose and can present fewer problems with undesired crystallization, for example when solutions are refrigerated or deposited on bottle threads (e.g. 'cap-locking').

At a given concentration fructose has a higher osmotic potential than sucrose, and therefore lower water activity in solution. This may be beneficial for microbial stability of solutions.

The compactibility of fructose based tablets is improved by the addition of a small amount of starch,[1] that is commercially available as *Advantose FS 95*,[2] *see also* Fructose and Pregelatinized Starch.

Table I: Relative sweetness of fructose and other sugars.

Sugar	Relative sweetness at 25°C (10% solids)
Fructose	117
Sucrose	100
High fructose syrup-55	99
High fructose syrup-42	92
Dextrose	65

8 Description

Fructose occurs as odorless, colorless crystals or a white crystalline powder with a very sweet taste.

9 Pharmacopeial Specifications

See Table II.

Table II: Pharmacopeial specifications for fructose.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1

Assay (dried basis)	≥98.0%	—	98.0–102.0%

10 Typical Properties

Acidity/alkalinity pH = 5.35 (9% w/v aqueous solution)
Density 1.58 g/cm^3. *See also* Table III.
Dissociation constant pK_a = 12.06 at 18°C
Heat of combustion 15.3 kJ/g (3.66 kcal/g)
Heat of solution 50.2 kJ/g (12 kcal/g)
Hygroscopicity At 25°C and relative humidities above approximately 60%, fructose absorbs significant amounts of moisture; *see* Figure 1.
Melting point ≈102–105°C (with decomposition)
Osmolarity A 5.05% w/v aqueous solution is isoosmotic with serum.

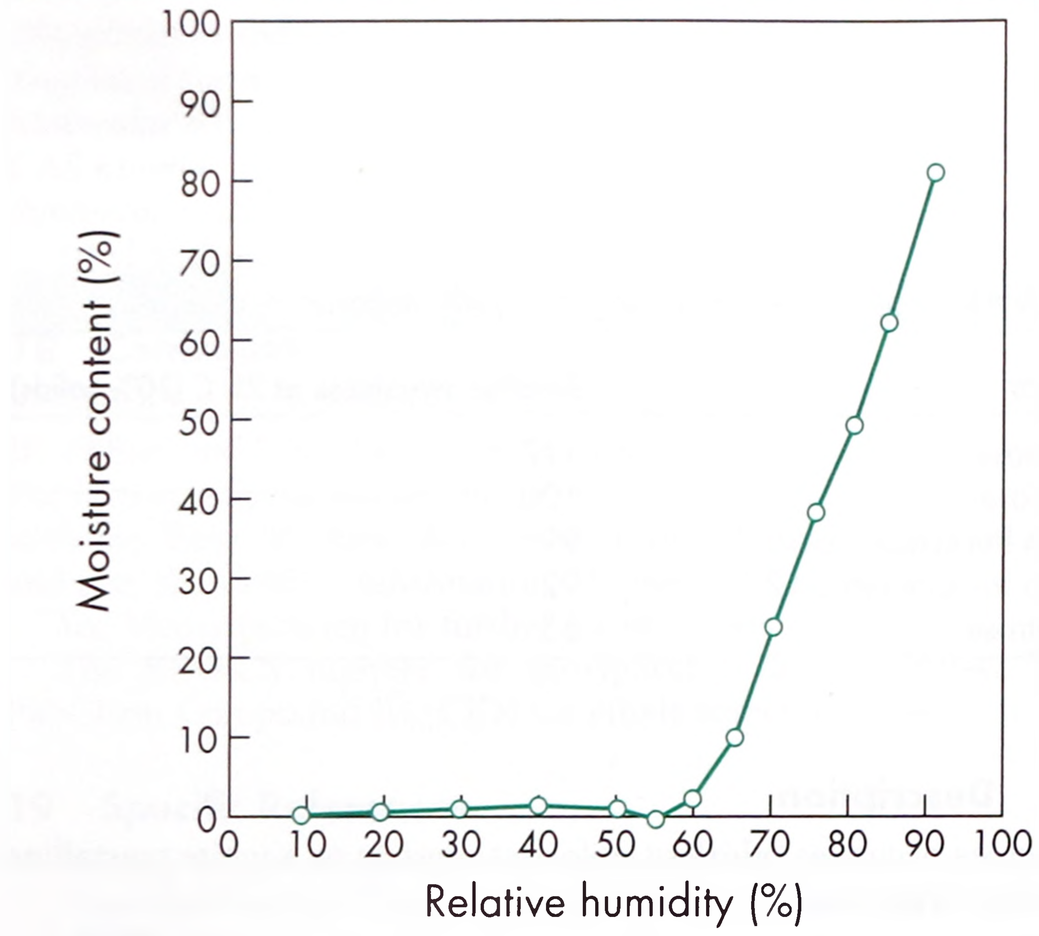

Figure 1: Equilibrium moisture content of fructose at 25°C.

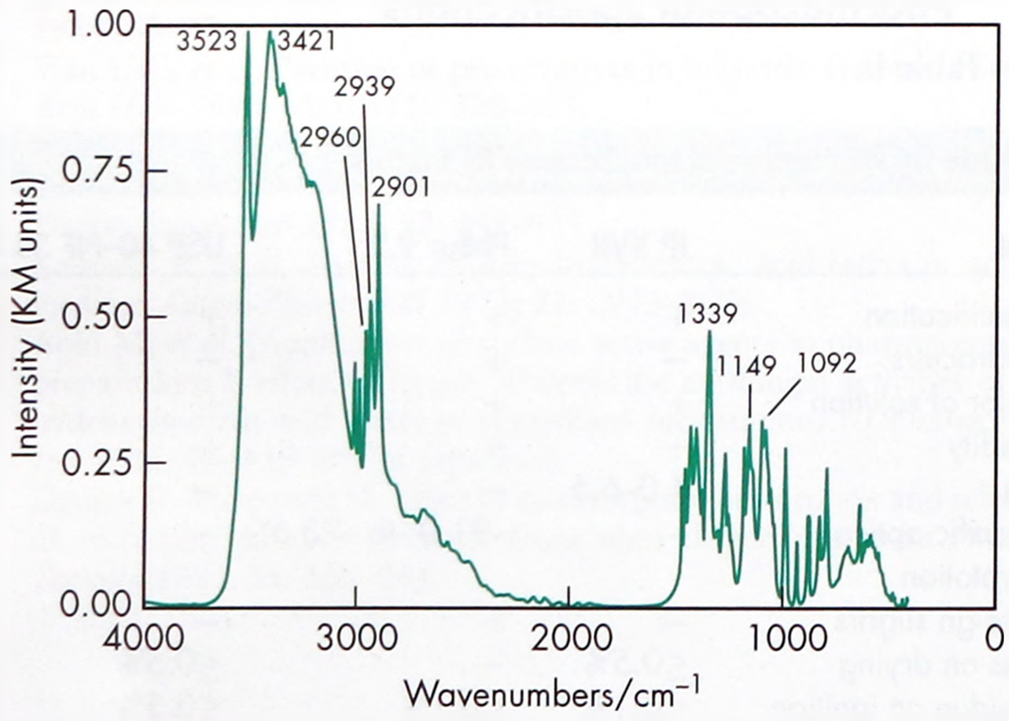

Figure 2: Infrared spectrum of fructose measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

Particle size distribution The average particle size of standard-grade crystalline fructose is 170–450 µm. The average particle size of powdered fructose is 25–40 µm.

Refractive index *see* Table III.

Solubility *see* Table IV.

Specific rotation $[\alpha]_D^{20}$ = −132° to −92° (2% w/v aqueous solution). Note that fructose shows rapid and anomalous mutarotation involving pyranose–furanose interconversion. The final value may be obtained in the presence of hydroxide ions. *See also* Section 18.

Spectroscopy

IR spectrum *see* Figure 2.

NIR spectrum *see* Figure 3.

Raman spectrum *see* Figure 4.

Viscosity (dynamic) *see* Table III.

11 Stability and Storage Conditions

Fructose is hygroscopic and absorbs significant amounts of moisture at relative humidities (RH) greater than 60%. If stored in the original sealed packaging at temperatures below 25°C/60% RH it can be expected to retain stability for at least 12 months.

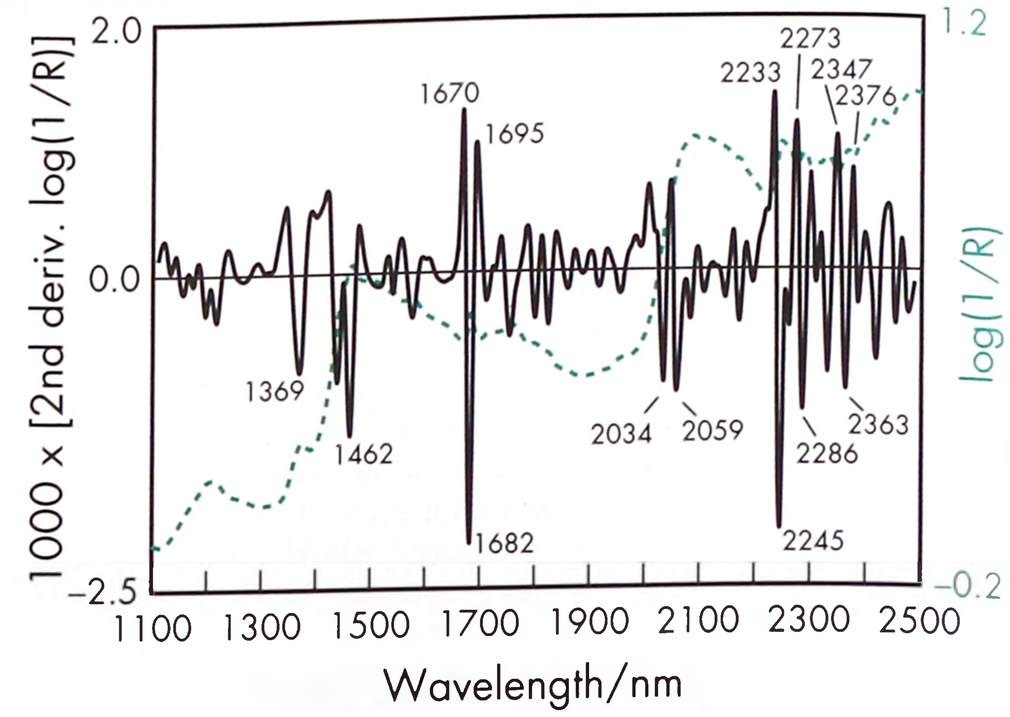

Figure 3: Near-infrared spectrum of fructose measured by reflectance.

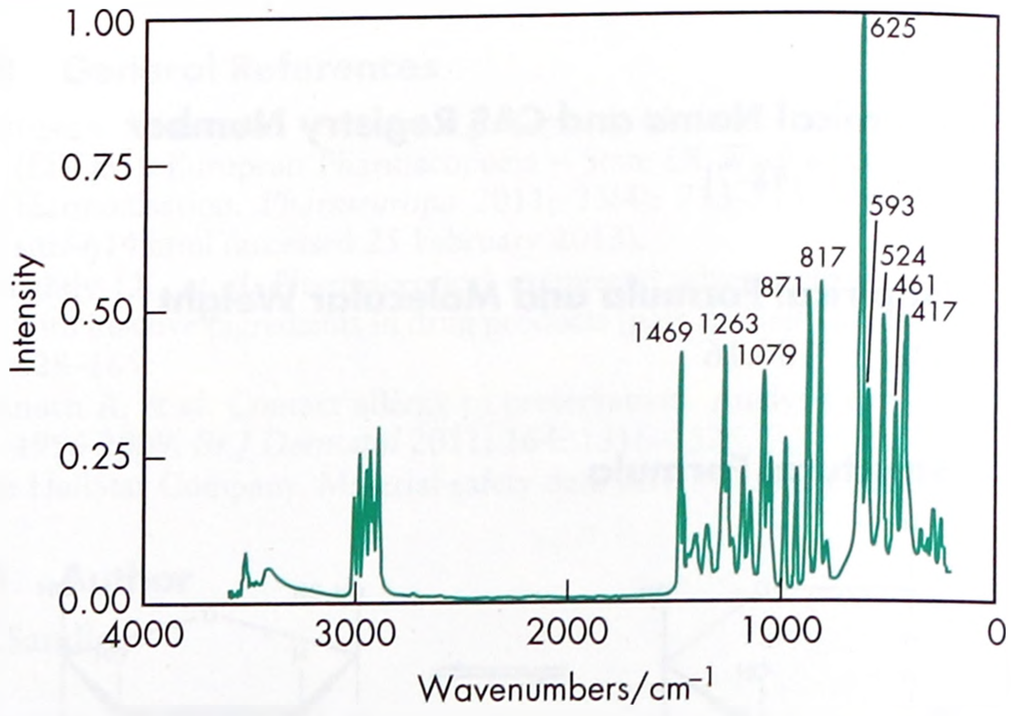

Figure 4: Raman spectrum of fructose measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

Table III: Physical properties of aqueous fructose solutions at 20°C.

Concentration of aqueous fructose solution (% w/w)	Density (g/cm³)	Refractive index	Viscosity, dynamic (mPa s)
10	1.04	1.3477	1.35
20	1.08	1.3633	1.80
30	1.13	1.3804	2.90
40	1.18	1.3986	5.60
50	1.23	1.4393	34.0
60	1.29	1.4853	309.2

Table IV: Solubility of fructose.

Solvent	Solubility at 20°C
Ethanol (95%)	1 in 15
Methanol	1 in 14
Water	1 in 0.3

Aqueous solutions are most stable at pH 3–4 and temperatures of 4–70°C; they may be sterilized by autoclaving.

12 Incompatibilities

Incompatible with strong acids or alkalis, forming a brown coloration. In the aldehyde form, fructose can react with amines, amino acids, peptides, and proteins. Fructose may cause browning of tablets containing amines.

13 Method of Manufacture

Fructose, a monosaccharide sugar, occurs naturally in honey and a large number of fruits. It may be prepared from inulin, dextrose, or sucrose by a number of methods. Commercially, fructose is mainly manufactured by crystallization from high-fructose syrup derived from hydrolyzed and isomerized cereal starch or cane and beet sugar.

14 Safety

Fructose has been used as an alternative to dextrose in parenteral nutrition, but its use is not recommended by some because of the risk of lactic acidosis. Although popular in many countries, it has therefore been suggested that the use of intravenous infusions containing fructose and sorbitol should be abandoned.[3,4] The use of parenteral or oral fructose is not advised in patients with hereditary fructose intolerance.[5] In addition, fructose-containing oral liquids, lozenges or chewable tablets may be harmful to the teeth.[5] Adverse responses to excessively high doses of fructose or as a result of fructose intolerance include diarrhea, abdominal cramps[6,7] and vomiting.[8]

The Cosmetic Ingredient Review Expert Panel has assessed fructose and concluded that the material is safe as used in cosmetics and personal care products.[9] On exposure to the eyes, skin and respiratory tract, fructose can cause irritation.[7]

LD_{50} (oral, rat): 4.0 g/kg[7]

LD_{50} (IV, rabbit): 15 g/kg[10]

See also Section 18.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Fructose may be irritant to the eyes. Eye protection and gloves are recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral tablets, solutions, syrups, suspensions, and chewable bars; rectal preparations; intravenous infusions). Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Dextrose; fructose and pregelatinized starch, coprocessed; high-fructose syrup; liquid fructose; powdered fructose; sucrose.

High-fructose syrup

Comments A syrup most commonly containing 42% or 55% fructose, with the remainder consisting of dextrose and small amounts of oligosaccharides. It is a colorless, odorless, highly viscous syrup with a sweet taste.

Included in the FDA inactive ingredients database (oral suspensions).

Liquid fructose

Comments A syrup containing ≥99.5% fructose, made by solubilizing crystalline fructose in water. It is a colorless, odorless, highly viscous syrup with a sweet taste.

Powdered fructose

Comments Finely ground crystalline fructose containing ≤2% silicon dioxide as a glidant.

18 Comments

Fructose can occur in both the furanose and pyranose forms. Fructose present in natural products occurs in the furanose form, while that produced by crystallization occurs in the pyranose form. An aqueous solution at 20°C contains about 20% of the furanose form.

Although it is absorbed more slowly than dextrose from the gastrointestinal tract, fructose is metabolized more rapidly. Metabolism of fructose occurs mainly in the liver, where it is converted partially to dextrose and the metabolites lactic acid and pyruvic acid. Entry into the liver and subsequent phosphorylation is insulin-independent. Further metabolism occurs by way of a variety of metabolic pathways. In healthy and well-regulated diabetics, glycogenesis (glucose stored as glycogen) predominates.

Literature reviews have shown fructose intake when substituted for other carbohydrates is unlikely to produce harmful effects and the evidence is not supportive of a relationship with cardiometabolic disease. However, excess intake may be problematic;[11,12] high consumption of fructose has been reported to increase serum triglyceride and insulin serum concentrations and elevate blood pressure that are features of metabolic syndrome onset.[6] In addition high consumption has been associated with increased serum uric acid levels,[13] and risk of type 2 diabetes.[14]

The Canadian Diabetic Association recommends up to 10% of total daily energy intake can be provided from fructose substitution of carbohydrates in mixed meals.[12] A low daily dose of fructose has been proposed in a diabetic diet as it may improve glycemic response to oral glucose.[15–17] However, at a daily intake above 60 g people with type 2 diabetes may experience an increase in triglyceride levels.[12]

A specification for fructose is contained in the *Food Chemicals Codex* (FCC).[18]

The EINECS number for fructose is 200-333-3. The PubChem Compound ID (CID) for fructose is 5984.

Fructose and Pregelatinized Starch, Coprocessed

1 Nonproprietary Names

None adopted.

2 Synonyms

Advantose FS 95.

3 Chemical Name and CAS Registry Number

See Section 8.

4 Empirical Formula and Molecular Weight

See Section 8.

5 Structural Formula

See Section 8.

6 Functional Category

Direct compression excipient; taste-masking agent.

7 Applications in Pharmaceutical Formulation or Technology

Coprocessed fructose and pregelatinized starch is used in the direct compression of tablets to improve flowability and compressibility.[1] Additionally, so-called 'chewable' tablets can be prepared using coprocessed fructose and pregelatinized starch.

Coprocessed fructose and pregelatinized starch is also used to mask undesirable flavors of components in tablet formulations.

8 Description

Coprocessed fructose and pregelatinized starch occurs as a white crystalline powder containing 95% fructose and 5% pregelatinized starch (a co-dried system of these two ingredients).[1]

9 Pharmacopeial Specifications

Both fructose and pregelatinized starch are listed as separate monographs in the BP 2017, JP XVII (only fructose), PhEur 9.2, and USP 40–NF 35 S1, but the combination is not listed. *See* Fructose, and Starch, Pregelatinized.

10 Typical Properties

Angle of repose 12° for *Advantose FS 95*[1]
Density (bulk) 0.55–0.75 g/cm^3 for *Advantose FS 95*[1]
Loss on drying ≤2.0% for *Advantose FS 95*[2]
Moisture content (KF) 1–2% for *Advantose FS 95*[1]
Particle size distribution Over 80% of the crystalline powder is retained on a #60 mesh (250 μm) screen for *Advantose FS 95.*[1]
Solubility Partially soluble in water for *Advantose FS 95.*[2]

See also Fructose, and Starch, Pregelatinized.

11 Stability and Storage Conditions

Coprocessed fructose and pregelatinized starch is a chemically stable mixture. Protect from excessive temperatures and humidity. Optimum storage conditions are 25°C and 50% relative humidity. The container should be kept tightly closed and in a cool, well-ventilated place.[2]

12 Incompatibilities

Coprocessed fructose and pregelatinized starch may react with oxidizing agents.[2] Fructose is a reducing sugar and can react with amines, amino acids, peptides, and proteins.

See Fructose, and Starch, Pregelatinized.

13 Method of Manufacture

Coprocessed fructose and pregelatinized starch is prepared by co-drying a mixture of the two ingredients.

14 Safety

Eye contact with coprocessed fructose and pregelatinized starch may produce slight irritation. No skin irritation may be expected from single short-term exposure, although prolonged or repeated contact may produce some irritation. Ingestion of large amounts may produce gastrointestinal disturbances. Overexposure to dusts may produce irritation of the respiratory system.[2]

See Fructose, and Starch, Pregelatinized.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of the material handled.

Coprocessed fructose and pregelatinized starch is a nonflammable. Upon decomposition, fructose and pregelatinized starch emits carbon monoxide, carbon dioxide and/or low molecular weight hydrocarbons. Accumulation of airborne dust may present an explosion hazard. Suitable eye protection is recommended.[2]

16 Regulatory Status

Coprocessed fructose and pregelatinized starch is a mixture of two materials both of which are generally regarded as nontoxic:

Fructose Included in the FDA Inactive Ingredients Database (oral tablets, solutions, syrups, suspensions, and chewable bars; rectal preparations; intravenous infusions). Included in the Canadian Natural Health Products Ingredients Database.

Starch, pregelatinized Included in the FDA Inactive Ingredients Database (oral capsules, suspensions, and tablets; vaginal preparations). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Fructose; starch, pregelatinized.

18 Comments

Coprocessed fructose and pregelatinized starch (*Advantose FS 95*) has lower hygroscopicity than standard fructose, making it easier to handle.[1] The mixture has been used in the pharmaceutical formulation of sublingual or buccal preparations for the administration of active substances with low to poor aqueous solubility.[3]

Fumaric Acid

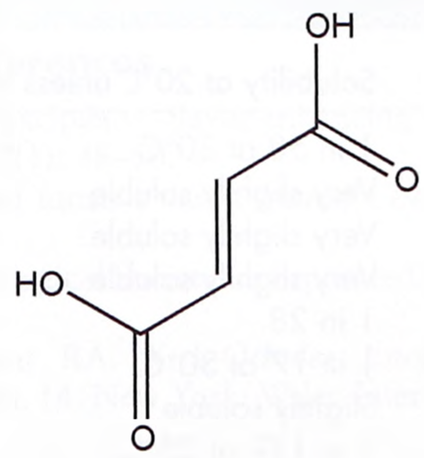
1 Nonproprietary Names

USP–NF: Fumaric Acid

2 Synonyms

Allomaleic acid; allomalenic acid; boletic acid; butenedioic acid; E297; 1,2-ethenedicarboxylic acid; lichenic acid; *trans*-butenedioic acid; NSC-2752; *trans*-1,2-ethylenedicarboxylic acid; tumaric acid; U-1149; USAF EK-P-583.

3 Chemical Name and CAS Registry Number



(E)-2-Butenedioic acid [110-17-8]

4 Empirical Formula and Molecular Weight

$C_4H_4O_4$ 116.07

Fumaric acid occurs as one of two isomeric unsaturated dicarboxylic acids, the other being maleic acid.

5 Structural Formula

6 Functional Category

Acidulant; antioxidant; complexing agent; flavoring agent; solubilizing agent.

7 Applications in Pharmaceutical Formulation or Technology

Fumaric acid is used primarily in liquid pharmaceutical preparations as an acidulant and flavoring agent, producing an intense acidic sour flavor. Fumaric acid may be included as the acid part of effervescent tablet formulations, although this use is limited as the compound has an extremely low solubility in water. It is also used as a chelating agent, which exhibits synergism when used in combin-

ation with other true antioxidants. It has been used in tablet and film-coated pellet formulations as an acidifying agent and also to increase drug solubility.[1,2]

8 Description

Fumaric acid occurs as white, odorless or nearly odorless granules or as a crystalline powder that is virtually non-hygroscopic.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for fumaric acid.

Test	USP 40–NF 35 S1
Identification	+
Water	≤0.5%
Residue on ignition	≤0.1%
Heavy metals	≤10 ppm
Maleic acid	≤0.1%
Assay (anhydrous basis)	99.5–100.5%

10 Typical Properties

Acidity/alkalinity

pH = 2.45 (saturated aqueous solution at 20°C);
pH = 2.58 (0.1% w/v aqueous solution at 25°C);
pH = 2.25 (0.3% w/v aqueous solution at 25°C);
pH = 2.15 (0.5% w/v aqueous solution at 25°C).

Boiling point 290°C (sealed tube)
Density 1.635 g/cm^3 at 20°C
Density (bulk) 0.77 g/cm^3
Density (tapped) 0.93 g/cm^3
Dissociation constant

pK_{a1} = 3.03 at 25°C;
pK_{a2} = 4.54 at 25°C.

Melting point 280–289°C (closed capillary, rapid heating); partial carbonization and formation of maleic anhydride occur at 230°C (open vessel); sublimes at 200°C.
Solubility *see* Table II.

Table II: Solubility of fumaric acid.

Solvent	Solubility at 20°C unless otherwise stated
Acetone	1 in 58 at 30°C
Benzene	Very slightly soluble
Carbon tetrachloride	Very slightly soluble
Chloroform	Very slightly soluble
Ethanol	1 in 28
Ethanol (95%)	1 in 17 at 30°C
Ether	Slightly soluble
	1 in 139 at 25°C
Olive oil	Very slightly soluble
Propylene glycol	1 in 33
Water	1 in 200
	1 in 432 at 0°C
	1 in 303 at 10°C
	1 in 159 at 25°C
	1 in 94 at 40°C
	1 in 42 at 60°C
	1 in 10 at 100°C

Spectroscopy

IR spectrum *see* Figure 1.
NIR spectrum *see* Figure 2.
Raman spectrum *see* Figure 3.

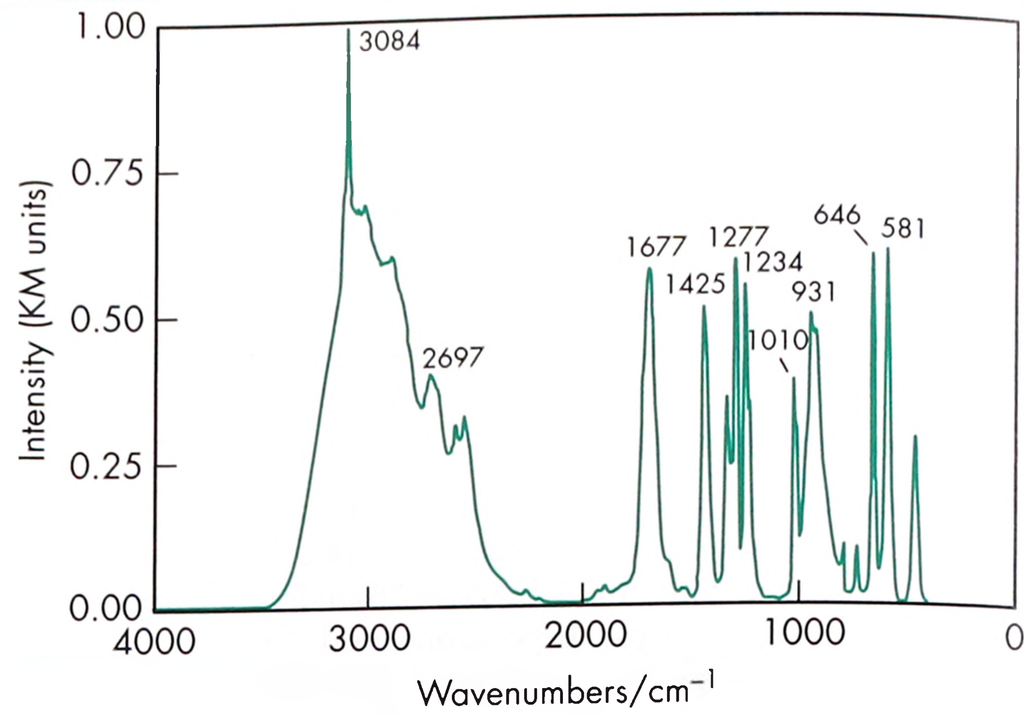


Figure 1: Infrared spectrum of fumaric acid measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

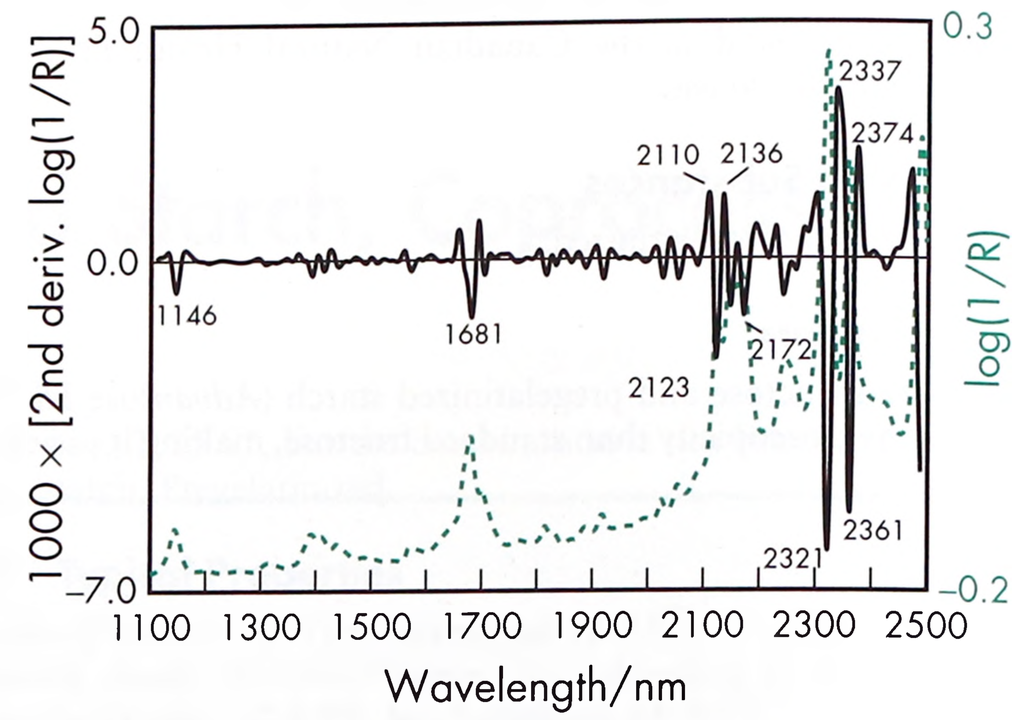

Figure 2: Near-infrared spectrum of fumaric acid measured by reflectance.

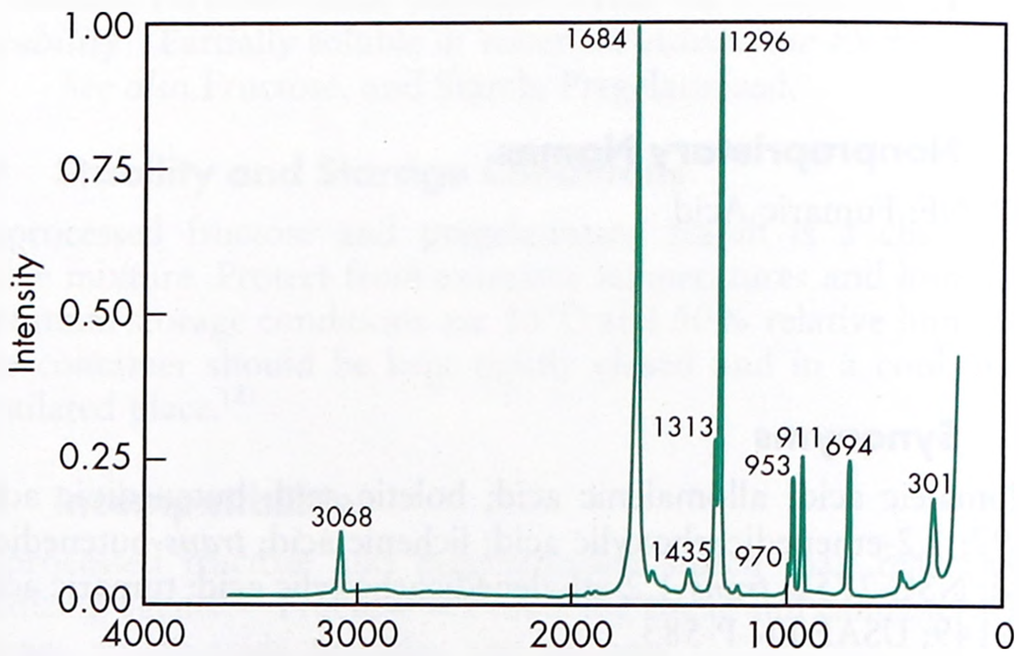

Figure 3: Raman spectrum of fumaric acid measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

11 Stability and Storage Conditions

Fumaric acid is stable although it is subject to degradation by both aerobic and anaerobic microorganisms. When heated in sealed vessels with water at 150–170°C it forms DL-malic acid.

The bulk material should be stored in a well-closed container in a cool, dry place.

12 Incompatibilities

Fumaric acid undergoes reactions typical of an organic acid.

13 Method of Manufacture

Commercially, fumaric acid may be prepared from glucose by the action of fungi such as *Rhizopus nigricans*, as a by-product in the manufacture of maleic and phthalic anhydrides, and by the isomerization of maleic acid using heat or a catalyst.

On the laboratory scale, fumaric acid can be prepared by the oxidation of furfural with sodium chlorate in the presence of vanadium pentoxide.

14 Safety

Fumaric acid is used in oral pharmaceutical formulations and food products, and is generally regarded as a relatively nontoxic and nonirritant material. However, acute renal failure and other adverse reactions have occurred following the topical and systemic therapeutic use of fumaric acid and fumaric acid derivatives in the treatment of psoriasis or other skin disorders.[3,4] Other adverse effects of oral therapy have included disturbances of liver function, gastrointestinal effects, and flushing.[5]

The WHO has stated that the establishment of an estimated acceptable daily intake of fumaric acid or its salts was unnecessary since it is a normal constituent of body tissues.[6]

LD_{50} (mouse, IP): 0.1 g/kg[7]
LD_{50} (rabbit skin): 20.0 g/kg
LD_{50} (rat, oral): 9.3 g/kg

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Fumaric acid may be irritating to the skin, eyes, and respiratory system, and should be handled in a well-ventilated environment. Gloves and eye protection are recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral capsules, powder for oral solutions, suspensions, syrups, extended release, controlled release, and sustained action chewable tablets). Included in nonparenteral medicines licensed in the UK. Fumaric acid is listed as a food additive in the EAFUS list compiled by the FDA. Accepted for use as a food additive in Europe. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Citric acid monohydrate; malic acid; tartaric acid.

18 Comments

In the design of novel pelletized formulations manufactured by extrusion-spheronization, fumaric acid has been used to aid spheronization, favoring the production of fine pellets.[8] It has also been investigated as an alternative filler to lactose in pellets.[3]

Fumaric acid has been investigated as a lubricant for effervescent tablets,[4] and copolymers of fumaric acid and sebacic acid have been investigated as bioadhesive microspheres.[9] Fumaric acid may be capable of creating a micro-environmental pH inside pellets and thus increasing solubility at higher pH.[10]

Fumaric acid is used as a therapeutic agent in the treatment of psoriasis and other skin disorders.[5,11]

Fumaric acid is used as a food additive at concentrations up to 3600 ppm.

A specification for fumaric acid is contained in the *Food Chemical Codex* (FCC)[12] and the *Japanese Pharmaceutical Excipients* (JPE).[13]

The EINECS number for fumaric acid is 203-743-0. The PubChem Compound ID (CID) for fumaric acid is 444972.

F

Galactose

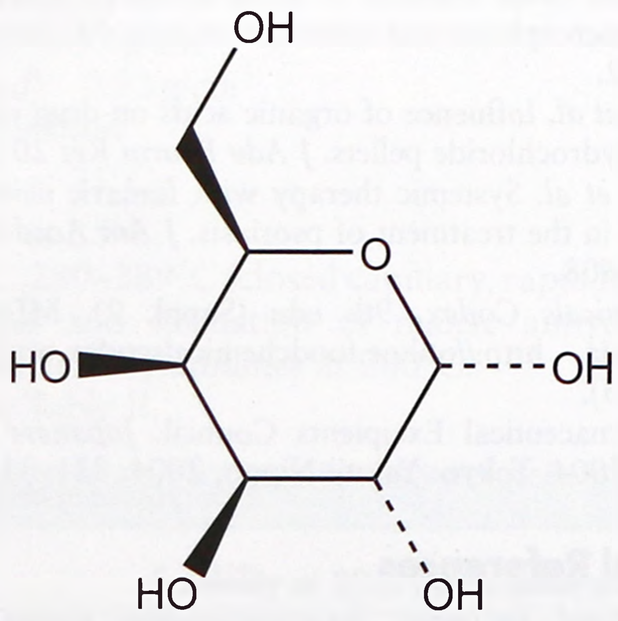
1 Nonproprietary Names

BP: Galactose
PhEur: Galactose
USP–NF: Galactose

2 Synonyms

Brain sugar; cerebrose; galactosum; lactoglucose.

3 Chemical Name and CAS Registry Number



α-D-Galactopyranose [3646-73-9]
D-Galactopyranose [59-23-4]

4 Empirical Formula and Molecular Weight

$C_6H_{12}O_6$ 180.16

The USP 40–NF 35 S1 describes galactose as α-D-galactopyranose, one of the products of the metabolism of lactose, a naturally occurring sugar in dairy products, by the digestive enzyme lactase. The PhEur 9.2 describes galactose as D-galactopyranose.

5 Structural Formula

α-D-Galactopyranose

6 Functional Category

Complexing agent; sweetening agent.

7 Applications in Pharmaceutical Formulation or Technology

Galactose is used as a sweetener in oral pharmaceutical preparations. In recent years, galactose has also been used in nanoparticles and drug–polymer conjugates as a targeting moiety for the liver; *see* Section 18.

8 Description

Galactose occurs as a white or almost white crystalline or finely granulated powder.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for galactose.

Test	PhEur 9.2	USP 40–NF 35 S1
Characters	+	–
Identification	+	+
Appearance of solution	+	+
Acidity or alkalinity	+	+
Specific optical rotation	+78.0 to +81.5°	+78.0 to +81.5°
Barium	+	+
Lead	≤0.5 ppm	≤0.5 µg/g
Water	≤1.0%	≤1.0%
Residue on ignition	≤0.1%	≤0.1%
Microbial limits	+	+
Aerobic bacteria	≤10^2 cfu/g	≤10^3 cfu/g[a]
Total combined molds and yeasts	–	≤10^2 cfu/g

(a) Tests for *Salmonella*, *Escherichia coli*, *Staphylcoccus aureus*, and *Pseudomonas aeruginosa* are negative.

10 Typical Properties

Density 1.5 g/cm^3 for D-galactopyranose.[1]
Dissociation constant pK_a 12.92[2]
Melting point 167°C (α and β forms);[3] 163–170°C for D-galactopyranose.[1]
pH of aqueous solution pH 4.5–6.0 for D-galactopyranose.[1]
Optical rotation $[\alpha]^{20}_D$ +150.7° → 80.2° and +52.8° → 80.2° (water) for the α and β forms, respectively.[3]
Solubility Soluble in 0.5 parts water and in 1.7 parts water for α and β forms, respectively.[3] Soluble in pyridine, alcohol, and ether. Solubility also reported as 47.25 g per 100 g of water (D-galactose);[4] 68.3 g per 100 g of water.[5]
Vapor pressure 1.82×10^{-8} mmHg at 25°C.[2]

11 Stability and Storage Conditions

Keep in a tightly closed container. Store in a cool, dry, ventilated area.

12 Incompatibilities

Galactose is a reducing sugar and may undergo Mailliard type reactions with amines.

13 Method of Manufacture

Galactose is mainly produced by hydrolyzing lactose (a disaccharide consisting of glucose and galactose), which is found in dairy products, such as milk. Non-animal derived D-galactose is manufactured from wood-based or other biomass hydrosylates using an aqueous chromatographic separation process.[6]

14 Safety

Galactose is generally regarded as a safe material, although it has been identified experimentally as having teratogenic or mutagenic effects.[7] Large doses may cause gastrointestinal upset.

Inhalation of dust may cause irritation in the respiratory tract. Contact with eyes and prolonged contact with skin may cause irritation, especially in people with galactosemia, a rare genetic disorder in which the body is unable to convert galactose to dextrose.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material being handled.

When heated to decomposition, galactose emits acrid smoke and irritating fumes.[7] Excessive generation of dust, or inhalation of dust, should be avoided as inhalation of dust may cause irritation to the respiratory tract. Suitable eye, respiratory and skin protection is recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral solutions, tablets; rectal solutions). Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Guar gum; lactose monohydrate; raffinose.

18 Comments

The USP 40–NF 35 S1 gives the CAS number for α-D-Galactopyranose as 3646-73-9 and PhEur for D-Galactopyranose as 59-23-4.

Galactose is usually found in nature combined with other sugars, for example, in lactose (milk sugar). It is also found in polysaccharides, such as gums, complex carbohydrates and in carbohydrate-containing lipids called glycolipids, which occur in the brain and other nervous tissues of most animals.

Galactose is used as an ultrasound contrast agent, either dissolved in water or as microgranules stabilized with palmitic acid and dispersed in water.

Galactose is also used to test the ability of the liver to remove galactose from the blood and convert it to glycogen in liver function tests, which estimate impaired liver function through measurement of the rate of galactose excretion after ingestion, or injection, of a measured amount of galactose.[8,9] Copolymeric nanoparticles end-capped with galactose, and polymer-drug conjugates containing galactose as a targeting moiety, have been investigated for liver-specific delivery.[10–12]

Galactose is licensed for use in infants and children in echocardiography and for diagnosis of vesicoureteral reflux.[13]

The EINECS number of galactose is 200-416-4. The PubChem ID for α-D-galactose is 439357 and for D-galactose is 6036.

3 Chemical Name and CAS Registry Number

Gelatin [9000-70-8]

4 Empirical Formula and Molecular Weight

Gelatin is a generic term for a mixture of purified protein fractions obtained either by partial acid hydrolysis (type A gelatin) or by partial alkaline hydrolysis (type B gelatin) of animal collagen obtained from cattle and pig bone, cattle skin (hide), pigskin, and fish skin. Gelatin may also be a mixture of both types.

The protein fractions consist almost entirely of amino acids joined together by amide linkages to form linear polymers, varying in molecular weight from 20 000–200 000.

The JP XVII also includes a monograph for purified gelatin.

5 Structural Formula

See Section 4.

6 Functional Category

Capsule shell material; coating agent; complexing agent; film-forming agent; gelling agent; microencapsulating agent; suspending agent; tablet and capsule binder; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Gelatin is widely used in a variety of pharmaceutical formulations, including its use as a biodegradable matrix material in an implantable delivery system,[1] although it is most frequently used to form either hard or soft gelatin capsules.[2–4]

Gelatin capsules are unit-dosage forms designed mainly for oral administration. Soft capsules on the market also include those for rectal and vaginal administration. Hard capsules can be filled with solid (powders, granules, pellets, tablets, and mixtures thereof), semisolid or liquid fillings, whereas soft capsules are mainly filled with semisolid or liquid fillings. In hard capsules, the active drug is always incorporated into the filling, while in soft capsules the drug substance can also be incorporated into the thick soft capsule shell. Gelatin is soluble in warm water (>40°C), and a gelatin capsule will initially swell and finally dissolve in gastric fluid to release its contents rapidly.[5]

Hard capsules are manufactured in two pieces by dipping lubricated stainless steel mold pins into a 45–55°C gelatin solution of defined viscosity, which depends on the size of the capsules and whether cap or body are to be formed. The gelatin is taken up by the pins as a result of gelation, and the resulting film thickness is governed by the viscosity of the solution. The capsule shells are passed through a stream of cool air to aid setting of the gelatin, and afterwards they are slowly dried with large volumes of humidity-controlled air heated to a few degrees above ambient temperature and blown directly over the pins. The capsule halves are removed from their pins, trimmed and fitted together. Gelatin that is used to produce hard capsules may contain various coloring agents and antimicrobial preservatives. Surfactants may be present in small quantities in the shells being a residue of the pin lubricant. However, the use of preservatives is no longer encouraged in line with current GMP principles. Capsule shells may be treated with formaldehyde to make them insoluble in gastric fluid. Standard capsules vary in volume from 0.13 to 1.37 mL. For veterinary use, capsules with a volume between 3 and 28 mL are available, and capsules with a capacity of 0.025 mL are available for toxicity studies in rats.

In contrast to two-piece hard capsules, soft gelatin capsules are manufactured, filled and sealed in one process. The gelatin used to form the soft shells has a lower gel strength than that used for hard capsules, and the viscosity of the solutions is also lower, which results in more flexible shells. Additives to soft shell formulations are plasticizers such as polyalcohols (glycerin, propylene glycol, polyethylene glycol). Sorbitol can be added as moisturizing agent, whereby the larger amount of water will act as plasticizer. Coloring and opacifying agents are also added. The filling can interact with the gelatin and the plasticizer chemically. There may be migration of filling components into the shell and plasticizer from the shell into the filling. These interactions have to be taken into account during the formulation of the gelatin shell and the filling. The main method to produce soft gelatin capsules is the rotary die method (RP Scherer), and an alternative method for small volumes of round capsules is the Globex system (Industrial Techno-logic Solutions Ltd).[4] *Soflet Gelcaps* (Banner Life Sciences at Patheon) are tablets that have been coated with a gelatin film.

Gelatin is also used for the microencapsulation of drugs, where the active drug is sealed inside a microsized capsule or beadlet, which may then be handled as a powder. The first microencapsulated drugs (beadlets) were fish oils and oily vitamins in gelatin beadlets prepared by coacervation.

Low-molecular-weight gelatin has been investigated for its ability to enhance the dissolution of orally ingested drugs.[6] Ibuprofen–gelatin micropellets have been prepared for the controlled release of the drug.[7] Other uses of gelatin include the preparation of pastes, pastilles, pessaries, and suppositories. In addition, it is used as a tablet binder and coating agent, and as a viscosity-increasing agent for solutions and semisolids.

Gelatin is added to vaccines (e.g. MMR, varicella, influenza, yellow fever, and rabies) as a protein stabilizer to protect the viruses against the effect of increased temperature during manufacture and storage. Recombinant human gelatins have been developed for use in vaccines and other biological formulations, to reduce the risk of an immune response, and also to eliminate the risk of contamination with pathogens such as viruses and prions.[8,9]

8 Description

Gelatin occurs as a light-amber to faintly yellow-colored, vitreous, brittle solid. It is practically odorless and tasteless, and is available as translucent sheets, flakes, and granules, or as a coarse powder.

9 Pharmacopeial Specifications

The pharmacopeial specifications for gelatin have undergone harmonization of many attributes for JP, PhEur, and USP–NF.

See Table I. *See also* Section 18.

Table I: Pharmacopeial specifications for gelatin.

Test	JP XVII	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+	+
Characters[a]	+	+	–
Microbial contamination[b]			
Aerobic microbial count	≤10^3 cfu/g	≤10^3 cfu/g	≤10^3 cfu/g
Yeasts and molds	≤10^2 cfu/g	≤10^2 cfu/g	≤10^2 cfu/g
Loss on drying	≤15.0%	≤15.0%	≤15.0%
Odor and water-insoluble substances	+	–	–

(a) This test has not been fully harmonized at the time of publication.
(b) Tests for *Salmonella* and *Escherichia coli* are negative.

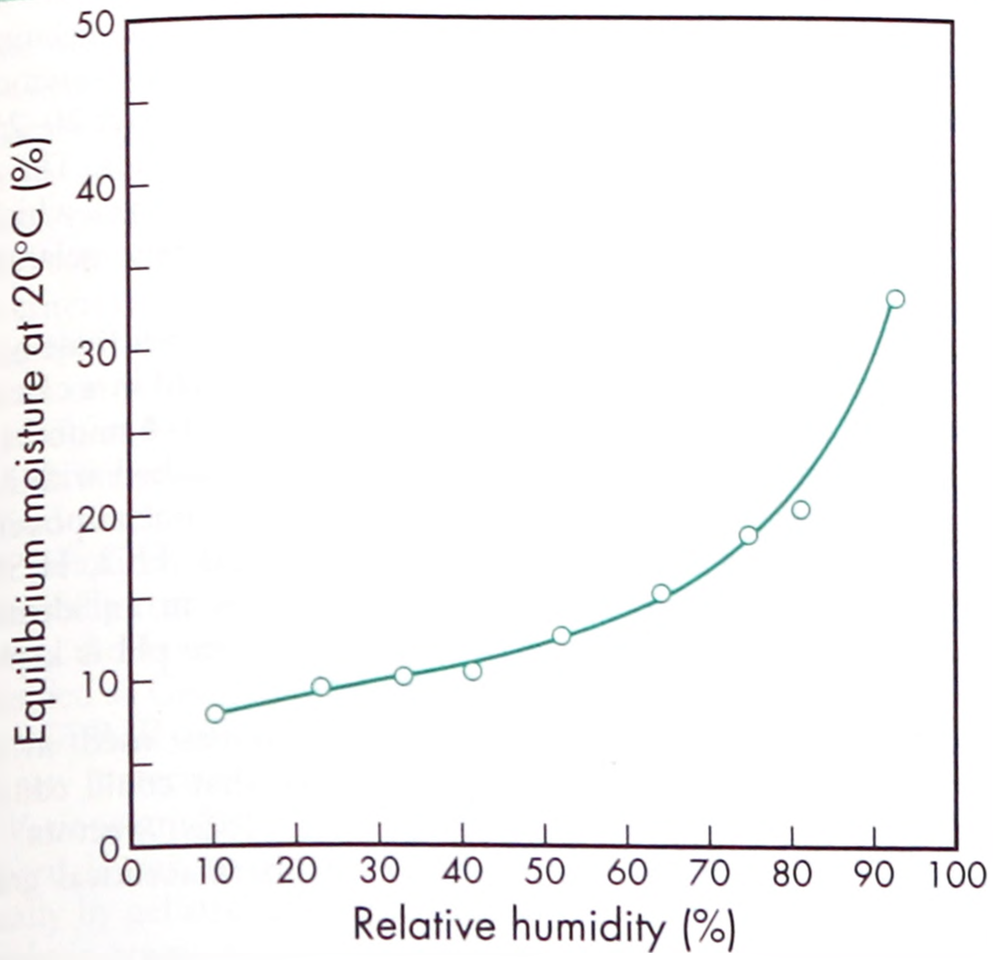

Figure 1: Equilibrium moisture content of gelatin (*Pharmagel A*).

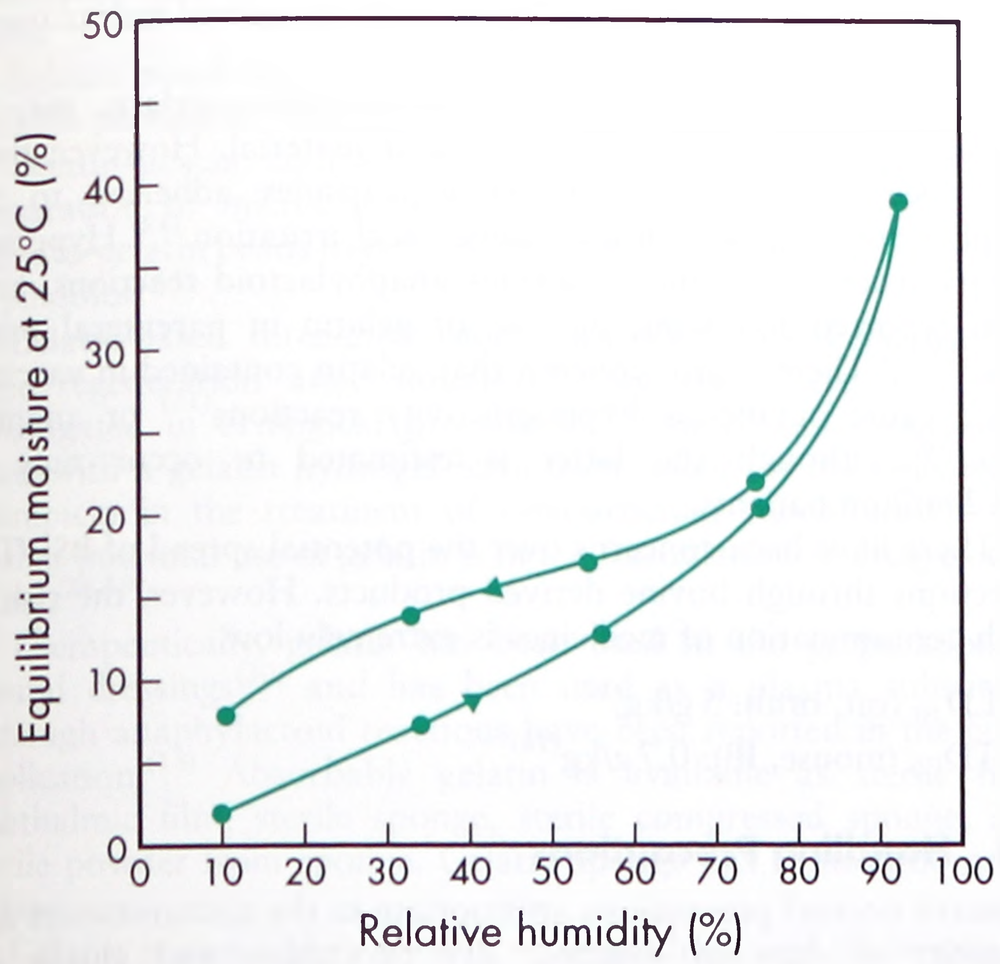

Figure 2: Sorption–desorption isotherm of gelatin.

10 Typical Properties

Acidity/alkalinity

For a 1% w/v aqueous solution at 25°C (depending on source and grade):

pH = 3.8–5.5 (type A);

pH = 5.0–7.5 (type B).

Density

1.32 g/cm^3 for type A;

1.28 g/cm^3 for type B.

Isoelectric point

7.0–9.0 for type A;

4.7–5.4 for type B.

Moisture content 9–11%.[10] *See also* Figures 1 and 2.

Solubility Practically insoluble in acetone, chloroform, ethanol (95%), ether, and methanol. Soluble in glycerin, acids, and alkalis, although strong acids or alkalis cause precipitation. In water, gelatin swells and softens, gradually absorbing between five and 10 times its own weight of water. Gelatin is soluble in water above 40°C, forming a colloidal solution, which gels on cooling to 35–40°C. This gel–sol system is thixotropic and heat-reversible, the melting temperature being slightly higher than the setting point; the melting point can be varied by the addition of glycerin.

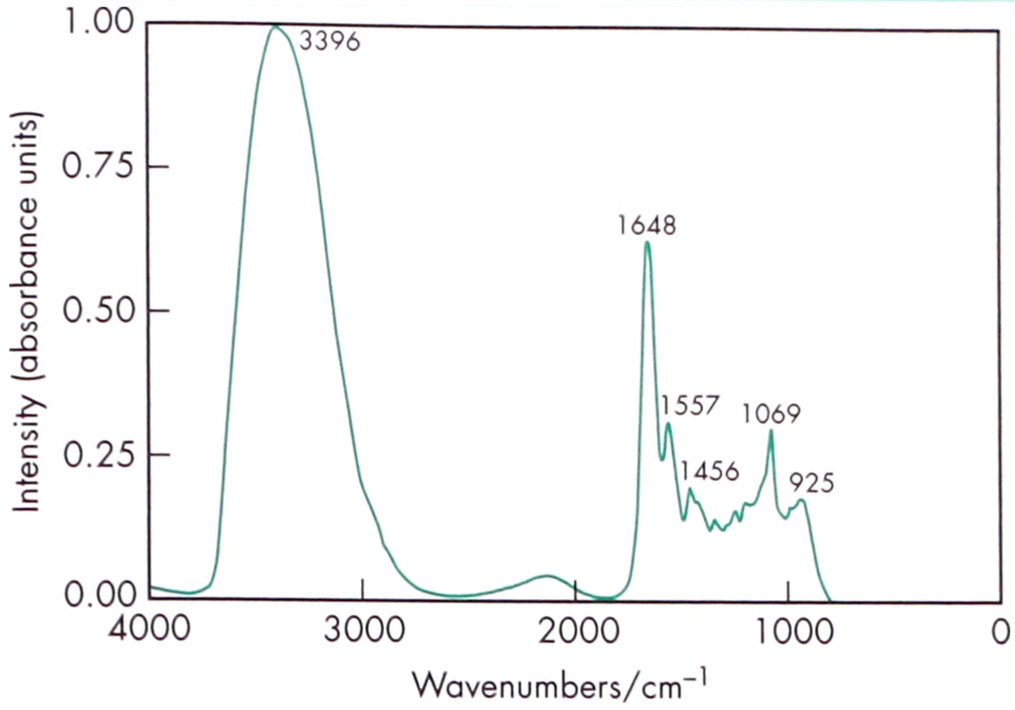

Figure 3: Infrared spectrum of gelatin measured by transmission. Adapted with permission of Informa Healthcare.

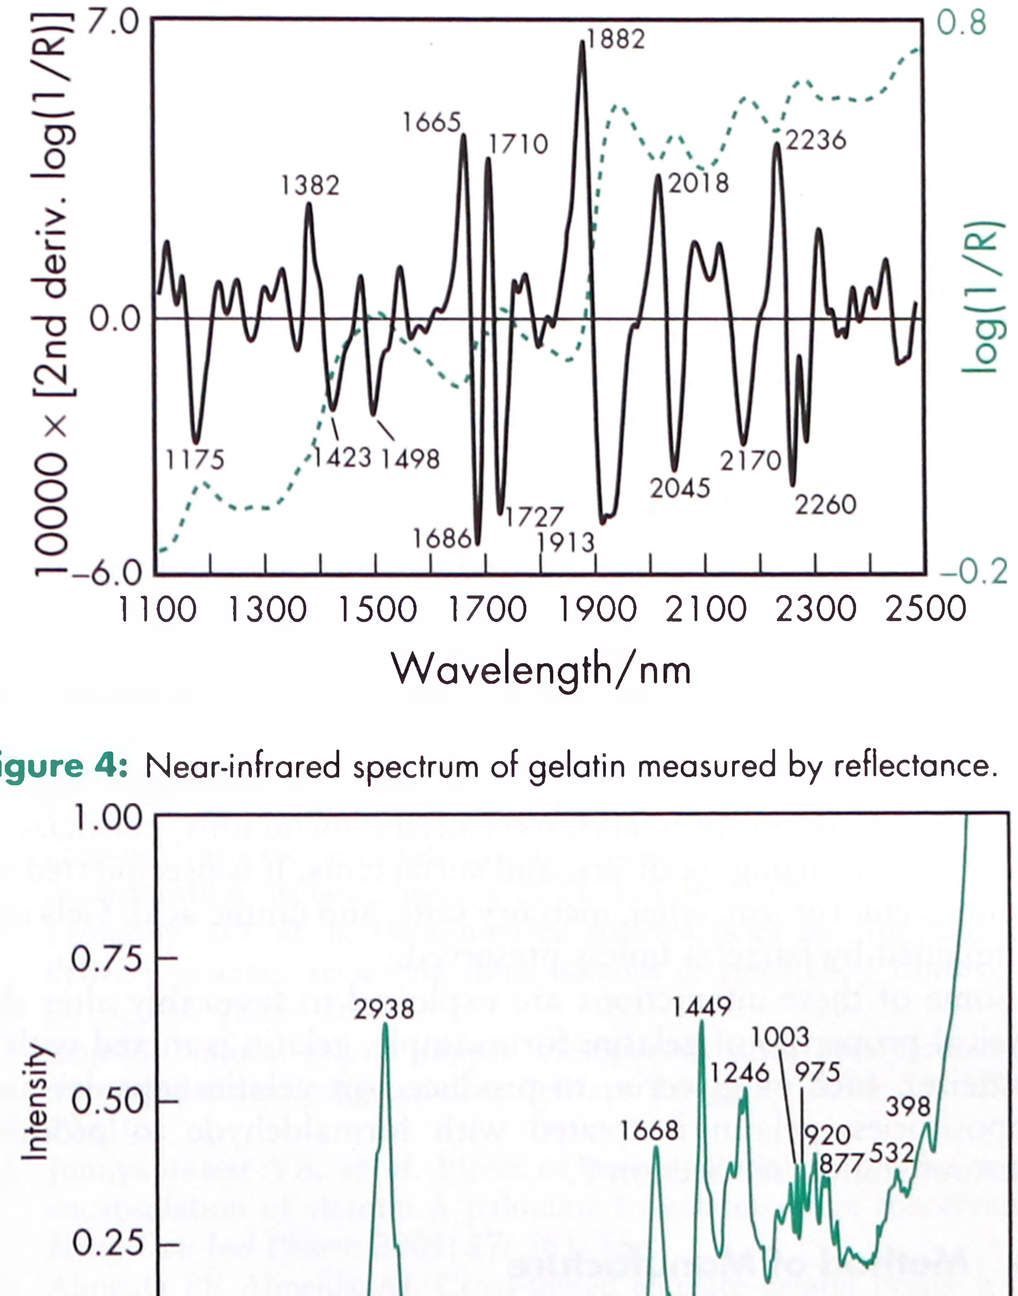

Figure 4: Near-infrared spectrum of gelatin measured by reflectance.

Figure 5: Raman spectrum of gelatin measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

Spectroscopy

IR spectrum *see* Figure 3.

NIR spectrum *see* Figure 4.

Raman spectrum *see* Figure 5.

Viscosity (dynamic) *see* Table II.[4]

Table II: Dynamic viscosity of gelatin solutions at 60°C.

Grade	Viscosity (dynamic)/mPa s	
	6.67% w/v aqueous solution	12.5% w/v aqueous solution
Acid ossein	2.7–3.7	12.5–14.5
Acid pigskin	4.2–4.8	19.0–20.5
Fish skin	3.0–4.5	13.0–20.0
Limed ossein/hide	3.6–4.8	19.0–20.5

11 Stability and Storage Conditions

Dry gelatin is stable in air. Aqueous gelatin solutions are also stable for long periods if stored under cool conditions but they are subject to bacterial degradation.[4] At temperatures above about 50°C, aqueous gelatin solutions may undergo slow depolymerization and a reduction in gel strength may occur on resetting. Depolymerization becomes more rapid at temperatures above 65°C, and gel strength may be reduced by half when a solution is heated at 80°C for 1 hour. The rate and extent of depolymerization depends on the molecular weight of the gelatin, with a lower-molecular-weight material decomposing more rapidly.[11]

Gelatin may be sterilized by dry heat.

The bulk material should be stored in an airtight container in a cool, well-ventilated, and dry place.

12 Incompatibilities

Gelatin is an amphoteric material and will react with both acids and bases. It is also a protein and thus exhibits chemical properties characteristic of such materials; for example, gelatin may be hydrolyzed by most proteolytic systems to yield its amino acid components.

Gelatin will also react with aldehydes and aldehydic sugars, anionic and cationic polymers, electrolytes, metal ions, plasticizers, preservatives, strong oxidizers, and surfactants. It is precipitated by alcohols, chloroform, ether, mercury salts, and tannic acid. Gels can be liquefied by bacteria unless preserved.

Some of these interactions are exploited to favorably alter the physical properties of gelatin: for example, gelatin is mixed with a plasticizer, such as glycerin, to produce soft gelatin capsules and suppositories; gelatin is treated with formaldehyde to produce gastroresistance; *see* Section 7.

13 Method of Manufacture

Gelatin is extracted from animal tissues rich in collagen such as skin, sinews, and bone. Although it is possible to extract gelatin from these materials using boiling water, it is more practical to first pretreat the animal tissues with either acid or alkali. Gelatin obtained from the acid process is called type A, whereas gelatin obtained from the alkali process is called type B.

The acid-conditioning process (manufacture of type A gelatin) is restricted to soft bone ossein (demineralized bones), sinew, pigskin, calfskin and fish skins for reasons of gaining sufficient yield. The material is cut in pieces and washed in cold water for a few hours to remove superficial fat. It is then treated with mineral acid solutions, mainly HCl or H_2SO_4, at pH 1–3 and 15–20°C until maximum swelling has occurred. This process takes approximately 24 hours. The swollen stock is then washed with water to remove excess acid, and the pH is adjusted to pH 3.5–4.0 (pigskin, fish skin) or 2.0–3.5 (all other tissues) for the conversion to gelatin by hot-water extraction.

The hydrolytic extraction is carried out in a batch-type operation using successive portions of hot water at progressively higher temperatures (50–75°C) until the maximum yield of gelatin is obtained. The gelatin solution is then filtered through previously sterilized cellulose pads, deionized, concentrated to about 20–25% w/v and sterilized by flashing it to 138°C for 4 seconds. The dry gelatin is then formed by chilling the solution to form a gel, which is air-dried in temperature-controlled ovens. The dried gelatin is ground to the desired particle size.

In the alkali process (liming), demineralized bones (ossein) or cattle skins are usually used. The animal tissue is held in a calcium hydroxide (2–5% lime) slurry for a period of 2–4 months at 14–18°C. At the end of the liming, the stock is washed with cold water for about 24 hours to remove as much of the lime as possible. The stock solution is then neutralized with acid (HCl, H_2SO_4, H_3PO_4) and the gelatin is extracted with water in an identical manner to that in the acid process, except that the pH is kept at values between 5.0–6.5 (neutral extraction).

During the preparation of the bovine bones used in the production of gelatin, specified risk materials that could contain transmissible spongiform encephalopathies (TSEs) vectors are removed. TSE infectivity is not present in pharmaceutical grade gelatin.

14 Safety

Gelatin is widely used in a variety of pharmaceutical formulations, including oral and parenteral products.

In general, when used in oral formulations gelatin may be regarded as a nontoxic and nonirritant material. However, there have been rare reports of gelatin capsules adhering to the esophageal lining, which may cause local irritation.[12] Hypersensitivity reactions, including serious anaphylactoid reactions, have been reported following the use of gelatin in parenteral products.[13,14] There is also concern that gelatin contained in vaccines could cause cutaneous hypersensitivity reactions[15] or anaphylaxis,[16] although the latter is estimated to occur only in 1 in 2 million patients.

There have been concerns over the potential spread of BSE/TSE infections through bovine derived products. However, the risk of such contamination of medicines is extremely low.

LD_{50} (rat, oral): 5 g/kg[17]

TD_{Lo} (mouse, IP): 0.7 g/kg[18]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Eye protection and gloves are recommended. Gelatin should be handled in a well-ventilated environment and kept away from sources of ignition and heat. Empty containers pose a fire risk, and the gelatin residues should be evaporated under a fume hood.

16 Regulatory Status

GRAS listed. Included in the FDA Inactive Ingredients Database (dental preparations; inhalations; injections; oral capsules, pastilles, solutions, syrups and tablets; topical and vaginal preparations). Included in medicines licensed in the UK, Europe, and Japan. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

18 Comments

Gelatin is one of the materials that have been selected for harmonization by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the

'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

In the past there has been a significant amount of regulatory activity and legislation due to the attention given to bovine sourced gelatin manufacturing processes and the potential transmission of TSE vectors from raw bovine materials into gelatin.[4] In Europe, the criteria by which the safety is assured involves controlling the geographical sourcing of animals used; the nature of the tissue used (based on scientific data showing where animal BSE infectivity is located); and the method of production.

Gelatin produced with hides as the starting material is considered much safer than using bones, although it is recommended that measures are undertaken to prevent cross-contamination with potentially contaminated materials. When gelatin is produced from bones, the bones should ideally not be sourced from countries classified as Geographical BSE Risk (GBR) I and II, although bones from GBR III countries can be used if the removal of vertebrae from the raw materials is assured (*see* Table III).[19]

Various grades of gelatin are commercially available that differ in particle size, molecular weight, and other properties. Grading is usually by gel strength, expressed as 'Bloom strength', which is the weight in grams that, when applied under controlled conditions to a plunger 12.7 mm in diameter, will produce a depression exactly 4 mm deep in a matured gel containing 6.66% w/w of gelatin in water.

Gelatin-based micro- and nanoparticles have been developed as drug (in particular antineoplastic) and gene delivery systems.[20–22]

Gelatin–acacia complex coacervation has been used in the preparation of microcapsules of vitamin A.[23] Pindolol-loaded alginate–gelatin beads have been developed for the sustained release of pindolol.[24]

Gelatin-based three-dimensional scaffolds have been used in bone regeneration after surgery,[25] and they have also been investigated in urological procedures.[26] Bioceramic composites filled with a gelatin hydrogel have been tested for the delivery of rifampicin in the treatment of osteoarticular tuberculosis.[27] A further potential use of gelatin is in the formulation of drug-eluting stents.[28,29]

Therapeutically, gelatin has been used in the preparation of wound dressings[30] and has been used as a plasma substitute, although anaphylactoid reactions have been reported in the latter application.[13] Absorbable gelatin is available as sterile film, ophthalmic film, sterile sponge, sterile compressed sponge, and sterile powder from sponge. Gelatin sponge has hemostatic properties.

Gelatin is also widely used in food products and photographic emulsions.

A specification for gelatin is contained in the *Food Chemicals Codex* (FCC).[31]

The EINECS number for gelatin is 232-554-6.

Table III: The European Scientific Steering Committee classification of geographical BSE risk (GBR).

GBR level	Presence of one or more cattle clinically or pre-clinically infected with BSE in a geographical region/country
I	Highly unlikely
II	Unlikely but not excluded
III	Likely but not confirmed or confirmed at a lower level
IV	Confirmed at a higher level

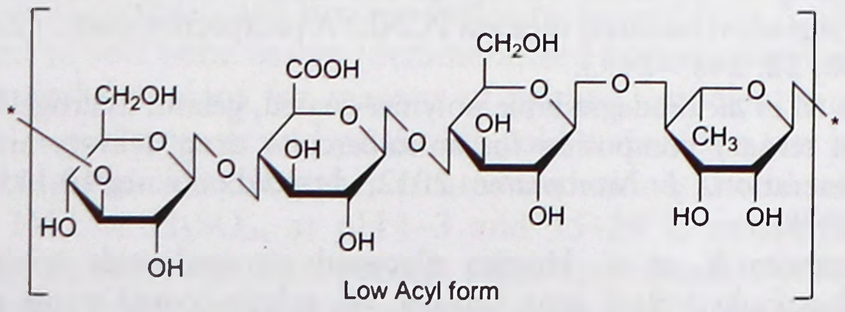
Gellan Gum

1 Nonproprietary Names

USP–NF: Gellan Gum

2 Synonyms

Deacetylated gellan gum; deacetylated polysaccharide S-60; E418; high acyl gellan gum; *Kelcogel*; low acyl gellan gum.



3 Chemical Name and CAS Registry Number

Gellan Gum [71010-52-1]

4 Empirical Formula and Molecular Weight

The USP 40–NF 35 S1 describes gellan gum as a high-molecular-weight heteropolysaccharide comprising a tetrasaccharide repeating unit of one rhamnose, one glucuronic acid, and two glucose units. The glucuronic acid is neutralized to mixed potassium, sodium, calcium, and magnesium salts. It may contain acyl (glyceryl and acetyl) groups as the *O*-glycosidically linked esters.

5 Structural Formula

6 Functional Category

Gelling agent; modified-release agent; mucoadhesive; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Gellan gum has been reported to have various applications in food, cosmetic and pharmaceutical industries as a gelling, coating and as a controlled release agent.[1]

Gellan gum, an anioinic mucoadhesive polysaccharide, is widely utilized for its ion-activated *in-situ* gelling property. The *in-situ* gelling system is a viscous polymer-based solution that exhibits sol-to-gel phase transition upon change in physicochemical parameters such as ionic strength (crosslink with cations), temperature or pH thus prolonging the residence time of a formulation on ocular and nasal surfaces.[2–4] Gellan gum has been investigated as a controlled release excipient for ocular,[5–8] nasal[9,10] and oral drug delivery.[11–13]

As a topical hydrocolloid, gellan gum was found to significantly enhance the skin permeation of ibuprofen.[14] The pseudoplastic flow of gellan gum gels combined with thixotropy and sustained release has been investigated for formulating vaginal gels with prolonged retention and decreased frequency of administration.[15]

Microspheres[16] and microbeads formulated with gellan gum alone and in combination with other polymers have been used as carriers for controlled[17,18] and floating[19,20] delivery systems.

8 Description

Gellan gum occurs as white to tan free-flowing, colorless powder.

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for gellan gum.

Test	USP 40–NF 35 S1
Identification	+
Lead	≤2.0 µg/g
Arsenic	≤3.0 µg/g
Isopropyl alcohol	≤0.075%
Microbial contamination	+
Aerobic bacteria	$\leq 10^3$ cfu/g
Yeasts and molds	$\leq 10^2$ cfu/g
Total ash (dried basis)	4.0%–14.0%
Loss on drying	≤15.0%
Assay (dried basis)	3.3%–6.8% CO_2

10 Typical Properties

pH Approximately neutral (1% solution deionised water).
Solubility Soluble in hot or in cold deionized water.

There are two basic forms of gellan gum; high-acyl and low-acyl. Their typical properties are listed in Table II.

Table II: Typical Properties of low- and high-acyl gellan gum.

Property	Low-acyl gellan gum	High-acyl gellan gum
Hydration temperature	45–90°C	65–90°C
Gel set temperature	35–55°C[a]	>55°C
Hot Viscosity (1% at 80°C)	<25 cp	>100 cp
Gel Texture	Hard, brittle	Soft, elastic
Ion Sensitivity	High (<10 mM Ca)	Low (>20 mM Ca)
Film Flexibility	Low	Medium

(a) Lower temperatures are possible with a cold hydrated system if cations are available from the substrate.

11 Stability and Storage Conditions

Store in a roofed and well ventilated area in the unopened original package.

Gellan gum demonstrates good stability over a wide range of pH from approximately pH 3 to pH 13. At very low pH, acid hydrolysis may occur leading to depolymerization, especially at elevated temperatures. Because the gel strength of gellan gum is governed by the type and concentration of ions, its gel strength may vary with changing pH, however, the gellan molecule remains chemically unchanged.

12 Incompatibilities

Gellan gum is degraded by strong oxidizing agents and mixtures of oxidizing and reducing agents. Water-miscible organic solvents, such as alcohols, may precipitate gellan gum from solution depending on the amount added. However, moderate concentrations (up to 10%) of these solvents may not cause precipitation.

Like other polysaccarides, gellan gum will undergo hydrolytic degradation at high temperatures, especially in acidic conditions. High acyl gellan gum is more susceptible to degradation so long hold times in acidic conditions should be avoided. However, at pH 3.5, a low acyl gellan gum solution can be maintained at 80°C for up to one hour with minimal deterioration in the quality of the subsequently formed gel.

Gellan gum is compatible with many pharmaceutically available nonionic surfactants. As an anionic polymer, gellan gum tends to be incompatible with cationic surfactants which can cause precipitation through association with the negatively charged carboxyl groups on the polymer. Anionic and amphoteric surfactants tend to salt out gellan gum above a surfactant concentration of 15%. This incompatibility can be controlled or prevented in certain cases by adding an electrolyte. The order of addition of surfactants when preparing formulations is important to the proper hydration of gellan gum.

13 Method of Manufacture

Gellan gum is produced by a pure-culture fermentation of *Sphingomonas elodea* (previously identified as *Pseudomonas elodea*, but later reclassified) in the presence of carbohydrate, purified by recovery with isopropyl alcohol, and then dried and milled.

14 Safety

Gellan gum is generally regarded as non-toxic and nonirritant material when used as a pharmaceutical excipient.

The Joint FAO/WHO Expert Committee on Food Additives has allocated an acceptable daily intake of 'not specified' for gellan gum. It may have a laxative effect when ingested as a food additive in high concentrations.[21]

LD_{50} (rat, oral): >5 g/kg[21]
LD_{50} (rat, inhalation): >6 mg/L
Irritation, Eye (rabbit): Nonirritating
Irritation, Skin (rabbit): Nonirritating

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Avoid dust formation. Gloves are recommended.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (ophthalmic solutions) and in the Canadian Natural Health Products Ingredients Database. Also accepted as a food additive in Europe.

17 Related Substances

Agar.

18 Comments

Gellan gum combined with sodium alginate/xanthan gum has been investigated for probiotic encapsulation in oral delivery applications.[22,23]

Hydrogel beads based on gellan gum combined with chitosan have been utilized for sustained drug delivery systems.[24]

Gellan gum possesses biocompatibility, biodegradation and mechanical properties that lend it potential as a tissue engineering scaffold or cell culture substrate.[25,26]

A specification for gellan gum is included in the Food Chemicals Codex (FCC).[27]

The EINECS number for gellan gum is 275-117-5.

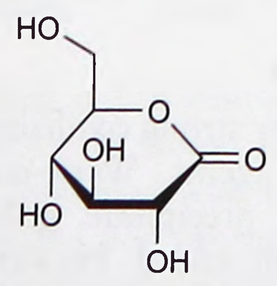
Gluconolactone

1 Nonproprietary Names

USP–NF: Gluconolactone

2 Synonyms

E575; Glucono delta lactone (GDL); Gluconic acid lactone; D-gluconic acid lactone; gluconic acid δ-lactone; D-gluconic acid δ-lactone; 1,5-gluconolactone; glucono δ-lactone; β-glucono-1,5-lactone; D-glucono-1,5-lactone; δ-gluconolatone.



3 Chemical Name and CAS Registry Number

D-Gluconic acid δ-lactone [90-80-2]

4 Empirical Formula and Molecular Weight

$C_6H_{10}O_6$ 178.14

5 Structural Formula

6 Functional Category

Acidulant; complexing agent.

7 Applications in Pharmaceutical Formulation or Technology

In the pharmaceutical industry, gluconolactone is used as an acidulant in oral and topical products. It has also been used in injectable formulations as a complexing agent.[1]

Gluconolactone has been evaluated as an excipient in direct compression and reported to give satisfactory tablets compared to anhydrous lactose.[2] It has also more recently been researched as a

carrier in solid dispersion formulations to enhance dissolution rate of piroxicam.[3]

8 Description

Gluconolactone occurs as a white odourless crystalline powder with a sweet taste. It is partially hydrolysed to gluronic acid with the addition of water, and the rate of this reaction is increased at higher temperatures and pHs.[4]

9 Pharmacopeial Specifications

See Table I.

Table I: Pharmacopeial specifications for gluconolactone

Test	USP 40–NF 35 S1
Identification	+
Lead	≤10 ppm
Heavy metals	≤20 ppm
Reducing substances	+
Assay	99.0%–101.0%

10 Typical Properties

pH Freshly prepared 1% aqueous solution has pH 3.6 changing to 2.5 within 2 hours.

Melting point 153°C, decomposes at 160°C

Solubility Freely soluble in cold water (59 g/100 ml). Slightly soluble in ethanol (1 g/100 ml). Insoluble in ether.

Specific gravity 0.6

Specific rotation +61.7° (c=1) at 20°C

11 Stability and Storage Conditions

Store in well-closed containers away from light.

12 Incompatibilities

Incompatible with strong oxidising agents and strong bases.

13 Method of Manufacture

There are 2 methods of manufacture:

1) Oxidation of glucose with bromine water.
2) Glucono-1,5-lactone crystallizes from a supersaturated aqueous gluconic acid solution between 36 and 57°C. A two-step continuous crystallization is said to result in increased productivity per unit volume under conditions that are favorable in terms of energy consumption. In the first step, a crystalline suspension (3 to 10 % crystalline material) is produced in a supersaturated gluconic acid solution held at 65 to 75°C. The second step involves controlled cooling to 40 to 45°C, followed by a period of crystal maturation at constant temperature. A portion of the resulting crystalline suspension is then recycled to the first step. The 1,5-lactone may also be obtained from an aqueous gluconic acid solution by dehydration involving azeotropic distillation with alcohols, followed by crystallization from the alcohol-containing residue. Crystallization above 70°C leads to the 1,4-lactone.[5]

14 Safety

LD_{50} (rat, oral): 7930 mg/kg[6]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Protective clothing, including eye protection is recommended. Ensure adequate ventilation and avoid breathing dust.

16 Regulatory Status

Included in the FDA Inactive Ingredient Database (intravenous and intramuscular injections; topical solutions, metered aerosols, and sponges) and the Canadian Natural Health Products Ingredients Database. Also included in parenteral (effervescent tablets) and topical products licensed in the UK.

17 Related Substances

—

18 Comments

Gluconolactone is more commonly used in the food industry as an additive with the E number E575.[7] It has also been evaluated as an alternative to benzoyl peroxide in the treatment of acne.[8]

A specification for gluconolactone is included in the Food Chemicals Codex (FCC).[9]

The EINECS number for gluconolactone is 202-016-5. The PubChem Compound ID (CID) for gluconolactone is 7027.

Glucose, Liquid

1 Nonproprietary Names

BP: Liquid Glucose

PhEur: Glucose, Liquid

USP–NF: Liquid Glucose

2 Synonyms

Corn syrup; C*PharmSweet; *Flolys*; *Glucomalt*; *Glucoplus*; glucose syrup; glucosum liquidum; *Glucosweet*; *Mylose*; *Roclys*; starch syrup.

3 Chemical Name and CAS Registry Number

Liquid glucose [8027-56-3]

4 Empirical Formula and Molecular Weight

See Section 8.

5 Structural Formula

See Section 8.

6 Functional Category

Coating agent; sweetening agent; tablet and capsule binder.

7 Applications in Pharmaceutical Formulation or Technology

Liquid glucose is used as a base in oral solutions and syrups and also as a granulating and coating agent in tablet manufacture. In sugar solutions for tablet coating, liquid glucose is used to retard the crystallization of the sucrose. *See* Table I.

Liquid glucose has been investigated as a filler in dry foam tablets to improve the dissolution behavior of poorly soluble drugs.[1]

Table I: Uses of liquid glucose.

Use	Concentration (%)
Granulating agent	5–10
Oral syrup vehicle	20–60
Tablet coating	10–20

8 Description

Liquid glucose is an aqueous solution of several compounds, principally dextrose, dextrin, fructose, and maltose, with other oligosaccharides and polysaccharides. It is a colorless, odorless, and viscous sweet-tasting liquid, ranging in color from colorless to straw-colored.

Liquid glucose is classified into four categories according to its degree of hydrolysis, expressed as dextrose equivalent (DE):

Type I: 20–38 DE;

Type II: 38–58 DE;

Type III: 58–73 DE;

Type IV: >73 DE.

9 Pharmacopeial Specifications

See Table II.

Table II: Pharmacopeial specifications for liquid glucose.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	–
Acidity	–	+
pH	4.0–6.0	–
Water	≤30.0%	≤21.0%

Sulfated ash	≤0.5%	–

(a) Or ≤400 ppm if intended for the production of hard boiled candies, provided the final product contains ≤50 ppm.

10 Typical Properties

Density 1.43 g/cm^3 at 20°C

Solubility Miscible with water; partially miscible with ethanol (90%).

Viscosity (dynamic) 13.0–14.5 mPa s (13.0–14.5 cP) at 21°C.

11 Stability and Storage Conditions

Liquid glucose should be stored in a well-closed container in a cool, dry place. Elevated temperatures will cause discoloration.

12 Incompatibilities

Liquid glucose is incompatible with strong oxidizing agents.

13 Method of Manufacture

Liquid glucose is prepared by the incomplete acidic or enzymatic hydrolysis of starch.

14 Safety

Liquid glucose is used in oral pharmaceutical formulations and confectionery products and is generally regarded as a nontoxic and nonirritant material.

See also Dextrose and Dextrose Anhydrous.

LD_{50} (mouse, IV): 9 g/kg[2]

LD_{50} (rat, oral): 25.8 g/kg[2]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

16 Regulatory Status

Included in the FDA Inactive Ingredients Database (oral solutions, syrups, and tablets). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Dextrin; dextrose; dextrose anhydrous; maltose.

18 Comments

Liquid glucose is used in confectionary products at a concentration of 20–60%.

A specification for glucose syrup is contained in the *Food Chemicals Codex* (FCC)[3] and *Japanese Pharmaceutical Excipients* (JPE).[4] The PhEur 9.2 also includes a specification for glucose, liquid, spray-dried.

The EINECS number for glucose is 200-075-1.

3 Chemical Name and CAS Registry Number

Propane-1,2,3-triol [56-81-5]

4 Empirical Formula and Molecular Weight

$C_3H_8O_3$ 92.09

5 Structural Formula

6 Functional Category

Antimicrobial preservative; emollient; humectant; lubricant; plasticizing agent; solvent; suppository base; sweetening agent; viscosity-increasing agent; tonicity agent.

7 Applications in Pharmaceutical Formulation or Technology

Glycerin is used in a wide variety of pharmaceutical formulations including oral, otic, ophthalmic, suppository, topical, and parenteral preparations; *see* Table I.

In topical pharmaceutical formulations and cosmetics, glycerin is used primarily for its humectant and emollient properties. Glycerin is used as a solvent or cosolvent in creams and emulsions.[1–3] Glycerin is additionally used in aqueous and nonaqueous gels and also as an additive in patch applications.[4–6] In parenteral formulations, glycerin is used mainly as a solvent and cosolvent.[7–10]

In oral solutions, glycerin is used as a solvent,[10] cosolvent,[8] sweetening agent, antimicrobial preservative, and viscosity-increasing agent. It is also used as a plasticizer and in film coatings.[11–14]

Glycerin is used as a plasticizer of gelatin in the production of soft-gelatin capsules, gelatin suppositories and fast dissolving films. Glycerin can be utilized in the production of glycerinated gelatin for suppositories and pessaries.[15–17]

Table I: Uses of glycerin.

Use	Concentration (%)
Antimicrobial preservative	>20
Emollient	≤30
Gel vehicle, aqueous	5.0–15.0
Gel vehicle, nonaqueous	50.0–80.0
Humectant	≤30
Ophthalmic formulations	0.5–3.0
Patch additive	Variable
Plasticizer in tablet film coating	Variable
Solvent for parenteral formulations	≤50
Suppository	Variable
Sweetening agent in alcoholic elixirs	≤20

8 Description

Glycerin is a clear, colorless, odorless, viscous, hygroscopic liquid; it has a sweet taste, approximately 0.6 times as sweet as sucrose.

Table VI: Specific gravity of glycerin.

Concentration of aqueous glycerin solution (% w/w)	Specific gravity at 15°C	Specific gravity at 20°C
5	1.01	–
10	–	1.024
20	1.049	1.049
30	–	1.075
40	–	1.101
50	1.129	1.128
60	1.157	1.156
70	1.185	–
80	1.213	–
90	1.240	1.238
95	1.253	1.251

11 Stability and Storage Conditions

Glycerin is hygroscopic. Pure glycerin is not prone to oxidation by the atmosphere under ordinary storage conditions, but it decomposes on heating with the evolution of toxic acrolein. Mixtures of glycerin with water, ethanol (95%), and propylene glycol are chemically stable.

Glycerin may crystallize if stored at low temperatures.

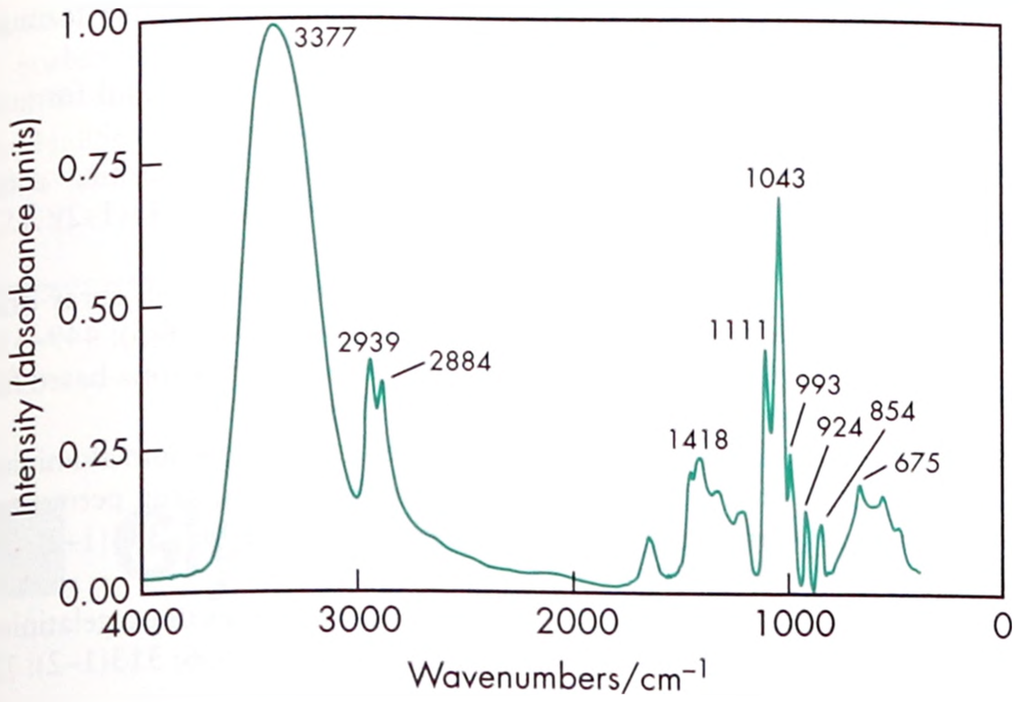

Figure 1: Infrared spectrum of glycerin measured by transmission. Adapted with permission of Informa Healthcare.

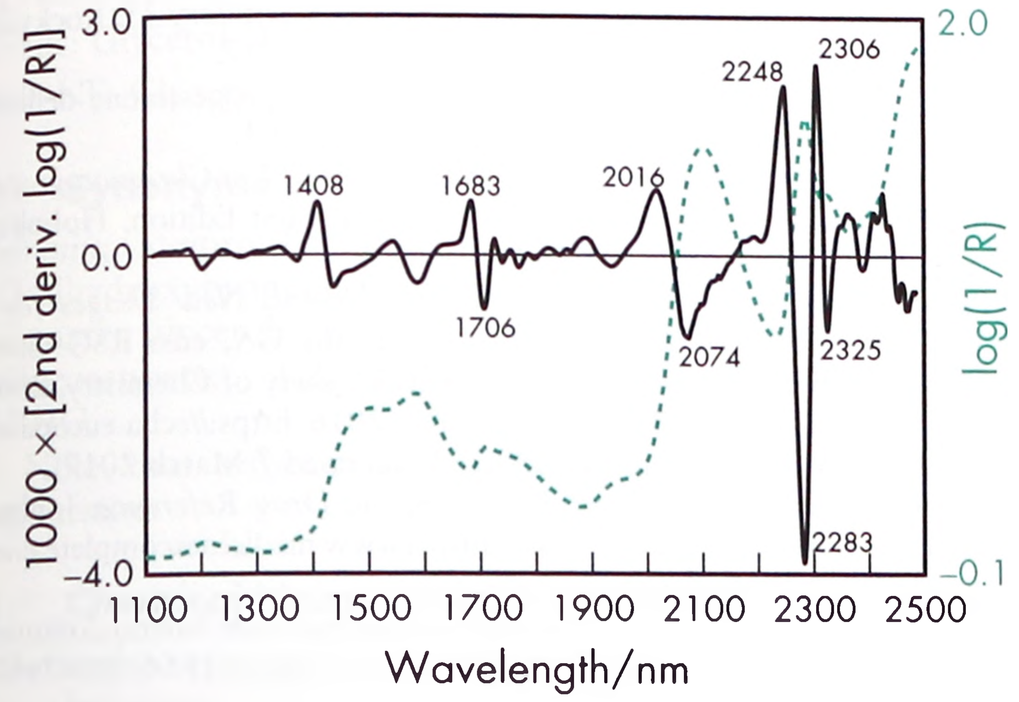

Figure 2: Near-infrared spectrum of glycerin measured by transflectance (1 mm path-length). The small peak at approx. 1950 nm is due to a trace of water (<0.5% m/m).

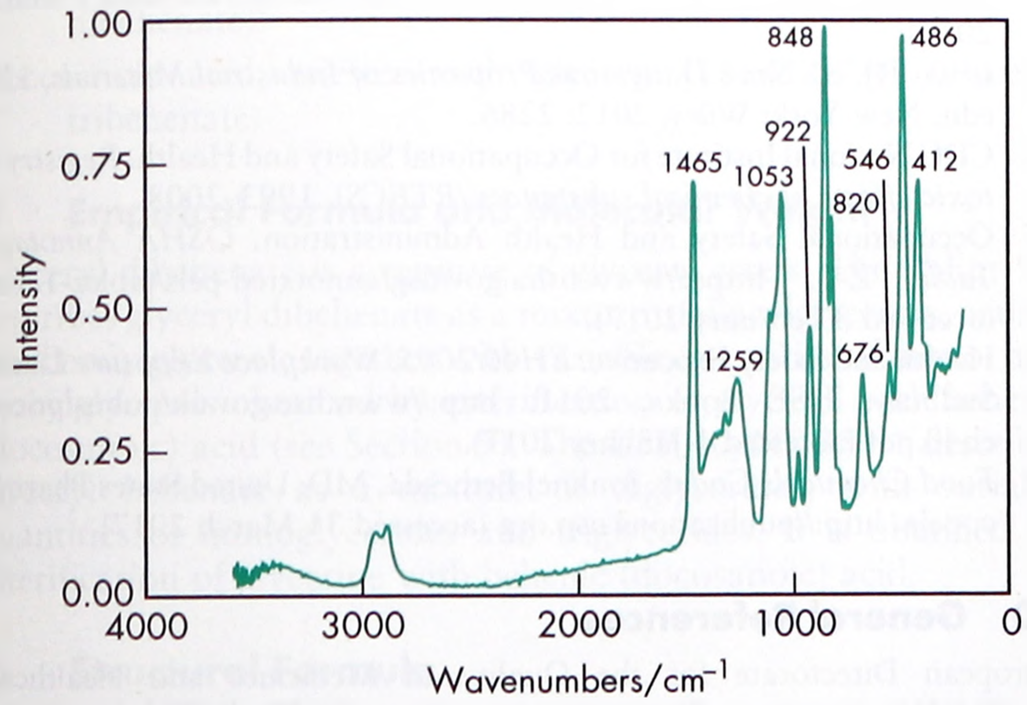

Figure 3: Raman spectrum of glycerin measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

Glycerin should be stored in an airtight container, in a cool, dry place.

12 Incompatibilities

Glycerin may explode if mixed with strong oxidizing agents such as chromium trioxide, potassium chlorate, or potassium permanganate. In dilute solution, the reaction proceeds at a slower rate with several oxidation products being formed. Black discoloration of glycerin occurs in the presence of light, or on contact with zinc oxide or basic bismuth nitrate.

An iron contaminant in glycerin is responsible for the darkening in color of mixtures containing phenols, salicylates, and tannin.

Glycerin forms a boric acid complex, glyceroboric acid, which is a stronger acid than boric acid.

Table VII: Viscosity (dynamic) of aqueous glycerin solutions.

Concentration of aqueous glycerin solution (% w/w)	Viscosity at 20°C (mPa s)
5	1.143
10	1.311
25	2.095
50	6.05
60	10.96
70	22.94
83	111.0

13 Method of Manufacture

Glycerin is mainly obtained from oils and fats as a by-product in the manufacture of soaps and fatty acids. It may also be obtained from natural sources by fermentation of, for example, sugar beet molasses in the presence of large quantities of sodium sulfite. Synthetically, glycerin may be prepared by the chlorination and saponification of propylene.

14 Safety

Glycerin occurs naturally in animal and vegetable fats and oils that are consumed as part of a normal diet. Glycerin is readily absorbed from the intestine and is either metabolized to carbon dioxide and glycogen or used in the synthesis of body fats.

Glycerin is used in a wide variety of pharmaceutical formulations including oral, ophthalmic, parenteral, and topical preparations. Adverse effects are mainly due to the dehydrating properties of glycerin.[21]

Oral doses are demulcent and mildly laxative in action. Large doses may produce headache, thirst, nausea, and hyperglycemia. The therapeutic parenteral administration of very large glycerin doses, 70–80 g over 30–60 minutes in adults to reduce cranial pressure, may induce hemolysis, hemoglobinuria, and renal failure.[22] Slower administration has no deleterious effects.[23]

Glycerin may also be used orally in doses of 1.0–1.5 g/kg bodyweight to reduce intraocular pressure.

When used as an excipient or food additive, glycerin is not usually associated with any adverse effects and is generally regarded as a nontoxic and nonirritant material.

The Cosmetic Ingredient Review (CIR) Expert Panel have assessed glycerin and concluded that the material is safe as used in cosmetics formulations in the present practices of use and concentration.[24]

LD_{50} (guinea pig, oral): 7.75 g/kg[25]
LD_{50} (mouse, IP): 8.98 g/kg[25]
LD_{50} (mouse, IV): 4.25 g/kg[25]
LD_{50} (mouse, oral): 4.09 g/kg[25]
LD_{50} (mouse, SC): 0.09 g/kg[25]
LD_{50} (rabbit, IV): 0.05 g/kg[25]
LD_{50} (rabbit, oral): 27 g/kg[26]
LD_{50} (rat, IP): 4.42 g/kg[25]
LD_{50} (rat, oral): 5.57 g/kg[26]
LD_{50} (rat, oral): 12.6 g/kg[25]
LD_{50} (rat, SC): 0.1 g/kg[25]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled. Eye protection and gloves are recommended. In the USA, the recommended Permissible Exposure Limit (PEL) (8-hour TWA) for glycerin mist (total dust) is 15 mg/m^3 for OSHA and 10 mg/m^3 for CAL/OSHA. Both OSHA and CAL/OSHA limit the glycerin mist (respirable fraction) PEL (8-hour TWA) to 5 mg/m^3.[27] In the UK, the recommended long-term (8-hour TWA) workplace exposure limit for glycerin mist is 10 mg/m^3.[28] Glycerin is combustible and may react explosively with strong oxidizing agents; *see* Section 12.

16 Regulatory Status

GRAS listed. Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (billary perfusion; buccal and dental preparations; inhalations; injections; iontophoresis drug delivery systems; nasal and ophthalmic preparations; oral chewable bars, capsules, drops, solutions, suspensions and tablets; otic, rectal, topical, transdermal, and vaginal preparations). Included in nonparenteral and parenteral medicines licensed in the UK. Included as a food additive in the EAFUS list compiled by the FDA. Accepted for use as a food additive in Europe. Included in the Canadian Natural Health Products Ingredients Database.

18 Comments

Glycerin is one of the materials that have been selected for harmonization by the Pharmacopeial Discussion Group. For further information see the General Chapter 5.8 in PhEur, along with the 'State of Work' document on the PhEur EDQM website, and also the General Information Chapter G10 in the JP.

Some pharmacopeias also contain additional specifications for diluted glycerin solutions: The JP contains a monograph for 'glycerin' that contains 84–87% of glycerin. The PhEur contains a monograph for 'glycerol 85 per cent' that contains 83.5–88.5% of propane-1,2,3-triol ($C_3H_8O_3$).

Glycerin is also used as a food additive and is employed therapeutically in various applications, including as a laxative.[19,24] A specification for glycerin is contained in the *Food Chemicals Codex* (FCC).[29]

The EINECS number for glycerin is 200-289-5. The PubChem Compound ID (CID) for glycerin is 753.

Glyceryl Behenate

1 Nonproprietary Names

BP: Glycerol Dibehenate
PhEur: Glycerol Dibehenate
USP–NF: Glyceryl Behenate

2 Synonyms

Behenin; *Compritol 888 ATO*; *Compritol E ATO*; docosanoic acid, 2,3-dihydroxypropyl ester; docosanoin; *DUB BG*; E471; glycerol behenate; glyceroli dibehenas; glyceryl monobehenate; glyceryl tridocosanoate; 1,2,3-propanetriol docosanoate; *Stelliesters DBHG*.

Note that tribehenin is used as a synonym for glyceryl tribehenate.

3 Chemical Name and CAS Registry Number

2,3-dihydroxypropyl docosanoate [77538-19-3] (glyceryl behenate)

Docosanoic acid, monoester with glycerin [30233-64-8] (glyceryl monobehenate)

Docosanoic acid, diester with glycerin [94201-62-4] (glyceryl dibehenate)

Docosanoic acid, triester with glycerin [18641-57-1] (glyceryl tribehenate)

4 Empirical Formula and Molecular Weight

Glyceryl dibehenate is a mixture of glycerol esters. The PhEur 9.2 describes glyceryl dibehenate as a mixture of diacylglycerols, mainly dibehenoylglycerol, together with variable quantities of mono- and triacylglycerols obtained by esterification of glycerol with behenic (docosanoic) acid (*see* Section 9). The USP 40–NF 35 S1 describes glyceryl behenate as a mixture of diglycerides, with variable quantities of monoglycerides and triglycerides. It is obtained by esterification of glycerine with behenic (docosanoic) acid.

5 Structural Formula

See Section 4.

6 Functional Category

Coating agent; modified-release agent; tablet and capsule binder; tablet and capsule lubricant; taste-masking agent; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Glyceryl behenate is used in cosmetics, foods, and oral and topical pharmaceutical formulations; *see* Table I.

In oral pharmaceutical formulations, glyceryl behenate powder is used at low concentrations as a lubricant in the preparation of oral tablets and capsules.[1–6] It is also used in oral formulations at higher concentrations to produce lipid matrix tablets for sustained drug release. In contact with aqueous fluid, a lipid matrix does not swell or erode, and therefore diffusion is the main drug release mechanism.

Glyceryl behenate decreases ejection force and improves compressibility in pharmaceutical formulations. The well-defined and controlled particle size is associated with reduced friction and improved powder flowability, which aids homogeneity and content uniformity. It is not sensitive to over-blending and does not interfere with tablet disintegration time, dissolution rate, or drug release. It is particularly effective in anhydrous products to formulate drugs that are unstable in aqueous media.

Basic processing techniques such as direct compression or wet granulation can be used to produce tablet matrices using glyceryl behenate.[7–11] Additional processing methods that fortify the sustained-release properties of the matrix may be used in particular cases, for example, in formulations with highly water-soluble drugs.[12–14] Such methods include solid dispersion[15–27] or tablet treatments.[20–22,28] Glyceryl behenate may also be incorporated via extrusion/spheronization into pellets that can be further compressed into tablets.[23,24,29] Glyceryl behenate can also be used in various hot-melt granulation techniques including as a coating agent sprayed onto a powder or granules.[30–41]

Along with acid-soluble or swellable polymers glyceryl behenate is also used to mask the bitter or unpleasant taste of the medicament with improved palatability.[42]

Glyceryl behenate has been used for the preparation of ophthalmic inserts.[43,44]

Glyceryl behenate has been investigated in the preparation of aqueous colloidal dispersions for the encapsulation of various drugs.[45–47] For example, solid lipid microparticles (SLM),[48–57] nanostructured lipid carriers (NLC),[58–60] and solid lipid nanoparticles (SLN)[61–93] have been prepared and investigated with a high drug-loading capacity,[76] to improve drug stability,[51,52] prolong drug release,[49,50,73–78] and enhanced penetration of drugs[71–74] for delivery via multiple routes.[53–92]

Table I: Uses of glyceryl behenate.

Use	Concentration (%)
Lipophilic matrix or coating for sustained-released tablets and capsules	>10.0
Tablet and capsule lubricant	1.0–3.0
Taste–masking agent	5.0–15.0
Viscosity-increasing agent in silicon gels (cosmetics)	1.0–15.0
Viscosity-increasing agent in w/o or o/w emulsions (cosmetics)	1.0–5.0

8 Description

Glyceryl behenate occurs as a fine, off-white or white-yellow powder, as a hard waxy mass or pellet, or as white or almost white unctuous flakes. It has a faint odor and is tasteless.

9 Pharmacopeial Specifications

See Table II.

Table II: Pharmacopeial specifications for glyceryl behenate.

Test	PhEur 9.2	USP 40–NF 35 S1
Identification	+	+
Characters	+	–
Acid value	≤4.0	≤4
Iodine value	≤3.0	≤3
Saponification value	145–165	145–165
Residue on ignition	≤0.1%	≤0.1%
Nickel	≤1 ppm	–
Water	≤1.0%	–
Heavy metals	–	≤10 ppm
Melting point	65–77°C	–
Content of 1-monoglycerides	–	12.0–18.0%
Content of acylglycerols (glycerides)	+	–
Monoacylglycerols	15.0–23.0%	–
Diacylglycerols	40–60%	–
Triacylglycerols	21–35%	–
Free glycerin	≤1.0%	≤1.0%
Composition of fatty acids	+	–
Arachidic acid	≤10.0%	–
Behenic acid	≥83.0%	–
Erucic acid	≤3.0%	–
Lignoceric acid	≤3.0%	–
Palmitic acid	<3.0%	–
Stearic acid	≤5.0%	–

10 Typical Properties

Flash point >200°C
HLB value 1
Solubility Soluble in methylene chloride, and, when heated, it is soluble in chloroform and dichloromethane and in many organic solvents; partly soluble in hot ethanol (96%); practically insoluble in cold ethanol (95%), hexane, mineral oil, and water.
Spectroscopy

IR spectrum *see* Figure 1.

Raman spectrum *see* Figure 2.

11 Stability and Storage Conditions

Glyceryl behenate should be stored in a dry, airtight container, at a temperature less than 35°C. It should be stored away from extreme heat and strong oxidizing agents in a well-ventilated place.

12 Incompatibilities

Glyceryl behenate is incompatible with strong oxidizing agents.

13 Method of Manufacture

Glyceryl behenate is prepared by the esterification of glycerin by behenic acid (C_{22} fatty acid) without the use of catalysts. In the case of *Compritol 888 ATO* (Gattefossé), raw materials used are of vegetable origin, and the esterified material is atomized by spray-cooling.

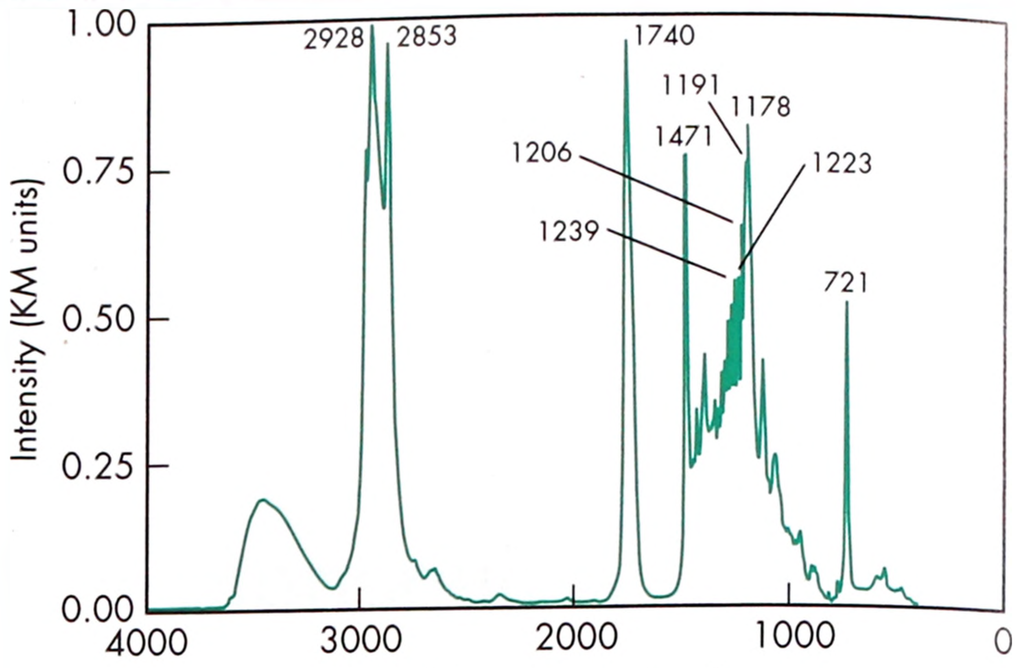

Figure 1: Infrared spectrum of glyceryl behenate measured by diffuse reflectance. Adapted with permission of Informa Healthcare.

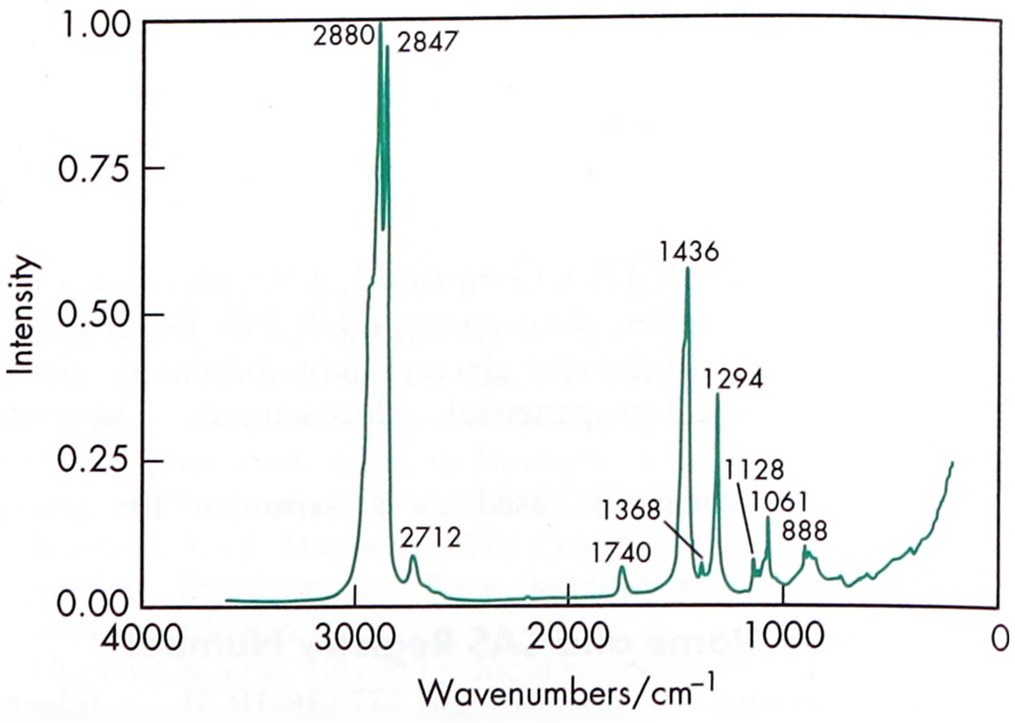

Figure 2: Raman spectrum of glyceryl behenate measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

14 Safety

Glyceryl behenate is used in cosmetics, foods and oral pharmaceutical formulations, and is generally regarded as a relatively nonirritant and nontoxic material. The US Cosmetic Ingredients Review Expert Panel evaluated glyceryl behenate and concluded that it is safe for use in cosmetic formulations in present practices of use and concentration.

LD_{50} (mouse, oral): 5 g/kg[94]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantities of material handled; protective gloves, glasses, and clothing are recommended. Glyceryl behenate emits acrid smoke and irritating fumes when heated to decomposition, and incomplete combustion releases carbon monoxide and carbon dioxide.

16 Regulatory Status

GRAS listed. Accepted for use as a food additive in Europe. Included in the FDA Inactive Ingredients Database (oral capsules, tablets, and suspensions). Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Glyceryl laurate; Glyceryl monooleate; Glyceryl monostearate; Glyceryl palmitostearate.

18 Comments

Investigation into the polymorphic nature of glyceryl behenate's solid state structure has identified a possible risk of its crystallization and solid state organization changing when mixed with pharmaceutical ingredients that could trap monoglycerides and modify the equilibrium of monobehenate, dibehenate, and tribehenate present in the pure excipient.[95]

In cosmetics, glyceryl behenate is used as an emollient and viscosity-increasing agent in emulsions. It also improves the heat stability of emulsions and is a gelifying agent for various oils. For topical formulations, it is used as a thickening agent for oily phases in emulsions and ointments.

A specification for glyceryl behenate is included in the *Food Chemicals Codex* (FCC).[96]

The EINECS numbers are: 250-097-0 for glyceryl behenate; 303-650-6 for glyceryl dibehenate; 242-471-7 for glyceryl tribehenate. The PubChem Compound ID (CID) for glyceryl behenate includes 62726 and 121658.

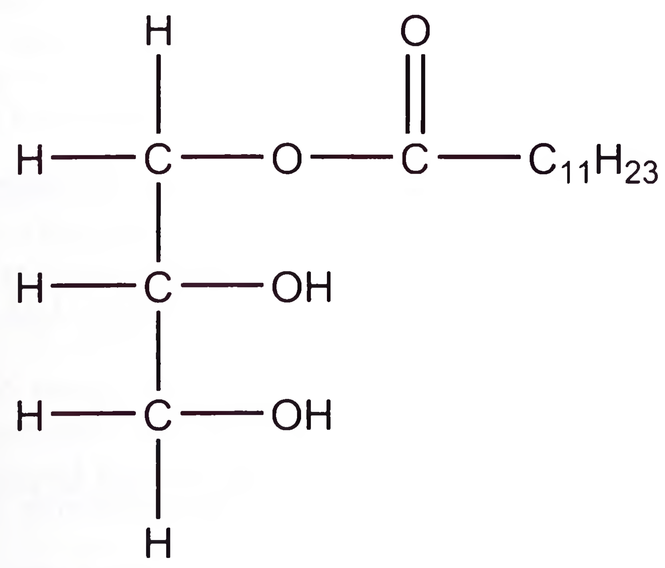
Glyceryl Laurate

1 Nonproprietary Names

None adopted.

2 Synonyms

Aldo MLD KFG; *Cithrol GML*; *Colonial Monolaurin*; dodecanoic acid, 2,3-dihydroxypropyl ester; dodecanoic acid, monoester with 1,2,3-propanetriol; glycerol laurate; glycerol monolaurate; glycerin 1-monolaurate; glyceryl monolaurate; GML; *Imwitor 312*; *lauricidin*; 1-lauroyl-rac-glycerol; *Lumulse GML K*; 1-monolaurin; monolaurin; *Ultrapure GML*.



3 Chemical Name and CAS Registry Number

2,3-dihydroxypropyl dodecanoate [142-18-7]

4 Empirical Formula and Molecular Weight

$C_{15}H_{30}O_4$ 274.40

5 Structural Formula

6 Functional Category

Emollient; emulsifying agent; emulsion stabilizing agent; solubilizing agent; nonionic surfactant; viscosity-increasing agent.

7 Applications in Pharmaceutical Formulation or Technology

Glyceryl laurate is used as a nonionic emulsifier, stabilizer, emollient, and thickener in topical pharmaceutical applications. Glyceryl laurate is reported to have some antimicrobial activity,[1–7] and penetration enhancing effect.[8,9] The absorption enhancing effect of glyceryl laurate[10,11] and its chitosan copolymers[12] has also been investigated, and is attributed to the ability of glyceryl laurate to increase the solubility of the active drug.[10]

Glyceryl laurate is available in both nonemulsifying (n/e) and self-emulsifying (s/e) grades, the self-emulsifying grade containing some sodium and/or potassium laurate.

8 Description

Glyceryl laurate occurs as a white to off-white powder, granules, pastilles, waxy beads, or cream-colored paste, with a faint fatty odor.

9 Pharmacopeial Specifications

—

10 Typical Properties

Acidity/alkalinity pH = 8–8.6
Acid value ≥3
Density 0.98 g/cm^3
Flash point 182°C[13]
HLB value 5.2
Hydroxyl value 395
Iodine value <1
Melting point 23–27°C (*see also* Section 13)
Saponification value 200–210
Solubility Soluble in chloroform, methanol, ethanol, toluene, naphtha and mineral oil; practically insoluble in water but may be dispersed in water at 60°C. The self-emulsifying grade is dispersible in water.
Specific gravity 0.96[13]

11 Stability and Storage Conditions

Glyceryl laurate should be stored in a closed container in a cool, dry environment away from strong oxidizing and reducing agents. Avoid excessive heat and light.

12 Incompatibilities

Glyceryl laurate is incompatible with strong oxidising agents, acids, alkalis, and spontaneously flammable products.

Glyceryl laurate's antimicrobial action is inactivated by ethoxylated and propoxylated nonionics such as polysorbate 80 (*see also* Polyoxyethylene Sorbitan Fatty Acid Esters), and sodium lauryl sarcosine.[14]

13 Method of Manufacture

Glyceryl laurate is a monoester prepared by the direct esterification of glycerin and lauric acid derived from vegetable sources. Commercially a transesterification glycerolysis reaction is used for the production of monoglycerides.[14] The composition and, therefore, the physical properties of glyceryl laurate may vary considerably

from manufacturer to manufacturer; e.g. the melting point may vary from 20–60°C.[13–15]

Several alternative heterogenous catalysts have been investigated as enhancements for this reaction, including solid cationic resins, zeolite molecular sieves[16] and mesoporous materials.[17,18] Lipase enzymatic synthesis has also been explored.[19–21]

14 Safety

Glyceryl laurate is generally regarded as a relatively nonirritant and nontoxic material. The US Cosmetic Ingredients Review Expert Panel evaluated glyceryl laurate and concluded that it is safe for use in cosmetic formulations in present practices of use and concentration.[14]

Overexposure to glyceryl laurate may cause headache, dizziness, tiredness, nausea and vomiting, moderate to severe erythema (redness) and moderate edema (raised skin).[22]

LD50 (rat, oral): >5 g/kg;[13] >20 g/kg;[14] 53 g/kg[23]

15 Handling Precautions

Observe normal handling precautions appropriate to the circumstances and quantity of material handled. Avoid contact with skin and eyes, and wash skin thoroughly after handling; protective gloves, glasses, clothing, and breathing apparatus (when aerosol, vapor or dust is formed) are recommended. Thermal decomposition can lead to release of irritating gases and vapours such as carbon oxides.

16 Regulatory Status

GRAS listed. Included in the FDA Inactive Ingredients Database (topical patch and transdermal film). Included in nonparenteral products licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Glyceryl behenate; glyceryl monooleate; glyceryl monostearate; glyceryl palmitostearate.

18 Comments

Glyceryl laurate is also used as an emulsifier, stabilizer, emollient, thickener, lubricant and preserving agent in a variety of food and cosmetic applications.

Glyceryl laurate has demonstrated an inhibitory effect on *Staphylococcus aureus*,[4,24,25] prompting research into the use of glyceryl laurate as a fiber coating in tampons to reduce the risk of toxic shock syndrome;[26] however, glyceryl laurate is degraded by *S. aureus* produced lipase.[24,25]

The microbicidal property of glyceryl laurate has also led to investigative work in prevention of HIV-1 transmission;[27,28] however, vaginal use of glyceryl laurate has been associated with epithelial toxicity at the application site,[29] and subsequent increased susceptibility to other viruses.[30]

The EINECS number for glyceryl laurate is 205-526-6. The PubChem Compound ID (CID) for glyceryl laurate includes 14871 and 74297.

Glyceryl Monooleate

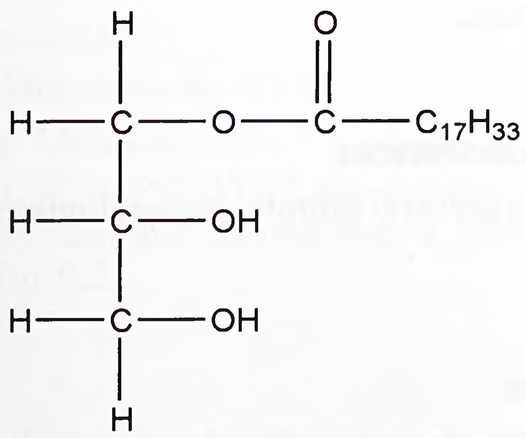
1 Nonproprietary Names

BP: Glycerol Mono-oleate
PhEur: Glycerol Mono-oleate
USP–NF: Glyceryl Monooleate

2 Synonyms

Aldo MO; *Atlas G-695*; *Capmul GMO*; *Drewmulse GMO*; *DUB OG*; *DUBCARE OG;* glycerol-1-oleate; glyceroli mono-oleas; glyceryl mono-oleate; glyceryl oleate; *HallStar GMO*; *Imwitor 948*; *Kessco GMO*; *Ligalub*; monolein; *Monomuls 90-O18*; mono-olein; α-mono-olein glycerol; *Peceol.*

3 Chemical Name and CAS Registry Number



9-Octadecenoic acid (*Z*), monoester with 1,2,3-propanetriol [25496-72-4]

4 Empirical Formula and Molecular Weight

$C_{21}H_{40}O_4$ 356.55 (for pure material)

Glyceryl monooleate is a mixture of the glycerides of oleic acid and other fatty acids, consisting mainly of the monooleate; *see* Section 8.

5 Structural Formula

6 Functional Category

Bioadhesive material; emollient; emulsifying agent; emulsion stabilizing agent; gelling agent; modified-release agent; nonionic surfactant.

7 Applications in Pharmaceutical Formulation or Technology

Glyceryl monooleate is a polar lipid that swells in water to give several phases with different rheological properties.[1] It is available in both nonemulsifying (n/e) and self-emulsifying (s/e) grades, the self-emulsifying grade containing about 5% of an anionic surfactant.

The nonemulsifying grade is used in topical formulations as an emollient and as an emulsifying agent for water-in-oil emulsions. It is also a stabilizer for oil-in-water emulsions. The self-emulsifying grade is used as a primary emulsifier for oil-in-water systems.[2,3]

Glyceryl monooleate gels in excess water, forming a highly ordered cubic phase that can be used to sustain the release of various water-soluble drugs.[4–9] It is also the basis of mucoadhesive drug delivery systems.[10–12]

Glyceryl monooleate is reported to enhance transdermal[13,14] and buccal penetration,[15] and it has been investigated in inhalation delivery systems.[16]

Glyceryl monooleate has been investigated for the encapsulation of drugs in liquid crystalline nanoparticles for the entrapment of drugs for oral and ocular delivery.[17–19]

8 Description

Glyceryl monooleate occurs as an amber oily liquid, which may be partially solidified at room temperature and have a characteristic odor.

The PhEur and USP–NF permit the addition of a suitable antioxidant.

9 Pharmacopeial Specifications

See Table I.

10 Typical Properties

Boiling point 238–240°C
Density 0.942 g/cm^3
Flash point 180°C
HLB value 3.3 (n/e); 4.1 (s/e).
Melting point 35°C (*see also* Section 13)
Refractive index 1.4626
Solubility Soluble in chloroform, ethanol (95%), ether, mineral oil, and vegetable oils; practically insoluble in water. The self-emulsifying grade is dispersible in water.

Table I: Pharmacopeial specifications for glyceryl monooleate.

Spectroscopy

IR spectrum *see* Figure 1.

Raman spectrum *see* Figure 2.

Viscosity (kinematic) 91 mm^2/s (91 cSt) at 38°C[20]

11 Stability and Storage Conditions

Glyceryl monooleate should be stored in an airtight container, protected from light in a cool, dry place.

12 Incompatibilities

Glyceryl monooleate is incompatible with strong oxidizing agents. The self-emulsifying grade is incompatible with cationic surfactants.

13 Method of Manufacture

Glyceryl monooleate is prepared by partial glycerolysis of vegetable oils mainly containing triacylglycerols of oleic acid or by the esterification of glycerol with fatty acids, chiefly oleic acid of vegetable or animal origin. As the fatty acids are not pure substances, but rather a mixture of fatty acids, the product obtained from the esterification will contain a mixture of esters, including stearic and palmitic. Di- and triesters may also be present. The composition and, therefore, the physical properties of glyceryl monooleate may thus vary considerably from manufacturer to manufacturer; e.g. the melting point may vary from 10–35°C.

14 Safety

Glyceryl monooleate is used in oral and topical pharmaceutical formulations and is generally regarded as a relatively nonirritant and nontoxic excipient.

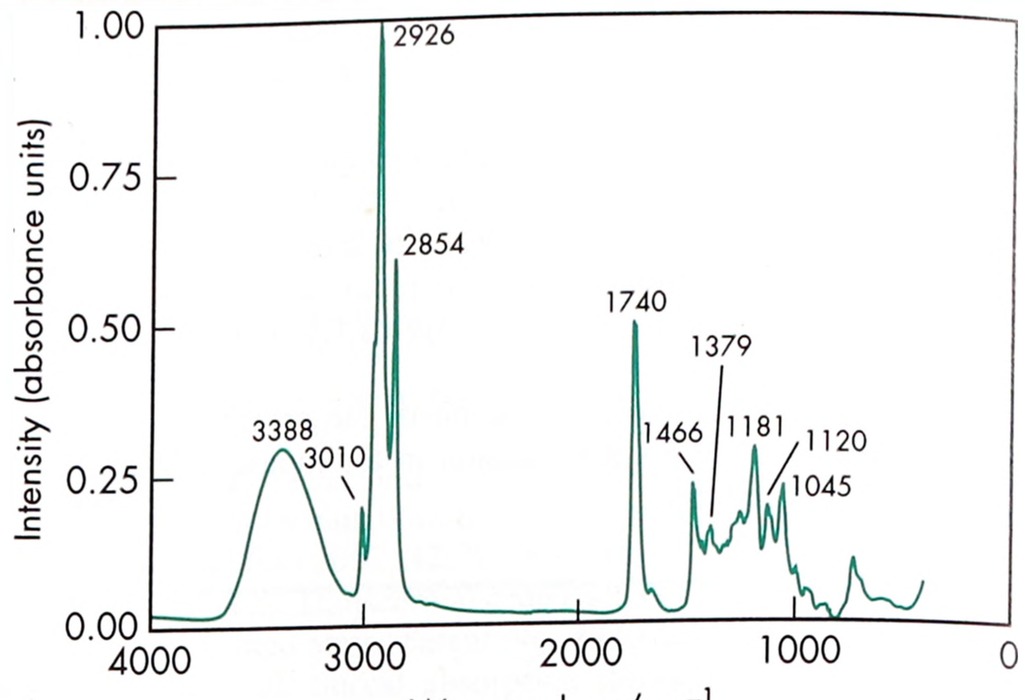

Figure 1: Infrared spectrum of glyceryl monooleate measured by transmission. Adapted with permission of Informa Healthcare.

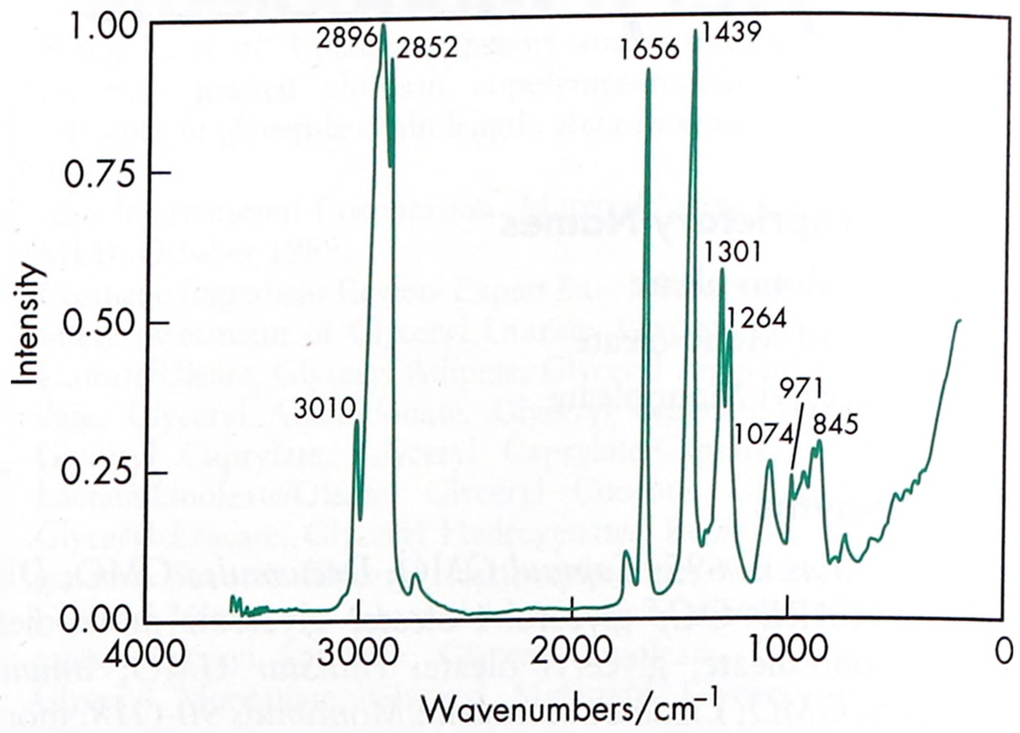

Figure 2: Raman spectrum of glyceryl monooleate measured in the 180° reflectance mode. Adapted with permission of Informa Healthcare.

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled.

16 Regulatory Status

GRAS listed. Included in the FDA Inactive Ingredients Database (oral capsules, oral powder, oral tablets; creams, controlled-release transdermal films). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

17 Related Substances

Glyceryl behenate; glyceryl laurate; glyceryl monostearate; glyceryl palmitostearate.

18 Comments

A specification for glyceryl monooleate is included in the *Food Chemicals Codex* (FCC).[21]

A specification for glyceryl monooleate is included in the *Japanese Pharmaceutical Excipients* (JPE).[22]

The EINECS number for glyceryl monooleate is 247-038-6. The PubChem Compound ID (CID) for glyceryl monooleate includes 5283468 and 33022.

3 Chemical Name and CAS Registry Number

Octadecanoic acid, monoester with 1,2,3-propanetriol [31566-31-1]

4 Empirical Formula and Molecular Weight

$C_{21}H_{42}O_4$ 358.6

5 Structural Formula

6 Functional Category

Emollient; emulsifying agent; emulsion stabilizing agent; modified-release agent; solubilizing agent; solvent; tablet and capsule lubricant.

7 Applications in Pharmaceutical Formulation or Technology

The many varieties of glyceryl monostearate are used as nonionic emulsifiers, stabilizers, emollients, and plasticizers in a variety of food, pharmaceutical, and cosmetic applications. It acts as an effective stabilizer, that is, as a mutual solvent for polar and nonpolar compounds that may form water-in-oil or oil-in-water emulsions.[1,2] These properties also make it useful as a dispersing agent for pigments in oils or solids in fats, or as a solvent for phospholipids, such as lecithin.

Glyceryl monostearate has also been used in various hot-melt techniques for the production of granules and tablets,[3–6] and experimentally for dental films.[7] It has also been evaluated as a dry powder inhaler carrier.[8]

Glyceryl monostearate is a lubricant for tablet manufacturing and may be used to form sustained-release matrices for solid dosage forms.[9–11] Sustained-release applications include the formulation of pellets for tablets[12] or suppositories,[13] and the preparation of a veterinary bolus.[14] Glyceryl monostearate has also been used as a matrix ingredient for a biodegradable, implantable, controlled-release dosage form.[15]

When using glyceryl monostearate in a formulation, the possibility of polymorphism should be considered.[16] The α-form is dispersible and foamy, useful as an emulsifying agent or preservative. The denser, more stable, β-form is suitable for wax matrices. This application has been used to mask the flavor of clarithromycin[17] and ondansetron[18] in pediatric formulations.

Glyceryl monostearate has been investigated for the encapsulation of various drugs in solid lipid nanoparticles (SLN)[19–30] and nanostructured lipid carriers (NLC)[31–33] to enhance bioavailability[27–31] and for oral,[27–31] topical,[22–24] ocular,[25] epidural,[26] and intralesional delivery.[33]

The improved topical absorption of piroxicam has been shown with organogels made with glyceryl monostearate.[34]

8 Description

While the names glyceryl monostearate and mono- and di-glycerides are used for a variety of esters of long-chain fatty acids, the esters fall into two distinct grades:

40–55 percent monoglycerides The PhEur 9.2 describes glyceryl monostearate 40–55 as a mixture of monoacylglycerols, mostly monostearoylglycerol, together with quantities of di- and triacylglycerols. It contains 40–55% of monoacylglycerols, 30–45% of diacylglycerols, and 5–15% of triacylglycerols. This PhEur grade corresponds to mono- and di-glycerides USP–NF, which has similar specifications (not less than 40% monoglycerides).

90 percent monoglycerides The USP 40–NF 35 S1 describes glyceryl monostearate as consisting of not less than 90% of monoglycerides of saturated fatty acids, mainly glyceryl monostearate ($C_{21}H_{42}O_4$) and glyceryl monopalmitate ($C_{19}H_{38}O_4$).

The JP specification describes glyceryl monostearate as a mixture of α- and β-glyceryl monostearate and other fatty acid esters of glycerin, and is not grade specific; *see* Section 9.

The commercial products are mixtures of variable proportions of glyceryl monostearate and glyceryl monopalmitate.

Glyceryl monostearate occurs as a white to cream-colored, waxlike solid in the form of beads, flakes, or powder. It is waxy to the touch and has a slight fatty odor and taste.

9 Pharmacopeial Specifications

Table I compares the specifications for the 40–55% grades, glyceryl monostearate PhEur and mono- and di-glycerides USP–NF. PhEur divides glyceryl monostearate 40–55 into three types according to the proportion of stearic acid ester in the mixture, and those specifications are presented in Table II. Table III presents the specifications for glyceryl monostearate USP–NF (90% monoglycerides). Since the JP specifications are broad enough to encompass both grades, JP is included in both Table I and Table III.

See also Section 18.

Table I: Pharmacopeial specifications for glyceryl monostearate (40–55%).

Polymorphs The α-form is converted to the β-form when heated at 50°C.[35]

Solubility Soluble in hot ethanol, ether, chloroform, hot acetone, mineral oil, and fixed oils. Practically insoluble in water, but may be dispersed in water with the aid of a small amount of soap or other surfactant.

Specific gravity 0.92

Spectroscopy

IR spectrum *see* Figure 1.

NIR spectrum *see* Figure 2.

Raman spectrum *see* Figure 3.

11 Stability and Storage Conditions

If stored at warm temperatures, glyceryl monostearate increases in acid value upon aging owing to the saponification of the ester with trace amounts of water. Effective antioxidants may be added, such as butylated hydroxytoluene and propyl gallate.

Glyceryl monostearate should be stored in a tightly closed container in a cool, dry place, and protected from light.

12 Incompatibilities

The self-emulsifying grades of glyceryl monostearate are incompatible with acidic substances.

13 Method of Manufacture

Glyceryl monostearate is prepared by the reaction of glycerin with triglycerides from animal or vegetable sources, producing a mixture of monoglycerides and diglycerides. The diglycerides may be further reacted to produce the 90% monoglyceride grade. Another process involves reaction of glycerol with stearoyl chloride.

The starting materials are not pure substances and therefore the products obtained from the processes contain a mixture of esters, including palmitate and oleate. Consequently, the composition, and therefore the physical properties, of glyceryl monostearate may vary considerably depending on the manufacturer.

14 Safety

Glyceryl monostearate is widely used in cosmetics, foods, and oral and topical pharmaceutical formulations, and is generally regarded as a nontoxic and nonirritant material.

LD_{50} (mouse, IP): 0.2 g/kg[36]

15 Handling Precautions

Observe normal precautions appropriate to the circumstances and quantity of material handled including wearing impervious gloves, safety glasses, protective clothing and a dust respirator if handling high concentrations.

G

16 Regulatory Status

GRAS listed. Included in the FDA Inactive Ingredients Database (oral capsules, pellets, tablets [including sublingual tablets] and suspensions; dental pastes; ophthalmic suspensions; otic suspensions; rectal suppositories; and topical and vaginal preparations). Included in nonparenteral medicines licensed in the UK. Included in the Canadian Natural Health Products Ingredients Database.

If glyceryl monostearate is produced from animal fats (tallow), there may be additional regulatory requirements that the source be free of contamination from bovine spongiform encephalopathy.

17 Related Substances

Glyceryl behenate; glyceryl laurate; glyceryl monooleate; glyceryl palmitostearate; self-emulsifying glyceryl monostearate.

Self-emulsifying glyceryl monostearate

Comments A specification for self-emulsifying glyceryl monostearate was previously included in the PhEur. Self-emulsifying glyceryl monostearate is a grade of glyceryl monostearate to which an emusifying agent has been added. The emulsifier may be a soluble soap, a salt of a sulfated alcohol, a nonionic surfactant, or a quaternary compound. It is used primarily as an emulsifying agent for oils, fats, solvents, and waxes. Aqueous preparations should contain an antimicrobial preservative.

18 Comments

Glyceryl monostearate was removed from the list of materials that were selected for harmonization by the Pharmacopeial Discussion Group in November 2011 due to the significantly different types manufactured in the Europe, Japan and the US.[37,38]

Glyceryl monostearate and other fatty acid monoesters are not efficient emulsifiers. However, they are useful emollients that are readily emulsified by common emulsifying agents and by incorporation of other fatty materials into the formulation. Addition of the monoester materials provides the creams with smoothness, fine texture, and improved stability.

In topical applications, glyceryl monostearate is less drying than straight stearate creams, and is not drying when used in protective applications.
